## CHIKUNGUNYA INFECTION DURING GESTATION: IMPACT ON PREGNANCY AND NEONATAL OUTCOMES

Priyanka Suresh<sup>1</sup>, Amy Krystosik<sup>1</sup>, Nikita Cudjoe<sup>2</sup>, Toni Murray<sup>2</sup>, Rashida Isaac<sup>2</sup>, George Mitchell<sup>3</sup>, Trevor Noël<sup>4</sup>, Barbara Landon<sup>5</sup>, Randall Waechter<sup>5</sup>, **A. Desiree LaBeaud**<sup>1</sup>

<sup>1</sup>Stanford University, Department of Pediatrics, Stanford, CA, United States, <sup>2</sup>Windward Islands Research and Education Foundation (WINDREF), St. George's, Grenada, <sup>3</sup>Ministry of Health, St. George's, Grenada, <sup>4</sup>Windward Islands Research and Education Foundation (WINDREF) @ St. George's University, St. George's, Grenada, <sup>5</sup>St. George's University, School of Medicine, Department of Bioethics, St. George's, Grenada

In July 2014, an outbreak of Chikungunya virus (CHIKV) occurred in Grenada, West Indies with an estimation of 65% of the population infected. During this outbreak, approximately 710 women gave birth with limited information available regarding the consequences of CHIKV infection on their pregnancies. Studies in La Reunion Island have identified neonatal complications resulting from mother-to-child CHIKV transmission at birth; however, no observable effect on pregnancy outcomes has been shown. Our objective was to study CHIKV impacts on pregnancy outcomes during the outbreak in Grenada. Mothers who gave birth during the 2014 CHIKV outbreak and up to 1 year after the outbreak were recruited. Questionnaire data was collected on the timing and symptoms of their CHIKV infection and pregnancy, delivery and newborn outcomes. To date 156 participants have been recruited and classified into 2 groups by reported history and confirmed exposure to CHIKV by IgG ELISA: those infected with CHIKV during pregnancy and those not infected during pregnancy. Demographic and symptom data, pregnancy and neonatal outcomes were compared. Of the 156 participants, 110 (71%) reported CHIKV during pregnancy and were CHIKV IgG positive. Infection occurred during the first trimester for 24 (22%) of women, second trimester for 40 (36%) of women and third trimester for 45 (41%) and during delivery for 1 (1%) woman. The most frequent maternal symptoms reported were, arthralgia (86%), fever (65%), muscle pains (39%), headache (38%), rash (38%), itchiness (37%) and generalized body aches (27%). There was no significant difference in duration or types of symptoms reported between those infected during pregnancy compared to those who experienced CHIKV infection prior to pregnancy. Pregnancy outcomes were similar between the two groups; however, neonatal complications were significantly higher in the CHIKV during pregnancy group (26% vs. 7%;  $p = 0.006$ ). This ongoing study adds to the limited data on the effects of CHIKV infection during pregnancy on birth outcomes and will be useful to inform physicians caring for pregnant women with CHIKV infection and their newborns.

## 2

## SAFETY AND IMMUNOGENICITY OF A LIVE RECOMBINANT MEASLES VECTOR BASED CHIKUNGUNYA VACCINE IN HEALTHY ADULTS: A RANDOMIZED, PLACEBO CONTROLLED PHASE 2 STUDY

Sabrina Schrauf, Katrin Ramsauer, Matthias Müllner, Andrea Pfeiffer, Alexander Kort, **Erich Tauber**

Themis Bioscience GmbH, Vienna, Austria

Themis is developing a safe, effective and affordable preventive vaccine platform against priority pathogen diseases that have the potential to cause epidemics such as Chikungunya or Zika virus infection by using a "plug-and-play" vaccine technology. This technology is based on a measles vaccine vector (MV) that can be easily genetically modified to express immunoprotective proteins for designated emerging infectious pathogens. This delivery platform technology has already demonstrated proof of principle in humans through a Phase 1 clinical trial in 42 healthy volunteers with a recombinant measles vaccine against Chikungunya virus (MV-CHIK). We showed that the vaccine was well tolerated. One immunization

induced functional, neutralizing antibodies in up to 90% of immunized subjects, a second immunization induced 100% seroconversion. Importantly, immunogenicity was independent of pre-existing anti-vector (measles) immunity. The vaccine efficacy was demonstrated in non human primates that were challenged with wildtype Chikungunya virus. All animals were protected against CHIKV viremia and disease symptoms. A Phase 2 clinical trial in 320 healthy subjects is currently ongoing in Austria and Germany with the goal to demonstrate the vaccine vector safety and immunogenicity in up to 300 subjects. Preliminary data will be presented here for the first time.

## 3

## AN INDEX CLUSTER STUDY OF CHIKUNGUNYA IN NICARAGUA WITH SPATIAL AND RISK FACTOR ANALYSES

**Fausto Bustos**<sup>1</sup>, Guillermina Kuan<sup>2</sup>, Nery Sanchez<sup>3</sup>, Sergio Ojeda<sup>3</sup>, Brenda López<sup>3</sup>, Raquel Burger-Calderon<sup>1</sup>, Lionel Gresh<sup>3</sup>, Aubree Gordon<sup>4</sup>, Angel Balmaseda<sup>5</sup>, Angel Balmaseda<sup>5</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Health Center Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, <sup>3</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>4</sup>Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, <sup>5</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Chikungunya virus (CHIKV) is a mosquito-borne pathogen that has recently emerged in the Americas. Three main lineages of CHIKV exist, and the Asian lineage is responsible for the American epidemic. In light of this recent introduction, an urgent need exists to understand the transmission and characteristics of CHIKV in this new ecology. Therefore, we carried out an index cluster study of 60 RT-PCR-confirmed symptomatic chikungunya index cases presenting to the study health center and 236 household family members (contacts). Baseline (day 1) and follow-up RT-PCR and serological testing via IgM ELISA and Inhibition ELISA (day 3 and day 14 or 35), combined with questionnaires of clinical manifestations at all time-points, enabled identification of incident symptomatic and asymptomatic infections among the at-risk household contacts. We identified 90 contacts with current infections at baseline and 21 contacts who were RT-PCR-negative at baseline but who seroconverted over the study period. We estimated a symptomatic-to-asymptomatic (S:A) ratio of 1:1.91 (95% bootstrapped-based CI: 1.06, 4.40). A variable importance analysis, combined with GEE logistic regression to account for clustered observations, identified a high frequency of trash collection (OR = 0.38, 95% CI: 0.21, 0.67), having an outside water faucet (OR = 0.41, 95% CI: 0.22, 0.76), ownership of a car or motorcycle (OR = 1.99, 95% CI: 1.11, 3.58), and age (OR = 1.02, 95% CI: 1.00, 1.03) as significant predictors of CHIKV infection over the study period and across households. Spatial analysis identified two households that were hotspots for seroconversions. Our analyses suggest that the Asian clade of CHIKV present in the Americas causes fewer symptomatic cases than the more widespread East/Central/South African CHIKV lineage, which has a reported S:A ratio of 1:0.03 to 1:0.39. Overall, these results help inform regionally specific public health planning for future CHIKV outbreaks as well as modeling of CHIKV transmission dynamics.

## 4

## IN THE SEARCH OF THE HIDDEN PATH: THE SOURCE AND SPREAD OF CHIKUNGUNYA AND ZIKA VIRUSES

**Adriano de Bernardi Schneider**, Lambodhar Damodaran, Zachary Witter, Daniel Janies

University of North Carolina at Charlotte, Charlotte, NC, United States

Recent outbreaks of taxonomically diverse arboviruses around the world have raised concern in the global health community about how to abate the spread of these viruses. A strategy to avoid future outbreaks is not only respond to current endemic events, but also isolate the regions

around the world that serve as hubs for the spread of the viruses. Using phylogenetic analysis of whole genomic sequences as the starting point, we analyze changes of place of isolation in transmission graphs to demonstrate not only the source of outbreaks but also key geographic regions that facilitate the spread. This work uses betweenness centrality of transmission networks to identify geographic hubs for the spread of viral lineages. The identification of hubs for the spread of viruses can show recurrent events that can help to design abatement strategies. Of interest in this comparison is the similarity of the transit across the world of these taxonomically diverse viruses that have similar vector biology. Thus, in addition to understanding hubs for the spread of these viruses, we underscore the importance of vector control. In our results, we observe a major hub for Chikungunya in SE Asia and Oceania as sources for the current outbreaks. In contrast, the outbreak of Zika, which had its origin in Asia, has a hub in South America. Increased viral surveillance, as well rapid sequencing of pathogens from infected patients worldwide is the current path that will allow more granular studies required to investigate emerging diseases as they evolve and spread.

## 5

### ADAPTED LONGITUDINAL MOSQUITO SALIVA COLLECTION METHOD FOR DETERMINING ARBOVIRUS VECTOR COMPETENCE INCREASES BIOSAFETY AND CAPACITY

**Nathaniel M. Byers**, Jeremy P. Ledermann, Ann M. Powers  
*Centers for Disease Control and Prevention, Fort Collins, CO, United States*

The recent emergences of Zika, chikungunya and yellow-fever viruses emphasize the need for rapid, reliable, and safe methods for assaying arbovirus transmission from various species of mosquitoes. For transmission to occur, arboviruses must replicate in the mosquito salivary glands and transmit in the saliva upon feeding on a vertebrate host. Hence, assaying titers of virus in mosquito saliva is an essential aspect of evaluating the transmission potential of the vector-virus system. Current collection methods are laborious and typically require sacrificing the mosquito, limiting researchers to a single saliva collection time point per insect. To optimize the collection of mosquito saliva, we adapted the field-oriented honey-trap method to the laboratory setting. The adaptation of this technique allows us to collect multiple individual saliva samples over time by providing filter paper soaked with a sucrose solution, into which the mosquitoes deposit their saliva. To detect chikungunya virus from experimentally infected mosquitoes, quantitative reverse-transcription PCR, normalized to a standard curve, was performed on RNA purified from the filter paper. We found that 12-well plates sealed with a specially designed lid (made by 3-D printing) and organoids were suitable habitats for both *Anopheles gambiae* and *Aedes aegypti*, as they provided a compact living space and improved biosafety. We optimized several aspects of the feeding, including filter paper size and type, food amount, and dye concentration for visually identifying fed mosquitoes. Our filter paper saliva collection technique is a promising method for assaying arbovirus transmission rates over time from experimentally infected mosquitoes as it facilitates rapid longitudinal collection of infected saliva from individual mosquitoes. Also, by eliminating the need for glass capillaries and reducing manipulation of mosquitoes, this technique improves biosafety, saves time and allows for increased numbers of mosquitoes per experiment.

## 6

### EMERGENCE OF RECOMBINANT MAYARO VIRUS STRAINS FROM THE AMAZON BASIN, THE DAWN OF A NEW EPIDEMIC?

**Carla N. Mavian**<sup>1</sup>, Brittany D. Rife<sup>1</sup>, James Jarad Dollar<sup>1</sup>, Eleonora Cella<sup>2</sup>, Massimo Ciccozzi<sup>2</sup>, Mattia C. Prosperi<sup>1</sup>, J Glenn Morris Jr<sup>1</sup>, Ilaria Capua<sup>1</sup>, Marco Salemi<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>Istituto Superiore di Sanità, Rome, Italy

Mayaro virus (MAYV), the causative agent of Mayaro fever, is an arbovirus transmitted by the *Haemagogus* species of mosquito endemic to the Amazonian forest in South America. Despite its role in a highly debilitating disease and recent evidence of spread areas outside of the Amazonian regions of Central and South America, limited information about the evolution and the epidemiology of MAYV represent an important barrier to prevention of further spread. We analyzed host adaptability, evolutionary and epidemiological history of MAYV strains collected within the Amazon basin, São Paulo State, and Haiti. Bayesian phylogeography based on molecular clock calibrated genealogies was used to investigate the spatiotemporal spread of MAYV lineages in South American and the Caribbean areas, as well as to infer the origin of detected recombination events. Our analysis revealed specific adaptations to a broad host and vector range, including humans and the *Aedes* mosquito species, and assessed recombination events. The first recombinant strain appeared between 2002 and 2013 in Pará State (Brazil), and moved to São Paulo State, giving rise to a second recombinant that was eventually isolated in Haiti in 2015. We hypothesize that human mobility and adaptability to a broad range of host and vector species played a central role in the emergence of recombinant strains, which are usually rare among arboviruses. Moreover, the potential urbanization of this virus might be the beginning of a much larger, more global epidemic and deserves, therefore, close monitoring in the immediate future.

## 7

### RE-EMERGING OF MAYARO VIRUS IN AREAS WITH CIRCULATION OF DENGUE VIRUS IN THE PERUVIAN AMAZON

**Marco Coaguila**, Maria Garcia, Maribel Figueroa, Nancy Merino, Adolfo Marcelo, Miguel Cobos, Cesar Cabezas  
*National Institute of Health, Lima, Peru*

Mayaro virus is an Alphavirus (family *Togaviridae*). The circulation of Mayaro virus is frequently a cause of enzootic disease. Climate change is altering its ecological niche and can affect populations of immunologically “virgin” humans. Infection with Mayaro virus presents symptoms similar to dengue, so it is important to consider the differential diagnosis with other arboviruses. The circulation of Mayaro virus in samples with a presumptive diagnosis of Dengue within the surveillance of Dengue in 4 regions of the Amazon region of Peru was investigated. A descriptive study was carried out between January and March 2017, including the analysis of 1,983 serum samples from patients presenting with acute febrile syndrome compatible with dengue, which were referred to the Viral Metaxenic Laboratory of the National Health Institute from dengue surveillance in Peru. Samples were inoculated into C6/36 HT (ATCC 1660, *Aedes albopictus*) and Vero (ATCC, CCL-81, *Cercopithecus aethiops*) cells. Cultures in which the cytopathic effect was evidenced, were evaluated for Dengue, Zika, EEV, Chikungunya, Mayaro and Oropuche virus, by Immunofluorescence Assay (IFA) using monoclonal and polyclonal antibodies (CDC, Puerto Rico). The results show the isolation of 186 viral strains: 155 cases of DENV2 (83.3%), 13 cases DENV3 (6.9%), 5 cases DENV4 (2.7%), 2 cases ZIKAV (1.1%) and 11 cases with MAYV (5.9%). The results obtained were corroborated by RT-PCR, confirming the circulation of Mayaro virus, in addition to Dengue virus in the Peruvian Amazon. It was evidenced the co-circulation of MAYV and DENV in the Peruvian

Amazon. These results highlight the importance to carry out surveillance of the febrile syndrome and the development of tests for a simultaneous and timely diagnostic of other arboviruses with febrile syndrome according to the different ecological niches.

## 8

### NON-INFERIORITY COMPARISON OF TAFENOQUINE SIX-MONTH RELAPSE-FREE EFFICACY VERSUS PRIMAQUINE IN *PLASMODIUM VIVAX* INFECTION: AN INDIVIDUAL PATIENT DATA META-ANALYSIS

Lindsay K. Kendall<sup>1</sup>, Khadeeja Mohamed<sup>2</sup>, John J. Breton<sup>3</sup>, Gavin C. Koh<sup>2</sup>, Justin A. Green<sup>2</sup>

<sup>1</sup>GlaxoSmithKline, Stevenage, United Kingdom, <sup>2</sup>GlaxoSmithKline, Uxbridge, United Kingdom, <sup>3</sup>GlaxoSmithKline, Philadelphia, PA, United States

Tafenoquine (TQ; SB-252263; WR238605) is an 8-aminoquinoline drug for the radical cure of *Plasmodium vivax* malaria being co-developed as a single dose treatment by GlaxoSmithKline (GSK) and Medicines for Malaria Venture (MMV). The phase 3 programme for tafenoquine consists of an efficacy study (DETECTIVE part 2, NCT01376167) and a safety study (GATHER, NCT02216123). DETECTIVE part 2 is designed to demonstrate superior efficacy of single-dose TQ 300mg over placebo. An arm taking primaquine (PQ 15mg for 14 days) is included for benchmarking, but the study is not powered to make a direct comparison of TQ versus PQ. GATHER is a safety study comparing the TQ versus PQ, the primary endpoint being clinically-relevant haemoglobin (Hb) decline (defined as a Hb decline >30g/L or ≥30% from baseline, or an absolute fall to <60g/L) and the need for blood transfusion. Recruitment was completed for both trials at the end of 2016. Patients were aged ≥16 years, with glucose-6-phosphate dehydrogenase activity levels ≥70% of the median in normal males for that site (or ≥40% for females in GATHER only). All patients received chloroquine at baseline and were followed up for six months to monitor for *P. vivax* relapse and for safety. Patients were recruited from Brazil, Cambodia, Colombia, Ethiopia, the Philippines, Peru, Thailand, and Vietnam. The studies were approved by the respective ethics committees governing each site. Together, these studies will contain data from ~420 patients treated with TQ and ~210 treated with PQ (exact numbers not known prior to unblinding). We will present a meta-analysis of six-month relapse-free efficacy using individual patient-level data to test the hypothesis that TQ is non-inferior to PQ. The TQ versus PQ hazard ratio and 95% confidence interval (from multivariable Cox regression) will be assessed for non-inferiority based on a pre-determined non-inferiority margin of 1.21 (translated from a 75% preserved effect of PQ versus placebo). Superiority of TQ over PQ will be claimed, if it exists. We will also present summaries for each study of adverse events by frequency and severity, including Hb decline and blood transfusions.

## 9

### CONFIRMATION OF THE BLOOD STAGE SCHIZONTICIDAL ACTIVITY OF TAFENOQUINE IN A RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED *PLASMODIUM FALCIPARUM* INDUCED BLOOD STAGE MALARIA CHALLENGE STUDY

James S. McCarthy<sup>1</sup>, Bryan L. Smith<sup>2</sup>, Lisa T. Read<sup>3</sup>, Geoffrey Dow<sup>2</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Herston, Australia, <sup>2</sup>60 Degrees Pharmaceuticals LLC, Washington, DC, United States, <sup>3</sup>USAMMDA, Fort Detrick, MD, United States

Tafenoquine (TQ), a primaquine analog, with a half-life of ~14 days, has appealing properties as a drug for malaria chemoprophylaxis. Previous studies have suggested that TQ is effective against both liver and asexual blood stages of *Plasmodium falciparum*. However, it was difficult to determine the contribution of the blood stage activity to its overall

prophylactic effect. To investigate its blood stage schizonticidal activity distinct from liver stage activity, a randomized, double-blinded, placebo-controlled blood stage challenge study with *P. falciparum* was undertaken in 16 healthy, malaria-naïve adults. The study was conducted in 2 cohorts of 8 (6 active/2 placebo), with subjects in each cohort receiving 200 mg of TQ or placebo on days 1, 2, 3 and 10, followed by an IV inoculation with 2,800 *P. falciparum* blood stage parasites on day 13. The primary endpoint was the number of participants requiring rescue treatment with artemether/lumefantrine due to PCR-determined parasitemia >5,000/mL before end of study (Day 32). Secondary endpoints include adverse effects, and TQ concentration if drug failure occurred. All 12 subjects in the TQ arm remained PCR-negative, while all 4 subjects allocated to placebo reached target parasitemia in the expected timeframe. Two subjects had a mild asymptomatic drop in Hb: A female subject allocated to the TQ arm had a 28g/L (20.3% from baseline of 138g/L) drop despite normal G6PD levels. G6pd Genotyping is underway; a male subject, also allocated to TQ had a transient 20g/L (13.7% from baseline of 146g/L) drop in Hb. In conclusion, the findings of this study support the hypothesis that TQ has sufficient blood stage schizonticidal activity to prevent clinical malaria if there is a small subpopulation of liver stage *P. falciparum* parasites that escape its causal prophylactic effect of TQ.

## 10

### BUZZOFF - A PHASE 1A, FIRST-IN-HUMAN STUDY OF (+)-SJ000557733 (SJ733), AN ORAL, NOVEL INHIBITOR OF *PLASMODIUM FALCIPARUM* PLASMA MEMBRANE PROTEIN PFATP4

Aditya H. Gaur<sup>1</sup>, John C. Panetta<sup>1</sup>, Ronald Dallas<sup>1</sup>, Li Tang<sup>1</sup>, Tracy B. Stewart<sup>1</sup>, Kristen C. Branum<sup>1</sup>, Burgess B. Freeman, III<sup>1</sup>, Nehali D. Patel<sup>1</sup>, Elizabeth John<sup>2</sup>, Stephan Chalon<sup>3</sup>, Shelley Ost<sup>4</sup>, Ryan N. Heine<sup>1</sup>, Julie L. Richardson<sup>1</sup>, Robbin Christensen<sup>1</sup>, Patricia M. Flynn<sup>1</sup>, Yvonne Van Gessel<sup>5</sup>, Branko Mitasev<sup>5</sup>, Jörg J. Möhrle<sup>3</sup>, Fabian Gusovsky<sup>5</sup>, Lidiya Bebrevska<sup>3</sup>, James McCarthy<sup>6</sup>, R. Kip Guy<sup>7</sup>

<sup>1</sup>St. Jude Children's Research Hospital, Memphis, TN, United States, <sup>2</sup>EJOHN Consulting, Richland, WA, United States, <sup>3</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>4</sup>University of Tennessee, Memphis, TN, United States, <sup>5</sup>Eisai Inc., Andover, MA, United States, <sup>6</sup>QIMR Berghofer Medical Research Institute, Herston, Australia, <sup>7</sup>University of Kentucky College of Pharmacy, Lexington, KY, United States

SJ773 is a novel, orally available inhibitor of *P. falciparum* ATP4 (PfATP4; a critical sodium-proton antiporter in the parasite), and the second in class to enter clinical development. Preclinical data indicating potent activity against both standard and drug resistant *P. falciparum* and no predicted significant toxicity prompted the conduct of a Phase 1a, First-In-Human Safety and Pharmacokinetic (PK) in adult healthy volunteer study (ClinicalTrials.gov: NCT02661373). The study employed a single ascending dose (SAD) escalation design with an adaptive component, allowing for modifications to the dose increments and number of subjects per cohort based on PK results. In the SAD, six dose increments were administered in a fasting state (75, 150, 300, 600, 900, 1200 mg) using a leap-frog study design. All 23 subjects (22 male, one female) administered 42 single doses of SJ733 tolerated the study drug well, with no serious adverse events, dose limiting toxicities, Grade 3 or 4 adverse events (AE), or clinically significant ECG/safety laboratory tests findings. A majority of the reported AEs were Grade 1 or less and considered unlikely or un-related to SJ733. Plasma exposure of SJ733 and its major N-oxide metabolite SJ506 following single oral doses of SJ733 were dose-proportional across the 75 - 600 mg dose range, but plateaued at 900 mg. The median CL/F for doses ≥ 900 mg was higher than the median value at 75 - 600 mg (56 vs 32 L/h for SJ733 and 27 vs 17 L/h for SJ506). The median Tmax for SJ733 was 1.2 h (range 0.7 - 3.0 h). The median t1/2 was dose-independent around 19 h for both SJ733 and SJ506. 14 of 15 subjects receiving ≥ 600 mg SJ733 exceeded the target efficacious exposure of 13,000 hr-ng/mL defined from a relevant preclinical murine malaria model. A standard FDA high-fat meal at 600 mg did not affect exposure of SJ733, but appeared to slow the absorption. A phase 1a multiple ascending dose study is currently

ongoing. In summary, SJ733 demonstrated favorable PK and safety profiles to date in healthy adults. These results prompted the interposed start of a Phase 1b human challenge study where SJ733 is tested against induced blood-stage malaria.

## 11

### PROPHYLACTIC ACTIVITY OF DSM265 AGAINST PRE-ERYTHROCYTIC *PLASMODIUM FALCIPARUM* CONTROLLED HUMAN MALARIA INFECTION BY MOSQUITO BITES AND DIRECT VENOUS INJECTION

**Sean C. Murphy**<sup>1</sup>, Elizabeth Duke<sup>2</sup>, Kelly J. Shipman<sup>2</sup>, Ryan L. Jensen<sup>2</sup>, Youyi Fong<sup>2</sup>, Sue Ferguson<sup>2</sup>, Holly E. Janes<sup>3</sup>, Kevin Gillespie<sup>3</sup>, Annette M. Seilie<sup>1</sup>, Amelia E. Hanron<sup>1</sup>, Laurie Rinn<sup>2</sup>, Matthew Fishbaugher<sup>4</sup>, Tracie VonGoedert<sup>4</sup>, Emma Fritzen<sup>4</sup>, Stefan H. Kappe<sup>4</sup>, Ming Chang<sup>1</sup>, Jason C. Sousa<sup>5</sup>, Sean R. Marcisin<sup>5</sup>, Thomas Rueckle<sup>6</sup>, Stephan Chalon<sup>6</sup>, Stephan Duparc<sup>6</sup>, Nicola Kerr<sup>6</sup>, Jorg J. Mohrle<sup>6</sup>, Nicole Andenmatten<sup>6</sup>, James G. Kublin<sup>2</sup>

<sup>1</sup>University of Washington Medical Center, Seattle, WA, United States, <sup>2</sup>Seattle Malaria Clinical Trials Center, Seattle, WA, United States, <sup>3</sup>Vaccine and Infectious Disease Division, Fred Hutch Cancer Research Center, Seattle, WA, United States, <sup>4</sup>Center for Infectious Disease Research, Seattle, WA, United States, <sup>5</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>6</sup>Medicines for Malaria Venture, Geneva, Switzerland

New anti-malarial drugs are needed for prophylaxis and radical cure. DSM265 is a triazolopyrimidine-based inhibitor of dihydroorotate dehydrogenase (DHODH), a key enzyme in pyrimidine biosynthesis. DSM265 demonstrated promising preclinical activities against liver and blood stages. The drug also showed causal prophylactic activity when given one day prior to controlled human malarial infection (CHMI) by direct venous inoculation (DVI) with *Plasmodium falciparum* (Pf) sporozoites (PfSPZ) but was less efficacious when administered one week before CHMI. This trial was performed to assess the safety, tolerability, pharmacokinetic profile and prophylactic activity of a single 400mg dose of DSM265 3 or 7 days prior to CHMI initiated by either DVI of PfSPZ or by five Pf-infected mosquito bites. The goal was to refine the dosing interval for prophylaxis. Subjects were treated with atovaquone-proguanil upon reaching a qRT-PCR treatment threshold of  $\geq 250$  estimated parasites/mL. Three cohorts (6 treated + 2 placebo control subjects) were completed with DSM265 dosing 3 (Cohort 1) or 7 (Cohort 2a) days prior to PfSPZ DVI CHMI or 7 days prior to mosquito bite CHMI (Cohort 2b). The most common AE related to DSM265/placebo dosing was Grade 1-2 headache. There were no Grade 3 AEs related to DSM265. DSM265 pharmacokinetics were similar for all cohorts (AUC[0-240hr] 1241  $\mu\text{g/mL} \times 240$  hrs). Placebo controls rapidly became treatment eligible a median of 8.3 days post-CHMI. For DSM265-treated subjects, 2/6 in each cohort were sterilely protected while 4/6 showed considerable delay in time to treatment compared to placebo controls [median time to treatment Cohort 1: 21.9 d; Cohort 2a: 15.3 d; Cohort 2b: 16.9 d;  $p = 0.004$ , log-rank test comparing time to treatment DSM265 vs. placebo for each cohort]. One dose of DSM265 (400 mg) given 3 or 7 days prior to CHMI was safe, well tolerated, sterilely protected 33% of subjects and delayed time to treatment in the rest. Future studies should evaluate weekly DSM265 dosing. This is the first drug study to directly compare DVI vs. mosquito bite CHMI, and times to positivity and treatment as well as parasite densities were comparable for both routes.

## 12

### A PHASE 1 EVALUATION OF THE PHARMACOKINETIC-PHARMACODYNAMIC INTERACTION OF THE ANTIMALARIAL AGENTS KAF156 AND PIPERAQUINE

F. Joel Leong<sup>1</sup>, Jay Prakash Jain<sup>2</sup>, Elie Feng<sup>3</sup>, Budhaditya Goswami<sup>2</sup>, Daniel S. Stein<sup>4</sup>, **Cornelis Winnips**<sup>5</sup>

<sup>1</sup>Novartis Institute for Tropical Diseases, Singapore, Singapore, <sup>2</sup>Novartis Healthcare Private Limited, Hyderabad, India, <sup>3</sup>Novartis Institutes for BioMedical Research, Shanghai, China, <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, <sup>5</sup>Novartis Pharma AG, Basel, Swaziland

KAF156, an imidazolopiperazine, represents a new antimalarial class with activity against asexual and sexual blood stages and the preerythrocytic liver stages. Based on *in vitro* data, a two way interaction was hypothesized for KAF156 use in combination with piperavaquine (PPQ), a long acting antimalarial, as both drugs are CYP3A4 substrates and inhibitors. PPQ is known to prolong the QT interval and therefore potential combination effects on the QT interval were also assessed. This was an open-label, parallel-group, single-dose study in healthy volunteers randomized to three parallel dosing arms (1:1:1) of 800 mg KAF156 + 1280 mg PPQ, 800 mg KAF156 alone and 1280 mg PPQ alone. Triplicate ECGs were done over the first 48 hours after dosing. Routine safety and pharmacokinetic assessments were carried out up to 61 days. Of the 72 healthy male subjects recruited, 68 completed the study. Co-administration of PPQ and KAF156 had no overall effect on AUC of both the drugs. However, C<sub>max</sub> values of both KAF156 (~23%) and piperavaquine (~70%) increased. Statistically it could not be concluded or ruled out an at least 30% increase in the C<sub>max</sub>. Both drugs given alone or in combination were well tolerated with no deaths and serious adverse events (SAEs). AEs were observed at the frequency of 87.5%, 79.2% and 58.3% respectively for the KAF156+PPQ, PPQ arm and KAF156 arm. The most common AEs were nausea and headache. There were no Grade 3 or 4 events. There were no ECG related AEs, no QTcF interval >480 msec and no QTcF interval increase from Baseline >60 ms. Mean maximum increase was observed at 24 hours post-dose for both KAF156+PPQ and KAF156 monotherapy arm; the mean increase from pre-dose was 7.9 msec and 6.6 msec, respectively. For PPQ monotherapy arm, the maximum increase from pre-dose was found to be 1.8 msec (mean) at 4 hour post-dose. There was no significant difference between the combination arm and other arms in maximum change QTcF ( $p > 0.05$ ). Overall, no safety/cardiac risk or drug-drug interaction was identified which would preclude use of KAF156 and PPQ combination in future studies.

## 13

### A RANDOMIZED TRIAL OF THE SAFETY AND EFFICACY OF LOW DOSE PRIMAQUINE IN THE TREATMENT OF ADULT PATIENTS WITH *PLASMODIUM FALCIPARUM* MALARIA IN SENEGAL

**Roger C. Tine**<sup>1</sup>, Khadime Sylla<sup>1</sup>, Babacar T. Faye<sup>1</sup>, Fatou B. Fall<sup>2</sup>, Doudou Sow<sup>1</sup>, Magatte Ndiaye<sup>1</sup>, Jean L. Ndiaye<sup>1</sup>, Babacar Faye<sup>1</sup>, Oumar Gaye<sup>1</sup>, Paul Milligan<sup>3</sup>

<sup>1</sup>Service de Parasitologie, Faculté de Médecine de Dakar, Dakar, Senegal, <sup>2</sup>National Malaria Control Programme, Ministry of Health Senegal, Dakar, Senegal, <sup>3</sup>Faculty of Epidemiology and Public Health, London School of Hygiene & Tropical Medicine, London, United Kingdom

The addition of a single dose of primaquine (0.25 mg base/kg) to artemisinin combination treatments (ACTs) is a potentially useful component of malaria pre-elimination or elimination programmes. But before it can be widely used in Africa more information about its safety in populations where G6PD deficiency (G6PDd) is common is required. This study assessed the safety of adding low-dose primaquine to the normal ACT regimen in adult patients treated for malaria in Senegal. Adults with *Plasmodium falciparum* malaria were randomized to receive one of three

ACT with or without primaquine (PQ) (0.25mg/kg). G6PD status was determined using a rapid test. Patients were followed for 28 days to record haemoglobin concentration, adverse events, and gametocyte carriage. The primary end point was the change in Hb at day 7. Other end points included: occurrence of severe anaemia (Hb<8), gametocyte carriage; incidence of clinical adverse events. A mixed model was used to estimate the effect of PQ on haemoglobin concentration at each time point, and to assess the interaction with G6PD status. 274 patients were randomized, 139 received an ACT alone, and 135 received an ACT+PQ. The mean reduction in Hb at day 7 was similar in each group with a difference in the ACT+PQ versus the ACT alone group of -0.04g/dL (95%CI -0.23,0.31) but the effect of primaquine differed according to G6PD status. In G6PDd patients the drop in Hb was 0.63g/dL (95%CI 0.03;1.24) greater in those who received PQ than in those who received an ACT alone. In G6PD-normal patients, the reduction in Hb was 0.22g/dL (95%CI -0.08;0.52) less in those who received PQ (interaction  $p=0.01$ ). Dark urine was more frequent in patients who received PQ. PQ was associated with a 73% (95%CI:24 - 90) reduction in gametocyte carriage ( $p=0.013$ ). In conclusion, Primaquine substantially reduced gametocyte carriage. However, the fall in Hb concentration at day 7 was greater in G6PD-deficient patients who received primaquine than in those who did not.

## 14

### THE PLASMODIAL ACYL CO-A SYNTHETASE 10 AND 11 ARE INVOLVED IN DRUG RESISTANCE TO TWO DISTINCT ANTIMALARIAL COMPOUNDS

**Selina Bopp**<sup>1</sup>, Pamela A. Magistrado<sup>1</sup>, Victoria C. Corey<sup>2</sup>, Maria G. Gomez-Lorenzo<sup>3</sup>, Virginia Franco<sup>3</sup>, Allison Demas<sup>1</sup>, Amanda K. Lukens<sup>4</sup>, Francisco-Javier Gamo<sup>3</sup>, Elizabeth A. Winzeler<sup>2</sup>, Dyann F. Wirth<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>University of California San Diego, San Diego, CA, United States, <sup>3</sup>Malaria DPU, GlaxoSmithKline, Tres Cantos, Spain, <sup>4</sup>The Broad Institute, Cambridge, MA, United States

The emergence and spread of drug resistance to current antimalarial therapies remains a pressing concern, escalating the need for compounds that demonstrate novel modes of action and prevent the development of drug resistance. The Malaria Drug Target Identification Project has adopted a chemogenomic approach to identify targets of the most promising compounds from chemically diverse libraries. Study compounds were selected based on availability, purity, and potency in a multi-drug resistant isolate, and lack of known mechanism of action. To generate resistant parasite lines 3D7 parasites were cultured in the presence of these novel compounds until they showed at least a 2-fold shift in EC50 at which time they were cloned and analyzed by whole genome sequencing. Two structurally unrelated compounds analyzed (MMV665924 and MMV019719) selected for parasites with mutations in the acyl Co-A synthetase 11 (ACS 11, PF3D7\_1238800) gene. Selection with MMV665924 also resulted in a single nucleotide polymorphism (SNP) in the ACS10 (PF3D7\_0525100) locus. ACS11 and ACS10 are both members of the ACS gene family that activate fatty acids (FA) scavenged from the host. To confirm the role of these mutations in resistance to the two compounds we used the CRISPR/CAS9 system to introduce the SNPs into a 3D7 line. Introduction of the SNPs increased the level of resistance to the same level as the drug selected lines confirming the role of these SNPs in drug resistance. These are the first functional mutations in this gene family. However, the ACS family is heterogeneous both with regards to gene number and diversity within natural populations. ACS10 and 11 alone have 65 different nonsynonymous SNPs reported. We discovered natural mutations at the same site at high prevalence in the Malawi parasite population. Indeed, an isolate containing the M3001 mutation in ACS10 was fourfold more resistant to MMV665924 than a matched wild-type Malawi isolate. These findings indicate that mutations in *loci* related to FA activation can confer drug resistance, and that these mutations are identified among natural *P. falciparum* isolates from Malawi implicating their importance.

## 15

### GENOMES OF TROMBIDIID MITES UNCOVER ADAPTATIONS TO PARASITISM IN THE SCRUB TYPHUS VECTOR, LEPTOTROMBIDIUM DELIENSE

Xiaofeng Dong<sup>1</sup>, Kittipong Chaisiri<sup>2</sup>, Martin J. Donnelly<sup>3</sup>, John W. McGarry<sup>4</sup>, Tatsuhiko Kadowaki<sup>1</sup>, Alistair C. Darby<sup>4</sup>, **Ben L. Makepeace**<sup>4</sup>

<sup>1</sup>Xi'an Jiaotong-Liverpool University, Suzhou, China, <sup>2</sup>Mahidol University, Bangkok, Thailand, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>4</sup>University of Liverpool, Liverpool, United Kingdom

The mite superfamily Trombidoidea, in which only the larvae are parasitic, contains two major families, the Trombidiidae and the Trombiculidae. Trombidiids (velvet mites) include species in which the larvae parasitize arthropods of agricultural, veterinary and/or medical importance, and some adult forms are predators of pest arthropods. Larval trombiculids, commonly known as "chiggers," parasitize a wide range of vertebrates, including humans, and are vectors of scrub typhus, a tropical disease of increasing importance worldwide. Here we present the genomes of the giant red velvet mite, *Dinotrumbium tinctorium*, and the primary South-East Asian scrub typhus vector, *Leptotrombidium deliense*. In support of the classical taxonomic scheme, these species form a distinct branch of the order Trombidiformes, with an estimated divergence time from the spider mites (Tetranychidae) of 250 million years. Relative to the phytophagous *Tetranychus urticae*, trombidioid mites exhibit a small expansion in ionotropic receptors involved in olfaction and temperature sensing. Approximately 25 orthologous clusters of putative salivary proteins in the trombidioid mites are shared with ticks but not the more closely related *T. urticae*, and include proteins with potential roles in folate metabolism, countering inflammation, and vasoconstriction. In *L. deliense*, several predicted allergens are present that were not found in other mite genomes, including *Sarcoptes scabiei*. Moreover, analysis of bacterial sequences revealed that *Borrelia* and *Francisella* are among the more abundant components of the *L. deliense* microbiome. These findings highlight adaptations to parasitism of the trombidioid mites and will facilitate further high-throughput and functional analyses for exploitation and control of this group.

## 16

### COMMUNITY DIRECTED VECTOR CONTROL FOR ONCHOCERCIASIS

Benjamin Jacob<sup>1</sup>, Denis Loum<sup>2</sup>, Thomson Lakwo<sup>3</sup>, Peter Alinda<sup>3</sup>, Peace Habomugisha<sup>4</sup>, **Thomas R. Unnasch**<sup>1</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Nwoya District Local Government Health Department, Gulu, Uganda, <sup>3</sup>Vector Control Division, Ministry of Health, Kampala, Uganda, <sup>4</sup>The Carter Center, Kampala, Uganda

Onchocerciasis elimination programs rely primarily upon mass distribution of ivermectin (MDA). However, supplementing MDA with vector control will accelerate, and in some cases may be necessary, to achieve elimination. Insecticide treatment of vector (*Simulium* spp) breeding sites is the accepted method of vector control for onchocerciasis. However, this is both expensive and potentially harmful to the environment. We have evaluated a novel vector control method based upon removal of vegetative substrates for black fly larvae by community members (Slash and Clear). *S. damnosum* s.l. breeding sites in Northern Uganda were identified using a previously developed remote sensing model. A total of eight communities located within 1km of a breeding site were identified and organized into pairs. Biting rates were monitored in all communities for 8 days. Volunteers from one community in each pair were then taught to remove the trailing vegetation at the breeding sites, while no interventions were carried out in the paired control community. Biting rates were then monitored for a period of 21 days post intervention. A significant reduction in the biting rates (averaging 90%) was observed at days 16-21 post intervention the intervention communities, while biting rates in the control averaged 100%

of those seen in the first seven days at days 16-21. Long-term followup in two villages indicated that the effect was long lasting, with fly numbers in two intervention communities reaching just 31% of pre-intervention levels at 130 days post-intervention. These data suggest that slash and clear may represent a viable alternative to insecticide treatment of breeding sites for reduction of *S. damnosum* s.l. biting in onchocerciasis endemic communities in Africa. Combining slash and clear with ivermectin MDA may accelerate elimination of onchocerciasis in many communities where this technique is feasible.

## 17

### ATTRACTION AND OVIPOSITION PREFERENCES OF *PHLEBOTOMUS PAPTASI*, VECTOR OF OLD-WORLD CUTANEOUS LEISHMANIASIS, TO LARVAL REARING MEDIA AND SAPROPHYTIC BACTERIA

Gideon Wasserberg<sup>1</sup>, Bhajat F. Marayati<sup>1</sup>, Tatsiana Symanovich<sup>1</sup>, Loganathan Ponnusamy<sup>2</sup>, Charles Apperson<sup>2</sup>, Eduardo Hatano<sup>2</sup>, Madhavi Kakumanu<sup>2</sup>, Coby Schal<sup>2</sup>

<sup>1</sup>University of North Carolina at Greensboro, Greensboro, NC, United States, <sup>2</sup>North Carolina State University, Raleigh, NC, United States

We report the preliminary results of a systematic assessment of media from various developmental stages of the sand fly using oviposition and olfactometer behavioral assays. We conducted multiple-choice oviposition assays in 500 mL Nalgene jars. Six treatments were placed on separate filter paper discs at the bottom of the jar: 2nd/3rd larval instar medium, 4th larval instar/pupae medium, frass from expired colonies, larval food (aged rabbit chow and rabbit feces mix), rabbit feces, and a solvent (water) control. Fifty gravid females were introduced into each jar. Cumulative number of eggs laid on each filter paper per jar was counted at different time intervals from digital images. Attraction of gravid sand flies to these six treatments was assayed with a 3-chamber linear olfactometer. Twenty gravid females were transferred to the middle chamber of the olfactometer and their distribution in treatment and control chambers was recorded after 3 h. Comparing mean cumulative egg deposition among the six treatments, we found that significantly more eggs were oviposited on 2nd/3rd larval rearing medium followed by 4th instar/pupae rearing medium. The olfactometer results were consistent with the oviposition assays. Twelve bacterial species were cultured from this most-attractive substrate and evaluated for their attractiveness to gravid females. Our finding indicates that sand fly-digested host food and feces is attractive to gravid females and suggests that the larvae and larval gut microbiome may be involved in conditioning the oviposition substrate and possibly the production of oviposition attractants and stimulants. Chemical structures of GC-EAD bioactive compounds isolated from attractive bacterial strains were elucidated by gas-chromatography-mass spectrometry (GC-MS). Analysis of volatile compounds using a capillary column of different polarity revealed that the antennal active compound was a mixture of two compounds.

## 18

### A LESS DIVERSE TICK MICROBIOME IS ASSOCIATED WITH *RICKETTSIA* INFECTED TICKS

Rebecca Trout Fryxell, Jennifer DeBruyn

University of Tennessee, Knoxville, TN, United States

Spotted Fever Group Rickettsiosis agents have been identified in more than ten ixodid tick species. Specifically, in southwestern Tennessee *Rickettsia amblyommatis* was recovered from *Amblyomma americanum*, *R. parkeri* from *A. maculatum*, and *R. montanensis* from *Dermacentor variabilis*. Knowing vector microbiomes modulate infection, our objectives were to define and compare the tick microbiome by describing the microbial communities within three different tick species and comparing those communities with the presence and absence of *Rickettsia* species. Field-collected ticks were screened for *Rickettsia* using *ompA* PCR to determine initial infection, then the V3-V4 region of the 16S rRNA segment of

bacterial genomes was amplified using the Illumina MiSeq platform. The Mothur pipeline was used to investigate the structure of the microbiome of each species and determine differences based on tick species, diversity, richness, and presence of *Rickettsia*. We identified unique microbial communities within each tick species, and discovered bacteria common in all three species. We also observed a significant difference in the diversity and richness of *Rickettsia* infected ticks, and that the microbiome of *Rickettsia*-positive ticks were enriched with specific bacteria and less diverse. We also noted that the traditional *ompA*-PCR had lower sensitivity and higher specificity than 16S MiSeq libraries for amplifying *Rickettsia*. These foundational data summarize the microbial communities of three tick species associated with *Rickettsia* infection, and demonstrate the potential use of Illumina sequencing for diagnostics. Identifying the microbiota within Ixodid ticks of different species and pathogen presence-absence can provide an additional option for vector-borne zoonotic disease management to improve human and animal health.

## 19

### SARCONESIN: A NEW ANTIBACTERIAL PEPTIDE FROM BLOWFLY *SARCONESIOPSIS MAGELLANICA* (DIPTERA:CALLIPHORIDAE) LARVAL EXCRETIONS AND SECRETIONS

Andrea Diaz-Roa<sup>1</sup>, Manuel A. Patarroyo<sup>2</sup>, Pedro I. da Silva Junior<sup>3</sup>, Felio J. Bello<sup>4</sup>

<sup>1</sup>Universidad Antonio Nariño, Bogotá-Colombia and Laboratório Especial de Toxinologia Aplicada, Instituto Butantan, Bogotá and São Paulo, Brazil, Colombia, <sup>2</sup>Molecular Biology and Immunology Department, Fundación Instituto de Inmunología de Colombia (FIDIC), Bogotá, Colombia and Basic Sciences Department, School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia, <sup>3</sup>Laboratório Especial de Toxinologia Aplicada, Instituto Butantan, São Paulo, Brazil, <sup>4</sup>Universidad Antonio Nariño, Bogotá, Colombia

Larval therapy (LT) is an alternative treatment for healing chronic wounds; its action is based on debridement, the removal of bacteria and stimulating granulation tissue. The most important mechanism when using LT for combating infection depends on larval excretions and secretions (ES). Larvae are protected against infection by a spectrum of antimicrobial peptides (AMPs); the goal of this study was to evaluate the presence of AMPs in the ES of a medically-important necrophagous fly previously used in LT: *Sarconesiopsis magellanica* (Diptera: Calliphoridae). The study of this specie becomes significant in wound healing, since they degrade necrotic tissue and kill different bacteria during LT. This study shows for the first time a small AMP being isolated from *S. magellanica* ES products obtained from third-instar larvae. For the first analysis, ES were fractionated by RP-HPLC using C18 columns; the antimicrobial activity of the fractions was evaluated by incubation with different pathogens. The primary sequences of the fractions were determined by mass spectrometry and *de novo sequencing*; five fractions with antimicrobial activity were obtained, the Sarconesin fraction was characterized and the minimum inhibitory concentrations (MIC) were tested in serial dilution starting at 1.2 µM. Potent inhibitory activity was shown against Gram-negative (*Escherichia coli* D31, *Pseudomonas aeruginosa* 27853) and Gram-positive (*Staphylococcus aureus* ATCC 29213, *Micrococcus luteus* A270) bacteria. Sarconesin shows similarity with Rho-family GTPases which are important in organelle development, cytoskeletal dynamics, cell movement and wound repair. The data reported here indicated that Sarconesin, a small 13 residues AMP, could be a promissory alternative candidate for use in therapeutics against Gram-negative and Gram-positive bacterial infection. Our study describes one peptide responsible for antibacterial activity when LT is being used. The results shown here support carrying out further experiments aimed at validating *S. magellanica* AMPs as novel resources for combating antibacterial resistance.

## 20

## MATHEMATICAL MODELLING OF FOCAL VECTOR CONTROL AS A COMPLEMENTARY STRATEGY FOR ONCHOCERCIASIS ELIMINATION

Isobel Routledge<sup>1</sup>, Martin Walker<sup>2</sup>, Robert A. Cheke<sup>3</sup>, Pierre Baleguel Nkot<sup>4</sup>, Graham Matthews<sup>5</sup>, María-Gloria Basáñez<sup>6</sup>

<sup>1</sup>Imperial College London and MRC Centre for Outbreak Analysis and Modelling, London, United Kingdom, <sup>2</sup>Royal Veterinary College and London Centre for Neglected Tropical Disease Research (LCNTDR), Hatfield, United Kingdom, <sup>3</sup>University of Greenwich at Medway, Chatham Maritime, Kent, United Kingdom, <sup>4</sup>Yaoundé Initiative Foundation, Yaoundé, Cameroon, <sup>5</sup>Imperial College London and Yaoundé Initiative Foundation, London, United Kingdom, <sup>6</sup>Imperial College London and London Centre for Neglected Tropical Disease Research (LCNTDR), London, United Kingdom

The control of onchocerciasis is considered a public health success story. The Onchocerciasis Control Programme in West Africa (OCP, 1974-2002), initially an anti-vectorial intervention in 11 countries, averted 600,000 cases of preventable blindness and made 25 million hectares of land habitable and productive. The African Programme for Onchocerciasis Control (APOC, 1995-2015), mainly an anti-parasitic intervention in the remaining endemic African countries, averted 17.4 million disability-adjusted life years (DALYs). None of these programmes, however, led to regional elimination of *Onchocerca volvulus* by the time of their closure. In 2012 the World Health Organization set goals for the elimination of onchocerciasis transmission by 2020 in selected African countries. Mathematical modelling has indicated that elimination will not be achieved with annual ivermectin distribution in all endemic foci; alternative treatment strategies (ATS) will be required. One such ATS is localized vector control in foci with intense transmission. Models need to consider the population dynamics and ecology of the main vector, *Simulium damnosum* sensu lato (s.l.), to evaluate the potential epidemiological impact of vector control in combination with current and complementary treatment strategies. We refined our simuliid population dynamics model to explore the impact of larviciding on *S. damnosum* s.l. biting rates. We calibrated the model with datasets from: a) OCP-era savanna sites in Ghana where larviciding was interrupted and then resumed; b) sites in Nigeria that underwent early-stage larviciding, and c) forested APOC sites in Equatorial Guinea and Cameroon. We explored the impact of varying the frequency, duration and efficacy of larvicidal treatments on the effectiveness of vector control, quantified as the number of blackfly bites prevented. We discuss our results in the context of implementing ATS for the control and elimination of onchocerciasis in Africa, and integrate our vector model into the EPIONCHO transmission model to explore how localized, low-cost, vector control might complement ivermectin-based interventions.

## 21

## SYSTEMIC INSECTICIDE TREATMENT OF THE CANINE RESERVOIR OF *TRYPANOSOMA CRUZI* INDUCES HIGH LEVELS OF LETHALITY IN *TRITOMA INFESTANS*, A PRINCIPAL VECTOR OF CHAGAS DISEASE IN BOLIVIA

Louisa A. Messenger<sup>1</sup>, A. Loza<sup>2</sup>, A. Talaga<sup>3</sup>, G. Herbas<sup>2</sup>, J. Canaviri<sup>2</sup>, T. Cahuasiri<sup>2</sup>, L. Luck<sup>2</sup>, A. Guibarra<sup>2</sup>, A. Monero<sup>2</sup>, R. Goncalves<sup>3</sup>, JA Peirera<sup>2</sup>, SA Gomez<sup>4</sup>, A. Picado<sup>4</sup>, C. Bern<sup>5</sup>, O. Courtenay<sup>3</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Universidad Autónoma Gabriel Rene Moreno, Santa Cruz, Plurinational State of Bolivia, <sup>3</sup>University of Warwick, Coventry, United Kingdom, <sup>4</sup>Barcelona Institute for Global Health, Barcelona, Spain, <sup>5</sup>University of California San Francisco, San Francisco, CA, United States

Despite large-scale reductions in Chagas disease prevalence across Central and South America, *Trypanosoma cruzi* infection remains a considerable public health problem in the Bolivian Gran Chaco region where vector-

borne transmission persists. In these communities, peridomestic animals are major blood-meal sources for triatomines, and dogs play an important role in maintaining bug populations, potentially compromising the long-term sustainability of current control efforts. This study evaluated the systemic activity of three commercial oral insecticides (Bravecto®, fluralaner; NexGard®, afoxolaner; and Comfortis®, spinosad) in canine feed-through assays against *Triatoma infestans*. Twelve healthy, outbred dogs were recruited from the national rabies control program in Santa Cruz, Bolivia, and randomized to three groups, containing one control and three treated dogs. Following treatment, starved 2nd and 3rd stage *T. infestans* instars were exposed to dogs for 30 minutes at 2, 7, 21, 34 and 51 days post-treatment. Eighty-five per cent (768/907) of *T. infestans* successfully blood-fed during bioassays, with significantly more bugs becoming fully-engorged when exposed to Bravecto® dogs ( $p < 0.001$ ). Bravecto® or NexGard® treatment induced 100% triatomine mortality in fully- or semi-engorged bugs within 5 days of feeding at every time point. The lethality effect for Comfortis® was much lower (50-70%) and declined almost entirely after 51 days. Instead Comfortis® resulted in substantial morbidity; a third of bugs fully recovered after 120 hours but were unable to feed even 30 days later. A single oral dose of Bravecto® or NexGard® was safe and well tolerated, producing complete triatomine mortality on treated dogs over 7.3 weeks. While both drugs were highly efficacious, more bugs exposed to Bravecto® were immediately knocked-down and took complete blood-meals. Coupled with its longer residual activity, Bravecto® represents an ideal insecticide to develop into an operationally-feasible, community-level method of reducing triatomine infestation and controlling *T. cruzi* transmission in the Bolivian Gran Chaco region.

## 22

## RENEWED MASS DRUG ADMINISTRATION'S IMPACT ON LYMPHATIC FILARIASIS IN A POPULATION WITH LONG LASTING INSECTICIDAL BEDNETS IN PAPUA NEW GUINEA

Daniel J. Tisch<sup>1</sup>, Brooke Mancuso<sup>1</sup>, Yao-Chieh Cheng<sup>1</sup>, Samson Satofan<sup>2</sup>, James Suamani<sup>2</sup>, Willie Pomat<sup>3</sup>, Christopher L. King<sup>1</sup>, James W. Kazura<sup>1</sup>, Peter A. Zimmerman<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Papua New Guinea Institute of Medical Research, Maprik, Papua New Guinea, <sup>3</sup>Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea

A community of 5000 people in Dreikikir, Papua New Guinea (PNG) received 5 annual Mass Drug Administrations (MDA) 20 years ago, dramatically decreasing lymphatic filariasis (LF) prevalence but failing to end transmission. Subsequent vector control against the anopheline vector with long lasting Insecticidal bednets (LLIN) in 2009 reduced mosquito density and LF vectorial transmission potential to the point where transmission cessation was considered possible. To assess the impact of renewed MDA in 2015, night-time finger prick blood samples were collected from a sentinel group of 530 children  $\leq 10$  years-of-age (y) and 732 individuals 11-80y in 14 villages characterized as "moderate" or "high" transmission (32-63% and 63-85% MF+ prior to any interventions, respectively) before MDA (January-May 2015) and one year after MDA. Samples were examined for Mf by microscopy and filarial antigen by rapid tests (ICT in 2015 and the more sensitive FTS in 2016; because the tests are not directly comparable only FTS are reported). Additional monitoring assays (BM14, WB123 and Og4C3) are ongoing. In the "moderate transmission" sites prior to renewing MDA, children  $\leq 10$ y had 0% MF+ and individuals  $> 10$ y 2.8% MF+. In 2016 ALL individuals were MF negative, however infections persisted: children  $\leq 10$ y 1.7% were FTS+ and individuals  $> 10$ y 21.0% were FTS+. In "high transmission" sites MF prevalence decreased from 2.8% to 0.6% in  $\leq 10$ y after MDA and from 22.0% MF+ to 15.1% MF+ in  $> 10$ y. FTS positivity remained high in both age groups, 12.2% FTS+ in  $\leq 10$ y and 59.9% in  $> 10$ y. Though MF+ fell below limits of detection in moderate transmission sites, sustained antigen positivity in the population, especially in sentinel age children, highlights ongoing transmission. The adjacent higher transmission villages (2 to

15 km away in the same treatment unit) remained above programmatic thresholds to continue MDA. Factors contributing to ongoing transmission are failure of current MDA combinations to completely eliminate Mf and the inability to achieve adequate coverage of individuals with high Mf counts. Continuing studies aim to address these limitations for current MDA programs.

## 23

### MAPPING OF LYMPHATIC FILARIASIS IN LOIASIS AREAS: A NEW STRATEGY SHOWS NO EVIDENCE FOR *WUCHERERIA BANCROFTI* ENDEMICITY IN CAMEROON

**Samuel Wanji**<sup>1</sup>, Mathias E. Esum<sup>1</sup>, Abdel N. Jelil<sup>1</sup>, Amuam A. Mbeng<sup>1</sup>, Chounna N. Patrick<sup>1</sup>, Raphael Abong<sup>1</sup>, Jerome Fru<sup>1</sup>, Fanny F. Fombad<sup>1</sup>, Gordon T. Nchanji<sup>1</sup>, Ngandjui Narcisse<sup>1</sup>, Peter Enyong<sup>1</sup>, Helen Storey<sup>2</sup>, Kurt C. Curtis<sup>3</sup>, Kerstin Fischer<sup>3</sup>, Peter U. Fischer<sup>3</sup>

<sup>1</sup>University of Buea, Buea, Cameroon, <sup>2</sup>PATH, Seattle, WA, United States,

<sup>3</sup>Washington University School of Medicine, St. Louis, MO, United States

Mapping of lymphatic filariasis (LF) caused by *Wuchereria bancrofti* largely relied on the detection of circulating antigen using the ICT card test. Several studies have recently shown that this test is cross-reactive with sera of subjects heavily infected with *Loa loa* and that mapping results in loiasis endemic areas may be inaccurate. In order to develop an LF mapping strategy for areas with high loiasis prevalence, we collected day blood samples from 5,000 subjects residing in 50 villages in 5 areas throughout Cameroon (south, central, south-east North-west and far-north). Antigen testing using FTS (a novel platform that uses the same reagents as ICT), revealed an average positivity rate of 1.1% and *L. loa* microfilaria (Mf) rates between 0.1 and 43.4%. Among the subjects with 0 to 8,000 Mf/ml only 0.5% were FTS positive, while 25% of 118 subjects with >8,000 Mf/ml were also FTS positive. None of the FTS positive samples was positive for *W. bancrofti* antibodies as measured by two different PoC Wb123 tests that use an antigen not found in *L. loa*. Night blood examination of the FTS positive subjects showed also a high prevalence of *L. loa* Mf with average densities of up to 9,180 Mf/ml, but no *W. bancrofti* Mf (confirmed by qPCR). Our results show that high *L. loa* Mf in day blood are a reliable predictor for FTS positivity and rapid Wb123 tests can be used to confirm the absence of *W. bancrofti*. Lymphedema cases that were encountered during our surveys were most likely not due to *W. bancrofti*, but due to podoconiosis or other factors. Our study provides a simple day blood-based algorithm for LF mapping in loiasis areas and indicates that Cameroon is mostly non-endemic for LF and does not require mass drug administration for the elimination of LF.

## 24

### IVERMECTIN PROTECTS AGAINST EPILEPSY IN ONCHOCERCIASIS ENDEMIC REGIONS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

**Robert Colebunders**<sup>1</sup>, Floribert Tepage<sup>2</sup>, Chellafe Ensoy-Musoro<sup>3</sup>, Michel Mandro<sup>4</sup>, Bethany Levick<sup>5</sup>, Patrick Suykerbuyk<sup>1</sup>, Caroline Bonareri Osoro<sup>6</sup>, Alliance Tagoto<sup>7</sup>, Anne Laudoit<sup>1</sup>

<sup>1</sup>University of Antwerp, Antwerp, Belgium, <sup>2</sup>Ministry of Health, Bas Uele, Democratic Republic of the Congo, <sup>3</sup>University of Hasselt, Diegem, Belgium, <sup>4</sup>Ministry of Health, Bunia, Democratic Republic of the Congo, <sup>5</sup>University of Liverpool, Liverpool, United Kingdom, <sup>6</sup>Nanyuki Teaching and Referral Hospital, Laikipia, Kenya, <sup>7</sup>Ministry of Health, Kisangani, Democratic Republic of the Congo

An increased prevalence of epilepsy has been reported in many onchocerciasis endemic areas. To determine the prevalence of epilepsy in onchocerciasis endemic areas in the Democratic Republic of the Congo (DRC) and investigate whether a higher annual intake of Ivermectin was associated with a lower prevalence of epilepsy. Between July 2014 and February 2016, house-to-house epilepsy prevalence surveys were carried out in areas with a high level of onchocerciasis endemicity: 3 localities in

the Bas-Uele, 24 in the Tshopo and 21 in the Ituri province. Ivermectin uptake was recorded for every household member. A case of epilepsy was defined as a patient who reported at least 2 unprovoked seizures without fever or any acute illness. This database allowed a village, age and gender matched case-control pair subset to be created that enabled putative risk factors for epilepsy to be tested using univariate logistic regression models. Risk factors relating to onchocerciasis were tested using a multivariate random effects model. Of 12, 408 people examined in the different health areas 407 (3.3%) were found to have a history of epilepsy. A high prevalence of epilepsy was observed in health areas in the 3 provinces: 6.8-8.5% in Bas-Uele, 0.8-7.4% in Tshopo and 3.6-6.2% in Ituri. Median age of epilepsy onset was 9 years, and the modal age 12 years. Using the whole survey database, male gender, and onchocerciasis skin lesions were associated with a significantly higher risk of being a person with epilepsy. A case control analysis of 96 cases and 96 controls demonstrated that before the appearance of epilepsy, compared to the same life period in controls, persons with epilepsy were around two times less likely (OR: 0.52; 95%CI: (0.28, 0.98) to have taken Ivermectin than controls. After the appearance of epilepsy, there was no difference of Ivermectin intake between cases and controls. In conclusion, our study showed that the epilepsy prevalence in onchocerciasis endemic regions in the DRC was 2-10 times higher than in most non-onchocerciasis endemic regions in Africa and that in these onchocerciasis endemic regions Ivermectin intake protects against epilepsy.

## 25

### A NOVEL RAPID TEST FOR DETECTING ANTIBODY RESPONSES TO *LOA LOA* INFECTIONS

**Marco A. Biamonte**<sup>1</sup>, Bijan Pedram<sup>1</sup>, Papa M. Drame<sup>2</sup>, Valérie Pasquetto<sup>1</sup>, Maria J. Gonzalez-Moa<sup>1</sup>, Yongchang Ji<sup>1</sup>, Richard K. Baldwin<sup>3</sup>, Thomas B. Nutman<sup>2</sup>

<sup>1</sup>Drugs and Diagnostics for Tropical Diseases, San Diego, CA, United States, <sup>2</sup>National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, <sup>3</sup>nanoComposix, San Diego, CA, United States

*Loa loa* affects over 10 million people in sub-Saharan Africa and is of particular significance in the context mass drug administrations (MDAs) aimed at eliminating onchocerciasis. Ivermectin is the only approved drug for such purposes but can induce severe adverse events in a subset of individuals with high levels of *L. loa* microfilariae. Extending MDAs to areas with coincident *L. loa* infection is problematic, and inexpensive point-of-care tests for *L. loa* are acutely needed to support programmatic decisions. Herein, we present the first lateral flow assay (LFA) to detect subjects serological response to *L. loa*. The assay detects antibodies directed against *L1-SXP-1*, a specific and validated marker of *L. loa* infection. The test was evaluated on serum samples from patients infected with *L. loa* (n=109) and other helminths (n=187), as well as on uninfected controls (n=78). When read with the naked eye, the test was 94% sensitive for *L. loa* infection and was 100% specific when sera from healthy endemic and non-endemic controls or from those with *S. stercoralis* infections were used as the comparators. When sera of patients with *O. volvulus* or *W. bancrofti* were used as the comparators, the specificity of the LFA was 82% and 87% respectively. A companion smartphone reader allowed measurement of the test line intensities and establishment of cutoff values. With a cutoff of 800 reader units, the assay sensitivity decreased to 56%, but the specificity increased to 97% for *O. volvulus* and 100% for *W. bancrofti*-infected individuals. The LFA may find applications in refining the current maps of *L. loa* prevalence, which are needed to eliminate onchocerciasis from the African continent.

## DEVELOPING THE FIRST NATIONAL DATABASE AND MAP OF LYMPHATIC FILARIASIS CLINICAL CASES IN BANGLADESH

**Mohammed J. Karim**<sup>1</sup>, Hayley E. Mables<sup>2</sup>, Rouseli Haq<sup>1</sup>, Mutasim B. Azad<sup>1</sup>, ASM Sultan Mahmood<sup>1</sup>, Abul Khair<sup>1</sup>, Mujibur Rahman<sup>1</sup>, Salim Chowdhury<sup>3</sup>, AKM Fazlur Rahman<sup>3</sup>, Sharmin Jahan<sup>3</sup>, Israt Hafiz<sup>1</sup>, Charles D. Mackenzie<sup>2</sup>, Mark Taylor<sup>2</sup>, Louise A. Kelly-Hope<sup>2</sup>

<sup>1</sup>Filaria Elimination and STH Control Program, Ministry of Health and Family Welfare, Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh, <sup>2</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>3</sup>Centre for Injury Prevention, Health Development and Research, Bangladesh, Dhaka, Bangladesh

The Bangladesh Filarial Elimination Programme (FEP) is on track to meet the Global Programme to Eliminate Lymphatic Filariasis (GPELF) targets of 2020 by interrupting transmission with mass drug administration (MDA) and alleviating suffering by managing morbidity and preventing disability (MMDP) for 70 million people at risk. This study aimed to highlight FEP's success in determining the number of people affected by lymphoedema and hydrocoele, and to develop risk maps for targeted interventions across the 34 endemic districts (19 high; 15 low prevalence). In the 19 high endemic districts, 8,145 community clinic (CC) staff were trained to search for LF cases household census in catchment areas between 2013-2016 and registering all cases. In the 15 low endemic districts a team of 10 trained field assistants conducted active case finding utilising health facility records, health worker and community informants to identify and medically verify cases, with cases reported via a SMS mHealth database. Data recorded included general demographic (location, patient name, address, age, gender), and clinical information (lymphoedema, hydrocoele, severity, acute dermato-lymphangioadenitis (ADLAs). In the 19 high endemic districts, a total of 43,678 clinical cases were identified; 30,616 lymphoedema [70.1%; female 55.3%], 12,824 hydrocoele [29.4%], and 238 breast/female genital swelling [0.5%]. Rangpur district reported the highest number (8,545 lymphoedema; 2,654 hydrocoele). Overall the prevalence rate was 126/100,000 [highest in Lalmonirhat district 583/100,000]. In the 15 low endemic districts, 733 cases were identified; 661 lymphoedema [90.2%; female 39.6%], 57 hydrocoele [7.8%], and 15 both conditions [2.0%]. Risk maps, spatial and statistical analysis found district clinical prevalence was geographically and statistically correlated to baseline microfilaria (Mf) prevalence at  $r=0.904$  [ $p<0.01$ ]. FEP's remarkable efforts to identify LF cases across all districts represents one of the most comprehensive national databases on clinical LF in the world and provides a template for other countries to learn from and develop.

## PROJECTED NUMBER OF PEOPLE WITH ONCHOCERCIASIS-LOIASIS CO-INFECTION IN AFRICA, 1995-2025

**Natalie V.S. Vinkeles Melchers**<sup>1</sup>, Afework H. Tekle<sup>2</sup>, Luc E. Coffeng<sup>1</sup>, Sébastien D. Pion<sup>3</sup>, Honorat G. Zouré<sup>2</sup>, Belén Pedrique<sup>4</sup>, Michel Boussinesq<sup>5</sup>, Samuel Wanji<sup>5</sup>, Hans J. Remme<sup>6</sup>, Wilma A. Stolk<sup>1</sup>

<sup>1</sup>Department of Public Health, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, <sup>2</sup>Department of Neglected Tropical Diseases, World Health Organization, Geneva, Switzerland, <sup>3</sup>UMI233-TransVIHMI, Institut de Recherche pour le Développement (IRD), INSERM U1175, University of Montpellier, Montpellier, France, <sup>4</sup>Drugs for Neglected Diseases initiative, Geneva, Switzerland, <sup>5</sup>Parasites and Vectors Research Unit, Department of Microbiology and Parasitology, University of Buea, Buea, Cameroon, <sup>6</sup>120 rue des Campanules, Ornex, France

In Central Africa, community-directed treatment with ivermectin (CDTI) against onchocerciasis is hampered by co-endemicity of *Loa loa*, as people with  $\geq 30,000$  *Loa* microfilariae/mL of blood can develop potentially fatal severe adverse events (SAEs). To be conservative, test and treat approaches

will likely use a threshold of  $\geq 20,000$  *Loa* microfilariae/mL for exclusion from ivermectin treatment. We estimate the number of individuals with *Onchocerca volvulus* and *Loa* co-infections who are at risk ( $\geq 20,000$  *Loa* microfilariae/mL) for post-ivermectin SAEs, for 1995, 2015 and 2025. We combined pre-control rapid assessment data (REMO and RAPLOA) on onchocerciasis and loiasis prevalence. The loiasis data were categorised by proportions of people with  $\geq 20,000$  *Loa* microfilariae/mL. We used the mathematical model ONCHOSIM to calculate the expected trends in *O. volvulus* prevalence for 1995 to 2025, accounting for local treatment history. The impact of ivermectin treatment on loiasis was considered based on published data, with a one-time reduction in *Loa* prevalence and intensity after one round of CDTI. Among areas where *Loa* is potentially endemic, the number of cases with *O. volvulus* declined from 19.5 million people in 1995, to 14.2 million in 2015 and 3.3 million in 2025. Of those, 114,771 people were co-infected with *Loa* microfilaraemia  $\geq 20,000$ /mL in 1995; 44,370 predicted in 2015 and 20,477 in 2025. In 2025, 89% of cases (N=18,320) will live in onchocerciasis hypoendemic areas which would not benefit from control/elimination programmes. Democratic Republic of Congo and Cameroon will contribute to 78% of all cases in 2025. Mass distribution of ivermectin as part of the onchocerciasis elimination efforts is problematic in many countries. We predict that in 2025 over 20,000 people will require treatment for onchocerciasis while being at high risk of SAEs, justifying increased effort in research and development for safer drugs and control strategies targeted especially towards onchocerciasis hypoendemic areas which are co-endemic for loiasis.

## PREVALENCE OF EXPOSITION TO RIVER BLINDNESS IN THE GAROUA-BOULAI HEALTH DISTRICT (EAST REGION, CAMEROON): POTENTIAL CROSS-BORDER ISSUE IN THE CONTEXT OF ELIMINATION

**Cédric Gaël Lenou Nanga**<sup>1</sup>, Hugues Clotaire Nana Djeunga<sup>1</sup>, Jules Brice Tchatchueng Mbougua<sup>2</sup>, Guy Roger Njitchouang<sup>1</sup>, André Domche<sup>1</sup>, Jean Bopda<sup>1</sup>, Stève Mbickmen Tchana<sup>1</sup>, Kisito Ogooussan<sup>3</sup>, Maria Rebollo<sup>3</sup>, Joseph Kamgno<sup>1</sup>

<sup>1</sup>Centre for Research on Filariasis and other Tropical Diseases (CRFiMT), Yaoundé, Cameroon, <sup>2</sup>Centre Pasteur du Cameroun, Yaoundé, Cameroon, <sup>3</sup>Task Force for Global Health, Atlanta, GA, United States

The control of onchocerciasis has been a success in many *foci* where the disease is endemic. However, large-scale preventive chemotherapy with ivermectin in *Loa* endemic areas to target hypo-endemic onchocerciasis is not recommended due to the risk of severe adverse events (SAE), thus slowing the momentum towards elimination. Since a safe threshold below which ivermectin can be administered through mass campaigns in communities was identified, additional epidemiologic investigations appeared essential to re-assess the distribution of infection in hypo-endemic areas that were not included in the original mass treatments, and particularly in the cross-border context. This study was carried out in the Garoua Boulai health district, belonging to the group of ivermectin naïve areas, and bordered to the east by the Central African Republic (CAR) where civil war led to an important refugee flow. A cross sectional survey following a community-based random cluster design was carried out to seek for exposure to *O. volvulus* using the newly developed SD Bioline onchocerciasis IgG4 rapid diagnostic test. The prevalence of exposure to river blindness ranged between 0.0% (95% CI: 0.0 - 8.0) and 20.0% (95% CI: 13.0 - 29.4), males being most exposed than females ( $p = 0.048$ ). An important geographical heterogeneity in the distribution of exposure to river blindness was observed among the clusters surveyed ( $p < 0.0001$ ). Amongst individuals with proven exposure to onchocerciasis, 30.2% were not native of the survey area, of whom 64.3% (95% CI: 49.2 - 77.0) were from CAR. The complete elimination of onchocerciasis implies the expansion of mass preventive chemotherapy in hypo-onchocerciasis areas which are up to now not targeted by mass treatments. This study

reveals a relatively high contribution of people from CAR, raising interest on effective collaboration between Cameroon and the CAR while envisioning the elimination of onchocerciasis in cross-border situations

### EVALUATION OF MORPHOLOGICAL CRITERIA DUE TO HEPATIC ALVEOLAR ECHINOCOCCOSIS BASED ON THE ECHINOCOCCUS MULTILOCULARIS ULM CLASSIFICATION

Tilmann Graeter, Wolfgang Kratzer, Aylin Senguel, Andreas Hillenbrand, Beate Gruener, Julian Schmidberger

University Hospital Ulm, Ulm, Germany

Computed tomography, mostly combined with PET, provides one of the most important diagnostic tools in suspected alveolar echinococcosis (AE). The recently established "Echinococcus multilocularis Ulm classification for computed tomography" (EMUC-CT) depicts the various morphologies of liver lesions due to AE. The classification scheme assigns morphological criteria of hepatic AE to five groups of primary morphologies (type I-V), including subcriteria and to six calcification patterns. Aim of this pilot study was to analyse several CT-morphological criteria of AE lesions in 72 patients based on the EMUC-CT classification and to make a comparison of those criteria in the clinical course under antihelminthic medication. The primary morphology showed to be very constant, whereas the subcriteria exhibited varying behavior. Between the patterns of calcification only slight changings could be registered. However the degree of calcification increases considerably over time. A slight regression of size in lesions under therapy could be noted. The extend and the count of lesions differ significantly between the various types. Obvious differences among the types were revealed regarding extrahepatic as well as biliar involvement. In conclusion the study could illustrate clear connections between the different morphological criteria within EMUC-CT and depicted morphological changings of AE liver lesions in the clinical course. Especially the observations concerning the extend and count of lesions in the different types and their varying behavior regarding extrahepatic as well as biliar involvement appears to be of clinical relevance. Larger studies should be done to reveal whether in future conclusions could be drawn thereout concerning prognosis of the disease and therapy planning.

<sup>3</sup>Department of International Health, Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Baltimore, MD, United States,

<sup>4</sup>Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru

Cystic echinococcosis (CE) is endemic in livestock-raising regions where surgery has been the main treatment approach used. Clinical series reported a prevalence of new cystic lesion after treatment between 5 and 15%; however they did not account those who developed a new lesion and never return. A prospective evaluation of subjects was performed to evaluate the cumulative incidence of new cystic lesion and the factors associated. A survival analysis was performed using subjects from a historical cohort of patients with CE between 01/2000 and 12/2011 in two referral hospitals. Subjects were evaluated by imaging methods. The primary study endpoint was the imaging evidence of a new cystic lesion in the same organ or cavity where the previous cyst was treated (index surgery). The "time to event" was the period elapsed between the index surgery and the time of diagnosis. Survival function was estimated using the algorithm developed by Turnbull for interval censored data and Cox

proportional hazard models were performed. One hundred eighty five subjects from the historical cohort were enrolled, 171 and 14 subjects registered one and two index surgeries, respectively. Therefore, we had 199 surgeries. Seventeen (8.54%) subjects developed a new cystic lesion after between 3 to 15 years (median 9 years; IQR 7-11) of index surgery; cumulative incidence was higher among liver involvement (14/115, 12.4% vs 3/86, 3.5%, p=0.026). Cox analysis, showed that the risk to develop a new cystic lesion was roughly 4 times higher among those who were operated at a hospital located in endemic area than those operated at a hospital located in a non-endemic area (HR: 3.45; 95% CI: 1.25 - 9.5). According to the results, there is a high proportion of subjects surgically treated who develop a new cystic lesion and were not account in clinical series

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru

The adult *Taenia solium*, the pork tapeworm, usually lives as a single individual in the small intestine of humans, its only known definitive host. Mechanisms of genetic variation in *T. solium* are poorly understood, but could be useful for tracing transmission. This study aimed to explore the utility of three microsatellite markers as potential transmission tracking tool. We first explored the genetic variability of *T. solium* from cysticerci recovered from experimentally infected pigs. We then explored the genetic epidemiology and transmission in naturally infected pigs and adult tapeworms recovered from human carriers from an endemic rural community in Peru. In the initial study on experimental infection, two groups of three piglets were each infected with proglottids from one of two genetically different tapeworms for each of the microsatellites. After 7 weeks, pigs were slaughtered, and necropsy was performed. Thirty-six (92.3%) out of 39 cysts originated from one tapeworm, and 27 (100%) out of 27 cysts from the other had exactly the same genotype as the parental tapeworm. This suggests that the microsatellite markers may be a useful tool for studying the transmission of *T. solium*. In the second study, we analyzed the genetic variation of *T. solium* in cysts recovered from eight naturally infected pigs, and from adult tapeworms recovered from four human carriers in the community; they showed low genetic variability. Six pigs harbored cysts with a genotype corresponding to one of the identified tapeworms from the human carriers. In the dendrogram, cysticerci appeared to cluster within the corresponding pigs as well as with the geographical origin, but this association was not statistically significant. Four pigs had cysts with only one genotype, and four pigs had cysts with two different genotypes, suggesting that multiple infections of genetically distinct parental tapeworms are possible. We conclude that genotyping of microsatellite size polymorphisms is a potentially important tool to trace the spread of infection and pinpoint sources of infection as pigs spread cysts with a shared parental genotype.

## 32

### INFLAMMATION IS A KEY RISK FACTOR FOR REFRACTORY SEIZURES IN PATIENTS WITH NEUROCYSTICERCOSIS

Jesica A. Herrick<sup>1</sup>, Anjali Garg<sup>1</sup>, Jin Suh Kim<sup>1</sup>, Biswajit Maharathi<sup>1</sup>, Gerardo Gomez Abundis<sup>1</sup>, Isidro Gonzales<sup>2</sup>, Herbert Saavedra<sup>2</sup>, Javier Bustos<sup>2</sup>, Hector H. Garcia<sup>2</sup>, Jeffery A. Loeb<sup>1</sup>

<sup>1</sup>University of Illinois at Chicago, Chicago, IL, United States, <sup>2</sup>Cysticercosis Unit, Department of Transmissible Diseases, Instituto Nacional de Ciencias Neurologicas, Lima, Peru

Neurocysticercosis (NCC) is the number one cause of adult epilepsy worldwide; 70-80% of people with NCC experience seizures that can persist (SP) despite treatment. Early intervention before recurrent seizures establish abnormal electrical circuits could impact disease progression, but to do so predictors of SP in NCC patients need to be identified. To identify such predictors, we conducted a retrospective review of 39 randomly selected subjects from one arm of a large clinical trial of patients with NCC and seizures. All patients in the study were treated with steroids, anti-parasitic, and anticonvulsant medications. Eleven subjects went on to develop SP (defined as seizures > 2 months after treatment for NCC despite anticonvulsant therapy) and 28 did not (seizure negative, SN, group). We examined a number of clinical factors in these patients in order to identify variables associated with SP. The primary risk factor identified was a strong and sustained inflammatory response to the parasite. This was demonstrated by an increased volume of edema on follow-up MRI scans (quantified by measuring pixels in Photoshop) in the SP group (8.2 cm<sup>3</sup>) compared to the SN group (0.6 cm<sup>3</sup>, p=0.02). Additionally, those in the SP group had twice as many degenerating lesions at the time of presentation compared to the SN group (median 2 in SP group, 1 in the SN group, p=0.002). There was a significantly increased number of bands seen on the initial NCC western blot in subjects who developed SP (GM 5.8 bands) compared to those who did not (GM 3.8 bands, p<0.05). As has been seen in prior studies, calcified lesions were also a risk factor for seizures; the SP group had a significantly increased number of calcified lesions on baseline imaging (median 4.9) compared to the SN group (median 0.9, p=0.005). Interestingly, edema around calcified lesions was also more likely in the SP group (13/120 calcified lesions had perilesional edema on baseline imaging, 10.8%) compared to the SN group (4/120, 3%, OR= 3.5, p=0.04). These findings provide a compelling rationale for further exploring signs and symptoms of ongoing inflammation as predictors of epilepsy development in NCC patients.

## 33

### BANDING PATTERNS OF THE ENZYME-LINKED IMMUNOELECTROTRANSFER BLOT (EITB) AND BRAIN IMAGING FINDINGS IN PATIENTS WITH NEUROCYSTICERCOSIS

Gianfranco Arroyo<sup>1</sup>, Silvia Rodriguez<sup>1</sup>, Andres G. Lescano<sup>1</sup>, Karen A. Alroy<sup>2</sup>, Javier A. Bustos<sup>1</sup>, Saul Santivañez<sup>3</sup>, Isidro Gonzales<sup>4</sup>, Herbert Saavedra<sup>4</sup>, Javier Pretell<sup>5</sup>, Armando E. Gonzalez<sup>6</sup>, Robert H. Gilman<sup>7</sup>, Victor C. Tsang<sup>8</sup>, Hector H. Garcia<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Instituto Peruano de Parasitología Clínica y Experimental, Lima, Peru, <sup>4</sup>Instituto Nacional de Ciencias Neurologicas, Lima, Peru, <sup>5</sup>Hospital Alberto Sabogal, Callao, Peru, <sup>6</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>7</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>8</sup>Georgia State University, Atlanta, GA, United States

Neurocysticercosis (NCC) is the infection of the central nervous system (CNS) by the larval form of the pork tapeworm *Taenia solium* (cysticercus). The enzyme-linked immunoelectrotransfer blot (EITB) is the reference serological test for NCC, detecting antibody bands reacting to seven defined parasite antigens belonging to three antigen families (GP50, T24-42 and 8kDa). A positive EITB result does not always correlate with

the presence of viable infections in the CNS, and individuals with a single viable brain cyst may be EITB negative. However, EITB banding patterns appear to be related with *T. solium* antigen families, and in turn with the characteristics of NCC in the CNS. This study evaluated the relationship between the EITB banding patterns and the characteristics of the infection in the CNS (location, stage and number of viable cysticerci). EITB banding patterns and brain images of 548 NCC cases were analyzed. Patients with similar banding patterns were grouped into homogenous classes using latent class analysis (LCA). The association between classes and brain image findings was assessed. A four-class model was specified by LCA as the best. Extra parenchymal NCC was strongly associated with banding patterns of class 4 (strongly positive to the 8kDa antigen family). Intra parenchymal infections with viable cysticerci was also strongly associated with banding patterns of classes 4 and 3 (positive to the 8kDa antigen family), and less with class 2 (positive to the T24-42 antigen family). Non-viable infections and single cysticerci in the brain were associated with banding patterns of class 1 (EITB negative or positive to the GP50 antigen family only). EITB banding patterns correlate with brain imaging and complement imaging information for the diagnosis of NCC and for staging NCC patients.

## 34

### STANDARDIZATION OF A DIRECT ELISA USING MONOCLONAL ANTIBODIES FOR THE DETECTION OF PARASITE ANTIGEN IN URINE SAMPLES OF PATIENTS WITH NEUROCYSTICERCOSIS

Yesica Santos<sup>1</sup>, Yesenia Castillo<sup>1</sup>, Luz Toribio<sup>1</sup>, Cindy Espinoza<sup>1</sup>, Kevin Martel<sup>1</sup>, Adriana Paredes<sup>1</sup>, Cristina Guerra-Giraldez<sup>1</sup>, Yagahira Castro-Sesquen<sup>2</sup>, Isidro Gonzales<sup>3</sup>, Herbert Saavedra<sup>3</sup>, Javier A. Bustos<sup>1</sup>, Theodore E. Nash<sup>4</sup>, Hector H. Garcia<sup>1</sup>, For the Cysticercosis Working Group in Peru<sup>1</sup>

<sup>1</sup>Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Department of International Health, Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Baltimore, MD, United States, <sup>3</sup>Cysticercosis Unit, Instituto Nacional de Ciencias Neurologicas, Lima, Peru, <sup>4</sup>Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Neurocysticercosis (NCC), a parasitic disease caused by the larval stage of *Taenia solium*, is the main cause of acquired epilepsy and thus a public health problem in developing countries such as Peru. Immunodiagnosis of NCC consists on the detection of either antibodies or antigens, usually in serum samples. Serological tests based on the detection of antibodies cannot differentiate between active and past infections and thus may not be used for the follow-up of treated subjects. We standardized a direct ELISA technique using monoclonal antibodies (mAbs) to detect antigens in urine samples as an alternative method that utilizes a sample which is easier to be obtained by noninvasive methods. Four mAbs: three IgM isotypes and one IgG isotype obtained against crude antigen of *T. solium* were purified and biotinylated; then, all potential combinations between these 4 mAbs were evaluated. Finally, using the best combination (two IgM isotypes: TsW8 [4ug/ml] for capture and TsW5 [4ug/ml] for detection), a preliminary exploratory evaluation was carried out with urine samples from 20 healthy volunteers and 20 patients with NCC (six with subarachnoid NCC and 14 with calcified NCC). All samples from subjects with subarachnoid cyst (6/6, 100%) tested positive for *T. solium* antigen, compared with only one subject with calcified NCC (1/14, 7%) and none of the controls (specificity 20/20 100%). These promising results suggest a good sensitivity and specificity of the ELISA test in the detection of antigens in urine samples from subjects with subarachnoid NCC. Further work will extend this evaluation to patients with other types of cysticercosis.

## RING STRATEGY AS AN EFFECTIVE ALTERNATIVE TO MASS DRUG ADMINISTRATION FOR CONTROL OF *TAENIA SOLIUM* TAENIASIS/CYSTICERCOSIS

Seth E. O'Neal<sup>1</sup>, Cesar Gavidia<sup>2</sup>, Ricardo Gamboa<sup>3</sup>, Claudio Muro<sup>3</sup>, Percy Vilchez<sup>3</sup>, Luz Maria Moyano<sup>3</sup>, Viterbo Ayvar<sup>2</sup>, Sukwan Handali<sup>4</sup>, Armando E. Gonzalez<sup>2</sup>, Robert H. Gilman<sup>5</sup>, Hector H. Garcia<sup>6</sup>, for the Cysticercosis Working Group in Peru (CWGP)<sup>6</sup>

<sup>1</sup>Oregon Health & Sciences University and Portland State University, Portland, OR, United States, <sup>2</sup>School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>3</sup>Centro de Salud Global - Tumbes, Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, <sup>6</sup>School of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Despite recent calls by the World Health Organization for increased efforts to control transmission of *Taenia solium* taeniasis/cysticercosis, optimal strategies have not been determined. In a previous small non-randomized study in Peru, we piloted a risk-based approach (Ring Strategy) in which screening and treatment for taeniasis targeted to residents living within 100 meters of heavily infected pigs reduced parasite transmission. Here we report on a larger cluster randomized trial that compared ring strategy vs. mass drug administration (MDA) in 23 villages (pop 9,183) randomly assigned to receive one of 3 interventions. In the Ring-Screening arm (n=8 villages), people living within 100-meters of a heavily-infected pig were offered screening for taeniasis using stool coproantigen ELISA followed by treatment of positives with niclosamide. In the Ring-Treatment arm (n=8), residents living within 100 meters of a heavily infected pig were offered presumptive treatment with niclosamide. Study teams examined tongues of all pigs every 4 months to determine intervention areas. In the MDA arm (n=7), all village residents were offered treatment with niclosamide every 6 months. A subgroup of villages within each arm also received oxfendazole for porcine cysticercosis, either within 100-meter rings or as MDA. We followed a cohort of >6000 pigs born during the study period to monitor parasite transmission using LLGP EITB. Preliminary analysis shows seroincidence reduced in all groups from baseline after 2 ½ years. The greatest and most rapid effect was seen in Ring-Screening, with 87.8% reduction in seroincidence after 8 months, a level maintained for the remainder of the study. This reduction was 1.4 times greater vs. Ring-Treatment (IRR 1.4 95% CI 0.8 – 2.4) and 2.1 times greater vs. MDA (IRR 2.1 95% CI 1.2 – 3.6). These results show that ring strategies are an effective alternative to MDA. Ring strategies have potential to operate as community-based programs given sufficient incentives for residents to report heavily infected pigs. Final results including prevalence of taeniasis and porcine cysticercosis determined by necropsy will be presented.

## MODIFIED MDA DID NOT SIGNIFICANTLY IMPROVE COVERAGE IN LGAS TREATING TWICE-PER-YEAR IN SOUTHERN NIGERIA

Emily Griswold<sup>1</sup>, Abel Eigege<sup>2</sup>, Cephas Itonzughul<sup>2</sup>, John Eguagie<sup>3</sup>, Emmanuel Emukah<sup>4</sup>, Emmanuel Miri<sup>2</sup>, Ifeoma Anagbogu<sup>5</sup>, Yisa Saka<sup>5</sup>, Frank Richards<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Jos, Nigeria, <sup>3</sup>The Carter Center, Benin City, Nigeria, <sup>4</sup>The Carter Center, Owerri, Nigeria, <sup>5</sup>Federal Ministry of Health, Abuja, Nigeria

The area along the border between Edo and Ondo states in southern Nigeria is highly endemic for onchocerciasis and parts are also co-endemic for lymphatic filariasis. Despite years of relatively high reported MDA coverage, anecdotal evidence and parasitological monitoring suggested that coverage may be poor, with persistent transmission of onchocerciasis. In 2016, twice-per-year treatment with ivermectin (with albendazole for

lymphatic filariasis added to the first round) began in five LGAs in Edo state bordering Ondo. We undertook a multistage cluster survey within three months after each round of MDA to assess coverage. In the first round, we randomly selected 30 clusters per LGA, then 7 households per cluster using systematic sampling at both stages; all household members present were interviewed. We found first-round coverage was very poor; among 4942 people interviewed from 145 clusters, coverage was 31.1% (95% CI 24.1% - 38.0%). To improve coverage in the second round, three LGAs were randomized to receive MDA through a "modified campaign" approach. This entailed doubling the travel reimbursement for drug distributors (to 3000 Naira), using a rapid coverage assessment tool to guide post MDA "mop up" activities, shortening the time for MDA delivery, and increasing supervision. The other two LGAs continued with the same MDA activities used in the first round. The coverage survey methodology after the second round differed from the first in that we randomly selected 48 clusters per group of LGAs and 9 households per cluster using systematic sampling; again, all household members present were interviewed (n = 3362 people in 87 clusters). Second-round coverage improved, but was not statistically different than in the first round [40.0% (95% CI 31.0% - 49.0%)] and there was no significant difference between the standard MDA and modified campaign groups (p = 0.7). The additional cost per treatment in the campaign was 1.6 times that of standard MDA. Different strategies must be deployed to improve treatment coverage in Edo state if transmission elimination is to be achieved.

## IMPLEMENTING THE SUPERVISOR'S COVERAGE TOOL IN THE PHILIPPINES: PILOTING TWO NOVEL ADDITIONS

Leda Hernandez<sup>1</sup>, Winston A. Palasi<sup>1</sup>, Camille Pauline Baladjay<sup>1</sup>, Katherine Gass<sup>2</sup>

<sup>1</sup>Infectious Disease Office, Disease Prevention and Control Bureau, Department of Health, Manila, Philippines, <sup>2</sup>Task Force for Global Health, Decatur, GA, United States

The Supervisor's Coverage Tool (SCT) is a rapid survey tool designed to help neglected tropical disease programs monitor and supervise the mass drug administration (MDA). In 2016, the Philippines conducted a harmonized MDA between the Ministry of Education and Department of Health for lymphatic filariasis (LF) and soil-transmitted helminthiasis (STH). Six villages, representing six different municipalities in two LF-STH-co-endemic provinces, were selected for the SCT. To supervise both the school- and community-based MDAs, a novel integrated SCT was conducted, whereby the survey teams randomly picked one school-aged child (5-18 years old), and one community member per household. For another innovation, the SCT was conducted *during* the current MDA (as opposed to after). Of the 12 SCTs conducted - six among school-aged children and six among community members - four of six among children resulted in a "good" coverage classification, meaning that MDA coverage was likely above the target threshold. One child and five community SCTs classified the villages as having "indeterminate" coverage, meaning that one cannot conclude if the coverage is above the target threshold; and one child and one community SCT classified village coverage as "inadequate". The results of the SCT highlighted several important issues with the MDA distributions including the need for stronger insistence on directly observed treatment, teaching the contraindications of the drugs, addressing fears of side effects, and improving coverage among private-school children. These issues were discussed with the local health workers during the SCT and action plans to address the issues was created for each participating municipality. Overall, the results from the SCT in the Philippines suggest that an integrated SCT is not only feasible but can save the program time and resources. By conducting the SCT during the latter half of the MDA, the program was able to identify coverage challenges and assess whether the target threshold was met in real-time and to take corrective actions to improve coverage during the remainder of the MDA and avoid the need for separate mop-up campaigns.

### INTEGRATED PREVALENCE SURVEY OF SKIN NTDs AND COMMON SKIN DISEASES AMONG SCHOOLCHILDREN IN GAGNOA, CÔTE D'IVOIRE: DIAGNOSIS AND RISK FACTOR ANALYSIS

**Rie R. Yotsu**<sup>1</sup>, Amari Akpa<sup>2</sup>, Konan N'Guessan<sup>2</sup>, Aubin Yao<sup>2</sup>, Aka N'Guetta<sup>3</sup>, Emma Yeboue<sup>4</sup>, Norihisa Ishii<sup>5</sup>, Kouamé Kouadio<sup>3</sup>, Tape R. Djakeaux<sup>4</sup>, Julien Aké<sup>6</sup>, Marie Constance A. Kadio<sup>7</sup>, Bamba Vagamon<sup>7</sup>

<sup>1</sup>National Center for Global Health and Medicine, Tokyo, Japan, <sup>2</sup>MAP International, Abidjan, Côte D'Ivoire, <sup>3</sup>Pasteur Institute, Abidjan, Côte D'Ivoire, <sup>4</sup>National Leprosy Control Program, Abidjan, Côte D'Ivoire, <sup>5</sup>Leprosy Research Center, Tokyo, Japan, <sup>6</sup>Effect Hope, Abidjan, Côte D'Ivoire, <sup>7</sup>Raoul Follereau Institute, Abidjan, Côte D'Ivoire

Many neglected tropical diseases - including Buruli ulcer (BU), leprosy, and yaws - present with skin symptom(s) (skin NTDs). They are co-endemic in Côte d'Ivoire which reports the highest number of BU cases globally. Children are especially vulnerable to these, as well as to a large number of common skin diseases (CSDs), but their epidemiology is incompletely understood. In the Gagnoa district of Cote d'Ivoire, we performed a school-based skin survey for early detection and treatment of skin NTDs and CSDs; and to describe the distribution and the risk factors of these diseases. The program consisted of two phases: 1) screening by a team of village nurses of all primary schoolchildren aged 5 to 15 in a total of 38 schools, and selection of those presenting with any skin lesion(s); 2) sensitization campaign followed by in-school examination of screened children by two medical teams including dermatologists, leprosy and BU experts, and laboratory technicians. A total of 9,930 children (9.2% of all schools in the district) were pre-screened by the village nurses, yielding 1,781 children with skin conditions. These, and an additional 883 children who self-reported skin disease(s) following sensitization campaign were consulted by the medical teams. Among these, we identified 8 cases of skin NTDs: 3 BU and 1 post-BU with contracture; 1 confirmed and 1 suspected leprosy; and 2 suspected yaws were found. For CSDs, the majority of diagnoses were fungal infections including tinea capitis (n=1220, 46%) and pityriasis versicolor (n=1052, 39%), but others included such diseases as scabies (n=68, 2.6%) and eczema (n=35, 1.3%). Survey on demographics and personal hygiene, e.g., washing hands, use of soap, nail cutting, was conducted. Treatment for skin NTDs and prescription for CSDs were provided. The program had a high rate of community acceptability. This was the first attempt at an integrated, multi-skin NTD and CSD screening and diagnosis in the country. This strategy has the potential of improving early detection of NTDs, especially in areas of co-endemicity. CSDs are highly prevalent and should be integrated in skin NTD control measures.

## 39

### DRAMATIC INCREASE IN THE PARTICIPATION WITH MECTIZAN TREATMENT IN SECOND ROUND OF TEST AND TREAT IN AN AREA COENDEMIC FOR LOIASIS AND ONCHOCERCIASIS

State University, East Lansing, MI, United States, <sup>7</sup>Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Ivermectin-based mass drug administration has revolutionized onchocerciasis control over the last 30 years, and the target shifted from control to elimination. Although transmission of infection has been interrupted in some foci, the fear of serious adverse events (SAEs) in Loa loa co-endemic areas in Central Africa has been an obstacle to elimination. Millions of people were excluded from mass drug administration, because the risk of SAE in people with high Loa loa mf counts (>20000 mf/ml) was considered too high. The Test and (not) Treat (TNT) strategy has been developed as a way forward. TNT relies on the LoaScope to rapidly identify Loa loa-infected people "at risk" for SAEs and exclude them from ivermectin treatment. To provide proof of principle, TNT strategy was implemented in Okola Health District, Cameroon in 2015, where 15469 people were treated with ivermectin without SAEs occurring. The therapeutic coverage rate in Okola was 67.7%, a level felt to reflect a reluctance of the population to participate due to the fact that 23 SAEs occurred in this district during the first (and only) Community-Directed Treatment with Ivermectin in 1999. As a prelude to the second TNT campaign in March 2017, a press briefing was held by the Cameroonian Minister of Public Health and Minister of Communication emphasizing the success of the TNT strategy in 2015 and the absence of SAEs. Traditional rulers of the villages with the best participation rates in 2015 were awarded during the launching of the 2017 campaign. With this additional sensitization, between 13 March and 9 April, 11472 individuals participated in the TNT screening. The mean number of patients treated daily in 2017 was significantly higher than in 2015 (459 vs. 352, P=0.002), and total population coverage in the district is expected to exceed that seen in 2015. Our data suggest that both the absence of SAEs in the 2015 TNT campaign and the communication efforts made prior to the launching of the 2017 campaign were important factors in increasing adherence to the TNT strategy. This is very encouraging for the implementation of the TNT strategy across the Loa endemic regions in Central Africa.

## 40

### LYMPHATIC FILARIASIS TRANSMISSION ASSESSMENT SURVEYS (TAS) AS AN OPPORTUNITY TO EVALUATE THE IMPACT OF MASS DRUG ADMINISTRATION (MDA) ON TRANSMISSION OF ONCHOCERCIASIS AND SOIL TRANSMITTED HELMINTHIASIS

**Hugues Nana Djeunga**<sup>1</sup>, Rufine Touka-Nounkeu<sup>1</sup>, Jules Brice Tchatchueng Mbougua<sup>1</sup>, Guy Roger Njitchouang<sup>1</sup>, André Domche<sup>1</sup>, Julie Akame<sup>2</sup>, Georges Nko'o-Ayissi<sup>3</sup>, Benjamin Didier Biholong<sup>3</sup>, Yaobi Zhang<sup>4</sup>, Kizito T Ogoussan<sup>5</sup>, Maria P Rebollo<sup>6</sup>, Joseph Kamgno<sup>7</sup>

<sup>1</sup>Centre for Research on Filariasis and Other Tropical Diseases, Yaoundé, Cameroon, <sup>2</sup>Helen Keller International, Yaoundé, Cameroon, <sup>3</sup>Ministry of Public Health, Yaoundé, Cameroon, <sup>4</sup>Helen Keller International, Regional Office, Dakar, Senegal, <sup>5</sup>NTDs Support Center, Task Force for Global Health, Decatur, GA, United States, <sup>6</sup>Expanded Special Project for Elimination of NTDs, World Health Organization-AFRO, Brazzaville, Republic of the Congo, <sup>7</sup>Centre for Research on Filariasis and other Tropical Diseases, and Faculty of Medicine and Biomedical Sciences, Yaoundé, Cameroon

The control of neglected tropical diseases (NTDs) reached new possibilities when MDA became the platform to simultaneously target multiple NTDs amenable to preventive chemotherapy (PC). The rationale for this integrated approach is the geographic overlap of highly-prevalent NTDs and the availability of donated PC drugs. It has been shown that Albendazole, Mebendazole, Ivermectin or Diethylcarbamazine can be safely co-administered in almost any combination, rendering feasible the control of Soil Transmitted Helminthiasis (STH), onchocerciasis (Oncho) and lymphatic filariasis (LF). A comprehensive algorithm was built by the GPELF

for coordinated implementation of PCs. Unlike STH and Oncho, six years MDA is enough to halt LF transmission, and programmatic steps (with regular assessments) are clearly defined to achieve LF elimination goals. This study aimed to utilize the implementation of LF TAS as a framework for integrating Oncho and STH evaluations. Eligible individuals were children aged 6-7 years, anticipated to be free from *Wuchereria bancrofti* circulating antigen if MDA had been successful. A community-based cluster survey was used because of the low school enrolment rate (<75%). Finger prick blood samples were collected for LF (filaria test strip, FTS) and Oncho/LF (Biplex IgG4 antibodies against *O. volvulus* Ov16 and *W. bancrofti* Wb123 antigens). Stool samples were collected and examined using the Kato-Katz technique. A total of 1,646 children originating from eight health districts provided both blood and stool samples. None was positive for FTS and Ov16 antigen, and only 1 (0.1%; 95% CI: 0.0-0.3) child harbored antibodies against Wb123 antigen. *Ascaris lumbricoides* was the only STH species found in stools, with a prevalence of 0.8% (95% CI: 0.5-1.3). These results indicate that it was very likely that the PC had significantly lowered LF, Oncho and STH prevalence toward elimination targets. They also show that LF TAS can provide a suitable and cost-effective platform to assess the situation of other PC-NTDs.

## 41

### LYMPHATIC FILARIASIS AND PODOCONIOSIS: INTEGRATED MORBIDITY MANAGEMENT AND DISABILITY PREVENTION SERVICES FOR LYMPHOEDEMA AND HYDROCOELE PATIENTS IN THREE CO-ENDEMIC DISTRICTS OF ETHIOPIA

Asrat Mengiste<sup>1</sup>, Dereje Assefa<sup>1</sup>, Fikre H/Kiros<sup>1</sup>, Mussie Tamiru<sup>2</sup>, Biruck Kebede<sup>2</sup>, Charles Mackenzie<sup>3</sup>, Mark Taylor<sup>3</sup>, Louise Kelly-Hope<sup>3</sup>, Sarah Martindale<sup>3</sup>

<sup>1</sup>National Podoconiosis Action Network, Addis Ababa, Ethiopia, <sup>2</sup>Federal Ministry of Health, Addis Ababa, Ethiopia, <sup>3</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Lymphatic filariasis (LF) and podoconiosis are endemic in Ethiopia and cause painful and disabling lymphoedema. A burden assessment conducted in 2015 found 26,123 cases of lymphoedema and hydrocoele across 20 districts of Ethiopia. To increase access to quality, integrated, morbidity management and disability prevention (MMDP) services for lymphoedema and hydrocoele cases, a pilot study was conducted in three co-endemic districts of the Southern Nations, Nationalities, and Peoples' Region (SNNPR) over a twelve-month period from September 2016. This included: i) training health professionals at each health facility; ii) cascade training of health extension workers (HEWs) and health development army (HDA); iii) patient mobilisation and recruitment; iv) provision of supplies and training on lymphoedema care; v) referral of hydrocoele patients to hospitals for surgery and; vi) patient prospective monitoring with key progress indicators such as severity of condition, wounds present and frequency of acute attacks. A mid-term review found a total of 483 health professionals (60.2% female), 163 HEWs and 2,330 HDA from 22 health facilities had been trained on MMDP and patient referrals; with 2,033 lymphoedema cases (68% female), and 82 men with hydrocoeles having accessed the MMDP service. Conditions ranged from mild (n=655, 32.2%), moderate (n=1,062, 52.2%), to severe (n=317, 15.6%). Two thirds of lymphoedema patients (n=1,344, 66.1%) had experienced an acute attack in the month prior to their enrolment, and 333 (16.4%) had visible wounds on the affected limb. The main challenge reported was a weakness in the referral of hydrocoele patients for surgery from health facilities to hospitals, however, this is being addressed through consultations with the hospitals. Overall, the mid-term results show promise for an MMDP service integrated into the existing health structure, which may be scaled-up across Ethiopia. This will be a significant contribution to patient care and will help to ensure all lymphoedema and hydrocoele patients have access to quality care. Full results will be presented at the meeting.

## 42

### ADDING ONCHOCERCIASIS MONITORING TO LYMPHATIC FILARIASIS TRANSMISSION ASSESSMENT SURVEYS: THE TANZANIA EXPERIENCE

Upendo Mwingira<sup>1</sup>, Maria Chikawe<sup>1</sup>, Cecilia Uisso<sup>1</sup>, Boniphace Idindili<sup>2</sup>, Sarah Craciunoiu<sup>3</sup>, Delali Bonuedi<sup>4</sup>, Kathryn Crowley<sup>4</sup>, Darin Evans<sup>5</sup>, Andreas Nshala<sup>2</sup>

<sup>1</sup>Tanzania Neglected Tropical Disease Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>IMA World Health, Washington, DC, United States, <sup>4</sup>RTI International, Washington, DC, United States, <sup>5</sup>U.S. Agency for International Development, Washington, DC, United States

The Tanzania NTD Control Program (TZNTDCP) has a goal of lymphatic filariasis (LF) elimination by 2020 and onchocerciasis (OV) by 2025. For LF, WHO recommends at least five rounds of MDA to reduce infections to levels below a threshold at which mosquitoes are unable to continue spreading the parasites from person-to-person. For OV elimination, annual treatment with ivermectin with coverage rates of at least 80% for a period of 12-15 years is recommended. In January 2017, the TZNTDCP added the OV16 rapid diagnostic test (RDT) to planned LF transmission assessment surveys (TAS) in Bumbuli and Lushoto districts where 15 treatment rounds were completed with sufficient coverage. The main objective of the surveys was to assess transmission of lymphatic filariasis and monitor onchocerca volvulus among school children in the two evaluation units (EUs). Using the TAS platform, thirty primary schools were selected in each EU. Filariasis test strips (FTS) and OV 16 RDTs were tested on site, while dried blood spots (DBS) for OV16 ELISA were collected for laboratory testing. Children in grades 1 and 2 (6 and 7 year olds) were tested for circulating filarial antigens and the presence of IgG4 antibodies to the OV16 antigen, and DBS was collected. To increase the sample size for OV monitoring, grades 3 and 4 (8 and 9 year olds) were tested by OV16 RDT and DBS only. Out of 3,537 children tested for CFA, only 2 (0.11%) were found positive for LF in Lushoto EU. For onchocerciasis, 2,123 children were tested for OV16 RDT and prevalence was found to be 0% and 0.06% by OV16 Bumbuli (n=1343) and Lushoto (n=780) EUs respectively. The fact that the positive cases for both LF and OV were found in children from one district may suggest ongoing transmission of the two infections. OV16 ELISA testing will provide more insight. Adding OV monitoring in TAS was not difficult, but did need careful planning and carried an extra cost (expanded sampling, extra field days, more diagnostics and larger team size). However, the added cost was less than a standalone OV survey, while yielding valuable information. Given the dearth of current OV data, this approach could be used in other LF surveys.

## 43

### REALIZING THE POTENTIAL OF COMMUNITY HEALTH WORKERS TO PROVIDE MALARIA CASE MANAGEMENT: SENEGAL'S SCALE UP OF PROACTIVE COMMUNITY CASE MANAGEMENT

Seynabou Gaye<sup>1</sup>, Julie Thwing<sup>2</sup>, Medoune Ndiop<sup>1</sup>, Alioune B. Gueye<sup>1</sup>, Fatou B. Fall<sup>1</sup>, Moustapha Cisse<sup>1</sup>, Moustapha Cisse<sup>1</sup>, Ibrahima Diallo<sup>1</sup>, Kathy Sturm-Ramirez<sup>2</sup>, Oumar Sarr<sup>1</sup>, Oumar Sarr<sup>1</sup>

<sup>1</sup>National Malaria Control Program, Dakar, Senegal, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Centers for Disease Control and Prevention, Dakar, Senegal

In 2008, the Senegal National Malaria Control Program (NMCP) introduced home-based malaria management, with diagnosis by rapid diagnostic test (RDT) and treatment with artemisinin-based combination therapy (ACT), known as prise en charge a domicile (PECADOM), and expanded to over 2000 villages by 2015. Together with district health officials and the American Peace Corps, the NMCP piloted an active model (called PECADOM Plus in Senegal) in one village in 2012 and 15 villages in 2013, in a rural area of seasonal, moderately high transmission, during the

approximately 20 weeks of high transmission season. Every week, CHWs visited every household in their village to identify fever cases, and offered case management based on RDTs and ACTs. In comparison villages, CHWs did their regular work, but households received visits at the beginning and end of the season. The proportion of cases treated by CHWs increased over 300% in intervention villages, but during the last week of household visits, there were far fewer cases of malaria in intervention than in comparison villages. Based on this evidence, the NMCP scaled the PECADOM Plus program to three districts in 2014 (132 villages), six districts in 2015 (246 villages), and 16 districts in 2016 (708 villages). In PECADOM Plus villages during active sweeps, DSDOMs tested 10,141 patients in 2014, 22,838 patients in 2015, and 63,603 patients in 2016, and diagnosed 8,071, 15,068, and 30,554 patients with malaria in 2014, 2015, and 2016, respectively. Over 96% of those with a positive RDT were treated with ACT, 1.5% referred for severe disease, with most of the rest referred for stock out of ACT. Patients who sought care between sweeps increased, with a 104% increase in the number of RDTs performed during regular CHW work and a 77% increase in the number of positive RDTs and patients treated with ACT. Overall the number of patients receiving an RDT increased by 307% and the number cases of malaria detected and treated by DSDOMs increased 274%, from the year prior to PECADOM Plus introduction to its first year of implementation. Based on these results, approximately 700 additional DSDOMs (in 24 districts) will be added in 2017.

## 44

### MALARIA COMMUNITY-BASED MANAGEMENT IN INFORMAL KORANIC RESIDENTIAL SCHOOLS: A PILOT IN SENEGAL

**Seynabou Gaye**<sup>1</sup>, Katharine Sturm-Ramirez<sup>2</sup>, Alioune Badara Gueye<sup>1</sup>, Medoune Ndiop<sup>1</sup>, Julie Thwing<sup>2</sup>, Fatou Ba<sup>1</sup>, Ibrahima Diallo<sup>1</sup>, Moustapha Cisse<sup>1</sup>, Mame Birame Diouf<sup>3</sup>, Omar Sarr<sup>1</sup>

<sup>1</sup>National Malaria Control Program, Dakar, Senegal, <sup>2</sup>U.S. Centers for Disease Control and Prevention, President's Malaria Initiative, Atlanta, GA, United States, <sup>3</sup>U.S. Agency for International Development and President's Malaria Initiative, Dakar, Senegal

Since 2008, the Senegal National Malaria Control Program (NMCP) has implemented malaria community case management to ensure rapid access to diagnosis and treatment. An analysis of reported malaria cases in Diourbel health district identified high morbidity and mortality within informal residential Koranic schools (*daaras*) where students often receive inadequate nutrition and health care, and poor living conditions are often favorable to malaria transmission. A new community case management initiative called *PECA Daara* was piloted to target the high malaria burden in *daaras*. School-based care providers (*DSDaaras*) are volunteers selected within the *daaras* and provided with theoretical and practical training. An installation ceremony with involvement of religious, administrative and community authorities was organized and *DSDaaras* received a kit containing malaria rapid diagnostic tests (RDTs) and first line medication. *DSDaaras* recorded all consultations in a registry. Monitoring included supervisory visits, coordination meetings and reviews with all partners and the NMCP. To date, 17 *DSDaaras* in eight health post catchment zones were trained and provide care to ~ 4,500 residential students (4% of the catchment population). In the first year, 1,586 patients sought care, of which 1,237 (78%) had a fever and were tested by RDT; all had sought care within 24 hours of symptom onset. There were 684 confirmed malaria cases (8% of catchment malaria cases for the year) and all were appropriately treated and recovered. Test positivity rate was > 50% in eight *daaras* and four *daaras* accounted for 72% of cases. After *PECA Daara* implementation, reported severe malaria cases within health facilities serving the *daaras* decreased by 35% within a year. On average, 18% of sick patients consulted by the *DSDaara* were referred to a health center for a negative RDT. The promising 1-year results of *PECA Daara* highlight the value of scaling-up this program to guarantee rapid access to quality malaria diagnosis and treatment to the vulnerable population of *daara* students and ensure equitable access to care throughout Senegal.

## 45

### IMPROVING EARLY ANTENATAL CARE (ANC) ATTENDANCE AND IPT UPTAKE THROUGH COMMUNITY HEALTH VOLUNTEERS (CHVS)

**Augustine Ngindu**<sup>1</sup>, Susan Ontiri<sup>1</sup>, Gathari Ndirangu<sup>1</sup>, Beth Barasa<sup>1</sup>, Evans Nyapada<sup>1</sup>, David Omoit<sup>2</sup>, Johnstone Akatu<sup>2</sup>, Mildred Mudany<sup>3</sup>

<sup>1</sup>Jhpiego - MCSP, Washington, DC, United States, <sup>2</sup>Ministry of Health, Bungoma, Kenya, <sup>3</sup>Jhpiego, Washington, DC, United States

Kenya adopted the use of intermittent preventive treatment with sulfadoxine pyrimethamine in 1998 but the proportion of pregnant women receiving at least two doses (22% (2010) and 56% (2015) has remained below the national target of 80%. In 2015, the country adopted an IPTp3 indicator for monitoring IPTp uptake; that year, the proportion of women taking at least 3 doses was 38% (2015). Some of the factors leading to low IPTp coverage include poor knowledge on the need for early antenatal care (ANC), distances to health facilities, sociocultural practices and a lack of financial resources. In 2012, community health volunteers (CHVs) were enlisted through a pilot program in one county to deliver messages aimed at increasing the proportion of women starting ANC ≤ 20 weeks of gestation and thus expand the proportion of women receiving IPTp early in the second trimester. A community survey in 2013 showed an increase in IPTp2 from 22% in 2010 to 63%. The practice was considered a success story, and was subsequently replicated in 30 sub-counties, in 4 out of 14 malaria endemic counties. The rollout involved training of 9,042 CHVs, in 761 community units. Between 2015 and 2016, the CHVs reached 86,433 women with MiP messages. During this time, there was an average increase in IPTp1 from 51% to 68%, and IPTp2 increased from 42% to 55% (p < 0.001). This could be attributed to early ANC attendance, which increased from 32% to 48% in the same period. The use of CHVs to sensitize pregnant women to start IPTp early in the second trimester and continue with scheduled ANC visits increases the probability that women will receive the recommended IPTp-SP doses. The rollout of the practice to other malaria endemic counties is likely to have contributed to increase in IPTp uptake in the four target counties.

## 46

### INCREASE IN DELIVERY OF INTERVENTIONS TO DECREASE MALARIA AMONG PREGNANT WOMEN IN SENEGAL

**Moustapha I. Cisse**<sup>1</sup>, Julie I. Thwing<sup>2</sup>, Medoune Ndiop<sup>1</sup>, Alioune B. Gueye<sup>1</sup>, Ibrahima Diallo<sup>1</sup>, Seynabou Gaye<sup>1</sup>, Mamadou L. Diouf<sup>1</sup>, Katherine Sturm-Ramirez<sup>3</sup>, Oumar Sarr<sup>1</sup>

<sup>1</sup>Senegal National Malaria Control Program, Dakar, Senegal, <sup>2</sup>Centers for Disease Control and Prevention and U.S. President's Malaria Initiative, Atlanta, GA, United States, <sup>3</sup>Centers for Disease Control and Prevention and U.S. President's Malaria Initiative, Dakar, Senegal

Pregnant women are known to be at high risk for malaria, and intermittent preventive treatment during pregnancy and long-lasting insecticidal nets (LLINs) are key interventions to reduce that risk. Intermittent preventive treatment during pregnancy (IPTp) consists of a treatment course of sulfadoxine/pyrimethamine (SP) given at intervals of at least 30 days during the second and third trimesters. In 2013, the Senegal National Malaria Control Program (NMCP) adopted the revised WHO guidelines for IPTp to increase number of doses of SP provided to pregnant women, introduced treatment of pregnant women with uncomplicated malaria with artemisinin-based combination therapy, and put increased emphasis on provision of LLINs during antenatal care. We analyzed routine malaria information system data reported to the NMCP from all publicly supported health facilities to evaluate the change in interventions delivered, calculated using to the estimated number of expected pregnancies as denominator, and the impact on incidence of uncomplicated malaria, severe malaria, and deaths among pregnant women. The number of pregnant women that received an LLIN during an antenatal visit increased from 105,686 in 2014 to 219,212 in 2016, 19% and 38% of expected

pregnancies, respectively. The proportion of expected pregnancies who received at least two doses of SP increased from 54% in 2014 to 58% in 2016, and those that received at least three doses of SP increased from 20% in 2014 to 40% in 2016. While the number of pregnant women diagnosed with malaria increased 9%, from 6,465 to 7,044, the test positivity rate fell from 28% to 20%. Hospitalizations of pregnant women for malaria fell 36%, from 1,414 to 900, and deaths of pregnant women due to confirmed malaria fell from 17 in 2014 to one in 2016. There is need for improvement in provision of LLINs and IPTp to pregnant women. More pregnant women were diagnosed with uncomplicated malaria, however, test positivity rate, hospitalizations, and deaths of pregnant women with confirmed malaria decreased from 2014 to 2016.

## 47

### ASSESSMENT OF FACILITATORS AND BARRIERS TO ACHIEVING THE TARGET IPTP MUTASA DISTRICT, MANICALAND PROVINCE, ZIMBABWE: A FORMATIVE ASSESSMENT

**Fadzai Mutseyekwa**<sup>1</sup>, Rugare Mandigo<sup>1</sup>, Simba Mashizha<sup>2</sup>, Munyaradzi Mukuzungu<sup>2</sup>, Zacharia Grand<sup>2</sup>, Charles Uzande<sup>2</sup>, Blessmore Chaibva<sup>2</sup>, Patron Mafaune<sup>2</sup>, Joseph Mberikunashe<sup>2</sup>, Davidzoyashe Makosa<sup>1</sup>, Kate Gilroy<sup>3</sup>, Rose Kambarami<sup>1</sup>

<sup>1</sup>Maternal Child Integrated Program (MCHIP), Harare, Zimbabwe,

<sup>2</sup>Manicaland Provincial Medical Directorate, Manicaland, Zimbabwe,

<sup>3</sup>Maternal Child Survival Program (MCSP), Washington, DC, United States

Use of intermittent preventive treatment (IPTp) is an evidence-based intervention for preventing malaria during pregnancy. Zimbabwe began implementing IPTp in 2004; however it has not achieved its target of 85% of eligible women receiving 2 or more doses. In 2016, the Ministry of Health and Child Care, with support from the President's Malaria Initiative, explored barriers and drivers of IPTp program uptake in Mutasa District, Zimbabwe. This preliminary assessment aimed to inform the questions and methods of a larger research study; methods included document review, secondary data review, facility visits and key informant interviews. The assessment identified factors within the health system requiring further study, for example: 1) limited physical availability of updated national IPTp guideline documents, 2) barriers to access such as antenatal care (ANC) services only offered on selected days and long wait times, and 3) non-provision of IPTp at private facilities. There were missed opportunities for IPTp (about 5% of 3,904 ANC visits reviewed), most due to facility stock-outs of sulfadoxine-pyrimethamine (SP). Data reporting was inaccurate, with facilities both under-reporting and over-reporting IPTp 1, 2 and 3 as compared to ANC registers. Additionally, IPTp coverage calculations need to factor in women ineligible to receive SP due to cotrimoxazole prophylaxis, which was 5% overall, but varied greatly by facility. Community health workers, community leaders and men were identified as influencing IPTp uptake, although how they drive or impede IPTp and ANC uptake and the best approaches to engage these groups require further study. Early ANC attendance was significantly associated with receiving more IPTp doses ( $p < 0.01$ ), thus examining factors influencing timing of ANC initiation is critical. Preliminary findings on supply and demand side factors influencing IPTp uptake were used to develop a conceptual framework for a research study to explore these and other factors influencing IPTp coverage in greater depth, using mixed research methods.

### TREATMENT OF YOUNG INFANT INFECTION IN NTCHU DISTRICT (TYIIN): IMPLEMENTATION RESEARCH ON SIMPLIFIED TREATMENT OF POSSIBLE SERIOUS BACTERIAL INFECTIONS AND FAST BREATHING AMONG YOUNG INFANTS IN NTCHU DISTRICT, MALAWI

**Tanya P. Guenther**<sup>1</sup>, Gladson Mopiwa<sup>2</sup>, Gomezgani Jenda<sup>2</sup>, Humphreys Nsona<sup>3</sup>, Regina Makuluni<sup>4</sup>, Chancy Banda Fundani<sup>4</sup>, Salim Sadruddin<sup>5</sup>

<sup>1</sup>Save the Children, Washington, DC, United States, <sup>2</sup>Save the Children, Lilongwe, Malawi, <sup>3</sup>Ministry of Health (MOH), Lilongwe, Malawi, <sup>4</sup>District Health Office, MOH, Ntcheu, Malawi, <sup>5</sup>World Health Organization, Geneva, Switzerland

Serious bacterial infection is a leading cause of newborn mortality and recommended inpatient treatment options are inaccessible to most families in low-income settings. In July 2015, the World Health Organization released guidelines for outpatient treatment of young infants with possible serious bacterial infection (PSBI) with simplified antibiotic regimens in cases where the caregiver refuses or is unable to complete referral to hospital. If implemented at scale, the outpatient regimen has the potential to prevent many young infant deaths in Malawi. We present results of implementation research to demonstrate the feasibility and acceptability of delivering simplified treatment for young infants in Malawi. The prospective cohort study is being conducted from December 2016 to September 2017 in 12 first level health facilities in Ntcheu district and will enroll ~368 sick young infants 0-59 days for whom referral is not possible. Health workers at study facilities are trained to treat eligible PSBI cases with injection gentamicin for 2 days and oral amoxicillin for 7 days and eligible fast breathing only cases with oral amoxicillin for 7 days. Health Surveillance Assistants (HSAs), trained in community-based maternal and newborn care, conduct home visits on days 3 and 6 to assess the child, encourage treatment adherence and remind the caregiver to take the child for facility follow up. Enrolled infants are followed up at health facility on day 4 and 8. The primary outcome is proportion of enrolled cases completing treatment per protocol. Secondary outcomes include proportion of eligible cases accepting outpatient treatment, completion of day 4 follow up, and completion of HSA follow up visits. Pilot phase results show that of 53 eligible cases, caregivers of 45 cases (85%) refused referral to district hospital and accepted outpatient treatment. Among enrolled cases (30 PSBI and 15 fast breathing only), 90% PSBI cases (27/30) completed day one and two gentamicin injections, 78% (35/45) completed day 4 follow up, and 53% (24/45) received at least one HSA home visit. Study results will inform replication and scale-up in Malawi and other countries.

## 49

### THE RESILIENCE OF INTEGRATED COMMUNITY CASE MANAGEMENT IN ACUTE EMERGENCY: A CASE STUDY FROM SOUTH SUDAN

**Naoko Kozuki**<sup>1</sup>, Katja Ericson<sup>2</sup>, Bethany Marron<sup>3</sup>, Yolanda Barbera Lainez<sup>4</sup>, Nathan P. Miller<sup>5</sup>

<sup>1</sup>International Rescue Committee, Washington, DC, United States,

<sup>2</sup>International Rescue Committee, Hatay, Turkey, <sup>3</sup>International Rescue

Committee, Nairobi, Kenya, <sup>4</sup>International Rescue Committee, New York,

NY, United States, <sup>5</sup>UNICEF, New York, NY, United States

The International Rescue Committee (IRC) was the first NGO to introduce integrated Community Case Management (iCCM) of childhood illness to South Sudan, then Southern Sudan, in 2005. An active conflict that began in December 2013 displaced approximately 2 million people over the course of few months. The IRC conducted in May 2015 a mixed-methods case study of the impact of the acute emergency in early 2014 on iCCM programming in Payinjar County, Unity State. The objective was to document the experience of operating an iCCM program during acute

crisis and to assess the ability of the program to continue operations. Semi-structured interviews and focus group discussions were conducted with key stakeholders such as policymakers, community health workers (CHW), and caregivers. Routine program data were examined to assess the effect of the crisis on key indicators. Internally displaced persons nearly doubled the population in Payinjar from 44,224 to 83,433. Some CHWs continued working despite displacement if they were able to take supplies with them. Despite no formal community mobilization effort by the iCCM program, the information that CHWs had drugs spread throughout displaced communities, with caregivers subsequently seeking care. The total number of treatments provided per month dropped from the July-December 2013 average of 3226 to the lowest level of 1420 in February 2014, but recovered to 3270 by August 2014. CHW supervisors attempted to continue supervision by utilizing their networks to track down displaced CHWs and by assessing the security situation prior to visits. The monthly supervision rate dropped from the July-December 2013 average of 93% to the lowest level of 77% in February 2014, but recovered to 91% by August 2014. Several CHWs and community leaders qualitatively validated this claim of sustained supervision. International donors and humanitarian actors should recognize iCCM as a potentially high-impact humanitarian response. Flexible funding from donors would allow for development of more evidence on iCCM approaches and improvements that can both sustain and enhance programming in acute crisis.

## 50

### PRIMED INNATE IMMUNE RESPONSES IN MONOCYTES FROM KENYAN CHILDREN WITH UNCOMPLICATED FALCIPARUM MALARIA

**Katherine R. Dobbs**<sup>1</sup>, Paula Embury<sup>1</sup>, John Vulule<sup>2</sup>, Peter Sumba Odada<sup>2</sup>, Bruce A. Rosa<sup>3</sup>, Makedonka Mitreva<sup>3</sup>, James W. Kazura<sup>1</sup>, Arlene E. Dent<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Washington University, St. Louis, MO, United States

Monocytes are innate immune cells that play a key role in host protection and pathogenesis during malaria. We sought to determine whether uncomplicated falciparum malaria in children modulates Toll-like receptor (TLR) responsiveness in monocytes. Freshly isolated monocytes were obtained from 8 children in western Kenya at presentation with acute uncomplicated malaria and 6 weeks following treatment and from 4 malaria-naïve North Americans (NAM). Monocytes were cultured for 18 hours with media alone, a TLR4 agonist (LPS), or a TLR2/TLR1 agonist (Pam3CSK4). Supernatant cytokine concentrations were measured using a magnetic bead-based immunoassay. Genomic DNA was isolated from monocytes from the same 8 acute-recovery pairs for DNA methylation analysis using the MethylationEPIC array. Monocyte gene expression profiles were analyzed in another 6 acute-recovery pairs and 5 NAM using a targeted digital RNA sequencing panel. Both acute and recovery monocytes showed robust and equivalent responses to LPS and Pam3CSK4, with markedly increased production over media alone of IL-1 $\beta$ , IL-6, IL-8, IL-10, IL-12p40, and TNF (Friedman test  $P$  values < 0.05). Compared to NAM, acute and recovery monocytes showed greater magnitude of responses to LPS and Pam3CSK4, especially for IL-6, IL-12p40, and TNF (Kruskal-Wallis test  $P$  values < 0.05). Monocyte gene expression for the cytokines IL-1 $\alpha$ , IL-1 $\beta$ , IL-6, IL-8, and TNF was not different between acute and recovery, though these genes were significantly overexpressed in acute and recovery monocytes compared to NAM (adjusted  $P$  values < 0.0001). Preliminary analysis of DNA methylation showed significant differential methylation in acute vs. recovery monocytes in the promoter regions for *IL1A*, *IL1R1*, *IL18R1*, *IL10*, *TNF*, *TLR1*, and *TLR6*. Complete methylation analysis is ongoing and will be correlated with functional and transcriptional data. These data suggest that uncomplicated malaria in children has a priming effect on innate immune responses that is maintained several weeks after clinical recovery, which may be mediated in part by epigenetic changes such as altered DNA methylation patterns.

## 51

### INDIVIDUAL AND COMPOSITE AMA-1 CELLULAR RESPONSES AND THEIR ASSOCIATION WITH CLINICAL MALARIA IN A PEDIATRIC COHORT IN MOZAMBIQUE AND TANZANIA

<sup>1</sup>ISGlobal, Barcelona, Spain, <sup>2</sup>Ifakara Health Institute, Bagamoyo Research and Training Centre, Bagamoyo, United Republic of Tanzania, <sup>3</sup>Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, <sup>4</sup>University of Indiana, Indianapolis, IN, United States, <sup>5</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>6</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>7</sup>Michigan State University, East Lansing, MI, United States

Naturally acquired cellular immunity (NAI) in malaria is based on the interplay of pro- and anti-inflammatory responses that control parasite load while moderating deleterious responses. Although responses involve many cellular mediators, studies of NAI have focused on a limited panel of markers. We aimed to identify individual and combination of responses elicited by exposure to *P.falciparum* and those protective from clinical malaria based on several markers. Peripheral blood mononuclear cells (PBMC) were isolated 3 months before and at start of follow-up in a cohort of 459 children aged 6 weeks to 17 months nested within the RTS,S/AS01 Phase III trial conducted in Mozambique and Tanzania. PBMC were stimulated with AMA-1 and DMSO (mock stimulation) and 28 cytokines, chemokines, and growth factors were measured. Children were prospectively followed and the association of individual and combinations of AMA-1 specific responses with 12-month risk of malaria was estimated using logistic regression fitted with elastic net and group lasso. Baseline AMA-1 specific responses were elicited and many were correlated with age including pro-inflammatory TNF and regulatory IL-10; chemokines (e.g., CXCL9); growth factors (e.g., G-CSF); and IFN- $\alpha$ . Of these, levels of markers did not change significantly over time, except TNF ( $P = 0.006$ ). At the start of follow-up, TNF and a cluster composed of IL-7, IL-17, MIG, IL-2, and HGF were consistently detected by principal component analysis and K-means clustering. However, these clusters were not correlated with risk of malaria. In single and multi-marker analyses adjusting by vaccination status, IFN- $\alpha$  (Odds ratio [OR]=0.1), G-CSF (OR=0.8), and the TH1-related cytokines IL-12 (OR=0.7), and IL-15 (OR=0.8) decreased the risk of malaria. Conversely, the chemokine eotaxin (OR=3.4) increased the risk of malaria, perhaps due to its association with apoptosis of B cells and/or its negative impact on production of anti-*Plasmodium* IgG. These results provide novel information about cellular responses, such as the importance of IFN- $\alpha$  and G-CSF, highlighting the role of innate responses in protection from malaria.

## 52

### ATYPICAL ACTIVATION OF DENDRITIC CELLS BY PLASMODIUM FALCIPARUM

**Anton Goetz**<sup>1</sup>, Mei San Tang<sup>2</sup>, Maureen Ty<sup>2</sup>, Charles Arama<sup>3</sup>, Aissata Ongoiba<sup>3</sup>, Didier Doumtabé<sup>3</sup>, Boubacar Traore<sup>3</sup>, P'ng Loke<sup>2</sup>, Ana Rodriguez<sup>4</sup>, Peter Crompton<sup>1</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>New York University School of Medicine, New York, NY, United States, <sup>3</sup>Mali International Centers for Excellence in Research, Bamako, Mali, <sup>4</sup>New York University School of Medicine, New York, NY, United States

Malaria is characterized by high levels of inflammation and while an early inflammatory response is important for parasite clearance, excessive and persistent inflammation can contribute to severe forms of the disease. At the same time, *Plasmodium falciparum* infections fail to induce sterile immunity and clinical immunity is only acquired after years of exposure. Reports about the role of dendritic cells (DCs) in the immune response to

*P. falciparum* and how they contribute to the activation of CD4+ T cells during blood stage have been contradictory. We found that the activation of DCs by *P. falciparum* induces a highly unusual phenotype by which DCs up-regulate co-stimulatory molecules and secretion of chemokines, but not of cytokines typical of inflammatory responses (IL-1 $\beta$ , IL-6, IL-10, TNF). Contact-dependent cross-talk between the main DC subsets, plasmacytoid DCs and myeloid DCs, was necessary for increased chemokine and IFN $\alpha$  secretion in response to the parasite. Despite their atypical activation phenotype, myeloid DCs incubated with *P. falciparum*-infected erythrocytes activated autologous antigen-specific naive CD4+ T cells to proliferate and secrete high levels of the Th1 cytokines IFN $\gamma$  and TNF, but also IL-10 and IL-5, characteristic for a T regulatory type 1 (Tr1) response. Initial experiments with DCs obtained from uninfected malaria-experienced donors from Mali suggest a comparable activation phenotype in malaria-naïve and malaria-experienced individuals. We will further analyze the DC response to the parasite in Malian individuals in a longitudinal study comparing responses during the dry season to malaria season. Our findings might contribute to a better understanding of the mechanisms involved in the initiation of the adaptive immune response against *P. falciparum*.

Antibodies effectuate immunity to malaria, however, there is incomplete understanding of protective mechanisms. Susceptibility of *Plasmodium falciparum* living inside infected red blood cells (RBC) to antibody-dependent cellular cytotoxicity (ADCC) remains unexplored. ADCC can be triggered by interaction of antibody Fc region to activating receptor Fc $\gamma$ R11 (CD16) present on natural killer (NK) cells. During ADCC, NK cells degranulate and deliver serine proteases, such as granzyme, into target cells where they activate apoptotic pathways. Here, we have evaluated the response of primary human NK cells towards parasitized RBC, its effect on RBC integrity and parasite viability. In the presence of serum from individuals clinically immune to malaria, NK cells degranulated and produced pro-inflammatory cytokines in response to parasitized RBC. Addition of immune plasma led to NK cell-mediated selective lysis of infected RBC as confirmed by live cell imaging and several lysis assays. Importantly, NK cell-mediated ADCC also inhibited the growth of *P. falciparum* in RBC. Intracellular parasite susceptibility to NK-mediated ADCC prompted us to further explore the cellular and molecular basis of parasite death. The variant surface protein PfEMP1 is the immunodominant antigen expressed at the surface of infected RBC, and parasites switch PfEMP1 expression to evade variant-specific antibody responses. RBC infected with a transgenic *P. falciparum* lacking PfEMP1 were not sensitive to NK cells in presence of immune plasma. In addition, ADCC was effective when PfEMP1-specific antibodies were bound to wild-type parasitized RBC, reaffirming the role of PfEMP1 as antigen during NK-mediated ADCC. ADCC affected the integrity of parasitized RBC, as shown by hemoglobin release, RBC membrane damage, granzyme-B delivery and caspase-3 activation. NK cells treated with granzyme inhibitor lose their cytotoxic potential towards infected RBC and the parasite survives. These findings suggest additional immune mechanisms that could contribute to natural protection to malaria.

## 54

### IMPACT OF PLACENTAL MALARIA ON CORD BLOOD V $\delta$ 2 T LYMPHOCYTES IN MALAWI

Haoting Hsu<sup>1</sup>, Sarah E. Boudova<sup>2</sup>, Godfrey Mvula<sup>3</sup>, Titus Divala<sup>3</sup>, Randy Mungwira<sup>3</sup>, David Pauza<sup>1</sup>, Christopher Harman<sup>4</sup>, Karl Seydel<sup>5</sup>, Miriam K. Laufer<sup>2</sup>, Cristiana Cairo<sup>1</sup>

<sup>1</sup>Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Blantyre Malaria Project, University of Malawi College of Medicine, Blantyre, Malawi, <sup>4</sup>Obstetrics, Gynecology and Reproductive Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>5</sup>College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States

*P. falciparum* (Pf) placental infection primes the fetal immune system and in some instances reduces infant immunity against malaria and other pathogens. The mechanisms leading to these outcomes are not completely understood. We focused on V $\delta$ 2 cells, which respond to a broad range of pathogens including mycobacteria and Pf. These unconventional lymphocytes are triggered by small, non-peptidic antigens (including metabolites of Pf) independently of MHC presentation. We hypothesized that placental malaria (PM), which may cause fetal exposure to high levels of Pf metabolites, induces measurable changes in neonatal V $\delta$ 2 lymphocytes. We analyzed cord blood mononuclear cells from Malawian neonates born to women with PM, peripheral malaria or no malaria during pregnancy, using North American specimens as an external reference group. The PM group was stratified into past, chronic and acute infections. V $\delta$ 2 cell phenotype, repertoire and function were compared for Pf-exposed and unexposed newborns. A preliminary analysis showed that neonates exposed to chronic PM had increased frequencies of V $\delta$ 2 cells in cord blood compared to the acute PM group. Neonates exposed to active PM (including both chronic and acute infections) had higher proportions of CD16+ V $\delta$ 2 T cells than the past PM group; moreover, they displayed higher proportions of CD25+ V $\delta$ 2 cells and lower proportions of PD1+ V $\delta$ 2 cells than unexposed controls, overall indicating altered activation/differentiation state. We hypothesize that *in utero* exposure to Pf, at least in some cases, attenuates V $\delta$ 2 cell function in early life, thus impairing responses to BCG vaccination and innate protection against some infectious agents; we are currently testing whether the observed phenotypic differences for PM-exposed neonates are associated with altered function and/or perturbed T cell receptor gamma repertoire at birth. By determining whether V $\delta$ 2 cells represent a useful biomarker or possibly a key mediator of the impact of PM on neonatal immune system, we can contribute to public health interventions directed at mitigating the negative effects of PM on infant immunity.

## 55

### ANTIBODIES TO PLASMODIUM VIVAX PVDBP REVEAL A MECHANISM FOR CROSS-SPECIES IMMUNITY TO P. FALCIPARUM PLACENTAL MALARIA

<sup>1</sup>University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Universidad de Antioquia, Medellin, Colombia, <sup>3</sup>FIOCRUZ, Belo Horizonte, Brazil, <sup>4</sup>University of South Florida, Tampa, FL, United States, <sup>5</sup>University of Ghana, Accra, Ghana, <sup>6</sup>University of Copenhagen, Copenhagen, Denmark, <sup>7</sup>Griffith University, Gold Coast, Australia

During infection with *Plasmodium falciparum* in pregnancy, parasites express the surface antigen VAR2CSA that mediates adherence of infected erythrocytes to chondroitin sulphate A (CSA) in the placenta.

Antibodies to VAR2CSA are acquired with successive exposures to *P. falciparum* in pregnancy and the presence of VAR2CSA antibodies has been associated with protection from placental malaria. In Colombia, we previously observed a high frequency of antibodies to VAR2CSA in non-pregnant populations. However, the origin of these VAR2CSA cross-reactive antibodies and their role in protecting against placental malaria is unknown. Here, we tested the hypothesis that acquisition of VAR2CSA antibodies outside of pregnancy can arise due to exposure to *P. vivax*. We tested over 200 sera from men and children living in malaria-endemic regions of Colombia and Brazil and over 50% of individuals exposed only to *P. vivax* had antibodies that recognized VAR2CSA. We further showed that antibodies against the PvDBP protein from *P. vivax* can mediate this cross-reactivity. PvDBP affinity-purified antibodies from human sera and a monoclonal antibody raised against PvDBP recognized VAR2CSA through shared epitopes in DBL domains, showing that protective antigenic determinants can be evolutionarily conserved between these proteins. The monoclonal antibody also recognized the native protein on the surface of infected erythrocytes by IFA and flow cytometry, and significantly inhibited the binding of infected erythrocytes to CSA. Inhibition was similar to the level observed with sera from multigravid African women, which is the primary *in vitro* correlate of protection from placental malaria. These data show that exposure to PvDBP can induce antibodies that functionally recognize VAR2CSA. We thus identify a novel mechanism for cross-species immunity to falciparum malaria that can be exploited as a new approach to develop a vaccine against malaria in pregnancy.

## 56

### DECLINING MALARIA TRANSMISSION DIFFERENTIALLY IMPACTS ON THE MAINTENANCE OF HUMORAL IMMUNITY TO *PLASMODIUM FALCIPARUM* IN CHILDREN

Cleopatra K. Mugenyi<sup>1</sup>, Salenna R. Elliott<sup>1</sup>, Xi Zen Yap<sup>1</sup>, Gaoqian Feng<sup>1</sup>, Gregory Fegan<sup>2</sup>, Philippe Boeuf<sup>1</sup>, Faith F. Osier<sup>2</sup>, Freya J. Fowkes<sup>1</sup>, Marion Avril<sup>3</sup>, Thomas N. Williams<sup>2</sup>, Kevin Marsh<sup>2</sup>, **James G. Beeson<sup>1</sup>**

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>Kenya Medical Research Institute, Kilifi, Kenya, <sup>3</sup>Centre for Infectious Disease Research, Seattle, WA, United States

Antibodies play a major role in naturally-acquired immunity to *Plasmodium falciparum* malaria and predominantly target the blood-stages, including merozoites and infected erythrocytes (IEs). As a result of intensified control efforts, and other factors, *P. falciparum* transmission has declined in many regions in recent years, and these declines have been associated with higher rates and severity of clinical malaria, which may be attributed to declining naturally-acquired immunity in the population. While there is evidence that declines in malaria transmission are associated with reductions in antibodies to blood-stage antigens, what is less clear is whether significant humoral immune responses to key targets are maintained after reductions in transmission, or the impact on functional protective antibody responses. In a 3-year longitudinal cohort of 300 Kenyan children, levels of antibodies to different antigens were measured by ELISA, and levels of functional antibodies promoting opsonic phagocytosis of merozoites, fixation of complement to merozoites and antibodies to IEs were quantified. Over a period in which malaria transmission declined substantially, antibodies to merozoite antigens AMA1 and MSP2 decreased substantially (antibody half-lives 0.8 and 1-3 years); however, ~70% of children maintained their sero-positivity to AMA1 and ~45% to MSP2. Antibodies promoting opsonic phagocytosis of merozoites also declined rapidly (half-life 0.15 years). In contrast, complement-fixing antibodies to merozoites did not decline over the study period and antibodies to surface antigens of IEs expressing virulent phenotypes, targeting PfEMP1, were much better maintained (half-life 4-10 years). These data suggest that the loss of immunity as malaria transmission declines is not universal as some key functional responses and antibodies to IEs were well maintained and may continue to provide some protection. These findings have implications for malaria surveillance and

control measures. Understanding why some responses are well maintained may inform the development of vaccines that generate sustained protection.

## 57

### SINGLE-CELL RNA-SEQ REVEALS ACTIVATION OF CHROMATIN REGULATORS BY AP2-G DURING SEXUAL COMMITMENT IN MALARIA PARASITES

Asaf Poran, Christopher Noetzel, Olivier Elemento, **Bjorn F. Kafsack**

Weill Cornell Medical College, New York, NY, United States

Sexual commitment requires activation of *ap2-g*, the transcriptional master regulator of sexual development, from its epigenetically silenced-state during asexual replication. Expression of the AP2-G transcription factor during this "commitment cycle" poises gene expression in nascent merozoites to initiate sexual development through a hitherto unknown mechanism. In order to maintain a persistent infection, *ap2-g* expression is limited to a sub-population of parasites ranging from 1-30%, depending on genetic background and growth conditions. As sexually-committed schizonts comprise only a sub-population and are morphologically indistinguishable from their asexually-committed counterparts, defining their characteristic gene expression has been difficult using traditional, bulk transcriptome profiling. To determine the transcriptional changes induced by AP2-G within this sub-population, we applied highly-parallel, single-cell RNA sequencing to malaria cultures undergoing sexual commitment. In this first application of single-cell RNA-seq to malaria parasites, we surveyed the transcriptomes of over 16,000 parasites from multiple stages of development and found that, during merozoite formation, AP2-G robustly up-regulates key transcription factors, including histone modifying enzymes and regulators of nucleosome positioning. These epigenetic regulators act to poise the expression of genes necessary for initiation of gametocyte development in the subsequent cell cycle.

## 58

### A SATURATION-LEVEL PIGGYBAC MUTAGENESIS SCREEN OF THE *PLASMODIUM FALCIPARUM* GENOME DEFINES GENES IMPORTANT FOR *IN VITRO* ASEXUAL BLOOD-STAGE GROWTH

Min Zhang<sup>1</sup>, Chengqi Wang<sup>1</sup>, Jenna Oberstaller<sup>1</sup>, Thomas D. Otto<sup>2</sup>, Swamy Adapa<sup>1</sup>, Xiangyun Liao<sup>1</sup>, Justin Swanson<sup>1</sup>, Suzanne Li<sup>1</sup>, Kenneth Udenze<sup>1</sup>, Julian C. Rayner<sup>2</sup>, Rays H. Jiang<sup>1</sup>, **John H. Adams<sup>1</sup>**

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Wellcome Trust Sanger Institute, Hinxton, United Kingdom

*Plasmodium falciparum* is the most lethal eukaryotic microbial pathogen and yet the genetic basis of many of its unique biological properties and important metabolic pathways remains unknown. In this study, we fulfill the critical need for a robust analytical method to systematically define the genes and pathways indispensable for *in vitro* survival of asexual blood-stage *P. falciparum* NF54 at a whole-genome scale. This study exploits the efficiency of the *piggyBac* transposon method that primarily produces single-insertion mutant parasites and Quantitative Insertion-site Sequencing (Qlseq), our next-gen mutagenesis sequencing tool to identify *piggyBac* insertion sites, to achieve for the first time saturation-level mutagenesis of *P. falciparum*. At this level of mutagenesis each gene (intergenic + ORF) in the genome was targeted by multiple *piggyBac* insertions. Even at this high density of mutagenesis, no *piggyBac* insertions were recovered from half of the genes in *P. falciparum* genome and so disruption of the ORF of these genes was presumed deleterious to parasite survival. Therefore, the genes without insertions disrupting their ORFs are considered essential for asexual blood-stage growth. Examples of essential genes includes K13 implicated in ART-R, the essential egress kinase gene CDPK5, and the primary drug target gene DHFR. In contrast, about half of

the genes in genome had one of more ORF-disrupting *piggyBac* insertion and these genes are presumed to be dispensable for asexual blood-stage growth. Analysis of this dispensable gene set indicated about half of these genes (>1000) are likely to be important in sexual stage development, based upon peak gene expression patterns. Overall, by generation and analysis of saturation-level, whole-genome coverage of unique *piggyBac* insertions, we can discern genes and pathways most important for asexual intraerythrocytic growth of *P. falciparum* NF54 under ideal *in vitro* culture conditions. The *pB-Qseq* method now provides the robust genomic tool needed to accelerate progress to identify and validate essential candidate targets to develop the most effective new antimalarial therapies.

## 59

### FUNCTIONAL ANALYSIS OF A SPOROZOITE RHOPTRY PROTEIN DURING HEPATOCYTE INFECTION

Sirasate Bantuchai<sup>1</sup>, Mamoru Nozaki<sup>1</sup>, Amporn Thongkukiatkul<sup>2</sup>, Natcha Lorsuwannarat<sup>1</sup>, Mayumi Tachibana<sup>1</sup>, Kazuhiro Matsuoka<sup>1</sup>, Takafumi Tsuboi<sup>3</sup>, Motomi Torii<sup>1</sup>, **Tomoko Ishino**<sup>1</sup>

<sup>1</sup>Ehime University, Toon, Japan, <sup>2</sup>Brupha University, Chonburi, Japan,

<sup>3</sup>Ehime University, Matsuyama, Japan

Rhoptries, the apical end organelle in *Plasmodium* and *Toxoplasma* invasive forms, are known as containing secretory proteins required for parasite invasion of target cells. It has been well demonstrated in *Plasmodium* that rhoptry neck protein members (e.g. RON2, RON4, and RON5) are essential for merozoite invasion of erythrocyte by forming the tight junction between parasites and host cells, however their roles during sporozoite invasion of hepatocytes remain largely unknown. We demonstrated that most merozoite rhoptry proteins are also localized to sporozoite rhoptries. By applying sporozoite stage-specific gene silencing system in *Plasmodium berghei*, we revealed that several rhoptry proteins, including one containing EF hand domains (named RON), are involved in sporozoite invasion of mosquito salivary glands. Here, we examined whether RON in sporozoites is also required for the invasion of different target cells, mammalian hepatocytes. RON repressed sporozoites were collected from hemolymph of infected mosquitoes and injected into c57bl/6 mice intravenously. Livers were harvested at 24 h post inoculation and parasite burden was examined by real time RT-PCR. Compared with control sporozoites, RON repressed sporozoites have approximately 1000 times lower infectivity to mice. Furthermore, the sporozoite invasive ability to hepatoma culture cells was almost abolished by RON repression. Since RON repressed sporozoites demonstrated far less gliding motility, which is required for invasion of mosquito salivary glands and mammalian hepatocytes, sporozoite RON might contribute to the both invasion processes by either regulating sporozoite motility or attachment ability to the target cells.

## 60

### PLASMODIUM FALCIPARUM GENETIC COMPLEXITY INFLUENCES TRANSCRIBED VAR REPERTOIRE AND IMMUNE RECOGNITION AMONG HIGHLY RELATED GENOTYPIC CLUSTERS

As transmission intensity has declined in Senegal, so has the genotypic complexity of circulating *Plasmodium falciparum* parasites, resulting in specific genotypes emerging and persisting over many years. Such genetically related clusters could be transcriptionally and antigenically related as well, potentially representing related immunogenic types, having implications for population level immunity and vaccine development strategies. We directly test the hypothesis that changes in parasite genetic signatures can alter the host population's immune repertoire to variant surface antigens, and that the degree of genomic relatedness influences the expression of variant antigens and the degree of immune recognition. We characterize parasites within genotypic clusters, defined as identical by the 24-SNP molecular barcode and assigned a haplotype identifier, for other highly polymorphic *loci*; we measure expression of variant surface antigens (VSA) such as PfEMP-1 by upstream-region (Ups) *var* group expression typing and expressed *var* DBL1 $\alpha$  sequencing in *ex vivo* RNA samples and short-term adapted RNA samples; and we measure variant surface antigen IgG responses against short-term adapted parasite isolates. We quantify the extent to which isolates within clusters diversify their genomic *var* repertoires over time. Parasites within genotypic clusters are genetically identical at other highly polymorphic *loci* and are extremely similar in their genomic *var* repertoire, transcribed *var* repertoire, and host antibody recognition of their VSAs. The degree to which parasites share IgG recognition of VSAs is related to the level of genome-wide identity in addition to the specific transcribed *var* repertoires. Monitoring changes in population-level parasite genomics and transmission dynamics is critical, as fluctuations will influence the breadth of resulting host immune responses to circulating parasite genotypes. These findings suggest shared immune recognition of genetically similar parasites, which has implications for both our understanding of immunity and vaccine development strategies in malaria elimination settings.

## 61

### ALBA4 COORDINATES STAGE-SPECIFIC INTERACTIONS AND MRNA FATES DURING PLASMODIUM GROWTH AND TRANSMISSION

Elyse E. Munoz, Kevin J. Hart, Michael P. Walker, Mark F. Kennedy, Mackenzie M. Shipley, **Scott E. Lindner**

Pennsylvania State University, University Park, PA, United States

Transmission of the malaria parasite depends upon an unpredictable moment where a mosquito must take a blood meal from a host. *Plasmodium* parasites have therefore evolved strategies to be prepared for successful transmission, including translationally repressing and protecting the mRNAs they will need to establish the infection following transmission. This phenomenon has been well-described in sexual stage parasites for the DOZI/DDX6, CITH, and PUF RNA-binding proteins, and recently in sporozoites through investigations of PUF2. However, much of the translational repression mechanism is not worked out, including whether translational repressors change their protein binding partners and mRNA targets in transmission stages, or other portions of the life cycle. This is in large part due to severe technical limitations of biochemical, proteomic, and transcriptomic studies of sporozoites, where substantial mosquito contamination has stymied these efforts. We have recently described the means to produce minimally perturbed, purified sporozoites that are finally amenable to these types of investigations. Here, for the first time, we provide a proteomic comparison of a protein complex across asexual blood, sexual, and sporozoite stages, along with a transcriptomic comparison of the mRNAs that are affected in these stages. We find that the Apicomplexan-specific ALBA4 RNA-binding protein acts to regulate development of the parasite's transmission stages, and that ALBA4

associates with both stage-specific and stage-independent partners to produce opposing mRNA fates. These efforts expand our understanding and ability to interrogate both sexual and sporozoite transmission stages and the molecular preparations they evolved to perpetuate their infectious cycle.

## 62

### INVESTIGATING THE VECTOR COMPETENCE OF *CULEX QUINQUEFASCIATUS* FOR ZIKA VIRUS

Hannah J. MacLeod<sup>1</sup>, Yessenia I. Anglero-Rodriguez<sup>1</sup>, Xiao-xia Guo<sup>2</sup>, Tong-yan Zhao<sup>2</sup>, George Dimopoulos<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Institute of Microbiology and Epidemiology, Beijing, China

Following the recent outbreak of Zika virus (ZIKV) in the Americas, there has been a rapid investigation into the factors determining ZIKV transmission during this epidemic. While *Aedes aegypti* was demonstrated by several groups to be the major vector of ZIKV in the Americas, our collaborators have shown that a strain of *Culex quinquefasciatus* from the south of China may also be competent to transmit this pathogen. We were interested in investigating the vector competence of different strains of *Cx. quinquefasciatus* for an Asian ZIKV isolate. In order to assess viral infection, midguts and carcasses were dissected after infection via feeding on a ZIKV infected blood meal and viral titers were determined via plaque assay. We did not observe viral plaques in any *Cx. quinquefasciatus* tissues at the time points assayed, whereas plaques were found in *Ae. aegypti* control midguts as early as 3 days post-infection (dpi). We then infected *Cx. quinquefasciatus* via injection of ZIKV into the thorax and dissected salivary glands at 3, 5, and 7 dpi and virus was detected in the salivary glands at all time points. After infection of 2 *Cx. quinquefasciatus* strains via blood feeding, ZIKV RNA was detected in the saliva via RT-PCR. Alignment of the different ZIKV strains genomes identified potential polyprotein variations in geographic isolates that may explain varying competence phenotypes that have been observed in *Cx. quinquefasciatus*. Current studies focus on clarifying whether the discrepancy between plaque assay and RT-PCR results is due to a mosquito species-specific modification of the virus or a severe infection bottleneck in the *Cx. quinquefasciatus* midgut. This work is critical for understanding the role of *Cx. quinquefasciatus* in the transmission of ZIKV.

### LONG-TERM SURVEILLANCE DEFINES SPATIAL, TEMPORAL AND ENVIRONMENTAL PATTERNS THAT IMPLICATE *CULEX TARSALIS* AS THE PRIMARY VECTOR OF WEST NILE VIRUS TRANSMISSION

Brendan M. Dunphy, Kristofer B. Kovach, Ryan C. Smith

Iowa State University, Ames, IA, United States

West Nile virus (WNV) has become the most epidemiologically important mosquito-borne disease in the United States with ~46,000 cases since its introduction in 1999. Transmitted primarily by *Culex* species, WNV transmission requires the complex interplay between bird reservoirs and mosquito vectors that results in human cases. To better understand these interactions, we have compiled data over the last 15 years (2002-2016) in Iowa examining WNV seroprevalence in sentinel chickens, mosquito infection rates, and their impacts on human disease cases. By quantifying infection rates of these hosts from spatial and temporal perspectives, we have constructed an overall picture of when and where WNV is most actively being transmitted. Overlaying these findings with mosquito infection rates and abundance data, we provide strong support that *Culex tarsalis* is a more competent vector of WNV and that its abundance is highly correlated to human WNV cases. In addition, we have identified underlying climatic factors such as over-wintering temperatures and prolonged periods of drought as integral components that influence WNV transmission from year to year. From these insights, we have generated predictive models to determine the intensity of WNV infection

## 64

### MOSQUITO IMMUNITY BEFORE AND AFTER METAMORPHOSIS: EVIDENCE OF ADAPTIVE DECOUPLING IN *ANOPHELES GAMBIAE*

Garrett P. League, Tania Y. Estévez-Lao, Yan Yan, Valeria A. Garcia-Lopez, Julián F. Hillyer

Vanderbilt University, Nashville, TN, United States

As holometabolous insects, mosquitoes undergo dramatic changes in morphology and ecological niche as they transition from aquatic larvae to terrestrial adults. Because larvae encounter a high density and diversity of pathogens in their microbe-rich aquatic environments and selection pressures are strongest on younger individuals that have yet to reproduce, we hypothesized that larval immunity is stronger than that of adults. To test this, we surveyed a broad array of cellular and humoral immune parameters in *Anopheles gambiae* larvae and compared the strength of these responses to that of newly-emerged (1-day-old) adults and older (5-day-old) adults. Overall, we found that larvae display more robust immune responses compared to adults with respect to bacteria killing efficiency, circulating and sessile hemocyte numbers, phagocytic properties of hemocytes, antimicrobial and melanization activity of hemolymph, and infection-induced transcription of immunity genes. Furthermore, we found that adult immune responses tend to decline with age. These findings are suggestive of both immune senescence and adaptive decoupling, or the independent evolution of larval and adult traits made possible by metamorphosis.

## 65

### USING MOBILE PHONES AS ACOUSTIC SENSORS FOR HIGH-THROUGHPUT SURVEILLANCE OF MOSQUITO ECOLOGY

Haripriya Mukundarajan, Felix Hol, Erica Castillo, Cooper Newby, Manu Prakash

Stanford University, Stanford, CA, United States

Frequent, widespread, and high resolution surveillance of mosquitoes is essential to understanding their complex ecology and behaviour, in order to formulate strategies to mitigate or prevent mosquito-borne diseases. However, there is a scarcity of data on the abundance, temporal variation, and spatial distribution of mosquito vector species, due to the absence of high-throughput, low-cost surveillance techniques. Acoustic measurement of the species-specific wingbeat frequencies of mosquitoes has been proposed decades ago as a solution to automate surveillance. Yet, this approach has not taken flight on a large scale, due to technological limitations in signal acquisition and hardware scalability. In this work, we demonstrate that commercially available mobile phones are a powerful tool for acoustically mapping mosquito species distributions, thus establishing a new citizen-driven paradigm for crowdsourced mosquito surveillance that takes advantage of the existing and widespread mobile network infrastructure. We show that even low-cost mobile phones with basic functionality are capable of sensitively acquiring acoustic data on species-specific mosquito wingbeat sounds, while simultaneously recording the time and location of the human-mosquito encounter. We survey a wide range of medically important mosquito species, to quantitatively demonstrate how acoustic recordings supported by spatio-temporal metadata enable rapid, non-invasive species identification. As proof-of-concept, we carry out field demonstrations where minimally-trained users map local mosquito fauna using their personal phones. Thus, by leveraging the global mobile phone infrastructure with the potential for engaging citizen scientists, our approach enables continuous large-scale acquisition of mosquito surveillance data in resource-constrained areas.

## INTERROGATION OF THE SEASONAL MICROBIOME OF *ANOPHELES COLUZZII* IN MALI

Benjamin J. Krajacich<sup>1</sup>, Diana L. Huestis<sup>1</sup>, Adama Dao<sup>2</sup>, Alpha S. Yaro<sup>2</sup>, Moussa Diallo<sup>2</sup>, Asha Krishna<sup>1</sup>, Jiannong Xu<sup>3</sup>, Tovi Lehmann<sup>1</sup>

<sup>1</sup>National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>2</sup>ICER Mali, Bamako, Mali, <sup>3</sup>New Mexico State University, Las Cruces, NM, United States

The poorly understood mechanisms of the seasonal maintenance of *Anopheles* spp. mosquitoes through the dry season in West Africa remain a critical gap in our knowledge of *Plasmodium* disease transmission. While it is thought some mosquitoes remain in a dormant state throughout this seven-month dry season, the nature of this state remains unknown and has largely not been recapitulated in laboratory settings. To elucidate possible life history traits allowing for this phenotype, this study used molecular tools to investigate the spatiotemporal change in the microbiome of mosquitoes in the dry and wet seasons in Mali. We analyzed the 16S ribosome bacterial and internal transcribed spacer (ITS) fungal sequences present in mosquitoes collected from two locations with varying water availability. These locations were a village near the Niger River with year-round water sources (N'Gabakoro), and a Sahelian area with highly seasonal breeding sites (Thierola). Using 16S next-generation sequencing data, we found 449 unique genera across 29 families with 2771 unique 16S sequence variants. With these, we could discriminate several compositional differences that were seasonally and spatially linked. Counter to our initial hypothesis, we found a more pronounced seasonal difference in the bacterial microbiome in the area with year-round water sources (N'Gabakoro). These major seasonal shifts came in *Ralstonia* and *Duganella* spp. bacteria that are classically soil and water-associated, indicating that these changes may be from bacteria acquired in the larval environment, rather than during adulthood. Additionally, with fungal ITS-specific reads we found 209 unique fungal genera that showed a high degree of variability between individuals. Lastly, through 16S and cytochrome B analysis we found a greater heterogeneity in host choice of *An. coluzzii* in the dry season, which may indicate a relaxation of anthropophily in some locations during this time. With these findings, we help to further refine our knowledge of *Anopheles* spp. maintenance strategies during this cryptic period critical to the maintenance of the *Plasmodium* spp. transmission cycle.

## LARVAL BREEDING WATER: MICROORGANISMAL HETEROGENEITIES EFFECTS ON ADULT VECTOR COMPETENCE OF HUMAN PATHOGENS AND IMMUNITY

Jenny S. Carlson, Yessieina Anglero-Rodriguez, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The biotic characteristics of larval habitats have been shown to contribute to the growth and development of mosquito larvae and to adult fitness. The accretion of the current understanding of the role of bacteria in modulating mosquito permissiveness to human pathogens, although significant, still lacks understanding on how the microorganismal heterogeneity in the larval habitat may influence vector competence of the adult. In the current study, we tested the hypothesis that larval exposure to different Gram-positive and Gram-negative bacteria will result in a bacteria species-specific modulation of permissiveness to human pathogens through a prolonged transstadial modulation of mosquito physiological systems that can influence infection, such as the immune system. Late developmental larval stages of both *Aedes aegypti* and *Anopheles gambiae* were exposed to Gram-positive *Bacillus* sp. and *Staphylococcus* sp., and Gram-negative *Pseudomonas* sp. and *Enterobacter* sp. Here we present vector competence of the resulting adult mosquitoes as a measure of permissiveness to dengue and Zika viruses and *Plasmodium falciparum*.

For each bacteria we included experimental groups that had either been challenged at the larval (primed larvae) or adult (primed adults) stage, or both (primed larvae and adults) stages. The pupae were sterilized to avoid transstadial carry-over of bacteria. We also compared immune gene expression of bacteria-challenged larvae to the resulting adults, and we compared the daily survival of each experimental group. Our results show that each experimental group had different permissiveness to the pathogens. For example, the adults derived from the primed larvae group showed greater permissiveness to both viruses, indicating the existence of bacteria challenge-mediated transstadial influence on vector competence. We also observed a transstadial activation of immune genes and a significant difference in the survival rate of adults emerging from bacteria-challenged larvae. Our study predicts that bacterial heterogeneity in the larval habitat can impact the vector competence, immunity and fitness of adult mosquitoes.

## NORTHERN RANGE EXPANSION OF THE ASIAN TIGER MOSQUITO (*Aedes albopictus*): ANALYSIS OF MOSQUITO DATA FROM CONNECTICUT, USA

Philip Armstrong, Theodore G. Andreadis, John J. Shepard, Michael C. Thomas

The Connecticut Agricultural Experiment Station, New Haven, CT, United States

The Asian tiger mosquito (*Aedes albopictus*) is a highly invasive species that was introduced into the U.S. in the 1980's and continues to expand its range in the eastern half of the country. Winter temperature is an important constraint to this species northward expansion and Connecticut appears to be located at the thermal limit for overwintering survival of this species. In this study, we sampled mosquitoes from 91 statewide trapping sites from 1997-2016 to track the establishment and range expansion of *Ae. albopictus* in Connecticut. In addition, *Ae. albopictus* larvae were monitored in tire habitats and tires were retrieved from the field in the spring and flooded to evaluate overwintering success of hatching larvae. *Ae. albopictus* was first detected during statewide surveillance when a single specimen was collected in 2006. This species was not collected again until 2010 and was detected every year since then with increasing abundance and distribution except following exceptionally cold winters. *Ae. albopictus* mosquitoes were most abundant in urban and suburban locations along the Long Island Sound shoreline of southwestern Connecticut; however, single specimens were occasionally detected in central parts of the state. Field-collected females were also screened for arbovirus infection yielding two isolations of Cache Valley virus and one isolation of West Nile virus highlighting the threat posed by this mosquito. *Ae. albopictus* overwintered in Connecticut under mild winter conditions as shown by recovery of larvae hatching in spring and by early seasonal detection of larvae and adults. This study documents the establishment and expansion of *Ae. albopictus* at the northern boundary of its range in New England and provides a baseline for monitoring future range expansion and population increases anticipated under climate change.

## DENGUE VIRUS IN PATIENTS DIFFERS FROM CELL CULTURE DERIVED VIRUS

Rajendra Raut<sup>1</sup>, Kizzimekia S. Corbett<sup>1</sup>, Aruna D. De Silva<sup>2</sup>, Ananda Wijewickrama<sup>3</sup>, Aravinda M. de Silva<sup>1</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Genetech Research Institute, Colombo, Sri Lanka, <sup>3</sup>National Institute of Infectious Diseases, Gothatuwa, Sri Lanka

Recent results from vaccine trials have demonstrated that the presence of antibodies that neutralize cell culture derived DENVs does not necessarily correlate with protective immunity. These and other observations highlight the importance of defining the properties of DENVs that circulate within infected individuals. The goal of this study was to characterize

and compare DENV serotype 1 (DENV1) viruses circulating in viremic patients and the same patient viruses after 1 passage in cell culture. We collected blood from 20 viremic patients exposed to primary DENV1 infections during an epidemic in Sri Lanka in 2014, isolated the virus on commonly used C6/36 insect cells and Vero mammalian cell lines. The specific infectivity (viral genome copy number/infectious virus) of the human plasma viruses and corresponding cell culture passaged virus was determined using a digital drop polymerase chain reaction (ddPCR) and a Vero cell focus assay. Our results demonstrated that the specific infectivity of plasma viruses is 47 fold and 615 fold greater compared to the same virus amplified on mammalian (Vero) and Insect (C6/36) cell lines respectively. We evaluated the maturation state of plasma and cell culture derived DENV1 using a preMembrane (prM) protein specific MAb, which will capture partially or fully immature virions but not completely mature virions. The majority of the cell culture derived virus (>75%) was captured by the prM MAb whereas none of the plasma virus bound to the MAb. Thus, DENV1 in plasma is fully mature unlike cell culture grown DENV1, which was mostly immature. As DENV maturation stage can strongly alter sensitivity to antibody neutralization, we compared the ability of seven well-characterized human and mouse MAbs to neutralize plasma and cell culture derived DENV1. One DENV1 specific human MAb equally neutralized plasma and cell culture viruses. The remaining 6 MAbs neutralized the cell culture viruses much better than the plasma viruses. Our results demonstrate that the specific infectivity, maturation state and sensitivity to antibody neutralization are profoundly altered even after a single passage of DENV1 in cell culture.

## 70

### EVOLUTION OF B CELL RESPONSE IN PRIMARY DENGUE INFECTION

**Huy A. Tu**<sup>1</sup>, Usha K. Nivarthi<sup>2</sup>, Daniel Emerling<sup>3</sup>, Douglas G. Widman<sup>4</sup>, Ralph S. Baric<sup>4</sup>, Kristen E. Pierce<sup>1</sup>, Stephen S. Whitehead<sup>5</sup>, Beth D. Kirkpatrick<sup>1</sup>, Anna P. Durbin<sup>6</sup>, Aravinda M. de Silva<sup>2</sup>, Sean A. Diehl<sup>1</sup>

<sup>1</sup>Department of Medicine-Infectious Diseases and Vaccine Testing Center, University of Vermont, Burlington, VT, United States, <sup>2</sup>Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, NC, United States, <sup>3</sup>Atreca, Palo Alto, CA, United States, <sup>4</sup>Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, United States, <sup>5</sup>National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>6</sup>Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Any of the four mosquito-borne dengue virus (DENV) serotypes can cause disease, which affects more than one hundred million people worldwide per year. Antibodies are a key mechanism by which DENV is controlled, and is a desired feature of vaccination. The antibody response in dengue infection is characterized by both serotype-specific (TS) and cross-reactive (CR) antibodies, but the relationship between these pools of antibodies at a cellular level over time is not known. While neutralizing monoclonal antibodies have been isolated from both of these categories, non-neutralizing CR antibodies have also been implicated in severe secondary dengue. Understanding the dynamics and contribution of TS and CR antibodies is critical to understand how protection versus disease enhancement is generated after a dengue infection. To address this question, we analyzed the acute plasmablast and convalescent memory B cell repertoires in longitudinal samples from three subjects enrolled in a controlled human infection model for DENV-2. The early plasmablast response peaked at approximately 2-3 weeks post-DENV-2 infection, and accounted for approximately 6% of total B cells. Paired immunoglobulin heavy and light chains from single plasmablasts were sequenced. From a representative cross-section of IGH/IGL repertoire, we expressed recombinant IgGs. Up to 60% of these plasmablast-derived antibodies were specific to dengue antigen. The majority (74%) of the antigen-specific clones were specific to the infecting DENV-2 serotype. We immortalized and cloned memory B cells collected six months post-

infection and found that the frequency of DENV-specific memory B cells had contracted to an estimate of 0.02% of total B cells and consisted of both TS and CR clones at comparable proportions, with many clones targeting quaternary epitopes on complex virions. The information gained from exploring the antibody evolution in this primary infection model provides a foundation to evaluate the antibody response induced by vaccination and to assess the contribution of CR and TS antibodies to durable protective immunity against DENV.

## 71

### DENGUE VIRUS NS1-INDUCED ENDOTHELIAL CELL-INTRINSIC VASCULAR LEAK IS INDEPENDENT OF INFLAMMATORY CYTOKINES BUT DEPENDENT ON ENDOTHELIAL GLYCOCALYX INTEGRITY

**Dustin Glasner**, Kalani Ratnasiri, Henry Puerta-Guardo, P. Robert Beatty, Eva Harris

*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States*

Dengue virus (DENV) is the most medically important arbovirus, affecting 40% of people worldwide and infecting as many as 390 million individuals annually. Up to 96 million cases occur each year, ranging from uncomplicated dengue fever (DF) to life-threatening dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS), which is characterized by endothelial dysfunction and vascular leakage. Previously, we demonstrated that DENV nonstructural protein 1 (NS1) can induce endothelial hyperpermeability in both human cell culture and a systemic mouse model. Additionally, DENV NS1 has been shown to disrupt the endothelial glycocalyx, as well as trigger release of inflammatory cytokines from peripheral blood mononuclear cells via TLR4. Here, we examined the relative contributions of inflammatory mediators and endothelial cell-intrinsic pathways to DENV NS1-induced endothelial hyperpermeability and vascular leak. *In vivo*, we demonstrated that DENV but not West Nile Virus NS1 triggers dose-dependent, localized vascular leak in the dorsal dermis of wild-type C57BL/6 (WTB6) mice as measured by Alexa Fluor 680-conjugated dextran. *In vitro*, we showed that the human dermal endothelial cell line HMEC-1 does not produce inflammatory cytokines (TNF- $\alpha$ , IL-6, IL-8) in response to DENV NS1 but does in response to lipopolysaccharide (LPS) and that specific monoclonal antibodies to these cytokines do not block DENV NS1-induced endothelial hyperpermeability as measured by trans-endothelial electrical resistance (TEER). Further, we demonstrated that DENV NS1 induces vascular leak in B6 mice genetically deficient for TLR4 or TNF- $\alpha$  receptor at similar levels to WTB6 animals. Finally, we blocked DENV NS1-induced vascular leak in WTB6 using an inhibitor cocktail targeting sialidase, cathepsin L, and heparanase, molecules involved in endothelial glycocalyx disruption. Taken together, our results indicate that DENV NS1-induced endothelial cell-intrinsic vascular leak is independent from inflammatory cytokines but dependent on endothelial glycocalyx integrity and suggest potential molecular targets for the treatment of severe dengue disease.

## 72

### FLAVIVIRUS NONSTRUCTURAL PROTEIN 1 MODULATES ENDOTHELIAL PERMEABILITY AND VASCULAR LEAK IN A TISSUE- AND DISEASE-SPECIFIC MANNER

**Henry Puerta-Guardo**, Dustin Glasner, Milena Dimitrova, Kalani Ratnasiri, Diego Espinosa, Eva Harris

*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States*

The flavivirus genus includes the human pathogens dengue virus (DENV), yellow fever virus (YFV), Japanese encephalitis virus (JEV), West Nile virus (WNV), tick borne encephalitis virus (TBEV) and Zika virus (ZIKV). Flaviviral infections range from asymptomatic to self-limiting febrile illness to severe clinical manifestations, including encephalitis, hemorrhage, shock,

congenital birth defects and neurological complications. The flavivirus non-structural protein 1 (NS1) plays critical roles in virus replication and immune evasion. Recently, we showed that DENV NS1 alters the integrity of endothelial monolayers, leading to endothelial barrier dysfunction and vascular leak. However, the ability of other flavivirus NS1 proteins to alter endothelial permeability remains unknown. Here, we examined the ability of NS1 proteins from DENV, WNV, JEV, YFV and ZIKV to interact with and modulate the barrier function of different human endothelial cell (EC) lines, as well as their ability to cause tissue-specific vascular leakage *in vivo*. We demonstrated that flavivirus NS1 proteins selectively alter the permeability of ECs from lung, liver, skin, brain, and umbilical vein *in vitro* and cause vascular leakage in a tissue-dependent manner *in vivo*, which reflects the disease pathogenesis. Mechanistically, we showed that flavivirus NS1 proteins differentially induce disruption of the endothelial glycocalyx and mislocalization of intercellular junction proteins of ECs. In preliminary *in vitro* studies, we found that only DENV NS1 facilitates DENV dissemination through polarized lung ECs, consistent with leakage in the lung in severe dengue disease. Interestingly, this was not observed with other flaviviral NS1 proteins. Conversely, ZIKV but not WNV NS1 increased ZIKV translocation across human umbilical vein ECs. Ongoing *in vivo* experiments will clarify the role of NS1 in virus dissemination. Our findings reveal a previously unidentified ability of flavivirus NS1 proteins to modulate endothelial barrier dysfunction in a tissue-specific manner both *in vitro* and *in vivo*, potentially influencing flavivirus pathogenesis and disease.

### MAPPING THE TARGET EPITOPES OF THE TYPE SPECIFIC ANTIBODY RESPONSES INDUCED BY A LIVE-ATTENUATED DENGUE VACCINE

Jesica A. Swanstrom<sup>1</sup>, Usha K. Nivarthi<sup>1</sup>, Matt J. Delacruz<sup>1</sup>, Anna P. Durbin<sup>2</sup>, Stephen S. Whitehead<sup>3</sup>, Aravinda M. de Silva<sup>1</sup>, Ralph S. Baric<sup>1</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, MD, United States, <sup>3</sup>Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

The Laboratory of Infectious Diseases at the National Institutes of Health has developed, live attenuated Dengue (DENV) vaccines to each of the four serotypes (DENV1- DENV4). The LATV TV003, comprised of these four components, has been shown in a human challenge model, to completely protect all vaccinated subjects from infection following challenge with DENV2. An ideal DENV vaccine should elicit a balanced immune response against all four serotypes of DENV, in addition to being safe and inducing durable long-term protection. The safety, infectivity, and immunogenicity profiles of each monovalent DENV vaccine were characterized previously in healthy, flavivirus-naïve adult volunteers, however epitope-specific responses were not evaluated. To determine vaccine induced correlates of protection, we performed antibody depletions to determine the roles of serotype-specific and cross-reactive antibodies in the neutralization of each serotype. Once type-specific responses had been confirmed, we used recombinant DENV (rDENV) viruses to map the targets of type-specific neutralization epitopes targeted by the vaccine-induced antibody response. A portion of each of the type-specific neutralizing antibody responses were directed to previously identified epitope regions that mapped to strongly neutralizing quaternary type-specific antibodies against DENV1, DENV2, DENV4, and in limited cases, to DENV3. Interestingly, the importance of each epitope targeted by the type-specific response, appeared to be dependent on the cell type used for neutralization. The type-specific epitopes mapped for DENV1, DENV3, and DENV4 had a more significant impact on the neutralization in a human monocytic cell line expressing dendritic cell-specific intercellular adhesion molecule 3-grabbing non-integrin (DC SIGN). While, in the Vero cell line, the monovalent vaccine samples had an increased neutralization capacity against heterotypic DENV serotypes.

## 74

### THE EARLY PLASMABLAST DERIVED ANTIBODY RESPONSE TO PRIMARY DENGUE VIRUS INFECTION

Usha Nivarthi<sup>1</sup>, Bhumi Patel<sup>1</sup>, Matt Delacruz<sup>1</sup>, Anna Durbin<sup>2</sup>, Steve Whitehead<sup>3</sup>, Ralph Baric<sup>1</sup>, Sean Diehl<sup>4</sup>, Daniel Emerling<sup>5</sup>, Aravinda Desilva<sup>1</sup>

<sup>1</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Laboratory of Infectious Diseases, Bethesda, MD, United States, <sup>4</sup>The University of Vermont, Burlington, VT, United States, <sup>5</sup>Atreca Inc., San Francisco, CA, United States

The four mosquito-borne dengue virus (DENV) serotypes are responsible for dengue hemorrhagic fever. People exposed to acute viral infections develop a rapid but transient increase in antibody secreting plasmablasts. After recovery, memory B-cells (MBC) and antibody secreting long lived plasma cells (LLPC) are key components of protective immunity. For DENVs the origin and relationships between antibodies produced by the early plasmablast response and the MBC, LLPC responses are not well defined. The goal of this study was to characterize the plasmablast responses in primary dengue infection using a DENV2 human challenge model. Flavivirus-naïve subjects were challenged with a partially attenuated strain of DENV2. The plasmablast responses in three subjects were analyzed in terms of magnitude, antibody repertoire, antigen-specificity and neutralization properties. Peak plasmablast responses correlated with onset of peak viremia. The plasmablast antibody repertoire was determined using single-cell DNA barcoding and high throughput deep sequencing to determine the cognate heavy and light chain immunoglobulin genes expressed by a total of 1690 plasmablasts. The antibody sequences were analyzed to determine phylogenetic relationships of clones and antibody families within individuals as well as families convergent between individuals. A panel of 92 monoclonal antibodies representing families of expanded, proliferative clones were selected for antibody expression. Purified antibodies were screened for binding to and neutralization of the 4 DENV serotypes. A large fraction (60%) of the antibodies recognized one or more DENV serotypes. The majority of the DENV reactive antibodies were type-specific to serotype 2 and recognized epitopes displayed on intact DENV2 virions. Although lineages bound to DENV at a high rate, a small fraction of the DENV reactive antibodies strongly neutralized serotype 2. We will discuss the implications of our results for understanding the complex interplay of the early plasmablast and late memory B cell responses to primary DENV infection.

### USE OF STRUCTURAL EQUATION MODELS TO PREDICT DENGUE ILLNESS PHENOTYPE

Sangshin Park<sup>1</sup>, Anon Srikiatkachorn<sup>2</sup>, Siripen Kalayanarooj<sup>3</sup>, Louis Macareo<sup>4</sup>, Sharone Green<sup>5</sup>, Jennifer F. Friedman<sup>1</sup>, Alan L. Rothman<sup>2</sup>

<sup>1</sup>Brown University, Providence, RI, United States, <sup>2</sup>University of Rhode Island, Providence, RI, United States, <sup>3</sup>Queen Sirikit National Institute of Child Health, Bangkok, Thailand, <sup>4</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>5</sup>University of Massachusetts Medical School, Worcester, MA, United States

Early recognition of dengue illness, particularly patients at high risk for plasma leakage syndrome, is of critical importance to optimal clinical management. However, substantial overlap in the clinical profile of mild and severe dengue illness continues to present significant challenges to this goal. The objective of this study was to build predictive models for dengue, dengue hemorrhagic fever (DHF), and dengue shock syndrome (DSS) using structural equation modelling. Using data from 284 children from a hospital-based, prospective study in Thailand, we performed structural equation modelling to capture mechanistic pathways culminating in dengue, DHF, and DSS. Fever day 0 was defined as the point when temperature was <38°C for a consecutive 12 hours and

considered the day of defervescence; days before and after defervescence were numbered consecutively. Study day 1 was defined as the day when a child was enrolled in the study, and days were numbered consecutively afterward. Illness day 1 was defined as the day when fever was  $\geq 38^{\circ}\text{C}$ , and days were numbered consecutively afterward. Models for dengue, DHF, and DSS were separately developed based on data from fever days (days -3 and -1) and validated by data from 834 children not used for model development. At fever day -3, predictors for dengue and DSS included age, tourniquet test, aspartate aminotransferase, and white blood cell, lymphocyte, and platelet counts. Predictors for DHF included age, aspartate aminotransferase, hematocrit, tourniquet test, and white blood cell and platelet counts. The models showed good predictive performances, regardless of disease phenotype and data collection time points as indicated by comparable areas under the receiver operating curves (AUC). For example, the AUC for any acute dengue illnesses based on fever day 0, study day 3, and illness day 3 data were in the range of 0.93-0.97, 0.90-0.94, and 0.80-0.85, respectively. These predictive models have potential use in estimating the probability that a child has dengue and whether the child will ultimately manifest DHF or DSS based on clinical laboratory data available before the critical phase of illness.

### EFFECTIVENESS OF A COMBINED HOUSEHOLD-LEVEL PIPED WATER AND SANITATION INTERVENTION IN RURAL ODISHA, INDIA ON HEALTH: A MATCHED COHORT STUDY

Heather Reese<sup>1</sup>, Parimita Routray<sup>2</sup>, Sheela Sinharoy<sup>1</sup>, Belen Torondel<sup>2</sup>, Howard Chang<sup>1</sup>, Thomas Clasen<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Globally, almost one billion people practice open defecation—the majority reside in India. While government campaigns have increased toilet access in India, recent studies found limited impact on health, possibly due to sub-optimal sanitation coverage and use. Although coverage of community-level improved water sources is high even in rural India, household-level water access may be critical to the use of toilets in this context. Gram Vikas, an NGO in Odisha, India, has implemented a combined intervention in over 1000 villages since 2002. Their approach includes household-level piped water connections contingent on full community-level coverage of household toilets. We undertook a matched-cohort study in Ganjam and Gajapati districts in Odisha, India to assess intervention impact on water and sanitation coverage and use, and on health. Surveys and environmental samples from eligible households (N=2384) from 45 randomly selected intervention and 45 matched control villages were collected at four times from May 2015–Oct 2016. The intervention was associated with increased access to improved toilets (85% v. 18%), as well as increased toilet use by adults (74% v. 13%) and for child feces disposal (35% v. 6%) ( $p < 0.001$ ). The intervention was also associated with increased access to piped water (73% v. 8%,  $p < 0.001$ ) although almost all households in both study arms stored drinking water—a possible source of continued exposure. Adjusting for sociodemographic variables, the intervention was not associated with reduced diarrhea in children  $< 5$  (OR: 0.94, 95% CI: 0.74-1.20). Children  $< 5$  in intervention villages had improved nutritional status as measured by height-for-age z-score (HAZ) (+0.17 HAZ, 95% CI: 0.03-0.31), though over a third of children in both arms were moderately stunted (40% v. 33%). This study offers evidence that a combined water and sanitation intervention can substantially decrease open defecation and improve child nutrition in India. The mixed effects on health may be due to continued exposure to fecal pathogens and to subclinical infections.

## 77

### PREVALENCE AND ETIOLOGY OF ENTERIC INFECTIONS AMONG CHILDREN SHARING SANITATION IN LOW-INCOME NEIGHBORHOODS OF MAPUTO, MOZAMBIQUE: BASELINE DATA FROM THE MAPSAN TRIAL

Jacqueline Knee<sup>1</sup>, Trent Sumner<sup>1</sup>, Oliver Cumming<sup>2</sup>, Rassul Nala<sup>3</sup>, Joseph Brown<sup>1</sup>

<sup>1</sup>Georgia Institute of Technology, Atlanta, GA, United States, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Ministry of Health, Maputo, Mozambique

Persistent enteric infection can have long-term effects on child health. Risk of exposure to enteropathogens can be greater in low-income, informal, urban settlements where high population density and low-level access to safe sanitation coexist. The MapSan Trial examines the impact of providing shared sanitation on the risks of enteric infections in children living in Maputo, Mozambique. We report baseline data from MapSan, with a focus on etiologies of symptomatic and asymptomatic enteric infection. Stools collected from children  $< 4$  years were assayed using a multiplex, PCR-based, diagnostic assay to identify current infections of *Campylobacter jejuni*, *Salmonella* spp., *Shigella* spp., enterotoxigenic *Escherichia coli* [ETEC], Shiga toxin-producing *E. coli*, *E. coli* O157:H7, *Vibrio cholerae*, *Yersinia enterocolitica*, toxigenic *Clostridium difficile*, *Giardia lamblia*, *Cryptosporidium* spp., *Entamoeba histolytica*, Rotavirus A, Norovirus GI/GII, and Adenovirus 40/41. Self-reported diarrhea data were available for each child providing a stool. 87% of stools (n=684) were positive for  $\geq 1$  viral, bacterial, or protozoan target; only 14% of caregivers reported diarrheal symptoms in the 7 days prior to enrollment. The most frequently detected pathogens among both symptomatic and asymptomatic children included *Giardia* (52%), *Shigella* (44%), ETEC (30%), and *Salmonella* (21%); prevalence of *Giardia* and *Shigella* increased with age, and *Salmonella* prevalence decreased with age. 84% of detected infections were asymptomatic. Prevalence of coinfection was high: most (59%) children were infected with  $> 1$  pathogen and the average number of infections per child ranged from 1.3 in the youngest age stratum (0-11 months) to 2.1 in the eldest (24-48 months). Our results complement recent findings from the Global Enteric Multicenter Study and highlight the importance of surveillance for both symptomatic and asymptomatic infections as markers of child health. Chronic exposure to enteropathogens, regardless of symptomatology, may result long-term health effects in children including impairment of growth and cognitive development.

## 78

### EFFECT OF A SANITATION INTERVENTION ON SOIL-TRANSMITTED HELMINTH PREVALENCE AND CONCENTRATION IN HOUSEHOLD SOIL: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

Lauren Steinbaum<sup>1</sup>, John Mboya<sup>2</sup>, Ryan Mahoney<sup>3</sup>, Jared Otuke<sup>2</sup>, Sammy Njenga<sup>4</sup>, Clair Null<sup>3</sup>, Amy Pickering<sup>1</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Innovations for Poverty Action, Nairobi, Kenya, <sup>3</sup>Innovations for Poverty Action, New Haven, CT, United States, <sup>4</sup>Kenya Medical Research Institute, Nairobi, Kenya

Sanitation interventions have been associated with a reduced prevalence of soil-transmitted helminth (STH) infection, and it has been hypothesized that improved sanitation interventions prevent fecal contamination from spreading throughout the household environment. Our study investigates the hypothesis that an improved sanitation intervention, a pit latrine with slab and child feces management tools, reduced STH eggs in household soil. We collected soil samples from 2107 households that were enrolled in the control (N=898), sanitation (N=613), and combined water, sanitation and hygiene (WSH) (N=596) intervention arms of the WASH Benefits cluster randomized controlled trial in rural Kenya. We combined the sanitation and WSH households into one improved sanitation intervention

group and found the intervention did not significantly reduce the prevalence (17.0% versus 18.9% in the control group) or concentration (geometric mean of 0.24 egg/g dry soil in both arms) of total STH eggs in soil. There was also no difference in the impact of the sanitation and combined WSH intervention arms on STH eggs in household soil, and there were no effects of the intervention on single STH species or viable eggs. Notably, most households (98.1%, 881 out of 898) in the control group had access to a sanitation facility; upgrading from unimproved to improved sanitation facilities may not be enough to affect the presence of STH eggs in household soil. In the control group, we found use of a shared latrine, past deworming of young children in the household, child open defecation practices, and an indicator of household wealth were associated with the presence of STH eggs in soil. Our results indicate that in areas with high access to latrines, where open defecation is rare and latrine sharing is common, improving latrines with slabs and drop hole covers and facilitating safe disposal of children's feces may not be enough to interrupt environmental transmission of STH.

## 79

### SCHISTOSOMIASIS COUNTRYWIDE ASSESSMENT IN UGANDA: A NEGLECTED TROPICAL DISEASE OF CONCERN FOR WATER, SANITATION AND HYGIENE PRACTITIONERS

**Natalie G. Exum**<sup>1</sup>, Alexandra Shannon<sup>1</sup>, Fredrick E. Makumbi<sup>2</sup>, Simon P. Kibira<sup>2</sup>, John Ssempebwa<sup>2</sup>, Edridah M. Tukahebwa<sup>3</sup>, Kellogg J. Schwab<sup>1</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>Makerere University, Kampala, Uganda, <sup>3</sup>Vector Control Division, Ministry of Health, Kampala, Uganda

Schistosomiasis is a neglected waterborne disease transmitted indirectly through freshwater snails, estimated to affect over 200 million people in Sub-Saharan Africa. In Uganda, where the disease is considered endemic, control programs have focused mainly on chemotherapeutic intervention with Praziquantel (PZQ) with less emphasis on interrupting environmental transmission. To understand the prevalence of Schistosomiasis in Uganda and the associated risk factors, we undertook the first nationally representative survey of an African country, which included testing, diagnosis and treatment at the household level. We conducted rapid data collection using mobile technology under the Performance Monitoring & Accountability 2020 platform that utilizes a multi-stage cluster design with fixed, Census-derived enumeration areas (EAs) and random selection of households. Infection with Schistosomiasis was the main outcome of interest and was positive in 1,097 participants of the 4,515 tested. After adjustment with sampling probabilities for EA selection and selection of households within each EA, the overall prevalence of Schistosomiasis in Uganda was 22.1% (95% CI: 18.7%, 25.6%). There was no statistical difference in prevalence when comparing EAs that had received mass drug administration with PZQ versus those that had not (31% vs 21%, respectively; p-value=0.14). In the adjusted analysis, the factors significantly associated with prevalence of Schistosomiasis were age, religion, region, and whether an individual self-reported openly defecating in water bodies. Wealth and education were not statistically significant factors indicating that the prevalence of Schistosomiasis is geographically and demographically widespread beyond the known endemic areas. This suggests that using a strategy to target certain communities for mass drug administrations may be less effective in interrupting the transmission of Schistosomiasis without water, sanitation and hygiene interventions designed to reduce the contamination of water bodies with human urine and feces.

## 80

### IMPACT OF IMPROVED SANITATION AND HYGIENE ON STUNTING IN RURAL ZAMBIA IMPROVED SANITATION AND HYGIENE ON STUNTING IN RURAL ZAMBIA

**Kojo Yeboah-Antwi**, William Macleod, Godfrey Biemba, Davidson Hamer

Center for Global Health and Development, Boston, MA, United States

In 2015, an estimated 8.4 million people in Zambia lacked access to improved sanitation and 2.1 million practiced open defecation. Limited access to improved sanitation and safe water, and inadequate hand hygiene contribute to diarrhea and stunting among children under five in Zambia. The Zambian government, with support from DFID, UNICEF and other partners has been implementing the Zambia Sanitation and Hygiene Program to address these public health challenges. A key component of this program is the community led total sanitation (CLTS) initiative, which aims to have an additional 3 million people consistently using improved sanitation facilities and adopting hand washing with soap or ash. We conducted baseline and end-line cross-sectional surveys in 2013 and 2016 respectively, to measure relevant impact and outcome indicators. The use of improved not shared toilet facilities (defined as a facility that hygienically separates human excreta from human contact) improved from 36% (432/1204 households) to 51% (595/1170) and households having a specific place for handwashing improved from 21% (254/1204) to 33% (391/1170) between baseline and endline. While there was no impact of the CLTS intervention on two-week prevalence of diarrhea, there was a significant reduction in stunting (height-for-age Z score <-2 standard deviations) from 46% (309/670) to 41% (617/1507) (adjusted prevalence ratio [aPR] 1.18, 95%CI 1.06-1.31) and severe stunting (height-for-age Z score <-3 standard deviations) from 32% (217/670) to 18% (275/1507) (aPR 1.86, 95%CI 1.59-2.18) among under-five children. Stunting and severe stunting were significantly lower in households with improved not shared facilities and those with water/soap for handwashing relative to those without these improvements (stunting: 34% [78/228] vs. 41%, [539/1279]; aPR 0.75, 95%CI 0.61-0.93 and severe stunting: 14% [31/228] vs. 19% [244/1279] aPR 0.65, 95%CI 0.65-0.97). This impact evaluation demonstrates the importance of improved hygiene through development of facilities for handwashing coupled with improved sanitation for improving linear growth of children in Zambia.

## 81

### THE ASSOCIATION BETWEEN FECAL CONTAMINATION AND ENVIRONMENTAL ANTIBIOTIC RESISTANCE IN RURAL BRAZIL

**Patricia S. Bartley**<sup>1</sup>, Vanessa T. Moretto<sup>2</sup>, Luciano K. Silva<sup>2</sup>, Soraia M. Cordeiro<sup>3</sup>, Mitermayer G. Reis<sup>2</sup>, Ronald E. Blanton<sup>1</sup>, Lucio M. Barbosa<sup>4</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Gonçalo Moniz Research Center, Oswaldo Cruz Foundation, Salvador, Brazil,

<sup>3</sup>Federal University of Bahia School of Pharmacy, Salvador, Brazil, <sup>4</sup>Bahiana School of Medicine and Public Health, Salvador, Brazil

Human and animal fecal contamination of soil and water is likely an important factor for distribution of antibiotic resistance in rural areas with inadequate sanitation. We sought to determine the relative contribution of each of these sources to the prevalence of antimicrobial resistant bacteria in the environment. In 2017, we studied a small rural community in Bahia, Brazil (pop 617) where 40% of toilets flush to the local rivers. We measured the resistance to ciprofloxacin (CipR) and beta-lactamases in lactose fermenting (LF) *Enterobacteriaceae* (ESBL-E) from water collected at 5 different sites along these rivers, the piped water system, as well as 50 stools collected from a random sample of residents and 13 farm animals. Water and stool were screened for CipR (growth on 10 µg/ml of ciprofloxacin) and ESBL-E (growth on 2 µg/ml of cefotaxime). Sanitary conditions were poor given the high coliform counts in river samples and treated water. For humans and animals, the majority of CipR bacteria were LF (78%), while ESBL-E were more evenly divided (54% LF). By contrast,

in water samples, CipR was evenly distributed between LFs and non-LFs, but 88% of the ESBL-E were lactose negative. The highest percentages of individuals harboring resistant Enterobacteriaceae were found in pigs (100% CipR, 75% ESBL-E) and humans (42% CipR, 38% ESBL-E). For humans, carriage of resistance did not differ by age. Cows and horses had carriage rates of 0% for CipR and 0-17% for ESBL-E. Unexpectedly, this rural community has similar rates of antibiotic resistance found in urban communities in other parts of the world. This suggests a significant use of antibiotics in the rural population. The high carriage rate in pigs was unexplained, but may be due to feeding habits in animals that root in the soil as opposed to grazing, the clandestine use of antibiotics in feed. Although this use is banned in Brazil, we did find feed containing antibiotics available in the neighboring town. Given the poor level of sanitation, pig and human fecal contamination are the likely sources resistant bacteria in the surface waters that the local treatment plant ineffectively removes.

## 82

### IDENTIFYING ROBUST PROXY VARIABLES OF LATRINE USE: EXAMINING ACCESS TO IMPROVED SANITATION AS A PROXY

**Velma Lopez**, Philippa Clarke, Brady West, Joseph Eisenberg  
*University of Michigan, Ann Arbor, MI, United States*

Access to an improved sanitation facility is the standard proxy indicator for latrine use in the WASH sector. While there is growing evidence that latrine access does not ensure its use, there is little work that examines this relationship, due in part, to the difficulty in measuring latrine use behavior. The objective of this work is to create a proxy indicator for latrine use and test the association between estimated latrine use and sanitation facility. We use latent class analysis (LCA) with data from 253 individuals living in rural coastal Ecuador to model latrine use as a latent variable. The underlying probability of latrine use was predicted using 10 measured variables of attitudes, norms, and perceptions surrounding latrines. The LCA model did not show large uncertainty when predicting latrine use (entropy = 5.29). Using WHO/UNICEF Joint-Monitoring Programme definitions of household-level sanitation access, household access to an improved sanitation facility, relative to a unimproved facility, was regressed upon the latent variable of latrine use. The regression model accounted for household-level clustering and adjusted for individual-level educational attainment. Initial results show no association between access to a non-shared improved sanitation facility and the probability of latrine use (OR = 1.1, 95% CI = 0.60-2.1,  $p = 0.73$ ) when accounting for one's educational level. Further disaggregating access of improved sanitation between those that share and those that do not, this pattern holds: there is no association between shared, but improved household access and latrine use behavior (OR = 0.73, 95% CI = 0.25-2.2,  $p = 0.57$ ); and among non-latrine sharers with improved sanitation facilities, the association between improved sanitation access in the household and latrine use is null (OR = 0.90, 95% CI = 0.33-2.4,  $p = 0.83$ ). We show that latrine use can be quantitatively estimated through a set of proxy variables. Importantly, this analysis suggests that household-level access to sanitation infrastructure may be a poor proxy for one's behavior.

## 83

### LONGITUDINAL IMPACT OF INTESTINAL PARASITES ON MICROBIOME DIVERSITY AND METAGENOMIC CHANGES IN CHILDREN FROM ECUADOR AND ARGENTINA

**Rojelio Mejia**<sup>1</sup>, Rubén Cimino<sup>2</sup>, Ashish Damania<sup>1</sup>, Rebecca Jeun<sup>1</sup>, Patricia E. Bryan<sup>1</sup>, Paola Vargas<sup>3</sup>, Alejandro Krolwiecki<sup>3</sup>, Philip Cooper<sup>4</sup>, Barton Slatko<sup>5</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Universidad Nacional de Salta Argentina, Salta, Argentina, <sup>3</sup>Universidad Nacional de

Salta, Salta, Argentina, <sup>4</sup>Universidad Internacional De Ecuador, Quito, Ecuador, <sup>5</sup>New England BioLabs, Inc., Ipswich, MA, United States

Approximately 30% of children worldwide are infected with gastrointestinal (GI) parasites. Depending on the species, parasites can disrupt intestinal bacterial flora affecting nutritional status. We implemented a multi-parallel quantitative real-time PCR (qPCR) and whole genome sequencing analysis for bacterial microbiota and *Ascaris lumbricoides*, *Ancylostoma duodenale*, *Necator americanus*, *Strongyloides stercoralis*, *Trichuris trichiura*, *Cryptosporidium*, *Entamoeba histolytica*, and *Giardia lamblia*. Stool samples were collected from 122 asymptomatic children from rural Argentina and 85 children sampled at 3 and again at 5 years old from Ecuador. Separate analyses were done by country for uninfected, *Giardia* only, *Giardia*/helminth co-infections, and helminth only groups. For *Giardia* only infected children, longitudinal sequencing data showed a decrease in bacterial biodiversity compared to those uninfected that correlated with increasing *Giardia* burden (Shannon alpha diversity (*Giardia* only 2.1; uninfected 2.7,  $p = 0.0317$ ; Spearman  $r = -0.5491$ ,  $p = 0.0244$ )) within each age group but showed a significant increase in diversity from paired 3 to 5-year-old children ( $p = 0.01838$ ). In *Giardia* only infections, microbiome taxonomy shifted to *Prevotella copri*, with degree of shift related to intensity of infection compared to uninfected (43.2 % versus 12%,  $p = 0.012$ ). Abundance of *Prevotella copri* bacteria was decreased in the helminths only group, but increased for *Giardia*/helminth co-infections (12.5% versus 33.6%,  $p = 0.026$ ). Metagenomic analysis of the bacterial microbiota showed the proportion of vitamin B12 bacterial biosynthesis genes were diminished in the *Giardia* infected group compared to the non-infected group (0.98% to 1.89%, of total genes,  $p = 0.038$ ) with a compensatory increase in helminth only infected children. Our data provides possible evidence for an effect of parasitic infections on the intestinal environment allowing permissive growth of anaerobic bacteria such as *Prevotella*, decreasing in microbiota diversity and altering capacity of vitamin B12 biosynthesis.

## 84

### A NATURAL MOUSE MODEL FOR CRYPTOSPORIDIOSIS

**Adam Sateriale**<sup>1</sup>, Jan Slapeta<sup>2</sup>, Rodrigo Baptista<sup>1</sup>, Jessica Kissinger<sup>1</sup>, Carrie Brooks<sup>1</sup>, Gillian Herbert<sup>1</sup>, Ravi Pulusu<sup>1</sup>, Boris Striepen<sup>1</sup>

<sup>1</sup>University of Georgia, Athens, GA, United States, <sup>2</sup>University of Sydney, Sydney, Australia

Cryptosporidiosis is a leading cause of diarrhea and an important contributor to global infant mortality. There are no efficacious drugs or vaccines available and our knowledge of *Cryptosporidium* biology to drive their development is scant. *Cryptosporidium* research is greatly hindered by the lack of a continuous tissue culture system and poor animal models. To develop a more facile mouse model of *Cryptosporidium* infection, we have isolated a strain of *Cryptosporidium tyzzeri* (*C. parvum* mouse genotype I) from naturally infected *Mus domesticus*; strains which we now maintain continuously in our animal facility. De novo assembly of the *C. tyzzeri* genome shows 96% overall nucleotide identity to *C. parvum* and *hominis* and a high degree of synteny. The highest burden of *C. tyzzeri* infection is found in the distal ileum of the mouse small intestine, yet there is also significant infection of the jejunum and duodenum, similar to what is seen in human cryptosporidiosis. Perhaps of greatest importance, *C. tyzzeri* produces significant infections in healthy C57/BL6 mice. These infections produce high parasite burden but are self-limiting, and mice that have cleared *C. tyzzeri* appear resistant to future infection. Using CRISPR directed homology repair we have genetically engineered *C. tyzzeri* strains to express reporter genes for *in vivo* imaging and localization. In summary, we now have access to a natural mouse model that closely resembles the human infection in which both host and parasite are genetically tractable. We envision this model will lead to better understanding of cryptosporidiosis susceptibility, resolution, and subsequent protection in the context of a functioning immune system.

## CAREGIVERS AS A POTENTIAL SOURCE OF CRYPTOSPORIDIUM INFECTION IN KENYAN CHILDREN

Patricia B. Pavlinac<sup>1</sup>, Heidi K. Hillesland<sup>1</sup>, Carol A. Gilchrist<sup>2</sup>, Jaqueline M. Naulikha<sup>3</sup>, Christine J. McGrath<sup>1</sup>, Doreen Rwigy<sup>3</sup>, Wesley C. Van Voorhis<sup>1</sup>, Benson O. Singa<sup>3</sup>, Judd L. Walson<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>Kenya Medical Research Institute, Nairobi, Kenya

*Cryptosporidium* is a leading cause of diarrhea and linear growth faltering among children in sub-Saharan Africa. We aimed to determine whether caregivers are a potential source of *Cryptosporidium* infection. Between January-December 2015, Kenyan children aged 6-71 months of age presenting to two Nyanza province public hospitals with acute diarrhea, and their primary caregivers, provided stool samples for real-time PCR analysis. Univariate prevalence ratios (PR) estimating the association between child and caregiver *Cryptosporidium* infections were estimated using Poisson regression. Multivariable models adjusted for other potential transmission sources (unprotected water source, water improvement method, livestock ownership, and inadequate sanitation). To evaluate whether caregiver-child transmission was unique to *Cryptosporidium*, we also evaluated the association between child and caregiver *Giardia* infection accounting for other transmission sources. Among 212 child-caregiver pairs, 36% of children (median age: 25 months; interquartile range [IQR]: 12-38) and 23% of adults (median age: 24 years; [IQR]:22-28) had *Cryptosporidium* identified by PCR. Children with a *Cryptosporidium*-infected caregiver had a 1.7-fold higher prevalence of *Cryptosporidium* infection (95% confidence interval [CI]: 1.2, 2.4;  $p=0.006$ ). This relationship persisted after adjustment for other transmission sources (adjusted [a]PR: 1.7 [95%CI: 1.2, 2.4;  $p=0.004$ ]). Caregiver HIV-infection (12% of caregivers) was associated with child *Cryptosporidium* infection (PR: 1.7 [95%CI: 1.1, 2.6];  $p=0.009$ ) but not adult *Cryptosporidium* infection (PR: 1.0 [95%CI: 0.5, 2.2];  $p=0.9$ ). *Giardia* was commonly identified by PCR in children (54%) but less frequently in caregivers (14%); children of caregivers with *Giardia* were not more likely to have *Giardia* (aPR: 1.2 95%CI: 0.9-1.6),  $p=0.3$ ). There appears to be a unique relationship between caregiver and child *Cryptosporidium* infection that is unexplained by shared transmission sources. *Cryptosporidium* interventions may need to target both children and caregivers to achieve maximal benefit.

## NEW COMPOUND SERIES WITH POTENT AND SELECTIVE ACTIVITY AGAINST GIARDIA DUODENALIS

Tina S. Skinner-Adams<sup>1</sup>, Christopher Hart<sup>1</sup>, Andrew Riches<sup>2</sup>, Jack Ryan<sup>2</sup>, Katherine Andrews<sup>1</sup>

<sup>1</sup>Griffith University, Brisbane, Australia, <sup>2</sup>Commonwealth Scientific and Industrial Research Organization, Clayton, Australia

*Giardia duodenalis* infects a wide array of hosts and is the most frequently reported human intestinal parasite. On an annual basis this parasite is responsible for ~1 billion human infections of which >200 million result in symptomatic disease. While infections are more prevalent in the developing world, they are ubiquitous. In developed countries the prevalence of giardiasis is ~7%. However rates are higher in sub-populations where the burden is primarily borne by children (>60% in Australian Aboriginal children). *Giardia* infection can result in severe and chronic disease. There is also evidence that it is linked to post-infection disorders including irritable bowel syndrome. However, treatment options are inadequate. The frontline drug, metronidazole (MTZ), is associated with side-effects and drug resistance. It is also distasteful and must be taken in multiple doses over 5-7 days, factors which result in poor compliance, treatment failure, rapid re-infection and parasite resistance. There is also increasing evidence that MTZ has a collateral effect on the host microbiome. New drugs that are effective against *Giardia* parasites

at compliant doses while having limited activity against host cells are needed. To improve giardiasis treatment options in the long-term we have developed a high-content imaging assay to assess the activity of compounds against trophozoites *in vitro*. This assay permits the direct assessment of parasite growth and morphology at multiple time-points and has been validated using control compounds. We have recently used this assay to screen compounds from the Compounds Australia Open Access Scaffold Library for anti-*Giardia* activity (2451 compound subset; 2/scaffold; Z-factor 0.75) and after rational selection based on activity, novelty, and chemical liabilities have identified three compound series with potent (IC<sub>50</sub>≤1μM) and selective activity against *G. duodenalis*. These compound series have been chosen as starting points of new anti-*Giardia* drug development. Significantly, the most promising compound identified is 290-fold more potent than MTZ and has *Giardia* vs human selectivity index of >8000.

## HOUSEHOLD TRANSMISSION OF CRYPTOSPORIDIOSIS IN BANGLADESH

Poonum Korpe<sup>1</sup>, Carol Gilchrist<sup>2</sup>, Shah Nawaz Ahmed<sup>3</sup>, Emtiaz Ahmed<sup>3</sup>, Cecelia Burkley<sup>4</sup>, Masud Alam<sup>3</sup>, Mamun Kabir<sup>3</sup>, Tuhinur Arju<sup>3</sup>, William A. Petri, Jr.<sup>2</sup>, Rashidul Haque<sup>3</sup>, A.S.G. Faruque<sup>3</sup>, Priya Duggal<sup>1</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>4</sup>University of Virginia, Charlottesville, VA, United States

Diarrheal illness a leading killer of children under five years old worldwide, and *Cryptosporidium spp.* is a top contributor. *Cryptosporidium spp.* are apicomplexan protozoa, spread by fecal-oral contamination, with a very low infectious dose. As there is no vaccine and no approved drug for *Cryptosporidium spp.* in young children, a focus on prevention of infection is critical. We undertook a pilot case-control study to define the extent of person-to-person transmission of cryptosporidiosis within families in an urban (Mirpur) and rural (Mirzapur) community in Bangladesh. We enrolled 43 case families with a *Cryptosporidium*-infected child aged 6-18 months. Controls were age-sex matched *Cryptosporidium*-negative children (n=12). Once children were identified, we enrolled all household members (defined as persons sleeping under the same roof or eating from the same cooking pot). We then followed these individuals for 8 weeks, with weekly surveillance stools and testing with qPCR for *Cryptosporidium spp.* In the 43 case families, the rate of secondary infections with *Cryptosporidium* was 18.6% (22/118) compared to 0 new infections (0/35) in the 12 control families. In the 22 urban Mirpur households, the secondary attack rate was 30% (18/60) in cases compared to 0% (0/14) in controls (chi-square  $p = 0.018$ ). In contrast, in the 21 rural Mirzapur households, the secondary attack rate was 6.9% (4/58) in case households compared to 0% (0/21) in controls (chi-square  $p = 0.22$ ). In Mirpur, in 8 of 22 case families, multiple family members were infected at baseline, suggesting concurrent infections in household members may be commonplace. Person-to-person transmission is likely a major source of *Cryptosporidium* infection, and more important than environmental reservoirs, for children living in urban slums in Mirpur, Bangladesh. In rural households, there was more attenuated person-to-person transmission. Interventions aimed at interrupting anthroponotic spread of *Cryptosporidium* in children are needed to control transmission of this deleterious parasite.

## SEASONAL VARIATION OF CRYPTOSPORIDIUM GENOTYPES IN BANGLADESH

Cecelia G. Burkey<sup>1</sup>, Carol A. Gilchrist<sup>1</sup>, Poonum S. Korpe<sup>2</sup>, Priya Duggal<sup>2</sup>, Emtiaz Ahmed<sup>3</sup>, Mamun Kabir<sup>3</sup>, Rashidul Haque<sup>3</sup>, William A. Petri<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Cryptosporidiosis is one of the top 5 causes of diarrhea in the first 2 years in the life in low-income countries. *Cryptosporidium hominis* positive stool samples have been collected from our on-going longitudinal study of infants from an urban slum of Dhaka, Bangladesh. This study surveys children in a well-defined population at monthly intervals with clinical and laboratory characterization of all diarrheal episodes. Combining molecular typing and clinical data will allow us to determine the frequency of specific subtypes in times of high and low transmission. DNA was extracted from all collected fecal samples and *Cryptosporidium* positive samples identified using a qPCR assay that can detect a broad range of *Cryptosporidium* species. Species specific assays were then used to identify infections with the three species common at our study site. Subgenotyping was performed using a polymorphic region within the GP60 gene. The subtypes were determined and associated with clinical symptoms and date of collection. In 86.6% of the cases, species subtyping was successful. Sixteen different subtypes were identified in the Bangladesh cohort. The most abundant subtypes in our population were *C. hominis* IaA18 (16.3%), IbA9G3R2 (16.3%), IaA11G3T3\_V (15%), IaA19 (13.2%), IdA15G1 (12.8%), and IaA25 (6.6%). The remaining 19.8% of the population were subtypes IbA9G3R2\_V, Bang\_IaA13G1, IaA27, IaA14, IIdA13G1, IlcA5G3R2, IaA26, IfA16G1, IaA22, IaA11G3T3. *Cryptosporidium* infections markedly increase during the rainy season (early June-late September of 2015 and 2016). While types Ia and Ib occur year round, they are more prevalent during the rainy seasons. We observed that type Id was only present during the first rainy season while type Ie was exclusively present beginning in mid-April of 2016, becoming abundant during the following rainy season. *Cryptosporidium* infection is much more prevalent during the rainy season than the winter or summer within our cohort. Longitudinal study of population genetics can help us better understand the genetic diversity, transmission, and rate of infection in the next rainy season.

## DEVELOPMENT OF DRUG CANDIDATES FOR CRYPTOSPORIDIOSIS TARGETING THE CRYPTOSPORIDIUM METHIONYL-TRNA SYNTHETASE

Frederick S. Buckner<sup>1</sup>, Ranae M. Ranade<sup>1</sup>, Matthew A. Hulverson<sup>1</sup>, Zhongsheng Zhang<sup>1</sup>, Wenlin Huang<sup>1</sup>, Sayaka Shibata<sup>1</sup>, Ryan Choi<sup>1</sup>, Rajiv S. Juman<sup>2</sup>, Peter Miller<sup>2</sup>, Christophe L. Verlinde<sup>1</sup>, Wim G. Hol<sup>1</sup>, Christopher D. Huston<sup>2</sup>, Robert K. Choy<sup>3</sup>, Eugenio L. de Hostos<sup>3</sup>, Erkang Fan<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>University of Vermont, Burlington, VT, United States, <sup>3</sup>PATH, San Francisco, CA, United States

Enteric infection by the protozoan parasite *Cryptosporidium* is the cause of an estimated 7.6 million cases and 200,000 deaths annually among children under two years old in low-resource settings. Chronic infections contribute to malnutrition, growth stunting, cognitive impairment, and oral vaccine failure. Current treatment options are extremely limited, with only one US FDA-approved drug that has poor efficacy in malnourished children. To address this issue we are developing inhibitors against a novel drug target, the *Cryptosporidium parvum* methionyl-tRNA synthetase (CpMetRS). This enzyme is essential for protein synthesis and differs substantially from the human MetRS orthologues. From an in-house library of MetRS inhibitors over 200 compounds were tested for activity

on the CpMetRS, and 55 compounds demonstrated IC50 values of <40 nM (the lower limit of detection in the enzyme assay). Nineteen of these compounds had EC50 values against *C. parvum* cells in culture of <1 µM including three below 0.1 µM. Selected compounds were tested in a murine model of *Cryptosporidium parvum* infection using NOD-SCID-gamma mice with the best compound (#2093 dosed at 50 mg/kg orally twice per day) demonstrating 98.6% reduction in stool oocysts measured by PCR. The results were confirmed in the interferon gamma knockout mouse model employing luciferase expressing parasites showing a 4-log decrease in stool parasite load following treatment, and comparable to the most potent available positive controls. The compounds do not show toxicity in mammalian cells nor in mice at the doses tested. The compounds represent promising drug candidates to target diarrheal disease caused by *Cryptosporidium* parasites.

## SCOPING REVIEW ON IDENTIFYING GLOBAL KNOWLEDGE GAPS IN ACUTE FEBRILE ILLNESS SURVEILLANCE

Chulwoo Rhee<sup>1</sup>, Grishma Kharod<sup>1</sup>, Nathan Furukawa<sup>2</sup>, Nicolas Schaad<sup>1</sup>, Neil M. Vora<sup>1</sup>, John Crump<sup>3</sup>, David Blaney<sup>1</sup>, Kevin Clarke<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Department of Medicine, University of Washington, Seattle, WA, United States, <sup>3</sup>Division of Infectious Diseases and International Health, Duke University Medical Center, Durham, NC, United States

Acute febrile illness (AFI), a common clinical syndrome among people seeking medical care globally, represents a spectrum of infectious disease etiologies with important variations geographically and by population. Yet, there is no methodological standardization on AFI surveillance, limiting interpretation of data in a global context. We conducted a scoping review to characterize current AFI research methodologies, identify global research gaps, and inform the future direction of AFI surveillance standardization. We searched Medline, Embase, and Global Health, for publications from 1 January 2005 - 30 April 2016; search terms included "undifferentiated fever," "acute febrile illness," and "non-specific fever" with proximity and Boolean operators. After identifying and reviewing 948 abstracts, 779 (82.2%) studies were excluded as they did not identify AFI etiology, or were modeling studies, clinical trials, lab procedures or economic impact evaluation, single case reports, and outbreak investigations. A full review conducted on the remaining 169 studies used a standardized tool to abstract AFI surveillance-related data. There was variability in study objectives, terms describing febrile illness, and case definitions. Studies originating in three countries made up 54 (31.9%) of the 169 articles. Of the 52 pathogens reported on in the 169 articles, 38 (73.1%) were investigated in fewer than 10 studies. Pathogens represented most commonly across the 169 studies were: Dengue (66 studies, 39.1%), *Leptospira* spp. (46, 27.2%), and *Plasmodium* spp. (43, 25.4%). AFI studies focused on single pathogens made up 93 of 169 (55.0%). Knowledge gaps in causes of AFI and their regional distribution limit quality of care and public health intervention effectiveness, especially in resource-limited settings where clinical management and disease control rely on knowing the proportional contribution of AFI etiologies. Wider implementation of standardized AFI surveillance with multi-pathogen disease detection is needed to improve knowledge of the range of underlying etiologies and their relative contributions to the global AFI burden.

## MAPPING CHILDHOOD DIARRHEA IN AFRICA

Robert C. Reiner, Nick Graetz, Manny Garcia, Puja Rao, Jonathan Mosser, Aniruddha Deshpande, Aaron Osgood-Zimmerman, Roy Burstein, Chris Troeger, Simon Hay

University of Washington, Seattle, WA, United States

Across Africa, diarrheal diseases are the 3rd leading cause of mortality and morbidity in children under the age of five. In this decade, there has

been, in aggregate, a reduction in death and disability-adjusted life-years (DALYs) associated with diarrheal diseases; however, these gains vary substantially from country to country as well as within countries. In 2013, UNICEF and the WHO set forth goals to reduce childhood mortality from diarrhea to 1 per 1000 live births and reduce severe diarrhea in children by 75% compared to 2010 levels. Here, leveraging over 50,000 geo-located household survey clusters, Bayesian geostatistical techniques, and the existing machinery of the Global Burden of Disease, we produce high-resolution spatio-temporal estimates of diarrheal prevalence, incidence, and death. Half-way to their 2025 deadline, the goals identified by UNICEF and the WHO in reducing childhood death and severe disease attributable to diarrhea appear achievable (or even achieved) in many regions of Africa, but difficult to achieve in other regions given progress so far. Targeted interventions are necessary to focus resources on locations where gains will be highest and as interventions reap diminishing returns, health professionals must be flexible enough to adapt to face the remaining challenges. Understanding at a scale where policy can act where these challenges remain is but the first step in reducing preventable child deaths from diarrhea.

## 92

### ASSESSING THE NON-BIOLOGIC CONTRIBUTORS TO MORTALITY AMONG INPATIENTS WITH FEBRILE ILLNESS IN TANZANIA: A PROSPECTIVE COHORT SOCIAL BIOPSY STUDY

**Michael Snavely**<sup>1</sup>, Michael J. Maze<sup>2</sup>, Charles Muiruri<sup>1</sup>, Lilian Ngowi<sup>3</sup>, Flora Mboya<sup>3</sup>, Julia Beamesderfer<sup>4</sup>, Glory Makupa<sup>5</sup>, Anthon Mwingwa<sup>5</sup>, Bingileki F. Infectious diseases account for over half of annual deaths in Tanzania despite the existence of effective biomedical treatments. To quantify the impact of sociocultural and health systems factors on mortality from infection, we adapted the social autopsy framework for a prospective 'social biopsy' cohort study. From June 2015 to June 2016, we enrolled consecutive pediatric and adult febrile inpatients at two referral hospitals in Moshi, Tanzania. We interviewed participants to determine the burden of the 'Three Delays' in receiving health care: delays at home, in transport, and at health facilities. We assessed six-week mortality and matched fatal cases with non-fatal controls. We created two matched sets, one matched on age and gender for analyzing home and transport delays and one matched on age, gender, and severity of illness for health facility delays. We used chi-squared and Student's T tests to compare delays between cases and controls. We enrolled and obtained follow-up for 475 children, of whom 18 (3.8%) died, and 260 adults, of whom 34 (13%) died. The median age of participants was 2.9 (IQR 0.9-26.7) years and 326 (44%) participants were female. For home delays, there were no significant differences in the pediatric cohort, but adult cases took longer than controls to seek care outside the home (4.0 vs 2.9 days;  $p=0.038$ ). Twelve (35%) adult cases failed to recognize a severe symptom at home compared to 20 (17%) of 121 controls ( $p=0.017$ ). For health facility delays, cases were more likely to visit >2 facilities during their illness, with 7 (39%) pediatric cases versus 30 (18%) of 139 controls ( $p=0.038$ ) and 16 (47%) adult cases versus 7 (15%) of 48 controls ( $p=0.001$ ). Pediatric and adult cases reported more time between first facility presentation and study enrollment than controls (ped: 8.8 vs 3.5 days;  $p<0.001$ ; adult: 10.0 vs 4.4 days;  $p=0.027$ ). Sankey diagrams of care pathways show that cases were less likely to reach tertiary care within their first two facility visits

(ped:  $p=0.038$ ; adult:  $p=0.001$ ). Our findings suggest that delays at home and at health facilities are risk factors for mortality from febrile illness in northern Tanzania.

## 93

### POPULATION ACCESS TO ITN IS A BETTER INDICATOR OF 'UNIVERSAL COVERAGE' THAN HOUSEHOLD OWNERSHIP OF AT LEAST ONE ITN FOR TWO PEOPLE

**Hannah Koenker**<sup>1</sup>, Albert Kilian<sup>2</sup>

<sup>1</sup>Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, <sup>2</sup>Tropical Health LLP, Montagu, Spain

The World Health Organization currently defines universal coverage as the proportion of households that own at least 1 ITN for every 2 household members. WHO also uses an indicator of population access to ITN to describe coverage; both targets are set at 80%. Many countries have implemented mass ITN campaigns expecting to reach 80% household universal coverage, but surveys conducted shortly after high quality campaigns show while population access to ITN can be relatively close to target levels, household universal coverage is consistently well below target. Eighty datasets from 37 countries in sub-Saharan Africa were used to explore the causes of this low performance and discrepancy between indicators. The proportion of households with at least 1 ITN for 2 people (enough ITNs) and population access to ITN were calculated. The proportion of households with enough ITNs did not exceed 60% at the national level, except in Uganda's 2014 MIS. Population access to ITN was systematically higher than household ownership of enough ITNs (coef 1.45;  $p<0.001$ ;  $R^2=0.84$ ). Regional estimates for these two indicators were calculated in three datasets in which fieldwork occurred shortly after mass campaigns. In these 46 regions, the proportion of households with enough ITNs ranged from 31%-48% in Mali, 26-81% in Tanzania, and 46-76% in Uganda, while population ITN access ranged from 63-78%, 52-91%, and 67-90%, respectively. Large households were found to drive low rates of enough ITNs and controlling for the level of population access, increasing mean household size was associated with a 3.0 percentage-point reduction in proportion of households with enough ITNs for each additional person ( $p<0.001$ ;  $R^2=0.94$ ). At 80% population ITN access, the proportion of households with 1 ITN for 2 people will be only 65%, because individuals in households with some but not enough ITNs are captured as having access, but the household doesn't qualify as having 1 ITN for 2 people. Population access to ITNs, because it is based on people as the unit of analysis, provides a better indication of ITN protection, and should be considered as the better indicator of "universal coverage".

### SOCIAL BEHAVIOR CHANGE COMMUNICATION AND BEDNET RETENTION, CARE, REPAIR, USE AND IMPACT IN BENIN

**Andre Houtoukpe**<sup>1</sup>, Manzidatou Alao<sup>1</sup>, Liscovich Ademikpo<sup>1</sup>, Hilary Adjalla<sup>1</sup>, Jean Adjidjan<sup>1</sup>, Taylor Osborne<sup>2</sup>, Martin Akogbeto<sup>3</sup>, Filemon Tokponnon<sup>4</sup>, Steve C. Smith<sup>5</sup>, Michelle Kouletio<sup>6</sup>, Fortune Dagnon<sup>6</sup>, Luis Benavente<sup>7</sup>

<sup>1</sup>Medical Care Development Inc., Porto Novo, Benin, <sup>2</sup>Medical Care Development Inc. Peace Corps Volunteer, Porto Novo, Benin, <sup>3</sup>Center de Recherche Entomologique de Cotonou, Cotonou, Benin, <sup>4</sup>Programme National de Lutte contre le Paludisme, Cotonou, Benin, <sup>5</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>6</sup>U.S. Agency for International Development, Cotonou, Benin, <sup>7</sup>Medical Care Development Inc., Silver Spring, MD, United States

The use of durable, long-lasting insecticide treated nets (LLINs) is key to tackle malaria in Benin. In 2014, the President's Malaria Initiative (PMI) supported PADNET with an experimental random cluster study to increase net durability in a 900 household (HH) sample in Seme Podji commune, distributing one LLIN (PermaNet 3) per HH. The sample was split into 3 groups (arms) of 300 HH: arm1 received only Social Behavior Change Communication (SBCC); arm2 received SBCC and a net repair kit; and

arm3 was the control. SBCC consisted of monthly HH visits by Care Group Leaders, and community dialogues through interpersonal communication to promote continuous net use, reducing damage and repairing nets. For monitoring purposes, all HHs were visited every four months over a 33 month period. Data was collected using android tablets through Open Data Kit software. Databases were developed and analyzed using Excel pivot tables and SPSS 17. Results show that for net loss due to physical damage beyond repair as stated by net owners, the retention rate for arm1 was 90%, 94% for arm2 and 75% for arm3 ( $p < 0.0001$ ). Net washing more than once per trimester was more frequent in arm3 (60%) than arm1 (37%) and arm2 (30%) ( $p < 0.0001$ ). The % of nets with a proportional Hole Index (pHI) of 0 (no/few tiny holes) in arm3 was 20% while arm1 had 64% and arm2 had 75% ( $p < 0.0001$ ). The % of nets with a pHI>64 (not deemed a good barrier), was 38% in arm3, while arm1 had 4% and arm2 had 2%. The % of ever-damaged LLINs with signs of repair in arm3 was 34%, while arm1 had 95%, and arm2 had 98%  $p < 0.0001$ . The proportion of children <5 that slept under any LLIN with pHI=0 was 21% in arm3, 62% in arm1 and 55% in arm2. The proportion of <5 sleeping under a net deemed as a good barrier (pHI<65) was 51% in arm3, 88% in arm1 and 73% in arm2 ( $p < 0.0001$ ). The relative risk of developing fever in the fortnight prior to the survey associated with the lack of SBCC in arm3 was 1.9 ( $p < 0.001$ ), suggestive that SBCC cut fever risk by half via improved net integrity and continuous net use. SBCC for net use and preservation should be promoted in order to improve net durability in the protection against malaria

## 95

### EFFECTIVENESS AND SUSTAINABILITY OF A COLLABORATIVE IMPROVEMENT METHOD TO INCREASE THE QUALITY OF ROUTINE MALARIA SURVEILLANCE DATA IN KAYUNGA DISTRICT, UGANDA

**Nelli Westercamp**<sup>1</sup>, Sarah Staedke<sup>2</sup>, Eleanor Hutchinson<sup>2</sup>, Susan Naiga<sup>3</sup>, Christine Nabirye<sup>3</sup>, Lilian Taaka<sup>3</sup>, Catherine Maiteki-Sebuguzi<sup>3</sup>, Simon P. Kigozi<sup>3</sup>, John M. Okiring<sup>3</sup>, Grant Dorsey<sup>4</sup>, Alexander K. Rowe<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>4</sup>University of California San Francisco, San Francisco, CA, United States

Improving malaria surveillance data quality in Africa is a priority. We evaluated the effect of collaborative improvement method (CIM), an innovative quality improvement method, to increase malaria data quality in 5 health facilities (HFs) in Kayunga District, Uganda. Intervention began in November 2015 with in-service training, plan-do-study-act cycles to test changes by HF CIM teams, learning sessions, and CIM coaching. To assess data completeness and accuracy, we abstracted data from 156,707 entries in outpatient department (OPD) and lab registers and aggregate monthly reports (MR) for 12 months pre-intervention, 10 months of intervention, and 4 months of sustainability assessment. Monthly OPD register completeness was measured as the proportion of malaria patient entries with: 1) all data fields completed, and 2) clinically-relevant fields completed. Accuracy was calculated as the relative difference between: 1) monthly malaria patients in OPD registers versus MR, and 2) proportion of positive malaria tests in lab registers versus MR. Data were analyzed as interrupted time series with segmented linear regression modeling. Ethnographic observations and interviews with health workers were used to describe the context and inner processes of CIM. Baseline completeness for all data fields ranged from 0–19%, with an immediate increase by 71 %-points (95% CI: 62–81%) post-intervention to 85%. Completeness of clinically-relevant fields (17–34% at baseline) improved by 69 %-points (95% CI: 65–72%) immediately post-intervention to 98% and remained high for the duration of follow-up. Relative differences ranged from 3–21% for reporting malaria patients and 9–57% for the proportion of positive malaria tests at baseline, and only the latter improved with CIM (relative change of 77 %-points; 95% CI: 35–120%). All improvements were sustained 4 months post-CIM. Qualitative findings indicated that

healthcare hierarchy, financial incentives, and the relationship with the CIM mentor were key determinants of success. If these positive results are confirmed in larger studies, CIM may be a useful approach to improve malaria surveillance.

## 96

### ASSOCIATION BETWEEN INCREASING MALARIA CONTROL INTERVENTIONS AND REDUCTIONS IN STUNTING CHILDREN 6-59 MONTHS OF AGE: A MULTI-COUNTRY DECOMPOSITION ANALYSIS

Lia Florey, **Cameron Taylor**, Deborah Collison, Yodit Bekele, Jean de Dieu Bizimana

*ICF International, Rockville, MD, United States*

Malaria prevention is one essential element of successful child health programs in malaria endemic countries. Malaria impacts child health through direct and indirect pathways. Directly, malaria infection in pregnant women and in children can lead to severe anemia, premature birth, low birth weight and ultimately to death. Indirectly, repeated or continuous malaria infection can contribute to chronic inflammation limiting childhood growth and causing impaired physical and cognitive performance and a reduction in years of healthy life. To investigate the contribution of increasing coverage of malaria control interventions on stunting in children less than five years of age we analyzed data from 15 countries that had two or more demographic health surveys (DHS) conducted between 2005 and 2016 with data on insecticide-treated net (ITN) use and anthropometric measurements of children under five. Multivariate Oaxaca-Blinder decomposition for nonlinear response models with deviation contrast normalization for categorical variables were used to estimate the proportion of the decline in stunting prevalence over time due to increases in malaria control interventions. ITN use increased from 36% in baseline surveys to 46% in endline surveys and stunting decreased from 38% to 35%. Although significant in bivariate models, in pooled, multi-country logistic regression models controlling for socioeconomic and child and maternal health variables and malaria transmission risk, odds of stunting were not significantly lower for children who used an ITN the night before interview compared to those who did not. Decomposition models reveal that the increase in ITN use between baseline and endline surveys accounted for an insignificant proportion of the decrease in stunting. Changes in vitamin A coverage explained the greatest proportion of the total change in stunting between baseline and endline as compared to other covariates. Results suggest that the scale-up of ITN use are unlikely to have had a measurable impact on stunting.

## 97

### A MAJOR LOCUS ON CHR. 1 DETERMINES CERCARIAL SHEDDING TIME IN OMANI SCHISTOSOMES

Gabriel Mouahid<sup>1</sup>, Frédéric Chevalier<sup>2</sup>, Juliette Languard<sup>1</sup>, Mohamed A. Idris<sup>3</sup>, Salem Al Yafae<sup>4</sup>, Marina McDew-White<sup>2</sup>, Vinay Menon<sup>2</sup>, **Tim Anderson**<sup>2</sup>, Hélène Moné<sup>1</sup>

<sup>1</sup>Université de Perpignan Via Domitia, Perpignan, France, <sup>2</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>3</sup>Sultan Qaboos University, Muscat, Oman, <sup>4</sup>Sultan Qaboos Hospital, Salalah, Oman

The timing of cercarial shedding from schistosome infected snails is critical for successful transmission. Most *Schistosoma mansoni* populations that infect humans shed cercariae larvae in late morning, while parasite populations that primarily infect rats shed cercariae in late afternoon or night. As reported previously, dramatic variation in shedding time in Oman, with parasites collected from rats shedding cercariae nocturnally (~8pm) while parasites from humans shed cercariae during the day (11am). This project was designed to understand the genetic basis for nocturnal shedding. We conducted reciprocal genetic crosses between nocturnal and diurnally shedding Omani schistosomes, determined cercarial shedding profiles in parents, individual F1 and F2 (n= 65 in each cross) progeny. We then sequenced exomes of parasites from each cross, revealing 5295

and 6657 SNPs that were fixed for alternative alleles in the two crosses and therefore fully informative. We used linkage mapping approaches to determine the genome regions underlying this trait. We found a strong quantitative trait locus on chr. 1 (LOD = 6.1) and a secondary peak on chr. 6. The chr. 1 peak contains a compelling candidate locus (*Hes-1*) that encodes a transcription repressor known to influence cell proliferation, embryogenesis and developmental timing in *Drosophila*. In future work, we will exploit the growing functional genetics toolbox for schistosomes to determine the *loci* underlying this trait and the mechanisms underlying timing of cercarial release. Our central goal is to understand, at the molecular level, a key parasite trait critical for transmission and host specificity.

## 98

### COMPARISON OF THREE METHODS TO EVALUATE THE BURDEN OF INFECTION BY *FASCIOLA HEPATICA* IN SHEEP FROM AN ENDEMIC AREA

**Karina Bardales**<sup>1</sup>, Luis A. Gomez-Puerta<sup>1</sup>, Raul Enriquez<sup>1</sup>, Cesar Sedano<sup>1</sup>, Edinson Montoya<sup>2</sup>, Saul Santivanez<sup>3</sup>, Armando E. Gonzalez<sup>1</sup>

<sup>1</sup>Facultad de Medicina Veterinaria, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>2</sup>Instituto De Ciencias Neurologicas, Lima, Peru, <sup>3</sup>Center for Global Health, Universidad Peruana Cayetano Heredia, Lima, Peru

Fascioliasis caused by *Fasciola hepatica* mainly affects liver of ruminants from endemic areas. Diagnosis of this disease is based on the eggs detection by coproparasitological evaluation; however, its performance is influenced by the burden of infection and the stage of the parasite. On the other hand, imagenological techniques have been used to evaluate the damage produced by the parasite and could be used as a proxy to determine the burden of disease. We compared results obtained by coproparasitological and imagenological evaluation using ultrasound and computed tomography (CT) scan of 50 sheep from an endemic area. The preliminary results from 10 sheep were presented in the current abstract, and the complete results including all sheep will be presented at the meeting. Coproparasitological evaluation was done by direct observation of fecal sample after sedimentation; ultrasound evaluation was performed using convex probe; and computed tomography (CT) evaluation was performed using a spiral CT scan; animals were anesthetized for CT procedure. A positive result for imagenological evaluation was the presence of a parenchymal calcification; and agreement between evaluations was determined by Kappa test. Coproparasitological evaluation was positive in 90% (9/10) sheep; 5 of them had a low burden infection (100 - 167 eggs per gram). Ultrasound evaluation found calcification in 60% (6/10) of sheep; whereas CT scan revealed calcification in 90% (9/10) sheep. In terms of burden of infection, sheep with low burden infection showed a higher number of calcification (more than 20 calcifications). Fair agreement (K=0,286) was found between coproparasitological and ultrasound evaluation, as well as between ultrasound and CT evaluation (K=0,286); and poor agreement was observed between coproparasitological and CT evaluation (K=0,111). Despite that we expected a good correlation between burden and number of calcifications, this was not observed in this preliminary evaluation. Results obtained support the high correlation between presence of at least one calcification and a positive result in coproparasitological evaluation.

## 99

### MONITORING AND MEASURING SCHISTOSOMIASIS AT TRANSMISSION SITES IN KENYA: SENTINEL MICE COUPLED WITH GENOTYPING OF RECOVERED ADULT WORMS

**Sarah K. Buddenberg**<sup>1</sup>, Martin W. Mutuku<sup>2</sup>, Ibrahim N. Mwangi<sup>2</sup>, Gerald M. Mkoji<sup>2</sup>, Eric S. Loker<sup>1</sup>

<sup>1</sup>University of New Mexico, Albuquerque, NM, United States, <sup>2</sup>Kenya Medical Research Institute, Nairobi, Kenya

We lack quantifiable and spatially and temporally explicit estimates of the force of schistosome transmission from snails to their definitive hosts in natural transmission *foci* in Kenya. To address this problem, we have devised floating cages to expose sentinel mice and collect individual adult worms via perfusion for genotyping. With this approach, we can determine if some localities are more potent transmission *foci* than others, infer rates of acquisition of adult worms including at different times of the day or year, and learn if mice become infected with worms representing relatively few genotypes or if extensive mixing of genotypes occur. We can also learn how long some snails may persist in shedding cercariae in natural habitats. A preliminary study involving habitats along the shore of Lake Victoria and along Asao stream in west Kenya revealed that mice placed in the water between 10am-2pm were considerably more likely to become infected, coinciding with snail peak shedding times. Genotype clones were found across time points, suggesting that cercariae shed from one snail were in the water for up to 8 hours. Subsequent experiments were done along the course of Asao stream in a 7-week-long fine time scale and a year-long course time scale. In all experiments, a male-biased sex ratio was observed. The total number of worms acquired per mouse varied considerably among sites with transmission proving to be focal, but was as high as 1 worm per minute at Asao stream. Approximately 60% of mice had bisexual infections (at least one male and one female). A similar number of unique genotypes were seen at Asao stream and Lake Victoria but the average number of genotypes per mouse was almost 2-fold higher at the lake. At Asao stream, microhomogeneities were observed with identical genotypes found between sites. In total, we genotyped nearly 1,500 adult *S. mansoni* worms from sentinel mice experiments at Lake Victoria and Asao stream. This approach provides new insight into transmission dynamics that can be used to provide rate parameters in developing transmission models and guiding treatment programs.

### WHY DOES OXAMNIQUINE KILL *SCHISTOSOMA MANSONI* BUT NOT *S. HAEMATOBIIUM* OR *S. JAPONICUM*?

Anastasia Rugel<sup>1</sup>, Alexander B. Taylor<sup>1</sup>, Xiaohang Cao<sup>1</sup>, Peter J. Hart<sup>1</sup>, Stanton F. McHardy<sup>2</sup>, Reid Tarpley<sup>2</sup>, Frederic Chevalier<sup>3</sup>, Timothy J. Anderson<sup>3</sup>, **Philip T. LoVerde**<sup>1</sup>

<sup>1</sup>University of Texas Health Science Center, San Antonio, TX, United States, <sup>2</sup>University of Texas at San Antonio, San Antonio, TX, United States, <sup>3</sup>Texas Biomedical Research Institute, San Antonio, TX, United States

The major species of *Schistosoma* affecting humans are *S. mansoni*, *S. haematobium*, and *S. japonicum*. There is currently only one method of treatment (monotherapy), the drug Praziquantel. Constant selection pressure through mass chemotherapy - this year will see the administration of over 250 million doses - has yielded evidence of resistance to PZQ. Previous treatment of *S. mansoni* included the use of oxamniquine (OXA), a prodrug that is enzymatically activated in *S. mansoni* but is ineffective against *S. haematobium* and *S. japonicum*. The OXA activating enzyme was identified by our laboratories as being a sulfotransferase (SmSULT). One focus of this research is to understand why OXA does not kill *S. haematobium* or *S. japonicum* and with this information reengineer OXA to be effective against *S. haematobium* and *S. japonicum*. An alignment of the sulfotransferases (SULT) shows that SmSULT, ShSULT and SJSULT share considerable sequence identity (71% Sm/Sh; 58% Sm/Sj, and 58% Sh/Sj) and predicted structural similarity. We sought to understand how differences in the amino-acid composition of Sm-, Sh-, and SJSULTs gave

rise to species-specific drug action. Using site-directed mutagenesis, we demonstrated that SmSULT modified to look like ShSULT and vice versa each could activate OXA in an *in vitro* assay ie the SULTs were functional. We next evaluated the transcriptional differences between the SULTs by qPCR and Digital PCR. SmSULT transcription was 100X ShSULT and 1000X SjsULT. The differences in transcription account in part for the inability of OXA to be cidal in Sh and Sj. Next we employed an iterative process which lead to the identification an OXA derivative (CIDD790) that is effective against *S. mansoni* (100% killing), *S. haematobium* (80% killing) and *S. japonicum* (80% killing). These results demonstrate that understanding the mechanism of action of a drug and its structure function relationship can lead to novel drugs.

## 101

### IMPACT OF DIFFERENT TREATMENT STRATEGIES OVER FIVE YEARS FOR SCHISTOSOMIASIS IN MOZAMBIQUE

**Anna E. Phillips<sup>1</sup>**, Pedro Gazzinelli-Guinmaras<sup>2</sup>, Oswaldo Aurelio<sup>3</sup>, Josefo Ferro<sup>4</sup>, Rassul Nala<sup>5</sup>, Neerav Dhanani<sup>1</sup>, Alan Fenwick<sup>1</sup>

<sup>1</sup>Imperial College, London, United Kingdom, <sup>2</sup>National Institute of Health, Washington, DC, United States, <sup>3</sup>Universidade Catolica de Mocambique, Pemba, Mozambique, <sup>4</sup>Universidade Catolica de Mocambique, Beira, Mozambique, <sup>5</sup>Ministerio da Saude, Maputo, Mozambique

Schistosomiasis is highly endemic across Mozambique (overall prevalence of 47%), in particular the northern provinces. The recommended treatment strategy for schistosomiasis is preventive chemotherapy (PCT) with praziquantel, where frequency depends on the prevalence of infection among school-aged children. As recommended by the WHO, the treatment strategy usually implemented is school-based (SBT), however, in highly endemic areas community-wide treatment (CWT) may be necessary. Studies have found CWT in addition to SBT very effective, as often not all the children in a village attend school and CWT can help to reach them. The aim of SCORE is to provide an evidence base across several countries for programmatic decisions on how best to gain and sustain control of schistosomiasis. In Mozambique specifically, the goal was to understand the impact of alternative treatment strategies in a study area with prevalence of >21% urogenital schistosomiasis (*Schistosoma haematobium*) infection by hemastix. This was a cluster-randomised trial that compared a total of 150 schools in Cabo Delgado province. Each village was randomised to one of six possible combinations of CWT, SBT or drug holidays over four years. In each village two urine filtrations were carried out on 100 children aged 9-12 years, 100 first year students (5-8 years) and 50 adults (20-55 years) at baseline (2011) and the final year (2016). In total, data was collected from 81,167 individuals. Results showed *S. haematobium* was highly endemic throughout all schools, where many schools had 90% baseline prevalence. Praziquantel treatment resulted in a significant reduction in the prevalence of *S. haematobium* infection as well as the proportion of heavy infections over five years. Both gender and age had a significant effect, with higher prevalence and proportion of those heavily infected seen in males and among adolescents (9-12 years). There was no significant variation *S. haematobium* prevalence between the most intense treatment (CWT each year) and the least intense (SBT every two years). These results have a significant logistical and cost implications for a national control program.

## 102

### CONTROLLED HUMAN INFECTION WITH SINGLE-SEX *SCHISTOSOMA MANSONI* CERCARIAE

Marijke Langenberg, Jacqueline Janse, Marie-Astrid Hoogerwerf, Janneke Kos-van Oosterhoud, Arifa Ozir-Fazalakhani, Ron Hokke, Angela van Diepen, Eric Brienen, Lisette van Lieshout, Hermelijn Smits, Martha van der Beek, Pauline Meij, Richard Verbeek, Leo Visser, Maria Yazdanbakhsh, **Meta Roestenberg**

Leiden University Medical Center, Leiden, Netherlands

Controlled human infections (CHI) provide a core platform to accelerate the development of novel drugs and vaccines for infectious diseases and reduces the risk of failure in downstream clinical development. For schistosomiasis, no such model exists. To develop a CHI model for schistosomiasis we have taken the important conceptual step to produce single-sex *Schistosoma mansoni* cercariae according to regulatory requirements for human use. Single-sex worms cannot deposit eggs and consequently pathology is avoided when infecting healthy volunteers. We developed a multiplex real-time PCR to determine cercaria gender. In addition, we characterized the bioburden associated with a dose of male cercariae and produced the cercariae under highly controlled conditions. We now report the first data of a dose-escalating clinical trial to assess the safety, tolerability and infectivity male *Schistosoma mansoni* cercariae in a controlled human infection model. We exposed groups of three volunteers each to 10 and 30 male *Schistosoma mansoni* cercariae and present the safety data of these groups. Infection with 10 cercariae was well tolerated with mild adverse events mainly related to the skin penetration of the parasites. No serious adverse events occurred. Serum circulating anodic antigen (CAA) levels were measured in weekly samples and peaked at 6-8 weeks following infection. Peak CAA levels were close to the detection limit of the CAA lateral flow assay. All volunteers were treated with 40mg/kg praziquantel and CAA levels were followed over time. A second group was infected with 30 cercariae. Results from this group are still pending. In conclusion, we have established a male *Schistosoma mansoni* controlled human infection model. Initial results show that this model is safe and leads to detectable CAA levels in serum which can be followed over time. Future studies will focus on establishing a female controlled infection model as well as performing reinfection studies.

## 103

### GENOME SCALE APPROACHES TO UNDERSTANDING THE PERSISTENCE OF SCHISTOSOMIASIS IN RESIDUAL TRANSMISSION HOTSPOTS

**Elizabeth Carlton<sup>1</sup>**, Jonathan Shortt<sup>2</sup>, Will Eaton<sup>1</sup>, Yang Liu<sup>3</sup>, Bo Zhong<sup>3</sup>, Todd Castoe<sup>4</sup>, David Pollock<sup>2</sup>

<sup>1</sup>Colorado School of Public Health, University of Colorado, Aurora, CO, United States, <sup>2</sup>University of Colorado School of Medicine, Aurora, CO, United States, <sup>3</sup>Sichuan Center for Disease Control and Prevention, Chengdu, China, <sup>4</sup>University of Texas Arlington, Arlington, TX, United States

In China, public health officials are attempting to interrupt transmission of schistosomiasis. However, schistosomiasis has reemerged and persisted in some areas despite aggressive control efforts, for reasons that are not well understood. We are using a two pronged approach that incorporates field-based epidemiological surveys and next-generation sequencing to understand why schistosomiasis persists in residual transmission hotspots, and how control programs might be modified to attain permanent disease reductions. We followed two counties from 2007 through 2016 in Sichuan, China where schistosomiasis previously reemerged in order to evaluate infection patterns following reemergence. Residents in study villages were tested for *Schistosoma japonicum* infection, *S. japonicum* miracidia were archived, and demographic and geospatial data were collected. Approximately 100 miracidia were whole-genome amplified and sequenced using double digest restriction site associated DNA sequencing (ddRADseq), an affordable next generation sequencing method that

reliably samples 10,000-30,000 *loci*. Using these data, we estimated schistosome relatedness within and between hosts, and evaluated parasite population structure over space and time. We found schistosomiasis infection prevalence exceeded 10% in several villages despite ongoing disease control programs (12/36 villages in 2007, 10/36 in 2010 and 3/10 in 2016). There was strong evidence for population structure by village. We identified probable schistosome siblings within the same host at different timepoints, suggesting some individuals may harbor the same adult worms over time despite referral for treatment. It is unclear whether these retained infections are due to non-compliance with treatment, sub-optimal dosing, or drug resistance. Collectively, our findings suggest a role for local sources in sustaining local transmission hotspots and raise questions about the efficacy of treatment. More generally, our findings demonstrate the potential to integrate field-based studies of schistosomiasis and high-resolution genomic methods to advance disease control efforts.

## 104

### POST-DENGUE ACUTE DISSEMINATED ENCEPHALOMYELITIS: A NEW CASE REPORT, SYSTEMATIC REVIEW, AND META-ANALYSIS

Dengue fever (DF) is a debilitating flavivirus disease which can spread by *Aedes aegypti* mosquitoes. Acute disseminated encephalomyelitis (ADEM) in dengue is very rare and it may occur during the dengue infection acute phase or post-infectious phase. The aim of this study was to systematically review and meta-analyze ADEM and to represent a new case. We retrieved the articles from nine databases. We used Fisher's exact and Mann-Whitney U tests. Classification and regression tree (CART) was used to find the predictors of the DF outcomes. A 13 years old girl was admitted to the hospital due to fever. The examinations found no focal neurologic deficits. She lost the urination sensation and have urinary retention. The neurological examinations revealed that she became lethargic and quadriplegic. She had upper limbs weakness and lower limbs complete paraplegia. Her alertness gradually promoted. Although urinary retention remained, her muscle strength of upper and lower extremities increased. Her limbs weakness was significantly improved after two weeks of oral prednisolone then sphincter function was back to normal. She was nearly intact with the proximal part of her legs had a mild weakness in discharge. Our meta-analysis revealed that the prevalence of ADEM among DF patients, of all neurological disorders among dengue and of ADEM among neurological disorders were 0.3% [0.1 - 0.9%], 2.6% [1.8 - 3.8%], and 6.8% [3.4 - 13%], respectively. The most frequent manifestation of ADEM was altered sensorium/consciousness (58%). There was a significant difference between cases having bad outcomes, including partial recovery or death, or complete recovery in the neurological manifestations onset, being earlier, and in temperature, being higher, in cases having bad

outcomes (P-value < 0.05). This was confirmed by CART which included these two variables. Our findings suggest that the prevalence of ADEM among DF and other DF-related neurological disorders are not too rare. The high fever of ADEM cases at admission and the earlier neurological manifestations onset are associated with the DF bad outcomes.

## 105

### SECONDARY HETEROTYPIC DENV INFECTION OF DIFFERENT DENV GENOTYPES IN MARMOSETS

**Nor Azila Muhammad Azami**<sup>1</sup>, Meng Ling Moi<sup>2</sup>, Yasushi Ami<sup>3</sup>, Yuriko Suzaki<sup>3</sup>, Masayuki Saijo<sup>4</sup>, Tomohiko Takasaki<sup>5</sup>, Ichiro Kurane<sup>6</sup>

<sup>1</sup>Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, <sup>2</sup>Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, <sup>3</sup>Division of Experimental Animal Research, National Institute of Infectious Disease, Tokyo, Japan, <sup>4</sup>Department of Virology 1, National Institute of Infectious Diseases, Tokyo, Japan, <sup>5</sup>Kanagawa Prefectural Institute of Public Health, Kanagawa, Japan, <sup>6</sup>National Institute of Infectious Diseases, Tokyo, Japan

Marmoset, a new world monkey, has been proved useful as an animal model for primary and secondary dengue virus infection. However, there have been limited data on heterologous infection of different DENV genotypes. In this study, 9 marmosets that had been previously inoculated with DENV-2 were used. During the secondary DENV-1 infection experiment, 4 marmosets were inoculated with clinical isolates of DENV-1 genotype I and 5 marmosets were inoculated with DENV-1 genotype IV. We found that all the marmosets developed viremia by day 2 post-inoculation and peak viremia was observed at day 4 post-inoculation. The mean viremia duration is 5.3 days (GI= 5 days and GIV= 5.6 days). There were no differences in the viremia levels between the 2 genotypes groups. The marmosets inoculated with G1 and GIV also exhibited high levels of neutralizing antibody in secondary infection. Three marmosets exhibited mild hemorrhagic manifestation in the form of petechiae on day 4, day 10, and day 14 post-inoculation. The antibody response in marmosets also similar as the antibody response during DENV infection in humans. We confirmed that the marmoset model is a suitable animal model to study dengue virus infection.

### TRANSIENT MONOCYTOSIS SUBJUGATES LOW PLATELET COUNT IN ADULT DENGUE PATIENTS

**Jih-Jin Tsai**<sup>1</sup>, Jung-San Chang<sup>1</sup>, Ko Chang<sup>1</sup>, Po-Chih Chen<sup>1</sup>, Li-Teh Liu<sup>2</sup>, Tzu-Chuan Ho<sup>3</sup>, Sia Seng Tan<sup>3</sup>, Yu-Wen Chien<sup>4</sup>, Yu-Chih Lo<sup>5</sup>, Guey Chuen Perng<sup>6</sup>

<sup>1</sup>Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, <sup>2</sup>Department of Medical Laboratory Science and Biotechnology, College of Medicine and Life Science, Chung-Hwa University of Medical Technology, Tainan, Taiwan, <sup>3</sup>Microbiology and Immunology and I Public Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan, <sup>4</sup>Public Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan, <sup>5</sup>Department of Biotechnology and Bioindustry Sciences, College of Bioscience and Biotechnology, National Cheng Kung University, Tainan, Taiwan, <sup>6</sup>Center of Infectious Disease and Signaling Research, National Cheng Kung University, Tainan, Taiwan

Dengue is one of the most important vector-borne human viral diseases globally. The kinetic changes of hematological parameters of dengue in adult Taiwanese patients have seldomly been systematically investigated and characterized. Serial laboratory data of 1,015 adult patients who were diagnosed with dengue virus serotype 2 (DENV2) and 3 (DENV3) infections in southern Taiwan were retrospectively examined. Prominent parameters were verified with specimens from a 2015 dengue outbreak. Higher absolute monocyte counts on day 5 in severe patients than mild fever subjects after the onset of fever was seen. The absolute number of monocytes was significantly greater in those with DENV2 than DENV3

infections in spite of subtle differences in laboratory tests. Platelet counts were lowest and activated partial thromboplastin time was highest on day 5 in patients with severe conditions. In addition, sudden downward platelet counts corresponding to a transient surge of monocytes on day 4 onward was observed. Fluorescence-activated cell sorting analysis of peripheral blood mononuclear cells obtained from acute dengue patients and experimental investigations revealed that phagocytic effects of innate immune cells contribute to thrombocytopenia in dengue patients. Innate phagocytic cells play an essential role in low platelet counts in adult patients with dengue virus infections.

## 107

### HOUSEHOLD COSTS OF HOSPITALIZED DENGUE ILLNESS IN SEMI-RURAL THAILAND

**Yesim Tozan<sup>1</sup>**, Pitcha Ratanawong<sup>2</sup>, Annelies Wilder-Smith<sup>3</sup>, Pattamaporn Kittayapong<sup>4</sup>

<sup>1</sup>New York University College of Global Public Health, New York, NY, United States, <sup>2</sup>Institute of Public Health, Heidelberg University Medical School, Heidelberg, Germany, <sup>3</sup>Epidemiology and Global Health, Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden, <sup>4</sup>Center of Excellence for Vectors and Vector-Borne Diseases and Department of Biology, Faculty of Science, Mahidol University, Bangkok, Thailand

Dengue-related illness is a leading cause of hospitalization and death in Thailand and other Southeast Asian countries, imposing a major economic burden on households, health systems and governments. This study aims to assess the economic impact of hospitalized dengue cases on households in Chachoengsao province in eastern Thailand. We conducted a prospective cost-of-illness study of hospitalized pediatric and adult dengue patients at four public hospitals. We examined all hospitalized dengue cases regardless of disease severity. Patients or their legal guardians were interviewed using a standard questionnaire to determine household-level expenditures for medical and non-medical costs and income losses during the illness episode. Between March and September 2015, we recruited a total of 224 hospitalized patients (<5 yrs, 4%; 5-14 yrs, 20%, 15-24 yrs, 36%, 25-34 yrs, 15%; 35-44 yrs, 10%; 45+ yrs, 12%), who were clinically diagnosed with dengue. The total cost of a hospitalized case was higher for adult patients than pediatric patients and was US\$153.6 and US\$166.3 for pediatric DF and DHF patients and US\$171.2 and US\$226.1 for adult DF and DHF patients, respectively. The financial burden on households increased with the severity of dengue illness. Although 74% of the households reported that the patient received free medical care, hospitalized dengue illness cost approximately 20-25% of the monthly household income. These results indicated that dengue imposed a substantial financial burden on households in Thailand where a great majority of the population was covered by the Universal Coverage Scheme for health care.

## 108

### PHENOTYPES OF STEM AND PROGENITOR CELLS ACCOUNTING FOR THE ACUTE AND PERSISTENT INFECTION OF DENGUE VIRUS

**Amrita Vats**

National Cheng Kung University, Tainan, Taiwan

Dengue is an arthropod-borne viral disease of global importance, other routes of transmission are recipients of donor organs or tissues, blood and vertical transmission. Mostly dengue infected patients are asymptomatic with overt clinical presentation. The disease manifest markedly hypocellular marrow and abnormal early megakaryopoiesis. New findings demonstrates that stem and progenitor cells are highly permissive to dengue infection, but their actual identity unknown. Therefore we address to investigate the phenotypes of dengue infected stem and progenitor cells and their sustainability of infection. We have proposed an *ex vivo* method that human cord blood supported dengue infection, though a

variation in individual donor was observed. After infecting  $1 \times 10^6$  cells with 1MOI (Multiplicity of infection) three distinct stages, productive, silent and reactivation, in dengue infected Stem Progenitor Cells was observed. In addition, hematopoietic stem cells and early megakaryocyte progenitor cells were the most permissive to support DENV infection. Multi-color flow cytometry analysis revealed that the phenotypes of cells infected by dengue for acute stages were CD133+CD34-CD45-CD41-CD61+CD14- population, while CD133+CD34+CD45- CD41+CD61+CD14-CD11c- were for latent. Infectious virus was recovered from the sorted latent cells by co-culturing with indicator vero cells, suggesting dengue established as latent in these cells. We also observed a transition shift of cells from acute to latent rising to early Megakaryocyte Progenitor populations. Characterization through fluorescent microscopy of infected stem cells like CD61 and CD34 expression with NS-1 showed increasing trend gradually by Day 30, indicating that dengue might equip a machinery to manipulate the differentiation of Hematopoietic stem cell for the transition. Therefore it is imperative to determine how CD34+ cells is lost during early differentiation in dengue infected cord blood cells. The significance of our study may lead to further understand the complexity of dengue and its interaction with Hematopoietic stem cells, providing an avenue for developing new therapy.

## 109

### SEASONALITY OF ARBOVIRAL ILLNESS IN RURAL ECUADOR: 2009-2016

**Rachel J. Sippy<sup>1</sup>**, Diego Herrera<sup>2</sup>, David Gaus<sup>2</sup>, Ronald Gangnon<sup>1</sup>, Jorge Osorio<sup>1</sup>, Jonathan Patz<sup>1</sup>

<sup>1</sup>University of Wisconsin Madison, Madison, WI, United States, <sup>2</sup>Salud y Desarrollo Andino, Pedro Vicente Maldonado, Ecuador

Season is a major determinant of infectious disease rates, including mosquito-borne arboviruses, such as dengue, chikungunya, and Zika. Seasonal patterns of disease are driven by a combination of climate factors, such as temperature or rainfall, and human behavioral time trends, such as school year schedules, holidays, and weekday-weekend patterns. These factors affect both disease rates and healthcare-seeking behavior. Seasonality of mosquito-borne illnesses has been studied in the context of climate, but temporal trends are less well-understood. With 2009–2016 medical record data from patients diagnosed with arboviral illness at two hospitals in rural Ecuador, we used Poisson generalized linear modeling to determine short- and long-term seasonal patterns of mosquito-borne disease, and the effect of climate factors. The most important predictors of illness were annual fluctuations in disease, long-term trends, day of the week, and climate variables. Compared to Tuesday, weekends were the least likely days for arboviral illness to be diagnosed, with 34% ( $p=0.007$ ) and 40% ( $p=0.001$ ) less cases reported on Saturday and Sunday, respectively. Seasonal trends showed a single peak during April, with long-term trends showing an overall decrease in diagnoses and suggested inter-epidemic periods every two or three years. Important climate variables included total monthly precipitation ( $p=0.002$ ), Oceanic Niño Index ( $p=0.039$ ), interactions between total precipitation and monthly absolute minimum temperature ( $p=0.002$ ), total precipitation and monthly number of days with precipitation ( $p=0.019$ ), and three-way interaction between minimum temperature, total precipitation, and precipitation days ( $p=0.014$ ). Seasonality assessments revealed 10- to 30-day lags between peaks in climate variables and disease. This is the first report of arboviral disease seasonality in Ecuador, one of few reports from rural patients, and one of very few studies utilizing daily disease reports. These results can inform local disease prevention efforts, public health planning, and global or regional models of arboviral disease trends.

### FIRST REPORT OF COMPLETE GENOME ANALYSIS OF NEUROTROPIC DENGUE VIRUS SEROTYPE 3 ISOLATED FROM THE CEREBROSPINAL FLUID OF AN ENCEPHALITIS PATIENT

Rama Dhenni<sup>1</sup>, Nina D. Putri<sup>2</sup>, Mulya R. Karyanti<sup>2</sup>, Benediktus Johan<sup>1</sup>, Frilasita A. Yudhaputri<sup>1</sup>, Chairin N. Ma'roef<sup>1</sup>, Araniy Fadhillah<sup>1</sup>, Aditya Perkasa<sup>1</sup>, Restuadi Swatanto<sup>1</sup>, Hidayat Trimarsanto<sup>1</sup>, Jeremy P. Ledermann<sup>3</sup>, Ann M. Powers<sup>3</sup>, Khin S. Myint<sup>1</sup>, R. Tedjo Sasmono<sup>1</sup>

<sup>1</sup>Eijkman Institute for Molecular Biology, Jakarta, Indonesia, <sup>2</sup>DR. Cipto Mangunkusomo National Central Hospital, Medical Faculty University of Indonesia, Jakarta, Indonesia, <sup>3</sup>Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States

Neurological manifestations associated with dengue viruses (DENV) infection have been reported. However, there is a very limited information on the genetic characteristics of neurotropic DENV. Here we described the isolation and complete genome analysis of DENV serotype 3 (DENV-3) from cerebrospinal fluid (CSF) of an encephalitis pediatric patient in Jakarta, Indonesia. The 10-year old boy was diagnosed with dengue encephalitis based on the clinical symptoms and detection of DENV in CSF, anti-DENV IgM in serum, hemoconcentration, and thrombocytopenia. Vero cells inoculated with the CSF sample showed cytopathic effects at day 5 after inoculation and next-generation sequencing was employed to deduce the complete sequence of this neurotropic DENV-3 isolate (201610225). Compared with DENV-3 prototype strain and all other reference strains from GenBank (n=787), 46 amino acid changes were found within the genome of 201610225, in which two novel amino acid changes, R3259K and F3369Y, located in the NS5 protein coding sequence were not observed in any other complete DENV-3 genome. Additionally, while the remaining 44 amino acid changes were also observed in other DENV-3 strains in our complete genome data set, nine amino acid changes were only found in relatively few other DENV-3 strains (less than 1% occurrence). A phylogenetic tree and molecular clock analysis revealed that the neurotropic virus was a member of the endemic Sumatran-Javan clade of DENV-3 genotype I which includes strains from Sumatra, Jawa, and Sulawesi islands in Indonesia as well as strains from Timor Leste (formerly East Timor). To our knowledge, this is the first report of neurotropic DENV-3 complete genome analysis. Genetic characterization of additional neurotropic DENVs will allow further insights into the role of unique amino acid changes found in isolate 201610225. In addition, further studies are warranted to study the virulence of this isolate in animal models and its tropism for neural cells *in vitro*.

### HUMAN MONOCLONAL ANTIBODIES AGAINST DENGUE VIRUSES: REVEALS FROM A NOVEL ASSAY

Trung Vu<sup>1</sup>, Bridget Wills<sup>1</sup>, Lauren Carrington<sup>1</sup>, Cameron Simmons<sup>2</sup>

<sup>1</sup>Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam, <sup>2</sup>Department of Microbiology and Immunology, University of Melbourne, Melbourne, Australia

Dengue is the most important arboviral illness in humans. It is estimated that 390 million infections occur on a yearly basis around the globe. Among them, about 96 million people develop symptoms, and there are approximately 20,000 deaths. Treatment for patients with dengue is mainly supportive, with anti-pyretic medication and fluid management to treat the symptoms as needed. Antivirals against dengue viruses (DENV), the causative agent of dengue, are not available. Passive therapy with antibodies is considered a potential antiviral approach. To have the greatest effect, antibodies would need to be administered early in the acute phase of DENV infection, when viremia levels are high. Effective antibodies, if available, would be desired to reduce disease severity, the symptomatology, and the duration of illness. Moreover, the potential for virus transmission from infected humans to mosquitoes could also be mitigated due to a more rapid decline in viremia, to a level below the

mosquito infectious dose. However, there is a lack of clinical evidence for the efficacy of antibody therapy in dengue. We have access to 14 well-described antibodies, shown to neutralize DENV in the Plaque Reduction Neutralization Test (PRNT). However, there are limitations to this conventional assay i.e. PRNT employs laboratory-cultured cells which do not mimic the natural infection of DENV. We develop a novel, more biologically-relevant approach, the Viremic Blood Neutralization Assay (ViBNA). This assay was used to assess the neutralization profiles of those 14 antibodies against DENV. Results showed that only five antibodies effectively neutralized DENV in our assay. The neutralization caused by the therapeutic antibody candidates followed a dose-response relationship. These results demonstrate the increased sensitivity of ViBNA and have implications for the pharmacokinetics and the dosage of the promising antibody candidates.

### DENGUE AS A RURAL DISEASE? FINDINGS FROM A HOUSEHOLD STUDY IN KAMPHAENG PHET, THAILAND

Philip V. Bystrom<sup>1</sup>, Katie B. Anderson<sup>1</sup>, Darunee Buddhari<sup>2</sup>, Alan L. Rothman<sup>3</sup>, Alden L. Weg<sup>2</sup>, Damon W. Ellison<sup>2</sup>, Louis R. Macareo<sup>2</sup>, Timothy P. Endy<sup>4</sup>

<sup>1</sup>University of Minnesota Medical School, Minneapolis, MN, United States, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>3</sup>University of Rhode Island, Kingston, RI, United States, <sup>4</sup>State University of New York, Albany, NY, United States

With an estimated 3.9 billion people at risk of dengue virus infection, a better understanding of dengue epidemiology is needed to reduce the global burden of this life-threatening disease. Herein, we present an analysis of community- and household-level factors associated with risk of dengue infection. Data for this study is derived from the first year of a five-year prospective cohort study of dengue infection conducted in 500 family units in Kamphaeng Phet, Thailand. Acute dengue illnesses were identified by ELISA, RT-PCR, and HAI, and subclinical cases were identified by HAI during routine annual follow up. A total of 34 dengue infections were detected among 78 family units in the first year of the study; 22 infections were subclinical. Risk of dengue infection was compared in rural and urban areas with the finding that 31.7% of homes in agricultural areas experienced dengue infection, 33.3% within villages, and 0% within urban areas (p=0.15). The mean number of homes within a 100m radius was 9.6 for dengue-infected homes and 14.5 for non-dengue-infected homes (p=0.12). This suggestion of increased risk in rural areas was hypothesized to be primarily due to differences in housing construction and sanitation. Rural homes were more likely to be constructed primarily from corrugated metal sheeting, which was associated with an increased risk of dengue infection (62.5% of homes with metal sheeting experienced dengue versus 25.7%, p=0.04). Agricultural homes had more larval breeding sites, including water containers, organics such as coconut shells and bamboo, and tires (p<0.05 for all). These preliminary analyses were limited to enrolled houses that had completed annual follow-up at the time of writing; these findings will be further explored with accumulating data from this active prospective cohort study. Taken together, this data from Thailand suggests that dengue infection rates may be higher in rural areas and would challenge the current paradigm of dengue as an urban disease. This has implications for the appropriate targeting of vector control or community education campaigns, particularly in the absence of a readily-available vaccine.

Dengue virus (DENV) infection poses a great threat to about 2 billion people globally. Although several vaccine trials have been launched, there is no protective vaccine against infection. The serotype specific humoral immunity has been reported to show a limited protection against infection, and this fact suggested the importance of the cellular immunity. Dendritic cell (DC) is defined as a professional cell to present antigenic peptide coupled with MHC to T cells, and also known as the first target cell of DENV infection. In this study, we tried to set up an *in vitro* antigen priming system for T cells using induced pluripotent stem (iPS) cell derived DC like cells. We found that DENV efficiently infected iPS DC like cells. Moreover, the *in vitro* experiments showed clearly that the infected iPS DC like cells gave a significant antigenic stimulation to T cell even from naïve donor. It is concluded that it is possible to use the iPS DC like cells to identify T cell antigenic epitopes and to enhance development of both T and B stimulating dengue vaccine.

## 114

### PREVALENCE AND BURDEN OF DENGUE IN EUROPE: A SYSTEMATIC REVIEW AND META-ANALYSIS

**Ali Mahmoud Ahmed**<sup>1</sup>, Mohammed Khattab<sup>1</sup>, Thao Thanh Vu<sup>2</sup>, Abdelrahman Tarek Mohammed<sup>1</sup>, Mohamed Fahmy Doheim<sup>3</sup>, Ahmed Ashraf Mohamed<sup>1</sup>, Mai Mahmoud Abdelhamed<sup>4</sup>, Bahaa eldin Shamandy<sup>5</sup>, Mahmoud Tamer Dawod<sup>6</sup>, Wafaa Ali Alesaei<sup>7</sup>, Mahmoud Attia Kassem<sup>8</sup>, Omar Mohamed Mattar<sup>9</sup>, Safya Mohamed Al-agery<sup>1</sup>, Kenji Hirayama<sup>10</sup>, Nguyen Tien Huy<sup>10</sup>

<sup>1</sup>Faculty of Medicine, Al-Azhar University, Cairo, Egypt, <sup>2</sup>School of Health and Biomedical Sciences, RMIT University, Victoria, Australia, <sup>3</sup>Faculty of Medicine, Alexandria University, Alexandria, Egypt, <sup>4</sup>Faculty of Medicine, Tanta University, El-Gharbiya, Egypt, <sup>5</sup>Faculty of Medicine, Aswan University, Aswan, Egypt, <sup>6</sup>Faculty of Medicine, Zagazig University, El-sharkia, Egypt, <sup>7</sup>Faculty of Medicine, Misr University for Science and Technology, Giza, Egypt, <sup>8</sup>The Ohio State University Wexner Medical Center, Columbus, OH, United States, <sup>9</sup>Kasr Alainy Faculty of Medicine, Cairo University, Cairo, Egypt, <sup>10</sup>Institute of Tropical Medicine (NEKKEN), Nagasaki University, Nagasaki, Japan

The increase of air travel was concomitant with the importation of dengue to non-endemic areas as Europe. The imported dengue cases are thought to be an important source for transmission of autochthonous dengue in Europe. This systematic review and meta-analysis aims to investigate the prevalence of dengue in Europe, evaluate the severity, predict the future risk, and propose potential solutions to overcome this problem. Out of 5287 reports, resulted from the search in nine electronic search engines, we included 198 reports which reported confirmed dengue cases. The screening processes and the data extraction were performed by three independent reviewers. The meta-analysis was performed by pooling the event rate and 95% confidence interval (CI). Meta-regression and subgroup meta-analysis were performed to test the effect of the covariates. The protocol was registered into PROSPERO (CRD42015015037). Autochthonous dengue cases were detected in nine countries with the highest number of cases reported in Croatia (n=44). However, the highest level of imported dengue cases was in Germany

(n=6736) and subsequently France (n=4223). Most cases were imported from South-East Asia (n= 8986) especially Thailand. Total dengue cases increased during the last six years (n=6413), especially in in Germany and France, compared to the detected cases during the previous decades. The pooled rate of dengue infection among other imported infections to Europe was 0.275 (95% CI [0.177-0.401]). The estimated rate of severe dengue among all European dengue infection was 0.110 (95% CI [0.061-0.193]), while the rate of dengue with warning signs was 0.217(95% CI [0.156-0.293]). Meta-regression using age and sex of patients didn't reveal any significant effect on the estimated proportions. Publication bias was detected only in dengue cases with warning signs. In conclusion, imported dengue is increasing in Europe which in turn participates in the appearance of autochthonous cases. Severe dengue is not common among European dengue cases. European travel authorities should pay more attention for diagnosis and control dengue cases among returning travelers.

## 115

### A COMPARISON OF RAPID AND STANDARD DIAGNOSTIC ASSAY EFFICACY FOR THE DETECTION OF DENGUE VIRUS

**Elysse N. Grossi-Soyster**<sup>1</sup>, Amy R. Krystosik<sup>1</sup>, Jael Sagina<sup>2</sup>, Samuel G. Kimaru<sup>2</sup>, Francis M. Mutuku<sup>3</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Pediatrics Infectious Disease, Stanford, CA, United States, <sup>2</sup>Vector Borne Disease Control Unit, Msambweni, Kenya, <sup>3</sup>Technical University of Mombasa, Dept of Environmental and Health Sciences, Mombasa, Kenya

The burden of arthropod-borne viruses (arboviruses) is notoriously difficult to determine. A primary roadblock to determining the impact of these viruses in endemic regions and communities is the availability of reliable, accurate, and affordable diagnostic tests. Proteins targeted by diagnostic assays generally have a short window of expression, making it difficult to quickly and accurately diagnose acute infections. Viral proteins or viral RNA are identifiable within the first 3 days of infection, followed by IgM antibodies from days 3-10, and IgG antibodies thereafter to identify previous exposure to specific viral genera. We aimed to identify the sensitivity of a dengue virus (DENV) rapid diagnostic test (RDT), which functions as a triplicate assay providing results for DENV nonstructural glycoprotein 1 (NS1), IgM antibodies, and IgG antibodies in a single test, against traditional methods of detection. Febrile children participating in a larger study to estimate the burden of arboviruses in coastal Kenya provided blood samples during the initial and follow up visits. The follow-up visit samples were collected after one month. Initial blood samples were tested using the DENV IgG/IgM/NS1 RDT from Deangel Biological. Serum obtained from both initial and follow-up blood samples were tested for anti-DENV IgG antibodies by indirect ELISA. In total, samples from 180 children tested using both RDT and ELISA. All samples were negative for NS1, whereas 37% were IgM positive. RDT results for IgM should have correlated with IgG results obtained from follow-up indirect ELISA testing, yet only 5.3% of samples tested were positive for IgG antibodies during the follow-up testing. There were several discordant results when comparing IgG prevalence by RDT and indirect ELISA, with 7 false positives and 4 false negatives using indirect ELISA as the gold standard. We have concluded that the positive predictive and the negative predictive values for the RDT kit are 6.7% (CI95 1.9%-16.2%) and 95.4% (CI95 89.5%-98.5%), respectively. Improved rapid diagnostic testing is needed to facilitate diagnosis in remote settings, as current methods are substandard.

### IL-10 PROTECTS THE BLOOD-BRAIN BARRIER AGAINST LEAKAGE INDUCED BY SERUM FROM DENGUE PATIENTS

Jael Miranda<sup>1</sup>, Esteban Munoz<sup>2</sup>, Martha Medina<sup>3</sup>, Clara Santacruz<sup>2</sup>, Cesar Gonzalez<sup>2</sup>, Joaquin Gonzalez<sup>2</sup>, Lorenza Gonzalez-Mariscal<sup>1</sup>, Juan E. Ludert<sup>1</sup>

<sup>1</sup>Center for Research and Advanced Studies, Mexico City, Mexico, <sup>2</sup>Central Laboratory of Epidemiology, Mexican Social Security Institute, Mexico City, Mexico, <sup>3</sup>State Public Health Laboratory, Health Services of the State Government of Yucatan, Yucatan, Mexico

Dengue is a viral infection disease characterized by systemic symptoms ranging from self-limited undifferentiated fever to life threatening symptoms, including plasma leakage. Yet, less than 5 % of dengue patients present dengue virus (DV) infection in cerebrospinal fluid, neurons, microglia, astrocytes or brain endothelial cells. The inflammatory cytokines from the immune response against DV are thought to be responsible for endothelial tight junction (TJ) opening and plasma leakage. Here, we used a blood-brain barrier (BBB) *in vitro* model to compare the effect on TJs of sera from patients with dengue fever (DF, without plasma leakage) and sera from patients with dengue hemorrhagic fever (DHF). A functional assay, based on the continuous measurement of transendothelial electrical resistance (TER) of the BBB, was used to evaluate sera effect. Sera cytokine levels were determined using a commercial bio-plex assay. TJ proteins expression and localization were evaluated by Western blot and immunofluorescence assays. Our results indicate that both, DF and DHF sera had a biphasic effect: at earlier times (4 h) they induced a rapid and significant decrease of TER, while at later times (after 24 h) an increase of TER was detected. However, with FHD sera, the TER recovered to control levels, while with DF serum, the TER increased above control values. Exposure of BBB for 48 h to FD or FHD sera, decreased CI-5 and increased occludin expression. The levels of cytokines IL-1Ra, IL-6, IL-8, TNF- $\alpha$  and INF- $\gamma$  were not significantly different between DF and DHF sera; however, significantly higher levels of IL-10 were observed in DF sera which correlated with higher TER values. Finally, we exposed BBB to purified IL-10 or FHD sera supplemented with IL-10 (0.5 ng/ml) and observed an increase in TJs seal, together with CI-5 and occludin preservation at cell borders. These results suggest that IL-10 in DF sera acts as a protective factor for TJs and prevents the opening induced by other serum factors.

### THERAPEUTIC POTENTIAL OF INTERFERON-A AND RIBAVIRIN AS COMBINATION THERAPY AGAINST DENGUE VIRUS IN DIFFERENT CELL LINES

Camilly P. Pires de Mello, George L. Drusano, Justin J. Pomeroy, Evelyn J. Franco, Jaime L. Rodriguez, Ashley N. Brown  
University of Florida, Orlando, FL, United States

Dengue virus (DENV) is the most prevalent mosquito-borne viral illness in humans and is endemic in over 100 countries world-wide. Currently, there are no therapeutic agents available to prevent or treat DENV infections. Our objective was to fill this unmet medical need by evaluating the antiviral activity of interferon- $\alpha$  (IFN) and ribavirin (RBV) as combination therapy against DENV. IFN plus RBV is a currently approved therapy for the treatment of hepatitis C virus infections, a virus related to DENV. For these studies, Vero and Huh-7 cells were infected with DENV in the presence of increasing concentrations of IFN and/or RBV. Viral supernatants were harvested on the day of peak viral infection in the control arm and viral burden was quantified by plaque assay on Vero cells. A mathematical model was fit to the viral burden data to define drug-drug interactions for antiviral effect. In Vero cells, the effect of IFN and RBV was additive with EC50 values of 1,222 IU/ml and 100.7 mg/L for IFN and RBV, respectively. However, drug interactions were highly synergistic in Huh-7 cells, yielding EC50 values of 72.24 IU/ml for IFN and 46.58 mg/L for RBV. Despite additive and synergistic interactions, the EC50 values obtained for RBV in both cell lines are supraphysiological. We then evaluated the

antiviral activity of the IFN plus RBV at clinical exposures in an *in vitro* plate assay to further investigate the therapeutic promise of this regimen. Clinically-relevant exposures inhibited DENV by 2-log<sub>10</sub> at 24h and 48h post-treatment in Vero cells. Inhibition was much higher in Huh-7 cells, as viral burden was suppressed by 3.3-log<sub>10</sub> at 24h and 4.6-log<sub>10</sub> at 48h. Our findings highlight the importance of host cell selection for antiviral screening assays, as different cell lines may result in different conclusions. Since Huh-7 is a human hepatocyte cell line it may serve as a more relevant tissue culture model for DENV infection compared to Vero cells. Moreover, our results suggest that IFN plus RBV is a potential therapeutic strategy for the treatment of DENV, as it may be possible to achieve sufficient levels of viral inhibition at physiologic drug exposures.

### ASSESSING DENGUE VIRUS-INDUCED CHANGES IN GENE EXPRESSION PROFILES VIA RIBOSOME PROFILING

Diana S. Juarez<sup>1</sup>, Antón Vila-Sanjurjo<sup>2</sup>, Mariana Leguia<sup>1</sup>

<sup>1</sup>U.S. Naval Medical Research Unit-6, Lima, Peru, <sup>2</sup>Universidad de A Coruña, A Coruña, Spain

A majority of the research on dengue (DENV) virus-induced changes in gene expression has focused on the role of the adaptive immune response, which is undeniably important. However, epidemiological data suggest that the host's genetic background may also contribute important susceptibility factors that could exert their effect in a manner independent from the adaptive immune response. Thus, an understanding of differential global gene expression at the proteome level is essential to understand how DENV infection can result in dramatically different disease outcomes. Ribosome profiling enables direct measurements of protein expression at the whole cell level. In so doing, it generates all the information needed for a comprehensive understanding of how global gene expression may influence particular disease phenotypes. We have recently completed a ribosome profiling-based study of DENV-2 in infected K562 and A549 cells. The two models of DENV infection allow us to test both low and high infection rates. In the K562 low infection model we found 471 differentially expressed (DE) genes in response to DENV infection, whereas in the A549 high infection model we detect over 3000. Interestingly we detected a large number of regulatory RNA species that may be novel regulators of dengue pathogenesis. Our data indicates that ribosome profiling is a gene discovery tool with great potential to inform understanding of disease pathogenesis.

### THE PHYLOGEOGRAPHY AND PHYLODYNAMICS OF THE DENV-2 AMERICAN-ASIAN GENOTYPE IN PERU

Cristhopher D. Cruz<sup>1</sup>, Milena Alba<sup>1</sup>, Amy Morrison<sup>1</sup>, Christopher Mores<sup>1</sup>, Simon Pollett<sup>2</sup>, Mariana Leguia<sup>1</sup>

<sup>1</sup>Naval Medical Research Unit-6, Callao, Peru, <sup>2</sup>Viral Diseases Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Dengue virus and particularly the American-Asian genotype of Dengue virus type 2 (DENV-2) causes a large burden of morbidity in Peru and Latin America. Existing studies into the spatial epidemiology of DENV-2 in Peru have been limited by a relative paucity of Peruvian and Latin American sequence data. In particular, it is unclear what predicts diffusion of this virus within Peru and whether certain locales can serve as sources of persistent DENV-2 variants over time. We therefore sequenced the whole genome of 216 DENV-2 positive human sera collected from Peru and neighboring countries between 2007 and 2014, with additional background global sequence data obtained from GenBank. A maximum likelihood E-gene tree inferred under a GTR+I+G nucleotide substitution model confirmed the circulation of two large DENV-2 American-Asian (DENV-2 AA) lineages in Peru with a replacement of Lineage I by Lineage II in 2009. Overall, Peru experienced seven distinct DENV-2 AA introductions. Lineage I was most likely introduced into Peru via three different routes from either Brazil or Ecuador. Similarly, three geographic routes of lineage

Il into Peru were identified, a northern route from Ecuador/Colombia, and two eastern routes into Loreto and Madre de Dios from a Brazil/Paraguay/Bolivia mixed lineage. Regarding within-Peru viral traffic, the results show clear evidence of spatial division between coastal and Eastern regions of Peru and regional viral dispersal typically between departments sharing borders. A Loreto-specific analysis revealed Iquitos data in basal positions of multi-province Loreto sub-lineages, suggesting that Iquitos may have experienced multi-year persistence of DENV-2 strains and may have seeded other locations within Loreto. Taken together, our results indicate that Peruvian DENV-2 epidemics are spatially structured, that diffusion of DENV-2 into and within Peru is typically predicted by geographic distance and that the tropical city of Iquitos experiences multi-year persistence of DENV-2 variants and may act as a regional hub of viral traffic.

## 120

### DENGUE AND OTHER ARBOVIRUSES IDENTIFIED IN RESPIRATORY SPECIMENS OF UNKNOWN ETIOLOGY

**Gilda Troncos**, Alejandra Garcia, Jane Rios, Christopher Mores, Mariana Leguia

*U.S. Naval Medical Research Unit-6, Callao, Peru*

Dengue viruses (Family *Flaviviridae*; genus *Flavivirus*) are transmitted to humans through the bites of infected female mosquitoes. Dengue viruses cause dengue fever, a severe, flu-like illness that can lead to complications and cause death. During periods of peak viremia dengue virus can be easily detected in serum samples by PCR. Following peak viremia, dengue can also be diagnosed using ELISA-based assays. Here, we report identification of dengue viruses, as well as other arboviruses, in oropharyngeal swabs collected from patients with respiratory symptoms. Briefly, while conducting routine respiratory surveillance in Peru, we identified a large number of samples that had shown cytopathic effect (CPE) while in culture, but tested negative for all known respiratory pathogens using either PCR- or ELISA-based approaches. These samples (196 total), entered a pathogen discovery pipeline that uses next-generation sequencing (NGS) to generate unbiased amplifications of viral nucleic acids. Sequencing libraries were prepared with Nextera kits and sequenced on the Illumina MiSeq platform. We detected previously undiagnosed viruses in 35 samples (18% total positives). As expected, the majority of viruses detected were respiratory viruses (20, or 57% of those detected). However, we also detected a number of arboviruses, including dengue (2, or 6%), Western Equine Encephalitis (WEE, 2 or 6%) and Venezuelan Equine Encephalitis (VEE, 1 or 3%). Arboviruses like dengue, WEE and VEE are not usually detected from oropharyngeal swabs, but given that these pathogens can cause flu-like symptoms, it is not surprising these patients would be sampled. The duration and role of viral shedding in the upper oropharynx of these arboviral diseases should be explored further. These results indicate that unbiased NGS approaches are an effective way to detect viral pathogens from patient samples when traditional methods fail to provide etiologic confirmation.

## 121

### MODIFIED ELISPOT FOR THE ANALYSIS OF SPECIFIC AND CROSS-REACTIVE DENGUE VIRUS AND ZIKA VIRUS MEMORY B CELLS

**Awadalkareem Adam**, Marcia Woda, Alan L. Rothman, Anuja Mathew

*Institute for Immunology and Informatics, University of Rhode Island, Providence, RI, United States*

Dengue virus (DENV) and zika virus (ZIKV) are antigenically related flaviviruses that have a significant global health impact. Recently, immune sera and monoclonal antibodies from DENV patients were found to be cross-reactive with ZIKV suggesting that memory B-cells from a DENV infection or vaccination can be reactivated by a ZIKV infection. Conventional ELISpots have been used to effectively to measure antibody secreting B-cells (ASCs) but since it is limited to a single antigen at a

time, it is challenging to detect DENV serotype-specific and cross-reactive memory B cells in the same well. Furthermore, high concentrations of antigen are required to detect ASCs. Novel assays that measure flavivirus cross-reactive memory B cells with reduced assay cost are needed as they can be used to better understand the breadth and magnitude of cross-reactive flavivirus responses. Using a panel of DENV immune and naïve PBMC, we evaluated biotinylated recombinant Virus-like Particle (Bio-VLP) and fluorescently labeled viruses (FLVs) in modified ELISpot assays. Conjugation efficiency and recognition of Bio-VLPs and FLVs by virus specific antibodies were validated by flow cytometry. We were able to reduce the amount of antigen required 10 fold, without any loss of detection sensitivity, by utilizing biotinylated antigens as an alternative detection system. FLVs were able to simultaneously detect DENV serotype-specific and cross-reactive memory B cells. Our findings indicate that the biotinylated-DENV VLPs and fluorescently labeled viruses might provide sensitive and specific tools to detect DENV-specific and DENV-ZIKV cross-reactive memory B-cells.

## 122

### THE EFFECT OF GARLIC IN REDUCING INFLAMMATION IN DENGUE INFECTION

**Andrea J. Troupin**<sup>1</sup>, Alex Hall<sup>1</sup>, Berlin Londono-Renteria<sup>2</sup>, Nicholas Dopkins<sup>1</sup>, Tonya M. Colpitts<sup>1</sup>

<sup>1</sup>*University of South Carolina, Columbia, SC, United States*, <sup>2</sup>*Kansas State University, Manhattan, KS, United States*

Dengue virus (DENV) is a mosquito-borne flavivirus that causes significant human disease and mortality in the tropics and subtropics. There has been a recent global trend of increased epidemic activity and DENV infection is considered a serious reemerging health problem worldwide. A relatively unexplored approach is to develop new treatments for dengue infection and prevent severe disease development through the investigation of alternative and natural medicines. Inflammation plays both beneficial and harmful roles during the host response to dengue virus infection. Several studies have proposed that the oxidative stress response induced by dengue virus infection is responsible for triggering the pro-inflammatory cytokine response. Thus, blocking the oxidative stress response and reducing inflammation in dengue patients could together reduce the likelihood of severe disease development. There are several plant products and herbal supplements that have been suggested or proven to reduce inflammation, including flavonoids, curcumin and garlic. Garlic also has effects on the oxidative stress response and prevents intracellular glutathione depletion. To investigate the effects of garlic on inflammation during dengue virus infection, we used three active organosulfur garlic compounds: DAS, DADS and Aliin. We examined the levels of inflammatory cytokines TNF-alpha, IL-8 and IL-10 in the supernatants of dengue virus-infected cells with and without the garlic compounds. We found that the addition of garlic compounds reduced the levels of all 3 inflammatory cytokines at all doses tested. Oxidative stress is thought to be the mechanism through which dengue virus acts to trigger the pro-inflammatory immune response during infection. As we examined the anti-oxidant activity of garlic during dengue infection we found that garlic can reduce inflammation through the reduction of the oxidative stress response.

## 123

### CHARACTERIZATION OF IN VIVO T CELL ACTIVATION DURING ACUTE DENGUE ILLNESS

**Kirk Haltaufderhyde**<sup>1</sup>, Anon Srikiatkachorn<sup>1</sup>, Sharon Green<sup>2</sup>, Louis Macareo<sup>3</sup>, Anuja Mathew<sup>1</sup>, Alan Rothman<sup>1</sup>

<sup>1</sup>*University of Rhode Island, Providence, RI, United States*, <sup>2</sup>*University of Massachusetts, Worcester, MA, United States*, <sup>3</sup>*Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Several studies suggest that T cells play an important role in both protection against dengue virus (DENV) infection and pathogenesis of

dengue disease. What remains unclear is the relationship between the responses of T cell subsets to primary or secondary DENV infection and disease severity. In addition, the role of peripheral T follicular helper (pTfh) cells during acute DENV infection has not been well studied. To further characterize T cell activation during acute DENV infection, we studied the expression of activation markers on CD4 and CD8 T cell and pTfh cell subsets using flow cytometry in blood samples collected from Thai children during acute DENV infection. We demonstrated a massive activation of T cells during acute DENV infection. The most pronounced T cell activation occurred during the critical stage (fever day +1, one day after defervescence), as defined by a large increase in CD38 and PD-1 expression. On average, ~50% of CD8 T cells and ~20% of CD4 T cells were CD38+ PD-1+ on fever day +1. pTfh cells were also highly activated with increased expression of PD-1, CD38, and OX40. Interestingly, we also observed a 61% increase in the frequency of pTfh cells on fever day +1 when compared to 1 yr post-infection ( $p \leq 0.05$ ). Our study demonstrates a robust activation of CD4 and CD8 T cells during acute DENV infection. The expansion and activation of pTfh cells may be related to plasmablast activation and DENV-specific antibody production. Overall, our study supports the model that T cells contribute to disease evolution during the critical stage of infection. Future analysis will be performed to determine if there is a correlation between T cell activation and virus serotype, primary versus secondary infection and disease severity.

## 124

### PRE-EXISTING ANTI-DENGUE VIRUS ANTIBODY TITER PREDICTS SEVERITY OF DENGUE DISEASE IN A PEDIATRIC COHORT IN NICARAGUA: A CASE-CONTROL AND LONGITUDINAL STUDY

Leah C. Katzelnick<sup>1</sup>, Lionel Gresh<sup>2</sup>, M. Elizabeth Halloran<sup>3</sup>, Juan Carlos Mercado<sup>4</sup>, Guillermina Kuan<sup>5</sup>, Aubree Gordon<sup>6</sup>, Angel Balmaseda<sup>4</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Department of Biostatistics, University of Washington, Seattle, WA, United States, <sup>4</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, <sup>5</sup>Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, <sup>6</sup>Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States

The four dengue virus serotypes (DENV1-4) are mosquito-borne flaviviruses that cause up to ~100 million dengue cases and ~500,000 hospitalizations annually. Severe dengue disease, most common during secondary heterotypic DENV infection, is often attributed to antibody-dependent enhancement, but a direct relationship between pre-existing anti-DENV antibody (DENV-Ab) titer and disease severity has not been shown in human populations. Pre-existing DENV-Ab titers were measured in healthy annual blood samples from 6,684 children in the Nicaraguan Pediatric Dengue Cohort Study using Inhibition ELISA. Severe dengue disease was categorized by 1997 and 2009 WHO dengue severity criteria as well as a clinical management score. We studied the relationship between pre-existing DENV-Ab titer and 1) severe vs. non-severe secondary dengue using logistic regression; 2) severe and non-severe secondary dengue cases and matched controls using conditional logistic regression, Wilcoxon rank sum and signed rank tests; and 3) risk of severe and symptomatic dengue using Cox proportional hazards models. Statistical analyses adjusted for year of exposure, sex, previous infections, age, and serotype. Across all severity classification schema, dengue cases with pre-existing DENV-Ab titers between 21 and 80 had significantly greater odds of being severe (compared with non-severe) than primary dengue cases. Severe secondary dengue cases had lower DENV-Ab titers (peak 21-80) than non-severe dengue cases or matched controls (peak 81-320). Further, children with DENV-Ab titers of 21-80 had greater hazard of severe dengue as compared to DENV-naïve children (Hazard ratio=7.47 [95%CI 3.05-18.27]), whereas children with lower or higher DENV-Ab titers did not. In

contrast, children with DENV-Ab titers >320 had significantly lower hazard of symptomatic dengue. In sum, we observed the highest risk of severe dengue at pre-existing DENV-Ab titers of 21-80 and protection against symptomatic dengue at high DENV-Ab titers, thus providing a basis for identifying individuals at highest risk for severe disease in populations and vaccine trials.

## 125

### USING CARTOGRAPHY TO DEFINE ANTIGENIC RELATIONSHIP AMONG DENGUE VIRUSES (DENV) IMPORTED BY TRAVELLERS

Kritu Panta<sup>1</sup>, Timo Ernst<sup>1</sup>, Suzi McCarthy<sup>2</sup>, Kara Imbrogno<sup>1</sup>, David Smith<sup>2</sup>, Allison Imrie<sup>1</sup>

<sup>1</sup>The University of Western Australia, Perth, Australia, <sup>2</sup>Pathwest Laboratory Medicine WA, Perth, Australia

The dengue viruses (DENV) are genetically divergent and grouped as four distinct serotypes (DENV-1-DENV-4), based on recognition of the viral envelope by anti-DENV antibodies. The four serotypes are more precisely classified, using phylogenetic approaches, into distinct genotypes which have been defined as clusters with nucleotide sequence divergence of not more than 6%, and lineages within the genotypes may represent strains with similar geographic origins. Such antigenic variation among the four dengue viruses influences epidemic virulence, immunopathogenesis, and vaccine design. We sought to understand the immunological significance of virus diversity by assessing DENV-specific cross-recognition and cross-neutralization using a panel of isolates and acute and convalescent sera collected over a period of up to 4 years, from travellers with well-defined monotypic DENV infection. DENV was isolated from acute-phase serum from Western Australian (WA) travellers returning from Bali, Indonesia, where they were infected with DENV; phylogenetic analysis identified serotype genotypes and lineages circulating at the time and imported by the travellers. Antigenic maps were constructed from hemagglutination inhibition (HI) and focus reduction neutralization tests (FRNT) titers. We show that all DENV, representing diverse genotypes and lineages, are recognized and neutralized by heterologous and homologous anti-sera, within 2 months of infection. By 2 years after infection, broad cross-recognition of all four serotypes is still apparent, however cross-neutralization is more restricted and homologous DENV and anti-sera are loosely clustered in the antigenic map. By 4 years after infection, there is clear clustering of DENV neutralized by homologous anti-sera, and also increased DENV recognition as measured by haemagglutination inhibition. In this study, we show that DENV genetic classification does not necessarily represent antigenicity and immune dynamics. It is essential to explore antigenic properties to understand the evolution and level of DENV-specific immune response.

## 126

### USE OF NEEDLE-FREE JET INJECTION AND ELECTROPORATION TO ENHANCE THE IMMUNOGENICITY OF A TETRAVALENT DENGUE DNA VACCINE

Kanakatte Raviprakash<sup>1</sup>, Daniel F. Ewing<sup>1</sup>, Maria Blevins<sup>2</sup>, Peifang Sun<sup>1</sup>, Kevin R. Porter<sup>1</sup>, John W. Sanders<sup>2</sup>, Maya Williams<sup>1</sup>

<sup>1</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>2</sup>Wake Forest University School of Medicine, Winston-Salem, NC, United States

The Naval Medical Research Center has developed a tetravalent dengue DNA vaccine. Two phase 1 clinical trials, first with the monovalent dengue-1 product for proof-of-principle and a second with the tetravalent product, demonstrated that this vaccine is safe and well tolerated but produced less than optimal humoral immune responses. To determine if other methods of vaccine delivery could enhance the immunogenicity of this vaccine, we conducted a study in non-human primates. Animals were vaccinated at 0, 30 and 90 days with either 1 mg or 5 mg of a tetravalent dengue DNA vaccine via either the intradermal or intramuscular route using either a needle-free jet injection or electroporation device. Data

on neutralizing antibody titers assessed monthly up to five months after the last vaccination and cellular immune responses will be presented. Preliminary results suggest that intramuscular delivery of the tetravalent DNA vaccine by electroporation may generate the best anti-dengue neutralizing antibody response.

## 127

### DEVELOPMENT AND VALIDATION OF CLINICAL ALGORITHMS FOR THE DIAGNOSIS OF DENGUE IN ENDEMIC AREAS OF COLOMBIA

**Diana Caicedo**<sup>1</sup>, Andrés Méndez<sup>1</sup>, Rafael Tovar<sup>1</sup>, Jairo Celis<sup>2</sup>, Liliana Villegas<sup>2</sup>, Constanza Collazos<sup>2</sup>, Lyda Osorio<sup>1</sup>

<sup>1</sup>University of Valle, Cali, Colombia, <sup>2</sup>Comfandi, Cali, Colombia

Due to the increase in the incidence and mortality of dengue, its prompt and correct diagnosis is a priority for endemic countries. Clinical classifications and existing laboratory tests for diagnosis have a variable performance with sensitivities between 45% - 98% and specificities between 4% - 71%. To develop and validate clinical algorithms for dengue diagnosis in endemic areas of Colombia. A Bayesian-adaptive quasi-experimental clinical trial is being conducted with a target of 2000 febrile subjects. In the first phase, diagnostic algorithms based on Bayesian methodologies are being developed and validated prospectively. Demographics, signs and symptoms of dengue, leukocytes and platelets are collected from all participants; clinical algorithms are compared to gold standard diagnostic dengue tests. In the second phase, the diagnostic accuracy of the best algorithm identified in the first phase will be validated in the routine clinical practice. Interim analyses will be performed every 5 false negatives for dengue. To date, 6 clinical diagnostic algorithms have been developed. Three based on signs and symptoms and three that include leukocytes and platelet counts. The latter have reached up to 75% sensitivity. In an external validation in databases of suspected dengue the sensitivity was 80%. In addition, a pilot test of prospective validation was performed, 65 febrile subjects were recruited and the clinical algorithm (general pain, skin rash, hemorrhagic manifestations, warning signs, neurological alterations, absence of respiratory symptoms, absence of jaundice, leukopenia <4.500/mm<sup>3</sup> and thrombocytopenia <160.000/mm<sup>3</sup>) had a specificity of 95%. There were no positive cases of dengue by gold standard tests but 2 were positive by the clinical algorithm. The inclusion of blood count parameters improves the sensitivity of dengue diagnostic algorithms based only on signs and symptoms. The development of highly sensitive and specific dengue diagnostic tests based on clinical criteria useful at point of care remains a challenge for dengue research.

### TRIVALENT AND TETRAVALENT DENGUE VACCINES PROTECT AGAINST DENV-4 CHALLENGE IN NON-HUMAN PRIMATES

**Ginger Young**<sup>1</sup>, Allan Parker<sup>1</sup>, Yuping Ambuel<sup>1</sup>, Jeremy Fuchs<sup>1</sup>, Linda Strange<sup>1</sup>, Lovkesh Karwal<sup>1</sup>, Wendy Newton<sup>2</sup>, Saverio Capuano<sup>2</sup>, Hansi Dean<sup>1</sup>

<sup>1</sup>Takeda Vaccines, Inc., Cambridge, MA, United States, <sup>2</sup>Wisconsin National Primate Research Center, Madison, WI, United States

A successful dengue vaccine should elicit protective immune responses against all 4 dengue serotypes. Developing a vaccine formulation which elicits balanced immune responses to all serotypes is challenging, and immune correlates of protection may differ by serotype. Takeda's candidate tetravalent dengue vaccine (TDV), is comprised of an attenuated DENV-2 virus strain (TDV-2) and three chimeric viruses containing the pre-membrane and envelope genes of DENV-1, DENV-3 and DENV-4 genetically engineered into the attenuated TDV-2 genome backbone (TDV-1, TDV-3 and TDV-4). TDV elicits neutralizing antibodies and cellular immunity to all 4 dengue serotypes, with magnitude of responses against DENV-2 higher than against DENV-4. In order to determine the relative contribution of the DENV-2 and DENV-4 component of TDV to immunogenicity and efficacy against DENV-4, we evaluated immunogenicity and efficacy of a trivalent

(TDV-1, -3 and -4) and a tetravalent (TDV-1, -2, -3 and -4) vaccine against DENV-4 challenge in cynomolgus (*Macaca fascicularis*) macaques. Infected cynomolgus macaques develop immune responses and a subclinical infection detected by viremia. Vaccine efficacy against subcutaneous DENV-4 1228 challenge was determined by assessing presence of DENV-4 viral RNA and isolation of replicating DENV-4 from serum. Both trivalent and tetravalent vaccines were efficacious against DENV-4 challenge. Neutralizing antibody titers measured using a reporter-virus particle assay demonstrated a correlation between DENV-4 antibody levels and protection against DENV-4 challenge. These results demonstrate that TDV immunogenicity and efficacy against DENV-4 does not require the TDV-2 vaccine component. Characterization of the quantitative and qualitative features of the immune response to DENV-4 may help identify surrogate markers related to correlates of protection.

## 129

### COMPARISON OF ACTIVE AND PASSIVE SURVEILLANCE SYSTEMS FOR DENGUE FEVER IN MACHALA, ECUADOR IN 2014 AND 2015

**Melissa Vitale**, Aileen Kenneson-Adams, Christina D. Lupone, Paula F. Rosenbaum, Jefferson Adrian, Anna M. Stewart

SUNY Upstate Medical University, Syracuse, NY, United States

Dengue is a mosquito-borne pandemic with approximately 2.5 billion people at risk and approximately 400 million people infected annually. Although dengue reporting is mandatory in Ecuador, the current passive surveillance (PS) system is dependent upon people seeking care if symptomatic. Studies have shown that an active surveillance (AS) strategy allows for more cases to be detected and earlier within an outbreak. This could better inform prevention and control strategies. The purpose of this analysis was to compare an AS system to existing PS in Machala, Ecuador. Dengue cases reported to the Ecuadorian Ministry of Health's (MOH) PS data of from 2014 and 2015 were compared to data from an AS study of Dengue cases in Machala. All cases were laboratory confirmed. AS data were collected from individuals who were seen at one of four clinics or the sentinel hospital in Machala as well as family members and neighbors of the patient. Cases that were reported to both systems were identified based on matching on age, sex and date of visit. In both years, 218 cases were identified by PS, and 287 from AS. Of these 16 cases appeared in both systems. Younger patients were more frequently identified by PS while the AS system identified more dengue infections in the 20-64 age group, ( $p=0.014$  and  $0.358$  in 2014 and 2015). In 2014, the incidence rates were 8.35 per 10,000 for AS and 4.48 per 10,000 for the PS. In 2015, the incidence rates were 1.45 and 2.82 per 10,000 for active and passive surveillance, respectively. Combined active and passive incidence rates in 2014 and 2015 show the significantly higher incidence rates in the 5-19 age group than any other age group (22.97 per 10,000 in 2014 and 7.57 per 10,000 in 2015). Thus, the AS captured a different cohort possibly due to healthcare-seeking behaviors or disease dynamics such as differences in clinical presentation by age group. In addition, it helps improve understanding of the disease dynamics of Dengue infections for more effective, targeted interventions.

Global expansion of dengue virus (DENV), especially towards previously non-endemic areas, is a serious public health concern. Although DENV was introduced in Nepal nearly a decade ago in 2006, its molecular epidemiology remains unclear. We adopted a phylogenetic approach to understand the genetic diversity and potential origin(s) of the Nepal DENV strains. For this, complete envelope (E) gene sequences of all four DENV serotypes found in Nepal were obtained and maximum-likelihood (M-L) trees were constructed along with relevant global sequences from GenBank. Blood samples (n = 1215) were collected from acute dengue patients during the major outbreaks in Nepal (2010-2012), affecting at least 18 districts, with an estimated case fatality rate of 1.5%. All four serotypes were detected in acute sera by reverse transcription-polymerase chain reaction (RT-PCR). However, DENV 1 and 2 (92%) were found responsible for the major outbreaks in the country. Nepal DENV 1 strains belonged to genotype-V and formed two distinct clades, which showed spacio-temporal variation during these outbreaks. DENV 2, 3, and 4 strains were clustered into cosmopolitan genotype, genotype-III, and genotype-IIIB, respectively. M-L trees revealed that the vast majority of Nepal DENV strains were closely related to India and contemporaneous Singapore strains. India is the most plausible origin of Nepal DENV due to its physical proximity, extensive cross-border activities (open border) and similar geo-climatic features supporting the phylogenetic relations. To this end, we have outlined genetic diversity of DENV serotypes in Nepal. This sequence-based information is not only useful for Nepal in epidemic preparedness but also aids in the understanding of evolutionary dynamics at regional and global level. Additionally, these findings underscore the need of cross-border collaboration in dengue control where high public mobility exists across the porous borders.

## 131

### MUTAGENESIS OF DENGUE VIRUS ENVELOPE PROTEINS TO MAP ANTIBODY EPITOPES AND IDENTIFY RESIDUES ESSENTIAL FOR FUNCTION

Jennifer M. Pfaff, Srikar Reddy, Edgar Davidson, **Benjamin J. Doranz**

*Integral Molecular, Inc., Philadelphia, PA, United States*

To characterize the immune response to dengue virus (DENV) infection, we have developed a high-throughput strategy that enables the rapid identification of both linear and conformational epitopes on DENV prM/E envelope proteins from all four DENV serotypes. For each DENV serotype (1-4), we used Shotgun Mutagenesis technology to create a comprehensive library of single mutations in DENV prM/E, 3,380 mutations in total. Each library of individual mutant expression plasmids was arrayed into 384 well plates and transfected into human cells to achieve native protein expression and folding. The immunoreactivity of MAbs to the prM/E variant in each individual well was quantified by high-throughput flow cytometry, resulting in approximately 200 MAb epitopes. The epitopes obtained have been correlated with their abilities to protect against DENV infection. A number of these anti-DENV MAbs were found to cross-react with ZIKV prM/E, predominantly within the fusion loop but also within Domain II of the E protein, identifying critical immunogenic residues shared by DENV and ZIKV. We have also produced DENV virions from all four mutation libraries using a previously developed DENV reporter virus particle (RVP) system, allowing us to screen each individual DENV Env variant protein for DENV particle budding and infectivity. For DENV3, analyses of budding and infectivity, along with the MAb binding studies, identified residues whose mutation eliminated virus infectivity, but did not impact E protein expression, antigenicity, virion assembly, or particle budding. We identified variants that showed increased DENV virion budding, up to 5-fold above wild-type, indicating the ability to engineer highly expressed, non-infectious DENV variants that can be used for

vaccine design. Our research has identified neutralizing epitopes in DENV prM/E and specific sites that are critical for DENV infectivity, providing new targets and opportunities for vaccine development.

## 132

### ZIKA VIRUS QUANTITATIVE PCR RESULTS AMONG SYMPTOMATIC PEDIATRIC PATIENTS

Jennifer S. Read<sup>1</sup>, Brenda Torres-Velasquez<sup>1</sup>, Gilberto Santiago<sup>1</sup>, Olga Lorenzi<sup>1</sup>, Aidsa Rivera<sup>1</sup>, Sanet Torres-Torres<sup>2</sup>, Sheila Capre<sup>2</sup>, Carlos Garcia-Gubern<sup>3</sup>, Lillian Rivera<sup>2</sup>, Janice Perez-Padilla<sup>1</sup>, Jorge Munoz-Jordan<sup>1</sup>, Luisa Alvarado<sup>2</sup>

<sup>1</sup>Centers for Disease Control and Prevention, San Juan, PR, United States, <sup>2</sup>Department of Pediatrics, St. Luke's Episcopal Hospital-Ponce Health Sciences University Consortium, Ponce, PR, United States, <sup>3</sup>Department of Emergency Medicine, St. Luke's Episcopal Hospital-Ponce Health Sciences University Consortium, Ponce, PR, United States

In 2015-2016, over 38,000 Zika virus (ZIKV) infections were reported in Puerto Rico (PR). We previously characterized the clinical manifestations of symptomatic children (<18 years (y) old) with confirmed ZIKV infection (positive qualitative ZIKV polymerase chain reaction (PCR) result) enrolled in the Sentinel Enhanced Dengue and Acute Febrile Illness Surveillance System (SEDSS) in Ponce, PR. Our objective was to further characterize these patients by evaluating quantitative ZIKV PCR results (viral loads, VLs). The study population comprised symptomatic children enrolled in SEDSS by December 31, 2016 with confirmed ZIKV infection. Available PCR+ specimens underwent VL testing (copies/mL) using an RNA standard curve generated from Trioplex Real Time RT-PCR Assay target amplicons. The Mann-Whitney-Wilcoxon test (comparison of medians), Bonferroni correction (pairwise comparisons among age groups and days post-onset of illness (DPO) groups), and Jonckheere-Terpstra test (assessment of trends) were used. Of 353 patients, 351 had ≥1 specimen available. Among 484 specimens, the median (interquartile range (IQR)) of VLs was 19,603 (5465-95,598). The median DPO for specimen collection was lower in serum (1 day) than urine (2 days) (p<0.001). Analyzing only serum and urine specimens collected on the same day (n=131 patients), the median (IQR) VL was higher in serum [21,790 (8784-88,242)] than urine [10,352 (2880-56,481)] (p=0.002). Analyzing one serum sample/subject, there were no statistically significant differences in median VLs according to sex [males (n=171) (25,436) vs. females (n=148) (26,558) (p=0.99)] or age [44,372 (infants, n=21), 26,781 (1-4y, n=60), 22,828 (5-9y, n=88), and 25,621 (10-17y, n=150) (p=0.46)]. The median VL varied significantly according to DPO: 106,778 (DPO=0, n=33); 46,299 (DPO=1, n=131); 20,780 (DPO=2, n=78); 15,876 (DPO≥3, n=77) (p=0.001). Among symptomatic pediatric patients, ZIKV VLs were higher in serum vs. urine. In serum, no statistically significant differences in median VLs were observed according to sex or age, but median VLs decreased significantly with increasing DPO.

## 133

### NEUROLOGICAL OUTCOMES OF JAPANESE ENCEPHALITIS VIRUS INFECTION IN PEDIATRIC AND ADULT PATIENTS AT MAHOSOT HOSPITAL, VIENTIANE, LAO PDR

Phouvieng Douangdala<sup>1</sup>, Mayfong Mayxay<sup>2</sup>, Paul Newton<sup>3</sup>, Pope Kosalaraksa<sup>4</sup>, Pagakrong Lumbiganon<sup>4</sup>, Douangdao Soukaloun<sup>2</sup>

<sup>1</sup>LuangNamTha Provincial Hospital, LuangNamTha Province, Lao People's Democratic Republic, <sup>2</sup>University of Health Sciences, Lao PDR, Vientiane, Lao People's Democratic Republic, <sup>3</sup>Lao - Oxford University - Wellcome Trust - Mahosot Hospital - Research Unit, Vientiane, Lao People's Democratic Republic, <sup>4</sup>Khon Kaen University, Khon Kaen, Thailand

Japanese encephalitis virus (JEV) infection is a serious disease with a fatality rate of ~20-30% and 30-50% of survivors have significant neurological sequelae. In Laos, the frequency of death and neurological sequelae have never been studied. Better understanding of the consequences of JEV

infection will help improve disease management and reduce mortality, complications and neurological sequelae. This study aimed to follow patients with JEV infection to determine the frequency of fatality and neurological sequelae. Patients' hospital charts, forms and reports from Mahosot Hospital between 2003 and 2013 were retrospectively reviewed and patients were followed prospectively. Positive anti-JEV IgM, PCR or culture in CSF or sera was considered diagnostic. 183 patients (91 = or <15 years old and 92 >15 years old) with confirmed JEV infections were admitted and included in the study. The median age was 18 (0.1-70) years. 57% of them were male. The mean days of fever before admission was 6.1 (5.3-6.9) days. The fatality rate was at least 22% (40/183) as 49 (27%) patients were lost to follow-up. The proportion of deaths was not significantly different between children (21/91) and adults (19/92),  $p=0.87$ . Among patients who were still alive at the last follow-up, the median duration of follow-up was 55 (18-156) months. 38% of patients completely recovered (without neurological sequelae), with significantly more adults (49%) than in children (28%) recovering,  $p=0.007$ . Of patients 61% (51% in adults and 72% in children,  $p=0.007$ ) had neurological sequelae at follow up. Severe and moderate functional impairment at follow-up was also significantly higher in children (24%) compared to adults (2.1%),  $p<0.001$ , while at discharge neurological sequelae was not significantly different based on Liverpool Outcome Scores (74 vs 72,  $p=0.018$ ). At least 1/5 of the patients with JEV infection in this study died. Among those who are still alive, nearly 2/3 of them had neurological sequelae at last follow-up. Although mortality was similar for children and adults, the severity and frequency of neurological sequelae were higher in children than in adults.

## 134

### THE FIRST SEROLOGICAL EVIDENCE OF PREVIOUS ZIKA VIRUS TRANSMISSION IN ETHIOPIA

**Mesfin M. Tsegaye**<sup>1</sup>, Workenesh A. Moltotal<sup>1</sup>, Berhane B. Mentaye<sup>1</sup>, Almaz A. Tadesse<sup>1</sup>, Amadou A. Sall<sup>2</sup>, Sergio D. <sup>1</sup>Ethiopian Public Health Institute, Addis Ababa, Ethiopia, <sup>2</sup>Institute Pasteur Dakar, Dakar, Senegal, <sup>3</sup>World Health Organization, Geneva, Switzerland, <sup>4</sup>World Health Organization, Addis Ababa, Ethiopia, <sup>5</sup>World Health Organization, Harare, Zimbabwe, <sup>6</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

The the genus *Flaviviridae* contain the most important mosquito transmitted viruses such as Dengue and West Nile viruses that affect humans and cause millions of infections every year around the world. However, many of the other viruses in this genus such as Zika virus are generally believed to have a more limited geographical range and to cause few infections annually but this believe has been refuted with the recent large epidemics of Zika virus infections especially in Latin American countries. We show here evidence of past Zika virus transmission in Ethiopia. The evidence of Zika virus transmission here was generated as part of the yellow fever risk assessment study done in Ethiopia in 2014 in which the laboratory investigation required differential diagnosis for flavi viruses including Zika virus. In the study, the country was divided in to five ecological zones based on factors that affect the distribution and abundance of flavi virus vectors. Serum samples were collected from 1643 study participants and tested for flavi viruses namely; yellow fever, dengue fever, Zika and West Nile viruses specific IgG by ELISA and confirmed by Plaque Reduction Neutralization Test (PRNT). Demographic and laboratory data was analyzed using excel spreadsheet. Of the total serum samples tested, 7 (0.43%) showed a confirmed PRNT IgG positivity for previous Zika virus infection. Three of the five Ecological Zones of the country showed IgG positivity for Zika virus. The three Ecologic Zones represent areas of the country that span from North-South and East-West. Five of the total 7 positive cases (71.4%) were Females and the median age for the positive cases was 28; with the youngest study participant infected with the virus being a nine year old girl and the oldest a 60 year old

woman. This is the first serological evidence showing previous Zika virus transmission in Ethiopia. Further studies are required to see if there is active infection in the areas with Zika positivity and understand the risk factors for Zika virus infection and transmission. This study also warrants existing surveillance system in Ethiopia to consider and follow Zika virus infection more closely.

## 135

### YELLOW FEVER AND ARBOVIRUS SURVEILLANCE IN SYLVATIC AREAS FROM MISIONES PROVINCE, ARGENTINA

**Silvina Goenaga**<sup>1</sup>, Eduardo A. Lestani<sup>2</sup>, Gustavo C. Rossi<sup>3</sup>, Silvana C. Levis<sup>1</sup>, Delia A. Enria<sup>1</sup>, Ilaria Agostini<sup>4</sup>

<sup>1</sup>Instituto Nacional de Enfermedades Virales Humanas Dr. Julio I. Maiztegui (INEVH-ANLIS), Pergamino, Argentina, <sup>2</sup>Instituto Nacional de Medicina Tropical, Puerto Iguazú, Argentina, <sup>3</sup>Centro de Estudios Parasitológicos y de Vectores (CEPAVE), La Plata, Argentina, <sup>4</sup>Instituto de Biología Subtropical (CONICET-UNaM), Puerto Iguazú, Argentina

Yellow fever (YF) is a viral hemorrhagic fever endemic to tropical regions. In South America, the sylvatic cycle of Yellow fever virus (YFV) is maintained by viral circulation between monkeys and diurnally active mosquitoes that breed in the forest canopy. In Argentina, circulation of YFV was detected during 2007-2009, where a sylvatic outbreak affected monkeys and humans. However, the transmission cycles are not completely understood, and identification of vectors and reservoirs remains poorly known. Since 2015, we have captured mosquitoes in four protected areas of the Atlantic Forest of Misiones province, Argentina. In order to evaluate the YFV enzootic circulation, mosquitoes were tested for YFV and other arbovirus. During the day, we captured adult mosquitoes from human bites, focusing on *Sabethes* and *Haemagogus* genera, because of their known implication in the YFV transmission. Specimens were sorted according to location, date and species. RT-PCR for YFV, generic Flavivirus, Alphavirus and Bunyavirus from supernatant of mosquitoes pool homogenates were performed. Inoculation into Vero and C6/36 cells for virus isolation attempts were done from those pools positives for genome detection. A total of 696 mosquitoes sorted in 134 pools were analyzed. *Sabethes* mosquitoes were the most abundant genus (40%, 10 species), followed by *Trichoprosopon* (18%, 4 species). Among the mosquitoes taxa implicated in YFV transmission, only 5 captured specimens belonged to *Hg. leucocelaenus*, 2 belonged to *Sa. chloopterus* and 36 specimens belonged to *Ae. serratus*. No specimen of *Sa. albiprivus*, *Ae. aegypti* or *Ae. albopictus* were captured. No YFV genome was detected in any of the analyzed mosquitoes pools. Nevertheless, several arbovirus genomes were detected, such as Mercadeo virus, Madariaga virus, and one new flavivirus strain. Currently, isolation attempts are still ongoing. Even though YFV was not detected in our survey, the current YF outbreak in Brazil could spread to bordering countries representing a threat for public health. Continuous maintenance of surveillance is crucial to detect the potential spread of YFV to Argentina.

## 136

### INTERVALS OF POSITIVE AND NEGATIVE DETECTION OF THE ZIKV RNA IN THE URINE OF ZIKA-INFECTED PREGNANT WOMEN

**Ana C. Terzian**<sup>1</sup>, Cassia F. Estofolete<sup>1</sup>, Rafael A. da Silva<sup>1</sup>, Denise C. Vaz-Oliani<sup>2</sup>, Antônio H. Oliani<sup>2</sup>, Cinara C. Mattos<sup>2</sup>, Luiz C. Mattos<sup>2</sup>, Paula Rahal<sup>3</sup>, Maurício L. Nogueira<sup>1</sup>

<sup>1</sup>São José do Rio Preto School of Medicine (FAMERP), São José do Rio Preto, Brazil, <sup>2</sup>São José do Rio Preto School of Medicine Foundation (FUNFARME), São José do Rio Preto, Brazil, <sup>3</sup>São Paulo State University (IBILCE/UNESP), São José do Rio Preto, Brazil

Zika virus (ZIKV) is a re-emerging flavivirus that was first isolated in Uganda in 1947, and before the Brazilian outbreak, ZIKV infection was considered a mild febrile illness that did not produce severe outcomes. However, the cases of congenital malformations or neurological alterations reported in

Brazil reshaped knowledge on the course of infection caused by a flavivirus and demanded a rapid approach to diagnosing the virus. The molecular diagnosis of flavivirus is usually performed using blood/serum samples; however, urine, saliva, and semen have been identified as additional sources since detection can be prolonged in these fluids even after viremia clearance. This study describes the long-term detection of ZIKV RNA in the urine from a group of ZIKV-positive pregnant women. From February to October of the 2016 ZIKV outbreak, pregnant patients with Zika-like symptoms, with 4 to 38 weeks into their pregnancies, were treated at the Public Health Authority in the Brazilian city of São José do Rio Preto. Serum and/or urine samples were collected from the mothers during their first visits to facility after the onset of symptoms, and the patients were tested for ZIKV. The viral RNA was extracted and TaqMan® RT-qPCR assay was performed using primers targeting the ZIKV envelope (E) gene. After their first ZIKV-positive RT-qPCR (ct ≤ 38.5), these pregnant women were monitored, and viruria was measured until delivery. The viral RNA was detected by RT-qPCR more than four weeks (and up to seven months) after the first detection, even with intervals of negative detection. The use of urine for diagnosis represents an additional tool for virus detection. It is easy to obtain (as it does not put physiological stress upon pregnant women), and it can be obtained more than five days after the onset of clinical symptomatology. Because microcephaly and fetal abnormalities have been attributed to ZIKV, the monitoring of ZIKV viruria in pregnant women through the regular collection of urine samples proved to be an important approach over the course of the pregnancy; however, the meaning and the consequences for newborns will need to be evaluated in the future.

## 137

#### HOW IS ZIKA AFFECTING PREGNANT TRAVELERS? ZIKA VIRUS SURVEILLANCE IN A NON-ENDEMIC AREA

**Elena Marbán-Castro**<sup>1</sup>, Anna Goncés<sup>2</sup>, Miguel J. Martínez<sup>1</sup>, Victoria Fumadó<sup>1</sup>, Marta López<sup>2</sup>, Laura García<sup>2</sup>, Laura Salazar<sup>2</sup>, Dolors Salvà<sup>2</sup>, Inés Oliveira<sup>1</sup>, Natalia Rodríguez-Valero<sup>1</sup>, María Jesús Pinazo<sup>1</sup>, Ana Requena-Méndez<sup>1</sup>, Jara Llenas-García<sup>1</sup>, Adela Saco<sup>3</sup>, Paola Castillo<sup>3</sup>, Marina Fuente-Moreno<sup>1</sup>, Aina Casellas<sup>1</sup>, Raquel González<sup>1</sup>, José Muñoz<sup>1</sup>, Joaquim Gascón<sup>1</sup>, Jaume Ordí<sup>1</sup>, Clara Menéndez<sup>1</sup>, Azucena Bardají<sup>1</sup>

<sup>1</sup>Barcelona Institute for Global Health, Barcelona Centre for International Health Research (CRESIH), Hospital Clínic, Universitat de Barcelona, Barcelona, Spain, <sup>2</sup>Department of Maternal-Fetal Medicine, BCNatal - Barcelona Center of Maternal-Fetal and Neonatal Medicine, Hospital Clínic and Hospital Sant Joan de Déu, Universitat de Barcelona, Barcelona, Spain, <sup>3</sup>Department of Pathology, Hospital Clínic, Barcelona, Spain

Zika virus (ZIKV) represents a global threat with dramatic consequences on reproductive and infant's health. Epidemiological surveillance is key to ensure detection of imported cases in non-endemic areas. We aimed to assess the epidemiological characteristics and pregnancy outcomes in a cohort of pregnant travellers at risk of ZIKV and to evaluate its effects in their infants. An epidemiological surveillance system, which included screening for ZIKV (RT-PCR, serology and microneutralization assay) was established at the Hospital Clínic of Barcelona, Spain. Women were enrolled in the study and followed-up until delivery, as well as their infants during the first months of life. Infants' follow-up included weight, length, head circumference, hearing, eye fundus, physical, neurological and psychomotor evaluation, and ZIKV screening. We describe a cohort of 125 women screened for ZIKV; of them, nine were positive (3 by RT-PCR and 6 by microneutralization) and 22 were categorised as a suspected case (undetermined microneutralization or results pending). Infected pregnant women had travelled primarily to the Dominican Republic and Colombia, had been exposed to ZIKV predominantly during the peri-conceptual period or the first trimester, and the majority of them were symptomatic; being rash the most frequently reported symptom. Pregnancy outcomes included 15 live births at term, a miscarriage associated with ZIKV maternal viremia, 14 ongoing pregnancies and a termination of pregnancy. Subtle periventricular cysts were reported in one live birth. All placentas

tested negative, except the residues from the miscarried case that were positive by RT-PCR. All infants tested negative for ZIKV at birth. Psychomotor and anthropometric assessment of study infants during first months of life did not reveal any abnormal finding. Further data will be presented as recruitment is in process and both mothers and infants continue under follow up. Surveillance of ZIKV in pregnancy is important also in non-endemic areas. Prospective studies of infants born to ZIKV infected mothers are critical to understand long-term consequences of the infection.

## 138

#### LOW DENSITY CIRCULATION OF ZIKA VIRUS IN THE PHILIPPINES, 2016

**Janiza Lianne M. Foronda**, Ava Kristy D. Sy, Dominic Edward Z. Tomas, Amado O. Tandoc III

*Research Institute for Tropical Medicine, Muntinlupa, Philippines*

The Zika virus (ZIKV) outbreak in Brazil in late 2015 and its association with microcephaly made the virus global public health concern. In the Philippines, a single ZIKV case was reported in 2012 despite the abundance of the mosquito vectors of the virus, *Ae. aegypti* and *Ae. albopictus* in most areas of the country. Awareness for ZIKV and its complications started in 2016. In this study, we aimed to characterize the lineage of ZIKV circulating in the Philippines and determine possible origin of the virus by comparing with available sequences in GenBank. Around 2000 urine and serum samples were collected from all areas of the country in 2016. Samples were tested using real-time PCR, in which 59 samples were ZIKV positive. Phylogenetic analysis was done based on the partial coding region of the envelope protein (E gene) using maximum likelihood method. A two-step RT-PCR was used to amplify the 1890 bp of the ZIKV E gene and sequenced using Sanger method. Our findings reveal that majority of the ZIKV detected in the Philippines were of Asian-lineage and that resulting sequences clustered together with ZIKV isolated from Micronesia in 2007. This suggests low-level local transmission but remained at low levels, as symptoms are similar to other mosquito-borne viruses such as Dengue and Chikungunya. Continued surveillance of ZIKV is necessary to track its spread in the Philippines; to assist public health authorities to instigate prevention and control strategies for vectors; and contribute information for its related complications.

## 139

#### EVALUATION OF ACUTE ENCEPHALITIS SYNDROME/ JAPANESE ENCEPHALITIS SURVEILLANCE SYSTEM IN DEORIA AND GORAKHPUR DISTRICT, UTTAR PRADESH, 2016

**Rajesh Sahu**<sup>1</sup>, Uday Mohan<sup>1</sup>, Srinivas Venkatesh<sup>2</sup>

<sup>1</sup>King George's Medical University, Lucknow, India, <sup>2</sup>National Centre for Disease Control, Delhi, India

**Introduction:** Acute Encephalitis Syndrome (AES) including Japanese Encephalitis (JE) is public health problem due to high epidemicity, mortality and neuropsychiatric sequelae. In 2014, Uttar Pradesh accounted for 33% of 9693 AES cases and 1490 deaths in India. **Objectives:** We evaluated AES/JE surveillance system in Deoria and Gorakhpur Districts to improve surveillance as per CDC recommended surveillance evaluation attributes. **Methods:** We selected four blocks of Gorakhpur and Deoria districts to evaluate the AES surveillance based on selected CDC recommended attributes: data-quality, usefulness, representativeness, timeliness, acceptability, simplicity, and stability. We collected data using data abstraction forms by review of relevant reports and registers and interview of health workers. We studied 12 and 10 health facilities in Gorakhpur and Deoria districts respectively. **Results:** Of government health facilities in Gorakhpur and Deoria, 91% and 93% respectively were reporting, but no private facility was reporting. Of AES patients from Gorakhpur, 88% had JE tests compared to 77% from Deoria. Amongst AES deaths from Gorakhpur and Deoria, 83% and 66% respectively had been investigated. Among reported cases, 82% and 73% of cases were reported within

48hrs of onset in Gorakhpur and Deoria, and 91% and 82% of forms were complete. Most health workers (95% in Gorakhpur, 93% in Deoria) were able to recall correct case definition. Among health facilities, 88% and 80% didn't default in reporting >7 days consecutively anytime in one year. **Conclusion:** The AES / JE surveillance system in Deoria and Gorakhpur districts was useful for investigating deaths, representative of government health facilities, stable and timely for reporting, acceptable based on high reporting rates, and simple in terms of case definition recall. We recommend improving private provider representation and strengthening lab surveillance.

## 140

### PHASE 1 STUDY OF MV-ZIKA, A LIVE RECOMBINANT MEASLES VIRUS VACCINE TO PREVENT ZIKA VIRUS INFECTION

**Katrin Ramsauer**, Sabrina Schrauf, Raimund Vielnascher, Alexander Kort, Matthias Müllner, Erich Tauber  
*Themis Bioscience GmbH, Vienna, Austria*

Zika virus is an emerging mosquito-borne flavivirus. The virus emerged in the past 70 years only sporadically with self-limiting small outbreaks. In 2013, a large outbreak in French Polynesia resulted in over 30,000 cases. Since early 2015 Zika virus spread in the Americas and to date caused autochthonous, vector-borne transmission in 48 countries and territories. This rapid emergence of the previously unknown pathogen raised the urgent need for a vaccine that can be rapidly produced in response to a newly emerging pathogen. Themis took the challenge and developed a vaccine candidate from design to Phase 1 clinical trial within 14 months. The MV-ZIKA vaccine candidate is a live attenuated recombinant viral vectored vaccine for the prophylaxis of Zika virus infection. The measles virus (MV) Schwarz vaccine strain was used as the backbone into which nucleotide sequences encoding Zika virus structural proteins glycoprotein precursor (prM) and the Envelope (E) were inserted to produce the MV-ZIKA. In measles virus susceptible mice, single or multiple vaccinations with MV-ZIKA induced a robust protective immunity, as shown by the induction of ZIKV E protein specific antibodies. The immunization of *Cynomolgus* macaques resulted in the induction of Zika virus neutralizing antibodies in all vaccinated animals. To evaluate the optimal dose of MV-ZIKA in regard to immunogenicity, safety, and tolerability we initiated a double blinded, randomized, placebo-controlled, multi-center, phase 1 trial in 48 healthy volunteer subjects. The subjects will receive one or two vaccinations. The immunogenicity as confirmed by the presence of functional antibodies will be determined on day 28 after the second immunization. The clinical trial is currently ongoing and preliminary data will be presented here for the first time.

## 141

### IDENTIFICATION OF A NOVEL FLAVIVIRUS, NAKIWOGO VIRUS, IN KENYAN MOSQUITOES

**Collins M. Morang'a**, Kimita Gathii, David Abuom, Beth Mutai, Thomas Gilbreath, John Waitumbi  
*US Army Medical Research Directorate- Kenya, Walter Reed Army Institute of Research/ Kenya Medical Research Institute, Kisumu, Kenya, Kisumu, Kenya*

Nakiwogo flavivirus (NAKV) was first isolated in field collected *Mansonia* mosquitoes in Uganda and has never been described elsewhere. This is the second description of this virus. In this study we used NGS/BIO as a surveillance method for novel viruses in Kenyan female mosquitoes. Mosquitoes were collected from Budalangi in Western Kenya and pooled according to the species in 1-25 mosquitoes per pool. RNA was isolated, libraries prepared and sequenced on Illumina platform. Low quality read filtering and adapter trimming was done by dual index filter and Trimmomatic analysis softwares. CLC Genomics workbench was then used to align the reads to NAKV reference genome. After filtering the unaligned reads, variant calling, phylogenetic analysis and viral RNA structure

predictions were performed. NAKV was detected in 17 pools; two pools comprised of *Culex spp* while the rest of the pools had *Mansonia spp*. A full genome (10,122 bp) NAKV was isolated in one pool while the rest of the pools had sequence lengths ranging from 744 bp to 9,888 bp. The near full genome (9,888 bp) had 28 SNVs and the full genome had 89 SNVs occurring in both the structural and non-structural regions of the comparator NAKV. BLAST analysis of the highly conserved NS5 region showed highest homology (99%) to NAKV of Uganda, followed by CuaCua virus (92%), Palm creek virus (82%), and *Culex flavivirus* (74%). Phylogenetic analysis of the full genome indicates that the virus is genetically distant from mosquito and tick borne group of human pathogenic flaviviruses. The observed structural variations can be an adaptation to the Kenyan environment. To our knowledge this is the first report of NAKV in Kenyan *Mansonia* and *Culex* mosquitoes.

## 142

### PORTABLE GENOMIC SURVEILLANCE OF ZIKA VIRUS IN BRAZIL

**Nuno R. Faria**<sup>1</sup>, Josh Quick<sup>2</sup>, Ingra Morales<sup>3</sup>, Julien Thézé<sup>1</sup>, Jaqueline Jesus<sup>4</sup>, Marta Giovanetti<sup>4</sup>, Marcio R. Nunes<sup>5</sup>, Ester C. Sabino<sup>3</sup>, Luis C. Alcantara<sup>4</sup>, Nick Loman<sup>2</sup>, Oliver G. Pybus<sup>1</sup>

<sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>University of Birmingham, Birmingham, United Kingdom, <sup>3</sup>University of Sao Paulo, Sao Paulo, Brazil, <sup>4</sup>FioCruz Bahia, Salvador, Brazil, <sup>5</sup>Evandro Chagas Institute, Ananindeua, Brazil

Zika virus (ZIKV) transmission in the Americas was first confirmed in May 2015 in Northeast Brazil. Brazil has the highest number of reported ZIKV cases worldwide as well as the greatest number of cases associated with microcephaly and other birth defects. Following the initial detection of ZIKV in Brazil, 47 countries and territories in the Americas have reported local ZIKV transmission, with 24 of these reporting ZIKV-associated severe disease. Yet the origin and epidemic history of ZIKV in Brazil and the Americas remain poorly understood, despite the value of such information for interpreting past and future trends in reported microcephaly. To address this we generated 54 complete or partial ZIKV genomes, mostly from Brazil, and report data generated by the ZIBRA project - a mobile genomics lab that travelled across Northeast (NE) Brazil in 2016. One sequence represents the earliest confirmed ZIKV infection in Brazil. Joint analyses of viral genomes with ecological and epidemiological data estimate that ZIKV epidemic was present in NE Brazil by March 2014 and likely disseminated from there, both nationally and internationally, before the first detection of ZIKV in the Americas. Estimated dates of the international spread of ZIKV from Brazil indicate the duration of pre-detection cryptic transmission in recipient regions. NE Brazil's role in the establishment of ZIKV in the Americas is further supported by geographic analysis of ZIKV transmission potential and by estimates of the virus' basic reproduction number.

## 143

### DYNAMICS OF ANTI-ZIKA VIRUS IGM ANTIBODY IN A PROSPECTIVE COHORT STUDY

**Kate Doyle**<sup>1</sup>, Eli S. Rosenberg<sup>2</sup>, Gabriela Paz-Bailey<sup>1</sup>, Emma Little<sup>1</sup>, Liore Klein<sup>3</sup>, Jorge Munoz-Jordan<sup>1</sup>, Laura Adams<sup>1</sup>, Matt Lozier<sup>1</sup>, Tyler M. Sharp<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Protection, Atlanta, GA, United States, <sup>2</sup>Emory University, Atlanta, GA, United States, <sup>3</sup>Caduceus Healthcare, Inc., San Juan, PR, United States

The duration of detection of anti-Zika virus (ZIKV) IgM antibody is necessary to inform diagnostic testing algorithms. CDC recommends testing serum specimens collected 4 days to 12 weeks after symptom onset or ZIKV exposure for anti-ZIKV IgM. With interim data from an ongoing cohort in Puerto Rico of patients with ZIKV infection confirmed by RT-PCR, we estimated the time to loss of detection of anti-ZIKV IgM antibody. Index patients were recruited following detection of ZIKV RNA in serum or urine specimens. Index-patients' household contacts were also

tested, and if positive by RT-PCR, were invited to join the cohort. Follow-up visits occurred every week for four weeks and at 2, 4, and 6 months post-enrollment. Serum collected at each visit was tested by anti-ZIKV IgM antibody capture enzyme-linked immunosorbent assay (MAC ELISA). Data from participants that reported a recent illness consistent with ZIKV disease were used to determine time in days post symptom onset to loss of anti-ZIKV IgM detection. We used Weibull regression models to address interval censoring and estimate medians and percentiles. Of 270 symptomatic cohort participants, 139 (51.5%) were female, including 9 pregnant women, and median age was 36 years (range: 9 months-83 years). Anti-ZIKV IgM antibody was detected in 263 (97.4%) participants, and through January 31, 2017, 114 (43.4%) had become IgM-negative. Median time-to-loss of anti-ZIKV IgM was estimated as 117.5 days post symptom onset (95%CI: 107.4, 127.7), and the 75th percentile was 169.9 days (95%CI: 153.7, 186.1). Twelve weeks after illness onset, 69% of participants still had detectable anti-ZIKV IgM. No significant differences in duration of detection of anti-ZIKV IgM were observed by age or sex. Our data suggest nearly all symptomatic ZIKV-infected individuals develop anti-ZIKV IgM antibody. However, as few pregnant women were included, it is unclear if these findings can be generalized. The observed estimates for the duration of detection of anti-ZIKV IgM antibody are consistent with current CDC testing recommendations.

## 144

### CHARACTERISTICS OF RASH IN PATIENTS WITH ZIKA VIRUS INFECTION, PUERTO RICO, 2016

**Eduardo Cordero**, Kathleen B. Kopel, Luzeida Vargas, Ivan Iriarte, Luisa I. Alvarado

*Ponce Health Sciences University/Saint Luke's Episcopal Hospital, Ponce, PR, United States*

Zika virus is a flavivirus that is spread most frequently by the bite of an infected *Aedes* species mosquito, and presents with symptoms such as rash, fever, arthralgia, and nonpurulent conjunctivitis. ZIKV is a cause of microcephaly and has been associated with other congenital birth defects if spread from a pregnant mother to its fetus. Since ZIKV was first identified in the Americas in 2015, there has been a paucity of data describing the characteristics of rash in infected individuals. In this cross-sectional study, we describe the characteristics of the rash of patients with ZIKV infection at the time of presentation to the Emergency Room. Patients with rash were enrolled from the Sentinel Enhanced Dengue Surveillance System (SEDSS), a surveillance system that recruits patients presenting to an emergency department or out-patient clinic with fever, history of fever for <7 days, rash and arthralgia, or rash and nonpurulent conjunctivitis, and follows them through their illness. Blood, urine, nasopharyngeal and oropharyngeal specimens are collected and tested by RT-PCR and immunodiagnostic methods as appropriate for Zika and other infectious agents. Fifteen out of the 24 recruited patients were confirmed to be PCR positive for ZIKV. Rash was the initial symptom in only 2 (13.3%) patients, while a headache was the most common initial symptom (5 of 15 [33.3%]). The number of days between the start of symptoms other than rash and rash was a median of 2 days. The body parts where the rash most commonly started were the face in 6 (40%) and chest in 6 (40%). All 15 (100%) patients had rashes that were erythematous, maculopapular, generalized, blanching, and confluent. Rash itchiness was present in 11 (73.3%) patients compared to 4 of 9 (44.4%) of the negative cases ( $p=0.212$ ). The most common patterns of progression of the rash were cephalocaudal 5 (33.3%) and centrifugal 5 (33.3%). Correctly identifying the rash of a ZIKV infection can be useful in differentiating it from other viral diseases with similar presentation.

## 145

### IVERMECTIN INHIBITORY EFFECTS ON ZIKA VIRUS AND CHIKUNGUNYA VIRUS INFECTION

**Taweewun Hunsawong**<sup>1</sup>, Jindarat Lohachanakul<sup>1</sup>, Sarunyou Chusri<sup>2</sup>, Butsaya Thaisomboonsuk<sup>1</sup>, Kathryn B. Anderson<sup>1</sup>, Alden L. Weg<sup>1</sup>, Louis R. Macareo<sup>1</sup>, Damon W. Ellison<sup>1</sup>

<sup>1</sup>*U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand,* <sup>2</sup>*Faculty of Medicine, Prince of Songkla University, Songkla, Thailand*

Zika virus (ZIKV) and chikungunya virus (CHIKV) are co-circulating in many countries including Thailand. Both viruses are transmitted to humans through the bite of *Aedes* mosquitoes. Outbreaks of these viruses have sporadically occurred and there are no vaccines or antiviral treatments available for either of these potentially devastating diseases. Ivermectin is an anti-parasitic drug which is approved for use in humans at a concentration of 150-200 µg/Kg which has been shown in pharmacokinetic studies to correspond to serum concentrations in humans of 7-95 ng/ml. In this study, we investigated the potency of ivermectin to inhibit ZIKV (Asian genotype: SV127/14) and CHIKV (Vaccine strain clone 181) infections *in vitro*. Two mammalian cell lines (vero and LLC-MK2) and a mosquito cell line (C6/36) were treated with various concentrations of ivermectin and inoculated with ZIKV or CHIKV at MOI of 0.1. We found that ivermectin was able to reduce the number of plaques of ZIKV and CHIKV in both cell types. No impact on cytopathic effect in LLC-MK2 and C6/36 cell lines was observed but an inhibitory effect during virus penetration/replication was seen in both mammalian and mosquito cell lines. Importantly, the half maximal inhibitory concentration (IC50) of ivermectin for ZIKV (618 ng/ml) and CHIKV (2,360 ng/ml) infections in vero cells would fall within the range of serum concentrations previously deemed to be safe by the Food and Drug Administration for mass-drug administration for parasitic infections. These data suggest that ZIKV is more sensitive to ivermectin than CHIKV. The results from this study indicate a potential use for ivermectin as a treatment option for ZIKV and CHIKV.

## 146

### PASSIVE IMMUNIZATION AND CHALLENGE IN AN AG129 MOUSE MODEL OF YELLOW FEVER VIRUS INFECTION

**Kevin B. Walters**, Laurie A. Queen, Amy Sands, Kimberly Hagelin, Rebecca Leggieri, Travis J. Gahman, Nelson Martinez, Fusataka Koide

*Department of Infectious Disease Research, Drug Development, Southern Research Institute, Frederick, MD, United States*

Yellow fever virus (YFV) is a mosquito-borne Flavivirus that can cause hemorrhagic fever and liver disease. Despite the availability of an immunogenic and protective vaccine, YFV causes thousands of infections annually. Recent outbreaks have been exacerbated by vaccine shortages indicating the need for development of additional counter measures. Here we present a lethal mouse model of YFV infection that is suitable for testing both vaccine and therapeutic counter measures under BSL-2 containment. The fifty percent lethal dose of the attenuated YFV strain 17D-204 was determined in mice deficient in interferon  $\alpha/\beta$  and  $\gamma$  receptors (AG129). Groups of five mice received a single intraperitoneal (i.p.) inoculation of YFV-17D-204 ranging from 10 to 5x10<sup>5</sup> plaque forming units (PFU)/mouse and were observed daily for signs of morbidity. The majority of mice experienced drastic weight loss preceding euthanasia. Some mice developed neurological symptoms including weakness in limbs and limb paralysis. Overall, eight animals survived until the conclusion of the study; however, all had signs of infection including viral RNA in serum and tissues as detected by quantitative RT-PCR. To determine the immunogenicity of the World Health Organization's vaccine reference strain YFV 17D-168-73, groups of wild-type 129 mice were vaccinated by i.p. injection with 1,000 PFU. An additional group served as a naïve control. Serum collected following vaccination was used to determine

neutralizing antibody titers by plaque reduction neutralization test (PRNT). All mice vaccinated with YFV 17D-168-73 seroconverted to YFV. Serum with the five lowest PRNT50 titers were transferred into AG129 donor mice. The day after transfer, mice were challenged with a lethal dose of YFV 17D-204. Mice that received serum from unvaccinated animals developed lethal disease characterized by rapid weight loss and high viral loads in the brain. Mice that received serum from mice vaccinated with the YFV 17D-168-73 were protected from challenge. This model can be used for the evaluation of medical counter measures to YFV infection.

## 147

### **DISTINGUISHING SECONDARY DENGUE VIRUS INFECTION FROM ZIKA VIRUS INFECTION WITH PREVIOUS DENGUE BY A COMBINATION OF THREE SEROLOGICAL TESTS**

**Wen-Yang Tsai<sup>1</sup>**, Han Ha Han Ha<sup>1</sup>, Carlos Brites<sup>2</sup>, Jih-Jin Tsai<sup>3</sup>, Jasmine Tyson<sup>1</sup>, Celia Pedrosa<sup>4</sup>, Jan Felix Drexler<sup>5</sup>, Angel Balmaseda<sup>6</sup>, Eva Harris<sup>7</sup>, Wei-Kung Wang<sup>1</sup>

<sup>1</sup>Department of Tropical Medicine, Medical Microbiology and Pharmacology, John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, United States, <sup>2</sup>LAPI-Laboratório de Pesquisa em Infetologia - School of Medicine, Federal University of Bahia, Salvador, Brazil, <sup>3</sup>Division of Infectious Diseases, Department of Internal Medicine and Tropical Medicine Center, Kaohsiung Medical University Hospital, Department of Medicine, College of Medicine and Center for Dengue Fever Control and Research, Kaohsiung Medical Univer, Kaohsiung, Taiwan, <sup>4</sup>LAPI-Laboratório de Pesquisa em Infetologia - School of Medicine, Federal University of Bahia, Salvador, Brazil, <sup>5</sup>University of Bonn Medical Centre, Institute of Virology, German Centre for Infection Research, Bonn, Germany, <sup>6</sup>National Virology Laboratory, National Center for Diagnosis and Reference, Ministry of Health, Managua, Nicaragua, <sup>7</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, CA, United States

The explosive spread of Zika virus (ZIKV) and associated microcephaly present an urgent need for sensitive and specific serodiagnostic tests, particularly for pregnant women in dengue virus (DENV)-endemic regions. Recent reports of enhanced ZIKV replication by dengue-immune sera have raised concerns about the role of previous DENV infection on the risk and severity of microcephaly and other ZIKV complications. In this study, we established enzyme-linked immunosorbent assays (ELISAs) based on ZIKV and DENV non-structural protein 1 (NS1) to test convalescent-phase and post-convalescent-phase serum/plasma samples from reverse-transcription-polymerase chain reaction-confirmed-cases including 20 primary ZIKV, 20 ZIKV with previous dengue, 54 secondary DENV, and 16 primary DENV1 infections. ZIKV-NS1 IgM and IgG ELISAs combined can detect ZIKV infection with a sensitivity of 95% and specificity of 60%. ZIKV-NS1 IgG cross-reactivity by samples from cases with secondary DENV infection ranged from 67% to 28% (within 1 month to 1-2 years post-onset of symptoms, respectively). Addition of DENV1-NS1 IgG ELISA can distinguish primary ZIKV infection; the ratio of absorbance of ZIKV-NS1 to DENV1-NS1 IgG ELISA can distinguish ZIKV with previous DENV and secondary DENV infections with a sensitivity of 87% and specificity of 81.3%. An algorithm for ZIKV serodiagnosis based on three simple ELISAs is proposed to distinguish primary ZIKV, ZIKV with previous dengue, and secondary DENV infections; this could be applied to serological diagnosis for ZIKV vs DENV clinical infections, serosurveillance, monitoring ZIKV infection during pregnancy and in studies to understand the epidemiology, pathogenesis and complications of ZIKV in dengue endemic regions.

## 148

### **EVALUATION OF ZIKA CASES IN ACTIVE DUTY U.S. MILITARY AND DEPENDENTS**

**Mark P. Simons**, Susana Widjaja, Victor A. Sugiharto, Todd E. Myers, Maya Williams

*Naval Medical Research Center, Silver Spring, MD, United States*

The Naval Infectious Diseases Diagnostic Laboratory (NIDDL) is a DoD Clinical Laboratory Improvement Program (CLIP/CLIA) and College American Pathologist (CAP) accredited laboratory that serves as a reference clinical laboratory for the detection and identification of high-risk and emerging infectious diseases in support of joint services military treatment facilities (MTFs) across the globe. The NIDDL has been a major center for Zika virus (ZIKV) testing for the CONUS and OCONUS DoD healthcare facilities including the US Coast Guard since ZIKV was declared as a WHO emergency and began to impact military population in 2016. With the support from the CDC, the Triplex qRT-PCR that can detect ZIKV, dengue virus (DENV), and/or chikungunya virus (CHIKV) simultaneously was implemented to detect ZIKV in symptomatic cases. The CDC Zika IgM-capture ELISA and ZIKV PRNT were also applied to support ZIKV diagnosis. In addition to symptomatic cases, samples were also received from asymptomatic active duty members or their spouses who had traveled to endemic ZIKV areas or had unprotected sex. Of the 584 suspected ZIKV cases, 27 (4.6%) were confirmed ZIKV cases: 9.0% (15/167) symptomatic ZIKV cases, 1.9% (5/259) asymptomatic cases, and 4.4% (7/158) have no history provided. Four patients were pregnant at the time of diagnosis, one which was symptomatic and gave birth to a baby without microcephaly. Five of suspected ZIKV patients (3.0%) were confirmed to be DENV cases by Triplex qRT-PCR. The majority of ZIKV infections happened after the patients traveled to countries in Latin America, primarily Puerto Rico, Mexico, Jamaica, and Honduras. Two cases had previously traveled to Singapore. Phylogenetic analysis is in progress to characterize and compare the positive ZIKV cases. These findings present an initial assessment on the burden of Zika infections among DoD personnel and is the foundation for future studies to examine short and long-term clinical history in these cases.

## 149

### **CLINICAL AND EPIDEMIOLOGICAL FACTORS ASSOCIATED WITH ZIKA VIRUS INFECTION IN LEON, NICARAGUA, 2016-2017**

**Natalie M. Bowman<sup>1</sup>**, Filemon Bucardo<sup>2</sup>, Yaoska Reyes<sup>2</sup>, Matthew Collins<sup>1</sup>, Edwing Centeno<sup>2</sup>, Aravinda de Silva<sup>1</sup>, Sylvia Becker-Dreps<sup>1</sup>

<sup>1</sup>University of North Carolina Chapel Hill, Chapel Hill, NC, United States,

<sup>2</sup>Universidad Nacional Autonoma de Nicaragua-Leon, Leon, Nicaragua

Zika virus (ZIKV) is a flavivirus related to dengue that usually causes mild symptoms but was unexpectedly shown to cause severe congenital malformations like microcephaly in some infants born to women infected during pregnancy. Like dengue, ZIKV is spread by *Aedes* mosquitoes, it can also be sexually transmitted. The ZIKV epidemic arrived in Nicaragua in mid-2016. We conducted a cohort study of patients presenting to a health center with fever, rash, or conjunctivitis in Leon, Nicaragua, October 2016-February 2017. Acute ZIKV infection was diagnosed by PCR in blood, urine, or saliva. All participants completed a questionnaire about demographic and medical characteristics at baseline. We recruited 55 patients and detected ZIKV in 35 (64%). Median age was 22 years (range 2-75 years); 39% were under 18 years of age, and 69% were female. There was no significant difference in risk of ZIKV infection by age or sex. All 6 pregnant women enrolled were ZIKV-infected. History of prior dengue or chikungunya infection was not associated with ZIKV infection. Though not significant, water storage was associated with increased risk (OR 2.8, 95% CI 0.72, 12.02). There was a trend towards a protective effect of community spraying (OR 0.20, 95%CI 0.004, 1.84) but not personal bed net or repellent use. Recent sexual activity was not associated

with ZIKV infection. Rash was strongly associated with ZIKV infection (OR 13.50, 95%CI 2.19, 138.87) but fever (OR 0.24, 95%CI 0.02, 1.35) and conjunctivitis (OR 2.60, 95%CI 0.60, 11.30) were not. Retro-orbital pain (OR 0.19, 95%CI 0.04, 0.77) and myalgia (OR 0.19, 95%CI 0.03, 0.84) were associated with not having ZIKV. Total white blood cell counts were higher in ZIKV-infected subjects ( $p=0.03$ ), with a greater proportion of lymphocytes ( $p=0.005$ ); other cell lines were unaffected. Our findings are congruent with reports from other countries, confirming that rash and lack of fever are characteristic signs of ZIKV infection in the general population. Additionally, community-wide vector control campaigns stressing appropriate water storage and judicious use of insecticide may have a role in arbovirus epidemic control.

## 150

### DEVELOPMENT, CHARACTERIZATION, AND PRE-CLINICAL IMMUNOGENICITY AND EFFICACY OF A PURIFIED, INACTIVATED ZIKA VIRUS VACCINE (PIZV) CANDIDATE

Whitney Baldwin<sup>1</sup>, Holli Giebler<sup>1</sup>, Stephanie Sonnberg<sup>2</sup>, Kelly Bohning<sup>2</sup>, Janae Stovall<sup>3</sup>, Hetal Patel<sup>2</sup>, Yee Tsuey Ong<sup>3</sup>, Timothy Rindfleisch<sup>2</sup>, Jill Livengood<sup>1</sup>, Claire Huang<sup>3</sup>, Hansi Dean<sup>2</sup>

<sup>1</sup>Takeda Vaccines, Inc.; Centers for Disease Control and Prevention, Fort Collins, CO, United States, <sup>2</sup>Takeda Vaccines, Inc., Cambridge, MA, United States, <sup>3</sup>Centers for Disease Control and Prevention, Fort Collins, CO, United States

In 2015, clusters of Guillain-Barre Syndrome (GBS) in adults and microcephaly in newborns were temporally associated with Zika virus (ZIKAV) infection in Northern Brazil, prompting the World Health Organization (WHO) to declare ZIKAV a public health emergency of international concern (PHEIC). Takeda is responding to this global health emergency by developing a purified, inactivated vaccine for ZIKAV (PIZV). This report describes the generation of a ZIKAV pre-master virus seed (pre-MVS) and preclinical efficacy of PIZV derived from the pre-MVS. The pre-MVS was generated by amplifying a ZIKAV strain PRVABC59 isolate obtained from the CDC in Vero cells (P1), performing three rounds of plaque purification (P2-4), and twice amplifying in Vero cells (P5 and P6). Two pre-MVS clones were chosen for further pre-clinical development and analysis based on growth phenotype and genotype. Virus stocks amplified from the pre-MVS were purified and inactivated with formalin to generate the PIZV candidates. The PIZV candidates formulated with alum were immunogenic in CD1 mice. AG129 mice vaccinated with a low or high dose of PIZV candidates formulated with alum generated strong neutralizing antibodies against ZIKAV and were fully protected from lethal ZIKAV challenge. No weight loss or clinical signs of illness were observed in vaccinated mice, and none had detectable infectious viremia three days post challenge (PC). In contrast, challenge of all naïve mice resulted in high viremia on day 3 PC and morbidity/mortality between day 10 and 18 PC. Our results demonstrate that the PIZV candidates are highly efficacious against ZIKAV infection in the ZIKAV-susceptible AG129 mouse model.

## 151

### EVIDENCE OF HUMAN INFECTION BY A NEW MAMMARENAVIRUSES ENDEMIC TO SOUTHEASTERN ASIA

Veasna Duong<sup>1</sup>, Kim Blasdel<sup>1</sup>, Marc Eloit<sup>2</sup>, Fabrice Chretien<sup>2</sup>, Sowath Ly<sup>1</sup>, Vibol Hull<sup>1</sup>, Vincent Deubel<sup>1</sup>, Serge Morand<sup>3</sup>, Philippe Buchy<sup>1</sup>

<sup>1</sup>Institut Pasteur in Cambodia, Phnom Penh, Cambodia, <sup>2</sup>Institut Pasteur, Paris, France, <sup>3</sup>Institut des Sciences de l'Evolution, Montpellier, France

Southeast Asia is a recognised hotspot for emerging infectious diseases, many of which have an animal origin. Although known pathogens account for a large proportion of human infectious diseases in the region, a substantial number of febrile illnesses have an unknown aetiology. Mammarenavirus infections contribute significantly to the human disease burden in both Africa and the Americas, but to date only two mammarenaviruses, the widely spread lymphocytic choriomeningitis virus

and the Wenzhou virus recently described in Chinese rodents, are recorded from Asia. Here we report the presence of a novel mammarenavirus and of a genetic variant of the Wenzhou virus and provide evidence of mammarenavirus-associated human disease in Asia. The association of these viruses with widely distributed mammal species, commonly found in human dwellings and in peridomestic habitats, adds to the known aetiologies of infectious diseases for this region and illustrates the potential for widespread zoonotic transmission.

## 152

### ZIKA VIRUS: A SYSTEMATIC REVIEW AND META-ANALYSIS IN EPIDEMIOLOGY, CLINICAL MANIFESTATIONS, AND OUTCOMES

Zika virus is a mosquito-borne flavivirus that was recently declared as a global public health emergency due to its spreading around the world and its association with serious congenital malformations and neurological disorders. We aim to report the total Zika infected cases and the geographic distribution of those cases. We also intend to provide a thorough description of the epidemiological characteristics, signs and symptoms, biomarkers, outcomes, complications and route of transmission of Zika virus. We conducted a systematic review of the scientific literature, and meta-analyzed data that were sufficiently comparable. Data was obtained through an electronic search in 8 main databases, and the references lists of all included articles were also searched for relevant articles. Overall, this review included 258 articles. Most included articles were case reports and cross sectional studies, written in English language, and published between 2015 and 2016. The total number of confirmed, suspected, and probable cases of Zika virus infection was 54663. Confirmed cases span over 79 countries, with the highest frequency being in the region of the Americas. Excluding neonates with microcephaly, most patients were females and had a mean age of 35.8 years. Most common method of transmission was by mosquitoes, followed by sexual contact and blood transfusion. While most common clinical symptoms included skin rash, fever, arthralgia, myalgia, and headache, conjunctivitis and the most common lab abnormalities were leukopenia and thrombocytopenia. The medical literature reported 1018 cases of microcephaly, 288 Guillain-Barré Syndrome, and only one case of encephalitis in association with Zika virus infection. Death occurred in 17 cases with Zika virus infection, with a mean age of 50.5 years, and most of them had underlying diseases. Due to its serious complications, and since no cure or vaccine are available, Zika virus remains an important threat to the public health that necessitates a wide cooperation on a global scale in developing prevention and managing strategies.

## 153

### SPATIO-TEMPORAL ANALYSIS OF EBOLA VIRUS DISEASE IN SIERRA LEONE, MAY 2014-SEPTEMBER 2015

Adrienne Epstein, Marcia Castro

Harvard T.H. Chan School of Public Health, Boston, MA, United States

The 2014-2015 Ebola virus disease (EVD) outbreak was unprecedented, affecting ten countries, with the greatest burden of cases and deaths

occurring in Guinea, Sierra Leone, and Liberia. Over two years, Sierra Leone experienced 14,124 suspected and/or confirmed cases and 3,956 deaths. The timing and location of these cases, however, was not homogenous. We aim to measure the location and timing of EVD clustering using chiefdom-level data to shed light on the utility of geospatial tools in infectious disease surveillance. A total of 8,358 confirmed EVD cases were documented from May 23, 2014 to September 13, 2015 by the Sierra Leonean Ministry of Health and Sanitation. Spatial scan statistics were used to describe the trajectory of EVD clusters over space and time. Areas of high and low clustering were detected using cases aggregated into one- and two-week periods. Four clusters of high transmission were identified, the first of which was detected on June 20, 2014, three months prior to the deployment of the United Nations Mission for Emergency Ebola Response. Three regions of low transmission clustering were detected, beginning in January 2015 and persisting until the epidemic's end on September 13, 2015. The use of spatial scan statistics to identify clustering of EVD in Sierra Leone successfully described the timing and spread of the virus across the country. Disease surveillance that incorporates freely available geospatial tools to prospectively analyze routine data recorded by the health system can contribute to deploy early emergency responses, and therefore thwart the spread of infectious agents.

## 154

### DEVELOPMENT OF HIGHLY SENSITIVE SEROLOGICAL TESTS FOR REOVIRUS SEROPREVALENCE

**Anna Uehara**, Shailendra Mani, Danielle Anderson, Lin-Fa Wang  
*Duke-NUS Medical School, Singapore, Singapore*

Luciferase immunoprecipitation system (LIPS), offers the advantage of using easily produced crude cell lysate containing viral antigens that can be used directly for antibody detection in patient serum samples. This highly sensitive and quantitative serological assay is also an affordable and rapid alternative to conventional serology methods. We have developed the LIPS platform for two members of the pteropine reovirus family, the Melaka virus and Nelson Bay virus, to utilize for a seroprevalence study in Singapore, which is currently understudied and unknown. This study will help us to not only implement an efficient serology platform for use in the Singapore region, but also to enhance our capability in clinical research to differentially diagnose various diseases.

## 155

### DEMOGRAPHIC DETERMINANTS OF ANTI-POLIOVIRUS TYPE 3 ANTIBODIES AMONG ORALLY IMMUNIZED INDIAN CHILDREN

**Saravanakumar Puthupalayam Kaliappan**<sup>1</sup>, Jasmin Helan Prasad<sup>1</sup>, Sidhartha Giri<sup>1</sup>, Ira Praharaj<sup>1</sup>, Sudhir Babji<sup>1</sup>, Jacob John<sup>1</sup>, Nicholas Grassly<sup>2</sup>, Jayaprakash Muliyl<sup>1</sup>, Gagandeep Kang<sup>1</sup>  
<sup>1</sup>*Christian Medical College, Vellore, India*, <sup>2</sup>*Imperial College, London, United Kingdom*

Oral vaccines perform poorly in developing countries. The oral polio vaccine (OPV) is less immunogenic in developing countries. In India, the per-dose vaccine efficacy of OPV has been estimated at 21% as compared to 65% in industrialized countries and hence more doses of OPV are necessary to protect children in India compared to children in developed countries. This poor performance is associated with various factors like maternal antibodies, age at vaccination, malnutrition and micronutrient deficiencies, persistent exposure to pathogens in the environment and tropical enteropathy. Immunogenicity is lowest for serotype 3 among the three poliovirus serotypes in children vaccinated with OPV. We examined the demographic determinants of anti-poliovirus type 3 antibodies among children of age 1-59 months in Vellore, Southern India. We pooled data from three studies that had documented neutralizing antibodies (NAb) titres to poliovirus type 3 (PV3) and basic demographic data of 9518 children residing in rural and urban parts of Vellore. Of 9518 children

analysed at a mean age of 9.2 (standard deviation [SD]-7.3) months, 86% (95% confidence interval (CI): 85.3% - 86.7%) had protective antibodies to PV3. The seroprevalence was 87.33% (86.36% - 88.24%) for males and 84.68% (83.61% - 85.70%) for females. The number of OPV doses received was the main determinant of seroprevalence; children were twice likely to be seropositive for one dose increase of OPV. In multivariable logistic regression analysis OPV, male sex and age were independently associated with seropositivity while place of residence was not (Odds Ratios (OR): 1.87(95% CI: 1.75 - 2.00) per dose of OPV, 1.23 (1.09 - 1.39), 0.95 (0.92 - 0.97) and 1.07 (0.93 - 1.23) respectively). Though immunisation coverage in India has improved, immunogenicity to oral polio vaccine remains lower than in industrialised countries. Understanding the causes that play a role in poor performance of oral vaccines remains important for developing nations.

## 156

### ZIKA VIRUS INFECTION AND CHIKUNGUNYA FEVER OUTBREAKS IN RIO GRANDE DO SUL, BRAZIL, 2014-2016

**Ana B. Veiga**<sup>1</sup>, Tatiana S. Gregianini<sup>2</sup>, Tani Ranieri<sup>3</sup>, Cátia Favreto<sup>3</sup>, Gabriela Tumioto-Giannini<sup>2</sup>

<sup>1</sup>*Universidade Federal de Ciências da Saúde de Porto Alegre (UFCSA), Porto Alegre, Brazil*, <sup>2</sup>*Laboratório Central de Saúde Pública do Estado do Rio Grande do Sul, IPB-LACEN/RS, Secretaria de Saúde do Estado do Rio Grande do Sul – SES/RS, Porto Alegre, Brazil*, <sup>3</sup>*Centro Estadual de Vigilância em Saúde – CEVS, Secretaria de Saúde do Estado do Rio Grande do Sul – SES/RS, Porto Alegre, Brazil*

In the last years Brazil has experienced outbreaks of important arboviral diseases, including Yellow Fever, Dengue, Chikungunya and Zika. Of continental size and with a population of approximately 207 million people, with highly urbanized areas, the country's conditions favor the spreading of mosquitoes such as *Aedes aegypti* and *A. albopictus*, vectors of the above-mentioned viral diseases. The epidemiology of arboviral diseases varies throughout the country, with an increase in prevalence in all regions. Rio Grande do Sul (RS), the Southernmost state in Brazil, was free of such diseases until 2010, when the first autochthonous case of Dengue Fever was reported. Since then, not only DENV but also Chikungunya virus (CHIKV) and Zika virus (ZIKV) have been circulating in the state. This study reports the epidemiology of Chikungunya fever and Zika virus infection in RS from 2014 to 2016. The number of confirmed CHIKV cases increased from 7 to 79 in the period, most of them consisting of imported cases; autochthonous infections were reported only in 2016, with 5 cases. As for ZIKV, the first confirmed case in RS was in 2015 with a patient that had traveled to Recife, Northeast Brazil, where ZIKV had a high prevalence. In 2016, 86 cases of ZIKV were confirmed in RS, 44 of which were considered autochthonous infections. Furthermore, 2 cases of microcephaly due to Congenital Zika Syndrome were reported in the period in babies born from infected mothers. In conclusion, this study provides detailed information about the first cases of CHIKV and ZIKV in Rio Grande do Sul, contributing for arboviruses surveillance in Brazil and for disease control and prevention.

## 157

### THE MOLECULAR EPIDEMIOLOGY AND SPATIAL DYNAMICS OF HUMAN PARAINFLUENZA SEROTYPE 3 IN PERU

**Armando Torre**<sup>1</sup>, Mariana Leguia<sup>1</sup>, Suman Das<sup>2</sup>, Y. Tan<sup>2</sup>, Martha Nelson<sup>3</sup>, Simon Pollett<sup>4</sup>, Simon Pollett<sup>5</sup>

<sup>1</sup>*U.S. Naval Medical Research Unit-6, Callao, Peru*, <sup>2</sup>*J. Craig Venter Institute, Rockville, MD, United States*, <sup>3</sup>*National Institutes of Health, Bethesda, MD, United States*, <sup>4</sup>*Viral Diseases Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States*, <sup>5</sup>*Marie Bashir Institute, University of Sydney, NSW, Australia*

Human parainfluenza viruses (HPiVs) cause almost one third of lower respiratory tract infections and pose considerable burdens on the most vulnerable, who are infants, immunocompromised and chronically-ill

patients. The most prevalent serotype identified in these groups of people is HPIV-3. However, despite being frequently identified there is insufficient genomic data to clearly understand the evolution and temporo-spatial transmission dynamics of HPIV, particularly in low and middle-income countries such as Peru. Redressing this knowledge gap is critical for vaccine development and public health preparedness. We therefore undertook whole genome sequencing of 60 HPIV-3 positive respiratory specimens obtained from influenza-like illness surveillance between 2007 and 2012 in Lima (n =3), Piura (n=41) and Loreto (n =16), three ecologically and demographically distinct locations within Peru. These data were aligned with background sequence data from GenBank to yield hemagglutinin-neuraminidase gene (n = 545) and whole genome (n = 118) datasets. Recombinants were removed after screening with the RDP-4 software. Maximum-likelihood phylogenies were inferred using a GTR+I+G substitution model in the RAxML package. We found ample evidence of frequent viral diffusion in and out of Peru and extensive viral traffic between Latin America and other regions around the globe. There was some evidence of regional HPIV-3 circulation within South America, including viral traffic between Argentina and Peru. We also identified spatial clustering of HPIV-3 strains by location within Peru, indicating that Peruvian HPIV-3 epidemics are at least semi-localized. While the lack of data from Lima limited conclusions of fine-scale transmission dynamics between Peruvian locales, the mixing of data from the geographically and functionally distant locales of Piura and Loreto supported the rapid dispersal of this virus within a single country. Our findings indicate HPIV-3 is a spatially fluid virus in the tropics, with widespread diffusion on multiple spatial scales driven by human mobility.

## 158

### ISOLATION AND CHARACTERIZATION OF BUKAKATA ORBIVIRUS, A NOVEL VIRUS FROM A UGANDAN BAT, AND ASSOCIATED PULMONARY PATHOLOGY IN EXPERIMENTALLY INFECTED JAMAICAN FRUIT BATS (*ARTIBEUS JAMAICENSIS*)

Anna C. Fagre<sup>1</sup>, Robert Kityo<sup>2</sup>, Justin Lee<sup>1</sup>, Eric Mossel<sup>3</sup>, Mary Crabtree<sup>3</sup>, Betty Nalikka<sup>2</sup>, Teddie Nakayiki<sup>2</sup>, Julian Kerbis<sup>4</sup>, Amy Gilbert<sup>5</sup>, Nicholas Bergren<sup>1</sup>, Luke Nyakarahuka<sup>6</sup>, Julius Lutwama<sup>7</sup>, Mark Stenglein<sup>1</sup>, Alexandria Byas<sup>1</sup>, Ashley Malmlov<sup>1</sup>, Lauren Rice<sup>1</sup>, Barry Miller<sup>3</sup>, Tony Schountz<sup>1</sup>, Rebekah Kading<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Makerere University, Department of Biological Sciences, Kampala, Uganda, <sup>3</sup>Centers for Disease Control and Prevention, Division of Vector-borne Diseases, Arbovirus Diseases Branch, Fort Collins, CO, United States, <sup>4</sup>The Field Museum of Natural History, Chicago, IL, United States, <sup>5</sup>United States Department of Agriculture, Animal and Plant Health Inspection Service, Fort Collins, CO, United States, <sup>6</sup>Makerere University, Department of Biosecurity, Ecosystems, and Veterinary Public Health, Kampala, Uganda, <sup>7</sup>Uganda Virus Research Institute, Entebbe, Uganda

In 2013, a novel orbivirus (*Reoviridae: Orbivirus*) was isolated from an Egyptian fruit bat (*Rousettus aegyptiacus*) in Uganda. Preliminarily named "Bukakata orbivirus" after the region where the infected bat was captured, this virus is the fourth identified orbivirus of bats. The genomes of all four bat orbiviruses (Bukakata, Ife, Fomede, and Japanaut viruses) were sequenced to assess their phylogenetic placement within the genus *Orbivirus*, and develop hypotheses regarding virus-vector associations. Whole genomes of all four viruses were sequenced using an Illumina platform and assembled *de novo*. Phylogenetic analysis placed Fomede and Bukakata orbiviruses in the tick-borne clade, and Japanaut and Ife in the mosquito/*Culicoides* clade. To begin studying the effect of infection with Bukakata orbivirus on a bat host, three male Jamaican fruit bats (*Artibeus jamaicensis*) were inoculated intraperitoneally with 5.3 log<sub>10</sub> pfu Bukakata orbivirus and monitored daily for signs of clinical disease. On day 12, all three bats were diffusely hyperemic and tachypneic and, thus, were humanely euthanized. Histopathologic lesions of perivascular inflammation, hemorrhage and edema were present in varying degree of severity in the liver, lung and kidney of all three bats. Additional lesions included meningeal hemorrhage in two of

the bats and evidence suggestive of early hepatic vasculitis in the other. Eosinophilic and suppurative gastroenteritis affected all bats with one containing intraluminal bacilli, suggesting secondary bacterial infection. Immunohistochemistry and qPCR will be performed to assess relative abundance of virus in various organ systems to optimize future analyses. Future experimental infections will be performed to monitor temperature, physiological and immune parameters, virus shedding and viremia throughout the course of infection. These preliminary data are critical in the assessment of the potential role of bats as reservoirs for arboviruses.

## 159

### FACTORS INVOLVED IN HUMAN INFLUENZA VIRUS ISOLATION USING MDCK CELL CULTURE FROM SOUTH AND SOUTHEAST ASIAN SURVEILLANCE SPECIMENS

Chuanpis Ajariyakhajorn, Taweewun Hunsawong, Duangrat Mongkolsirichaikul, Thipwipha Phonpakobsin, Kittinun Hussem, Butsay Thaisomboonsuk, Anderson B. Kathryn, Alden L. Weg, Louis R. Macareo, Chonticha Klungthong, Damon W. Ellison

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Surveillance for influenza viruses is required for monitoring of influenza virus activity, preparedness for the upcoming season and evaluation of vaccine efficacy. USAMD-AFRIMS has conducted influenza surveillance in Bhutan, Nepal, Philippines, Maldives and Thailand since 2008. Real-time RT-PCR and virus isolation using Madin-Darby canine kidney (MDCK) cell culture are regularly used to detect and classify influenza virus subtypes. Here, we investigated potential factors that may affect the success of influenza virus isolation. Among 5,628 positive RT-PCR samples, 3,427 (60.9%) were successfully isolated and identified by hemagglutination inhibition assay. The positive virus isolation rate of influenza B was significantly higher than that of influenza A (68.3% versus 54.6%). 52.3% of RT-PCR positive specimens for influenza A were H1N1 and 47.4% were H3N2. The isolation rate for influenza A subtypes differed significantly, with an isolation rate of 65.5% for H1N1 and 53.8% for H3N2. Among influenza B isolates, B/Brisbane was the most common subtype (46.8%), then B/Massachusetts (31.3%). Rates of isolation increased with lower cycle-to-threshold values (Ct) from RT-PCR, which translates to higher viral load. The rates of influenza A virus isolation in high (Ct ≤ 20), moderate (20 < Ct < 25), low moderate (26 < Ct < 30) and low viral content (Ct ≥ 30) were 79.3%, 67.7%, 40.8% and 12.1%, respectively. For influenza B virus, isolation rates in high, moderate, low moderate and low viral content were 95.8%, 84.2%, 55.6% and 19.8%, respectively. One possible explanation for these results is that MDCK cells are more susceptible to influenza B than influenza A at all titers of viral inoculum. The relatively low isolation rate (60.9%) compared to RT-PCR might due to decreasing MDCK permissiveness with a high number of cell passages. Viral genetic differences may play an important role, as we have seen growth curve differences between subtypes at the same TCID<sub>50</sub>. Information from this study can be used to improve influenza virus isolation rates for influenza surveillance and vaccine development efforts.

## 160

### AVIAN INFLUENZA EXPOSURE IN YOUNG THAI MALES FROM SUPHANBURI PROVINCE OF THAILAND

Nattaya Ruamsap, Patchariya Khantapura, Siriphan Gonwong, Nuanpan Khemnu, Thippawan Chuenchitra, Dilara Islam, Brett E. Swierczewski, Carl J. Mason

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Highly pathogenic avian influenza A H5N1 virus outbreaks in Thailand resulted in human deaths during 2004-2006. Suphanburi Province reported the highest cumulative number of H5N1 poultry outbreaks in the country. The high density of rice crops and large number of free-grazing ducks in the Province are recognized as risk factors for avian to human H5N1 transmission. In this study, we determined seroprevalence of H5N1 virus exposure among Royal Thai Army recruits whose place of

birth and residence was located in Suphanburi (high-risk area of H5N1 exposure) as compared to recruits from Bangkok where has no report of H5N1 outbreak (low-risk area of H5N1 exposure). A total of 1,200 recruit sera collected during 2001-2002, 2004-2005, and 2010-2011 were analyzed to represent periods superseding, during, and following H5N1 human-case outbreaks in Thailand. H5N1 seropositivity by enzyme-linked immunosorbent assay (ELISA) was not indicated for any period evaluated in either province. Weak reactivity to A/Duck/Hong Kong/820/80 (H5N3) and A/Hong Kong/156/97 (H5N1) strains was displayed in 4 of 1,200 sera (0.3%) by hemagglutination inhibition assay. All samples were also measured for IgG antibody specific to seasonal influenza A (H1N1 and H3N2) using a commercial ELISA kit and 1,149 of 1,200 sera (95.8%) were seropositive. The seropositivity was significantly associated with study area, time periods (2001-2002 to 2010-2011), and residence area ( $p$  value < 0.05). The time period was significantly associated with IgG seropositivity by multivariate analysis (OR 8.4; 95% CI, 3.1 - 22.7 for 2004-2005, OR 21.3; 95% CI, 4.9 - 92.7 for 2010-2011). The IgG antibody prevalence of seasonal influenza A increases with later time period. The detectable antibody concentration was slightly higher in Bangkok than in Suphanburi. A high prevalence of seasonal influenza A was exhibited in this study but there was no serologic evidence of H5N1 infection, demonstrating that there were no cross-reacting between seasonal and avian influenza antibodies among this population.

## 161

### CHARACTERIZATION OF NOVEL NATURAL RNA VIRUSES OF THE AFRICAN MALARIA MOSQUITO, *ANOPHELES COLUZZII*

**Ferdinand Nanfack Minkeu**, Christian Mitri, Emmanuel Bischoff, Etienne Simon-Loriere, Kenneth Vernick

*Institut Pasteur, Paris, France*

Little is known about *Anopheles* mosquito interactions with arboviruses and other RNA viruses. Most research to date on *Anopheles* host-pathogen interactions and immunity has focused on *Plasmodium*, which has led to a relative lack of study of *Anopheles* and viruses. Only one arbovirus is known to be consistently transmitted by *Anopheles* mosquitoes, the alphavirus o'nyong-nyong. Culicine mosquitoes appear to be the major arbovirus vectors, although for unknown reasons because anthropophilic anophelines bite the same viremic hosts. In addition, mosquitoes are colonized by a largely undescribed natural virome with unknown potential to influence biology and immunity of mosquito vector populations. These observations pose the question of what it would require for other arboviruses to adapt to anopheline mosquitoes as transmission vectors, and highlight the importance of studying *Anopheles* antiviral immunity, but tractable experimental models are lacking. We recently discovered two novel viruses in *Anopheles coluzzii* by deep sequencing and de novo assembly of small RNAs. One is a dicistrovirus in the same family as Drosophila C virus (DCV), and was named *Anopheles C virus* (AnCV), the other is in the same family as the important livestock arbovirus, bluetongue virus, and was named *Anopheles cypovirus* (AnCPV). Prevalence of AnCV and AnCPV varies developmentally in mosquitoes, with significant differences between the larval and adult stages. Abundance of the two viruses is negatively correlated in individual mosquitoes. Functional analysis revealed the implication of mosquito immune signaling pathways on virus replication, in some cases with differential influence on the two viruses. An experimental model was developed for AnCPV infection of *Anopheles* by bloodmeal in order to study antiviral response during the primary midgut infection and subsequent disseminated infection. The interaction between AnCV/AnCPV and *Plasmodium* species in *Anopheles* could also result in environmentally friendly weapons against malaria transmission.

## 162

### COMPARISON OF SAMPLE PREPARATION METHODS FOR NEXT GENERATION SEQUENCING OF INFLUENZA A VIRUSES

Piyawan Chinnawirotpisan, **Khajohn Joonlasak**, Wudtichai Manasatienkij, Chonticha Klungthong, Angkana Huang, Duangrat Mongkolsirikul, Louis R. Macareo, and Damon W. Ellison

*U.S. Army Medical Directorate - Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Influenza virus (IFV) represents a major public health concern worldwide. Study of the IFV genome has led to a greater understanding of reassortment, variance, mutations associated with antiviral drug resistance and antigenicity changes. In this study, two methods of double-stranded (ds) cDNA synthesis, ds cDNA synthesis kit (Invitrogen) with random hexamer and Single-Reaction Genome Amplification (SRA) with Flu A universal primers (Uni12A, Uni12G and Uni13) were compared. In addition, two different methods of library preparation were also compared, the Illumina Nextera XT and QIAGEN QIAseq FX. Ten IFV Type A isolates were used in this study to include five pandemic 2009 isolates and five H3N2 isolates. Performance of the different methods was measured by comparing percent of reads mapped to the IFV reference genomes (A/California/07/2009(H1N1) and A/Brisbane/11/2010(H3N2)) and mean depth of coverage (DOC) of the mapping per million reads sequenced. Statistical comparisons between the different treatments were performed using the paired t-test. When using SRA, the percentage of mapped reads increased 87 times (95%CI: 65-109) and DOC increased 126 times (95%CI: 92-161) when compared to the ds cDNA synthesis with random hexamer method. Overall, QIAseq FX library preparation provided significantly higher DOC ( $p=0.018$ ) with a mean difference of 275 (95% CI: 50-500) despite a 2.7% (95%CI: 0.5%-4.9%) decrease in the number of reads generated ( $p=0.016$ ). Better coverage was seen when stratified by the ds cDNA synthesis method but not statistically significant ( $p=0.117$  for random hexamer,  $p=0.078$  for SRA) due to limited sample size. In summary, SRA followed by QIAseq FX library preparation provided the whole genome of IFV for each sample with high IFV sequence reads and coverage through each genome segment especially at the 5' and 3' regions.

## 163

### PREVALENCE OF NOROVIRUS INFECTION IN HOSPITALIZED CONGOLESE CHILDREN IN BRAZZAVILLE, REPUBLIC OF CONGO

**Vivaldie E. Mikounou Louya**<sup>1</sup>, Félix Koukoukila-Koussounda<sup>1</sup>, Christevy Vouvongui<sup>1</sup>, Simon Charles Kobawila<sup>2</sup>, Francine Ntoumi<sup>1</sup>

<sup>1</sup>Fondation Congolaise pour la Recherche Médicale, Brazzaville, Republic of the Congo, <sup>2</sup>Faculty of Science and Technics, Marien Ngouabi University, Brazzaville, Republic of the Congo

In the Republic of Congo (RoC), diarrheal diseases are the third cause of consultation and hospitalization after malaria and acute respiratory infections. Parasites, bacteria and viruses are the main agents responsible for these severe diarrheas. Our institution was the first to characterize pathogens responsible for severe diarrheal infections in Congolese children. Therefore, epidemiological data on Rotaviruses and Adenoviruses infections were recently published. In the same hospitalized children, we determined the prevalence of Norovirus infections according to the rainy or dry season and age and identified co-infection with rota- and or adenoviruses. Stool samples used in this descriptive study were collected between June 2012 and June 2013 in 249 children aged under five years and hospitalized in the pediatric ward at Makélékélé hospital (Southern Brazzaville, capital of RoC) for severe diarrhea. Viral RNA was extracted from stool samples and the presence of norovirus was screened by duplex nested Reverse Transcription Polymerase Chain Reaction (RT-PCR) using specific primers for genogroup I and II. The prevalence of Noroviruses either of genogroup I or II was 27.7 % (69/249). Children between 7 and

12 months were the most infected (59.4 %). There was no significant difference according to sex however higher proportion of infected children was found during the dry season (June-September). We detected Rotavirus-norovirus, Norovirus-adenovirus and Rotavirus-norovirus-adenovirus co-infections in 3, 1%, 1% and 0, 9% respectively. This study shows that Norovirus is an etiological agent that must not be ignored among causes of severe diarrhea in Congolese children. This investigation should be extended to other parts of the country.

## 164

### **RICKETTSIA PARKERI IN AMBLYOMMA MACULATUM (ACARI: IXODIDAE) COLLECTED FROM MULTIPLE LOCATIONS IN SOUTHERN ARIZONA**

**Michelle Allerdice**<sup>1</sup>, Lorenza Beati<sup>2</sup>, Hayley Yaglom<sup>3</sup>, R. Ryan Lash<sup>1</sup>, Jesus Delgado-de la Mora<sup>4</sup>, Jesus D. Licona-Enriquez<sup>4</sup>, David Delgado-de la Mora<sup>5</sup>, Christopher D. Paddock<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Georgia Southern University, Statesboro, GA, United States, <sup>3</sup>Arizona Department of Health Services, Phoenix, AZ, United States, <sup>4</sup>University of Sonora, Sonora, Mexico, <sup>5</sup>Technologic Institute of Sonora, Sonora, Mexico

*Rickettsia parkeri* is an emerging human pathogen transmitted by *Amblyomma* ticks in predominately tropical and subtropical regions of the western hemisphere. In 2014 and 2015, 1 confirmed and 1 probable case of *Rickettsia parkeri* rickettsiosis were reported from the Pajarita Wilderness Area, a semi-arid mountainous region in southern Arizona. To examine more closely the potential public health risk of *R. parkeri* in this region, a study was initiated to investigate the pervasiveness of *Amblyomma* ticks in mountainous areas of southern Arizona as well as to ascertain the infection prevalence of *R. parkeri* in these tick populations. During July 2016, a total of 182 adult ticks were collected and evaluated from the Pajarita Wilderness Area in Santa Cruz County and 2 additional sites in Cochise and Santa Cruz counties in southern Arizona. DNA of *R. parkeri* was detected in 44 (24%) ticks. DNA of "*Candidatus Rickettsia andeanae*" and *Rickettsia rhipicephali* was detected in 3 (2%) and 1 (0.5%) of the samples, respectively. These observations corroborate previous collection records and indicate that established populations of *A. maculatum* exist in multiple foci in southern Arizona. The high incidence of *R. parkeri* in these tick populations suggests a public health risk as well as the need to increase education of *R. parkeri* rickettsiosis for those residing, working in, or visiting this area.

## 165

### **ENTOMOLOGICAL SURVEILLANCE IDENTIFY PRESENCE OF LUTZOMYIA VERRUCARUM SANDFLY (DIPTERA: PSYCHODIDAE) IN LEISHMANIASIS ENDEMIC COMMUNITY IN MEXICO**

**Adebiji A. Adeniran**<sup>1</sup>, Jesús F. González-Roldán<sup>2</sup>, Nadia A. Fernández-Santos<sup>2</sup>, Nancy Treviño-Garza<sup>2</sup>, Herón Huerta-Jiménez<sup>3</sup>, Pedro C. Mis-Ávila<sup>4</sup>, Raúl Cámara<sup>4</sup>, Wilbert Pérez<sup>4</sup>, Aldo I. Ortega-Morales<sup>5</sup>, Mario A. Rodríguez-Pérez<sup>1</sup>

<sup>1</sup>Instituto Politécnico Nacional, Reynosa, Tamaulipas, Mexico, <sup>2</sup>Centro Nacional de Programas Preventivos y Control de Enfermedades, Secretaría de Salud (SS), Mexico, Mexico, <sup>3</sup>Laboratorio de Entomología e Insectario, Instituto Nacional de Diagnóstico y Referencia Epidemiológicos, SS, Mexico, Mexico, <sup>4</sup>Servicios de Salud del Estado de Quintana Roo, SS, Quintana Roo, Mexico, <sup>5</sup>Laboratorio de Biología Molecular, Universidad Autónoma Agraria Antonio Narro, Unidad Laguna, Mexico

Continuous endemicity and re-emergence of vector-borne disease in Mexico have call for new approaches to vector control programs including regular surveillance. Correct and accurate identification of vectors is essential for successful surveillance program. This study is using DNA barcoding under the Mexican Barcode of Life (MexBol) project to improve vector surveillance and accurately delineate arthropod vector diversities

including sandfly for leishmaniasis control in Mexico. In October and November, 2016, sandflies were collected from different regions in leishmaniasis endemic state of Quintana Roo, Mexico using CDC light and Shannon traps as part of the health ministry surveillance program. Samples collected were sorted by sex and female samples were pooled for PCR for pathogen examination. Thirty-three (33) male samples were morphologically identified as 2 species with *Lutzomyia cruciata*, 28 (84.8%) and *Lutzomyia deleoni* 5 (15.2%). However, molecular identification using the 658-bp fragment of mitochondrial cytochrome oxidase subunit 1 gene revealed earlier identified *L. deleoni* to be *L. verrucarum* with nucleotide sequence having 90-93% identity match with species described from Peru after analysis on NCBI Basic Local Alignment Search Tool. Phylogenetic analysis with the Neighbour-Joining (NJ) tree also showed these species to cluster 100% with *L. verrucarum* that was also isolated from leishmaniasis endemic community in Peru. Although, further sample collection has been planned at the geographical location where these species were collected to confirm presence of local population, the role of exotic *L. verrucarum* on local transmission of leishmaniasis is currently unknown as this species has not been previously reported in Mexico. There is the need for a detailed ecological study to fully understand the role of this species in the transmission dynamics of leishmaniasis in Mexico.

## 166

### **PHLEBOTOMINE SAND FLIES (DIPTERA: PSYCHODIDAE) AS POTENTIAL VECTORS OF LEISHMANIA PARASITES IN TSATEE, A NEW ENDEMIC COMMUNITY, VOLTA REGION**

**Seth O. Addo**<sup>1</sup>, Bright Agbodzi<sup>1</sup>, Mba-tihssommah Mosore<sup>1</sup>, Clara Yeboah<sup>1</sup>, Godwin Kwakye-Nuako<sup>2</sup>, Emmanuel K. Amoako<sup>1</sup>, Naiki Puplampu<sup>1</sup>, John A. Larbi<sup>3</sup>, Michael D. Wilson<sup>1</sup>

<sup>1</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>2</sup>Department of Biomedical and Forensic Sciences, School of Biological Sciences, University of Cape Coast, Cape Coast, Ghana, <sup>3</sup>Department of Theoretical and Applied Biology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Leishmaniasis is a disease caused by *Leishmania* parasites which are transmitted by infected female sand flies. In Ghana, cutaneous leishmaniasis (CL) continues to spread to previously non-endemic areas. Trapping methods employed in the Ho District have caught predominantly large numbers of *Sergentomyia* species and very few *Phlebotomus* species. Identified *Leishmania* parasites were *L. tropica* and *L. major*, found in pools of *Sergentomyia ingrami* and *S. hamoni* and none in any of the *Phlebotomus* species found there. It suggests that contrarily to published works, *Phlebotomus* species played no role in the transmission of the disease in the affected communities, a major role ascribed to *Sergentomyia* species. This study expanded the scope by conducting similar studies in Tsatee, a new endemic community in the adjoining South Dayi District. It aimed to identify the potential vector species and detect *Leishmania* parasites that are responsible for CL transmission in the study area. Sand flies were collected using CDC light traps and aspirators. The non-blood fed sand flies studied were 99.91% *Sergentomyia* (n=3272) and 0.09% (n=3) *Phlebotomus*. All the blood fed species were of the genus *Sergentomyia*. *Leishmania* infections were detected using primers which target the conserved region of *Leishmania* spp. minicircle DNA of the parasite kinetoplast. *Leishmania* infection rates were *S. africana* (0.16%), *S. ingrami* (1.92%), *S. schwetzi* (1.80%), *S. hamoni* (2.60%), *S. similima* (0.32%), *S. ghesquierei* (1.05%), *S. antennata* (0.63%), *S. durenii* (3.30%) and for the first time in Ghana, *P. rodhaini* (33.33%). With the individual blood fed sand flies, infections were detected at rates *S. africana* (12.12%), *S. ingrami* (50.50%), *S. schwetzi* (33.33%), *S. similima* (7.69%) and *S. antennata* (50.00%). Detecting infections in *Sergentomyia* species further support the notion that they may play a significant role in the transmission process. The findings suggest an efficient *P. rodhaini* vector (33.33%), thus a major role of *Phlebotomus* in disease transmission cannot be discounted. The PCR products will be sequenced to identify the *Leishmania* species.

## 167

### IMPACT OF IRRADIATION ON REPRODUCTIVE PERFORMANCE OF WILD AND LABORATORY *ANOPHELES ARABIENSIS* MOSQUITOES

Serge B. Poda<sup>1</sup>, Edwige Guissou<sup>1</sup>, Jérémie Gilles<sup>2</sup>, Jean-Baptiste Rayaisse<sup>3</sup>, Thierry Lefèvre<sup>4</sup>, Olivier Roux<sup>4</sup>, Roch K. Dabiré<sup>1</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Santé (IRSS)/Centre Muraz, Bobo-Dioulasso, Burkina Faso, <sup>2</sup>International Atomic Energy Agency (IAEA), Vienna, Austria, <sup>3</sup>Centre International de Recherche-Développement sur l'Élevage en zone Subhumide (CIRDES), Bobo-Dioulasso, Burkina Faso, <sup>4</sup>Institut de Recherche pour le Développement (IRD), Maladies Infectieuses et Vecteurs: Ecologie, Génétique, Evolution et Contrôle (MIVEGEC), Montpellier, France

Sterile Insect Technique (SIT) aims at suppressing or decreasing insect pest population by introducing irradiated mass-reared insects into wild populations. However, both mass rearing and radiations can affect life history traits of some insects making them less competitive than their wild counterparts. In the malaria mosquito *Anopheles arabiensis*, many progress have been done to improve mating competitiveness of mass-reared irradiated males. However, to date, no study has been done to decipher entangled negative effects of laboratory rearing and irradiation on important reproductive traits. Such data could help to target more precisely research efforts to improve current techniques. Here, we used two sources of *An. arabiensis* from the same locality; one reared in laboratory for 5 generations and the other collected at late larval instar in the field. Pupae were irradiated and adult insemination rate, fecundity, oviposition behavior, fertility and male survivorship were assessed. Results revealed different impacts of both mosquito origin and irradiation onto reproductive processes. First, insemination rate was more intensively affected by irradiation in laboratory-reared mosquitoes than in wild ones. Second, oviposition behavior was different between the two mosquito origins with a quick "adaptation" of laboratory-reared mosquitoes to artificial conditions. Third, a greater proportion of eggs hatched in irradiated field than in laboratory-reared mosquitoes, but conversely, a larger proportion of larvae survived to the first instar in laboratory-reared than in field mosquitoes. Finally, while irradiation had no effect on longevity, field males survived better than those from laboratory. Effects of both mass-rearing and irradiation must be taken into account when investigations attempt to improve insect quality used in SIT.

## 168

### HIGH THROUGHPUT SCREENING OF THE MICROBIOTA ASSOCIATED WITH TWO MALARIA VECTORS OF COLOMBIA

Priscila Bascañan<sup>1</sup>, Juan Pablo Niño-García<sup>2</sup>, Stefani A. Piedrahita<sup>1</sup>, Yadira Galeano-Castañeda<sup>1</sup>, David Serre<sup>3</sup>, Margarita M. Correa<sup>1</sup>

<sup>1</sup>Group of Molecular Microbiology, School of Microbiology, University of Antioquia, Medellín, Colombia, <sup>2</sup>School of Microbiology, University of Antioquia, Medellín, Colombia, <sup>3</sup>Institute for Genome Sciences, University of Maryland, Baltimore, MD, United States

The number of deaths caused by malaria has decreased worldwide, however, the dramatic increase in insecticide-resistant *Anopheles mosquitoes* has accelerated the search for alternative strategies to diminish or eliminate malaria vector populations. Recent studies have shown that some bacteria of the mosquito microbiome have important negative effects on the parasite development within the mosquito midgut, as in the vector's survival. However, little is known about the microbiota of Latin American anopheline mosquitoes and its significance for parasite blocking. Therefore, the purpose of this study is to characterize the midgut microbiota composition of two main Latin American malaria vectors, *Anopheles darlingi* and *A. nuneztovari*, collected in two malaria-endemic regions of Colombia. We characterized the bacterial microbiome of 64 adult (A) mosquito midguts, 12 larvae (L) midguts and 7 breeding sites (BS). A total of 15,909,048 bacterial 16S rRNA reads were grouped

into 274,990 swarms, from which we identified 14,440 unique OTUs. Preliminary results showed that the composition of the microbiota differs between regions and groups but not between species or feeding status. A deeper examination of the metadata is currently in progress and will reveal the microbiome composition at a more detailed taxonomical level, which is essential to discover novel potential candidates for vector biocontrol strategies.

## 169

### SPECIES COMPOSITION OF PHLEBOTOMINE SAND FLIES AND BIONOMICS OF *PHLEBOTOMUS ARGENTIPES* IN AN ENDEMIC FOCUS OF VISCERAL LEISHMANIASIS IN BIHAR STATE, INDIA

Rajesh B. Garlapati<sup>1</sup>, Shanta Mukherjee<sup>1</sup>, Rahul Chaubey<sup>1</sup>, Md. Tahfizur Rahaman<sup>1</sup>, Vishnu Prakash Tripathi<sup>1</sup>, Aakanksha Bharti<sup>1</sup>, Suman Prakash<sup>1</sup>, McCall Calvert<sup>2</sup>, Larisa Polyakova<sup>2</sup>, David M. Poche<sup>2</sup>, Richard M. Poche<sup>2</sup>

<sup>1</sup>Genesis Laboratories, Patna, India, <sup>2</sup>Genesis Laboratories, Inc., Wellington, CO, United States

Visceral leishmaniasis (VL) also known as Kala-azar in India is transmitted to man by *Phlebotomus argentipes*. In the Indian subcontinent, Bihar state is endemic to VL. A year-long study was initiated in twenty four villages, within two districts of Bihar, to examine the species composition of Phlebotomine sand flies. In each village twelve CDC light traps were installed in three locations which include houses, cattle dwellings, and vegetation. In each location, 4 traps were installed. Traps were activated every two weeks for 12 hours from 1800 to 0600 hours. Sand flies trapped were transferred to the lab in Patna, identified, and recorded as to sand fly species. Our trapping was initiated in February 2016 and continued to December 2016. Sand flies were identified morphologically and molecular techniques were used to confirm identification. Blood meals were identified from trapped blood fed sand flies. We trapped 126,394 *P. argentipes*, of which 76,554 were males and 49,840 were females. We also trapped 1,465 *P. papatasi* and 24,218 *Sergentomyia* species. Earlier studies suggested sand fly behavior is more exophilic now, contrary to previous reports. We also trapped a large proportion of sand flies outside of houses and cattle sheds in vegetation. This suggest a new sand fly management tool is required to control the vector in peri-domestic vegetation in order to achieve elimination of VL in India.

## 170

### DENGUE VECTOR CONTROL: BUILDING THE EVIDENCE BASE

Olaf Horstick<sup>1</sup>, Ross Boyce<sup>2</sup>, Silvia Runge Ranzinger<sup>1</sup>

<sup>1</sup>University of Heidelberg, Heidelberg, Germany, <sup>2</sup>Division of Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Dengue is endemic in many parts of the world with an estimated 390 million infections annually. Vector control remains the primary method of prevention and control. Despite substantial investment, the evidence guiding such interventions is limited in its quality and scope and is widely disbursed among academic journals and within national control programmes. Here we summarise our efforts to consolidate and evaluate the existing evidence base for dengue vector control. We have conducted a series of systematic literature reviews covering both single vector control interventions, including peridomestic space spraying (Esu 2010), Temphos (George 2015), *Bacillus thuringiensis israelensis* (Boyce 2013), copepods (Lazaro 2015) and larvivorous fish (Han 2015), pyriproxifen (Moaz 2017, submitted) and indoor residual spraying (Samuel 2017, submitted), as well as outbreak response (Pilger 2010) and service delivery (Horstick 2010). Our analysis shows that 1) vector control can be effective, but implementation and sustainability remain issues 2) single interventions are probably not effective, but even combinations of interventions have mixed results, 3) Interventions in response to outbreaks have limited effectiveness and, 4) the quality of service delivery, rather than the choice

of intervention, is likely the most important determinant of effectiveness. Based on these findings, we recommend a combination of chemical methods such as indoor residual spraying and insecticide treated materials, together with biological methods, where possible. Both larvae and adult mosquitos should be targeted simultaneously, while addressing waste and environmental management may have an incremental benefit. Our results also show that there is an urgent need to develop rigorous guidance for vector control studies, ensuring the validity and comparability of results. Studies should include measurements of human transmission data, where and when possible.

## 171

### RESPONSES OF *GLOSSINA PALLIDIPES* AND *G. MORSITANS MORSITANS* TSETSE FLIES TO ANALOGUES OF DELTA-OCTALACTONE AND SELECTED BLENDS

Benson M. Wachira<sup>1</sup>, Paul O. Mireji<sup>2</sup>, Sylvance Okoth<sup>2</sup>, Margaret M. Ng'ang'a<sup>3</sup>, Ahmed Hassanali<sup>3</sup>

<sup>1</sup>Biotechnology Research Institute and Kenyatta University, Nairobi, Kenya,

<sup>2</sup>Biotechnology Research Institute, Nairobi, Kenya, <sup>3</sup>Kenyatta University, Nairobi, Kenya

Previous studies have shown that delta-octalactone is an important component of the tsetse-refractory waterbuck (*Kobus defassa*) repellent odour blend. In the present study, structure-activity comparison was undertaken to determine the effects of the length of the side chain and ring size of the lactone on adult *Glossina pallidipes* and *Glossina morsitans morsitans*. The responses of the flies to each compound were studied in a two-choice wind tunnel. Increasing the chain length from C3 (delta-octalactone) to C4 (delta-nonalactone) enhanced repellency to both species (*G. pallidipes* from 60.0 to 72.0%, and *G. m. morsitans* from 61.3 to 72.6%), while increasing the ring size from six (delta-octalactone) to seven members (delta-nonalactone) changed the activity from repellency to attraction that was comparable to that of the phenolic blend associated with fermented cow urine ( $p > 0.05$ ). Blending delta-nonalactone with 4-methylguaiaicol (known tsetse repellent) significantly ( $p < 0.05$ ) raised repellency to 86.7 and 91.7% against *G. pallidipes* and *G. m. morsitans* respectively. Follow-up Latin Square Designed field studies (Shimba hills in coastal areas in Kenya) with *G. pallidipes* populations confirmed the higher repellence of delta-nonalactone (with/without 4-methylguaiaicol) compared to delta-octalactone (also, with/without 4-methylguaiaicol). The results show that subtle structural changes of olfactory signals can significantly change their interactions with olfactory receptor neurons, and either shift their potency, or change their activity from repellence to attraction. Our results also lay down useful groundwork in the development of more effective control of tsetse by 'push', 'pull' and 'push-pull' tsetse control tactics.

## 172

### POPULATION GENETICS ANALYSIS OF *PHLEBOTOMUS PAPTASI* SAND FLIES FROM NORTH AFRICA AND MIDDLE EAST REGIONS BASED ON MITOCHONDRIAL CYTOCHROME B HAPLOTYPES

Catherine M. Flanley<sup>1</sup>, Omar Hamarsheh<sup>2</sup>, Gwen Stayback<sup>1</sup>, Mariha Wadsworth<sup>1</sup>, Douglas A. Shoue<sup>1</sup>, Mehmet Karakus<sup>3</sup>, Mohammad Reza Yaghoobi-Ershadi<sup>4</sup>, Andreas Kruger<sup>5</sup>, Mary Ann McDowell<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Al-Quds University, Jerusalem, Palestinian Territory, <sup>3</sup>Ege University, Izmir, Turkey,

<sup>4</sup>Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,

<sup>5</sup>Bundeswehr Hospital Hamburg, Hamburg, Germany

The *Phlebotomus papatasi* sand fly is a vector of cutaneous leishmaniasis (CL) over a widespread geographic range. Population genetics is a valuable tool in understanding the level of genetic variability present in vector populations, vector competence, and the development of novel control

strategies. This study elucidated the genetic differentiation between *P. papatasi* populations in Egypt and Jordan that inhabit distinct ecotopes and compared this structure to *P. papatasi* populations from a broader geographical range. The mtDNA cytochrome *b* gene was amplified and sequenced from 116 individual sand flies from Aswan and North Sinai, Egypt, as well as Swaymeh and Malka, Jordan. Haplotypes were identified and used to generate a median-joining network,  $F_{ST}$  values, and isolation-by-distance were evaluated. Additional sand fly individuals from Afghanistan, Iran, Israel, Jordan, Libya, Tunisia, and Turkey were included as well as previously published haplotypes to provide a robust genetic variation analysis. Thirteen haplotypes were identified with nine variant sites from the Egypt and Jordan. No unique haplotypes were identified from samples in North Sinai, Egypt, two were observed in Aswan, Egypt, four from Swaymeh, Jordan, and two in Malka, Jordan. The Jordan populations clustered separately from the Egypt populations and produced more unique haplotypes than Egypt. Pairwise  $F_{ST}$  values fall in the range 0.024-0.648 and indicate a strong differentiation between Egypt and Jordan populations, although this population structure is not due to isolation-by-distance. Other factors, such as environmental influences and the genetic variability in the circulating *L. major* parasites, may contribute significantly to this heterogeneity. The present study aligns with previous reports in that genetic differentiation exists between the populations of this widely dispersed species but overall, the species remains relatively homogeneous.

## 173

### ALTERNATIVE USE OF INSECTICIDE TREATED BED NETS IN COMMUNITY BASED EDUCATION AND SERVICE CENTERS IN WESTERN KENYA

Arthur M. Kwena

Moi University, Eldoret, Kenya

In Kenya, the use of Insecticide treated bed nets for control of malaria is widespread especially in endemic areas. The western part of the country is one such area. Cross-sectional surveys were carried out in 20 Health Centres as part of the Community Based Education and Service programme of Moi University College of Health Sciences to determine the prevalence of mosquitoes, malaria and use of ITNs. Cluster sampling technique was used with each health centre as the sampling unit. In a random sample of 3, 326 households, the mosquito prevalence showed a range of 19% (Mautuma) to 100% (Sirisia) in the health centres sampled. The corresponding malaria prevalence was between 13% to 95% in children and 18% to 90% in adults. The malaria prevalence was assessed from the Health centre records. All the households reported use of insecticide treated bed nets. Cases of alternative use of the bed nets were also reported and observed. The results of this study show alternative use of ITNs to be rampant in COBES centres in Western Kenya. Efforts should be made to intensify Public Health Education to sensitize the Community on proper use of ITNs which would otherwise negate the malaria control programme in the country.

## 174

### COMMUNITY OPERATED BLACK FLY TRAPS FOR ONCHOCERCIASIS SURVEILLANCE

Thomas R. Unnasch<sup>1</sup>, Denis Loum<sup>2</sup>, Charles Katholi<sup>3</sup>, Thomson Lakwo<sup>4</sup>, Peace Habomugisha<sup>5</sup>, Edridah M. Tukahebwa<sup>4</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Nwoya District Local Government Health Department, Gulu, Uganda, <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL, United States, <sup>4</sup>Vector Control Division, Ministry of Health, Kampala, Uganda, <sup>5</sup>The Carter Center, Kampala, Uganda

Entomological measures of transmission are key data necessary to document the suppression and interruption of transmission of *Onchocerca volvulus*, the causative agent of onchocerciasis. Black fly collection has relied upon human landing collections, which are inefficient and carry

the risk of promoting pathogen transmission. The Esperanza Window Trap (EWT) has shown promise as an alternative method for collection of *Simulium damnosum* sensu lato, the primary vector of *O. volvulus* in Africa. Here, we report the results of a community directed trial of the EWT in Northern Uganda. Traps operated by residents were compared to human landing collections in two communities over five months. EWTs collected numbers of *S. damnosum* that equaled or exceeded those obtained by a two-person human landing collection team. Three traps, when operated by a single village resident, collected over four times as many *S. damnosum* as did the two-man collection team. The results suggest that the EWT may be effectively operated by community residents and that the trap represents a viable alternative to human landing collections for entomological surveillance of *O. volvulus* transmission.

## 175

### SITE-SPECIFIC OCCUPANCY AND SIMULATED EXPANSION DYNAMICS OF A SECONDARY VECTOR OF CHAGAS DISEASE: A THREE-YEAR FOLLOW-UP IN THE ARGENTINE CHACO

Lucía I. Rodríguez-Planes, María Sol Gaspe, Gustavo F. Enriquez, Ricardo E. Gürtler

Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto de Ecología, Genética y Evolución de Buenos Aires (IEGEB), Facultad de Ciencias Exactas y Naturales, Buenos Aires, Argentina, Ciudad Autónoma de Buenos Aires, Argentina

Sylvatic triatomine species may adapt to domestic or peridomestic habitats (domestication) and become relevant for the transmission of *Trypanosoma cruzi*, the causal agent of Chagas disease. *Triatoma sordida* occasionally colonized human sleeping quarters in Paraguay, Bolivia and Brazil whereas the few studies conducted in Argentina found sylvatic and peridomestic colonies marginally infected with *T. cruzi*. Following a 12-year period free of vector control actions, over three years we surveyed site-specific triatomine infestations before and every 4-5 months after a community-wide house spraying with pyrethroids in a well-defined rural area of northern Argentina including 353 houses. Timed-manual searches found 78 of 2177 (peri)domestic sites occupied by *T. sordida* at baseline, with most (85.9%) insects in chicken nests, chicken coops and chicken trees (suitable habitats). A large fraction of suitable habitats were empty despite their proximity to occupied sites. An incidence function metapopulation model (including distances between sites and maximum local catch across the 3-year period as a proxy of vector carrying capacity) was fitted to the baseline pattern of occupancy. Simulation over 500 time steps predicted a steep increase up to an equilibrium of 250 occupied patches, almost fourfold the observed occupancy. Simulations using R were unable to recover the data fitted by the model, indicating that the observed occupancy pattern represented a transient state (not a quasi-stationary equilibrium) despite the absence of major disturbances (deforestation, insecticide). The prevalence of house infestation with *T. sordida* decreased from 19.0% at baseline to a minimum (8.1%) at 8 months post-spraying (MPS), and then increased gradually to a mean of 14.2% over 22-32 MPS. Only 1% of *T. sordida* bugs (mainly invading adults) were collected in human sleeping quarters. Our study shows that *T. sordida* thrived in peridomestic habitats, and occasionally invaded domestic quarters but failed to colonize them. Its expansion at a mesoscale was likely limited by the instability of peridomestic habitats and its low dispersal ability between them.

## 176

### EFFECTIVENESS OF TWO TYPES OF LONG LASTING INSECTICIDAL NETS AFTER TWO YEARS OF USE FOR MALARIA VECTOR CONTROL IN AN AREA OF HIGH PYRETHROID RESISTANCE, MULEBA -TANZANIA

Jackline L. Martine<sup>1</sup>, Natacha Protopopof<sup>2</sup>, Steven Magesa<sup>3</sup>, Prof. Franklin W. Mosha<sup>4</sup>

<sup>1</sup>NIMR Mwanza, Mwanza, United Republic of Tanzania, <sup>2</sup>Department of Disease Control, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>AIRS, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania

Long Lasting Insecticidal Nets (LLIN) provide a physical and chemical barrier to mosquitoes, but in areas with high pyrethroid resistance, when net become holed and insecticide efficacy decline with net age. As reported previously, resistant mosquitoes will penetrate easily through holes and survived. Of key concern is whether an LLIN that is subject to wear and tear under everyday household conditions fail to protect LLIN users. Prospective cross-sectional survey were carried in four villages, two with Olyset nets and two with Olyset Plus nets, Muleba district 2016/2017. The houses were selected randomly by using random table number in each village. Total of 40 houses (10 from each village) were selected with total 80 study nets. Physical integrity, number of mosquito found resting inside nets, and insecticidal activity was quantified. Physical integrity was categorized by proportionate hole index (pHI). LLIN were assigned based on pHI value following WHO category. The field mosquitoes were used to test for susceptibility status of Olyset Plus nets in comparison to standard Olyset nets. In all villages 87.5% of nets were more than 20 month of use, and had at least one hole of any size. The totals of 189 blood fed mosquitoes were collected inside standard Olyset nets, no mosquitoes was collected inside Olyset Plus nets regardless of holes size. In Standard Olyset nets, the number of resting mosquitoes were increasing with hole size with proportional hole index >643. Adopted WHO resistance assay, field mosquitoes tested for 0 month net were 7%, 13% and 60%, 63% (*An.gambiae*, *An.funestus*) resistant to Olyset Plus and standard Olyset nets. After 20 months of net use 25, 60% and 69, 90% (*An.gambiae*, *An.funestus*) were resistant to Olyset Plus and for standard olyset. In area with high pyrethroid resistance mosquitoes, Olyset Plus nets, treated with pyrethroid in additional to PBO provide protection to an individual's regardless of age and holes size. All type of nets develops large holes after one and half year of use...

## 177

### LANDSCAPE GENETICS OF INSECTICIDE RESISTANCE IN ANOPHELES ANOPHELES SINENSIS

Xuelian Chang

University of California Irvine, Irvine, CA, United States

*Anopheles sinensis* is one of the most abundant vectors of malaria and other diseases in Asia. Vector control through the use of insecticides is the front line control method of vector-borne diseases. However, the extensive use of insecticides has imposed strong selection pressure on mosquito populations for resistance. Despite the importance of kdr mutations in pyrethroid resistance, the evolutionary origin of the kdr mutations is unknown. We examined the evolutionary genetics of kdr mutations in relation to spatial population genetic structure of *An. sinensis* China. We found three non-synonymous mutations at the kdr codon L1014 of paratype sodium channel gene. A patchy distribution of kdr mutation allele frequencies from southern to central China was found. Near fixation of kdr mutation was detected in populations from central China, but no kdr mutations were found in populations from southwestern China. More than eight independent mutation events were detected in the three kdr alleles, and at least one of them evolved multiple times subsequent to their first divergence. Significant and large genetic differentiation was detected

between populations from southwestern China and central China. The patchy distribution of *kdr* mutation frequencies is likely a consequence of geographic isolation in the mosquito populations and the long-term insecticide selection. Our results indicate multiple origins of the *kdr* insecticide-resistant alleles in *An. sinensis* from southern and central China. Local selection related to intense and prolonged use of insecticide for agricultural purposes, as well as frequent migrations among populations are likely the explanations for the patchy distribution of *kdr* mutations in China. On the contrary, the lack of *kdr* mutations in Yunnan and Sichuan is likely a consequence of genetic isolation and absence of strong selection pressure. The present study demonstrated the combined impact of demographic and selection factors on population structure.

## 178

### QUANTIFYING THE INTENSITY OF PERMETHRIN INSECTICIDE RESISTANCE IN *ANOPHELES* MOSQUITOES IN WESTERN KENYA

Seline Omondi<sup>1</sup>, Wolfgang R. Mukabana<sup>1</sup>, Eric Ochomo<sup>2</sup>, Margaret N. Muchoki<sup>3</sup>, Nabie M. Bayoh<sup>2</sup>

<sup>1</sup>The University of Nairobi, Nairobi, Kenya, <sup>2</sup>Kenya Medical and Research Institute/Centers for Disease Control and Prevention, Kisumu, Kenya, <sup>3</sup>The Presidential Malaria Initiative Africa Indoor Spraying Project, Kisumu, Kenya

Resistance among malaria vectors to classes of insecticides used in long lasting insecticidal nets and indoor residual spraying poses a challenge to malaria vector control. Methods for evaluating insecticide resistance in malaria vectors include WHO tube and CDC bottle assays. Upgrade to CDC bottle assay using different insecticide dosages has proved applicable in ascertaining intensity of resistance. We determined prevalence and intensity of permethrin resistance and investigated efficacy of commonly used long lasting insecticidal nets (LLINs) against 3 day old *Anopheles* mosquitoes from four sub counties in western Kenya (Nyando, Bondo, Rachuonyo and Teso). *Anopheles* larvae were reared to 3 day old adults for exposure to; WHO tube, CDC bottle and cone assay. For resistance intensity, mosquitoes were exposed to 21.5µg/ml, 43µg/ml, 107.5µg/ml and 215µg/ml doses of permethrin using CDC bottle assays. Mortality after 24h was recorded for WHO assays, time of knockdown for bottle assays while both were used for cone assay. Mortality to 0.75% permethrin ranged from 23.5-96.1%. Intensity of permethrin resistance was highest in Barkanyango Bondo with 84% knockdown at 30 minutes diagnostic time when exposed to 215µg/ml dose. Mortality for nets was (0-39) %, (12-88) % and (26-89) % for Olyset, PermaNet 2.0 and PermaNet 3.0 respectively. Efficacy of nets was reduced in Bondo and Teso. Study results shows that there was confirmed resistance in all sites, however, intensity assays were able to differentiate Bondo and Teso as sites with highest levels of resistance, which coincidentally were two sites with reduced net efficacy. This portrayed that at certain resistance intensities, vector control using LLINs may be compromised. Therefore it is necessary to incorporate intensity assays in order to determine the extent of threat that resistance poses to malaria control.

## 179

### UNDERSTANDING THE COMMUNITY CONTEXT OF *Aedes aegypti* MOSQUITO BREEDING IN COASTAL KENYA: IMPLICATIONS FOR CONTROL

Jenna Forsyth<sup>1</sup>, Francis Mutuku<sup>2</sup>, Lydia Kibe<sup>3</sup>, Julius Kamoni<sup>4</sup>, Luti Mwashree<sup>4</sup>, Nicole Ardoin<sup>1</sup>, Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Kenya Medical Research Institute, Kilifi, Kenya, <sup>4</sup>Msambweni District Hospital, Msambweni, Kenya

Community engagement is crucial for controlling *Aedes aegypti* mosquito-borne diseases since these mosquitoes primarily breed in water storage containers around people's homes. Mosquito source reduction often provides the greatest benefit at a minimal cost; however, only an

estimated 15% of coastal Kenyans engage in source reduction due to lack of awareness and motivation. This study in Kwale County, Kenya had three objectives: i) to identify target containers, ii) to understand current perspectives on source reduction, and iii) to explore how to encourage parents and children to adopt source reduction practices. Entomological surveys were conducted in 500 households between May and July 2016 to locate mosquito habitats and measure abundances of mosquito larvae. Based on these surveys, 40 houses were selected for semi-structured in-depth interviews to determine perspectives about mosquitoes and source reduction. Finally, educational materials and behavioral recommendations were developed during a stakeholder workshop and pilot tested in 3 villages. The entomological surveys identified 893 mosquito habitats. Tires, discarded plastic bottles, trash, buckets, jerry cans, and animal drinking troughs contained the greatest number of mosquito larvae. The in-depth interviews revealed common misconceptions, including a fear that drinking mosquito larvae could transmit malaria or cause diarrhea. Therefore, many people considered it important to cover containers used for drinking or cooking, but did not consider water for laundry or sanitation a concern. Based on the container types and perceptions, we pilot tested a curriculum with children and parents emphasizing mosquito types and diseases, life cycle, breeding sites, and recommendations for source reduction. Parents and children understood the new information well. Children practiced source reduction by collecting unwanted plastic containers for re-use, while parents practiced various types of source reduction but still prioritized covering water containers for drinking and cooking water. Changing behavior requires continuous effort and community engagement.

## 180

### INSECTICIDE SUSCEPTIBILITY IN *ANOPHELES GAMBIAE* S.L.: A NATIONWIDE SURVEY PRIOR TO A MASS DISTRIBUTION OF LONG LASTING INSECTICIDE TREATED NETS IN TOGO

<sup>1</sup>University of Lomé, Lomé, Togo, <sup>2</sup>National Malaria Control Program/Ministry of Health, Lomé, Togo

A nationwide survey of insecticide susceptibility tests was conducted between June and July 2016 to inform the decision on the type of LLIN to be distributed during the universal coverage campaign in Togo. Susceptibility tests were performed on 4,932 unfed adult female *Anopheles gambiae* s.l. aged 2 to 5 days. These female mosquitoes were obtained from larvae collected from 6 NMCP sentinel sites. Overall 8 insecticides were used: 4% DDT, pyrethroids and 0.05% deltamethrin, 0.75% Permethrin and 0.05% lambda-cyhalothrin, carbamates and 0.1% bendiocarb and 0.1% propoxur and organophosphates and 0.1% malathion and 0.1% fenitrothion. The Kisumu strain was used as reference. The knock-down and 50 and 90% values were calculated and the 24 hours post-exposure mortality rates were recorded. Based on WHO criteria, results showed very high knock-down values for pyrethroids while it was impossible to determine those of 4% DDT. The mortality rates recorded for 4% DDT were less than 5% in most of the sites. All the mosquitoes were resistant to pyrethroids. The highest mortality rate was recorded with 0.05% deltamethrin and 44% and 5% malathion led to a 100% mortality rate in the Plateau region. This study showed that insecticide resistance in *An. gambiae* s.l. is a matter of great concern and there is an urgent need for a countrywide insecticide resistance management.

## 181

### EVIDENCE OF MULTIPLE DDT RESISTANCE MECHANISMS IN THE MALARIA VECTOR *ANOPHELES GAMBIAE* FROM DAR ES SALAAM, TANZANIA

Bilali I. Kabula<sup>1</sup>, Johnson Matowo<sup>2</sup>, Bernard Batengana<sup>1</sup>, Craig S. Wilding<sup>3</sup>, Emily Rippon<sup>3</sup>, Keith Steen<sup>3</sup>, William Kisinza<sup>1</sup>, Stephen Magesa<sup>1</sup>, Franklin Moshia<sup>2</sup>, Martin J. Donnelly<sup>3</sup>

<sup>1</sup>National Institute for Medical Research (NIMR), Tanzania, Muheza, Tanga, United Republic of Tanzania, <sup>2</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Significant reductions in malaria transmission have been achieved over the last 16 years. However, increasing drug and insecticide resistance threatens these gains. *Anopheles gambiae*, which is a major vector of the malaria parasite *Plasmodium falciparum* in Africa, has over the years developed resistance to insecticides including dieldrin, 1,1-bis(*p*-chlorophenyl)-2,2,2-trichloroethane (DDT), and pyrethroids. The objective of this study was therefore to determine the mechanisms contributing to DDT resistance in *Anopheles gambiae* s.s. from Dar es Salaam, Eastern Tanzania. Female mosquitoes of standard age, reared from larvae sampled across varieties of natural breeding sites, were used in the study. Members of the *An. gambiae* complex were PCR-identified and screened for *Vgsc-1014S* and *Vgsc-1014F* mutations. A DDT-resistant population of *An. gambiae* s.s. with two controls (sympatric and allopatric controls) were screened for GSTe2 and P450 genes-expression profiles using real-time quantitative polymerase chain reaction (qPCR). We found significantly higher allelic frequencies of the *Vgsc-L1014S* mutation in DDT-resistant *An. gambiae* s.s. than in the controls ( $p < 0.001$ ). Cytochrome P450 genes: *Cyp6m2*, *Cyp6p3*, *Cyp6z3* and *Cyp6z1* were significantly over-expressed in DDT-resistant *An. gambiae* s.s. compared with the control populations. We report the increased expression of multiple DDT-associated resistance mechanisms in the primary African malaria vector, *An. gambiae* s.s. from Dar es Salaam. The presence of multiple resistance mechanisms in *An. gambiae* that are common in both DDT and pyrethroids may have confounding effect in resistance-management strategies. However, the geographical extent of the insecticide resistance mechanisms observed in this study need to be investigated.

## 182

### FITNESS EFFECTS OF VSSC MUTATIONS S989P+V1016G IN A PYRETHROID RESISTANT STRAIN OF THE YELLOW FEVER MOSQUITO, *Aedes aegypti*

Leticia B. Smith, Juan J. Silva, Jeffrey G. Scott  
Cornell University, Ithaca, NY, United States

*Aedes aegypti*, an important vector of many human diseases, is a serious threat to human health due to its wide geographic distribution and preference for living near humans. Pyrethroid insecticides are commonly used to control *Ae. aegypti* in endemic areas, especially during disease outbreaks. Insecticides are still the only way to control *Ae. aegypti* in dengue endemic areas, which has led to extensive use of pyrethroids in the past decades. Consequently, *Ae. aegypti* resistance against pyrethroids is now found worldwide and directly impacts our capacity to control the diseases this species transmits. Resistance alleles often have a cost to the individuals carrying when there is no insecticide present. Understanding the fitness costs and evolution of resistance is critical in integrated resistance management practices for it helps to determine how quickly resistance will be lost under field conditions after pesticide application has ceased. An important mechanism of resistance to pyrethroids is due to mutation in the voltage-sensitive sodium channel (*Vssc*). A common resistance allele contains the S989P+V1016G mutations (*kdr*). I developed a congenic strain of *Ae. aegypti* that contains a voltage-sensitive sodium channel (*Vssc*) allele, S989P+V1016G (IsoKDR), but has the same genetic background as the laboratory susceptible ROCK strain. The goal of

this study was to estimate the fitness cost of this resistance allele by quantifying the susceptible (S) and resistant (R) allele frequencies in a laboratory cage experiment. This was accomplished by crossing ROCK and IsoKDR and then rearing the progeny for 9 generations while evaluating the change in the *kdr* frequency. Our results support our hypothesis that these two *Vssc* mutations have a fitness cost. Further studies are in progress to determine how these mutations impact fitness by looking at changes in fertility, fecundity, and development of IsoKDR relative to ROCK. The implications of these results to the control of *Ae. aegypti* will be discussed.

## 183

### INSECTICIDE RESISTANCE IN *ANOPHELES GAMBIAE* S.L. (DIPTERA: CULICIDAE) FROM ETHIOPIA (2012-2016): A NATIONWIDE STUDY FOR INSECTICIDE RESISTANCE MONITORING

Louisa A. Messenger<sup>1</sup>, J. Shililu<sup>2</sup>, S. Irish<sup>1</sup>, G. Anshebo<sup>2</sup>, A. Getachew<sup>2</sup>, Y. Ye-Ebiyo<sup>2</sup>, S. Chibsa<sup>3</sup>, D. Dengela<sup>4</sup>, G. Dissanayake<sup>3</sup>, E. Kebede<sup>5</sup>, E. Zemene<sup>5</sup>, A. Asale<sup>5</sup>, H. Solomon<sup>6</sup>, K. George<sup>7</sup>, C. Fornadel<sup>7</sup>, A. Seyoum<sup>4</sup>, R. Wirtz<sup>1</sup>, D. Yewhalaw<sup>5</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Abt Associates, Addis Ababa, Ethiopia, <sup>3</sup>U.S. Agency for International Development, Addis Ababa, Ethiopia, <sup>4</sup>Abt Associates, Bethesda, MD, United States, <sup>5</sup>Jimma University, Jimma, Ethiopia, <sup>6</sup>National Malaria Control Program, Addis Ababa, Ethiopia, <sup>7</sup>President's Malaria Initiative, Arlington, VA, United States

Indoor residual spraying (IRS) and long-lasting insecticidal nets (LLINs) remain the cornerstones of malaria vector control. However, the development of widespread insecticide resistance and its implications for operational failure of preventative strategies are of increasing concern. We characterized contemporary nationwide insecticide resistance among *Anopheles gambiae* s.l. populations in Ethiopia and describe temporal changes in resistance between 2012 and 2016. Mosquito larvae were sampled from a range of breeding sites in seven regions annually during the long rainy season, and susceptibility levels to organochlorines, pyrethroids, organophosphates, and carbamates, assessed using WHO susceptibility tests and CDC bottle bioassays. In select sites, specimens were identified to species-level and underlying resistance mechanisms investigated using CDC synergist assays based on pre-exposing mosquitoes to piperonyl butoxide (PBO), and by PCR screening for knockdown resistance (*kdr*). Intense resistance to DDT and pyrethroids was pervasive across Ethiopia and over time, consistent with historic use of DDT for IRS and concomitant increases in insecticide-treated net coverage over the last 15 years. Temporal changes in resistance to malathion, bendiocarb, propoxur and pirimiphos-methyl corresponded to shifts in the national insecticide policy. By 2016, resistance to the latter two insecticides had emerged, with the potential to jeopardize future long-term effectiveness of vector control activities in these areas. Restoration of mosquito susceptibility to pyrethroids following pre-exposure to PBO, a lack of association between *kdr* allele frequency and vector mortality rate, and the absence of cross-resistance between insecticides belonging to the same chemical class, indicates the existence of metabolic mechanisms conferring insecticide-specific resistance. If inter- and intra-class rotation of different insecticides could be exploited to reduce selection pressures, this may have the potential to safeguard continued efficacy of IRS and other malaria control strategies in Ethiopia.

### MICROBIAL LARVICIDES FOR MOSQUITO CONTROL: IMPACT OF LONG LASTING FORMULATION OF *BACILLUS THURINGIENSIS* VAR. *ISRAELENSIS* AND *BACILLUS SPHAERICUS* ON NON TARGET ORGANISMS IN WESTERN KENYA HIGHLANDS

Yahya A. Derua<sup>1</sup>, Samuel C. Kahindi<sup>2</sup>, Franklin W. Mosha<sup>1</sup>, Eliningaya J. Kweka<sup>3</sup>, Harrysone E. Atieli<sup>4</sup>, Guofa Zhou<sup>5</sup>, Ming-Chieh Lee<sup>5</sup>, Andrew K. Githeko<sup>6</sup>, Guiyun Yan<sup>5</sup>

<sup>1</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, <sup>2</sup>Department of Zoology, School of Pure and Applied Sciences, Pwani University, Kilifi, Kenya, <sup>3</sup>Department of Medical Parasitology and Entomology, Catholic University of Health and Allied Sciences, Mwanza, United Republic of Tanzania, <sup>4</sup>School of Public Health, Maseno University, Kisumu, Kenya, <sup>5</sup>Program in Public Health, College of Health Sciences, University of California Irvine, Irvine, CA, United States, <sup>6</sup>Climate and Human Health Research Unit, Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

Microbial larvicides *Bacillus thuringiensis* var. *israelensis* and *Bacillus sphaericus* have been used extensively globally for mosquito control. These larvicides have been found to be effective and safe to non target organisms co-habiting with target vectors. Recent advent of long lasting microbial larvicides, though evade the previous challenge of short duration of activity, increase the risk of persistence of crystal toxins in the treated larval habitats. The current study monitored the impact long lasting microbial larvicides FourStar® and LL3 on non target organisms co-habiting with mosquito larvae in an operational study to control malaria vector in western Kenya highlands. A total of 300 larval habitats were selected from three highland villages in western Kenya. The larval habitats were monitored for five weeks to collection baseline information on non target organisms co-habiting with mosquito larvae and then randomized into two treatments (respective FourStar® and LL3) and control arms. Following treatments, non target organisms were sampled weekly for five months to assess the impact of long lasting microbial larvicides intervention. Before treatment, the mean density of all non target organisms combined in the control, LL3 and FourStar® habitats was 1.42, 1.39 and 1.49 individuals per habitat per sampling occasion, respectively. Following treatment, the mean density of all non-target organisms remained fairly unchanged for 21 weeks in which the mean density at that point was 1.82, 2.11 and 2.05 for the respective control, LL3 and FourStar® habitats. Statistical analysis revealed that the two microbial larvicides did not significantly alter abundance, richness and diversity of 11 taxa studied, when compared the intervention and control larval habitats. However, both FourStar® and LL3 significantly reduced the density of malaria vector. In conclusion, one round of label application of long lasting microbial larvicide FourStar® or LL3 in natural larval habitats did not alter richness, abundance and diversity of aquatic non-target organisms co-habiting with mosquito larvae to an ecologically significant level.

### INSECTICIDE RESISTANCE STATUS OF THREE MALARIA VECTORS: *AN.OPHELES GAMBIAE* S.L., *AN. FUNESTUS* AND *AN. MASCARENSIS* FROM THE SOUTH, CENTRAL HIGHLANDS AND EAST COASTS OF MADAGASCAR

Jean D. Rakotoson<sup>1</sup>, Christen M. Fornadel<sup>2</sup>, Allison Belemvire<sup>2</sup>, Laura C. Norris<sup>2</sup>, Kristen L. George<sup>2</sup>, Angela Caranci<sup>2</sup>, Bradford Lucas<sup>3</sup>, Dereje O. Dengela<sup>3</sup>

<sup>1</sup>Abt Associates, Antananarivo, Madagascar, <sup>2</sup>PMII/USAID, Washington, DC, United States, <sup>3</sup>Abt Associates, Bethesda, MD, United States

Insecticide-based vector control is the key method to malaria control in Madagascar. This study investigated the resistance status of malaria vectors in Madagascar to various insecticides. Adult female *Anopheles gambiae* s.l. mosquitoes reared from field-collected larvae and pupae were tested

for their resistance to DDT, permethrin, deltamethrin, alpha-cypermethrin, lambda-cyhalothrin, bendiocarb and pirimiphos-methyl. Resting *An. funestus* and *An. mascarensis* female mosquitoes collected from unsprayed surfaces were tested against permethrin, deltamethrin and pirimiphos-methyl. The effect on insecticide resistance of pre-exposure to the synergists piperonyl-butoxide (PBO) and S,S,S-tributyl phosphorothioate (DEF) also was assessed. Molecular analyses were done to identify species and determine the presence of knock-down resistance (*kdr*) and acetylcholinesterase resistance (*ace-1<sup>R</sup>*) gene mutations. *An. funestus* and *An. mascarensis* were fully susceptible to permethrin, deltamethrin and pirimiphos-methyl. *An. gambiae* s.l. was fully susceptible to bendiocarb and pirimiphos-methyl. Among the 17 *An. gambiae* s.l. populations tested for deltamethrin, no confirmed resistance was recorded, but suspected resistance was observed in two sites. *An. gambiae* s.l. was resistant to permethrin in four sites (mortality 68-89%) and to alpha-cypermethrin (89% mortality) and lambda-cyhalothrin (80% and 85%) in one site. Pre-exposure to PBO restored full susceptibility to all pyrethroids tested except in one site where only partial restoration to permethrin was observed. DEF fully suppressed resistance to deltamethrin and alpha-cypermethrin, while it partially restored susceptibility to permethrin in two sites. Molecular analysis suggests absence of *kdr* and *ace-1<sup>R</sup>* gene mutations. This study suggests involvement of detoxifying enzymes in the phenotypic resistance of *An. gambiae* s.l. to pyrethroids. The absence of resistance in *An. funestus* and *An. mascarensis* to pirimiphos-methyl and pyrethroids and in *An. gambiae* s.l. to carbamates and organophosphates presents greater opportunity for managing resistance in Madagascar.

### MULTIPLE KNOCKDOWN RESISTANCE (KDR) MUTATIONS IN INDIAN *Aedes Aegypti*

Om P. Singh, Taranjeet kaur, Rajababu S. Kushwah

National Institute of malaria research, Delhi, India

*Aedes Aegypti* is a primary vector for several arboviral infections like dengue, chikungunya, Zika virus and yellow fever. In absence of specific drug or vaccine against these infections vector-control is the only option to control these infections. Development of insecticide resistance in this vector poses serious threat to control these infections. Knockdown resistance (*kdr*) mutations in the voltage gated sodium channel (VGSC)—target site of action for DDT and pyrethroids, is one of the mechanisms of resistance against these two insecticide groups. Several such *kdr* mutations are reported in *Aedes aegypti* globally, however in India, we earlier reported presence of two *kdr* mutations (F1534C and a novel mutation T1520I) in domain III-S6 of VGSC. Here we report presence of multiple *kdr* mutations in Bengaluru viz., S989P and V1016G present in domain IIS6 and F1534C and F1534L present in domain IIIS6. Among these F1534L is not reported earlier from anywhere in this species. Other novel mutation T1520I reported in Delhi (India) is absent in this population. Among these mutations S989P and V1016G were found tightly linked. In addition S989P+V1016G were always linked to F1534. We developed PCR based methods for identification of all *kdr* mutations reported in India (S989P, V1016G, F1534C, F1534L and T1520I).

### ADAPTATION OF THE CDC BOTTLE BIOASSAY FOR NEONICOTINOIDS AND BUTENOLIDES

Sebastian Horstmann, Dunja Prumbaum, Tatjana Leirich, Karin Horn, Justin Fraser McBeath, Frederic Schmitt

Bayer AG CropScience Division, Monheim am Rhein, Germany

The CDC bottle bioassay is an established tool for mosquito susceptibility monitoring. Prolonged discriminating time or an increase of the discrimination dose concentration can detect upcoming resistance of wild caught mosquitoes at an early stage. Therefore such a monitoring tool is of tremendous importance for effective vector control programs with existing products as well as for new active ingredients with no or

low cross-resistance entering the market. Clothianidin is a promising new compound being developed by Bayer as a combination product for indoor residual spraying against malaria vectors. The methodology of the standard bottle assay recommends acetone as practical solvent. However, clothianidin and the active ingredients imidacloprid, thiamethoxam and flupyradifurone show incompatibility for this assay if acetone as single solvent is used. We determined that the addition of Mero® (81% Rapeseed oil methyl ester) has shown to improve efficacy of the named compounds in the described bottle assay. The combination of Mero® and acetone reduces crystallization effects, keep the active ingredient for a longer period of time in a dissolved state and probably improves the uptake of the compound. This study highlights the practical benefits of adding Mero® to the acetone solvent, if used in the CDC bottle bioassay with selected neonicotinoids and butenolides. More than 2000 mosquitoes of the susceptible *Anopheles gambiae* Kisumu strain and 1000 of the RSPH strain were used in several bottle bioassays to identify the discriminating dosage and time for clothianidin, imidacloprid, thiamethoxam and flupyradifurone. 90µg of the named neonicotinoids solved in an acetone/Mero® mixture revealed 100% knockdown to the test insects within 45min. For flupyradifurone a higher active ingredient concentration of 200µg per bottle was necessary. This study highlights a simple adaptation to an existing method which will allow determination of susceptibility of mosquitoes in-field to these new compounds.

## 188

### IDENTIFYING HEME IMPORTERS AND EXPORTERS THROUGH RNA SEQ ANALYSIS IN *Aedes aegypti*

Heather L. Eggleston, Kevin M. Myles, Zach N. Adelman  
Texas A&M University, College Station, TX, United States

After a bloodmeal, mosquitoes import heme into the midgut epithelium. Heme acts as an essential signal for oogenesis in *Aedes aegypti*. However, the mechanisms behind heme import in *Ae. aegypti* are largely unexplored. In this study, RNA sequencing data from 4 different *Ae. aegypti* cell culture experiments where cells were exposed to an overabundance or deficiency of heme was examined to identify heme-responsive genes. Zinc mesoporphyrin (ZnMP), a heme fluorescent analog, was used to measure changes in heme uptake prior to mRNA sequencing. A soft cluster analysis was performed to identify genes encoding potential membrane bound importers and exporters based on expression profiles across the samples for each experiment. Stronger candidates were obtained by comparing genes in each dataset to each other. In total, 168 potential importers were found to be heme-regulated in only 2 datasets, 36 were heme-regulated in 3 datasets and 1 was heme-regulated in all 4 datasets. In contrast, 105 potential exporters were common to only 2 datasets, with just 2 present in 3 of the 4 datasets. Future work will focus on generating an RNA seq dataset from adult midgut exposed to overabundance or deficiency of heme and comparing those results to current cell culture results to find those differentially expressed transcripts common amongst all or most of the datasets which should lead to stronger predictions of possible heme transporters. Finally reverse genetic analysis will be performed on the top candidate genes to confirm their status as importers or exporters in *Aedes aegypti*.

## 189

### EVOLUTIONARY HISTORY OF THE MACULIPENNIS GROUP OF MALARIA MOSQUITOES REVEALED BY TRANSCRIPTOME AND CHROMOSOME-REARRANGEMENT ANALYSES

Maria V. Sharakhova<sup>1</sup>, Andrey A. Yurchenko<sup>2</sup>, Anastasia N. Naumenko<sup>1</sup>, Gleb N. Artemov<sup>3</sup>, Alina A. Kokhanenko<sup>3</sup>, Semeon M. Bondarenko<sup>3</sup>, Alena I. Velichevskaya<sup>3</sup>, Vladimir N. Stegny<sup>3</sup>, Igor V. Sharakhov<sup>1</sup>

<sup>1</sup>Virginia Tech, Blacksburg, VA, United States, <sup>2</sup>University of Glasgow, Glasgow, United Kingdom, <sup>3</sup>Tomsk State University, Tomsk, Russian Federation

The Maculipennis group of malaria mosquitoes is subdivided into two North American and one Eurasian subgroups. Although previous studies considered the Nearctic subgroups as ancestral, the details of the malaria mosquitoes' migration from North America to Eurasia remains a subject of debate. To reconstruct historic relationships between the North American to Eurasian mosquitoes, we conducted a multigene phylogenetic analysis of 7 Palearctic and 2 Nearctic species based on their transcriptomes. Maximum likelihood trees were generated using 2267 orthologous genes for each autosomal arm and the X chromosome separately. The transcriptome analysis indicated a closer relationship of *An. beklemishevi* with other Palearctic members rather than with the Nearctic members of the group. Also, *An. beklemishevi* clusters more closely with *An. freeborni* that occupies the Western United States rather than with *An. quadrimaculatus*, a species from the Eastern United States. Our time-calibrated tree strongly suggests a single migration of the mosquitoes of the Maculipennis group from North America to Eurasia through the Bering Bridge Land about 11 million years ago and their further divergence into the Asian and European clades. In addition, we constructed a rearrangement-based phylogeny using 21 genes located at a 1 Mb distance from each other on chromosome X. Positions of these genes were determined on X chromosomes of seven Palearctic species using fluorescent *in situ* hybridization. The mapping demonstrated that all species differ from each other by several fixed inversions on the X chromosome. The obtained inversion-based dendrogram supports a more basal position of *An. beklemishevi* among other Palearctic species in agreement with the molecular phylogeny. The research was supported by the Russian Science Foundation grant 15-14-20011.

## 190

### GENETIC STRUCTURE AND PHENOTYPIC VARIATION OF *ANOPHELES DARLINGI* AT THE MICROGEOGRAPHIC LEVEL IN AN IMPORTANT MALARIA ENDEMIC REGION OF COLOMBIA

Mariano Alatmairanda-Saavedra<sup>1</sup>, Julian Rodriguez-Zabala<sup>1</sup>, Nelson Naranjo-Diaz<sup>1</sup>, Jan E. Conn<sup>2</sup>, Margarita M. Correa<sup>1</sup>

<sup>1</sup>Grupo de Microbiología Molecular, Escuela de Microbiología, Universidad de Antioquia, Medellín, Colombia, <sup>2</sup>Department of Biomedical Sciences, School of Public Health, State University of New York at Albany, Albany, New York, United States of America. Wadsworth Center, New York State Department of Health, Albany, New York, NY, United States

Various studies have demonstrated that ecological heterogeneity derived from human activities promotes ecological adaptation and evolutionary divergence of mosquito vectors. This study, conducted at the microgeographic level, evaluated the influence of environmental heterogeneity on *Anopheles darlingi* genetic and morphometric traits. Specimens of *An. darlingi* collected from multiple municipalities in the Colombian malaria endemic region Urabá-Bajo Cauca and Alto Sinú (UCS) were analyzed using 13 microsatellite *loci*. We estimated spatial genetic structure and population variation among and within populations and wing geometric morphometrics analysis was performed. The microsatellite results showed low genetic differentiation and high gene flow among populations. Additionally, four highly admixed subpopulations were detected with no particular association among them and the

municipalities. Wing geometric morphometrics analysis showed a subtle but significant difference in wing shape for only El Bagre vs Mutata populations, possibly influenced by geographical distance. Discrimination among populations in the morphospace, defined by the canonical variance axes, showed a slight separation of the Tierralta population. There was no significant correlation between the genetic and geographic or genetic and environmental distances. We hypothesize that environmental heterogeneity in the UCS region is not enough to promote *An. darlingi* population structure. It remains to be ascertained which local factors govern phenotypic variation among these populations and how these may impact mosquito physiological and bio-ecological traits

## 191

## 20-HYDROXYECDYSONE (20E) INDUCES PRIMING OF MOSQUITO IMMUNITY AND LIMITS MALARIA PARASITE INFECTION IN *ANOPHELES GAMBIAE*

**Rebekah Reynolds**, Ryan Smith

*Iowa State University, Ames, IA, United States*

The act of acquiring a blood meal provides reproductive and physiological advantages for mosquitoes, however little is known about the impacts of blood feeding on mosquito immunity. With a critical role in determining vector competence, understanding the influence of mosquito physiology on pathogen development is important for the identification of potential targets to reduce transmission of mosquito-borne diseases. Given this importance, we are interested in the influence of hormones, specifically 20-hydroxyecdysone (20E), which significantly increases 18-24 hours post blood feeding. Coinciding with the timing of pathogen challenge, emerging evidence suggests that 20E may also influence mosquito immunity, arguing that targeting 20E synthesis may function as a potential tool to interfere with pathogen development in the mosquito host. Here we report the effects of 20E on mosquito physiology and innate immune responses through *in vitro* and *in vivo* experiments, highlighting the roles of 20E on mosquito immune regulation. We found that the injection of 20E, as well the topical application of Halofenozide, a 20E-mimicking insecticide, lead to an increase in 20E-regulated gene expression in *An. gambiae* and a significant decrease in malaria parasite numbers. Additionally, topical applications of Halofenozide increased mosquito survival following bacterial challenge. Together, this suggests that 20E primes the mosquito immune system for pathogen challenge. Experiments are currently underway to extend these studies to other mosquito vectors to investigate the effects of Halofenozide application on arbovirus infections. With direct public health applications, we believe repurposing hormone mimicking insecticides will be an important new tool to reduce the transmission of mosquito-borne disease.

## 192

## NOVEL INSIGHTS INTO *ANOPHELES* IMMUNE FACTORS WITH PRO/ANTI-*PLASMODIUM* MELANIZATION FUNCTIONS IN DIVERSE VECTOR-PARASITE SPECIES COMBINATIONS

**Maria L Simoes**, Godfree Mlambo, Yuemei Dong, Abhai Tripathi, George Dimopoulos

*Johns Hopkins University, Baltimore, MD, United States*

*Anopheles-Plasmodium* interactions have been the subject of intense study, given the importance of the mosquito vector for malaria transmission. The functions of the *Anopheles* immune system receptors C-type lectins CTL4 and CTLMA2, and leucine-rich repeat protein LRIM1, were first described based on the *A. gambiae-P. berghei* laboratory model, and field *A. gambiae-P. falciparum*. The two C-type lectins were identified as *P. berghei* agonists, that inhibit parasite melanization, and LRIM1 as an antagonist involved in killing this parasite. None of these factors appeared to have an effect on the human *P. falciparum* parasite. The functions of these genes in mosquito immunity to *Plasmodium* were not further explored. Here we show that the implication of the *A. gambiae* C-type lectins, in protecting parasites from melanization, is infection intensity

dependent, and not *Plasmodium* species-specific as previously thought. We then explored the influences of these genes on *Plasmodium* infection in the New World vector *A. albimanus*. Our findings revealed that silencing the predicted orthologues of CTL4 and CTLMA2 in *A. albimanus* had the opposite effect than that in *A. gambiae*, while LRIM1 had a conserved function, for both parasite species, suggesting that the C-type lectin genes have diverged their function in different mosquito species. Only a moderate degree of identity was observed between the *A. gambiae* CTL4 and its *A. albimanus* predicted orthologue, suggesting that it may not be a true orthologue. Interestingly, *Plasmodium* infection in *A. albimanus* results in a variety of oocyst/sporozyte phenotypes depending on the silenced gene. Moreover, our data suggests that the functions of the C-type lectins in regulating infection intensity and melanization, are unlinked.

## 193

## CHARACTERIZE THE FUNCTION OF HOST IMMUNITY MIRNAS TO BLOCK *PLASMODIUM FALCIPARUM* INFECTION BY MOSQUITO TRANSGENESIS IN *ANOPHELES GAMBIAE*

**Shengzhang Dong**<sup>1</sup>, Yuemei Dong<sup>1</sup>, Maria Luisa Simoes<sup>1</sup>, Jinsong Zhu<sup>2</sup>, George Dimopoulos<sup>1</sup>

<sup>1</sup>*Johns Hopkins University, Baltimore, MD, United States*, <sup>2</sup>*Virginia Polytechnic Institute and State University, Blacksburg, VA, United States*

Malaria, caused by the protozoan parasite *Plasmodium falciparum* and transmitted by *Anopheles gambiae* mosquitoes, is a major threat to human health, responsible for up to half of million deaths worldwide in 2016. *Plasmodium* invasion of the *Anopheles* tissues represents a critical step in the parasite-transmission cycle. Recent studies showed that insect innate immunity plays an important role in blocking *Plasmodium* transmission in *Anopheles*. Overexpression of immune effector gene (*Relish 2*) in transgenic *Anopheles* mosquitoes have been shown to significantly block parasite transmission. MicroRNAs (miRNA) are small regulatory noncoding RNAs and sized from 21 to 25 nt, has been shown to play a central role in the regulation of gene expression. miRNAs target the 3' untranslated regions (3'-UTR) of mRNAs, thereby repressing their translation. Previously, we reported that aga-miR-989 and aga-miR-305 exhibited elevated abundance of expression in midguts of the mosquito infected by *Plasmodium*, and artificial aga-miR-305 mimics increased susceptibility to *P. falciparum* infection and resulted in expansion of midgut microbiota, suggesting that aga-miR-305 acts as a *P. falciparum* and gut microbiota agonist by negatively regulating the mosquito immune response. Here, we report an approach to characterize the function of aga-miR-305 and other selected miRNAs with regards to their influence on *Plasmodium* infection in *A. gambiae* using mosquito transgenesis by overexpressing miRNA sponges in female mosquitoes and thus eliminating miRNA function, thereby increasing mosquito immunity, and reveal the possible miRNA targets by transcriptome analysis in transgenic mosquitoes.

## 194

## GENETIC MANIPULATION OF MOSQUITO NERVOUS SYSTEM

**Keshava Mysore**, Ping Li, Molly Duman-Scheel

*IU School of Medicine at Notre Dame, South Bend, IN, United States*

Although mosquitoes transmit pathogens responsible for some of the most devastating diseases, relatively little is known about their neurobiology or behavior. Investigating the neurobiological basis of fundamental mosquito behaviors could facilitate modification of these behaviors for vector and disease control. To study and eventually manipulate neural control of a particular behavior, tools are needed to identify neurons involved in the behavior, determine how activity of the neurons influences the behavior, and explore how the neurons form a functional circuit. While such tools are available for analysis of genetic model organisms, mosquito neurobiologists lack such sophisticated genetic tools for analysis of the neural basis of behaviors. The binary expression system of Gal4-UAS, is routinely utilized for neurobiological studies in model organisms. Although the Gal4-UAS system has been introduced

in mosquitoes, very few Gal4 and UAS strains have been developed. To enhance the genetic tractability of *Aedes aegypti*, the principle mosquito vector for many arboviruses like Zika & dengue we performed a FAIRE-seq open chromatin profiling study that permitted genome-wide discovery of >121,000 putative cis-regulatory elements (Behura et al., 2016). GFP reporter assays were used in a screen to identify regulatory elements that drive gene expression in the central and sensory nervous systems. The screen performed in *Drosophila* using putative regulatory elements from *A. aegypti* was designed to enhance for the selection of elements that drive neural gene expression in *A. aegypti*. Select elements from the screen have been cloned into a Gal4 transgenic vector that is compatible with multiple modes of transformation in *A. aegypti* and other insect species. In the present study, an *A. aegypti* Gal4 ofactory driver line was identified and characterized. Additional driver lines, including one that generated sex-specific neural gene expression in reporter assays, are presently being generated. Future studies will focus on generation of UAS responder lines that will allow us to study and manipulate the mosquito nervous system.

## 195

### MAPPING QTLs IN *CULEX QUINQUEFASCIATUS* THAT CONTROL THE DENSITY OF BACTERIAL SYMBIONT *WOLBACHIA PIPIENTIS*

Robert L. Glaser<sup>1</sup>, Kevin J. Emerson<sup>2</sup>

<sup>1</sup>Wadsworth Center, New York State Department Health, Albany, NY, United States, <sup>2</sup>St. Mary's College of Maryland, St. Mary's City, MD, United States

The unique characteristics of *Wolbachia* are being exploited to develop *Wolbachia* infection of vector mosquitoes as an approach for interrupting the transmission cycle of viral disease pathogens. This approach hinges on the ability of *Wolbachia* infection to increase host resistance to viral pathogens, determined, in part, by the density of *Wolbachia* in host tissues. Little is known, however, about how *Wolbachia* density is regulated in native or heterologous hosts. We measured the broad-sense heritability of *Wolbachia* density between families in field populations of the mosquito *Culex pipiens*, and found that densities in ovary and non-gonadal tissues of females in the same family are not correlated, suggesting that *Wolbachia* density is determined by distinct mechanisms in the two tissues. Using introgression analysis between two different strains of the closely-related species *Culex quinquefasciatus*, we found that *Wolbachia* densities in ovary tissues are determined by cytoplasmic genotype, while densities in non-gonadal tissues are determined by both cytoplasmic and nuclear genotypes and their epistatic interactions. Quantitative-trait locus mapping using a high-density SNP-based genetic map of the *Cx. quinquefasciatus* genome identified two major-effect quantitative-trait loci explaining a combined 23% of variance in *Wolbachia* density specifically in non-gonadal tissues. A better understanding of how *Wolbachia* density is regulated will provide insights into how *Wolbachia* density can vary spatiotemporally in mosquito populations, leading to changes in *Wolbachia*-mediated phenotypes such as viral pathogen resistance.

## 196

### IMPACTS OF ELIMINATION AND EXOGENOUS TRANSFECTION OF *WOLBACHIA* ON GUT MICROBIOTA AND TRANSCRIPTOME OF *AEDES ALBOPICTUS*

Xiaoming Wang<sup>1</sup>, Daibin Zhong<sup>1</sup>, Tong Liu<sup>2</sup>, Guofa Zhou<sup>1</sup>, Zetian Lai<sup>2</sup>, Dongjing Zhang<sup>3</sup>, Xiaoying Zheng<sup>3</sup>, Zhiyong Xi<sup>4</sup>, Kun Wu<sup>2</sup>, Xiaoguang Chen<sup>2</sup>, Guiyun Yan<sup>1</sup>

<sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>Southern Medical University, Guangzhou, China, <sup>3</sup>Sun Yat-sen University, Guangzhou, China, <sup>4</sup>Michigan State University, East Lansing, MI, United States

*Aedes albopictus* is an important vector of dengue, Zika and Chikungunya worldwide and a sole vector for dengue in southern China. Intracellular bacteria *Wolbachia* is known to cause cytoplasmic incompatibility, recent

studies also demonstrated that it plays an important role in limiting infectivity of arboviruses in the mosquito vectors. Novel *Wolbachia* strains are being introduced to mosquito populations to modify vector competence and block arbovirus transmission. However the mechanisms of immuno-modulation of *Wolbachia* on the mosquito vectors are not well understood, one potential mechanism is that novel *Wolbachia* strain introduction modify mosquito gut microbiota and subsequently enhance mosquito immune response to arboviruses. The objective of this study was to examine the impact of elimination and exogenous transfection of *Wolbachia* on gut microbiota and transcriptome of *Aedes albopictus* mosquitoes. The assemblages of bacterial microbiota in *Ae. albopictus* wildtype strain, *Wolbachia*-free strain and a strain transfected by new types of *Wolbachia* in egg, larvae and adult (day 1, 7, 14, 21, blood feeding and non-blood feeding) stages were examined using 16S rRNA MiSeq amplicon-sequencing on Illumina. We found that removal of natural *Wolbachia* from *Aedes albopictus* populations by tetracycline reshaped the structure of bacterial microbiota and significantly increased gut bacterial diversity. Similarly, transfection of exogenous *Wolbachia* strain also significantly increased diversity of the bacterial microbiota. Such impacts are most pronounced at the egg stage. We are currently using RNA-seq technique to determine the impact of elimination and exogenous transfection of *Wolbachia* on transcriptome of immune genes. The information obtained from this study would help to establish a metagenomic foundation for better understanding the impact of bacterial microbials on vector development and disease transmission.

## 197

### GENOMIC BASIS OF BLOODFEEDING BEHAVIOR IN *ANOPHELES MINIMUS*, THE PRIMARY MALARIA VECTOR IN SOUTHEAST ASIA

Daibin Zhong<sup>1</sup>, Xiaoming Wang<sup>1</sup>, Guofa Zhou<sup>1</sup>, Elizabeth Hemming-Schroeder<sup>1</sup>, Liwang Cui<sup>2</sup>, Guiyun Yan<sup>1</sup>

<sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>The Pennsylvania State University, University Park, PA, United States

*Anopheles minimus* represents one of the most important malaria vectors in Southeast Asia. The adult behavior of the species was reported to be highly diverse with regards to blood meal source preferences, as well as biting and resting behavior. Understanding the genomic basis of host feeding preference and biting activity of vector species is valuable to identify their potential to adapt to new environments and malaria control interventions, and the information helps to develop appropriate strategies of vector control management. The aim of the study is to examine the genomic basis of host bloodfeeding preference in *An. minimus* by next-generation whole genome sequencing. Bloodfed mosquitoes were collected using CDC light traps in a malaria endemic area of the China-Myanmar border region. Molecular identification of *An. minimus* species and host blood meal was conducted by PCR using DNA from the abdomen. Head and legs of 24 mosquitoes with human blood meal (H-group) and 24 mosquitoes with animal blood meal (A-group) were used to extract DNA individually for whole genome sequencing by Illumina. A total of 336,451 variants were identified in the 48 mosquito genomes (median coverage =22.4x). Among them, 310,254 and 279,699 genomic variants were found in H-group and A-group, respectively. A total of 1,268 differential genomic variants were detected between H-group and A-group, including SNPs in genes of odorant receptor protein, cuticular protein, hormone-related protein and other proteins. The results suggested that mosquito host preference is associated with genetic variation in a large number of genes. Further analysis is being conducted to identify the key genes for mosquito bloodfeeding preference. Such information is valuable to understand the evolution of mosquito host preference in response to vector control measures.

### ANOPHELES FUNESTUS IN CENTRAL AND SOUTHERN AFRICA: ANALYSIS OF MITOCHONDRIAL DIVERSITY

Christine M. Jones<sup>1</sup>, Yoosook Lee<sup>2</sup>, Travis C. Collier<sup>2</sup>, Julia C. Pringle<sup>1</sup>, Jennifer C. Stevenson<sup>1</sup>, Maureen Coetzee<sup>3</sup>, Mbanga Muleba<sup>4</sup>, Youki Yamasaki<sup>2</sup>, Anthony J. Cornel<sup>2</sup>, Douglas E. Norris<sup>1</sup>, Giovanna Carpi<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>University of California Davis, Davis, CA, United States, <sup>3</sup>University of the Witwatersrand, Johannesburg, South Africa, <sup>4</sup>Tropical Disease Research Center, Ndola, Zambia

*Anopheles funestus* s.s. is a primary vector of malaria in sub-Saharan Africa. Despite its important role in malaria transmission, knowledge of *An. funestus* s.s. evolutionary history and population differentiation in southern Africa remains understudied. In this study, we examined the phylogenetic relationships and demographic history of *An. funestus* s.s. populations throughout southern Africa using mitogenome sequences. We deep sequenced and analyzed the complete mitochondrial genome of 43 *An. funestus* s.s. from 3 sites in Zambia, Democratic Republic of Congo and Tanzania. We found a high genetic diversity of *An. funestus* s.s. with 41 unique haplotypes out of 43 mitogenome sequences, and 355 parsimony informative sites. Phylogenetic reconstruction using the novel mitogenomes confirmed the existence of two divergent *An. funestus* mitochondrial lineages, I and II, in northern Zambia and revealed new records for lineage II in Tanzania. Statistical parsimony network analysis revealed two major groups within lineage I, and no general structure for those samples in lineage II, likely due to under sampling within this population. Studies are ongoing with regard to the biological relevance of these mitochondrial lineages within *An. funestus* s.s., which may have implications for vector control.

### IMPACT OF OPTIMALLY AND SUB-OPTIMALLY CLOSED EAVES ON THE HOUSE ENTRY BEHAVIOR OF MALARIA VECTORS

Monicah M. Mburu<sup>1</sup>, Malou Jurlink<sup>1</sup>, Jeroen Spitzen<sup>1</sup>, Themba Mzilahowa<sup>2</sup>, Robert S. McCann<sup>1</sup>, Willem Takken<sup>1</sup>

<sup>1</sup>Wageningen University and Research, Wageningen, Netherlands, <sup>2</sup>Malaria Alert Centre, Blantyre, Malawi

A surge in malaria transmission is feared due to the increasing resistance of malaria vectors to insecticides. Structural house improvement (e.g. closed or screened eaves; screened windows) is a promising complimentary tool to other malaria interventions such as insecticide treated nets. House improvement covers and protects all individuals in a house equally. When implemented on a large scale, house improvement may not be employed wholly in 100% of houses; and therefore it's critical to assess whether sub-optimal (partial) house improvement will have any effect on mosquito house entry. We investigated the effect of partial house improvement on the house entry behaviour of malaria vectors and other mosquitoes in southern Malawi. Houses were modified according to five treatments: fully closed eaves, three different levels of partially closed eaves, and completely open eaves. All houses had fully screened windows and closed doors. We sampled host seeking mosquitoes inside these houses using Centers for Disease Control (CDC) light traps. The effect of house improvement level on the number of mosquitoes caught was tested using non-parametric tests (Kruskal-Wallis and Mann-Whitney U tests). Fully improved houses had significantly fewer *Anopheles* mosquitoes than houses that were partially improved. Likewise, the catches of *Culicine* mosquitoes were significantly different in houses that were fully and partially improved. The results highlight the importance of quality control measures when implementing structural house improvements as a malaria intervention.

### THE REAPPEARANCE OF ANOPHELES FUNESTUS AS A MAJOR MALARIA VECTOR IN THE ETHIOPIAN RIFT VALLEY AFTER 40 YEARS

Solomon Kibret<sup>1</sup>, G. Glenn Wilson<sup>2</sup>, Darren Ryder<sup>3</sup>, Guiyun Yan<sup>1</sup>

<sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>University of Southern Denmark, Odense, Denmark, <sup>3</sup>University of New England, Armidale, Australia

Construction of dams and irrigation schemes is critical to increase agricultural productivity and boost economy in Africa. With this regard, many dams are currently under construction in Ethiopia, with primarily purposes of irrigation and hydroelectricity generation. While these water development schemes are of paramount importance for economic growth, their impact on malaria transmission has been a public health challenge. This study aims to elucidate malaria transmission linked to Kesem dam and irrigation scheme in central Ethiopian Rift Valley. Larval and adult mosquito was collected monthly from two villages close (<1 km) from the dam and another two further away (>8 km; control villages) between September 2014 and October 2015. Determination of blood meal sources and detection of *Plasmodium falciparum* sporozoites was done using enzyme-linked immunosorbent assay (ELISA). Five years of monthly malaria case data (2010-2014) were also collected from health centers in the study villages. *Anopheles funestus* s.l. was believed to have been disappeared from the Ethiopian Rift Valley after introduction of DDT in 1970s. However, our sampling detected both larval and adult stages in the study area. Mean monthly malaria incidence was three times higher in the dam villages than the non-dam villages. Larvae of *An. funestus* s.l. and *An. arabiensis* were largely collected from the shoreline of the dam and irrigation canals. CDC light trap captures showed that *An. arabiensis* was predominant indoors while *An. funestus* s.l. was equally found both indoors and outdoors. For the first time in 40 years, this study confirmed the role of *Anopheles funestus* s.l. as a primary vector of malaria as evidenced by its high human blood index (0.81) and entomological inoculation rate (157 infective bites per person per year). The findings of this study indicate the reappearance of *An. funestus* s.l. and its role in malaria transmission in the newly irrigated areas of the Ethiopian Rift Valley. Proper water resource management that incorporates malaria intervention strategies is therefore required to mitigate malaria related to water resources development.

### BITING BEHAVIOR OF ANOPHELES DARLINGI IN FOUR COMMUNITIES IN THE MAZAN DISTRICT OF THE PERUVIAN AMAZON

Freddy Alava<sup>1</sup>, Marlon Saavedra<sup>1</sup>, Marta Moreno<sup>2</sup>, Dionicia Gamboa<sup>3</sup>, Jan Conn<sup>4</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Peru, <sup>2</sup>Division of Infectious Diseases, Department of Medicine, University of California San Diego, La Jolla, CA, United States, <sup>3</sup>Universidad Peruana Cayetano Heredia, Peru, <sup>4</sup>Wadsworth Center, New York State Department of Health, Albany, NY, United States

*Anopheles darlingi* is considered the main vector of malaria in the Loreto Region, where its seasonal abundance is strongly influenced by river levels and rainfall. In the Mazan district northwest of Iquitos, the highest levels of the Napo and Mazan rivers and the greatest anopheline densities occur during the rainy season, when malaria transmission is also greatest. Despite control measures undertaken by the Ministry of Health, between 2011-2015 (IRS, LLINs and Active Case Detection) malaria cases increased substantially, possibly the result of increased residual transmission (exophagic behavior of *An. darlingi*). Previous studies in 2008-2009 reported 98.6% (of 8,246) *An. darlingi*, with a Human Biting Rate (HBR) ranging 0.102-41.13 bites/person/hour. To characterize the vector biology behavior in the area, in the present study, mosquito surveys were carried out in 4 endemic malaria communities located near the confluences of the

Napo and Mazan rivers 35 km from the city of Iquitos. In each community, indoor and outdoor collections were performed two nights in March, June, September, and November 2016, each night from 6PM-6AM. Two barrier screens, to collect those mosquitoes seeking for blood meals, were set up one night/month and twelve hours collection (6PM-6AM). In total, 5,787 mosquitoes were collected by HLC and 746 by barrier screens. *An. darlingi* was the most abundant species (5,520, 95.39%) in each community and every survey. HBR varied among localities and by season (0-341 bites/night/person) reaching the highest in Visto Bueno and Libertad (both in Mazan river) in Jun. Overall, a high degree of exophagy (79%) was observed during the four collections. Similar densities of mosquitoes, most of which were *An. darlingi* (89.68%) were captured by barrier screens located near the forest (408) and near the river (388). In conclusion, communities located in Mazan river reported a higher abundance and HBRs of *Anopheles darlingi*, compared to communities in the Napo River. In addition, malaria transmission may be maintained due to the preference of these mosquito populations to bite outdoors, when people are not under malaria protective measures.

## 202

### STUDIES ON THE BITING BEHAVIOR OF AEADES MOSQUITOES' IN SOME SELECTED COMMUNITIES IN NORTHERN GHANA

**Millicent Captain-Esoah<sup>1</sup>**, Philip Kweku Baidoo<sup>2</sup>, Samuel Dadzie<sup>3</sup>, Daniel Adjei Boakye<sup>3</sup>

<sup>1</sup>Department of Applied Biology, University for Development Studies, Navrongo, Ghana, <sup>2</sup>Department of Theoretical and Applied Biology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, <sup>3</sup>Department of Parasitology, Noguchi Memorial Institute for Medical Research, Legon-Accra, Ghana

The mosquito *Aedes aegypti* maintains close association with human populations and it is the principal vector of yellow fever and dengue fever, as well as chikungunya virus (CHIKV) which is responsible for high disease burden and the recent Zika virus. In Ghana *Aedes* mosquitoes are the main vectors of yellow fever and are known to have locale-specific distribution. There have been an increase in the incidence of arboviral disease, most of which are transmitted mainly by *Aedes* species, it has become imperative to study the biting behavior of this important vector species in order to prepare for any future outbreaks and also to implement appropriate vector control programmes. There is also the need to update the existing information on biting patterns of *Aedes* mosquitoes since very little information available in Ghana is scanty and scattered in few reference journals. We studied the comparative biting patterns of *Aedes* in (Damongo) Northern Region, (Bolgatanga), Upper East Region and (Nadowli), Upper West region of Ghana for 16 months, from 2015 to 2016. Female adult mosquitoes were collected both indoor and outdoor between the hours of 06:00 and 18:00 hours GMT from all the study areas using human landing collections. All mosquitoes were sorted and identified morphologically using appropriate taxonomic keys. In all an average of 1196 mosquitoes were collected, 61 % which were *Aedes aegypti*, 1 % were *Aedes vittatus*, 10 % were *Anopheles* and 28 % were *Culex*. *Aedes aegypti* was the predominant biting species in Bolgatanga (43.4%), followed by Damongo (35.6%), with the least number being 21% in Nadowli. *Aedes vittatus* was found biting only in Nadowli and more in the rainy season of 2015 than in the rainy season of 2016. *Aedes aegypti* had a bimodal biting behavior peaking at 07:00 - 08:00 and 16:00 - 17:00 hours GMT. The information on the biting behavior is important for planning and implementing effective vector control programmes in the three regions of the North and in Ghana as a whole.

## 203

### PRESENCE AND ABUNDANCE OF AEADES AEGYPTI ADULT MOSQUITOES IN RURAL AND URBAN AREAS OF WESTERN AND COASTAL KENYA: A POTENTIAL RISK FOR THE OCCURRENCE AND TRANSMISSION OF ARBOVIRAL DISEASES

**Bryson A. Ndenga<sup>1</sup>**, Francis M. Mutuku<sup>2</sup>, Harun N. Ngugi<sup>3</sup>, Joel O. Mbakaya<sup>1</sup>, Peter Aswani<sup>1</sup>, Peter S. Musunzaji<sup>4</sup>, John Vulule<sup>5</sup>, Dunstan Mukoko<sup>6</sup>, Uriel Kitron<sup>7</sup>, Angelle D. LaBeaud<sup>8</sup>

<sup>1</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Chuka University, Chuka, Kenya, <sup>4</sup>Vector Borne Disease Unit, Msambweni, Kenya, <sup>5</sup>Kenya Medical Research Institute, Busia, Kenya, <sup>6</sup>Vector Borne Disease Unit, Nairobi, Kenya, <sup>7</sup>Emory University, Atlanta, GA, United States, <sup>8</sup>Stanford University, Stanford, CA, United States

*Aedes aegypti* is the main vector for yellow fever, dengue fever, chikungunya and Zika viruses. Presence and abundance of this adult vectors is associated with the risk for the occurrence and transmission of these arboviruses and potential introduction of new viruses. **Methods:** Presence and abundance of *Ae. aegypti* adult mosquitoes were determined indoors and outdoors in two western (urban Kisumu and rural Chulaimbo) and two coastal (urban Ukunda and rural Msambweni) sites in Kenya. Sampling was performed using human landing catches, Prokopack automated aspirators and Biogents-sentinel traps. A total of 2,247 *Ae. aegypti* mosquitoes were collected: 785 by human landing catches, 459 by Prokopack and 1003 by Biogents-sentinel traps. About three times as many *Ae. aegypti* mosquitoes were collected in urban than rural sites (1665 versus 582). Comparable numbers of them were collected in western (1201) and coastal (1046) sites. Over 80% of them (999/1244) were collected outdoors through human landing catches and Prokopack aspiration. The probability of collecting *Ae. aegypti* mosquitoes by human landing catches was significantly higher in the evening than morning hours ( $P=0.002$ ), outdoors than indoors ( $P<0.001$ ) and in Ukunda than in Chulaimbo ( $P<0.001$ ). Significantly more *Ae. aegypti* mosquitoes were collected using Prokopack aspiration outdoors than indoors ( $P<0.001$ ), in Ukunda than in Chulaimbo ( $P<0.001$ ) and in Kisumu than in Chulaimbo ( $P=0.005$ ). Significantly more mosquitoes were also collected using Biogents-sentinel traps in Kisumu than in Chulaimbo ( $P<0.001$ ). In conclusion, *Aedes aegypti* mosquitoes were found in all the study sites with the probability of exposure to their bites being highest outdoors, in urban areas and in evening hours.

## 204

### COMBINING AREA-WIDE MOSQUITO REPELLENTS AND LONG-RANGE ATTRACTANTS TO CREATE A "PUSH-PULL" SYSTEM THAT PROTECTS AGAINST DISEASE TRANSMITTING MOSQUITOES IN TANZANIA

**Arnold S. Mmbando**, Fredros O. Okumu, Masoud Kilalangongono, Halfan S. Ngowo, Said Abbas, Nancy S. Matowo, Sarah J. Moore

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Despite high coverage of indoor interventions such as insecticide-treated nets, mosquito-borne infections persist partly because of outdoor-biting, early-biting and insecticide-resistant vectors. This study assessed protective efficacy of a push-pull system against outdoor-biting and indoor-biting pyrethroid resistant mosquitoes in a Tanzanian village. A partially randomized cross-over design was used to test the efficacy of push-pull for 32 nights in four experimental huts and 16 nights in four local houses, in an area with high pyrethroid resistance. The push-pull system consisted of repellent dispensers which actively dispensing transfluthrin vapors and one lure-and-kill device the odour-baited mosquito landing box situated outside two huts and households. Two other huts and households without push-pull were used as controls. Mosquitoes were collected

indoors hourly using exit traps in huts and outdoor by HLC. *Anopheles gambiae* complex and *An. funestus* group were caught during huts and household experiments were distinguished between sibling species by using PCR. *Plasmodium falciparum* antigens in mosquito salivary glands were detected by ELISA method. Primary outcomes were, 1) number of mosquitoes caught outdoors and indoors, 2) sibling species composition and 3) number of *P. falciparum* infected mosquitoes. Push-pull offered marginal protection against host-seeking mosquitoes, in experimental huts there was a significant 30% reduction in outdoor-biting for *An. arabiensis* ( $P < 0.001$ ), and 41.5% for *Ma. uniformis* ( $P < 0.014$ ). There were no significant biting reductions for other mosquito species. Number of mosquitoes caught inside exit traps between treated and control huts were statistically similar. All *An. gambiae* analyzed by r-DNA PCR were identified as *An. arabiensis*, but for *An. funestus* group, 86.9% were *An. funestus* s.s., 9% *An. rivulorum* and 3.9% *An. lesoni*. No *Plasmodium* infected *Anopheles* were detected. Push-pull provided modest protection against early-biting and outdoor-biting mosquitoes. This approach could possibly contribute to reducing transmission of mosquito-borne infections, if optimized.

## 205

### EFFICACY AND PERSISTENCE OF LL3 AND FOURSTAR MICROBIAL LARVICIDES AGAINST DIFFERENT LARVAL STAGES OF MALARIA VECTORS IN WESTERN KENYA HIGHLANDS

**Samuel C. Kahindi**<sup>1</sup>, Yahya Derua<sup>2</sup>, Goufa Zhou<sup>3</sup>, Ming-Chieh Lee<sup>3</sup>, Simon Muriu<sup>1</sup>, Joseph Mwangangi<sup>4</sup>, Harrysone Atieli<sup>5</sup>, Andrew Githeko<sup>6</sup>, Guiyan Yan<sup>3</sup>

<sup>1</sup>Pwani University, Kilifi, Kenya, <sup>2</sup>Tumaini University, Moshi, United Republic of Tanzania, <sup>3</sup>University of California, California, CA, United States, <sup>4</sup>Kenya Medical Research Institute, Kilifi, Kenya, <sup>5</sup>Maseno University, Kisumu, Kenya, <sup>6</sup>Kenya Medical Research Institute, Kisumu, Kenya

The chemical based malaria vector control interventions are threatened by development of insecticide resistance and change in behavior of the vectors calling for the need for alternative control methods. Bacterial larvicides have the potential to target insecticide resistant and outdoor biting mosquitoes and safe to the environment. The currently available microbial larvicide formulations have short duration of activity requiring frequent re-applications which increase cost of interventions. This study was designed to evaluate efficacy and duration of activity of two (LL3 and FourStar®) long-lasting formulations of *Bacillus thuringiensis israelensis* (Bti) and *Bacillus sphaericus* (Bs) under field conditions in western Kenya highlands. Three sites were selected for this study in the highlands of western Kenya. In each site, one hundred anopheline larval habitats were selected and randomized into three arms, namely: 1) LL3; 2) FourStar® and 3) untreated control larval habitats. The habitats were sampled for mosquito larvae by using standard dipping technique and larvae found were recorded according to the larval stages of the different *Anopheles* species. The larvicides were applied at manufacturers recommended dosage of 1 briquette per 100 square feet. Both treatment and control habitats were sampled for mosquito larvae just before treatment (day 0), and then 24hrs, 3 days and weekly post treatment for 5 months. Results show that after intervention with the larvicides, larval density in the treatment habitats was significantly reduced as compared with the control habitats. Both larvicides showed a higher impact in larval stages of *Anopheles gambiae* s.l. than in *An. funestus*. A higher reduction in *Anopheles* larval density was observed in the abandoned goldmines, pond and abandoned fish ponds with the least reduction observed in drainage channels. The LL3 larvicide had a relatively higher percent reduction than FourStar though not significantly different. This study showed that both LL3 and FourStar® long lasting microbial larvicides were effective in reducing larval of *An. gambiae* complex and *An. funestus* group mosquitoes for three months.

## 206

### DYNAMICS OF MALARIA TRANSMISSION, PREVALENCE AND INCIDENCE RATES IN KORHOGO AREA, NORTHERN CÔTE D'IVOIRE

**Barnabas Zogo**<sup>1</sup>, Dieudonné Kouadio<sup>1</sup>, Soromane Camara<sup>1</sup>, Amal Dahounto<sup>2</sup>, Nicolas Moiroux<sup>3</sup>, Ludovic Alou<sup>4</sup>, Serges Brice Assi<sup>4</sup>, Alphonsine A. Koffi<sup>4</sup>, Cédric Pennetier<sup>1</sup>

<sup>1</sup>Institut de Recherche pour le Développement, Bouaké, Côte D'Ivoire,

<sup>2</sup>Institut de Recherche en Sciences de la Santé (IRSS), Bobo Dioulasso, Burkina Faso, <sup>3</sup>Institut de Recherche pour le Développement, Bouaké, Burkina Faso, <sup>4</sup>Institut Pierre Richet, Bouaké, Côte D'Ivoire

Despite the striking successes achieved last decade against malaria, there is a compelling need to find alternative methods for maintaining the effectiveness of mosquito vector control. REACT project aims to assess novel malaria vector control strategies in combination with the community-wide coverage of Long-Lasting Insecticidal Nets (LLINs) in 30 villages of Korhogo, northern Côte d'Ivoire. Epidemiological studies in this malaria endemic area need to be updated since the last data was published more than 10 years ago. In an attempt to fill this gap and get baseline data for the REACT randomized control trial, an entomological and epidemiological surveys were carried out in six randomly selected villages. Clinical malaria cases were collected retrospectively in the local health centers records from July 2016 to January 2017. During the rainy and dry seasons, mosquitoes were collected in each village using human landing catch method on volunteers from 5:00 pm to 09:00 am. *Anopheles* species were morphologically identified and a sub-sample dissected for parity determination based on the tracheolar skeins. Polymerase chain reaction (PCR) analysis were used to ascertain the species of the *An. gambiae* complex, *Plasmodium.sp* sporozoite infection and insecticide resistance mechanisms. Furthermore, malaria active case detection was performed on all individuals aged from 6 months to 14 years in the rainy and dry seasons. Blood samples were collected for malaria detection using Rapid Diagnostic Test (RDT) and positive samples were confirmed by examination of Giemsa-stained thick blood films. We will therefore present the dynamics of malaria transmission, prevalence and incidence in sentinel villages in the North of Côte d'Ivoire.

## 207

### SEASONAL VARIATION IN ABUNDANCE AND BITING BEHAVIOR OF MALARIA VECTORS, ANOPHELES GAMBIAE S.L. AND AN. FUNESTUS USING CLIMATE DATA IN RURAL TANZANIA

**Halfan Ngowo**<sup>1</sup>, Heather Ferguson<sup>2</sup>, Fredros Okumu<sup>1</sup>

<sup>1</sup>Department of Environmental Health and Ecological Sciences, Ifakara Health Institute, Ifakara, United Republic of Tanzania, <sup>2</sup>Institute of Biodiversity, Animal Health and Comparative Medicine, University of Glasgow, Glasgow, Scotland, United Kingdom

Malaria prevalence can be highly influenced by climatic conditions that drive the abundance and seasonal dynamics of *Anopheles* vectors. In particular, rainfall influences the breeding habitat while microclimatic conditions determine the survival and biting behaviours of adult *Anopheles* mosquitoes. Household data on mosquito abundance and microclimatic conditions from South-east Tanzania were analysed to quantify its effect on *Anopheles* abundance and biting behaviour. Mosquitoes were sampled using human landing catches (HLC) both inside houses outdoor area for 616 nights trap. Climatic information (temperature and humidity) and mosquito were simultaneously collected. Daily rainfalls were aggregated in three time bands 1-2, 2-3 and 3-4 weeks before sampling day. Aggregated and current rainfall records were used to explain mosquito abundance. Generalized additive mixed models (GAMMs) and linear mixed models (GLMMs) were used to estimate the seasonal abundance and proportion of outdoor biting in *Anopheles* species respectively. *An. gambiae* s.l. was observed to be more abundant during the high rain season, while *An.*

funestus were observed to be more abundant during the month of little/no rainfall. An increase in mean temperature of 1°C caused an increase in *An. arabiensis* abundance by ~11% and *An. funestus* by 66%. *An. gambiae* s.l. abundance was positively influenced by rainfall 2-3 and 3-4 weeks before while, *An. funestus* abundance was positively influenced by rainfall 3-4 weeks before. An increase in mean temperature of 10C indoors relative to outdoors resulted in high proportional of *An. gambiae* s.l. biting outdoors while *An. funestus* ability to rest outdoor was not significantly influenced by an increase in indoor temperature relative to outdoor ( $p=0.962$ ). We show that not only the abundance of *Anopheles* vectors, but also their relative propensity to bite outdoors vs. indoor changes in response to seasonally varying microclimatic conditions. With these results it is possible to say that, the effectiveness of the vector control currently in place varies throughout the year with changes in microclimatic condition

## 208

### ESTIMATING THE POPULATION AT RISK OF ZIKA IN THE ASIAN REGION

**Amir S. Siraj**, Alex Perkins

*University of Notre Dame, Notre Dame, IN, United States*

On November 18, 2016, the World Health Organization ended its designation of Zika virus (ZIKV) as a Public Health Emergency of International Concern (PHEIC). At the same time, ZIKV transmission continues in Asia, with the number of Asian countries reporting Zika cases increasing over the last two years. Applying a method that combines epidemiological theory with data on epidemic size and drivers of transmission, we characterized the population at risk of ZIKV infection in 15 countries in Asia. Projections made under the assumption of no pre-existing immunity suggest that up to 785 (range: 730-992) million people in Asia could be at risk of ZIKV infection under that scenario. Assuming that 20% of ZIKV infections are symptomatic, this implies an upper limit of 146-198 million for the population at risk of a clinical episode of Zika. Due to limited information about pre-existing immunity to ZIKV in the region, we were unable to make specific numerical projections under a more realistic assumption about pre-existing immunity. Even so, combining numerical projections under an assumption of no pre-existing immunity together with theoretical insights about the extent to which pre-existing immunity may lower epidemic size, our results suggest that the population at risk of ZIKV infection in Asia could be substantially larger than in the Americas. As a result, we conclude that the WHO's removal of the PHEIC designation for Zika virus should not be interpreted as an indication that the threat has subsided.

## 209

### THE IMPACT OF AVIAN MALARIA ON VECTOR COMPETENCE AND WEST NILE VIRUS TRANSMISSION INTENSITY

**Andrew Golnar**, Gabriel Hamer

*Texas A&M University, College Station, TX, United States*

Empirical evidence demonstrates that variability in epidemiological metrics, such as host competence, vector competence, and parasite virulence, contribute to transmission heterogeneity across space and time. Accounting for these heterogeneities can improve disease control programs by targeting biological mechanisms that disproportionately impact pathogen transmission at the population-level. Polyparasitism, the simultaneous infection with multiple parasitic species, is a widespread phenomenon in nature known to drive transmission heterogeneity. *Culex* mosquitoes, the main vectors of West Nile virus (WNV), may ingest a variety of viral, protozoan, and macro-parasitic organisms found among avian and mammalian hosts. However, the downstream transmission consequences of mosquitoes ingesting these organisms are unknown. Here, we use experimental infections to assess how co-circulating plasmodium parasites impact West Nile virus (WNV) competence in *Culex quinquefasciatus* mosquitoes. Vector competence metrics, such as survivorship, midgut infection, dissemination, salivary gland infection, and

transmission, were recorded daily to parameterize mathematical models. Vectorial capacity,  $R_0$ , and global sensitivity analyses were used to evaluate how WNV-*Plasmodium* co-infection of *Culex* mosquitoes changes the intensity of WNV transmission.

## 210

### COULD THE RECENT ZIKA EPIDEMIC HAVE BEEN PREDICTED?

Angel G. Munoz<sup>1</sup>, Madeleine C. Thomson<sup>2</sup>, **Anna M. Stewart-Ibarra**<sup>3</sup>, Xandre Chourio<sup>4</sup>, Patricia Nájera<sup>5</sup>, Zelda Moran<sup>2</sup>, Xiaosong Yang<sup>6</sup>

<sup>1</sup>Princeton University, Princeton, NJ, United States, <sup>2</sup>Columbia University, New York, NY, United States, <sup>3</sup>State University of New York Upstate Medical University, Syracuse, NY, United States, <sup>4</sup>Centro de Modelado Científico (CMC), Universidad del Zulia, Maracaibo, Bolivarian Republic of Venezuela, <sup>5</sup>Pan American Health Organization, Washington, DC, United States, <sup>6</sup>Geophysical Fluid Dynamics Laboratory, NOAA/Princeton University, Princeton, NJ, United States

The recent zika epidemic probably could not have been predicted. Without the prior knowledge of the zika virus being already present in South America, and given the lack of understanding of key epidemiological processes and long-term records of zika cases in the continent, the best related prediction was for potential risk of an Aedes-borne disease epidemic. Here we use a recently published two-vector capacity model to assess the predictability of the conditions conducive to epidemics of diseases like zika, chikungunya or dengue, transmitted by the independent or concurrent presence of *Aedes aegypti* and *Ae. albopictus*. We compare the potential risk of transmission forcing the model with the observed climate and with state-of-the-art operational forecasts from the North American Multi Model Ensemble (NMME, 116 realizations in total), finding that the predictive skill of this new seasonal forecast system is highest for multiples countries in Latin America and the Caribbean during the December-February and March-May seasons, and slightly lower -but still of potential use to decision-makers- for the rest of the year. In particular, we find that suitable conditions for the occurrence of the zika epidemic at the beginning of 2015 could have been successfully predicted in several zika hotspots. Nonetheless, the initiation and spread of an epidemic depends on the confounding effect of multiple factors beyond climate conditions, and thus this type of approach must be considered as a guide and not as a formal predictive tool of vector-borne epidemics.

## 211

### THE ROLE OF ANOPHELES GAMBIAE, AN. ARABIENSIS AND AN. COUSTANI IN INDOOR AND OUTDOOR MALARIA TRANSMISSION IN FIVE ECOLOGICAL ZONES OF NIGERIA

<sup>1</sup>PMI AIRS Project, Abuja, Nigeria, <sup>2</sup>Ebonyi State University, Abakaliki, Nigeria, <sup>3</sup>Nasarawa State University, Keffi, Nigeria, <sup>4</sup>National Malaria Elimination Program FMOH, Abuja, Nigeria, <sup>5</sup>Department of Medicine, University of Uyo, Uyo, Nigeria, <sup>6</sup>Department of Zoology, University of Ibadan, Ibadan, Nigeria, <sup>7</sup>Abubakar, Tafawa Balewa University, Bauchi, Nigeria, <sup>8</sup>Usmanu Danfodiyo University, Sokoto, Nigeria, <sup>9</sup>PMI AIRS Project, Abt Associates, Tamale, Ghana, <sup>10</sup>PMI AIRS Project, Abt Associates, Bethesda, MD, United States, <sup>11</sup>U.S. President's Malaria Initiative/U.S. Agency for International Development, Abuja, Nigeria, <sup>12</sup>U.S. President's Malaria Initiative/U.S. Agency for International Development, Washington, DC, United States

Long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) against indoor biting and resting malaria vectors have reduced the burden of malaria in Africa. However significant transmission may be

ongoing outdoors. We evaluated indoor and outdoor malaria transmission dynamics of *Anopheles* mosquitoes in Nigeria. Malaria vectors were collected using Human-baited Centre for Disease Prevention and Control Light Trap (CDC LT) and Pyrethrum Spray Sheet Collections (PSC) in five ecozones of Nigeria. Specimens were identified morphologically with subsequent identification of sibling species using PCR. The proportions of mosquitoes harbouring sporozoite (sporozoite rates) were determined by ELISA. Entomological inoculation rates (EIR) were calculated using standard methods. A total of 2794 *An. gambiae* sensu lato mosquitoes and 500 *An. coustani* were analysed by ELISA. The highest indoor sporozoite rate of 7.4% was recorded in *An. gambiae* s.s. in Akwa Ibom in the mangrove forest collected using CDC LT, followed by 7.3% in Nasarawa using PSC method. A sporozoite rate of 4.2% was recorded for *An. arabiensis* in Bauchi and 3.1% in Sokoto, both from the PSC collections. For outdoor transmission, the highest sporozoite rate of 6.7% was recorded in *An. arabiensis* in Nasarawa in the Guinea Savannah using CDC LT whereas among *An. gambiae* s.s. outdoor collections, sporozoite rate of 2.9% was reported in Akwa Ibom. For the first time in Nigeria, sporozoite positive *An. coustani* was found both indoors and outdoors (sporozoite rate of 1.8% and 0.8% respectively) from the CDC LT in Nasarawa. EIRs ranged from 50.95 infectious bites per person per year (ib/p/yr) for *An. gambiae* s.s., 18.0 ib/p/yr for *An. arabiensis* recorded in Nasarawa, to 9.0 ib/p/yr for *An. arabiensis* in Ebonyi. Malaria transmission is occurring both indoors and outdoors, the main vectors being *An. gambiae* s.s. and *An. arabiensis*, with *An. coustani* playing a role as secondary vector both indoors and outdoors in Nasarawa. Effective malaria control programs may require new tools that target both indoor and outdoor transmission.

## 212

### INCREASING MALE MOSQUITO CATCH WITHIN VECTOR SAMPLING COLLECTIONS MALE MOSQUITO CATCH WITHIN VECTOR SAMPLING COLLECTIONS

**Krystal Lorna Birungi**, Paul Mabuka, Victor Balyesima, Matthew Lukenge, Jonathan Kayondo

*Uganda Virus Research Institute, Entebbe, Uganda*

Sample collection is essential to the study of disease vectors, and various methods have been developed for this. However, many malaria vector sampling tools/methods end up collecting mostly female mosquitoes. Traditional collection methods such as Human Landing Catch, indoor Pyrethroid Spray Catch and CO<sub>2</sub>-baited traps bias collections towards females that are either seeking blood meals or resting indoors, yet balanced vector sampling of both males and females would provide more comprehensive study parameter estimates for understanding vector dynamics. We have tested several additional methods thought to target male mosquito populations. We present the results of these collections, carried out in Uganda, with an aim to generate discussion on effective male mosquito collection methods. We have used aspirations (ASP) in inhabited buildings and in the eaves of inhabited houses, Clay Pot Traps (CPT), Bush aspiration, resting bucket traps (RBT) and swarm sampling (SWN). The use of additional male targeted methods increased the percentage of males caught to more than 30% compared to less than 10% in our previous sampling. ASP in the eaves of inhabited houses appears most productive and caught the highest number of males. However, SWN which is effective in other African regions, has been challenging and unpredictable at our study sites. Mosquitoes have been observed swarming low over larval habitats making it difficult to sweep samples. When swarming over bare ground, swarms were not more than 1m off the ground. An additional complication was mosquitoes swarming within lake fly swarms when lake flies are abundant. It is likely that SWN is not reaching its full potential. With new and innovative vector-targeted control methods such as sterile male technique and genetic modification of mosquitoes being developed, there is an increasing need for an effective male mosquito collection method for use in East Africa. Possible options to improve current traps could include adding lures to target males. We are hoping to promote an open dialogue on the methods that other experienced mosquito biologists may have found promising.

## 213

### ENTOMOLOGICAL SURVEILLANCE OF MALARIA IN BURUNDI: AN IMPORTANT STEP FOR THE SUCCESS OF VECTOR CONTROL STRATEGIES

**Virgile A. Gnanguenon**<sup>1</sup>, Anatolie Ndashiyimiye<sup>2</sup>, Gilbert Ntampuhwe<sup>1</sup>, Djenam Jacob<sup>3</sup>, Alexandra Hulme<sup>3</sup>, Dionis Nizigiyimana<sup>2</sup>, Lievin Nsabayumwa<sup>4</sup>, Akllilu Seyoum<sup>3</sup>, Christen Fornadel<sup>5</sup>

<sup>1</sup>U.S. Agency for International Development PMI AIRS Project/Abt Associates, Bujumbura, Burundi, <sup>2</sup>PNLIP, Bujumbura, Burundi, <sup>3</sup>U.S. Agency for International Development PMI AIRS Project/Abt Associates, Bethesda, MD, United States, <sup>4</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Bujumbura, Burundi, <sup>5</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States

Malaria remains among the most important public health problems in Burundi and constituted 48% of all causes of death. Since 2011, the Government of Burundi and USAID have worked on increasing the national capacity to use entomological data to inform the country's malaria prevention and control program. This study was conducted from March 2014 to February 2017 in 8 sentinel sites to assess vector behavior, infectivity and susceptibility to insecticides. Human landing catches, pyrethrum spray catches and CDC light trap collection methods were used to collect mosquitoes from sentinel sites. The study showed that *Anopheles gambiae* s.s. and *Anopheles funestus* s.s. are predominant (84%) vectors of malaria. The human biting activity of malaria vectors varied significantly ( $p=0.009$ ) among the sentinel sites with an average human biting rate of 9.89 [9.65-10.14] bites/man/night for *An. gambiae* s.l. and 1.91 [1.81-2.02] bites/man/night for *An. funestus*. The average indoor biting rate of *An. gambiae* s.l. was 9.76 [9.38-10.15] bites/man/night versus 10.33 [9.94-10.74] bites/man/night outdoors. For *An. funestus*, the indoor biting rate was 2.19 [2.01-2.38] bites/man/night versus 1.41 [1.26-1.56] bites/man/night outdoors. The average parous rate was 76.94% [71.64-82.53] for *An. gambiae* s.l. versus 72.26% [58.73-87.97] for *An. funestus*. Infectivity of *Plasmodium falciparum* was around 2% for both species. Estimated entomological inoculation rates were 5 infectious bites/person/month for *An. gambiae* s.l. and 1.14 infectious bites/person/month for *An. funestus*. Resistance of *An. gambiae* s.l. to pyrethroids and DDT was observed in 7 sentinel sites, while susceptibility to organophosphates and carbamates was observed in 6 sites with no confirmed resistance to pirimiphos-methyl. The *kdr*-East allele was only detected in *An. gambiae* s.s. populations with frequencies ranging from 96-100%. These results represent an important source of information to guide the implementation of vector control in Burundi. It will be important to consolidate entomological data and extend surveillance activities to the majority of regions where malaria epidemics occur.

## 214

### JOB SATISFACTION OF BRIGADISTAS IN NICARAGUA: A CRITICAL ASPECT FOR TASK-SHIFTING

**Rashed Shah**<sup>1</sup>, Jeanne Koepsell<sup>1</sup>, Dixmer Rivera<sup>2</sup>, Eric Swedberg<sup>3</sup>, David R. Marsh<sup>3</sup>

<sup>1</sup>Save the Children U.S., Washington, DC, United States, <sup>2</sup>Save the Children U.S., Managua, Nicaragua, <sup>3</sup>Save the Children U.S., Fairfield, CT, United States

*Brigadistas* are the community health workers (CHWs) in Nicaragua, and are responsible for classifying and diagnosing common childhood illnesses, counseling mothers and care givers, administering treatment, encouraging referral of serious cases and making follow-up home visits. Current trends in task-shifting and integrated program delivery require CHWs (e.g., *brigadistas*) to deliver several essential services, including maternal, newborn and child health, and family planning, and thereby to expand the scope of their responsibilities. In 2014, we conducted a cross-sectional study, among *brigadistas* who were assigned in hard to reach

areas ('C' category communities) in five *municipios* in the departments of Matagalpa and Jinotega in north central Nicaragua, with an aim to assess their job satisfaction, prior to adding newborn care to their responsibilities. Following stratified random sampling strategy, 15 *brigadistas* were selected from each of the following four strata: each of four strata: male vs. female and age <25 vs >30 years. We completed in-person interviews for 45 eligible and available *brigadistas* (75% of planned 60 interviews). Measured on a 0-5 Likert scale, *brigadistas'* job satisfaction was high (mean: 4.2, range: 2.5 - 5.0; 1 rated as 2.5, 16 rated as 4.0 and 25 rated as 5.0). Facilitators of job satisfaction included training (53%) and "doing good for the community" (31%). The main barrier was lack of time (36%) due to family, work, or study commitments. These results can be useful for policy makers and program managers for making an informed decision before expanding the scope of work for *brigadistas* in Nicaragua.

## 215

### VALIDATION AND USABILITY OF MEDSINC - AN INTEGRATED MOBILE HEALTH (MHEALTH) SOFTWARE PLATFORM FOR CLINICAL ASSESSMENT OF COMMON CHILDHOOD ILLNESSES

Barry Finette

University of Vermont Medical Center, Charlotte, VT, United States

A lack of access to healthcare professionals and limited healthcare infrastructure are the major causes for the high mortality and morbidity in children under five (U5) years of age in low and middle income countries (LMICs). THINKMD and strategic partners have performed validation, usability and acceptability field studies of an integrated community health worker (CHW) specific mobile health (mHealth) clinical assessment platform, MEDSINC®, for children U5, to determine if utilization of the platform could address the shortage of healthcare professionals and limited health care infrastructure in these regions. MEDSINC® is a simple to use, self-teaching next-generation integrated clinical assessment software platform, which enables minimally skilled users to quickly determine how sick a child is by simultaneously determining an integrated clinical severity assessment (none/mild; moderate; severe) for respiratory distress, dehydration, infection risk (sepsis-SIRS), and malnutrition. MEDSINC® also screens for possible malaria, meningitis, anemia, urinary tract infection, skin infection, measles, ear infection and dysentery. CHWs were trained on the MEDSINC platform using a training of trainer strategy. Total training time was between 1.5-2.5 hours. Children within the 2-59 months of age range presenting to or residing in testing sites were eligible to be enrolled in this study. Upon receiving informed written consent from respective caregivers/parents, CHWs generated integrated clinical assessments using the MEDSINC® platform on children which were correlated with blinded local physician's clinical assessments of the same child (not by using the MEDSINC® platform). MEDSINC® has validation data from 995 patient assessments by minimally skilled workers using the MEDSINC® platform. To date, in each region tested, independent assessments by minimally skilled users using MEDSINC® compared with local health professionals have consistently shown between 80% to above 95% integrated clinical assessment correlation, demonstrating the ability of CHW using MEDSINC® to increase healthcare capacity in LMICs.

## 216

### HEALTH BELIEFS OF YOUNG RURAL CHILDREN AT HIGH RISK FOR PODOCONIOSIS: A QUALITATIVE STUDY IN SOUTHERN ETHIOPIA

Ababayehu Tora<sup>1</sup>, Getnet Tadele<sup>1</sup>, Abraham Aseffa<sup>2</sup>, Colleen M. McBride<sup>3</sup>, Gail Davey<sup>4</sup>

<sup>1</sup>Addis Ababa University, Addis Ababa, Ethiopia, <sup>2</sup>Armauer Hansen Research Institute/ALERT, Addis Ababa, Ethiopia, <sup>3</sup>Rollins School of Public

Health, Emory University, Atlanta, GA, United States, <sup>4</sup>Brighton and Sussex Medical School, Falmer, Brighton, United Kingdom

Though investigation of health beliefs among children is one of important condition for primary prevention of disease, little effort has been made to understand these in the context of podoconiosis. This study aimed to explore the health beliefs of rural children at high risk for the disease. A cross sectional qualitative study was conducted in March 2016 in Wolaita Zone, Southern Ethiopia. Data were collected through in-depth individual interviews and focus group discussions, with a total of one hundred seventeen 9 to 15-year-old children recruited from podoconiosis affected families. The study revealed various misconceptions regarding risk factors for podoconiosis. Most children believed barefoot exposure to dew, worms, snake bite, frog urine, other forms of poison, and contact with affected people to be major causes of the disease. Their knowledge about the role of heredity and that of long term barefoot exposure to irritant mineral particles was also poor. Though most participants correctly appraised their susceptibility to podoconiosis in relation to regular use of footwear and foot hygiene, others based their risk perceptions on factors they think beyond their control. They described several barriers to preventive behaviors, including uncomfortable footwear, shortage and poor adaptability of footwear for farm activities and sports, and shortage of soap for washing. Children also perceived low self-efficacy to practice preventive behaviors in spite of the barriers. Health education interventions may improve children's knowledge and risk perceptions, while family-based socioeconomic empowerment programs may help overcome practical challenges that children perceived as barriers and boost their confidence to engage sustainably in podoconiosis preventive behaviors.

## 217

### CHOICE OF UNDERGRADUATE COURSES OF SICKLE CELL DISEASE PATIENTS - BAILOUT OR FRANKENSTEIN?

Ayokunle Osonuga<sup>1</sup>, Odusoga Osonuga<sup>2</sup>, Jamiu Folorunsho<sup>3</sup>

<sup>1</sup>Overcomers Specialist Hospital, Ilisan remo, Ogun State, Nigeria,

<sup>2</sup>University Health Services, Olabisi Onabanjo University, Ogun State,

Nigeria, <sup>3</sup>University Health Services, Olabisi Onabanjo University, Ogun State, Nigeria

In recent times, attention has been drawn to a Global disease which stands awkwardly alone between the traditional tropical communicable disease and non-communicable diseases. With worldwide distribution and highest burden in the tropics - amongst the impoverished population, serious morbidity and mortality, comorbidity for other life-threatening diseases, relatively simple diagnosis, indeed sickle cell disease (SCD) meets the criteria to be tagged an NTD. However, it is quite different from the other tropical diseases in that it has genetic basis of inheritance. Various studies have evaluated its cognitive and systemic dilapidating consequences. However, no study has studied the pattern of undergraduate course choices among this cohort. The study was conducted at the Olabisi Onabanjo University, Nigeria, among 1st year undergraduate students who were routinely screened before University admission. SCD was defined as HbSS, HbSC and HbCC disease. A total of 6,661 students were screened. The prevalence of SCD among the screened students was 0.92% (n=61, male:female=1.03:1, mean age=18+2.8years) with HbSS, HbSC, and HbCC having prevalence of 0.42%, 0.46% and 0.03% respectively. Among the SCD cohort the highest prevalence was found in the HbSC group (50.8%), then HbSS group (45.9%) and least by HbCC group (3.3%). Most of the students with SCD were in the social sciences (n=20), Basic medical sciences (n=12) and General sciences (n=9). The least cohort were in the clinical sciences, law, and Pharmacy (n=1 respectively). The rest were distributed across other faculties, mostly in the Arts. The above clearly shows the preference of these cohort for less physically and academically tasking courses perhaps to reduce the frequency SCD crisis - bailout. It could also be in keeping with previous workers that suggest cognitive decline and performance among patients hence their cut off points couldn't meet up with the "prestigious courses" in the University -

Frankenstein. There is need for proper counselling and follow up among these patients from early school years till University by a multidisciplinary team, to improve academic outcomes.

## 218

### VACCINATION AND SOCIOECONOMIC RISK FACTORS FOR CHOLERA IN AN ENDEMIC SETTING OF BANGLADESH

Amit Saha<sup>1</sup>, Andrew Hayen<sup>2</sup>, Mohammad Ali<sup>3</sup>, Alexander Rosewell<sup>4</sup>, C. Raina MacIntyre<sup>4</sup>, Firdausi Qadri<sup>5</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Faculty of Health, University of Technology, Sydney, Australia, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>4</sup>School of Public Health and Community Medicine, UNSW, Sydney, Australia, <sup>5</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Cholera remains a public health threat globally. Oral cholera vaccines (OCV) are considered an important preventive tool, with global uptake on the rise. However, the protection offered by OCVs is sub-optimal. This study is to identify socioeconomic factors affecting OCV performance in urban population in Dhaka, Bangladesh. A large feasibility study on OCV included 30 clusters in each of three arms: vaccine, vaccine plus behavioural change, and a non-intervention arm. A structured questionnaire used for Socio-economic characteristics of the study population. Vaccination records and hospitalization case reports were documented. The data were analysed for the three populations: A. recipient of two-doses of OCV in the intervention arm (vaccine and vaccine plus behavioural change arms), B. non-dose recipients in the intervention arm and C. all persons in the non-intervention arm. A generalized estimating equation was used to assess the socioeconomic association with cholera among these different populations adjusting for household level correlation in the data. A total of 4295 diarrhoeal cases in 268,896 participants were observed in the two-year follow-up. Of which, 528 cholera cases and 226 severely dehydrated cholera cases were identified. Among vaccinated individuals, those in lower age groups had marginally higher risk for any cholera episode (RR=0.98, 95% CI=0.97-1.00), and those living in a household having more than 4 family members were at significantly higher risk of a severe cholera episode (RR=0.55, 95% CI=0.32-0.96). Among non-recipients living in the intervention areas, having diarrhoea at baseline census was found to be a risk factor for cholera. Among these individuals, females or individuals having diarrhoea at baseline were more likely to have severe cholera. In contrast, individuals living in a house having poor floor construction material, living in a high density area or living a long distance to the icddr hospital were at significantly higher risk of cholera and severe dehydrated cholera indicating that Cholera vaccination reduces the risk of cholera due to socioeconomic disparities in a high burden setting.

## 219

### UNDERSTANDING PERCEPTIONS AND EXPERIENCES OF TRACHOMA AMONG MAASAI IN TANZANIA

Tara B. Mtuy<sup>1</sup>, Matthew Burton<sup>1</sup>, Upendo Mwingira<sup>2</sup>, Shelley Lees<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

The World Health Organization set a target for elimination of blinding trachoma by 2020. Despite decades of achievements in trachoma control worldwide, challenges remain in endemic communities including social issues. The aim of this study was to explore socio-cultural factors that may impact this disease among hyperendemic Maasai communities. This study was situated in a larger ethnographic study of trachoma among Maasai in Northern Tanzania. We used semi-structured interviews for an in-depth examination of the knowledge and understanding of the nature of trachoma. Stratified random sampling was used. Interviews

were conducted and recorded in Maa, by a native Maa speaking trained interviewer. Transcripts were translated into English to conduct a framework analysis. Results show a poor understanding of trachoma. The causes of trachoma were attributed to pollen, dust, and smoke. Although water was recognized as beneficial for trachoma, it was seen as treatment and not prevention. Traditional medicines from plants and roots were most often used for treating inflammation. The most common was a rough leaf used to scratch the inside of the eyelid until it bleeds. Veterinary medicines for cattle were also used to treat inflammation in children. Knowledge of mass drug administration (MDA) was inconsistent. Although many thought it helped the community, they perceived it as only for children and the sick. Many reported not taking the drug and some had no recollection of the previous MDA, six months earlier. There was little connection between childhood infection, trichiasis and related blindness. Trichiasis was often seen as a problem of old women, and treated locally by epilation. Although blindness was considered a burden to members of the boma, it was mostly attributed to old age, God and a curse from others. These findings can help guide approaches to SAFE in Maasai communities. Despite limited knowledge, the community recognized trachoma as a public health problem. A targeted education program would be an important step in effective control programs. These challenges are likely to exist in other marginalized populations in trachoma endemic areas.

## 220

### SCIENTIFIC AUTHORSHIP AND COLLABORATION NETWORK ANALYSIS ON MALARIA RESEARCH IN BENIN: PAPERS INDEXED IN THE WEB OF SCIENCE (1996-2016)

Roseric Gbedegnon Azondekon, Zachary J. Harper

University of Wisconsin Milwaukee, Milwaukee, WI, United States

To sustain critical progress in the national malaria control program in Benin, prioritization and a multidisciplinary approach to malaria research remain important. To document the structure of the malaria collaborative research in Benin, we analyze authorship of the scientific documents published on malaria from Benin from January 1996 to December 2016. We generated a multigraph co-authorship network with authors representing nodes. Edges are drawn between two authors when they co-author a paper. We compute vertex degree, betweenness, closeness, and eigenvectors among other metrics to identify prolific authors (hubs). We further assess the articulation points and how information flows in the network. Finally, we perform hierarchical clustering analysis and Monte-Carlo simulations to test significance of the metrics. Overall, 427 publications are included in this study. The generated network contains 1792 authors with 116,388 parallel edges. This network is converted into a weighted graph of 1792 nodes and 95,787 edges. Descriptive analyses suggest that prolific authors with higher degrees tend to collaborate. The hierarchical clustering reveal 23 clusters, 7 of which form a giant component containing 94% of all the nodes in the network. Closer attention to this giant component show characteristics of small-world network: a small shortest path distance of 3 between pairs, a diameter of 10 and a high clustering coefficient of 0.964. Though, Monte-Carlo simulations suggest our observed network is an unusual type of small-world network. A cut vertex analysis of the network reveals the presence of 16 articulation points. The malaria research collaboration network in Benin is a complex, with some small-world network characteristics. This research reveals the presence of closed research groups where collaborative research likely happens only between members. Interdisciplinary collaboration appears to occur mostly between prolific researchers. Advanced analyses involving statistical modeling are needed to better explain the malaria co-authorship network in Benin.

## 221

**GLOBAL HEALTH JOBS ANALYSIS PROJECT: CHARACTERIZING THE GLOBAL HEALTH AND DEVELOPMENT EMPLOYMENT MARKET**

**Brianne L. Riggin-Pathak**<sup>1</sup>, Jessica Keralis<sup>2</sup>, Theresa Majeski<sup>3</sup>, Kathleen Cullinen<sup>1</sup>, Janine Foggia<sup>4</sup>, Abhirami Rajagopal<sup>5</sup>, Heidi West<sup>6</sup>

<sup>1</sup>APHA International Section, Toledo, OH, United States, <sup>2</sup>APHA International Section, Austin, TX, United States, <sup>3</sup>APHA International Section, Los Angeles, CA, United States, <sup>4</sup>APHA International Section, St. Louis, MO, United States, <sup>5</sup>APHA International Section, India, India, <sup>6</sup>APHA International Section, Kenya, Kenya

Global health has become an integral component of discussions of policy, economics, and global security. As a result, graduate programs in global health have flourished and public health graduates interested in global health and development are entering the job market in ever-growing numbers. However, the job market remains difficult to navigate for graduates and young professionals, and there is growing concern that the training and experience provided by these programs do not equip graduates with the skills and experience needed to succeed in the field. This session will present the final results of the Global Health Jobs Analysis, which collected data on publicly posted global health job vacancies with the aim of providing insight into the current global health job market. Data on position, location, education level required, years of experience required, regional and technical area of focus, language skills and international work experience required were analyzed for 1,007 global health job vacancies open to U.S. citizens and employment-eligible residents by 127 private and non-profit companies and six U.S. government agencies over a six-month period from November 2015 to May 2016. The quantitative analysis will include descriptive statistics and associations between variables. The qualitative analysis will focus on trends in the vacancy descriptions, with a focus on positions requirements and preferred qualifications. The presentation will discuss key insights from the mixed-methods analysis, examining the amount of work experience and the most common skills and technical competencies required for the global health profession. We will examine how able current global health graduates are to meet the needs of the profession and steps they can take to prepare to enter the market.

## 222

**MAKING HEALTH MARKETS WORK FOR LOW-INCOME POPULATIONS IN KENYA AND GHANA: HOW CHANGES IN NATIONAL HEALTH INSURANCE FINANCING AFFECT PRIVATE PROVIDERS**

**Lauren Suchman**, Dominic Montagu

*University of California San Francisco, San Francisco, CA, United States*

The cost of healthcare is often a barrier to access for low-income populations. In Kenya and in Ghana, National Health Insurance (NHI) schemes have expanded coverage beyond civil servants, and both countries have programs that aim to expand NHI to people with low income. African Health Markets for Equity (AHME) is a multi-organization partnership that aims to increase coverage of health interventions amongst the poor through engagement with private providers in Kenya, Ghana, and Nigeria. Since 2013, AHME has worked with NHI officials to increase private provider accreditation rates and connect newly enrolled NHI patients with quality care in AHME-affiliated clinics. A qualitative evaluation was conducted in Kenya and Ghana to assess the effect of AHME on attitudes and practices of patients, providers, and government regulators. Between July 2013 and March 2017, we interviewed 214 private providers, 74 AHME partners, and 9 government officials about their experiences: (1) reaching low-income populations; (2) incorporating private-sector clinics into the NHI schemes; (3) views of collaboration between government and private provider networks. Analysis combined

the findings and trends from both data sources. Our findings highlight the need for NHI programs to balance supply and demand actions: programs to enroll poor populations have shown some success and are scaling up. Facility accreditation programs have been effective in Ghana, and are slowly becoming more efficient in Kenya. AHME experiences highlight the need to intensify outreach to low-income communities to connect them with accredited providers.

**STRENGTHENING THE PUBLIC HEALTH WORKFORCE IN BANGLADESH THROUGH SCIENTIFIC TRAINING AND MENTORSHIP: A LESSON FOR LOW INCOME COUNTRIES**

**Golam Dostogir Harun**<sup>1</sup>, Dorothy Southern<sup>1</sup>, Diana DiazGranados<sup>1</sup>, Meghan Scott<sup>1</sup>, Stephanie Doan<sup>2</sup>, Emily S. Gurley<sup>1</sup>, Stephen P. Luby<sup>3</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Stanford University, Stanford, CA, United States

Developing independent scientists who rigorously research public health questions and publish findings contributes to a strong public health workforce able to respond to global threats. Fostering high-quality scientific skills requires a long-term commitment to training and mentorship. Since 2009, the Global Disease Detection center (GDD) in Bangladesh has allocated resources to promote an approach to public health research that guides junior scientists through analyzing and publishing research. The key elements used by GDD-Bangladesh for building critical-thinking and writing skills includes committed mentorship by senior scientists, classroom trainings, data collection assistance, support for statistical analysis, English language writing, and a writing guide. Senior scientists, statisticians, and writing coaches use a structured approach and timeline for providing actionable feedback; re-writing manuscript text by senior authors is explicitly discouraged. Between 2009 and 2016, GDD-Bangladesh provided training and mentorship to 75 junior Bangladeshi scientists through group training and one-on-one mentoring; 34 of them became first-time first authors in peer-reviewed journals. Approximately 95% of abstracts submitted to international conferences by junior researchers have been accepted. Twenty-six researchers trained at GDD-Bangladesh have gone on to pursue PhD degrees and continue to contribute to the public health science base. Field Epidemiology Training Programs in Bangladesh, Kenya, Zambia and South Africa have used this mentee-centered approach to build scientific skills; for example, 10 of 13 (77%) residents of the 2015 South Africa cohort graduated from an accredited university requiring a manuscript ready for publication. This systematic approach to scientific research and writing, with clearly outlined roles and responsibilities for first authors and mentors, has set out a pathway to publication that supports junior researchers to become first authors. This approach can be further leveraged to enhance surveillance and research skills throughout the government and academic health sectors.

## 224

**PERSISTENT STUNTING FROM EARLY CHILDHOOD IMPAIRS COGNITIVE PERFORMANCE IN LATE CHILDHOOD: RESULTS FROM A BIRTH COHORT IN A SEMI-URBAN SLUM IN SOUTH INDIA**

**Arun S. Karthikeyan**, Prasanna Samuel, VenkataRaghava Mohan, Sumithra E, Sunita Bidari, Meghana Paranjape, Beena Koshy, Jayaprakash Muliyl, Gagandeep Kang

*Christian Medical College, Vellore, India*

Deprivation of developmental potential of children in the developing countries plays a key role in the intergenerational transmission of poverty. Exposures to genetic and environmental factors result in growth faltering in early childhood and further deprive the developmental goals in late

childhood. This study assessed the effects of early childhood risk factors like linear malnutrition, socio-economic status, burden of gastrointestinal infections and early morbidity on the cognitive development of children during late childhood. The study recruited 303 children from a birth cohort study in urban slums of Vellore at 12th year of life. The cognitive performance (Malin's Intelligence Scale for Indian Children) and anthropometry of the children were assessed. Children were classified into persistent, caught-up, less stunted and never stunted based on stunting at 2nd, 3rd and 12th-year assessment. Multiple linear regression analysis was performed to study associations between the prevalence of stunting, early childhood infection, illness and socio-demographic variables like maternal education and maternal occupation on the cognitive performance (IQ scores) of children in late childhood (12th year). The mean (SD) intelligence quotient (IQ) of the cohort was 87.4 (7.7). Persistently stunted children had impaired cognitive performance in the late childhood (3.90, 95%CI 1.12 to 5.67) when compared to the children who were never stunted, whereas "caught up" children had lesser impairment in cognitive performance (3.18, 95%CI 0.87 to 5.49). After adjusting for the maternal education, early childhood respiratory illness, and infections like *giardia* and *helminths*, persistent stunting was significantly associated with reduced cognitive performance of the children during late childhood. Children who exhibited catch up growth after early childhood had an advantage in their cognitive performance over those persistently stunted. Targeted interventions are needed during both early and late childhood in order to alleviate the burden of malnutrition and its long-term consequences.

## 225

### COMMUNITY PARTICIPATION IN MOSQUITO BREEDING SITE CONTROL: A MULTIDISCIPLINARY MIXED METHODS STUDY IN CURAÇAO

**Jelte Elsinga**<sup>1</sup>, Henry T. van der Veen<sup>2</sup>, Isaac Gerstenbluth<sup>3</sup>, Johannes G. Burgerhof<sup>4</sup>, Martin P. Grobusch<sup>5</sup>, Arie Dijkstra<sup>6</sup>, Adriana Tami<sup>1</sup>, Ajay Bailey<sup>7</sup>

<sup>1</sup>Department of Medical Microbiology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, <sup>2</sup>Faculty of Spatial Sciences, University of Groningen, Groningen, Netherlands, <sup>3</sup>Epidemiology and Research Unit, Medical and Public Health Service of Curaçao, Willemstad, Curaçao, Netherlands Antilles, <sup>4</sup>Department of Epidemiology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, <sup>5</sup>Center of Tropical Medicine and Travel Medicine, Department of Infectious Diseases, Academic Medical Center, University of Amsterdam, Groningen, Netherlands, <sup>6</sup>Department of Social Psychology, University of Groningen, Groningen, Netherlands, <sup>7</sup>Population Research Center, Faculty of Spatial Sciences, University of Groningen, Groningen, Netherlands

As the arboviral diseases dengue, chikungunya and Zika emerge in the Americas, so does the need for sustainable vector control policies. To successfully achieve mosquito control, joint efforts of both communities and governments are essential. This study investigates this important but by-and-large neglected topic. In June and July 2015, a cross-sectional mixed method study applying a survey questionnaire (n=339), in-depth interviews (n=20) and focus group discussions (FDGs)(n=7) was performed in Curaçao. The study was designed based on an integrated theoretical framework of the Health Belief Model and the Theory of Planned Behaviour. Participants showed a good knowledge of, and a high-level performance of mosquito breeding site control (MBSC) practices. Personal protection against mosquitoes was perceived as less valuable than MBSC practices and was consequently applied to a lesser extent. The study highlights three possible ways of improving community participation in MBSC. First, it highlights the need for ongoing media coverage, based on communities' lived realities. Second, it shows a two-directional influence of governments' policies on communities' actions, which should be addressed in campaigns. Third, the presence of key persons in communities, which could be engaged in mosquito control policies to improve MBC in neighbourhoods, is described. In conclusion, this study reveals gaps between policy and communities' lived realities. These gaps

might be overcome with the proposed interventions, resulting in a higher performance of MBC of the community in Curaçao. Furthermore, this study shows how interdisciplinary mixed methods research can provide comprehensive and in-depth insights for mosquito control policies.

## 226

### TASK SHIFTING THE IDENTIFICATION, EMERGENCY MANAGEMENT AND REFERRAL OF WOMEN WITH PRE-ECLAMPSIA IN MOZAMBIQUE, AND FACILITY CAPACITY TO RESPOND

Esperança Sevene<sup>1</sup>, **Helena E. Boene**<sup>1</sup>, Marianne Vidler<sup>2</sup>, Anifa Vala<sup>1</sup>, Orvalho Augusto<sup>1</sup>, Salésio Macuacua<sup>1</sup>, Sumedha Sharma<sup>2</sup>, Quinhas Fernandes<sup>3</sup>, Cassimo Bique<sup>4</sup>, Mohsin Sidat<sup>5</sup>, Eusébio Macete<sup>1</sup>, Khátia Munguambe<sup>1</sup>

<sup>1</sup>Centro de Investigação em Saúde da Manhica, Vila da Manhica, Mozambique, <sup>2</sup>Department of Obstetrics and Gynecology, and the Child and Family Research Unit, Vancouver, BC, Canada, <sup>3</sup>Ministério da Saúde, Maputo, Mozambique, <sup>4</sup>Hospital Central de Maputo, Maputo, Mozambique, <sup>5</sup>Universidade Eduardo Mondlane, Faculdade de Medicina, Maputo, Mozambique

Maternal mortality is an important public health problem in low income countries. In Mozambique, maternal mortality in 2013 was still high on 480 deaths per 100,000 live births with eclampsia counting for the third obstetric cause. Delays in reaching health facilities and insufficient health professionals calls for community-level interventions. The aim of this study was to describe the feasibility of task-shifting the initial screening and initiation of obstetric emergency care for pre-eclampsia/eclampsia by community health workers in Mozambique and to document facility readiness to respond to this task-shift. The study took place in Maputo and Gaza Provinces in Mozambique using mixed methods. The qualitative data was collected through focus group discussions and in-depth interviews with various community groups, health care providers, and policy makers. All discussions were audio-recorded and transcribed verbatim prior to thematic analysis using QSR NVivo 10 software. Quantitative data was collected through self-administered questionnaires to community health workers and health facility assessment survey, analysed using Stata version 13. Community health workers in Mozambique are skilled to identify the basic danger signs of pregnancy; however, they are not able to manage these emergencies, or refer to the facility. Nurses at primary facilities were trained to manage eclampsia before referral. The necessary equipment for obstetric emergency care was not available in most primary facilities. MgSO<sub>4</sub> was available in most primary facilities (83%). Most health facilities (96%) had an ambulance for referrals. Although community health workers and patients favoured task-shifting, other healthcare providers highlighted the need to first address current barriers at health facilities including lack of equipment, shortage supervisors, and drugs stock out. This study showed that task-shifting initial screening and pre-referral management of pre-eclampsia/eclampsia is acceptable by the community, but an effort should be in place to address health system readiness to appropriately manage the emergency cases.

## 227

### COMMUNITY ENGAGEMENT FOR EXCEPTIONALLY DANGEROUS PATHOGENS CONTAINMENT: THE POTENTIAL OF SENTINEL COMMUNITY SURVEILLANCE

**Ibanga J. Inyang**

University of Uyo Teaching Hospital, Uyo, Nigeria

Sustaining Ebola virus disease (EVD) containment is a journey, not a step. That reality provides the justification for sentinel community surveillance (SCS). Consider if the Ebola index case in Nigeria was a Nigerian trader who contracted the virus outside Nigeria, returned to his rural community family by road and fell ill within a few days, his most likely point of reporting illness may have been a faith-based setting, a primary health

care centre, a one-doctor private clinic, or a general hospital. The chain of contacts and exposure, and the consequences would have been different from the trajectory consequent to that of Mr. Sawyer, the Liberian identified as Nigeria's Ebola index case. Nigeria and other West African and east African countries need sentinel community surveillance for active community engagement and mobilization to sustain their EVD containment and to drive proactive measures against other quick-kill infections that may emerge<sup>7</sup>. SCS would reinforce inclusiveness of the national preparedness and response effort, if developed as an integral part of the country's primary health care system.

## 228

### VALIDATION OF MATERNAL REPORTS FOR LOW BIRTHWEIGHT AND PRETERM BIRTH INDICATORS IN RURAL NEPAL

**Karen T. Chang<sup>1</sup>**, Luke C. Mullany<sup>1</sup>, Subarna K. Khatry<sup>2</sup>, Steven C. LeClerq<sup>1</sup>, Melinda K. Munos<sup>1</sup>, Joanne Katz<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>The Nepal Nutrition Intervention Project, Sarlahi, Lalitpur, Nepal

Tracking progress towards global newborn health targets depends largely on maternally reported data from nationally representative surveys. We evaluated the validity, across recall periods (1 to 24 months post-delivery), of maternal reports of birthweight, birth size and length of pregnancy. We compared maternal reports to 'gold' standards of birthweight measured within 72 hours of delivery and gestational age generated from reported first day of the last menstrual period (LMP) prospectively collected in a population-based study (n=1513). We calculated sensitivity, specificity, area the under the receiver operating curve (AUC) as a measure of individual-level accuracy, and the inflation factor (IF) to quantify population-level bias for each indicator. We assessed whether recall period modified accuracy by stratifying measurements across time bins and using a modified Poisson regression with robust error variance to estimate the relative risk (RR) of correctly classifying newborns as low birthweight (LBW) or preterm (PTB), adjusting for child sex, place of delivery, maternal age, maternal education, parity, and ethnicity. LBW using maternally reported birthweight in grams had low individual-level accuracy (AUC=0.69) and high population-level bias (IF=0.62). The LBW indicator using maternally reported birth size and the PTB indicator had lower individual-level accuracy (AUC=0.58, 0.56, respectively) and higher population-level bias (IF=0.28, 0.35, respectively) up to 24 months following birth. Accuracy did not generally change with recall time; however, it statistically significantly improved for the PTB indicator at 20 months post-delivery and on. The use of maternal reports may underestimate and bias LBW and PTB indicators. In settings with high prevalence of LBW and PTB, indicators from maternal reports may be subject to misclassification. In populations where a high proportion of births occur at home or where weight is not routinely measured, mothers perhaps place less importance on remembering birth weight. Further work is needed to see whether these conclusions hold in other similar rural and low-income settings.

## 229

### THE PREVALENCE AND CONTRIBUTING FACTORS OF EARLY CHILDHOOD STUNTING IN RURAL COASTAL KENYA

**Shanique Martin<sup>1</sup>**, Francis Mutuku<sup>2</sup>, Julia Kao<sup>1</sup>, Justin Lee<sup>1</sup>, Dunstan Mukoko<sup>3</sup>, Indu Malhotra<sup>4</sup>, Charles King<sup>4</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Vector-Borne Diseases Control Unit, Ministry of Health, Nairobi, Kenya, <sup>4</sup>Case Western Reserve University, Center for Global Health and Diseases, Cleveland, OH, United States

This study measured prevalence of early childhood stunting in rural coastal Kenya as associated with maternal parasitic infection status, socioeconomic status (SES), and nutritional intake. Pregnant mothers were

enrolled and tested for parasitic infections during their prenatal period and at delivery through stool, urine and blood testing. In a 6-week sub-study conducted in 2016, 244 of the resulting children, 6-37 months of age, who had been followed biannually since birth with parasitic infection and anthropometric testing, were assessed for current stunted growth using height-for-age Z-scores (HAZ). An environment index that included water, sanitation, assets, maternal education, and income (WAMI) was used to evaluate SES, while nutritional intake was assessed by questionnaire. Linear regression was used to examine contributions of maternal parasitic infection status, SES, and nutritional intake on current HAZ. At the 2016 visit, 25% of the children were stunted (HAZ < -2) and retrospective analysis showed that 54% were stunted during at least one prior biannual visit. Of the currently stunted children, 73% had mothers with at least one parasitic infection during the prenatal period, and 45% had mothers with at least one parasitic infection at delivery. There was no correlation between maternal prenatal or delivery parasitic infection status and current HAZ. WAMI was not significantly correlated with current HAZ (p = 0.31). Analysis of components of the WAMI showed that household ownership of a table (p = <0.001) or a bank account (p = 0.02) was significantly associated with higher current HAZ, while there was no association found for water, sanitation, maternal education, or income. Consumption of leafy vegetables was associated with higher HAZ (p = 0.02) while consumption of legumes was associated with lower HAZ (p = 0.03). These results demonstrate the high prevalence of early childhood stunting in rural coastal Kenya. Stunting was not predictable by WAMI, suggesting that factors beyond SES must be considered when evaluating the risk of childhood stunting and identifying ways of preventing this serious threat to global child health.

## 230

### EXAMINING PERCEPTIONS AND ACCEPTABILITY OF FULL DIAGNOSTIC AUTOPSY IN KILIMANJARO REGION, TANZANIA

**Francis P. Karia<sup>1</sup>**, Elizabeth Msoka<sup>2</sup>, Martha Oshoseny<sup>2</sup>, John A. Crump<sup>3</sup>, Mathew P. Rubach<sup>3</sup>, Lauren S. Blum<sup>4</sup>

<sup>1</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, <sup>2</sup>Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, <sup>3</sup>Duke University, Durham, NC, United States, <sup>4</sup>Consultant, Duke University, Durham, NC, United States

Uncertainty about the causes of death in low- and middle-income countries (LMIC) has been recognized as a constraint to global health and development. While full diagnostic autopsy (FDA) is the best way to assess the cause of death, it is uncommon in LMICs due to low investment priority and assumptions about acceptability. Social science research was conducted from May 2016 through March 2017 to examine issues related to acceptability of FDAs in northern Tanzania where autopsy is being offered in two referral hospitals to assess the cause of death from febrile illness. Initial formative research entailed 29 key informant interviews, six observations of burial practices, and four group discussions. Subsequently, in-depth interviews were conducted with families of deceased, including 10 families that accepted and 10 families that refused FDA. The formative research illuminated beliefs that FDAs are conducted to obtain organs, make medicine, and train medical students, raising skepticism about hospital motives. Barriers to acceptance included perceptions that FDAs will not provide valuable information, disfigure the body, inflict pain, and delay burial, while facilitators involved learning how to protect family members from illness and discovering explanations for sudden death. Findings were used to develop educational approaches and make authorization culturally appropriate prior to initiation of autopsy procedures. Preliminary FDA acceptance is 39%. Families of deceased cited the desire to gain information about the cause, including if witchcraft contributed, so that similar conditions do not afflict family members in the future. Refusals mentioned the cause of death was already known, stigma associated with illness, and objections to the consent process. Findings highlight commonalities and differences in the formative research compared to actual reasons families accept or refuse autopsy. Results show

that FDAs can be acceptable in settings where traditional disease models prevail, highlighting the need to identify local understandings and beliefs and present information about procedures in a culturally relevant fashion.

## 231

### PERFORMANCE EVALUATION OF THE AMAZON MALARIA INITIATIVE ON THE MALARIA PREVENTION AND CONTROL IN THE AMERICAS

**Daniel A. Antiporta**<sup>1</sup>, Angel Rosas-Aguirre<sup>2</sup>, Laura C. Altobelli<sup>2</sup>, Elisa Juarez-Chavez<sup>3</sup>, Juan F. Sanchez<sup>3</sup>, Elisa Vidal-Cardenas<sup>2</sup>, Percy Soto-Becerra<sup>1</sup>, Jaime A. Chang<sup>4</sup>, Andres G. Lescano<sup>1</sup>

<sup>1</sup>EMERGE, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>4</sup>United States Agency for International Development, Washington, DC, United States

The Amazon Malaria Initiative (AMI) supported by USAID since 2001, aims to reduce the burden of mortality and morbidity due to malaria in the region of the Americas, through a collaborative malaria decision-making model implemented in six countries from the Amazon Basin (Brazil, Colombia, Ecuador, Guyana, Peru, Surinam) and five from Central America (Belize, Guatemala, Honduras, Nicaragua and Panama). A performance evaluation was conducted in partner countries in 2016 to: (1) identify the contribution of AMI to the capabilities of the National Malaria Control Programs (NMCP) between 2001 to 2015; (2) evaluate the capabilities of partner countries to address the changing scenarios of malaria transmission; and (3) identify the main challenges in addressing such changing scenarios (challenges at both NMCPs and international cooperation agencies). A mixed-methods approach was used, with emphasis on gender and populations in vulnerable conditions. The qualitative component included in-depth interviews with key informants from all partner countries, content analysis of selected documents, and case studies of four partner countries. We also analyzed national and regional trends of malaria epidemiology. AMI partner countries have shown a substantial but heterogeneous reduction of malaria cases since 2001, with some setbacks and slower recent progress, especially in the last four years. Partner countries have achieved significant progress and developed essential capabilities in all of AMI's six lines of work. AMI supported capacity development that addressed country-specific malaria control needs and scenarios. Furthermore, AMI has been a platform for inter-country collaboration, introducing innovations and strengthening information systems through national communication strategies and alliances. Key capacities for malaria control have been built and enhanced, allowing for an appropriate response to changing epidemiological scenarios. However, needs for improvement remain to consolidate the progress achieved, prevent reintroduction in near-elimination scenarios, and advance safely to malaria control in the region.

## 232

### WHOSE CAPACITY? COLLABORATION THROUGH CAPACITY BUILDING

**Ferdinand Okwara**

*University in Oslo, Oslo, Norway*

This paper examines collaboration in transnational medical research from the viewpoint of African scientists working in partnerships with 'Northern' counterparts. It draws on ethnographic fieldwork in an HIV laboratory of an East African state university, with additional data from interviews with scientists working in related research institutions. 'Collaboration' is the preferred framework for the mechanisms by which Northern institutions support research in the South. The concept signals a shift away from the legacy of unequal (post-) colonial power relations, although, amidst persisting inequalities, the rhetorical emphasis on equality might hinder critical engagement with conflicts of interest and injustice. In order to 'collaborate', African scientists engage various strategies: they establish a qualified but flexible, non-permanent workforce, diversify collaborators

and research areas, source complementary funding to assemble infrastructures, and maintain prospective research populations to attract transnational clinical trials. Through this labour of collaboration, they sustain their institutions under prevailing conditions of scarcity.

## 233

### THE EFFECTIVENESS OF STRATEGIES TO IMPROVE HEALTH WORKER KNOWLEDGE IN LOW- AND MIDDLE-INCOME COUNTRIES AND THE ASSOCIATION BETWEEN KNOWLEDGE AND CLINICAL PRACTICE: A SYSTEMATIC REVIEW

**Alexander K. Rowe**<sup>1</sup>, Samantha Rowe<sup>1</sup>, David H. Peters<sup>2</sup>, Kathleen A. Holloway<sup>3</sup>, John Chalker<sup>4</sup>, Dennis Ross-Degnan<sup>5</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>International Institute of Health Management Research, Jaipur, India, <sup>4</sup>Management Sciences for Health, Arlington, MD, United States, <sup>5</sup>Harvard Medical School, Boston, MA, United States

Improving health worker (HW) performance in low- and middle-income countries (LMIC) is a priority. Strategies often aim to increase HW knowledge, which is assumed to be on the causal path to improved clinical practice and better patient outcomes; and compared to HW practices, knowledge is easier to measure. To characterize the effectiveness of strategies to improve HW knowledge in LMIC and the association between knowledge and practice, we conducted a systematic review of 15 electronic databases, 30 document inventories, and bibliographies of 510 articles. We included studies meeting accepted criteria for methodological adequacy (e.g., controlled trials) of any strategy to improve HW performance on any health topic in any language, published or not. This analysis focuses on studies that measured HW knowledge and clinical practice outcomes expressed as a percentage. Effect sizes were calculated as adjusted risk differences. We screened 105,299 citations, and 824 reports were included. Overall, 27 studies measured HW knowledge outcomes, 16 of which also assessed HW practices. These studies tested 14 strategies, usually with multiple intervention components, and most tested by only one study. Among 25 studies of facility-based HWs, short in-service training courses without other intervention components increased HW knowledge by a median of 13% (interquartile range [IQR]: 12, 29), and strategies that included both training and supervision increased HW knowledge by a median of 23% (IQR: 9, 31). Only providing printed information to HWs had essentially no effect. For lay HWs, strategies that included training increased HW knowledge by a median of 11%. The median change in clinical practice outcomes in these studies was 16%; however, we found no association between baseline HW knowledge and baseline practice (Pearson's  $r = 0.18$ ,  $p = 0.47$ ) or change in knowledge and practice improvement ( $r = 0.13$ ,  $p = 0.62$ ). Contextual and methodological heterogeneity made comparisons difficult. These results, which support a focus on improving HW clinical practices rather than only knowledge, should inform decision-making on improving HW performance in LMIC.

## 234

### THE ROLE OF COMMUNITY ENGAGEMENT IN THE SUCCESS OF THE FIRST CLINICAL MALARIA VACCINE TRIALS IN EQUATORIAL GUINEA

**Esther L. Ebur-Losoha**<sup>1</sup>, Ally Olotu<sup>2</sup>, Vicente Urbano<sup>3</sup>, Ali Hamad<sup>2</sup>, Ali Mtoro<sup>2</sup>, Mwajuma Chemba<sup>2</sup>, Stephen Manock<sup>4</sup>, Maximilian Mpina<sup>2</sup>, Elizabeth Nyakarungu<sup>2</sup>, Antonio Enrique Nguema Sama Roca<sup>1</sup>, Martin Eka Ondo Mangué<sup>3</sup>, Thomas Stabler<sup>4</sup>, Yonas Abebe<sup>4</sup>, Carl D. Maas<sup>5</sup>, Mitoha Ondo'o Ayekaba<sup>5</sup>, Salomón Nguema Owono<sup>3</sup>, Matilde Riloha Rivas<sup>3</sup>, Chris Schwabe<sup>6</sup>, Julie Niemczura de Carvalho<sup>6</sup>, Luis Segura<sup>6</sup>, Wonder Phiri<sup>1</sup>, Tobias Schindler<sup>7</sup>, Elizabeth Saverino<sup>4</sup>, Peter F. Billingsley<sup>4</sup>, B. Kim Lee Sim<sup>4</sup>, Claudia Daubenberger<sup>7</sup>, Thomas Richie<sup>4</sup>, Salim Abdulla<sup>2</sup>, Stephen L. Hoffman<sup>4</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>3</sup>Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, <sup>4</sup>Sanaria, Rockville, MD, United States, <sup>5</sup>Marathon Oil, Malabo, Equatorial Guinea, <sup>6</sup>Medical Care Development International, Maryland, MD, United States, <sup>7</sup>SwissTPH, Basel, Switzerland

In 2015, the Equatorial Guinea Malaria Vaccine Initiative (EGMVI) conducted the first ever clinical trial in Equatorial Guinea (EG) to evaluate the safety and immunogenicity of Sanaria PfSPZ Vaccine® in healthy young adults (18-35 years). This paved the way for the second PfSPZ Vaccine® trial to evaluate safety and immunogenicity in participants aged 6 months to 65 years, and a head-to-head comparison of safety, immunogenicity and efficacy between PfSPZ Vaccine® and PfSPZ-CVac® in young adults (18-35 years) (Sanaria, Inc.). Because these were the first clinical trials ever conducted in EG, community engagement played a critical role in gaining the trust of local government officials, health workers, and community members. Tapping into existing local social systems facilitated access to study participants living in the targeted communities. During the community engagement, it was important to distinguish between existing, traditional malaria control interventions, e.g. bed nets and indoor spraying, and the research of investigational products such as the candidate malaria vaccines. Several challenges were encountered during the recruitment of study participants, particularly stemming from the influence that political factors and donors had on community perceptions. Understanding the purpose, procedures and potential risks and benefits of the study through sensitization meetings increased community involvement and willingness to participate in the trials. Building on the lessons learned from the first trial, community engagement resulted in high acceptance and positive feedback from the community in the second trial, in which 135 volunteers including infants were successfully recruited within 28 weeks. An effective community engagement strategy enabled the EGMVI to successfully recruit study subjects for the first malaria vaccine trials in the history of the country, and has enabled the nation to contribute to scientific research on the whole sporozoite malaria vaccines. Key points will include trust building, community-based health education and communication, and community engagement strategy models.

## 235

### IMPACT OF MATERNAL INTERVENTIONS: TREND OF COVERAGE AND PROJECTIONS FOR 2030 OF ADDITIONAL LIVES SAVED IN MOZAMBIQUE

**Reka Cane**

*Instituto Nacional de Saude, Maputo, Mozambique*

Globally, maternal mortality ratio declined by only 2.3 % per year between 1990 and 2015. Mozambique has made important progress on maternal mortality (MNCH), reducing its mortality ratio by over 63 per cent by the year 2013. Nevertheless, there is a lot more to be done in order to accelerate maternal mortality reduction. We explored the use of projections, to see the potential of each intervention to contribute

on reducing preventable deaths. This study was undertaken determine which interventions will contribute more to prevent maternal deaths in Mozambique until 2030. We used historical coverage data in a Bayesian model to fit the trend of the interventions linked to maternal deaths (labor and delivery management, clean birth practices, active management of third stage of labor, MgSO<sub>4</sub> management pre-eclampsia/eclampsia, antibiotics for pPRoM, intermittent preventive treatment of malaria during pregnancy, tetanus toxoid vaccination, hypertensive disorder case and malaria case management) coverage up to the year 2030. We used the estimates produced in the model to generate the mortality changes and the addition lives saved by interventions using Lives Saved Tool (LiST; *Spectrum* version 5.27) in order to see the impact of each intervention across the time. The top 10 lifesaving interventions were scaled up to expose the missed opportunities that exist for intensify even more the mortality reduction. Clean postnatal practices is expected to be the intervention with the fastest coverage growth, observing 53.14% of absolute percentage increase, rising from 26.70 % in 2011 to 79.84% in 2030. Interventions related to malaria for prevention and treatment will also observe important coverage growth, with artemisinin compounds for malaria estimated to grow 27.06 % starting from 35.60% in 2015 to 62.66% in 2030. Labour and delivery management is expected to be the higher contributor in lives saving, being responsible for 23.91% of the lives saved. Preventive interventions such as facility delivery will be the top contributor on averting deaths with an aggregated number of 2524 extra additional lives saved.

## 236

### STRENGTHENING SURVEILLANCE IN THE RETAIL PRIVATE SECTOR THROUGH MOBILE REPORTING IN TANZANIA

**Sigsbert Mkude**<sup>1</sup>, Rebecca S. Goldstein<sup>2</sup>, Rose Rutizibwa<sup>3</sup>, Happy Ndomba<sup>3</sup>, Lyudmila Nepomnyashchiy<sup>2</sup>, Deepa Pindolia<sup>2</sup>, Arnaud Le Menach<sup>2</sup>, Richard Silumbe<sup>3</sup>

<sup>1</sup>National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>Clinton Health Access Initiative, Dar es Salaam, United Republic of Tanzania

Tanzania's national malaria strategy calls for targets of 80% confirmatory diagnosis of suspected malaria patients and appropriate treatment with artemisinin combination therapy (ACTs) for 80% of confirmed malaria patients by 2020. Given that 26% of patients with a fever seek care among drug shops in the retail private sector, it is imperative that the malaria program track case management practices in this sector. The National Malaria Control Program (NMCP) rolled out a system for drug shops to report aggregate monthly data using an SMS-based mobile platform. This platform was implemented in Morogoro Region, where 451 drug shops (75%) received case management training in July 2016 and paper registers to record individual case information and aggregated sums. Drug shops receive 2 reminders per month to report aggregated data for 8 key indicators on case management. Data reported between August and December 2016 were descriptively analyzed for reporting rate (% trained shops sending reports each month), completeness (% expected questions answered), data quality (consistency and logic of figures), test uptake (% fever cases receiving a malaria rapid test (RDT)) and adherence to test results (ACTs provided for positive RDTs, no ACTs provided for negative RDTs). Monthly reporting rates were lower than 50%, peaking at 47% in December 2016. Reporting was inconsistent: 10% reported for the full 5 months. Of the 887 reports received, 813 (92%) were complete. Approximately 30% of reports each month had quality errors. More than 90% of reported fever cases received an RDT, and 98% and 3% of positive and negative tests respectively received ACTs across the 5 months. Monthly reports from the retail private sector indicate strong case management practices, but there remain challenges with reporting rates and data quality. Limitations contributing to low reporting rates may include SMS formatting challenges, technical bottlenecks with the central

database, and difficulty with aggregated data entry and reconciliation. Upcoming focus group discussions with shops will provide insights on potential improvements to the system.

## 237

### **BUILDING THE INFECTIOUS DISEASE DIAGNOSTIC CAPACITY OF A DEVELOPING NATION: EXPERIENCE FROM THE INDONESIA RESEARCH PARTNERSHIP ON INFECTIOUS DISEASE (INA-RESPOND)**

**Wahyu Nawang Wulan**, Dewi Lokida, Muhammad Karyana, Herman Kosasih, Ungke Antonjaya, Deni Pepy R. Butarbutar  
*The Indonesia Research Partnership on Infectious Disease (INA RESPOND), Jakarta, Indonesia*

The laboratory diagnostic capacity of developing countries is often insufficient to identify even the most common causes of illness. In Indonesia, this limited capacity forces many clinicians to rely solely on empirical diagnoses when prescribing treatments. Without known etiological agents, the risks of misdiagnosis and treatment failure are high, particularly when diseases share difficult-to-differentiate signs such as fever and rash. INA-RESPOND, established in 2011, has strengthened the infectious disease diagnostic capacity of the country using an applicable approach. A centralized reference laboratory was established so that diagnostic tests are developed, evaluated, and perfected before field implementation. Limited resources were optimally used by prioritizing assay development by: (1) pathogens generally known as the primary causes of fever-associated illness in Indonesia (e.g. Dengue, *Salmonellae*); (2) pathogens with circulating hosts/vectors but no known cases (e.g. *Rickettsiae*, Hantavirus); (3) pathogens likely to cause severe outbreaks (e.g. anthrax, H5N1); and (4) pathogens with known cases but poor awareness among clinicians (e.g. influenza, RSV, HHV-6). Molecular and serological tests were developed concurrently to ensure accurate laboratory diagnoses. The capacity was validated during two observational studies of hospitalized patients from 7 cities across Indonesia between July 2015 and March 2017. From 1566 subjects, 52 pathogens were identified by molecular tests and 16 by serology, leading to diagnoses for 66% of patients. Interestingly, 34% of diagnoses determined by field sites were found to be incorrect by the reference laboratory, which was later able to improve local capacity in a targeted manner. The expanded diagnostic capacity also revealed a previously unknown *Rickettsia spp.* burden, with 103 cases, and generated baseline prevalence data on diseases such as Chikungunya, Leptospirosis, and HHV-6. As the diagnostic capacity of Indonesia continues to grow, lessons from INA-RESPOND's success can inform the disease treatment and control efforts of other developing nations.

## 238

### **A QUALITATIVE ASSESSMENT OF THE CONTRIBUTIONS OF THE AMAZON MALARIA INITIATIVE TO THE CAPACITIES OF NATIONAL MALARIA CONTROL PROGRAMS IN THE AMERICAS**

**Elisa Juarez Chavez**<sup>1</sup>, Daniel A. Anitiporta<sup>1</sup>, Catharine De Freitas<sup>1</sup>, Angel Rosas<sup>2</sup>, Laura Altobelli<sup>2</sup>, Jaime Chang<sup>3</sup>, Andres G. Lescano<sup>1</sup>

<sup>1</sup>EMERGE, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>U.S. Agency for International Development/Peru, Lima, Peru

Launched in 2011 with support of USAID, the Amazon Malaria Initiative (AMI) is a regional program implemented in 11 countries: Brazil, Colombia, Ecuador, Guyana, Peru, Suriname, Belize, Guatemala, Honduras, Panama and Nicaragua. AMI aims to reduce the morbidity and mortality of malaria in the Americas by working in six specific lines of action (LoA): antimalarial efficacy monitoring and prevention of emergence of resistance to antimalarials (LoA1); access to quality diagnosis and treatment (LoA2); quality assurance and control of antimalarial drugs and supplies

(LoA3); vector surveillance and integrated vector management (LoA4); epidemiological surveillance (LoA5); networking and systems strengthening (LoA6). In 2016, we did a performance evaluation of AMI, including a qualitative exploration of the stakeholders' perceptions about the AMI's contribution to national capacities by LoA, and factors that enabled AMI's success and barriers along the process. A total 38 in-depth interviews with leaders of National Malaria Control Programs (NMCP) in partner countries were done. The most recognized contributions were the generation of evidence via antimalarial resistance and efficacy studies (LoA1); training of health workers and generation of treatment/diagnosis guidelines (LoA2); and, strengthening of management systems of antimalarial drugs and supplies at NMCP (LoA3). According to all informants, AMI provided a platform that facilitated the exchange of resources and ideas between participating countries, strategic partners and institutions within the countries (LoA6). Contributions in LoA 4 and 5 were less perceived and variable, including support to the surveillance system and training in vector control strategies. Informants agreed that the political will towards malaria control and the participation of partner countries in the selection of AMI's strategies and priorities were key components in its success. Bureaucracy and personnel turnaround were identified as the main barriers for AMI's success. In summary, qualitative results suggest a positive impact of AMI and potentially replicable results in other regions.

## 239

### **REGIONAL DIVIDE ON PERCEPTION AND MEANING OF HEALTH AND WELL-BEING OF KENYANS: AN ECOLOGICAL PERSPECTIVE**

**Elizabeth Opiyo Onyango**

*University of Waterloo, Waterloo, ON, Canada*

The past three decades have seen the growth in prominence of the concept of wellbeing in academia and the world over. As such, attempts to conceptualize and develop benchmarks for assessing the wellbeing of individuals, communities, cities and nations have been made, especially in the global north. This study explored contextual and place-based meaning and perception of health and wellbeing in low-middle income countries (LMICs), using Kenya as a case study. This was an ecological study where qualitative methods such as focus groups (FGs), key informant interviews and policy document reviews were conducted with in four representative provinces; Nyanza, Nairobi, Eastern and Central provinces of Kenya. FGs with homogenous groups of lay people male and female of the ages 15-24 years, 25-49 years and 50 years and above were conducted. Key informant interviews with male female and NGO representatives and member of county assemblies were also conducted. The results indicate a regional divide on perception and meaning of health and wellbeing. Preliminary analysis reveal that the indicators that matter to Kenyans are place based. For instance, in Eastern province, the most valuable indicator of health and wellbeing is water and food availability, whereas in the informal settlements in Nairobi, water and sanitation was given the first priority. These findings are important in providing indices relevant for policy making and to highlighting gaps in the measurement of the health and wellbeing of Kenyans which has always been based on morbidity and mortality statistics such as infant mortality.

## 240

### **POSTPARTUM MANAGEMENT EVALUATION OF NEWBORNS WITH LOW BIRTH WEIGHT FROM A MALARIA ENDEMIC AREA IN COLOMBIA**

**Astrid Natalia Palacio**, Sara María Feo, Erika Francisca Garrido  
*Uniremington, Medellin, Colombia*

Nearly three hundred million pregnancies occur in endemic areas of malaria in Africa every year, which poses a high risk for pregnant women and their fetuses. Yet, malaria is not an African issue only. Despite several Latin American countries show unstable transmission for malaria, epidemiological surveillance during pregnancy does not exist. Twenty

million children with low birth weight are born every year in the world and, in endemic areas, malaria during pregnancy as well as placental malaria are the main causes of low birth weight. Infants who are not diagnosed by the thin smear test for neonatal malaria are treated as cases of neonatal sepsis and the underlying problem is not solved. In order to tackling low weight, the over-feeding is a common practice and this in turn leads to early development of metabolic diseases such as diabetes and metabolic syndrome in the middle and long term. The aim of this research is to determine if the newborns diagnosed with low birth weight had an appropriate management and if the obstetrics-gynecology staff established a potential relation between this condition and placental malaria. This is a retrospective and descriptive study based on the review of 2014-2016 medical files of women who attended to antenatal care and had their deliveries at the Antonio Roldan Betancur Hospital in Apartadó, all of whom also had a postpartum follow-up note. Apartadó is an area endemic for malaria where a small percentage of newborns with low birth weight have access to medical follow-up. This research reveals that obstetrics-gynecology services in endemic areas of malaria in Colombia do not apply an appropriate epidemiological surveillance. In newborns with low birth weight, placental malaria was not thought of as a possible etiology in any case. The implementation of a surveillance protocol that includes placental studies and anthropometric measures of fetuses will promote an adequate management of newborns diagnosed with low birth weight and will decrease early neonatal death.

241

### CREATING COLLABORATIONS FOR ARBOVIRAL RESEARCH IN COLOMBIA

**Juan F. Arias**, Cristhian Salas-Quinchucua, Jorge E. Osorio  
*University of Wisconsin, Madison, WI, United States*

Arboviral infections are important issues in Colombia representing major causes of morbidity. Zika virus (ZIKV), a mosquito-borne RNA flavivirus, has caused a major outbreak in the Americas since it was first reported in Brasil in early 2015. Colombia alone reported more than 100,000 suspected cases of Zika virus infection between September 2015-November 2016, including nearly 20,000 in pregnant women. As part of a large multicountry study of pregnant women in areas affected by ZIKV, we have begun to evaluate the magnitude of health risks that Zika virus infection poses to pregnant women and their developing fetuses and infants in Colombia. To avoid some of the pitfalls of traditional international research set in resource-limited countries, we seek to build independent research capacity. In this report, we discuss the biggest challenges to the implementation of such a model of collaboration, as well as strategies for scaling up Colombia's participation in international arboviral research using examples from ongoing ZIKV studies. In our experience, a number of findings are relevant for improving collaborative efforts: 1) Language barriers still impose big challenges; although this has been slowly decreasing in basic research, it's still an enormous hurdle in clinical research still, particularly considering the regulatory burden of international rules and regulations for conducting research in human subjects. Regulatory agencies need to provide better access to training material in Spanish for conducting clinical research, because knowledge of the English language among local clinicians is low. 2) Besides the limitations in resources and laboratory space, international researchers need to consider the impact that bureaucracy, cumbersome regulations, and lengthy delays in obtaining supplies and reagents locally, will have in the logistics of their experimental work and plan accordingly. 3) Differences in the timeframes for regulatory approval between US-based and local institutions also require careful advance planning.

242

### FIELD SEROSURVEY LOGISTICS FOR VACCINE PREVENTABLE DISEASES IN RESOURCE LIMITED SETTINGS: CHALLENGES AND OUTCOMES IN THE DEMOCRATIC REPUBLIC OF THE CONGO

**Daniel B. Mukadi**<sup>1</sup>, Nicole A. Hoff<sup>2</sup>, Patrick Mukadi<sup>1</sup>, Kamy Musene<sup>3</sup>, D'Andre Spencer<sup>2</sup>, Patrick Mavungu<sup>4</sup>, Rachel Mutombe<sup>1</sup>, Emile Okitolonda-Wemakoy<sup>4</sup>, Sue Gerber<sup>5</sup>, Ado Bwaka<sup>5</sup>, Jean-Jacques Muyembe-Tamfum<sup>1</sup>, Anne W. Rimoin<sup>2</sup>

<sup>1</sup>*Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo*, <sup>2</sup>*University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States*, <sup>3</sup>*University of California Los Angeles-DRC Research Program, Kinshasa, Democratic Republic of the Congo*, <sup>4</sup>*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo*, <sup>5</sup>*Bill & Melinda Gates Foundation, Seattle, WA, United States*

Infectious diseases represent the main factor of morbidity and mortality in developing countries, including the DRC. The DRC, the largest sub-Saharan country, has many inaccessible regions due to geographical obstacles, lack of communication, and other logistical issues. To accomplish their goals, all field and laboratory activities must successfully overcome many challenges. Therefore, it is useful to produce, set up, and carry out a consistent and coordinated protocol for all foreseen activities in the field in various conditions. Our team aimed to set up a functional laboratory in which viable samples could be collected and handled through any kind of obstacle while maintaining the cold chain until sample analysis in Kinshasa. From July to August 2016, we conducted a serosurvey of children 6-59 months in seven health zones of the Kabondo-Dianda Antenne, Haut-Lomami Province. Among the many logistical challenges the project faced were: mountainous and lacustrine regions; impassable roads and solid bridges, lack of transport or communication options, lack of electricity to run and charge electronic devices, sanitation issues and moving with a group of over 30 persons. Despite very challenging conditions, we were able to set up the laboratory (3 portable freezers, a centrifuge, a generator, 15 tablets, 2 batteries and chargers, stabilizers and all materials) in 5 different health zones covering an area of 33,361 Km<sup>2</sup>. We collected questionnaire data and viable samples including serum, plasma, and buffy coat from 1,900 children. This work was completed in close collaboration with local and traditional authorities; this was key and critical for successful field deployment and data collection, and was incorporated at each stage. Research and public health activities can noticeably reduce morbidity and mortality in resource-limited settings such as DRC. Although DRC's size and geographical obstacles do not allow for easy field deployment, it is possible to deploy high quality field laboratories by creating a consistent and sustained plan. Using these protocols, valuable samples and data can be produced despite suboptimal work conditions.

243

### SMALL SCALE MIGRATION ALONG THE INTEROCEANIC HIGHWAY IN MADRE DE DIOS, PERU: AN EXPLORATION OF COMMUNITY PERCEPTIONS AND DYNAMICS DUE TO MIGRATION

Christina O'Neal<sup>1</sup>, **Kelly Jensen**<sup>1</sup>, Nehal S. Naik<sup>2</sup>, Amy R. Riley-Powell<sup>3</sup>, Gabriela Salmon-Mulanovich<sup>4</sup>, Gwenyth O. Lee<sup>3</sup>, Stella M. Hartinger<sup>4</sup>, Valerie A. Paz Soldán<sup>5</sup>

<sup>1</sup>*Tulane University School of Medicine, New Orleans, LA, United States*, <sup>2</sup>*Virginia Commonwealth University School of Medicine, Richmond, VA, United States*, <sup>3</sup>*Tulane University Health Office for Latin America, Lima, Peru*, <sup>4</sup>*Universidad Peruana Cayetano Heredia, Lima, Peru*, <sup>5</sup>*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States*

Madre de Dios, a southern state in the Peruvian Amazon basin, has experienced rapid development as well as an influx of migrants since the

construction of the interoceanic highway (IOH). This highway connecting Brazil, Bolivia, and the Peruvian coast, was completed in 2011. This study explores perceptions of migration and development in 8 communities along the IOH in Madre de Dios following construction of the highway. This was a multiple methods study involving interviews with key informants (KIs), focus group (FG) discussions, and application of a survey in the selected communities. A total of 12 FGs and 34 KI interviews were conducted in 2014 and 2015. Surveys were applied to 522 participants and included questions on demographics, financial, personal, social, human, and physical capital. Comparing migrants (self-reported moving after construction of the IOH) and non-migrants, we found no difference in food security or access to health services. Additionally, over 60% of respondents from both groups reported that illness was their primary threat to well-being. There were significant differences in land ownership and access to water. On average, non-migrants owned more land than migrants ( $p=0.041$ ). Non-migrants were also more likely to have piped water directly in their home ( $p=0.027$ ). Looking at perceptions about migrants, KIs and FGs discussed both positive perceptions of migrants – increased cultural exchange and new technology – and negative perceptions – increased drugs and alcohol in their communities and a lack of investment in the community. Both migrants and non-migrants reported trusting the local government more than the national government. Although we hypothesized that migrants would have decreased access to food, water, health services, and land, the only significant differences were in land ownership and water access. Even within these categories, the majority of migrants had access to water and owned some amount of land suggesting there is a level of community integration. Efforts to improve community infrastructure should be carried out at the local level and focus on improving issues reported by both groups.

## 244

### EMOTIONAL PERCEPTIONS DURING PREGNANCY WITH POTENTIAL EXPOSURE TO ZIKA VIRUS: A PILOT STUDY

**Katherine O. Ryken**<sup>1</sup>, Joanna G. Valverde<sup>2</sup>, Sonia M. Barreto<sup>2</sup>, Flavio V. Pereira<sup>2</sup>, Mary E. Wilson<sup>1</sup>, Selma Jeronimo<sup>2</sup>

<sup>1</sup>University of Iowa Carver College of Medicine, Iowa City, IA, United States, <sup>2</sup>Federal University of Rio Grande do Norte, Natal, Brazil

Common mood disorders are common during pregnancy. The development of gestational depression has been linked to low socioeconomic status and lack of social support. High-risk pregnancies, accounting for 22% of pregnancies worldwide, are associated with higher levels of stress than uncomplicated pregnancies. Pregnant women living within the host range of the Zika virus (ZIKV) likely experience additional traumatic stress. This project is part of a larger community study on pre-eclampsia, the leading cause of maternal mortality in developing nations. A recently published meta-analysis indicates that chronic infection is also a risk factor for this condition. We are now exploring the risk of chronic viral infection during pregnancy, specifically Zika virus and other emerging flaviviruses. We expected that experiencing a high-risk pregnancy in addition to possible ZIKV exposure would result in a multi-layered trauma and significantly higher rates of emotional distress. A cohort of women was surveyed at the Maternidade Escola Janeiro Cicco as well as community centers within Natal. Patients were recruited between January-March 2017. The survey included qualitative questions about family planning, exposure to insect bites, and knowledge about Zika virus infection during pregnancy. The Self Reporting Questionnaire (SRQ-20) developed by the World Health Organization (WHO) was also administered. This screening questionnaire was developed by the WHO to screen for psychiatric disturbance and is validated for use in Brazil. 100 patients were enrolled. Significant emotional disturbances were identified in a majority of patients. The majority of pregnancies were unplanned, although most women said they would use contraception after this pregnancy. Zika virus affected women's concerns about their current pregnancies. Few women routinely used insect repellent. No women surveyed had received insect repellent from the national government

or other organizations. Zika virus continues to be of great concern to pregnant women, and a number of interventions could potentially reduce concern about and transmission of the virus.

## 245

### STRENGTHENING NATIONAL INTEGRATED COMMUNITY CASE MANAGEMENT (ICCM) PROGRAMS: AN EVALUATION OF RAPID ACCESS EXPANSION (RACE) CONTRIBUTIONS IN DRC, MALAWI, MOZAMBIQUE, NIGER AND NIGERIA

**Jennifer Yourkavitch**<sup>1</sup>, Debra Prosnitz<sup>1</sup>, Samantha Herrera<sup>1</sup>, Kirsten Zalisk<sup>1</sup>, Yodit Fitigu<sup>1</sup>, Helen Coelho<sup>2</sup>, Sujata Ram<sup>1</sup>, Ramine Bahrambegi<sup>1</sup>

<sup>1</sup>ICF, Rockville, MD, United States, <sup>2</sup>ICF, Atlanta, GA, United States

Over the last decade integrated community case management (iCCM) emerged as a strategy to expand child health services in hard to reach communities in sub-Saharan Africa. This strategy of recruiting and training community health workers to diagnose, treat, and refer children under five for malaria, pneumonia, and diarrhea had great momentum at global and national levels in 2013. Harnessing this momentum, in 2013 WHO launched the Rapid Access Expansion (RACE) Program in the Democratic Republic of Congo, Malawi, Mozambique, Niger, and Nigeria (Abia and Niger States). The goal of the program was to increase coverage of diagnostic, treatment, and referral services for malaria, pneumonia and diarrhea and to decrease mortality and the number of severe cases among children under five. At the same time there was a need to understand how to best measure success and build country ownership and capacity to sustain iCCM interventions. ICF provided monitoring and evaluation support to RACE to assist with measuring progress and strengthening data quality. ICF is also conducting a final evaluation of each RACE project site. The final evaluation uses a comprehensive and innovative mixed method approach that will: 1) assess changes in outcome and coverage indicators through analysis of baseline and endline household survey data and trend analysis of routine project monitoring data; 2) assess potential gender differentials in careseeking and iCCM coverage through analysis of baseline and endline household survey data; 3) estimate change in child mortality and number of lives saved using the lives saved tool (LiST) model; 4) document project contextual and external factors that may have influenced child health in project areas via document review, interviews, and trend analyses; 5) conduct an equity analysis; and 6) make a plausibility argument to demonstrate the plausible contribution of RACE to changes in careseeking, assessment and treatment coverage and estimated mortality change. Final evaluations will be completed in August 2017 and results will be available to present at the ASTMH conference. The presentation will include key findings from each country.

## 247

### STRATEGIES TO IMPROVE COVERAGE OF COMMUNITY-BASED DISTRIBUTION PROGRAMS: A SYSTEMATIC REVIEW OF THE LITERATURE

**Katrina V. Deardorff**, Arianna Rubin-Means, Kristjana H. Ásbjörnsdóttir, Judd Walson

University of Washington, Seattle, WA, United States

Community-based public health services aim to provide public health interventions at scale. However, many of these programs, including those targeting soil-transmitted helminths (STH), vitamin A supplementation, and child immunization, often fail to achieve World Health Organization (WHO) coverage targets. The purpose of this systematic literature review was to identify successful interventions to increase coverage of community-based distribution and to quantify the magnitude of observed change in coverage associated with each strategy. We systematically searched PubMed, Embase, and CAB Direct for studies that compared coverage estimates of community-based distribution of drugs, vaccines, or other public health services in the presence and absence of an

intervention intended to increase distribution coverage. We identified 2,561 studies from which 119 full text articles were evaluated for possible inclusion. After review, twelve studies describing 14 interventions met inclusion criteria. Data abstracted from articles included location and design of study, strategy used to increase coverage, baseline coverage, and coverage obtained with the intervention. Local Ministries of Health funded eight of the interventions described, while six interventions were implemented using supplemental donor funding. Strategies identified to increase coverage included community involvement in the design and implementation of distribution (n=3, range of reported differences in coverage: +9%, +23%), increased distribution of health education and awareness materials (n=5, range: -4%, +26%), distributor incentives (n=1, +20%), converting from school- to community-based distribution (n=2, range: -2%, +82%), management by a non-governmental organization (n=1, +9%), and integrated distribution through Child Health Days (CHDs) (n=2, range: -31%, +72%). Several specific interventions to improve coverage of community-based public health service distribution have demonstrated impact. These results may be useful in the design of future community-based public health intervention programs.

## 248

### POLICY REVIEW ON THE MANAGEMENT OF PRE-ECLAMPSIA AND ECLAMPSIA BY COMMUNITY HEALTH WORKERS IN MOZAMBIQUE

**Salésio E. Macuácuá**<sup>1</sup>, Raquel Catalao<sup>1</sup>, Sumedha Sharma<sup>2</sup>, Anifa Vala<sup>1</sup>, Marianne Vidler<sup>2</sup>, Eusébio Macete<sup>3</sup>, Mohsin Sidat<sup>4</sup>, Khátia Munguambe<sup>5</sup>, Peter Von Dadelszen<sup>6</sup>, Esperança Sevens<sup>6</sup>, CLIP Working Group<sup>1</sup>

<sup>1</sup>*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique,*

<sup>2</sup>*Department of Obstetrics and Gynaecology, and the Child and Family Research Unit, University of British Columbia, Vancouver, BC, Canada,*

<sup>3</sup>*Centro de Investigação em Saúde de Manhiça and Ministério de Saúde, Maputo, Mozambique,* <sup>4</sup>*Universidade Eduardo Mondlane, Faculdade de Medicina, Maputo, Mozambique,* <sup>5</sup>*Centro de Investigação em Saúde de Manhiça and Universidade Eduardo Mondlane, Faculdade de Medicina, Maputo, Mozambique,* <sup>6</sup>*Molecular and Clinical Sciences Research Institute, St. George's, University of London and Department of Obstetrics and Gynaecology, St. George's University Hospitals NHS Foundation Trust, London, United Kingdom*

Maternal mortality ratio still high in Mozambique, being 480 per 100,000 live births in 2015. Pre-eclampsia is one of the leading causes of maternal death within the country. Limited access to health care facilities and a lack of skilled health professionals contribute to the high maternal morbidity and mortality rates and indicate a need for community-level interventions. The aim of this review was to describe the health policies related to the role of community health workers in the management of Pre-eclampsia and Eclampsia in Mozambique. A review of policy documents regarding the community health workers programme in Mozambique was performed through desk review of relevant documents from Mozambique's Ministry of Health, literature review and contact with key informants in the field of health policy in Mozambique. These documents included peer reviewed articles, government and institutional policies and relevant official documents. After independence in 1975, Mozambique introduced new policies to strengthen and extend primary health care. In 1978 the community health worker programme was established, with the primary goal of promoting health and preventing disease in remote and rural populations. In the late 80's and early 90's, this programme was scaled down due to several factors including a prolonged civil war; however, the decision to revitalize the programme was made in 1995. In 2010, the reformed programme expanded to include management of common childhood illnesses including malaria, diarrhoea and acute respiratory infections. According to their curriculum, community health workers have a limited role in maternal health which includes simple health promotion, detection of warning signs in pregnancy, and referrals. Their role does not include the management of Pre-eclampsia or Eclampsia. To strengthen community-level care and reduce maternal mortality, there is a need to

design policies to promote task-sharing to community health workers. The provision of basic maternal health services should be broadened to include the detection and pre-referral management of Pre-eclampsia and Eclampsia.

## 249

### RELUCTANCE TO SUBMIT MANUSCRIPTS TO SCIENTIFIC JOURNALS: AS EXPERIENCED BY RESEARCHERS IN DIFFERENT DISCIPLINES IN THAILAND

**Pornpimon Adams**, Jaranit Kaewkungwal

*Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand*

It is axiomatic among the scientific community that even the most brilliant research is useless unless it is reported. At the same time, it can be a struggle for researchers to deal with the constant pressure to "publish or perish". Peer review and publication are major concerns among scientific and other researchers. The objective of this study was to explore the self-reported experiences of researchers regarding the most important factors influencing reluctance to submit their manuscripts. An anonymous online questionnaire was sent to researchers in different disciplines in a variety of academic and scientific research institutes in Thailand, during March 2017. Based on the level of problematic issues reported using a Likert rating scale, the highest rating for each item was considered potentially significant. The respondents comprised 45 (55%) researchers in basic science or laboratory-based fields, 17 (21%) researchers involved in clinical research, and 10 (24%) researchers in the fields of behavioral or public health. The problematic ratings were mainly at the "to some extent" and "to large extent" levels. The percentages of problematic issues varied across the three groups. The ratings for highly problematic issues for researchers in basic science, clinical science and behavioral science, were as follows: deciding on the journal for publication (35%, 7%, 50%); identifying the "selling point" of the paper (38, 38%, 53%); authorship-related issues (4%, 25%, 5%); submission process (16%, 19%, 30%); conflict of interest (9%, 13%, 20%); data sharing (16%, 6%, 16%); likelihood of acceptance after revision (25%, 38%, 45%); and experience of rejection (9%, 25%, 25%). Significant differences were found for journal selection and authorship issues. The study results, however, revealed different weightings for the problematic issues faced by researchers in submitting their manuscripts. Identifying "reluctance to submit" issues can inform the planning of research and publication supports for researchers.

## 250

### A NEW APPROACH TO ASSURING THE QUALITY OF COMMUNITY-BASED HEALTH SERVICES IN MADAGASCAR

**John Yanulis**<sup>1</sup>, Hajamamy Rakotoarisoa<sup>1</sup>, Andritiana Tsarafihavy<sup>1</sup>, Delord Ramiaramanana<sup>1</sup>, Aishling Thurow<sup>2</sup>, Elke Konings<sup>2</sup>

<sup>1</sup>*U.S. Agency for International Development Mikolo, Antananarivo, Madagascar,* <sup>2</sup>*Management Sciences for Health, Medford, MA, United States*

In Madagascar, community health volunteers (CHVs) play a critical role in providing primary health care, especially to rural populations who live more than five km from a health facility. CHVs are trained and supported by the nearest health center and the USAID Mikolo project to provide integrated community case management (iCCM) treatment (diarrhea, malaria, and pneumonia); short-acting family planning (FP) methods; maternal health care (MH); and health promotional activities. However, assuring the quality of CHV services has been a significant challenge. The absence of effective and sustainable quality control to improve CHV performance is not only demotivating for CHVs, but potentially harmful for women and children receiving poor-quality services. To address these quality issues, the Project created a new approach hypothesized to assure, improve, and sustain the quality of community-based health services. The Project's quality improvement approach includes formal training or refresher training every year, on-the-job coaching and mentorship every

two months, monthly performance monitoring and group supervision at the health facility, standards-based competency evaluation every quarter, and annual certification or re-certification. From October 2014 to April 2015, the project introduced this performance improvement package in 375 communes. After the first six months, the project assessed compliance with national standards among 2,154 CHVs offering MH/FP and 2,909 CHVs offering iCCM. Among the CHVs offering MH/FP, 1,462 (68%) achieved a compliance score of 80% or higher for FP, compared to 49% at baseline ( $p < 0.002$ ). Among iCCM CHVs, 1,979 (68%) achieved a compliance score of 80% or higher for iCCM, compared to 60% at baseline ( $p < 0.02$ ). All CHVs who achieved at least 80% were cross-trained to become polyvalent. Ultimately, these results demonstrate that this approach has actively improved the performance of CHVs. As such, the USAID Mikolo Project quality assurance and improvement approach is a critical component of sustainable health service availability and uptake and to achieving universal health coverage in Madagascar.

## 251

### COMPETENCY TEST FOR VISUAL INSPECTION OF CERVICAL CANCER LESIONS WITH ACETIC ACID IN EQUATORIAL GUINEA

Farshid Meidany<sup>1</sup>, Manuel Ondo Oyono<sup>2</sup>, Erica Liebermann<sup>3</sup>, Kimberly McLeod<sup>1</sup>, Luis Benavente<sup>1</sup>

<sup>1</sup>Medical Care Development International, Silver Spring, MD, United States,

<sup>2</sup>Hospital Regional de Malabo, Malabo, Equatorial Guinea, <sup>3</sup>Grounds for Health, Williston, VT, United States

As part of MCDI-Equatorial Guinea Cervical Cancer Screening and Treatment Project, a training on Visual Inspection with Acetic Acid was held in March 2017 in Malabo. Twenty six gynecologists, doctors, midwives and nurses, as well as relevant Ministry of Health managers, were trained. To assess participants' competency 36 printed images from JHPiEGO were used. The images were inspected prior to the training to ensure they were not pixelated or had poor resolution. Response sheets were entered into an Excel template that automatically assigned a score to each of the answers, aggregated for a general score for 4 competencies: identify cancer, diagnosis of VIA positive, identify Squamocolumnar Junction and identify correct management plan. The individual and occupational category scores were mainly affected by the fourth competency, management of the case. Possibly due to selection bias (i.e., due to recruitment being based on the recommendations of knowledgeable clinician very familiar with their prior work experience), the three auxiliaries showed a competence comparable to the rest. The 4 clinicians with largely managerial roles tended to perform better than the other participants, who saw patients in public facilities. At the group level, the highest competency corresponded to identification of cancer (86%), followed by seeing clearly the Squamocolumnar Junction (78%). The lowest competencies were in correctly classifying the images shown as VIA negative/positive (64%), and specifying the required treatment (none, cold coagulation, refer for cancer treatment) with only 50% correct. Regression analysis of the post-test knowledge score derived from a comprehensive final examination regressed on the competency score gave a linear regression coefficient of  $R^2 = 0.8234$ , indicating that the competency assessment was a good predictor of clinical knowledge. On average, a little more than a third (38%) of the participants obtained correct answers in all 4 questions. This indicates that at this early stage of the program it is more useful to analyze the 4 competencies separately and identify and prioritize the next training steps accordingly.

## 252

### SUBSTANTIATING FREEDOM FROM DISEASE BY COMBINING DYNAMIC MODEL PREDICTIONS WITH INFECTION SURVEYS

Morgan Smith, Edwin Michael

University of Notre Dame, Notre Dame, IN, United States

Regions endemic for onchocerciasis, a debilitating vector-borne helminth infection, are currently approaching elimination targets after years of mass drug administration and vector control efforts. As large scale control programs transition their focus from active treatment deployment to post-treatment surveillance, the need for evidence-based measures of disease absence grows more pronounced. Freedom from infection tools, originally established in veterinary science, offer a framework for integrating surveillance statistics and mathematical transmission models to quantify the confidence of freedom, thus providing policy makers with a reproducible metric on which to base program decisions. We describe an application of this approach using Ugandan onchocerciasis monitoring data from eight sentinel sites collected by country programs and The Carter Center as a case example. Our dynamic Bayesian transmission model was calibrated to the local baseline conditions of each site, ranging in pre-intervention microfilaria prevalence from 53.8% to 100%. The locally parameterized models were used to estimate site-specific transmission thresholds, which range from 0.03% to 0.68% microfilaria prevalence. The current infection status of each site was determined by hypothesis testing based on probability calculations which consider post-intervention survey sample size, test sensitivity and specificity, and model-generated transmission thresholds. Four Ugandan sites where infection is thought to be interrupted were indeed declared free from infection with greater than 96% confidence while infection was considered to be present in two sites in a region with ongoing transmission. An important finding was that in the four sites found to be infection-free, the method showed that declarations of freedom from infection could have been made at least five years earlier, a result which could have saved unnecessary annual treatments. These results highlight how the synthesis of model predictions and survey data by this new freedom from infection framework can facilitate robust decision making in parasite elimination programs.

## 253

### THE GLOBAL HEALTH NETWORK: IMPLEMENTING RESEARCH CAPACITY DEVELOPMENT, IMPROVING EVIDENCE AND DATA QUALITY ACROSS THE WORLD

Alex Segrt

The Global Health Network, Oxford, United Kingdom

The Global Health Network (TGHN) is a platform that is implementing research capacity development, improving evidence generation and data quality across the world, with a specific focus on low and middle-income countries (LMICs). This is being achieved through two key interdependent mechanisms: a platform for delivering training and research career development for healthcare workers and research staff, and a mechanism for sharing knowledge, experience and tools between regions, organisations and disease areas. TGHN is an online science park that enables research groups to disseminate and share their methods and know-how, thus speeding up research by raising standards and removing duplication. The network achieves this by adapting and applying the latest digital technology and harnessing the online 'sharing' phenomenon to develop, strengthen and encourage clinical research efforts. Since 2010, TGHN has garnered over 1 million visits from a broad spectrum of researchers and health care professionals. Over 100,000 members have registered to the network to take part in online community activities from 196 country locations. TGHN now comprises 37 membersites with world class scientific collaborators that cover specific research areas such as Zika virus and Dengue to broader subject areas such as new-born and maternal health, methodologies and data management. Cross-cutting tools such as Sitefinder aim to match research sites with researchers looking for suitable study locations and capacity to take forward clinical trials. E-Learning

within The Global Health Training Centre has become a trusted and well-regarded training hub offering free online training. Over 214,000 modules have been taken covering a wide range of subjects. TGHN runs free face-to-face workshops with 23 workshops across 15 countries have reached nearly 2,000 research staff to gain practical skills for running successful research projects. TGHN has demonstrated that the research community do want to work together and speed up the process of developing life-saving treatments and new ways to manage disease in the most vulnerable populations across the globe.

## 254

### DOMINANCE OF SIALIC ACID INDEPENDENT INVASION PATHWAYS IN *PLASMODIUM FALCIPARUM* ISOLATES FROM SENEGAMBIA

**Haddy Nyang**<sup>1</sup>, Aminata Jawara<sup>1</sup>, Fatoumatta Foon<sup>1</sup>, Sukai Ceesay<sup>1</sup>, Ambroise Ahouidi<sup>2</sup>, Alfred A. Ngwa<sup>1</sup>

<sup>1</sup>Medical Research Council, The Gambia Unit, Fajara, Gambia, <sup>2</sup>Dantec Hospital, Dakar, Senegal

Erythrocyte invasion by *Plasmodium falciparum* merozoites is a vital step in establishing parasitaemia during malaria. This process is mediated through several combinations of parasite ligands and erythrocyte receptors depicting the major sialic acid dependent and independent pathways. The influence of declining prevalence of malaria on the epidemiology of these pathways across endemic regions is not known. Here we determined invasion pathways for 60 isolates from uncomplicated malaria, collected from Gambia (Basse) and Senegal (Pikine), where there have been intensive interventions towards elimination. Invasion of each isolate was assayed against erythrocytes treated; Neuraminidase to cleave glycophorin A-C, trypsin removes glycophorin A and C, and chymotrypsin which removes glycophorin B and other surface proteins. The mean inhibition for neuraminidase, trypsin and chymotrypsin was 10%, 49% and 53% respectively across all isolates. There was a positive correlation between neuraminidase and low trypsin inhibition (Spearman  $P=0.0007$ ). Inhibition by low trypsin also positively correlated with chymotrypsin (Spearman  $P=0.0022$ ). Unlike previous reports, this study found higher levels of sialic acid independent invasion. This suggests switching of invasion pathways as malaria prevalence and immunity to non-sialic acid ligands declines.

## 255

### CIRCULATING MICRORNA MIR-1976 PROMOTES MALARIA PATHOGENESIS BY INTERACTING WITH CD40 TRANSCRIPT

**Keri Oxendine**<sup>1</sup>, Toluwalase Ashimolowo<sup>2</sup>, Duo Li<sup>3</sup>, Michael Wilson<sup>4</sup>, Andrew Adjei<sup>4</sup>, Felix Botchway<sup>4</sup>, Jonathan Stiles<sup>1</sup>, Adel Driss<sup>1</sup>

<sup>1</sup>Morehouse School of Medicine, Atlanta, GA, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>Indiana University, Bloomington, IN, United States, <sup>4</sup>University of Ghana, Accra, Ghana

There are multiple theories of how the malaria parasite evades the host immune system. One theory proposes that the parasite acquires host's antigens to make them unrecognizable by the host immune system prior to initiation of the erythrocytic stages. The parasites also modulate host immune cell populations by increase systemic cellular apoptosis. MicroRNAs are small non-coding RNAs that endogenously regulate the gene expression in a post transcriptional manner. MiRNAs have shown to be significantly altered during infections with microbes and are being utilized more in studies relating to biomarkers for diagnostic and drug targeting purposes. However, the role of microRNAs (miRNAs) in mediating malaria pathogenesis is not known. Deep sequencing of circulating miRNAs of five malaria infected patients and three individuals without malaria resulted in twenty-one differentially expressed miRNAs. By using five different gene predictions software (MirBD, DIANA, TargetScan, RNA22, MicroRNA), we identified possible targets of the microRNAs including an upregulated microRNA of interest (has-mir-1976). Using all five-prediction software, the CD40 gene was identified as a predicted target

astmh.org

for has-mir-1976. CD40 has been shown to enhance immunity via T cells activation and is needed for full development of liver dendritic cells during a *Plasmodium* infection. Inoue et al. showed that *Plasmodium berghei* can be eliminated in mice by stimulating CD40. Additionally, an anti-malarial plant extract (*Artemisia rupestris* L) increases signaling of CD40 which mediates the TLR4 pathway during dendritic cell development. Our data suggests that mir-1976 may interfere with CD40 function to promote severe malaria pathogenesis. Understanding the mechanisms mediating has-mir-1976 induction and its effects on CD40 expression will enable the development of novel treatments against severe malaria.

## 256

### IDENTIFICATION OF PFEMP1 PROTEINS ASSOCIATED WITH THE DEVELOPMENT OF PROTECTIVE IMMUNITY

**Brittany Pease**<sup>1</sup>, Patricia Gonzales-Hurtado<sup>1</sup>, Robert Morrison<sup>1</sup>, Alassane Dicko<sup>2</sup>, Patrick Duffy<sup>1</sup>, Michal Fried<sup>1</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>University of Sciences Techniques and Technologies of Bamako, Bamako, Mali

*Plasmodium falciparum* is the deadliest of the human malaria parasites. The virulence of *P. falciparum* is related to the ability of infected erythrocytes (IEs) to bind to the endothelium and sequester in vascular beds. The *P. falciparum* erythrocyte membrane protein 1 (PfEMP1) family of clonally variant proteins mediates adhesion of infected RBCs and is responsible for antigenic variation. Studies in malaria-exposed individuals identified naturally acquired protective antibodies to PfEMP1, blocking cytoadhesion in pregnant women, demonstrating the potential of a PfEMP1 based vaccine. PfEMP1 is encoded by the *var* multi-gene family with each parasite expressing a single gene while the remaining ~60 are silenced. PfEMP1 sequences are very diverse; however, they possess organized domain architectures, providing the parasites with a conserved PfEMP1 repertoire that determines the binding phenotype. PfEMP1 proteins are composed of 2-9 Duffy-binding-like (DBL) and cysteine-rich interdomain region (CIDR) domains that are subdivided into domain cassettes (DCs). Previous qPCR-based transcriptome studies have shown that DC8 and DC13 are upregulated in parasites from children with severe malaria. The purpose of this work is to use a global unbiased approach to identify PfEMP1 proteins in circulating parasites of young children using proteomics tools with the goal of identifying targets of immune protection. 289 PfEMP1 proteins identified in 34 clinical isolates were analyzed to determine the most commonly expressed. It is hypothesized that cross-reactivity will be observed between similar PfEMP1s; therefore, identified PfEMP1 proteins were subjected to phylogenetic clustering. 35 representatives were selected from the phylogenetic trees to best represent the entire population. These potentially cross-reactive population representatives will be investigated further through immunosurveillance assays to associate antibody levels to recombinant PfEMP1 domains with protection from disease.

## 257

### ELIMINATION OF MALARIA: A PARASITE RESERVOIR QUESTION

**Miles B. Markus**

University of the Witwatersrand, Johannesburg, South Africa

The hypnozoite theory of malarial relapse does not adequately explain the fact that genetically homologous relapse-like *Plasmodium vivax* recurrences are so commonly encountered. It is feasible, theoretically, that hypnozoites can be responsible for such recurrences, despite there being no *in vivo* parasitological proof hereof in humans. However, considering the ubiquity of genotypic homology in recurrent *P. vivax* malaria, the question arises as to whether there could be, in addition to a presumed hypnozoite origin, another non-circulating source(s) of homologous relapse-like *P. vivax* recurrences. Associated with this question, it should be noted that accumulation of blood stages of *P. vivax* in bone marrow and the spleen has been reported, although the frequency and extent of their occurrence

in these sites are currently unknown. Are such erythrocytic forms a part of the hidden parasite reservoir? If so, they may be responsible for renewed peripheral parasitemia as immunity wanes; or, alternatively, merely contribute to an increase in the number of homologous parasites in the bloodstream (where erythrocytic schizogony might also be taking place). Either way, parasitemic recurrence would then lead to formation of gametocytes, the possibility of ingestion thereof by mosquitoes, and potential ongoing transmission of malaria. A novel (late 2017) analysis of relevant aspects of the biology of recurrent *P. vivax* infection will be presented and research suggestions made. This subject is both topical and practically important in relation to malaria eradication.

## 258

### DEVELOPMENT OF SEE-THROUGH IMAGING METHODS FOR SEXUAL REPRODUCTION OF MALARIA PARASITES

**Toshiyuki Mori**, Makoto Hirai, Toshihiro Mita

*Juntendo University, Tokyo, Japan*

Similar to animals and plants, malaria parasites perform sexual reproduction based on fusion between male and female gametes. The stage for sexual reproduction is the midgut of mosquito vector, in which the male- and female gametocytes get mature and fuse with each other. The resulting zygote differentiates into a motile ookinete, and migrates outside the midgut to form an oocyst, in which numerous sporozoites are produced. Because only one pair of gamete fusion leads to production of tens of thousands sporozoites, the sexual reproduction of malaria parasites is one of the most formidable stage in their life cycle. As development of transmission blocking vaccine is recently highlighted, analytic methodologies of sexual reproduction of malaria parasites in the mosquito vector may be further required. However, the complicated midgut tissues and the pigment of red blood cells have prevented observation of parasite gamete behaviors in the mosquito body. To overcome such technical difficulties, we tried to develop methods to make the mosquito body transparent and produce gamete marker lines, in which mature male and female gametes are differently labeled with fluorescent proteins. Our methods should enable to observe not only the whole process of sexual reproduction from gamete maturation to fusion moment, but also sporozoite behaviors of malaria parasites in the mosquito stage.

## 259

### TARGETING THE HAP2 FUSION LOOP INHIBITS TRANSMISSION OF *PLASMODIUM BERGHEI* AND *P. FALCIPARUM*

**Fiona Angrisano**<sup>1</sup>, Katarzyna A. Sala<sup>1</sup>, Dari Y. Frederic<sup>2</sup>, Yanjie Liu<sup>3</sup>, Nick V. Grishin<sup>3</sup>, Jimin Pei<sup>3</sup>, William J. Snell<sup>3</sup>, Andrew M. Blagborough<sup>1</sup>

<sup>1</sup>Imperial College, London, United Kingdom, <sup>2</sup>Institut de Recherche en Sciences de la Santé, Bobo Dioulasso, Burkina Faso, <sup>3</sup>University of Texas Southwestern Medical Center, Dallas, TX, United States

Fertilization in *Plasmodium* is a complex process that occurs in the gut of the *Anopheles* mosquito upon uptake of blood meal. HAP2 has been postulated to mediate membrane adhesion in *Plasmodium* fertilization between male and female gametes. The presence of HAP2 in a number of Eukaryotic taxa suggests a common gamete fusion mechanism. Recently, *Chlamydomonas reinhardtii* HAP2 was revealed to be a class II fusion protein, additionally suggesting that HAP2 function is largely analogous to viral fusion. This opens novel avenues to block HAP2-mediated transmission of *Plasmodium* through the mosquito host. Here we target a region of HAP2 with homology to the hydrophobic cd loop of *C. reinhardtii* in *P. falciparum* and *P. berghei* using a combination of *in vivo* and *in vitro* assays to assess the potential of targeting the HAP2 fusion loop to inhibit transmission. Immunization with peptides to the cd loop in *P. berghei* reduces infection prevalence within the mosquito host by 58.9% and prevalence of infection by up to 38.44%. Targeting the cd loop in *P. berghei* with peptide antibodies reduces *in vitro* formation of ookinetes by

up to 89.9%. whilst targeting the *P. falciparum* cd loop with purified IgG in field isolated by DMFA reduces oocyst intensity by 75.5% and infection prevalence by 36.46%. These results emphasise conserved mechanisms of fusion in Apicomplexa, suggesting that HAP2 fertilization mirrors that of viral fusion, potentially highlighting a way to design for future anti-malarial transmission-blocking vaccines.

## 260

### A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE RISK OF TRANSFUSION TRANSMITTED MALARIA FROM BLOOD DONORS IN SUB-SAHARAN AFRICA

**Philippe J. Guerin**<sup>1</sup>, Selali Fiamanya<sup>1</sup>, Pierre Buffet<sup>2</sup>

<sup>1</sup>WorldWide Antimalarial Resistance Network, Oxford, United Kingdom,

<sup>2</sup>Université Paris Descartes, Paris, France

Transfusion transmitted malaria (TTM) is a major component of global transfusion transmitted infections, however estimates of its incidence are scarce. It is important as it may increase the morbidity and mortality of blood donation recipients, the majority of whom are young children and pregnant women who are often anaemic or suffering from other co-morbidities. It may also jeopardise global malaria elimination efforts by acting as a reservoir for subclinical parasite transmission. This systematic review aims to assess the current prevalence of *Plasmodium* parasite carriage in blood donors in high-endemic regions in sub-Saharan Africa and to provide estimates of spatial and temporal heterogeneity of TTM risk across Africa. Publication databases and clinical trial registries were searched for articles reporting prevalence studies of malaria parasitemia amongst blood donors in sub-Saharan Africa, written in English and French published between 2000 and 2016. Grey literature sources such as the World Health Organization (WHO) website and individual countries' ministry of health websites were searched for published reports, and reference lists of papers were also screened. Risk of Bias was assessed using the Joanna Briggs Institute Prevalence Critical Appraisal Tool. Fourteen studies were included in the qualitative synthesis and 13 in the meta-analysis (4,035 subjects). This included ten studies from Nigeria, one from the Democratic Republic of Congo, Benin, Cameroon and Senegal. Pooled prevalence of malaria parasitaemia was 34.1% (95%CI: 24.3% - 43.8%), ranging from 6.5% to 74.1%. Considering the location of included countries in this review, a prevalence of one third of blood donors carrying *Plasmodium* provides a robust estimate of the risk of TTM in high transmission areas. As transmission and immunity wane in Africa this prevalence will likely decrease but the severity of TTM will likely increase, thereby posing a potentially serious threat to recipients, and possibly interfering with elimination efforts.

## 261

### SEXUAL DIMORPHISM IN DEVELOPING GAMETOCYTES

**Henry C.H. Law**<sup>1</sup>, Krithika Rajaram<sup>2</sup>, Rhoel D. Dinglasan<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Malaria remains a devastating global health problem. *Plasmodium* parasites, the causative agent of malaria, has a complex life cycle, involving asexual and sexual replication in the human host and sporogony in the *Anopheles* vector. During asexual replication in host red blood cells, a small proportion of asexual parasites develops into gametocytes (sexual stages) of the parasite, the only transmissible stage to mosquitoes. It is known that environmental triggers such as anemia, antimalarial drug exposure, and mixed parasite genotype infections could affect the sexual conversion rates and sex ratios. However, a detailed description of the molecular mechanism controlling male/female differentiation during gametocytogenesis is lacking. As the gametocytes progress through the five stages of maturation, the morphology of male and female gametocytes can be differentiated under a microscope. However, bona fide protein biomarkers for developing male and female gametocytes that can help unravel sexual divergence remain missing. It was reported

that the disruption of PfPuf2 gene, a translational repressor increases the number of male gametocytes generated. In addition, the majority of the male-specific proteins are expressed early from stage II onwards. Therefore we hypothesized that gametocytes are predestined to be male but actively switch to female gametocyte maturation during the stage III-IV transition phase. To establish a list of putative early sex-specific gametocyte markers, we used Click-Chemistry to profile de novo protein synthesis over 5 days; spanning the gametocyte transition period from stage III-IV. We compared the protein list for each 24 period to our predicted male- and female-specific gametocyte proteome to identify proteins and pathways that are putatively involved in gender switching.

## 262

### ANTI-PHOSPHATIDYLSERINE IGM AND IGG ANTIBODIES ARE INCREASED IN FALCIPARUM AND VIVAX MALARIA AND CORRELATE WITH ANAEMIA

**Bridget E. Barber**<sup>1</sup>, Matthew J. Grigg<sup>1</sup>, Kim Piera<sup>1</sup>, Tim William<sup>2</sup>, Michelle Boyle<sup>1</sup>, Gabriella Miningo<sup>1</sup>, Ric N. Price<sup>1</sup>, Tsin W. Yeo<sup>3</sup>, Nicholas M. Anstey<sup>1</sup>

<sup>1</sup>Menzies School of Health Research, Darwin, Northern Territory, Australia, <sup>2</sup>Jesselton Medical Centre, Kota Kinabalu, Malaysia, <sup>3</sup>Nanyang Technological University, Singapore, Singapore

Malarial anaemia results primarily from the loss of uninfected erythrocytes, although its aetiology is incompletely understood. Phosphatidylserine (PS) is a membrane phospholipid normally located on the internal leaflet of the lipid bilayer, which in malaria becomes exposed on the surface of infected and uninfected erythrocytes. In a mouse model anti-PS antibodies have been shown to contribute to anaemia by binding to the surface of uninfected erythrocytes and mediating their phagocytosis. To investigate the role of anti-PS antibodies in malarial anaemia in humans, we measured anti-PS IgG and IgM antibodies in Malaysian adults hospitalised with falciparum and vivax malaria, and correlated with day 0 and nadir haemoglobin. Compared to controls, anti-PS IgM and IgG in patients with falciparum malaria were increased at baseline: 129 (80 - 205) U/ml vs. 27 (19 - 41) U/ml for IgM ( $p < 0.0001$ ), and 81 (65 - 116) U/ml vs 17 (14 - 21) U/ml for IgG ( $p < 0.0001$ ). The corresponding values for *P. vivax* were 117 (75 - 215) U/ml vs. 27 (19 - 41) U/ml ( $p < 0.0001$ ) and 65 (54 - 172) U/ml vs 17 (14 - 21) U/ml ( $p = 0.0001$ ). In falciparum malaria, anti-PS IgG correlated inversely with day 0 haemoglobin ( $r = -0.37$ ,  $p = 0.041$ ) and haemoglobin nadir ( $r = -0.41$ ,  $p = 0.025$ ). In vivax malaria, anti-PS IgM correlated inversely with baseline haemoglobin ( $r = -0.72$ ,  $p = 0.029$ ) and haemoglobin nadir ( $r = -0.81$ ,  $p = 0.008$ ). In vivax malaria, anti-PS IgM antibodies also correlated inversely with the percentage loss of haemoglobin, from baseline to nadir ( $r = 0.70$ ,  $p = 0.036$ ). No correlation was detected between anti-PS antibodies and parasitemia. In adults with vivax and falciparum malaria, anti-PS antibodies are increased and correlate inversely with haemoglobin. This may have implications for development of therapeutic strategies for malarial anaemia.

## 263

### ELEVATED CEREBROSPINAL FLUID TAU PROTEIN LEVELS ARE ASSOCIATED WITH LONG-TERM NEURODEVELOPMENTAL IMPAIRMENT IN UGANDAN CHILDREN WITH CEREBRAL MALARIA

**Dibyadyuti Datta**<sup>1</sup>, Robert O. Opoka<sup>2</sup>, Paul Bangirana<sup>3</sup>, Kathleen F. Ireland<sup>4</sup>, Chanday C. John<sup>1</sup>

<sup>1</sup>Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States, <sup>2</sup>Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda, <sup>3</sup>Department of Psychiatry,

Makerere University, Kampala, Uganda, <sup>4</sup>University of Minnesota School of Medicine, Minneapolis, MN, United States

Microtubule associated protein (MAP) tau is a known marker of brain parenchymal damage. Elevated levels of total tau protein in cerebrospinal fluid (CSF) has been linked with neurodegeneration and cognitive impairment in several forms of dementia and Alzheimer's disease. Studies conducted in Vietnamese adults and in Kenyan children with severe malaria (SM) have shown that levels of tau proteins were increased in patients with SM and associated with poor acute neurologic outcomes. To assess the association of total tau with mortality and long-term neurodevelopmental outcomes, we measured CSF tau levels in a prospective study of 145 Ugandan children 18 months-12 years of age with cerebral malaria (CM). CSF tau levels did not differ significantly between those who died ( $n = 8$ ) and those who survived ( $n = 137$ ,  $P = 0.27$ ). However, CSF tau levels were significantly higher in children with retinopathy positive CM ( $n = 100$ ) compared to retinopathy negative CM ( $n = 45$ ,  $P = 0.03$ ). CSF tau levels also associated with duration of coma ( $\beta = 0.2$ ,  $P < 0.0001$ ) but not with number of seizures, and CSF tau levels were higher at discharge and 6, 12 and 24 months after discharge in children with neurologic deficits than children without deficits (all  $P < 0.05$ ). Finally, higher CSF tau levels were associated with worse scores for overall cognition ( $\beta = -0.8$ ,  $P = 0.03$ ) and working memory ( $\beta = -0.9$ ,  $P = 0.05$ ) 12 months after discharge, but only in children over 5 years of age. Higher CSF tau levels also correlated with higher plasma levels of the endothelial function markers soluble P-selectin (Spearman's  $\rho = 0.22$ ,  $P = 0.007$ ) and angiotensin-2 (Spearman's  $\rho = 0.47$ ,  $P < 0.0001$ ). Thus, in children with CM, CSF tau levels are associated with endothelial damage and predict acute and long-term neurologic and cognitive impairment.

## 264

### RETICULOCYTE DISCONTINUOUS ENRICHMENT USING PERCOLL GRADIENT HAS A NEGATIVE IMPACT ON *IN VITRO* GROWTH OF *PLASMODIUM VIVAX*

D'Arbra Blankenship, Sebastien Dechavanne, Brenden Jenks, Peter A. Zimmerman, **Brian T. Grimberg**

Case Western Reserve University, Cleveland, OH, United States

*In vitro* cultures of *Plasmodium* parasites have provided important insights into malaria research. Unfortunately, culturing *P. vivax* (*Pv*) in adult human peripheral blood has presented significant challenges. Recent improvements have made short-term culturing possible with the addition of reticulocyte-enriched human blood. Reticulocyte enrichment is considered an essential process to increase invasion events by providing numerous preferable target cells for the parasites to invade. However, the process of isolating reticulocytes, based on density properties requires further optimization to justify efforts, and results in small quantities. In this study, we tested the invasion efficiency of cryopreserved *Pv* Vietnam/ Palo Alto strain in human adult peripheral blood that was reticulocyte enriched using 40%, 70%, and 80% Percoll gradients, with reticulocytes harvested from the 70% layer. Initial flow cytometry of *Pv* invasion events after 48 hours of *in vitro* culture was higher in reticulocyte enriched blood ( $41.0 \pm 10$ ) compared to unenriched blood ( $13.5 \pm 3.5$ ). However, continued parasite maturation with subsequent invasion cycles is more successful at 72 hours in unenriched blood ( $92 \pm 1$ ) when compared to enriched blood ( $51 \pm 1$ ). After repeated observation of improved parasite propagation in unenriched human blood and the obligate binding of *Pv* Duffy Binding Protein (PvDBP) to host cell Duffy antigens we further investigated, by flow cytometry, the impact of discontinuous gradient Percoll selection of reticulocytes on the red blood cells from three adult donors expressing three different Duffy blood groups  $FY^*A/*A$ ,  $FY^*A/*B$ , and  $FY^*B/*B$ . All three donors showed decreased binding of PvDBP to their RBCs after Percoll treatment  $FY^*A/*A$  (45.3 Unenriched, 36.2 Enriched),  $FY^*A/*B$  (67.1 Unenriched, 41.3 Enriched), and  $FY^*B/*B$  981.9 Unenriched, 62.9 Enriched). Our data illustrates that the use of Percoll to isolate reticulocytes

is potentially detrimental to the *in vitro* culturing of *Pv* in adult peripheral blood and helps to explain early observations made by Lanners (1992) that Percoll enriched blood could not support *Pv* growth.

## 265

### EX-VIVO RING-STAGE SURVIVAL ASSAYS (RSAs), PFKELCH13-PROPELLER MUTATIONS, AND PFMDR1 VARIANTS IN PLASMODIUM FALCIPARUM ISOLATES FROM MALARIA PATIENTS IN COLOMBIA

Lidia M. Montenegro<sup>1</sup>, Rick Fairhurst<sup>2</sup>, Aaron T. Neal<sup>2</sup>, Alberto Tobon<sup>1</sup>, Tatiana M. Lopera<sup>1</sup>, Briegel De las Salas<sup>1</sup>

<sup>1</sup>Universidad de Antioquia, Medellin, Colombia, <sup>2</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Delayed parasite clearance times observed in Southeast Asia provided the first evidence of *Plasmodium falciparum* resistance to artemisinins. The *ex vivo* ring-stage survival assay (RSA) was subsequently developed in the laboratory to better mimic parasite exposure to pharmacologically-relevant artemisinin concentrations achieved during patient treatment. *In vitro*, the RSA0-3h is able to discriminate resistant and sensitive parasites, showing survival rates above and below 1%, respectively. Mutations in the C-terminal propeller domain of the putative kelch protein PF3D7\_1343700 are associated with artemisinin resistance. Additionally, amplification and mutations in the *Pfmdr1* gene are associated with resistance to artemisinin partner drugs like mefloquine and lumefantrine. To clarify the unknown landscape of artemisinin resistance in Colombia, 71 uncomplicated malaria patients from 3 localities were enrolled in an observational study from June 2014 to July 2015. *Ex-vivo* RSAs were performed using parasite samples obtained from each patient, and all isolates were examined for *Pfkelch13*-propeller mutations, *Pfmdr1* copy number variations, and known resistance-associated *Pfmdr1* mutations at codons 86, 184, 1034, 1042, and 1246 using new amplification-sequencing protocols for both genes. *Ex-vivo* RSAs were successfully completed for 56% (40/71) of isolates, 9 of which showed greater than 1% survival. A cycle sequencing of dried blood spots revealed that all isolates were *Pfkelch13* wild-type. Sequencing also revealed that 75.8% of isolates possessed the *Pfmdr1* haplotype NFSDD, and 24.2% had the haplotype NFSDY. Two of 40 isolates showed *Pfmdr1* amplification by qPCR; there were no correlations between increased *ex vivo* RSA survival and *Pfmdr1* haplotype or copy number. The unexpected identification of Colombian parasite isolates with increased *ex vivo* RSA survival rates is of concern, particularly since none of the parasites possessed *Pfkelch13* mutations. Continued monitoring for the emergence of artemisinin resistance is necessary in Colombia and other countries using artemisinin-based therapies.

## 266

### PLASMODIUM FALCIPARUM FALCIPAIN 2A POLYMORPHISMS IN SOUTHEAST ASIA AND ITS CONTRIBUTION TO ARTEMISININ RESISTANCE

Faiza A. Siddiqui<sup>1</sup>, Mynthia Cabrera<sup>1</sup>, Meilian Wang<sup>1</sup>, Zenglie Wang<sup>1</sup>, Awtum Brashear<sup>1</sup>, Gang Dong<sup>2</sup>, Xiayong Liang<sup>1</sup>, Sony Shreshtha<sup>1</sup>, Liwang Cui<sup>1</sup>

<sup>1</sup>Pennsylvania State University, State College, PA, United States, <sup>2</sup>Max F. Perutz Laboratories, Medical University of Vienna, Vienna, Austria

Falcipain-2a (FP2a; PF3D7\_1115700) has been linked to artemisinin resistance recently due to its role in hemoglobin degradation. The inhibition of this protease resulted in decreased artemisinin activity. A mutation at codon 69 of the FP2 gene was detected in Tanzanian isolate exposed to a 5-year *in vitro* artemisinin selection previously by another research group. In order to investigate the association of FP2a with artemisinin resistance and characterize the diversity of the FP2a haplotypes in parasites from the China-Myanmar border, we sequenced the full-length FP2a gene in 141 *Plasmodium falciparum* isolates collected between 2007-

2011. We identified 34 point mutations and 26 distinct haplotypes in 97.1% (137/141) parasite isolates, of which five point mutations were not reported earlier. Nine isolates also showed a deletion at residue 115-116. However, when the samples were stratified by the year of collection, no major change was observed in the frequencies of the different mutations/haplotypes. T343P, D345G, A353T, V393I, A400P, and Q414E mutations lie in the protease domain, while M245I, E248D, E249A, K255R, and N257E mutations are present upstream of the protease domain. Residues A353, A400 and Q414 lie in the binding interface of FP2a and its inhibitor (falstatin) and mutation in these residues may hinder the interaction of FP2a with its inhibitor. It would be of interest to characterize the contribution of these FP2a SNPs to drug resistance, and ART resistance in particular. There has been no previously reported significant correlation between the Falcipain 2a SNPs and artemisinin resistance. The preponderance of Falcipain 2a mutations prompted us to analyze our K13 sequences and RSA Survival rates in the context of Falcipain 2a SNPs, haplotypes, as well as growth and fitness phenotypes. Our preliminary analysis hint of Falcipain 2a mutations/haplotypes those are present in isolates that show artemisinin resistance *in vitro*.

## 267

### HIGH RESOLUTION MELT ANALYSIS REVEALS A POTENTIAL SHIFT IN THE MOLECULAR EPIDEMIOLOGY OF ANTIMALARIAL DRUG RESISTANCE IN NIGERIA

Kolapo M. Oyebola<sup>1</sup>, Emmanuel Idowu<sup>2</sup>, Adeola Olukosi<sup>3</sup>, Samson Awolola<sup>3</sup>, Gordon Awandare<sup>4</sup>, Alfred Amambua-Ngwa<sup>1</sup>

<sup>1</sup>Medical Research Council Unit The Gambia, Fajara, Gambia, <sup>2</sup>Parasitology and Bioinformatics, Faculty of Science, University of Lagos, Nigeria, Lagos, Nigeria, <sup>3</sup>Nigerian Institute of Medical Research, Lagos, Nigeria, <sup>4</sup>WACCBI, University of Ghana, Accra, Ghana

Artemisinin resistance and decline in the efficacy of first line artemisinin-based combination (ACT) drugs for malaria treatment in some endemic regions threatens the success towards global elimination of malaria. Though resistance has not been confirmed in Africa, molecular survey for drug resistance alleles is vital to detect the emergence, and spread of resistant strains. Here we describe the prevalence of antimalarial drug resistance markers during an ACT efficacy trial in Nigeria. Sixty-five patients were screened pre- and post-treatment with ACT on days 0, 1, 3, 7, 14, 21 and 28. Parasite clearance rates during treatment were determined by microscopy and the highly sensitive VarATS diagnostic PCR which targets multi-copy subtelomeric DNA. 18.5% of participants presented with parasitaemia 3 days post-treatment. 17% of patients presented with day 28 parasitaemia. High resolution melt analysis was carried out to amplify codons Pfcrt-76, Pfmdr1-86, Pfmdr1-184, and PfK-13 C580Y in isolates. 18.5% participants presented with parasitaemia 3 days post-treatment. 17% of patients presented with day 28 parasitaemia. The drug resistance Pfcrt-76T allele was present in 37.2% of isolates in the population. Pfmdr1-86 mutant allele was found in 12.5% of isolates. No mutant allele of the K-13 C580Y was recorded. These results indicate that withdrawal of chloroquine and use of ACTs are selecting for wildtype variants at these chloroquine resistance *loci* in Nigeria. However, persistence of parasitaemia in more than 10% of cases after treatment warrants further investigation of a larger population for any signs of reduced ACT efficacy in Nigeria.

## 268

### THE CONTRIBUTORY ROLE OF SOCIOECONOMIC FACTORS TO THE DEVELOPMENT AND SPREAD OF ANTIMALARIAL DRUG RESISTANCE

Philip E. Anyanwu, John Fulton, Timothy Paget, Etta Evans  
University of Sunderland, Sunderland, United Kingdom

Malaria remains a global health issue with the burden unevenly distributed to the disadvantage of the developing countries of the world. As a socioeconomic issue, the high level of poverty in Nigeria is an important

factor that reinforces the persistent malaria burden in Nigeria. The development of resistance to artemisinin-based combination therapies threatens the sustainability of the present success in malaria control. Antimalarial drug use practices/behaviours remain critical drivers of drug resistance as they can affect some of the other factors. This study adopted a social epidemiological stance in investigating the role of socioeconomic factors in determining drug use behaviours promoting antimalarial drug resistance. Methods: A cross-sectional survey design using questionnaires developed from the findings of a previous qualitative study on the same population. Survey data was analysed for relationships between variables using statistical packages. Findings: Significant differences were found between participants of different levels of socioeconomic measures on antimalarial drug use practices like adherence to malaria treatment guideline (educational level:  $p < 0.001$ , partial eta squared = 0.33; HH income:  $p = 0.025$ , partial eta squared = 0.022; type of settlement:  $p < 0.001$ , partial eta squared = 0.038); getting the complete course of antimalarial drugs (HH income:  $p < 0.001$ , OR = 1.46, 95% CI = 1.20-1.76; Urban settlement  $p < 0.002$ , OR: 0.32, 95% CI: 0.16-0.66); and use of mixed drugs (a form of polypharmacy) for malaria treatment (HH income  $p < 0.001$ , OR: 0.72, 95% CI: 0.61-0.85). Also, the adoption of some of these treatment behaviours was significantly associated with the outcome of suspected treatment failure. Conclusions: The distribution of drug use behaviours that promote the development and spread of antimalarial drug resistance is patterned in line with the stratification of socioeconomic position in the population. Most of the resistance-promoting behaviours reported in this study were more of coping strategies by those at the lower levels of socioeconomic measures.

## 269

### ASSESSMENT OF PFMDR1 AND PF CRT MUTATIONS AFTER SIX YEARS OF IMPLEMENTATION OF ARTEMISININ BASED COMBINATION IN DAKAR, SENEGAL

Annie W. Abiola

Abiola, Dakar, Senegal

ACT have been shown to be effective for uncomplicated *P. falciparum* malaria in Africa including in Senegal. In South East Asia, Pfm<sub>dr1</sub> Single Nucleotide Polymorphism are frequent and tentatively associated with reduced susceptibility to ACT partner drugs mefloquine and lumefantrine. In Africa where amodiaquine is one the most partner drugs of ACT, studies on molecular marker of AQ resistance are urgent. The objective of this study is to monitor molecular markers of AQ the partner drug of ACT in Senegal. Methods: Blood samples were collected from patients with uncomplicated malaria in Deggo health post in 2010 N=124 and 2012 N=160. Pfm<sub>dr1</sub> and Pfcrt SNPs were determined by PCR-RFLP in *Plasmodium falciparum* positive samples. Results: A total of 283 samples positives were analysed for various Pfm<sub>dr1</sub> and Pfcrt SNPs. Pfcrt-76T mutant type haplotype was present at 12.90% and 15.90% in 2010 and in 2012 respectively. Prevalence of 16.94% and 15.62% were found for Pfm<sub>dr1</sub>-86Y in 2010 and in 2012 respectively. Low prevalence of Pfm<sub>dr1</sub>-184F was noted in 2010 7.26% and in 2012 6.88%. Conclusions: Overall a low prevalence of Pfcrt and Pfm<sub>dr1</sub> SNPs associated with CQ and AQ resistance were noted in our study area. Similar results were found in West Africa. Results suggested that partner drug of ACT still be effective in Senegal, however a regular monitor of antimalarial drug is essential in the context of while use of ACT.

## 270

### SUBPATENT PLASMODIUM FALCIPARUM INFECTIONS AFTER TREATMENT OF UNCOMPLICATED FALCIPARUM MALARIA WITH DIHYDROARTEMISININ-PIPERAQUINE AND ARTEMETHER-LUMEFANTRINE IN WESTERN INDONESIA

Inke N. Lubis<sup>1</sup>, Hendri Wijaya<sup>2</sup>, Munar Lubis<sup>2</sup>, Chairuddin P. Lubis<sup>2</sup>, Khalid B. Beshir<sup>1</sup>, Colin J. Sutherland<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>University of North Sumatera, Medan, Indonesia

Recent evidence of treatment failure following dihydroartemisinin-piperazine (DHA-PQ) treatment for *Plasmodium falciparum* infection in Cambodia and Myanmar is a cause for concern in neighbouring countries. Western Indonesia previously used artesunate-amodiaquine (ASAQ) as the first-line ACT from 2004 before frequent drug failures led to a policy change in 2012 to DHA-PQ. We conducted a randomised controlled trial of DHA-PQ vs artemether-lumefantrine (AL) for the treatment of uncomplicated falciparum malaria. Between January and June 2015, we enrolled 302 adults and children in Batubara, Langkat and South Nias regencies in North Sumatera, Indonesia. Patients were given a standard 3-dose of DHA-PQ or 6-dose of AL, and followed for 6 weeks. Drug resistance markers for *P. falciparum* were determined. Primary outcome was cumulative risk for parasitological failure at day-42 determined by microscopy following a standard WHO protocol. Subpatent parasitaemia during follow-up detected by PCR targeting the *pfmdr1* gene was a secondary outcome. Of the 302 enrolled participants, 12.9% (39/302) had mixed infections with *Plasmodium vivax*. Most patients harboured genotypes Pfcrt-SVMNT (88.8%, 63/71), Pfm<sub>dr1</sub>-86Y/184Y (70.1%, 68/97) and Pfk13-wild type alleles (88%, 66/75) prior to treatment. The known-mutants of Pfk13 T474A and M476I were identified in 2 and 1 patients, with the remainder being previously undescribed *pfk13* mutations. Per-protocol analysis showed day-42 uncorrected treatment failures at 6.0% (8/133) and 2.21% (3/136) in DHP and AL groups ( $P > 0.05$ ). By PCR, the parasitological failures increased to 27.1% (36/133) and 27.8% (37/133) ( $P > 0.05$ ), with a reduction in the Pfm<sub>dr1</sub>-YY haplotype prevalence to 0% and 13.8% ( $P < 0.05$ ). Subpatent recurrence was most common among patients from Langkat regency (OR 3.3, 95% CI 1.6-6.7;  $P < 0.001$ ). The predominant SVMNT and Pfm<sub>dr1</sub>-YY alleles in this population may have been selected by ASAQ in the past. DHP and AL appear to remain effective for *P. falciparum* infection in western Indonesia, however submicroscopic recurrence may contribute to further transmission from treated individuals.

## 271

### MOLECULAR EPIDEMIOLOGY AND GENETIC DIVERSITY'S ANALYSIS OF THE CHLOROQUINE RESISTANT GENE PF CRT IN CAMEROONIAN FIELD ISOLATES REVEAL NOVEL INSIGHTS WHICH COULD IMPACT THE MALARIA CONTROL STRATEGIES IN CAMEROON

Huguette Gaelle Ngassa Mbenda<sup>1</sup>, Aparup Das<sup>2</sup>

<sup>1</sup>University of Witwatersrand, Johannesburg, South Africa, <sup>2</sup>Indian Council of Medical Research-Centre for Research in Medical Entomology (CRME), Madurai, Tamil Nadu, India

Understanding the epidemiology and population genetics of drug-resistant genes can help in devising novel control strategies. The high spread of the resistant strains of the malaria parasite *Plasmodium falciparum* pose a greater challenge than before to the control programs across the world. Specific mutations in the *P. falciparum* chloroquine resistant transporter gene "Pfcrt" have been associated with resistance to not only chloroquine, but also to amodiaquine, one of the artemisinin partners used in Cameroon for the treatment of uncomplicated malaria. We here present not only data of the first attempt to assess genetic variation at the Single Nucleotide Polymorphisms (SNPs) level in the Pfcrt gene in five distinct geographical settings of the Southern-Cameroon (the

most malaria endemic part), but also the distribution of different Pfcrt genotypes in these areas. Mutations in the Pfcrt gene and chloroquine-resistant Pfcrt haplotypes hitherto unreported in Cameroon were detected, with the surprise appearance of the S(agt)VMNT haplotype. Variable genetic diversity was observed across the populations. High linkage disequilibrium was found between few SNPs suggesting a synergistic work for conferring/maintaining a higher level of resistance. Inference of evolutionary pattern of this gene in Cameroon based on the genetic diversity data depicts a signature of Darwinian positive natural selection on these *loci*. Observation of novel mutations might traduce new variants in chloroquine/or amodiaquine resistance (proposal awaiting an experimental verification) and signal of positive selection can be the result of drug pressure exerted by misuse of chloroquine (though officially banned from the country) and/or amodiaquine. Our findings thus, provide a baseline understanding of the evolution of a malaria drug resistant gene in Cameroon and suggest a successful establishment of chloroquine-resistant strains which requires urgent attention of the malaria control program in Cameroon.

## 272

### SUSTAINED HIGH CURE RATE OF ARTEMETHER LUMEFANTRINE IN TANZANIA

Billy Ngasala<sup>1</sup>, Richard Mwaiswelo<sup>1</sup>, and Andreas Mårtensson<sup>2</sup>

<sup>1</sup>Department of Parasitology and Medical Entomology, Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania,

<sup>2</sup>Department of Women's and Children's Health, International Maternal and Child Health (IMCH), Uppsala University, Sweden

We assessed the temporal trend of artemether-lumefantrine (AL) cure rate after 8 years of its wide-scale use for treatment of uncomplicated *Plasmodium falciparum* malaria from 2006 to 2014 in Bagamoyo district, Tanzania. A trend analysis was performed for 4 studies conducted in 2006, 2007-8, 2012-13 and 2014. Patients with acute uncomplicated *P. falciparum* malaria were enrolled, treated with a standard AL regimen and followed-up for 3 (2006), 28 (2014), 42 (2012-13) or 56 (2007-8) days for clinical and laboratory evaluation. The primary outcome was day 28 polymerase chain reaction (PCR)-adjusted cure rate across years from 2007 to 2014. Parasite clearance was slower for the 2006 and 2007-8 cohorts with less than 50% of patients cleared of parasitemia on day 1, but was rapid for the 2012-13 and 2014 cohorts. The day 28 PCR-adjusted cure rate was 168/170 (98.8%) (95% confidence interval [CI], 97.2-100), 122/127 (96.1%) (95% CI, 92.6-99.5) and 206/207 (99.5%) (95% CI, 98.6-100) in 2007-8, 2012-13 and 2014, respectively. There was no significant change in the trend of cure rate between 2007 and 2014 ( $\chi^2$ -trend test=0.06,  $p=0.90$ ). Pre-treatment *Pfmdr1* N86 prevalence increased significantly across years from 13/48 (27.1%) in 2006 to 183/213 (85.9%) in 2014 ( $p<0.001$ ), and *Pfcr* K76 prevalence increased significantly from 24/47 (51.1%) in 2006 to 198/205 (96.6%) in 2014 ( $p<0.001$ ). The AL cure rate remained high after 8 years of its wide-scale use in Bagamoyo district for the treatment of uncomplicated *P. falciparum* malaria despite an increase in the prevalence of pre-treatment *Pfmdr1* N86 and *Pfcr* K76 between 2006 and 2014.

## 273

### FORMULATION AND EVALUATION OF ETHOSOMES CONTAINING ARTESUNATE

Chinazom P. Agbo, Ejike N. Offor, Harrison U. Nwabueze, Anthony A. Attama, Kenneth C. Ofokansi

University of Nigeria, Nsukka, Nsukka, Nigeria

Ethosomes are nano-sized drug delivery systems that can permeate biological barriers. Nasal delivery is becoming a promising technique considered as an alternative route to achieve non-invasive delivery of drugs directly and rapidly to the brain (by-passing the blood-brain-barrier) and the systemic circulation. Artesunate administered parenterally and orally is used for treating cerebral and server malaria and uncomplicated

malaria respectively. Parenteral drug administration is difficult to achieve in some rural areas in Africa where access to healthcare professionals may be challenging. Moreso, the oral route may not be convenient for some groups of patients. The aim of this research work was to formulate and investigate the intranasal delivery of artesunate-loaded ethosomes as an alternative, non-invasive route of administration for the treatment of cerebral, server and uncomplicated malaria. Ethosomes containing artesunate were formulated using 30% and 50% ethanol, Phospholipon 90H® (2%W/V) and Tween 80 (5.2%). pH stability test, encapsulation efficiency, *in vitro* release and *in vivo* studies were carried out on all batches of ethosomes. The results obtained from *in vitro* release analysis were fitted into mathematical models. All batches of artesunate-loaded ethosomes showed high encapsulation efficiencies (77.46-84.63%). However, the pH stability study revealed reduction in pH after two months. *In vitro* release analysis of formulations showed sustained release of drugs with an initial burst release after 30 mins. All batches of ethosomes followed zero order drug release. *In vivo* evaluation of artesunate in ethosomes and a commercial sample administered intramuscularly showed a significant decrease in parasitaemia ( $p<0.05$ ). However, ethosomes and commercial formulations of artesunate could not reduce parasitaemia level when administered through the nasal route. Artesunate-loaded ethosomes were successfully formulated and achieved sustained release of drugs with significant clearance of parasitaemia when administered intramuscularly but not intranasally.

## 274

### SURFACE CHARACTERIZATION OF HEMOZOIN: IMPLICATIONS IN UNDERSTANDING MALARIA PATHOGENESIS IN THE DEVELOPMENT OF NOVEL ANTI-MALARIAL DRUGS

Elizabeth D. Guerra<sup>1</sup>, Mifong Tam<sup>2</sup>, Mary Stevenson<sup>2</sup>, David S. Bohle<sup>3</sup>, Marta Cerruti<sup>1</sup>

<sup>1</sup>Department of Materials Engineering, McGill University, Montreal, QC, Canada, <sup>2</sup>Department of Microbiology and Immunology, McGill University, Montreal, QC, Canada, <sup>3</sup>Department of Chemistry, McGill University, Montreal, QC, Canada

During intra-erythrocytic multiplication, *Plasmodium* parasites convert heme into the inert crystal, hemozoin (Hz), to detoxify hemoglobin. Because Hz is associated with the pathogenesis of malaria, including severe malarial anemia, and affects the function of phagocytic cells that play an important role in immunity to malaria, Hz remains an attractive target for drug development. An important strategy is to develop novel anti-malarials that bind to the surface of Hz and inhibit further accumulation of this crystal and, thereby, reduce parasite multiplication within the host red blood cells. Previous studies identified several biochemical properties of Hz as well as its synthetic analog,  $\beta$ -hematin, but little is known about the surface properties of either. Such information is crucial to understand the biochemical nature of Hz more precisely and identify target sites for drug development. Here, we used X-ray photoelectron spectroscopy (XPS) combined with matrix-assisted laser desorption/ionization time of flight (MALDI-ToF) to study the surface of Hz obtained from *P. falciparum* and *P. chabaudi* AS. These analyses revealed for the first time the presence of inorganic species on the Hz surface. Based on our findings, we hypothesized that naturally-occurring molecules, such as riboflavin or epigallocatechin gallate, may exert anti-plasmodial activity by interacting with the surface of Hz. To address this, we used a screening assay to assess the potential of these compounds as inhibitors of  $\beta$ -hematin growth and analyzed the resulting crystals using MALDI-ToF and Fourier Transform-Infrared (FT-IR) spectroscopy. Our preliminary studies show that both riboflavin and epigallocatechin gallate dramatically modified the morphology of  $\beta$ -hematin. Together, these data will help to understand how immunogenic molecules may bind to Hz as well as provide new insight on Hz biomineralization. Importantly, our findings support the usefulness of this approach to develop new anti-malarial drugs.

## 275

## CHANGING ANTIMALARIAL DRUG EFFICACIES IN UGANDA

Stephanie A. Rasmussen<sup>1</sup>, Frida Ceja<sup>1</sup>, Melissa D. Conrad<sup>2</sup>, Patrick Tumwebaze<sup>3</sup>, Oswald Byaruhanga<sup>3</sup>, Thomas Katairo<sup>3</sup>, Samuel L. Nsoyba<sup>3</sup>, Philip J. Rosenthal<sup>2</sup>, Roland A. Cooper<sup>1</sup>

<sup>1</sup>Dominican University of California, San Rafael, CA, United States,

<sup>2</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>3</sup>Infectious Diseases Research Collaboration, Kampala, Uganda

Dihydroartemisinin-piperazine (DHA/PQ) has demonstrated excellent efficacy for the treatment and prevention of malaria in Uganda. However, resistance to both components of this regimen has emerged in SE Asia. The antimalarial efficacy of artemether-lumefantrine (AM/LM), the first-line regimen to treat malaria in Uganda, has also been excellent, but continued AM/LM pressure may select for parasites with decreased sensitivity to LM. We characterized the *ex vivo* drug sensitivity and molecular features of 58 *P. falciparum* isolates collected in the Tororo district of Uganda from May-July, 2016 and compared results with those for 442 isolates collected in 2010-13. Drug sensitivity was assessed by *ex vivo* 72 h growth inhibition (IC50) assays; molecular results were assessed by standard methods. The sensitivities of the aminoquinolines chloroquine, amodiaquine, and PQ all improved significantly from 2010-13 to 2016 (geometric mean IC50s 248, 76.9, and 19.1 nM in 2010-13 and 36.1, 15.6, and 7.3 nM in 2016, respectively), sensitivity to LM decreased marginally (IC50 3.0 nM in 2010-13 and 4.3 nM in 2016), and sensitivity to DHA was unchanged (IC50 1.4 nM in 2010-13 and 2016). Molecular analysis showed decreased prevalence over time of the transporter mutations *pfcr*t 76T, *pfmdr*1 86Y, and *pfmdr*1 1246Y, consistent with the observed sensitivity changes. Sequencing of the *k13* propeller-encoding domain showed 2 of 58 samples from 2016 with an A578S mutation, which has been previously reported in Africa. All samples from 2016 had one copy of *pfmdr*1. Increased *plasmepsin-2* copy number (> 1.6 copies by qPCR) was seen in 7 of 58 samples from 2010-13 and 7 of 58 samples from 2016, but was not associated with increased PQ IC50. The E415G mutation in a putative *exonuclease* gene, linked with PQ resistance in SE Asia, was not present in any samples from 2010-13 or 2016. In summary, after heavy use of AM/LM, parasites demonstrated improved sensitivity to aminoquinolines and decreased sensitivity to LM over time. These results may portend decreasing antimalarial efficacy of AM/LM. Continued studies of the relative antimalarial efficacies of ACTs are needed.

## 276

FITNESS LOSS UNDER AMINO ACID STARVATION IN ARTEMISININ-RESISTANT *PLASMODIUM FALCIPARUM* ISOLATES FROM CAMBODIA

Thanat Chookajorn<sup>1</sup>, Duangkamon Buditvorapoom<sup>1</sup>, Theerarat Kochakarn<sup>1</sup>, Namfon Kotanan<sup>1</sup>, Krittikorn Kumpornsin<sup>1</sup>, Charin Modchang<sup>1</sup>, Duangkamon Loesbanluechai<sup>1</sup>, Thanyaluk Krasae<sup>1</sup>, Kesinee Chotivanich<sup>1</sup>, Liwang Cui<sup>2</sup>, Nicholas J. White<sup>1</sup>, Olivo Miotto<sup>3</sup>

<sup>1</sup>Mahidol University, Bangkok, Thailand, <sup>2</sup>Pennsylvania State University, State College, PA, United States, <sup>3</sup>Oxford University, Oxford, United Kingdom

Artemisinin is the most effective drug for *Plasmodium falciparum* malaria treatment currently in clinical use without any parallel in its fast parasite clearance. Emerging artemisinin-resistant parasites poses a great global health risk. At present, the level of artemisinin resistance is still relatively low with evidence pointing towards a trade-off between artemisinin resistance and fitness loss. Here we show that artemisinin-resistant isolates from Cambodia manifested fitness loss, showing fewer progenies during the intra-erythrocytic developmental cycle. The loss in fitness was exacerbated under the condition of low exogenous amino acid supply. The resistant parasites failed to undergo maturation, whereas their drug-sensitive counterparts were able to complete the erythrocytic cycle under amino acid deprivation condition. The artemisinin-resistant phenotype

was not stable, and loss of the phenotype was associated with change in the expression of a putative target of artemisinin, Exp1, a membrane glutathione transferase. Analysis of SNPs in haemoglobin processing genes revealed association with shift in clearance time, suggesting relevancy of changes in haemoglobin catabolism and artemisinin resistance. Analysis of SNPs associated with fast clearance time revealed Plasmeprin III to be linked to artemisinin sensitivity. These findings on fitness and protein homeostasis could provide clues on how to contain emerging artemisinin-resistant parasites.

## 277

HIGH FREQUENCY OF MULTI-CLONALITY INFECTION AND DRUG-RESISTANT ALLELES OF *PLASMODIUM FALCIPARUM* ISOLATES FROM GABON FOUR YEARS AFTER THE IMPLEMENTATION OF ACT

Jacques Mari Ndong Ngomo

Faculty of Medicine, Department of Parasitology, Owendo, Gabon

The main objective of this investigation was to compare the assessment of the frequencies of *Pfcr*t-76T, *Pfmdr*1-86Y, *Pfdhfr* and *Pfdhps* before (2005) and after the implementation of Artemisinin based Combination Therapy (ACT) (2008) and multi-clonal infections based on analysis of merozoite surface protein 1 and 2 genes (*msp*1 and *msp*2) during rebound malaria of country in 2011. The *Pfcr*t-76T, *Pfcr*t-86Y alleles and polymorphic codons 108, 59 and 51 of *Pfdhfr* and 437, 580 and 540 of *Pfdhps* genes were analyzed by PCR-RFLP. The *msp*1 and *msp*2 genes were analyzed using nested PCR-method. A total, 107 *Plasmodium falciparum* isolates of 2005 (n=29) and 2008 (n=78) at the regional hospital were analyzed. The frequencies of *Pfcr*t-76T mutant allele in 2005 (82.5%) and 2008 (70.0%) were comparable (p=0.3). The prevalence of *Pfmdr*1-86Y mutant allele was comparable between 2005 (82.8%) and 2008 (70.5%) (p=0.1). The proportion of the triple *Pfdhfr* was increased: 72.4% in 2005 vs 91.9% in 2008 (P= 0.03); as with quadruple mutation including A437G: 34.4 (35/55) vs 64.8 (p= 0.01). The Multiple Infections (MI) was found in 61.7% (29/46) of isolates from Oyem. For *Pfmsp*2 gene, MI were more frequent at Oyem (55.3%; 26/47). ≥5 genotypes were found with analysis of each gene. Using *Pfmsp*1 gene, complexity of infection (COI) was Oyem (1.85±0.62). The COI was at 2.1±0.48, Oyem with *Pfmsp*2 gene analyzed. In conclusion, an increase of the frequency of *P. falciparum* wild type allele *Pfcr*t-76T, *Pfmdr*1-86Y and quadruple mutation (triple mutation *Pfdhfr*+*Pfdhps*-437G) were observed within a short period after chloroquine withdrawal and higher of MI should increased the morbidity in Gabon.

## 278

SURVEILLANCE *IN VIVO* OF THE EFFICACY OF ARTESUNATE-AMODIAQUINE FOR UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN MADAGASCAR

Tovonahary Rakotomanga, F. Ralinoro, T. Rakotomanjaka, S. Rabearimanana, Y. Ralaiseheno, M. Marolahy, O. Raobela, A. Ratsimbasa

National Malaria Control Program Madagascar, Antananarivo, Madagascar

The malaria situation has been worsening in Madagascar. In 2005, the Ministry of Public Health adopted a new antimalarial treatment policy, with Artesunate Amodiaquine (ASAQ) and Artemether-Lumefantrine (AL) as the first and second line antimalarial drugs, respectively. As part of routine surveillance on the therapeutic efficacy of ACT in Madagascar, the efficacy of ASAQ was studied. The villages of Anjoma Ramartina situated in highland fringe with seasonal transmission were selected for the study. In the site, the study was a one arm prospective evaluation of the clinical parasitological and hematological responses to directly observed therapy for uncomplicated malaria with ASAQ among all patients recruited. The study was powered to estimate site-specific efficacy for ASAQ. Blood was collected for malaria microscopy and molecular testing on days 0-3,

7, 14, 21, and 28. Recrudescence and reinfection were differentiated using polymerase chain reaction (PCR) genotyping of merozoite surface protein and Glurp. The primary outcome was the PCR-corrected day 28 Kaplan-Meier cumulative success rate. A total of 60 patients with uncomplicated malaria were recruited. Per protocol analyses on day 28 showed an overall PCR uncorrected cure rate of 100% for ASAQ (95% CI 93.3 - 100), Kaplan-Meier survival analysis showed similar outcomes. Prevalence of fever decreased by 90% after the first day of treatment with ASAQ in the site. By microscopy, no patient studied was parasitaemic on day 3. With PCR, four patients were detected to be infected on day 28. The polymorphism (msp1, msp2 and glurp) study outcomes showed that these infections were new infections and not recrudescences due to treatment failure. In conclusion, as evidenced by the day 28 PCR-corrected cumulative success rates observed in the study site, ASAQ remains an efficacious first-line treatment for uncomplicated malaria in Madagascar. Evidence of rapid reinfection suggests that there is a continued need to scale-up effective malaria prevention interventions and surveillance to reduce transmission.

## 279

### THE WWARN VIVAX SURVEYOR: OPEN ACCESS ONLINE MAPPING DATABASE FOR CLINICAL TRIALS OF *PLASMODIUM VIVAX*

R. J. Commons<sup>1</sup>, K. Thriemer<sup>1</sup>, G. Humphreys<sup>2</sup>, I. Suay<sup>2</sup>, C. S. Sibley<sup>2</sup>, P. J. Guerin<sup>2</sup>, R. N. Price<sup>1</sup>

<sup>1</sup>Menzies School of Health Research, Darwin, Australia, <sup>2</sup>WorldWide Antimalarial Resistance Network, Oxford, United Kingdom

Recurrent infection with *Plasmodium vivax* is associated with significant morbidity and mortality. Although radical cure can reduce recurrent infection, it is confounded by antimalarial resistance and the lack of safe and effective hypnozoitocidal treatment. The WWARN Vivax Surveyor documents the available literature of published clinical trials of *Plasmodium vivax*, providing an up-to-date, online, open access tool to view and download available information. A systematic review was conducted to identify prospective *P. vivax* therapeutic clinical trials with at least 28 days follow-up published between January 1960 and October 2016. Treatment arms and evidence of chloroquine resistance based, on the risk of recurrent *P. vivax* by day 28 and whole blood chloroquine concentrations, were mapped to trial sites. Since 1960, a total of 1,152 antimalarial clinical trials with a minimum 28 days follow-up have been published, of which 230 (20.0%) enrolled patients with *P. vivax* and were included. Trials were conducted in 38 countries: 168 (73.0%) in the Asia-Pacific, 13 (5.7%) in Africa and 43 (18.7%) in the Americas. The proportion of antimalarial trials assessing *P. vivax* rose from 10.7% (12/112) in 1991-1995, to 24.9% (56/225) in 2011-2015. Overall, 188 (81.7%) *P. vivax* trials included a chloroquine treatment arm, either alone or in combination with primaquine, and 107 (46.5%) trials included a chloroquine treatment arm with early primaquine to assess radical cure. There has been a recent increase in treatment arms with artemisinin derivatives. Of the 131 sites in which chloroquine resistance could be quantified resistance was present in 59 (45.0%) sites in 15 endemic countries. Over the last 20 years there has been a substantial increase in clinical research on the treatment of *P. vivax*, which has generated a greater awareness of the global extent of chloroquine resistance. The review also highlights the lack of safe and effective hypnozoitocidal regimens and information gaps in some regions. The open access, interactive WWARN Vivax Surveyor provides up to date information of areas where drug resistant *P. vivax* is emerging.

### THE EFFECT OF AGE, WEIGHT AND PHARMACOGENETICS ON THE PHARMACOKINETICS OF PRIMAQUINE IN CHILDREN - IMPLICATIONS FOR DOSING AND THE RELATIONSHIP WITH DRUG-INDUCED HAEMOLYSIS

Rob ter Heine<sup>1</sup>, Bronner Gonçalves<sup>2</sup>, Helmi Pett<sup>1</sup>, Alfred Tiono<sup>3</sup>, Darryl Murry<sup>4</sup>, Sodiomon Sirima<sup>3</sup>, Mikko Niemi<sup>5</sup>, Teun Bousema<sup>1</sup>, Chris Drakeley<sup>2</sup>

<sup>1</sup>Radboudumc, Nijmegen, Netherlands, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>4</sup>University of Nebraska Medical Center, Omaha, NE, United States, <sup>5</sup>University of Helsinki and Helsinki University Hospital, Helsinki, Finland

Low dose primaquine is recommended to prevent *Plasmodium falciparum* malaria transmission in areas threatened by artemisinin resistance and areas aiming for malaria elimination. Community treatment campaigns with artemisinin-based combination therapy in combination with the gametocytocidal primaquine dose target all age groups but no studies thus far have assessed the pharmacokinetics of this gametocytocidal drug in African children. We recruited forty children with normal G6PD function participating in a primaquine efficacy trial in Burkina Faso to study primaquine pharmacokinetics. These children received artemether-lumefantrine and either a 0.25 or a 0.40 mg/kg primaquine dose. Physiological population pharmacokinetic modelling was used to assess the impact of weight, age and CYP2D6 genotype on primaquine and carboxy-primaquine pharmacokinetics. Furthermore, as primaquine may induce haemolysis, the relationship between pharmacokinetics and haemolysis was investigated. Despite weight-normalized dosing, the areas under the plasma concentration-time curves and the peak concentrations for both primaquine and carboxy-primaquine increased with age and body weight. Children who were genetically determined CYP2D6 poor metabolizers had higher primaquine levels, indicating lower PQ CYP2D6-mediated metabolism. Furthermore, higher primaquine exposure was correlated with a greater decline in haemoglobin. In conclusion, our data indicate that primaquine and carboxy-primaquine pharmacokinetics are influenced by age, weight and CYP2D6 genotype and suggest that dosing strategies may have to be re-considered to maximize the transmission-blocking properties of primaquine. Furthermore, besides G6PD phenotype, drug exposure may be an important covariate explaining development of primaquine induced haemolysis. We are currently expanding our PK/PD-model to the adult population.

## 281

### HIGH PREVALENCE OF MALARIA SUBMICROSCOPIC INFECTION IN WOMEN UNDER SULFADOXINE-PYRIMETHAMINE PREVENTIVE TREATMENT AT DELIVERY IN THE REPUBLIC OF CONGO

Yvon Mbouamboua, Félix Koukouikila-Koussounda, Michael Kombo, Dagené Ebouroumbi, Christevy Vouvongui, Francine Ntoui

Fondation Congolaise pour la Recherche Médicale, Brazzaville, Republic of the Congo

Malaria infections undetectable by microscopy but detectable by Polymerase Chain Reaction (PCR) (defined as submicroscopic malaria) are common in endemic areas. A cross-sectional study was conducted in Madibou, a southern district of Brazzaville in Republic of Congo (country with high malaria resistance to SP), between March 2014 and April 2015. The objective of the present cross-sectional study was to assess the frequency of submicroscopic *Plasmodium falciparum* infection among Congolese women with asymptomatic *P. falciparum* infection at delivery and its relationship with IPTp administration. We recruited 366 women at delivery. Placental blood samples were obtained and tested from all asymptomatic women for *P. falciparum* infection by microscopy

and nested polymerase chain reaction, using the *P. falciparum* merozoite surface protein-2 (*mssp2*) gene. Of the 366 pregnant women recruited, 83.6% had received IPTp-SP. With regard to peripheral and placental blood, 25.8% (79/306) and 17.3% (53/306) of those who received IPTp-SP were submicroscopic malaria positive while 74.2% (227/306) and 82.7% (253/306) were negative, respectively. In multivariable logistic regression analysis, pregnant women who received  $\geq 2$  doses of SP in their third trimester showed decreased risk of peripheral (Adjusted OR (AOR) = 0.5; 95% CI [0.3-0.9];  $P = 0.01$ ) and placental (AOR = 0.4; 95% CI [0.3-0.8];  $P = 0.003$ ) *P. falciparum* infection. We observed a high frequency of submicroscopic peripheral and placental *P. falciparum* infection, probably due to residual uncleared gestational infections. The study shows that 2 or 3 SP doses during pregnancy were associated with a lower rate of peripheral and placental *P. falciparum* infection. These findings confirm that IPTp-SP in Congolese pregnant women reduces the risk of *P. falciparum* infection and remains a necessary and efficient preventive tool. This might suggest that IPTp-SP remains a valid recommendation for malaria prevention in the Republic of Congo.

## 282

### NEW INSIGHTS ON EPIGENETICS TARGETS TO TREAT PARASITIC DISEASES

Felix Calderon<sup>1</sup>, Raquel Gabarro<sup>1</sup>, Francisco J. Gamo<sup>1</sup>, Julio Martin<sup>1</sup>, Robert Kirkpatrick<sup>2</sup>

<sup>1</sup>GlaxoSmithKline, Tres Cantos, Spain, <sup>2</sup>GlaxoSmithKline, Upper Providence, PA, United States

There is a growing appreciation that epigenetic misregulation makes a significant contribution to human diseases. Many of the recently identified protein families that control the expression of genes through epigenetic mechanisms are finally proving tractable for the discovery and development of small molecules that modulate their function; hence representing new target classes for drug discovery<sup>1</sup>. Particularly outstanding is the recent development of potent and selective small molecule inhibitors of bromodomains (BRD). BRDs are conserved structural modules in chromatin-associated proteins that recognize acetyl-lysine residues on histone and non-histone proteins. Despite these advances, the role of BRDs in the regulation of cellular processes in parasites that cause human disease remains poorly understood. Therefore, a systematic evaluation of BRD protein essentiality in parasitic diseases is needed to identify the best targets for intervention. In contrast to current drug intervention strategies under investigation for parasitic diseases, which primarily affect parasite cell physiology, metabolism and homeostasis; epigenetic target approaches offer an opportunity to explore new mode of actions including the disruption of interactions between the host immune system, host cell receptors and parasite ligands at specific stages of the infection cycle.

## 283

### MALARIA PREVENTION WITH NUTRIENT SUPPLEMENTATION IN ADDITION TO SEASONAL CHEMOPREVENTION IN CHILDREN AGED 6-59 MONTHS IN RURAL MALI

Anne Thomas<sup>1</sup>, Mahamadou Doutchi<sup>2</sup>, Abdelkader Issaley<sup>3</sup>, Issa Kanta<sup>4</sup>, Maguy Daures<sup>1</sup>, Ali Ouattara<sup>3</sup>, Susan Shepherd<sup>3</sup>, Renaud Becquet<sup>1</sup>

<sup>1</sup>University of Bordeaux, Inserm, Bordeaux Population Health Research Center, team IDLIC, UMR 1219, Bordeaux, France, <sup>2</sup>University of Zinder, Faculty of Medicine, Zinder, Niger, <sup>3</sup>Alliance for International Medical Action (ALIMA), Dakar, Senegal, <sup>4</sup>ALIMAMedical Alliance Against Malaria (AMCP), Bamako, Mali

Susceptibility to malaria and malnutrition are inter-related in young children. We hypothesized that the response to seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine and amodiaquine may be boosted by concurrent distribution of a lipid-based nutrient supplement (LNS). The objective of this study was to determine

whether the association of SMC+LNS reduces the occurrence of malaria episodes when compared to SMC alone among children aged 6-59 months. A paired cluster cohort was carried out between August and November 2016 in 18 rural health areas of Koulikoro region, Mali. All children aged 6-59 months participating in community-based SMC distribution sessions were eligible: they received 4 monthly rounds of SMC+LNS or SMC alone in the intervention and control groups, respectively. At each round, malaria cases were identified by community health workers through rapid diagnostic tests among children presenting with fever or a history of fever in the past 48 hours. The primary outcome was the occurrence of malaria episodes detected from the 2nd through the 4th round. The secondary outcome was the occurrence of a repeat malaria episode in the 3rd or 4th round. Generalized linear mixed model were used for both outcomes in intention-to-treat (ITT) and per-protocol (PP) analyses; PP analysis included children who actually attended all 4 rounds of SMC distribution. ITT and PP analyses included 11,666 and 8,497 children: 30.1% and 31.5% in the intervention group, 69.9% and 68.5% in the control group, respectively. No significant association was found between the intervention and the occurrence of malaria episodes (aOR: 0.93; 95% CI: 0.61-1.41 and 0.93; 95%CI: 0.62-1.38 for ITT and PP, respectively). However, a statistically significant positive association was found between the intervention and the occurrence of repeated malaria episodes in PP analysis (aOR: 0.61; 95% CI: 0.37-1.01 and 0.49; 95% CI: 0.29-0.82 for ITT and PP, respectively). While the association of LNS and SMC did not impact on the occurrence of malaria episodes in children when compared to SMC alone, it seemed to reduce the risk of repeated malaria episodes.

## 284

### MOLECULAR EVIDENCE FOR PLASMODIUM FALCIPARUM RESISTANCE TO SULFADOXINE-PYRIMETHAMINE BUT ABSENCE OF K13 MUTATIONS IN MANGALORE, SOUTHERN INDIA

Jakob Wedam<sup>1</sup>, Costanza Tacoli<sup>1</sup>, Prabhanjan P. Gai<sup>1</sup>, Konrad Siegert<sup>1</sup>, Suyamindra Kulkarni<sup>2</sup>, Rashmi Rasalkar<sup>2</sup>, Animesh Jain<sup>3</sup>, Chakrapani Mahabala<sup>3</sup>, Shantaram Baliga<sup>3</sup>, Damodara Shenoy<sup>3</sup>, Pramod Gai<sup>2</sup>, Rajeshwari Devi<sup>4</sup>, Frank P. Mockenhaupt<sup>1</sup>

<sup>1</sup>Charité-Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Karnataka Institute for DNA Research, Dharwad-Hubli, India, <sup>3</sup>Kasturba Medical College, Manipal University, Mangalore, India, <sup>4</sup>Wenlock Hospital, Mangalore, India

The first-line treatment of *Plasmodium falciparum* malaria in most of India is sulfadoxine-pyrimethamine-artesunate (*plus primaquine*). Among 107 *P. falciparum* isolates obtained from patients attending Wenlock Hospital in Mangalore, Karnataka, southern India, we determined by sequencing mutations associated with sulfadoxine-pyrimethamine in the dihydrofolate hydrogenase gene (*pfdhfr*; codons 51, 59, 108, 164) and dihydropteroate synthase gene (*pfdhps*; codons 436, 437, 540, 581, 613). In addition, the *P. falciparum* Kelch 13 (*K13*) propeller domain was sequenced to identify variants associated with artemisinin resistance. For *pfdhfr*, all isolates revealed wildtype alleles at codons 51 and 164 but the mutations 59R and 108N co-occurred in 71%. *Pfdhps* codons 436, 581, and 613 were wildtype. The *pfdhps* variants 437G and 540E were present in 72% and 24%, respectively. All isolates exhibiting *pfdhps* 540E also had 437G. Combined, *pfdhfr/pfdhps* triple (59R-108N-437G) and quadruple (59R-108N-437G-540E) mutants were seen in 45% and 25%, respectively. No *K13* variants were observed. These molecular data show a substantial degree of sulfadoxine-pyrimethamine resistance in the region of Mangalore, southern India, but the absence of antifolate super-resistance (*pfdhfr* 164L, *pfdhps* 581G). Reassuringly, *K13* mutants affecting artesunate efficacy were absent. Nevertheless, sulfadoxine-pyrimethamine resistance may affect the protection against emerging artemisinin resistance afforded by combinatory treatment. Anticipating the intensification of sulfadoxine-pyrimethamine resistance in this region, monitoring clinical efficacy and drug resistance markers including non-antifolate partner drugs and *pfmdr1* alleles is needed.

### SPREAD OF ARTEMISININ RESISTANT *PLASMODIUM FALCIPARUM* IN FIVE SOUTHERN PROVINCES OF LAO PDR IN 2015-2016

Moritoshi Iwagami<sup>1</sup>, Masami Nakatsu<sup>1</sup>, Sengdeuane Keomalaphet<sup>2</sup>, Phonepadith Khattignavong<sup>2</sup>, Pheovaly Soundala<sup>2</sup>, Lavy Lorphachan<sup>2</sup>, Phonepadith Xangsyalath<sup>2</sup>, Virginie Pommelet<sup>2</sup>, Bouasy Hongvanthong<sup>3</sup>, Paul T. Brey<sup>2</sup>, Shigeyuki Kano<sup>1</sup>

<sup>1</sup>Research Institute, National Center for Global Health and Medicine, Tokyo, Japan, <sup>2</sup>Institut Pasteur du Laos, Vientiane, Lao People's Democratic Republic, <sup>3</sup>Center of Malariology, Parasitology and Entomology, Vientiane, Lao People's Democratic Republic

Government of the Lao PDR and WHO have set an ambitious goal to eliminate malaria by 2030, and malaria burden in the country has been gradually decreasing. However, malaria is still prevalent especially in remote rural areas in the country, and in 2013, a trial conducted in a southern part of the Lao PDR showed that 5%-22% of the *Plasmodium falciparum* malaria patients treated with artemether-lumefantrine were still parasitemic on day 3 after treatment. Moreover, about 20% of isolates of *Plasmodium falciparum* collected from the southern part of the country in 2013 possessed mutations in *kelch 13 propeller (k13)* gene that was associated with artemisinin resistance. In the present study, we examined 1,156 *P. falciparum* isolates collected from malaria patients who visited health facilities in 5 southern provinces in Lao PDR from 2015-2016. DNA analysis revealed that 55.5% (642/1,156) of the isolates showed artemisinin resistant mutations (mainly C580Y) in the *k13* gene. Moreover, frequencies of the mutations in each province were heterogeneous: 73% in Champasak, 69% in Attapeu, 59% in Salavan, 39% in Sekong and 28% in Savannakhet. The frequency was the highest in the southern-most provinces of the country (Champasak and Attapeu) and decreasing toward the north (Savannakhet). These distribution patterns of the *k13* mutations suggest that the resistant isolates may have been introduced by human movement from Thailand/Cambodia and subsequently migrated northward in Lao PDR. We also found that *P. falciparum* infected adult male populations were predominant (65%: 754/1,156) and their occupations were stated as mainly agriculturally related. These results suggest that targeted prevention plans for adult male populations should be designed and implemented to ensure the containment of artemisinin resistance and towards the elimination of malaria in Lao PDR.

### IMPROVING METHODS FOR SURVEILLANCE OF ANTIMALARIAL DRUG RESISTANCE: AN ASSESSMENT OF THE CURRENT LANDSCAPE

Christian Nsanzabana<sup>1</sup>, Djibrine Djalle<sup>1</sup>, Philippe J. Guerin<sup>2</sup>, Didier Menard<sup>3</sup>, Iveth J. Gonzalez<sup>1</sup>

<sup>1</sup>Foundation for Innovative New Diagnostics (FIND), Geneva, Switzerland, <sup>2</sup>WorldWide Antimalarial Resistance Network (WWARN), Oxford, United Kingdom, <sup>3</sup>Institut Pasteur, Phnom Penh, Cambodia

Surveillance of antimalarial drug resistance is undertaken using three approaches: therapeutic efficacy studies to assess the efficacy of drugs in patients; *in vitro/ex vivo* studies to evaluate parasite susceptibility to the drugs; or molecular studies to identify known gene mutations and/or copy number changes associated with drug resistance. These methods are complementary, as they evaluate different aspects of resistance. One key issue when comparing these techniques is the variability of methods used by investigators when conducting such approaches. We have conducted a review of the different methods used to monitor antimalarial resistance, and assessed their strengths and weaknesses. The World Health Organization (WHO) has developed a standard protocol for evaluating the efficacy of antimalarial drugs, used by Control Programs and research groups to conduct antimalarial efficacy studies. Parts of the WHO protocol, however, are not prescriptive and are subject to investigators' choices,

such as aspects concerning microscopy quality control, pharmacology assessment and the genotyping methods used to differentiate recrudescence from new infections. For *in vitro/ex vivo* techniques, a number of different methods are being used, and it has proven difficult to compare results across the different methods. Standardisation of common steps, such as parasite culture, and consistent approaches to data analysis could decrease the high inter-laboratory variability of results. For molecular assessments, different techniques exist as well. The technology landscape for molecular analysis of drug resistance genes is changing quite rapidly, and techniques such as sequencing and real time polymerase chain reaction (PCR) are becoming available at low cost. Strengthening the work of national or regional reference laboratories and research institutions with precise procedures, quality control and assurance schemes and training could improve the quality of antimalarial resistance assessment. Moreover, new technologies in development may be simpler and more user friendly, and could potentially be used directly at peripheral level.

### RETURN OF CHLOROQUINE SENSITIVE *PLASMODIUM FALCIPARUM* MALARIA OF MUTASA DISTRICT, ZIMBABWE

Zvifadzo Matsena Zingoni<sup>1</sup>, Nobert Mudare<sup>2</sup>, Aramu Makuwaza<sup>1</sup>, Shungu Munyati<sup>3</sup>, Lovemore Gwanzura<sup>4</sup>, Susan L. Mutambu<sup>1</sup>, Peter Mason<sup>3</sup>, Tamaki Kobayashi<sup>5</sup>, William Moss<sup>5</sup>, Sungano I. Mharakurwa<sup>6</sup>

<sup>1</sup>National Institute of Health Research, Harare, Zimbabwe, <sup>2</sup>Biomedical Research Institution, Harare, Zimbabwe, <sup>3</sup>Biomedical Research and Training Institution, Harare, Zimbabwe, <sup>4</sup>University of Zimbabwe, Harare, Zimbabwe, <sup>5</sup>John Hopkins School of Public Health, Bloomberg, MD, United States, <sup>6</sup>Africa University, Mutare, Zimbabwe

The emergence of *Plasmodium falciparum* drug resistance erodes the arsenal of effective antimalarials and poses one of the major threats for malaria control and elimination programmes. It is imperative to monitor parasite resistance profiles to available programme antimalarials, both old and new. It has been shown that *P. falciparum* resistance to chloroquine, the former safest and most effective antimalarial, may recede after years of drug withdrawal from use. The current study determined the levels of the chloroquine resistance-conferring PfCRT K76T mutation among *falciparum* malaria infections of Mutasa District, Zimbabwe in 2013, compared to 2003, when chloroquine monotherapy was suspended. Cross-sectional surveys were conducted in 2003 and 2013, on 408 and 373 study participants, respectively, from representative households of Mutasa District. Parasite DNA samples were collected using dry blood spots. DNA was extracted by the Chelex method and *P. falciparum* infections were genotyped at PfCRT amino acid codon 76 using nested PCR and restriction enzyme digestion. Of the participants screened in 2003 and 2013, 66 (17.7%) and 49 (12%), respectively were PCR-positive for *P. falciparum* and all were successfully genotyped at the key chloroquine resistance-conferring PfCRT codon 76. In 2003, there was a high prevalence (63.6%) of the K76T chloroquine resistance mutant, including 3% mixed mutated and wild type infections, leaving only 33% wild type infection. By contrast, 2013 malaria infections had only 3% K76T mutants, the rest (97%) being wild type. No K76T mutant was found among *P. falciparum* infections in the mosquito mid-gut phase. There has been a considerable return of chloroquine-sensitive *P. falciparum* malaria in Mutasa, less than ten years after suspension of chloroquine use. Resumption of indoor residual spraying, sporogonic selection in the local vector *An. funestus* and adoption ACTs since 2008 may be contributing to the rapid restoration of the wild type parasitaemia. Further monitoring is recommended as it may later be viable to consider incorporating chloroquine as an ACT partner drug.

287

## PERFORMANCE OF PFHRP-2 BASED RDT MALARIA DIAGNOSTIC TESTS IN RURAL ZIMBABWE

**Nobert Mudare**

*Biomedical Research and Training Institute, Harare, Zimbabwe*

Accurate identification of *Plasmodium* infections in community surveys is essential to successful malaria control. Microscopy and rapid diagnostic tests (RDTs) are the main techniques used to diagnose malaria in field-based surveys. RDTs are growing in popularity as they allow for rapid and inexpensive diagnosis. Using data from a malaria survey conducted in Mutasa District, Zimbabwe, Paracheck P.f® and Immunochromatographic Test (ICT) RDTs performance using cytochrome b gene polymerase chain reaction (Cyt b PCR) as a gold standard were compared. This was a cross-sectional survey in which households were identified using the Geographic Position System (GPS). Paracheck P.f® and ICT RDT kits were used in parallel to screen for malaria in all age groups in the selected households from October 2012 up to June 2014. The smears were stained with Giemsa stain and examined for parasites using a compound microscope. Parasite DNA was extracted from the dried blood spot (DBS) samples using the Chelex method and a nested PCR for mitochondrial cytochrome b gene. The proportion of *P. falciparum* infections confirmed by PCR, microscopy, Paracheck- Pf® and ICT were 7.17%, 1.90%, and 6.78%, respectively. The sensitivity of microscopy was 60.7% with a 95% confidence interval (CI) of (40.6-78.5) and a specificity of 93.8%, CI (92.5-94.9). Microscopy had a positive predictive value of 14.5%, CI (8.7-22.2). The sensitivity of the two RDTs was 47.8% with a 95% confidence interval (CI) of (37.1-58.6) and a specificity of 95.3%, CI (94.1-96.3). The RDTs had a positive predictive value of 37.4%, CI (28.5-46.9). There was no significant difference between the two RDT brands, Paracheck- Pf and ICT, so they can be used interchangeably. Both microscopy and RDTs showed limited sensitivity of 60.7% and 37.4%, respectively. However, microscopy performed better than RDT possibly owing to low parasitemia.

288

## CASE REPORT: RECURRENT FALCIPARUM MALARIA IN A COMMUNITY HOSPITAL IN NEW YORK

**Yanqing Mei, Eileen Chang, Javeria Shakil, Marta Niederland**

*Flushing Hospital Medical Center, New York, NY, United States*

Case: A 38-year-old man presented with acute-onset fever and chills with nausea and vomiting for three days. The symptoms relapsed on the third day. Fever could be resolved by ibuprofen. He denied diarrhea, dizziness, confusion, neck pain or stiffness, visual or hearing changes, or rashes. He recently visited Senegal in Africa for two weeks and came back six days ago. He didn't take malaria prophylaxis. He denied any tick or rodent bites but reported exposure to mosquitos. Patient was treated for malaria 5 years ago in Africa. He came to the US 4 years ago. Blood parasites showed *Plasmodium falciparum* >5%. Patient was started on quinine sulfate doxycycline. Blood glucose dropped below 60mg/dl after treatment. Patient was on POCT glucose monitoring as both malaria and quinine may induce hypoglycemia. After treatment for 5 days, patient had three consecutive negative blood parasites smear. Patient was discharged with quinine and doxycycline to finish 7-day course. Discussion: The attack occurred every other day, which is a characteristic of the "tertian" parasites (*Plasmodium falciparum*, *P. vivax*, and *P. ovale*). Patient had hyperparasitemia according to the criteria (*Plasmodium falciparum* >5%). However, he didn't develop severe complications except transient hypoglycemia. It is noted that patient had previous malaria infection five years ago. Even though it might not be *P. falciparum* infection at that time. Patient could have developed partial immunity that prevented him from severe complications this time. The majority of malaria cases in the US occur in travelers or immigrants returning from malaria-endemic areas. It is recommended to take prophylactic medications considering the drug-resistance in different countries. Conclusion: Periodic fever and chills should arise the suspicion for malaria. Blood smear parasite is the test of choice.

*astmh.org*

Faster diagnosis leads to better outcomes even in hyperparasitemia. Travelers to malaria-endemic areas are recommended to take prophylactic medications and use personal protective measures.

289

## ESTABLISHMENT OF THE MAJOR SUBCLINICAL SYMPTOMS ASSOCIATED WITH MALARIA IN OWERRI SOUTHEASTERN NIGERIA

**Precious O. Eteike, Evangeline T. Oparaocha**

*Federal University of Technology, Owerri, Nigeria*

Malaria still remains a life threatening disease of great public health importance especially in sub-Saharan Africa. Detection of malaria at the early stage of the disease could prompt early treatment and subsequently reduction in the morbidity and burden of the disease. We aimed at establishing the major symptoms associated with subclinical malaria in Owerri, South Eastern Nigeria. We utilized a community based and interventional (therapeutic) approach to conduct the study between September and December in two communities (Naze and Ikenegbu) in Owerri, South Eastern Nigeria. The study population consisted of males and females aged 18 years and above, who fulfilled the inclusion criteria and were living in the study areas as at the period of study. We employed a systematic house to house sampling technique and a total of 117 participants from the study sites who tested positive to malaria parasite by microscopy but with no classical clinical symptoms were enlisted. The subjects were later treated with artemeter-lumefantrine. The major symptoms of subclinical malaria we established were; body itching, 111(12.9%), bone pains, 110(12.8%), sleepiness, 110 (12.8%), bad dreams, 107(12.4%), dizziness, 92(10.7%), bitter/soar taste, 90(10.5%), joints/muscular pains, 77(9.0%), and weakness of the body, 75(8.7%). Others, 88 (10.2%) participants reported cough/catarrh 23(2.7%), abdominal discomfort 23(2.7%), loss of appetite 23(2.7%), yellow urine 7(0.8%), constipation 7(0.8%), and sleeplessness 5(0.6%). These subclinical symptoms create suspicion of impending malaria attack and could cause patients to take immediate actions towards proper diagnosis and treatment at the early stage. A recent study done in the same study area showed a better treatment outcome with artemeter-lumefantrine initiated at the subclinical stage than during the clinical stage. Early detection and treatment of malaria could lead to reduction of morbidity, mortality and burden associated with malaria.

290

## HIGH-THROUGHPUT SCREENING OF *PLASMODIUM FALCIPARUM* HRP2 DELETION FOR MONITORING OF RDT EFFICACY FOR MALARIA DIAGNOSIS

**Cristian Koepfli<sup>1</sup>, Kingsley Badu<sup>2</sup>, Eugenia Lo<sup>1</sup>, Elizabeth Hemming-Schroeder<sup>1</sup>, Guiyun Yan<sup>1</sup>**

<sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Due to ease of use and low costs, rapid diagnostic tests (RDTs) have become the main alternative to microscopy for malaria diagnosis in the field, with over 300 million RDTs sold in 2014. The majority of RDTs detects the *Plasmodium falciparum* HRP2 protein, yet recent reports of *hrp2* deletion question the efficacy of these tests. Due to a lack of appropriate laboratory methods for high-throughput screening, the extent of *hrp2* deletion is not well understood. We present a novel assay to detect *hrp2* and *hrp3* deletions based on droplet digital PCR (ddPCR). The assay is highly sensitive and thus suited to screen asymptomatic infections, can detect mixed infections with *hrp2*- and wild-type parasites, and greatly reduces the number of reactions to be run and the amount of template DNA required. Each sample is partitioned into approx. 15000 droplets that are amplified and screened individually. Depending on parasite density, dozens to thousands of repeats are run in a single well, thus minimizing the risk of false-negative results. Among samples from Eastern Africa, where previously no reports on *hrp2* deletion were available, *hrp2* deletion

was found in 1/23 isolates from southwestern Ethiopia, while all 71 *P. falciparum* positive samples from Western Kenya carried the *hrp2* gene. Screening of samples from other African countries is ongoing. In summary, ddPCR allows for simplified screening for *hrp2* deletion and thus can inform control programs on the efficacy of RDTs for malaria diagnosis.

### FIELD EVALUATION OF SELEXON MALARIA ANTIGEN *PLASMODIUM FALCIPARUM* SYSTEM FOR MALARIA DIAGNOSIS IN WESTERN KENYA

Adano Godana<sup>1</sup>, Kephas Otieno<sup>2</sup>, James Gachugia<sup>3</sup>, Winnie J. Chebore<sup>2</sup>, Andrew Obala<sup>4</sup>, Zeinabu Gura<sup>1</sup>, Sara Iowther<sup>5</sup>, Tura Galgalo<sup>5</sup>, Ya Ping Shi<sup>6</sup>, Simon Kariuki<sup>7</sup>, Aaron Samuel<sup>8</sup>

<sup>1</sup>Field Epidemiology and Laboratory Training Program, Ministry of Health, Kenya, Nairobi, Kenya, <sup>2</sup>Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, <sup>3</sup>Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, <sup>4</sup>School of Public Health, Moi University, Kenya, Eldoret, Kenya, <sup>5</sup>Centers for Disease Control and Prevention, Kenya, Nairobi, Kenya, <sup>6</sup>Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>7</sup>Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, <sup>8</sup>Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, USA, Nairobi, Kenya

Use of rapid diagnostic tests (RDTs) for malaria is increasing as the tests are relatively inexpensive and do not require highly specialized personnel or infrastructure. However, RDT results are dependent on accurate interpretation of test bands, and bands may be faint, leading to inter-operator variability and misclassification. The SelexOn™ Malaria Antigen *Plasmodium falciparum* point of care automated reader system (Dong-A ST, Seoul, South Korea) consists of a RDT and an automated reader that uses a lateral flow immunoassay to qualitatively detect *Plasmodium falciparum* histidine-rich protein II (HRP-II) antigen in blood. This system may improve diagnostic accuracy compared to light microscopy and visually-read RDTs. However, it has not been evaluated in the field. We enrolled individuals presenting to four health facilities in western Kenya with presumed malaria infection and tested their blood samples by the SelexOn™ automated reader, and Carestart™ Malaria HRP-2/pLDH (Pf/PAN) Combo Test (Access Bio, Inc., Somerset, NJ, USA) RDTs to evaluate the performance of these tests to diagnose malaria infection. We calculated the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of each test, in Graph Pad Prism version 5 (Graph Pad Software, La Jolla, CA, USA), using Fisher's exact test to determine 95% confidence intervals (CI), using expert microscopy as the gold standard. We enrolled 465 patients (age range: 6-1085 months; median= 192 months). Malaria rates were: 29% (n=136) based on expert microscopy; 39% (n=181) by the SelexOn™ automated reader; and 36.9% (n=170) by Carestart™ RDT. The sensitivity, specificity, PPV, and NPV of SelexOn™ automated reader were 93.4% (CI: 87.8-96.9), 83.6% (CI: 79.1-87.6), PPV=70.2%, and NPV=96.8%; for CareStart™ RDTs sensitivity was 92.6% (CI: 86.8-96.4), specificity was 86.2% (CI: 81.2-89.8), PPV was 73.5% and NPV was 96.6%. In our study, the performance characteristics of the SelexOn™ system were similar to that of CareStart™ in our study.

## 292

### DETECTION OF MALARIA GAMETOCYTES CARRIAGE IN KISUMU COUNTY, WESTERN KENYA FOR DETERMINATION OF TRANSMISSION DYNAMICS

Benjamin H. Opot<sup>1</sup>, Raphael Okoth<sup>1</sup>, Gladys Chemwor<sup>1</sup>, Irene Omollo<sup>1</sup>, Irene Onyango<sup>1</sup>, Dennis Juma<sup>1</sup>, Tom Gilbreath<sup>1</sup>, Derek Monthei<sup>2</sup>, Hosea Akala<sup>1</sup>, Ben Andagalu<sup>1</sup>, Edwin Kamau<sup>3</sup>, Matthew Brown<sup>1</sup>, Jessica Cowden<sup>1</sup>

<sup>1</sup>United States Army Medical Research Directorate - Kenya, Kisumu, Kenya, <sup>2</sup>United States Army, Washington, DC, United States, <sup>3</sup>Walter Reed National Military Medical Centre, Maryland, MD, United States

Owing to the declining malaria burden globally, malaria endemic countries are endeavouring to enter the pre-elimination phase. *Plasmodium falciparum* gametocytes are vital to sustained malaria transmission. Microscopy is one of the most widely used tools for the diagnosis of malaria; however, molecular methods are more sensitive in detection of both sexual and asexual parasites, especially in asymptomatic carriers.

**Aim:** To determine gametocyte carriage among the asymptomatic malaria cases in Kisumu, Kenya. A cluster designed cross-sectional study was carried out in Kisumu, Kenya between July 2015 and June 2016 to establish the role of asymptomatic individuals in transmission of malaria. Two ml of whole blood was collected from each individual living in the enrolled households. RNA extracts from the blood were used for diagnosis and quantification of the parasite's asexual stage using RT-PCR, and presence of sexual stage parasites was determined as either early (Pf16) or late (Pf25) stage gametocytes. Microscopic analyses of the sexual and asexual parasites were performed by blinded expert microscopists. 2384 (55%) out of 4333 asymptomatic individuals tested positive for malaria by RT-PCR as compared to 1090 (25%) by microscopy. Of the 2384 *P. falciparum* positive specimens, 1292 (54%) were positive for gametocytes with 1055 (82%) having both Pf16 and Pf25, 200 (15%) with Pf16 only and 37 (3%) having Pf25 only. Gametocyte carriage by microscopy was 93 (8%) of the 1090 samples. In conclusion, Kisumu County is in a high malaria transmission setting. This study showed more than half of the asymptomatic residents serve as a reservoir for malaria transmission regardless of the season. This study underscores the importance of understanding the contribution of submicroscopic infections to malaria disease transmission and the value of using molecular diagnostics in malaria control and elimination efforts.

## 293

### LUMINEX-BASED QUANTIFICATION OF *PLASMODIUM SP* HRP2 AND PLDH IN *PLASMODIUM*-INFECTED PREGNANT WOMEN

Xavier Martiáñez-Vendrell<sup>1</sup>, Alfons Jiménez<sup>2</sup>, Ana Campillo<sup>3</sup>, Iveth J. González<sup>3</sup>, Alfredo Mayor<sup>4</sup>

<sup>1</sup>Institute for Global Health (ISGlobal), Hospital Clinic, Universitat de Barcelona, Barcelona, Spain, <sup>2</sup>Institute for Global Health (ISGlobal), Barcelona, Spain, <sup>3</sup>Foundation for Innovative New Diagnostics (FIND), Geneva, Switzerland, <sup>4</sup>Institute for Global Health (ISGlobal), Hospital Clinic, Universitat de Barcelona, Barcelona, Spain; Centro de Investigação em Saúde da Manhiça (CISM), Manhiça, Maputo, Mozambique

Malaria diagnostics and surveillance relies mainly upon the detection of *Plasmodium falciparum* histidine-rich protein 2 (HRP2) and *Plasmodium spp* lactate dehydrogenase (pLDH). The available reference immunoassays for HRP2 and pLDH are based on ELISAs with limited sensitivity. We are currently developing a highly-sensitive Luminex-based assay for the multiplex detection and quantification of HRP2 and pLDH. This assay will be applied for HRP2 and pLDH quantification in plasma from 51 *P. falciparum*-infected pregnant women from Manhiça, Southern Mozambique, and 100 *P. falciparum* or *P. vivax*-infected pregnant women from Urabá-Antioquia region in Colombia. Blood samples from Mozambique were collected at three time points: 2 before receiving

intermittent preventive treatment (IPTp) doses, and 1 at delivery. Quantification of HRP2 in this set of samples will allow us to estimate the persistence of HRP2 in plasma, as currently its dynamics in blood is not well understood. Detection of both antigens is expected to be in the sub-picomogram level. Subsequently, HRP2 half-life and time to negativization will be accurately determined within our sample set. This highly-sensitive multiplex immunoassay will serve as reference method for the validation of malaria rapid diagnostics tests, as a tool for estimating the time of persistence of HRP2 in blood after clearance of infection, and to determine the value of HRP2 detection as an indicator of recent exposure to *P. falciparum*.

## 294

### MULTIPLE ANTIGEN RAPID DIAGNOSTIC TESTS FOR THE DIAGNOSIS OF SEVERE MALARIA IN HIGH-TRANSMISSION, RESOURCE-LIMITED SETTINGS

Ross M. Boyce<sup>1</sup>, Raquel Reyes<sup>1</sup>, Moses Ntaro<sup>2</sup>, Edgar Mulogo<sup>2</sup>, Michael Matte<sup>2</sup>, Mark J. Siedner<sup>3</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Mbarara University of Science and Technology, Mbarara, Uganda, <sup>3</sup>Massachusetts General Hospital, Boston, MA, United States

Many malaria-endemic countries have adopted community case management programs for the diagnosis and treatment of malaria using lay health workers. While effective for the management of uncomplicated malaria, the ability of these programs to identify and refer cases of severe malaria is limited. New tools are needed to improve diagnostic and management algorithms for severe malaria. This prospective, observational cohort study assessed the accuracy of a multiple antigen RDT compared to clinical and laboratory criteria to identify patients with severe malaria. All individuals presenting to a rural clinic in Western Uganda underwent testing with a HRP-2/pLDH RDT. Those with a positive RDT result had thin/thick blood smears prepared and blood and urine collected for measurement of hemoglobin, serum chemistries, and urinalysis. We estimated the sensitivity, specificity and negative and positive predictive values for a HRP-2+/pLDH+ result compared to WHO defined clinical and laboratory reference standards for severe malaria. A total of 2,678 children <12 years of age underwent testing for malaria with a RDT. Nearly half (1,248, 46.6%) had a positive RDT result, of whom 76 (8.3%) satisfied criteria for severe malaria. The sensitivity and specificity of a HRP-2+/pLDH+ result for severe malaria was 97.4% (95% CI 90.0 - 99.5), and 75.4% (95% CI 73.6 - 77.2%), respectively. A HRP-2+/pLDH+ result was significantly more sensitive (97.4% vs. 67.1%,  $p < 0.001$ ) and had a higher negative predictive value (99.9% vs. 98.8%,  $p < 0.001$ ) for the detection of severe malaria than clinical findings. In conclusion, a multiple antigen RDT has high sensitivity for the detection of severe malaria, making it a promising tool in the management and triage of children with malaria in low-resource settings. Further work is needed to validate and operationalize diagnostic and treatment algorithms so as not to overwhelm tenuous referral networks.

## 295

### IMPROVED POINT-OF-CARE TESTING FOR THE DETECTION OF INFECTION WITH MALARIA PARASITES DURING PREGNANCY IN BUSIA, UGANDA

Patience Nayebare<sup>1</sup>, Bakar Odongo<sup>1</sup>, Martin Okitwi<sup>1</sup>, Harriet Adrama<sup>1</sup>, Abel Kakuru<sup>1</sup>, Richard Kajubi<sup>1</sup>, Teddy Ochieng<sup>1</sup>, Peter Olwoch<sup>1</sup>, Martin Chamai<sup>1</sup>, Jaffer Okiring<sup>1</sup>, Joaniter Nankabirwa<sup>2</sup>, Christine Bachman<sup>3</sup>, Bernhard H. Weigl<sup>3</sup>, Kevin P. Nichols<sup>3</sup>, Moses R. Kamya<sup>2</sup>, David Bell<sup>3</sup>, Grant Dorsey<sup>4</sup>, Bryan Greenhouse<sup>4</sup>

United States, <sup>4</sup>Department of Medicine, University of California San Francisco, San Francisco, CA, United States

Prompt and accurate diagnosis of malaria remains a challenge to malaria elimination efforts especially during pregnancy. Currently available rapid diagnostic tests (RDTs) lack the sensitivity to detect low level parasitemia common during pregnancy among women living in highly endemic areas. In the bid to bridge this gap, we are evaluating two technologies, each of which may independently increase sensitivity by an order of magnitude compared to visual reading of commercial RDTs; sensitive, portable RDT reader based on photo-thermal spectroscopy, and an optimized high sensitivity prototype plasma-specific HRP2 RDT. The study is nested within an ongoing cohort of pregnant women in Uganda. Seven hundred eight two (782) HIV uninfected women were enrolled at 12-20 weeks of gestation and followed through delivery. A Carestart RDT, prototype plasma-specific HRP2 RDT and malaria microscopy were performed on routine visits. Both RDTs were evaluated visually and by the reader, and a whole blood sample is being stored for quantitative PCR (qPCR), which will soon be performed and used as a gold standard for detection of malaria parasites. Of the 366 tested samples, 27% were positive by standard Carestart RDT, while, 55% by the prototype RDT ( $P < 0.001$ ). Of the microscopy negative samples ( $n=274$ ), 6.2 and 41% were positive by Carestart and the prototype RDTs respectively ( $P < 0.001$ ). Of the 28 samples with parasite densities greater than 0 but less than 100 parasites/ $\mu$ l, more samples were identified as positive by the prototype RDT (83% vs. 75%), though this was not statistically significant. The 3 low density infections not detected by either RDTs remain to have the presence and species of parasites to be confirmed by qPCR. All infections with greater than 100 parasites/ $\mu$ l were equally detected by microscopy and both RDTs. Both of these new technologies, used alone or in combination, offer promise for the easy, prompt and accurate diagnosis of submicroscopic malaria infections in pregnancy. Availability of both qPCR and photo-thermal reader data prior to the ASTM meeting will enable us to ascertain this conclusion.

## 296

### AN ULTRASENSITIVE LOOP MEDIATED ISOTHERMAL AMPLIFICATION (US-LAMP) METHOD FOR DIAGNOSIS AND SURVEILLANCE OF MALARIA

Md Abu Naser Mohon, Kevin Perera, Dylan Ravindran Pillai  
University of Calgary, Calgary, AB, Canada

Loop mediated Isothermal Amplification (LAMP)-based methods have proven their potential as field-adaptable molecular test for Point of Care (POCT) diagnosis of malaria. LAMP methods were found to be efficient for diagnosis of symptomatic malaria in multiple settings. At the same time, the efficiencies of LAMP-based methods were inconsistent to detect asymptomatic infections. So, far LAMP-based methods have achieved a lower limit of detection of 1-5 parasites/microliter of whole blood using 18S rRNA gene and mitochondrial cytochrome b gene as the target. We have developed an ultrasensitive (US)-LAMP for diagnosis of falciparum malaria targeting 18S rRNA transcripts. Since a single parasite at the ring stage contains approximately 10,000 copies of 18S rRNA, the limit of detection has improved to 0.05-0.1 parasites/microliter of whole blood. Optimization of US-LAMP from filter paper has also been performed. US-LAMP will be an excellent alternative for both molecular surveillance and POCT in resource-limited settings. This study will be extended on-field specimens.

### HIGH PREVALENCE OF *PLASMODIUM FALCIPARUM* HISTIDINE RICH PROTEIN 2 AND 3 GENE DELETIONS AND THEIR IMPLICATIONS FOR MALARIA DIAGNOSIS IN ETHIOPIA

Sisay Getie<sup>1</sup>, Aline Lamien Meda<sup>2</sup>, Meseret Birhanie<sup>1</sup>, Aberham Abere<sup>1</sup>, Harald Noedl<sup>2</sup>

<sup>1</sup>University of Gondar, Gondar, Ethiopia, <sup>2</sup>Medical University of Vienna, Vienna, Austria

PfHRP2-based rapid diagnostic tests have become a mainstay of malaria diagnosis in resource-limited environments throughout the malaria-endemic world. In Ethiopia rapid diagnostic tests are mainly used at village level, whereas microscopy remains the gold standard for malaria diagnosis at health center and hospital level. Deletions of the *pfhrp2*, *pfhrp3* and flanking genes have previously been shown to be associated with negative results from rapid diagnostic devices mainly in Latin America. Conflicting results from rapid diagnostic devices as compared to microscopy and molecular techniques in Ethiopia suggest that *pfhrp2* and *pfhrp3* gene deletions may be common in Ethiopia. Out of a total number of 303 blood samples collected from children under 5 years at three health centers (Aykel, Negade Bahir, and Sanja) in northwestern Ethiopia 33 (10.9%) tested positive in nested PCR for *P. falciparum* malaria, 19 (6.3%) for *P. vivax*, and 3 (1%) for *P. ovale*, respectively. The *pfhrp2*, *pfhrp3* (exon 1, the intron, and exon 2) and flanking genes (MAL7P1\_228 and MAL7P1\_230 for *pfhrp2*, and MAL13P1\_475 and MAL13P1\_485 for *pfhrp3*) were amplified using standard nested PCR. *Pfhrp2* and both of its flanking genes, MAL7P1.230 and MAL7P1.228, were found to be present in only 12 (36.4%) out of the 33 samples testing positive for *P. falciparum*. Twenty one (63.6%) samples tested negative for the *pfhrp2* gene, out of which 19 samples (57.6%) tested positive for at least one of the flanking genes. Only 5 (15.2%) samples gave positive results for the *pfhrp3* gene and both of its flanking genes, whereas 16 (48.5%) tested negative for all three and 12 (36.4%) for *pfhrp3* and at least one of the flanking genes. Our study provides clear evidence of widespread deletions in the *pfhrp2* and *pfhrp3* genes in Ethiopia thereby confirming anecdotal reports of diagnostic failure with HRP2-based rapid diagnostic tests in the region. The potential implications of our findings for the current diagnostic paradigm, which relies on the detection of *P. falciparum* by HRP2-based rapid diagnostic tests in remote areas, may need rethinking.

### POTENTIAL BIOMARKERS OF *PLASMODIUM FALCIPARUM* INFECTIONS IN PREGNANT WOMEN: A CASE-CONTROL STUDY FROM NANORO, BURKINA FASO

Petra Mens<sup>1</sup>, Esmee Ruizendaal<sup>1</sup>, Maminata Traore-Coulibaly<sup>2</sup>, John Bradley<sup>3</sup>, Palpuigni Lompo<sup>4</sup>, Herman Zango<sup>4</sup>, Umberto d'Alessandro<sup>5</sup>, Halidou Tinto<sup>2</sup>, Henk Schallig<sup>1</sup>

<sup>1</sup>Academic Medical Centre, Amsterdam, Netherlands, <sup>2</sup>Clinical Research Unit Nanoro, Nanoro, Burkina Faso, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Clinical Research Unit, Nanoro, Burkina Faso, <sup>5</sup>Medical Research Council, Banjul, Gambia

Diagnosis of malaria in pregnancy is problematic due to reduced sensitivity of conventional diagnostic tests (rapid diagnostic tests and microscopy). In this study the potential of six biomarkers for diagnosing malaria in pregnancy was evaluated. At enrollment at the antenatal care clinic, at a follow-up antenatal care visit and at delivery blood was collected from pregnant women for diagnosis of malaria by microscopy and real-time PCR, and for biomarker analyses by ELISA (interleukin 10, IL-10; tumor necrosis factor- $\alpha$ , TNF- $\alpha$ ; soluble tumor necrosis factor receptor II, sTNF-RII; soluble fms-like tyrosine kinase 1, sFlt-1; leptin and apolipoprotein B, Apo-B). At delivery a placental biopsy was collected for histological analysis. Both IL-10 and sTNF-RII were significantly increased at all time points in malaria infected women compared with uninfected women ( $p < 0.001$ ) and the levels were positively associated with parasite density ( $p$

$< 0.001$  and  $p = 0.003$  for IL-10 and sTNF-RII respectively). IL-10 was also negatively associated with birth weight and in malaria infected women with low birth weight ( $< 2500$  g). A scoring model was created using IL-10 and sTNF-RII cut-off points. For primigravida the model had a sensitivity of 92.3% (95%CI 62.3 - 98.9) and specificity of 95.2% (95%CI 71.1 - 99.4) for diagnosing malaria during pregnancy. IL-10 and sTNF-RII are potential biomarkers for diagnosing malaria in pregnancy and can be combined in a model, although this should be confirmed in future surveys. Furthermore, additional markers might be necessary to ensure sufficient specificity when other inflammatory diseases are prevalent.

### GENETIC ORIGINS OF *PLASMODIUM FALCIPARUM* PARASITES WITH *HRP2* GENE DELETIONS IN PERU AND ERITREA

Karryn Gresty<sup>1</sup>, Karen Anderson<sup>1</sup>, Dionicia Gamboa<sup>2</sup>, Araia Berhane<sup>3</sup>, Selam Mihreteab<sup>3</sup>, Norman C. Waters<sup>4</sup>, Jane Cunningham<sup>5</sup>, Iveth Gonzalez<sup>6</sup>, Xavier Ding<sup>6</sup>, Qin Cheng<sup>7</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>Universidad Peruana de Cayetano Heredia, Lima, Peru, <sup>3</sup>Ministry of Health, Asmara, Eritrea, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>World Health Organization, Geneva, Switzerland, <sup>6</sup>FINN, Geneva, Switzerland, <sup>7</sup>Australian Army Malaria Institute, Brisbane, Australia

The worldwide deployment of malaria rapid diagnostic tests (RDTs) has greatly improved malaria diagnosis and case management, contributing to the marked decline of malaria incidence and deaths in recent years. Most of the currently available RDTs detect a specific protein in the patient blood called histidine-rich protein 2 (HRP2) which is expressed only by *Plasmodium falciparum*. HRP2 is not essential for parasite survival, with some parasites deleting the *hrp2* gene encoding this protein. Parasites lacking HRP2 are undetectable by HRP2-detecting RDTs causing false negative RDT results, delaying lifesaving treatment. Parasites lacking HRP2 were first reported in Peru and subsequently reported in several South American, Asian-Pacific and African countries, posing a serious threat to malaria case management and the success of global malaria control/elimination programs. It is important to understand whether the emergence of parasites lacking HRP2 in these regions was due to introduction or simultaneous de novo development. In this study, we investigated genetic origins of parasites with *hrp2* gene deletions in Peru and Eritrea using a 7-loci microsatellite genotyping. The results reveal multiple haplotypes in *hrp2*-positive and *hrp2*-negative parasite populations in each location. This indicates *hrp2*-negative parasites have emerged from different genetic backgrounds. Importantly, in Peru and Eritrea, *hrp2*-negative parasite populations showed distinct haplotypes, strongly suggesting de novo development of these parasite populations in both locations. The outcome of this study will inform malaria control and elimination policy and strategy, and highlight the need for improved non-HRP2 based RDTs.

### ESTABLISHMENT AND APPLICATION OF A NOVEL FIELD BASED LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) ASSAY FOR MONITORING ANTI-MALARIAL DRUG RESISTANCE IN *PLASMODIUM FALCIPARUM*

Madhvi Chahar, Neelima Mishra, Anup Anvikar, Neena Valecha  
National Institute of Malaria Research (NIMR), New Delhi, India

*Plasmodium falciparum* malaria is still one of the most threatening diseases and resistance to anti-malarial drugs is one of the main serious evil for the control and elimination of malaria. Relatively high incidence of chloroquine (CQ) and sulphadoxine-pyrimethamine (SP) resistant *P. falciparum* cases have been reported in India. Detection of anti-malarial drug resistance is mainly based on highly sophisticated, costly and time-

consuming molecular techniques including DNA sequencing; these techniques could not cope with the current demand of field based methods for point of care need. In this study we developed a novel field based easy to use loop mediated isothermal amplification (LAMP) assay for rapid detection of chloroquine resistance (*Pfcr* K76T) in *P. falciparum*. Our data provide strong evidence that this new LAMP method could be used for early warning of CQ resistant *P. falciparum* in field conditions. We believe that pre-establishment of a novel isothermal amplification molecular assay for K76T detection could also be useful to develop similar technique valuable for the other important molecular markers including *Plasmodium falciparum* dihydrofolate reductase (*Pfdhfr*), *P. falciparum* dihydropteroate synthase (*Pfdhps*) associated with sulfadoxine-pyrimethamine (SP) resistance and most importantly Kelch13-propeller region constitutes a useful molecular marker for large-scale surveillance of artemisinin resistance in *P. falciparum*. Thus in the view of above targeted marker information we believe that the standardized protocol to detect CQ resistance may be helpful for rapid LAMP optimization to detect the sulfadoxine-pyrimethamine (SP) and artemisinin resistance in malaria-endemic settings.

### 301

#### SCREENING FOR MALARIA IN PREGNANCY WITH RDTs BY COMMUNITY HEALTH WORKERS IN NANORO, BURKINA FASO

**Henk Schallig**<sup>1</sup>, Esmee Ruizendaal<sup>1</sup>, Maminata Traore<sup>2</sup>, Palpigium Lompo<sup>2</sup>, Natama Magloire<sup>2</sup>, John Bradley<sup>3</sup>, Susanna Scott<sup>4</sup>, Osmane Traore<sup>2</sup>, Innocent Valea<sup>2</sup>, Koen Peeters<sup>5</sup>, Franco Pagnoni<sup>6</sup>, Umberto d'Alessandro<sup>4</sup>, Halidou Tinto<sup>2</sup>, Petra Mens<sup>1</sup>

<sup>1</sup>Academic Medical Centre, Amsterdam, Netherlands, <sup>2</sup>Clinical Research Unit Nanoro, Nanoro, Burkina Faso, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Medical Research Council, Banjul, Gambia, <sup>5</sup>Institute for Tropical Medicine, Antwerp, Belgium, <sup>6</sup>World Health Organization-TDR, Geneva, Switzerland

One of the current strategies to prevent malaria in pregnancy is intermittent preventive treatment with sulfadoxine-pyrimethamine (IPTp-SP). However, in order for pregnant women to receive an adequate number of SP doses, they should attend a health facility on a regular basis. In addition, SP resistance may decrease IPTp-SP efficacy. New or additional interventions for preventing malaria during pregnancy are therefore warranted. Our study aimed to evaluate the effect of home-based screening for malaria with rapid diagnostic tests (RDT) by community health workers (CHWs) in a cluster-randomized controlled trial in a malaria endemic region in Burkina Faso. The proposed intervention was added to the standard IPTp-SP strategy. Artemether-lumefantrine was given in case of a positive RDT. RDT results were compared with microscopy or real-time PCR, and the sensitivity and specificity of RDTs performed by CHWs was estimated. The adherence to test results and treatment was assessed for both CHWs and pregnant women. Overall, CHWs were able to conduct

RDTs with a sensitivity of 81.5% (95%CI 67.9 - 90.2) and high specificity of 92.1% (95%CI 89.9 - 93.9). After a positive RDT, 79.1% of women received artemether-lumefantrine. When treatment was not given, this was largely due to the woman being already under treatment. Almost all treated women finished the full course of artemether-lumefantrine (96.4%). CHWs are capable of performing RDTs with high specificity and acceptable sensitivity. Furthermore, CHWs showed excellent adherence to test results and treatment guidelines, suggesting this is a feasible approach. However, the effect of this intervention on malaria-related morbidity during pregnancy needs to be elucidated before firm conclusions can be drawn.

### 302

#### DIAGNOSTIC CHALLENGE OF NON-FALCIPARUM SPECIES IN SENEGAL

**Mamadou Alpha Dialo**, Khadim Diongue, Aida Sadikh Badiane, Mouhamadou Ndiaye, Mame Cheikh Seck, Daouda Ndiaye  
*Cheikh Anta Diop University, Dakar, Senegal*

As *falciparum* malaria is decreasing in Senegal, clinicians are challenging with undetermined causes of fever. We investigated the occurrence of non-*falciparum* species and other endemic pathogens that could lead to similar symptoms. From October 2015 to December 2016, we included 4 sites in Senegal: Dakar, Thies (malaria hypoendemic regions), Richard Toll (pre-elimination stage) and Kedougou (high prevalence of malaria). We conducted a prospective study where feverish patients were selected. For each sample, microscopic examination of Giemsa stained slides and RDTs were performed and filter paper was spotted with fingertip blood for PCR. In the site, slides were read by health center (HC) microscopists and all slides were checked once in Dakar by an expert microscopist. PCR was used to resolve discrepancies. In total, 927 samples were collected. Overall *Plasmodium falciparum* was detected in 213 samples by expert microscopist. HC missed 11 *falciparum* positive samples: 7 samples were under 100 parasites/ul and 4 samples were under 500 parasites/ul. All missed samples were located in Richard Toll. Non-*falciparum* species occurred in 6 samples detected by expert microscopy: 4 *P. ovale* and 2 *P. malariae*. Among those samples, 1 *P. ovale* was missed by HC microscopist, 2 *P. ovale* were not detected by RDT LDH bands. One HC microscopist misdiagnosed *P. ovale* for *P. vivax*. *P. malariae* samples were correctly diagnosed by HC microscopist. In 15 samples, spirochetes of *Borrelia* were observed. Only one HC microscopist was able to detect spirochetes in thick smear. As *P. falciparum* is decreasing it becomes an urgent need to train technicians to recognize unfamiliar malarial parasites and other pathogens responsible for fever such as *Borrelia*.

### 303

#### LAMPREY MONOCLONAL VLR ANTIBODIES AGAINST PLASMODIUM FALCIPARUM HISTIDINE RICH PROTEIN-2

Deepak Tomar<sup>1</sup>, **Balwan Singh**<sup>2</sup>, Eric Rogier<sup>3</sup>, Masa Hirano<sup>1</sup>, Oskar Laur<sup>1</sup>, Venkatachalam Udhayakumar<sup>3</sup>, Brantley Herrin<sup>1</sup>, Max Cooper<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Atlanta Research and Foundation, Atlanta, GA, United States, <sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Lampreys use variable lymphocyte receptors (VLR) composed by leucine-rich-repeat (LRR) segments for antigen recognition instead of the immunoglobulin (Ig)-based receptors used by jawed vertebrates. VLRs in lampreys are as diverse and antigen-specific as Ig-based antibodies made by mammals and other jawed vertebrates. Furthermore, they have unique properties that may make them advantageous over the traditional mouse and human antibodies for diagnostic tests, including better thermostability, high avidity, long shelf-life and recognition of novel antigen epitopes when compared to mammalian antibodies. Here we describe the generation of VLR monoclonal antibodies directed against the histidine rich protein-2 (HRP-2) of *Plasmodium falciparum*. HRP2 based rapid diagnostic tests (RDTs) are the most commonly used tests for malaria diagnosis and this test is highly sensitive and specific to *P. falciparum* as HRP2 protein is not produced by other human malaria parasites. As a first step to test the hypothesis that lamprey-based antibodies may enhance the stability and durability of RDTs, especially for use in tropical countries, we immunized lamprey larvae with purified HRP-2 protein to elicit production of high titer VLR antibodies specific for HRP-2. Lymphocytes from immunized lampreys were then used to construct VLR cDNA libraries, which were expressed on the yeast surface by fusion to the Aga2p yeast protein and tagged with a myc epitope to enable detection of surface expression. HRP-2 binding clones were selected by incubating the yeast cells with biotinylated HRP-2 antigen and staining with streptavidin-PE. Using this methodology, we

selected two recombinant VLRB antibodies with high affinity and specificity for recombinant HRP-2 and that also recognize the native HRP-2 protein in *P. falciparum* culture supernatants. The immunological characterization of these antibodies will be presented.

### 304

#### ANALYTICAL SENSITIVITY OF PCR TESTS FOR OPTIMUM VIVAX MALARIA DIAGNOSIS

**Maria de Fatima Ferreira-da-Cruz**, Natalia Almeida-Oliveira, Otacilio Moreira, Claudio Tadeu Daniel-Ribeiro

*Fundação Oswaldo Cruz, Rio de Janeiro, Brazil*

The prompt diagnosis of plasmodial species for correct and effective patient treatment prevents the transmission and reintroduction of malaria, as well as the worsening of health condition of the patient. The PCR method allows the diagnosis below the detection threshold of microscopic examination. The precision of real time PCR for diagnosis purposes, comprising the repeatability and reproducibility parameters, is scarcely reported. Thus, we developed a real-time PCR assay with SYBR® Green and TaqMan® systems for the diagnosis of *Plasmodium vivax* malarial infection. Our experimental design included the construction of a standard curve with *P. vivax* DNA, cloned or not, to determine linearity; the setting of the lower detection limit and analytical sensitivity to measure sensitivity and; intra assay variations (repeatability) as well as oscillations between assays, operators and equipment (reproducibility) to set precision. The performance of these parameters in the standardization of real time PCR showed linearity in SYBR® Green and TaqMan® systems with 1 and 5 copies / microliter with cloned DNA and 1 parasite /microliter with uncloned *P. vivax* DNA; quantification threshold of 1.77 and 0.94 and; analytical sensitivity of 1.13 and 1.17 copies / microliter, respectively. When compared conventional PCR with real time one, the detection limit remained 0.00001 parasite / microliter and the precision with 0.1 parasite / microliter for SYBR® Green and 1 parasite / microliter for TaqMan® and conventional PCR was also 100%. We concluded that real-time PCR is the eligible methodology for the detection of *P. vivax* parasites; the TaqMan® system is the most indicated for quantitative assays and that real time PCR should be adopted as a gold standard for vivax malaria diagnosis in reference laboratories.

#### RANDOMIZED TRIAL TO ASSESS THE EFFECT ON QTc INTERVAL OF REPEATED TREATMENT OF UNCOMPLICATED MALARIA WITH ACTs IN BOBO-DIOULASSO, BURKINA FASO: RELATION BETWEEN PARASITEMIA AND PROLONGED QTc

**Talato Naomie Kabore**<sup>1</sup>, Nouhoun Barry<sup>1</sup>, Yves Daniel Compaore<sup>1</sup>, Frédéric Nikiéma<sup>1</sup>, Zakari Kabre<sup>1</sup>, Aminata Fofana<sup>1</sup>, Kadidia Wermi<sup>1</sup>, Moussa Zongo<sup>1</sup>, Serge Yerbanga<sup>1</sup>, Fabrice Somé<sup>1</sup>, Issaka Zongo<sup>1</sup>, Abdoulaye Djimé<sup>2</sup>, Jean Bosco Ouedraogo<sup>1</sup>

<sup>1</sup>Institut de Recherche en Science de la Santé (IRSS), Bobo-dioulasso, Burkina Faso, <sup>2</sup>MRTC, Bamako, Mali

ACTs are widely used for the management of malaria and even tested for chemoprevention. In single episode efficacy studies, these drugs were well clinically tolerated but cardiac effects over repeated treatment are less investigated. We conducted a prospective randomized controlled trial in Bobo-Dioulasso from August 2012 to October 2013 where patients aged 6 months and over were randomly allocated to receive either Pyronaridine-artesunate or Dihydroartemisinin-piperaquine or Artemether-lumefantrine on first and on subsequent episodes. Each participant was screened against inclusion criteria including the ECG which was repeated again 2 hours after the last dose and blood smear each 12 hours until the third day. We were considered that QTc interval more than 450 ms is abnormal, but prolonged QTc interval over 500 ms was reported as adverse event. Drugs tolerance was compared using chi square test and p value of less than 0.5 is significant. Patients were randomized to receive PA (n=224) DHAPQ (n=224) or AL (n=296). During the 2 years follow up we observed

a total of 149 (in 1834 electrocardiogram performed on day 2 monitoring) prolonged QTc more than 450 ms (19/521 for PA, 92/548 for DHAPQ and 38/765 for AL, p<0.001). These proportions of QTc prolonged decreased over the subsequent episodes irrespective of the drug (57 QTc>450 in episode 1 to 0 in episode 8 until episode 10). Therefore, there are no relation between prolonged QTc and parasites elimination at day 2. A higher number of QTc prolonged was observed in DHA-PQ group than other groups. Otherwise, three drugs were well tolerated despite repeated treatment of malaria which seems to improve over consecutive episodes.

### 306

#### EFFICACY OF PRIMAQUINE AND METHYLENE BLUE FOR PREVENTING PLASMODIUM FALCIPARUM TRANSMISSION AMONG GAMETOCYTEMIC MALES IN MALI

**Alassane Dicko**<sup>1</sup>, Michelle E. Roh<sup>2</sup>, Halimatou Diawara<sup>1</sup>, Almahamoudou Mahamar<sup>1</sup>, Harouna Soumare<sup>1</sup>, Koualy Sanogo<sup>1</sup>, Daouda T. Kone<sup>1</sup>, Kalifa Diarra<sup>1</sup>, Sekouba Keita<sup>1</sup>, Djibrilla Issiaka<sup>1</sup>, Sekou F. Traore<sup>1</sup>, Kjerstin Lanke<sup>3</sup>, Charles McCulloch<sup>4</sup>, Chris Drakeley<sup>5</sup>, Olaf Müller<sup>6</sup>, Joelle Brown<sup>4</sup>, Roly Gosling<sup>2</sup>, Ingrid Chen<sup>2</sup>, Teun Bousema<sup>3</sup>

<sup>1</sup>Malaria Research and Training Centre, Bamako, Mali, <sup>2</sup>Global Health Group, Malaria Elimination Initiative, San Francisco, CA, United States, <sup>3</sup>Department of Medical Microbiology, Radboud University Medical Center, Nijmegen, Netherlands, <sup>4</sup>Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States, <sup>5</sup>Department of Immunology and Infection, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>6</sup>University of Heidelberg, Heidelberg, Germany

Primaquine (PQ) and methylene blue (MB) are two gametocytocidal compounds that have the potential to prevent transmission of *P. falciparum* malaria to mosquitoes. We aimed to establish the efficacy and safety of single low-dose PQ and MB combined with blood schizonticides in male patients in Mali. In this phase 2, four arm, randomized control trial, we enrolled males 5-50 years of age with uncomplicated *P. falciparum* malaria at the Malaria Research and Training Centre (MRTC) field site in Ouelessebouyou, Mali. All participants were positive carriers of gametocytes assessed through microscopy and glucose-6-phosphate dehydrogenase (G6PD) normal defined by rapid diagnostic test (CareStart™ G6PD RDT). Participants were randomized 1:1:1:1 in blocks of 8 to receive either sulfadoxine-pyrimethamine plus amodiaquine (SP-AQ) alone, SP-AQ plus 0.25 mg/kg PQ, dihydroartemisinin piperaquine (DP) alone, or DP plus 15 mg/kg/day for 3 days of MB. The primary endpoint was mean within-person percent change in mosquito infectivity 7 days after treatment initiation among participants who were infectious at baseline. Mosquito infectivity was measured using membrane feeding assays. Between June to December 2016, we enrolled 80 participants. In the primary analysis sample (n=52), all participants who received either PQ or MB exhibited a 100% within-person reduction in infectivity by day 7 and this reduction was significantly higher compared to either SP-AQ (p<0.001) and DP alone (p=0.002), respectively. No clinically meaningful or statistically significant drops in hemoglobin were observed during follow-up. No significant differences in AEs were observed between the SP-AQ (85%) and SP-AQ plus PQ arm (65%) (p=0.10), or between the DP (55%) and DP plus MB arm (60%) (p=0.20), excluding blue urine. One participant in SP-AQ arm reported a severe headache on day 7, but this AE was considered unlikely due to the study drug. A single dose of 0.25 mg/kg of PQ and 15 mg/kg/day x 3 days of MB, given alongside SP-AQ or DP, respectively, were safe and highly efficacious for preventing *P. falciparum* transmission in G6PD normal males. (ClinicalTrials.gov, number NCT02831023)

307

### IMPROVING PROSPECTIVE STANDARDIZATION OF MALARIA CLINICAL TRIALS DATA USED TO MONITOR TRENDS IN ANTIMALARIAL EFFICACY AND RESISTANCE: THE WORLDWIDE ANTIMALARIAL RESISTANCE NETWORK RESOURCES PLATFORM

**Clifford G. Banda**, on behalf of WWARN Toolkit project  
*WorldWide Antimalarial Resistance Network, Oxford, United Kingdom*

Standards for conducting clinical trials are fairly uniform irrespective of disease, but have with time been improved by the introduction of guidelines and resources aimed at improving the quality of design and conduct of clinical trials. It is these tools that have continuously evolved according to different diseases and are ideally aimed at simplifying this process. Malaria scientists in endemic settings have been faced with a growing availability of tools and resources. Such a wide unstandardized platform has led to heterogeneity in the quality and completeness of data from clinical trials. The lack of a simplified accessible toolkit to help set up clinical trials, in the presence of a vast source of information, has often resulted in difficulties for malaria investigators to fully utilise the available resources with ease. The WorldWide Antimalarial Resistance Network (WWARN), a collaborative initiative that generates and collates innovative resources to inform the malaria community on factors affecting antimalarial efficacy, has over the past decade developed specific resources for use in malaria studies. We will present findings from WWARN's recent scoping exercise aimed at understanding the variation in tools and resources commonly used to design and conduct malaria clinical trials in low and middle income countries (LMICs), and provide an update of an ongoing project that is aimed at establishing an open access platform of resources to malaria trialists in LMICs. This toolkit will support the standardisation of prospective data collection, aiming at optimising the usability and comparability of data.

### LOW DOSE PRIMAQUINE EFFICACY AND SAFETY: A REVIEW AND INDIVIDUAL PATIENT DATA META-ANALYSIS

**Georgina S. Humphreys**  
*IDDO/WWARN, Oxford, United Kingdom*

Primaquine is the only commercially available drug that kills mature *P. falciparum* gametocytes, the lifecycle stage responsible for the transmission of malaria from the human to the mosquito. Primaquine can cause haemolysis in individuals with glucose-6-phosphate dehydrogenase deficiency (G6PD). The severity of haemolysis is dependent on the dose of primaquine used and the level of G6PD enzyme activity. The WHO recommends the use of a single low (0.25 mg/kg) dose of primaquine (SLD PQ) with an artemisinin-based combination treatment, without prior G6PD testing, to individuals with uncomplicated malaria in countries targeting elimination and/or facing drug resistance against artemisinin-based therapies. Adoption of the WHO recommendation to use SLD PQ has been slow, particularly in African countries where there is a perceived lack of evidence for its safety and efficacy. Numerous clinical trials have been conducted, presenting a valuable dataset for further scrutiny. WWARN is undertaking an individual patient data meta-analysis of studies conducted in Africa testing SLD-PQ. Data for inclusion were identified from a review of trial registries. The objectives of the safety analysis are to quantify the reduction in haemoglobin between days 0 and 7 associated with the administration of SLD PQ and to investigate potential factors predicting these reductions. In addition, the analysis characterizes the incidence, type, and study drug relationship of reported serious adverse events and adverse events of special interest with particular attention to mortality, blood transfusion and reports of dark urine. The objectives of the efficacy analysis are to quantify the change in gametocyte prevalence and density and to assess the infectivity of gametocytes to mosquitoes as measured by membrane feeding, following administration of SLD PQ. The impact

of age, sex, and G6PD status on the efficacy and safety of PQ given at single doses  $\leq 0.75$  mg/kg will be evaluated and modelled to generate a therapeutic dose range to inform safe deployment in Africa. Results will be presented from analyses on a pool of 13 studies, representing a total of 5,017 participants.

309

### INVESTIGATION OF G6PD ENZYME ACTIVITY IN NORMAL SUBJECTS FOR ENTRY INTO TAFENOQUINE CLINICAL STUDIES

**Kim Fletcher**<sup>1</sup>, Jenny Scott<sup>2</sup>, Khadeeja Mohamed<sup>1</sup>, Donna Clover<sup>3</sup>, David Roper<sup>4</sup>, Justin Green<sup>1</sup>

<sup>1</sup>GlaxoSmithKline, Uxbridge, United Kingdom, <sup>2</sup>JMS Statistics Ltd, Pinner, United Kingdom, <sup>3</sup>GlaxoSmithKline, Research Triangle Park, NC, United States, <sup>4</sup>Northolt, United Kingdom

Tafenoquine (TQ) is an investigational 8-aminoquinoline (8-AQ) in development as a single dose treatment for the radical cure of *P. vivax* malaria. However, 8-AQs cause hemolysis in glucose-6-phosphate dehydrogenase deficient (G6PDd) individuals. Although TQ will be contra-indicated in G6PDd individuals, it is important to exclude subjects with insufficient levels of G6PD from participation in clinical studies and beyond. We undertook TAF115226, a G6PD assay validation study as part of an integrated phase IIb/III program with the primary objective to establish a centre specific median value for G6PD activity in healthy normal males, since they are truly normal or deficient unlike females. 70% of the median was used as entry criteria in TQ trials. A total of 824 subjects were screened, resulting in 808 enrolled from 19 centres across 3 continents. A blood sample was obtained to confirm eligibility criteria based upon reticulocyte count ( $\leq 2.5\%$ ) and hemoglobin level ( $\geq 120$  g/L). A second sample was analysed for G6PD quantitative activity using a commercial spectrophotometric assay (Trinity Biotech, Ireland). The secondary objective was to determine the intra-laboratory variability of the G6PD assay. To further understand intra-laboratory variability, after completion of Phase IIb, blinded samples with known G6PD activity were sent for G6PD analysis by United Kingdom National External Quality Assessment Service. A number of steps were taken to improve accuracy and precision of assay measurements and to harmonise methodology in absolute values at future sites in Phase III resulting in reduced inter-and-intra laboratory variability. Median G6PD activity did not subsequently vary greatly between centres (range 7.17-10.51 IU/gHb). Furthermore, we have determined a global median G6PD activity of 8.16 IU/gHb, (70% of which is 5.71 IU/gHb) in G6PD normal males. In conclusion, we have been able to harmonise a reproducible quantitative G6PD assay across three continents to support TQ clinical studies and set global G6PD values to assist potential future real world use of TQ.

### TRIAL COMPARING TWO ARTEMISININ BASED COMBINATION THERAPIES FOR THE TREATMENT OF PLASMODIUM FALCIPARUM MALARIA IN RWANDA

**Uwimana Aline**<sup>1</sup>, Nisingizwe Marie Paul<sup>2</sup>, Uyizeye Didier<sup>3</sup>, Mbituyumuremyi Aimable<sup>1</sup>, Penkunas James Michael<sup>2</sup>

<sup>1</sup>Rwanda Biomedical Center, Kigali, Rwanda, <sup>2</sup>Demand-Driven Evaluations for Decisions, Clinton Health Access Initiative, Kigali, Rwanda, <sup>3</sup>Maternal Child Survival Project, Kigali, Rwanda

Artemisinin-based combination therapies (ACTs) have been prescribed in Rwanda as first-line treatments for malaria since 2006. Although these drugs have contributed substantially in the battle against malaria, recent data from sub-Saharan Africa suggest that *Plasmodium falciparum* are beginning to develop resistance against some forms of ACTs. The aim of this study was to compare the effectiveness of two ACTs, Coartem and Duo-Cotexin, for the treatment of uncomplicated *P. falciparum* malaria among children in Rwanda. Five hundred thirty-six patients aged 1 to 14 years with uncomplicated *P. falciparum* malaria were randomized

to receive treatment with Coartem (n=267) or Duo-Cotexin (n=269) between September 2013 and December 2015. Chi-squared tests were used to compare rates of adequate clinical and parasitological response (ACPR) for the two ACTs at three and 28 days after initiating treatment. These preliminary data are not genotype-corrected and therefore do not differentiate between treatment failure due to recurrent parasitaemic episodes versus re-infections. ACPR at three days was recorded for 265 patients treated with Coartem and for 266 patients treated with Duo-Cotexin ( $\chi^2 = 0.194$ ;  $p = .659$ ). At 28 days, the ACPR was significantly lower for patients treated with Coartem (86.5%) compared to those treated with Duo-Cotexin. (97.4%) ( $\chi^2 = 21.03$ ;  $p < .0001$ ). In conclusion, unadjusted ACPR data indicated that Coartem and Duo-Cotexin were both highly effective at treating children diagnosed with uncomplicated malaria at three days post-treatment; ACPR was 99% for both ACTs. At 28 days, a higher proportion of children who received Duo-Cotexin remained asymptomatic and parasite free compared to those treated with Coartem. This difference between the three- and 28-day results suggests that Duo-Cotexin provides protection against reinfection for longer compared to Coartem. Genotype-corrected data will allow for more robust conclusions to be drawn. Malaria control programs must enact resistance surveillance and mitigation plans to ensure treatments remain effective.

#### MOLECULAR DETECTION METHODS TO ESTIMATE *PLASMODIUM FALCIPARUM* GAMETOCYTE CARRIAGE IN NORTHWESTERN CAMBODIA

**Panita Gosi<sup>1</sup>**, Mariusz Wojnarski<sup>1</sup>, Jessica Lin<sup>2</sup>, Michele Spring<sup>1</sup>, Catherine Berjohn<sup>3</sup>, Dustin Harrison<sup>3</sup>, Somethy Sok<sup>4</sup>, Piyaporn Saingam<sup>1</sup>, Kirakarn Kirativanich<sup>1</sup>, Chaiyaporn Chaisatit<sup>1</sup>, Mali Ittiverakul<sup>1</sup>, Nillawan Buathong<sup>1</sup>, Soklyda Chann<sup>1</sup>, Worachet Kuntawunginn<sup>1</sup>, Montri Arsanok<sup>1</sup>, Rifat Rahman<sup>2</sup>, Vireak Heang<sup>3</sup>, Nareth Kong<sup>5</sup>, Bolin Chum<sup>3</sup>, Agus Ratchmat<sup>3</sup>, Andrew Vaughn<sup>3</sup>, Satharath Prom<sup>4</sup>, Dysoley Lek<sup>5</sup>, Mark Fukuda<sup>1</sup>, Philip Smith<sup>1</sup>, David Saunders<sup>6</sup>, Chanthap Lon<sup>1</sup>

<sup>1</sup>U.S. Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Division of Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, <sup>3</sup>Naval Medical Research Unit 2, Phnom Penh, Cambodia, <sup>4</sup>Ministry of National Defense, Department of Health, Phnom Penh, Cambodia, <sup>5</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>6</sup>U.S. Army Medical Materiel Development Activity, Fort Detrick, MD, United States

Gametocyte carriage and density are critical factors in malaria transmission from human to anopheline hosts, though defining precise transmission risk remains challenging to study. While molecular methods have greatly improved understanding of submicroscopic gametocyte carriage, it is unclear how much these low-density infections contribute to clinical transmission. We compared the burden of microscopic vs. submicroscopic gametocytemia in *Plasmodium falciparum* malaria patients in a randomized, open label clinical trial of atovaquone-proguanil (AP) vs. artesunate + atovaquone-proguanil (ASAP). All patients received a 3 day course of oral therapy with their assigned regimen, as well as a single low dose of 15 mg primaquine on the first day of treatment. Light microscopy (LM) and a nested reverse transcriptase PCR assay (nRT-PCR) targeting Pfs25 RNA expression indicative of mature gametocytes (stage V) was performed on blood samples from 205 volunteers daily for 3 days, and then weekly to estimate gametocyte density and duration of carriage. At screening, *P. falciparum* gametocyte positivity was 25% (51/205) by LM compared to 28% based on pfs25 RNA detection (57/205). At enrollment, 23% of volunteers had detectable gametocytemia by LM which was reduced to 1% by day 14 in the ASAP group but only 8% in AP group ( $p = 0.03$ ). Volunteers in the AP only group had a longer duration and higher density of gametocyte carriage by LM than those receiving ASAP. Follow-up submicroscopic parasitemia assessments in follow-up remain pending at the time of submission. *P. falciparum* gametocyte carriage at baseline by LM was higher than the rate typically seen in other recent studies performed in this area (approximately 10%). While those receiving

ASAP had substantial reductions in risk as well as carriage, 8% of those receiving AP alone remained gametocytemic, even by LM despite receiving primaquine. This suggests that additional studies to more carefully evaluate the efficacy of single low dose primaquine on gametocyte reduction are warranted.

### 312

#### TOWARDS MALARIA ELIMINATION: ANALYSIS OF MALARIA SURVEILLANCE DATA AMONG UNDER FIVES IN OYO STATE, NIGERIA (2010 - 2014)

**Oyindamola B. Yusuf<sup>1</sup>**, Onoja M. Akpa<sup>1</sup>, Taiwo Abiona<sup>1</sup>, Kehinde Akinpelu<sup>1</sup>, Abass O. Gbolahan<sup>2</sup>, IkeOluwapo Ajayi<sup>1</sup>

<sup>1</sup>College of Medicine, Ibadan, Nigeria, <sup>2</sup>Planning Research and Statistics, State Ministry of Health, Oyo State, Nigeria

In Nigeria, malaria among under fives remains a major public health problem in terms of morbidity and mortality. We conducted a secondary data analysis to determine the morbidity, mortality and seasonal variations of malaria among under fives in Oyo State, Nigeria. We reviewed and analysed data obtained from the Integrated Disease Surveillance and Response System for the period; 2010 to 2014. Abstracted data were number of malaria cases among under-5 children disaggregated by Local Government Areas (LGA), year of reporting and season. Incidence, proportion of malaria morbidity and number of deaths across months per LGA were determined. Data were analysed using descriptive statistics while trigonometric regression was used to examine seasonal variations. A total of 404,216 malaria cases were reported between 2010 and 2014. The incidence of malaria among under-5 children per 100,000 population was 5,602 in 2010; 14,005 in 2011, 18,938 in 2012; 14,005 in 2013 and 7674 in 2014. The highest incidence recorded in 2012 accounted for 31.4% of the total malaria morbidity. Incidence was highest from the month of July to August 2013 with an increase from 1764 cases per 100,000 in July to 3,129 cases per 100,000 population in August. The total number of malaria deaths was 15. A sinusoidal pattern was observed in the monthly distribution with malaria peak rates in June to August and lowest rates in October to December. Seasonal index showed that the peak number of malaria cases was in the second quarter of the year. The annual trend of malaria among under-5 children in Oyo state showed a gradual rise in incidence from 2010 to 2014 in spite of the scale up of interventions. The findings also suggest that there exists a significant monthly variation in malaria rates in Oyo State, Nigeria.

### 313

#### USE OF THE IMMUNO-EPIDEMIOLOGICAL BIOMARKER OF HUMAN EXPOSURE TO ANOPHELES BITES IN THE MONITORING OF MALARIA TRANSMISSION IN (PRE) ELIMINATION AREAS

**Andre Barembaye Sagna<sup>1</sup>**, Jean Biram Sarr<sup>2</sup>, Lobna Gaayeb<sup>3</sup>, Simon Senghor<sup>2</sup>, Anne Poinsignon<sup>1</sup>, Ngor Faye<sup>4</sup>, Gilles Riveau<sup>5</sup>, Franck Remoué<sup>1</sup>

<sup>1</sup>Institut de Recherche pour le Développement, Montpellier, France, <sup>2</sup>Centre de Recherche Biomédicale Espoir Pour La Santé, Saint-Louis, Senegal, <sup>3</sup>Centre d'Infection et d'Immunité de Lille (CILL), Inserm U1019, Université Lille Nord, Lille, France, <sup>4</sup>Département de Parasitologie, Faculté des Sciences et Techniques, Université Cheikh Anta Diop de Dakar, Dakar, Senegal, <sup>5</sup>Centre de Recherche Biomédicale Espoir Pour La Santé, Lille, France

The burden of malaria is gradually declining in many parts of Africa, and is characterized by spatial and temporal variability that presents new and evolving challenges for malaria control programs. New, sensitive and large-scale monitoring indicators that measure the actual risk of malaria transmission/infection over time and space need to be prioritized in a context of elimination. Here, we present the use of an indicator based on the human IgG antibody responses to the gSG6-P1 peptide of the

Anopheles saliva as a pertinent tool for monitoring malaria transmission in very low malaria transmission areas, which can be considered as a "picture" of a malaria pre-elimination area. Two longitudinal studies that cover different seasons of malaria transmission were carried out in northern and central Senegal. At each visit, entomological, parasitological and sociological data were collected. Parasitological and clinical data were correlated with the quantitative level of IgG responses to the gSG6-P1 salivary peptide in children. In northern Senegal, the biomarker of exposure to Anopheles bites indicated that some children were exposed to Anopheles bites during the dry season that has no or very low Anopheles density. Interestingly, children with *P. falciparum* infection in the dry season had higher levels of anti-gSG6-P1 IgG responses than non-infected ones ( $P < 0.01$ ). This biomarker even seemed to discriminate non-infected children from asymptomatic carriers of the parasite ( $P < 0.01$ ). In central Senegal area, the level of specific IgG level increased significantly within the exposure season in area with very low exposure to Anopheles, determined by classical entomological methods ( $P < 0.01$ ). This increase was observed in 69% of children. The biomarker of exposure to Anopheles bites appears to be a sensitive and relevant tool for detecting a risk of *P. falciparum* transmission and assessing the level and heterogeneity of malaria transmission (hot spots). The use of such an immunological indicator may be essential for monitoring malaria and assessing the effectiveness of vector control strategies in (pre)elimination malaria areas.

### 314

#### RISK FACTOR ASSESSMENT FOR MALARIA AMONG FOREST-GOERS IN A PRE-ELIMINATION SETTING, PHU YEN PROVINCE, VIETNAM

Thuan H. Vo<sup>1</sup>, Sara E. Canavati<sup>2</sup>, Cesia E. Quintero<sup>2</sup>, Long Khanh Tran<sup>3</sup>, Colin Ohrt<sup>4</sup>, Thang Duc Ngo<sup>5</sup>, Duong Thanh Tran<sup>5</sup>, Nicholas J. Martin<sup>6</sup>

<sup>1</sup>Vysnova Partners Inc.; Faculty of Social Sciences, University of Tampere, Tampere, Finland, Ha Noi, Vietnam, <sup>2</sup>Vysnova Partners Inc.; Center for Biomedical Research, Burnet Institute, Melbourne, Australia, Ha Noi, Vietnam, <sup>3</sup>Vysnova Partners Inc.; Department of Environmental Health, Ha Noi School of Public Health, Ha Noi, Vietnam, <sup>4</sup>Vysnova Partners, Inc., Ha Noi, Vietnam, <sup>5</sup>National Institute of Malaria, Parasitology and Entomology (NIMPE), Ha Noi, Vietnam, <sup>6</sup>Naval Medical Research Center, Singapore, Singapore

Progressing from malaria control to elimination requires understanding and targeting interventions to populations at high risk. In Vietnam, forest-goers are often not reached by health services. These mobile populations are difficult to test, treat, and track via routine measures. If undiagnosed, forest goers can maintain parasite reservoirs and contribute to ongoing transmission. A case-control study was conducted to identify malaria risk factors associated with forest-goers in Dong-Xuan District, Phu Yen Province. A case was considered anyone residing in the target area with malaria, confirmed by rapid diagnostic test (RDT) or microscopy and had slept overnight in the forest. Controls were healthy neighbors of cases and negative for malaria by RDT. Participants were interviewed face-to-face using a standard questionnaire. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (CI) for risk factors after adjusting socio-demographic characteristics. In 2015, we found 81 cases of which 66.7% were positive for *Plasmodium falciparum*, 29.6% for *P. vivax*, and 3.7% had a mixed infection. The majority of cases were male (88%) with a mean age of 34.2 years. Cases were less likely to use treated nets (OR=0.3; 95% CI 0.1-0.8), but more likely to sleep in a hut without walls (OR=5.1; 95% CI 1.6-16), work after dark (OR=2.7; 95% CI 1.3-5.6), bathe in the stream after dark (OR=2.6; 95% CI 1.1-6.0) and collect water after dark (OR=2.0; 95% CI 1.1-3.8) as compared to 94 neighborhood controls. Risk factors for malaria among forest-goers in Vietnam are similar to risk factors for malaria in other areas. As Vietnam moves toward malaria elimination, targeted education and malaria prevention strategies are needed for this hard-to-reach group.

### 315

#### ESTABLISHING NEW LINE OF *PLASMODIUM FALCIPARUM* INFECTED CLONAL STRAINS IN SUPPORT OF CONTROLLED HUMAN MALARIA INFECTION STUDIES

Redemptah A. Yeda, Lorna Chebon, Charles Okudo, Agnes Cheruiyot, Hosea Akala, Ben Andagalu, Mathew Brown

Walter Reed Project, Kisumu, Kenya

Malaria causes 212 million new cases and approximately 429 000 deaths in 2015. This far, antimalaria drug resistance has developed for all classes of drugs and no licensed vaccine is in place. However, there are efforts to develop new and/or improved anti-malarial drugs and vaccines. Controlled human malaria infection (CHMI) studies have shown some correlation between natural and experimental infections. Conversely, these experimental infections and challenges are mostly done using laboratory clones obtained > 30 years ago. This limits data interpretation because experimental and natural infections might not correlate because field parasites are highly genetically and phenotypically diverse. The field displays a wide genetic diversity which currently is not represented by available laboratory strains for CHMI. Other strains including the South American 7G8 *Plasmodium falciparum* clone of Brazilian strain IMTM22 have been used in limited volunteers. This study will provide an opportunity to have a new clone with different characteristics that will offer an opportunity for protectiveness, which can lead to further optimization of the vaccine or the candidate drug. Forty field isolates from different regions in Kenya underwent limiting dilution to generate single clones. For each of the 40 parent parasites, 3-10 clones were obtained, generating a total of 212 clones. Of the 212 clones, 80 lines were confirmed to be single clones based on neutral microsatellites. After successful limiting dilution assays, the next phase of super-cloning of these for subsequent single clones is underway.

### 316

#### TIMELINESS AND COMPLETENESS OF MALARIA CASE NOTIFICATION AND RESPONSE IN ZANZIBAR, 2013-2015

Humphrey R. Mkali<sup>1</sup>, Abdul-wahid Al-mafazy<sup>2</sup>, Mohamed Ali<sup>2</sup>, Abdullah Ali<sup>2</sup>, Lynn Paxton<sup>3</sup>, Naomi Kaspar<sup>4</sup>, George Greer<sup>4</sup>, Wahida Hassan<sup>2</sup>, Joshua Yukich<sup>5</sup>, Willis Odek<sup>1</sup>

<sup>1</sup>MEASURE Evaluation, Dar Es Salaam, United Republic of Tanzania, <sup>2</sup>Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, <sup>3</sup>U.S. President's Malaria Initiative, US Centers for Disease Control and Prevention, Dar Es Salaam, United Republic of Tanzania, <sup>4</sup>U.S. President's Malaria Initiative, United States Agency for International Development, Dar Es Salaam, United Republic of Tanzania, <sup>5</sup>Center for Applied Malaria Research and Evaluation, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

Zanzibar has made significant progress toward malaria elimination over the past decade and now considered a low transmission setting with the potential to achieve elimination, but challenges still exist. Malaria surveillance plays a key role in identifying new malaria cases rapidly to reduce transmission. This study aimed to assess timeliness and completeness of malaria case notification and response. Timeliness and completeness were assessed using an evaluation tool developed by the University of California, San Francisco. Data collected from 2013 to 2015 through individual case reporting system, the Malaria Case Notification (MCN). Each District Malaria Surveillance Officer (DMSO) was equipped with tablet. Once a new case is notified, a household follow up will be guided through an active case response protocol and data transmitted through the system. Additional case data are entered into the tablet at the facility and household. Each household member is tested and new cases are treated immediately. Timeliness was defined as the number of reactive case detection (RACD) events followed up within 48 hours of notification divided by the total number of RACD events reported within 48 hours. Completeness was defined as the number of individuals screened during the RACD divided by the total number of individuals living in the

index household. In 2013, on average 91% of notified malaria cases were followed up at the household level within 48 hours of occurrence. This number improved to 93% in 2014 and 93.1% in 2015. In 2013, on average 84% of case household members was screened during RACD activities. The average proportion of household members screened in 2014 and 2015 was 84.4% and 90% respectively. The case follow up and household members' screening for malaria fall short of the national target of 100% due to heavy workload among DMSOs, incomplete patient information and technical malfunctions. Our results suggest that while the MCN system has improved malaria case reporting from health facilities, efforts should also focus on improving data quality and timely household level follow-up to eliminate malaria in Zanzibar.

## 317

### EVALUATING *PLASMODIUM* HRP2 PLASMA CONCENTRATION FOR DEVELOPMENT OF HIGHLY SENSITIVE PLASMA-SPECIFIC RAPID DIAGNOSTIC TEST IN UGANDA

**Martin Chamai<sup>1</sup>**, Kevin P. Nichols<sup>2</sup>, David Bell<sup>2</sup>, Bryan Greenhouse<sup>3</sup>, Moses Kanya<sup>1</sup>, Grant Dorsey<sup>3</sup>, John Rek<sup>1</sup>, Emmanuel Arinaitwe<sup>1</sup>, Patience Nayebare<sup>1</sup>, David J. Gasperino<sup>2</sup>, Spencer H. Garing<sup>2</sup>, Anna Astashkina<sup>2</sup>, Bernhard H. Weigl<sup>2</sup>, Joaniter Nankabirwa<sup>1</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Global Good Fund/Intellectual Ventures Laboratory, Seattle, WA, United States, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States

HRP2-specific rapid diagnostic tests (RDTs) form the primary mode for malaria diagnosis in most resource-limited settings in Africa. However, sensitivity is hampered by products of hemolysis, which increase background and limit the volume of blood which can be evaluated. This limitation is partly responsible for the inadequacy of current malaria RDTs in detecting low-density (asymptomatic) parasitemia, of importance in elimination programs. Despite the 2-decade history of targeting HRP2 for malaria diagnosis, its distribution within clinical samples has not been well defined; if sufficient concentrations of HRP2 are present in the plasma in low-density infections, larger volumes of blood could be evaluated by excluding cellular components of sample, increasing assay sensitivity. We measured by ELISA the relative distribution of HRP2 within whole blood and plasma samples from patients with asymptomatic *Plasmodium falciparum* parasitemia as determined by quantitative PCR. Our findings demonstrate that a significant proportion of the distribution of HRP2 in whole blood is found in plasma, and this proportion increases with reducing parasite density, with HRP2 concentrations approaching that of whole blood at parasite densities below 1 parasite/μL. Representative data include: 1) mean HRP2 concentration of 10<sup>1</sup> ng/mL vs. 5<sup>1</sup> ng/mL in whole blood vs. plasma at 1 parasite/μL for a ratio of ~ 2:1 whole blood HRP2: plasma HRP2; and 2) mean HRP2 concentration of 10<sup>2</sup> ng/mL vs. 1 ng/mL in whole blood vs. plasma at 10<sup>4</sup> parasite/μL for a ratio of ~ 100:1 whole blood HRP2: plasma HRP2. This finding offers scope for greatly improving the sensitivity in detecting *P. falciparum* by separating cells and plasma prior to testing, particularly in low-density infections, if the gains accrued through a plasma-only assay can be made to outweigh the loss of the intracellular component of HRP2. The authors are currently developing non-centrifuge-based methods to achieve this.

## 318

### UTILIZATION OF INSECTICIDE-TREATED BED NETS AMONG OVER-FIVES IN LAGOS, NIGERIA

**Babatunde A. Odugbemi<sup>1</sup>**, Kikelomo O. Wright<sup>2</sup>, Tinuola O. Odugbemi<sup>3</sup>, Yetunde A. Kuyinu<sup>2</sup>, Adebayo T. Onajole<sup>3</sup>, Olumuyiwa O. Odusanya<sup>2</sup>

<sup>1</sup>Lagos State University Teaching Hospital, Lagos, Nigeria, <sup>2</sup>Lagos State University College of Medicine, Lagos, Nigeria, <sup>3</sup>University of Lagos, Lagos, Nigeria

Insecticide-treated bed nets are an important preventive measure for malaria. Over-fives, although less vulnerable to malaria than under-fives, also need to be protected as they are also at risk of the disease and are an important reservoir for malaria infection. The objective of this study was to assess the utilization of insecticide treated bed nets by over-fives (5-14 years) in a rural community of Lagos, Nigeria. This was a community-based, descriptive, cross-sectional study. A multi-stage sampling technique was used to select the households included in the study. All children living in each selected household were enumerated and for each child, information was elicited on if the child slept under a bed net the previous night. Utilization among over-fives was compared with that of under-fives in the household. The data was analyzed using SPSS version 20 statistical software. A total of 773 children were listed across 242 households giving a mean of 3 children in each household. Eighty-nine (36.8%) households owned at least 1 insecticide treated bed net. Over-fives constituted a sizable proportion (68.7%) of children. A lower proportion (29.6%) of over-fives slept under nets compared to under-fives (32.6%). Over-fives were less likely to sleep under an insecticide treated bed net compared to under-fives. Utilization of insecticide treated bed nets for older children was relatively low among over-fives. This is not completely unexpected as control interventions have been targeted mainly at younger children. Efforts should be made to ensure that this sub-population is covered with the life saving intervention.

## 319

### THE USE OF ANTIBODY MEASUREMENTS TO SUPPORT MALARIA ELIMINATION ACTIVITIES IN HAITI

**Lotus L. van den Hoogen<sup>1</sup>**, Eric Rogier<sup>2</sup>, Gillian Stresman<sup>1</sup>, Thomas Druetz<sup>3</sup>, Thomas P. Eisele<sup>3</sup>, Ruth Ashton<sup>3</sup>, Alexandre Existe<sup>4</sup>, Jacques Boncy<sup>4</sup>, Michelle A. Chang<sup>2</sup>, Jean F. Lemoine<sup>2</sup>, Kevin K. Tetteh<sup>1</sup>, Chris Drakeley<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Center for Applied Malaria Research and Evaluation, Tulane University School of Public Health & Tropical Medicine, New Orleans, LA, United States, <sup>4</sup>Laboratoire National de Santé Publique, Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti, <sup>5</sup>Programme National de Contrôle de la Malaria, Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti

Measuring and monitoring malaria is challenging in elimination settings. Antimalarial antibody measurements are a unique metric as they reflect historical and recent exposure to malaria. We describe antimalarial antibody patterns by age group and malaria infection status using multi-antigenic responses in Haiti, a country considered suitable for elimination with low *Plasmodium falciparum* prevalence, parasites sensitive to chloroquine, an inefficient vector and low risk of importation. Data were collected from easy-access-groups across all ages (schools, health facilities and churches) in areas with recent or ongoing transmission in Haiti (n~6500). Participants were tested with malaria highly-sensitive (HS-) rapid diagnostic tests (RDT) and conventional RDTs, and samples were assayed for presence of IgG against twenty *P. falciparum* antigens, including markers of short and long-term exposure, using a bead-based assay. Results from the initial collections in the southern peninsula of Haiti detected fourteen positives by either RDT (3.8%; 14/368). Preliminary results suggest a greater breadth of antibody responses in those with

positive RDTs (median 17, interquartile range 10 - 20) than those with negative RDTs (3, 1 - 7),  $p < 0.001$ . Multiple linear regression showed that the breadth of antibody responses increased with age (0.1 per year,  $p < 0.001$ ) and was higher in males than females (2.4,  $p < 0.001$ ). Our results show the potential of using multi-antigenic responses to describe exposure to *P. falciparum* malaria in an elimination context and may help to determine how to incorporate antibody measurements to guide elimination activities in Haiti.

## 320

### PLASMODIUM FALCIPARUM GAMETOCYTE CARRIAGE BEFORE AND AFTER TREATMENT WITH ARTEMISININ COMBINATION THERAPIES

Raphael O. Okoth<sup>1</sup>, Benjamin H. Opot<sup>1</sup>, Gladys Chemwor<sup>1</sup>, Lorna J. Chebon<sup>1</sup>, Irene A. Onyango<sup>1</sup>, Dennis W. Juma<sup>1</sup>, Hoseah M. Akala<sup>1</sup>, Ben Andagalu<sup>1</sup>, Edwin Kamau<sup>2</sup>, Matthew Brown<sup>1</sup>

<sup>1</sup>U.S. Army Medical Research Directorate - Kenya WRP, Kisumu, Kenya,

<sup>2</sup>Walter Reed National Military Medical Center, Maryland, MD, United States

Gametocytes play a crucial role in promoting malaria transmission and its surveillance is significant in transmission-blocking interventions. Lack of an approved malaria vaccine leaves antimalarial drugs as one of the best tools towards malaria parasite control. However, with the limited investigation of gametocytocidal properties of antimalarial drugs in the current era, efforts to reduce malaria transmission and elimination could be in jeopardy. Here, we sought to determine *falciparum* gametocyte carriage before and following treatment with different artemisinin-based combination therapies. We analysed a set of 133 isolates in time-points collected from 19 participants in a study to examine *in-vivo* and *in-vitro* efficacy of artemisinin combination therapy in Kisumu County, Western Kenya in 2013. We genetically determined gametocyte carriage using reverse transcription real-time PCR to detect both early and late stage gametocytes through different time-point from Day 0 to Day 42. Subsequently, gametocyte carriage for a subset of the samples will be correlated to parasite clearance rates. Finally, comparison of malaria episodes in our isolates as either recrudescence or re-infection will be done. 63% (12/19) of the participants in this study received Artesunate-mefloquine (ASMQ) whereas 37% (7/19) received Artemisinin-lumefantrine (AL). Prior to treatment, gametocyte carriage was 100% (12/12) and 85.7% (6/7) among participants in the ASMQ and AL arms respectively. Following treatment, gametocyte carriage was significantly lowered by the two arms of treatment at Day 14 (8% (ASMQ) & 0% (AL)). Subsequent time-points reveal an increase in gametocyte carriage which stood at 33% and 28% for ASMQ and AL arms respectively. The increase in gametocyte carriage observed after Day 14 could be attributed to either parasite recrudescence or re-infection which we aim to determine in our subsequent assays. Some antimalarial drugs have been shown to instigate gametocytogenesis but so far this has not been associated with artemisinin derivatives. The results presented here are preliminary pending analysis of more isolates.

## 321

### VULNERABILITY AND ELIMINATION OF MALARIA AND LYMPHATIC FILARIASIS IN THE DOMINICAN REPUBLIC: A NATIONWIDE BATEY SURVEY

Hunter Keys<sup>1</sup>, Gregory Noland<sup>2</sup>, Madsen Beau De Rochars<sup>3</sup>, Stephen Blount<sup>2</sup>, Manuel Gonzalez<sup>4</sup>

<sup>1</sup>University of Amsterdam, Amsterdam, Netherlands, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>University of Florida, Gainesville, FL, United States, <sup>4</sup>Centro de Control de Enfermedades Tropicales (CENCET), Santo Domingo, Dominican Republic

Identifying and reaching vulnerable groups is crucial to malaria and lymphatic filariasis (LF) elimination. The island of Hispaniola, shared by Haiti and the Dominican Republic (DR), is the last malaria-endemic island

astmh.org

in the Caribbean and accounts for >90% of LF cases in the Americas. In the DR, malaria outbreaks occur in areas historically dependent on migrant labor from Haiti. A legacy of political exclusion and stigma against migrants and their descendants in the DR may exacerbate vulnerability to disease. The goals of this study were to: 1) determine malaria and LF prevalence in *bateyes*, or company towns historically home to migrant laborers; 2) characterize illness experiences, treatment-seeking, and malaria knowledge and intervention practices; and 3) measure stigma and its association with illness and access to care. In 2016, a cross-sectional survey was conducted in three major agricultural regions of the DR. 780 individuals completed household questionnaires and 1418 provided blood samples. No cases (0%) of *Plasmodium* infection were detected by RDT or microscopy. Six (6) individuals (0.4%) were positive for LF antigen. The sample population was composed of three distinct social groups: Haitian-born persons (33.1%), persons of Haitian descent (29.4%), and those without Haitian descent (37.5%). Only 10.5% were migrants (from Haiti or within the DR). Vulnerability trended strongly across social groups: recent fever, forgoing care, limited knowledge, not owning a mosquito net, and stigma were highest among Haitian-born persons, followed by persons of Haitian descent, and lastly by those without Haitian descent. Stigma was not associated with fever or care-seeking after controlling for social group, suggesting that disease-related stigma is less important than stigma due to poverty, origin, or skin color. In this low-transmission setting, social groups that have been historically marginalized remain vulnerable to disease. As elimination efforts try to improve surveillance, access-to-care, and uptake of knowledge and interventions, these findings can contribute to more holistic framings of risk and outreach strategies.

## 322

### HARNESSING DHIS2 AND MHEALTH TOOLS TO STRENGTHEN PRIVATE SECTOR MALARIA SURVEILLANCE IN THE GREATER MEKONG SUBREGION

Rebecca Potter<sup>1</sup>, Cristina Lussiana<sup>2</sup>, Stephen Poyer<sup>3</sup>

<sup>1</sup>Population Services International, Vientiane, Lao People's Democratic Republic, <sup>2</sup>Population Services International, Nairobi, Kenya, <sup>3</sup>Population Services International, Washington, DC, United States

Governments in the Greater Mekong Subregion have ambitious targets to eliminate malaria by 2030. While 20% of positive malaria cases in the region are detected through private sector channels, data from the private health care sector are not readily available in national surveillance systems. National systems are set up to store caseload data; they lack functionality to combine program data with epidemiological data to deliver effective intervention monitoring and resource allocation. Since 2016 Population Services International has used DHIS2 as an integrated health management information system for malaria in Cambodia, Laos and Myanmar. DHIS2 and its complementary Android-based mHealth tools have been leveraged to monitor data on caseload, quality of care and stock management at private providers and worksites with the goal of integrating data with national surveillance systems. Data is available to program officers in actionable DHIS2 dashboards. Our experience has produced valuable lessons learned: 1) mobile tools reduce the lag time between data collection and actionable data analysis by 50%, 2) data triangulation on malaria caseload, quality of care and stock management in DHIS2 can be used to prioritize program interventions, and 3) complex DHIS2 configuration and custom coding of mHealth tools highlight the challenges of creating standardized tools for malaria surveillance that can be adapted across countries, and the flexibility of DHIS2 to synthesize data from multiple sources into automated dashboards. Our results provide actionable evidence for transforming surveillance into a core intervention: 1) appropriately designed mHealth tools increase accuracy and timeliness of surveillance data, 2) integration of multiple data sources in a single system like DHIS2 enables triangulation of data for supporting decision making processes and effective resource allocation, and 3) there is a need for standardized and customizable malaria surveillance tools. Learnings

should inform the development of standard system design principles for strengthening national surveillance systems to become fit for malaria elimination.

### 323

#### EXPANDING THE ANTIMALARIAL PIPELINE: THE DISCOVERY OF PYRIMIDINEDIONES, A NEW SERIES TO CURE AND BLOCK MALARIA TRANSMISSION

**Mariola Gordo-Lopez**

*GlaxoSmithKline, Madrid, Spain*

In 2010 GSK published the Tres Cantos antimalarial set (TCAMS) which comprises over 13,533 hits derived from whole cell screening of 2M compounds from the GSK corporate collection against *Plasmodium falciparum*. [1] Identification of a new class of anti-malarial agents that possess dual activity and are able to inhibit the asexual blood-stage as well as to block transmission was initiated in our group. [2] Quinazolindione series was identified as a very promising family presenting submicromolar potency against both schizonts and gametocytes, efficacy in an *in vivo* model and a promising physico-chemical profile. Quinazolindiones were found to target *Plasmodium falciparum* ATP4. During lead optimization program a novel related series containing a pyrimidinedione core was found. Medicinal chemistry efforts lead to an advanced molecule with an *in vivo* potency comparable with assets in clinical development, a physico-chemical profile compatible with an oral administration and no cross-resistance with current antimalarials in the market. The strategy to optimize this novel scaffold as well as the profiling of the most advanced compound will be disclosed in this communication.

### 324

#### A CASE FOR INVESTMENT IN THAILAND'S MALARIA ELIMINATION PROGRAM: A COST-BENEFIT ANALYSIS STUDY

**Prayuth Sudathip**<sup>1</sup>, Suravadee Kitchakorn<sup>2</sup>, Darin Kongkasuriyachai<sup>3</sup>, Surasak Sawang<sup>3</sup>, David Sintasath<sup>4</sup>, Jeffrey Sine<sup>3</sup>

<sup>1</sup>Bureau for Vector Borne Diseases Department of Disease Control, Ministry of Public Health, Bangkok, Thailand, <sup>2</sup>Bureau for Vector Borne Diseases Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, <sup>3</sup>RTI International, Bangkok, Thailand, <sup>4</sup>U.S. Agency for International Development/Regional Development Mission for Asia, Bangkok, Thailand

In the past decade Thailand had remarkable success in reducing malaria morbidity and mortality. The country's new National Malaria Elimination Strategy (2017–2026) supports a programmatic shift from malaria control to elimination. To advocate for full programmatic funding for the national malaria elimination operational plan, a cost-benefit analysis was conducted to monetize the value of expected benefits from malaria financing to total investment costs over a 10-year investment period (2017–2026). The overall analysis spanned 20 years (2017–2036) to ensure that projections extend into a post-elimination timeframe, during which the malaria program can fully be integrated into the national health system. Analyses assessed two investment scenarios: the first assumed full financing for all elimination interventions included in the 2017–2026 National Malaria Elimination Strategy, while the second assumed no commitment to fully fund elimination interventions. Programmatic data collected from decades of Thai malaria prevention and control efforts were used to project the impact of differing levels of financing in different sectors for malaria elimination; historical epidemiological trend data were used to model potential worse-case resurgence. The analyses estimated that approximately 3,000,000 malaria cases could be averted if all elimination interventions were supported. The financial support required to acquire and maintain malaria-free status would be substantially lower than the projected amount lost in a no investment scenario. Our analyses also projected that it would cost 2.9 billion Thai Baht to eliminate malaria by 2024, and stay malaria-free for 20 years, whereas a no or

limited investment scenario would ultimately result in a cost of 19.4 billion Thai Baht to the national health system. The economic impact of inadequate funding for malaria would be felt at both micro and macro levels; for example, households would experience a decline in income and productivity, and tourism would be affected due to changes in perceptions of Thailand as an attractive travel destination.

### 325

#### AUTODISSEMINATION OF PYRIPROXYFEN FOR CONTROLLING SELF-SUSTAINING CAPTIVE POPULATION OF ANOPHELES ARABIENSIS

**Dickson W. Lwetoijera**<sup>1</sup>, Fredros Okumu<sup>1</sup>, Thomas Mascari<sup>2</sup>, Mercy Opiyo<sup>1</sup>, Samson Kiware<sup>1</sup>, Gregor Devine<sup>3</sup>, Philip McCall<sup>4</sup>, Silas Majambere<sup>5</sup>

<sup>1</sup>Ifakara Health Institute, Ifakara, Morogoro, United Republic of Tanzania, <sup>2</sup>SC Johnson, Racine, WI, United States, <sup>3</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>Integrated Vector Control Consortium, Liverpool, United Kingdom

Autodissemination of pyriproxyfen (PPF), i.e. co-opting adult female malaria vectors to transfer PPF, a synthetic juvenile hormone to their aquatic habitats has proven effective in controlling malaria vectors, *Anopheles arabiensis* under semi-field settings. This approach has potential to amplify treatment coverage of mosquito's habitats that are hard to locate via conventional larviciding. This study demonstrated the impact of PPF intervention in crashing self-sustaining population of *An. arabiensis* under semi-field conditions in rural Tanzania. A stable population of *An. arabiensis* mosquitoes were established inside a semi-field systems from laboratory reared larvae. The larvae were fed on natural occurring food in the 12 habitats installed in each study chamber, and the emerging adults were fed on cattle. Before and after introducing clay pots treated with PPF, population was monitored using emergence traps and supervised HLC. All collected mosquitoes were counted, identified and released back into the chamber. At 38th generations, four treated clay pots with 0.2gAI PPF were introduced in the treatment chamber and its impact on established colonies was monitored in parallel with untreated chamber. In conclusion, the emergence between control and treatment chamber were similar with average catch of 14 and 13 mosquitoes respectively before PPF treatment. The numbers of adult *An. arabiensis* mosquitoes emerging from the aquatic habitats declined gradually reaching zero on week 11 post treatment, which was done only once. Similarly, numbers of mosquitoes attempting to bite HLC volunteers inside treatment chambers also decreased gradually, reaching zero at week 14. The numbers of adults in the control chamber however continued to rise. These results form the basis for designing autodissemination field trial to control wild population of *An.arabiensis*.

### 326

#### SPATIO-TEMPORAL DETERMINANTS OF SUCCESS AND FAILURE OF ANTI-MALARIA INTERVENTIONS IN HIGH ENDEMIC AREAS: A MODEL BASED RE-EXAMINATION OF THE GARKI PROJECT

**Prashanth Selvaraj**, Edward Wenger, Jaline Gerardin  
*Institute for Disease Modeling, Bellevue, WA, United States*

While malaria control efforts have greatly reduced its burden over the past two decades in Africa, the Sahel remains one of the most challenging regions for effective control where transmission is mostly confined to the short rainy season. The Garki project provides a comprehensive dataset of the entomology and parasitology of malaria as well as the effect of a combination of intervention techniques on the control of the disease in the Sahel between 1969 and 1975. While vector populations were greatly suppressed, parasitological prevalence rates didn't respond as well to intervention, and even rebounded to higher baseline levels after control

interventions were halted. Incomplete coverage, migration of people and vectors into, out of and within the region, and poorly administered and ineffective intervention techniques are among the most cited reasons for failure. More importantly, a lack of understanding of the spatial dynamics of malaria in the region seems to be one of the strongest underlying themes for failure. Here, we take advantage of the demographic, entomological, and parasitological data from the project, as well as weather and more recent topographical data from the region to construct a spatiotemporal map of vector and human populations within the region to infer migration trends, and to study the spatiotemporal efficacy of interventions that were carried out. With the use of a mathematical model of malarial and intervention dynamics that has been calibrated to match vector and parasitological dynamics observed in the Garki region, the map helps answer more nuanced questions in connected areas on both seasonal and multi-year timescales about permanent vector habitats and vector migration impact effect sizes of vector control interventions, and the magnitude of human mobility on sustaining gains from effective interventions. Additionally, it aids in the selection of intervention combinations and deployment strategies, and highlights potential failure modes and vulnerabilities in elimination operations.

### 327

#### THE IMPACT OF MASS DRUG ADMINISTRATION ON SUBMICROSCOPIC MALARIA INFECTION: A PILOT STUDY ON NGodhe ISLAND IN LAKE VICTORIA, KENYA

**Wataru Kagaya**<sup>1</sup>, Chim Chan<sup>2</sup>, Jesse Gitaka<sup>3</sup>, James Kongere<sup>4</sup>, Zulkarnain Md Idris<sup>5</sup>, Changsheng Deng<sup>5</sup>, Guoqiao Li<sup>5</sup>, Lucy Okell<sup>6</sup>, Akira Kaneko<sup>7</sup>

<sup>1</sup>Osaka City University, Osaka, Japan, <sup>2</sup>Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Mount Kenya University, Thika, Kenya, <sup>4</sup>Nairobi Research Station, Nagasaki University, Nairobi, Kenya, <sup>5</sup>Guangzhou University of Chinese Medicine, Guangzhou, China, <sup>6</sup>Imperial College London, London, United Kingdom, <sup>7</sup>Karolinska Institutet/Osaka City University, Stockholm, Sweden

The 2017 WHO framework for malaria elimination calls for all endemic countries to work towards the ultimate goal of elimination, regardless of their current malaria burden. In this context mass drug administration (MDA) has received renewed interest, however evidence supporting its use in moderate to high transmission settings is missing. Our study site, Lake Victoria basin in Kenya, has heterogeneity in malaria prevalence, high in main land and moderate to low on islands, with high percentage of asymptomatic and submicroscopic infection. On Ngodhe, one of the small islands, we conducted two rounds of MDA with a 35-day interval in January-March 2016, before the start of the long rainy season. Pre-intervention parasite rates were 3% by microscopy and 10% by PCR. Artequick (artemisinin and piperazine) and a single low-dose primaquine were administered under direct supervision to cover all islanders (N~500) by house and school visits. Compliance, defined as the proportion of population that completed treatment, was 91% and 87% for rounds 1 and 2, respectively. No serious adverse events were observed, except for a few minor side effects such as dizziness (N=7) and abdominal pain or cramp (N=6). MDA succeeded in suppressing malaria prevalence to 0% by microscopy and to 2% by PCR. However, malaria prevalence rebounded to 9% by PCR two months after MDA. This post-MDA resurgence was largely owed to imported cases (62%), of which 80% were submicroscopic. The beach survey on Ngodhe Island conducted prior to MDA which characterized the arrival on the beach suggested returning residents, such as students and church visitors, as a possible risk group of parasite importation rather than visitors from outside. Our findings indicate that while MDA provided short-term suppression of malaria prevalence to undetectable level by microscopy, measures against imported cases from surrounding endemic areas and local vector mosquitoes are crucial for sustainable malaria elimination. This is the first report showing the effect of MDA on submicroscopic infections and provides detailed information for the future expansion of MDA in moderate to high transmission settings.

#### EVALUATING THE EFFECTIVENESS AND FEASIBILITY OF REACTIVE TARGETED PARASITE ELIMINATION VS. REACTIVE CASE DETECTION, WITH AND WITHOUT REACTIVE VECTOR CONTROL, AS A COMMUNITY LEVEL INTERVENTION IN RESPONSE TO CONFIRMED, PASSIVELY IDENTIFIED MALARIA CASES IN ZAMBEZI REGION, NAMIBIA: PRELIMINARY RESULTS FROM A CLUSTER RANDOMIZED CONTROLLED TRIAL

**Henry M. Ntuku**<sup>1</sup>, Kathryn Roberts<sup>1</sup>, Patrick McCreesh<sup>2</sup>, Jenny Smith<sup>1</sup>, Petrina Uusiku<sup>3</sup>, Stark Katokele<sup>3</sup>, Ronnie Bock<sup>4</sup>, Cara Smith Gueye<sup>1</sup>, Lisa Prach<sup>1</sup>, Oliver Medzihradsky<sup>5</sup>, Hugh Sturrock<sup>1</sup>, Mi-Suk Kang Dufour<sup>6</sup>, Bryan Greenhouse<sup>6</sup>, Adam Bennett<sup>1</sup>, Immo Kleinschmidt<sup>7</sup>, Davis Mumbengegwi<sup>4</sup>, Michelle S. Hsiang<sup>2</sup>

<sup>1</sup>Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Department of Pediatrics, University of Texas Southwestern, Dallas, TX, United States, <sup>3</sup>Namibia Ministry of Health and Social Services, Windhoek, Namibia, <sup>4</sup>Multidisciplinary Research Centre, University of Namibia, Windhoek, Namibia, <sup>5</sup>Department of Pediatrics, University of California San Francisco Benioff Children's Hospital, San Francisco, CA, United States, <sup>6</sup>Division of HIV, Infectious Diseases, and Global Medicine, Department of Medicine, University of California San Francisco, San Francisco, CA, United States, <sup>7</sup>School of Pathology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, Johannesburg, South Africa

Reactive case detection (RACD), testing and treating individuals around passively detected cases is a strategy commonly used to reduce or interrupt malaria transmission though its effectiveness may be limited by low sensitivity of RDT for low density infections and logistical challenges. Other interventions such as reactive-Targeted Parasite Elimination (TPE), a form of presumptive treatment, or reactive vector control (RAVC) with Actellic CS may be feasible and more effective. We are conducting a cluster randomized controlled trial with 2x2 factorial design to compare TPE vs. RACD, and RAVC vs. no RAVC in the surrounding 500m of index cases. The primary outcome is cumulative malaria incidence. Secondary outcomes include seroprevalence and infection prevalence both to be measured in a post-intervention cross-sectional survey, intervention coverage, safety, acceptability, adherence, and cost-effectiveness. As of April 3rd 30, 30, 26 and 45 index case interventions have been conducted in the TPE, TPE+RAVC, RACD and RACD+RAVC arms respectively. Among TPE intervention events (N=2018), 83% of individuals received the intervention, 5% were ineligible, 11% were missed, and 1% refused. In RACD intervention events (N=2269), 92% of individuals were tested (3% RDT positive), 18% were missed, and 0.3% refused. Reasons for TPE ineligibility include use of contraindicated medication (39%), allergy to the study drug (18%), and age under 6 months old (21%). Eight adverse events have been reported, none was serious. 60 RAVC interventions have been conducted, in which 739 sleeping structures in 446 households were sprayed. This resulted in 87% of households achieving the minimum target of 85% sleeping structures sprayed (N=446). The intervention has been safe and acceptable. Responding to cases during an ongoing regional outbreak has been a challenge. Data collection and analysis on primary and secondary outcomes are in progress and will be shared.

### SHORT-TERM CHANGES IN ANAEMIA AND MALARIA PREVALENCE IN CHILDREN UNDER-FIVE YEARS DURING ONE YEAR OF REPEATED CROSS-SECTIONAL SURVEYS IN RURAL MALAWI

**Alinune N. Kabaghe**<sup>1</sup>, Michael G. Chipeta<sup>2</sup>, Dianne J. Terlouw<sup>3</sup>, Martin P. Grobusch<sup>4</sup>, Michèle van Vugt<sup>4</sup>, Robert S. McCann<sup>5</sup>, Willem Takken<sup>5</sup>, Kamija S. Phiri<sup>1</sup>

<sup>1</sup>College of Medicine, Blantyre, Malawi, <sup>2</sup>University of Lancaster, Lancaster, United Kingdom, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>4</sup>Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands, <sup>5</sup>Wageningen University and Research, Wageningen, Netherlands

Pre-school-aged children bear the highest proportion of anaemia, mainly in Africa. In stable transmission areas, malaria accounts for the highest proportion of anaemia. Haematocrit as an indicator of anaemia is easy to measure in the field and has been proposed as an additional and sensitive indicator of changes in malaria prevalence in communities. We report short-term temporal variations of malaria, and anaemia prevalence in children in rural Malawi. We repeated five cross-sectional surveys over one year in rural communities in Chikwawa district, Malawi. Different households were sampled per survey; all children, 6-59 months, in the household were tested for malaria parasitaemia and haemoglobin levels using rapid diagnostic tests (mRDT), and Hemocue 301, respectively. Anthropometric measurements and sociodemographic details were also recorded. Adult mosquitoes sampling, using odour-baited traps, was done in two-thirds of households; ambient temperature and rainfall were recorded using a HOBO® weather station. A total of 894 children were included from 1568 households. Overall, mRDT-positive and anaemia (Hb < 11g/dL) prevalence were 33.8 and 58.7%, respectively. Relative risk of anaemia in mRDT-positive children was 1.45 (95% CI: 1.22, 1.72 p <0.001). Mean haemoglobin was higher in parasitaemic [9.9 g/dl (95% CI: 9.7, 10.1)] than children recently treated for malaria [9.2 g/dl (95% CI: 8.7, 9.7)] p=0.0106. Temporal anaemia and parasite prevalence varied differently. Mean z-scores for weight-for-age, weight-for-height and height-for-age were all less than 0. In conclusion, anaemia prevalence is an unsuitable indicator for short-term changes in malaria prevalence, although malaria is an important factor in anaemia. High burden of undiagnosed malaria, anaemia and malnutrition in rural communities requires integrated control strategies.

### DIFFERENCES IN TREATMENT-SEEKING RATE FOR MALARIA-ATTRIBUTABLE FEVER AND NON-MALARIAL FEBRILE ILLNESS IN AFRICAN CHILDREN

**Ursula Dalrymple**, Ewan Cameron, Samir Bhatt, Daniel J. Weiss, Peter W. Gething

University of Oxford, Oxford, United Kingdom

The rate at which febrile individuals seek care is a critical determinant of health system effectiveness for febrile illnesses including malaria. For malaria, understanding the fraction of cases that seek care is also crucial for correctly interpreting data on reported cases as part of burden estimation processes. Currently, data on care seeking for fever is used as a proxy for malaria, but this ignores that treatment seeking rates are likely to differ for malaria versus non-malaria febrile causes. Here, we use household survey data on fever positivity rate and treatment seeking behaviour in African children with a multinomial modelling approach to generate treatment-seeking rates for malaria-attributable and non-malarial febrile illness. The national estimates of treatment-seeking rate for malaria-attributable fever presented here can be used to generate more accurate predictions of the burden of *Plasmodium falciparum* malaria in Africa.

### THE IMPACT OF URBANIZATION AND POPULATION DENSITY ON CHILDHOOD *PLASMODIUM FALCIPARUM* PARASITE PREVALENCE RATES IN AFRICA

**Caroline W. Kabaria**<sup>1</sup>, Marius Gilbert<sup>2</sup>, Abdisalan M. Noor<sup>3</sup>, Robert W. Snow<sup>3</sup>, Catherine Linard<sup>2</sup>

<sup>1</sup>African Population and Health Research Centre, Nairobi, Kenya, <sup>2</sup>Spatial Epidemiology Laboratory, Université Libre de Bruxelles, Brussels, Belgium, <sup>3</sup>Spatial Health Metrics Group, Kenya Medical Research Institute/Wellcome Trust Research Programme, Nairobi, Kenya

Although malaria has been traditionally regarded as less of a problem in urban areas compared to neighbouring rural areas, the risk of malaria infection continues to exist in densely populated, urban areas of Africa. Despite the recognition that urbanization influences the epidemiology of malaria, there is little consensus on urbanization relevant for malaria parasite mapping. Previous studies examining the relationship between urbanization and malaria transmission have used products defining urbanization at global/continental scales developed in the early 2000s, that overestimate actual urban extents while the population estimates are over 15 years old and estimated at administrative unit level. This study sought to discriminate an urbanization definition that is most relevant for malaria parasite mapping using individual level malaria infection data obtained from nationally representative household-based surveys. Boosted regression tree (BRT) modelling was used to determine the effect of urbanization on malaria transmission and if this effect varied with urbanization definition. In addition, the most recent high resolution population distribution data was used to determine whether population density had significant effect on malaria parasite prevalence and if so, could population density replace urban classifications in modelling malaria transmission patterns. The risk of malaria infection was shown to decline from rural areas through peri-urban settlements to urban central areas. Population density was found to be an important predictor of malaria risk. The final boosted regression trees (BRT) model with urbanization and population density gave the best model fit compared to the models with urbanization only. Given the challenges in uniformly classifying urban areas across different countries, population density provides a reliable metric to adjust for the patterns of malaria risk in densely populated urban areas. Future malaria risk models can, therefore, be improved by including both population density and urbanization which have both been shown to have significant impact on malaria risk in this study.

### HIGH MALARIA TRANSMISSION INTENSITY IN A REMOTE PERUVIAN AMAZON VILLAGE: THE ACHILLES HEEL OF MALARIA ELIMINATION

**Raul Chuquiyaury**<sup>1</sup>, Marta Moreno<sup>2</sup>, Huw Davies<sup>3</sup>, Dionicia Gamboa<sup>4</sup>, Daniel Wong<sup>4</sup>, Sonia Torres<sup>5</sup>, Roberson Ramirez<sup>4</sup>, Douglas M. Molina<sup>6</sup>, Xiaowu Liang<sup>6</sup>, Daniel E. Neafsey<sup>7</sup>, Jan E. Conn<sup>8</sup>, Philip Felgner<sup>9</sup>, Alejandro Llanos-Cuentas<sup>4</sup>, Joseph M. Vinetz<sup>2</sup>

<sup>1</sup>Instituto Nacional de Salud del Peru, Iquitos, Peru, <sup>2</sup>University of California San Diego, San Diego, CA, United States, <sup>3</sup>University of California Irvine, Irvine, CA, United States, <sup>4</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>5</sup>Dirección Regional de Salud de Loreto, Iquitos, Peru, <sup>6</sup>Antigen Discovery Inc., Irvine, CA, United States, <sup>7</sup>Malaria Research Group, Broad Institute of Massachusetts Institute of Technology and Harvard University, Cambridge, MA, United States, <sup>8</sup>Wadsworth Center, New York State Department of Health, Albany, NY, United States, <sup>9</sup>Division of Infectious Diseases, Department of Medicine, University of California Irvine, Irvine, CA, United States

A prospective cohort study was conducted in a remote rural village in the Peruvian Amazon named Santa Emilia. Microscopy and a species-specific qPCR assay were used to assess the presence of parasitemia. Plasmas were

obtained for genome-scale protein microarray analysis using a combined Pf500/Pv500 chip containing a down-selected list of the 500 most seroreactive antigens. Considering qPCR as gold standard, microscopy was able to detect 40.2% and 22% of any Pv and Pf infection, respectively. Considering passive surveillance, microscopy detected 48.1% and 54.5% of the Pv and Pf cases, respectively; while considering active surveillance, microscopy was detected 38.3% and 19.6% of the Pv and Pf cases, respectively. This study was able to detect *Plasmodium* infections through very active surveillance and qPCR that otherwise would go undetected under current surveillance and diagnostic tools. Protein microarray analysis was performed during high and low (September) malaria seasons: 324 samples for protein microarray analysis. The top 200 most seroreactive antigens were selected for comparison. Seroreactivity increased with age, and in response to documented malaria infection, but was lower in September than in March for all age groups. While there was a gradual increase in seroreactivity associated with age, the differential seroreactivity between high and low transmission season was greatest in youngest and this difference decreased with age. Monitoring changes in transmission intensity and identification of malaria foci is mandatory for best intervention efforts. Without better strategies accounting for remote underserved villages, asymptomatic, and submicroscopic infections, and better diagnostic and surveillance tools, it will not be sufficient to decrease the continued malaria transmission due to a high reservoir of infection impeding progress towards attaining a sustainable control and even to progress into elimination of malaria transmission. Elimination efforts will most likely need a more sensitive assay such as a q-PCR or other field deployable molecular based assay.

### 333

#### FINE SCALE MAPPING OF MALARIA INFECTION CLUSTERS BY USING ROUTINELY COLLECTED HEALTH FACILITY DATA IN URBAN DAR ES SALAAM, TANZANIA

**Yeromin P. Mlacha**<sup>1</sup>, Prosper P. Chaki<sup>1</sup>, Alpha D. Malishee<sup>1</sup>, Victoria M. Mwakalinga<sup>1</sup>, Nicodem J. Govella<sup>1</sup>, Alex J. Limwagu<sup>1</sup>, John M. Paliga<sup>1</sup>, Daniel F. Msellemu<sup>1</sup>, Zawadi D. Mageni<sup>1</sup>, Dianne J. Terlouw<sup>2</sup>, Gerry F. Killen<sup>1</sup>, Stefan Dongus<sup>3</sup>

<sup>1</sup>Ifakara Health Institute, Environmental Health and Ecological Sciences Department, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom, <sup>3</sup>Swiss Tropical and Public Health Institute, Department of Epidemiology and Public Health, Basel, Switzerland

This study investigated whether passively collected routine health facility data can be used for mapping spatial heterogeneities in malaria transmission at the level of local government housing cluster administrative units in Dar es Salaam, Tanzania. From June 2012 to Jan 2013, residential locations of patients tested for malaria at a public health facility were traced based on their local leaders' names and georeferencing the point locations of these leaders' houses. Geographic information systems (GIS) were used to visualize the spatial distribution of malaria infection rates. Spatial scan statistics were deployed to detect spatial clustering of high infection rates. Among 2,407 patients tested for malaria, 46.6% (1,121) could be traced to their 411 different residential housing clusters. One small spatially aggregated cluster of neighborhoods with high prevalence was identified. While the home residence housing cluster leader was unambiguously identified for 73.8% (240/325) of malaria-positive patients, only 42.3% (881/2,082) of those with negative test results were successfully traced. It was concluded that recording simple points of reference during routine health facility visits can be used for mapping malaria infection burden on very fine geographic scales, potentially offering a feasible approach to rational geographic targeting of malaria control interventions. However, in order to tap the full potential of this approach, it would be necessary to optimize patient tracing success and eliminate biases by blinding personnel to test results.

### 334

#### EVALUATION OF MALARIA URBAN RISK BY USING AN IMMUNO EPIDEMIOLOGICAL BIOMARKER OF HUMAN EXPOSURE TO ANOPHELES BITES

**Dipomin F. Traore**<sup>1</sup>, André B. Sagna<sup>1</sup>, Akré M. Adja<sup>2</sup>, Dounin D. Zoh<sup>3</sup>, Kouassi N. Lingue<sup>3</sup>, Issa Coulibaly<sup>3</sup>, Bertin N. Tchikoi<sup>3</sup>, Serge B. Assi<sup>3</sup>, Anne Poissonon<sup>1</sup>, Mamadou Dagnogo<sup>4</sup>, Franck Remoue Remoue<sup>1</sup>

<sup>1</sup>Institut de Recherche pour le Développement, Montpellier, France, <sup>2</sup>Université Félix Houphouët Boigny, Abidjan, Côte D'Ivoire, <sup>3</sup>Institut Pierre Richet, Bouaké, Côte D'Ivoire, <sup>4</sup>Université Nangui Abrogoua, Abidjan, Côte D'Ivoire

Urban malaria represents an underestimated serious health concern in African countries. This study aims to evaluate the risk of malaria transmission in urban area by evaluating the level of human exposure to *Anopheles* bites using an *Anopheles* salivary biomarker (gSG6-P1 peptide). Two multidisciplinary cross-sectional studies were undertaken in five sites of Bouaké city (three urban districts and two surrounding villages, used as control; Côte d'Ivoire) during the rainy season and the dry season. Blood samples were obtained from children aged 6 months to 14 years-old for immunological tests. The level of anti-gSG6-P1 IgG antibodies was significantly higher in rainy season compared to dry season ( $p < 0.0001$ ) in the urban sites. Interestingly, children with the highest anti-gSG6-P1 IgG responses in rainy season were infected by *P. falciparum*. Surprisingly, no difference of anti-gSG6-P1 IgG level was observed between urban and rural areas, whatever the season. The *Anopheles* salivary biomarker is a suitable tool for accurately assessing the risk of malaria transmission in urban areas. It shows that urban population could be as highly exposed to *Anopheles* bites as children living in rural area. This study highlights, highlighting the high risk of malaria transmission in African urban settings.

### 335

#### PREVALENCE OF MIXED-SPECIES MALARIA INFECTIONS IN UGANDA

**Victor Asua**<sup>1</sup>, Stephen Tukwasibwe<sup>1</sup>, Melissa Conrad<sup>2</sup>, Andrew Walakira<sup>1</sup>, Joaniter Nankabirwa<sup>1</sup>, Levicatus Mugenyi<sup>1</sup>, James San<sup>1</sup>, Emmanuel Arinaitwe<sup>1</sup>, Adoke Yeka<sup>1</sup>, Moses R. Kanya<sup>1</sup>, Samuel L. Nsobya<sup>1</sup>, Philip J. Rosenthal<sup>2</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Department of Medicine, University of California, San Francisco, CA, United States

In sub-Saharan Africa malaria is principally caused by *Plasmodium falciparum*, and contributions of other plasmodial species are uncertain. As part of a drug resistance surveillance program, we collected blood samples from 50 children aged 6 months - 10 years presenting with malaria at each of 10 diverse sites around Uganda in 2016. Children presenting with fever were diagnosed by clinic personnel by either Giemsa-stained blood smear (176 subjects) or HRP-2-based rapid diagnostic test (RDT; 323 subjects). To assess infecting species, DNA was extracted from blood spots with Chelex, species-specific primers were used to amplify 18S ribosomal RNA genes, and species were discriminated based on amplicon size using electrophoresis. Of 499 studied samples, 474 (95.0%) demonstrated plasmodial infection. *P. falciparum* was identified in 472 samples, *P. malariae* in 22, *P. ovale* in 15, and *P. vivax* in 4. 435 were pure *P. falciparum*, 2 did not contain *P. falciparum* (one pure *P. malariae*, one *P. malariae/P. vivax*), and the remainder were mixed infections including *P. falciparum*. Non-falciparum species varied geographically, with 0-13 samples demonstrating *P. malariae*, 0-9 demonstrating *P. ovale*, and 0-2 demonstrating *P. vivax* at different sites. No pure non-falciparum infections were identified in RDT-positive samples. Results were complicated by use of two different diagnostic tests, but 41/474 (8.7%) samples with molecular identification of plasmodial infection included non-falciparum infections. Five of 10 study sites underwent regular indoor residual spraying of insecticide (IRS) programs either from 2010-14 or from 2014 to

the present, with consequent decreases in malaria prevalence. Stratifying samples based on history of IRS at collection sites, mixed species or non-falciparum infections were seen in 27/189 (14.8%) samples from IRS sites and 13/285 (4.6%) samples from non-IRS sites ( $p = 0.0013$ ). Our results demonstrate that non-falciparum malaria infection is common in Uganda and they suggest that decreased prevalence of malaria due to IRS may be associated with increased relative prevalence of non-falciparum infections.

#### TOWARD DECREASING MALARIA TRANSMISSION IN RURAL COMMUNITIES IN MADAGASCAR RESULT FROM A BASELINE SURVEY FOR A CLUSTER RANDOMIZED TRIAL IN MANANJARY DISTRICT

**Rila Ratovoson**<sup>1</sup>, Jemima Ravelonarivo<sup>1</sup>, Matthew Mc Laughlin<sup>2</sup>, Mamina Herizo<sup>3</sup>, Ghislain Ravelonjatovo<sup>3</sup>, Laurie Ohlstein<sup>3</sup>, Voahangy Razanakotomalala<sup>4</sup>, Jocelyn Razafindrakoto<sup>5</sup>, Laurent Kapesa<sup>5</sup>, Vanessa Dickey<sup>3</sup>, Milijaona Randrianarivojosia<sup>1</sup>, Patrice Piola<sup>6</sup>, Laurence Baril<sup>1</sup>

<sup>1</sup>Institut Pasteur de Madagascar, Antananarivo, Madagascar, <sup>2</sup>Peace Corps Volunteers, Washington, DC, United States, <sup>3</sup>Peace Corps Volunteers, Antananarivo, Madagascar, <sup>4</sup>National Malaria Control Program, Ministry of Public Health, Antananarivo, Madagascar, <sup>5</sup>U.S. Agency for International Development Madagascar, Health Population and Nutrition Office (HPN), Antananarivo, Madagascar, <sup>6</sup>Institut Pasteur du Cambodge, Phnom Penh, Cambodia

Community-based interventions may facilitate reducing malaria infection in high-transmission areas. In Madagascar, febrile patients are routinely screened by malaria rapid diagnostic test (RDT) and patients with positive RDTs are treated by artemisin-based combination therapy (ACT). We initiated a cluster-randomized study to compare active malaria infection case detection by RDT and routine case management. We randomized 22 villages (11 per arm) that met the study criteria. During December 2016–February 2017, we conducted a baseline survey in which all study participants were screened by RDT and completed a questionnaire including demographic and fever ( $>37.5^{\circ}\text{C}$ ) information. Following survey completion, community health workers in intervention villages began fortnightly household visits to perform RDT on participants and treat those with a positive RDT using ACT; visits will continue for eight months. The study was designed to detect a decrease in the RDT-positivity from 10% to 5% in the intervention arm. We present the results of the baseline survey. A total of 27,076 participants (95.2% of the eligible population) from 6,340 households were screened: 14,263 (56.2%) and 12,868 (47.4%) in the intervention and control villages, respectively. Participants in the intervention group were older (mean age = 21.1 years CI95% [20.8–21.4] vs 19.5 years CI95% [19.2–19.8];  $p = >10^{-5}$ ) and more likely to be female (55% CI95% [54.1% - 55.7%] vs 53% CI95% [51.7% - 53.5%];  $p = 10^{-3}$ ) than those in the control arm. A total of 2,016 (7.4% CI95% [7.1% - 7.7%]) participants with positive RDTs were treated by ACT; 1141 (8.0%) in intervention and 875 (6.8%) in control villages ( $p < 10^{-3}$ ); 287 (28.5% CI95% [25.7% - 31.3%]) were febrile. There was no difference in RDT positivity among febrile participants ( $n=1005$ ) between intervention and control villages ( $p=0.6$ ). Participation in the baseline survey was nearly 100% suggesting a strong interest among villagers to identify interventions to reduce malaria. Over 85% of RDT-positive participants were afebrile indicating that asymptomatic malaria infection may be an important contributor to parasite transmission.

#### THE WEEKLY ASSOCIATIONS BETWEEN CLIMATIC FACTORS AND *PLASMODIUM VIVAX* AND *P. FALCIPARUM* MALARIA IN CHINA 2005-2014

**Samuel H. Hundessa**<sup>1</sup>, Gail Williams<sup>2</sup>, Shanshan Li<sup>2</sup>, Jinpeng Guo<sup>3</sup>, Wenyi Zhang<sup>3</sup>, Yuming Guo<sup>4</sup>

<sup>1</sup>University of Queensland, Brisbane, Australia, <sup>2</sup>The University of Queensland, Brisbane, Australia, <sup>3</sup>Academy of Military Medical Science, Beijing, China, <sup>4</sup>Monash University, Melbourne, Australia

Malaria, a deadly parasitic disease of tropics is transmitted by Anopheles mosquitoes, which is sensitive to the environment. While many environmental factors influence malaria transmission, the role of climatic factors is crucial. However, there are few in-depth epidemiological studies on the effect of short-term variation of climatic factors on transmission of *Plasmodium vivax* and *P. falciparum* malaria in China. **Methods:** We modelled the national malaria data collected between 2005 and 2014 to examine the effect climatic factors, including weekly temperature, rainfall, relative humidity, hours of sunshine, wind speed and atmospheric pressure on *P. vivax* and *P. falciparum* malaria. We combined the distributed Lag Non-linear Model (DLNM) with quasi-Poisson regression. DLNM is a modelling framework which simultaneously describe exposure-response relationship with a potential of non-linearity and delayed effects. The significant effect of temperature first appeared at 2 week lag and consistently increased up to 10 weeks for *P. vivax*, and at a lag of 3-7 week for *P. falciparum*. The effect of relative humidity was significant at a lag of 1-6 week with the highest effect at 3 weeks for *P. vivax*, and at a lag of 5-6 week for *P. falciparum*. Rainfall was significantly associated with *P. vivax* at a lag of 3-7 week, but no association with *P. falciparum* at any lag. The significant effect of hours of sunshine was observed at an early lag of 0-5 weeks for *P. vivax*, and at 1-3 weeks for *P. falciparum*. Wind speed and atmospheric pressure were also associated with *P. vivax* at a lag of 0-7 week, and 5-8 week, respectively. In conclusion, overall climatic factors play a crucial role in transmission of *P. vivax* and *P. falciparum* malaria in China, at different lag periods. The delayed time estimated overlaps with the time required for development of mosquitoes and *Plasmodium*. Health authorities can use this as an evidence base for malaria early-warning system.

### 338

#### SEROSURVEILLANCE TO INFORM MALARIA ELIMINATION PROGRAMS IN SOUTHEAST MYANMAR

**Katherine O'Flaherty**<sup>1</sup>, Win Han Oo<sup>2</sup>, Ricardo Ataide<sup>1</sup>, Kyaw Zayar Aung<sup>2</sup>, Myat Mon Thein<sup>2</sup>, Sophie Zaloumis<sup>3</sup>, Naanki Parischa<sup>1</sup>, Aung Thi<sup>4</sup>, Wai Yan Min Htay<sup>2</sup>, Aung Paing Soe<sup>2</sup>, Paul Agius<sup>1</sup>, Freya Fowkes<sup>1</sup>

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>Burnet Institute Myanmar, Yangon, Myanmar, <sup>3</sup>Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia, <sup>4</sup>Department of Public Health, Myanmar Ministry of Health, Nay Pyi Taw, Myanmar

Malaria prevalence in Myanmar has declined dramatically over the past decade. *Plasmodium* cases, however, are still highest in Myanmar compared to other countries within the Greater Mekong region. The presence of artemisinin-resistant *P. falciparum* in the region prompted the WHO and National Malaria Control Programs to strive for malaria elimination by 2030. Accurate surveillance of *Plasmodium* transmission in Myanmar is therefore imperative to achieving this goal. The objective of this study was to explore the use of serosurveillance to identify populations at high risk of infection in Southeast Myanmar, and to longitudinally observe changes in the immune response to *Plasmodium* spp. in a region that has recently achieved a marked decline in malaria transmission ( $> 90\%$  reduction in disease incidence between 2005 - 2014 in some provinces). We performed a longitudinal study of 114 villages across South-East Myanmar from April 2015 to June 2016. Rapid diagnostic tests and ELISAs were performed on  $> 15,000$  participant dried blood

spots to determine current infection and exposure levels. Prevalence of *Plasmodium* spp. infection by RDT was extremely low (<1%), however, serology revealed high levels of IgG specific for *P. falciparum* schizont extract. IgG seroprevalence was greater in high-risk populations (migrant workers (41%) and forest dwellers (50 %) compared to village residents (36%). IgG responses were sustained (>40% seroprevalence) throughout the 14 months of the study, peaking in high malaria transmission season each year despite the extremely low incidence of infection. Through measuring serological responses to malaria, we have revealed that antibodies are being maintained in a pre-elimination setting despite recent large reductions in malaria incidence. Antibodies were also capable of identifying high-risk populations, and the maintenance of high IgG levels over time may be indicative of an undetected parasite reservoir in the region. Combined with molecular diagnosis, serosurveillance could prove to be an important surveillance tool to inform the ambitious target of malaria elimination by 2030 in the Greater Mekong region.

### 339

#### ADAPTIVE GEOSTATISTICAL SAMPLING ENABLES EFFICIENT IDENTIFICATION OF MALARIA HOTSPOTS IN REPEATED CROSS-SECTIONAL SURVEYS IN RURAL MALAWI

**Michael G. Chipeta**<sup>1</sup>, Alinune N. Kabaghe<sup>2</sup>, Robert S. McCann<sup>3</sup>, Kamija S. Phiri<sup>4</sup>, Michèle Van Vugt<sup>2</sup>, Willem Takken<sup>3</sup>, Dianne J. Terlouw<sup>5</sup>

<sup>1</sup>Lancaster University, Lancaster, United Kingdom, <sup>2</sup>Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands, <sup>3</sup>Laboratory of Entomology, Wageningen University and Research, Wageningen, Netherlands, <sup>4</sup>College of Medicine, University of Malawi, Blantyre, Malawi, <sup>5</sup>Malawi Liverpool Wellcome Trust, Blantyre, Malawi

Adaptive geostatistical designs (AGD) allow collection of geostatistical data over time to depend on information obtained from previous information to optimise data collection towards the analysis objective. AGDs offer exciting opportunities as spatial mapping is increasingly used in health programmes, particularly in poor resource settings where uniformly precise mapping may be unrealistically costly but identification of critical areas could help optimise use of available interventions and resources. Two AGD constructions are *singleton* and *batch* sampling. In singleton sampling, locations  $x_i$  are chosen sequentially and at each stage,  $x_{k+1}$  depends on data obtained at locations  $x_1, \dots, x_k$ . In batch sampling, locations are chosen in batches of size  $b > 1$ , allowing a new batch,  $x(kb+1), \dots, x(kb+b)$ , to depend on data obtained at locations  $x_1, \dots, x_{kb}$ . We assessed the efficiency of specific batch AGD relative to their singleton adaptive and non-adaptive counterparts using simulations. We used batch AGD guided sampling design to determine malaria prevalence in children aged 6-59 months in the communities living around Majete Wildlife Reserve in Chikwawa district, Malawi using a rolling cross-sectional survey with five sampling rounds over a 1 year period, and fitted a geostatistical model to predict malaria prevalence in the area. Simulations suggested a significant gain in predictive efficiency using AGD approaches. While batch adaptive sampling proved (necessarily) less efficient statistically than singleton sampling, the suggested loss in efficiency was limited, and is more realistic in most practical settings because of the associated field-work costs. Among 876 recruited children from 1,377 households over a 12-month period, malaria prevalence was associated with age, socio-economic status and ownership of insecticide-treated mosquito nets, as well as additional spatially structured stochastic component. Predictive maps identified *hotspots* defined as a predicted malaria prevalence over 30%. AGD sampling approaches can be implemented successfully in surveys, and support fine scale mapping to guide intervention strategies.

#### INSECTICIDE-TREATED NETS AND PROTECTION AGAINST INSECTICIDE-RESISTANT MALARIA VECTORS IN WESTERN KENYA

**Eric Ochomo**<sup>1</sup>, Mercy Chahilu<sup>1</sup>, Jackie Cook<sup>2</sup>, Teresa Kinyari<sup>3</sup>, Nabie M. Bayoh<sup>4</sup>, Philippa West<sup>2</sup>, Luna Kamau<sup>5</sup>, Aggrey Osangale<sup>1</sup>, Maurice Ombok<sup>1</sup>, Kiambo Njagi<sup>6</sup>, Evan Mathenge<sup>5</sup>, Lawrence Muthami<sup>5</sup>, Krishanthi Subramaniam<sup>7</sup>, Tessa Knox<sup>8</sup>, Abraham Mnavaza<sup>8</sup>, Martin J. Donnelly<sup>7</sup>, Immo Kleinshmidt<sup>2</sup>, Charles Mbogo<sup>9</sup>

<sup>1</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>University of Nairobi, Nairobi, Kenya, <sup>4</sup>Centers for Disease Control-Kenya, Nairobi, Kenya, <sup>5</sup>Kenya Medical Research Institute, Nairobi, Kenya, <sup>6</sup>National Malaria Control Program, Ministry of Health, Nairobi, Kenya, <sup>7</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>8</sup>World Health Organization, Geneva, Switzerland, <sup>9</sup>Kenya Medical Research Institute, Kilifi, Kenya

Insecticide resistance might reduce the efficacy of malaria vector control. In 2013 and 2014, malaria vectors from 50 villages, of varying pyrethroid resistance, in western Kenya were assayed annually for resistance to deltamethrin. Long-lasting insecticide-treated nets (LLIN) were distributed to households at universal coverage. Children were recruited into cohorts, cleared of malaria-causing parasites, and tested fortnightly for reinfection. The infection incidence rates in our 2 cohorts were 2.2 (95% CI 1.9–2.5) infections/person-year and 2.8 (95% CI 2.5–3.0) infections/person-year. LLIN users had lower infection rates than non-LLIN users in both low resistance (rate ratio 0.61, 95% CI 0.42–0.88) and high resistance (rate ratio 0.55, 95% CI 0.35–0.87) villages ( $p = 0.63$ ). The association between insecticide resistance and infection incidence was not significant ( $p = 0.99$ ). Although the incidence of infection was high among net users, LLINs provided significant protection ( $p = 0.01$ ) against infection with malaria parasite regardless of vector insecticide resistance.

### 341

#### INCREASING PREVALENCE OF *PLASMODIUM OVALE* DURING IMPLEMENTATION OF ARTEMISININ COMBINATION THERAPY IN KENYA

**Hoseah M. Akala**<sup>1</sup>, Luise A. Ingasia<sup>1</sup>, Kenneth K. Mitei<sup>1</sup>, Dennis W. Juma<sup>1</sup>, Lorna J. Chebon<sup>1</sup>, Agnes C. Cheruiyot<sup>1</sup>, Redemptah A. Yeda<sup>1</sup>, Charles O. Okello<sup>1</sup>, David P. Kateete<sup>2</sup>, Ben M. Andagalu<sup>1</sup>, Edwin Kamau<sup>1</sup>, Matthew L. Brown<sup>1</sup>

<sup>1</sup>Kenya Medical Research Institute/U.S. Army Medical Research Unit - Kenya, Kisumu, Kenya, <sup>2</sup>College of Health Sciences, Makerere University, Kampala, Uganda, Kampala, Uganda

The predominant malaria species in Kenya, *Plasmodium falciparum* (Pf), occurs sympatrically with *P. ovale curtisi* (Poc), *P. ovale wallikeri* (Pow), and *P. malariae* (Pm). Though studies show that diagnosis of non-*falciparum* strains using microscopy or rapid diagnostic kits is inconclusive, accurate information on temporal malaria species prevalence across Kenya, determined using molecular methods is rare. 1294 surveillance study samples collected from five locations across Kenya, between 2013 and 2015, were diagnosed for malaria and *Plasmodium* species composition using polymerase chain reaction (PCR) method. Out of the 1294 samples, there were 80% ( $n=1044$ ) positive for malaria comprising 689 (66%) Pf mono-infections, 38 (4%) single non-*falciparum* species mono-infections while 355 (34%) were multiple species infections. 1% ( $n=6$ ) comprised four species namely Pf, Poc, Pow and Pm while the remainder comprised either two or three species. Pf/Poc was the most prevalent two species infection 64% ( $n=228$ ) followed by Pf/Pm 8% ( $n=27$ ) whereas Pf/Pow was at 4% ( $n=16$ ). Notably, the prevalence of non-*falciparum* malaria rose to 53% from 33% with Pf/Poc increasing by two-fold to 22% in 2015 from 13% in 2013. The study reveals significant high burden of the non-

*falciparum* parasite species than previously reported in periodic malaria indicator surveys. Similar studies need to be undertaken in other regions of Africa, across longer periods in order to provide evidence to improve intervention strategies.

### 342

#### BIOMARKER DEVELOPMENT AND PRIORITIZATION OF GLOBALLY SUITABLE *PLASMODIUM FALCIPARUM* MEROZOITE-STAGE VACCINE CANDIDATE ANTIGENS

**Ikhlaiq Hussain Kana**

*Department for Congenital Disorders, Statens Serum Institut, and Centre for Medical Parasitology at Department of International Health, Immunology and Microbiology, University of Copenhagen, Copenhagen, Denmark*

*Plasmodium* species antigens accessible at the time of merozoite release are likely targets of biologically functional antibodies. Since, most of the immune-epidemiological correlates of protection against leading malaria vaccine candidates have been developed in African settings, it is important for these parameters to be tested in other malaria endemic settings in order to assess the global suitability of these vaccine candidates. Naturally acquired Immunoglobulin G (IgG) antibodies against fifteen *Plasmodium falciparum* merozoite-stage vaccine candidate antigens were analyzed in the plasma of Indian residents from a longitudinal cohort. The same antibodies were quantified and their functionality was assessed using flow cytometry-based immunofluorescence and opsonic phagocytosis of merozoites (OP) assays, respectively. Antibody levels against each antigen were significantly associated with protection against clinical malaria in a univariate analysis. However, only merozoite surface protein 1 (MSP-1), glutamate-rich protein (GLURP) and Pf12 antibody responses remained significantly associated with protective immunity, when all antibody measures together with age (confounder) were fitted in a single multivariate model. Opsonic phagocytosis mechanism previously shown to be protective in Africa showed a similar effect (hazard ratio [HR] = 0.36; 95% confidence interval [CI] = .19–.70; P = .002) in this study. Of the antimerozoite-specific antibodies, only IgG3 was significantly associated with both OP and protection (HR = 0.50; 95% CI = .27–.91; P = .02). These findings support previous studies in Africa that found OP of merozoites and IgG3 to be associated with protection against malaria and further shows MSP1, GLURP and Pf12 are strong vaccine candidates, thus giving further impetus for the prioritization and development of globally successful vaccines.

#### 343 BURDEN OF ASYMPTOMATIC MALARIA IN CHILDREN 2-17 YEARS FROM MALARIA ENDEMIC REGIONS OF KENYA

**Francis M. Mutuku**<sup>1</sup>, Bryson Alberto Ndenga<sup>2</sup>, Charles Ng'ang'a<sup>3</sup>, Said Lipi<sup>3</sup>, Loice Lwamba<sup>2</sup>, Francis Denga<sup>2</sup>, John Vulule<sup>4</sup>, Dunstan Mukoko<sup>5</sup>, Desiree LaBeaud<sup>6</sup>

<sup>1</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>2</sup>KEMRI, Kisumu, Kenya, <sup>3</sup>VBDCU, Msambweni, Kwale County, Kenya, <sup>4</sup>KEMRI, Busia, Kenya, <sup>5</sup>VBDCU, Nairobi, Kenya, <sup>6</sup>Stanford University, California, CA, United States

In the last decade, preschool and school age children have been identified among the groups at the highest risk of asymptomatic malaria irrespective of the transmission setting. Persistence of parasitaemia in this age group negatively impacts on their health and school performance. We estimated the burden of asymptomatic malaria in children aged 2-17 years residing in four sites located in the two malaria endemic regions of Kenya (western and coastal Kenya). The four sites comprised a rural and urban site each

in coast and western Kenya. Four cross-sectional surveys were conducted during a 24 month period (2014-2016). The average interval between the initial survey and the first follow up, the first follow up and second follow up, and the second and third follow up was 8.8, 7.3, and 5.9 months, respectively. A total of 3446 apparently healthy children were recruited in the study. Parasitaemia presence was determined by microscopy, and all parasitized children were treated with artemether-lumefantrine. On average the prevalence of asymptomatic malaria was 18.5% and

ranged between 14% and 19% during the four cross-sectional surveys. Asymptomatic malaria was significantly higher among boys (P=<0.01), in the western region (P=<0.0001), and in the rural sites (P=<0.0001). Of the 1391 children who participated in all four surveys, 41% (572) were parasitized at least once: 14 had asymptomatic malaria during all four surveys, 77 during three surveys and 170 during two surveys. In the children who participated in all four surveys, asymptomatic malaria increased with increasing age from 15.8% during the initial survey to 22.1% during the fourth survey. These results show the burden of asymptomatic malaria in Kenyan children is substantial; therefore, as malaria control programs move towards elimination, both symptomatic and asymptomatic cases must be targeted.

### 344

#### A FRAMEWORK FOR MALARIA SURVEILLANCE IN TANZANIA

**Sumaiyya G. Thawer**<sup>1</sup>, Anna Wilfred Mahendeka<sup>2</sup>, Ikupa Akim<sup>1</sup>, Ally Mohamed<sup>2</sup>, Renata Mandike<sup>2</sup>, Frank Chacky<sup>2</sup>, Jeremiah Ngondi<sup>3</sup>, Fabrizio Molteni<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Dar-es-Salaam, United Republic of Tanzania, <sup>2</sup>National Malaria Control Programme, Ministry of Health, Community Development, Gender, Elderly and Children, Dar-es-Salaam, United Republic of Tanzania, <sup>3</sup>Research Triangular Institute International, Dar-es-Salaam, United Republic of Tanzania

Tanzania is entering a new era of malaria control, with a realistic possibility of reducing malaria prevalence to less than 1% by 2020. As prevalence across the country continues to decline and heterogeneity in transmission increases, a timely and accurate surveillance system will become increasingly important in the transition from control to potential elimination. A suitable malaria surveillance-response system must include key indicators relating to the disease that can be used to trigger additional investigations and direct targeted response action. Due to the changing epidemiology, particularly the increasing heterogeneity of malaria, the surveillance approaches of the past may no longer be adequate. The complex context of malaria transmission which includes the parasite, the vector, the human host, as well as multiple factors related to the environment and health system context, requires a systematic and operationally feasible surveillance approach. For this purpose, an innovative malaria surveillance framework proposed for Tanzania will be presented. It contains three major elements: (i) disease surveillance, (ii) programmatic surveillance, and (iii) transmission surveillance. Data will be collected through several complementary approaches, such as: passive routine disease reporting, routine programmatic data reporting, parasitological and entomological surveys, and climatic surveillance. This surveillance framework is based on three key pillars and is strictly linked to targeted response action. Each element of the framework will generate an alert if an abnormal situation or disruption of equilibrium occurs. Malaria disease surveillance, one of the major elements of the framework, can indicate possible outbreaks. In such cases, a full investigation is initiated, and appropriate responses are implemented. The system will explore the role of various drivers of trends in malaria incidence. It will offer useful information to guide decision-makers in outbreak detection, risk assessment, investments for malaria control and intervention choice.

### 345

#### SUBMICROSCOPIC MALARIA INFECTIONS IN PREGNANT WOMEN FROM SIX DEPARTMENTS IN HAITI

**Maha A. Elbadry**

*University of Florida, Gainesville, FL, United States*

Hispaniola is the last island in the Caribbean where malaria transmission remains endemic, with the majority of infections occurring in Haiti. Though pregnant women are a high-risk group for malaria infections, surveillance or intervention programs targeting pregnant women in Haiti are rudimentary at best. Thus, data on malaria in pregnancy (MIP) in Haiti are sparse and risk factors for infection have not previously been

investigated. A cross-sectional study was conducted among pregnant women in six departments of Haiti. After obtaining informed consent, whole blood samples and demographic surveys were collected to investigate malaria prevalence, anemia and socio-behavioral risk factors for infection, respectively. A total of 311 pregnant women were screened for *Plasmodium falciparum* infection using a rapid diagnostic test (RDT), microscopy, and a novel, quantitative reverse-transcriptase polymerase chain reaction methodology (qRT-PCR). Overall, 1.2% (4/311) of pregnant women were positive for malaria infection by both microscopy and RDT. However, using the qRT-PCR, 16.4% (51/311) of pregnant women were positive. The prevalence of malaria infection varied with geographic locations ranging between 0% to 46.4%. Additionally, 53% of pregnant women had some form of anemia; however no significant association was found between anemia and submicroscopic malaria infection. The socio-behavioral risk factors identified to be protective of malaria infection were marital status ( $P < 0.05$ ) and travel within one month prior to screening ( $P < 0.05$ ). In conclusion, this study is the first to document the high prevalence of submicroscopic malaria infections among pregnant women in Haiti and identify social and behavioral risk factors for disease transmission.

### 346

#### FREQUENCIES OF *PLASMODIUM FALCIPARUM* GENE MUTATIONS IN ASYMPTOMATIC INFECTIONS: EVALUATING MALARIA TRANSMISSION REDUCTION IN AN ENDEMIC AREA

**Titilope M. Dokunmu**, David Oladejo, Cynthia Adjekukor, Oladeji Olanrewaju, Olubanke Ogunlana  
Covenant University, Ota, Nigeria

Malaria transmission in endemic areas remains high due to a circulating reservoir of asymptomatic parasites which are usually undetected or untreated. Determining inherent traits in asymptomatic parasite isolates transmitted from one infection to another accounts for parasite susceptibilities to drugs when infection is treated. Artemisinin-based combination treatments have proved to be effective in clearing resistant parasites but only from treated infections. This study determined malaria transmission rates in asymptomatic individuals and frequencies of multidrug resistance 1 gene mutation in *Plasmodium falciparum* (*Pfmdr1*) isolates from a pool of asymptomatic and symptomatic infections from two communities in southwest Nigeria, using RFLP-PCR specific for mutation detection at codon 86 and 1246. Of the 165 healthy children and adults evaluated, 39 (23.6%) had asymptomatic parasitemia and similar proportion of isolates harbored the mutant 86Y and 1246Y alleles compared to isolates from symptomatic infections with higher parasitemia. Strategies to reduce transmission of infection from asymptomatic carriers is limited in endemic areas due to drug resistance, because most parasites harbor mutant genes. Other strategies to reduce asymptomatic infection are needed such as mass drug administration should be advocated to eliminate the reservoir of malaria infection.

### 347

#### SEROLOGICALLY DEFINED HETEROGENEITY IN *PLASMODIUM VIVAX* MALARIA TRANSMISSION USING A NOVEL CHIMERIC RECOMBINANT PROTEIN IN RIVERINE VILLAGES OF THE PERUVIAN AMAZON

**Jose Luis Barboza**<sup>1</sup>, Diamantina Moreno<sup>2</sup>, Anthony Torres<sup>3</sup>, Juan Contreras-Mancilla<sup>4</sup>, Dionicia Gamboa<sup>5</sup>, Hugo Rodriguez<sup>6</sup>, Joseph Vintez<sup>7</sup>, Irene S. Soares<sup>8</sup>, Niko Speybroeck<sup>9</sup>, Angel Rosas-Aguirre<sup>10</sup>  
<sup>1</sup>Instituto de Medicina Tropical "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional de la Amazonia Peruana, Loreto, Peru, Iquitos, Peru, <sup>3</sup>Universidad Nacional de la Amazonia Peruana, Loreto, Peru; <sup>4</sup>Research Institute of Health and Society (IRSS), Université Catholique de Louvain, Brussels, Belgium, Iquitos, Peru, <sup>5</sup>Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>Instituto

de Medicina Tropical "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru; <sup>7</sup>Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru; <sup>8</sup>Laborato, Lima, Peru, <sup>9</sup>Instituto de Medicina Tropical "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru; <sup>10</sup>Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, Lima, Peru, <sup>11</sup>Universidad Nacional de la Amazonia Peruana, Loreto, Iquitos, Peru, <sup>12</sup>Division of Infectious Diseases, Department of Medicine, University of California San Diego School of Medicine, La Jolla, CA, United States, <sup>13</sup>Departamento de Análises Clínicas e Toxicológicas, Faculdade de Ciências Farmacêuticas, Universidade de São Paulo, Sao Paulo, Brazil, <sup>14</sup>Research Institute of Health and Society (IRSS), Université Catholique de Louvain, Brussels, Belgium, <sup>15</sup>Instituto de Medicina Tropical "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru; <sup>16</sup>Research Institute of Health and Society (IRSS), Université Catholique de Louvain, Brussels, Belgium

Serological tools for stratifying malaria risk are needed to guide and monitor control efforts. Here, we determined the antibody levels and seroconversion rates to a *Plasmodium vivax* novel chimeric recombinant protein in individuals living in riverine villages of Mazan district in the Peruvian Amazon, and related those serological measures with malaria incidence rates. Population-based surveys were conducted in June 2015, collecting dried blood spot samples from participants in Gamitanacocha (GC), Libertad (LI) and Primero Enero (PE) (villages along Mazan River), and Urco Miraño (UM) (Napo River). ELISA was used to detect IgG responses to a chimeric protein containing the Apical Membrane Antigen 1 (AMA-1) and the Merozoite Surface Protein 1-19 (MSP1-19), expressed in a *Pichia pastoris* culture system. Age-specific seroprevalence (sPrev) was analysed using a reversible catalytic model that estimated seroconversion rates (SCR,  $\lambda$ ). *P. vivax* incidence rates (IR) were obtained from the malaria surveillance data (i.e. passive and active case detection). Due to the proximity between LI and PE, joint sPrev, SCR, and IR estimates were calculated for these villages. Local Moran's I with an empirical Bayesian rate method was used to detect spatial clusters of serology-positive individuals. A total 812 individuals participated in surveys (87.0% of census population): GC (90 individuals; 89.1% of population), LI-PE (391; 83.5%), UM (331; 90.9%). sPrev and SCR by village were: GC (sPrev= 26.7%;  $\lambda = 0.038$  [95%CI: 0.022-0.057]), LI-PE (38.9%; 0.066 [95%CI: 0.054, 0.080]), and UM (30.8%; 0.048 [95%CI: 0.038-0.060]). SCR estimations strongly correlated with *cP. vivax* malaria incidence rates in 2015 ( $r = 0.99$ ,  $p = 0.02$ ): GC (IR=0.346 confirmed cases/person/year), LI-PE (0.423), UM (0.371). The spatial analysis identified well-defined clusters of *P. vivax* seropositive individuals in all villages. In conclusion, antibody responses to the chimeric protein PvAMA1-PvMSP1-19 has efficiently and accurately characterized the heterogeneity in *P. vivax* malaria transmission at micro-geographical level in the study area.

### 348

#### ASSOCIATION OF MALARIA AND ANEMIA WITH MALNUTRITION IN CHILDREN FOLLOWING A SEASONAL MALARIA CHEMOPREVENTION PROGRAM IN A RURAL AREA OF BURKINA FASO

**Yves D. Compaore**<sup>1</sup>, Issaka Zongo<sup>1</sup>, Sharon E. Cox<sup>2</sup>, Frederick Nikiema<sup>1</sup>, Halidou Tinto<sup>1</sup>, Daniel Chandramohan<sup>3</sup>, Jean Bosco Ouedraogo<sup>1</sup>, Brian Greenwood<sup>3</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso, <sup>2</sup>School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The burden of undernutrition and malaria or undernutrition and anemia co-morbidities is unwell known in West Africa. A pre-implementation study on seasonal malaria chemoprevention (SMC) plus azithromycin in Burkina Faso, provided suitable circumstances to deepen knowledge on the association between malnutrition and both malaria and anemia

in under five year old children. Three consecutive annual cross-sectional studies were conducted in a rural area in the health district of Houunde a month after the end of SMC drugs administration from 2014 to 2016. At each survey anthropometric measurements (weight, height) were realized. Clinical malaria, diagnosed using RDTs and blood smears, and hemoglobin concentration were recorded from 2000 randomly selected children. Data were pooled and malnutrition status were determined and classified as stunting (HAZ<-2), underweight (WAZ<-2) and wasting (WHZ<-2), parameters which were also categorized into moderate (-3< Z score < -2) and severe (Z score <-3). Bivariate analysis and multivariate logistic regression were used to estimate the relationship between undernutrition and clinical malaria as well as anemia. The overall prevalence of undernutrition remained high (60.39%). Underweight was the most prevalent type of undernutrition (52.44%) representing 31.67% of the study population. The prevalence of clinical malaria and moderate anemia were low among children, 4.6% and 3.0% respectively. There was no significant association between undernutrition overall and clinical malaria ( $p>0.05$ ). In addition, there was no evidence of association between severe and moderate aspects of undernutrition and clinical malaria ( $p>0.05$ ). Severely underweighted and moderately stunted children were more at risk of moderate anemia  $aOR=2.85$  (95%CI (1.79; 4.54),  $p<0.001$  and  $aOR=3.37$  (95% CI (2.30; 4.95),  $p<0.001$ . After three consecutive annual SMC drugs administrations, clinical malaria and moderate anemia were rare. No association was found between clinical malaria and undernutrition. Moderate anemia was associated with severe underweight and moderate stunting.

#### SPANNING THE ELIMINATION SPECTRUM: EVALUATING THE MALARIA SURVEILLANCE SYSTEM IN MOZAMBIQUE

**Baltazar Candrinho**<sup>1</sup>, Inessa Ba<sup>2</sup>, Ana Rita Chico<sup>2</sup>, James Colborn<sup>2</sup>, E. Mosse<sup>3</sup>, Elsa Nhantumbo<sup>1</sup>, Guidion Mathe<sup>1</sup>, Nyasatu Ntshalintshali<sup>4</sup>, Deepa Pindola<sup>4</sup>, Zeferino Saugene<sup>3</sup>

<sup>1</sup>Mozambique National Malaria Control Program, Maputo, Mozambique, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>SAUDIGITOS, Digital Innovation Services, Maputo, Mozambique, <sup>4</sup>Clinton Health Access initiative, Boston, MA, United States

Malaria transmission throughout Mozambique is extremely variable, with prevalence ranging as high as 68% in the north, to below 3% in the south. As a result, the country is simultaneously pursuing elimination in the south of the country and addressing high burden areas in the north. Reorienting the routine health information system (HIS) for malaria such that it addresses the needs of the different transmission levels is a challenge, yet one that is vital to eventually achieving elimination. In order to help the country tailor their system to the unique epidemiology of the country, an assessment of the passive surveillance systems in the country was conducted. This assessment consisted of both qualitative and quantitative methods involving documentation review, key stakeholder interviews from the central to the community level, and data analysis to evaluate the performance of the system including key indicators such as timeliness and completeness of the system. Although the study found high acceptability at health facilities in the country, a number of weaknesses were also identified. Specifically, a lack of standardized reporting tools was found at the health facility and district levels, along with poor integration of other malaria indicators into the HIS. Availability and timeliness were also low, due to poor internet connectivity and long delays (> 3 months) in reporting, respectively. Data quality issues, including accuracy and completeness, were also found to be major gaps, as was poor data use and the lack of a case-based system to support elimination efforts. In response to this assessment, it was recommended that the country ensure the use of a standardized set of collection tools and that the availability of these tools is guaranteed, and that the IT infrastructure and data management capacity of districts and provinces be strengthened to improve data quality. Finally, in order to support ongoing elimination efforts in the country, it was recommended that the program

create a case-based surveillance system with timely case notification, investigation and classification, active case detection when required, and foci investigation.

### 350

#### WHAT PROPORTION OF *PLASMODIUM FALCIPARUM* AND *P. VIVAX* MALARIA INFECTIONS ARE IN MOSQUITOES?

**Amanda Ross**<sup>1</sup>, Jo Lines<sup>2</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

To design effective malaria intervention strategies, it would be beneficial to know where the infections are before and after implementation. The proportion of infections that are in mosquitoes is generally not known. In some sites, some component measures are available such as the number of infections detected in humans using high-resolution genotyping or the number of infected host-seeking mosquitoes per person. However, frequently all the component measures together are not available, are restricted to younger age-groups or suffer from low detectability. We use simulation models to predict the proportion of *Plasmodium falciparum* and *P. vivax* infections that are in mosquitoes. We use OpenMalaria, an established comprehensive simulator of *P. falciparum* malaria epidemiology and control which has been extensively fitted to data, and a recent simulation model of *P. vivax*, validating where possible. We predict the proportions by transmission intensity, seasonality, mosquito species, and after the introduction of long-lasting insecticidal nets (LLIN) and mass drug administration (MDA). The predicted proportion of *P. falciparum* infections that are in mosquitoes is approximately 60% for a setting with 200 infectious bites per person per year (EIR) and decreases to a floor of roughly 15% when the EIR is lower than 10. A similar pattern is predicted for *P. vivax*, but the floor is slightly lower since humans harbour a higher number of infections. The patterns stem from saturation in the number of infections in humans at high transmission intensities, chiefly driven by the relationship between EIR and the force of infection. A mass campaign with LLIN covering 80% of the population decreases the proportion of infections in mosquitoes with the proportion slowly recovering. For *P. falciparum*, MDA with a blood-stage drug effective for one month and 80% coverage resulted in a sharp spike in the proportion of infections in mosquitoes in the following five-day time-step. For *P. vivax*, MDA with liver-stage or both blood- and liver-stage drugs produced a sharp spike. Predictions of where the infections are may inform the timing and combination of interventions.

### 351

#### TEMPORAL TRENDS OF PARASITEMIA IN UNCOMPLICATED *FALCIPARUM* INFECTIONS IN KENYA DURING THE PERIOD OF ARTEMISININ COMBINATION THERAPY USE IN 2008 TO 2016

**Agnes Cheruiyot**, Redemptah Yeda, Charles Okudo, Dennis Juma, Benard Andagalu, Matthew Brown, Hosea Akala

Kenya Medical Research Institute/United States Army Medical Research Directorate-Kenya (USAMRD-K), Walter Reed Project, Kisumu, Kenya

*Plasmodium falciparum* parasitemia correlates with clinical features and prognosis, aiding clinical decision-making depending on malaria endemicity. World health organization identifies high parasitemia as an indicator of severe malaria infection. However there is little information about periodical malaria parasitemia in symptomatic individuals with uncomplicated malaria during the deployment of artemisinin combination therapy (ACTs) in Kenya. This study determined parasitemia in uncomplicated *falciparum* infections in Kenya during the era of ACTs. Malaria parasitemia prevalence in 6 different demographical regions in Kenya was assessed between 2008 and 2016 using microscopy and polymerase chain reaction (PCR). A total of 3738 samples were analyzed consisting of Kisumu site (1,697), Kombewa (569), Kisii (989), Kericho (322), Marigat (51) and Malindi (110). Overall median parasitemia was 1.55 interquartile ranges (IQR) 0.25 to 3.62, 95% confidence interval).

Median parasitemia was lowest in 2013 with median of 1.13,  $n=550$  (IQR 0.13 to 3.10) and highest in 2016 2.2,  $n=243$  (IQR 0.25 to 4.5). Parasitemia was lowest at Marigat and highest at Kombewa and Kisii. Parasitemia fluctuated during the entire period of study. Kisumu site had varied median 1.35  $n=258$  (IQR 0.18 to 3.03) and 3  $n=81$  (IQR 1.35 to 5.15) as the lowest and highest median for the year 2013 and 2016 respectively. Kericho district hospital had steady increase in median parasitemia 0.30  $n=59$  (IQR 0.1 to 2.20) year 2008 to 1.9  $n=19$  (IQR 0.90 to 5.75) in 2011 thereafter a decline in median parasitemia. PCR results are underway. These findings show parasitemia among symptomatic individuals with uncomplicated malaria during deployment of ACTs. Despite significant regional variation in parasite density, there were no periodical changes to imply the effect of ACT usage during the study period. Since ACTs are still effective in Kenya, it is useful to continue monitoring changes in parasitemia to assess if it would presage resistance.

### 352

#### MALARIA SURVEILLANCE DATA ANALYSIS IN SOUTHERN ETHIOPIA

Adamu Addissie, Engidayehu Gebetu

Addis Ababa University, Addis Ababa, Ethiopia

Ongoing analysis of surveillance data is important for detecting outbreaks, monitoring disease trends, evaluating the effectiveness of disease control programs and policies and to determine efficient allocation of public health resources. The purpose of this analysis is to assess three (2011-2013) years of malaria morbidity and mortality data collected through PHEM and HMIS sections of Halaba Woreda. We conducted descriptive cross-sectional study using Microsoft Excel to describe the occurrences and distributions of malaria cases by person, place and time. A total of 123,344 (22.4%) malaria cases were reported by PHEM and HMIS. Proportion of falciparum cases reported to PHEM and HMIS were 48.2% and 43.4%; *P. vivax* was 51.8% and 56.6% respectively. The average total malaria incidence was 247 cases per 1000 person. The average annual incidence of total malaria was 390 and 247 per 1000 persons per year in PHEM and HMIS data respectively. Total malaria cases declined by 11.1% in all ages and by 10.1% in <5 year children over the three years. However, admissions increased by 301 in <5 children and by 1788 in all ages of malaria inpatient cases. The average mortality per 100,000 persons during the study period was 2.8. Overall malaria positivity rate was 55.6% from parasitological tests received. Eighty-three percent of cases were reported from health centres. In conclusion, malaria morbidity is declining but admissions are increasing. Also, a shift in the proportion of plasmodium species was observed. Increase in malaria admissions could be due to the increasing number of new health facility. Due to the discrepancies in PHEM and HMIS data, data quality is in question which should be evaluated and action be taken.

### 353

#### FACTORS ASSOCIATED WITH SEEKING TREATMENT FOR FEBRILE CHILDREN IN HEALTH CENTERS IN MALI

Drissa Konate<sup>1</sup>, Souleymane Diarra<sup>2</sup>, Mariam Tall<sup>3</sup>, Sory I. Diawara<sup>1</sup>, Seydou Doumbia<sup>1</sup>, Mahamadou Diakite<sup>1</sup>

<sup>1</sup>MRTC, Bamako, Mali, <sup>2</sup>Malaria Research & Training Center, Bamako, Mali,

<sup>3</sup>National Program of Malaria Control, Bamako, Mali

Fever in children is a common reason for outpatient visits to health centers. Malaria is the main cause evoked in Mali. According to Mali's 2015 Malaria Indicator Survey (MIS), among children less than five years of age who had fever the two weeks before the survey only 32.4% sought medical care at health facilities. The goal of this study was to analyze factors associated with care seeking for children with fever using data from the 2015 Mali MIS. A total of 2055 children who had fever in the two weeks preceding the survey were included in a multiple logistic regression analysis. After adjusting for urban/rural residence, region and mother's age, mother's educational level and household wealth quintile were significantly

associated with care seeking for febrile children. Care was less likely to be sought for children whose mothers had no educational level compared to children whose mothers had secondary or higher level of education (AOR=0.68; 95% CI [0.48-0.97]). Children living in households in the middle wealth quintile or higher were more likely to seek care for fever than those in the lower wealth quintiles (AOR=0.61; 95% CI [0.45-0.84]; AOR=0.60; 95% CI [0.42-0.84]). Mother's age, region and urban/rural residence were not significantly associated with care seeking for fever in adjusted models. However seeking traditional healers was associated with non-seek to medical treatment in health centers when children has fever (AOR=19.75 95% CI [7.78-50.13]). But a significant association was not observed with the age category and place residence to seek medical care for febrile children. The results suggest that more educated mothers and households with middle or higher wealth index were likely to seek care for their febrile children. The seeking traditional healers were associated with non-seek to medical care in health centers in Mali.

### 354

#### MALARIA AND ANEMIA AMONG PREGNANT WOMEN IN MALI, WEST AFRICA

Ismaila Coulibaly<sup>1</sup>, Ibrahim Sanogo<sup>1</sup>, Merepen dite Agnes Guindo<sup>1</sup>, Drissa S. Konate<sup>1</sup>, Seidina A. Diakite<sup>1</sup>, Sory Ibrahima Diawara<sup>1</sup>, Gordon A. Awandare<sup>2</sup>, David J. Conway<sup>3</sup>, Mahamadou Diakite<sup>1</sup>

<sup>1</sup>USTTB, Bamako, Mali, <sup>2</sup>University of Ghana, Accra, Ghana, <sup>3</sup>Pathogen Molecular Biology Department, London School of Hygiene & Tropical Medicine, London, United Kingdom

Malaria and anemia in pregnancy remains a major health problem in Sub-Saharan Africa. To investigate the effect of increased control efforts on pregnancy-associated malaria, we carried out this study over three consecutive annual transmission seasons in Niore du Sahel, located in a Sahelian area in the northwest of Mali. Our goal was to determine the prevalence of malaria and anemia in pregnant women and assess the coverage rate of both intermittent preventive treatments using sulphadoxine-pyrimethamin and insecticide-treated bednets (ITN) among pregnant women A cross-sectional study at the Reference Health Centre of Niore-du-Sahel was conducted to recruit 478 pregnant women during antenatal visit. Capillary blood was collected for malaria parasitemia using microscopy and for hemoglobin levels using HemoCue 301+. Malaria infection and anemia proportion (Hb<11g/dL) was 13.8% and 49.6%, respectively. Self-reported ITN use rate was 80.3% while IPTp – SP all 3 doses proportion was 55.4%. The prevalence of malaria (17.7%;  $P=0.548$ ) and anemia (68.9%;  $P=0.009$ ) was higher among age group 14 – 17 years compared to >27 years. Anemia proportion was higher in primigravid (59.6%) compared to multigravid women (47.1%;  $P=0.05$ ). Malaria was also more prevalent during the third trimester (18.3%) comparing to the first trimester (11%;  $P=0.071$ ). Anemia increased from the first trimester (29.9%) to the third trimester (62.5%;  $P<0.05$ ). Malaria was higher in pregnant women not using any preventive measure (28.8%; OR = 6.85 [2.78 – 16.86];  $P<0.0001$ ), followed by those using ITN alone (23.9%; OR = 5.31 [2.32 – 12.11];  $P<0.0001$ ), and IPTp – SP alone (16.7%; OR = 3.37 [0.82 – 13.83];  $P=0.074$ ) compared to those using ITN and IPTp – SP (5.6%). In conclusion, malaria and anemia are still common in young primigravid women and most prevalent during the third trimester. Additional control interventions are needed for malaria elimination in Niore du Sahel.

### 355

#### NATURALLY ACQUIRED ANTIBODY RESPONSE TO PLASMODIUM FALCIPARUM DESCRIBES HETEROGENEITY IN TRANSMISSION ON ISLANDS IN LAKE VICTORIA

Zulkarnain Md Idris<sup>1</sup>, Chim W. Chan<sup>2</sup>, James Kongere<sup>3</sup>, Tom Hall<sup>4</sup>, John Logedi<sup>5</sup>, Jesse Gitaka<sup>6</sup>, Chris Drakeley<sup>4</sup>, Akira Kaneko<sup>2</sup>

<sup>1</sup>Department of Parasitology and Medical Entomology, Faculty of Medicine, Universiti Kebangsaan Malaysia Medical Centre, Kuala Lumpur, Malaysia, <sup>2</sup>Island Malaria Group, Department of Microbiology, Tumor

and Cell Biology, Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Nagasaki University Nairobi Research Station, NUITM-KEMRI Project, Nairobi, Kenya, <sup>4</sup>Department of Immunology and Infection, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>5</sup>National Malaria Control Programme, Ministry of Public Health and Sanitation, Nairobi, Kenya, <sup>6</sup>Department of Clinical Medicine, Mount Kenya University, Thika, Kenya

As markers of exposure anti-malaria antibody responses can help characterise heterogeneity in malaria transmission. In the present study antibody responses to *Plasmodium falciparum* AMA-1, MSP-119 and CSP were measured to describe transmission patterns and heterogeneity in meso-endemic settings in Lake Victoria. Two cross-sectional surveys were conducted in Lake Victoria from January to August 2012. The study area comprised of three settings: mainland (Ungoye), large island (Mfangano) and small islands (Takawiri, Kibuogi, and Ngodhe). Individuals provided a finger-blood sample to assess malaria infection by microscopy and PCR. Antibody response to *P. falciparum* was determined in 4,112 individuals by ELISA using eluted dried blood from filter paper. The overall seroprevalence was 64.0% for AMA-1, 39.5% for MSP-119, and 12.9% for CSP. Within settings, seroprevalences for merozoite antigens were similar between Ungoye and Mfangano (AMA-1; 68.6% vs. 66.3%, MSP-119; 43.4% vs. 45.4%), but higher when compared to the small islands ( $P < 0.01$  for all comparison). The overall serological outcomes generally increase with age ( $P < 0.001$ ). For AMA-1 antigen, the seroconversion rates (SCRs) ranged from 0.121 (Ngodhe) to 0.202 (Ungoye), and are strongly correlated to parasite prevalence. No evidence was found of an increase of antibody levels with parasite densities and sub-microscopic parasite carriage in our study areas. Enlarged spleen was independently associated with antibody levels to all the antigens tested in children  $\leq 12$  years old in all study areas. We observed heterogeneity of parasite prevalence and serological indices across study sites in Lake Victoria. These data suggest that AMA-1 and MSP-119 sero-epidemiological analysis may provide further evidence in assessing variation in malaria exposure and evaluating malaria control/elimination efforts in high endemic area.

#### SPATIOTEMPORAL EPIDEMIOLOGY OF MALARIA IN MYANMAR 2012-2015

Win Zaw<sup>1</sup>, Aung Thi<sup>2</sup>, Zaw Lin<sup>3</sup>, July Ko Ko<sup>1</sup>, Neriza M. Pantanilla<sup>4</sup>, Steeve Ebener<sup>4</sup>, **Richard J. Maude**<sup>1</sup>

<sup>1</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>National Malaria Control Programme, Vector Borne Disease Control, Department of Public Health, Ministry of Health and Sports, Nay Pyi Taw, Myanmar, <sup>3</sup>Vector Borne Disease Control, Department of Public Health, Ministry of Health and Sports, Nay Pyi Taw, Myanmar, <sup>4</sup>AeHIN GIS Lab, Manila, Philippines

Malaria in Myanmar has greatly reduced by 53% from 2012 (391,679 confirmed cases) to 2015 (182,616 confirmed cases) but numbers remain much higher than in other countries in the Greater Mekong Subregion. Reducing the disease burden has been a constant challenge in populations in hard to reach areas and among migrant populations and seasonal workers travelling across the country. The National Strategic Plan for malaria elimination in Myanmar 2016-2030 states that the country aims to eliminate Malaria in three phases. Elimination by 2020 in areas with multidrug resistance including artemisinin resistance, reduction of overall incidence by 60% and mortality by 75% from 2014 values by 2020 and elimination from all areas by 2025 with prevention of reintroduction where it has been eliminated. To support achieving these goals it is essential to have an accurate picture of malaria incidence over space and time. Malaria Surveillance data were obtained from the National Malaria Control Programme, Department of Public Health, Myanmar from 2012 to 2015. A detailed analysis of routine incidence data over space and time, including annual parasite index, annual examination rates and positivity rates was done to examine the spatial and temporal trends in malaria cases in Myanmar. Township level analyses on numbers of confirmed cases were produced and analysis were performed on spatial temporal variations, seasonality and correlated with non-disease variables such as

temperature, rainfall and humidity. Testing rates increased in 2015 with annual blood examination rates from 2.1 in 2012 to 5.1 in 2015. In 2015 more tests were done in vulnerable populations and as a result more than 30,000 additional positive cases were identified than in 2014. Several high risks areas were identified including in Rakhine State where 100% of the population are at risk, with 90% in Kayin and 89% in Kachin States. The peak season of positive cases was found to be in June and July during the wet season. Myanmar has made great progress towards the goal of malaria elimination and ongoing improvements in surveillance and increased testing will greatly assist the NMCP in achieving this.

### 357

#### INCREASE IN PFDHFR AND PFDHPS MUTATIONS AFTER DISCONTINUATION OF COTRIMOXAZOLE PROPHYLAXIS FROM HIV-1 INFECTED INDIVIDUALS IN MALARIA ENDEMIC AREAS

**Dennis W. Juma**<sup>1</sup>, Peninah Muiruri<sup>1</sup>, Benson Singa<sup>2</sup>, Grace John Stewart<sup>3</sup>, John Waitumbi<sup>1</sup>, Krista Yuhua<sup>3</sup>, Hoseah Akala<sup>1</sup>, Ben Andagalu<sup>1</sup>, Matthew Brown<sup>1</sup>, Christina Polyak<sup>3</sup>, Edwin Kamau<sup>4</sup>

<sup>1</sup>U.S. Army Medical Research Directorate Kenya, Kisumu, Kenya, <sup>2</sup>KEMRI, Kisumu, Kenya, <sup>3</sup>U.S. Military HIV Research Program (MHRP), Bethesda, MD, United States, <sup>4</sup>Walter Reed National Military Medical Center, Bethesda, MD, United States

The WHO recommends cotrimoxazole (CTX) prophylaxis for HIV-1 infected individuals in regions with high prevalence of infectious diseases. However, with scale-up of antiretroviral therapy (ART), the usefulness of CTX is not well defined especially since there is debate that its usage might increase risk of developing cross-resistance to closely related sulfadoxine-pyrimethamine (SP) that is recommended for Intermittent preventive treatment in pregnancy/infants (IPTP/i). We conducted a non-blinded non-inferiority randomized controlled trial in Homabay, western Kenya to assess the effect of stopping CTX prophylaxis among HIV-1 infected adults. The subjects had to be on ART for >18 months with CD4 >350 cells/mm<sup>3</sup>. 500 subjects were enrolled; 250 in STOP-CTX arm and 250 in CTX arm. Blood samples were collected at time points 0, 3, 6, 9 and 12 months. Prevalence of mutations associated with SP-resistance was determined in the STOP-CTX arm at 3.2% (85/2625) and the CTX arm at 0.6% (16/2625) in the malaria positive cases. The triple mutant haplotype (*pfdhfr* 511/59R/108N) was the most prevalent at 52.9% (n = 45/85) in the STOP CTX arm and 6.3% (n = 1/16) in the CTX arm whereas the double mutant (*pfdhps* 437G/540E) was the most prevalent at 57.6% (n = 49/85) in the STOP CTX arm and 25% (n = 4/16) in the CTX arm. The prevalence of quintuple haplotype (511/59R/108N/437G/540E) was 51.8% (n = 44/85) in the STOP-CTX arm and 6.3% (n = 1/16) in the CTX arm. The triple mutant haplotype (511/59R/108N) increased from 14.3% (1/7) in M0 to 55.6% (20/36) in M12 in the STOP-CTX arm. Similarly, there was a two-fold increase in prevalence of double mutant haplotype (437G/540E) in *pfdhps* gene from 28.6% (2/7) to 69.4% (25/36) in M0 and M12 respectively. These findings suggest that cotrimoxazole is protective against malaria infections among HIV-infected individuals and does not select for SP-resistant parasites. In the context of malaria elimination, a decision to use cotrimoxazole for mass drug administration could reduce malaria carriage and therefore lower transmission without jeopardizing IPTP/i.

### 358

#### PFHRP2 GENE MUTATION IN BANGLADESH

**Maisha Khair Nima**

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

More than 90% of symptomatic malaria cases in Bangladesh are caused by *Plasmodium falciparum*. Species-specific diagnoses are crucial to case management, because severity and treatment varies between species. Diagnoses can be made using rapid diagnostic tests (RDTs) which are used in field sites to rapidly detect the presence and type of malaria. *P. falciparum* causes the most virulent cases of malaria, and *P. falciparum*

histidine-rich protein 2 (PfHRP2) is a common target of falciparum malaria RDTs. Here we report a case in which a blood sample from malaria patient in Bangladesh which tested negative on PfHRP2-based RDTs. Three different brands of RDTs were used to reconfirm failure of diagnosis: InTec® Pan/Pf Combo and Pf/Pv Combo (InTec® Products Inc., Xiamen, China), SD Bioline Pf/Pv Combo (Standard Diagnostics, Yongin, Republic of Korea), and Falcivax Pv/Pf Combo (Falcivax; Zephyr Biomedicals, India). The sample was confirmed to be a *Plasmodium falciparum* infection by PCR and microscopy. A parasitemia of 5120 parasites/μl was counted in a thin blood film, corresponding to 0.1024% of erythrocytes infected. Low parasitemia resulting in false negative result was ruled out because the parasitemia was 50 times of that normally required for RDTs. The negative results is attributed to a deletion of part of the *Pfhrp2* gene. The exon1/intron1 part of gene was found to be deleted and the initial portion of exon 2 was found to be deleted by sequencing. The missing regulatory upstream region accounts for the negative results on PfHRP2-based RDTs. This is a first report of *hrp2* gene deletion in Bangladesh. This finding may have implications for malaria diagnostics and case management in Bangladesh and other regions of South Asia.

### 359

#### GENETIC VARIATIONS IN *PLASMODIUM FALCIPARUM* APICAL MEROZOITE PROTEIN PF34 FROM CENTRAL INDIA

Sri Krishna, Praveen K. Bharti, Neeru Singh

National Institute for Research in Tribal Health, Jabalpur, India

The genetic diversity and evolutionary plasticity are the major obstacle for malaria control. Due to diversity in the *Plasmodium* genes, new forms of drug resistance have emerged and it is also a major challenge to malaria vaccine development. There are challenges for development of a new biomarker for rapid diagnostic test (RDT) as deletion in already existing target for RDT, histidine rich protein (HRP2), has been reported. In this study genetic diversity of *P. falciparum* GPI anchored protein (Pf34) was assessed. Previous studies have shown that Pf34 is expressed later during erythrocytic stage as well as sporozoite stage of parasite and localized in the rhoptry neck of merozoite apex. It is encoded by a single exon gene (978 bp) located on chromosome 4 and having a molecular weight of ~34 kDa. Rhoptry proteins, that play important role in the invasion of host cell and formation of parasitophorous vacuole, are considered as potential vaccine candidate. Amino acid sequence analysis of Pf34 was done from reference strain of *P. falciparum* (PF3D7\_0419700) and it was found that Pf34 is having amino acid repeats (NNI, NND, NNN). Samples were collected from Darbha CHC hospital, district Bastar, Chhattisgarh, India. Amplification of *Pf34* gene was done using designed primers through polymerase chain reaction (PCR). Sequencing of PCR products was done by Dideoxy chain termination method using 3130 XL genetic analyzer. Out of 160 samples, 140 samples were successfully sequenced and analyzed. Among these 140 samples 5 types of nucleotide substitutions (A160G, G179T, C229A, G279T, T483A) and one insertion (272\_273 ins TAA) were observed. All these substitutions and insertion lead to change in the amino acids (Non-synonymous substitutions). Total six types of variants of Pf34 protein (N54D, G60V, H77N, N90\_K91 ins N, Q93H and S161R) were observed and about 8% of isolates were harbouring variant Pf34. This study may help in estimating the potential of Pf34 as a vaccine candidate or biomarker for further studies to develop malaria control methods.

#### GENETIC RELATEDNESS ANALYSIS OF *PLASMODIUM FALCIPARUM* INFECTIONS IN SPATIALLY CLUSTERED COMMUNITIES OF WESTERN KENYA

Ebenezer K. Aidoo<sup>1</sup>, Maxwell Gesuge Machani<sup>2</sup>, Winnie Chebore<sup>2</sup>, Yaw A. Afrane<sup>3</sup>, Bernard Walter Lawson<sup>1</sup>, Harrysone Atieli<sup>4</sup>, Simon Kariuki<sup>2</sup>, Ming-Chieh Lee<sup>5</sup>, Guofa Zhou<sup>5</sup>, Andrew K. Githeko<sup>2</sup>, Guiyun Yan<sup>5</sup>

<sup>1</sup>Kwame Nkrumah University of Science & Technology, Kumasi, Ghana,

<sup>2</sup>Kenya Medical Research Institute/Centre for Global Health Research, Kisumu, Kenya, <sup>3</sup>Department of Medical Microbiology, College of Health Sciences, University of Ghana, Korle - Bu, Accra, Ghana, <sup>4</sup>School of Public Health, Maseno University, Maseno, Kenya, <sup>5</sup>Program in Public Health, College of Health Sciences, University of California, Irvine, CA, United States

Establishing genetic relatedness in parasites of index malaria cases and reactive case detection outcomes ensures intervention targeting by identifying locations and risk groups driving transmission. We hypothesized that limited parasite types yield transmission of highly related parasites and proceeded to investigate genetic relatedness in reactive case detection. Between October, 2015 – August, 2016, index household members, five neighbouring and control households within 100m radius and ≥ 500m of the index case compound were respectively identified. Using MSP-1 and MSP-2, *Plasmodium falciparum* isolates were genotyped for genetic relatedness in 136 (22 index cases, 11 index household members, 76 neighbours, 27 controls) and 190 (36 index cases, 18 index household members, 101 neighbours, 35 controls) samples respectively. Of these, 254 (77.9%) were positive for MSP-1 (116) and MSP-2 (138) with K1, RO33 and FC27 as the predominant allelic families. Multiplicity of infection was highest in neighbours (1.21 and 1.36) for MSP-1 and MSP-2 respectively with no polyclonality in MSP-2 controls. A significant heterozygosity was observed between index case and control ( $P < 0.02$ ). 36.3% of index household members showed relatedness with index case, 17.1% of neighbours with index case and 11.1% of controls with index case in MSP-1. However, MSP-2 showed 11.1% of index household members with genetic relatedness to index case, 15.8% of neighbours with index case and 14.8% of controls with index case. Results indicate highest genetic relatedness in index case and its household members and neighbour in MSP-1 and MSP-2 respectively.

### 361

#### VARIABILITY OF MALARIA PARASITES FROM NON-HUMAN PRIMATES IN THE BRAZILIAN ATLANTIC FOREST

Denise A. Alvarenga, Denise A. Alvarenga

Rene Rachou Research Center/CPqRR - The Oswaldo Cruz Foundation/ FIOCRUZ, Belo Horizonte, Brazil

Non-human primates (NHPs) as a source for *Plasmodium* infections in humans are a challenge for malaria elimination. Autochthonous malaria in the Brazilian Atlantic Forest seems to be related to non-human primates infected with *Plasmodium simium* and *Plasmodium brasilianum*. These parasites are similar to the human parasites *Plasmodium vivax* and *Plasmodium malariae*, respectively. This study was motivated by the report of 932 autochthonous cases in the Atlantic Forest between 2007 and 2013. Of importance, an outbreak was reported in 2015 and 2016 with 49 autochthonous cases in Rio de Janeiro State. We studied 280 captive NHPs housed in the Primatology Center of Rio de Janeiro State (CPRJ) in the Atlantic forest. The samples were collected from 2011 to 2016 and they were screened for the presence of *Plasmodium* using optical microscopy and nested PCR for detection of 18S SSU rRNA gene. Here, we investigate the phylogenies and genetic diversity among these parasite species using DNA sequencing and microsatellite genotyping. The result of the molecular diagnosis identified an infection rate of 30% (9/30) in 2011, 25% (7/27) in January/2015 and 18% (2/11) in July/2015 and 6.6% January/2016. The sequencing of a small fragment of the 18S SSU

rRNA encoding gene showed a high genetic similarity between *P. vivax* and *P. simium*, and between *P. malariae* and *Plasmodium brasilianum*, as demonstrated by other authors. This high identity is also observed in the phylogenetic reconstruction of isolates studied here. Three *loci* of microsatellite and two polymorphic blocks of PvMSP-1 showed that there is a great genetic diversity among the circulating parasites. The data from microsatellites will be also very useful for comparing recurrent infections in the same animal, to verify if they are the same chronic infection or a different one. The present results provide evidence that non-human primates may act as reservoirs for parasites of the genus *Plasmodium*, highlighting the potential of zoonotic transmission of the parasite in areas of the Atlantic forest, hampering the elimination of malaria in the country.

### DRAMATIC CHANGES IN MALARIA POPULATION GENETIC COMPLEXITY IN DIELMO AND NDIOP, SENEGAL REVEALED USING GENOMIC SURVEILLANCE

Amy K. Bei<sup>1</sup>, Makhtar Niang<sup>2</sup>, Awa B. Deme<sup>3</sup>, Rachel F. Daniels<sup>1</sup>, Fatoumata D. Sarr<sup>2</sup>, Cheikh Sokhna<sup>4</sup>, Joseph Faye<sup>2</sup>, Nafissatou Diagne<sup>4</sup>, Souleymane Doucoure<sup>4</sup>, Souleymane Mboup<sup>5</sup>, Dyann F. Wirth<sup>1</sup>, Adama Tall<sup>6</sup>, Daouda Ndiaye<sup>7</sup>, Sarah K. Volkman<sup>1</sup>, Aissatou Toure-Balde<sup>2</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Institut Pasteur de Dakar, Dakar, Senegal, <sup>3</sup>Laboratory of Parasitology and Mycology, Le Dantec Hospital, Faculty of Medicine and Pharmacy, Cheikh Anta Diop University, Dakar, Senegal, <sup>4</sup>Institute for Research and Development, Dakar, Senegal, <sup>5</sup>Institut de Recherche en Santé, de Surveillance Épidémiologique et de Formations, Dakar, Senegal, <sup>6</sup>Institut Pasteur de Dakar, Dakar, Senegal, <sup>7</sup>Laboratory of Parasitology and Mycology, Faculty of Medicine and Pharmacy, Cheikh Anta Diop University, Dakar, Senegal

The challenges of calculating traditional estimates of malaria transmission in low transmission areas emphasize the need for exploring innovative strategies, including harnessing genomics. A simple genotyping tool comprised of 24 independent single nucleotide polymorphisms (SNPs) revealed changes in *Plasmodium falciparum* transmission dynamics across multiple years of intervention application in Thiès, Senegal, including declines and rebounds in transmission through epidemiological modeling of *R0*. We applied this tool to an extensive longitudinal collection in Dielmo and Ndiop Senegal, where determinants of malaria infection have been conducted for decades. Using blinded samples from two distant time-points in this longitudinal cohort, we applied the molecular barcode tool to detect changes in parasite genotypes related to changes in transmission intensity. The goal of this genetic surveillance study was to validate the molecular barcode as a tool to assess parasite population diversity changes related to transmission dynamics and to track parasite genotypes across space and time. We observed a striking difference in the genetic diversity between the two parasite populations. In one population, we detected a high percentage (50%) of polygenomic infections, no shared genotypes, and no previously detected genotypes. In the alternate population we detected only monogenomic infections, three shared parasite genotype clusters representing two-thirds (67%) of the population. Upon unblinding it was revealed that the first population was from 2001-2002 where EIR was high (~350 in Dielmo and 79 in Ndiop) and that the second population was from 2014 where EIR was low (26 in Dielmo and 0 in Ndiop). Using neighbor-joining tree analysis we found no strict clustering of barcodes suggesting that parasite genotypes were shared between Dielmo and Ndiop. However, when we compared these genotypes with over 1000 other Senegal parasite genotypes from distinct locales, we detected that one of the 2014 genotypes from Dielmo had been previously detected in Thiès, Senegal in 2007 and again in 2010, suggesting possible importation of malaria.

## 363

### SURVEILLANCE OF PFMDR1, PFATPASE SINGLE NUCLEOTIDE POLYMORPHISM (SNP) PREVALENT AMONG PLASMODIUM FALCIPARUM UNCOMPLICATED MALARIA CASES OF NORTHEAST INDIA (YEAR 2015) AS ANTIMALARIAL DRUG RESISTANT MARKER

Shelly Goomber, Neelima Mishra, Anup Anvikar, Neena Valecha  
National Institute Malaria Research, New Delhi, India

North east India is corridor to south east asian countries that historically remained first to report antimalarial drug resistance. Though Artemisinin combined therapy (ACT) is still effective in region but there is serious concern about progressive decline in parasite clearance rate to therapy. Study districts Mizoram, Meghalaya, Tripura are endemic with high proportion of *Plasmodium falciparum* malaria cases. Membrane transporter Pfm<sup>dr1</sup> and Pfatp6 polymorphism is reported to be associated with lumefantrine and artemisinin tolerance respectively worldwide. Pfm<sup>dr1</sup> 86,184, 1246 codons and Pfatp6 codons 402, 431 polymorphism were studied by nested PCR, restriction fragment length polymorphism (RFLP) and Sanger sequencing techniques. There observed significant trend towards predominance of Pfm<sup>dr1</sup> N86 allele among population since introduction of Artemether-Lumefantrine in year 2013. Pfatp6 codon L402V, E431K polymorphism was observed among 3/73 and 7/73 samples respectively. Predominance of Pfm<sup>dr1</sup> N86 allele in malaria parasite isolates of north East India establishes its increased tolerance to lumefantrine. Insufficient pfatp6 polymorphism based reports from region limits to determine its efficacy as Artemisinin resistant marker. Continued molecular surveillance should take place to develop robust markers to track disease and to take timely action measures.

## 364

### PREVALENCE OF PFMDR1 AND PFK13 POLYMORPHISMS IN THREE PROVINCES IN ANGOLA, 2015

Dragan Ljolje<sup>1</sup>, Pedro Rafael Dimbu<sup>2</sup>, Julia Kelley<sup>1</sup>, Ira Goldman<sup>3</sup>, Aleixo Macaia<sup>4</sup>, Eric S. Halsey<sup>3</sup>, Pascal Ringwald<sup>5</sup>, Filomeno Fortes<sup>2</sup>, Venkatachalam Udhayakumar<sup>3</sup>, Eldin Talundzic<sup>3</sup>, Naomi Lucchi<sup>3</sup>, Mateusz M. Plucinski<sup>3</sup>

<sup>1</sup>Atlanta Research and Education Foundation, Atlanta, GA, United States, <sup>2</sup>National Malaria Control Program, Ministry of Health, Luanda, Angola, <sup>3</sup>Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>4</sup>Faculty of Medicine, Agostinho Neto University, Luanda, Angola, <sup>5</sup>Global Malaria Programme, World Health Organization, Geneva, Switzerland

Artemisinin-based combination therapy is the first-line anti-malarial treatment for uncomplicated *Plasmodium falciparum* infection in Angola. With the recent emergence of artemisinin resistance in the Greater Mekong sub-region and suspected lumefantrine resistance in Angola, it is important to characterize the background prevalence of polymorphisms in *pfk13*, associated with artemisinin resistance, and *pfmdr1*, associated with lumefantrine resistance. DNA was isolated from 506 dried blood spots collected at enrollment during the 2015 round of therapeutic efficacy studies in Benguela, Zaire and Lunda Sul Provinces in Angola. The *pfk13* propeller domain and *pfmdr1* segments were sequenced using the Sanger method and analyzed for polymorphisms. Additionally, *pfmdr1* copy number was assessed using a real-time PCR method. The majority of samples, 99% (413/416), were wildtype for *pfk13*, and all three non-wildtype samples (1%) carried the A578S mutation commonly observed in Africa and not associated with artemisinin resistance. The *pfmdr1* wildtype NYD haplotype (N86Y, Y184F, D1246Y) was predominant in all three provinces, with a frequency of 63% (133/209) of isolates in Benguela, 46% (105/227) in Zaire and 62% (69/109) in Lunda Sul, counting mixed infections as single infections. The NFD (N86Y, Y184F, D1246Y) haplotype, was found in 23% (49/209) of isolates in Benguela, 31% (72/227) in Zaire and 31% (35/109) in Lunda Sul. A total of 98% (497/506) samples were

successfully analyzed for *pfmdr1* copy number, all of which carried one copy of *pfmdr1*. The lack of *pfk13* mutations associated with artemisinin resistance support the clinical outcome data showing greater than 99% Day 3 clearance rates in Angola. Our results indicate no molecular evidence of emergence of artemisinin resistant K13 alleles in Angola's therapeutic efficacy sites, but reveal a high prevalence of N86, a potential marker for lumefantrine resistance. A 2017 follow-up study is underway.

### 365

#### COMPARATIVE LANDSCAPE GENETICS OF *PLASMODIUM FALCIPARUM*, *ANOPHELES ARABIENSIS*, AND *AN. GAMBIAE* IN KENYA

Elizabeth Hemming-Schroeder<sup>1</sup>, Eugenia Lo<sup>1</sup>, Daibin Zhong<sup>1</sup>, Harryson Atieli<sup>2</sup>, Andrew Githeko<sup>2</sup>, Guiyun Yan<sup>1</sup>

<sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya

Malaria parasite dispersal patterns are complex, as they are affected by both the movement of mosquitoes and humans. Mosquito dispersal distance ranges from less than one to several kilometers throughout a lifetime, whereas humans can carry malaria parasites over immense distances. Previous population genetic studies suggest that the highlands surrounding the Rift Valley are barriers to mosquito gene flow (dispersal) across Kenya. However, the arid landscape and sparse human densities between Western and Eastern Kenya may also restrict gene flow. Here, we disentangle the effects of elevation, land cover type, and human population density on gene flow of malaria parasites and mosquitoes across Kenya using a landscape genetics approach. Landscape genetics uses techniques in population genetics, landscape ecology, and spatial statistics to quantify the effects of landscape factors on genetic differentiation. We genotyped *Plasmodium falciparum*, *Anopheles arabiensis*, and *An. gambiae* specimens collected from 14 sites across Kenya at 10 microsatellite loci. We created landscape resistance surfaces in ArcGIS and optimized them using ResistanceGA. ResistanceGA optimization increases the ability to detect the effect of landscape and is based on a genetic algorithm, pairwise genetic distances (FST), and pairwise landscape resistance distances (measured in Circuitscape). Lastly, mixed effect models were fit by maximum likelihood. Initial analyses indicate that low human population densities primarily restrict gene flow of *An. arabiensis* across Kenya. Analyses for *An. gambiae* and *P. falciparum* will be similarly conducted. As many countries are approaching malaria elimination, it is critical to understand the underlying factors that influence the dispersal of malaria parasites and vectors in order to effectively sustain local control and elimination. Moreover, knowledge of how malaria parasites and vectors disperse is also important to predicting how insecticide and antimalarial resistance spread.

### 366

#### PREVALENCE OF HUMAN GENETIC POLYMORPHISMS ASSOCIATED WITH PROTECTION FROM MALARIA IN REGIONS OF UGANDA WITH DIFFERENT LEVELS OF MALARIA ENDEMICITY

Moses Kiggundu

Infectious Diseases Research Collaboration, Kampala, Uganda

Mutations in several human genes have been associated with protection against malaria. In particular, the sickle hemoglobin mutation (E6V in the globin gene), the  $\alpha$ -thalassemia 3.7kb deletion, a common African variant of the gene encoding glucose-6-phosphate dehydrogenase (G6PD A-), and the CD36 T188G mutation have been associated with protection against different clinical presentations of malaria. We hypothesized that the prevalence of genetic polymorphisms that are protective against malaria would be lower in regions of Uganda with lower, compared to higher malaria endemicity. To test this hypothesis, we compared the prevalence of these polymorphisms in 1,344 subjects enrolled in cohorts from Kanungu,

Jinja, and Tororo Districts, which are historically believed to have had low, moderate, and high malaria endemicity. DNA was purified from buffy coat samples using a Qiagen column. Genes of interest were amplified with nested PCR, amplicons were subjected to mutation-specific restriction endonuclease digestion, reaction products were resolved by agarose gel electrophoresis, and genotypes were determined based on the sizes of reaction product. For simplicity, heterozygous and homozygous mutations were considered together in our analysis; in all cases most non-wild type results were heterozygous. The prevalences of the sickle hemoglobin mutation (28% Tororo, 25% Jinja, 7% Kanungu), the  $\alpha$ -thalassemia 3.7kb deletion (53% Tororo, 45% Jinja, 18% Kanungu) and G6PD A- (29% Tororo, 18% Jinja, 8% Kanungu) were significantly greater in Tororo and Jinja compared to Kanungu (chi square  $p < 0.0001$  for all 3 alleles). For the CD36 T188G mutation (27% Tororo, 17% Jinja, 18% Kanungu), the prevalence was significantly greater in Tororo compared to Kanungu and Jinja ( $p < 0.0001$ ). These results are consistent with our hypothesis, and suggest that human malaria-protective genetic polymorphisms were selected by evolutionary pressure from longstanding endemic malaria.

### 367

#### AN OVERVIEW OF *PLASMODIUM VIVAX* GENOME STRUCTURE FROM A DUFFY NEGATIVE PATIENT AND ITS RELEVANCE TO ERYTHROCYTE INVASION

Eugenia Lo<sup>1</sup>, Jessica Hostetler<sup>2</sup>, Elizabeth Hemming-Schroeder<sup>1</sup>, Delenasaw Yewhalaw<sup>3</sup>, Julian Rayner<sup>4</sup>, Karthigayan Gunalan<sup>2</sup>, Louis Miller<sup>2</sup>, Guiyun Yan<sup>1</sup>

<sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>Jimma University, Jimma, Ethiopia, <sup>4</sup>Wellcome Trust Sanger Institute, Hinxton, United Kingdom

*Plasmodium vivax* invasion depends on the Duffy that recognizes and interacts with the Duffy antigen. Our previous study has shown that mutations in *P. vivax* Binding Protein 1 (*PvDBP1*) do not explain how the parasite invades Duffy negative human erythrocytes. While expansion of *PvDBP1* may allow low affinity binding to another receptor on Duffy null erythrocytes, there are potentially other protein ligands such as *PvDBP2/EBP*, *PvRBP1* and *PvRBP2* that can recognize host cell receptors prior to erythrocyte invasion. Here, we used an Illumina Hi-Seq sequencing platform to obtain whole genome sequence of *P. vivax* isolated from a Duffy-negative patient in Ethiopia. Between 16 and 322 million pair-end 150bp reads were generated for 11 Ethiopian *P. vivax* samples, including one from a Duffy-negative and 10 from Duffy-positive patients. A range of 10-95% of the reads was mapped to PvP01, a new *P. vivax* reference genome sequence generated from an Indonesian isolate. Average *P. vivax* genome coverage was 28-582x and over 95% of the genome was covered by at least 15 reads for all 11 samples. Over 80 million reads were generated for the Duffy-negative *P. vivax* sample, and 63% of which were mapped to the *P. vivax* reference genome resulting in 106x average coverage. Comparisons of five erythrocyte-binding genes obtained by whole genome sequencing across these samples indicated that *PvRBP2* is most polymorphic between the Duffy-negative and Duffy-positive *P. vivax*, as well as among the Duffy-positive isolates. Such diversity may suggest the presence of different binding domains that are under differential selective pressure. Polymorphisms in genome structure and position will be discussed among the Ethiopian *P. vivax* isolates in the context of erythrocyte invasion.

### STATISTICAL INFERENCE OF *PLASMODIUM FALCIPARUM* TRANSMISSION NETWORKS BASED JOINTLY ON GENETIC AND EPIDEMIOLOGICAL DATA

Alex Perkins<sup>1</sup>, Rasmus Nielsen<sup>2</sup>, Michelle Hsiang<sup>3</sup>, Max Murphy<sup>4</sup>, David Smith<sup>5</sup>, Bryan Greenhouse<sup>4</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>University of California, Berkeley, CA, United States, <sup>3</sup>University of Texas Southwestern, Dallas, TX, United States, <sup>4</sup>University of California, San Francisco, CA, United States, <sup>5</sup>University of Washington, Seattle, WA, United States

Decisions about how to target resources for malaria surveillance and control depend on accurate characterization of spatiotemporal variability in transmission. For viral and bacterial pathogens, recent advances in genetic sequencing and statistical methods have made this possible through the estimation of transmission linkages between individual infections. To date, no method has offered a similar capability for malaria parasites, given distinct features of their genetics as compared to viruses and bacteria. To provide such a capability, we developed a new statistical method for making inferences about transmission linkages between individual cases of *Plasmodium falciparum* malaria in low-transmission settings. This method makes use of the multi-locus genetic composition of an individual's parasites, their home location, and their detection date. We make explicit assumptions about the processes that generate and erode genetic variation, including parasite importation and stochastic loss during transmission, and we explicitly account for three distinct sources of genotyping error. Using Bayesian inference techniques, we validated the method with simulated data and made inferences about individual-level transmission networks with empirical data from low-transmission settings in Africa. In analyses of simulated data, we found that >80% of individual-level transmission linkages were correctly identified by our method. Compared to spatial and temporal data, genetic data contributed significantly more information to transmission network estimates, although the combination of all three data types improved accuracy and reduced uncertainty. Using transmission network estimates based on empirical data, we derived spatiotemporal estimates of key epidemiological metrics, such as the reproduction number under control,  $R_c$ , and the proportion of known infections that were imported from elsewhere or that derived directly from imported infections. In combination, our analyses of simulated and empirical data show that this new method provides robust estimates of localized metrics to inform malaria elimination efforts.

### DELETION OF *PFDXR* REVEALS ESSENTIAL ISOPRENOID FUNCTIONS IN *PLASMODIUM FALCIPARUM* CYTOSTOME FORMATION AND MAINTENANCE OF DIGESTIVE VACUOLE

T.R. Santha Kumar<sup>1</sup>, Rachel L. Edwards<sup>2</sup>, Melanie Shears<sup>3</sup>, Tao Li<sup>4</sup>, Adam Richman<sup>4</sup>, Sumana Chakravarty<sup>4</sup>, Pradeep Chopra<sup>5</sup>, Mark von Itzstein<sup>5</sup>, Kim L. Sim<sup>4</sup>, Fyodor D. Urnov<sup>6</sup>, Stephen L. Hoffman<sup>4</sup>, Photini Sinnis<sup>3</sup>, Audrey R. Odom John<sup>2</sup>, David A. Fidock<sup>1</sup>

<sup>1</sup>Columbia University, New York, NY, United States, <sup>2</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>3</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>4</sup>Sanaria Inc., Baltimore, MD, United States, <sup>5</sup>Griffith University, South Brisbane, Australia, <sup>6</sup>Sangamo Biosciences, Richmond, CA, United States

Isoprenoids comprise a large and diverse class of biomolecules synthesized from two basic components, isopentenyl pyrophosphate (IPP) and dimethylallyl pyrophosphate (DMAPP), which perform many essential cellular functions. Prokaryotes and plastid-containing eukaryotes, such as Apicomplexan parasites, synthesize isoprenoids via a mevalonate-independent metabolic pathway involving methylerythritol phosphate (MEP), which is not present in humans. The enzyme 1-deoxy-D-xylulose-5-phosphate reductoisomerase (DXR) catalyzes the first committed step in the MEP pathway. In this study, we generated *Plasmodium falciparum*

DXR (PF3D7\_1467300) deletion mutants (*PfΔdxr*), using the zinc-finger nuclease technology for targeted genome editing. *PfΔdxr* parasites reveal an absolute requirement for an exogenous supply of IPP for viability, firmly establishing the lack of alternative routes to isoprenoid precursor synthesis in this parasite. Using the *PfΔdxr* strain, we characterize the biological effects resulting from loss of *de novo* isoprenoid biosynthesis. Compared to wild-type *P. falciparum*, the *PfΔdxr* parasites accumulated the DXR substrate DOXP. All metabolites downstream of the disruption were below the limit of detection in the *PfΔdxr* strain, thereby confirming that the MEP pathway is non-functional downstream of DXR. *PfΔdxr* parasites also exhibited marked abnormalities in cellular architecture, including dramatically altered cytostomes. As compared to the parental strain, the number and size of cytostomes were significantly higher in *PfΔdxr* parasites, probably indicating the inability of these cytostomes to fuse to digestive vacuoles. *PfΔdxr* parasites also appeared to be devoid of digestive vacuolar membrane, as indicated by the absence of an electron-lucent region surrounding hemozoin crystals. All these morphological features were reverted by the addition of IPP. Taken together, our data suggest that the MEP pathway, which generates IPP for downstream cellular processes, is critical for preserving the normal cellular architecture of *P. falciparum* asexual blood stage parasites.

### VAR CODE: A NEW MOLECULAR EPIDEMIOLOGY TOOL FOR MONITORING *PLASMODIUM FALCIPARUM* IN A HIGH TRANSMISSION AREA OF GHANA, WEST AFRICA

Shazia Ruybal-Pesántez<sup>1</sup>, Kathryn E. Tiedje<sup>1</sup>, Gerry Tonkin-Hill<sup>2</sup>, Shai Pilosof<sup>3</sup>, Abraham Oduro<sup>4</sup>, Kwadwo A. Koram<sup>5</sup>, Mercedes Pascual<sup>3</sup>, Karen P. Day<sup>1</sup>

<sup>1</sup>Bio21 Institute/University of Melbourne, Melbourne, Australia, <sup>2</sup>Walter and Eliza Hall Institute, Melbourne, Australia, <sup>3</sup>University of Chicago, Chicago, IL, United States, <sup>4</sup>Navrongo Health Research Centre, Navrongo, Ghana, <sup>5</sup>Noguchi Memorial Institute for Medical Research, Legon, Ghana

*Plasmodium falciparum* Erythrocyte Membrane Protein 1 (*PfEMP1*) is encoded by the *var* multi-gene family and is a major target of naturally acquired immunity. Variation in *PfEMP1* underlies parasite fitness, measured as its ability to evade the host immune response and establish a chronic infection to optimize transmission. We investigated the extent of *PfEMP1 var* (DBL $\alpha$ ) sequence diversity and population structure in the asymptomatic *P. falciparum* reservoir in an area with seasonal transmission from Bongo District, Ghana. We sampled individuals across all ages with asymptomatic *P. falciparum* infections detected by microscopy and, for the first time, those with sub-microscopic infections to examine *var* genetics of the entire parasite reservoir. Our analysis of 1284 *P. falciparum* isolates revealed 45,513 DBL $\alpha$  variants. Strikingly, this extensive diversity was uniquely structured into DBL $\alpha$  repertoires that had minimal overlap, with most isolate repertoires sharing <10% of their DBL $\alpha$  variants. The absence of related parasites was demonstrated by pairwise type sharing (PTS) regardless of whether we looked at single (median PTS=0.02), multiple (median PTS=0.04), microscopic (median PTS=0.03) or sub-microscopic (median PTS=0.02) infections. Here we define an isolate repertoire as a *var* code as it is frequently composed of >1 parasite genome. The extensive diversity and lack of relatedness of *var* codes allowed us to gain valuable information from multiple infections, often excluded from traditional population structure analyses with neutral SNPs and microsatellite markers, with orders of magnitude lower diversity than *var*. Fingerprinting parasite isolates using this *var* code revealed a transmission system composed of a large parasite population of 1283 distinct *var* codes in a relatively small human population of 1284 individuals where only two people shared the same *var* code (PTS=0.97). Using computational experiments, this large effective parasite population with essentially non-overlapping *var* codes was shown to have profound implications for understanding the epidemiology and control of malaria.

### THE STUDY OF MULTIPLE EDITING OF *PLASMODIUM FALCIPARUM* GENES USING A TANDEM SGRNAS EXPRESSION CASSETTE

Hui Xia<sup>1</sup>, Lingwen Meng<sup>1</sup>, Yuemeng Zhao<sup>2</sup>, Qiang Fang<sup>1</sup>, Qingfeng Zhang<sup>2</sup>

<sup>1</sup>Bengbu Medical College, Bengbu, China, <sup>2</sup>Medical College, Tongji University, Shanghai, China

This study was undertaken to edit multiple genes by utilizing a transfectant vector carrying a tandem sgRNAs expression cassette. Two sgRNA which from the *Plasmodium falciparum* K13 (kelch protein) and NUP116 (Nucleoporin) gene respectively tandem in a clone expression framework, while the corresponding directed mutation of homologous recombination sequences were cloned into the same expression vector, the vector and the Cas9 expression plasmid together with electroporation into the 3D7 strain of *Plasmodium falciparum*. Transgenic strains were obtained by drug screening. The *Plasmodium falciparum* of double site-mutations of k13 and nup116 genes were successfully obtained. In conclusion, the tandem sgRNAs expression vector based on CRISPR/Cas9 editing technique can be used to edit different genes of *Plasmodium falciparum* simultaneously.

## 372

### PREREQUISITE EMERGENCE OF BACKGROUND MUTATIONS FOR *KELCH13*-RELATED ARTEMISININ-RESISTANT *PLASMODIUM FALCIPARUM* ISOLATES

Shin-Ichiro Tachibana, Toshiyuki Mori, Makoto Hirai, Toshihiro Miita

Juntendo University School of Medicine, Tokyo, Japan

Spread of resistant *Plasmodium falciparum* to artemisinin derivatives (ART) is a great concern in Greater Mekong subregion. So far, six SNPs in *kelch13* gene have been validated to confer ART resistance. Recent genome-wide association study revealed that the *kelch13* mutations often arise in combination with mutations in some specific genes, hereafter referred as background mutations. These mutations might augment the level of artemisinin resistance or compensate for the potential disadvantage induced by *kelch13* mutation(s). The aim of this study is to clarify evolutionary processes for the acquirement of ART resistance in the context of *kelch13* and background mutations. We sequenced *kelch13* and genotyped six background genes (V127M in *arps10*, D193Y in *fd*, T484I in *mdr2*, C1484F in *pibp*, I356T in *crt*, and V1157L in *nif4*) in 587 global *P. falciparum* isolates taken before the introduction of artemisinin combination therapy. Results showed that background mutations were prevalent in the Greater Mekong sub-region, whereas scarcely distributed in Melanesia, South America and Africa, and which was well correlated with the prevalence of mutant-*kelch13*. In some background genes, the mutant allele reached high frequencies prior to the increase in *kelch13* mutations. These results suggest that the background mutations are prerequisite for the emergence of ART resistance accompanied with the *kelch13* mutations.

Queensland, Australia, <sup>3</sup>Department of Medicine, University of Melbourne, Melbourne, Victoria, Australia

Malaria in pregnancy is a leading cause globally of poor maternal health, and low birth weight and premature delivery of neonates leading to greatly increased mortality and morbidity. Malaria in pregnancy (MiP) is characterised by the accumulation of *Plasmodium falciparum*-infected red blood cells (pRBCs) in the placenta. Infection is less prevalent with successive pregnancies partly due to the acquisition of antibodies directed against parasite antigens that mediate pRBC sequestration. However, effector mechanisms of antibodies are incompletely understood. Antibody responses are predominantly IgG1 and IgG3 subtypes, supporting a potential role for complement, but this has not been defined. Using sera collected from a longitudinal cohort of 350 pregnant women from a malaria-endemic province in Papua New Guinea we have established that acquired antibodies among pregnant women promote the deposition of complement on the surface of placental-binding pRBCs through binding C1q, and activate complement leading to fixation of C3b. Interestingly, complement fixation does not lead to cell lysis or parasite killing. Instead, antibodies with complement inhibit binding of pRBCs to placental vascular receptors and enhance phagocytosis by monocytes, mechanisms likely to provide protection against MiP. Using genetically-engineered *P. falciparum*, we identified the parasite antigen *P. falciparum* erythrocyte membrane protein 1 (PfEMP1) as the major target of complement-fixing antibodies. Analysis of longitudinal data among pregnant women supports a role for complement fixation by acquired antibodies in protection against placental infection and adverse pregnancy outcomes. These findings provide new insights into the mechanisms mediating immunity to malaria in pregnancy to advance vaccine development.

## 374

### AN IMMUNOSUPPRESSIVE ROLE FOR LAG3 IN TR1 CELLS DURING MALARIA AND VISCERAL LEISHMANIASIS

Chelsea Edwards<sup>1</sup>, Susanna Ng<sup>1</sup>, Marcela Montes de Oca<sup>1</sup>, Mitchell Imoda<sup>2</sup>, Fabian de Labastida Rivera<sup>1</sup>, Fiona Amante<sup>1</sup>, Shivangi Wani<sup>1</sup>, Nicole Cloonan<sup>1</sup>, Rajiv Kumar<sup>3</sup>, James McCarthy<sup>1</sup>, Christian Engwerda<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia,

<sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>Banaras Hindu University Institute of Medical Sciences, Varanasi, India

Immunoregulatory mechanisms determine the balance between immune pathology and disease resolution. Many factors contribute to these mechanisms, but IL-10 production has been shown to be critical in a number of inflammatory diseases. Recently a Foxp3- regulatory CD4+ T (Tr1) cell subset has been identified as key producers of IL-10 in many diseases. They are prominent in visceral leishmaniasis (VL) patients, and their frequency was positively correlated with chronic malaria exposure in Ugandan children. In mouse models of VL and malaria, we recently reported that Tr1 cells suppressed anti-parasitic immune responses, but also played a key role in preventing immunopathology. Hence, if Tr1 cells can be appropriately manipulated, they have the potential to be used as immunotherapeutic tools. To be able to do this, we need to be able define them more clearly and identify unique immune checkpoint molecules they express that can be targeted for functional effects. Here we used RNAseq to compare gene signatures in Tr1 and Th1 cells from human volunteers participating in controlled human malaria infection (CHMI) studies with *Plasmodium falciparum*, as well as from mice with experimental VL caused by infection with *Leishmania donovani* to define a Tr1 profile which is independent of host and infection type. Furthermore, we functionally validated a number of the molecules identified, which included a variety of chemokine receptors, immune checkpoint inhibitors, and transcription factors. Lymphocyte activating gene 3 (LAG3) was one such molecule upregulated in Tr1 cells at both the RNA and protein level, and we showed that blockade of this molecule modulated Tr1 cell function. During experimental VL, both *ex vivo* and *in vivo* blockade of LAG3 reduced Tr1 cell numbers, which corresponded with reduced parasite burden *in vivo*. Additionally, LAG3 blockade increased parasite-specific IFN $\gamma$  production

in VL patient whole blood assays, as well as antigen-specific IFN $\gamma$  and TNF by murine splenocytes. Together these data identify LAG3 as a potential immune checkpoint target for modulation during malaria and VL.

### NEUREGULIN-1 ATTENUATES MALARIAL MORTALITY ASSOCIATED WITH EXPERIMENTAL CEREBRAL MALARIA

Juan Cespedes, Wesley Solomon, Nana Wilson, Mingli Liu, Byron Ford, Jonathan Stiles

*Morhouse School of Medicine, Atlanta, GA, United States*

Cerebral malaria (CM) is a neurological manifestation of the infection caused by *P. falciparum*. *P. falciparum* causes endothelial dysfunction through parasite sequestration and expression of adhesion molecules which in turn disrupts blood brain barrier (BBB) integrity leading to high inflammation. Recently associated with CM is a neurotrophic growth factor Neuregulin-1 (NRG-1). NRG-1 has shown to protect against several brain injuries related to neurotoxin exposure and acute ischemic stroke. However, whether NRG-1 has a potentially inhibiting role in BBB disruption and attenuates CM associated mortality remain unknown. Neuregulin-1 will improve survival and reduce ECM-associated inflammatory response in mice with late stage ECM. The effects of NRG-1 were tested on ECM-associated mortality and brain inflammation in *P. berghei* ANKA (PbA)-infected mice. These effects were then compared to current treatment used today, artemether (ARM). Results show ARM treatment (25mg/kg/day) was effective in clearing parasites and reducing mortality in PbA-infected mice by 82%. Despite the increase in parasite level with NRG-1 treated mice, NRG-1 therapy (1.25 ng/kg/day) increased survival against ECM by 73%. Additionally, NRG-1 therapy lowered levels of systemic and brain pro-inflammatory factors IL-6, IL-1 $\alpha$ , TNF $\alpha$ , and CXCL10. NRG-1 therapy increased anti-inflammatory factors IL-5 and IL-13 while simultaneously inhibiting leukocyte accumulation in brain parenchymal vessels of PbA infected mice. Results suggests that NRG-1 treatment attenuates ECM-associated brain injury and inflammation. NRG-1 may serve as a novel therapeutic addition for the treatment and management of CM.

## 376

### THE TRANSCRIPTION FACTOR T-BET SUPPRESSES GERMINAL CENTRE DEVELOPMENT AND HUMORAL IMMUNITY TO BLOOD-STAGE PLASMODIUM INFECTION

Ann Ly<sup>1</sup>, Victoria Ryg-Cornejo<sup>1</sup>, Chris Y. Chiu<sup>1</sup>, Lisa J. Ioannidis<sup>1</sup>, Kim L. Good-Jacobson<sup>2</sup>, Gabrielle T. Belz<sup>1</sup>, Axel Kallies<sup>1</sup>, Diana S. Hansen<sup>1</sup>

<sup>1</sup>Walter and Eliza Hall Institute of Medical Research and Department of Medical Biology, The University of Melbourne, Parkville, Australia, <sup>2</sup>B cells and Antibody Memory Laboratory, Department of Biochemistry and Molecular Biology, Monash University, Clayton, Australia

Natural immunity to *Plasmodium* parasites is long-known to require years of repeated infections to develop, and only provides non-sterilizing protection from clinical disease. The reasons for this are elusive to date, however, increasing evidence from immuno-epidemiological studies in malaria endemic areas indicate that parasite-specific antibodies and memory B cells, which mediate protection, are acquired inefficiently and short-lived. Conversely, individuals exposed to infrequent symptomatic infections have been shown to generate stable memory B cells in the absence of frequent boosting. These findings suggest that acute malaria infections impede the establishment of B cell-mediated humoral immunity. In support of this, recent evidence revealed that pro-inflammatory pathways that drive malaria pathology can impair the humoral immune response to murine malaria infection, by inhibiting the differentiation of T follicular helper (Tfh) cells and impairing germinal centre (GC) responses. Using the *P. berghei* ANKA murine model, we investigated the role of the pro-inflammatory T helper 1 transcription factor T-bet in regulating the development of GC responses during blood-stage malaria. Genetic

ablation of T-bet significantly restored Tfh cell differentiation and the formation of GCs in the spleen, which led to an enhanced production of parasite-specific antibodies following infection. We found that T-bet expression by CD4<sup>+</sup> T cells inhibited Tfh cell differentiation, and compromised the development of the extrafollicular plasma cell and GC response to infection. Furthermore, B cell-specific expression of T-bet during infection affected the maturation of the GC B cell response by modulating the cellular dynamics of the GC reaction. Together these findings show that pro-inflammation mediated by T-bet, suppresses the development of the GC response and the generation of protective humoral immunity to blood-stage malaria.

## 377

### NOVEL PLASMODIUM VIVAX DUFFY BINDING PROTEIN VACCINE CANDIDATE ARE ASSOCIATED STRONG AND PERSISTENT NATURALLY ACQUIRED IGG AND BINDING-INHIBITORY ANTIBODIES RESPONSE, IN LONG-TERM EXPOSURE POPULATION

Camilla V. Pires<sup>1</sup>, Jéssica R. Alves<sup>1</sup>, Barbara A. Lima<sup>1</sup>, Flora S. Kano<sup>1</sup>, Francis B. Ntumngia<sup>2</sup>, John H. Adams<sup>2</sup>, Luzia H. Carvalho<sup>1</sup>  
<sup>1</sup>Research Center René Rachou, Fundação Oswaldo Cruz (FIOCRUZ), Belo Horizonte, Brazil, <sup>2</sup>Department of Global Health, College of Public Health, University of South Florida, Tampa, FL, United States

In natural infections, the *Plasmodium vivax* Duffy binding protein II (DBPII), which is a leading *vivax* vaccine candidate, is weakly immunogenic and induces strain-specific immunity. DEKnull2 is an engineered DBPII vaccine with modified strain variant surface residues that can elicit broadly neutralizing, strain-transcending anti-DBP inhibitory antibodies. DEKnull2 evolved from proof-of-concept studies that demonstrated that a synthetic DBPII allele, DEKnull, which lacked the dominant variant Bcell epitope can induce in mice more broadly inhibitory antibodies. Here, we investigated whether DEKnull and DEKnull2 are immunogenic in individuals naturally exposed to malaria in the Brazilian Amazon region. ELISA-detected IgG antibody responses to non-mutated DBPII variants (Sal1 and Brazil) and to synthetic DBPII immunogens (DEKnull, DEKnull2) were evaluated in a native community with long-term exposure to malaria. The study design included four cross-sectional surveys, three carried-out during the first year (baseline, 6 and 12 months), and two carried-out 6 years later, at the time that malaria cases had declined dramatically in the area. During the first year, consecutive serological surveys demonstrated that while few exposed-individuals responded to the original DEKnull, similar frequencies of responders (~50%) were obtained by using either enhanced DEKnull2 immunogen or native DBPII variants; of interest, the levels of DEKnull2 IgG-antibodies was much more higher than those obtained from native DBPII-variants. Six years later, the number of responder to native proteins decreased significantly, however, the levels and frequency of responders to the DEKnull2 remained relatively stable. Remarkable, long-term DEKnull2 responders with high levels of antibodies (reactivity index >20) were individuals able to produce broadly reactive binding-inhibitory antibodies (as detected by COS cell assay). DEKnull2 is highly immunogenic in naturally exposed-individuals, suggesting that the engineered vaccine could be a promising candidate towards the development of protective blood-stage *vivax* malaria vaccine.

**INFLUENCE TO MOSQUITOES BITES ON ANTIBODY RESPONSES SPECIFIC TO MALARIA ANTIGENS**

Ghislain K. Aka<sup>1</sup>, André B. Sagna<sup>2</sup>, François D. Traore<sup>2</sup>, Danielle D. Zoh<sup>1</sup>, Bertin N. Tchiekoi<sup>1</sup>, Norbert K. Lingue<sup>1</sup>, Issa Coulibaly<sup>1</sup>, Serge Assi<sup>1</sup>, Akré M. Adja<sup>1</sup>, Franck Remoue<sup>2</sup>, Joseph A. Djaman<sup>3</sup>, Anne Poinçon<sup>2</sup>

<sup>1</sup>Institut Pierre Richet, Bouaké, Côte D'Ivoire, <sup>2</sup>Institut de Recherche pour le Développement, Montpellier, France, <sup>3</sup>Institut Pasteur de Côte d'Ivoire, Abidjan, Côte D'Ivoire

In malaria endemic areas, populations are frequently exposed to salivary components of blood-sucking mosquitoes that could modulate the immune response of the human host by their immunomodulatory properties. Consequences on pathogen-specific immune responses are not well known. Thus, we studied the influence of exposure to the main mosquitoes on the development of antibody (Ab) responses specific to *Plasmodium* antigens acquired during natural infection according to 1/ individual level of exposure to *Anopheles* bites and 2/ the presence of other mosquitoes (*Aedes* and *Culex*). A study was carried out in Bouaké (Côte d'Ivoire) where entomological data and blood samples from children (0-14 years) were collected. We evaluated the Ab responses (IgG, IgG1, IgG3) to 2 blood-stage antigens of *P. falciparum* (AMA-1, MSP-1) by ELISA. The individual level of child exposure to *Anopheles* bites was evaluated by quantifying specific IgG responses to the *Anopheles* gSG6-P1 salivary peptide. Immunological profiles of the anti-*Plasmodium* Ab responses in children were different according to the *Plasmodium* antigens. The comparison of immunological profiles according to the individual exposure level to *Anopheles* bites showed that anti-*Plasmodium* Ab responses were higher in children with low exposure level compared to those highly exposed to *Anopheles* bites. High and low exposed children to *Anopheles* but highly exposed to *Culex* bites have a low level of anti-*Plasmodium* immune responses. These findings suggest that anti-*Plasmodium* immune responses are modulated with the level of exposure to *Anopheles* bites but also to other hematophagous mosquito species. The immunosuppressive effect of the saliva of the mosquitoes has been highlighted. The immunomodulatory properties of mosquitoes' saliva on anti-plasmodial immune responses should be taken into account in epidemiological studies and especially in vaccine trials.

de Manhica (CISM), Manhica, Mozambique, <sup>8</sup>Laboratory of Malaria and Vaccine Research, School of Biotechnology, Jawaharlal Nehru University, New Delhi, India

A main criterion to identify vaccine candidates against malaria is the proof that acquired immunity against them is associated with protection from disease. We aimed to study the protective role of IgG/IgM antibody responses against 23 pre-erythrocytic and erythrocytic antigens from *Plasmodium falciparum*, including members of the EBA and Pfrh families, and novel antigens merely or not previously studied in malaria-exposed populations (AARP, CyRPA, P41). We measured antibody levels by Luminex® in plasma from Mozambican children (n=261) who were monitored from birth until 3 years of age for clinical malaria. Aiming for a better approach to find correlates of protection against clinical malaria and overcome heterogeneity in malaria exposure that can confound our results, we compared classical cox regression models to models estimated after excluding children unexposed during the follow-up, defined by clinical and serological data. Also, to measure the antibody direct effect on the malaria episode, we limited the follow-up time to the time the specific IgG drop to 25% of their levels at first contact, that ranged from 78 days (PTRAMP) to 550 days (P41). Either excluding the non-exposed individuals or limiting the follow-up time in the analyses was useful to avoid antibodies' associations with higher risk of clinical malaria (which are exposure markers). Protective associations were found for IgG (and IgG breadth) at 24 months old (and not at younger ages), although the antibody levels were not necessarily higher than at younger ages. Together, these findings show the importance of age in the acquisition of protective immunity and of either excluding non-exposed population or limiting the follow-up time according to antibody decay when studying correlates of protection.

## 380

**THE IMPACT OF CONCURRENT EXPOSURE TO *PLASMODIUM FALCIPARUM* ON THE DEVELOPMENT OF NATURALLY ACQUIRED IMMUNITY TO MALARIA IN YOUNG MALAWIAN CHILDREN**

Priyanka Barua<sup>1</sup>, Upeksha P. Chandrasiri<sup>1</sup>, James G. Beeson<sup>2</sup>, Kathryn G. Dewey<sup>3</sup>, Kenneth Maleta<sup>4</sup>, Per Ashorn<sup>5</sup>, Stephen J. Rogerson<sup>1</sup>

<sup>1</sup>The Department of Medicine (RMH), Peter Doherty Institute for Infection and Immunity, The University of Melbourne, Melbourne, Australia, <sup>2</sup>Burnet Institute for Medical Research and Public Health, Melbourne, Australia, <sup>3</sup>University of California, Davis, CA, United States, <sup>4</sup>University of Malawi, Malawi, <sup>5</sup>University of Tampere and Tampere University Hospital, Tampere, Finland

Antibodies targeting the blood-stage of malaria and variant antigens expressed on the surface of infected erythrocytes are important indicators of naturally-acquired immunity against malaria. To identify their role in development of immunity in infancy, the levels of antibodies against merozoite surface proteins (MSP1 19kD, MSP2), erythrocyte binding antigen 175 (EBA175), reticulocyte binding protein homologue 2A (Pfrh2), schizont extract and variant surface antigens for parasite lines E8B, R29, 3D7 overexpressing Var A were measured in plasma from 18 month old Malawian infants in a randomised controlled trial of nutrient supplements. Children were actively followed from birth and had malaria testing for febrile episodes. Of 601 children, 144 experienced malaria episodes before 18 months. Antibody prevalence was higher in children who had experienced episodes of clinical malaria, or who were parasitaemic at the time of sample collection than children with no malaria history. Children who had experienced clinical malaria were significantly more commonly seropositive for MSP1, MSP2, schizont extract and E8B parasite-line. Antibody prevalence did not differ between children having single and multiple episodes. Antibody levels also differed with history of malaria episodes or parasitaemia. Children who were parasitaemic at sample collection had significantly higher levels of antibodies for all the antigens except Pfrh2. Children with malaria episodes had higher antibody levels

than those who had no episodes, but multiple episodes did not increase antibody levels compared to single episodes. Antibody levels at 18 months were similar in children who had episodes before 6 months of age or between 6 and 18 months. We observed boosting of malaria antibodies following clinical malaria and in children with current parasitaemia episodes in early childhood, but neither the number of episodes or time since malaria episode influenced antibody levels or prevalence. The results suggest that some merozoite antigens may be useful biomarkers of malaria exposure in infancy.

## 381

### PFEMP1 SPECIFIC IGG ANTIBODIES PROFILES FROM BIRTH TO TWELVE MONTHS OF AGE IN BENINESE INFANTS

**Azizath Moussiliou**

Research Institute in Public Health, IRSP/UAU (University of Abomey Calavi, Benin), Ouidah, Benin

The cytoadherence properties of *Plasmodium falciparum* infected erythrocytes (IE) represent a major contributor to the pathogenesis of malaria through interactions with various endothelial cell surface receptors. These interactions are mediated by members of the highly variable *P. falciparum* erythrocyte membrane protein 1 (PfEMP1) expressed on the IE surface. One particular component of PfEMP1 proteins, the cysteine-rich interdomain region (CIDR), is known to play a very important role in the adhesive interactions between IE and endothelial receptors, making this region a potential vaccine target of interest. Here, we investigated the dynamics of maternally-transferred IgG antibodies targeting the CIDR of a panel of different PfEMP1 proteins, as well as infants' own acquisition of antibodies with the same specificities during the first year of life. We used plasma samples collected longitudinally from the offspring of a cohort of pregnant women who had themselves been followed closely through pregnancy. We show that the levels of all anti-CIDR antibodies quantified declined to the point of disappearing over the 6 first months of life. Antibodies with specificity for the CIDR predicted to adhere to selected receptors (CD36, EPCR) or for the CIDR associated with the unknown phenomenon on were subsequently acquired by infants between 7-12 months of age, their levels being a function of *P. falciparum* history during infancy. Infected infants developed stronger antibody responses to the CIDR associated with either EPCR binding or unknown compared to uninfected infants. Parasites infecting children before 6 month of age preferentially transcribed *var* gene belonging to the group B and those encoding DBLb containing PfEMP1.

### IMMUNE RESPONSE AGAINST A NOVEL *PLASMODIUM VIVAX* ERYTHROCYTE BINDING PROTEIN IN A BRAZILIAN NATURALLY EXPOSED POPULATION

Leticia M. Torres<sup>1</sup>, Camilla V. Pires<sup>1</sup>, Flora S. Kano<sup>1</sup>, Francis B. Ntungia<sup>2</sup>, John H. Adams<sup>2</sup>, **Luzia H. Carvalho<sup>1</sup>**

<sup>1</sup>Centro de Pesquisas René Rachou, FIOCRUZ-MG, Belo Horizonte, MG, Brazil, <sup>2</sup>South Florida University, Tampa, FL, United States

Recently, a new member of the Duffy binding protein family was discovered in *Plasmodium vivax* – named Erythrocyte binding protein (EBP2) -- and this protein may play a role as a ligand mediating an alternative invasion pathway for young Duffy-positive reticulocytes (Ntumngia et al., MBio. e01261-16, 2016). In individuals naturally exposed to malaria in the Amazon region, we investigated the antibody response against EBP2 and their relationship to antibodies induced by the Duffy binding Protein (DBPII), the major ligand involved in *P.vivax* reticulocyte invasion. An open cohort study was carried among 425 volunteers from a native Amazonian community with long-term *P.vivax* exposure. ELISA-detected IgG antibodies were evaluated by using recombinant proteins based on ligand-domain of EBP2 and DBPII. The study design included five cross-sectional surveys, three carried-out during the first year (baseline, 6 and 12 months), and two 6 and 7 years later. Taken together, the results

demonstrated that (1) during the first follow-up year, the frequencies of anti-EBP2 (50-60%) was higher than frequencies of anti-DBPII (30-36%); (2) Six to 7 years later, at the time that malaria transmission had declined dramatically in the study area, the profile of EBP2 antibody response remained relatively stable while DBPII antibodies dropped significantly. Conclusion: As compared with DBPII, EBP2 is highly immunogenic and induces a long-term immune response. Further studies should investigate whether antibodies against EBP2 are able to block reticulocytes *P.vivax* invasion.

## 383

### IMMUNE RESPONSE IN PATIENTS WITH DIFFERENT PARASITIC PROFILES IN FIVE PROVINCES OF GABON, CENTRAL AFRICA: CROSS-SECTIONAL STUDY

**Noé Patrick M'bondoukwé<sup>1</sup>**, Jacques-Mari Ndong Ngomo<sup>1</sup>, Jeanne Vanessa Koumba Lengongo<sup>1</sup>, Fanny Bertrande Batchy Ognagosso<sup>1</sup>, Christian Nziengui Tirogo<sup>2</sup>, Denise Patricia Mawili-Mboumba<sup>1</sup>, Marielle Karine Bouyou-Akotet<sup>1</sup>

<sup>1</sup>Département Parasitologie-Mycologie, USS, Gabon, Libreville, Gabon,

<sup>2</sup>Centre Hospitalier Universitaire d'Agondjé, Libreville, Gabon

Malaria, blood filariasis (*Loa loa* and *Mansonella perstans*) and intestinal parasites (helminths and protozoan) are endemic in Gabon. This geographical codistribution leads to polyparasitism with for consequences the possible interaction between parasites. It is possible that intestinal protozoan and helminths could modulate malaria immunity increasing susceptibility to malaria. A cross-sectional study was conducted between September 2013 and November 2016. Blood and stool samples were collected in five of the nine provinces of Gabon. Parasitological diagnosis were performed to detect malaria parasites, blood filariasis and intestinal parasites. Then, six groups were constituted presenting either malaria only, helminths only, intestinal protozoan only, helminths and malaria coinfection, protozoan and malaria coinfection and no parasites. Flow cytometer was used to measure IL-10, IL-6 and TNF-alpha inflammatory cytokines levels and ELISA sandwich, to detect total IgG directed against GLURP R0, GLURP R2, MSP1-19, MSP2 3D7 and FC27, AMA-1 surface proteins of *falciparum* merozoite asexual form. Globally, 843 subjects were enrolled and 414 returned stool samples. Malaria, filariasis and intestinal parasites prevalence were respectively 21.7, 13.3, and 37.7%. IL-10 and IL-6 levels were higher in malaria group. Moreover, IL-10/TNF-alpha ratio was higher among patients without parasites ( $p < 0.0001$ ). Specific IgG directed against MSP3, GLURP R2 and AMA-1 were elevated in helminths group (respectively  $p_{MSP3}$ ,  $AMA-1=0.01$ ,  $p_{GLURP R2}=0.002$ ). Correlation analysis showed an inverse relation between specific IgG level to MSP2 FC27 and TNF-alpha concentration ( $r=-0.3$ ;  $p=0.03$ ). Strong Th2 response was observed in all patients in this study and IgG directed against surface protein were predominant in patients with helminths infection.

## 384

### ANTIBODIES PROMOTE COMPLEMENT ACTIVATION AGAINST *PLASMODIUM FALCIPARUM* SPOOROZOITES, PROVIDING A NOVEL MECHANISM OF ANTI-MALARIAL IMMUNITY

**Liriye Kurtovic<sup>1</sup>**, Marije Behet<sup>2</sup>, Gaoqian Feng<sup>1</sup>, Linda Reiling<sup>1</sup>, Freya Fowkes<sup>1</sup>, James Kazura<sup>3</sup>, Kiprotich Chelimo<sup>4</sup>, Arlene Dent<sup>3</sup>, Robert Sauerwein<sup>2</sup>, James Beeson<sup>1</sup>

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>Radboud University Medical Centre, Nijmegen, Netherlands, <sup>3</sup>Case Western University, Cleveland, OH, United States, <sup>4</sup>Kenya Medical Research Institute, Kisumu, Kenya

At present, we lack an in depth understanding of the immune mechanisms against *Plasmodium falciparum* sporozoites, and consequently lack reliable correlates of protective immunity. Without this fundamental knowledge, the development and evaluation of existing or candidate malaria vaccines is severely impaired. Antibodies to sporozoites and their major surface

antigen, circumsporozoite protein (CSP), have been loosely associated with protection in studies of naturally acquired and vaccine-induced immunity, but it remains unclear how they function, and there is limited knowledge of key functional epitopes. Here we investigated the functional role of antibodies to CSP and sporozoites in activating the complement system via the antibody-dependent classical pathway. We have established that antibodies form malaria-exposed individuals can fix the complement protein, C1q, to recombinant CSP, which is an essential interaction that initiates the classical activation pathway, and leads to formation of the membrane attack complex. These C1q-fixing antibodies were strongly correlated with IgG1, IgG3 and IgM antibody types, and could recognise multiple CSP epitopes. Malaria-specific antibodies mediated C1q-fixation and subsequent classical activation on the surface of *P. falciparum* sporozoites, which consequently inhibited parasite migration through cells and could lead to cell death *in vitro*. Therefore complement activation may be an important antibody mechanism to inhibit sporozoite infection and pre-erythrocytic development. Effective C1q-fixing antibodies were poorly acquired though natural malaria exposure in children and only a minority of highly exposed adults had anti-CSP antibodies with strong complement-fixing activity. In summary, we identified a novel function of malaria-specific antibodies in activating the human complement system and consequently inhibiting sporozoite function and leading to cell death, which provides important insights for vaccine development and evaluation.

### 385

#### EFFECT OF ALLELIC POLYMORPHISM ON MALARIA PARASITE SPECIFIC *EX VIVO* INTERFERON-GAMMA RESPONSE TO APICAL MEMBRANE ANTIGEN 1 IN A MALARIA EXPOSED REGION.

Omarine Nlinwe Nfor Epse Njimented<sup>1</sup>, Asamoah Kusi Kwadwo<sup>1</sup>, Martha Sedegah<sup>2</sup>

<sup>1</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>2</sup>Naval Medical Research Center, Silver Spring, Maryland, MD, United States

Despite extensive genetic diversity in leading candidate antigens, vaccines have been and continue to be formulated using recombinant antigens representing only one or two strains. However, narrowing the focus to immunologically relevant polymorphisms would enhance the identification of relevant antigenic diversity. The effect of allelic polymorphism on malaria parasite specific *ex vivo* IFN- $\gamma$  response to Apical Membrane Antigen 1 (AMA 1) in a malaria exposed population was investigated in this study. Five study subjects with known HLA A and/or B super types were recruited and peripheral blood mononuclear cells (PBMCs) isolated from their venous blood samples. Bioinformatically selected MHC class I-specific AMA1 epitopes from the 3D7 parasite strain were aligned with corresponding sequences from 7G8, FVO, tm284, FC27 and AAN35928 AMA1 strains and peptides with amino acid variability were selected. A total of 133 peptides (62 allelic sets of 3 or 2 peptides each) were selected and synthesized for stimulation of subjects' PBMCs in IFN- $\gamma$  ELISpot Assays. Out of the 62 allelic set sequences, 17.74% were partially positive, and were of the HLA A01, A02, A03 and B44 specific alleles. Variation in peptide responses among allelic sets were common among alleles with amino acid alterations at the peptide binding sites. Further broad-based research in this area may help inform the design of an effective malaria vaccine using recombinant antigens.

### 386

#### VALIDATION AND OPERATIONAL FEASIBILITY OF THREE STRATEGIES FOR GEOLOCATING MALARIA INFECTIONS DETECTED AT HEALTH FACILITIES, SCHOOLS AND CHURCHES IN HAITI

Thomas Druetz<sup>1</sup>, Gillian Stresman<sup>2</sup>, Ruth Ashton<sup>1</sup>, Michelle A. Chang<sup>3</sup>, Jean Frantz Lemoine<sup>4</sup>, Chris Drakeley<sup>2</sup>, Thomas P. Eisele<sup>1</sup>

<sup>1</sup>Center for Applied Malaria Research and Evaluation, Tulane University, New Orleans, LA, United States, <sup>2</sup>London School of Hygiene & Tropical

Medicine, London, United Kingdom, <sup>3</sup>Division of Parasitic Diseases and Malaria, Centers for Diseases Control and Prevention, Atlanta, GA, United States, <sup>4</sup>Programme National de Contrôle de la Malaria, Port-au-Prince, Haiti

With a total number of 21,167 confirmed cases in 2016, malaria prevalence is estimated to be <1% in Haiti and infections are likely to be spatially clustered. Due to this heterogeneity and the need to target elimination interventions to such areas, it is essential to identify the location of cases detected through the passive surveillance system. This is a challenge in rural areas where formal household addresses are unavailable. This study will be conducted in the Artibonite Department in Haiti, where we will investigate the accuracy of three geolocation strategies: the self-reported nearest landmark, the location of residence identified by the participant on a digital map, and the location of residence of school children by using a GPS data logger. Landmarks will be catalogued during parallel census activities and include schools, markets, and health facilities. The likely area of participants' residence will be triangulated by the overlapping catchment areas of these landmarks based on the Euclidian distance. Digital maps will be displayed on a tablet screen (6 x 3.5 inch) using free Landsat imagery with 50-foot resolution. These strategies will be tested by recruiting 2100 randomly selected individuals per venue type during an easy access group study to be conducted in 25 primary schools, 8 churches, and 10 health facilities. A random sample of 25% of all participants from schools and health facilities will be traced to their households with a Garmin GPS receiver to serve as a gold standard for validation purposes. Accuracy will be assessed by the proportion of households correctly identified within given tolerance zones around the true location as well as the straight-line distance between the identified and true locations. The precision of these geolocation strategies will be compared along with their respective costs, feasibility and expected usefulness for malaria passive surveillance in health facilities and in sentinel populations. This study will provide evidence with respect to the accuracy and operational feasibility of different geolocation strategies in resource-poor settings where malaria elimination efforts are implemented.

### 387

#### IDENTIFYING THE COMPONENTS OF SEVERE MALARIA ACIDOSIS BY METABOLOMICS

Stije J. Leopold

Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Metabolic acidosis is common in severe malaria and predicts mortality in all age groups. During severe infection, a large parasite biomass sequesters in the microvasculature resulting in acidosis and subsequent clinical deterioration. We hypothesized that previously uncharacterized acids besides lactic acid contribute to acidosis. We enrolled 108 adult patients with *P. falciparum* malaria and 48 healthy controls in an observational study in 2014-2015 in Bangladesh. Out of 108 malaria patients, 61 had severe malaria and 23 had WHO defined severe malaria acidosis (base deficit >8mEq/L); the severe malaria case fatality rate was 33%. In severe malaria acidosis, lactate only explained on average 49% (95%CI; 11%) of the base deficit. We applied ultra-high performance liquid-chromatography mass spectrometry to measure the complete plasma acid load and detected 355 unique metabolites. In addition to lactate, we identified 12 acids and 6 additional metabolites associated with standard base deficit in severe malaria patients (false detection rate (FDR) <20%, adjusted  $p < 0.05$ ). Metabolic pathway analysis revealed enrichment of arginine and proline metabolism (FDR 1.5%,  $p < 0.001$ ) and glycine and glyoxylate metabolism (FDR <1%,  $p < 0.01$ ). Increases in metabolite levels were associated with mortality in univariate regression ( $p < 0.05$ ), including dimethylglycine, pipercolic acid, homoserine, and glutamine. Metabolites implicated in host-acidosis were further evaluated using an *in vitro* Pf3D7 culture and analyte secretion was assessed using the same analytical platform. A total of 3 out of 12 acids were found to be secreted by Pf3D7 *in vitro*, including proline, pyruvic acid, and lactic acid, potentially contributing to hyperlactataemia. Our results show acidosis in severe malaria is associated with circulating arginine and glycine metabolites.

Arginine metabolites are likely accumulating due to its catabolism in severe malaria; Glycine metabolites indicate dysregulated energy metabolism. These results further characterize acidosis in severe malaria, and may provide markers of infection and potential targets for adjunctive therapy.

### 388

#### TARGETING *PLASMODIUM* SPOROZOITE LIVER INVASION WITH A PHAGE DISPLAY LIBRARY

Sung-Jae Cha, Marcelo Jacobs-Lorena

Johns Hopkins University, Baltimore, MD, United States

After inoculation by the bite of an infected mosquito, the *Plasmodium sporozoite* enters the blood stream. To initiate a productive infection, sporozoites must exit the blood vessels in the liver by preferentially traversing liver macrophages (Kupffer cells). Using a phage display library we previously identified peptides which bind to Kupffer cells and by doing so, inhibit sporozoite invasion. We determined that the peptides bind to the Kupffer cell receptor CD68 and that during invasion, sporozoite surface GAPDH interacts with CD68. Importantly we showed that one of the CD68-binding peptides serves as a pre-erythrocytic vaccine candidate. We screened the same phage display library to investigate *P. berghei* sporozoite interaction with mouse hepatocytes. Our candidate hepatocyte-binding peptides competitively inhibit sporozoite hepatocyte invasion *in vitro*. We are now seeking the identification of a sporozoite ligand, which presumably competes with the peptides for hepatocyte binding and invasion. These experiments may lead to the identification of an additional pre-erythrocytic vaccine candidate.

### 389

#### ADVANCED MEDICAL IMAGING IN IN EARLY MALARIA: CAN IT HELP US UNDERSTAND WHERE THE PARASITES GO AND ORGAN-SPECIFIC HOST RESPONSES?

John Woodford<sup>1</sup>, Paul Thomas<sup>2</sup>, Stephen Rose<sup>3</sup>, Nicholas Dowson<sup>3</sup>, Ashley Gillman<sup>3</sup>, Jennie Roberts<sup>4</sup>, Jeffrey Hocking<sup>4</sup>, Nicholas Anstey<sup>5</sup>, Stephan Chalon<sup>6</sup>, James McCarthy<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>Herston Imaging Research Facility, Brisbane, Australia, <sup>3</sup>Commonwealth Scientific and Industrial Research Organization, Brisbane, Australia, <sup>4</sup>Royal Brisbane and Women's Hospital, Brisbane, Australia, <sup>5</sup>Menzies School of Health Research, Darwin, Australia, <sup>6</sup>Medicines for Malaria Venture, Geneva, Switzerland

Functional imaging to study biological changes is being increasingly utilized. We hypothesized that non-invasive imaging in human experimental malaria will provide insights into both parasite location and disease pathogenesis. We performed whole body 18F FDG-PET/MRI at baseline, and just prior to treatment in 5 participants undergoing induced blood stage malaria (IBSM) infection with *P. falciparum* (n=2) and *P. vivax* (n=3). At the time of imaging participant parasitemia were between 2,753 and 27,704 parasites/mL. MRI sequences were performed to assess cerebral vascular and blood brain barrier integrity. MRI data was qualitatively reported, including review of cerebral imaging. PET data was qualitatively reported to assess for changes by a nuclear medicine physician. Semi-quantitative standardized uptake values were reported for the liver, spleen, bone marrow, skeletal muscle and brain. Quantitative analysis of FDG uptake the spleen by PATLAK is underway. Preliminary review of MRI data did not identify any gross changes from baseline, including specific neuroimaging reporting. Preliminary quantitative PET analysis found increased post-inoculation 18F FDG uptake in the liver and spleen of *P. falciparum* participants. Increased uptake was found in the liver, spleen, bone marrow, skeletal muscle and cortex of *P. vivax* participants, with reduced uptake in the cerebellum. These findings indicate early activation of the reticuloendothelial system in subpatent malaria infection, and present material for further *in vivo* analysis, including investigation for sequestration of *P. vivax* in non-endothelial

lined compartments. Refined imaging sequences will be applied to a further population of *P. falciparum* and *P. vivax* participants in experimental malaria infection studies.

### 391

#### DEVELOPMENT OF A NOVEL AMPLICON DEEP SEQUENCING MARKER AND DATA ANALYSIS PIPELINE FOR GENOTYPING OF MULTI-CLONAL *PLASMODIUM FALCIPARUM* INFECTIONS

Anita Lerch<sup>1</sup>, Cristian Koepfli<sup>2</sup>, Natalie Hofmann<sup>1</sup>, Ivo Mueller<sup>2</sup>, Ingrid Felger<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

Amplicon deep sequencing permits sensitive detection of minority clones and improves discriminatory power for genotyping multi-clone *Plasmodium falciparum* infections. Currently used genotyping methods based on length polymorphic markers such as merozoite surface proteins 1 and 2 (*msp1*, *msp2*) may suffer from competition of templates in PCR. Diversity in amplicon sequencing relies on haplotypes created from several SNPs. In search for highly diverse markers 3'411 genomes from 23 countries, published by the *Plasmodium falciparum* Community Project (MalariaGEN), were screened for high diversity within a stretch of 500 bp. A 430 bp fragment of PF3D7\_0104100 (conserved *Plasmodium* membrane protein, *cpmp*) was identified. Targeted *cpmp* sequencing was conducted in duplicate on mixtures of parasite culture strains and on 153 archived field samples from 34 children aged 1-5 years from a cohort study conducted in Papua New Guinea (PNG). A protocol to multiplex up to 384 samples in a single sequencing run was applied. Software "HaplotypR" was developed for data analysis with the aim to distinguish true minority clones from sequencing errors. HaplotypR was validated using experimental mixtures of *P. falciparum* *in vitro* culture strains and tested on field samples. Expected heterozygosity (He) of *cpmp* was 0.93 in the worldwide MalariaGEN dataset and 0.96 in field samples from PNG. Results from amplicon sequencing were compared to those obtained from length polymorphic marker *msp2*, which had a He of 0.95 in field samples. Highly multiplexed amplicon sequencing of marker *cpmp* displayed greater sensitivity in detecting minority clones, which was reflected in a mean multiplicity of infection (MOI) 2.48 for *cpmp* compared to 2.03 for *msp2*. False haplotype calls owing to sequencing errors were observed below a frequency of 1%.

### 392

#### AN OPTIMIZED METHOD FOR LARGE-SCALE PRODUCTION OF SYNCHRONIZED STAGE V *PLASMODIUM FALCIPARUM* GAMETOCYTES FOR USE IN HIGH-THROUGHPUT ANTIMALARIAL ASSAYS

Samantha Aylor<sup>1</sup>, Lacy Gaynor-Ohnstad<sup>1</sup>, Jane Kelly<sup>2</sup>, Christina Nolan<sup>1</sup>, Sophia Kish<sup>1</sup>, Chad Black<sup>1</sup>, Mara Kreishman-Deitrick<sup>1</sup>, Brian Vesely<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>Oregon Health & Science University, Portland, OR, United States

In a global effort for malaria elimination, there has recently been renewed interest in studying ways to reduce transmission of the parasite by targeting mature sexual stage gametocytes. Recent drug studies have shown that current antimalarial drugs act on *Plasmodium falciparum* gametocytes differently than asexual stages and are usually less efficacious. Therefore, it is essential that drug discovery efforts include finding transmission-blocking compounds that are effective at eliminating metabolically quiescent Stage V gametocytes. Experimental Therapeutics' (ET) mission to develop a once a week prophylactic drug is aided by knowledge of candidate compounds' anti-gametocyte activity to discriminate against similar structures and help align with potential partners target product profile. One of the major obstacles with researching gametocytes is the length of time it takes to prepare

an adequate amount of these transmissible forms for high-throughput screenings. Although there have been several protocols recently published on obtaining large amounts of synchronized gametocytes, current approaches involve very laborious bulk-up procedures that include multiple rounds of time-consuming synchronization and enrichment techniques over the course of several weeks. Therefore, we sought to improve current protocols by comparing various synchronization, enrichment, and cryopreservation techniques to ultimately create a simplified, time-saving method of producing large amounts of viable gametocytes to be included in high-throughput drug screening. Using a combination of traditional and novel methods, we have greatly reduced bulk-up time and increased in-house capacity. Using a 384-well plate format, we currently have the capability to screen approximately 140 compounds and prescreen over 700 compounds in duplicate per assay run, with the potential to further increase throughput. This optimized and validated assay will serve as an important tool to access candidate compounds' transmission blocking ability for Experimental Therapeutics' ET's plasmodium drug evaluation paradigm.

### 393

#### TRACKING LONG-LASTING INSECTICIDE-TREATED NETS DISTRIBUTED THROUGH SCHOOLS IN A MALARIA ENDEMIC REGION OF NORTHERN ZAMBIA

**Japhet M. Matoba**<sup>1</sup>, Mukuma Lubinda<sup>1</sup>, Philip E. Thuma<sup>1</sup>, Muleba Mbangwa<sup>2</sup>, Mike Chaponda<sup>2</sup>, James Lupiya<sup>2</sup>, Alex Chilabi<sup>3</sup>, Douglas E. Norris<sup>4</sup>, William J. Moss<sup>5</sup>, Jennifer C. Stevenson<sup>4</sup>

<sup>1</sup>Macha Research Trust, Choma, Zambia, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>3</sup>National Malaria Elimination Program, Lusaka, Zambia, <sup>4</sup>W. Harry Feinstone Department of Molecular Microbiology and Immunology, The Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>5</sup>Department of Epidemiology, The Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Zambia has adopted mass campaigns every 3 years as the main distribution channel of long-lasting insecticide-treated nets (LLINs). Models, however, show that household LLIN coverage following mass distribution drops to 65% and 35% after 2 and 3 years, respectively. To ensure sustained coverage above the target of 100%, a program was piloted in Luapula Province, northern Zambia, using primary schools as points of distribution. The Southern Africa ICEMR project sought to track nets distributed in Nchelenge District of Luapula Province to determine whether the objectives of increasing household coverage and use of LLINs were met. From 12 primary schools 2,225 nets were distributed in October 2016. Monthly surveys of nets were conducted in 25 randomly selected households in the catchment area of these schools alternating between cross-sectional and longitudinal cohorts from December 2016 to March 2017. A total of 76 households were sampled. Sixty-seven nets of different origins were found in 46 households; 29 households had only one LLIN, 13 had two and 4 households had three nets. Twenty-five percent of nets were obtained through mass campaigns, 16.4% came from schools, 10.4% from community health workers and 14.9% were purchased. Of all nets found, 84% (56 out of 67) were hanging and being used. Of the 11 nets obtained from schools, 8 were in use at the time of the visits, all being occupied by school-aged children. Despite only sampling 0.25% of households across the district (76 out of 31,000), 32 of these had primary school-going children likely to be in grades that received nets, yet only 10 households had a school-distributed net. Across all households, school-net distribution increased the household coverage of LLINs from 56.6% (43 households) to 60.5% (46 households) and the mean number of LLINs per household from 1.22 to 1.46 nets in the 5 months post-distribution. Usage, however, did not increase as nets already present in the house were used; three school nets were still wrapped. In addition to helping understand utility, studies like this need to be expanded to help better understand mechanisms of getting interventions (LLINs) into communities.

### 394

#### COMPLETENESS OF MALARIA INDICATORS REPORTED THROUGH THE DISTRICT HEALTH INFORMATION SYSTEM IN KENYA, 2011-2015

**Sophie W. Githinji**<sup>1</sup>, Robinson Oyando<sup>1</sup>, Josephine Malinga<sup>1</sup>, Waqo Ejersa<sup>2</sup>, David Soti<sup>3</sup>, Josea Rono<sup>4</sup>, Robert W. Snow<sup>1</sup>, Ann M. Buff<sup>5</sup>, Abdisalan M. Noor<sup>1</sup>

<sup>1</sup>KEMRI Wellcome Trust Research Programme, Nairobi, Kenya, <sup>2</sup>National Malaria Control Programme, Ministry of Health, Nairobi, Kenya, <sup>3</sup>Division of Monitoring and Evaluation, Health Research Development and Health Informatics, Ministry of Health, Nairobi, Kenya, <sup>4</sup>E&K Consulting Firm, Nairobi, Kenya, <sup>5</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, U.S. Centers for Disease Control and Prevention, Nairobi, Kenya

The adoption of District Health Information Systems (DHIS2) has contributed to improved availability of routine health facility-based data in many countries. We conducted a 5-year retrospective, longitudinal assessment of DHIS2-reported malaria data from January 2011-December 2015 in Kenya. Malaria data were analyzed for 6,235 public and 3,143 private facilities. Completeness of reporting was measured as the percentage of data values reported over the expected number in a given year. Between 2011 and 2015, completeness of reporting in the public sector increased significantly for confirmed malaria [26.5% to 41.8% in children aged <5 years and 30.6% to 51.2% in persons aged ≥5 years [both p<0.0001] and for new antenatal care (ANC) clients [53.7% to 70.5%, p<0.0001] but decreased for intermittent preventive treatment in pregnancy (IPTp) doses 1 and 2 [64.6% to 53.7% and 64.6% to 53.4%, respectively, both p<0.0001]. The number of people tested for malaria was not available in DHIS2 from 2011 to 2014, although 59%-91% of facilities had malaria diagnostics available. In 2015, only sparse malaria-test data for microscopy [11.5% for <5 years; 11.8% for ≥5 years] and rapid diagnostic tests (RDT) [8.1% for all ages] was reported. In the private sector, completeness of reporting increased significantly for confirmed malaria [16.7% to 23.1% in <5 years; 19.4% to 28.6% in ≥5 years], new ANC clients [16.2% to 23.6%], and IPTp doses 1 and 2 [16.6% to 20.2% and 15.5% to 20.5%, respectively] [all p<0.0001]. In 2015, <3% of malaria-test data was reported. Key malaria indicator reporting completeness improved since DHIS2 implementation in 2011 in Kenya. The major gaps identified were in malaria-testing data in both sectors and overall low reporting of malaria indicators in the private sector. Integrating malaria-test data into DHIS2 by including total number tested and number of test-positives will improve the data available to determine Kenya's progress towards meeting the test, treat, track initiative. Providing standard data reporting forms and training on DHIS2 implementation are recommended to improve private-sector reporting.

### 395

#### IMPROVING ADHERENCE TO THE KENYA NATIONAL MALARIA DIAGNOSIS AND TREATMENT GUIDELINES; AN OUTREACH TRAINING AND SUPPORT SUPERVISION (OTSS) APPROACH IN VIHIGA COUNTY, WESTERN KENYA

**Tony C. Mugasia**

*PATH, Kisumu, Kenya*

The Kenya national malaria diagnosis, treatment and prevention guidelines fifth edition May 2016 recommends the following: All people with suspected malaria should have a parasitological test to confirm the diagnosis, a rapid diagnostic test or microscopy, treatment should be administered to confirmed malaria cases, recommended first line for uncomplicated malaria is Artemether Lumefantrine and severe malaria treatment first line is Artesunate. The 2015 Kenya Malaria Indicators Survey report, 72% of under 5 years with fever who sought treatment, 39% were tested for malaria, instead of 100% confirmation as per the guidelines, Malaria Care Kenya health facility assessment baseline Final

report, October 2015 There were 153 observations of post-test diagnosis and treatment of the 81 negative malaria diagnostic test results recorded, 11 (14%) were prescribed an antimalarial, this is against the national malaria treatment guidelines. In Vihiga County of the 5 health facilities sampled in this assessment 40% of these facilities patients with a negative malaria test result received an antimalarial treatment. Outreach training support supervision is an approach implemented by Malaria Care project a USAID partnership whose aims is to scale up high-quality diagnosis and case management services for malaria and other febrile illnesses. Implemented by a team of skilled supervisors a clinician and laboratory technologist trained on case management and advanced malaria microscopy, this team visited 45 public health facilities through scheduled visits in Vihiga County western Kenya, for the period November 2015 to December 2016 to assess malaria core indicators of Clinical Observation, Laboratory observation, RDT Competence, Adherence to testing prior to treatment, Negative and positive test adherence and general using an electronic checklist, they provided onsite mentorship, based on the outreach training support supervision report their was improvement of the Malaria Care core indicators in adherence to the Kenya national guidelines fifth edition 2016 across the three rounds of outreach support supervision conducted in Vihiga County.

<sup>1</sup>St. Joseph's Catholic Hospital, Monrovia, Liberia, <sup>2</sup>Barcelona Institute of Global Health, Barcelona, Spain, <sup>3</sup>Juan Ciudad Foundation, Madrid, Spain

Liberia is one of the countries with a lowest public spending as a % of GDP allocated to health. Two civil wars and a recent Ebola outbreak have contributed to a health system that needs vast investment to see its capacity to lead infectious diseases research strengthened. Malaria is highly endemic. It affects 45% of the 6-59 months children according to the last Malaria Indicator Survey. Due to the diversion of resources for health during the Ebola crisis, a 62% increase of malaria-attributable mortality was estimated. In spite of these constraints, there is a paucity of epidemiological research. With the aim to map barriers to engage pregnant women in malaria prevention and research, we conducted a qualitative inquiry nested in a malaria prevalence study at the St Joseph Catholic Hospital in Monrovia. Grounded theory guided data collection and analysis. We sought for hospital staff, community leaders, and pregnant women participants to the prevalence study as key informants. Recruitment started in November 2016 and ended in February 2017. Thirty-nine informants partook in twenty-six in-depth interviews and in three focus group discussions. Common agreement was that cultural beliefs and widespread corruption deter people from adhering to prevention advices. Witchcraft and vectors other than mosquitoes as perceived causes of malaria impel people to first seek care from African herbalists. So does lack of trust in health staff, experiences of bribery, low awareness of vulnerabilities, and the introduction of cost recovery in some clinics. The informants suggested that researchers should design prevention tools inspired on the ointments and concoctions provided by the herbalists, and that community-tailored education may help allay fears induced from previous exposure to clinical trials that may discourage women from engaging in any academia-led activity. We conclude that these identified deterrents shaped by recent historical events must be addressed, in partnership with local leaders, at the outset of any future program, as these are drivers that may influence Liberians deciding not to accept take part in malaria research and prevention.

#### **DO DEMOGRAPHIC AND HEALTH SURVEYS ACCURATELY MEASURE MALARIA DIAGNOSIS AND TREATMENT RECEIVED BY CHILDREN UNDER FIVE YEARS? A TREATMENT RECALL VALIDATION STUDY IN MALI**

**Ruth Ashton**<sup>1</sup>, Bakary Doumbia<sup>2</sup>, Diadier Diallo<sup>3</sup>, Thomas Druetz<sup>4</sup>, Seydou Fomba<sup>5</sup>, Diakalia Koné<sup>6</sup>, Jules Mihigo<sup>6</sup>, Lia Florey<sup>7</sup>, Erin Eckert<sup>8</sup>, Thomas P. Eisele<sup>4</sup>

<sup>1</sup>MEASURE Evaluation, Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Info-Stat, Bamako, Mali, <sup>3</sup>MEASURE Evaluation, ICF, Bamako, Mali, <sup>4</sup>Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>5</sup>Programme National de Lutte Contre le Paludisme, Bamako, Mali, <sup>6</sup>President's Malaria Initiative, U.S. Agency for International Development, Bamako, Mali, <sup>7</sup>The DHS Program, ICF, Rockville, MD, United States, <sup>8</sup>President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States

Access to and treatment with artemisinin-based combination therapy (ACT) is monitored periodically through large-scale, nationally representative household surveys. These estimate the proportion of children under five years (U5s) with a fever in the past 2 weeks who received an ACT, among those who received any antimalarial. However, this indicator is subject to a caregiver's recall of events during the fever episode and ability to differentiate between drugs. In Mali, it is hypothesized that estimates of reported treatment received by U5s during a fever episode contain information bias due to seasonal malaria chemoprevention (SMC), generic local language terms for antimalarials, and low caregiver literacy. The 2015 Mali Malaria Indicator Survey (MIS) showed that only 32% of children receiving antimalarials reportedly received ACT, while 26% received amodiaquine and 21% sulfadoxine-pyrimethamine. A prospective case control study was designed to validate the ability of caregivers to recall diagnosis and treatment received by U5s when seeking care for a fever in Mali, replicating a study previously performed in Zambia. Details of the consultation (if diagnostic test was done, test result, drugs recommended and received) were recorded at the facility during or immediately after the consultation and serve as the gold standard to which caregiver recall was compared. Consenting caregivers received a follow-up interview at home within 14 days of the consultation, comprising standard questions from MIS and Demographic and Health Survey. 1600 caregivers of febrile U5s seeking care from urban public and private facilities, rural public facilities, and community health workers were recruited. Sensitivity and specificity of caregivers' recall of ACT treatment is presented, along with description of factors associated with incorrect recall of treatment. This evidence will help determine the reliability of standard DHS questions regarding reported malaria treatment in a West African setting with ongoing national SMC, and inform global ACT coverage estimates generated from nationally-representative household surveys such as DHS.

### 398

#### **CLINICAL RISK FACTORS FOR MORTALITY IN UGANDAN CHILDREN WITH SEVERE MALARIA**

**Ruth Namazzi**<sup>1</sup>, Andrea Conroy<sup>2</sup>, Richard Idro<sup>1</sup>, Paul Bangirana<sup>1</sup>, Chandy John<sup>2</sup>, Robert Opika Opoka<sup>1</sup>

<sup>1</sup>Makerere University, Kampala, Uganda, <sup>2</sup>Indiana University, Indianapolis, IN, United States

Few studies have assessed risk factors for mortality in severe malaria since artesunate replaced quinine as first-line therapy for severe malaria in most African countries. We assessed clinical risk factors for mortality in Ugandan children admitted to a regional (Jinja) or national (Mulago) referral hospital with one or more of the five most common manifestations of severe malaria: cerebral malaria (CM), respiratory distress (RD), malaria with

complicated seizures (MS), severe malarial anemia (SMA) or prostration. Children were treated according to national guidelines for severe malaria, which included parenteral artesunate as first-line anti-malarial therapy. 581 children age 6-48 months were enrolled in the study, with a mean (SD) age of 2.1 ±0.9 years. The overall mortality rate was 43/581(7.4%), and 60% of the deaths occurred within 24 hours of admission. Mortality was highest in CM (29/84, 34.5%) and RD (12/115, 10.4%), while mortality in MS, SMA and prostration was low (1/158, 0.6%; 0/150, 0%; and 1/74, 1.3%, respectively). Coma (odds ratio, 95% confidence interval, 16.0, 6.9-37.5), acidosis (base excess ≤ -8mmol/L) (6.1, 1.6-22.5), blood urea nitrogen ≥ 20mg/dL (2.6, 1.1-6.1) and respiratory distress (3.6, 1.5-9.0) were independently associated with increased mortality among all children with severe malaria. The presence of coma, acidosis and elevated blood urea nitrogen was associated with 58.8% mortality, and the addition of respiratory distress increased mortality to 71.4%. Research to identify and prevent the causes of coma, acidosis, respiratory distress and uremia in severe malaria has the potential to substantially decrease malaria-associated mortality.

### 399

#### COVERAGE OF AND FINANCIAL RISK ASSOCIATED WITH UNCOMPLICATED MALARIA TREATMENT AMONG CHILDREN UNDER FIVE YEARS IN MALAWI: EVIDENCE FROM NATIONAL SURVEYS

**Wala Kamchedzera**, Jobiba Chinkhumba, Patrick Mwale, Atupele Kapito-Tembo, Don Mathanga

*College of Medicine, University of Malawi, Malaria Alert Centre, Blantyre, Malawi*

Universal health coverage (UHC) entails access to quality healthcare without incurring financial hardships from healthcare payments. Despite UHC gaining traction as a priority public health goal in the post 2015 development agenda, and tracking progress and social protection being essential to the strategy's monitoring framework, few studies have assessed UHC for priority tropical diseases. This study investigated the coverage of and financial risk associated with treatment of uncomplicated malaria in children ≤ 5 years in Malawi. Using secondary data from two sources, the 2010 Malaria Indicator Survey (MIS) and the 2010-11 Integrated Household Survey (IHS), we obtained information on episodes of fever, use of health services, time of treatment, days lost seeking and receiving care, and welfare in relation to consumption. We estimated coverage of uncomplicated malaria treatment and associated financial risk ascertained as the ratio of malaria expenditure to non-food expenditure. We present results by social economic tertiles; poor, middle poor and least poor. Of the 2115 children with complete data, 23.8% had uncomplicated malaria of which 30.1%, 27.1% and 12.3% were poor, middle poor and least poor respectively. Overall, 26.4% of the children ≤ 5 years obtained treatment within 48 hours of fever onset. The proportions were 14.2%, 35.7% and 32.7% among the poor, middle poor and least poor respectively. Overall financial risk was 0.90%; across social economic groups this was 0.92%, 0.98% and 0.65% for the poor, middle poor and least poor respectively. No household experienced catastrophic health expenditure. The economic burden of uncomplicated malaria among children ≤ 5 years in Malawi is very low; thus household costs on uncomplicated malaria are not catastrophic. This indicates that the health system, with regards to uncomplicated malaria adequately protects households from financial risk. However, the results showed relative disparities across social economic groups in both malaria and financial burden, implying that Malawi's health policy needs to be adjusted to address these inequalities.

### 400

#### CONGENITAL MALARIA AND ANEMIA IN NEONATES FROM LIBREVILLE, GABON

**Bridy Moutombi Ditombi**, Julienne Minko, Ornella Anaise Mbang Nguema, France Ovengue, Denise Patricia Mawili-Mboumba, Marielle Karine Bouyouk Akotet

*Universite des Sciences de la Sante, Libreville, Gabon*

In Gabon, a rebound of malaria morbidity is observed since 2011 and more than 79% of febrile children are anemic. The frequency of congenital malaria and its relationship with anemia was estimated among newborns hospitalized for neonatal infections in GABON. This was a prospective, cross-sectional study conducted between June and November 2015 in a sentinel site for malaria survey. All newborns hospitalized for a suspected neonatal infection were screened for malaria by microscopy and for anemia using an ABX system. A total of 100 newborns were included, the majority (77%) was less than 8 days old, 23% were very preterm and half the population had a low birth weight. Malaria was the most common mother infectious disease presented during pregnancy. The frequency of congenital malaria was 21%, with 13 children having both malaria and bacterial infection. The median parasitemia was 1500[750-4000]p/μL. The median Hb level was 15.4[11.4-17.1]g/dL and the frequency of anemia was 52%; almost all (89%) the 8 to 15-day-old babies were anemic and 66.6% of them had moderate to severe anemia. Among newborns with malaria, 62% were anemic (*versus* 38% of malaria negative ones). IPTp-SP, number of ANC visits, HbSS, were not associated with anemia in newborns. In conclusion, congenital malaria and neonatal anemia burden seems to be high among neonates and malaria is strongly associated with neonatal anemia.

### 401

#### IMPACT OF AGE ON DIHYDROARTEMISININ-PIPERAQUINE EXPOSURE IN YOUNG UGANDAN CHILDREN

**Meghan E. Whalen**<sup>1</sup>, Nona Chamankhah<sup>1</sup>, Liusheng Huang<sup>1</sup>, Richard Kajubi<sup>2</sup>, Catherine A. Koss<sup>1</sup>, Abel Kakuru<sup>2</sup>, Francis Orukan<sup>2</sup>, Moses R. Kamya<sup>2</sup>, Grant Dorsey<sup>1</sup>, Philip J. Rosenthal<sup>1</sup>, Francesca T. Aweeka<sup>1</sup>, Norah Mwebaza<sup>2</sup>

<sup>1</sup>*University of California San Francisco, San Francisco, CA, United States,*

<sup>2</sup>*Infectious Diseases Research Collaboration, Kampala, Uganda*

Artemisinin-based combination therapies (ACTs) are standard for the treatment of malaria in children in Africa. Dihydroartemisinin-piperazine (DHA-PQ), an ACT with excellent antimalarial efficacy in Africa, is being evaluated for chemoprevention in children. However, our understanding of the impact of age on DHA-PQ pharmacokinetics (PK) is limited. We compared the PK of PQ in Ugandan children enrolled in a DHA-PQ chemoprevention trial at 32 and 104 weeks of age using an intensive PK design. PQ levels were collected after the 3rd dose of a standard weight-based regimen of DHA-PQ (daily dose x 3 days). Venous blood samples were taken at 0, 0.5, 1, 2, 3, 4, 6, 8, and 24 hours after the dose. Capillary blood samples were also collected 24 and 48 hours after the third dose, and on days 7, 14, and 21. To determine the impact of maturation on PQ disposition, PK parameters were compared between the same 31 children at 32 and 104 weeks of age, and between children at 104 weeks of age (n=31) and non-pregnant adult women (n=24) to compare PK in children and adults. PQ levels were measured by LC-MS/MS and the PQ area under the concentration-time curve (AUC) was measured over 21 days. Preliminary data indicate reduced PQ exposure in children aged 104 versus 32 weeks of age, as measured by AUC (6.60 vs 9.54 hr.ug/mL, p<0.01) and terminal PQ concentrations on days 7, 14, and 21 (6.19, 3.46, 2.14 ng/mL vs 12.6, 6.20, 3.55 ng/mL; all p values <0.03). Comparing children at 104 weeks of age to adults, we found decreases in PQ AUC (6.60 hr.ug/mL vs 17.6 hr.ug/mL, p<0.0001) and terminal levels on days 7, 14 and 21 (6.19, 3.46, 2.14 ng/mL vs 30.9, 17.7, 11.2 ng/mL, p<0.0001, respectively). PQ exposure was significantly lower at 104 weeks compared to 32 weeks of age. Children at 104 weeks of age exhibited significantly

lower exposure than adults. Children at both ages exhibited terminal PQ concentrations (7, 14, and 21 days) <15 ng/mL. The clinical relevance of these findings requires further study.

## 402

### QUALITY OF CARE DETERMINANTS OF COMMUNITY CASE MANAGEMENT OF UNCOMPLICATED MALARIA IN WESTERN KENYA

**Enock O. Marita<sup>1</sup>**, Jared O. Oule<sup>1</sup>, Margaret Mungai<sup>1</sup>, Sylla Thiam<sup>2</sup>, Sarah Karanja<sup>1</sup>, Richard Gichuki<sup>1</sup>

<sup>1</sup>Amref Health Africa, Nairobi, Kenya, <sup>2</sup>Amref Health Africa, Dakar, Senegal

Quality of service is important in management of malaria. Prevention and control of malaria will not be achieved without timely diagnosis, treatment and monitoring. Kenya, a country with high poverty rate, has adopted World Health Organization's recommendation of community case management of malaria (CCMM). This concept has now been implemented for over four years and little or no information is available on the quality of services provided by community health volunteers (CHVs). Amref Health Africa with Global Fund has supported this in western Kenya. This study established determinants of quality of service of CCMM by CHVs. A cross sectional survey was conducted and the study lasted four weeks. The CHVs were observed as they carried out their duties and various aspects were noted and thereafter administered a questionnaire. Data was analysed using SPSS. Majority (62%) of the CHVs were found to offer quality services based on 75% cut off score considering their low literacy levels. It was realised that there was relationship at  $P < 0.05$  among stock outs of Artemether lumefantrine ( $P=0.037$ ), rapid diagnostic test kits ( $P=0.001$ ) and support supervision ( $P=0.007$ ) to quality of services offered by CHVs. Other factors including sociodemographics (such as marital status, gender, religion, and education level), referrals, other commodities except ALS and RDTs had no association with quality of services. CHVs who had ever had support supervision were 4 times likely to perform better than those not support supervised. CHVs who did not experience Artemether lumefantrine and rapid diagnostic test kits stock outs were most likely to perform three times better than those who experienced stock outs (AUOR 3.2 and 3.3 respectively at 95% CI). A good percentage of CHVs offered quality services in CCMM. Steady and continuous supply of RDTs, ALS and provision of support supervision are essential in the performance of CHVs in management of uncomplicated malaria at community level.

## 403

### TOWARD IMPROVED HEALTH SYSTEMS RESPONSIVENESS: A CROSS-SECTIONAL STUDY OF MALARIA ENDEMICITY AND READINESS TO DELIVER SERVICES IN KENYA, NAMIBIA AND SENEGAL

**Elizabeth Lee<sup>1</sup>**, Cara H. Olsen<sup>2</sup>, Tracey Koehlmoos<sup>2</sup>, Penny Masuoka<sup>1</sup>, V. Ann Stewart<sup>2</sup>, Jason Bennett<sup>3</sup>, James Mancuso<sup>4</sup>

<sup>1</sup>The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, <sup>2</sup>The Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>3</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>4</sup>United States Army Medical Research Directorate-Kenya, Nairobi, Kenya

New, straightforward approaches for measuring health system responsiveness to disease are needed toward continued health systems strengthening. Despite good progress toward elimination, malaria continues to contribute substantially to the sub-Saharan African disease burden. Sustaining previous gains requires continued readiness to deliver health services in response to actual disease burden. In this study, as a measure of health system responsiveness, we examined whether malaria prevalence is a driver of health facility readiness to deliver services. Using a cross-sectional design, we examined the relationship between malaria prevalence, or endemicity, and facility readiness to deliver services

using facility survey data for Kenya, Namibia, and Senegal geo-linked to endemicity data. We tested the validity and reliability of the malaria service readiness index, the primary study outcome, and mapped service readiness components in a geographic information system. We conducted a weighted multivariable linear regression analysis of the relationship between endemicity and malaria service readiness, stratified for urban or rural facility location. As endemicity increased in rural areas, there was a concurrent, modest increase in service readiness at the facility level [ $\beta$ : 0.028; (95% CI: 0.008, 0.047)], whereas no relationship existed in urban settings. Private-for-profit facilities were generally less prepared than public [ $\beta$ : -0.102; (95% CI: -0.154, -0.050)]. Most facilities had the necessary supplies to diagnose malaria, yet availability of malaria guidelines and adequately trained staff as well as medicines and commodities varied. Findings require cautious interpretation outside the study sample, which was a more limited subset of the original surveys' sampling schemes. Our approach and findings may aid national malaria programs in identifying variations in facility performance for targeted service delivery interventions.

## 404

### ANTIPLASMODIAL ACTIVITY IN *COCOS NUCIFERA* LEAVES FROM THE NATURAL RESERVE OF PUNTA PATIÑO, DARIÉN

**Nicole Tayler<sup>1</sup>**, Liuris Herrera<sup>2</sup>, Michelle Ng<sup>3</sup>, Laura Pineda<sup>3</sup>, Alejandro Almanza<sup>3</sup>, Sara Rosero<sup>3</sup>, Lorena Coronado<sup>1</sup>, Ricardo Correa<sup>1</sup>, Christopher A. Boya<sup>1</sup>, Ricardo Santamaria<sup>4</sup>, Zuleima Caballero<sup>3</sup>, Marcelino Gutierrez<sup>4</sup>, Armando Durant<sup>4</sup>, Kevin Tidgewell<sup>2</sup>, Jamie Moy<sup>2</sup>, Marcy Balunas<sup>5</sup>, William H. Gerwick<sup>6</sup>, Alida Spadafora<sup>7</sup>, Carmenza Spadafora<sup>3</sup>

<sup>1</sup>Department of Biotechnology, Acharya Nagarjuna University, Guntur, India, <sup>2</sup>Smithsonian Tropical Research Institute, Panama, Panama, <sup>3</sup>Centro de Biología Celular y Molecular de Enfermedades, Instituto de Investigaciones Científicas y Servicios de Alta Tecnología AIP, Panama, Panama, <sup>4</sup>Centro de Biodiversidad y Descubrimiento de Drogas, Instituto de Investigaciones Científicas y Servicios de Alta Tecnología AIP, Panama, Panama, <sup>5</sup>Division of Medicinal Chemistry, Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT, United States, <sup>6</sup>Skaggs School of Pharmacy and Pharmaceutical Sciences Scripps Institution of Oceanography, San Diego, CA, United States, <sup>7</sup>Asociación Panameña para la Conservación de la Naturaleza (ANCON), Panamá, Panama, Panama

For the past few decades the search for biologically active compounds from nature has been intensified, in response to the failure of commercially available drugs due to malaria parasite resistance and costs. *Cocos nucifera*, the coconut tree, has been traditionally used to fight a number of human diseases and symptoms like diarrhea and fever, including malaria. Previous studies have associated its therapeutic activity with the presence of phenolic metabolites in the plants' husk, inflorescence, fruit and water. To date, only the husk has been reported of containing compounds against *Plasmodium falciparum*, despite other plant parts being traditionally used to treat patients. In this study we analyzed the leaves of *C. nucifera* in order to test its activity against *P. falciparum*. We sampled the leaves from *C. nucifera* plants collected from a private natural reserve in Punta Patiño, Darién. The aqueous extract of a 15 min decoction of the leaves was used against *P. falciparum* *in vitro*. Positive results with the extract (up to 70% growth inhibition at 10% v/v) led to a solid phase extraction (SPE) of the crude extract which produced fractions for further testing. The active fraction and the decoction were used in ultra performance liquid chromatography (UPLC) coupled to a mass spectrometer (LC – MS/MS) for the identification of the chemical compounds in the extracts. A series of polyphenols were found, most of them belonging to the flavan-3-ol, with epicatechin being one of them, and some flavones such as isoorientin (luteolin-6-C-glucoside). The aqueous decoction of leaves as well as the active fraction obtained by SPE were tested for cytotoxicity in Vero cells at the same antiplasmodial concentrations and no effect was observed. This suggests that the activity against *P. falciparum* from the leaves of *C. nucifera* might be caused by phenolic compounds, and that this finding merits further research to isolate and identify the possible active molecules.

## 405

### USING GENOMIC DATA FOR OPERATIONAL DECISION MAKING IN MALARIA ELIMINATION IN SENEGAL

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Cheikh Anta Diop University, Dakar, Senegal, <sup>3</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>4</sup>SLAP, Thies, Senegal, <sup>5</sup>Senegal National Malaria Control Program, Dakar, Senegal, <sup>6</sup>Broad Institute, Cambridge, MA, United States, <sup>7</sup>Harvard University, Cambridge, MA, United States

Progress toward malaria elimination requires new tools and strategies to guide decision-making at a programmatic level. Molecular genetic signatures including parasite relatedness can help track drug resistance, transmission dynamics, and sources of new infections. Combining molecular genetic signatures with clinical, epidemiological, and serological indicators can identify parasite population structure and connectivity between different transmission foci. Integration of these data with health management information systems like DHIS2 can better inform decision-making. We applied molecular epidemiological tools to estimate transmission trends in Senegal based on metrics including complexity of infection, parasite relatedness, and clonality. Epidemiological modeling of genetic data detected both declines and rebounds in malaria transmission (R0) over the past decade in Thies, Senegal. In the high transmission area of Kedougou, Senegal, increased intervention deployment over the past 4 years resulted in comparable genetic signals of increasing parasite relatedness and greater clonality. Between 2013 and 2015 we observed increased monogenomic infections (from 44% to 72%), and 8% of monogenomic infections exhibit shared genomic signatures in 2015 versus none in 2013. Hence simple genomic tools, such as a molecular barcode to identify parasite lineages, rapidly reveal trends of parasite relatedness and clonality related to transmission dynamics across Senegal. Drug resistance marker surveillance tracks the consequences of increasing drug pressure on these populations. These results exemplify the utility of barcoding relatively small numbers of individual samples to provide real-time, informative data with operational implications for national and regional policies and practices to eliminate malaria. We present development of a dashboard that integrates molecular epidemiology with DHIS2 monitoring of health interventions toward malaria elimination.

## 406

### MANIFESTATION OF MALARIA IN MANGALORE, SOUTHERN INDIA

Prabhanjan P. Gai<sup>1</sup>, Frank P. Mockenhaupt<sup>1</sup>, Konrad Siebert<sup>1</sup>, Jakob Wedam<sup>1</sup>, Archith Bolor<sup>2</sup>, Suyamindra Kulkarni<sup>3</sup>, Rashmi Rasalkar<sup>3</sup>, Animesh Jain<sup>2</sup>, Chakrapani Mahabala<sup>2</sup>, Pramod Gai<sup>3</sup>, Shantharam Baliga<sup>2</sup>, Rajeshwari Devi<sup>4</sup>, Damodara Shenoy<sup>2</sup>

<sup>1</sup>Charité-Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Kasturba Medical College, Manipal University, Mangalore, India, <sup>3</sup>Karnataka Institute for DNA Research, Dharwad-Hubli, India, <sup>4</sup>Wenlock Hospital, Mangalore, India

Severe *Plasmodium vivax* malaria including cerebral cases and fatalities has been reported from India. In Mangalore, Karnataka, southern India, malaria is focused in urban areas and potentially associated with importation by migrant workers from endemic regions of the country. In the largest governmental hospital, we aimed at assessing the clinical, parasitological, and biochemical characteristics of malaria patients and at determining respective differences between vivax and falciparum malaria. 960 patients with PCR-confirmed *Plasmodium* infection were included. Patients were predominately male (92%), migrants from other parts of India (77%), and of overall low socio-economic status. The mean age was 30 years (range, 1-82). *P. vivax* mono-infection (69.4%) predominated

over *P. falciparum* mono-infection (9.0%) and mixed *P. vivax-P. falciparum* infection (21.4%). The geometric mean parasite density was 3776/mcl (95%CI, 3403-4189). 5.3% of patients were hospitalized, with a slightly increased proportion among *P. falciparum* infected patients (7.2%). As compared to vivax malaria patients, those infected with *P. falciparum* had significantly higher parasite density, higher axillary temperature, and lower hemoglobin levels. Moreover, patients with *P. falciparum* more frequently showed vomiting, splenomegaly, an impaired general condition, and a reduced level of consciousness. One patient each had prostration, cerebral malaria, and hyperparasitemia, two patients had severe anemia (Hb<5 g/dL), and 3.1% had increased creatinine (>1.4 mg/dL). No fatality occurred. In this study from southern India, uncomplicated cases of malaria largely predominated with *P. falciparum* causing slightly more intense manifestation. Severe malaria was infrequent, and no fatal cases occurred. This contrasts with the reported pattern of manifestation in other parts of India, which requires the analysis of underlying causes.

## 407

### RAPID ACQUISITION OF ANTIBODIES TO BOTH PREERYTHROCYTIC AND ERYTHROCYTIC ANTIGENS FOLLOWING CONTROLLED HUMAN MALARIA INFECTION WITH PLASMODIUM VIVAX AND P. FALCIPARUM

Cysha E. Hall, Lisa Hagan, Elke Bergmann-Leitner, Haylee Hollenbeck, Jessica Joyner, Evelina Angov, Sheetij Dutta, Anjali Yadava

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Seroepidemiological studies on the prevalence of antibodies to malaria antigens are primarily conducted on individuals from endemic regions. It is, therefore, difficult to accurately correlate the antibody responses to the timing, number and species of prior malaria infections. This study was undertaken to assess the evolution of antibodies to the dominant surface antigens of *Plasmodium vivax* and *P. falciparum* following primary malaria infection in naïve individuals. Serum samples from malaria-naïve adults were collected before and after controlled human malaria infection (CHMI) with either *P. vivax* or *P. falciparum*. Serum samples were tested for the presence of antibodies to the circumsporozoite protein (CSP) and the 42 kilodalton fragment of the merozoite surface protein-1 (MSP-142) of both *P. vivax* and *P. falciparum* by enzyme-linked immunosorbent assay. Approximately one month following CHMI with *P. vivax* or *P. falciparum* 72% and 67% of subjects, respectively, seroconverted to homologous CSP. A higher proportion of subjects - 78% for *P. vivax* and 100% for *P. falciparum* - seroconverted to homologous MSP-142. More than 60% of the subjects demonstrated reactivity to heterologous CSP and MSP-142 and a similar proportion of subjects remained seropositive to homologous MSP-142 at > 5 months post CHMI. This study demonstrates the immunogenic nature of sporozoites as despite the short duration for which they are present in circulation prior to their migration to the liver, they are able to induce detectable anti-CSP antibodies. As expected, a higher proportion of subjects react to the blood stage antigen MSP-1 and more than half the subjects continue to demonstrate reactivity to MSP-1 several months post exposure. Presence of long-lived and heterologous reactivity may confound the determination of time and species of exposure in field settings.

### FURTHER EVALUATION OF THE PROTOTYPE NON-WOVEN FABRIC (NWF) FILTER FOR THE PURIFICATION OF *PLASMODIUM VIVAX*-INFECTED ERYTHROCYTES UNDER FIELD CONDITIONS

Qiang Fang<sup>1</sup>, Jiangyang Li<sup>1</sup>, Zhiyong Tao<sup>1</sup>, Qian Li<sup>1</sup>, Awtum Brashear<sup>2</sup>, Ying Wang<sup>3</sup>, Hui Xia<sup>1</sup>, Liwang Cui<sup>2</sup>

<sup>1</sup>Bengbu Medical College, Bengbu, China, <sup>2</sup>Pennsylvania State University, University Park, PA, United States, <sup>3</sup>Third Military Medical University, Chongqing, China

Isolation of *Plasmodium*-infected red blood cells (iRBCs) is often required for experiments such as *ex vivo* drug assays, *in vitro* invasion assays, and genome sequencing. A prototype non-woven fabric (NWF) filter was developed for the purification of iRBCs, which showed great efficiency for removing WBCs in a pilot study. With the commercialization of the filters, this study aims to evaluate the efficiency and suitability of the commercial NWF filter for the purification of *Plasmodium vivax*-infected RBCs in smaller volumes of blood in a field laboratory, and to compare its performance with that of Plasmodipur® filters. Forty three clinical *P. vivax* blood samples taken from symptomatic patients at the China-Myanmar border were processed using the NWF filters. The numbers of WBCs and iRBCs and morphology of *P. vivax* parasites in the blood samples before and after NWF filtration were compared. The viability of *P. vivax* parasites after filtration from 27 blood samples was examined by *in vitro* short-term culture. In addition, the effectiveness of the NWF filter for removing WBCs was compared with that of the Plasmodipur® filter in six *P. vivax* blood samples. Filtration of 1-2 mL of *P. vivax*-infected blood with the NWF filter removed 99.68% WBCs. The densities of total iRBCs, ring and trophozoite stages before and after filtration were not significantly different ( $P > 0.05$ ). After filtration, the *P. vivax* parasites did not show apparent morphological changes. Culture of 27 *P. vivax*-infected blood samples after filtration showed that parasites successfully matured into the schizont stage. The WBC removal rates and iRBC recovery rates were not significantly different between the NWF and Plasmodipur® filters ( $P > 0.05$ ). In conclusion, when tested with 1-2 mL of *P. vivax*-infected blood under field laboratory conditions, the NWF filter could effectively remove WBCs and the recovery rates for ring- and trophozoite-iRBCs were high. The performance of the NWF and Plasmodipur® filters for removing WBCs and recovering iRBCs was comparable.

### IS TARGETED REACTIVE VECTOR CONTROL A NON-INFERIOR SUBSTITUTE FOR GENERALIZED INDOOR RESIDUAL SPRAYING IN AREAS OF VERY LOW MALARIA TRANSMISSION - RESULTS FROM A CLUSTER RANDOMIZED TRIAL

Immo Kleinschmidt<sup>1</sup>, John Govere<sup>2</sup>, Jackie Cook<sup>1</sup>, Phillemon Matebula<sup>2</sup>, Khumbulani Hlongwana<sup>3</sup>, Natashia Morris<sup>4</sup>, Jaishree Raman<sup>2</sup>, Eunice Agubuzo<sup>2</sup>, Ishen Serocharan<sup>5</sup>, David Bath<sup>1</sup>, Joseph Biggs<sup>1</sup>, Alpheus Zitha<sup>6</sup>, Elliot Machaba<sup>7</sup>, Aaron Mabuza<sup>6</sup>, Philip Kruger<sup>7</sup>, Chris Drakeley<sup>1</sup>, Maureen Coetzee<sup>2</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>University of the Witwatersrand, Johannesburg, South Africa, <sup>3</sup>University of KwaZulu Natal, Durban, South Africa, <sup>4</sup>South Africa Medical Research Council, Durban, South Africa, <sup>5</sup>Consultant, Durban, South Africa, <sup>6</sup>Mpumalanga Provincial Malaria Control Programme, Nelspruit, South Africa, <sup>7</sup>Limpopo Provincial Malaria Control Programme, Polokwane, South Africa

In areas of very low, pre-elimination malaria transmission the small number of incident cases make it difficult to sustain resources for spraying all houses annually with insecticide (generalised indoor residual spraying (GIRS)). An alternative that may be more sustainable is to target IRS (TIRS) reactively only at houses in the immediate neighbourhood of

incident cases as they arise. Of 62 clusters consisting of settlements of approximately 5000 persons each in the provinces of Mpumalanga and Limpopo in South Africa, half were randomly allocated to receive the currently practised GIRS whilst the other half received reactive TIRS in response to every passively reported local case. TIRS was carried out in the immediate neighbourhood of about 8 houses per index case. Dried blood spots were collected from neighbourhoods of index cases, and in randomly selected neighbourhoods where there were no cases. Non-inferiority of TIRS was assessed in comparison to GIRS based on passive case incidence in the two study arms. Age-standardised antibody responses, sero-prevalence and seroconversion rates to malarial antigens were compared between neighbourhoods of index cases and randomly selected comparison neighbourhoods, to determine whether new cases arise predominantly in areas of previous exposure to parasites. Results of the trial will be presented. If cases arise predominantly in areas with populations who have elevated seroprevalence, then serological surveys would be highly informative for proactive targeting of vector control interventions. If targeted IRS is non-inferior to generalised IRS, it could make vector control in very low transmission settings more sustainable and more effective.

### STUDY OF QUALITY OF ANTIMALARIAL DRUGS IN INDIA

Taruna Katyal Arora, N. Mishra, N. Valecha

National Institute of Malaria Research, Delhi, India

Substandard and counterfeit antimalarial medicines poses a serious threat to public health. These counterfeit/ substandard medicines increases the mortality by decreasing efficacy; it also increases the threat of emergence of drug resistance, adverse effect from incorrect excipients/ active ingredients which may be potentially dangerous to the patients. Owing to this, a pilot study was conducted to survey quality of drugs collected from different malaria endemic areas of India. The survey was conducted in different geographical regions on the basis of malaria endemicity i.e. Uttar Pradesh (U.P.), Mizoram, Meghalaya, Gujarat, Madhya Pradesh. Antimalarial samples of ACT (Artesunate+ Sulphadoxine-pyremethamine), (Artesunate+Lumefantrine), Chloroquine, Primaquine were collected for qualitative analysis. A mystery shopper approach was used for collection of samples. The quality of antimalarial drugs from these areas were assessed by using Global Pharma Health Fund Minilab test kit. This includes physical/visual inspection and disintegration test, thin-layer chromatography. High performance liquid chromatography was carried out for quantitative assessment of active pharmaceutical ingredient. A total of 101 brands out of which 38 were for CQ, 38 for AL, 7 for AS+ SP, 18 for primaquine were tested from different sites. In this study 97.03% of the tablets passed minilab disintegration, 2.97% consisting did not passed disintegration test. The variable disintegration and retention factor might be due to improper handling during storage, humid temperature, transportation and distribution. However, HPLC analysis confirms standard active pharmaceutical ingredient in the tablets.

### ASSOCIATION BETWEEN PLASMA AND CEREBROSPINAL FLUID BIOMARKERS AND NEUROPSYCHOLOGICAL OUTCOMES AMONG CHILDREN WITH CEREBRAL AND SEVERE MALARIA IN UGANDA

Horacio Ruiseñor-Escudero<sup>1</sup>, John Chandy<sup>2</sup>, Itziar Familiar Lopez<sup>1</sup>, Alla Sikorskii<sup>1</sup>, Datta Dibyadyuti<sup>2</sup>, Noeline Nakasujja<sup>3</sup>, Robert Opoka<sup>3</sup>, Michael Boivin<sup>1</sup>

<sup>1</sup>Michigan State University, East Lansing, MI, United States, <sup>2</sup>Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, IN, United States, <sup>3</sup>Makerere University, Kampala, Uganda

Cognitive impairment following severe malaria can result in compromised social and behavioral performance in children. We aimed

to explore the association between immunological biomarkers (IB) and neuropsychological (NP) outcomes among Ugandan children surviving cerebral malaria (CM), severe malaria anemia (SMA) and community controls (CC). Sample included 300 children: 93 (31%) with CM, 57 (19%) with SMA, and 150 (50%) CC. Von Willebrand Factor (VWF), Granulocyte Colony Stimulating Factor (GCSF), and Tumor Necrosis Factor-alpha (TNF- $\alpha$ ) were collected in plasma for all and in CSF in children with CM. NP tests included Kaufman Assessment Battery for Children (2nd ed., KABC-II), Behavior Rating Inventory for Executive Function (BRIEF), and Achenbach Child Behavior Checklist (CBCL). For each group, general linear models were used to relate NP scores to IB. Models were adjusted for anthropometric and socioeconomic variables. 158 boys and 142 girls (p=0.01) ages 5-12.8 years were enrolled. Median time from clinical disease to NP test was 2.6 years. In plasma, higher VWF was associated with lower KABC-II scores in 3 memory subtests (p=0.01, p=0.05, p=0.02) in SMA and with 2 subtests in CC children (p=0.05, p=0.04). Higher VWF was related to lower BRIEF in CM (p=0.01) but higher scores among SMA children (p=0.02). Higher VWF was associated with more Externalizing Problems (CBCL) in SM children (p=0.03). Higher GCSF in CSF was associated with more Externalizing Problems (p=0.03) (CBCL) in CM children. In plasma, higher GCSF was associated with lower KABC-II score (p<0.01) in SM children, and with lower BRIEF scores (p=0.02), and CBCL's Total Problems (p=0.03) in CC. Differences could respond to multiple comparisons performed, increasing the chance of a random association of p<0.05. Results suggest preliminary evidence towards the role of endothelial activation and angiogenesis factors in predicting neurological damage among children surviving severe malaria. Further assessment is needed to fully characterize these pathways, specifically, longitudinal studies that will allow to assess time related association between IB and NP.

#### 412

### A PILOT STUDY TO DETERMINE THE FEASIBILITY OF FAMILY PLANNING WORKERS IN BANDARBAN, BANGLADESH DELIVERING MALARIA CASE MANAGEMENT IN THEIR COMMUNITIES

**Wasif A. Khan<sup>1</sup>**, Ching Swe Phru<sup>1</sup>, Sabeena Ahmed<sup>1</sup>, Mohammad Shafique<sup>2</sup>, Siddhi Aryal<sup>2</sup>, Madeleine Marasciulo<sup>2</sup>, Prudence Hamade<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Malaria Consortium, London, United Kingdom

Malaria is endemic in border districts (13/64) of Bangladesh mainly in remote areas with poor access to appropriate and timely care. Pregnant women and children are at risk. To deliver quality malaria care at community level, coordination between departments of the Ministry of Health and Family Welfare (MOHFW) and the National Malaria Control Program (NMCP) is crucial. A previous study in the Bandarban Hill district observed first-line family planning health workers (FPHW) lacked adequate training to deliver malaria care at the primary level. Results indicated community members with malaria symptoms seek care elsewhere, causing delays in treatment, increased risk of severe illness and death. This pilot study was commissioned by the NMCP and the Family Planning Department to determine the feasibility of increasing access to malaria diagnosis and treatment, especially for pregnant women and children U5, in communities where they live. A central training of the trainers (ToT) was conducted for National Trainers (n=29) from the MOHFW. Trainers learned adult learning and facilitation skills; malaria epidemiology; rapid diagnostic testing; treatment for uncomplicated malaria; referral of severe cases; use of interpersonal communication skills in treating and preventing malaria; supervision skills and use of tools to improve performance of FPHWs during routine supervision. Trainers then trained FPHWs (n=57) in Bandarban. The average improvement in trainer knowledge was 37% (pre- and post-tests scores, 51% and 88% respectively), and average trainee improvement was 36% (pre- and post-tests 49% and 85% respectively). Following the training, 3 supervision visits were conducted to observe FPHWs proficiency in malaria management competencies. Competency

scores improved from 54% during visit 1, to 57% in visits 2 and 3. This pilot study showed it was feasible and acceptable to integrate FPHWs in malaria elimination initiatives and to deliver quality community malaria case management. Additional districts could benefit from a similar training and supervision programme towards malaria elimination.

#### 413

### SOCIO-DEMOGRAPHIC FACTORS INFLUENCING INSECTICIDE TREATED NET USE AMONG NIGERIAN UNDER-FIVES: EVIDENCE FROM A NATIONAL SURVEY

**Efena Tosin Orhorhamreru<sup>1</sup>**, Temitope Olumuyiwa Ojo<sup>2</sup>, Adewumi Basirat Joseph<sup>3</sup>, Olufemi Ajumobi<sup>1</sup>, Moronke Orhorhamreru<sup>4</sup>

<sup>1</sup>African Field Epidemiology Network, Abuja, Nigeria, <sup>2</sup>Department of Community Health, OAUTHC, Ile-Ife, Nigeria, <sup>3</sup>National Malaria Elimination Programme, Abuja, Nigeria, <sup>4</sup>Catholic Relief Services, Abuja, Nigeria

The use of Insecticide-treated nets (ITN) is the most cost-effective malaria preventive measure. However, malaria remains a big killer of children in Nigeria, accounting for 11 percent of maternal mortality, 25 percent of infant mortality and 30 percent of the under-fives (U5) deaths. Despite massive distribution campaigns nationwide, ITN use among (U5s) is low. This study assessed factors influencing ITN use among U5s across households in Nigeria. We analyzed the 2015 Nigeria Malaria Indicator Survey with specific focus on ITN use in children. A total of 7,008 under-fives all slept in the surveyed households a night before the survey. However, 5,397 (77%) under-fives (U5s) slept in households with at least one ITN the night prior to the survey were studied. Binary logistic regression analysis was conducted to identify factors influencing ITN use by U5s in (1) households that have at least one ITN and (2) households with at least one ITN for every two people (universal coverage). Data analysis was conducted using STATA (version 14.0). In households with ITN ownership, only 56.6% of U5s slept under the ITN the night before the survey. Significantly, children less than one year old, those who reside in rural areas, those from other regions of the country except the South East had higher odds of using ITN the night before the survey. Also, children from households with less than 7 members and those from the lowest and second wealth quintiles had significantly higher odds of using ITN. On the second regression model among households with universal coverage, U5s who reside in rural areas, those from other regions of the country except the South West and those from the lowest and second wealth quintiles still had significantly higher odds of sleeping under ITN the night before the survey. In conclusion, our findings have programmatic implications for malaria control among U5s and malaria elimination in Nigeria. Interventions to improve ITN use should be intensified among urban dwellers, and residents of South-Western and South-Eastern Nigeria.

### ASSESSING THE USEFULNESS OF A THRESHOLD FOR DETECTING MALARIA EPIDEMICS IN TANZANIA: A CASE STUDY IN HAI DISTRICT (KILIMANJARO REGION) AND BUKOBA MUNICIPAL COUNCIL (KAGERA REGION)

**Ritha A. Willilo<sup>1</sup>**, Franky Chacky<sup>2</sup>, Renata Mandike<sup>2</sup>, Anna Mahendeka<sup>2</sup>, Naomi Kaspar<sup>3</sup>, George Greer<sup>3</sup>, Joshua Yukich<sup>4</sup>, Willis Odek<sup>1</sup>

<sup>1</sup>U.S. Agency for International Development-funded MEASURE Evaluation-Tanzania, Dar es salaam, United Republic of Tanzania, <sup>2</sup>National Malaria Control Program, Dar es salaam, United Republic of Tanzania, <sup>3</sup>U.S. President's Malaria Initiative, United States Agency for International Development, Dar es salaam, United Republic of Tanzania, <sup>4</sup>U.S. Agency for International Development-funded MEASURE Evaluation at the University of North Carolina at Chapel Hill and the Center for Applied

Health officials need a threshold to detect an emerging malaria epidemic so they can take quick action to contain the spread of infection and reduce morbidity and mortality. Most methods to define epidemic thresholds require data going back five years or more. In settings such as Tanzania, where such data are not available, precise thresholds are hard to establish. There, the World Health Organization recommends the use of a three-week rolling average to set the threshold. Our study sought to assess the usefulness of this threshold. Weekly malaria data are reported from health facilities through electronic Integrated Disease Surveillance and Response (e-IDSR) using mobile technology and can be viewed in the District Health Information System (DHIS). The system sets the threshold at a twofold increase of malaria cases in the current week compared to the average of malaria cases in the previous three weeks (3 weeks AVG\*2). An alert is supposed to be triggered if the threshold is exceeded by the number of malaria cases reported in that particular week. Because no such alert has been triggered to date, we analyzed all positive malaria cases reported from week 11 of 2014 to week 12 of 2017 in Bukoba Municipality (Kagera Region) and Hai district (Kilimanjaro region) for trends in malaria cases, to see if epidemics had been undetected. In year 2015, we found that in Hai district, the reporting rate was 53% and malaria cases reported were 1,317. In weeks 18 (102 cases reported) and 23 (144 cases reported), the set thresholds were 42 and 65 cases respectively, which should have triggered the alarm. In Bukoba Municipality, we found that, in year 2016, the reporting rate was 91% and malaria cases reported were 7,461. The highest number of malaria cases were reported in weeks 3, 4, 5 and 6 with 327, 359, 326 and 316 cases which should have been investigated but, the set epidemic threshold were 653, 695, 735 and 718 cases which did not exceed to trigger alarm. These findings suggest a need to further review available historical data in order to calibrate more accurate thresholds for the malaria surveillance system to generate automatically, maximizing the system's usefulness.

### MALARIA CONTROL: A REALIST REVIEW

**Tumaini C. Malenga<sup>1</sup>**, Lucinda D. Manda-Taylor<sup>1</sup>, Frances E. Griffiths<sup>2</sup>

<sup>1</sup>University of Malawi College of Medicine, Blantyre, Malawi, <sup>2</sup>University of Warwick, Coventry, United Kingdom

This paper presents a qualitative systematic review on various malaria control strategies, to uncover what works or doesn't work, for whom and in what context. The paper works to inform what current malaria control strategies are most useful and what barriers exist with access and use, to discover the gaps in current knowledge and suggest possible areas requiring further research. We structured the search with the following steps: a scoping review of literature on malaria control to map the evidence base and define the scope of the review; a search for evidence of what works or doesn't work; extraction of data and synthesis of evidence; and development of a narrative which includes a hypothesis. We restricted the literature to focus on tools that were available in endemic countries. There is a wealth of evidence that speaks to why malaria interventions don't work. Experiences speaking to sustained use of interventions depends on understanding how the intervention works and seeing it work consistently over time. This improves the buy in and likelihood of an individual to comply with use and maintain use in the long term, assuming they accept the design and experience minimal barriers. Results so far suggest Behaviour Change Communication is a fruitful strategy to improve uptake and use of malaria control interventions. However, more work needs to be done on promoting maintenance of change in behaviour.

### REDUCED MALARIA COMMODITY STOCK-OUTS AT HEALTH FACILITY LEVEL THROUGH MONTHLY SUPERVISION IN BENIN

Aadjibabi Cherifatou<sup>1</sup>, Angélique Gbaguidi<sup>2</sup>, Ricardo Missihoun<sup>3</sup>, Alexis Tchevoede<sup>1</sup>, Adicatou-Lai Adeothy<sup>3</sup>, Michelle Kouletio<sup>3</sup>, **Jean Fortuné S. Dagnon<sup>3</sup>**, Gilbert Andrianandrasana<sup>2</sup>, Christopher Schwabe<sup>4</sup>, Pablo Aguilar<sup>4</sup>, Maria Arias-Coscaron<sup>4</sup>

<sup>1</sup>National Malaria Control Program/MOH Benin, Cotonou, Benin,

<sup>2</sup>Accelerating the Reduction of Malaria Mortality and Morbidity (ARM3/MCDI), Cotonou, Benin, <sup>3</sup>United States President's Malaria Initiative/U.S. Agency for International Development-Benin, Cotonou, Benin, <sup>4</sup>Medical Care Development International, Silver Spring, MD, United States

To reduce stock-outs of essential malaria commodities at health facilities (HFs), the President's Malaria Initiative (PMI) piloted a monthly supervision approach in two purposively selected health districts in Benin, Parakou-N'Dali (PKN) and Come-Bopa Houeyogbo-Grand Popo (CBGH). These districts were selected based on having average (PKN) and low (CBGH) Logistics Management Information System (LMIS) performance scores, which was comprised of completeness, timeliness and accuracy of the LMIS reports and data. Quality Improvement Teams (QITs) made monthly visits to all HFs in PKN (20) and CBGH (48) for a nine-month period in 2015. During the monthly visits, the QITs collected information on malaria commodity availability, prescription data, and pharmacy records. They also assessed compliance with the LMIS parameters, completeness and timeliness of LMIS reports, as well as consistency, accuracy and quality of the LMIS data. During the intervention period, the proportion of HFs with health workers able to correctly fill out a LMIS report increased from 21% to 84% in CBGH and from 16% to 90% in PKN. During the same time period, the degree of discordance between the quantities of Artemisinin Combination Therapy (ACT) prescribed (as recorded in the treatment registers), and the quantity dispersed (as documented in the monthly pharmacy logs), reduced from 93% to 19% in CBGH, and from 73% to 18% in PKN. Stock-outs of Artesunate/Lumefantrine (as a proxy for all ACT presentations) also declined in both districts. Close follow-up and coaching by the QITs contributed to more reliable logistics data and improved tracking and availability of malaria commodities at the point of service delivery. The team based approach fostered effective problem solving and local resource mobilization to address identified needs by the District Management Teams. Chief Medical Doctors are able to conduct quality control by linking prescription and dispensation data. This capacity building approach is recommended in health districts with poor supply chain management at the HF level. Further assessment is needed to determine the sustainability of the approach.

## 417

### MALARIA PROGRAMS IMPLEMENTATION IN EBONYI STATE, NIGERIA: WHERE ARE WE?

**Bright Orji**, Daniel Umezurike, Lawrence Nwankwo, Boniface Onwe, Gladys Olisaekee, Enobong Ndekhedehe, Emmanuel Otolorin

*Jhpiego, Baltimore, MD, United States*

Despite important strides in recent years, Nigeria has yet to achieve global targets of universal coverage for malaria case management nor 80% coverage for malaria in pregnancy. While available malaria interventions are effective, critical health system challenges undermine implementation. Jhpiego has developed a health systems framework and planning tool to assist malaria control programs identify and respond to these challenges. The tool was recently used with the Ebonyi State Malaria Control Program (MCP) with Jhpiego's guidance. An initial situational analysis used the 2015 Malaria Information Survey to highlight that 89% of state households had long lasting insecticide treated bed-nets but only 50% of children under five used them. Likewise, intermittent preventive treatment during pregnancy (IPTp) was only 44% for two IPTp doses and 41% for three. Use of parasitological diagnosis for malaria was low and

unacceptable. A subsequent meeting among MCP and Jhpiego staff was held to review nine health systems areas to determine reasons for the low performance on malaria indicators. The group reviewed strategies and annual workplans and then ranked each health system area on a scale from 1 (low) to 4 (high) to reflect level of progress, and then the average score computed. The highest scoring components were human resource capacity (3) and integration and coordination (3), based on findings such as integrated supportive supervision and the holding of monthly coordination and review meetings among partners at the state and local level. Community Involvement (1.9) and finance (1.8) scored lowest, based on lack of community outreach and engagement, in control efforts, and late/ sporadic release of funds for program implementation, respectively. In response, the group drew up action plans to address identified weaknesses and used monthly partners meetings for advocacy and learning. In conclusion Nigerian health workers can use health systems analysis and planning tools to identify best practices, address challenges, and create an action plan to help advance their state (and country) along the pathway to malaria elimination.

## 418

### REGULATORY T CELL-MEDIATED SUPPRESSION OF HUMAN IMMUNE RESPONSES TO INVESTIGATIONAL MALARIA VACCINES

**Richard A. Morter**<sup>1</sup>, Francis M. Ndungu<sup>2</sup>, Adrian V. Hill<sup>1</sup>, Philip Bejon<sup>2</sup>, Katie Ewer<sup>1</sup>

<sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>KEMRI/Wellcome Trust Research Programme, Kilifi, Kenya

Natural malaria and helminth infections induce upregulation of Regulatory T cell (Treg) responses in humans. Increased Treg frequencies may play a role in causing the immunosuppression known to be associated with malaria infection and may contribute to the reduced immunogenicity observed for some experimental malaria vaccines when trialled in malaria-endemic sites in Africa. Increased total CD4+ CD25+ FoxP3+ CD127lo Treg frequencies at baseline, as measured by flow cytometry, negatively correlate with peak antigen-specific CD4+ T cell and antibody titres in the investigational vaccine regime ChAd63 ME-TRAP / MVA ME-TRAP, but only with antigen-specific CD4+ T cell responses to RTS,S in malaria-naïve European volunteers. Both vaccine regimes themselves induced antigen-specific Treg responses, however these do not correlate with decreased antibody or effector CD4+ T cell titres. Instead, high baseline Treg frequencies appeared to be suppressive of antigen-specific Treg induction as well, demonstrating that pre-existing Tregs might be most important in suppression of vaccine-induced immunity. Therefore, in a setting where populations have naturally higher circulating Treg frequencies due to parasite infections, responses to vaccines could be suppressed. Immunogenicity and Treg frequency data from a Kenyan cohort vaccinated with ChAd63 ME-TRAP / MVA ME-TRAP will be presented. Functional data from Treg suppression assays will also be presented to understand the mechanistic basis of the heterologous effects of Tregs on different experimental malaria vaccines.

### SAFETY AND IMMUNOGENICITY OF THE MALARIA VACCINE CANDIDATE R21 ADJUVANTED WITH MATRIX-M1 IN WEST AFRICAN ADULT VOLUNTEERS, BURKINA FASO

**Alfred B. Tiono**<sup>1</sup>, Alphonse Ouedraogo<sup>1</sup>, Sam Aboubacar Coulibaly<sup>1</sup>, Edith C. Bougouma<sup>1</sup>, Issa N. Ouedraogo<sup>1</sup>, Venkatraman Navin<sup>2</sup>, Georgina Bowyer<sup>2</sup>, Katie Ewer<sup>2</sup>, Nicola Viebig<sup>3</sup>, Amidou Diarra<sup>1</sup>, Gregory Glenn<sup>2</sup>, Odile Leroy<sup>3</sup>, Adrian V. Hill<sup>2</sup>, Sodiomon Bienvénu Sirima<sup>1</sup>

<sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>2</sup>Centre for Clinical Vaccinology and Tropical

Medicine, The Jenner Institute, University of Oxford, Oxford, United Kingdom, <sup>3</sup>European Vaccine Initiative, Heidelberg, Germany

A highly effective malaria vaccine would help reduce disease burden in malaria endemic countries. We have assessed the safety and immunogenicity of the malaria vaccine candidate R21, a virus-like particle comprising a fusion protein of part of the *P. falciparum* circumsporozoite protein with the hepatitis B surface antigen. A phase Ib randomised, controlled, single-blind study was conducted. Volunteers were randomly assigned in a 2:1 ratio to receive 3 doses of the malaria vaccine or the control (normal saline) intramuscularly 1 month apart. Participants were actively followed up at home daily during the 7 days following each vaccination to collect local and systemic solicited adverse events. Serious adverse events were recorded throughout the study duration. Venous blood samples were obtained for clinical safety and immunological evaluations. The study duration was 140 days for each participant. A total of 8 and 5 participants have received respectively 10µg of the malaria vaccine or a saline control immunisation. The most reported local solicited symptoms post vaccination were mild to moderate pain (25%, 2/8) and swelling (12.5%; 1/8) at injection site following each vaccination; all reported in the R21 vaccine group. Solicited systemic symptoms include moderate joint pain and headache. Neither severe adverse event nor serious adverse event was recorded. There was significant increase of anti-NANP IgG following vaccination in the R21 group compared to the controls. This was the first administration of R21 malaria vaccine candidate in Africa. The vaccine was immunogenic in semi immune adults with a good safety profile. These data are supportive for further development of the R21 malaria vaccine candidate.

## 420

### PROTEOMIC CHARACTERIZATION OF ERYTHROCYTE DERIVED MICROVESICLES FROM MALARIA INFECTED CHILDREN

**Christopher S. Spencer**

National Institutes of Health, Rockville, MD, United States

Red blood cells infected with *Plasmodium* parasites produce microvesicles containing parasite derived proteins and mRNA. Previous studies have shown that the production of red blood cell-derived microvesicles (RMVs) is increased during malaria infection, with a correlation between elevated RMV concentration and increased severity of disease. These microvesicles have been shown to have numerous effects, including induction of transmission, upregulation of inflammation and inter-parasite communication. Purified RMVs from infected individuals have previously been seen to elicit an acquired immune response and diminish lethality from *Plasmodium* infections in mice. The goal of this study is to explore the role of RMVs from infected erythrocytes in the development of humoral immune response to malaria. We hypothesize that RMVs play a role in displaying *Plasmodium* proteins to the host immune system, leading to the production of protective antibodies. To achieve this, RMVs from malaria-infected children's plasma were isolated and analyzed using electron microscopy and proteomic approaches. Proteomic analysis indicates that several *Plasmodium* proteins are enriched in the microvesicles. Conserved proteins indicated to be consistently present in RMVs will be recombinantly expressed for characterization and use in immunosurveillance studies. The presence of naturally acquired antibodies against putative *Plasmodium* antigens in RMVs is to be cross-referenced with reduction in parasite burden and protection against disease. Results from this immunosurveillance will indicate the viability of using antigens found to be enriched in RMVs as malaria vaccine targets.

### LYMPH NODE TARGETING NANOPARTICLE BASED PLATFORM FOR MALARIA VACCINE DELIVERY

Garima Verma<sup>1</sup>, Gregory Howard<sup>2</sup>, Xiyu Ke<sup>2</sup>, Elena Lepekhina<sup>2</sup>, Jose L. Santos<sup>2</sup>, Tori Baxter<sup>2</sup>, Dillon Muth<sup>2</sup>, Magdalena Plebanski<sup>3</sup>, Margarita H. Alonso<sup>2</sup>, Hai Q. Mao<sup>2</sup>, Rhoel R. Dinglasan<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>Monash University, Melbourne, Australia

Transmission-blocking vaccines that disrupt malaria transmission between the human and the mosquito host are considered one of the key interventions in the global effort to eradicate malaria. A highly conserved *Anopheles* mosquito midgut surface glycoprotein, Alanyl aminopeptidase N (AnAPN1), is a promising malaria transmission-blocking vaccine candidate. The AnAPN1 antibodies have been shown to completely block the development of naturally circulating isolates of *Plasmodium falciparum* and *P. vivax*. The AnAPN1-based vaccine is safe and highly immunogenic, but lacks natural boosting because the target antigen is not naturally presented to the human immune system. To circumvent this problem and improve vaccine efficacy, we have developed a polymeric biodegradable nanoparticle-based vaccine delivery platform. These biodegradable nanoparticles target the draining lymph nodes to allow effective presentation of the antigen, AnAPN1, to generate a robust priming immune response. A high-energy, multi-inlet vortex mixer based flash nanoprecipitation method was developed to generate a series of tightly size regulated virus-like biodegradable nanoparticles loaded with near infrared and Alexa488 dyes. Several biodegradable nanoparticles with different hydrodynamic diameters (30, 50, 70, and >100 nm) were tested for safety, inflammation, and mistargeting in mice. *In vivo* mice imaging studies suggest that biodegradable nanoparticle size is a key determinant of trafficking and retention in the draining lymph nodes. Our studies show that the smaller biodegradable nanoparticles (30 and 50 nm) drained more efficiently than their larger counterparts (70 and >100 nm). The co-localization of smaller biodegradable nanoparticles with macrophages and dendritic cells suggest cellular uptake by lymph node resident antigen presenting cells. We will leverage the lymph node targeting biodegradable nanoparticles (30 nm) as part of a bimodal, nano-/microparticle vaccine delivery system to induce a long-lasting AnAPN1-specific immune response in vaccinated individuals.

### A NOVEL VIRUS-LIKE PARTICLE-BASED PLATFORM FOR MULTI-ANTIGEN MALARIA VACCINES

Jo-Anne Chan<sup>1</sup>, David Wetzel<sup>2</sup>, Dean Andrew<sup>1</sup>, Linda Reiling<sup>1</sup>, Paul Gilson<sup>1</sup>, David Anderson<sup>1</sup>, Jack S. Richards<sup>1</sup>, Volker Jenzelewski<sup>2</sup>, Michael Piontek<sup>2</sup>, James G. Beeson<sup>1</sup>

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>ARTES Biotechnology, Langenfeld, Germany

Malaria remains a global health priority despite numerous interventions and is worsened by the emergence and spread of drug resistant *P. falciparum*. Currently, the most advanced vaccine, known as RTS,S, has only shown modest efficacy in clinical trials and new more efficacious vaccines are needed. The RTS,S vaccine is based on the presentation of a fragment of the sporozoite antigen CSP on the surface of virus-like particles (VLPs) based on human hepatitis B virus (HBV). However, a limitation of the HBV platform is that only small antigens or antigen fragments can be incorporated into VLPs, and not larger proteins that are typical of malaria vaccine candidates. We have developed and evaluated a novel VLP platform based on duck HBV (known as Metavax) for malaria vaccine development. This platform can incorporate large and complex proteins into VLPs and is produced in a *Hansenula* cell line compatible with cGMP vaccine production. We have established the expression of several leading *P. falciparum* malaria vaccine candidates as chimeric VLPs. This includes Pfs25 and Pfs230, which are candidate transmission-

blocking vaccine antigens, the sporozoite antigen CSP, and a candidate vaccine antigens expressed during blood-stage infection. VLP formation and display of vaccine antigens was confirmed using super resolution microscopy with antigen-specific antibodies, and electron microscopy. Correct folding and antigen presentation was evaluated by western blotting and ELISA using defined antibodies. Initial studies demonstrated that the VLPs effectively induce antibodies to malaria vaccine candidates with minimal induction of antibodies to the duck HBV scaffold antigen, and that VLPs are more immunogenic than standard recombinant antigen. These results establish the utility of this VLP platform for malaria vaccines. The expression of multiple vaccine antigens in a single platform will facilitate the development of multi-stage multi-component vaccines to achieve high vaccine efficacy and transmission-blocking immunity.

### TRUNCATION OF PFRIPR REVEALS REGION THAT INDUCES ANTIBODY WITH THE MOST POTENT GROWTH INHIBITORY ACTIVITY AGAINST PLASMODIUM FALCIPARUM

Hikaru Nagaoka<sup>1</sup>, Eizo Takashima<sup>1</sup>, Akihisa Fukushima<sup>2</sup>, Edward H. Ntege<sup>1</sup>, Takafumi Tsuboi<sup>1</sup>

<sup>1</sup>Division of Malaria Research, Proteo-Science Center, Ehime University, Matsuyama, Japan, <sup>2</sup>Drug Development Research Laboratories, Sumitomo Dainippon Pharma, Osaka, Japan

Blood-stage malaria vaccine candidates of high efficacy against *Plasmodium falciparum* remain elusive, mainly because of antigen polymorphisms and resultant allele-specific immunity in natural parasite populations. We recently reported *P. falciparum* reticulocyte binding protein homologue 5-interacting protein (PFRipr) as a promising blood-stage vaccine candidate, and highly conserved among Ugandan isolates. PFRipr is known to interact with previously reported conserved merozoite proteins, reticulocyte binding protein homologue-5 (PFRH5) and Cysteine rich protective antigen (PfCyRPA) in an invasion complex. PFRH5 binds to basigin receptor on the surface of red blood cells and is currently in clinical development. Antibodies against wheat germ cell-free system (WGCFs) expressed recombinant PFRipr based on Pf 3D7 sequences demonstrated potent growth inhibition assay (GIA) activity of both 3D7 and heterologous FVO. However, because of difficulties associated with synthesizing a large PFRipr immunogen that consists of 1086 amino acids (aa) and 83 cysteine residues, we attempted to identify the protein region(s) with functional epitope(s). The WGCFs successfully expressed 11 PFRipr antigen truncates, each containing approximately 200 aa. Rabbit antibodies against each truncate were generated, and performed GIA. We demonstrated that antibody against PFRipr region containing 215 aa had the highest GIA activity, and a promising blood stage vaccine candidate.

### ASSESSMENT OF PLASMODIUM FALCIPARUM PFS47 AS A TRANSMISSION BLOCKING TARGET FOR MALARIA

Alvaro Molina-Cruz, Gaspar Canepa, Lampouguin Yenkeidiok Doui, Carolina Barillas-Mury

National Institutes of Health, Rockville, MD, United States

Malaria transmission-blocking vaccines rely on functional antibodies that interact with proteins present on the surface of sexual/sporogonic stages of *Plasmodium* or in the mosquito midgut, and disrupt vector-parasite interactions critical for malaria transmission. We recently identified the female gametocyte surface protein *Pfs47*, a three domain 6-cys protein, as a key determinant of parasite immune evasion in the mosquito vector. Polymorphisms in the domain 2 of *Pfs47* were shown critical to determine immune evasion by the parasite. We investigated whether monoclonal antibodies (mAb) to *Pfs47* have transmission blocking activity by decreasing infection of mosquitoes in a standard membrane feeding assay. Thirteen mAbs generated against the full length *Pfs47* showed modest and variable transmission-blocking activity but, through domain mapping, we observed that none of these mAbs reacted against the domain 2 of

*Pfs47*. A modified version of *Pfs47* domain 2 was expressed in *E. coli* for polyclonal and monoclonal antibody production. Purified IgG from the sera of domain 2 immunized mice showed a robust and reproducible transmission-reducing activity when compared to naïve purified mouse IgG. Two independent spleen fusions were carried out using the immunized mice for monoclonal antibody production. Monoclonal antibodies against *Pfs47* domain 2 showed transmission blocking activity. Ongoing work is directed to narrow down the specific epitopes of *Pfs47* domain 2 to target. Overall, we show that *Pfs47* domain 2 can be a target for transmission blocking strategies.

## 425

### PBG37 IS A POTENTIAL NOVEL MALARIA TRANSMISSION BLOCKING VACCINE CANDIDATE

Yaming Cao<sup>1</sup>, Fei liu<sup>1</sup>, Liwang Cui<sup>2</sup>, Li Li<sup>1</sup>, Yaru Wang<sup>1</sup>

<sup>1</sup>China Medical University, Shenyang, China, <sup>2</sup>Pennsylvania State University, University Park, PA, United States

Transmission-blocking vaccines (TBVs) that interrupt parasite transmission are potentially important tools for malaria eradication. However, only a handful of TBV candidates have been characterized, highlighting the urgent demand to explore novel antigens for TBVs. Here, we identified a putative *Plasmodium berghei* gametocyte-stage protein, Pbg37, and evaluated its potential for TBV. A partial fragment of predicted protein was expressed in bacteria and purified recombinant protein was used to immunize mice. Antisera against the recombinant protein elicited high titers of total IgG in mice. Western blot analysis demonstrated that Pbg37 was expressed on the gametocytes, zygotes and ookinetes. IFA showed that protein localized the outer membrane of gametocytes, gametes, zygotes, retorts and ookinetes. To elucidate the function of Pbg37, the gene was knocked out in *P. berghei* ( $\Delta$ *pbg37*). The  $\Delta$ *pbg37* line exhibited considerable defects during sexual development, including a significant reduction in gametocyte number (~60%), an altered female/male ratio (~6:1) and mature male gametocytes, and a decrease in exflagellation (~36%) and ookinete numbers (~75%). Direct mosquito feeding assay showed a reduction in oocyst numbers per midgut (~90%) and infection prevalence (~24%) of the  $\Delta$ *pbg37* line. Antisera from active immunization against Pfg37 displayed significant TB ability, shown as a significant reduction in exflagellation and in ookinete number *in vitro*, and a decrease in oocyst intensity and infection prevalence after mosquito feeding. These data, together with the conservation of the gene in *Plasmodium*, suggested that Pbg37 could be a new TBV target candidate worth of future investigations.

## 426

### ANTI-CELTOS TRANSMISSION BLOCKING ACTIVITY IN VIVO AND IN VITRO AGAINST PLASMODIUM FALCIPARUM BY EPIOTOPE-SPECIFIC MONOCLONAL ANTIBODIES

Shulin Xu<sup>1</sup>, Alison E. Roth<sup>1</sup>, Richard T. Luque<sup>1</sup>, Nichole D. Salinas<sup>2</sup>, Niraj H. Tolia<sup>2</sup>, Samantha Barnes<sup>1</sup>, Courtney Herman<sup>1</sup>, John H. Adams<sup>1</sup>

<sup>1</sup>Department of Global Health, College of Public Health, University of South Florida, Tampa, FL, United States, <sup>2</sup>Departments of Molecular Microbiology, and Biochemistry and Molecular Biophysics, Washington University School of Medicine, St. Louis, MO, United States

*Plasmodium falciparum* is responsible for most of the morbidity and mortality associated with malaria. Continued success in the global malaria elimination campaign will require development effective vaccines to prevent malaria transmission. The cell-traversal protein for ookinetes and sporozoites (CeITOS) has emerged as a leading transmission blocking vaccine (TBV) candidate. We investigated the ability of epitope-specific CeITOS monoclonal antibodies (mAbs) to block transmission of *P. falciparum* sexual blood stages to mosquito stage oocyst using both *in vitro* with a standard membrane-feeding assays (SMFA) and *in vivo* with a *P. falciparum*-humanized mouse model. Standard *in vitro* culture methods

were used to produce mature gametocytes for the SMFA. The *in vivo* studies relied on an NF54 line carrying a luciferase-expressing cassette integrated in the genome. NSG mice treated with clodronate liposome supported high-level engraftment of huRBC and can be infected by this *P. falciparum* luciferase reporter line, including development of mature gametocytes infectious for mosquitoes and leading to salivary gland sporozoites. This *in vivo* laboratory model permitted a highly sensitive *in vivo* transmission blocking assay to reliably quantify early oocyst development on day 22 post infection when stage V gametocytemia reached 0.07-0.18%. Mice were randomly divided into 4 groups and 60 min. before direct mosquito feed, each mouse in the antibody-treatment group received 16 mg/kg mAb in 200µl RPMI by *iv* injection; a blank control group received of equal volume RPMI. For the *in vitro* SMFA, 400 µg/ml of CeITOS mAb was added to gametocyte culture 60 min. prior to the mosquito feed. The presence of CeITOS mAb significantly inhibited oocyst development in mosquitoes in both *in vivo* and *in vitro* assays. Importantly, the experimental results with an innovative *in vivo* humanized mouse model confirmed that circulating anti-CeITOS antibody effectively inhibits *P. falciparum* ookinete development to oocyst in mosquitoes. These results support the development of CeITOS as a transmission blocking vaccine.

## 427

### BRIDGING HISTORICAL LUMINEX® 200™ DATA WITH LUMINEX® FLEXMAP 3D™ DATA

Danielle C. Jateng, Sneha Patel, Kingsley Jarret, James Moon, Jennifer Kookan, Christian Darko

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Malaria, a disease caused by *Plasmodium* parasites, influences the tropical and subtropical region of the world: Sub-Saharan Africa, South-East Asia, Latin America and Middle East with ~92% death rate among children below the age of five; creating an urgent need for a vaccine. The Walter Reed Army Institute of Research (WRAIR) International Reference Laboratory for Malaria Serology (MSL) characterizes, and quantifies serum antibody responses in malaria vaccine clinical trials. The methods commonly used include enzyme-linked immunosorbent assay (ELISA), indirect fluorescent antibody test (IFAT) and, recently, multiplex assays such as xMAP technology (Luminex Corporation, Austin, TX, USA). Previously, the Luminex® 200™ instrument was utilized for acquisition of multiplex data; with obtaining more advanced instrument, the Luminex® FLEXMAP 3D™, there was a need to compare data from Luminex 200 to the data of Luminex® FLEXMAP 3D™. The advancement of technology and the need to rapidly acquire data has driven science towards multiplexing strategies. When acquiring new instrumentation comparisons of sensitivity, resolution, and accuracy from one instrument to another is key. Therefore, comparative and quantitative testing is necessary in technology transfers such as this. In this report, several assays of *Plasmodium falciparum* immune serum samples including controls from previous clinical trials were reacted with *P. falciparum* antigen-coupled magnetic beads and analyzed simultaneously on Luminex® 200™ and Luminex® FLEXMAP 3D™ instruments. Our results shows a wider linear range and a higher MFI values on the Luminex® FLEXMAP 3D™ instrument compared with Luminex® 200™ instrument. It became evident that, the instrument used in data acquisition is as equally important as the study itself.

**PRESERVING THE INTEGRITY OF EXPERIMENTAL HUMAN INFECTION MODELS BY ANALYTICAL TESTING**

Jason W. Bennett<sup>1</sup>, Jessica J. Cowden<sup>2</sup>, Susan B. Cicatelli<sup>2</sup>, Chau T. Vuong<sup>2</sup>, Brittney M. Potter<sup>2</sup>, Jason C. Sousa<sup>2</sup>, Sean R. Marcisin<sup>2</sup>, Evelina Angov<sup>2</sup>, Christian F. Ockenhouse<sup>2</sup>

<sup>1</sup>Walter Reed Army Institute of Research/Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States

Clinical trials rely on the voluntary participation of subjects. Lack of subject integrity can lead to results that may jeopardize the analysis of a study. We report the case of a volunteer who was one of six control subjects undergoing controlled human malaria infection (CHMI) by the bites of malaria-infected mosquitoes. This model uses drug-susceptible 3D7 *P. falciparum* parasites. Subjects were instructed to avoid anti-malarials or drugs that might inhibit parasite development or prevent infection. It was expected that they would become parasitemic between days 9-15 post-challenge. Five of six subjects were diagnosed with malaria on days 12-14 and successfully treated with chloroquine. The last subject remained negative by blood smear and PCR through day 28. The subject reported taking an over-the-counter cold medicine on the day of CHMI but denied the use of other drugs. To explore the cause of this challenge failure, blood specimens from this subject were analysed by ultra performance liquid chromatography-mass spectrometry to look for components of the cold medicine and anti-malarial drugs that could have prevented infection. Samples from 2 days pre- through 16 days post-CHMI were available. Blood levels of the components of the cold medicine, doxycycline, primaquine, quinine, and chloroquine were measured. Chloroquine was found in all serum samples beginning day 7 after mosquito bite challenge through day 16. Serum levels of chloroquine ranged from 6.5-12.6 nM corresponding with concentrations that induce 50% growth inhibition in this strain *in vitro*. No other anti-malarials were detected. While components of the cold medicine purportedly have anti-malarial activity, none was found in the subject's blood in significant concentrations. The presence of chloroquine in the blood may explain why they did not become parasitemic. Undisclosed self-administration of anti-malarials by even one control subject disrupts the integrity of the CHMI model. Investigators designing trials incorporating experimental human infection should consider analytical testing for compounds that could adversely impact the integrity of the model.

## 429

**COMPARISON OF A MULTIPLEX AVIDITY ASSAY FOR PLASMODIUM FALCIPARUM MALARIA ANTIBODIES AT ROOM TEMPERATURE VERSUS PHYSIOLOGICAL BODY TEMPERATURE**

Shanai Browne, Kingsley Jarrett, James Moon, Jennifer Kookan, Christian Darko

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Enzyme-linked immunosorbent assay (ELISA) is the dominant method of testing the avidity of antigen-antibody bonds using chaotropic agents such as urea, sodium thiocyanate, and potassium thiocyanate. Chaotropic agents work to disrupt the antigen-antibody binding by breaking hydrogen bonds of tertiary proteins which allow us to measure the avidity of specific antigen-antibody bonds. Avidity encompasses traits such as binding affinity, antibody valency, epitope density, and antibody reactivity which collectively define the strength of multiple binding interactions between an antigen and antibody. With the introduction of Luminex Corporation's xMAP technology, multiplex assays are on the rise to becoming a more rapid and efficient way of testing for multiple analytes. Multiplex avidity assays offer the ability to simultaneously detect, quantify, and categorize the avidity of antibodies across multiple antigens per microwell. We have developed the multiplex avidity assay for determining IgG subclasses

against *Plasmodium falciparum* circumsporozoite protein, a dominant target for malaria vaccine research along with its immunodominant NANP repeat region peptide, and Pf16 C-term peptide. While many commercially available multiplex kits are sold with recommended assay temperature set at room temperature (25°C), we highlight the importance of comparing our multiplex avidity assay run at the human physiological temperature (37°C). Our new multiplex avidity assay enables determination of human serum total IgG levels against *P. falciparum* antigens and has been developed and tested at room temperature in comparison to the human physiological temperature offering a more time efficient and inexpensive alternative to the traditional ELISA.

## 430

**SAFETY, IMMUNOGENICITY AND DURABILITY OF A NOVEL MALARIA VACCINE CANDIDATE, R21 ADJUVANTED WITH AS01<sub>B</sub>**

Navin Venkatraman<sup>1</sup>, Georgina Bowyer<sup>1</sup>, Katharine Collins<sup>1</sup>, Philip Angell-Manning<sup>1</sup>, Jonathan Powlson<sup>1</sup>, Carly Bliss<sup>1</sup>, Nathan Brendish<sup>2</sup>, Oliver Griffiths<sup>1</sup>, Ian Poulton<sup>1</sup>, Sarah Moyle<sup>1</sup>, Eleanor Berrie<sup>1</sup>, Nicola Green<sup>1</sup>, Ekta Mukhopadhyay<sup>1</sup>, Marc Lievens<sup>3</sup>, Danielle Morelle<sup>3</sup>, Alison Lawrie<sup>1</sup>, Rachel Roberts<sup>1</sup>, Saul Faust<sup>2</sup>, Katie Ewer<sup>1</sup>, Adrian V. Hill<sup>1</sup>

<sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>NIHR/Wellcome Trust Southampton Clinical Research Facility, Southampton, United Kingdom, <sup>3</sup>GlaxoSmithKline Vaccines, Rixensart, Belgium

Falciparum malaria remains one of the leading infectious causes of morbidity and mortality worldwide. Though the search for an effective vaccine has seen unprecedented advances in recent years and one of the leading vaccine candidates, RTS,S/AS01 is going to enter pilot deployments in Africa in 2018, there has been no vaccine that has demonstrated durable high level efficacy. R21 has been developed at the Jenner Institute, University of Oxford. This is an RTS,S like construct, an antigen derived from the pre-erythrocytic circumsporozoite protein, which is an abundant coat protein that is pivotal in sporozoite development and hepatocyte invasion. Similar to RTS,S, it comprises recombinant particles expressing the central repeat and the C-terminus of the circumsporozoite protein (CSP) fused to Hepatitis B surface antigen (HBsAg). It does not include the unfused HBsAg protein found in RTS,S, which was required to allow it to form a particle. CSP comprises less than 20% of the total protein content of RTS,S and a large proportion of the antibody response induced by RTS,S is towards the HBsAg. In contrast, R21 comprises only fusion protein moieties, i.e. as 100% of its molecules, which increases the density of CSP antigen on the VLP surface. This was made possible by expressing R21 in the better expressing yeast *Pichia pastoris*, rather than in *Saccharomyces cerevisiae* and it spontaneously forms a particle just like RTS,S. In pre-clinical studies, R21 induces predominantly malaria rather than hepatitis antibodies and it has been shown to be safe, non-toxic and highly immunogenic with comparable immunogenicity and similar high level efficacy to RTS,S. We undertook a Phase I, open-label clinical trial to assess the safety and immunogenicity of R21 administered at 10µg (n=10) and 50µg (n=10) with the liposome-based adjuvant, AS01B. Volunteers in both groups received three vaccinations, 4 weeks apart. Our data show that the vaccine was well tolerated and antibody responses were durable with titres at 6 months comparable to those reported for RTS,S/AS01, at both the doses tested.

## 431

### MALARIA PREVENTIVE PRACTICES AND ACCEPTABILITY OF SEASONAL MALARIA CHEMOPREVENTION AMONG CAREGIVERS OF UNDER FIVE CHILDREN IN RURAL AND URBAN COMMUNITIES OF KANO, NIGERIA, 2017

Usman L. Shehu

AFENET/Nigeria Field Epidemiology and Laboratory Training Program, Abuja, Nigeria

Worldwide, malaria kills more than one million people yearly and remains a leading cause of morbidity and mortality in Africa of which majority are young children. Malaria control strategies now targets specific populations for maximal effectiveness. The WHO now recommends Seasonal Malaria Chemoprevention for the prevention of malaria among children under 5 in areas with high malaria transmission. This study assessed and compared malaria preventive practices and acceptability of seasonal malaria chemoprevention including factors associated. A comparative cross-sectional study was conducted in Gwale and Gezawa districts of Kano state using mixed methods. The multi-stage sampling method and structured questionnaires were used to collect quantitative data from 325 households in each LGA while qualitative data were collected through 6 Focus Group discussions and In-depth Interviews. Quantitative data were analysed using SPSS version 21 while qualitative data were analysed using a thematic framework. Majority (72%) of the rural respondents use LLINs for malaria prevention compared to less than 5% of the urban respondents ( $p < 0.05$ ). Non-treated mosquito net was commonly (82%) used in the urban areas while mosquito coil was mainly used in the rural areas (23.3%) followed by window/door netting (5.2%) and burning of mosquito paper (4.2%). The least preventive practices in both communities were mosquito repellent cream, aerosol insecticide spray and interior wall spray as they were used by less than 2% of respondents in both communities. A higher proportion of urban residents (85.7%) were more willing to accept SMC. Age (AOR 7.6, 95% CI 1.1-54.7) and awareness of SMC (AOR 6.6, 95% CI 1.9-23.5) significantly predicted SMC acceptability in the urban community while literacy status (AOR 0.3, 95% CI 0.09-0.79) significantly predicted SMC acceptability in the rural community. Distribution of SMC drugs free, use of incentives and involvement of traditional/religious leaders would enhance SMC acceptability in both communities. The government should undertake awareness campaign on the use of LLINs in the urban communities.

## 432

### ESTABLISHMENT OF THE FIRST EXPERIMENTAL FIELD SITE IN MADAGASCAR FOR STUDYING ANOPHELES COMPETENCY TO TRANSMIT PLASMODIUM FALCIPARUM AND P. VIVAX

Jessy Marlène Goupeyou Youmsi<sup>1</sup>, Thiery Nirina Jean Jose Nepomichene<sup>1</sup>, Majoline Tchioffo Tsapi<sup>2</sup>, Sebastien Boyer<sup>1</sup>, Romain Girod<sup>1</sup>, Milijaona Randrianarivelosia<sup>1</sup>, Inès Vigan-Womas<sup>1</sup>, Mamadou Ousmane Ndiath<sup>1</sup>, Catherine Bourgouin<sup>2</sup>

<sup>1</sup>Institut Pasteur in Madagascar, Antananarivo, Madagascar, <sup>2</sup>Institut Pasteur, Paris, France

Malaria is still a major health concern in Madagascar. *Plasmodium falciparum* and *Plasmodium vivax* are the major parasite species. *Anopheles gambiae* s.l. and *Anopheles funestus* are the main vectors. However, *Anopheles mascarensis*, a Malagasy endemic species, and *Anopheles merus* can also be vectors of malaria parasites locally. Additionally, *Anopheles coustani* has recently been detected carrying *Plasmodium* sporozoites. Although *Anopheles* surveillance including *Plasmodium* carriage determination is well developed in Madagascar for malaria transmission control, no vector competence studies have been carried out in this country yet. Such studies are important for a better understanding of the effective contribution of each potential vector to transmit *P. falciparum* and/or *P. vivax* and to contribute to the development of alternative strategies to interrupt malaria transmission. Towards these

aims, we have set up an experimental platform within a rural health center in a district where both *P. falciparum* and *P. vivax* are prevalent. There *Anopheles* mosquitoes are locally produced as F0 from larval catches or as F1 from gravid female catches. Female mosquitoes are fed using a membrane feeding system on the blood of *P. falciparum* gametocyte carriers and any *P. vivax* carriers who are selected among children (5-15 years) attending local schools by thick blood smears. In addition, in the same locality we performed a survey of the local mosquito population to evaluate the rate of *Plasmodium* carriage in these mosquitoes. During the 2016 and 2017 campaigns, among roughly 1000 children screened each year, 10% were detected carrying *Plasmodium* parasites with *P. falciparum* representing the major species (8-9%). Up to now we have performed 15 successful experimental infections of *An. gambiae* s.l. leading to a higher rate of infection of this mosquito species with *P. falciparum* than with *P. vivax* (55% prevalence compared to 34% - microscopic oocyst counts at D7). Our full set of data will be presented. Our data clearly show that we have now at hand the capacity to study the competence of *Anopheles* mosquitoes of Madagascar to transmit *P. falciparum* and *P. vivax*.

## 433

### CHARACTERIZATION OF PYRETHROID RESISTANCE IN POPULATIONS OF ANOPHELES GAMBIAE S. L FROM ETHIOPIA AND EVALUATION OF LONG-LASTING INSECTICIDAL NETS

Balkew Meshesha<sup>1</sup>, Woyessa Adugna<sup>2</sup>, Eticha Getachew<sup>2</sup>

<sup>1</sup>Addis Ababa University, Addis Ababa, Ethiopia, <sup>2</sup>Ethiopian Public Health Institute, Addis Ababa, Ethiopia

In Ethiopia, long-lasting insecticidal nets together with indoor residual spraying are key vector control interventions. PermaNet 2.0 and MAGNet nets are widely in use and the role of PBO nets in areas with confirmed pyrethroid resistance is implicated in the recently approved insecticide resistance monitoring and management strategic document. The resistance status of *Anopheles gambiae* s.l. to deltamethrin, permethrin and alphacypermethrin, the enzymatic mechanism of resistance indirectly by synergist test and the bioefficacy of LLINs including PermaNet 3.0 was assessed in five districts using the standard WHO tube test and the WHO cone bioassay tests. Pyrethroid resistance was confirmed in populations of *An. gambiae* s.l. (mortality 30-65%) and the presence of metabolic resistance was observed as the synergist test restored susceptibility (mortality 95% to 100%) to alphacypermethrin and deltamethrin. In the case of permethrin, mortality ranged from 70% -93% after PBO test showing the involvement of two or more resistance mechanisms. Of all the four LLINs, PermaNet 3.0 was more efficacious with 90-100% knockdown and 67-100% mortality. The roof that contains PBO killed 100% of test mosquitoes. The pyrethroid-only nets produced 1-48% knockdown and 1-69% mortality, less than WHO cut-offs of 95% knockdown or 80% mortality.

## 434

### CROSS SECTIONAL SURVEY OF LONG LASTING INSECTICIDETREATED BEDNET DURABILITY AND USE AMONG FISHING AND PASTORALIST COMMUNITIES, KENYA, 2015

Angeline Aboto<sup>1</sup>, Nabie Bayoh<sup>2</sup>, Maurice Ombok<sup>3</sup>, Waqo Boru<sup>1</sup>, Andrew Obala<sup>4</sup>, Rebecca Kiptui<sup>5</sup>, Wako Ejersa<sup>5</sup>, Ann Buff<sup>2</sup>, Ann Buff<sup>6</sup>

<sup>1</sup>Kenya Field Epidemiology and Laboratory Training Program, Ministry of Health, Nairobi, Kenya, <sup>2</sup>Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Kenya Medical Research Institute-Centre for Global Health Research Institute, Kisumu, Kenya, <sup>4</sup>Moi University, School of Public

Health, Eldoret, Kenya, <sup>5</sup>National Malaria Control Program, Nairobi, Kenya, <sup>6</sup>President's Malaria Initiative-Kenya, Nairobi, Kenya

Malaria accounts for ~15% of outpatient visits in Kenya. Mass distribution of long-lasting insecticide-treated bednets (LLINs) every 3 years is a key malaria control strategy. We compared LLIN attrition, damage and net use between two communities in Kenya. Cross-sectional household surveys were conducted 1 year after mass net distribution to determine net attrition, damage and use in two communities in western Kenya from December 2015–January 2016. Initially, 720 and 628 LLINs with unique identifiers were distributed in Siaya, a fishing community, and West Pokot, a pastoralist community, respectively. Standardized household questionnaires were administered to determine net use. A household net census determined attrition (net missing) and damage through visual inspection and hole-size (area) measurement. Proportionate hole index (pHI) was calculated following World Health Organization guidelines; nets were categorized as “serviceable” (pHI <643) or “damaged beyond repair” (pHI ≥643). Use was defined as sleeping under an LLIN the night before the survey. Data were analyzed using SAS 9.1 to compare community net attrition, damage and use. At 1-year post-distribution, mass campaign nets present in fishing community households were 508 (70.6%) of 720 compared to 303 (48.2%) of 628 in pastoralists. Net attrition was lower in the fishing community (16.1%) compared to pastoralists (36.3%,  $p < 0.0001$ ), net damage was higher in fishing community (25.4%) compared to pastoralists (8.3%,  $p < 0.0003$ ), and net use was also higher in fishing community (96.7%) compared to pastoralists (81.9%,  $p < 0.0001$ ). Net attrition was significantly higher in the pastoralist community while net damage and use were significantly higher in the fishing community. Additional distribution channels to replace nets should be considered by malaria-control stakeholders in both communities where over one-third of nets were missing 1-year post-distribution. Alternative net replacement strategies and net-care messaging are needed to maintain high coverage and prevent malaria in western Kenya.

### 435

#### IMPACT OF SEASONAL MALARIA CHEMOPREVENTION AFTER 3 YEARS AT SCALE IN SOUTHERN SENEGAL

Jean Louis A. Ndiaye<sup>1</sup>, Isaac A. Manga<sup>2</sup>, Fassia Tairou<sup>3</sup>, Medoune NDIOP<sup>4</sup>, Ibrahima Diallo<sup>4</sup>, Roger Tine<sup>5</sup>, Maguette Ndiaye<sup>3</sup>, Babacar Faye<sup>5</sup>, Daouda Ndiaye<sup>5</sup>, Omar Sarr<sup>4</sup>, Oumar Gaye<sup>6</sup>, Paul Milligan<sup>7</sup>

<sup>1</sup>Service de Parasitologie, Thies University, Senegal, <sup>2</sup>Department of Parasitology Cheikh Anta Diop University, Dakar, Senegal, <sup>3</sup>Service de Parasitologie UCAD, Dakar, Senegal, <sup>4</sup>NMCP Ministry of Health, Dakar, Senegal, <sup>5</sup>Department of Parasitology UCAD, Dakar, Senegal, <sup>6</sup>Department of Parasitology, Dakar, Senegal, <sup>7</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

In Senegal, SMC is provided children up to the age of 10 years. The objective of this project was to evaluate the delivery and impact of SMC by measuring coverage using surveys, monitoring treatment efficacy using case control studies and surveys of the prevalence of molecular markers of resistance, monitoring safety through enhanced spontaneous reporting and active follow-up, and assessment of impact using sentinel surveillance. Records on outpatients and inpatients with a diagnosis of malaria were collected from 2012 to 2016 from registers in all hospitals and health centres, and from a probability sample of health posts. After a pilot implementation in 2013, over 5 million treatments were administered from 2014-2016. 92% of children received at least three monthly treatments in 2014, 90% in 2015 and 83% in 2016. A total of seven serious adverse events have been reported (2 Stevens Johnson syndrome, 1 Lyell syndrome, 1 extra-pyramidal syndrome, and 3 allergic reactions). To estimate the impact of SMC we fitted a Poisson regression model to the data on the number of cases, with covariates for the season, year, age group (3-59 months; 5-9 years; 10-19 years; and 20 years and above), and with an indicator variable for SMC set to 1 for ages 3 month to 9 years during the months of September to December from 2014-2016, and set to zero otherwise, with a random effect for the health facility. SMC was associated with a 44% reduction in outpatient cases

of malaria, a 39% reduction in malaria inpatient admissions, and a 43% reduction in hospital deaths associated with malaria. It has been assumed that SMC would prevent malaria deaths, but this is the first evidence to show that SMC programmes can reduce mortality. The SMC programme in Senegal is highly effective. Continued monitoring will be necessary to ensure the quality of delivery is maintained. In many other countries with SMC programmes there is a similarly high burden of malaria in older children. Extending the age range to include these children can be done cost efficiently and would substantially increase the impact of those programmes.

### 436

#### EXPERIENCES AND PERCEPTIONS ABOUT INSECTICIDES TREATED WALL LINERS AS A SUPPLEMENT TO BED NETS IN A HIGH MALARIA TRANSMISSION AREA IN TANZANIA, A MIXED METHODS STUDY

Peter E. Mangesho<sup>1</sup>, Donald Shephard<sup>2</sup>, Louisa Messenger<sup>3</sup>, Yara Halasa<sup>2</sup>, Aggrey Kihombo<sup>2</sup>, George Mtove<sup>1</sup>, Joseph Mugasa<sup>1</sup>, Seif Mohammed<sup>4</sup>, Ruth Mnzava<sup>1</sup>, Robert Kihomo<sup>2</sup>, William Kisinza<sup>1</sup>

<sup>1</sup>National Institute for Medical Research-Amani Medical Research Centre, Muheza, United Republic of Tanzania, <sup>2</sup>Heller School, Brandeis University, Waltham, MA, United States, <sup>3</sup>Faculty of Infectious Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>National Institute for Medical Research, Muheza, United Republic of Tanzania

Ambivalent reception to new health interventions is not uncommon in Sub-Saharan Africa and feedback is essential to improve participant receptivity. A cluster-randomized trial of the effectiveness of non-pyrethroid insecticide-treated durable wall lining (ITWL) to control malaria in combination with long-lasting insecticidal nets (LLINs), offered an opportunity to assess levels of ITWL acceptability among communities in rural Tanzania. Focus group discussions (n=14) and quantitative surveys (n=268) were conducted 6 and 12 months after ITWL installation, respectively. In general, ITWL was well received throughout the study and judged an important contribution to the fight against malaria. Many of the positive comments related to how ITWL beautified houses, especially those build from mud and sticks and with cracked walls (87.7%; 235/268). While most participants were satisfied with ITWL installation (86.9%; 233/268), often a space was left between the wall and the material, which became a hideout for pests, including rats and snakes, leading some to perceive ITWL as a rodent attractant. An additional negative behavior was participants reporting not using their LLIN, undermining the objective of the study, where participants considered ITWL an improved replacement to LLINs. After 12 months, the majority of ITWL installations were still intact. However, most householders felt they did not have the equipment or expertise to repair damaged or fallen ITWL (89.2%; 239/268), raising issues of long-term sustainability without external maintenance. In cases where ITWL had been prematurely removed, it was re-purposed to cover outdoor pit latrines, external house walls and to protect brick stacks from rain. Importantly, at the end of the study, most respondents wished to keep their ITWL and have it repeated in future (60.5%; 162/268). ITWL would be widely accepted at the community level, if complemented with reinforced concomitant use of LLINs and with periodic maintenance and modifications to the installation design to better-fit house walls.

## 437

### NUMBER OF PERSONS SHARING A BED NET IS POSITIVELY ASSOCIATED WITH THE RISK OF *PLASMODIUM* INFECTION IN WESTERN KENYA: IMPLICATIONS FOR MALARIA PREVENTION

Noriko Tamari<sup>1</sup>, James O. Kongere<sup>2</sup>, George O. Sonye<sup>3</sup>, Beatrice Awuor<sup>3</sup>, Lucy Oketch<sup>3</sup>, Charles O. Gunga<sup>3</sup>, Fredrick O. Sonye<sup>3</sup>, Peter S. Larson<sup>1</sup>, Noboru Minakawa<sup>1</sup>

<sup>1</sup>Nagasaki University, Nagasaki, Japan, <sup>2</sup>Centre for Research in Tropical Medicine and Community Development, Nairobi, Kenya, <sup>3</sup>ASK Project, Mbita, Kenya

Long-lasting insecticidal bed nets (LLINs) are a core tool for preventing malaria. While the World Health Organization (WHO) recommends one LLIN for every two persons in a household, a LLIN is often shared with three or more people. However, little is known about the relationship between number of persons per net and malaria risk. We assessed net sharing and the risk of *Plasmodium falciparum* infection among children in Gembe East, western Kenya. Infection was determined for children under 10 years of age with a rapid diagnostic test (RDT), and caretakers were interviewed about net use and sharing. Of 275 children studied, 233 (84.7%) reportedly slept under LLINs the previous night. The RDT-positive prevalence was 70.8% for net users and 81.0% for non-net users. The number of persons sleeping under a LLIN ranged from 1 to 6 (median=3), with infection prevalence increasing as more people slept (53.8% for one person, 71.0% for two persons, 71.4% for three persons and 74.4% for four or more persons). Overall, infection among children who slept alone under a net was significantly lower than those of children sharing a net with two or more other persons (OR=3.92, 95%CI: 1.05-14.22 against two other person; OR=4.40, 95%CI: 1.02-19.97 against three or more other persons) while it was not significantly lower than that of children sharing a net with one other person (OR=2.22, 95%CI: 0.59-8.12). When the number of person per a net increased by one, the risk of infection increased 49% (95%CI: 1.02-2.27). These results suggest that the number of persons sleeping in a net should be fewer than three, and sleeping alone may further reduce the risk.

## 438

### ASSOCIATION BETWEEN INDOOR RESIDUAL SPRAYING OF INSECTICIDE AND IMPROVED BIRTH OUTCOMES AMONG HIV-INFECTED PREGNANT WOMEN IN UGANDA

Michelle Roh<sup>1</sup>, Catherine Koss<sup>2</sup>, Paul Natureeba<sup>3</sup>, Stephen Shiboski<sup>4</sup>, Abel Kakuru<sup>3</sup>, Mary Muhindo<sup>3</sup>, Teddy Ochieng<sup>3</sup>, Albert Plenty<sup>5</sup>, Tamara Clark<sup>2</sup>, Miriam Nakalamba<sup>6</sup>, Deborah Cohan<sup>7</sup>, Prasanna Jagannathan<sup>8</sup>, Roly Gosling<sup>1</sup>, Diane Havlir<sup>2</sup>, Moses Kanya<sup>9</sup>, Grant Dorsey<sup>2</sup>

<sup>1</sup>Global Health Group, Malaria Elimination Initiative, San Francisco, CA, United States, <sup>2</sup>Department of Medicine, University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>4</sup>Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States, <sup>5</sup>Center for AIDS Prevention Studies, University of California San Francisco, San Francisco, CA, United States, <sup>6</sup>Department of Obstetrics and Gynecology, Makerere University College of Health Sciences, Kampala, Uganda, <sup>7</sup>Department of Obstetrics, Gynecology and Reproductive Sciences, University of California San Francisco, San Francisco, CA, United States, <sup>8</sup>Department of Medicine, Stanford University, Palo Alto, CA, United States, <sup>9</sup>School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda

Despite effective interventions to prevent malaria during pregnancy, the risk of adverse birth outcomes among HIV-infected pregnant women living in sub-Saharan Africa remains high. A recent study demonstrated a reduction in adverse birth outcomes among HIV-uninfected pregnant women protected by indoor residual spraying of insecticide (IRS). Evidence

regarding its impact on HIV-infected pregnant women is lacking. To assess the association between IRS and preterm birth (gestational period < 37 weeks), low birthweight (< 2500 grams), and fetal/neonatal death, data was pooled from two clinical trials conducted before and after a large-scale IRS campaign in Tororo District, Uganda. Participants were HIV-infected pregnant women who received insecticide treated bed nets, daily trimethoprim-sulfamethoxazole, and combination antiretroviral therapy at study enrollment. Exposure was measured as the percentage of IRS protection experienced by the mother during her gestational period. Multivariate Poisson regression with robust standard errors was used to estimate adjusted risk ratios (aRR). Of the 565 women included in our analysis, 380 (68%), 88 (16%), and 97 (17%) women were protected by IRS for 0%, > 0-90%, and > 90% of their pregnancy, respectively. Compared to women with no IRS protection during pregnancy, IRS protection for > 90% of pregnancy was associated with a significantly lower risk of preterm birth (17.1% vs. 6.2%; aRR = 0.37; 95% CI: 0.16-0.84). Preterm birth risk decreased with increasing IRS protection, indicating a dose-dependent effect (p = 0.03). IRS protection for > 90% of pregnancy was also associated with a lower risk of low birthweight (18.5% vs. 9.3%; RR = 0.58; 95% CI: 0.25-1.32) and fetal/neonatal death (5.3% vs. 2.1%; RR = 0.25; 95% CI: 0.05-1.37), although these associations did not reach statistical significance. IRS may further reduce the risk of adverse birth outcomes among HIV-infected pregnant women who are already using currently available interventions to prevent malaria during pregnancy.

## 439

### EFFECTIVENESS OF VECTORS CONTROL INTERVENTION ON MALARIA INFECTION AND CLINICAL CASES, BENIN, WEST AFRICA

Damien Georgia<sup>1</sup>, Badirou Aguemou<sup>2</sup>, Franck Remoue<sup>1</sup>, Christophe Rogier<sup>3</sup>

<sup>1</sup>Centre de Recherche Entomologique de Cotonou/Ministère de la santé (MS)/Institut de Recherche pour le Développement, Cotonou, Benin, <sup>2</sup>Faculty of Health Science, University of Abomey-Calavi, Benin, Cotonou, Benin, <sup>3</sup>Institut Pasteur de Madagascar, Antananarivo, Madagascar/ Institut de Recherche Biomédicale des Armées, Brétigny sur Orge, France/ Aix-Marseille Université, Unité de Recherche sur les Maladies Infectieuses et Tropicales Emergentes, UM 63, CNRS 7278, IRD 198, Antananarivo, Madagascar

The most commonly used methods to prevent mosquito bites are sleeping under the Long lasting insecticide treated net (LLIN) and spraying the inside walls of a house with an insecticide called indoor residual spraying (IRS). The present study aimed to evaluate the effectiveness of post deployment LLIN and IRS on *P. falciparum* infection and clinical cases. A case-control study was carried out among all age groups in the north-west Benin in 2014. Nine villages were included in the commune of Djougou (urban area) and in the commune of Coby (rural area) respectively. A case of *P. falciparum* infection was defined as positive rapid diagnosis test. A total of 594 cases of infection and 1495 controls were recruited in urban area compared to 1030 cases and 1135 controls in rural area. The malaria clinical case was defined as positive thick blood films plus fever. A total of 112 cases and 1362 controls were recruited in urban compared 90 cases and 1445 controls in rural. The prevalence rate of *P. falciparum* infection was 36.0% and 70.0% among children aged two to nine years old in urban and rural area respectively. The use of LLIN was 38.9% in urban area and 50.9% in rural. The coverage of IRS was 95.8%. In urban area, the LLINs induced 50% significant reduction of infection in only one neighbourhood but any reduction in malaria clinical cases. In the rural area, a significant protection (49%) was obtained among all population only if the LLINs were associated to IRS. Malaria remains a major public health problem in Benin. It is an urgent need to build a strong surveillance system of malaria and evaluated as soon as possible what are working and which intervention need better management and a large behavior change communication.

## QUANTIFYING SEASON PATTERNS OF ITN USE ACROSS CLIMATIC ZONES IN SUB-SAHARAN AFRICA

Hannah Koenker, Bolanle Olapeju

Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States

Insecticide-treated nets (ITNs) are the primary tool for malaria prevention in sub-Saharan Africa, and while population access to ITN is often below the RBM target of 80%, the ITN use:access ratio, the primary indicator for ITN use among those with access, is regularly above the target of 0.80 in a majority of countries. The main barriers to ITN use are known to be low perceived mosquito abundance and feelings of discomfort, primarily related to heat, but seasonal determinants of ITN use have never been quantified. We examined subnational patterns of seasonal ITN use and access in three countries to assess relationship with seasonal rainfall and for mosquito density (rainfall lagged by 1 month), controlling for zone and urban/rural residence. Cluster means for ITN use:access ratio were generated from cluster means for ITN use and ITN access derived for each survey. Clusters were categorized as dry, early rainy, or late rainy season based on month of survey fieldwork and monthly average rainfall patterns (1990-2012 averages) for three zones per country. Cluster use:access ratios were linearly correlated with rainy season in Senegal 2014 cDHS and 2015 cDHS (coef 0.151 and 0.192,  $p < 0.05$  respectively), but lagged mosquito abundance was a stronger predictor than rainy season (coef 0.170 and 0.226,  $p < 0.05$  respectively), controlling for zone and urban/rural residence. In Tanzania, cluster use:access ratios were also linearly correlated with rainy season in 2015-16 (coef 0.045,  $p < 0.05$ ) and to a slightly higher degree with lagged mosquito abundance (coef 0.069,  $p < 0.05$ ). In Ghana, no seasonal correlation was observed with three seasonal categories, but binary categorization of rainfall showed a 0.05 point increase in use:access ratio from dry to rainy season ( $p < 0.05$ ). Urban residence was associated with decreased use:access ratio in Senegal and Tanzania, but with increased ratio in Ghana. These preliminary results demonstrate that mosquito abundance drives use of ITNs among those with access to a greater degree than rainfall itself, boosting use:access ratios by 6-22 points. Additional surveys will be analyzed and comprehensive results presented.

## WHO BUYS NETS? FACTORS ASSOCIATED WITH MOSQUITO NET PURCHASE IN SUB-SAHARAN AFRICA

Bolanle Olapeju, Hannah Koenker

Johns Hopkins University, Baltimore, MD, United States

Bednets, particularly long-lasting insecticidal nets are the primary tool for preventing malaria infection and reducing associated morbidity and mortality. While bednets are typically obtained free from public sources, nets are often purchased from private retail channels. Using data from the 2015/16 Tanzania DHS data, we explore household level factors associated with the purchase of nets in Tanzania. Nets were defined as purchased if obtained from private health facilities, shops, markets or accredited drug dispensing outlets. Both rural and urban households across all wealth quintiles in all regions of Tanzania owned purchased nets. The following household factors were included in a logistic regression model: sex and age of the head of household, presence of a child under five or currently pregnant woman; household size; indoor residual spraying, distance to market, wealth quintile; urban/rural residence; regional zone and altitude. Presence of an under five or pregnant woman (adjusted odds ratio: 1.26 and urban residence (aOR: 5.32) were significantly associated ( $< 0.05$ ) with increased odds of owning a purchased net. Odds of owning a purchased net also significantly increased with wealth (aOR: 2.08, 2.91, 4.95, 8.19 among poorer, middle, richer and richest quintiles respectively). However, female heads of household, altitudes above than 1000m and household sizes of more than 3 people were significantly associated with lower odds of owning purchased nets (aOR: 0.80, 0.44 and 0.80 respectively).

Compared to Western zone, residence in Eastern zone was significantly associated with higher odds (aOR: 2.04) while residence in Southern Highlands or Zanzibar was significantly associated with reduced odds of purchasing nets (aOR: 0.65 and 0.40 respectively). Findings can help donors and the National Malaria Control Program gain insight on the contribution of net sales on their overall ITN strategy as well as inform the design and implementation of market shaping strategies to shift consumers to purchase ITNs. Additional findings on ITN purchase behavior will be presented along with data from other countries in sub-Saharan Africa.

## HUMAN, PARASITE AND ENVIRONMENTAL FACTORS ASSOCIATED WITH ANOPHELES MOSQUITO HETEROGENEITY AMONG HOUSEHOLDS OF SOUTHERN MALAWI

Jenna E. Coalson<sup>1</sup>, Dan Frechtling<sup>2</sup>, Lauren M. Cohee<sup>3</sup>, Chifundo Kadangwe<sup>4</sup>, Karl B. Seydel<sup>5</sup>, Andrew Nyambalo<sup>4</sup>, Clarissa Valim<sup>6</sup>, Terrie E. Taylor<sup>5</sup>, Don P. Mathanga<sup>4</sup>, Andy Bauleni<sup>4</sup>, Andrew Pike<sup>3</sup>, Edward Walker<sup>7</sup>, Themba Mzilahowa<sup>4</sup>, Miriam K. Laufer<sup>3</sup>, Mark L. Wilson<sup>2</sup>

<sup>1</sup>Center for Insect Science, University of Arizona, Tucson, AZ, United States, <sup>2</sup>University of Michigan School of Public Health, Ann Arbor, MI, United States, <sup>3</sup>Division of Malaria Research, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>4</sup>Malaria Alert Centre, University of Malawi College of Medicine, Blantyre, Malawi, <sup>5</sup>Blantyre Malaria Project, Blantyre, Malawi, <sup>6</sup>Department of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, <sup>7</sup>Department of Entomology, Michigan State University, East Lansing, MI, United States

Simulation models show that transmission heterogeneity enables pathogen persistence even when population averages are theoretically too low to maintain endemicity. For malaria, heterogeneous exposure to *Anopheles* mosquitoes creates both differential infection risks and potential transmission contributions. Further, asymptomatic human reservoirs of *Plasmodium falciparum* infection are common. We investigated factors that influence spatial distribution of competent vectors to understand heterogeneity in human population transmission potential, hypothesizing that humans with gametocytes are exposed to more *Anopheles* mosquitoes than those without. We surveyed ~80 households (HH) in each of 4 endemic villages during the rainy and dry seasons of 2015. HH locations and land use/cover within 50m were observed. Consenting HH members were asked about malaria symptoms, treatments and prevention. Blood was collected to test for *P. falciparum* parasites by PCR and gametocytes by qRT-PCR for *Pfs25*. Mosquitoes were sampled by CDC light traps in most houses (rainy,  $n=247$ ; dry,  $n=303$ ) and identified to species by microscopy and PCR. Female *Anopheles* were found in 26% of houses during the dry season (median where present: 1; range: 1-15) and 71% during the rainy season (median: 7, range: 1-215). Better housing materials and closed eaves were associated with lower *Anopheles* abundance in both seasons; nearby grazing animals were associated with lower abundance only in the dry season. The HH-level association between *Anopheles* presence and at least one HH member with gametocytes was strongly modified by a village interaction (interaction  $p=0.01$ ), being positive in three but significantly negative in one. These results suggest that despite relative proximity between villages (20 – 65 km), risk factors for household exposure to *Anopheles* are significantly modified by season and village-level factors. Further analyses of the factors underlying geographic differences in relationships between human parasite reservoirs and vector heterogeneity should reveal predictors of transmission 'hot spots' and enhance future targeting of interventions.

### EVALUATION OF FOUR ROUNDS OF LONG LASTING INSECTICIDAL NET DISTRIBUTION THROUGH SCHOOLS IN SOUTHERN TANZANIA

Logan Stuck<sup>1</sup>, Ester Elisaria<sup>2</sup>, Rose Nathan<sup>2</sup>, Frank Chacky<sup>3</sup>, Joshua Yukich<sup>1</sup>

<sup>1</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>National Malaria Control Programme, Dar es Salaam, United Republic of Tanzania

In order to explore and evaluate innovative strategies for increasing use and ownership of ITNs, National Malaria Control Programme (NMCP) and partners are piloting the distribution of long lasting insecticidal nets (LLINs) through schools in Southern zone of Tanzania as a Keep-Up-Strategy to maintain universal coverage following a mass distribution. The pilot is funded through the United States Agency for International Development, the President's Malaria Initiative (USAID/PMI) and implemented by a consortium of partners (including: RTI International, Tanzania Red Cross Society, PSI, JHU/COMMIT) led by the NMCP with support from the Swiss Tropical and Public Health Institute. The evaluation consists of annual cross-sectional surveys in both implementing and non-implementing areas to compare changes in net coverage and use over time. Across the first three evaluation rounds, data was collected on 2828 and 1869 implementation area and non-implementation area households, respectively. Results from the second round evaluation showed that population access to LLINs in implementation areas was maintained, increasing from 63% in 2013 to 68% in 2015 ( $p$  for change=0.683) while access in the non-implementing areas dropped significantly from 51% to 39% during the same time period ( $p$  for change=0.002). Results from the third round evaluation in 2016 are currently still under review, however population-level access to LLINs in implementation areas declined significantly to 55% ( $p=0.013$ ). Data from the fourth round evaluation will be analyzed using repeated-measures logistic regression methods to model change in access over time, allowing adjustment for potential confounders such as socioeconomic status and school attendance. The potential for school-based distribution of LLINs as an effective Keep-Up-Strategy may be complex and dependent on a variety of factors. The results of this research provide new information on this method of LLIN distribution and the factors associated with its performance.

444

### A SYSTEMATIC REVIEW OF INDOOR RESIDUAL SPRAYING TO INVESTIGATE THE IMPACT OF PYRETHROID RESISTANCE ON MALARIA TRANSMISSION

Ellie Sherrard-Smith<sup>1</sup>, Peter Winskill<sup>1</sup>, Jamie T. Griffin<sup>2</sup>, Thomas S. Churcher<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Queen Mary University of London, London, United Kingdom

Vector control, delivered through the mass distribution of long-lasting insecticide treated bednets (LLIN) and indoor residual spraying (IRS) of insecticide, is one of the most effective tools for preventing malaria. There are growing concerns that recent gains in malaria control are under threat due to the emergence of mosquitoes that are resistant to pyrethroid insecticides. IRS offer a greater range of insecticide options for protecting indoor areas whilst pyrethroids are the only class of insecticide currently used in LLINs. Long-lasting IRS formulations with novel active ingredients are now available. In this study, a meta-analysis of experimental hut trial data is used to characterise the entomological impact of pyrethroid resistance on IRS in Africa. The epidemiological consequences are assessed using a dynamic transmission model of malaria which is used to predict the public health significance in areas with differing epidemiology and history of malaria control. The benefit of IRS campaigns using these new products is investigated throughout sub-Saharan Africa considering different levels

astmh.org

of pyrethroid resistance, seasonality in vector abundance and existing use of LLINs. Results indicate that the effectiveness of IRS campaigns can be substantially improved when switching from pyrethroids to new insecticide compounds but that IRS coverage and impact vary substantially between locations.

445

### CONSIDERATIONS FOR FORECASTING IRS INSECTICIDES

Chris Warren

JSI Research and Training Institute, Inc., Arlington, VA, United States

Indoor residual spraying (RS) is a powerful tool in the fight against malaria. The success of an IRS program depends on several requirements, including adequate and sustainable logistics resources. For IRS to be effective there must be high spray coverage of all structures in a defined area. In order to obtain high coverage, sufficient quantities of insecticide and related materials must be available. A deliberate, data-informed quantification is a critical step in planning for a successful spray campaign. Forecasting considerations for IRS insecticides, include the following: -Spray campaigns are short in duration and the timeframe for conducting them is fixed. Delays in product arrival can be detrimental to an IRS program. -For 3GIRS, demand is uncertain, and there are a limited number of manufacturers. 3GIRS manufacturers must cover the risk in the uncertain demand, which has contributed to higher prices compared to other insecticides. -Given the duration of spray season and lead times, national malaria control programs (NMCPs) may need to place an order for the following year's spray season, before they have the most recent spray season data available, and well before any post-spray entomological monitoring data are available. When conducting a forecast, the total cost of managing the insecticide must be considered. Different insecticides have different supply chain considerations, i.e. a capsule suspension will have significantly higher freight and storage costs compared to a wettable powder. -Unlike other health commodities, where maximum and minimum stock levels are utilized, consumption of IRS insecticides is concentrated in a limited time, so products do not need to continually be managed between max and min. Managers should strive for accurate forecasts and include minimal buffer stock. Other factors may influence the confidence that managers have in an IRS forecast: whether new areas are being sprayed, whether the spray season is shifting, whether an enumeration activity has been conducted, whether funding is firm, and whether stock on hand from the previous campaign is known.

### EVALUATING THE EPIDEMIOLOGICAL IMPACT OF SHIFTING IRS PRODUCTS FROM 2011-2014 IN NORTHERN GHANA

Christelle Gogue<sup>1</sup>, Joseph Wagman<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Jason Richardson<sup>2</sup>, Andrew Saibu<sup>3</sup>, Yemane Yihdego<sup>3</sup>, Sylvester Coleman<sup>3</sup>, Constance Bart-Plange<sup>4</sup>, Wahjib Mohamed<sup>4</sup>, Anthony Ofose<sup>5</sup>, Richard Steketee<sup>1</sup>, Molly Robertson<sup>1</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>IVCC, Washington, DC, United States, <sup>3</sup>Abt Associates, Accra, Ghana, <sup>4</sup>National Malaria Control Program, Accra, Ghana, <sup>5</sup>Ghana Health Services, Accra, Ghana

The indoor residual spraying (IRS) of insecticides has contributed substantially to recent successes in malaria control, positioning IRS as one of the key components of the global malaria control strategy. In Ghana, insecticide resistance concerns prompted a switch from pyrethroids to a microencapsulated formulation of pirimiphos-methyl (PM CS) starting in 2012. In conjunction with this switch, Africa Indoor Residual Spraying (AIRS) entomological surveillance has tracked the resistance status of local vector populations and the effect of IRS on key vector indicators through sentinel site monitoring. Previous analysis of data from Bunkpurugu-Yunyoo, Savelugu Nanton, Tolon/Kumbungu, and Tamale districts found that compared to IRS with a pyrethroid in 2012, IRS with PM CS in 2013 had a much more robust impact on reducing the indoor resting density of *An. gambiae*. In addition, from 2010 to 2014, the US President's Malaria

Initiative (PMI) supported enhanced anemia and parasitemia monitoring via longitudinal cross sectional surveys in Bunkpurugu-Yunyoo. This monitoring was previously reported to show a small 5% decline in parasite prevalence from 2011 (52.4%) to 2012 (47.7%), when a pyrethroid insecticide was used for IRS. In 2013 the insecticide was switched to an organophosphate and a much larger 57% decline in parasite prevalence, from 47.7% to 20.6%, was observed, suggesting a positive impact on transmission reduction resulting from a change in the class of insecticide. To supplement these analyses, we conducted a retrospective, observational analysis of the epidemiological impact of IRS with the varying insecticide classes, using routine health facility data to compare malaria incidence rates in the aforementioned districts. Changes in incidence observed in these districts are compared from year to year in the context of their varying IRS implementation status and products to provide an estimate of intervention impact. These analyses are triangulated with the previous entomological and parasitemia results to further our understanding of the impact of IRS with PM CS in a region with documented pyrethroid resistance.

## 447

#### DETERMINATION OF ESBL PREVALENCE AND COMMON MECHANISMS IN ENTEROTOXIGENIC *ESCHERICHIA ISOLATED FROM DIARRHEA SAMPLES COLLECTED IN NEPAL DURING 2001-2016*

**Katie R. Margulieux<sup>1</sup>**, Apichai Srijan<sup>1</sup>, Panida Nobthai<sup>1</sup>, Sirigade Ruekit<sup>1</sup>, Ladaporn Bodhidatta<sup>1</sup>, Prativa Pandey<sup>2</sup>, Oralak Serichantalergs<sup>1</sup>, Sanjaya K. Shrestha<sup>3</sup>, John M. Crawford<sup>1</sup>, Brett Swierczewski<sup>1</sup>

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>CIWEC Hospital and Travel Medicine Center, Kathmandu, Nepal, <sup>3</sup>Walter Reed/Armed Forces Research Institute of Medical Sciences Research Unit Nepal, Kathmandu, Nepal

Multidrug resistant (MDR) bacteria have rapidly spread globally and are now endemic in many areas of South Asia. However, there are a lack of comprehensive data from many developing countries in the region to determine the extent of MDR prevalence and common antimicrobial resistance mechanisms. In Nepal, Enterotoxigenic *Escherichia coli* (ETEC) is one of the leading causes of both acute infant and traveler's diarrhea. The MDR prevalence and resistance mechanisms of ETEC isolates responsible for enteric infections are unknown. From 2001-2016, 273 ETEC isolates were collected from acute diarrheal samples from traveler's clinics and hospitals in Nepal. The isolates were first characterized using multiplex PCR assays to determine toxin genes and colonization factors (CFs). Isolates were then screened for Extended Spectrum Beta-lactamase (ESBL) production via the Microscan Automated Microbiology System. ESBL-positive isolates were further screened for genetic components potentially responsible for the observed resistance, and conjugation studies were performed to characterize plasmid-mediated components. ETEC toxins were confirmed in the isolates (97%) and the CFs CS2 (12.8%), CS3 (22.7%), CS6 (25.6%), and CS21 (59.7%) were shown to be the most prevalent. 40/273 isolates were identified as ESBL positive. Isolates from 2008, 2013, 2014, and 2016 had ESBL prevalence rates of 1.5%, 34.8%, 31%, and 35% respectively. CTX-M-15 was identified as the most dominant ESBL gene (77.5%) followed by TEM (40.0%), SHV (20.0%), CTX-M-14 (2.5%), and CIT (2.5%). 42.5% of the isolates carried multiple ESBL genes. The ESBL-positive ETEC isolates showed a higher association with the CFs CS2 (35%), CS3 (32.5%), CS6 (45%), and CS21 (70%) compared to the whole population. A significant number of post-2013 ETEC isolates demonstrated ESBL resistance, and this prevalence will most likely increase over time. Persistent surveillance and characterization of enteric ETEC isolates are vital to track the community presence of MDR bacterial species in order to recommend treatment strategies and mitigate the spread of resistant pathogens.

## 448

#### SPECIATION, SEROTYPING AND ANTIMICROBIAL SUSCEPTIBILITY PATTERN OF *SHIGELLA* ISOLATES IN NORTHERN SRI LANKA

**Fathima Nasmiya Mubarak<sup>1</sup>**, Sujatha Pathirage<sup>2</sup>, Shayshananth Thavapalan<sup>1</sup>, Menuka Ratnadurai<sup>1</sup>, Keerthika Ahilan<sup>1</sup>, Sameera Jayawardene<sup>1</sup>, Mark Mithulan Jeyaseelan<sup>1</sup>, Selvi Kamalasingam<sup>1</sup>, Umakanthan Shanmuhathan<sup>1</sup>

<sup>1</sup>Teaching Hospital, Jaffna, Sri Lanka, <sup>2</sup>Medical Research Institute, Colombo, Sri Lanka

Shigellosis causes high disease burden, especially in children below 5 years. *Shigella flexneri* (SF) is the predominant cause of morbidity and mortality. With socioeconomic improvement the circulating species changes from *S flexneri* to *S sonnei* (SS). In Sri Lanka the highest number of cases is reported from Jaffna district of Northern Province, mostly based on clinical diagnosis. Microbiological information is lacking from this region for three decades due to an ethnic war which ended in 2009. *S sonnei* is now the commonest cause of shigellosis reported in Sri Lanka. This study aimed to determine the *Shigella* species, antimicrobial susceptibilities, age and outcome related to shigellosis in northern Sri Lanka. A prospective descriptive study was done of stool cultures received from June 2014 to December 2016. Culture processing, organism identification and antimicrobial susceptibility testing were performed according to standard laboratory methods. Serotyping was done at Medical Research Institute, Colombo. 45/1126 (4%) stool cultures yielded *Shigella* species in 41 children and 4 adults; all residents of Northern Province. 92.7% (38/44) children were ≤ 5 years and predominantly male [57.9% (22/38)]. No deaths reported. 64.4% (29/45) were SF and 35.6% (16/45) were SS. At time of writing, 10/29 SF II and 5/29 SF VI serotypes and 2/16 SS phase I and 12/16 SS phase II were identified. All SF and SS demonstrated sensitivity to mecillinam and ceftriaxone. 96.6% SF and 93.8% SS were ciprofloxacin sensitive. Almost all SF (93.1%) and SS (93.8%) were resistant to co-trimoxazole and all isolates showed either complete/intermediate resistance to furazolidone. All SF were resistant to nalidixic acid but all SS were sensitive. Ampicillin sensitivity in SS was 100% but 58.2% (17/29) SF were resistant. Of the serotyped SF, all SF II were resistant to ampicillin and all SF VI sensitive. *Shigella flexneri* is the predominant species in northern Sri Lanka. All SF and SS were non-susceptible to furazolidone, a commonly used antibiotic in other regions. Long term analysis will determine if *Shigella* species will change with socioeconomic improvements in this region.

## 449

#### EARLY CHILDHOOD STUNTING AMONG HIV-EXPOSED, UNINFECTED INFANTS IN KENYA; THE IMPACT OF MATERNAL AND INFANT DIARRHEA

**Emily L. Deichsel<sup>1</sup>**, Patricia B. Pavlinac<sup>1</sup>, Judd L. Walson<sup>1</sup>, Barbra A. Richardson<sup>1</sup>, Christine J. McGrath<sup>2</sup>, Rose K. Bosire<sup>3</sup>, Elizabeth Meleche-Obimbo<sup>4</sup>, Carey Farquhar<sup>1</sup>, Grace C. John-Stewart<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>University Texas Medical Branch, Galveston, TX, United States, <sup>3</sup>Karolinska Institutet, Stockholm, Sweden, <sup>4</sup>University of Nairobi, Nairobi, Kenya

The growing population of HIV exposed uninfected (HEU) children in sub-Saharan Africa is at increased risk of stunting (length-for-age z score [LAZ] ≤ -2) as compared to HIV unexposed children. Risk factors for stunting in HEU children may differ from other populations due to differences in acquired and passive immunity from HIV exposure, breastfeeding practices, and/or socioeconomic vulnerability. Associations between maternal factors (age at birth, education, income, malnutrition, HIV viral load, CD4 percent, diarrhea) and infant factors (low birth weight, preterm birth, diarrhea, breastfeeding) and infant stunting were assessed using data from a pre-antiretroviral therapy era cohort (1999-2002) of HIV-infected Kenyan mothers and their uninfected infants. Mothers were enrolled

during pregnancy and mother-infant pairs were followed for 12 months postpartum. Surviving infants with 12-month LAZ data were included in the analysis. Using log binomial regression models, stunting prevalence at 12 months was compared between infants with and without cofactors of interest during the first 10-months postpartum (assuming 2-month length effect lag). Among 273 HEU infants who completed follow-up, 18% (48) were stunted at 12 months. During the first 10 months of life, mothers reported that 71% (193) of infants had any diarrhea, 25% (68) had diarrhea  $\geq 3$  times, 14% (40) had at least one episode of prolonged diarrhea ( $> 7$  days), and 22% (61) reported that they themselves had experienced at least one episode of diarrhea. Any maternal diarrhea (prevalence ratio [PR]=1.74; 95% confidence interval [CI]=1.02, 2.94;  $p=0.04$ ) and  $\geq 3$  infant diarrhea episodes (PR=1.88; 95% CI=1.08, 3.03;  $p=0.02$ ) during the first 10 months postpartum were associated with infant stunting. Statistical tests for other maternal and infant risk factors did not reach significance. Prevention and expedited management of diarrhea in HIV-infected mothers and infants may reduce the burden of chronic malnutrition in HEU children, a population at particularly high risk of mortality and developmental shortfalls.

## 450

### QUANTITATIVE ANALYSIS OF DIARRHEA ETIOLOGY IN TRAVELERS' DIARRHEA IN NEPAL

**Paphavee Lertsethakarn-Ketwalha**<sup>1</sup>, Pimmada Sakpaisal<sup>1</sup>, Sasikorn Silapong<sup>1</sup>, Sanjaya Sherstha<sup>2</sup>, Prativa Pandey<sup>3</sup>, Jie Liu<sup>4</sup>, Eric Houpt<sup>4</sup>, Ladaporn Bodhidatta<sup>1</sup>, Brett E. Swierczewski<sup>1</sup>, Carl J. Mason<sup>1</sup>

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Walter Reed Armed Forces Research Institute of Medical Sciences Research Unit, Nepal, Kathmandu, Nepal, <sup>3</sup>CIWEC Clinic Travel Medicine Center, Kathmandu, Nepal, <sup>4</sup>University of Virginia, Charlottesville, VA, United States

Traveler's diarrhea (TD) is one of the most common illnesses experienced by western travelers traveling to developing countries. Nepal is one of the major destinations for trekking and its undisturbed natural beauty. The risk of developing TD is high due to the developing tourism infrastructure in Nepal. Studies describing TD diarrhea etiology in Nepal are limited with the most recent reporting of samples collected in 2001-2003. More recently, a clinic-based surveillance study was conducted in Nepal collecting TD samples from 2012-2014. A wide range of conventional diagnostic assays were performed to determine diarrhea etiology which were time and labor intensive. Previously reported at ASTMH 2016, partial TD samples from Nepal and Thailand were combined for quantitative analyses to further demonstrate pathogen-disease association using the enteropathogenic panel TaqMan® Array Card (TAC), which was developed and evaluated by the University of Virginia. This current study focused on 631 TD samples from Nepal composed of 425 cases and 206 asymptomatic controls. Analyses of these pathogens have shown that there is a significant risk of developing TD by *Campylobacter* spp., enterotoxigenic *Escherichia coli* (ETEC), norovirus, rotavirus, *Shigella* spp., and *Cryptosporidium*. Comparison of the diarrheagenic *E. coli* (enteroaggregative *E. coli*, enteropathogenic *E. coli*, and ETEC) detected by TAC and conventional methods showed that TAC detected diarrheagenic *E. coli* at a significantly higher percentage and EAEC was significantly detected more in the cases when compared to the controls. *Cyclospora*, endemic to Nepal, was detected at a lower percentage with no significant associated risk of diarrhea. However, the collection time of positive samples coincided with the seasonal infection peak in June/July. Attributable fraction of each pathogen to TD was calculated and each of these pathogens attributed over 70% of TD cases with the highest attributable fraction by ETEC and *Shigella* spp. at 88% each. Further quantitative analyses will provide a greater insight into a limited knowledge of diarrhea etiology and TD epidemiology in Nepal.

## 451

### DETECTION *CRYPTOSPORIDIUM* AND *CYCLOSPORA* OF DIGITAL DROPLET PCR (DDPCR) FROM TRAVELERS' DIARRHEA AND NEPALESE STOOL SAMPLES

**Sasikorn Silapong**<sup>1</sup>, Paphavee Lertsethakarn-Ketwalha<sup>1</sup>, Sanjaya Sherstha<sup>2</sup>, Prativa Pandey<sup>3</sup>, Ladaporn Bodhidatta<sup>1</sup>, Carl Mason<sup>1</sup>, Brett Swierczewski<sup>1</sup>

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Walter Reed Armed Forces Research Institute of Medical Sciences Research Unit, Nepal, Kathmandu, Nepal, <sup>3</sup>CIWEC Clinic Travel Medicine Center, Kathmandu, Nepal

*Cryptosporidium* (CR) and *Cyclospora* (CY) are microscopic parasites that cause diarrhea in both children and adults worldwide. Specifically, CY is endemic to Nepal with peak infection between May and October. Western travelers visiting endemic regions are at a greater risk of infection. Both CR and CY exist in the environment as oocysts before sporulation upon entering the host. Microscopy is the gold standard for parasite detection but variability in oocyst characteristics and the low infectious dose for both parasites (10-100 oocysts) can lead to misidentification. Diagnostic methods such as ELISA and real-time PCR have been developed to alleviate the sensitivity issue but have not been adopted as alternative methods of detection. Previous detection of CR and CY by real-time PCR showed an increased number of CR and CY detected but at a high threshold cycle (Ct) indicating a low copy number which suggested that CR and CY might be under-detected. Digital droplet PCR (ddPCR) is reported to have increased detection sensitivity and an assay using ddPCR was developed and evaluated to detect CR and CY from positive samples with high Cts and samples that were pathogen negative from diarrhea; stool samples collected from travelers and the indigenous population in Nepal. The assay was developed based on a real-time PCR assay and evaluated under various ddPCR conditions using both genomic and plasmid DNA containing the target gene and was further optimized for a duplex assay. Two hundred and forty six samples (66 previously CR and/or CY positive and 180 pathogen negative) were used for the study. Results generated by ddPCR were 100% concordant with the previous CY and CR positive results by real-time PCR with an additional 12 CR and/or CY positive samples detected from previously pathogen negative samples. This is a 6.7% detection rate from pathogen negative samples which can decrease the burden of pathogen negative samples. With an expanded evaluation of ddPCR on a larger number of samples, ddPCR has the potential as an alternative diagnostic platform with increased sensitivity for other relevant low infectious dose pathogens.

## 452

### ANTIBIOTIC RESISTANCE OF *SALMONELLA ENTERICA* ISOLATES FROM PORK CARCASSES IN SLAUGHTERHOUSES IN LIMA, PERU

**Guillermo S. Salvatierra R.**<sup>1</sup>, Chris Pinto J.<sup>2</sup>, David Centeno S.<sup>2</sup>, Edwin Inga<sup>2</sup>, Sonia Calle E.<sup>2</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru

The aim of this study was to detect the frequency of resistant *Salmonella* by isolation techniques in pork carcasses intended for human consumption. Three hundred carcasses from two slaughterhouses in Lima, Peru were studied. Samples were taken by swabbing the skin of the head, abdomen, back and leg. They were processed following the protocol for isolation of bacteria based on ISO 6579:2002. The isolates were identified by biochemical tests and specific antisera. In the next phase of the study, sensitivity tests were performed. The Kirby Bauer technique was used, following the CLSI recommendations against 10 antimicrobials: Amikacin, Ampicillin, Chloramphenicol, Oxytetracycline, Streptomycin, Nalidixic acid, Tobramycin, Ciprofloxacin, Neomycin and Gentamicin. Finally, the detection of extended spectrum (Cefotaxime,

Ceftazidime, Cefepime, Aztreonam with Amoxicillin with Clavulanic acid disk diffusion test) and AmpC (Cefotaxime-Ceftazidime with Cloxacillin disk diffusion test, Cefoxitin-Ceftriaxone disk diffusion test) betalactamases were performed. In 6.3% (19/300) of pork carcasses were detected *Salmonella* spp. The isolates were serotyped and identified as *Salmonella enterica* subsp. *enterica* serotype Derby. Resistance was detected mainly to Chloramphenicol 100% (19/19), Oxytetracycline 100% (19/19), Tobramycin 47.4% (9/19), Streptomycin 36.8% (7/19), Ampicillin 5.3% (1/19) and Gentamicin 5.3% (1/19). All isolates were negative for extended spectrum and Ampc betalactamases. The detection of resistant *Salmonella* strains could lead to problems in the treatment of the disease, because the antimicrobials no longer work or no desired results are obtained. The results confirm the need to implement control measures and detection of the bacteria to reduce the frequency of contaminated pork that reaches the consumer.

### ENTEROPATHOGEN PROFILE IN HUMANS AND DOMESTIC ANIMALS IN COASTAL DISTRICT OF ODISHA, INDIA: POSSIBLE ZONOTIC TRANSMISSION AND CONCERNS

Arpit K. Shrivastava<sup>1</sup>, Nirmal K. Mohakud<sup>2</sup>, Subrat Kumar<sup>1</sup>, Priyadarshi S. Sahu<sup>3</sup>

<sup>1</sup>School of Biotechnology, KIIT University, Bhubaneswar, Odisha, India,

<sup>2</sup>Kalinga Institute of Medical Sciences, KIIT University, Bhubaneswar, Odisha, India, <sup>3</sup>Division of Pathology, School of Medicine, International Medical University, Kuala Lumpur, Malaysia

Infectious diarrhea is a major cause of morbidity and mortality particularly among children of <5 years of age. The source of diarrheal pathogens can be varied that depends largely on an interplay between human, environment, animals and food/water. In this study we investigated presence of major diarrheal pathogens in human and animal fecal samples to assess epidemiology and possible transmission routes responsible for disease burden. We examined human fecal samples (n=310) and animal fecal samples (n=150) during May 2016 to January 2017. PCR amplifying targeted pathogen specific genes was employed to diagnose different strains of diarrhoeogenic *Escherichia coli* or DEC, *Shigella* species, *Salmonella* sp., *Vibrio cholera*, *Cryptosporidium* sp., and *Giardia* sp. PCR positive samples were subjected to sequence analysis for further confirmation. We observed DEC was the most frequently detected pathogen in both humans (29.03%) and animals (38.66%). Other enteropathogens viz., *Shigella* (13.87%), *Cryptosporidium* (4.1%), Adenovirus (3.87%) and *Giardia* (0.64%) were also detected in humans. *Cryptosporidium* sp. was predominately detected among goats (17.77%) followed by cow (11.11%). The detection rates were remarkable for Shiga toxin-producing *E. coli* or STEC (10.32% in humans and 21.33% in domestic animals) and enteropathogenic *E. coli* or EPEC (15.80% in humans and 14.66% in domestic animals). Detection rate of *Cryptosporidium* sp in humans was significantly higher in rural area in comparison to urban counterpart (p=<0.0001). Co-infection with two or more enteric pathogens were also found in humans as well as animals (14.19% and 19.33% respectively). Sequencing results showed STEC, EPEC and *Cryptosporidium parvum* infection were the predominant infections both in humans and common domesticated animals in the studied region. Genetic similarity study suggests a great potential of transmission of infections from domestic animals to the inhabitants in the resource poor communities. Further studies are warranted to understand more on persistence, transmission dynamics, and associated consequences of these enteric pathogens in this region.

### EVALUATION OF THE MULTIPLEX LUMINEX GASTROINTESTINAL PATHOGEN PANEL (XTAG GPP) TESTING IN THE DIARRHEIC MILITARY DEPLOYED TO COBRA GOLD AND BALIKATAN EXERCISES

Patchariya Khantapura, Nattaya Ruamsap, Siriphan Gonwong, Woradee Lurchachaiwong, Paphavee Lertsethakarn, Dilara Islam, Brett E. Swierczewski

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Traveler's diarrhea is a major infectious disease threat to US military forces deployed to Southeast Asia and can greatly hinder operations. Eighty-four stool samples collected from 2012-2016 during the US military exercises, Cobra Gold (Thailand) and Balikatan (Philippines), were evaluated for enteric pathogens using routine microscopy, ELISA and real-time RT-PCR and results were compared with the FDA approved Gastrointestinal Pathogen Panel (GPP) (Luminex). The GPP assay is able to detect 15 pathogens as compared to conventional diagnostic tests which can be time and labor intensive. By conventional methodology, *Campylobacter* was the most prevalent pathogen at 70.6% (12/17) for Balikatan and 41.8% (28/67) for Cobra Gold. Other pathogens detected in the Balikatan samples included enterotoxigenic *Escherichia coli* (ETEC) (11.8%) and *Salmonella* (5.9%). Additional pathogens detected in the Cobra Gold samples were *Salmonella* (16.4%), Norovirus (11.9%) and ETEC (4.5%). No pathogen was detected in 5.9% and 19.4% of the Balikatan and Cobra Gold samples respectively. A total of 15 samples were reported as negative by all assays, however, an additional 5 samples were negative by GPP, these 5 additional samples were positive for Rotavirus, Adenovirus, *Campylobacter* and *Vibrio cholera* by conventional methods. Two negative samples by routine methods were identified as *Salmonella* positive by GPP. The GPP assay showed increased sensitivity towards *Campylobacter*, *Salmonella*, Norovirus GII, ETEC and Shiga-toxin producing *E. coli* (STEC) with sensitivities ranging from 97.6 - 100% and specificities ranging from 94.0 - 100%. Multiple pathogens were identified by the GPP assay in 9/84 (10.7%); these were 66.7% *E. coli* O157, 44.4% *Campylobacter*, 33.3% Norovirus and 22.2% for both ETEC and *Salmonella*. GPP was shown to be convenient, rapid and sensitive assay that allowed for faster turnaround time and for identification of co-infections in a single assay. Although GPP may replace conventional methods in certain areas, there is still a need for culture to perform antibiotic susceptibility tests and for certain organism confirmation testing.

## 455

### ANTIMICROBIAL RESISTANCE IN *ESCHERICHIA COLI* AND *SALMONELLA* SPP. ISOLATES FROM FRESH PRODUCE IN THE PHILIPPINES AND THE IMPACT TO CONSUMERS' HEALTH AND SAFETY

Pierangeli Vital<sup>1</sup>, Marie Bernadine Caballes<sup>2</sup>, Windell Rivera<sup>1</sup>

<sup>1</sup>Institute of Biology, Quezon City, Philippines, <sup>2</sup>Institute of Biology, University of the Philippines, Philippines

Foodborne diseases associated with fresh produce consumption have escalated worldwide, making the microbial safety of produce of critical importance. Bacteria that have increasingly been detected in fresh produce are *Escherichia coli* and *Salmonella* spp., both of which have been shown to progressively display antimicrobial resistance. The study focused on the assessment of bacterial antimicrobial resistance from different kinds of fresh produce from various open air markets and supermarkets in the Philippines. Using the disk diffusion assay on a total of 50 bacterial isolates obtained from 410 fresh produce surveyed, monoresistance to tetracycline was observed to be the most prevalent (38%), followed by multidrug resistance to tetracycline, chloramphenicol, ciprofloxacin, and nalidixic acid (4%), and lastly by dual resistance to tetracycline and chloramphenicol (2%). Using multiplex and simplex polymerase chain reaction (PCR) assays, *tetA* (75%) and *tetB* (9%) were found in tetracycline

resistant isolates, whereas *catI* (67%) and *catIII* (33%) were detected in chloramphenicol resistant isolates. Sequence analysis of *gyr* and *par* genes from the ciprofloxacin and nalidixic acid resistant isolates revealed different mutations. Based on the results, fresh produce act as a reservoir of these antibiotic resistant bacteria which may pose health threats to consumers.

## 456

### PROJECTING THE POTENTIAL IMPACT AND COST-EFFECTIVENESS OF A DIAGNOSTIC FOR LONG-TERM CARRIAGE IN TYPHOID FEVER

**Nathan C. Lo**, Jason R. Andrews

*Stanford University School of Medicine, Stanford, CA, United States*

Typhoid fever remains a major public health problem globally, causing an estimated 12 million illnesses and 130,000 deaths annually. As new public health strategies against typhoid fever are considered, there are key questions on the importance of addressing the reservoir of long-term carriage, which may represent a barrier to control and elimination in many settings. While new serologic diagnostic markers hold promise for identifying long-term carriers, the potential population health impact and cost-effectiveness remains unclear. We modeled typhoid transmission dynamics across a range of settings, varying the contribution of carriers to endemic transmission, and simulated the changes in typhoid incidence and cost-effectiveness of a hypothetical carriage diagnostic for typhoid fever. We developed a dynamic, age-structured transmission and cost-effectiveness model that simulated a hypothetical carriage diagnostic under two potential strategies: 1) population-wide household screening; and 2) continual screening through the healthcare system. We simulated a 10-year vaccination program, and sourced data on costs, disability, and typhoid natural history and biology from literature. We estimated a test cost of US\$4.00 with US\$1.00 delivery cost (for population-wide screen), and 1% case fatality rate from typhoid fever. We performed sensitivity analyses on key model parameters. The incremental cost-effectiveness ratio (ICER) was calculated in 2016 US\$ per disability-adjusted life year (DALY) averted. We defined strategies as highly cost-effective if the ICER was less than the GDP per capita of a low-income country (US\$1,035). We found that aggressive strategies to diagnose and treat carriers provided substantial reductions in incidence across a range of settings, although more realistic uses of the diagnostic test yielded only modest reductions in incidence. Our results indicate that population-wide screening for carriage would be unlikely to be cost-effective in resource-constrained settings, although targeted usage to high-risk subpopulations could potentially be impactful and cost-effective.

## 457

### ASSOCIATION BETWEEN ORAL REHYDRATION SALTS DURING HOME TREATMENT, AND DEHYDRATION AND EXTENDED CASE FATALITY FOLLOWING A MODERATE-TO-SEVERE DIARRHEAL EPISODE IN LOW AND MIDDLE INCOME COUNTRIES

Diarrhea causes a high burden of disease globally, with most deaths occurring in low- and middle-income countries. Despite extensive promotion of oral rehydration salts (ORS), continued feeding, and zinc supplementation for diarrhea treatment at home, multiple surveys have reported inadequate uptake of these interventions. The cross-sectional design and lack of clinical outcome data in most studies limit understanding of effectiveness of home treatment, across developing countries. We hypothesized that home treatment with ORS and zinc will reduce dehydration and extended case-fatality risk. Using data from the 7 sites of the Global Enteric Multicenter Study of diarrhea in sub-Saharan Africa and South Asia, we conducted secondary analyses to estimate prevalence of ORS and zinc administration during home treatment of moderate-to-severe diarrhea (MSD). We estimated risk ratios (RR) and 95% confidence intervals (CI) for dehydration (requiring IV rehydration) and death at 50-90 days follow-up visit, in relation to ORS administration

at home before seeking care. Zinc administration was low across countries, during home treatment (3.9%) and at health facilities (10.0%), more so in the African sites (0.0 – 9.4%) than in the Asian sites (7.8 – 37.9%). In multivariable pooled analyses adjusted for age, sex and socioeconomic status, home treatment with ORS was associated with lower incidence of dehydration (RR 0.90, 95% CI 0.83-0.97). Home treatment with ORS was also associated with lower case-fatality at 50-90 days following an MSD episode, but the association was not statistically significant (0.87, 0.60-1.26). The role of other factors, such as nutritional status, socioeconomic parameters, and concomitant therapy, in this association still needs to be examined. Our analysis suggests that home treatment with ORS protects against dehydration, and might protect against short-to-intermediate term extended case-fatality among children with MSD in low-income settings. Further studies should address a broader range of potential confounders and evaluate interventions to facilitate uptake and effective use of home treatment.

## 458

### VIABILITY OF *VIBRIO CHOLERAE* ISOLATED DURING THE CHOLERA EPIDEMIC IN PERU IN 1991

Rito Zerpa<sup>1</sup>, Lilian Patiño<sup>2</sup>, Ana María Huamán<sup>1</sup>, Jimmy Ibarra<sup>3</sup>

<sup>1</sup>Instituto de Medicina Tropical "Daniel Alcides Carrión", Lima, Peru, <sup>2</sup>Instituto Nacional de Salud del Niño, Lima, Peru, <sup>3</sup>Faculty of Biology, National University San Marcos, Lima, Peru

*Vibrio cholerae*, is the etiological agent of cholera and caused the great epidemic that affected Peru in 1991 and lately an epidemic in Haiti. There are few reports of its viability in routine culture media. The objective of the study was to observe the viability of *V. cholerae* isolated at the Microbiology Service of the National Institute of Child Health, Lima, Peru, during the 1991 epidemic. Fifty strains of *Vibrio cholerae* O1, Inaba and Ogawa serotypes, were processed and that were stored in 4mL glass vials, hermetically sealed with rubber caps, using the following medium: LIA, SIM, Simmons Citrate, Peptonade Broth with 0% ClNa and a semisolid preservation medium with peptone, ClNa and agar. The cultures were kept at room temperature. Cultures were realized to verify viability after one, 5, 10, 20 and 25 years; 45 of 50 strains were found viable with phenotypic characteristics in all of the mentioned media, while 5 strains were discarded (10%), due to contamination or dryness. Conclusion: 90% of *V. cholerae* strains stored previously were found viable; these results suggest that the medium used is a simple alternative to keep *V. cholerae* viable for research and teaching purposes.

### A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL TO ASSESS THE PROTECTIVE EFFICACY OF ORALLY DELIVERED BOVINE SERUM IMMUNOGLOBULIN (BSIGG) SPECIFIC FOR THE COLONIZATION FACTOR CS6 FOLLOWING CHALLENGE WITH THE CS6-EXPRESSING ENTEROTOXIGENIC *E. COLI* (ETEC) STRAIN B7A

Kawsar R. Talaat<sup>1</sup>, A. Louis Bourgeois<sup>1</sup>, Christopher Duplessis<sup>2</sup>, Chad Porter<sup>2</sup>, Milton Maciel Jr<sup>2</sup>, Ramiro Gutierrez<sup>2</sup>, Barbara DeNearing<sup>1</sup>, Rachel Adkinson<sup>1</sup>, Jane Halpern<sup>1</sup>, Brittany Feijoo<sup>1</sup>, Jessica Brubaker<sup>1</sup>, Aleksandra Beselman<sup>3</sup>, Subhra Chakraborty<sup>1</sup>, David Sack<sup>1</sup>, Mark Riddle<sup>2</sup>, Kayla Jaep<sup>2</sup>, Stefanie Trop<sup>2</sup>, Sabrina Joseph<sup>2</sup>, Steven Poole<sup>2</sup>, Michael Prouty<sup>2</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>3</sup>Johns Hopkins Bayview Medical Center, Baltimore, MD, United States

Enterotoxigenic *Escherichia coli* (ETEC) is a major cause of diarrhea in children and travelers. The pathogenesis of ETEC diarrhea involves colonization (via colonization factors (CFs)) which are surface proteins mediating intestinal adhesion. The role of CFs as protective antigens has been substantiated by a number of population-based studies. There is

a dearth of evidence supporting CS6 in diarrheal pathogenesis, nor is a correlation in the host immune response to CS6 and protection. The development of CF-based vaccines against a majority of circulating ETEC strains is dependent on the protective capability of included antigens. We designed a passive immunoprophylaxis trial to estimate the protective efficacy of serum-derived hyperimmune bovine immunoglobulins (BSIgG) against CS6 following challenge with CS6-expressing ETEC (strain B7A). Up to 60 volunteers were enrolled in this double-blind study and randomized 1:1:1 to receive (1) BSIgG generated against whole cell, killed ETEC strain B7A (O148:H28 CS6+ LT+ST+), (2) BSIgG raised against purified CS6, or (3) non-hyperimmune BSIgG. All groups received 1.0 g of their assigned product orally three times daily for 7 days. On the third day of administration, all volunteers were challenged with 1x10<sup>10</sup> colony forming units of B7A. The primary endpoint for this study was post-challenge development of moderate to severe diarrhea (MSD) as determined by an independent adjudication board. Fifty-nine subjects were recruited, enrolled and have completed the challenge phase of this study. BSIgG was well tolerated without incurring serious adverse-events. MSD was induced in a subset of volunteers, however the study remains blinded to the investigative team. Data are being processed and data entry and cleaning are underway. The primary endpoint data will be adjudicated in June 2017 after which the study will be unblinded. The results from this study may provide insight into the potential of CS6 as a protective antigen (critical to ETEC vaccine development), and the efficacy of BSIgG (fostering studies investigating the protective efficacy of a multivalent anti-ETEC BSIgG product).

## 460

### CASES OF METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS: ASSESSING ITS RISE IN HOSPITAL AND COMMUNITY-ASSOCIATED CASES

Chinedu O. Oraka<sup>1</sup>, Obiageli L. Ofori<sup>2</sup>

<sup>1</sup>Build Africa Research Capacity, Ottawa, ON, Canada, <sup>2</sup>University of Texas, Health Science Center at Houston, School of Public Health, Houston, TX, United States

Methicillin-resistant *Staphylococcus aureus* (MRSA) has since become a major cause of illness and death in our healthcare setting. Risk factors for HA-MRSA include hospitalization, older age, invasive devices, and residence in long-term care facility, including exposure to antimicrobial agents. HA-MRSA isolates are often resistant to several antimicrobial drug classes in addition to beta-lactams. The CA-MRSA infections usually affects young, healthy persons and associated with sharing towels or athletic equipment, participating in contact sports, living in unsanitary and crowded areas, using illegal intravenous drugs. Directions were given out for clinical microbiology laboratories to submit invasive isolates of MRSA to our unit, where we perform antimicrobial drug susceptibility tests on all isolates and characterize all isolates that were resistant to <3 non-beta-lactam antimicrobial drug classes. Most isolates were obtained from blood cultures. The full model for predicting invasive infection with CA-MRSA compared with HA-MRSA included age, seasonality, and hospital exposure, plus specimen type. The only significant predictors of CA-MRSA infection compared with HA-MRSA were age <69 years, which was associated with increased risk ([OR] 5.1, 95% [CI] 2.06-12.64), and hospital exposure (OR 0.07, 95% CI 0.01-0.51), which was associated with decreased risk. Most patients were hospitalized for their infections and the proportion of patients admitted to intensive care units did not vary by strain. Patients infected by MRSA were younger than those infected by other strains. The number of invasive MRSA infections reported and the number of invasive infections caused by CA-MRSA is on the increase. The increase of CA-MRSA poses a unique public health threat. It is now clear that CA-MRSA no longer causes only SSTIs but now causes an increased proportion of invasive infections in a rural state.

## 461

### HIGH PREVALENCE OF SUSPECTED NOSOCOMIAL COLONIZATION WITH METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS* AT A TERTIARY CARE HOSPITAL IN SOUTHERN SRI LANKA

Ruvini Kurukulasooriya<sup>1</sup>, L. Gayani Tillekeratne<sup>2</sup>, W.M.D. Gaya B. Wijayaratne<sup>1</sup>, Champica K. Bodinayake<sup>1</sup>, Malindu D. Rajapakshe<sup>1</sup>, B. G. Umeha<sup>1</sup>, T. D. Abewickrama<sup>1</sup>, K.V. Thamali Anuradha<sup>1</sup>, Aruna D. De Silva<sup>3</sup>, Bradly P. Nicholson<sup>2</sup>, Truls Østbye<sup>2</sup>, Christopher W. Woods<sup>2</sup>, Ajith Nagahawatte<sup>1</sup>

<sup>1</sup>Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, <sup>2</sup>Duke University, Durham, NC, United States, <sup>3</sup>Genetech Research Institute, Colombo, Sri Lanka

Methicillin-resistant *Staphylococcus aureus* (MRSA) causes a high burden of community-acquired and nosocomial infection. Prior colonization with MRSA is a recognized risk factor for MRSA infection. In resource-limited settings, few studies have explored MRSA colonization prevalence. The purpose of this study was to describe prevalence, risk factors, and frequency of in-hospital acquisition of MRSA colonization in Sri Lanka. From Sep 2016- Mar 2017, consecutive patients admitted to orthopedic wards and every fifth patient admitted to medical and general surgical wards were enrolled at a 1,500-bed tertiary care hospital in Sri Lanka. A nasal swab was collected from the anterior nares within 24 hrs of admission and in the 48 hrs prior to discharge. Clinical and demographic data were collected. Standard microbiologic procedures were performed to identify MRSA. A total of 502 patients were enrolled, including 152 medical, 201 general surgical, and 150 orthopedic patients. Median (IQR) age was 45 (28- 61) years and 57% were male. Median (IQR) hospitalization duration was 3 (2- 5) days. At admission, 31 (6.2%) were colonized with MRSA; colonization was higher in orthopedic (12.0%) compared to medical (4.0%) and surgical (3.5%) patients,  $p=0.002$ . Patients colonized with MRSA were younger (median 38 vs 46 years,  $p=0.03$ ) and more likely male (74.2% vs 56.3%,  $p=0.05$ ). At discharge, 24 (6.7%) patients were colonized with MRSA (12.8% orthopedic, 8.4% medical, and 1.3% surgical patients,  $p=0.001$ ). Of the 24 patients, almost half (10, 41.7%) were not colonized with MRSA at admission. MRSA isolates showed low susceptibility to oral antibiotics (tetracycline 64.5%, clindamycin 19.4%, trimethoprim/ sulfamethoxazole 0%). MRSA colonization was much higher in orthopedic than in surgical or medical patients at this Sri Lankan hospital. Almost half of patients with MRSA at discharge were not colonized at admission, raising concern for nosocomial MRSA acquisition. MRSA isolates showed low susceptibility to traditional oral antibiotics. Improved infection control and targeted decolonization may decrease MRSA colonization and infection in this setting.

## 462

### WHAT IS THE MAJOR ISSUE TO TACKLE NEONATAL INFECTIONS IN LOW INCOME COUNTRIES? EVIDENCE FROM A COMMUNITY-BASED COHORT STUDY IN MADAGASCAR

Bich-Tram Huynh<sup>1</sup>, Elsa Kermorant-Duchemin<sup>2</sup>, Perlinot Herindrainy<sup>3</sup>, Michael Padget<sup>1</sup>, Feno Rakotoarimanana<sup>3</sup>, Herisoa Feno<sup>3</sup>, Elisoa Hariniaina-Ratsima<sup>3</sup>, Tanjona Rahelariavao<sup>3</sup>, Patrice Piola<sup>1</sup>, Frederique Randrianirina<sup>3</sup>, Benoit Garin<sup>3</sup>, Jean-Marc Collard<sup>3</sup>, Didier Guillemot<sup>1</sup>, Elisabeth Delarocque-Astagneau<sup>1</sup>

<sup>1</sup>Institut Pasteur, Paris, France, <sup>2</sup>APHP - Necker Hospital, Paris Descartes University, Paris, France, <sup>3</sup>Institut Pasteur, Antananarivo, Madagascar

Tackling neonatal sepsis is extremely challenging in low-income countries. Critical data on the burden of severe bacterial infections in neonates is scarce because neonatal deaths may occur rapidly when access to care may be limited. There is a particular lack of data regarding infections occurring in the community, which may differ from cases admitted to the hospital. Also, the role of the different factors involved in the transmission of multiresistant bacteria remains unclear, particularly mother-to-child.

Data are needed for these countries to prioritize interventions to decrease neonatal infections. We conducted a prospective cohort of 981 newborns in Madagascar between September 2012 and October 2014. Exhaustive identification of pregnant women on a geographic basis allowed us to enroll newborns at birth. Children were followed-up using active (home-visits) and passive monitoring. Data on clinical symptoms developed by the children and all results of biological and bacteriological samples taken were collected. The prevalence of extended-spectrum beta-lactamase producing Enterobacteriaceae and *agalactiae streptococcus* carriage among pregnant women was 18% and 13%, respectively. The incidence of community-acquired neonatal infections was 35.8 cases per 1,000 live births [95% CI, 25.4-50.8], with a great majority during the first week of life (85%). The incidence rate for multiresistant neonatal infection was 5.5 cases per 1,000 live births [2.2-13.2]. Almost two-thirds of the pathogens isolated were resistant to current WHO-recommended treatment for neonatal sepsis. In Madagascar, the incidence of bacterial neonatal infections is alarmingly high in the community. No evidence of high rates of multiresistant infections was found. The role of the mother as a potential reservoir of transmission of multiresistant neonatal infection has been highlighted. Public health measures should prioritize interventions to improve the prevention, early diagnosis, and case management of neonatal infections to decrease neonatal mortality due to severe bacterial infection, rather than bacterial resistance.

## 463

### TYPHOID FEVER OUTBREAK IN HARARE, ZIMBABWE, 2016-2017

William W. Davis<sup>1</sup>, Prosper Chonzi<sup>2</sup>, Kudzai P. Masunda<sup>2</sup>, Lindsey McCrickard<sup>1</sup>, Innocent Mukeredzi<sup>2</sup>, Portia Manangazira<sup>3</sup>, Emmaculate Govore<sup>2</sup>, Rachel Aubert<sup>1</sup>, Haley Martin<sup>1</sup>, Elizabeth Gonese<sup>4</sup>, John B. Ochieng<sup>5</sup>, Norah Vere<sup>4</sup>, Bonaventure Juma<sup>6</sup>, Hammad Ali<sup>1</sup>, Kristi Allen<sup>1</sup>, Eric Mintz<sup>1</sup>, Grace Appiah<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>City of Harare City Health Department, Harare, Zimbabwe, <sup>3</sup>Ministry of Health and Child Care, Harare, Zimbabwe, <sup>4</sup>Centers for Disease Control and Prevention, Harare, Zimbabwe, <sup>5</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>6</sup>Centers for Disease Control and Prevention, Nairobi, Kenya

Typhoid fever is a bacterial infection caused by *Salmonella* Typhi and spread through fecal-oral transmission. It causes an estimated 20 million illnesses and 200,000 deaths worldwide annually. Zimbabwe has experienced repeated outbreaks of typhoid fever over the last decade. On October 13, 2016, an outbreak was detected in the Mbare suburb of Harare. The City of Harare City Health Department (CHCHD) led an investigation in collaboration with the Ministry of Health and Child Care, WHO and CDC to characterize and identify opportunities to control the outbreak. Suspect cases were defined as fever  $\geq 38.0^{\circ}\text{C}$  and presence of at least one of the following: chills, malaise, headache, sore throat, cough, constipation or diarrhea. Investigators generated a line list cases from 36 clinics and three hospitals. Cases were confirmed by isolation of *S. Typhi* from stool and blood samples at the CHCHD laboratory, and antibiotic susceptibility testing was done using the disk diffusion technique. Investigators conducted an environmental assessment to test and map water sources. From October 13, 2016 to March 8, 2017, 867 suspected and 77 confirmed cases, with 4 deaths (case fatality rate 0.5%) were reported. Suspected cases occurred in persons aged <1 to 78 years (median 18); 48% were female. Eighteen (23%) of 77 *S. Typhi* isolates were resistant to ciprofloxacin and 10 (13%) showed decreased ciprofloxacin susceptibility. All but one of the 18 ciprofloxacin-resistant isolates were from patients who presented after Dec 31, 2016, representing 39% of the 44 isolates from this time period. Sewage contaminating underground water, which was the main water source in a suburb with erratic piped water supplies, likely contributed to this outbreak. Of 30 boreholes tested, 15 (50%) were contaminated with fecal coliforms; mapping indicated that cases were clustered around contaminated boreholes. Response efforts included: repairing sewer lines and boreholes, providing point-of-use water

treatment products, educating affected communities, training in rapid response, correct case management, improved surveillance and continued monitoring of antibiotic resistance.

## 464

### IMPACT OF NUTRITIONAL STATUS ON PEDIATRIC PATIENTS AGED FROM 6 TO 59 MONTH HOSPITALIZED FOR SUSPECTED INVASIVE BACTERIAL INFECTIONS AT CHU-GT, BAMAKO, MALI

**Seydou Sissoko**<sup>1</sup>, Adama Mamby Keita<sup>1</sup>, Moriba Camara<sup>1</sup>, Aliou Touré<sup>1</sup>, Nana Kourouma<sup>1</sup>, Mamadou Sylla<sup>1</sup>, Aminata Diallo<sup>2</sup>, Boubou Tamboura<sup>1</sup>, Uma Onwuchekwa<sup>1</sup>, Doh Sanogo<sup>1</sup>, Brehima Coulibaly<sup>1</sup>, Modibo Sidibé<sup>1</sup>, Mahamadou Fofana<sup>1</sup>, Diakaridia Sidibé<sup>1</sup>, Bintou Traoré<sup>1</sup>, Hamidou Diallo<sup>1</sup>, Abdoulaye Diakit<sup>1</sup>, Namory Camara<sup>1</sup>, Milagritos D Tapia<sup>3</sup>, Karen Kotloff<sup>3</sup>, Samba O Sow<sup>1</sup>

<sup>1</sup>Center for Vaccine Development, CVD-Mali, Bamako, Mali, <sup>2</sup>Département de Pédiatrie CHU-GT - Mali, Bamako, Mali, <sup>3</sup>University of Maryland, School of Medicine, Baltimore, MD, United States

Malnutrition and invasive bacterial infections are major causes of morbidity and mortality in the world. In Mali, under five mortality rate is one of the highest in the world and one half of under-five death is somehow linked to malnutrition. Few studies assess the impact of nutritional status on patients with suspected invasive bacterial infection in Mali. We retrospectively paired malnourished and well-nourished children aged from 6 to 59 month enrolled in the hospital based surveillance of invasive bacterial infection from January 2013 to December 2015. Cases and controls were paired by age group and date of enrollment  $\pm$  15 days. Case was defined as children 6-59 month malnourished (Z-score  $\leq$  -2) admitted with suspicion of invasive bacterial infection (SIBI). Blood culture or culture of any normally sterile body fluid was performed to identify potential pathogens. Controls were well-nourished children with Z-score  $>$  -2 and hospitalized for SIBI. 172 patients were enrolled (86 cases and 86 control). The mean weight of malnutrition cases was 6.59 Kg (Min 3; Max 13) while it was 9.94 Kg (Min 5; Max 19) for Non-malnourished. 10 Blood culture (4.65%) were positive (8 cases and 2 control). Cases were 4 time at risk of having pathogen in blood culture (95%CI 0.87 - 18.29) compared to control. Streptococcus pneumoniae is the predominant pathogen in cases (5/8, 62.5%). 12 deaths (9 cases and 3 control) all with no pathogen isolated in blood culture (OR= 2.13, 95%CI 0.79-5.74). Malnutrition is an important risk factor of death in patient with or without confirmed bacterial infection. Nutritional support should be implemented to support patients.

## 465

### USE OF C-REACTIVE PROTEIN AND PROCALCITONIN TO TARGET ANTIBIOTIC PRESCRIPTION IN CHILDREN UNDER-FIVE WITH UNDIFFERENTIATED FEVER: RESULTS FROM A CLINICAL TRIAL IN TANZANIA

**Kristina Keitel**<sup>1</sup>, Josephine Samaka<sup>2</sup>, Tarsis Mlaganile<sup>2</sup>, Frank Kagoro<sup>2</sup>, Zamzam Said<sup>2</sup>, Hosiana Temba<sup>2</sup>, Blaise Genton<sup>3</sup>, Valérie D'Acromont<sup>3</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Boston Children's Hospital, Basel, Switzerland, <sup>2</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Swiss Tropical and Public Health Institute, University Hospital Lausanne, Basel, Switzerland

At the outpatient level about 1/4 of febrile children have no localizing symptoms, and test negative for malaria. Given the lack of diagnostic tools, antibiotic overuse is a major challenge. We assessed the use of point-of-care inflammatory marker results (C-reactive protein [CRP] and procalcitonin [PCT]; intervention arm) versus disease-specific criteria (urine dipstick, typhoid rapid test, or ear discharge; control arm) in deciding on antibiotic prescription for undifferentiated fever among pediatric

outpatients (sub-cohort of a larger trial, e-POCT, that included consecutive febrile patients). Antibiotics were prescribed only to children with CRP  $\geq$ 80mg/L or PCT  $\geq$ 4 $\mu$ g/L (intervention), and to patients with positive urine dipstick, typhoid test or acute ear discharge (control). 13% (52/401) met criteria for antibiotic prescription in the intervention, versus 16% (67/413) in the control arm ( $p=0.19$ ). 12% (47/402) had PCT  $\geq$ 4 $\mu$ g/L, 2% (8/402) CRP  $\geq$ 80mg/L and 1% (3/402) both. There were 3 clinical failures (1 death) and 6 clinical failures (3 deaths) by day 7 in the intervention and control arms ( $p=0.33$ ). 1.2% (10/814) and 2.7% (22/814) had a positive blood or urine culture, respectively (result available late in the episode, not used for clinical management). In the intervention arm, 3/4 and 9/13 of children with positive blood /urine culture, respectively, had been identified by CRP/ PCT and thus treated with antibiotics. In the control arm, 2/6 of those with positive blood culture (1 positive urine dipstick, 1 ear discharge) were treated. All patients with positive blood/urine culture but not treated with antibiotics were cured at day 7. In the Dar es Salaam outpatient population, using a simplified approach of combined CRP and PCT cutoffs to decide on antibiotic prescription among children with undifferentiated fever was comparable in terms of antibiotic prescription and clinical outcome to a disease-specific diagnostic strategy. The limited relationship between the presence of bacterial disease and clinical outcome speaks in favor of using host biomarkers to identify serious infection, whatever type of pathogen is causing it.

## 466

### BACK-CALCULATION OF THE INCIDENCE OF LEPROSY-RELATED IMPAIRMENT - GLOBAL PATTERNS AND FORECASTS

**Ronald E. Crump**<sup>1</sup>, Graham F. Medley<sup>2</sup>

<sup>1</sup>The University of Warwick, Coventry, United Kingdom, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The primary approach to reducing the public health burden of leprosy is early diagnosis of symptomatic cases thereby reducing both transmission and the incidence of leprosy-related impairment (commonly reported as cases with grade 2 disability; G2D). The 2020 target for leprosy is less than 1 new case with G2D per 1,000,000 of the global population; using the incidence of new cases with G2D both as an aim and as a proxy for reduced detection delays and transmission. Annual national-level data published by the World Health Organisation in the Weekly Epidemiological Record were analysed, each country being analysed separately. A back-calculation method was used in a fully Bayesian framework to make probabilistic inferences about the incidence of leprosy-related impairment in 2020 and beyond, and in which years the number of new leprosy cases with G2D are expected to be less than 1 per 1,000,000 of the population nationally and internationally.

## 467

### DESCRIPTION OF THE LOCAL EPIDEMIOLOGY OF BACTERIAL ETIOLOGY IN CLINICAL NEONATAL SEPSIS IN RURAL SOUTHEASTERN CAMBODIA

**Sarah Labuda**<sup>1</sup>, Var Chivorn<sup>2</sup>, Seng Bunly<sup>3</sup>, Vantha Te<sup>4</sup>, Sosorphea Seang<sup>4</sup>, Alessandra Bazzano<sup>5</sup>, Richard Oberhelman<sup>5</sup>

<sup>1</sup>Tulane University School of Medicine, New Orleans, LA, United States, <sup>2</sup>Reproductive Health Association of Cambodia, Phnom Penh, Cambodia, <sup>3</sup>BN Consult, Phnom Penh, Cambodia, <sup>4</sup>Takeo Provincial Hospital, Takeo, Cambodia, <sup>5</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Neonatal deaths are the largest contributor to under-5 mortality worldwide, and sepsis is the second most prevalent diagnosis among neonatal deaths in low and middle income countries (LMIC). Most data and evidence informing guidelines for the treatment of neonatal sepsis in LMICs comes from the US and western Europe, which a growing body of evidence is showing to have a very different epidemiology when compared to LMICs. We performed an 18 month prospective study in a rural provincial hospital in southeastern Cambodia to describe the local

epidemiology of bacterial causes of neonatal sepsis. Neonatal nurses completed a 1-page data sheet in Khmer at time of admission. One-half to 1ml blood was collected by aseptic technique and inoculated into locally produced pediatric blood culture bottles, then incubated for 7 days and checked once daily based on the microbiology laboratory's protocol. Organisms were identified by Gram stain and basic biochemical testing. A total of 128 blood cultures were obtained from patients between April 2015 and November 2016. Three isolates identified were presumed pathogens, and all were gram negative rods (1 *Escherichia coli*, 1 *Klebsiella pneumoniae*, and 1 *Acinetobacter* spp.). Eleven were coagulase negative *Staphylococcus* and 2 were other skin contaminants, resulting in 2.3% true positives and 10.2% contaminants. High rates of contaminants pose a challenge to obtaining and interpreting blood culture results in neonates with clinical sepsis in a rural region of Cambodia. The positive rate is approximately 10 times that seen in the United States and western Europe, and the presence of gram negative rods rather than group B *Streptococcus* as the primary pathogens could help influence local treatment guidelines.

## 468

### EXPERIMENTAL CONFIRMATION OF UNIQUE, FUNCTIONAL RICIN-B LIKE LECTIN DOMAINS IN PATHOGENIC *LEPTOSPIRA*

**D. Jake Harrington**, Kailash P. Patra, Michael A. Matthias, Kira Chaiboonma, Andrew R. Lee, Joseph M. Vinetz

*University of California San Diego, La Jolla, CA, United States*

Comparative genomic analysis of the genus *Leptospira* predicts that a large family (2-15) paralogous members) of secreted proteins—so-called Virulence Modifying [VM] proteins—are involved in leptospirosis pathogenesis. *In silico* analysis predicts that VM proteins contain amino-terminal ricin B-like lectin (RBLL) domains, which are found only as large gene families in pathogenic *Leptospira* (and, notably, Andean *Bartonella* spp), but no other known pathogens. RBLL domains are predicted to bind terminal galactosyl residues on glycoproteins, based on known properties of the B chain of the potent toxin, ricin. This study aimed to understand potential functional roles of leptospiral RBLL-domain-containing VM proteins. Soluble recombinant RBLL-domains as mCherry fusion proteins with an HA epitope tag and His6 affinity purification tag from two VM proteins (LA-3, LA-6) were produced in *E. coli* and purified using nickel affinity chromatography. Recombinant protein solubility, hence presumably proper folding of the cysteine-rich proteins, could be easily seen by pink color seen in the supernatant of the cell pellet lysate, allowing for rapid tracking in purification. Pulldown assays using the terminal galactosyl exposed model protein, asialofetuin, plus recombinant VM RBLL domains in the presence of 1% Tween-20, demonstrated that both VM RBLL domains interacted with asialofetuin, as detected using Western immunoblot and SDS-PAGE silver staining. IFA using specific mouse polyclonal antisera did not yield signal with *in vitro*-grown *L. interrogans*. These data demonstrate that soluble, recombinant, cysteine-rich VM proteins are functional, and supports the hypothesis that RBLL domains in pathogenic *Leptospira* bind to host glycoproteins, supporting their potential role in host-pathogen interactions. Ongoing work to identify potential host cell binding targets for VM proteins, cell binding *in vitro* and *in vivo* using fluorescence tracking, and investigation of *in vivo* VM protein expression will shed light into mechanistic functional roles of the VM protein family in leptospirosis pathogenesis.

## 469

### SALMONELLA SEROGROUP C1 SEROVARS ISOLATED FROM BLOOD OF INFANTS IN BAMAKO, MALI, FROM 2002 TO 2014

**Fabien J. Fuche**, Sunil Sen, Jennifer A. Jones, Joseph Nkeze, Sofie Livio, Jasnehta Permala-Booth, Sharon M. Tennant

*University of Maryland, Baltimore, MD, United States*

Non-typhoidal *Salmonella* (NTS) are the leading cause of foodborne infections worldwide, and a major cause of bloodstream infections in infants and HIV-infected adults in sub-Saharan Africa (SSA). *Salmonella*

Typhimurium (serogroup B) and *Salmonella* Enteritidis (serogroup D) are the most common serovars that cause invasive NTS disease in this region. However, data describing rarer invasive NTS serovars, particularly those belonging to serogroups C1 and C2, circulating in SSA are lacking. We previously conducted systematic blood culture surveillance on pediatric patients in Bamako, Mali from 2002 to 2014. Of 687 NTS isolates, 87% belonged to four serovars: *Salmonella* Enteritidis (36%), *Salmonella* Typhimurium (32%), *Salmonella* I 4,[5],12:i:- (6%) and *Salmonella* Dublin (13%). Here, we present data on 27 *Salmonella* serogroup C1 strains that were isolated during this previous study. No serogroup C2 strains were identified. The 27 serogroup C1 strains were typed by serum agglutination and molecular methods including Multi-Locus Sequence Typing (MLST). Of these, sixteen strains were *Salmonella* Paratyphi C, four were *Salmonella* Colindale and two were *Salmonella* Virchow. Interestingly, five strains were identified as the very rare *Salmonella* Brazzaville using a combination of O- and H-agglutination and flagellin gene typing. Phenotypic characterization showed that *Salmonella* Brazzaville produced biofilm, as measured by crystal violet binding, and exhibited catalase activity, which were not statistically different to the gastroenteritis-associated *Salmonella* Typhimurium sequence type (ST) 19. All tested *Salmonella* Paratyphi C strains were poor biofilm producers and showed significantly less catalase activity than *Salmonella* Typhimurium ST19. Overall, our study provides insight into the *Salmonella* serogroup C1 serovars that cause invasive disease in infants in Mali. Additionally, we show that MLST and flagellin gene sequencing, in association with traditional serum agglutination, are invaluable tools to help identify rare *Salmonella* serovars.

## 470

### THE DEVELOPMENT OF A DUAL-TARGET REAL-TIME PCR ASSAY FOR THE DETECTION OF *BRUCELLA* SPECIES

**Wanwen Su**, Soma Chanda, Mikeljon P. Nikolich

*Walter Reed Army Institute of Research, Silver Spring, MD, United States*

Brucellosis is one of the most widespread zoonotic diseases and is endemic in many countries across the globe. To advance brucellosis surveillance and control, it is important to continue to develop methods for rapid detection of *Brucella* species. Though many PCR assays have been developed for the detection of *Brucella* species, currently there is only one commercial kit available for PCR-based detection of *Brucella* species. During previous *Brucella* surveillance efforts it was found that a commercial kit provided false positive results because it had only a single target that shared homology with *Ochrobactrum* species. *Ochrobactrum* is close to the genus *Brucella*, is commonly found in soil and can cause opportunistic infections. To develop an improved assay for PCR detection of *Brucella* species, two genes (*bcs31* and *IS711*) were selected as targets through literature search and bioinformatics tools. The *bcs31* target has a single copy in the *Brucella* genome and encodes a 31 kDa immunogenic protein, while *IS711* is an insertion sequence specific to the genus with variable copy number in different *Brucella* species. We developed and optimized a dual-target TaqMan real-time PCR assay for detection of *Brucella* species. The target genes had no significant DNA sequence homology with other bacteria in the NCBI database. We tested *Brucella* species [*B. abortus* (11), *B. melitensis* (2), *B. suis* (4), *B. ovis* (4), *B. neotomae* (4), *B. canis* (2), *B. ceti* (3) and *B. pinnipedialis* (1)], commonly found bacteria [*B. anthracis* (2), *Y. pestis* (2), *E. coli* (2), *F. tularensis* (2), *Staphylococcus aureus* (2), *P. aeruginosa* (2), *K. pneumoniae* (2), *E. gergoviae* (2), *E. cloacae* (2), *E. aerogenes* (2), *S. sakazaki* (2), *Shigella* (2) and *Proteus* (2)] and *Ochrobactrum* species (2) for specificity. The specificity was 100% for both targets. To estimate limits of detection, *Brucella abortus* strain S19 DNA was used. For *bcs31* target, the LOD was 100 fg of DNA, while for *IS711* it was 10 fg of DNA. Because of its specificity and sensitivity this dual-target TaqMan real-time PCR assay provides an advanced tool for the detection of *Brucella* species for future use in surveillance.

## SPECTRUM OF MULTI-DRUG RESISTANT GRAM NEGATIVE BACTERIA ISOLATED FROM HOSPITALIZED CHILDREN WITH FEBRILE ILLNESS IN THREE REGIONAL REFERENCE HOSPITALS IN UGANDA

**James A. Kapisi**<sup>1</sup>, Asadu Sserwanga<sup>1</sup>, Ruth Kigozi<sup>1</sup>, Catherine Maiteki<sup>1</sup>, Mohammed Lamorde<sup>2</sup>, Richard Walemwa<sup>2</sup>, Franklin Kizito<sup>2</sup>, Gilbert Aniku<sup>3</sup>, Jane Frances Nanteza<sup>4</sup>, Abner Tagoola<sup>5</sup>, Jeff N. Borchert<sup>6</sup>, Matthew Mikoleit<sup>6</sup>, Paul S. Mead<sup>7</sup>, Kiersten Kugeler<sup>7</sup>, Ron Rosenberg<sup>7</sup>, Henry M. Kajumbula<sup>8</sup>, Hannington Baluku<sup>8</sup>, Molly Freeman<sup>9</sup>, Eric Mintz<sup>9</sup>, Moses R. Kanya<sup>10</sup>, Arthur Mpimbaza<sup>11</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Infectious Diseases Institute, Kampala, Uganda, <sup>3</sup>Arua Regional Referral Hospital, Arua, Uganda, <sup>4</sup>Mubende Regional Referral Hospital, Mubende, Uganda, <sup>5</sup>Jinja Children's Hospital, Jinja, Uganda, <sup>6</sup>Division of Global Health Protection, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>7</sup>Division of Vector-Borne Disease, Centers for Disease Control and Prevention, Fort Collins, CO, United States, <sup>8</sup>Department of Microbiology, Makerere University, Kampala, Uganda, <sup>9</sup>Division of Foodborne, Waterborne and Environmental Diseases, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>10</sup>Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, <sup>11</sup>Child Health and Development Centre, Makerere University, Kampala, Uganda

Antimicrobial resistance is a global public health problem contributing to childhood morbidity and mortality. In resource-constrained countries identification of bacterial isolates and antimicrobial susceptibility testing (AST) is a challenge due to limited laboratory capacity. As part of an ongoing acute febrile illness (AFI) sentinel surveillance program, we report the prevalence of multidrug-resistant (MDR) gram-negative bacteria (GNB) among children at three regional reference hospitals in Jinja (eastern), Mubende (central), and Arua (northwestern), Uganda. All hospitalized children  $\leq 14$  years old with a history of fever or documented temperature  $\geq 37.5^\circ\text{C}$  were tested for malaria by microscopy or rapid diagnostic test; those with a negative malaria test result qualified for blood culture. A single blood culture bottle per patient was collected and incubated in BACTEC machines; species identification was performed at a Makerere University medical microbiology laboratory. AST was done using Kirby-Bauer disk diffusion method. MDR was defined as resistance to  $\geq 3$  of the following antimicrobials: ampicillin-sulbactam, ceftazidime, ciprofloxacin, gentamicin, trimethoprim-sulfamethoxazole, and meropenem. Among 7,360 children hospitalized during July 2016-Feb 2017, blood cultures were performed on 1,351 (18.4%), with 1,246 (92.2%) yielding no growth; 38 (2.8%) yielding a likely contaminant, and 67 (5.0%) yielding a likely pathogen. Of the pathogens isolated, 43 (64.2%) were GNB of which 10 (14.9%) were MDR, including *Klebsiella pneumoniae* (3), *Citrobacter freundii* (2), *Escherichia coli* (2), *Enterobacter species* (2), and *Klebsiella oxytoca* (1). Of the 10 MDR GNB, 6 were isolated from patients in Jinja, 5 from patients in Arua, and 5 produced extended spectrum  $\beta$ -lactamase (ESBL). MDR-GNB are isolated frequently from pediatric inpatients and pose a treatment dilemma for health workers. The ongoing surveillance project will continue to yield critical information on bacterial pathogens and their antimicrobial susceptibility patterns to inform patient care and antimicrobial stewardship guidelines.

## A NOVEL DIAGNOSTIC KEY FOR LEPROSY BASED ON ARTIFICIAL INTELLIGENCE

**Marcio L. Souza**<sup>1</sup>, Katuscia C. Ramalho<sup>2</sup>, Lucia A. Fraga<sup>1</sup>

<sup>1</sup>Universidade Federal de Juiz de Fora - Campus Governador Valadares - Programa Multicentrico de Bioquímica e Biologia Molecular, Governador

Valadares, Brazil, <sup>2</sup>Secretaria Municipal de Saude - Epidemiologia, Governador Valadares, Brazil

Leprosy is an infectious disease caused by *Mycobacterium leprae* and approximately 200,000 new cases are registered each year. Brazil is one of the countries most affected by the disease and Governador Valadares, city of Minas Gerais state, has presented high incidence along the years, making it an ideal location to study epidemiologic interactions and to determine clinical patterns for this disease diagnosis. This diagnosis remains based on the appearance of clinically relevant manifestations what give margin to misunderstandings. This work propose a fast, accurate and friendly method of clinical classification of leprosy in order to optimize the public health service. Using the Brazilian National Notifiable Disease Surveillance System (SINAM), data were collected on cases of leprosy between January 5, 2001 and January 24, 2017, for the microregion surrounding Governador Valadares, totaling 3,368 patients in the analysis of pattern recognizing. The database include the follow variables: age, gender, number of lesions, entry mode, detection mode, bacilloscopy, number of affected nerves, clinical form and operational classification of leprosy. The median age at notification was 39 years (range 1 to 97), 55.5% were female and 39.5% were Tuberculoid cases. The data set of these variables was analyzed using a type of artificial intelligence called Random Forest (RF) to predict the clinical form of leprosy of new suspect patients. The RF proved to be quite robust for the classification of leprosy even with an error about 30% in the clinical classification (Indeterminate, Tuberculoid, Dimorph, Virchowian). On the other hand, in the operational classification (Paucibacillary and Multibacillary) this error decreased to 9%. The main source of error comes from Indeterminate cases which are mostly classified as Tuberculoid by RF, emphasizing the importance of more tests to make an accurate diagnosis. Once this situation is minimized or solved, could be created a clinical classification key for leprosy which public health professionals can use with great precision. Financial support: FAPEMIG

## UNRECOGNIZED BURDEN OF LEPTOSPIROSIS IN RURAL NEPAL: EVIDENCE FROM A SERO-EPIDEMIOLOGIC SURVEY

**Jason R. Andrews**<sup>1</sup>, Krista Vaidya<sup>2</sup>, Dipesh Tamrakar<sup>2</sup>, Camila Hamond<sup>3</sup>, Caryn Bern<sup>4</sup>, Isaac I. Bogoch<sup>5</sup>, Albert I. Ko<sup>3</sup>, Elsie A. Wunder<sup>3</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Dhulikhel Hospital, Kathmandu University Hospital, Dhulikhel, Nepal, <sup>3</sup>Yale School of Public Health, New Haven, CT, United States, <sup>4</sup>University of California San Francisco, San Francisco, CA, United States, <sup>5</sup>University of Toronto, Toronto, ON, Canada

Leptospirosis is an important cause of morbidity and mortality globally, but there is significant geographical heterogeneity in the burden of disease. In Nepal, there are limited data on the burden of leptospirosis, particularly outside of the Kathmandu Valley. Furthermore, most published data are based upon IgM ELISAs, which have poor specificity. To investigate the burden of leptospirosis in peri-urban and rural areas and identify the predominant serogroups circulating within Nepal, we conducted a sero-epidemiologic survey. We sampled an age and sex-stratified population of patients seeking care with mild acute febrile illness lasting  $\geq 3$  days at a tertiary referral hospital serving a peri-urban and rural population. We performed microscopic agglutination tests (MAT) using a panel of 29 reference strains representing globally important serogroups. We assumed positive titers  $>1:100$  to represent prior exposure. We used generalized linear and additive models to investigate trends in seropositivity according to age, sex and population density of residence. Among 210 individuals, 35 (16.7%) had a positive titer for at least one serovar. The most common serogroups detected were Icterohaemorrhagiae (29), Australis/Bratislava (20), and Cynopteri (13). We found no difference in seropositivity between men and women (13.8% vs 18.7%;  $p=0.45$ ). Seropositivity increased with age from 0% (0/15) among children  $<5$  years; 14% among children 5-9 years (3/22), 20% among 10-19 year olds (12/61), and 18% among those  $>20$  years of age (20/112). We found a trend towards higher seropositivity in lower population density areas ( $p=0.16$ ). There is a substantial burden

of exposure to leptospires among both men and women in peri-urban and rural areas in Nepal, which may be underappreciated as a cause of illness. Improved awareness of leptospirosis and access to accurate diagnostics are needed in clinical settings to improve management of patients with acute febrile illnesses.

### PATHOGENS AND THEIR SUSCEPTIBILITY TO ANTIMICROBIALS USED FOR EMPIRIC TREATMENT OF INFECTIONS

**John K. Owuoth<sup>1</sup>**, Janet Oyieko<sup>2</sup>, Ben Andagalu<sup>2</sup>, Lucas O. Tina<sup>2</sup>, Jessica Cowden<sup>3</sup>, Stephen Ondolo<sup>2</sup>, Bernhards Ogutu<sup>2</sup>, Walter Otieno<sup>2</sup>

<sup>1</sup>Henry Jackson Foundation Medical Research International/Walter Reed Project Kisumu, Kisumu, Kenya, <sup>2</sup>Kenya Medical Research Institute/Walter Reed Project Kisumu, Kisumu, Kenya, <sup>3</sup>Defense Institute for Medical Operations, Lackland, TX, United States

Antimicrobial resistance is a global health challenge. Significant gaps in surveillance remains, especially in Africa where blood cultures are not done routinely in public hospitals and treatment of suspected infections is mainly empirical. We here report data obtained from hospitalized children in a pilot study and the phase III RTS,S/AS01 malaria vaccine trial. This cross-sectional study was conducted at Kombewa County Hospital in the periods September 2008 to March 2009, when all admitted acutely ill children aged 2 months to 4 years were eligible for inclusion, and January 2010 to October 2013 when all admitted children in the RTS,S vaccine trial were eligible. Using a protocol defined algorithm, patients were clinically evaluated and routinely had blood cultures by the BACTEC® system and antibiotic susceptibility assays done. In 2008/2009, of the 75 positive cultures, 26 (34.67%) were positive for *Salmonella paratyphi* type B (*S. paratyphi* B). While all were susceptible to ceftriaxone, > 95% were resistant to amoxicillin/clavulanate (amoxiclav), chloramphenicol and cotrimoxazole (CTX). Of 4 (5.3%) *Streptococcus pneumoniae* (*S. pneumoniae*) isolates, 75% and 100% were susceptible to penicillin and chloramphenicol respectively but all were resistant to CTX. The 16 (17%) *Staphylococcus aureus* isolates were susceptible to Penicillin but resistant to CTX. Between 2010 and 2013, of 56 positive cultures, 24 (42.9%) were *S. paratyphi* B isolates with susceptibility to ciprofloxacin at 100% and to ceftriaxone at 70.8%. Resistance to chloramphenicol was 81.8%, to amoxiclav and CTX 100%. There were 4 (5.3%) *S. pneumoniae* isolates; 100% were susceptible to penicillin, chloramphenicol and ceftriaxone but all were resistant to amoxiclav and CTX. In conclusion, *S. paratyphi* B remained the commonest organism isolated within the time periods. There was increased chloramphenicol resistance in *S. paratyphi* B isolates. *S. pneumoniae* susceptibility to penicillin remained high. Resistance to CTX and amoxiclav was high.

## 475

### THE BURDEN AND DISTRIBUTION OF TYPHOID FEVER IN AFRICA

**Jong-Hoon Kim**, Ligia Cruz Espinoza, Prerana Parajulee, Justin Im, Florian Marks

International Vaccine Institute, Seoul, Republic of Korea

The existing estimates of the global burden of typhoid fever (ranging between 10 and 20 million infections in 2010) are based on rather simplistic extrapolation of the incidence observed during some 20 longitudinal studies. We revisited these estimates for Africa using more statistically sound methods backed by more informative explanatory covariates. We collated historic typhoid occurrence data from peer-reviewed literature, ProMED online articles, and databases of country's health administrations. After locating typhoid occurrences onto 5x5 km square grids of a map of Africa, we explored the impact of the covariates (e.g., access to improved water and sanitation and environmental covariates such as precipitation and temperature) on typhoid occurrence

using a boosted regression tree method. This led to a 5x5 km square grid map of probability of typhoid occurrence in Africa. We then examined the association between estimated probability of typhoid occurrence and observed typhoid annual incidence again on 5x5 km square grids, creating a map of predicted typhoid incidence at the (sub) national and continental level. The occurrence probability and incidence rate of typhoid fever appear to be influenced more by socioeconomic factors such as access to clean water or population density while environmental factors such as precipitation or altitude still have an impact. The estimated annual incidence of typhoid fever in Africa is around one million and thus is lower than the previous estimates (e.g., ~3 million) although its 95% credible interval includes them. Recent typhoid transmissions have been more frequent in Middle and Eastern Africa, potentially influenced by El Niño-Southern Oscillation. The updated disease burden shows significant spatiotemporal heterogeneity of typhoid fever transmission in Africa, implying that simplistic extrapolation of observed transmission events may not be adequate for estimating its continent-wide burden and we need more sophisticated tools to account for various factors influencing the transmission of typhoid fever.

## 476

### CLINICAL CHARACTERIZATION OF LEPROSY IN A TERTIARY CENTER IN PERU

Wilder Melgarejo<sup>1</sup>, Jorge Nakazaki<sup>1</sup>, Sofia Zavala<sup>2</sup>, Nestor Vasquez<sup>1</sup>, Robert Rolfe<sup>3</sup>, Martin Montes<sup>2</sup>, **German Henostroza<sup>3</sup>**, Pedro Legua<sup>4</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru, <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL, United States, <sup>4</sup>Instituto de Medicina Tropical Alexander von Humboldt, UPCH, Lima, Peru

Leprosy diagnosis requires a high-index of suspicion, recognition of clinical signs and symptoms and, if available, laboratory confirmation. In low-resource settings, the limited access to specialized diagnostic tools makes clinical diagnosis important, and early clinical recognition has implications for appropriate management and prevention of disability. We describe the experience in clinical diagnosis of leprosy in a tertiary health facility in Lima, Peru. We reviewed the data collection forms of the patients diagnosed with leprosy in the Cayetano Heredia Hospital in Lima, Peru between January 2001 and December 2016. We registered the patients' sex, age at onset, duration of disease, clinical diagnosis using the Ridley-Jopling clinical classification, and slit-skin smears for identifying acid-fast bacilli. A total of 26 patients were clinically diagnosed with leprosy, 19 (73.1%) were males. The mean age at disease onset was 43.5 ± 15.3 years (19 - 69) and the median of disease duration was 18 months (3 - 120). Out of the total number of patients, 3 (11.5%) had been previously treated and 9 (37.5%) had a known leprosy contact. Clinically, 11/26 (42.3%) patients were classified as lepromatous leprosy, 7/26 (26.9%) as mid-borderline leprosy, 4/26 (15.4%) as borderline lepromatous leprosy, and 4/26 (15.4%) as borderline tuberculoid leprosy. Acid-fast bacilli were found in 23/26 (88.5%) patients. Disability grade I (anesthesia) was found in 5/21 (23.8%) patients. Clinical diagnostic approach to leprosy using the Ridley-Jopling classification represents a valuable tool in resource-constrained settings where no laboratory confirmation is available. Further evaluation of this diagnostic approach in leprosy treatment outcomes is needed.

### RICKETTSIAL INFECTION: AN UNEXPECTED CAUSE OF FEVER IN PATIENTS HOSPITALIZED WITH ACUTE FEBRILE ILLNESS IN INDONESIA

Bachti Alisjahbana<sup>1</sup>, Khie Chen<sup>2</sup>, Muhammad Karyana<sup>3</sup>, Dewi Lokida<sup>4</sup>, I Made Susila<sup>5</sup>, Rizka Humardewayanti<sup>6</sup>, Ungke Antonjaya<sup>7</sup>, Herman Kosasih<sup>8</sup>, Aaron Neal<sup>9</sup>

<sup>1</sup>Hasan Sadikin Hospital, Bandung, Indonesia, <sup>2</sup>Cipto Mangunkusumo Hospital, Jakarta, Indonesia, <sup>3</sup>NIHRD, Jakarta, Indonesia, <sup>4</sup>Tangerang Hospital, Banten, Indonesia, <sup>5</sup>Sanglah Hospital, Denpasar, Indonesia, <sup>6</sup>Sardjito Hospital, Yogyakarta, Indonesia, <sup>7</sup>Eijkman Institute, Jakarta, Indonesia, <sup>8</sup>INA-RESPOND, Jakarta, Indonesia, <sup>9</sup>U.S. National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

*Rickettsia typhi*, the etiological agent of murine typhus, is a flea-borne Gram-negative rod found in tropical and sub-tropical areas worldwide. The global burden of human infection is unknown, primarily due to the similarities in clinical presentation with other infectious diseases, particularly typhoid fever. While *R. typhi* infection is generally mild, presenting as an acute fever and rash, it can become severe and even fatal if not accurately diagnosed and treated. Unfortunately, developing countries often lack the diagnostic capacity to accurately distinguish infections of *R. typhi* from other tropical diseases. To understand the etiological profile of acute febrile illness in Indonesia, an observational study was conducted at 8 top-referral hospitals across the country from 2013-2016. 1,486 patients were enrolled and monitored at three time points: at enrollment, once between days 14-28, and at 3 months after enrollment. Demographic and clinical data were collected, and blood samples were obtained at each study visit for standard-of-care diagnostics and study-specific serological and molecular tests. 102/1486 (7%) patients were found to be infected with *R. typhi* and 1 patient was found to be infected with *R. felis* by PCR. In all cases, patients were misdiagnosed, most frequently with typhoid fever. *Rickettsial* infections were observed at all study sites, the highest prevalence being in Surabaya, East Java (12.5% of cases). Of the 89 patients who died during the study, *R. typhi* was identified as the etiological agent in 6 (6.7%/7%) cases. The detection of *Rickettsia spp.* highlights both the importance of including these pathogens in the differential diagnosis of acute febrile illness and the need for enhanced diagnostic capacity in Indonesia to improve clinical case management and decrease morbidity.

### CLINICAL, SEROLOGICAL AND MOLECULAR DIAGNOSIS OF TYPHOID FEVER, A SIGNIFICANT CAUSE OF ACUTE FEBRILE ILLNESS AMONG HOSPITALIZED PATIENTS IN INDONESIA FROM 2013-2016

Emiliana Tjitra<sup>1</sup>, I Made Susila<sup>2</sup>, Mansyur Arief<sup>3</sup>, Ida Parwati<sup>4</sup>, MMDEAH Hapsari<sup>5</sup>, Ninny M. Pelupessy<sup>3</sup>, I Made Gede Dwi Lingga<sup>2</sup>, Herman Kosasih<sup>6</sup>, Aaron Neal<sup>7</sup>

<sup>1</sup>NIHRD, Jakarta, Indonesia, <sup>2</sup>Sanglah Hospital, Denpasar, Indonesia, <sup>3</sup>Wahidin Sudirohusodo Hospital, Makassar, Indonesia, <sup>4</sup>Hasan Sadikin Hospital, Bandung, Indonesia, <sup>5</sup>Kariadi Hospital, Semarang, Indonesia, <sup>6</sup>INA-RESPOND, Jakarta, Indonesia, <sup>7</sup>U.S. National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Typhoid fever remains a significant public health problem, with an estimated 21 million infections and 222,000 deaths occurring annually worldwide, primarily in developing countries. In Indonesia, the burden of disease is unknown, largely due to both challenges in clinical differentiation and reduced laboratory diagnostic capacity at health centers nationwide. To better understand how hospitalized patients presenting with an acute febrile illness are diagnosed and managed in Indonesia, an observational study was conducted at 8 top-referral hospitals across the country from 2013-2016. 1,486 patients were enrolled and monitored during enrollment, once during the 14-28 days following enrollment,

and at 3 months after enrollment. Demographic and clinical data were collected at enrollment, and blood samples were collected at each study visit for use in standard-of-care diagnostics and advanced, study-specific testing. Typhoid fever was clinically diagnosed in 248 cases, of which 43 were confirmed by blood culture and 167 by rapid diagnostic test. Only 34 of the 167 cases could be verified by ELISA and/or PCR, leading to additional testing that identified the misdiagnosed etiological agents *Rickettsia spp.* (30), dengue virus (19), chikungunya virus (7), influenza A (3), *Leptospira spp.* (2), other pathogens (6), and unknown (66). This discordance between standard-of-care and study-specific diagnoses revealed that the TUBEX TF rapid diagnostic test frequently generated false-positive results, particularly for patients infected with *Rickettsia spp.* A clinical diagnosis of typhoid fever was missed in 15 cases where *Salmonella Typhi* was identified by molecular testing. The results from this observational study suggest that typhoid fever remains a significant cause of hospitalization for patients with acute febrile illness in Indonesia. This outcome, along with our findings regarding laboratory diagnostics, will strengthen and improve the successful diagnosis of typhoid fever in Indonesia and other developing countries.

### HUMAN ECHINOCOCCOSIS: EVALUATION OF DISEASE ACTIVITY BY SEROLOGY

Rini Bandyopadhyay<sup>1</sup>, Laura Eve Nabarro<sup>2</sup>, Zahir Amin<sup>3</sup>, David Lawrence<sup>3</sup>, Theodora Pissanou<sup>4</sup>, Charles Imber<sup>4</sup>, Gauri Godbole<sup>2</sup>, Peter L. Chiodini<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>The Hospital for Tropical Diseases, London, United Kingdom, <sup>3</sup>University College London Hospitals, London, United Kingdom, <sup>4</sup>Royal Free Hospital, London, United Kingdom

Burden of human echinococcosis has changed worldwide with varied clinical profile and wider therapeutic options. A retrospective survey hydatid disease cases between 2006 and 2016 was conducted at the Hospital for Tropical Diseases, London. Clinical outcome, serological response and factors associated with adverse outcomes were assessed. Cyst-specific total IgG antibody and IgG2 subclass antibody response were serially measured by enzyme-linked immunosorbent assay (ELISA) as correlates of disease activity. 160 cases were diagnosed during the study period. Cystic echinococcosis (CE) accounted for 97% (n=155) of cases while 5 (3.1%) cases had alveolar echinococcosis. Pre-and post-treatment total IgG and IgG2 among WHO cyst types showed the mean ODs of total IgG to be significantly higher across all cyst types than those of IgG2. Post-treatment change in mean ODs was similar for both total IgG and IgG2 for all cyst types. Drug therapy was received by 127 (79.4%) cases, of which 99 (78%) received combined albendazole and praziquantel while 28 (22%) received albendazole alone. The median duration of albendazole therapy was 12 months. Radical surgery was performed in 70 (71.4%) cases while 28 (28.6%) had conservative surgery. Significant change in total IgG and IgG2 was demonstrated following surgical intervention. The median OD remained the same for total IgG after radical or conservative surgery while the greatest change in IgG2 was in the conservative surgery group. Both total IgG and IgG2 antibody levels remained elevated in active persistent disease as compared to inactive disease. IgG2 antibody response had better correlation with disease activity during post-treatment follow-up. Serologic follow-up over the years showed steady decline in total IgG and IgG2 following treatment and concurrent rise with disease reactivation. There was no disease recurrence. Serology is a useful tool for monitoring of disease activity and evaluation of response to treatment of human echinococcosis. Prospective trials are required to establish the optimal IgG2 antibody response during treatment using standardized serologic methods.

### LUNG AND LIVER CYSTIC ECHINOCOCCOSIS - FACTORS ASSOCIATED WITH HEALTH-RELATED QUALITY OF LIFE AFTER SURGICAL TREATMENT

Saul J. Santivanez<sup>1</sup>, Maira Arce<sup>1</sup>, Maria Valcarcel<sup>2</sup>, Luis Tello<sup>1</sup>, Lawrence H. Moulton<sup>3</sup>, Hector H. Garcia<sup>4</sup>

<sup>1</sup>Instituto Peruano de Parasitología Clínica y Experimental, Lima, Peru, <sup>2</sup>Department of Surgery, Hospital Nacional Dos de Mayo, Lima, Peru, <sup>3</sup>Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, <sup>4</sup>Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru

The burden of Cystic Echinococcosis (CE) considers the impact of the disease and its treatment on the health of subjects which is measured by the reduction in health related quality of life (HRQoL). Current estimates of CE disease burden did not include important variables such as involved organ, type of surgical treatment, time since surgery, and disease relapse. To obtain a more detailed assessment of the impact of the disease and its treatment, we evaluated the HRQoL in a historical cohort of surgically treated individuals. The Short Form 36 questionnaire (SF-36) was applied to study population. Health domains' scores obtained by the SF-36 were standardized using means and standard deviations from the general non-institutionalized Peruvian population, and the probability to have a score below the population mean was estimated. A total of 163 subjects were evaluated. There were CE-attributable long-term effects in all health domains, except for the general health domain. The domains of vitality, role limitations due to physical problems and due to emotional problems are the most affected. Among the characteristics associated with the probability to have a score below population mean, females showed an association with vitality and mental health domain; living in endemic areas with, social functioning, and role limitations due to emotional and physical problems; and disease relapse with the general health domain. Our study demonstrated a long-term effect in HRQoL among surgically treated CE patients, predominantly in the domains of the mental health component. Among the factors related to the disease, development of a new cystic lesion was the only one that showed an impact in the general health domain.

## 481

### NEUROINFLAMMATION IN NEUROCYSTICERCOSIS USING RAT ORAL INFECTION VERSUS INTRACRANIAL INFECTION

Manuela R. Verastegui<sup>1</sup>, Rogger Carmen<sup>1</sup>, Alan Mejia<sup>1</sup>, Danitza Davila<sup>1</sup>, Cesar Gavidia<sup>2</sup>, Nancy Chile<sup>1</sup>, Jemima Morales<sup>1</sup>, Ana Delgado<sup>2</sup>, Laura Baquedano<sup>2</sup>, Edson Bernal<sup>1</sup>, Robert H. Gilman<sup>3</sup>, Cysticercosis Working group in Peru<sup>4</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>3</sup>Bloomberg School Public Health, Johns Hopkins University, Baltimore, MD, United States, <sup>4</sup>Lima, Peru

Neurocysticercosis (NCC), a disease caused by *Taenia solium* larval stage (cysticerci) in the Central Nervous System, is the most common neurological disease of parasite etiology. NCC is a leading cause of seizures and epilepsy in the developing world. Research into the pathophysiology of the disease and appropriate treatment is hindered by lack of cost-effective and physiologically similar animal models. To address that, a novel rat NCC model using oral infection with activated *T. solium* oncospheres was developed, by the natural route of infection. Holtzman rats were infected in two separate groups: one group was inoculated by oral route and the second group by intracranial route. Histological examination of the tissue surrounding cysticerci was performed and compared by the two route of infection. Results show that using oral route, the infected rats developed cysticerci in the brain tissue after three months and the cysticerci can be located in the parenchymal, ventricle, or submeningeal brain tissue. When compare the two route of infection we found a statistically significant difference in the proportion of rats that develop cysticerci. Using oral infection the proportion of infected rats was less than

intracranial infection. Conversely, the infection dose in oral infection was higher (more than 5000 activated oncosphere) than intracranial infection (less than 500 activated oncospheres). However, the histopathology and neuroinflammation was not different. We observed, a layer of collagen tissue, inflammatory infiltrate cells, perivascular infiltrate, angiogenesis, spongy change, neuronal damage, and mass effect in the tissue surrounding the cysticerci. This study presents a suitable animal model for the study the pathogenesis and epileptogenesis of human NCC.

## 482

### NEUROINFLAMMATION AT DIFFERENT TIMES AFTER INFECTION WITH *TAENIA SOLIUM* LARVA STAGE USING RAT MODEL

Yudith Cauna-Orcollo<sup>1</sup>, Nancy Chile-Andrade<sup>1</sup>, César Quispe-Asto<sup>2</sup>, Rogger P. Carmen-Orozco<sup>1</sup>, Edson Bernal-Terán<sup>1</sup>, Nataly Bailon-Gonzales<sup>1</sup>, Manuela Verástegui-Pimentel<sup>1</sup>, Robert H. Gilman<sup>3</sup>, Cysticercosis working group in Peru<sup>4</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Society of Medical Technicians of Peru, Lima, Peru, <sup>3</sup>Johns Hopkins University, Lima, MD, United States, <sup>4</sup>Cysticercosis Working Group in Peru, Lima, Peru

The neurocysticercosis (NCC) is a parasitic infection caused by the establishment of *Taenia solium* cysts in the human brain. This infectious disease is a major cause of adult acquired epilepsy. It is reported that the parasite cause inflammation in the tissue surrounded the cyst. Therefore, some studies mentioned that the epileptogenesis could be associated with neuroinflammation and alteration of the blood-brain barrier integrity. One of the limitations to study the brain tissue neuroinflammation in patients with NCC is the difficulty in accessing to brain tissue, so it is necessary to use an animal model. Our group developed rat NCC animal model, that we used in the present study to evaluate the brain immune histopathology. The aim of this study was to evaluate neuroinflammation at different times after infection. We infected 30 Holtzman rats by intracranial route, with *T. solium* post oncospheres, and six rats none infected as control group. After infection, they were euthanized at different times (15, 30, 60, 90 days after infection). The rat brains tissue were processed to detect neuroinflammation using GFAP and Iba-1, to measure activation of astrocytes and microglia respectively, and CD68 to identify macrophages. We evaluated BBB disruption by detected IgG extravasation in the parenchymal brain tissue. We compared the proportion of immunoreactivity between the groups. The results show that reactivity to GFAP was lower at 15 days compared to 30, 60, and 90 days after infection ( $p < 0.05$ ). But the reactivity between 30, 60 and 90 days was not statistically different ( $p > 0.05$ ). The reactivity to Iba-1 and CD68 had the same pattern at the time, to 15 and 60 days both showed greater reactivity than to 30 and 90 days. Also, we observed, that immunoreactivity to IgG in the tissue surrounded the cyst at different times after infection (15, 30 and 60 days) were not statistically different ( $p > 0.05$ ), but the reactivity increased to 90 days. In conclusion, the development of the parasite in rat brain tissue caused neuroinflammation, have shown astrogliosis and to Iba-1 and CD68 decreased the reactivity with the time after infection.

## 483

### CLONING AND EXPRESSION OF THE TRYPSIN-LIKE PROTEIN TSAG5 IN AN INSECT'S CELLS EXPRESSION SYSTEM FOR ITS POTENTIAL USE IN THE IMMUNODIAGNOSTICS OF SINGLE CYST NEUROCYSTICERCOSIS

Sueline Luis<sup>1</sup>, Monica J. Pajuelo<sup>1</sup>, Nancy Leon<sup>1</sup>, Elisa Roncal<sup>1</sup>, Patricia Sheen<sup>1</sup>, Robert H. Gilman<sup>2</sup>, Hector H. Garcia<sup>2</sup>, Armando Gonzalez<sup>2</sup>, Mirko Zimic<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>John Hopkins University, Baltimore, MD, United States, <sup>3</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru

Neurocysticercosis is a disease caused by the accidental ingestion of *Taenia solium* eggs and it is the major cause of acquired epilepsy in Peru. The diagnosis is based on the observation of the cysts using imaging tests, such as magnetic resonance imaging (MRI) and computer tomography (CT) scan. The diagnosis can be complemented using serological tests. TsAg5 is a protein with trypsin-like activity, which has been detected in cyst's fluid and in excretion/secretion antigens of *T.solium*. In this study, we express the trypsin-like domain of TsAg5 using baculovirus as a vector to transfect Sf9 insect's cells. The expression of the domain was checked using a Western Blot assay. Then, we purified the protein using Affinity chromatography and Ion exchange chromatography. A sensitivity of 39.62% has been detected to diagnose single cyst Neurocysticercosis using TsAg5 expressed in prokaryotic vectors (Rueda *et al*, 2011). It is thought that TsAg5 expressed in a eukaryotic system would be more sensitive to diagnose single cyst Neurocysticercosis due to the post-translational modifications the system provide. This would be confirm using serological tests such as ELISA and EITB, in blood serums of patients positive to single cyst Neurocysticercosis.

## 484

### PRODUCTION OF KIT INHOUSE IMMUNOELECTROTRANSFER BLOT TEST WITH PURIFIED CYSTICERCUS VESICULAR FLUID ANTIGEN OF TAENIA SOLIUM MIX-NATIVE FOR DIAGNOSIS OF HUMAN CYSTICERCOSIS

Eduardo R. Ayala

Health National Institute, Lima, Peru

Peru does not produce a kit in-house with purified antigen for diagnosis of human cysticercosis. The objectives are to purify Ag.by four methods.- Evaluate EITB test for serological diagnosis of Cysticercosis using purified Ag. Were selected pigs parasitized with cysticercosis from endemic areas of Peru.-Cysticerci were collected to obtain Ag.and quantifi the proteic concentration. Protein profile was performed by elctrophoresis. The purification of the Ags.were performed by four methods: Ammonium sulfate, Chromatography of molecular exclusion, Electroelution, and Affinity Chromatography with Lentil-Lectin. The affinity chromatography method was evaluated and selected; the sensitivity of the purified Ag.was determined with EITB and were evaluated with 50 cysticercosis-positive sera, Specificity with 50 cysticercosis-negative. -The study determined that the Ags.totals had a higher proteic concentration(3.6-2.7µg/µL), and purified Ag.had 0.82µg/mm. -Affinity Chromatography by electrophoresis identified 8 specific antigenic glycoproteins between 13-35KDa. The other methods were not evaluated by EITB because they did not correspond to the specific antigenic proteins between 13-35KDa. Using EITB test with purified Ag. we showed 100% sensitivity and specificity. -Electrophoresis with Coomassie Blue and silver nitrate, allowed to visualize purified antigenic proteins. -We conclude that of the four purification methods, affinity chromatography is of choice and recommended for purifying glycoproteins from Ag.LVC.*T.sol*. Eight specific diagnostic glycoproteins were identified(13-35KDa).-The purified Ag. improved the diagnostic efficacy of the EITB test. -Purification of glycoproteins to produce kit in-house for diagnostic NCC reliable, affordable and quality, could benefit and solve this public health problem in developing countries

of South America(Peru) and could be applied in Asia, Africa and other countries, after standardization, field validation to transfer and implement laboratories in endemic areas. The kit can be patented.

## 485

### BANDING PATTERNS OF THE ENZYME-LINKED IMMUNOELECTROTRANSFER BLOT (EITB) CORRELATE WITH THE INFECTION STATUS IN PORCINE CYSTICERCOSIS

Gianfranco Arroyo<sup>1</sup>, Andres G. Lescano<sup>1</sup>, Juan F. Calcina<sup>2</sup>, Javier A. Bustos<sup>1</sup>, Teresa Lopez-Urbina<sup>2</sup>, Silvia Rodriguez<sup>1</sup>, Luis A. Gomez-Puerta<sup>2</sup>, Seth O'Neal<sup>3</sup>, Robert H. Gilman<sup>4</sup>, Victor C. Tsang<sup>5</sup>, Hector H. Garcia<sup>1</sup>, Armando E. Gonzalez<sup>2</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>3</sup>Oregon Health & Science University, Portland, OR, United States, <sup>4</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>5</sup>Georgia State University, Atlanta, GA, United States

The enzyme-linked immunoelectrotransfer blot (EITB) detects antibody bands against seven antigens of the *Taenia solium* larvae and is the serological reference test for porcine cysticercosis. *T. solium* antigens comprise three protein families (GP50, T24-42, and 8kDa) with different structure and function, and the heterogeneity of the antibody responses (banding patterns) against these protein families seems to be related with the characteristics of infection in humans. Nonetheless, the immune response in pig infections may differ from that observed in humans for many reasons including a heavier infective dose, different age at infection, maternal immunity, concomitant larval cestode infections, life span of infection among others. We analyzed the data on EITB banding patterns and *T. solium* infection status (not infected and infected with degenerated or viable cysts) of 491 pigs from two cross-sectional studies conducted in two endemic areas of Tumbes and Piura, in northern Peru. EITB banding patterns were grouped in homogenous classes using Latent Class Analysis (LCA), and its association with infection status, age and sex of pigs was assessed. A four-class model was specified by LCA. Infection status of pigs was strongly associated with classes ( $p < 0.001$ ), being the absence of cysts more frequent in classes 1 (negative or positive to GP50 protein family, 91.9%) and 2 (positive to T24-42 protein family, 69.9%), and viable cysts more frequent in classes 3 (positive to the 8kDa protein family, 55.6%) and 4 (strongly positive to the 8kDa protein family, 100%). Degenerated cysts were not found in the class 4, and viable cyst burden was higher in class 4 (median 1775.5, range 14-4492) and statistically significant ( $p = 0.001$ ). Pigs >8 months were more frequent in classes 3 and 4 (75% and 90%) and pigs ≤8 months were more frequent in class 1 (57%). Sex distribution was similar in all classes. EITB banding patterns correlated with the infection status of cysticercosis in pigs, so their interpretation improves the diagnosis of cysticercosis in porcine populations.

*Taenia solium* is a common cause of preventable epilepsy in developing nations worldwide. Ring control strategy, which involves targeted screening and treatment for taeniasis in households in proximity to heavily infected pigs, was shown to be effective when surveillance is carried out by research teams. However, for ring strategy to be sustainable, surveillance and reporting would ideally be implemented and maintained by community members. Community based participatory research (CBPR) theory suggests education alone is not sufficient to promote nor sustain this type of community-level behavior change. This was demonstrated in a recent education pilot study in which scarce adoption of community reporting led to inadequate parasite control in community-led ring strategy. By comparison, a process called SEPA has been shown to be effective and sustainable for dengue prevention in Nicaragua and Mexico. The process employs multiple modalities to socialize physical, economic, and epidemiologic evidence of disease in communities, and invests in developing community members' capacity to facilitate community-level behavioral change. In a mixed-methods pilot study involving 7 villages in Peru (pop. 1,673), we are applying a community-engagement intervention based on SEPA principles in an effort to improve adoption of community surveillance and reporting in ring-strategy. The main outcome measure is seroincidence of porcine cysticercosis in pigs born during the 12-month study period. Preliminary qualitative results are promising, including improved knowledge and retention of *Taenia* lifecycle, stronger statements of intention to change, and community generation of prevention and surveillance alternatives. Furthermore, increased willingness to publicly share experiences with *Taenia* (porcine cysticercosis, human taeniasis and neurocysticercosis) suggest this community-based process intervention also may diminish disease stigma, a previously stated barrier to behavior change and reporting. We will present methodologic insights and interim results of this on-going pilot study.

### A NOVEL MAGNETIC PARTICLE-BASED APPROACH FOR THE PURIFICATION AND CONCENTRATION OF MONOCLONAL ANTIBODIES FROM CELL CULTURE SUPERNATANT

**Agueda Perez**<sup>1</sup>, Luz Toribio<sup>1</sup>, Cindy Espinoza<sup>1</sup>, Kevin Martel<sup>1</sup>, Yagahira Castro-Sesquen<sup>2</sup>, Javier A. Bustos<sup>1</sup>, Theodore E. Nash<sup>3</sup>, Hector H. Garcia<sup>1</sup>, For the Cysticercosis Working Group in Peru<sup>1</sup>

<sup>1</sup>Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Department of International Health, Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Baltimore, MD, United States, <sup>3</sup>Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Affinity chromatography is the most common method of antibody purification. This method requires samples (serum or ascitic fluid) with high antibody concentrations. However, in other samples such as large volume cell culture supernatants (CCS), this method requires one or more pre-concentration steps, complicating the experimental procedure as well as potentially damaging the antibody's native structure due to precipitation. We used a magnetic-particle based platform to evaluate the performance of the Protein L which is a multi-domain bacterial surface protein that interacts with the variable region of the kappa light chain of many immunoglobulins without interfering with the antigen binding site. First, IgM antibodies were captured by a protein L monolayer covalently coupled to the surface of iron oxide magnetic particles (mean diameter 1µm); then these particles were separated by using a magnetic field within the first 2 minutes without the need for centrifugation, an ELISA assay was performed to evaluate the performance of the purification. Then, purified antibodies were eluted as usual using regular buffers utilized in

affinity chromatography (0.1M glycine pH2). Finally, the purified antibodies were concentrated by ultracentrifugation. The loading efficiency of this magnetic platform was 2000 IgM antibodies per mg of particles, in other words, in 100 ml of CCS, using 50 mg of particles, we obtained from 0.7 up to 1 mg of IgM antibodies; these particles can be re-used up to 15 times without affecting their purification performance (OD first use 2.41; last use 2.56). Furthermore, the ELISA assay showed a clear difference in the absorbance before and after purification (OD 0.89-2.23 and 2.42-2.92, respectively). SDS-PAGE analysis showed the presence of two bands corresponding to the molecular weights of 70kDa and 25kDa, related to IgM antibodies. The use of magnetic particles combined with an ultracentrifugation method can be exploited to purify and concentrate IgM monoclonal antibodies from CCS without damaging of the structure and simplifying the procedure.

### FIELD BASED SCREENING FOR CIRCULATING ANTIGEN IN URINE SAMPLES FOR THE DETECTION OF SEVERE FORMS OF NEUROCYSTICERCOSIS

**Percy M. Vilchez Barreto**<sup>1</sup>, Seth O'Neal<sup>2</sup>, Ricardo Gamboa-Morán<sup>1</sup>, Claudio Muro-Ecca<sup>1</sup>, Luz-Maria Moyano<sup>3</sup>, Michelle Beam<sup>2</sup>, Javier Bustos<sup>4</sup>, Sarah Gabriel<sup>5</sup>, Pierre Dorny<sup>2</sup>, Hector H Garcia<sup>4</sup>, for the Cysticercosis Working Group in Peru<sup>6</sup>

<sup>1</sup>Centro de Salud Global Tumbes, Tumbes, Peru, <sup>2</sup>School of Public Health, Oregon Health & Science University and Portland State University, Portland, OR, United States, <sup>3</sup>Epidemiology Unit, Hospital Regional IJAMO II-2, Tumbes, Peru, <sup>4</sup>Department of Microbiology, School of Sciences, Universidad Peruana Cayetano Heredia, Peru, <sup>5</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>6</sup>Universidad Peruana Cayetano Heredia, Tumbes, Peru

Neurocysticercosis (NCC), resulting from infection with *Taenia solium* larvae, exerts a heavy burden of epilepsy and other neurological disease in most developing countries. Infection is quite frequent in endemic regions: 5 to 20% of general population show antibody responses to cysticercosis and 10 to 20% of all villagers show residual brain calcifications in the very few available imaging studies performed in field conditions. In this context, while serological testing of endemic populations is easy and practical compared to imaging, the high prevalence of asymptomatic infection and the high background seroprevalence make it difficult to identify a practical outcome of serological screening initiatives. We aimed to screen a highly endemic population looking for the subgroup of individuals with elevated parasite antigens using noninvasive urine sampling, on the hypothesis that some asymptomatic villagers may harbor multicystic NCC or early subarachnoid NCC and may potentially benefit from early detection. We performed a cross sectional study in Sapillica (Piura, Peru). Initially, adult villagers were invited to provide a 5-ml urine sample that was processed in a sandwich ELISA using monoclonal antibody B158/B60. Those with high antigen levels were offered non-contrast magnetic resonance imaging of the brain machine including FLAIR and FIESTA sequences using a 1.5 T machine in a nearby city. Urine samples were collected from 429 out of 601 eligible participants. There were 25 participants with urine ELISA ratios above 2.5 (maximum 36.4). From these, 17 accepted to have a MRI performed. Three people had subarachnoid NCC diagnosed by MRI. In this population, a minimum of 0.7% of all sampled individuals had viable subarachnoid NCC. Urine antigen screening can identify asymptomatic individuals in early stages of subarachnoid NCC.

## ANGIOGENESIS AND BLOOD-BRAIN BARRIER DISRUPTION IN RAT MODEL FOR NEUROCYSTICERCOSIS

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States

The main infectious disease affecting the central nervous system (CNS) is caused by *T. solium* metacestode. This disease called Neurocysticercosis (NCC) is a major health problem in developing countries, especially in regions having poor sanitary conditions where pigs are raised. The study of molecular changes and host response in this infection have been difficult due to the organ affected. For this reason, animal models have been used in order to elucidate NCC pathology. A common feature presented in many CNS disease are vascular alteration and blood-brain-barrier (BBB) disruption, we hypothesized that angiogenesis and BBB disruption are presented in NCC as well. The following study uses a rat model for NCC to test this hypothesis exploring the expression of the vascular endothelial growth factor A (VEGF-A), the endothelial barrier antigen (EBA), and the presence of immunoglobulin G (IgG). Additionally, we used an *in vitro* experiment to test whether cysticercus antigens can induce angiogenesis. We found that VEGF-A is overexpressed in the tissue surrounding parenchymal and corticomeningeal cyst. BBB evaluation showed low expression of EBA in vessels close to the parasite and IgG was found in the tissue surrounding the cyst suggesting the compromise of the BBB. An endothelial cell tube formation assay using human umbilical vein endothelial cells (HUVECs), showed that excretory and secretory antigens of *T. solium* cysticercus can induce the formation of tubes. This data supports the idea that angiogenesis in NCC might be caused by the parasite itself and not only by the inflammatory response. Together this novel finding reports a new characteristic in NCC pathology and shows the effects of parasite antigens. These results indicate that further studies are needed to study the role the contribution of parasite antigen in BBB disruption in NCC.

## ANTIPARASITIC TREATMENT IN NOVEL RAT MODEL FOR NEUROCYSTICERCOSIS

**Gino Castillo**<sup>1</sup>, Lizbeth Fustamante<sup>1</sup>, Ana Delgado<sup>1</sup>, Rogger Carmen<sup>1</sup>, Maria del Carmen Ferrufino<sup>1</sup>, Javier Bustos<sup>2</sup>, Robert Gilman<sup>2</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Neurocysticercosis is an infection caused by the larvae stage of *Taenia solium* and it is considered an eradicable disease. Among symptoms associated with it are seizures, headache, dementia, and other neurological disorders. We have not known exactly how these symptoms are started but they are correlated with the parasite's viability stage. Using a rat model of neurocysticercosis we standardize a treatment using different combinations of albendazole, oxfendazole and praziquantel. Also we use magnetic resonance imaging and serology as a complement to check the efficacy of treatment. A total of 48 infected rats were divided in 3 groups: 17 rats received 30mg/Kg albendazole with 100 mg/Kg praziquantel, 17 rats received 100mg/Kg oxfendazole with 100 mg/Kg praziquantel, and 14 rats received vehicle solution as a control. We reduced the parasite's viability in 30% using albendazole, and 40% using oxfendazole, although treatment with oxfendazole caused an increment of 14.9% of fibrosis. MRI post-treatment was used to assess cyst resolution but it was not a good estimator when there are several cysts. Which both drug interventions we obtained all stages of viability as we can find in an infected human brain, therefore, it will allow us to study the underlying mechanisms associated with parasite's viability stage and pathological host response.

## POTENTIAL CROSS REACTION OF GP50 WITH TAENIA HYDATIGENA IN SEROLOGIC DIAGNOSIS OF PORCINE CYSTICERCOSIS USING ON ENZYME-LINKED IMMUNOELECTROTRANSFER BLOT (LLGP EITB)

**Claudio A. Muro**<sup>1</sup>, Percy M. Vilchez<sup>1</sup>, Ricardo Gamboa<sup>1</sup>, Luz María Moyano<sup>1</sup>, Luis A. Gómez<sup>2</sup>, Armando E. González<sup>2</sup>, Héctor H. García<sup>3</sup>, Seth E. O'Neal<sup>4</sup>, for the Cysticercosis Working Group in Perú (CWGP)<sup>5</sup>

<sup>1</sup>Centro de Salud Global - Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>2</sup>Facultad de Medicina Veterinaria, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>3</sup>Department of Microbiology, School of Sciences, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>School of Public Health, Oregon Health & Science University/Portland State University, Portland, OR, United States, <sup>5</sup>School of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

The antibody detection assay, enzyme-linked immunoelectrotransfer blot (LLGP EITB), is often used as a serologic marker of *Taenia solium* porcine cysticercosis exposure given its excellent reported performance (sens. 99%, spec. 100%). However, only a limited number of parasites were originally evaluated as potential cross reactors. Other *Taenia* sp. are often co-endemic, including *Taenia hydatigena* which also infects pigs, raising the possibility of potential cross-reaction. In particular, the specificity of the LLGP EITB diagnostic band GP50 has been questioned. Antigen-detection assays, such as the ELISA B158/B60, are known to cross-react with other *Taenia* sp. In an ongoing study in Tumbes, Peru, where a successful cysticercosis elimination demonstration project had previously been conducted, we routinely purchase 6-8 week-old seronegative piglets from community corrals to use as sentinels in a transmission study. We encountered a corral in which 14/19 (73.7%) of tested piglets were seropositive on LLGP EITB, all of which were reactive only to the GP50 diagnostic band. These piglets were also strongly positive to Ag-detection ELISA (mean ODR 51.4) suggesting active infection with *Taenia* sp. We were able to purchase 7 of these GP50 positive piglets for subsequent necropsy; in 4/7 we found active *T. hydatigena* metacestode infection while none had *T. solium* metacestode infection. We returned to the corral where these pigs were raised to capture and purge resident dogs with Arecolin; 2/5 of the dogs captured excreted *T. hydatigena* adult stage tapeworms in their stool. The results of this investigation suggest that the GP50 glycoprotein band on LLGP EITB is likely to cross-react with *T. hydatigena* in pigs and should be interpreted with caution. Controlled experimental infection of pigs with *T. hydatigena* and other related cestodes is needed to confirm whether there is indeed cross-reactivity. These results should not be generalized to the use of LLGP EITB for diagnosis of neurocysticercosis, as humans are not known to be susceptible to *T. hydatigena* infection.

## COMMUNITY ENGAGEMENT AND HEALTH EDUCATION TO INCREASE KNOWLEDGE OF THE TAENIA SOLIUM LIFE CYCLE IN NORTHERN PERU: BASELINE AND PRELIMINARY RESULTS

*Taenia solium* infection is a leading cause of acquired epilepsy in low and middle income countries. In Northern Peru, we are piloting a community-based research (CBR) intervention, inspired by a model called Socializing Evidence for Participatory Action (SEPA), which was developed in a community-level dengue prevention study. SEPA was shown to be effective in increasing community knowledge of dengue risk factors, as well as increasing community-developed prevention and control activities in Nicaragua and Mexico. The model includes sharing physical and epidemiologic evidence, while facilitating the collection of local knowledge through dialogue to plan community-led interventions. The model also emphasizes the formation of community-led work groups to provide outreach to community members and to develop locally relevant prevention and control strategies. Our pilot study, began in December 2016, includes 4 intervention and 3 comparison villages in northern Peru (pop. 1,673). Intervention villages are receiving the CBR approach described above, while comparison villages are receiving standard door-to-door education. Baseline data was collected on household-level knowledge of the *T. solium* life cycle, attitudes, social norms, intention to change behavior, and current *T. solium* prevention and control activities. Follow up household measures are being collected every 4 months. We are using qualitative methods to measure household-level knowledge, asking open-ended questions about three stages of the *T. solium* life cycle, then categorically classifying answers as correct or incorrect. Our poster will present results from baseline, 4-month, and 8-month follow up time points for the effects of our community-based, SEPA-inspired intervention on household-level knowledge of the *T. solium* life cycle, comparing proportional improvements in knowledge between the intervention and comparison groups.

## 493

### DIAGNOSIS OF TAENIASIS USING A FIELD ASSAY FOR DETECTION OF COPROANTIGENS IN RURAL COMMUNITIES OF NORTHERN PERU

**Ricardo Gamboa Moran**<sup>1</sup>, Seth O'Neal<sup>2</sup>, Percy Mc Quén Vilchez-Barreto<sup>1</sup>, Mayra Elizalde<sup>1</sup>, Luz-María Moyano<sup>3</sup>, Claudio Muro-Ecca<sup>1</sup>, Silvia Rodríguez<sup>4</sup>, Yesenia Castillo<sup>4</sup>, Armando E. González<sup>5</sup>, Robert H. Gilman<sup>6</sup>, Hector H. García<sup>4</sup>, for the Cysticercosis Working Group in Peru<sup>7</sup>

<sup>1</sup>Centro de Salud Global-Tumbes, Tumbes, Peru, <sup>2</sup>School of Public Health, Oregon Health & Science University and Portland State University, Portland, OR, United States, <sup>3</sup>Epidemiology Unit, Hospital Regional JAMO II-2, Tumbes, Peru, <sup>4</sup>Department of Microbiology, School of Sciences, Universidad Peruana Cayetano Heredia, Peru, <sup>5</sup>School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Peru, <sup>6</sup>Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, MD, United States, <sup>7</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

*Taenia solium*, the etiologic agent of neurocysticercosis, is an important cause of preventable epilepsy in low and middle income nations. The gold standard diagnostic test is the coproantigen-detection ELISA (CoAg ELISA) which has high sensitivity (98%) and specificity (99%) to detect *Taenia* species. However, the assay requires advanced laboratory infrastructure and expensive reagents which limits its use and results in delays in diagnosis. An inexpensive alternative that can be employed in rural health posts in endemic areas is needed. We previously developed a modified version of the assay (field CoAg ELISA) using commercial bottled water for preparation of the buffers, powdered milk in place of fetal bovine serum as a blocking agent, and a toner-based plate to bypass the need for a spectrophotometer. Reagents are stored at -20 °C instead of -70 °C. In

this study we compared the performance of the field CoAg ELISA against the standard CoAg ELISA, as described by Allan et al, in a set of 1602 stool samples collected from 9 endemic communities in Piura, Peru. 1.5 ml aliquots of stool stored in PBS 5% formaldehyde were used for both assays. Cut-off points used in Peru for the CoAg ELISA are: Negative, percent positivity (PP)<7.5; Suspect, repeat test 7.5≤PP<14; Suspect, collect additional sample 14≤PP<4; Positive, PP≥40). A previously developed visual scale of color intensity corresponding to these 4 cut-off levels was used to classify the samples using the field CoAg ELISA. Inter-test agreement was excellent when comparing 4 categories (k=0.92). When samples were categorized dichotomously as positive (PP≥40) or negative (PP<40) on the standard CoAg ELISA, and positive at only the highest color intensity category vs negative (all others), agreement was lower (k=0.67); however, the field CoAg ELISA detected all true positives (28/28; 100% sensitivity) and correctly identified most true negatives (1547/1574; 98.3% specificity). These results demonstrate that the field CoAg ELISA is an excellent alternative to the standard CoAg ELISA for diagnosis of taeniasis in regions without advanced laboratory infrastructure.

## 494

### SPATIAL AND TEMPORAL VARIATIONS IN TAENIA SOLIUM EXPOSURE AMONG PIGS IN RURAL PERU

**Ian W. Pray**<sup>1</sup>, Ricardo Gamboa<sup>2</sup>, Percy Vilchez<sup>2</sup>, Claudio Muro<sup>2</sup>, Luz María Moyano<sup>3</sup>, Armando E. González<sup>4</sup>, Hector H. García<sup>5</sup>, Seth E. O'Neal<sup>1</sup>, for the Cysticercosis Working Group in Peru<sup>5</sup>

<sup>1</sup>School of Public Health, Oregon Health and Science University and Portland State University, Portland, OR, United States, <sup>2</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Epidemiology Unit, Hospital Regional JAMO II-2, Tumbes, Peru, <sup>4</sup>School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>5</sup>Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

*Taenia solium*, the pork tapeworm, is a leading cause of seizure disorders in Peru. Humans carry the intestinal tapeworm and release infectious eggs into the environment during open field defecation. Past studies have shown that pigs testing positive for exposure to *T. solium* antibodies tend to cluster around the locations of human tapeworm carriers. Little is known, however, about how these spatial clusters vary over time in natural endemic settings. In this analysis, we examined the spatial-temporal patterns of seroincidence in pigs with the goal of identifying and characterizing persistent hotspots of *T. solium* transmission. This analysis was conducted on pigs from six rural villages in Peru. Serum samples were drawn from the full pig population every 4 months over a period of 16 months, and samples were analyzed with enzyme-linked immunoelectrotransfer blot (EITB) for antibodies against *T. solium* exposure. Incident seropositive pigs were those that had 1 or more reactive EITB band and were part of the at-risk cohort born into the villages during the study period. To detect spatial-temporal clusters, we used the SaTScan space-time scan statistic, which accounts for natural spatial variations in population density while scanning space-time windows for elevated disease rates. Overall, we detected 10 spatial-temporal clusters in the six study villages that had a combined rate ratio of 2.49 (95% CI: 2.29, 2.91), as compared to non-cluster pigs. The median cluster size had a radius of 170m (IQR: 115, 190) and spanned approximately 8 months. The existence of distinct spatial-temporal foci of transmission with extreme rates of disease occurrence indicates persistent (≥8 months) focal sources of *T. solium* eggs in the environment of endemic villages in rural Peru. These are likely attributable to persistent untreated tapeworm carriers residing in close proximity to cluster sites. Spatial-temporal analysis of pig infection may allow control programs to target persistent foci of transmission for anti-helminthic treatment or improved sanitation infrastructure, which may ultimately help reduce the burden of cysticercosis in these communities.

### EFFECTS OF IMMEDIATE VS. DELAYED IRON THERAPY ON NEUROBEHAVIORAL FUNCTION IN UGANDAN CHILDREN WITH SEVERE MALARIA

Meredith R. Hickson<sup>1</sup>, Paul Bangirana<sup>2</sup>, Andrew S. Ssemata<sup>2</sup>, Sarah E. Cusick<sup>3</sup>, Robert O. Opoka<sup>2</sup>, Maria Kroupina<sup>3</sup>, Chandy C. John<sup>4</sup>

<sup>2</sup>Makerere University College of Health Sciences, Kampala, Uganda,

<sup>3</sup>University of Minnesota Medical School, Minneapolis, MN, United States,

<sup>4</sup>Indiana University School of Medicine, Indianapolis, IN, United States

Malaria-induced inflammation may limit iron availability in the immediate post-infectious period, and may act on the developing brain via pathways similar to nutritional iron deficiency (ID). We conducted a randomized clinical trial to determine the effects of 4-week delayed (D) vs. immediate (I, current standard of care) iron therapy on neurobehavioral outcomes in children with severe malaria (SM) and ID. Children <5 years of age with severe malarial anemia (SMA) (n=77) or cerebral malaria (CM) (n=79), and healthy community children (CC) (n=83) were enrolled. All children with CM or SMA and 38 CC had ID as assessed by zinc protoporphyrin (ZPP) concentration ( $\geq 80 \mu\text{mol/mol}$  heme), and were randomized to I or D iron therapy. Assessments of executive function, socioemotional function, and observer-rated behavior were performed at baseline and 6 and 12 months later. At 12 months, no differences were seen in executive function, socioemotional function or observed behavior between the I and D arms in children with SMA, CM, or the CC. Delayed iron therapy does not appear to improve neurobehavioral outcomes in children with SM, but it is also unclear how many of these children require iron, since ZPP is affected by inflammation. Further investigation on which iron measures best reflect brain iron status may help to unravel the complex relationships between malaria infection, ID, and cognitive and behavioral development.

### PARASITIC INFECTIONS DURING PREGNANCY IN GABON: BIRTH OUTCOMES AND IMMUNOLOGICAL CHANGES

Ghyslain Mombo-Ngoma<sup>1</sup>, Maria Yazdanbakhsh<sup>2</sup>, Ayola Akim Adegnikia<sup>1</sup>, Peter G. Kremsner<sup>3</sup>, Michael Ramharter<sup>4</sup>

<sup>1</sup>Centre de Recherches Medicales de Lambaréné (CERMEL), Lambaréné, Gabon, <sup>2</sup>Leiden University Medical Centre, Leiden, Netherlands, <sup>3</sup>Institute for Tropical Medicine, University of Tübingen, Tübingen, Germany,

<sup>4</sup>Department of Internal Medicine, Division III Infectious Diseases, Medical University of Vienna, Vienna, Austria

Low birthweight (LBW) remains important in sub-Saharan Africa and particularly in Gabon. In a multicentre study in Benin, Gabon, Mozambique and Tanzania on HIV-negative pregnant women and their offspring, determinants of LBW were malaria, very young maternal age, first pregnancy, poor gestational nutrition and small stature of the mother. In Gabon, the major parasitic infections including malaria, schistosomiasis and *Loa loa* are common in pregnant women. Most research groups in affluent countries have assessed the interaction between helminths and host's immune system and whether by modulation of bystander responses, helminths could influence the outcome of vaccinations or inflammatory diseases or conditions such as pregnancy, and only a few groups have taken these questions to areas where helminth infections are highly endemic. We showed that malaria and urogenital schistosomiasis during pregnancy are associated with higher proportions of LBW in Gabon. In immunological studies maternal infection with *L. loa* was associated with expansion in the neonatal cord blood of functionally active regulatory T cells (Tregs) that kept Th1 and Th17 immune responses in check, providing some insights on the impact of *in utero* exposure on the offspring's development and health. Schistosomiasis was associated with significant increases of frequencies of Tregs that play an important role in controlling Th1 and Th2. Despite expansion of Tregs during loiasis and schistosomiasis, there was no evidence these changes induce adverse pregnancy outcomes,

raising the question regarding their clinical impact. Mefloquine as an alternative preventive treatment showed more effective than sulfadoxine-pyrimethamine in preventing malaria infection and anemia, despite a poor tolerability. Interestingly, it was effective against concomitant schistosomiasis suggesting it could serve as a combined intervention for both infections during pregnancy. More intervention studies are necessary to further determine whether getting rid of parasites either by screening, prevention or treatment strategies would improve the outcome of pregnancies in endemic areas.

### PREDICTING MORTALITY FOR ADOLESCENT AND ADULT PATIENTS WITH FEVER IN RESOURCE-LIMITED SETTINGS

Manuela Carugati<sup>1</sup>, Helen L. Zhang<sup>1</sup>, Venance P. Maro<sup>2</sup>, Matthew P. Rubach<sup>1</sup>, John A. Crump<sup>3</sup>

<sup>1</sup>Duke University Medical Center, Durham, NC, United States, <sup>2</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania,

<sup>3</sup>Centre for International Health, University of Otago, Dunedin, New Zealand

Febrile illnesses are a major cause of mortality in sub-Saharan Africa. Early identification of patients at increased risk of death may expedite interventions to avert adverse outcomes. We aimed to evaluate the performance of the Integrated Management of Adolescent and Adult Illness (IMAI) criteria, quick Sequential Organ Failure Assessment (qSOFA) score, Modified Early Warning Score (MEWS), Assimwe score, Rapid Emergency Medicine Score (REMS), and Rapid Acute Physiology Score (RAPS) to predict in-hospital mortality among a prospective cohort of febrile patients in Tanzania. We evaluated 420 patients aged 10 years or old hospitalized in the period 2007-08. Of the 45 patients who died, 32 (71.1%) were HIV-infected. The respiratory and central nervous system (CNS) were the most common sites of infection among the patients who died. At univariate analysis (OR [95%CI]), in-hospital mortality was significantly associated with peripheral oxygen saturation <90% [3.7 (1.7-8.0)], Glasgow coma scale <15 [11.4 (5.1-25.3)], haemoglobin <9 g/dl [4.5 (2.4-8.4)], CD4+ <200 cells/ $\mu\text{l}$  [4.1 (1.4-12.4)], and CNS infection [3.7 (1.8-7.9)]. IMAI severe respiratory distress without shock, IMAI severe pneumonia, qSOFA score  $\geq 2$ , and REMS score  $\geq 16$  were also significantly associated with in-hospital mortality. After controlling for confounders, only IMAI severe respiratory distress without shock (OR 3.2, 95% CI 1.2-8.3) and IMAI severe pneumonia (OR 2.6, 95% CI 1.2-5.6) remained significantly associated with in-hospital mortality, but areas under the receiver operating characteristic curve (AUROC) showed poor discrimination (0.57 [95%CI 0.47-0.66] and 0.61 [95%CI 0.52-0.70], respectively). Severity scores did not perform well in predicting fatal outcome among febrile in-patients in Tanzania. Although impractical, IMAI severe respiratory distress without shock and severe pneumonia criteria were significantly associated with in-hospital mortality. Further studies are needed to develop a robust and simple tool for early identification of severely ill febrile patients in sub-Saharan Africa.

### PREDICTING MORTALITY FOR ADOLESCENT AND ADULT PATIENTS WITH FEVER IN RESOURCE-LIMITED SETTINGS

Manuela Carugati<sup>1</sup>, Helen L. Zhang<sup>1</sup>, Venance P. Maro<sup>2</sup>, Matthew P. Rubach<sup>1</sup>, John A. Crump<sup>3</sup>

### ASSOCIATION OF MIRNA-122 WITH LIPIDS IN A SUB-POPULATION OF HYPERTENSIVE PATIENTS IN SUB-SAHARAN AFRICA

Ijeoma Angela Meka<sup>1</sup>, Samuel Onuzulike Ebede<sup>1</sup>, Obumneme Benneth Anyim<sup>2</sup>, Martin Chukwuka Ugonabo<sup>1</sup>

<sup>1</sup>University of Nigeria, Enugu, Nigeria, <sup>2</sup>University of Nigeria Teaching Hospital, Ituku-Ozalla, Enugu, Nigeria

Dyslipidemia contributes to atherosclerosis and is a risk factor for cardiovascular disease. miRNA-122 is liver specific with suggested roles in cholesterol, fatty acid and lipid metabolism. This study was aimed at determining the association between dyslipidemia and plasma levels of miRNA-122. Triglycerides, total cholesterol, high density lipoprotein-cholesterol (HDL-c) and Low density lipoprotein-cholesterol (LDL-c) were quantified in plasma samples of hypertensive (n=200) and control (n=200) subjects. miRNA-122 was extracted and quantified with qPCR. Lyophilized qPCR miRNA-122 template standards were obtained from Origene Technologies, Rockville, USA. After lipid profile analysis, subjects were further divided into dyslipidemic and non-dyslipidemic groups. Results show that 44% (n=88) of hypertensive patients and 23.5% (n=47) of the control group had dyslipidemia. Dyslipidemic hypertensives and controls showed significantly ( $p < 0.05$ ) higher levels of miRNA-122 when compared with non-dyslipidemic subjects. LDL-c and total cholesterol showed significant positive correlation with miRNA-122 ( $r = 0.53$ ,  $r = 0.51$  respectively,  $p < 0.05$ ). Whereas correlation with triglycerides and HDL-c was weak and not significant ( $r = 0.10$ ,  $r = -0.10$  respectively,  $p > 0.05$ ). This findings support earlier studies suggesting that miRNA-122 may have a role in lipogenesis. Therapeutically targeting miRNA-122 using RNA-based gene silencing strategies will possibly ameliorate dyslipidemia, thereby reducing the risk of atherosclerosis and cardiovascular disease.

### Q FEVER IN SOUTHERN CALIFORNIA, A CASE SERIES OF TWENTY-ONE PATIENTS

Christine M. Akamine<sup>1</sup>, Mario L. Perez<sup>2</sup>, Michael B. Ing<sup>3</sup>

<sup>1</sup>Loma Linda University Health, Loma Linda, CA, United States, <sup>2</sup>Kaiser Permanente Fontana Medical Center, Fontana, CA, United States, <sup>3</sup>VA Loma Linda Healthcare System, Loma Linda, CA, United States

Q fever was first described in Southern California in 1947, when the dairy industry was flourishing and geographically concentrated. It was found to be endemic and enzootic to the region, mostly associated with exposure to livestock. Since the 1950s few regional studies have been conducted. We describe 21 patients diagnosed with Q fever in Southern California with the aim of contributing toward the understanding of Q fever and its clinical presentation, geographic distribution and risk factors. A retrospective chart review was conducted on patients diagnosed with Q fever at our institution between 2000 and 2016. Cases were categorized as either acute or chronic based on available titers. Demographic information, laboratory data, imaging results, data on risk factors and treatment were reviewed and analyzed. The majority of patients presented with an acute febrile illness (85.7%), other common presenting symptoms included headache, cough, hepatomegaly, and arthralgias or myalgias. In 12 of the 21 cases, diagnostic titers were obtained greater than 15 days from symptom onset and 57.1% of cases went on to develop either chronic infection or death. Q fever was thought to be a contributing factor to death in most cases. The geographic distribution of cases appeared to favor rural and less populated areas. The delay in obtaining diagnostic titers by more than 15 days for the majority of patients was associated with increased severity and mortality seen in the cases. The majority of the chronic cases went on to develop endocarditis, which is the most common manifestation of chronic Q fever. We feel that Q fever is underdiagnosed in this region, which can be attributed to its frequent asymptomatic presentation or ability to present with nonspecific symptomatology. Cases in Southern California continue to occur intermittently over long periods of time in a long-standing endemic pattern. Although further epidemiologic studies are needed, it appears that the locality of our cases was closely linked with local dairy farms.

### ANTI-MOSQUITO SALIVA IMMUNITY, MAST CELLS AND CLINICAL PRESENTATION OF DENGUE

Karina A. Luque-Burgos<sup>1</sup>, Berlin L. Londono-Renteria<sup>2</sup>, Michael Conway<sup>3</sup>, Natasha Duggan<sup>4</sup>, Jenny C. Cardenas<sup>5</sup>, Tonya M. Colpitts<sup>6</sup>

<sup>1</sup>Erasmio Meoz Hospital, Cucuta, Colombia, <sup>2</sup>Kansas State University, Manhattan, KS, United States, <sup>3</sup>Foundational Sciences, Central Michigan University College of Medicine, Mount Pleasant, MI, United States, <sup>4</sup>University of Miami, Miami, FL, United States, <sup>5</sup>Los Patios Hospital, Los Patios, Colombia, <sup>6</sup>University of South Carolina, Cucuta, SC, United States

Mosquito saliva has a profound impact on transmission of vector-borne pathogens such as dengue virus (DENV) and immunity against saliva modifies the local response during pathogen transmission. To investigate the effect with of anti-saliva immunity, we measured IgG and IgE antibody levels against DENV and *Ae. aegypti* salivary proteins, in volunteers from a DENV endemic area. We also looked at the impact of antibodies on the role of mast cells by incubating pre-sensitized human mast cells (LAD2) with human serum from dengue patients. We found that histamine levels in the supernatant of pre-sensitized mast cells were significantly correlated with total anti-DENV-IgG antibodies, and that IgG antibody levels against salivary D7-long protein were significantly correlated with TNF $\alpha$  gene expression in mast cells challenged with SGE. We also found a significant association between platelet count and TNF $\alpha$  gene expression in mast cells challenged with DENV and SGE, while leucocyte count was associated with histamine concentration. DENV infection and mast cell degranulation were significantly correlated with anti-DENV-IgG4 antibodies

levels. We also found that DENV-exposed individuals presented higher hybrid IgG4 molecules when compared with European controls, although total IgG4 antibody levels were not significantly different between the groups. Our data also showed a significant positive correlation between the concentration of hybrid DENV-SGE antibodies and the immune response against salivary proteins in controls versus dengue patients. We hypothesize that the presence of hybrid DENV-SGE antibodies may influence antibody-mediated responses against dengue. Thus, we prepared antibody fractions and incubated them with U937 monocyte cell line and primary dendritic cells along with DENV. Our pilot analysis showed significant differences in virus infection in cells incubated with either specific anti-DENV, anti-SGE or hybrid antibodies. The full results will be discussed during the presentation.

### **CORD BLOOD MATERNAL MICROCHIMERISM PREDICTS DECREASED RISK OF NON-MALARIAL FEVER DURING CHILDHOOD**

**Whitney E. Harrington<sup>1</sup>**, Sami Kanaan<sup>2</sup>, Robert Morrison<sup>3</sup>, Michal Fried<sup>3</sup>, Patrick Duffy<sup>3</sup>, J. Lee Nelson<sup>2</sup>

<sup>1</sup>Seattle Children's Hospital/University of Washington School of Medicine, Department of Pediatrics, Seattle, WA, United States, <sup>2</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>3</sup>National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Despite large improvements in global childhood mortality in the last 20 years, an astonishing 5.9 million children died before their fifth birthday in 2015. Three of the top five causes of death are infectious, including pneumonia, diarrhea, and neonatal sepsis. Little is known about the host intrinsic factors that affect susceptibility to these illnesses, and in particular, thus far overlooked is the role of a small number of maternal cells and DNA acquired by the fetus during pregnancy, known as maternal microchimerism (MMC). We recently found that children with MMC at delivery were more likely to become infected with malaria but, surprisingly, when infected were less likely to become sick or to be hospitalized as compared to children without MMC. We hypothesized that this effect is the result of maternal regulation of pro-inflammatory fetal and infant immune responses, limiting immune-mediated pathology, and that such regulation may extend to other infections of global health importance. We additionally hypothesized protection from those infections in which pathology may be immune-mediated (e.g. pneumonia) but a neutral effect for those in which pathology is predominantly pathogen-mediated (e.g. diarrheal illness). Using samples and data from a nested birth cohort from Tanzania, we investigated the ability of MMC to predict four outcomes in longitudinal models: 1) non-malaria fever, 2) non-malaria hospitalization, 3) lower respiratory tract infection, and 4) diarrheal illness. Cord blood MMC was protective against non-malarial fever (AOR=0.42, p=0.01) but not non-malarial hospitalization. In addition, there was a suggestion of protection against lower respiratory tract infection (AOR=0.72, p=0.2) but not diarrheal illness. In conclusion, MMC may protect from immune-mediated pathology secondary to common childhood infections, which has broad implications for perinatal and postnatal infections and response to immunization. Future studies should investigate the direct effect of maternal cells on fetal and infant immune responses.

### **WHERE HAS THE BLOOD GONE IN PATIENTS WITH SEVERE ANAEMIA IN SEVERE MALARIA DUE TO PLASMODIUM FALCIPARUM INFECTION AND SEPTICEMIA**

**Babajide J. Puddicombe**, Banji Oyegbami, Tolulope A. Puddicombe

*Malaria Society of Nigeria, Lagos, Nigeria*

Malaria tops the list of sicknesses seen regularly by most general practitioners especially at the grassroots in Lagos Nigeria. Between 1991

and 2014, 10,721 patients were treated for malaria in our grassroots hospital located in Bariga a high density area of Lagos state Nigeria. All but 9 cases responded very well to treatment. The 9 cases presented with severe anaemia as a complication. The first case died, 8 survived but one was almost fatal. Trying to correct the severe anaemia with blood transfusion was counterproductive. The improvement in the haemoglobin level of the patients after the transfusion was short lived as the patient became pale again within 24 to 72 hours of the transfusion. Further transfusion was of no use as the patient reverted to square one. The liver and spleen which might not be palpable on admission gradually became so and could attain huge sizes. None of these 9 patients had haematemesis or melena. Jaundice if present was mild. Bilirubin and urobilinogen if raised, were just slightly so. In 2014, this picture which was hitherto seen in patients with severe malaria due to *Plasmodium falciparum* infection was also seen in our 9th case who presented with sepsis. In the absence of indexes of severe haemolysis, haematemesis and melena capped with the phenomenon of transient improvement in haemoglobin level after blood transfusion, a pertinent question to ask is where has the blood gone in these patients? In a country with a galloping inflation and a national minimum wage less than \$50 per month, the grassroots from where all these cases came cannot afford the investigations that will be required for more detailed studies on a large scale. We look forward to getting sponsors for the project.

### **ASSESSMENT OF ENDOTHELIAL PROGENITOR CELLS IN HYPERTENSIVE DISORDERS OF PREGNANCY**

**Dorotheah Obiri<sup>1</sup>**, Daniel Oduro<sup>2</sup>, John Tetteh<sup>3</sup>, Thomas Addison<sup>3</sup>, Amma Larbi<sup>3</sup>, Emmanuel Kakra Dickson<sup>3</sup>, Kwame Adu-Bonsaffoh<sup>4</sup>, Samuel A. Obed<sup>4</sup>, Kwadwo A. Kusi<sup>3</sup>, Michael Ofori<sup>3</sup>, Ben Gyan<sup>3</sup>

<sup>1</sup>West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana, <sup>2</sup>Cornell University, New York, NY, United States, <sup>3</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>4</sup>Department of Obstetrics and Gynecology, Korlebu Teaching Hospital, Accra, Ghana

Hypertensive disorders of pregnancy particularly preeclampsia, are a global challenge associated with maternal and foetal mortality. The resultant systemic inflammation has been linked to endothelial activation and subsequent dysfunction to the endothelium. Host immune response to this damage has been associated with the recruitment of rare endothelial progenitor cells (EPCs) to sites of damage where they repair or form new blood vessels. This study accessed the levels of endothelial progenitor cells in women having a normal delivery and those diagnosed with hypertensive disorders in pregnancy. EPCs were measured by the co-expression of surface antigens on progenitor cells originating from the bone marrow to sites of injury. EPC levels from normal pregnancy (controls) and hypertensive disorders (cases) were estimated using antibodies specific to CD309, CD34, and CD133. Blood was sampled from the peripheral, cord and placental blood. The percentage EPC levels were assessed at the different blood collection sites (periphery, cord, and placenta) in normal and hypertensive pregnancies. No difference were found in these sites between cases and controls. A higher number of EPCs were found in the placental blood than the cord blood among normal pregnancies. Placental and peripheral blood did not show any significant difference. For hypertensive pregnancies, there was a higher number of EPCs in the placenta compared to periphery but not in the cord blood. The high levels of EPCs in the placental blood for both normal and hypertensive pregnancies indicate the high vascularisation that occur within the placenta. Lower EPCs in peripheral blood in hypertensive pregnancy might indicate an impaired endothelial repair hence the pathology.

**JAPANESE ENCEPHALITIS VACCINE: IS THE BOOSTER DOSE REGULARLY ADMINISTERED?**

**Ana Pinto de Oliveira**<sup>1</sup>, João Valente<sup>2</sup>, Amélia Robalo<sup>2</sup>, Margarida Cosme<sup>2</sup>

<sup>1</sup>Public Health Unit Arnaldo Sampaio, Lavradio, Portugal, <sup>2</sup>Public Health Unit Almada-Seixal, Almada, Portugal

Japanese encephalitis (JE) is one of serious vector-borne viral encephalitis disease found worldwide, especially in Asian, the Western Pacific countries, and in northern Australia. Although JE rarely affects travellers, its serious consequences and unpredictable epidemiology makes its prevention a very important part of the pre-travel consultation. The aim of this study was to evaluate the JE vaccination patterns of travellers into a pre-travel consultation. For this purpose, we used the electronic centralized vaccination database (ARSLVT, I.P.) to collected data of prescribed JE vaccines, from the Travelers Medical Center of ACES Almada-Seixal, Portugal, between January 2000 and December 2015. The nominal information extracted included, sex, date of birth, vaccine type, vaccine scheme and inoculation date. Data was entered into Microsoft Excel® and descriptive analyses performed. Of the 374 surveyed travellers, 228 (61%) were male, 146 (39%) were female, and the mean age was 41 years (range: 18-83 years). Regarding the JE vaccine, 240 had received the total scheme of the vaccine (25% JE-VAX conventional, 8% JE-VAX accelerated, 25% IX-conventional, 11% IX-accelerated), and 134 had been given only the first dose. Regarding the booster dose, only 5 (1%) travellers had received the vaccine, 2 had not yet received it and 367 had no administration dates. Results shows that the majority of individuals who had been previously immunized with JE vaccine before traveling, had not administrated the booster dose after arrival.

**DYING ONE WAY OR ANOTHER: AN ANALYSIS OF COMBAT AND NON-COMBAT DEATHS AMONG U.S. TROOPS IN VIETNAM, 1960-1975**

**David Adams**<sup>1</sup>, Femi Taiwo<sup>1</sup>, Joseph Miller<sup>2</sup>, Valerie Adams<sup>2</sup>, Kali Neil<sup>3</sup>

<sup>1</sup>Point University, Savannah, GA, United States, <sup>2</sup>Armstrong State University, Savannah, GA, United States, <sup>3</sup>Baltimore County, Public Health, Baltimore, MD, United States

An extensive literature exists on US casualties of the Vietnam War, 1960-1975. Much, however, has focused attention on mortality from engagements with pro-communist forces. An equally large body of literature has examined morbidity and mortality from infectious diseases, not least malaria. One largely ignored area of research, however, is mortality as the result of personal and interpersonal violence. More specifically, in-country deaths caused by "suicide"; "intentional" and "accidental" homicide; and "accidental self-destruction". This study will draw on archival data (RG 330) from the National Archives of the United States. We will compare "cases" (deaths by "accidental homicides," "intentional homicides," "accidental self-destruction," and "suicide") with a randomly selected group of "controls" who were killed during engagements with Vietnamese communist forces. Analysis of these data reveals that risk for specific types of non-combat violent death and in-country survival differentials significantly varied according to a number of factors, i.e., proximity to the Demilitarized Zone (DMZ), rank, service branch, climatological factors, and time of year—not least holidays such as Thanksgiving and Christmas.

## 506

**LIFE AND DEATH IN 17TH CENTURY JAMAICA: TROPICAL DISEASE AND BRITISH COLONIAL AMBITIONS**

**David Adams**<sup>1</sup>, Valerie Adams<sup>2</sup>, Femi Taiwo<sup>1</sup>, Kali Neil<sup>3</sup>, Joseph Miller<sup>2</sup>

<sup>1</sup>Point University, Savannah, GA, United States, <sup>2</sup>Armstrong State University, Savannah, GA, United States, <sup>3</sup>Baltimore County, Public Health, Baltimore, MD, United States

Much has been written about the rise of European colonization of the Americas in the 16th and 17th centuries. To the British went various slices of the Americas, to the French others, to the Spanish others, and to the Portuguese yet others. Therein lay the problem, however, as these nations maneuvered for control of as much territory as possible. It was the Caribbean, though, that proved an especially interesting international free-for-all. This presentation is a case-study of the impact of tropical disease on British troops in Jamaica during the 1650s. Although accounts by the ranks are few, those written by their officers offer an important window into maladies that afflicted officers and men alike. They shed significant light on infectious diseases that often killed more efficiently than a Spanish or French sword or round. Utilizing the first-hand account by General Robert Venables, this study highlights the impact of tropical diseases on British ambitions in mid-17th century Jamaica.

## 507

**TELEPHONE ADMINISTRATION OF THE PATIENT SPECIFIC FUNCTIONAL SCALE (PSFS): A VALID, RELIABLE, AND PATIENT-REPORTED OUTCOME IN GLOBAL SNAKEBITE RESEARCH**

**Rebecca G. Theophanous**<sup>1</sup>, Joao R. Vissoci<sup>1</sup>, Victoria E. Anderson<sup>2</sup>, Eric J. Lavonas<sup>3</sup>, Charles J. Gerardo<sup>1</sup>

<sup>1</sup>Duke University Medical Center, Durham, NC, United States, <sup>2</sup>Rocky Mountain Poison & Drug Center - Denver Health, Denver, CO, United States, <sup>3</sup>University of Colorado School of Medicine, Aurora, CO, United States

The lack of inexpensive, reliable, validated patient-reported outcomes (PRO) is a gap in global snakebite trials. With the widespread use of cellphones in LMIC, a telephone-administered validated PRO would be a useful tool in future trials. In a recent snakebite clinical trial the in-person administered Patient Specific Functional Scale (PSFS) performed well. Telephone administered PSFS was used between in-person assessments. The objective of this study is to determine if the administration of PSFS via telephone has similar performance to in-person administration in snakebites. We performed a secondary analysis of the "The Efficacy of Fab Antivenom versus Placebo plus Optional Rescue Therapy on Recovery from Copperhead Snake Envenomation: a Randomized, Double-Blind, Placebo-Controlled Clinical Trial." We compared telephone to in-person administration of PSFS by evaluating the following scale psychometric properties: (a) content validity (ceiling and floor effects), (b) internal structure and consistency (Cronbach's alpha coefficient), and (c) temporal and external validity using Intraclass Correlation Coefficient (ICC). In-person PSFS was performed on 3, 7, 14, 21 and 28 days post-envenomation. Telephone PSFS was performed on 10, 17, 24, and >28 days post envenomation. All seventy-four patients were included in the analysis. The mean age was 43 (SD17.6) years. Fifty-two percent were male and 89% were adults. There was a tendency towards floor effects in the total PSFS with a median score of 3 (range 0–8) and Q1 0–0, Q3 5–8, with 28% of the participants scoring 0 at baseline. At follow up, the ceiling effects were seen as the median total PSFS score was 9 (range 5–10) with Q1 5–8, Q3 10–10, and 48% of the participants scored 10. We found good to excellent internal consistency (Cronbach alpha 0.91 (95% CI 0.88, 0.95) in-person and 0.81 (0.73, 0.80) via telephone. There was good temporal stability with ICC 0.83 (0.72, 0.89) in-person and

0.80 (0.68, 0.88) via telephone. Telephone-administered PSFS is a valid and reliable PRO to assess recovery in snakebite compared to in-person administered PSFS.

### RICKETTSIOSIS IN PEDIATRIC PATIENTS: CLINICAL SERIES IN LABORATORY CONFIRMED CASES IN SOUTHERN MEXICO

**Martin Inurreta**<sup>1</sup>, Karla Dzul-Rosado<sup>2</sup>, Cesar Lugo-Caballero<sup>2</sup>, Salvador Gomez-Carro<sup>3</sup>, Nina Mendez-Dominguez<sup>1</sup>

<sup>1</sup>Universidad Marista de Merida, Merida, Mexico, <sup>2</sup>CIR-Hideyo Noguchi, Unidad Biomedica, Merida, Mexico, <sup>3</sup>O'Horan General Hospital, Merida, Mexico

Wild and domestic animals can be carriers of ectoparasites like ticks, fleas or dust mites, which constitute vectors of *rickettsial* infections in humans. The identification of epidemiological traits and clinical manifestations of the infection and is relevant for clinical research purposes regarding the true incidence and physiopathological processes associated with *rickettsial* infections. In the state of Yucatan, Mexico four confirmed cases of rickettsioses were reported by the Department of Epidemiology in 2016. *This study was undertaken to analyze the epidemiological and clinical characteristics of four confirmed cases. The four cases occurred in different locations, but the exposure to dog's ectoparasites was reported in all four cases. Common clinical manifestations were fever, rash, blood analysis regarding leukocytosis, neutrophilia and presence of lymphopenia with or without hepatic or splenic hypertrophy. We observed that the presence of antecedents of contact with the arthropod vector in domestic dogs were readily advised by the family members of the patients. However, we cannot assure that it was intentionally investigated during the initial anamnesis in the first medical consultation. Without a doubt, the anamnesis is an orienting process and it is relevant in the process of differential diagnosis, which is why it should not be ignored during the initial medical consultations nor in the elaboration of hospital clinical histories. Each of the four cases were poorly diagnosed. The patients' symptomatic profiles of fever and rash were misdiagnosed with viral entities transmitted by the Aedes vector. The doctors who made the diagnoses did not initial suspect the presence of a bacterial infection. Even though the emergent and reemerging illnesses transmitted by vectors of the Aedes genre have been the cause of recent epidemics in the region, it is always important to conduct a pertinent anamnesis that will allow one to distinguish between different etiologies, particularly when the existing evidence does not support a viral profile.*

## 509

### IDENTIFYING RISK FACTORS FOR PERINATAL DEATH AT TORORO DISTRICT HOSPITAL, UGANDA

**Martha A. Tesfalul**<sup>1</sup>, Paul Naturreba<sup>2</sup>, Nathan Day<sup>2</sup>, Stephanie G. Valderramos<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Tororo, Uganda

Many countries in sub Saharan Africa face a disproportionate burden of perinatal deaths, defined as stillbirths (fetal deaths before delivery, at or after 22 weeks gestation) and neonatal deaths within 7 days of birth. However, data to inform targeted interventions is often lacking. To identify risk factors for perinatal death, we conducted a retrospective case-control study using data from birth registers at Tororo District Hospital, Uganda on all cases of pregnancies with perinatal deaths from January to December 2014. Controls were derived from the admissions immediately preceding and following the cases of perinatal death. There were 185 case pregnancies with perinatal deaths, including 7 sets of twins with 2 perinatal deaths each, and 354 control pregnancies. Stillbirths accounted for 145/192 (75.5%) of the perinatal deaths, and 69/145 (47.6%) of these were "macerated," that is with findings suggestive of death prior to labor. The remaining 47/192 (24.5%) of perinatal deaths were neonatal demises. The following factors were associated with increased risk of perinatal

death: prematurity (odds ratio (OR) 19.9; 95% confidence interval (CI) 7.6 - 65.3), multiple gestation (OR 8.0; CI 2.8-27.7), breech presentation (OR 8.0, CI 1.6-77.1), low birth weight (OR 6.8; CI 4.1-11.5), antepartum hemorrhage (OR 3.6, CI 1.1-13.7). Presenting in spontaneous labor (OR 0.1; CI 0.1-0.3) and vaginal delivery (OR 0.3; CI 0.2-0.6) were associated with decreased risk of perinatal death. There were no associations between perinatal death and nulliparity, HIV infection, preeclampsia, or prior uterine scar. To assess for factors more likely associated with perinatal death during or secondary to labor, fresh stillbirths and neonatal deaths were compared to macerated stillbirths. Multiple gestation (OR 3.4; CI 0.9 - 18.9) and presentation in labor (OR 2.8; CI 1.4 - 5.6) were the only of the aforementioned factors that were associated with increased risk of perinatal death during or after labor and delivery rather than before. Our results identify potential areas for focused intervention to decrease the frequency of adverse birth outcomes in similar settings.

## 510

### CREATIVE SOLUTIONS FOR NEONATOLOGY CARE IN A LIMITED RESOURCE SETTING IN BURUNDI

**Alyssa A. Pfister**

Hope Africa University, Bujumbura, Burundi

Kibuye Hope Hospital (KHH) is a rural hospital that serves approximately 2 million people in the center of Burundi. To address the high rates of morbidity and mortality for premature infants in the region, a Neonatal Intensive Care Unit (NICU) was developed using creative solutions despite limited resources. The 11-bed NICU was opened in September 2016. Common complications of prematurity and challenges related to limited resources were addressed in the following innovative ways: Hypothermia: Incubators were designed and fabricated using local materials including a battery back-up system. Limited nursing staff: Hospital engineers created a unique bed design with built-in incubator to enable mothers to stay with their babies under a shared mosquito net. Mothers are educated in how to express breast milk and give it to their infants via nasogastric tube. Jaundice: The Bili-Hut™ provides portable phototherapy to treat neonatal jaundice. Respiratory complications: Prophylactic aminophylline is given to premature infants to reduce the risk of apnea of prematurity given the lack of continual monitoring. No surfactant is available to treat respiratory distress syndrome, but oxygen by nasal cannula assists many premature infants. Infections: No cultures are available, but two negative CRPs are used as a surrogate for eliminating the risk of bacterial sepsis and thus stopping unnecessary antibiotics. Risk of necrotizing enterocolitis (NEC): Given the lack of parenteral nutrition available, prevention of NEC is the primary goal through slow advancement of expressed breast milk feeds. At the first signs of feeding intolerance, feeds are stopped and D10 is given along with broad-spectrum antibiotics. In the first 6 months after the opening of the NICU, 172 patients were admitted including transfers from surrounding provinces. Babies with birth weights as low as <900 grams and gestational ages <28 weeks have survived. The overall mortality rate is 29.7%. Forty infants have been treated for neonatal jaundice. Mothers have learned how to effectively care for their infants and mother-baby bonding has been enhanced through the unique KHH bed design.

## 511

### MITIGATING IRON DEFICIENCY ANEMIA IN SCHOOL AGED CHILDREN IN MADURAI, INDIA

**Sidarth R. Ganpati**

Edgemont High School, Scarsdale, NY, United States

Iron Deficiency Anemia (IDA) is one of the most common nutritional deficiencies in the world. The objective of our research was to demonstrate to the Balamandram school and City of Madurai that IDA can be significantly mitigated via cost effective intervention. The research was conducted in two stages. The first stage consisted of demonstrating that IDA levels can be mitigated via iron and vitamin supplements. The second part of the research consisted of developing a diet plan that

would augment iron levels by similar amounts as the supplements yet be much more cost effective and easy to implement. The goal was to convince the Balamandiram School and Corporation of Madurai to increase funds for mitigating IDA and bringing the children's IDA levels above the WHO recommended thresholds. The first part of the study involved measurement of IDA levels bi-monthly which allowed for close and consistent monitoring of the effectiveness of the newly introduced iron and vitamin supplements. Over a 15-month period, the research demonstrated a 19.3% average improvement in hemoglobin levels for the 34-student (ages 7-17) control group. While almost all students in the control group showed low (well below WHO thresholds) hemoglobin levels initially, the iron and vitamin supplements helped the 7-9 and 10-11 age groups significantly improve their hemoglobin levels and surpass the WHO thresholds. The other age groups also demonstrated significantly improved hemoglobin levels although they were still slightly under the WHO thresholds for their age brackets. Although the supplements provided to the students proved to be effective and won approval from the school, the cost of the supplements were considered too high. Therefore, the second part of the research consisted of working with the Food Technology Department at Fatima College in Madurai to develop a diet based iron augmentation that provided an equivalent amount of nutritional iron. The Corporation of Madurai approved additional funds of \$0.30 per student per day for the augmented diet, a 66.67% increase.

## 512

### INCIDENCE OF SERIOUS PATHOLOGY IN PATIENTS PRESENTING WITH CHRONIC LOW BACK PAIN IN A SUB-SAHARAN AFRICAN OUTPATIENT SETTING

Michael Parsa<sup>1</sup>, Peter Halestrap<sup>2</sup>, Alysa Nash<sup>1</sup>

<sup>1</sup>Paul L. Foster School of Medicine, Texas Tech University Health Sciences Center, El Paso, TX, United States, <sup>2</sup>Africa Inland Church (AIC) Kijabe Hospital, Kijabe, Kenya

Locally applicable diagnostic guidelines for patients presenting with chronic low back pain in sub-Saharan Africa are lacking. Local practice typically includes lumbar spine x-rays and an erythrocyte sedimentation rate, but there is no evidence to justify this practice. To determine whether current developed world recommendations should be used or the current local practice continued, the incidence of serious pathology in chronic low back pain patients presenting in these settings must be more clearly understood. This study seeks to evaluate the incidence of serious pathologies in patients presenting with more than one month of low back pain to the outpatient department of a rural hospital in Kenya. IRB approval was obtained from the hospital. Patients presenting to the outpatient clinic at AIC Kijabe hospital in July 2015 endorsing low back pain lasting longer than 1 month with no previous diagnosis for their symptoms were included. Final diagnoses were evaluated for serious pathology defined as infection (bacterial, tuberculosis, HIV/AIDS related), or cancer (primary or metastatic), and the prevalence of these serious etiologies was calculated. Preliminary results of 40 patients indicate a serious pathology rate of 10%, with a possible rate of 17.5% (some diagnoses were inconclusive). Of the 4 cases with serious pathology identified, 3 were attributable to tuberculosis (7.5%) and 1 was confirmed malignancy (2.5%). This is significantly higher than reports from the developed world of 0.7% and 0.01%, respectively. This pilot study indicates significantly higher rates of serious pathology in patients presenting with low back pain in a sub-Saharan African setting than in the developed world. This is congruent with similarly conducted studies in African settings, and suggests that the local diagnostic practice may be justified. Further studies conducted with a larger sample size and more varied population are needed to assess whether these results translate to the sub-Saharan African population on a larger scale.

## 513

### PREVALENCE OF SKIN CONDITIONS IN SCHOOLCHILDREN IN URBAN WESTERN AND NORTHERN UGANDA

Aileen Y. Chang<sup>1</sup>, Amy Scheel<sup>2</sup>, Alyssa Dewyer<sup>2</sup>, Ian Hovis<sup>2</sup>, Craig Sable<sup>2</sup>, Toby Maurer<sup>1</sup>, Andrea Z. Beaton<sup>2</sup>

<sup>1</sup>University of California San Francisco, Department of Dermatology, San Francisco, CA, United States, <sup>2</sup>Children's National Health System, Division of Cardiology, Washington, DC, United States

Skin conditions account for 25% of physician visits in sub-Saharan Africa, but there are few studies reporting skin disease prevalence in the community. Within the structure of a larger group A streptococcal study in Uganda, aimed at understanding drivers of rheumatic heart disease (RHD), our aims were (1) to determine prevalence of skin conditions seen in children and (2) to characterize skin bacterial infections--which some data suggest may contribute to RHD. Consented children at 3 primary public schools in Mbarara (west) and Gulu (north) were eligible for skin examination. Nurses conducted total body skin exams, except for the anogenital region and female breasts. The dermatology team then evaluated those with positive screens. Bacterial infection was defined as clinical evidence of impetigo, cellulitis, folliculitis, furuncles, pustules, and abscesses. When pus or crust was present on exam, a specimen was obtained and stored/transported in STGG (skim milk, tryptone, glucose, glycerin) media for microbiology culture and sensitivity. For cases of tinea capitis presenting with pustules, a specimen was obtained for microbiology, but these cases were not considered to be clinically suspected bacterial infection as tinea capitis can present with pustules. Of 3,261 children screened, 41% (1310/3261) had a skin condition including: tinea capitis (71%), tinea corporis (9.6%), eczematous dermatitis (4.5%), acne (4.1%), trauma (3.0%), tinea versicolor (2.3%), post-inflammatory changes (2.3%), interdigital toe web infection (2.1%), clinically suspected bacterial infection (1.8%), warts (1.3%), arthropod bites (0.8%), seborrheic dermatitis (0.8%), and scabies (0.5%). No case of scabies or eczematous dermatitis was impetiginized. Dermatophyte infections were most prevalent, consistent with other studies from this region. The significance of bacterial infection prevalence will need to be considered in the context of microbiology results and known RHD prevalence at these primary schools in order to draw conclusions on the role that group A streptococcal skin infection plays in the development of RHD in these urban areas of Uganda.

## 514

### THE CLINICAL FEATURES, COMPLICATIONS AND TREATMENT OF NODDING SYNDROME

Richard Idro<sup>1</sup>, Ronald Anguzu<sup>1</sup>, Pamela Akun<sup>1</sup>, Rodney Ogwang<sup>1</sup>, Bernard Opar<sup>2</sup>, Angela Vincent<sup>3</sup>, Kevin Marsh<sup>3</sup>

<sup>1</sup>Makerere University College of Health Sciences, Kampala, Uganda, <sup>2</sup>Ministry of Health, Kampala, Uganda, <sup>3</sup>University of Oxford, Oxford, United Kingdom

Nodding syndrome (NS) is a debilitating neurologic disorder affecting children and adolescents in East Africa. We are conducting a series of studies in the most affected districts of Uganda. Our aim is to determine the aetiology and pathogenesis, provide a comprehensive description of clinical features, comorbidities and complications, develop a staging system and supportive treatments and initiate studies of specific treatments. First, we conducted a pilot study of 22 patients to describe the clinical features, determined patients' treatment needs and used this data to develop a supportive treatment program. Secondly, we conducted a detailed clinical, neurophysiologic and imaging study of 223 patients to describe the progressive development of symptoms, complications and comorbidities of NS. Third, based on preliminary aetiology studies that suggest potential cross-reacting antibodies with *Onchocerca volvulus*, we are enrolling 230 patients in phase II placebo-controlled trial of doxycycline as treatment. The studies suggest that NS is a neurologic disorder with multisystem involvement. Complications of the untreated disease develop

through five worsening clinical stages. Treatment with anticonvulsants and a program of physical, occupational, speech and language, psychological and nutritional rehabilitation therapy improves outcomes, function and wellbeing. The doxycycline trial is due to complete recruitment end of 2017. The clinical manifestations and function of patients with NS improve with symptomatic treatments. A definitive cure and preventive intervention is awaited.

## 515

### PUBLIC ENGAGEMENT WITH SCIENCE: A COMMUNITY DRAMA PROJECT AGAINST MALARIA IN CAMBODIA

Rupam Tripura<sup>1</sup>, Renly Lim<sup>2</sup>, Thomas J Peto<sup>1</sup>, Ma Sareth<sup>1</sup>, Nou Sanann<sup>1</sup>, Christopher Pell<sup>3</sup>, Chan Davoeung<sup>4</sup>, Chea Nguon<sup>5</sup>, Lorenz von Seidlein<sup>1</sup>, Nicholas J White<sup>1</sup>, Arjen M Dondorp<sup>1</sup>, **Phaik Yeong Cheah<sup>1</sup>**

<sup>1</sup>Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, Australia, <sup>3</sup>University of Amsterdam, Amsterdam, Netherlands, <sup>4</sup>Battambang Provincial Health Department, Battambang, Cambodia, <sup>5</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Malaria is declining in Southeast Asia but transmission persists in many rural areas and among forest workers and isolated populations. In these remote communities, conventional health services and education are limited. Community and public engagement requires unconventional approaches such as using arts. A participatory drama project was conducted in twenty remote villages in Battambang province, Cambodia with three key messages: to use insecticide-treated bednets, to get early diagnosis and treatment, and learn about risks of forest-acquired malaria. The project combined Cambodian drama, art, music workshops and village concerts and competitions to provide health education in a fun and engaging way. We conducted an evaluation of this project using qualitative and quantitative methods. A total of 29 villagers, community engagement staff and key workers were interviewed while 141 villagers filled in a 5-item questionnaire. Analysis of the interviews resulted in development of the following seven themes: i) exposure to malaria and engagement activities, ii) readiness and barriers to participation, iii) understanding and learning about malaria using drama, iv) entertainment value and engagement method preferences, v) challenges to community engagement, vi) future participation and vii) sustainability. The quantitative data echoed findings of the qualitative analysis, with almost all participants agreeing that the drama has helped them learn more about malaria. The event also saw positive response, with an encouraging average participation rate of 66%. Our assessment demonstrated that the drama project was effective in promoting awareness and understanding of malaria prevention and control. Villagers perceived drama as entertaining and as the preferred choice of engagement activity. Using drama is a promising way for community engagement and could be considered when mobilising communities for malaria elimination.

## 516

### DEMOGRAPHIC SURVEILLANCE TO MONITOR IMPACT OF MALARIA ON PREGNANT WOMEN IN OUELESSEBOUGOU, MALI

**Amadou Barry<sup>1</sup>**, Gaoussou Santara<sup>1</sup>, Moussa Traoré<sup>1</sup>, Djibril Touré<sup>1</sup>, Almahamoudou Mahamar<sup>1</sup>, Oumar Attaher<sup>1</sup>, Sekouba Keita<sup>1</sup>, Bakary Diarra<sup>1</sup>, Patrick E Duffy<sup>2</sup>, Alassane Dicko<sup>1</sup>, Michal Fried<sup>2</sup>

<sup>1</sup>Malaria Research and Training Center, University of Bamako, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Pregnancy malaria is associated with poor outcomes for pregnant women and their babies. To reduce poor pregnancy outcomes associated with

malaria infection, WHO recommends monthly anti-malarial treatment with sulfadoxine pyrimethamine (SP) during the second and third trimester and the use of insecticide-treated bed nets. However, in East and Southern Africa, SP has lost its efficacy due to the spread of drug-resistant parasites. Therefore, an effective vaccine for PM is needed. Some researchers and scientists are focusing on developing a PM vaccine. Before testing new interventions to improve pregnancy outcomes, it is important to obtain background information on these outcomes in the population that can be used as a baseline to differentiate between adverse outcomes that might be associated with the intervention (vaccine or new drugs) and malaria infection. To investigate the impact of malaria on the outcomes of pregnancy, we are assessing pregnancy outcomes in women in the community with access to the WHO recommended standard of care. Census of the population including child bearing women was conducted and all women presenting for an antenatal visit in health centers in Ouelessebouguou are recruited into the study. Pregnancy outcome information is collected after the birth of the child or pregnancy termination (i.e. miscarriage/stillbirth). To assess the rates of malaria infection and parasite resistance to SP, cross-sectional surveys on a subset of 330 pregnant women and 450 children in the community will be conducted at the peak of malaria transmission (around September-October) for pregnant women and twice a year (July and December) for children age 0-10 years. Results on first malaria transmission season will be analyzed and presented.

## 517

### PEDIATRIC INPATIENT ANTIBIOTIC PRESCRIPTION PRACTICES IN THE CHAIN NETWORK HOSPITALS AT BASELINE

**Stephanie N. Tornberg-Belanger<sup>1</sup>**, Kirkby D. Tickell<sup>1</sup>, Dorothy I. Mangale<sup>1</sup>, Tahmeed Ahmed<sup>2</sup>, Chisti M. Jobayer<sup>2</sup>, Zaubina Kazi<sup>3</sup>, Al F. Khan<sup>4</sup>, John Mukisa<sup>5</sup>, Ezekiel Mupere<sup>5</sup>, Jenala Njirammadzi<sup>6</sup>, Ali Saleem<sup>3</sup>, Johnstone Thitiri<sup>7</sup>, Molly Timbwa<sup>7</sup>, Priya Sukhtankar<sup>7</sup>, Judd L. Walson<sup>1</sup>, Jay A. Berkley<sup>7</sup>, Donna Denno<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh-Dhaka Hospital, Dhaka, Bangladesh, <sup>3</sup>Aga Khan University Hospital, Karachi, Pakistan, <sup>4</sup>International Centre for Diarrhoeal Disease Research, Bangladesh - Matlab, Chandpur, Bangladesh, <sup>5</sup>Mulago National Referral Hospital, Kampala, Uganda, <sup>6</sup>Queen Elizabeth Central Hospital, Blantyre, Malawi, <sup>7</sup>KEMRI/Wellcome Trust, London, United Kingdom

Antimicrobial resistance (AMR) is a growing global concern. Antibiotic stewardship is being promoted to reduce AMR. However, few studies have documented inpatient antibiotic prescription practices in low-resource settings. We audited the 240 clinical notes of 2-23 month-old inpatient children in Bangladesh (2), Kenya (3), Malawi (1), Pakistan (1) and Uganda (1) as part of a baseline assessment in a study to identify risk factors for mortality in acutely ill inpatients, particularly in undernourished children. This analysis describes adherence to antibiotic guidelines during the first 48 hours of admission. Adherence was defined as a regimen consistent with institutional, national, or international recommendations. The cases reviewed included diagnoses of diarrhea (n:107), severe acute malnutrition (n:101), pneumonia (n:76), malaria (n:35), sepsis (n:25), meningitis (n:12), and shock (n:8). Antibiotics were prescribed to 98% with at least one documented indication for antibiotics (n:173); 80% of these were consistent with recommended regimens. Antibiotics were prescribed in 93% of admitted diarrhea cases, 85% of whom had a comorbidity warranting antimicrobials (n:85) or dysentery (n:1). Among children with malaria noted as a diagnosis and without a documented indication for antibiotics (n:22), those who did not receive a malaria test (n:6) were all prescribed antibiotics. In comparison, 63% of those with a documented positive malaria test (n:16) were prescribed antibiotics without indication. Among those with diarrhea (n:15) and malaria (n:16) without a documented indication for antibiotics, 58% were prescribed an antimicrobial regimen consistent with treatment for a severe bacterial infection. Antibiotics were almost universally prescribed when indicated and adherence to a recommend regimen was comparable to other studies.

Antimicrobials were commonly prescribed for diarrhea and malaria. This may be a response to difficulty excluding severe infections amenable to antibiotics such as sepsis. Improved diagnostic support and education may be critical to improve antibiotic stewardship in many settings.

## 518

### DIAGNOSTIC CHALLENGE OF SKIN LESIONS IN RETURNED TRAVELER FROM IVORY COAST

Rapeephan R. Maude<sup>1</sup>, Sujit Suchindran<sup>2</sup>, Richard J. Maude<sup>3</sup>

<sup>1</sup>Tufts Medical Center, Boston, MA, United States, <sup>2</sup>Lahey Medical Center, Burlington, MA, United States, <sup>3</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

A 63-year old Haitian female who migrated to the US over 20 years returned from the Ivory Coast after missionary work for 1 month. In Ivory Coast, 13 days prior to admission (PTA), she first noticed many itchy 1-mm lesions on her buttocks. She denied fresh water exposure, bath tub usage, or insect bites and had a history of impaired glucose tolerance. The lesions became larger and more painful and she took ciprofloxacin for 5 days to no effect. She visited a dermatologist 3 days PTA for painful furuncles with 3 lesions on her buttocks, 7 lesions on upper thighs and 1 lesion on the left arm. She underwent incision and drainage (I&D) and treatment with trimethoprim-sulfamethoxazole. On admission, she had worsening episodic pain and enlarging lesions. On exam, she was in distress but afebrile. There were 11 lesions of 3-cm with erythema and induration and a white dot in the centre draining serosanguineous fluid plus overlying cellulitis. White blood cell count was 4,920 cell/ $\mu$ L, neutrophils 48%, band forms 7% and eosinophils 3%. Creatinine was 1.4 mg/dL (baseline 0.8 mg/dL). C-reactive protein was elevated to 56.1. Vancomycin and cefepime were prescribed for presumed bacterial infection. Surgical I&D was performed and samples were negative on bacterial, mycobacterial and fungal culture. On hospital day 3, larvae were seen emerging from the lesions and 9 were extracted surgically. They were identified as Tumbu fly larvae (*Cordylobia anthropophaga*). Clinical still photographs and video of the larvae were taken. Two lesions did not have living larvae. The patient improved significantly after the extraction and was discharged home without pain. The patient had furuncular myiasis caused by Tumbu fly larvae which is endemic in Tropical Africa. It is rarely seen in the US and could cause a delay in diagnosis and treatment leading to unnecessary use of antibiotics in areas where physicians are not familiar it. It is possible that the female Tumbu fly laid its eggs on the patient's clothes or linens while hanging to dry. As part of pretravel clinic encounters, travelers to endemic areas should be advised to iron all clothes including underwear to kill the eggs and larvae.

## 519

### CLINICAL OUTCOMES OF VENOMOUS SNAKEBITES IN THE ECUADORIAN AMAZON RAINFOREST AFTER IMPLEMENTATION OF A NATIONAL PROTOCOL

Francisco E. Mora<sup>1</sup>, Norman Beatty<sup>1</sup>, Isabel Freire<sup>2</sup>, Gail Pritchard<sup>3</sup>

<sup>1</sup>Internal Medicine Program at South Campus, University of Arizona, Tucson, AZ, United States, <sup>2</sup>Hospital Basico Sucua, Ministerio de Salud del Ecuador, Sucua, Ecuador, <sup>3</sup>University of Arizona, Tucson, AZ, United States

The incidence of snakebite envenomation in Ecuador is not well established. Some reports estimate between 1200-1600 cases annually with mortality rates ranging between 1 and 5.4%. In 2010 the ministry of health of Ecuador (MOH) implemented a national snake envenomation management protocol. We collected retrospective data from January 2012 through December 2014 on all venomous snakebites admitted to Hospital Basico Sucua a rural tertiary medical center, located in the town of Sucua which is found in the Ecuadorian Amazon rainforest. Epidemiological data and clinical outcomes were analyzed. During the study period we identified 211 venomous snakebites. 59.7% were male and 74.4% were farmers of indigenous origin. 64% were between the ages of 15-65. Incidence ranged from 183 to 224 per 100,000 inhabitants per year. 97%

were bitten in the extremities. 27.5% (58/211) of these venomous snake bites were deemed without clinical evidence of envenomation. Among the 153 cases of envenomation, 42.4% (65/153) were classified as mild upon presentation to the hospital, 52.2% (80/153) moderate, and 5.2% (8/153) severe. The pit viper known as "equis" in Ecuador (*Bothrops spp.*) accounted for 40% of the total envenomation cases. After initiating the MOH national snake envenomation management protocol in the hospital, only 21.5% (33/153) suffered further complications. There were no recorded fatalities. Only 3 patients developed permanent neurological disability. Hospitalization days averaged between 4-7 days. Time from bite to hospital ranged from 1 to 96 hours. 64% were transported by ambulance. Total vials administered per patient was between 4 and 12. The cost of each vial ranged from 42-100 US dollars. The incidence of snakebite envenomation in southeast Ecuador is high. This retrospective analysis is the first attempt to analyze the clinical outcomes of the MOH national snake envenomation protocol. Our preliminary results show improving clinical outcomes, with low complication rates and long term disability among snake envenomation cases. Further observational studies are need to fully validate this protocol.

## 520

### THE EFFECTS OF MALNUTRITION AND DIARRHEA TYPE ON THE ACCURACY OF CLINICAL SIGNS OF DEHYDRATION IN CHILDREN UNDER FIVE: A PROSPECTIVE COHORT STUDY IN BANGLADESH

Saadiyah Bilal<sup>1</sup>, Kelly Skrable<sup>1</sup>, Rashmi Sharma<sup>1</sup>, Sarah Robertson<sup>2</sup>, Yokabed Ashenafi<sup>3</sup>, Sabiha Nasrin<sup>4</sup>, Nur H. Alam<sup>4</sup>, Adam C. Levine<sup>1</sup>

<sup>1</sup>Warren Alpert Medical School of Brown University, Providence, RI, United States, <sup>2</sup>Brown University School of Public Health, Providence, RI, United States, <sup>3</sup>Brown University, Providence, RI, United States, <sup>4</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

The World Health Organization (WHO) recommends assessing dehydration in children with diarrhea based on standard clinical signs. However, no prior studies have compared the accuracy of these clinical signs of dehydration in children based on nutritional status or diarrhea type. This study is a planned secondary analysis of data from two prospective cohort studies of children with acute diarrhea in Bangladesh. Dehydration was determined using percent weight change with rehydration. Malnutrition was calculated using mid-upper arm circumference. The effects of malnutrition and diarrhea type on the accuracy of nine clinical signs of dehydration were assessed using the Cochran-Mantel-Haenszel test. The accuracy of three clinical diagnostic models of dehydration was compared in children by nutritional status and diarrhea type using the area under their receiver-operator characteristic curve (AUC). Of the 1,282 patients included in the final analysis, 685 (53%) had dehydration, 240 (19%) had malnutrition, and 446 (35%) had rice-water (cholera) diarrhea. There was no significant association between malnutrition and any of the clinical signs, but seven signs were significantly less predictive of dehydration status among those with rice-water diarrhea. The AUC for the DHAKA Dehydration Score, the Clinical Dehydration Scale (CDS) and the WHO algorithm were similar in children with and without malnutrition. The CDS was significantly less predictive for dehydration in children with rice-water diarrhea. This study provides evidence that clinical signs of dehydration and dehydration scales predict dehydration with similar accuracy in children with malnutrition, but may be less predictive in children with rice-water diarrhea.

## EVALUATING INTESTINAL PROTEINS IN *BRUGIA MALAYI* ADULT WORMS AS POTENTIAL DRUG TARGETS

Alexander Francis Flynn<sup>1</sup>, C. Paul Morris<sup>2</sup>, Edward Mitre<sup>1</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Johns Hopkins Pathology, Baltimore, MD, United States

Over 70 million people are infected worldwide with lymphatic filariasis (LF). Clinical disease manifestations include lymphedema, hydrocele, and elephantiasis. The infectious agents include *Wuchereria bancrofti*, *Brugia malayi* and *B. timori*, tissue-invasive nematodes that are transmitted to humans by mosquitoes. Once in humans, these helminths migrate to lymphatic vessels where they mature into adult worms 4-8 cm in length over a period of 2-3 months, mate and release circulating microfilariae (L1 stage larvae) that are infective to mosquitoes. While global mass drug administration has significantly reduced the worldwide prevalence and transmission of LF, the strategy is limited. Current anti-filarial drugs such as albendazole, diethylcarbamazine, and ivermectin are effective against the microfilaria stage but not against adult worms. Development of macrofilaricidal agents would greatly enhance efforts to control filariasis. A key anatomical feature of adult filarial worms is a fully developed mouth to anus intestinal tract. We therefore conducted a proteomic analysis of the *B. malayi* intestinal tract to identify potential drug targets in adult filarial worms. A total of 396 proteins were identified as being solely expressed in the intestinal tract. Of these proteins, we identified a subset that have high homology to *W. bancrofti* and other pathogenic filarial worms, low homology to humans, and are predicted to be expressed at the luminal surface of the filarial intestinal tract. A group of 10 candidate protein targets were selected that are involved in cellular adhesion, proteolysis, waste removal and metabolism. To determine whether these candidate proteins are essential for adult *B. malayi* survival, we are using siRNA interference to knock down protein expression. We have recently optimized siRNA knockdown of alpha-actin in *Brugia* worms and are currently assessing the effects of siRNA knockdown on our candidate proteins. Outcomes to be measured include worm viability, motility and fecundity.

## THE MOLECULAR BASIS OF *LOA LOA* CROSS-REACTIVITY IN THE RAPID DIAGNOSTIC TEST FOR LYMPHATIC FILARIASIS

Marla Hertz<sup>1</sup>, Amy Rush<sup>1</sup>, Samuel Wanji<sup>2</sup>, Gary Weil<sup>1</sup>, Philip Budge<sup>1</sup>

<sup>1</sup>Washington University in St. Louis, St. Louis, MO, United States, <sup>2</sup>University of Buea, Buea, Cameroon

The Global Program to Eliminate Lymphatic Filariasis relies on rapid diagnostic tests such as the filariasis test strip (FTS) and immunochromatography card test (ICT), which detect circulating filarial antigen via a carbohydrate epitope termed the AD12 epitope. Although the AD12 epitope is not unique to *Wuchereria bancrofti*, it was not initially found on circulating antigens of other filarial infections of humans. The recent recognition of ICT and FTS cross-reactivity in some patients with *Loa loa* suggests the presence of the AD12 epitope on *L. loa* antigens. To identify which *Loa* antigens might be responsible for ICT/FTS cross-reactivity, we immunoaffinity purified AD12 epitope-containing antigens from the sera of an FTS-positive patient with loiasis. Surprisingly, western blot analysis detected many AD12 epitope-containing antigens in the cross-reactive *Loa* sera. Proteomic analysis of FTS+ *Loa* sera identified over 80 cross-reactive *Loa* proteins. These proteins are functionally diverse and predicted to localize to all regions of the cell including the plasma membrane, cytosol and nucleus. This pattern of antigenemia suggests that the origin of the cross-reactivity is worm lysis and release of cellular content, rather than secretion of a specific filarial antigen by adult worms (as seems to be the case for bancroftian filariasis). Why antigen is released in some loiasis patients but not others is not clearly understood and is the focus of ongoing research.

## WOLBACHIA REGULATES *BRUGIA MALAYI* MICRORNA TO MAINTAIN THEIR MUTUALISTIC INTERPLAY

Denis Voronin<sup>1</sup>, Michael Shlossman<sup>1</sup>, Alexandra Grote<sup>2</sup>, Elodie Ghedin<sup>2</sup>, Thomas Unnasch<sup>3</sup>, Sara Lustigman<sup>1</sup>

<sup>1</sup>New York Blood Center, New York, NY, United States, <sup>2</sup>New York University, New York, NY, United States, <sup>3</sup>University of South Florida, Tampa, FL, United States

Human lymphatic filariasis is caused by the filarial parasites *Wuchereria bancrofti*, *Brugia malayi*, and *B. timori*, and is the second leading cause of global disability, affecting 120 million people in 73 countries. As with most filarial nematodes, *B. malayi* has evolved a mutualistic association with its bacterial endosymbiont, *Wolbachia*. *Wolbachia* is crucial for parasite development, fertility, and viability. It is known that the bacteria and its filarial host share essential metabolic and biosynthetic processes (such as glycolysis, nucleotide biosynthesis, iron metabolism). However, how these two organisms can orchestrate the major bioprocesses is still poorly known. Recent studies in *Wolbachia*-arthropod systems demonstrated that *Wolbachia* influences host gene expression by altering the host microRNA (miRNA) profile. Additionally, deep-sequencing studies of small RNAs in *Brugia* and other nematodes have identified several miRNAs found only in filariae that harbor *Wolbachia*. This suggests that the filarial parasites may encode miRNAs that regulate functions unique to the *Wolbachia*-host endosymbiosis. Our study is focused on understanding the role of *Brugia* miRNAs in the molecular interdependency between the bacteria and its filarial host. We identified 33 *B. malayi* miRNAs that show differential expression in response to the elimination of *Wolbachia* by antibiotic treatment. The differential expression of four *Wolbachia*-responsive *Brugia* miRNAs was confirmed in adult *B. malayi* females treated with doxycycline *in vitro* using a specifically designed qPCR assay. We also established that *Brugia* miRNAs potentially regulate apoptotic pathway, suppress autophagy and regulate the expression of proton/amino acid symporters in the filarial host. Future studies will characterize the potential roles the *B. malayi* miRNA target genes have in the *Wolbachia*-parasite interplay. We demonstrate that a defined subset of *B. malayi* regulated genes could constitute one aspect of the molecular foundation for *Wolbachia*-*Brugia* symbiosis, and could be therefore considered as potential drug targets for anti-*Wolbachia* and filaria treatment.

## ASYMPTOMATIC *LOA LOA* INFECTION IN EQUATOGUINEAN ADULT SUBJECTS IN A WHOLE SPOOROZOITE MALARIA VACCINE TRIAL: WHAT IS A RESEARCHER TO DO?

Beltrán Ekua Ntutumu Pasialo<sup>1</sup>, Ally Olotu<sup>2</sup>, Vicente U. Nsue Ndong Nchama<sup>1</sup>, Ali Mtoro<sup>2</sup>, Rufino Nguema<sup>1</sup>, Stephen R. Manock<sup>3</sup>, Maximilian Mpina<sup>2</sup>, Elizabeth Nyakarungu<sup>2</sup>, Jose Raso<sup>1</sup>, Salomón Nguema Owono<sup>4</sup>, Matilde Riloha Rivas<sup>1</sup>, Julie Niemczura de Carvalho<sup>5</sup>, Wonder Phiri<sup>6</sup>, Tobias Schindler<sup>7</sup>, Claudia Daubenberger<sup>7</sup>, Thomas Richie<sup>8</sup>, Stephen L. Hoffman<sup>8</sup>, Salim Abdulla<sup>2</sup>

<sup>1</sup>Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, <sup>2</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>3</sup>Sanaria Inc., Malabo, Equatorial Guinea, <sup>4</sup>Ministry of Health of Equatorial Guinea, Malabo, Equatorial Guinea, <sup>5</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>6</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>7</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>8</sup>Sanaria Inc., Rockville, MD, United States

The filarial nematode *Loa loa* is common in West and Central Africa and can cause Calabar swellings and eye worm in its human hosts. Loiasis is of particular concern in onchocerciasis-endemic areas, since ivermectin used in mass treatment programs can cause potentially fatal adverse reactions in people with a high *Loa loa* parasite load. *Loa loa* microfilariae were incidentally found on routine malaria blood smears in 5 of 248 (2.0%) individuals aged 6 months to 65 years undergoing screening for,

or already enrolled in, a *Plasmodium falciparum* whole-sporozoite malaria vaccine trial on Bioko Island, Equatorial Guinea. All were adult males, ranging in age from 21-61 (mean=32) years. All were asymptomatic and had normal physical exams. Microfilariae were detected in one of the affected individuals on their first screening blood smear, but were not seen in the other four until their second (2), fourth (1) or fifth (1) smears, 2-12 weeks after the initial negative smear. Blood smears were generally done around mid-day (the period of highest sensitivity for microfilaria detection). Eosinophilia was common, ranging from 0.81 to 1.93 X 10<sup>3</sup>/mm<sup>3</sup> (14.1-31.4%). Creatinine levels were all normal. The five men were referred to the national onchocerciasis control program, where the diagnosis of loiasis was confirmed by repeat blood smear and a 21-day course of diethylcarbamazine (DEC) prescribed per program guidelines. At the time of writing, one subject had completed a course of DEC and required a second course due to persistent microfilaremia. The other four subjects were either in treatment or had yet to begin it. The plan was to follow all subjects until microfilariae cleared. Three of the men had already received a malaria vaccine dose; they were deemed ineligible for additional doses of vaccine. The other two subjects were also excluded from the trial. Complete details will be presented, as well as a discussion of the rationale for treating incidental, asymptomatic loiasis discovered during an unrelated clinical trial.

Kingdom, <sup>8</sup>Imperial College London and London Centre for Neglected

Tropical Disease Research (LCNTDR), London, United Kingdom, <sup>9</sup>Makerere

University, Kampala, Uganda

From 12 to 14 October 2017, the first International Workshop on Onchocerciasis-Associated Epilepsy (OAE) will have been held in Antwerp, Belgium. This workshop follows the first conference on nodding syndrome (NS), organized in 2012 by the World Health Organization and the Ugandan Ministry of Health in Kampala, and the NS conference organized by Gulu University, Uganda in 2016. Since then, substantial progress has been made in understanding NS. Recent studies suggest that NS is only one of various clinical presentations of OAE and that *Onchocerca volvulus* (the parasite causing onchocerciasis) is potentially the aetiological trigger of this type of epilepsy. Although the exact pathophysiological mechanism(s) of OAE remain unknown, there is increasing epidemiological evidence indicating that by eliminating onchocerciasis, the incidence of this form of epilepsy will likely decrease. To this end, it is crucial that onchocerciasis control programmes be strengthened, especially as those already affected will continue suffering even after onchocerciasis elimination has been achieved. Consequently, more advocacy is needed to obtain funding to organize the treatment, care and support for persons with OAE. By joining forces and expertise through partnerships between communities, advocacy groups, health care workers, ministries of health, NGOs, pharmaceutical industry and funding bodies, we hope to prevent children from developing OAE and improve the affected patients' quality of life. It is urgent that the global scientific community joins this partnership to eliminate this major cause of epilepsy in resource-poor countries, specifically in Africa. A summary of recommendations of the

Antwerp workshop will be presented including a research agenda aimed to: (i) identify the pathophysiological mechanism(s) of OAE; (ii) prevent incidence of and improve surveillance for OAE; (iii) determine the disease burden caused by OAE; (iv) improve access to treatment/care for persons with OAE and their families and (v) fund an OAE policy plan (including prevention of stigma, discrimination and gender violence associated with OAE).

### ASSESSING THE AVAILABILITY, READINESS AND QUALITY OF MORBIDITY MANAGEMENT AND DISABILITY PREVENTION SERVICES FOR CLINICAL LYMPHATIC FILARIASIS IN BANGLADESH

**Salim Choudhury**<sup>1</sup>, Hayley E. Mableson<sup>2</sup>, AKM Fazlur Rahman<sup>1</sup>, Sharmin Jahan<sup>1</sup>, Mohammed J. Karim<sup>3</sup>, ASM Sultan Mahmood<sup>3</sup>, Hannah Betts<sup>2</sup>, Mark Taylor<sup>2</sup>, Louise A. Kelly-Hope<sup>2</sup>

<sup>1</sup>Centre for Injury Prevention, Health Development and Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>3</sup>Filariasis Elimination and STH Control Program, Ministry of Health and Family Welfare, Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh

The Bangladesh Filarial Elimination Programme (FEP) has made great strides forward in the elimination of lymphatic filariasis (LF) infection, with the absence of transmission confirmed in all endemic districts where initially 70 million people were at risk. The FEP is now focussed on morbidity management and disability prevention (MMDP), and recent patient searching activities in endemic areas confirmed over 43,000 clinical cases of lymphoedema and hydrocele. To fulfil requirements of the Global Programme to Eliminate LF (GPELF), the Bangladesh FEP must provide evidence of the availability of the minimum package of care, and readiness and quality of services for MMDP in all areas of known patients. This work specifically aimed to address these requirements by conducting a series of patient and health system surveys including i) access to care of lymphoedema patients assessed through patient surveys ii) readiness and quality of lymphoedema care assessed through health facility inspections at community clinics iii) quality of MMDP training assessed through community health workers pre- and post-training surveys and iv) quality of hydrocele surgery assessed through patient pre- and post-surgery quality of life surveys. The work related to the access to- and readiness and quality of- lymphoedema care, and community health worker training (n=3468 trained) is being conducted in seven districts and the full results will be presented. The patient pre- and post- surgery survey was conducted in Panchagar District where a total of 143 men received surgery, and a subset of 39 men were assessed pre- and 3 months' post-surgery to determine change in quality of life across different aspects of their lives. Results showed 85% of men experienced improvement in levels of pain, 92% in mobility and 100% in psychological aspects of life post-surgery. This work will provide evidence of the access, quality and readiness of services for patients with clinical LF in the most endemic districts in Bangladesh, and will support the FEP in the documentation of elimination of LF as a public health problem in Bangladesh.

## MULTI-COUNTRY PROSPECTIVE COHORT TO MEASURE THE IMPACT OF SURGERY ON MEN WITH HYDROCOELE CAUSED BY LYMPHATIC FILARIASIS

Mableson<sup>1</sup>, Charles D. Mackenzie<sup>1</sup>, Mark Taylor<sup>1</sup>

<sup>1</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom,

<sup>2</sup>Ministry of Health, Lilongwe, Malawi, <sup>3</sup>Filariasis Elimination and STH Control Program, Ministry of Health and Family Welfare, Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh, <sup>4</sup>Centre for Injury Prevention, Health Development and Research, Bangladesh, Dhaka, Bangladesh, <sup>5</sup>Epidemiology and Disease control division, Department of Health Services, Ministry of Health and Population, Government of Nepal, Kathmandu, Nepal

Hydrocoele is the most common clinical manifestation of lymphatic filariasis (LF), affecting approximately 19.4 million men worldwide. The condition can have significant negative physical, social, psychological and economic impact on men and their families. The recommended treatment is simple, surgical repair (hydrocoelelectomy), and in recent years the UK Department for International Development has committed funding to address this burden by supporting National LF Programmes to scale up access to surgery in 12 countries (10 African; 2 Asian). To determine how surgery affects men's lives, a prospective cohort impact assessment was initially conducted in Malawi where the survey tool was refined, and expanded to Bangladesh and Nepal. As part of the campaigns in each country, men enrolled for hydrocoelelectomy were randomly selected to take part in the survey. A semi-structured questionnaire was administered pre-surgery, and 3- and 6-months post-surgery to compare demographic and socio-economic information, LF knowledge, barriers to surgery, and quality of life information; the latter relating to pain, mobility, usual activities, self-care, social participation and psychological health domains, measured using a model disability scoring system (1=no problem, 2=mild, 3=moderate, 4=severe). In Malawi (Chikwawa and Nsanje district), 137 men from 6 hospitals were surveyed; in Bangladesh (Panchagar district) 39 men were surveyed, and in Nepal, surveys are planned to include approximately 300 men from 10 hospitals. Results from Malawi and Bangladesh indicate a statistically significant improvement in men's lives 3-months post-surgery with the majority (>80%) experiencing a change from 'moderate-severe' problems pre-surgery to 'mild-no problems' post-surgery across all domains. A significant reduction in the proportion of men having to take days off work due to their condition was also found in Malawi (pre-surgery 52%; 3-months post-surgery 16%; 6-months post-surgery 0%) and Bangladesh (pre-surgery 64%; 3-months post-surgery 7%). This study shows that hydrocoelelectomies are life changing for men.

## SAFETY OF CO-ADMINISTRATION OF A SINGLE DOSE OF IVERMECTIN, ALBENDAZOLE AND DIETHYLCARBAMAZINE IN SUBJECTS WITH AND WITHOUT WUCHERERIA BANCROFTI INFECTION IN CÔTE D'IVOIRE

Catherine M. Bjerum<sup>1</sup>, Edi Constant<sup>2</sup>, Allassane Ouattara<sup>3</sup>, Benjamin Koudou<sup>4</sup>, Aboulaye Meite<sup>5</sup>, Gary Weil<sup>6</sup>, Christopher King<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Centre Suisse de Recherche Scientifique en Côte d'Ivoire, Abidjan, Côte d'Ivoire,

<sup>3</sup>Université Nangui Abrogoua, Abidjan, Côte d'Ivoire, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>Programme national de la lutte contre la schistosomiase, les geohelminthiases et la filariose

lymphatique, Abidjan, Côte D'Ivoire, <sup>6</sup>Infectious Diseases Division, Washington University School of Medicine, St. Louis, MO, United States

Recent studies in Papua New Guinea and Côte d'Ivoire have shown that a single co-administered dose of ivermectin (IVM), diethylcarbamazine (DEC), and albendazole (ALB, IDA) cleared microfilaria (Mf) more effectively than current two-drug regimens of DEC+ALB or IVM+ALB. However, the safety of IDA in subjects infected with lymphatic filariasis (LF+) versus uninfected participants (LF-) is unknown. Participants with moderate to heavy *W. bancrofti* infections (>50 Mf/mL, N=32) and individuals from the same communities who were LF- (N=26) were hospitalized for 3 days and actively monitored for adverse events (AEs), which included repeated vital signs, targeted physical examinations, urine and biochemical analysis and for the presence of Mf before and following IDA treatment. Participants were passively monitored between days 4 and 7. All participants had at least one drug-associated AE and 86% participants had more than one AE. Mild AEs were similar between LF+ and LF- participants; however, moderate (level 2) AEs were more common in LF+ individuals (38% vs 21%, p=0.034). There were no severe or serious AEs. The most common subjective AEs were headache, abdominal pain and diarrhea. Scrotal pain and swelling was the only subjective AE that occurred with greater frequency for LF+ (19%) compared to LF- men (0%, p=0.005). Amongst objective AEs, fever, hypotension and hematuria by urine dipstick were most common. For LF+ individuals 15/32 (47%) had a recorded fever at least once (mean=2 episodes, range 1-4) compared to 4/26 (15%, p=0.01) with fewer febrile episodes (mean = 1, range 1) for LF- participants. All other objective AEs were similar between the treatment groups. All AEs resolved without intervention within 72 hours and all LF+ participants cleared Mf at 39 hours and 7 days post-treatment. Triple drug therapy is highly effective and safe in both LF infected and uninfected individuals, making it a viable alternative for mass drug administration in areas that are endemic for LF, but not coendemic for onchocerciasis.

## SUSTAINED RESPONSE CRITERIA FOR CHEMOTHERAPEUTIC STUDIES IN ONCHOCERCIASIS: A SENSITIVE AND CLINICALLY RELEVANT OUTCOME MEASURE

Clearance and sustained clearance of *Onchocerca volvulus* microfilariae (mf) from skin and eyes is a relevant goal of onchocerciasis treatment: mf cause the disease and skin mf are the reservoir for transmission. Chemotherapeutic efficacy has been historically assessed based on mean skin mf density over time or percent (%) change from pre-treatment density, masking variability in individual response. We propose using sustained microfilariae response (SMR) analyses for comparative drug efficacy, modelled from regulatory-acceptable efficacy outcome measures in other infectious diseases. In two double blind Phase II and III studies conducted to regulatory-standard good clinical practice in areas without community directed treatment with ivermectin (IVM) in Ghana, DRC and Liberia, people were randomized to 8 mg moxidectin (MOX) or 150 µg/kg

IVM. Mean mf density/mg skin (SmfD) was determined based on four snips per person obtained pre-treatment and at least 1, 6 and 12 months (M) post-treatment. Pre-specified analyses of skin snip data (mean SmfD and mean % change SmfD from pre-treatment) over time were complemented by complete SMR (% achieving zero SmfD at M1 sustained to M6 (SMR6) and/or M12 (SMR12)). In Phase III (pre-treatment SmfD 10-299 mf/mg; treated MOX n=978, IVM n=494), M12 SmfD (unadjusted mean  $\pm$  SD) for MOX vs IVM was  $1.25\pm 3.00$  vs  $9.97\pm 12.93$ , respectively; mean  $\pm$  SD %SmfD reduction pre-treatment to M12 was  $97\% \pm 3.40$  vs  $77\% \pm 28.9$ , respectively ( $p < 0.0001$ , mixed model). Complete SMR6 for MOX vs IVM occurred in 76% vs 8% and SMR12 in 37% vs 2% subjects, respectively ( $p < 0.0001$ ). In subjects with pre-treatment SmfD  $\geq 80$  mf/mg, MOX SMR6 was 43% and SMR12 16% vs 0% at both timepoints for IVM. In Phase II (pre-treatment SmfD 0.3-83.1 mf/mg; treated MOX 8 mg n=38, IVM n=45), M12 mean % SmfD reduction from pre-treatment for MOX 8 mg vs IVM was 98.2% vs 84.1%; complete SMR6 occurred in 95% vs 24% (MOX vs IVM,  $p < 0.0001$ ) and SMR12 in 53% vs 13% (MOX vs IVM,  $p < 0.0001$ ). SMR criteria is a more sensitive, clinically and onchocerciasis control/elimination-relevant analysis method of SmfD data for anti-onchocercal drugs than mean or percent change-based methods.

### 530

#### SAFETY OF TRIPLE DRUG TREATMENT WITH IVERMECTIN, DEC AND ALBENDAZOLE COMPARED TO STANDARD TREATMENT WITH DEC PLUS ALBENDAZOLE FOR *BRUGIA TIMORI* INFECTION IN INDONESIA

Taniawati Supali<sup>1</sup>, Yenny Djuardi<sup>1</sup>, Michael Christian<sup>1</sup>, Joshua Bogus<sup>2</sup>, Gary J. Weil<sup>2</sup>, Peter U. Fischer<sup>2</sup>

<sup>1</sup>University of Indonesia, Jakarta, Indonesia, <sup>2</sup>Washington University School of Medicine, St. Louis, MO, United States

Recent studies have shown that treatment with ivermectin, diethylcarbamazine and albendazole (IDA) is superior to standard treatment with DEC + albendazole for clearing *Wuchereria bancrofti* microfilariae (Mf). We performed a hospital-based study and a community study to compare the safety profiles of these two regimens for treating *Brugia timori* infections in Indonesia. The hospital study was a randomized, open label trial. Microfilaremic adults were treated with IDA (N=28) or DA (27). Adverse reactions (AEs) were actively assessed for 2 days after treatment and passively assessed through day 7. Mf were detected by membrane filtration of night blood before and 24 h after treatment. Mf were completely cleared in 89.3% and 29.6% of subjects after IDA or DA treatment ( $p < 0.0001$ ). AEs were more common after IDA (53.6 vs. 37.0%,  $p > 0.05$ ). However, almost all AEs in both groups were mild (grade 1); two subjects in the IDA group had grade 2 fevers. We then conducted a community trial in 18 neighborhoods (dusuns) in endemic areas in Sumba and Flores islands that were randomly assigned to receive IDA or DA. 3,880 eligible (not pregnant and age  $> 5$  years) subjects were enrolled and tested for Mf. Mf rates in the dusuns (mostly *B. timori* with lower rates of *W. bancrofti*) were between 1% and 9%. 99% of subjects treated with IDA and 94% of subjects treated with DA were assessed for AEs on days 1 or 2 after treatment. AE rates were similar after IDA and DA (5.9% IDA vs 5.8%), and rates were no higher in persons with Mf. Two all-cause grade 3 AEs occurred after IDA, but no serious adverse events were observed. The most common AEs were headache, abdominal pain, dizziness, fever and myalgia. Thus, IDA was more effective than DA for early clearing of Mf in the hospital-based trial (where all participants were Mf positive) with more frequent mild AEs. In contrast, AE rates were very low in the community study, and both treatments were well tolerated. Our results suggest that IDA is approximately as safe as standard DA in community settings, and it appears to be a reasonable option for programs to eliminate brugian filariasis.

Debrah<sup>3</sup>, Jubin Osei-Mensah<sup>1</sup>, Bettina Dubben<sup>2</sup>, Sabine Mand<sup>2</sup>, Yusif Mubarik<sup>1</sup>, Arcangelo Ricchiuto<sup>2</sup>, Rolf Fimmers<sup>4</sup>, Kelly Johnston<sup>5</sup>, Mark Taylor<sup>5</sup>, Achim Hoerauf<sup>2</sup>

<sup>1</sup>Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, <sup>2</sup>Institute for Medical Microbiology, Immunology and Parasitology, University Hospital of Bonn, Bonn, Germany, <sup>3</sup>Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, <sup>4</sup>Institute for Medical Biometry, Informatics and Epidemiology, University Hospital of Bonn, Bonn, Germany, <sup>5</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

As recently stated by the WHO, alternative treatment strategies are needed for the treatment of onchocerciasis. One of these strategies are drugs or drug combinations that have a permanently sterilising or macrofilaricidal effect. In order to refine existing regimens with known activity against *Wolbachia*, a randomised double-blind trial was carried out in Ghana by members of the A-WOL consortium, with the aims to reduce treatment duration by combination of doxycycline (DOX) plus rifampicin (RIF), or to reduce the daily dosage of DOX. In total 508 participants were treated with either 1) the current best macrofilaricidal regimen of DOX 200mg for 6 weeks (DOX200, N = 153), 2) DOX 100mg for 6 weeks (DOX100, N = 100), 3) DOX 200mg plus RIF 10mg/kg for 3 weeks (DOX+RIF, N = 102), 4) RIF 10mg/kg for 6 weeks (RIF, N = 102) or 5) Placebo (N = 51). Participants were additionally treated with IVM 150 $\mu$ g/kg after 6 months. At 6 months 102 participants got part of their onchocercosmata surgically removed for histological analysis. This procedure was repeated at 20 months for all participants present (411/508, 80.9%). Analysis of the primary endpoint "onchocercosmata with embryogenesis in female worms" revealed 1.2% in both DOX regimens, 12.7% in the DOX+RIF group as well as 35.2% in the RIF and 28.8% in the placebo group, showing that the two DOX regimens were superior to all other groups, and DOX+RIF superior to RIF and placebo. The proportion of dead female worms in onchocercosmata was highest in the DOX200 group with 58%, followed by the DOX100 group with 48% (not significant). Both DOX regimens showed complete absence of *Wolbachia* by immunohistology in  $> 96\%$  of worms, corresponding to the anti-parasitic effect.

### 532

#### DESIGNING ANTIFILARIAL DRUG TRIALS USING CLINICAL TRIAL SIMULATORS

Martin Walker<sup>1</sup>, Philip Milton<sup>2</sup>, Frédéric Monnot<sup>3</sup>, Belén Pedrique<sup>3</sup>, Maria-Gloria Basáñez<sup>2</sup>

<sup>1</sup>Royal Veterinary College, Hatfield, United Kingdom, <sup>2</sup>Imperial College London, London, United Kingdom, <sup>3</sup>Drugs for Neglected Diseases initiative, Geneva, Switzerland

Lymphatic filariasis and onchocerciasis are targeted for elimination by mass drug administration (MDA) of antifilarial drugs. These drugs are predominantly active against the microfilarial progeny of the adult worms (macrofilariae) of these neglected tropical diseases (NTDs). New drugs are needed both to improve patient therapies and outcomes in the clinical setting and to enhance the effectiveness of public health interventions where elimination is unfeasible by 2020/2025 with current treatment strategies. Several novel and repurposed therapies for the treatment of filarial infections are currently in both pre-clinical and clinical testing. Clinical trial simulators project patient outcomes to assist with the planning and design of clinical trials. They are used in the pharmaceutical sector but are underdeveloped and underused in the NTD domain, where their resource-optimising payoffs could be highly beneficial to the research

and development pipeline. Using onchocerciasis as an example, we demonstrate the utility of clinical trial simulation with illustration from an individual-participant simulator of a novel (hypothetical) macrofilaricidal drug. We show how predicted participant outcomes based on desired pharmacodynamic properties inform the target product profile; the choice of where to conduct trials; how many patients should be recruited; which parasite stages should be sampled from the patients, and when these patients should be followed up to maximise statistical power for demonstrating superiority over existing treatment(s). We also consider how simulations can help to resolve the unique complications that arise when designing clinical trials that are to be conducted in a backdrop of MDA and ongoing transmission.

## 533

### THE ADDITION OF ALBENDAZOLE TO IVERMECTIN DOES NOT REDUCE FEMALE WORM FERTILITY IN ONCHOCERCIASIS

**Ute Klarmann-Schulz**<sup>1</sup>, Linda Batsa-Debrah<sup>2</sup>, Jubin Osei-Mensah<sup>3</sup>, Bettina Dubben<sup>1</sup>, Kerstin Fischer<sup>3</sup>, Yusif Mubarik<sup>2</sup>, Arcangelo Ricchiuto<sup>1</sup>, Rolf Fimmers<sup>4</sup>, Gary J. Weil<sup>3</sup>, James W. Kazura<sup>5</sup>, Christopher L. King<sup>6</sup>, Alexander Y. Debrah<sup>6</sup>, Achim Hoerauf<sup>1</sup>

<sup>1</sup>Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, <sup>2</sup>Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, <sup>3</sup>Infectious Diseases Division, Washington University School of Medicine, St. Louis, MO, United States, <sup>4</sup>Institute for Medical Biometry, Informatics and Epidemiology, University Hospital of Bonn, Bonn, Germany, <sup>5</sup>Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States, <sup>6</sup>Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

A randomised open-label clinical trial was performed in an endemic area of Central Ghana to address the question whether ivermectin (IVM) combined with albendazole (ALB) at higher doses and given more than once per year might generate sustained reduction in microfilariae (Mf) by reducing female fertility or by killing adult worms in onchocerciasis. In total 272 Mf-positive participants, with at least one palpable onchocercoma were treated with either 1) IVM 200µg/kg annually (0, 12, 24 months; N = 68), 2) IVM 200µg/kg biannually (0, 6, 12, 18, 24 months; N = 68), 3) IVM 200µg/kg plus ALB 800mg annually (N = 70) or 4) IVM 200µg/kg plus ALB 800mg biannually (N = 66). 76 participants had not taken part in previous mass drug administration (MDA) of annual IVM, the other 198 had done so in at least one round (median 2 (1 – 10)). 36 months after treatment start, 218 patients (80%) got their onchocercomata surgically removed. Skin snips were taken at 0, 6, 18 and 36 months. Histological analysis showed normal embryogenesis in 15/135 (11% [7-18, 95% CI]) adult female worms in the IVM annual group, compared to 22/155 (14% [10-21]) in the IVM biannual, 35/154 (23% [17-30]) in the ALB+IVM annual and 20/125 (16% [11-23]) in the ALB+IVM biannual group (p = 0.1229, comparison over all 4 groups). With a range of 55 - 59% the proportion of dead worms did not differ between the 4 groups. The proportion of individuals that completely cleared Mf at 36 months (after 3 annual/5 biannual treatments) was 35/56 (63% [49-74]) in the IVM annual, 42/59 (71% [59-81]) in the IVM biannual, 39/64 (61% [49-72]) in the ALB+IVM annual and 43/53 (81% [69-89]) in the ALB+IVM biannual group. In the subgroup without prior IVM, there was a trend to more Mf-negative individuals in the ALB+IVM biannual group. In conclusion, addition of ALB to IVM did not improve the efficacy against female worm fertility or the macrofilaricidal effect. However, the increase from annual to biannual drug administration resulted in a sustained increase of Mf negative individuals (annual: 62% [53-70], biannual: 76% [67-83], p = 0.024). It will be interesting to compare these results to an ongoing trial with a similar design in Eastern Ghana.

### DETECTING ALBENDAZOLE METABOLITES IN SERUM AND URINE: A FIRST STEP IN DEVELOPING AN INDICATOR OF MDA COMPLIANCE IN HUMANS

**Laura L. Ceballos**<sup>1</sup>, Ruben Cimino<sup>2</sup>, Marisa Juarez<sup>2</sup>, Laura Moreno<sup>1</sup>, Juan Pablo Banal<sup>2</sup>, Luis Alvarez<sup>1</sup>, Alejandro Krolewiecki<sup>2</sup>, Judd Walson<sup>3</sup>, Carlos Lanusse<sup>1</sup>

<sup>1</sup>Laboratorio de Farmacología, Centro de Investigación Veterinaria de Tandil (CIVETAN), CICPBA-CONICET, Tandil, Argentina, <sup>2</sup>Instituto de Investigaciones en Enfermedades Tropicales. Universidad Nacional de Salta, Salta, Argentina, <sup>3</sup>DeWorm3, Natural History Museum, London, United Kingdom; University of Washington, Departments of Global Health, Medicine, Pediatrics and Epidemiology, Seattle, WA, United States

The neglected tropical diseases are a group of pathogens affecting individuals in the poorest regions of the world. Among them, Soil Transmitted Helminth infections directly impact nutritional status, educational development, individual productivity, and physical and mental development in human populations. Currently, these infections are controlled through mass drug administration (MDA) programs using albendazole (ABZ) or mebendazole. However, not all programs have demonstrated expected impact on prevalence or intensity of infections. These failures may be related to poor programmatic coverage, suboptimal adherence or the exposure of parasites to sub-therapeutic drug concentrations due to poor drug dissolution, insufficient gastrointestinal absorption and/or systemic availability of the active ingredient. Accordingly, improved knowledge of the basic pharmacokinetics of ABZ in treated people is critical. As part of the DeWorm3 project, we sought to characterize the serum disposition kinetics and pattern of urinary excretion of ABZ and its metabolites (ABZ sulphoxide (ABZSO) and ABZ sulphone (ABZSO<sub>2</sub>)) in human volunteers. In addition, we sought to determine the duration and optimal timepoint where ABZ/ metabolites can be measured in urine as an indirect assessment of an individual's adherence to treatment. Venous blood and urine samples were collected from eight (8) volunteers between 2 and 72 h (serum) and 4 and 72 h (urine) for HPLC analysis following administration of a single postprandial oral dose of ABZ (400 mg Glaxo SmithKline). The ABZSO was the main analyte recovered either in serum and urine samples. ABZSO serum concentrations reached its peak concentration (C<sub>max</sub> = 1.20 ± 0.44 µg/mL) at 4.75 h post-treatment. In urine ABZSO C<sub>max</sub> value was 3.24 ± 1.51 µg/mL, reached at 6.50 h post ABZ administration. The urinary AUC value, resulted higher (2.3 fold) compared to that measured in serum. The overall, PK-based information reported here demonstrates that the measurement of ABZSO concentrations both in serum and urine could be useful to confirm compliance to ABZ treatment and an objective measurement of program coverage.

## 535

### FURTHER EVIDENCE OF COLLATERAL IMPACT OF CDTI ON STH PREVALENCE AND INTENSITY: IMPLICATIONS IN DEWORMING STRATEGIC PLAN AND GLOBAL ELIMINATION

**Floribert Fossuo**<sup>1</sup>, Hugues Clotaire Nana Djeunga<sup>1</sup>, Laurentine Sumo<sup>2</sup>, Flobert Njiokou<sup>3</sup>, Joseph Kamgno<sup>1</sup>

<sup>1</sup>Centre for Research on Filariasis and other Tropical Diseases (CRFiMT), Yaoundé, Cameroon, <sup>2</sup>University of Bamenda, Bamenda, Cameroon, <sup>3</sup>University of Yaoundé 1, Yaoundé, Cameroon

Soil-transmitted helminthiasis (STHs) are among the most prevalent afflictions of the developing world, responsible of physical and mental growth retardation and hindrance of economic development. Periodic deworming with Albendazole or Mebendazole of high-risk groups (school-age children, preschool children, and pregnant women) can significantly lower the levels of infections below the threshold associated with morbidity. Control efforts are mostly focused on school aged children. However, it was shown that age groups other than school-age children

can have similar exposure risk, and might contribute to the persistence of these diseases despite repeated treatments. Mathematical models also revealed that it would be better to broaden treatments across all age classes if one needs to interrupt transmission. After more than 10 years of Mebendazole-based MDA in Cameroon, the disease still persist with relatively high prevalence and intensities of infections in some areas. In order to investigate factors associated with this persistence, we collected at the district level, baseline (1985-1987) and 26-years follow-up (2010) nationwide prevalence data, together with environmental (type of soil, climate, vegetation) and demographic (occupation/habits of populations) factors, as well as mass interventions against other diseases. We found that although environmental factors can explain reduction in prevalence, the persistence of the disease was negatively associated with the implementation of community directed treatment with ivermectin (CDTI) against onchocerciasis (ivermectin alone) and/or lymphatic filariasis (combination of ivermectin and albendazole). This study supports the important collateral impact of CDTI in deworming adults who are not taken into account in the Albendazole/Mebendazole-based deworming strategy, and appears as an advocacy for drug donation to the up to now not targeted age groups that can contribute in the persistence of the disease, thus slowing the momentum towards elimination.

### 536

#### JOINT WATER, SANITATION AND HYGIENE (WASH) AND NEGLECTED TROPICAL DISEASES (NTD) MONITORING: A PRACTICAL EXAMPLE

Leah Wohlgemuth<sup>1</sup>, Geordie Woods<sup>2</sup>, Angelia Sanders<sup>3</sup>

<sup>1</sup>Sightsavers, Addis Ababa, Ethiopia, <sup>2</sup>Sightsavers, New Orleans, LA, United States, <sup>3</sup>The Carter Center, Atlanta, GA, United States

The intersection of and collaboration needed between Water, Sanitation and Hygiene (WASH) and Neglected Tropical Diseases (NTDs) has been identified, prioritized and recently emphasized by Ministries of Health and development partners. As outlined in the Joint WASH and NTD strategy published by the WHO in 2015, one of the key objectives focused on the development of joint WASH and NTD indicators. In conjunction with the development of the WHO strategy experts from both sectors underwent a Delphi consultation to identify joint indicators for WASH and NTDs. As part of this consultation, many diverse experts across both sectors participated in 3 rounds of surveys to rank possible joint indicators, their order of importance, and feasibility of measurement. A fourth round was held for disease specific indicators. Using the final list from the Delphi Process and specifically looking at facial cleanliness and environmental sanitation (F&E) interventions for trachoma control, the indicators were adapted into monitoring and evaluation (M&E) frameworks across five countries: Ethiopia, Kenya, Malawi, Tanzania, and Uganda. The DFID SAFE program and the Queen Elizabeth Diamond Jubilee Trust Trachoma Initiative grants supported the development of a project wide F&E M&E (FEME) framework to be implemented at country level. These FEME frameworks include process indicators on joint WASH and NTD coordination, community level indicators on the presence of hand and face washing stations, latrines and clean faces as well as school indicators. Between January and March 2017, Malawi, Tanzania and Uganda conducted baseline surveys to collect these indicators. Data analysis is currently underway. Ethiopia and Kenya are using routine monitoring visits and existing WASH data to report on these indicators. The experience of these 5 country programs' use of data collection for M&E provides examples of different methods of using joint WASH NTD indicators in a NTD program.

### 537

#### COLLATERAL BENEFIT OF INDOOR RESIDUAL SPRAYING FOR MALARIA VECTOR CONTROL ON THE TRANSMISSION OF CUTANEOUS LEISHMANIASIS IN THE DISTRICT OF BAROUELI, CENTRAL MALI

Cheick A. Coulibaly<sup>1</sup>, Bourama Traore<sup>1</sup>, Sibiri Samake<sup>1</sup>, Ibrahim Sissoko<sup>1</sup>, Ousmane Faye<sup>1</sup>, Adama Dicko<sup>1</sup>, Sekou Fantamady Traore<sup>1</sup>, Jennifer M. Anderson<sup>2</sup>, Jesus Valenzuela<sup>2</sup>, Shaden Kamhawi<sup>2</sup>, Fabiano Oliveira<sup>2</sup>, Seydou Doumbia<sup>1</sup>

<sup>1</sup>International Center of Excellence in Research (ICER), Bamako, Mali, <sup>2</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Cutaneous leishmaniasis (CL) is an endemic neglected tropical disease prevalent in areas with seasonal malaria transmission in Mali. We assessed the effect of the introduction of indoor residual spraying (IRS) for malaria control on sand fly population diversity and abundance, and its impact on the risk of *Leishmania* transmission in the district of Baroueli, Mali. We conducted entomology surveys from March to September 2016 to determine sand fly species composition, density and infection rates using PCR. We also carried out a leishmanin skin test (LST) survey to determine the incidence of *Leishmania* infection. Historical data collected before the introduction of IRS (2005-2008) were compared with data collected in 2016, after five continuous years of IRS in Baroueli, to determine the effect of IRS on CL transmission. We found a substantial reduction in sand fly density after IRS of nearly 70% (9532 versus 2936). Sand fly species composition remained unaltered with *Sergentomyia schwetzi* continuing to be the most abundant sand fly species in the area. The density of sand flies of the *Phlebotomus* genus was significantly decreased compared with *Sergentomyia*. Despite the reduction in the density of *P. duboscqi*, *L. major* parasite infection rates did not vary significantly between the two study periods, 2.6% in 2005 and 3.5% in 2016 (P= 0.40). However, the incidence of exposure to *Leishmania* parasite as measured by LST in the human population was reduced by 50% (from 9% in 2008 to 4.2% in 2016). The substantial reduction in the density of *Phlebotomus duboscqi*, and in the incidence of exposure to *Leishmania infection* in human is most likely attributable to the collateral benefit of the 5 years IRS campaign. Interestingly, the lack of change in *L. major* infection rates in sand fly vector suggests that the reservoirs of disease remain available and that disruptions in the IRS campaign can lead to new outbreaks in this region.

### 538

#### UNDERSTANDING ADHERENCE/COMPLIANCE TO NEGLECTED TROPICAL DISEASE MASS DRUG ADMINISTRATION PROGRAMS: AN IMPORTANT TOOL FOR THE ENDGAME

Alison A. Bettis<sup>1</sup>, Julia C. Dunn<sup>1</sup>, Nay Yee Wyine<sup>2</sup>, Aye Moe Moe Lwin<sup>3</sup>, Nay Soe Maung<sup>3</sup>, Roy M. Anderson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Myanmar NTD Research Collaboration, Yangon, Myanmar, <sup>3</sup>University of Public Health, Yangon, Myanmar

Mass drug administration (MDA) has been ongoing for years in many areas endemic for helminth neglected tropical disease (NTD) infections. While coverage of MDA is regularly reported and documented, compliance/adherence to treatment is, by comparison, poorly understood. Using data collected in two villages in southern Myanmar (2015-16), we examine associations between non-adherence to MDA (specifically for soil-transmitted helminths and lymphatic filariasis) and various demographic factors, as well as identifying the primary reasons for non-adherence (as reported by study participants). 9% of the study population reported refusing drugs offered through the government MDA programme in the past year, with the most commonly cited reasons for this being distrust of the drugs (17.6%), not needing the drugs (13.2%), and fear of side-effects (9.5%). It is worth noting that overall compliance, as well as the

reasons behind it, varied between our two study villages (despite relatively similar demographic and socioeconomic profiles). Additionally, it was found that a proportion (approximately 7%) of the population had been engaging in self-treatment outside of the study and/or government-led MDA. Inadequate levels of compliance to MDA have a substantial effect both on the individual's morbidity as well as on the community, as individuals who remain untreated can act as reservoirs of infection and continue to contribute to the transmission cycle. Many MDA programmes do not require directly observed therapy (DOT), and as such must rely on individual reporting of past compliance - which is problematic for a number of reasons (e.g. recall bias, reporting bias). Regular and consistent reporting of compliance/adherence to MDA will be essential as some endemic areas shift their goal from morbidity control to elimination of helminth NTD infections. This is particularly true in areas of low prevalence, as targeted treatment may be required to reach the goal of elimination. It is important to understand levels of non-compliance, as well as the reasons behind it, in order to maximise the efficiency of MDA programmes.

### 539

#### IMPORTANCE OF INTEGRATED VECTOR MANAGEMENT IN VECTOR CONTROL AGAINST VECTOR BORNE DISEASES IN THE DISTRICT OF VATOMANDRY MADAGASCAR

**Herizo Ramandimbiarjaona**, Nambinisoa Mauricette Andriamananjara, Arsene Ratsimbao

*NMCP Madagascar, Antananarivo, Madagascar*

Vector-Borne Diseases are the infectious diseases transmitted by insect vectors; these diseases are heavy burdens in Madagascar. The main VBD in Madagascar are malaria, lymphatic filariasis and dengue. Integrated vector management is the rational decision-making process for the optimal use of resources for vector control. It is characterized by evidence-based decision-making, intersectoral collaboration, integration of chemical and non-chemical methods, advocacy and social mobilization, and legislation. In Madagascar, IVM is located in a pilot area in Vatomandry and which involves the Afro I project. The objective of this study is to demonstrate the effectiveness of 3 strategies including LLINs + IRS, LLINs + Social mobilization and LLINs alone to reduce the dependence on the use of DDT in the fight against malaria. A distribution of the LLINs in universal campaign mode was carried out in all the communes of Vatomandry, 4 Communes carried out an IRS of Actellic 300CS, some Fokontany of the District implemented a social mobilization and training for the capacity building of the different actors on IVM was carried out in this District. The results of these strategies are: for the IRS, 99.4% of the census structures are treated, 99.55% of the census populations are protected, 2037 children under 5 years old and 366 pregnant women are protected. For the LLINs distribution campaign, 103,500 nets distributed in this district, 195,606 populations and 49,245 households are protected. For the entomological study, the malaria and other VBD vectors are present in the 4 study communes: *Anopheles gambiae sl*, *Aedes albopictus* and *Culex sp. An. gambiae sl* is rather exophilic. Rice fields and stagnant waters are the potential larval breeding sites. The detection of vector resistance to insecticides in study sites is not yet very significant. In order to design an appropriate vector control program, a comprehensive assessment of VBD is essential, such as the systematic collection of epidemiological data, the development of entomological research and the follow-up of all IVM training.

### 540

#### MASS DRUG ADMINISTRATION IN CROSS-BORDER COLLABORATION: CASE OF MALIAN REFUGEES IN NIGER

Boubacar Kadri<sup>1</sup>, Youssouf Yayé<sup>2</sup>, Aichatou Alfari<sup>1</sup>, Zakari Madougou<sup>2</sup>, Zeinabou Trapsida<sup>2</sup>

<sup>1</sup>Ministry of Public Health, Niamey, Niger, <sup>2</sup>Helen Keller International, Niamey, Niger

Since 2007, Niger and Mali have been implementing annual integrated mass drug administration (MDA) for the elimination and control of lymphatic filariasis (LF), soil-transmitted helminths (STH), schistosomiasis (SCH) and trachoma with the support of technical and financial partners. During the political crisis in Mali, Niger welcomed more than 50,000 refugees from the endemic regions in Mali, and these refugees settled in the Tillaberi, Tahoua and Niamey regions. To protect the health of the refugees and the program impact of both countries, in 2013, with funding from the END Fund, the Ministry of Public Health, Niger organized an integrated MDA campaign for Malian refugees, supported by Helen Keller International (HKI)-Niger in collaboration with HKI-Mali that provided information on refugees' places of origin and treatment history, UNHCR that advised on access procedures in the camps, the Ministry of Interior that authorized the intervention within the camps and provided military escorts for the field teams, and the regional governor and directorate for Tillaberi region. MDA with ivermectin/albendazole (IVM/ALB), praziquantel (PZQ), and Zithromax and 1% tetracycline eye ointment (TEO) was conducted in 7 out of 8 refugee camps in the Tillaberi and Tahoua regions from June to August, 2013. A total of 16 supervisors and 86 drug distributors were used. During the MDA, drug distributors recorded data on distribution registers for each drug package and the data was subsequently summarized by health center chiefs and district NTD focal points. The LF/STH MDA with IVM/ALB treated 21,541 people out of targeted 29,761 (72% coverage: 46.9% male and 53.1% female). The SCH MDA with PZQ treated 23,741 people out of 29,761 (80% coverage: 50.4% male and 49.6% female) and the trachoma MDA with Zithromax/TEO treated 14,456 people out of 20,271 (71% coverage: 50.4% male and 49.6% female). The results show that good therapeutic coverage was achieved for all three drug packages despite the challenges in refugee camp settings. The intervention ensured that the refugees had not missed treatment and minimized the risk of cross-border transmission of the diseases.

### 541

#### A COMMUNITY STUDY OF THE IMPACT OF SEMIANNUAL ALBENDAZOLE ON LYMPHATIC FILARIASIS AND SOIL-TRANSMITTED HELMINTH INFECTIONS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

**Sebastien D. Pion**<sup>1</sup>, Cedric B. Chesnais<sup>1</sup>, Pitchouna N. Awaca - Uvon<sup>2</sup>, Jean Paul Tambwe<sup>2</sup>, Gary J. Weil<sup>3</sup>, Michel Boussinesq<sup>1</sup>

<sup>1</sup>Institut de recherche pour le Développement, Montpellier, France, <sup>2</sup>Programme National de Lutte contre l'Onchocercose, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Infectious Diseases Division, Department of Internal Medicine, Washington University School of Medicine, St. Louis, MO, United States

Implementation of mass drug administration (MDA) with ivermectin plus albendazole (Alb) for lymphatic filariasis (LF) has been delayed in Central Africa, because ivermectin can induce serious adverse events in people with very high *Loa loa* microfilaraemia. In 2012, the WHO recommended use of Alb MDA together with vector control to combat LF in areas with co-endemic loiasis. This strategy has been supported by the results of a 3-year community trial conducted in the Republic of Congo, where baseline circulating filarial antigenaemia (CFA, assessed using the immunochromatographic card test - ICT) and microfilaraemia (Mf) rates were 17.3% and 5.3%, respectively. In June 2014, we started a parallel trial in an area with higher baseline infection rates (31.6% for antigenemia

and 11.8% for microfilaremia) in the Democratic Republic of the Congo. Therapeutic coverage for the population > 2 years of age was ~ 75% at all treatment rounds. Evaluation at year 1 and 2 showed that the circulating filarial antigen (assessed using Filarial Test Strip - FTS) rate in the community decreased to 28.7% in 2015 and to 20.6% in 2016. Among 530 individuals who were examined both in 2014 and 2016, 185 were positive at baseline; 52 of those 185 (28.1%) cleared their antigenemia in 2016. Mf prevalence in the community decreased to 8.1% in 2015 and to 3.7% in 2016. Mf density (geometric mean of positive microfilariae (mf) counts) decreased from 171 mf/mL in 2014 to 104.4 mf/mL in 2015 and to 68.1 mf/mL in 2016 (60.2% reduction from baseline value). A total of 63/97 (65%) microfilaremic individuals at baseline have cleared their microfilaremia by 2016. Soil-transmitted helminth infections were monitored using Kato-Katz method. Between 2014 and 2016, prevalence of *Ascaris lumbricoides* infection in the community decreased from 14% to 2.3%, prevalence of hookworm infection from 58.6% to 38.3%, and prevalence of *Trichuris trichiura* from 8% to 3.6%. Year 3 results from that study will be presented at the meeting. This study should provide additional evidence regarding the use of semiannual MDA with Alb for elimination of LF in central Africa.

## 542

### STRENGTHENING THE TRANSMISSION ASSESSMENT SURVEY FOR LYMPHATIC FILARIASIS AND ONCHOCERCIASIS IN MUHEZA DISTRICT, TANGA, TANZANIA

**Maria J. Chikawe**<sup>1</sup>, Andreas Nshala<sup>2</sup>, Cecilia Uisso<sup>1</sup>, Kimberly Won<sup>3</sup>, Katherine Gass<sup>4</sup>, Deus Ishengoma<sup>5</sup>, Upendo Mwingira<sup>1</sup>

<sup>1</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>4</sup>NTD Support Center, Task Force for Global Health, Atlanta, GA, United States, <sup>5</sup>National Institute for Medical Research, Tanga, United Republic of Tanzania

Transmission Assessment Surveys (TAS) are used by lymphatic filariasis (LF) elimination programs to determine whether LF transmission has been interrupted and mass drug administration (MDA) can be stopped. In Tanzania, TAS have been conducted in 76 out of 186 LF endemic districts, and have resulted in LF MDA being stopped in 74 districts. A programmatic TAS conducted in Muheza district in 2014 showed that 13 of 1664 tested children were antigen positive. Though the number of antigen-positive children was below the critical cutoff of 20, the results raised a concern that transmission could be ongoing in some areas within the district. In 2016, a community-based TAS was conducted in Muheza with the aim of testing the sensitivity of the TAS for detecting evidence of recent LF transmission. The study design was modified to accommodate assessment of antibodies to *Onchocerca volvulus*, allowing assessment of program impact for both onchocerciasis and LF. A total of 1,439 children aged 6-7 years and 3,115 individuals with ≥8 years of age were tested for *Wuchereria bancrofti* circulating filarial antigen (CFA) using the Filariasis Test Strip (FTS), and 4,502 individuals were tested for antibodies to *O. volvulus* by Ov16 rapid diagnostic test (RDT). Five children (0.35%) aged 6-7 year and 80 individuals (2.6%) with ≥8 year old were positive by FTS. Overall, 98 (2.18%) individuals were positive by Ov16 RDT and the prevalence for OV16 antibodies among children aged <10 years 0.14%. The FTS results among young children support the TAS results from 2014 while the Ov16 RDT results among children suggest that MDA has had a significant impact on transmission of onchocerciasis in the district. This study demonstrated the feasibility of integrating onchocerciasis and LF elimination program activities. However, there was clear evidence of LF antigenemia and antibodies to *O. volvulus* among older individuals. These findings confirm the decision of stopping Mass drug administration for Lymphatic Filariasis in Muheza district. However due to presence of onchocerciasis in adult population, there may be a need for additional rounds of Mass drug administration.

## 543

### CHALLENGES AND PROSPECTS FOR TAKING DRUGS DURING MASS DRUG ADMINISTRATION WITH PRAZIQUANTEL AND ALBENDAZOLE: CASE OF THREE HEALTH DISTRICTS IN TILLABERI REGION, NIGER

Issa Gnanou<sup>1</sup>, **Issoufou Mounkaila**<sup>2</sup>, Aichatou Alfari<sup>1</sup>, Youssef Yaye<sup>2</sup>, Soumana Issifi<sup>1</sup>, Mahaman Naroua Dogo<sup>1</sup>, Idé Niandou<sup>1</sup>

<sup>1</sup>Ministry of Health, Niamey, Niger, <sup>2</sup>Helen Keller International, Niamey, Niger

The Niger Ministry of Health Neglected Tropical Disease (NTD) Program organizes annual mass drug administration (MDA) campaigns with the support of Helen Keller International through funding from USAID's END in Africa project. In 2017, the first round of MDA with praziquantel/ albendazole was held between February and March 2017 in four regions: Niamey, Diffa, Dosso and Tillaberi, where schistosomiasis is highly endemic. Supervision activities were conducted in four selected districts along the Niger River in the Tillaberi region, which is characterized by population displacement around Kandaji dam and insecurity in the northern area. A rapid survey was conducted at the end of drug distribution to assess compliance with taking the drugs. A convenience sample of 200 people aged ≥five years were surveyed in 10 villages (20 per village) of 8 health areas in Tillaberi, Tera and Kollo districts. The age range of 200 respondents was 5-85 years. Overall, 145 (72.5%) people received drugs and 130 (65%) ingested drugs. Of those aged 5-14 years (92), 64 (69.6%) received drugs and 63 swallowed them (68.5%). Of those aged ≥15 years (108), 81 (75%) received drugs and 67 swallowed them (62%). Among women (95), 72 (75.8%) received drugs and 63 swallowed them (66.3%). Among men (105), 73 (69.5%) received drugs and 67 swallowed them (63.8%). In those not receiving drugs the reasons given included absence (44%), the community drug distributor (CDD) did not come (25%), and stock-out (22%). Those who received but did not ingest the drugs reported being sick (6/15) and fear of side effects (6/15). The results showed that only 68.5% children and 62% adults actually ingested drugs (66.3% in women and 63.8% in men), lower than the minimum 75% required, though such rapid surveys do not reflect the true coverage. The factors affecting the receipt and ingestion of drugs reflect the challenges in MDA in these areas. More efforts for improving coverage include reducing CDDs' workload and providing training for key community actors such as public town criers and female volunteers.

## 544

### A COMPREHENSIVE SUSTAINABILITY FRAMEWORK FOR NEGLECTED TROPICAL DISEASE ELIMINATION PROGRAMS

**Irene Wangeci Thuo**, Sangeeta Mookherji

The George Washington University, Arlington, VA, United States

Great progress is being made in the push to eliminate Lymphatic Filariasis (LF) by 2020. However, additional guidance is required to ensure that elimination is sustained. A typical LF elimination program cycle has three phases: program initiation to identify infection prevalence; treatment to at-risk populations for 4-6 years to suppress transmission; and validation of elimination. This qualitative research was conducted in two steps using a multi-case study methodology: a literature review of sustainability frameworks to identify the optimum approach for LF, and the testing of the new sustainability framework on the Kenya National Programme for Elimination of Lymphatic Filariasis (NPELF). The research aimed to answer the following: (1) what elements of an LF elimination program need to be sustained?; (2) what factors influence sustainability of these elements?; and (3) how does decentralization of health services impact sustainability?. In-depth interviews were conducted with key stakeholders, programmatic documents were reviewed and key meetings attended. Data were subsequently arranged into the two key themes of interest- programmatic and contextual factors affecting sustainability. Within each of these, data were coded to specific programmatic or contextual factors and to the

phase of the LF program. The main findings of this research were, (1) sustainability of elimination programs is influenced by: technical factors related to the intervention; implementation factors; and those related to the broader environment in which the program operates; (2) the relative dominance of the three categories of sustainability factor varies with a program; (3) the goal of integrating NTD activities into national health systems needs to be rethought as health systems are inherently weak and their capacity to handle the intricacies of NTD surveillance is questionable; and (4) funding remains a constant factor that influences sustainability. With three years left to reach the 2020 elimination target, this key decision making tool is timely not only for Kenya but for NTD elimination programs at large.

## 545

### SCHOOL AND COMMUNITY BASED DEWORMING IN KENYA: WHAT ARE THE BARRIERS AND ENABLERS FOR SUSTAINING LONG-TERM IMPLEMENTATION?

Mishal S. Khan<sup>1</sup>, Maria Nyikuri<sup>2</sup>, Dina Balabanova<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>KEMRI, Nairobi, Kenya

In recognition of the substantial negative impact of soil transmitted helminths (STHs) on health and productivity in Kenya, where approximately 15 million people are infected, a national School-Based Deworming Programme (SBDP) was launched in 2009. To expand coverage to members of the community not reached by the SBDP, a door-to-door Community Based Deworming Programme (CBDP) is being tested through a randomised controlled trial in one high STH burden county, Kwale. While effectiveness of these two models for deworming are being assessed in terms of STH infection rates, less is known about factors facilitating or hampering programme implementation. These factors can be intrinsic (programme-specific) and extrinsic (related to the wider health system). Data were obtained from 43 in-depth interviews with respondents involved in design and implementation of the two programmes: community health workers (CHWs), teachers, government health and education officers at the county and subcounty level in Kwale, and national policy makers in Nairobi. A thematic analysis revealed that strong support and coordination from high-level health and education policymakers, association of deworming with improvements in school performance, and students' comfort levels in accepting deworming tablets from teachers, worked in favour of the SBDP. However, the SBDP relies on continued support from teachers during deworming campaigns, and misses children who are not in school. In contrast, interviewees reported that the CBDP reaches a wider population and that visible excretion of worms led to growing community support. The need for investment in CHW training and transport allowances, and in consistent engagement with community leaders and members to ensure acceptance of the CBDP were identified as critical factors for ensuring long-term success. We conclude that assessments of the fit of programmes with existing systems and policy processes such as decentralisation, informed by experiences of local implementers and planners, should complement evaluations of impact on parasitological outcomes in informing deworming strategies.

## 546

### EVALUATION OF SD BIOLINE ONCHO/LF IGG4 BIPLEX AND SD BIOLINE LF IGG4 SCREENING TOOLS IN FILARIAL-ENDEMIC REGIONS OF CAMEROON

Helen Storey<sup>1</sup>, Emily Gerth-Guyette<sup>1</sup>, Allison L. Golden<sup>1</sup>, Michael Kalnoky<sup>1</sup>, Abdel Njouendou Jelil<sup>2</sup>, Relendis Ekanya<sup>2</sup>, Amuam Andrew Mbeng<sup>2</sup>, Bertrand Ndzesang<sup>2</sup>, Kelsey Barrett<sup>1</sup>, Jeffrey Wellhausen<sup>1</sup>, Roger Peck<sup>1</sup>, Tala de los Santos<sup>1</sup>, Peter U. Fischer<sup>3</sup>, Samuel Wanji<sup>2</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>University of Buea, Buea, Cameroon, <sup>3</sup>Washington University School of Medicine, St. Louis, MO, United States

Lymphatic filariasis (LF) is a disfiguring disease caused primarily by *Wuchereria bancrofti*. In central Africa, LF can be coendemic with the filarial parasites *Loa loa*, *Mansonella perstans*, and *Onchocerca volvulus*. The main strategy to eliminate onchocerciasis and LF in Africa is mass drug administration (MDA) with ivermectin alone or in combination with albendazole, respectively. The elimination programs have a need for rapid point-of-care diagnostics for mapping, monitoring and post-MDA surveillance. In *L. loa*-endemic regions, ivermectin can lead to serious adverse events in individuals heavily infected with *L. loa* and treatment may need to be prevented. Furthermore, previous studies have shown that commercial antigen-detection tests for *W. bancrofti* cross-react with sera from individuals heavily infected with *L. loa*. The Wb123 antigen, a specific biomarker for detection of IgG4 antibodies against *W. bancrofti*, was identified and first evaluated National Institute of Allergy and Infectious Diseases at the NIH, Bethesda, MD, USA. Two new IgG4 rapid tests incorporating Wb123 are available from Standard Diagnostics, Inc.: the SD BIOLINE LF IgG4 rapid test (Wb123 RDT) and SD BIOLINE Oncho/LF IgG4 biplex rapid test (Ov16/Wb123 RDT). In order to evaluate these tests in areas with high prevalence of loiasis, fingerstick blood samples from 5000 individuals residing in 50 villages in 5 areas in Cameroon were screened with the Wb123 RDT and the Ov16/Wb123 RDT. No evidence was found for the presence of *W. bancrofti* by microscopy or qPCR of night blood of antigen. Only 0.2% of total samples were IgG4-positive by Wb123 RDT and 0.4% by Ov16/Wb123 RDT. Positive Wb123 tests did not cluster in any area. In contrast, the prevalence of Ov16 positive samples as measured by Ov16/Wb123 RDT varied between the areas from 0.1 to 28.8%. The results of the both RDTs were compared to ELISA. This study provides key evidence of performance of Wb123-based RDTs in areas endemic for multiple filarial diseases and results may be informative to NTD programs interested in adopting new tools and facing similar coendemicity.

## 547

### IMPROVING MASS DRUG ADMINISTRATION PERFORMANCE USING MHEALTH: FINDINGS FROM NORTHERN NIGERIA

Sarah Bartlett<sup>1</sup>, Nazaradden Ibrahim<sup>2</sup>

<sup>1</sup>Sightsavers, New Orleans, LA, United States, <sup>2</sup>Sightsavers, Kaduna, Nigeria

Onchocerciasis and lymphatic filariasis are slated for elimination by 2025 and 2020 respectively. Mass drug administration (MDA) is the core strategy to eliminate the two, but there are known challenges with how MDA is done. Lack of visibility means issues in the field cannot be identified in time to remedy them; data collected at the community directed distributor (CDD) level is rarely checked for errors; drugs are often allocated based on incorrect census numbers and there is little drug tracking in the field. A smarter process and better tools are needed to counter these issues if we want to reach elimination. In August 2016 Sightsavers, with the UNITED Project, piloted MDA monitoring in the Bungudu LGA of Zamfara State in Nigeria. This involved a change in process 1) census done before treatment and drugs allocated based on that census and 2) health facility workers sending in MDA data (census, treatment, drug use/waste) over their own mobile phones weekly, working towards personalized targets. These data were made immediately available for view online by LGA, State and National teams on custom reports made to monitor progress

against targets and access stock reports. Taking into account the census increase, Bungudu's oncho/LF campaign performance from the year before was compared with 2016. Therapeutic coverage increased 2.96%. Mectizan and Albendazole waste decreased 70% and 90% respectively, saving an estimated \$20,520 in drug waste for 237,875 persons treated. For a qualitative evaluation, extensive feedback sessions were held with participating health facility workers. During these newly prescribed weekly visits to collect data they reported that: 58% fixed mistakes on CDD registers; 15% saw a migrational increase in population and directed CDDs on what to do; 13% identified and regulated drug shortages in certain communities. Sightsavers, with UNITED, plan to scale-up monitoring in additional states in 2017. Sightsavers will also use this new platform and process to monitor both oncho/LF and trachoma MDAs in multiple countries in 2017.

### **PARTNERSHIP FOR NTD ELIMINATION: THE TANZANIA FIXED OBLIGATION GRANT APPROACH WITH LOCAL GOVERNMENT AUTHORITIES**

**Micah Musa**<sup>1</sup>, Ali Ngomelo<sup>2</sup>, Louis Lyimo<sup>3</sup>, Romanus Juma<sup>1</sup>, Raymond Mfugale<sup>1</sup>, Lulseged Alemayehu<sup>4</sup>, Delali Bonuedi<sup>5</sup>, Cheri Brown<sup>5</sup>, Edward Kirumbi<sup>2</sup>, Andreas Nshala<sup>1</sup>, Boniphace Idindili<sup>1</sup>, Neema Rusibamayila<sup>3</sup>, Upendo Mwingira<sup>6</sup>

<sup>1</sup>IMA World Health, Dar-es-Salaam, United Republic of Tanzania, <sup>2</sup>Tanzania NTD Control Program, Dar-es-Salaam, United Republic of Tanzania, <sup>3</sup>Ministry of Health, Community Development, Gender and Children, Dar-es-Salaam, United Republic of Tanzania, <sup>4</sup>IMA World Health, Washington, DC, United States, <sup>5</sup>RTI International, Washington, DC, United States, <sup>6</sup>National Institute for Medical Research; Tanzania NTD Control Program, Dar-es-Salaam, United Republic of Tanzania

Neglected tropical diseases (NTDs) which include schistosomiasis, soil transmitted helminths (STH), onchocerciasis, trachoma and lymphatic filariasis are still a public health concern in Tanzania. Control and eventual elimination of NTDs require multi-sectoral collaboration to address the key determinants of these diseases. Effective management and coordination of elimination efforts in Tanzania has relied on clear collaborative mechanisms among stakeholders. The councils (local government authorities (LGAs)) are the implementation units (IUs) for disease control and elimination activities. IMA World Health, through the ENVISION Project works with the central government and LGAs to manage funds related to NTD activities. In the past, activities had been delayed due to the time required to reconcile expenses against planned activities. Currently, the Tanzania NTD Control Program through its partner NGO provides fixed obligation grants (FOGs) to all supported IUs, a framework through which planning, implementation and reporting is streamlined. Annual plans are developed with all key stakeholders and reviewed prior to approval. Once plans are finalized, deliverables are set and upon approval, implementation units are funded based on implementation plans. Councils are reimbursed after completion of planned activities. In 2017, 142 district councils and 20 region councils received funding via FOGs ranging from US \$8,433 to \$92,250 based on the district population size. The use of FOGs has improved financial accountability by reducing delays in financial reporting. All districts (100%) have a dedicated accountant for NTD activities and 96% (n=136) of councils report timely access (within 7 days) to funds from the LGA finance system. Overall, there has been reduction in implementation and reporting delays. The use of FOGs at the LGA level has improved transparency, accountability and financial management practices, as well improving local ownership, thus positively impacting implementation of NTD elimination activities. This mechanism can be scaled up for use in other LGA funded activities beyond the NTD program.

### **STRENGTHENING THE SUPPLY CHAIN FOR NEGLECTED TROPICAL DISEASE PREVENTIVE CHEMOTHERAPY AND TRANSMISSION CONTROL MEDICINES IN TANZANIA**

**Frank Komakoma**<sup>1</sup>, Fay Venegas<sup>2</sup>, William Reuben<sup>1</sup>, Maria Chikawe<sup>3</sup>, Andreas Nshala<sup>4</sup>, Boniphace Idindili<sup>5</sup>, Sarah Craciunoiu<sup>6</sup>, Delali Bonuedi<sup>7</sup>, Jeremiah Ngondi<sup>7</sup>, Upendo Mwingira<sup>8</sup>

<sup>1</sup>Tanzania NTD Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>PATH, Seattle, WA, United States, <sup>3</sup>Tanzania NTD Control Program, National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>Tanzania NTD Control Program; IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>IMA World Health, Washington, DC, United States, <sup>7</sup>RTI International, Washington, DC, United States, <sup>8</sup>Tanzania NTD Control Program; National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

In Tanzania, preventive chemotherapy (PCT) for neglected tropical diseases (NTDs) has been undertaken as an integrated national program since 2009. The integrated Tanzania NTD Control Program (TZNTDCP) evolved from several vertical programs and each program had a separate supply chain. After integration, NTD medicine supply chain management became more complex and system improvements were needed. In 2014, the NTD program and partners undertook a logistics assessment in four districts and found a number of challenges with the PCT medicines supply chain. These included poor inventory management, incomplete MDA data forms, lack of reverse logistics and inadequate understanding of quantification formulas. The assessment revealed that better coordination of supply chain for NTD medicines was needed at the district level. The TZNTDCP developed guidelines documenting the supply chain management of NTD medicines, including: inventory management; quantification of medicines for the community; reverse logistics; completion of summary data forms; and reporting of adverse events. The guidelines were initially piloted with 30 district pharmacists who were trained as trainers for frontline health workers (FLHWs) and community drug distributors (CDDs). Routine supervision revealed that inventory records were kept at the district and health facility level; quantification of medicines sent to health facilities and schools was more accurate; left over medicines after MDA were minimized; summary data forms were completed appropriately; and medicines remaining after MDA were returned to districts stores. After the pilot, training on the supply chain was integrated into the routine training on MDA for district pharmacists. As of the end of 2016, an additional 158 district pharmacists have been trained on supply chain for PCT based on the national guidelines. Improved efficiency and reliability of supply chain management is important to reduce wastage of medicines and improve outcome of MDA campaigns. Based on the findings from the pilot, future activities will focus on FLHWs and CDDs nationwide.

### **SUPPORTIVE SUPERVISION FOR MASS DRUG ADMINISTRATION IN TANZANIA**

**Isaac Njau**<sup>1</sup>, Andrea Nshala<sup>2</sup>, Edward Kirumbi<sup>1</sup>, Abdallah Ngenya<sup>3</sup>, Boniphace Idindili<sup>4</sup>, Maria Chikawe<sup>5</sup>, Lynsey Blair<sup>6</sup>, Frank Komakoma<sup>4</sup>, Jeremiah Ngondi<sup>7</sup>, Upendo Mwingira<sup>5</sup>

<sup>1</sup>Tanzania Neglected Tropical Diseases Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Tanzania Neglected Tropical Diseases Control Program; IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>Tanzania Neglected Tropical Diseases Control Program; National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>Schistosomiasis Control Initiative, London, United Kingdom, <sup>7</sup>RTI International, Washington, DC, United States

Two neglected tropical diseases (trachoma and lymphatic filariasis) are targeted for elimination by 2020. Mass drug administration (MDA)

for preventive chemotherapy and transmission control (PCT) are key interventions for disease elimination. In Tanzania, supportive supervision with a cascade approach was designed to allow a supervisor to work closely with colleagues to establish goals, monitor progress and identify opportunities for improvement of MDA. To implement effective supportive supervision a checklist was developed in 2011, and reviewed in November 2015. The checklist comprises the following components: 1) advocacy, sensitization and mobilization 2) training activities 3) availability of PCT medicines; 4) availability MDA supplies; 4) availability of funds for MDA; 5) pre-MDA activities such as food preparation for school-based MDA; 6) timeliness of submission of programmatic and financial reports; and 7) success stories. Use of the checklist was shown to increase health worker motivation, improve service quality and increase uptake of interventions, particularly MDA. In 2016, supervision was carried out for school-based MDA in 102 councils and community-based MDA in 71 councils. This approach resulted in increased awareness and participation of council members in MDA activities; improved training at regional, districts, health facility and community levels; better commitment by MDA implementers at all levels; improved coordination of MDA activities; and better involvement of key decision makers and stakeholders. In addition, the proportion of councils achieving coverage targets increased from 71% in 2014 to 81% in 2016. Further, MDA activities were included in Council Comprehensive Health Plans (CCHP), and some councils allocated funds to top up MDA activities in their budgets. Supportive supervision is key for optimal implementation of MDA. Continuous improvement of the checklist as well as supervision before and during MDA activities will help the program reach its control and elimination goals for NTDs.

## 551

### DISSECTING THE ROLE AND PATHOGEN BENEFITS OF TRYPANOTHIONE SYNTHETASE OVEREXPRESSION IN *TRYPANOSOMA CRUZI*

Andrea C. Mesias<sup>1</sup>, Natalia Sasoni<sup>2</sup>, Diego G. Arias<sup>2</sup>, Nisha J. Garg<sup>3</sup>, María P. Zago<sup>1</sup>

<sup>1</sup>Instituto de Patología Experimental, Universidad Nacional de Salta - Consejo Nacional de Investigaciones Científicas y Técnicas, Salta, Argentina, <sup>2</sup>Instituto de Agrobiotecnología del Litoral, Universidad Nacional del Litoral - Consejo Nacional de Investigaciones Científicas y Técnicas, Santa Fe, Argentina, <sup>3</sup>Department of Microbiology and Immunology, School of Medicine, University of Texas Medical Branch, Galveston, TX, United States

Chagas disease is a tropical neglected illness caused by *Trypanosoma cruzi* that remains to be endemic in Latin America. This pathogen has to deal with different oxidant challenges such as the respiratory burst triggered inside the macrophage. Thus, it has an effective antioxidant system capable of overcoming the host barriers and maintaining the redox balance. The parasite antioxidant network utilizes trypanothione (TSH), a low MW dithiol, as substrate. The trypanothione synthetase (TryS) enzyme (produces TSH metabolite) is uniquely present in kinetoplastids, and so it is a good candidate for drug design. In order to characterize its role in the host-parasite interaction, we have overexpressed pTREX encoding TryS in *T. cruzi* SylvioX10 isolate by electroporation. Recombinant parasites (TryS+) exhibited stable overexpression (>2-fold increase) of the TryS protein and a significant increase in TryS enzymatic activity as compared to controls. The TryS+ showed a higher rate of metacyclogenesis, and ~20% more of infective forms were obtained in TryS+ cultures compared to the cultures of parasites transfected with empty pTREX. Furthermore, transfectant parasites tolerated higher doses of benznidazole (IC50 value: 21.3 µM and 11 µM, TryS+ vs. controls, respectively, p<0.05). To get insight into TryS role in host-parasite interaction, HL-1 cells were infected. After 36 h incubation, cells infected with TryS+ (vs. control) *T. cruzi* exhibited 2-fold lower levels of intracellular ROS, determined by H2DCFDA fluorescence (p<0.05). Our results suggest that *T. cruzi* utilizes TryS to promote differentiation from insect stage to infective forms and to maintain the redox balance in the host cells that support intracellular survival of the parasite.

## 552

### SPIROPLASMA PREVALENCE IN *GLOSSINA FUSCIPES FUSCIPES* IN UGANDA

Maria G. Onyango

Yale School of Public Health, New Haven, CT, United States

Tsetse flies (*Glossina* spp.) are vectors of African trypanosomes, which cause human and animal African trypanosomiasis (HAT and AAT respectively). In Uganda, *Glossina fuscipes fuscipes* (*Gff*) is the primary vector species and displays high genetic diversity, currently revealing four genetic units. While three endosymbiotic bacteria (i.e. *Wigglesworthia*, *Sodalis* and *Wolbachia*) have been described from *Gff* in Uganda, here we describe a fourth endosymbiont *Spiroplasma* from one of the *Gff* populations. *Spiroplasma* in *Drosophila* has been shown to protect its host against parasitic nematode as well as induce male killing. Bayesian phylogenetic analysis carried out on *Spiroplasma glossinidius* in comparison with other *Spiroplasma* strains show that it is close to pathogenic *S. Penaei*. Individuals collected from four genetic units were screened for *Spiroplasma* infection. An overall infection frequency of 23% (n=936) was detected. The trypanosome infection in the four genetic units was 5% (n=792). The regions with high *Spiroplasma* infection revealed a lower trypanosome infection and vice versa. A model of analysis of the deviance indicate that the source of the fly collection (genetic region) and trypanosome infection status were the main variables structuring *Spiroplasma* infection P < 2e-16 P (0.001). The *Spiroplasma* infection is detected in flies associated with 15% of the haplotypes (nine haplotypes out of the total 62 haplotypes). Ongoing work is focusing on infecting *Glossina morsitans* with *Spiroplasma poulsonii* to enable *in vivo* studies of its fitness effects and studying the effect of *Spiroplasma* on *Trypanosome* infection. *Spiroplasma* infections prevalence was high in the northwest genetic unit; this genetic unit recorded the lowest trypanosome infection. We detected a strong association of infection status with mitochondrial haplogroups A and B. Better understanding of the *Spiroplasma* infection prevalence in different *Gff* populations can help advance knowledge on its role in the evolution of the genetic patterns observed in host species in Uganda. This knowledge can help towards development of new vector control strategies.

### GENETIC BACKGROUND OF AN ATYPICAL *LEISHMANIA DONOVANI* CAUSING CUTANEOUS LEISHMANIASIS IN SRI LANKA

Sumudu R. Samarasinghe, Nilakshi Samaranyake, Nadira D. Karunaweera

Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

*Leishmania* protozoan parasites cause a complex spectrum of diseases in many tropical countries. *Leishmania donovani* causes visceral leishmaniasis, the most severe form of this disease. An atypical *L. donovani* is responsible for mostly cutaneous (CL-SL) and few visceral (VL-SL) cases in Sri Lanka. Here, we explain some genetic factors possibly underlying these different disease tropisms. Genomes of six CL-SL and two VL-SL clinical isolates were sequenced by Illumina MiSeq. Reads were mapped to *L. donovani* reference (BPK282A1). Read depth data was used to infer chromosome copy number and copy numbers of protein-coding genes. Tandem gene arrays were identified using OrthoMCL. Most genes with high SNP counts in CL-SL were kinases. Protein kinase networks have a potentially important role in virulence. Additionally, midasin and hypothetical proteins were found. In VL-SL most high SNP count genes were hypothetical. A Tm vesicle-mediated sorter implicated in regulating host immunity, ubiquitin protein with a potential role in pathogenesis and concanavalin A-like lectin were also found. In CL-SL, most chromosomes were disomic, except for monosomic chromosome 2 and trisomic chromosomes 22 and 26. Chromosome 31 showed pentasomy. In VL-SL, most chromosomes demonstrated disomy or intermediate somy (E.g. 2, 3, 5, 8, 21, 22, and

26). Supernumerary chromosome 31 was tetrasomic. Some differences may have a role in altered pathology. We found 192 and 241 tandem gene arrays in CL-SL and VL-SL respectively with 42 arrays with at least a 2-fold change in gene copy number. Among them D-lactate dehydrogenase-like protein involved in pyruvate metabolism, branched-chain amino acid aminotransferase involved in amino acid metabolism, HUS 1 protein which helps the parasite to cope with replicative stress, GP63/leishmonolysin, a virulence factor were observed with a higher copy number in VL-SL arguing that these genes may have an important role in causing different pathologies. These differences between the CL-SL and VL-SL provide insights in to understanding the genetic background for attenuated visceralizing ability of Sri Lankan *L. donovani*.

## 554

### IDENTIFICATION OF *TRYPANOSOMA CRUZI* LINEAGES ASSOCIATED WITH CONGENITAL CHAGAS IN THE POPULATION OF SANTA CRUZ, BOLIVIA

**Leny Sanchez**<sup>1</sup>, Edward Valencia<sup>1</sup>, Angela Vidal<sup>1</sup>, Edith Malaga<sup>1</sup>, Raul Ynocente<sup>2</sup>, Daniella C. Bartholomeu<sup>3</sup>, Louisa Messenger<sup>4</sup>, Caryn Bern<sup>5</sup>, MG Finn<sup>6</sup>, Alexandre Ferreira<sup>3</sup>, Ramon Brito<sup>3</sup>, Manuela Verastegui<sup>1</sup>, Maritza Calderon<sup>1</sup>, Robert Gilman<sup>7</sup>

<sup>1</sup>UPCH, Lima, Peru, <sup>2</sup>UNMSM, Lima, Peru, <sup>3</sup>Universidade Federal de Minas Gerais, Minas Gerais, Brazil, <sup>4</sup>Department of Disease Control, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>5</sup>Department of Epidemiology and Biostatistics, School of Medicine, University of California, San Francisco, San Francisco, CA, United States, <sup>6</sup>Instituto de Tecnologia Georgia-EUA, Georgia, GA, United States, <sup>7</sup>Johns Hopkins University, Baltimore, MD, United States

Congenital transmission is one of the main problems of Chagas' disease, involving endemic and non-endemic countries. In Bolivia Chagas disease is a serious public health problem. Currently, the implementation of control programs for Chagas disease by WHO allowed the control and interruption of vector transmission of *Trypanosoma cruzi*, but in urban areas Chagas' disease is maintained due to the non-vectorial transmission of the disease like congenital transmission. The objective was identifying the lineages of *T. cruzi* associated with congenital Chagas. We analyzed 11 samples of Umbilical Cord Tissue of newborns congenitally transmitted from the population of Santa Cruz (Bolivia). The diagnosis and quantification of parasites was determined by the Real Time technique (qPCR) using the Taqman probe directed to the *T. cruzi* nuclear DNA. Identification of lineages was determined by the PCR-RFLP technique using three molecular markers: 1) CoxII + AluI, 2) rDNA 24S $\alpha$  and 3) Mini-exon SL-IRac. The results obtained from the 11 samples determined an average parasite load of 19x10<sup>6</sup> parasites / mg and an average of 9x10<sup>5</sup> parasites / mg. The PCR-RFLP technique identified the presence of the DTU V Lineage in the 11 umbilical cord tissue samples. Concluding that was possible to determine the parasitic load in Umbilical Cord Tissue specimens and it was also possible to identify the presence of the DTU V lineage from umbilical cord tissue of newborns congenitally infected with *T. cruzi* from the population of Santa Cruz- Bolivia.

## 555

### MAPPING METABOLOME ALTERATIONS IN *LEISHMANIA AMAZONENSIS* PROMASTIGOTES INDUCED BY LONG TERM AXENIC CULTIVATION, THROUGH A MULTIPLATFORM METABOLOMIC FINGERPRINT APPROACH

**Frederico Crepaldi**<sup>1</sup>, Juliano Simões de Toledo<sup>1</sup>, Leopoldo Ferreira Machado<sup>1</sup>, Anderson Oliveira do Carmo<sup>1</sup>, Daniela Diniz de Brito<sup>1</sup>, Angela Vieira Serufo<sup>1</sup>, Ana Paula Almeida<sup>1</sup>, Leandro Gonzaga de Oliveira<sup>1</sup>, Michelle Adriane Amantea<sup>1</sup>, Ángelez López-González<sup>2</sup>, Eduardo Antonio Coelho<sup>1</sup>, Lirlândia Pires de Sousa<sup>1</sup>, Coral Barbas<sup>2</sup>, Ana Paula Salles Fernandes<sup>1</sup>

<sup>1</sup>UFMG, Belo Horizonte, Brazil, <sup>2</sup>Universidad CEU San Pablo, Madrid, Spain

Leishmaniasis are widespread neglected endemic diseases with an incidence of 1.6 million new cases and 40 thousand deaths per year. *Leishmania* parasites may show distinct, species-specific patterns of virulence leading to different disease manifestations. It is well known that successive *in vitro* passages (SIVP) leads to attenuation of virulence, but neither the metabolism nor the pathways involved in these processes are well understood. Here, a virulent *L. amazonensis* (R0) strain was compared to three SIVP attenuated strains, R10, R40 and R60, submitted to the 10, 40 and 60 of axenic passages, respectively. *In vitro* assays and *in vivo* tests were performed to characterize and confirm the strains attenuation profile. By applying capilar electrophoresis, liquid chromatography and gas chromatography, coupled to mass spectrometry, a metabolomic fingerprint approach was performed, comparing R0, R10 and R60. The identified metabolites were clustered in biochemical categories and mapped in metabolic pathways: 67 metabolites were associated to 8 metabolic pathways. Metabolism of fatty acids was considered the most significant pathway altered post-SIVP. The metabolomic approach met correlations with previous proteomic findings of related to these same same SVIP strains. The biochemical pathways' analysis allowed the identified metabolites to be mapped in several biochemical pathways potentially involved in *L. amazonensis* infectivity and virulence.

## 556

### MULTISYSTEM METABOLOMIC FINGERPRINT ANALYSIS, ASSOCIATED TO IN VIVO CELLULAR DIFFERENTIATION PROCESS OF A WILD TYPE STRAIN OF *LEISHMANIA AMAZONENSIS*

**Frederico Crepaldi**<sup>1</sup>, Juliano Simões de Toledo<sup>1</sup>, Coral Barbas<sup>2</sup>, Ana Paula Salles Fernandes<sup>1</sup>

<sup>1</sup>UFMG, Belo Horizonte, Brazil, <sup>2</sup>Universidad San Pablo-CEU, Madrid, Spain

*Leishmaniasis* are widespread neglected endemic diseases with an incidence of 1.6 million new cases and 40 thousand deaths per year. *Leishmania* parasites may show distinct, species-specific patterns of virulence leading to different disease manifestations. Their processes of cellular differentiation are induced by their host's physical-chemical microenvironments, culminating in two main stages, promastigote and amastigote. Despite their importance as potential therapeutic targets or as research material for the development of vaccines, little is known about the biochemical and metabolic phenomena associated to the cellular differentiation in *Leishmania*. This research proposed to identify metabolites and metabolic pathways related to the *in vitro* cellular differentiation process, using a multi-analytic system based in Gaseous Chromatography (GC-MS), Liquid Chromatography (LC-MS) and Capillary Electrophoresis (CE-MS). Said multi-analytic system was able to compare polars, non-polars and low molecular weight metabolites simultaneously. After 3, 6, 12, 24, 48 e 96 hours of amastigogenesis, parasites' metabolomes were compared and the ions identified on their particular times of retention submitted to multivariate (PCA, PLS, OPLS) and univariate (t-Student, U Mann-Whitney) statistical analyses. Those showing statistical significance were selected to the putative identification of metabolites; those identified were confirmed by MS-MS or by

comparative analysis to standards and mapped in metabolic pathways with the help of bioinformatics. CE-MS and LC-MS identified 63 metabolites and confirmed 16. GC-MS analyses, the mapping and association of the identified metabolites to metabolic pathways have been concluded. The research only remains to be biologically validated.

## 557

### PATHOGENIC INFECTION ANALYSIS IN VITRO AND IN VIVO OF TRIPOMASTIGOTES: EVALUATION OF AREQUIPA STRAIN IN COMPARISON WITH COLOMBIANA AND CL BRENER TRYPANOSOMA CRUZI STRAINS

Bartholomeu<sup>4</sup>, Maritza Calderon<sup>1</sup>, Robert Gilman<sup>5</sup>

<sup>1</sup>UPCH, Lima, Peru, <sup>2</sup>UNMSM, Lima, Peru, <sup>3</sup>Instituto de Tecnología Georgia-EUA, USA, GA, United States, <sup>4</sup>Universidade Federal de Minas Gerais, Minas Gerais, Brazil, <sup>5</sup>Johns Hopkins University, Baltimore, MD, United States

*Trypanosoma cruzi* is a complex and heterogeneous parasite, including strains with intraspecific variations (pathogenic, antigenic and genetic variability). In this work we evaluated *T. cruzi* isolate from "La Joya", Arequipa-Peru and compared to the Colombian and CL Brener *T. cruzi* strain. The genotyping analysis showed that Arequipa strain is from DTU TcI, similar to Colombian strain and different from CL Brener strain (DTU TcVI). Analysis *in vitro* of proliferative capacity within peritoneal macrophages obtained from BALB/c mice showed that the Arequipa strain was the least pathogenic with the lowest rates of infection and multiplication. The effector responses of the macrophages were analyzed and the results showed that the Arequipa strain induces higher percentages of the oxidant molecules eROS and NO when compared to the Colombiana and CL Brener strains, on the other hand, the evaluation of the antioxidant defenses of the enzymes TcAPX, TcCPX, TcMPX, TcTrS, TcTrR, TcSodA and TcSodB, showed that the genome of these *T. cruzi* strains had similar gene copy numbers, although they had a differential repertoire in expression levels. The CL Brener strain presented higher expression of TcAPX, TcMPX, TcSodA, TcSodB and TcCPX and the Colombiana and Arequipa strains, higher expression of TcSodA, TcSodB and TcCPX, respectively. Likewise, the nonpathogenic Arequipa strain was reactivated (RE) into the triatomine vector, which resulted in increased expression of the enzymes TcAPX, TcMPX, and TcCPX. Finally, *in vivo* infection of C57BL/6 mice naturally resistant to *T. cruzi* was evaluated, the results showed that the Arequipa - RE strain had low parasitemia peaks, with a preferentially cardiac and intestinal tropism, although they had a low parasitic load when compared with the Colombian strain that had the highest cardiac and intestinal tropism and the CL Brener strain that had a higher cardiac and skeletal muscle tropism. Cytokine expression analyzes showed the same immunological profile during infection with the three *T. cruzi* strains evaluated.

## 558

### USE OF IMMUNOGENIC EPI TOPE ALPHA GALACTOSYL (A-GAL) FOR THE DIAGNOSIS OF CHAGAS DISEASE IN CHAGASIC PATIENTS FROM BOLIVIA AND PERU

Edward Valencia<sup>1</sup>, Edith Malaga<sup>1</sup>, Leny Sanchez<sup>1</sup>, Angela Vidal<sup>1</sup>, Juana Calderon<sup>1</sup>, Raul Ynocente<sup>2</sup>, Alejandro Florentini<sup>1</sup>, MG Finn<sup>3</sup>, Alexandre Ferreira<sup>3</sup>, Ramon Brito<sup>3</sup>, Maritza Calderon<sup>1</sup>, Robert Gilman<sup>4</sup>

<sup>1</sup>UPCH, Lima, Peru, <sup>2</sup>UNMSM, Lima, Peru, <sup>3</sup>Universidade Federal de Minas Gerais, Minas Gerais, Brazil, <sup>4</sup>Johns Hopkins University, Baltimore, MD, United States

Chagas disease affects about 8 million people in Latin America, with 50,000 deaths/year and more than 100 million people living in at-risk areas. This disease can represent a terrible economic loss for the

affected countries because of the high cost of vector control measures, diagnosis and treatment of patients and adverse effects of treatment. For the diagnosis of Chagas disease, up to now, serological methods are more widely used indirect hemagglutination (IHAS), indirect immunofluorescence (IIF) and Enzyme-Linked Immunosorbent Assay (ELISA) assays using total parasite, semi-purified antigenic fractions or non-infectious epimastigote homogenized. These presented variations in the reproducibility and reliability of the results, being necessary to develop new and more effective methods for the diagnosis of Chagas disease. The objective was to develop a immunology test using coupled  $\alpha$ Gal with synthetic viral particle (Q.beta- $\alpha$ Gal) to diagnosis of Chagas' disease based on the use of highly immunogenic epitopes present in glycoproteins and glycolipids on the surface of infectious forms of *T. cruzi*, such as Gal $\alpha$ 1,3Gal $\beta$ 1,4GlcNAc ( $\alpha$ Gal), not normally expressed in human cells, responsible for the induction of protective antibodies (anti-Gal). The humoral immune response to Q.beta- $\alpha$ Gal was tested using genetically modified animal models, such as  $\alpha$ 1,3-galactosyltransferase ( $\alpha$ GalT-KO) knockout mice, these animals, humans and old world monkeys do not express  $\alpha$ -Gal epitope on the surface of cells and tissues, being excellent producers of IgG anti- $\alpha$ Gal. With this methodology, the sensitivity and specificity for the diagnosis was tested with sera of infected and no infected population from Arequipa (Endemic area in Peru), We found a 53% and 90%, sensitivity and specificity respectively. We found moderate agreement with another serological test ( $Kappa=0.44$ ). Because of this, we suggest to increase the sample size to obtain more accurate results.

## 559

### HOST-TSETSE FLY INTERACTIONS IN TRYPANOSOMIASIS ENDEMIC COMMUNITY IN GHANA: IMPLICATIONS FOR HUMAN AFRICAN TRYPANOSOMIASIS (HAT)

Takashi Suzuki<sup>1</sup>, Kwabena M. Bosompem<sup>2</sup>, Daniel Boamah<sup>3</sup>, Kofi Afakye<sup>4</sup>, Jeffrey Agyapong<sup>2</sup>, Kojo Frempong<sup>2</sup>, Martine Abavana<sup>5</sup>, Thomas Azurago<sup>6</sup>, Samuel Kyei-Faried<sup>6</sup>, Tutu Osei<sup>7</sup>, Andrew Alhassan<sup>5</sup>, Nobuo Ohta<sup>8</sup>

<sup>1</sup>Kobe-kokiwa University, Kobe, Japan, <sup>2</sup>Noguchi Memorial Institute for Medical Research, Legon, Accra, Ghana, <sup>3</sup>Center for Plants Medicine Research, Mampong, Ghana, Mampong, Ghana, <sup>4</sup>University of Ghana, Legon, Ghana, <sup>5</sup>Ghana Veterinary Service Department, Accra, Ghana, <sup>6</sup>Ghana Health Services, Accra, Ghana, <sup>7</sup>Ghana Veterinary Service Department, Kintampo, Ghana, <sup>8</sup>Tokyo Medical and Dental University, Tokyo, Japan

Trypanosomiasis control in Ghana and many other African countries faces constraints as a result of difficulties in assessing the exact epidemiologic situation. To avoid HAT outbreak, control and surveillance of the disease must be continued and sustained. This work aimed at evaluating the current situation of HAT in terms of tsetse fly distribution and density, blood meal sources, and species of trypanosomes in circulation at the New Juaben Municipality (trypanosomiasis endemic community), Ghana. Tsetse flies were trapped using un-baited bi-conical traps deployed in various locations of the study site. The DNA extraction was conducted on blood samples spotted on filter papers from fed flies and mid gut sections using the Qiagen DNeasy kit. Portions of the mid gut samples were used for serological analysis. The results showed that, 176/259 (68%) tsetse flies captured were identified with undigested blood meal that was used in ELISA to determine the blood meal sources. The main sources of blood meal identified were: humans (16.9%), pigs (26.2%), goats (12.3%) and chicken (16.2%). There were 130/259 (50.2%) mid-gut tissues for nested PCR using ITS1 and other primer sets. About 58.5% (76/130) were positive for trypanosomes DNA with 64.5% (49/76) having single infection while 27/76 (35.5%) had mixed infections. The results further showed that, 89.5% (68/76) of the flies carried only *T. congolense* Forest subgroup, 24.1% (19/76) had *T. b. brucei* and none carried *T. b. gambiense*. There were 13/76 (17.1%) flies carrying *T. evansi*, *T. congolense* forest and *T. b. brucei* DNA. The study site was inhabited by a single tsetse fly species, *G. p. palpalis* in higher densities during the dry season, which was noted to have taken most of the blood meal from the pigs. The *T. congolense* Forest

type was the dominant sub-species carried by the tsetse fly. Even though *T. b. gambiense* was not identified, in a situation of unexpected introduction into the Municipality, the high populations of pigs and *G. p. palpalis* would present potential risk of sleeping sickness outbreak. Regular and integrated surveillance system is therefore recommended.

## 560

### EFFICACY OF GENETICALLY MODIFIED LIVE ATTENUATED LEISHMANIA VACCINES AGAINST INFECTED SAND FLY BITES

**Ranadhir Dey**<sup>1</sup>, Parna Bhattacharya<sup>1</sup>, Hamide Aslan<sup>2</sup>, Fabiano Oliveira<sup>2</sup>, Claudio Meneses<sup>2</sup>, Amritanshu Joshi<sup>3</sup>, Laís Pereira<sup>2</sup>, Shannon Townsend<sup>2</sup>, Anderson Guimaraes Costa<sup>2</sup>, Waldione de Castro<sup>2</sup>, Tiago Donatelli Serafim<sup>2</sup>, Iliano Coutinho Abreu<sup>2</sup>, Philip Castrovinci<sup>2</sup>, Robert Duncan<sup>1</sup>, Shaden Kamhawi<sup>2</sup>, Jesus Valenzuela<sup>2</sup>, Hira L. Nakhasi<sup>1</sup>

<sup>1</sup>CBER/Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>National Institutes of Health, Rockville, MD, United States, <sup>3</sup>John Hopkins, Baltimore, MD, United States

During natural transmission, an infected sand fly deposits parasites along with saliva and vector-derived components of the infectious inoculum. The enhanced virulence observed in sand fly-mediated transmission has been attributed to a sustained recruitment of neutrophils. The mechanism underlying this phenomenon remains unknown. In addition, previous studies have demonstrated that several experimental *Leishmania* vaccines protected mice against needle-challenge but failed against vector-mediated challenge. These studies clearly demonstrate that a vector-initiated infection is crucial for understanding pathogenesis, immunity and vaccine evaluation for leishmaniasis. Vector-transmission of *L. donovani* resulted in the intense accumulation of neutrophils and resulted in a 100-fold increased IL1 $\beta$  induction compared to needle injected parasites. Further, our studies demonstrated that IL1 $\beta$  is the main cause of neutrophil persistence following sand fly-transmission. Importantly, neutralizing the effect of IL1 $\beta$  by blocking IL1R abrogated neutrophil recruitment after infected bites and abolished parasite visceralization. To address whether live attenuated parasites can protect against the enhanced virulence of a sand fly-initiated infection, hamsters were immunized with *LdCen*<sup>-/-</sup> and sand fly salivary gland protein rLJM19, a potent immunomodulatory component of sand fly saliva. Five weeks post immunization hamsters were challenged with *L. donovani*-infected sand flies. We monitored these hamsters for up to 14 months post-challenge. During this period 50% of hamsters from the non-immunized group developed severe VL and died. None of the hamsters from the immunized group developed any VL symptoms. Immunized hamsters induced a strong Th1 type of immune response upon challenge with infected sand fly. The protection observed by survival of immunized hamsters was corroborated by a significantly lower splenic and hepatic parasite burden compared to non-immunized animals. The study demonstrates that *LdCen*<sup>-/-</sup> immunization is efficacious in controlling VL initiated by the sand fly vector.

## 561

### EVALUATION OF SAFETY AND EFFICACY OF LEISHMANIA MAJOR CENTRIN DELETED LIVE ATTENUATED PARASITES AS A PROPHYLACTIC VACCINE AGAINST CUTANEOUS AND VISCERAL LEISHMANIASIS

**Subir Karmakar**<sup>1</sup>, Ranadhir Dey<sup>1</sup>, Nevien Ismail<sup>1</sup>, Wenwei Zhang<sup>2</sup>, Greg Matlashewski<sup>2</sup>, Abhay Satoskar<sup>3</sup>, Hira Lal Nakhasi<sup>1</sup>

<sup>1</sup>U.S. Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>Dept of Microbiology and Immunology, McGill University, Montreal, QC, Canada, <sup>3</sup>Departments of Pathology and Microbiology, The Ohio State University, Columbus, OH, United States

Protozoan parasites of the genus *Leishmania* are responsible for a spectrum of human diseases known as leishmaniasis. Visceral leishmaniasis (VL) is most fatal if not treated and there is no licensed vaccine. Previous studies have shown that vaccination with low dose of dermatotropic

*Leishmania major* confers protection against reinfection as well as cross-protection against VL. However such method of immunization is not practical because of the greater risk of infection in naïve population. Therefore, genetically modified live attenuated parasites that are non-pathogenic might induce the same protective immunity as leishmanization. Previously, we have shown that centrin gene deleted *Leishmania donovani* induces a protective immunity in various animal models against homologous as well as heterologous challenge. In this study, we have developed centrin-gene deficient *Leishmania major* (*LmCen*<sup>-/-</sup>) using CRISPR-Cas methodology and evaluated the safety and immune stimulating efficacy using hamster model. Our results demonstrated that intradermal immunization of hamster with *LmCen*<sup>-/-</sup> by needle injection did not develop any detectable lesion in the ear of the hamsters up to seven weeks after immunization and there was no parasite persistence compared to *L. major* wild type (*LmWT*) infection. *LmCen*<sup>-/-</sup> immunization significantly induced the expression of IFN- $\gamma$  with a concomitant down regulation of IL-10 in the ear, draining lymph node and spleen compared to *LmWT* infection suggesting induction of a Th1 type of immunity. Compared to *LmWT* infected animals, *LmCen*<sup>-/-</sup> immunized hamsters showed a protective IgG2 dominant response as observed by a higher IgG2/IgG1 ratio further indicating the development of Th1 response. We also showed that *LmCen*<sup>-/-</sup> parasites alone is sufficient to induce a host protective immune response and addition of adjuvant (Glucopyranosyl Lipid Adjuvant, GLA) does not enhance the protective immune response. Studies are underway to demonstrate the efficacy of this vaccine against cutaneous and VL infections. Taken together, the study demonstrates that the *LmCen*<sup>-/-</sup> parasite is safe and immunogenic vaccine candidate.

## 562

### COMPARATIVE STUDY OF VARYING CONCENTRATIONS OF A NIGERIAN PLANT EXTRACT (E557) ON LOCAL AND STANDARD STRAINS OF MYCOBACTERIUM TUBERCULOSIS

**Wisdom O. Iyanda-Joel**, Emeka E. Iweala, Shalom N. Chinedu  
Covenant University, Ota, Nigeria

The widespread recurrence of drug-resistant tuberculosis particularly fluoroquinolone-resistant multidrug-resistant and extensively drug-resistant tuberculosis has counterbalanced the Millennium Development Goal of reversing the global spread of tuberculosis by 2015. In this study, antimycobacterial sensitivity testing of a Nigerian plant extract, E557 was carried out to discover its possible effect at both extremely low and mildly high concentrations against clinical isolates (MTB-584) and control strains (H37Rv) of *Mycobacterium tuberculosis* (MTB). The proportion method for drug susceptibility testing on Löwenstein Jensen (LJ) media was utilized for antimycobacterial screening in a Biosafety Level-3 (BSL-3) facility. The extract was also assessed for its phytochemical constituents. The extremely low concentrations of E557 were 1, 40 and 250  $\mu$ g/ml while the high concentration was 100 mg/ml. Löwenstein Jensen media was prepared with respective concentrations of E557 and inspissated. Afterwards, the LJ media were inoculated with 10<sup>-3</sup> and 10<sup>-5</sup> dilutions of both local (MTB-584) and standard (H37Rv) strains of *Mycobacterium tuberculosis*. The positive control for the test was Rifampicin while untreated inoculated media was engaged as negative control. All the prepared LJ media were incubated at 37°C and observed every seven days for six weeks. At the end of six weeks, the result showed that both MTB-584 and H37Rv exhibited resistance (> 250 colonies: ++) to the extracts at 1, 40 and 250  $\mu$ g/ml as revealed by the creamy non-pigmented colonies observed on all the LJ media prepared with extracts. Contrariwise, there was no growth at all (zero colony: 0%) on all the LJ media prepared with 100 mg/ml of E557 when matched with the negative control (150 and 500 colonies respectively for MTB-584 and H37Rv strains). Phytochemicals such as alkaloids, antocyanins and betacyanins, flavonoids, steroids and terpenoids were present in E557. Conclusively, higher concentrations of E557 possibly contain potent bioactive phytochemicals which can be developed into effective antibiotics against *Mycobacterium tuberculosis* strains.

## EVALUATION OF ANTIMYCOBACTERIAL ACTIVITY OF FIVE CAMEROONIAN PLANTS

Celine N. Nkenfou<sup>1</sup>, Carine T. Tchoufou<sup>2</sup>, Isabelle K. Mawabo<sup>3</sup>, Elvis N. Ndzi<sup>1</sup>, Jules R. Kuiate<sup>3</sup>

<sup>1</sup>CIRCB, Yaounde, Cameroon, <sup>2</sup>Catholic University of Central Africa, Yaounde, Cameroon, <sup>3</sup>University of Dschang, Dschang, Cameroon

Tuberculosis is considered as one of the most important public health problems worldwide. The inappropriate use of existing anti-tuberculosis drugs over the years has led to an increase in the prevalence of resistant strains, hence the need to develop new effective agents. The present study was carried out to evaluate the *in vitro* antimycobacterial activity of ethanolic and aqueous extracts (decoction) of *Spathodea campanulata* (Bignoniaceae), *Newbouldia laevis* (Bignoniaceae), *Canarium schweinfurthii* (Burseraceae), *Zanthoxylum heitzii* (Rutaceae) and *Drypetes gossweileri* (Euphorbiaceae) on *Mycobacterium smegmatis* ATCC 700084. These plants are used in traditional pharmacopoeias in Cameroon and other countries in Africa and Asia to treat people with symptoms of tuberculosis and others respiratory ailments. The ethanolic and aqueous extracts (decoction) obtained after drying and grinding of the bark of different plants enabled us to determine the antimycobacterial activity of the various extracts. This antimycobacterial activity was done using the microdilution method in liquid medium to determine the Minimum Inhibitory Concentration (MIC) and the Minimum Bactericidal Concentration (MBC). The results of the antimycobacterial tests showed that the ethanolic extracts of the barks of our plants were active on the strain of *Mycobacterium smegmatis* ATCC 700084 with MIC ranging from 62.5 to 500 µg / ml and a MBC ranging from 125 to 500 µg / ml. However, the most active plant with a MIC of 62.5 was *Zanthoxylum heitzii* (Rutaceae). The MBC / MIC ratio showed that the ethanolic extracts of the various plants had a bactericidal action on *Mycobacterium smegmatis* ATCC 700084. Phytochemical screening revealed the presence of the secondary metabolites that may be responsible for these activities. The results of this study suggest that the aforementioned plants could be important sources for the development of new antimycobacterial molecules.

## TUBERCULOSIS INFECTION IN MYASTHENIA GRAVIS PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Ahmed Kamal Sayed<sup>1</sup>, Ahmed Elmarazy<sup>2</sup>, Elsayed Ali Taha<sup>3</sup>, Zaheer Ahmad Qureshi<sup>4</sup>, Mohamed Fahmy Doheim<sup>5</sup>, Kadek Agus Surya Dila<sup>6</sup>, Doaa Alaa Ibrahim Ahmed<sup>7</sup>, Kenji Hirayama<sup>8</sup>, Nguyen Tien Huy<sup>9</sup>

Tuberculosis (TB) infection has been documented to exacerbate myasthenia gravis (MG) patients' condition and precipitate myasthenic crisis. Mechanism by which TB occurs and worsen MG patients condition is not fully understood. Therefore, we conducted a systematic review and meta-analysis to explore this phenomenon by collecting clinical and laboratory data on the complications and mortality of patients with concurrent conditions. Electronic databases and manual search were conducted. Retrieved papers were selected against inclusion and exclusion criteria, underwent full-text review, and data extraction. Quality

assessment was done using The Joana Briggs Institute Critical Appraisal Tool for cohort and case report studies. Data synthesized using open meta-analyst software and narrative review approach. Thirteen studies were included in our review: 10 of them were case reports and three retrospective cohorts. Pooled results of three cohort studies, involving 14150 patients, showed that prevalence of TB in MG patients was 0.6% (95% CI 0 to 1.4%). Two cohort studies reported that there is significantly increased rate of pulmonary TB following MG admission. Of interest, this association was absent for extra-pulmonary TB. Age more than 60 years old and corticosteroids administration prone MG patients to higher risk of developing TB. From 10 case reports of concurrent MG and TB, clinical signs and symptoms identified were ptosis associated with generalized fatigue and weakness of the lower extremities, shortness of breath in five cases with persistent productive cough in three of them, dysphagia and food regurgitation in three cases. MG patients are highly predisposed to the risk of developing pulmonary TB. This risk is enhanced by corticosteroids administration. Since TB infection aggravates the symptoms of MG, patients should be followed up with regular investigations for early diagnosis and management of TB.

## ANTIMYCOBACTERIAL 2-AMINOQUINAZOLIN-4-ONES: SYNTHESIS, BIOLOGICAL AND PHARMACOLOGICAL EVALUATION

Paul Njaria<sup>1</sup>, Rudolf Mueller<sup>2</sup>, Aloysius Nchinda<sup>2</sup>, Ronnett Seldon<sup>3</sup>, Dale Taylor<sup>4</sup>, Mathew Njoroge<sup>4</sup>, Leslie Street<sup>2</sup>, Digby Warner<sup>3</sup>, Anne Lenaerts<sup>5</sup>, Gregory Robertson<sup>5</sup>, Kelly Chibale<sup>6</sup>

<sup>1</sup>Department of Chemistry, University of Cape Town, Cape Town, South Africa, <sup>2</sup>Drug Discovery and Development Centre (H3D), Department of Chemistry, University of Cape Town, Cape Town, South Africa, <sup>3</sup>Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, <sup>4</sup>Division of Clinical Pharmacology, University of Cape Town, Cape Town, South Africa, <sup>5</sup>Department of Microbiology, Immunology and Pathology, Colorado State University, Fort Collins, CO, United States, <sup>6</sup>South African Medical Research Council Drug Discovery Unit, University of Cape Town, Cape Town, South Africa

Tuberculosis (TB) is a life-threatening infectious disease caused by *Mycobacterium tuberculosis* (*Mtb*). Globally, TB is a major public health burden with an estimated 10.4 million new cases and 1.8 million deaths reported in 2015. Although TB is curable, the treatment options currently available are beset by numerous shortcomings such as lengthy and complex treatment regimens, drug-drug interactions, drug toxicities, as well as emergence of widespread multi-drug resistance. Therefore, there is an urgent and compelling need to develop new, more effective, safer drugs with novel mechanisms of action, and which are capable of shortening treatment duration. 2-aminoquinazolinones with low µM antimycobacterial activity were identified through phenotypic whole-cell *in vitro* screening. In this study, about 90 analogues were synthesized in an effort to deliver an optimized lead compound. When evaluated against H37Rv *Mtb* strain grown on GASTE-Fe media, several compounds exhibited potent activity ( $\leq 10$  µM) and clear SAR trends. In addition, potent compounds had low cytotoxicity ( $> 25$  µM) and high microsomal metabolic stability. Candidates subjected to *in vivo* pharmacokinetics studies in mice exhibited good plasma exposures, favorable half-lives and were well tolerated. However, the representative compound evaluated for *in vivo* efficacy studies in an acute mouse model lacked activity. Further studies, including use of different growth media, showed that 2-aminoquinazolinones killed *Mtb in vitro* via a glycerol-dependent mechanism of action. These findings correlated well with the results from resistant mutant generation and whole genome sequencing studies, which revealed that all strains resistant to the investigational compound had SNPs in glycerol metabolism genes: *glpD2* and *glpK*.

566

## THE ROLE OF SOCIAL MEDIA IN A NATIONAL TUBERCULOSIS DRUG RESISTANCE SURVEY: LESSONS FROM AN ONGOING SURVEY IN GHANA

Augustina A. Annan

*Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana*

There is currently no countrywide representative, reliable data on the prevalence of Anti-Tuberculosis drug resistance in Ghana. The National Tuberculosis Control Programme and other stakeholders in collaboration with the Kumasi Centre for Collaborative Research (KCCR) as a technical agency are conducting a nationwide survey on drug resistance TB for the first time. Sputa from selected diagnostic sites some of which are more than 500km have to be transported to the laboratories of KCCR in Kumasi. We report on preliminary experiences of transporting and tracking samples using social media. The ongoing survey begun in April 2016 and involves 32 TB diagnostic sites selected on the basis of a two-stage cluster randomized sampling design on both anticipated yield and probability proportional to size method. We engaged the services of a conglomerate of privately owned vehicles' union, which are accessible to these sites to transport samples to the laboratories of the KCCR for further processing. We then created a mobile social group platform on Whatsapp (an application for social network) consisting of two representatives from each site as well as other stakeholders and named it 'National TBDRS'. The purpose is to notify the team at KCCR, on the following details about the sample; date and time of dispatch, driver's name, car number, estimated time of arrival, and bus terminal name. The group is administered by the KCCR Receptionist and the Coordinator of the survey at KCCR. A total 680 sputum samples have been transported from 32 survey sites. There have been no major delays (11:44±03:50) and all samples arrive within a three-day window from sputum collection sites. Additionally, 2.5% of samples received have been contaminated indicating a possibility of an efficient transport system. Although early days yet, we are of the opinion that the use of Whatsapp platform as well as privately owned transport system is an innovative technique that could be used in transporting and tracking potentially infectious and contagious samples in national drug resistance surveys for TB in resource poor settings.

567

## CLINICAL AND RADIOLOGIC FEATURES OF PNEUMONIA CAUSED BY STAPHYLOCOCCUS AUREUS AND STREPTOCOCCUS PNEUMONIAE

Malick Ndiaye<sup>1</sup>, Yekini Olatunji<sup>1</sup>, Bilquees S. Muhammad<sup>1</sup>, Jayani C. Pathirana<sup>1</sup>, Augustin E. Fombah<sup>1</sup>, Baderinwa Abatan<sup>1</sup>, Ebrim Ahamfula<sup>1</sup>, Muhammad I. Hossain<sup>1</sup>, Shah Sahito<sup>1</sup>, Rasheed Salaudeen<sup>1</sup>, Usman N. Ikumapay<sup>1</sup>, Ahmed Manjang<sup>1</sup>, Henry Badji<sup>1</sup>, Aliu Akano<sup>2</sup>, Philip Hill<sup>3</sup>, Brian Greenwood<sup>4</sup>, Grant Mackenzie<sup>1</sup>

<sup>1</sup>Medical Research Council The Gambia Unit, Banjul, Gambia, <sup>2</sup>The National Hospital, Abuja, Nigeria, Abuja, Nigeria, <sup>3</sup>Centre for International Health, School of Medicine, University of Otago, Dunedin, Otago, New Zealand, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The introduction of conjugate vaccines against *Haemophilus influenzae* type b and *S. pneumoniae* will cause these bacteria to be less common causes of pneumonia and *Staphylococcus aureus* will become a relatively more common cause of pneumonia. Clinicians are often faced with the decision whether empiric therapy should cover *S. aureus*. Even though textbook descriptions of *S. aureus* pneumonia are often quite distinctive, there are few objective data that describe the clinical and radiologic findings in pneumonia due to *S. aureus* compared to *S. pneumoniae*. We hypothesized that pneumonia due to the two different etiologies would exhibit different characteristics. We conducted population-based surveillance (365 days of the year, 24/7) in rural Gambia, West Africa, for

suspected pneumonia, in all health facilities in Basse Health Demographic Surveillance System (population 179,000) from 12 May 2008 to 31 December 2015 and Fuladu West district (population 97,000) from 12 September 2011 to 31 December 2014. Children aged <5 years were evaluated and investigated according to standardized criteria. Surveillance nurses collected blood cultures, doctors performed lung or pleural aspirations and chest radiographs were taken for all patients. We detected 306 cases of pneumonia proven by culture to be caused by *S. pneumoniae* and 72 cases of *S. aureus*. Comparing cases caused by *S. pneumoniae* vs *S. aureus*, 23 (8%) vs 8 (11%) died; median respiratory rate was 63 (IQR 55-76) vs 60 (52-64); median oxygen saturation was 96% (94-99) vs 97% (94-100), lower chest wall indrawing was observed in 168 (55%) vs 34 (47%); consolidation > half the hemithorax was observed in 60 (20%) vs 3 (4%), pleural effusion > half the hemithorax was observed in 39 (13%) vs 3 (4%), abscess was observed in 1 (<1%) vs 3 (4%), and WHO defined end-point consolidation was present in 214 (70%) vs 21 (29%). There is substantial overlap in the features of staphylococcal and pneumococcal pneumonia. With increasing prevalence of staphylococcal pneumonia in sub-Saharan Africa, and the difficulty in its diagnosis, it will be increasingly difficult for clinicians to prescribe targeted antimicrobial therapy.

568

## IMPACT OF THE INTRODUCTION OF PCV7/13 ON ANTIMICROBIAL RESISTANCE IN INVASIVE PNEUMOCOCCAL DISEASE OF LESS THAN 5 YEARS CHILDREN IN RURAL GAMBIA

Rasheed Adewale Salaudeen

*Medical Research Council Unit, The Gambia, Basse, URR, Gambia*

The routine use of pneumococcal conjugate vaccines (PCV) has been associated with reductions in the incidence of invasive pneumococcal disease (IPD) associated with antimicrobial resistance. We describe antimicrobial resistance in IPD due to all serotypes and NVTs pre- and post-introduction of PCV in The Gambia, West Africa, in the 0-59 month age group. We identified, serotyped and performed Clinical Laboratory Standard Institute guided-antimicrobial susceptibility testing on invasive pneumococcal isolates obtained during standardised population-based surveillance in the Basse Health & Demographic Surveillance System. PCV7 was introduced in August 2009 and PCV13 in May 2011. We report data from 2009 to the end of 2016. Of the 20,616 patients recruited, 301 pneumococcal isolates were screened against five antimicrobial agents. In the 2-23 month age group, incidence of oxacillin, chloramphenicol, and tetracycline resistant IPD fell from 78-96 and 75-106 per 100,000 person-years in 2009 and 2010 respectively to 14-47 /100,000 person-years in 2016. In the 24-59 month age group, there was a large fall in oxacillin and tetracycline resistant cases from 66-54 /100,000 person-years in 2009 to 5-9 /100,000 person-years in 2016. Resistance fell primarily due to reductions in vaccine-serotypes 5, 6A, 14, 19F and 23F. In contrast, the incidence of resistant NVT cases increased over time, particularly in the 2-23 month age group, primarily due to an increase in the incidence of NVT IPD with antimicrobial resistance from 0-20 /100,000 person-years (which is 0-27% of proportion of total resistance incidence) to 7-41 /100,000 person-years (which is 50-100% of proportion of total resistance incidence) in 2016. Tetracycline resistance generally rise mainly in serotypes 12F, 19F, and 14. The isolates were generally sensitive to erythromycin but were 95-98% resistant to cotrimoxazole throughout the study. Overall, antimicrobial resistant IPD is reducing as emerging resistance in NVT is moderately rising in 2016. Ongoing surveillance is important to determine future trends in resistance as it has both clinical and public health importance in PCV era.

## SELECTING A REFERENCE STANDARD FOR EVALUATING RESPIRATORY RATE DEVICES TO DIAGNOSE SYMPTOMS OF PNEUMONIA IN CHILDREN UNDER 5: LESSONS LEARNED FROM RESOURCE-POOR SETTINGS IN SUB-SAHARAN AFRICA AND ASIA

**Charlotte Ward**, Kevin Baker, Sarah Marks, Karin Källander  
*Malaria Consortium, London, United Kingdom*

Manually counting a child's respiratory rate (RR) for 60 seconds using an acute respiratory infection (ARI) timer is the WHO-recommended method for diagnosing symptoms of pneumonia. Evaluating new respiratory diagnostic aids is challenging due to the absence of an appropriate gold standard. A major difficulty is that automated monitors do not measure chest movements but derive the RR from other variables including carbon dioxide (CO<sub>2</sub>), blood oxygen saturation (SpO<sub>2</sub>) and sound. Other difficulties include measuring RR over a simultaneous time period, inconsistencies in medical expert RR counting, logistical difficulties when using videography to record chest movements for retrospective RR assessment, and poor performance of automated and manual RR counting aids. Here, we review evidence from the Pneumonia Diagnostics Project which trialled four RR devices using three reference standards, across four countries in Sub-Saharan Africa and South-East Asia, to share lessons learned about selecting a suitable reference standard for evaluating the performance of new RR counting aids for resource-poor settings. Three reference standards were used: a video recording of the child's chest movements with RR assessment by a 3-person expert panel; medical experts manually counting RR with a stopwatch, and a continuous respiratory patient monitor with a capnography CO<sub>2</sub> module. Results from the video reference standard show that of 120 readable videos, 97 (81%) had panel agreement ( $\pm 2$  breaths per minute (bpm)). The 97 video references were merged with the contemporaneous (<5 minutes) medical expert RR and the simultaneous capnography RR reference standards. For the medical expert, 34 (38.6%) were within  $\pm 2$  bpm and 48 (54.6%) were within  $\pm 5$  bpm from the video reference. Of the 77 matched pairs for the capnography, 31 (40.3%) were within  $\pm 2$  bpm and 45 (58.4%) were within  $\pm 5$  bpm. These results show that agreement with the video reference for both medical expert counting and capnography is low. For future studies, we recommend using the video expert panel reference standard until it can be proven that a simultaneously medical expert count is equally accurate.

## EVALUATION OF THE LOOP MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) METHOD ON THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS IN CAMEROON

**Laure Ngando**

*Centre Pasteur Cameroun, Yaounde, Cameroon*

Pulmonary tuberculosis is a bacterial infection caused by mycobacteria belonging to the *Mycobacterium tuberculosis* complex (Mtb). Tuberculosis is a major public health concern in the world. In 2012, 8.6 million persons developed tuberculosis and 1.3 million deaths. More than 95% of deaths from tuberculosis are recorded in low and middle income countries. In 2011 in Cameroon, 25,126 cases of tuberculosis were recorded. An efficient fight against this disease depends on reliable early diagnosis and proper management. Due to the importance of an early and accurate diagnosis, many efforts have been made to improve the management of tuberculosis. Amongst the techniques of nucleic acid amplification, a new method, LAMP (loop mediated isothermal amplification) used in the diagnosis of tuberculosis and easily applicable in limited resource settings has been recently implemented with sensitivity and specificity rates of 80% and 96% respectively. This is why we decided to undertake a study to assess this LAMP method in the early and rapid diagnosis of pulmonary tuberculosis at the Yaoundé Jamot hospital. Our general objective was to

assess the LAMP method (Loop Mediated Isothermal Amplification) for the rapid diagnosis of tuberculosis. We conducted a cross-sectional and prospective study which took place from 14th April to 5th June 2014 at the Yaoundé Jamot Hospital and *Centre Pasteur du Cameroun*. On the basis of an informed consent, we recruited 539 suspected TB (Tuberculosis) patients to assess the lamp method. We compared the LAMP method with microscopy using culture as the reference standard. Results obtained showed that the sensitivity and specificity of LAMP were 83.0% and 96.2% respectively. The sensitivity and specificity of microscopy were 53.9% and 99.1% respectively. We concluded that the sensitivity of LAMP was higher than that of microscopy. In other words, when a patient is sick, it will be easier to diagnose using the Lamp method, than microscopy.

## DIAGNOSTIC, MANAGEMENT AND REFERRAL PATTERNS AMONG PRIVATE HEALTH CARE PROVIDERS FOR PEDIATRIC RESPIRATORY ILLNESSES IN SOUTH INDIA

**Rajan Srinivasan**<sup>1</sup>, Anita Mathews<sup>2</sup>, Venkat Raghava Mohan<sup>1</sup>, Gagandeep Kang<sup>1</sup>

<sup>1</sup>*Christian Medical College, Vellore, India*, <sup>2</sup>*Tufts University School of Medicine, Boston, MA, United States*

Acute Respiratory tract Infections (ARI) cause approximately 30% of all pediatric deaths and is the leading cause of morbidity in developing countries. The Integrated Management of Newborn and Childhood Illness (IMNCI) focuses on reducing pediatric morbidity and mortality. Understanding diagnosis, management and referral patterns among health care providers promotes effective use of health care resources and understand antibiotic usage. A survey identified private health care providers in one block of Vellore district of whom a stratified subset representing allopathic, non-allopathic providing primary and secondary level care (65/312) were interviewed. Of those surveyed, 38/52 (73%) had diagnosed pediatric Acute Lower Respiratory Tract Infection (ALRI) in the last year. A majority 45/53 (85%) preferred supportive care for Upper Respiratory Infection (URI) while 21/53 (40%) preferred antibiotics. For severe ALRI 19/47 (39%) preferred chest X-Ray, 18/47 (37%) blood tests with 83% (44) choosing to treat with oral antibiotics along with bronchodilators (36, 68%). Penicillins were commonest for URI (18, 32%) while a combination of antibiotics was preferred for non-severe ALRI (10, 20%) and severe-ALRI (15, 27%). High respiratory rate (45, 83%), grunting (34, 63%), X-Ray findings (34, 63%), seizures and cyanosis were commonest causes for referral to higher centers and most (41/47, 87%) chose to refer children with severe-ALRI. Preferred referral centers were Government Vellore Medical College (30, 56%) and Christian Medical College Hospital (26, 48%). While most had diagnosed ALRI among children, most preferred supportive therapy for URI with some choosing to give antibiotics. While most preferred supportive therapy for URIs some added antibiotics, a quarter did not provide nebulization for severe and very-severe ALRI. Half the providers preferred not observe or admit children with ALRI but provided out-patient antibiotic therapy, which may have been due to their primary care setting. Understanding the basis of antibiotic therapies followed by private health care providers will improve tackling antibiotic resistance.

## APTAMERS SPECIFIC FOR PYRAZINOIC ACID AS A NEW TOOL TO DETERMINE PYRAZINAMIDE RESISTANCE DIRECTLY FROM SPUTUM SAMPLES CULTURES

**Roberto Alcántara**<sup>1</sup>, Mirko Zimic<sup>2</sup>, Patricia Sheen<sup>2</sup>, Pohl Milon<sup>3</sup>

<sup>1</sup>*Universidad Peruana Cayetano Heredia and Universidad Peruana de Ciencias Aplicadas, Lima, Peru*, <sup>2</sup>*Universidad Peruana Cayetano Heredia, Lima, Peru*, <sup>3</sup>*Universidad Peruana de Ciencias Aplicadas, Lima, Peru*

Tuberculosis (TB) is still an important infectious disease that affects low-income countries. The most important problem related to TB is the increase of multidrug-resistant and extensively drug-resistant

tuberculosis. Susceptibility tests exist for Rifampin and Isoniazid, including microbiological and molecular methods. However, for pyrazinamide (PZA) there are not any standard test to evaluate susceptibility. The detection of PZA resistance shows several disadvantages, i.e. necessity of an acid pH or the variable correlation index between PZA resistance and pncA mutation. Previous studies in our laboratory have demonstrated that the detection of pyrazinoic acid (POA) can be used as a biomarker to predict PZA resistance. PZA susceptibility of *Mycobacterium tuberculosis* strains can differentiate by the production of POA. Sputum samples cultures in presence of PZA can produce POA in the supernatant. In order to detect POA in culture, DNA aptamers were identified through SELEX. Each SELEX cycle included an amplification, a transcription, and a retro-transcription step. A library of 20N random aptamers was used in the process. A complex of POA linked to sepharose beads was target for positive rounds of SELEX. Sepharose beads were target for negative rounds of SELEX. To evaluate the enrichment, a Nuclease 1 assay was performed using dsDNA of each SELEX round. Libraries of different SELEX rounds were sequenced in Illumina MiSeq Platform. Sequences present in the negative round were discarded from all positive round sequence populations before to evaluate the abundance and enrichment across the SELEX process to identify the aptamers candidate. At least four sequences were identified. Currently, the binding capacity and specificity of the selected aptamers are being evaluated by ELISA and Cyclic voltammetry. This is the first time to use aptamers to detect POA. The use of aptamers can let to develop fast and specific susceptibility tests to determine PZA resistance directly from primary cultures of clinical samples, contributing in this way to increase the adherence treatment by a fast and correct susceptibility drug profile for the patients.

### BACTERIAL PROFILE AND DRUG RESISTANT PATTERNS IN PNEUMONIA SUSPECTED HIV PATIENTS AT ART CLINICS IN NORTHERN ETHIOPIA

Gebre Adhanom, **Muthupandian Saravanan**

*Mekelle University, Institute of Biomedical Sciences, Mekelle, Ethiopia*

HIV infected patients are susceptible to infectious agents. Pneumonia is one among the most frequently encountered diseases, where bacterial pneumonia are believed to be one of the most common causes of co-morbidity and mortality in HIV patients. In Ethiopia, there is scarcity of data which shows real burden of bacterial pneumonia and their antimicrobial susceptibility and associated risk factors. A cross-sectional study design was conducted from August- December, 2016 at ART clinics in Northern Ethiopia. A total of 252 HIV positive individuals who presented with signs and symptoms of pneumonia were consecutively included. Structured questionnaire was used to collect socio-demographic, clinical and associated risk factors data. Sputum specimens were collected, transported, and processed using standard operating procedures. The data was analyzed by descriptive statistics, bivariate and multivariate logistic regression. P-value < 0.05 and corresponding 95% confidence interval were considered for statistically significance. Out of the 252 samples from HIV patients, significant bacterial pneumonia was observed in 110 (43.7%) samples. The predominant bacterial isolates were *K. pneumoniae*, 23.6 %, *S. pneumoniae*, 15.5 % and *E.coli*, 14.5 %. Age, number of CD4+ cell count, alcohol consumption, and WHO stage of HIV infection, were potential risk factors to have bacterial pneumonia. Bacterial isolates showed resistance for penicillin, 9 (81.8%), followed by co-trimoxazole, 40 (39.8%) and tetracycline, 26 (24.5%). In addition to this, MDR was observed among 17.9% of the isolates. Significant number of bacterial pneumonia and high resistance for co-trimoxazole was observed in this study. Therefore, identification of the etiologic agent and performing the antimicrobial susceptibility pattern should be done to select the appropriate antimicrobial agent for the management of bacterial pneumonia in HIV patients.

## 574

### MULTI-DRUG RESISTANT TUBERCULOSIS TREATMENT OUTCOMES IN A HIGH HUMAN IMMUNODEFICIENCY VIRUS (HIV) PREVALENCE PROGRAMMATIC COHORT IN UGANDA

**Nansumba Margaret**<sup>1</sup>, Norbert Tiishekwa<sup>2</sup>, Agnes Ngabirano<sup>2</sup>, Provia Tumukunde<sup>3</sup>, Bright Twinomugisha<sup>2</sup>, Francis Mugabi<sup>4</sup>

<sup>1</sup>*Mbarara University of Science and Technology, Mbarara, Uganda*, <sup>2</sup>*Track TB/MSH, Mbarara, Uganda*, <sup>3</sup>*Mbarara Regional Referral Hospital, Mbarara, Uganda*, <sup>4</sup>*Mbarara Regional Referral hospital, Mbarara, Uganda*

Multidrug-resistant (MDR) tuberculosis (TB) is a threat to TB control and a public health concern. We present treatment outcomes of the first patients treated for MDR TB at Mbarara regional referral hospital, Uganda. MDR TB suspects are referred from peripheral health facilities where X-pertMTB/RIF is performed. If positive with resistance to rifampicin, patient is immediately started on a standardized MDR TB treatment regimen. The sample is then transported to the national TB reference laboratory where drug resistant testing, TB microscopy and culture are done. Data were collected retrospectively from the MDR TB register and hospital files. Only patients' data who had completed the treatment period were analysed. A total of 53 MDR TB patients were initiated on MDR TB treatment from the 14th January 2013 to 11th November 2015. Majority were male 39 (73.6%) and HIV co-infected, 29 (55%) with a CD4 cell count of 240 IQR [63-551] and median was of 35 years [30-40]. Out of these, 45 (89%) were analysed. Treatment success was registered in 35 (77.8%) patients, 9 (20%) died and only 1(2.2%) was a treatment failure. There was no association with HIV status  $p=0.37$ . Median times to culture conversion and death were 104 [62-112], and 122 IQR [21-82] days respectively. Out of 38 available patient files, 36 (95%) recorded 115 drug related adverse events of which the majority were gastrointestinal symptoms 31 (27%). Others were; hearing impairment 17(14.8%), other central nervous system toxicities; 21(18.3), dysaesthesia and arthralgia; 12 (10.4%) and 10 (8.7%) respectively, hypothyroidism and body itching; 6 (5.2%) each, gynaecomastia; 5(4.3%), loss of libido and renal impairment, 2(1.7%) each, and others 3 (2.6) were TB IRIS, weight loss and deteriorating condition leading to death in a patient with severe malnutrition. There was very good treatment success with only one failure despite the several drug toxicities and long treatment duration in the context of high HIV prevalence and this was enhanced by the short conversion time (4months). Treatment experience and outcomes could be improved by use of less toxic TB drugs or shorter MDR TB regimens.

## 575

### 13-VALENT PCV AGAINST INVASIVE

**Ilias I. Hossain**

*Medical Research Council Unit, The Gambia, Banjul, Gambia*

In 2011 a 13-valent pneumococcal conjugate vaccine (PCV13) was introduced in The Gambia to replace the 7-valent vaccine (PCV7). The effectiveness of PCV7 against invasive pneumococcal disease (IPD) is well established. However, PCV13 was licensed based on the non-inferiority of immunological correlates of protection compared with PCV7, so the effectiveness of PCV13 against IPD still needs to be confirmed, particularly in countries with a high disease burden. We conducted a population-based case control study to estimate the effectiveness of PCV13 against IPD. Cases of IPD (i.e. *Streptococcus pneumoniae* isolated from the blood or cerebrospinal fluid), were recruited from two hospitals in the Upper River Region and Central River Region of The Gambia, and four community controls, matched on date of birth and season, were identified for each case. We used conditional logistic regression to estimate the effectiveness (1-adjusted odds ratio) of PCV13. We recruited 159 cases (28 vaccine type) and 628 controls. The median age of cases and controls was 58 weeks. For three compared to zero doses of PCV13, effectiveness was 49% (95% CI: -36%, 81%) against all IPD and 64% (95% CI: -130%, 94%) against

vaccine-type IPD. Current results suggest that PCV13 is effective against IPD in The Gambia, although study power is limited by high vaccine coverage. Enrolment is ongoing.

## 576

**ENTAMOEBA SPP IN BANGLADESH**

**Tuhinur Arju<sup>1</sup>**, Brittany N. Schnider<sup>2</sup>, Mamun Kabir<sup>1</sup>, Md. Masud Alam<sup>1</sup>, William A. Petri<sup>2</sup>, Rashidul Haque<sup>1</sup>, Carol A. Gilchrist<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>University of Virginia, Charlottesville, VA, United States

Diarrheal diseases are a leading cause of mortality and morbidity in low and middle income countries. Two members of the *Entamoeba* genus (*E. histolytica* and *E. moshkovskii*) are known to cause diarrhea. However other morphologically similar non-pathogenic members of the genus also infect humans. Diagnosis by microscopy of fecal specimens therefore can lead to false-positive results. To determine the prevalence of four of the *Entamoeba* species known to be present in the Bangladesh population (*E. histolytica*, *E. dispar*, *E. moshkovskii* and *E. bangladeshi*) a new *Entamoeba* species specific real time PCR assay was developed. Fecal samples (7134) were collected from Bangladesh children aged between 1 and 11 years were screened for the presence of *Entamoeba* cysts and trophozoites by direct microscopy and fecal culture. DNA was extracted from microscopy positive samples (334; 4.7%) and the infecting *Entamoeba* species was identified in 180 cases (54%). *E. dispar* was present in 107 of the 180 samples (60%); *E. histolytica* in 59 (33%), *E. bangladeshi* in 27 (15%). *E. moshkovskii* infected only one child in this study. Co-infections result in a total higher than 180 and as might be expected these most commonly involved the *Entamoeba* species with the highest prevalence (*E. histolytica* and *E. dispar*) although co-infections with *E. bangladeshi* were also observed. In conclusion: *E. bangladeshi* and *E. dispar* are both common in our study population and can significantly inflate the numbers in microscopy based diagnosis of amebiasis. The frequency of *E. dispar*, *E. bangladeshi* and *E. histolytica* co-infections support the hypothesis that cross-species immune protection does not occur in the *Entamoeba* genus. Interestingly, *E. moshkovskii* highly prevalent in previous studies was infrequent in the current study, suggesting that in the Bangladesh population outbreaks with this species may only occur periodically. Additional surveillance studies will be required to understand the epidemiology of *E. moshkovskii* associated diarrhea.

## 577

**ENTAMOEBA BANGLADESHI IN SOUTH AFRICA**

**Renay Ngobeni<sup>1</sup>**, Samie Amidou<sup>1</sup>, Shannon Moonah<sup>2</sup>, Koji Watanabe<sup>3</sup>, William A. Petri<sup>2</sup>, Carol A. Gilchrist<sup>2</sup>

<sup>1</sup>University of Venda, Thohoyandou, South Africa, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>National Center for Global Health and Medicine, Tokyo, Japan

*Entamoeba bangladeshi* is an anaerobic amoebozoan. It was firstly described in Bangladesh. *Entamoeba* species have been identified in different endemic regions of the world. In a recent study in S. Africa stools positive for amoeboid organisms by microscopy were now commonly PCR negative for the *E. histolytica* pathogen. This led to the hypothesis that other species of *Entamoeba* were now more frequent in the South African population. Stool samples were collected from November 2013 to June 2015 (rural=227) and (urban=257) from diarrheal and non-diarrheal patients. DNA was extracted and a highly sensitive qPCR assay for the and amplicon sequencing were used to detect and characterize infecting *Entamoeba*. *Prevotella copri* and *Enterobacteriaceae* were also detected by qPCR. The broad range *Entamoeba* probe however identified only 129 of the 484 as members of the *Entamoeba* genus (26.6%). Of these 49 were not able to be initially identified at the species level by the qPCR assay. The *Entamoeba* identified were *E. dispar* (8%), *E. histolytica* (6.4%), *E. bangladeshi* (4.5%) (co-infections result in a number higher than 26.6%). The amplicons of the 34 of the 49 unassigned *Entamoeba* were purified

and sequenced. Of these 10 were *E. histolytica* (adjusted prevalence 8.5%) and one *E. bangladeshi* (adjusted prevalence 4.75%) the remainder proved to be derived from *E. hartmanni* (2.6%), which was not discriminated against by the *Entamoeba* genus probe. *E. moshkovskii* was not identified in this population. A high parasite burden and expansion of the *P. copri* level was associated with diarrhea due to *E. histolytica*. In conclusion, *E. bangladeshi*, first discovered in an urban cohort in Bangladesh, was identified in urban and rural S. Africa. This is the first description of *E. bangladeshi* outside of Bangladesh. We were also able to observe changes in the host microbiome and the parasite burden associated with *E. histolytica* infections in S. African diarrhea cases versus infected asymptomatic controls but not with *E. bangladeshi* or the non-pathogenic *E. dispar*.

## 578

**IMPACT OF INTESTINAL PROTOZOA INFECTIONS ON CYTOKINE PROFILES OF INDIVIDUALS INFECTED BY FILARIAL AND/OR INTESTINAL HELMINTHS IN DIFFERENT AREAS OF GABON**

**Reinne Moutongo ep Mouandza**, Noé Patrick Mbondoukwe, Vanessa Jeanne Lengogo, Jacques Mari Ndong Ngomo, Denise Patricia Mawili Mboumba, Marielle Bouyou Akotet

Département de Parasitologie Mycologie, Libreville, Gabon

Filarial and Intestinal Protozoa Infections are prevalent in Gabon, an endemic area of Malaria. Thus, coinfection with these infections is not an exception. Complex Immunological interactions are implicated on the outcome of many infections. Therefore, this study estimated the level of Proinflammatory (IL-6, TNF-alpha) and down regulatory (IL-10) cytokines. Patients were included between January 2013 and June 2016, in Urban and Rural areas through a partnership between the Red Cross and Department of parasitology-Mycology of Université des Sciences de la Santé of Libreville, the capital City. Filaria and IPI were detected by using direct microscopy examination and Merthiolate Iode Formaldehyde concentration technics. Coproculture was used for the identification of helminths larvae. Cytokines were detected by flow cytometry. A total of 154 patients were included. Prevalence of Filarial, Protozoa, Helminthes+Protozoa, Filarial+Protozoa, Filarial+Helminthes infections were 20.8%, 25.3%, 20.8%, 7.1%, 3.2% respectively. The frequency of uninfected ones was 22.7%. Significantly lower levels of IL-6 were found in individuals infected by protozoa only compared to uninfected group (P=0,0024). Also, lower IL-10 levels were detected in group of individuals coinfectes by IPI and Filarial or Helminthes (P=0,0072). Whereas, TNF-alpha levels were higher in the group of individuals coinfectes by Filarial+Helminthes and Protozoa+Helminthes. TNF-alpha levels were lower in the group with Filarial+Protozoa. The ratio IL10/IL6 was significantly elevated in the group of individuals infected by protozoa and lower in the Filarial+Helminthes groups. Our results suggest that IPI reduce proinflammatory cytokines which play an important role in the protection against several infection such acute intracellular pathogen like *Plasmodium*. Coinfection with IPI+Helminthes also reduces down regulatory cytokine levels implicated in the protection during inflammation.>

## 579

**EVALUATION OF A NEW RAPID TEST FOR AMOEBIASIS, THE E. HISTOLYTICA QUIK CHEK™**

Blake Hanbury<sup>1</sup>, **Li Chen<sup>1</sup>**, Carol Gilchrist<sup>2</sup>, Jodie Stevens<sup>1</sup>, Susan Doyle<sup>1</sup>, Kristen Schwab<sup>1</sup>, Abdullah Siddique<sup>3</sup>, Biplob Hossain<sup>3</sup>, Cecilia Burkey<sup>2</sup>, Rashidul Haque<sup>3</sup>, William Petri<sup>2</sup>, Joel Herbein<sup>1</sup>

<sup>1</sup>TechLab Inc., Blacksburg, VA, United States, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>ICDDR, Dhaka, Bangladesh

*Entamoeba histolytica* and *E. dispar* are intestinal parasites that infect approximately half a billion people worldwide annually. Of the huge number of persons infected, most are infected with *E. dispar*, which has not been associated with disease. *E. histolytica* is well recognized

as a pathogenic amoeba, associated with intestinal and extraintestinal infections. *E. histolytica* is responsible for 100 million cases of amoebiasis annually, causing diarrhea, dysentery, and colitis. It is necessary to distinguish between the two species, as inaccurate diagnosis may result in unwarranted and unnecessary treatment. The most common method used to diagnose amoebiasis has been wet mount microscopy, which has poor sensitivity and specificity. Trophozoites and cysts are not easily identified in a single fecal specimen, and only rarely can *E. dispar* and *E. histolytica* be visually distinguished using light microscopy. The *E. HISTOLYTICA QUIK CHEK™* test is a rapid membrane enzyme immunoassay for the qualitative detection of pathogenic *E. histolytica* in human stools. This test offers an alternative to labor-intensive microscopy and PCR, and provides results in less than 30 minutes with simple and clear interpretation. A total of 851 human fecal samples including 755 fresh and 96 frozen specimens from male and female subjects aged from less than 1 year to 100 years were evaluated with the *E. HISTOLYTICA QUIK CHEK™* test at three geographically distinct clinical sites, including two US sites and one endemic site at Bangladesh. A Composite Reference Method (CRM), including microscopy, Luminex xTAG® GASTROINTESTINAL PATHOGEN PANEL test, and PCR with sequencing for the identification of *E. histolytica*, was used for analysis of the performance of the *E. HISTOLYTICA QUIK CHEK™* test. The test showed 91.4% sensitivity and 100% specificity, with positive and negative predictive values of 100% and 99.6%, respectively. The overall correlation with the CRM is 99.6%. In conclusion, the *E. HISTOLYTICA QUIK CHEK™* test, the only rapid device specific for *E. histolytica*, accurately detects this protozoan pathogen in human fecal specimens.

## 580

### EVALUATION OF A DIAGNOSTIC SCREENING TEST, THE TRI-COMBO PARASITE SCREEN, FOR DETECTION OF ENTAMOEBA.HISTOLYTICA, GIARDIA, AND CRYPTOSPORIDIUM PARASITES IN HUMAN FECAL SPECIMENS

Janice Hencke<sup>1</sup>, Li Chen<sup>1</sup>, Carol Gilchrist<sup>2</sup>, Jodie Stevens<sup>1</sup>, Susan Doyle<sup>1</sup>, Kristen Schwab<sup>1</sup>, Abdullah Siddique<sup>3</sup>, Mamun Kabir<sup>3</sup>, Cecilia Burkey<sup>2</sup>, Rashidul Haque<sup>3</sup>, William Petri<sup>2</sup>, Joel Herbein<sup>1</sup>

<sup>1</sup>TechLab Inc., Blacksburg, VA, United States, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>ICDDR, Dhaka, Bangladesh

Diarrheal diseases account for 1 in 9 child deaths worldwide, making diarrhea the second leading cause of death among children under the age of 5. The three most common causes of protozoan diarrheal infections are *Giardia spp.*, *Cryptosporidium spp.*, and *Entamoeba histolytica*. The traditional screening method, microscopic ova and parasite (O&P) examination of stool, is laborious, suffers from poor sensitivity and specificity, and requires expertly trained personnel to interpret results. In addition, it is very difficult to distinguish between pathogenic and non-pathogenic species of *Entamoeba* using microscopy. The TECHLAB® TRI-COMBO PARASITE SCREEN test, an enzyme immunoassay, qualitatively detects *Giardia spp.*, *Cryptosporidium spp.*, and *Entamoeba histolytica* rapidly from a single stool sample in a single reaction. This test is designed as the primary screening method for fecal specimens submitted for parasite analysis. The format allows the rapid screening of large numbers of clinical specimens. A panel of 850 human fecal specimens including 754 fresh and 96 frozen specimens from male and female subjects aged from less than 1 year to 100 years was tested with the TRI-COMBO test at two US sites and one endemic site at Bangladesh. The performance of the TRI-COMBO PARASITE SCREEN test was compared to a Composite Reference Method (CRM) which included microscopy, Luminex xTAG® GASTROINTESTINAL PATHOGEN PANEL test, and PCR with sequencing for the detection of *Giardia spp.*, *Cryptosporidium spp.*, and *E. histolytica*. The TRI-COMBO test exhibited a sensitivity of 91.6%, a specificity of 98.6%, a predictive positive value of 91.6%, a predictive negative value of 98.6%, and an overall correlation of 97.6% with the CRM. The results indicate that the TRI-COMBO test is a highly sensitive and specific ELISA that can be used as a primary screening assay to eliminate negative specimens

astmh.org

and identify specimens that require additional testing for *Giardia*, *Cryptosporidium*, and *E. histolytica*. The TRI-COMBO PARASITE SCREEN test makes parasite screening simple to perform, more cost efficient, and accurate.

## 581

### THE SEARCH FOR A SMALL MOLECULE THERAPEUTIC FOR THE TREATMENT OF GRANULOMATOUS AMEBIC ENCEPHALITIS

Corin V. White<sup>1</sup>, Matthew T. Laurie<sup>1</sup>, Kip Guy<sup>2</sup>, Joseph L. DeRisi<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>St. Jude Children's Research Hospital, Memphis, TN, United States

*Balamuthia mandrillaris* is a pathogenic free-living amoeba found in soil that exists in two forms. The trophozoite form is proliferative while the non-proliferative cyst form is resistant to harsh physical and chemical conditions. In rare instances, these protists cause granulomatous amebic encephalitis (GAE), a central nervous system disease that is almost always fatal. Among the few survivors of GAE, a multi-drug regimen including miltefosine, an anti-leishmanial agent and antifungals such as fluconazole, albendazole and flucytosine have been reported. However, studies evaluating the susceptibility of *B. mandrillaris* to these compounds and other potential therapeutics are limited. Here, we examined the *in vitro* efficacy of 1,134 FDA approved compounds for amoebicidal activity at high, moderate and low micromolar concentrations. Viability was determined using CellTiter-Glo reagent post-incubation with drug. Our most promising candidates include an antidepressant and an anticancer drug that achieve EC50s (the concentrations at which each drug gives half the maximal response) at moderate micromolar concentrations. Current work involves validation of amoebicidal activity and determining the interaction between these compounds and amoeba forms. Ultimately, we seek amoebicidal agents that are effective against both cyst and trophozoite forms to serve as pre-clinical leads for further medicinal chemistry optimizations. Additional future work includes the determination of cyst and trophozoite protein profiles to identify distinct surface proteins that interact with human cells. Such proteins may serve as candidate targets for novel treatments of GAE.

## 582

### IMPACT OF GASTROINTESTINAL PARASITES ON GROWTH USING QUANTITATIVE PCR IN A LONGITUDINAL ECUADORIAN BIRTH COHORT

Patricia E. Bryan<sup>1</sup>, Andrea Arévalo Cortés<sup>2</sup>, Carlos Sandoval<sup>2</sup>, Martha Chico<sup>2</sup>, Ashish Damania<sup>1</sup>, Philip J. Cooper<sup>2</sup>, Rojelio Mejía<sup>1</sup>

<sup>1</sup>National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Universidad Internacional de Ecuador, Quito, Ecuador

Gastrointestinal (GI) parasites are a public health concern with over 600 million school-age children and over 270 million pre-school children affected worldwide. These fecal-oral transmitted parasites may influence childhood growth. Previous studies investigating GI parasites and growth largely use poorly sensitive microscopy-based assays with few epidemiologic data on GI parasitic infections in pre-school children from rural Ecuador. To investigate the effects of GI parasites on growth, longitudinal data from a birth cohort in rural Ecuador were analyzed, correlating impact of GI parasites on anthropometric measures. Stool from a random sample of 400 children was collected at 1, 2, 3 and 5 years and analyzed using high throughput, multi-parallel qPCR assay for helminths (*Ascaris l.*, *Ancylostoma d.*, *Necator a.*, *Strongyloides s.*, and *Trichuris t.*) and protozoa (*Cryptosporidium spp.*, *Entamoeba h.*, and *Giardia l.*). At these time points, anthropometric measures (height, weight, head circumference) were collected. Overall prevalence of GI parasites peaked at 3 yrs. ( $p = 0.01$ ). Prevalence for *Giardia* (31.5%, 45.6%, 52.1%, and 43.3%) and *Ascaris* (6.8%, 12.9%, 16.4%, and 14.4%) was greatest at 1, 2, 3 and 5 yrs., respectively. *Trichuris* prevalence increased >200%

with peak burden by 2 yrs. ( $p = 0.013$ ). *Ascaris* burden was greater at 1 to 3 yrs. (0.72 fg/ul to 2.3 fg/ul,  $p = 0.001$ ), peaking at 2 yrs. with more moderate-to-heavy burden ( $p = 0.01$ ). *Giardia* burden increased with age and was greatest at 5 yrs. ( $p = 0.0001$ ). Infected children subsequently re-infected with higher burden of *Ascaris* and *Giardia* ( $p < 0.05$ ). GI parasites were associated with low anthropometric measures compared to WHO growth curves. At 5 yrs., infected children had lower height ( $p = 0.003$ ) and at 2 and 3 yrs., children with polyparasitism had lower height ( $p = 0.02$ ). At 3 and 5 yrs., infection with both helminth and protozoa was associated with reduced height ( $p = 0.006$ ). Our multi-parallel qPCR assay provided accurate epidemiologic data on GI parasitic infections in rural Ecuadorian pre-school children further, that GI parasitic infections may affect growth in early childhood.

## 583

### SEROLOGICAL DIAGNOSIS OF PARAGONIMIASIS USING A RECOMBINANT *PARAGONIMUS KELLICOTTI* ANTIGEN

**Kurt C. Curtis**<sup>1</sup>, Iya Sasse R. Nyaba<sup>2</sup>, Makedonka Mitreva<sup>1</sup>, Chounna Ndongmo Winston Patrick<sup>2</sup>, Ngongeh Glory<sup>2</sup>, Ndzeshang Bertrand<sup>2</sup>, Gary J. Weill<sup>1</sup>, Samuel Wanji<sup>2</sup>, Peter U. Fischer<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>University of Buea, Buea, Cameroon

Paragonimiasis (lung fluke infection) affects about 23 million people in Asia, Africa and the Americas. *P. kellycotti* is enzootic in North America and it occasionally causes human disease. While the infection is easily cured with praziquantel, diagnosis is difficult and often delayed. Paragonimiasis is commonly mistaken for community acquired pneumonia, tuberculosis or lung cancer. We have previously reported results from a study that used proteomics to identify *P. kellycotti* adult worm antigens with diagnostic potential such as a cysteine protease (Pkc-6) that were affinity purified with serum antibodies from infected patients. Full-length Pkc-6 was expressed in *E. coli* and purified and its diagnostic value was compared to crude total *P. kellycotti* extract. A IgG4 Western blot detected antibodies to Pkc-6 in 27 of 27 serum samples from subjects with either proven *P. kellycotti* or *P. westermani* (Philippines) infection. The recombinant antigen did not cross-react with sera of 30 subjects with other trematode or cestode infections or with sera from healthy U.S. volunteers. A Western blot with crude worm extract had similar results but higher background than the Pkc-6 assay. We evaluated the Pkc-6 assay with 161 serum samples from 3 villages in South West Cameroon that are endemic for paragonimiasis. We detected IgG4 antibodies to Pkc-6 in 12.4% of these samples, while microscopic detection of eggs in sputum or stool identified only 2 positives (1.2%). Both egg-positive subjects were also strongly positive by Western blot. Thus, the Pkc-6 Western blot appears to be sensitive diagnostic tool for *Paragonimus* infections in Africa, in Asia, and in the Americas. Additional studies are needed to further define the value of this new tool for clinical diagnosis and to better understand the epidemiology of paragonimiasis in different endemic settings.

## 584

### CLINICAL STAGES, EPIDEMIOLOGICAL AND LABORATORY CHARACTERISTICS OF FASCIOLIASIS IN CHILDREN POPULATION AT ANTA COMMUNITY IN CUSCO, PERU

**Karen Mozo**<sup>1</sup>, Maria L. Morales<sup>1</sup>, Clinton A. White<sup>2</sup>, Andres G. Lescano<sup>3</sup>, Karen E. Neira<sup>3</sup>, Miguel M. Cabada<sup>1</sup>

<sup>1</sup>Instituto de Medicina Tropical Alexander von Humboldt, Universidad Cayetano Heredia, sede Cusco, Cusco, Peru, <sup>2</sup>Department of Internal Medicine, University of Texas Medical Branch, Galveston, TX, United States, <sup>3</sup>EMERGE, Unidad de Investigación en Enfermedades Emergentes y Cambio Climático. Universidad Peruana Cayetano Heredia, Lima, Peru

*Fasciola hepatica* is a hyperendemic zoonosis in the Andes of Peru and Bolivia. The clinical course of the infection in the community has not been well described. We conducted a cross-sectional analysis of information from a fascioliasis community cohort of children 3-16 years old from Anta

province in Cusco. The aim was to define the clinical differences between fascioliasis phases in a community. Demographic and clinical information was collected from parents through household surveys. Each participant provided 3 stool samples that were tested by rapid sedimentation and Kato Katz tests and 1 blood sample that was tested for *F. hepatica* antibodies (ELISA), complete blood counts, and transaminases. Fascioliasis phases were defined as acute (stool (-), ELISA (+), and eosinophilia or elevated AST/ALT), subacute (stool (+), ELISA (+), and eosinophilia or elevated AST/ALT), chronic (stool (+), any ELISA result, and any eosinophils and AST/ALT result excluding subacute phase), and non-classified (ELISA (+) only). Chronic phases were categorized as C-ELISA (+) and C-ELISA (-). We compared clinical characteristics of the phases excluding the unclassified cases. The overall prevalence of *Fasciola* was 10% (250/2497). Four cases lacking blood results were excluded, 77 (31.3%) were non-classified, 18 (7.3%) acute, 26 (10.6%) subacute, 41 (16.7%) were C-ELISA (-) and 84 (34.1%) C-ELISA (+). C-ELISA (+) children were older than subacute children (11.2 ± 3.1 vs. 9.0 ± 3.0 years,  $p=0.001$ ) and were also more likely to present cough ( $p=0.007$ ), history of treatment for anemia ( $p=0.027$ ) or malnutrition ( $p=0.004$ ). Children with C-ELISA (+) were more likely than children with C-ELISA (-) to have fever ( $p = 0.022$ ), cough ( $p=0.031$ ), diarrhea ( $p=0.01$ ) or infection with *H. nana* ( $p=0.018$ ). No significant differences were found between acute vs. subacute phases, possibly due to limited statistical power. The sex and socioeconomic status distribution was similar between phases. Chronic disease was the most frequent phase in this community. Few clinical differences were significant between children in different phases of the infection which may hinder diagnosis.

## 585

### REGULATION OF GENE TRANSCRIPTION BY JNK AND P38 MAPK SIGNALING PATHWAYS IN *SCHISTOSOMA MANSONI*

**Sandra Grossi Gava**<sup>1</sup>, Naiara Tavares<sup>1</sup>, Anna Salim<sup>1</sup>, Flávio Araújo<sup>1</sup>, Guilherme Oliveira<sup>2</sup>, Marina Mourão<sup>1</sup>

<sup>1</sup>CPqRR, Belo Horizonte, Brazil, <sup>2</sup>ITV, Belém, Brazil

The identification and characterization of mechanisms and molecules involved in cell signaling are essential to the understanding of the *Schistosoma mansoni* parasite's biology. The *S. mansoni* genome encodes 252 eukaryotic protein kinases (ePKs), however, only 32 have some experimental functional evidence. Our group has demonstrated through functional studies that MAPKs are involved in parasite development, reproduction and/or survival and may therefore be considered potential targets for the development of new drugs. Due to the data scarcity on the *S. mansoni* ePKs function, this work has the main motivation to contribute to their experimental characterization by correlating expression data with *S. mansoni* development and reproduction. For this, SmJNK and Smp38 ePKs were knockdown in schistosomula by RNA interference, including three biological replicates. After two days, extraction of total RNA and evaluation of transcript levels by RTqPCR were performed. For all genes selected, we observed approximately 75% reduction on transcript levels. The extracted RNA was used to construct paired-end libraries sequenced on Illumina HiSeq 2500 platform. The reads obtained were mapped to the latest version of the *S. mansoni* reference genome and differentially expressed genes (DEGs) were identified by comparing each MAPK knockdown relative to untreated parasites. We identified 390 DEGs in SmJNK knockdown schistosomula and 810 DEGs in Smp38 knockdown schistosomula. UniProt, KEGG and GO databases were used to elucidate the functional roles of DEGs. This work allowed a better understanding of SmJNK and Smp38 signaling pathways, elucidating the functional roles of these MAPKs and the targets they regulate.

586

### A SYSTEMS BIOLOGY APPROACH LINKING GENETIC, EPIGENETIC, CYTOPLASMIC AND HOLOBIONT INHERITANCE TO UNDERSTAND RAPID ADAPTATION OF PARASITIC FLATWORMS (*SCHISTOSOMA SP.*)

**Christoph Grunau**, Celine Cosseau, Eve Toulza, Richard Galinier, Benjamin Gourbal

*University of Perpignan Via Domitia, Perpignan, France*

The GxE concept, meaning that genotype x environment interactions bring about the phenotype is widely used to describe adaptation phenomena. We propose to extend the initial notion of the GxE concept, and to replace G by "Inheritance system". This system is composed of several elements: the genotype, the epigenotype, cytoplasmic components but also microorganisms. They interact as an inheritance system with the environment, leading to the development of a phenotype. The elements of this system can be defined using their molecular composition, for instance the DNA as genetic information carrier and then the bearers of epigenetic information such as the chromatin marking system. However, it is not the system itself that generates the phenotype but the developmental process that produces over time and in interaction with the environment a phenotypic trait. In each of these processes, genetic, epigenetic, cytoplasmic (e.g. mitochondria) and holobiont diversity can change and result in ephemeral, fluctuating or stable, i.e. heritable phenotypic variations that are important for adaptation. To understand how parasitic worms can sometimes rapidly adapt to changing environments the parasitologist must 'simply' define (i) the units or elements of interactions i.e. the boundaries of these elements, and (ii) the types of interactions that interrelates them. The major consequence of our systems approach to inheritance is that if one wishes to understand the heritability of a trait, all elements of the inheritance system must be analyzed comprehensively using a range of different genotypes, epigenotypes, haplotypes and holotypes of the Inheritance System. However, we believe it is legitimate to exclude some of the elements from the experiment as long as one does not exclude them from the conclusions and generalizations, e.g. the finding that genetic variants have a strong association with a phenotype does not exclude similar or even stronger epiallelic associations and vice-versa. Our approach will be illustrated using the human parasite *Schistosoma sp.* a tropical platyhelminth that recently invaded the European continent via Corsica (France).

### KNOCKDOWN OF A *SCHISTOSOMA MANSONI* TRPML CHANNEL (SMTRPML) DISRUPTS ADULT WORM TEGUMENTAL STRUCTURE

**Swarna Bais**, Gordon Ruthel, Bruce D. Freedman, Robert M. Greenberg

*University of Pennsylvania, Philadelphia, PA, United States*

Praziquantel is currently the only drug available for treatment and control of schistosomiasis, a disease affecting over 200 million people. There is thus an urgent need for new antischistosomal. Several current anthelmintic drugs target ion channels of the parasite neuromuscular system. TRP channels are a large superfamily of non-selective cation channels that display an extraordinary diversity of functions and activation mechanisms. They play important roles in sensory signaling and other functions. Members of the TRPML (mucolipin) channel family are non-selective, predominantly intracellular channels that play key roles in endolysosomal physiology, including vesicular trafficking and biogenesis. They also function in nutrient acquisition and in regulating and maintaining neuronal development and integrity (in humans, mutations in one of the three TRPML subtypes causes mucopolipidosis type IV, a childhood neurodegenerative disorder). *Schistosoma mansoni* has a single predicted TRPML gene (SmTRPML; Smp\_198800). Knockdown of SmTRPML using RNAi in adult worms results in large, bubble-like sub-tegumental vacuoles

*astmh.org*

along with tegumental blebbing, effects similar to those found for TRPML loss in other organisms, and consistent with a role for SmTRPML in regulating the parasite endolysosomal system. MLSA1, a potent and selective cell-permeable agonist of TRPML channels, evokes an increase in adult worm motility, perhaps indicating a potential role for these channels in neuromuscular activity as well. These results indicate that SmTRPML may be a useful target for disrupting parasite endolysosomal regulation and nutrient acquisition.

587A

### QUANTITATIVE PROTEOMIC ANALYSIS OF THE HUMAN URINE FOR NOVEL PROTEIN BIOMARKERS FOR SCHISTOSOMIASIS AND ITS ASSOCIATED BLADDER PATHOLOGIES USING LABEL FREE MASS SPECTROMETRY

**Olugbenga Samson Onile<sup>1</sup>**, Bridget Calder<sup>2</sup>, Nelson X. C. Soares<sup>2</sup>, Chiaka I. Anumudu<sup>3</sup>, Jonathan M. Blackburn<sup>2</sup>

<sup>1</sup>Elizade University, Nigeria, Ilara-Mokin, Ondo State Nigeria, <sup>2</sup>Division of Chemical and System Biology, Department of Integrative Biomedical Sciences, IDM, University of Cape Town, Cape Town, South Africa, <sup>3</sup>Cellular Parasitology Programme, Department of Zoology, University of Ibadan, Nigeria, Ibadan, Nigeria

The failure to elicit an adequate immune response to adult *Schistosoma haematobium* is characterized by continuing inflammatory challenges to the exposed population, and it has been established as a possible risk factor in the aetiology of bladder cancer. Improved diagnosis of schistosomiasis and its associated pathology is possible through the use of a mass spectrometry approach for biomarker discovery among the infected population, which will influence early detection of the disease and its subtle morbidity. A high-throughput proteomic approach was used to analyse human urine samples for 49 volunteers from Eggua, a schistosomiasis endemic community in South-West, Nigeria. The individuals were previously screened for *Schistosoma haematobium* and structural bladder pathologies via microscopy and ultrasonography respectively. Samples were categorised into schistosomiasis, schistosomiasis with bladder pathology, bladder pathology and No pathology and schistosomiasis. These samples were analysed for potential protein biomarkers. A total of 1306 proteins and 8752 unique peptides were observed in this study (FDR = 0.01). Fifty-four human proteins were found to be potential biomarkers for schistosomiasis and bladder pathologies due to schistosomiasis by label free quantification. 36 parasite derived potential biomarkers were also identified, which include some existing putative schistosomiasis biomarkers which had been previously reported. Some of these proteins include Elongation factor 1 alpha, phosphopyruvate hydratase, histone H4 and heat shock proteins (HSP 60, HSP 70). These findings provide an detailed analysis of schistosoma and human host protein biomarkers for diagnosis of chronic schistosomiasis due to *Schistosoma haematobium* and its pathogenesis.

588

### *SCHISTOSOMA MANSONI* EXOSOMES AS MODULATORS OF THE HOST IMMUNE SYSTEM

**Maude Dagenais**, Jerry Aldridge, Timothy Geary, Paula Ribeiro  
*McGill University, Ste-Anne-de-BelleVue, QC, Canada*

Schistosomiasis is a parasitic disease that currently affects over 240 million people worldwide. In humans, schistosomiasis develops from infection with one of five *Schistosoma* species, including *S. mansoni*. As is the case for most parasitic helminths, the host response is generally not sufficient on its own to clear the infections with *Schistosoma* species, due, at least in part, to the ability of the parasite to evade the host immune system. Although many evasion mechanisms employed by *Schistosoma* species have been described, the potential contribution of parasite-derived extracellular vesicles (EVs) in immune evasion remains unexplored. EVs are known to transfer molecules from one cell to another via membrane vesicle trafficking, thus explaining the broad array of functional activities

attributable to them. Importantly, there is increasing evidence of the release of EVs in parasitic diseases, with roles both in parasite-parasite inter-communication as well as in parasite-host interactions. Here we describe a protocol for the isolation and purification of *Schistosoma mansoni*-derived exosomes-like vesicles and show that the vesicles elicit a response in bone marrow-derived macrophages (BMDMs) and alter the BMDMs' response to LPS. We also show that *S. mansoni*-derived exosomes elicit a humoral immune response in mice.

## 589

### IDENTIFICATION OF A CD193+ SUBPOPULATION OF B CELLS IN PRE-ADOLESCENT CHILDREN WITH SCHISTOSOMIASIS

Isaac O. Onkanga<sup>1</sup>, Huldah Sang<sup>1</sup>, Bartholomew Ondigo<sup>1</sup>, Rachael Hamilton<sup>2</sup>, Thomas Schneider<sup>2</sup>, Maurice Odier<sup>1</sup>, Pauline Mwinzi<sup>1</sup>, Lisa Ganley Leal<sup>2</sup>

<sup>1</sup>KEMRI/Centers for Disease Control and Prevention, Kisumu, Kenya, <sup>2</sup>STC Biologics, Cambridge, MA, United States

CD193 is a chemokine receptor expressed on inflammatory cells and has been associated with the migration and activation of eosinophils and T helper 2 (Th2) cells at sites of allergic diseases and helminth infections. In the spleen follicles, B cell CD23-bound IgE is thought to augment protective Th2 responses through induction of CD193+ T cells. However, to date, CD193 expression on B cells has not been reported. We sought to evaluate whether B cells express CD193 in human schistosomiasis. Seventy five children aged 10-12 years old were enrolled from five primary schools located within 5 kilometers of the shores of Lake Victoria in western Kenya. *S. mansoni* infection was determined prior to blood collection. Whole blood was stained for CD19, CD3, CD193 and CD23 and their expression levels measured using flow cytometry. Overall, the percentage expression of CD193 on CD19+ and CD19+CD23+ B cells were 50.44% (95% CI= 44.6256.27%) and 56.20% (95% CI=49.9362.47%) respectively while those on CD3+T cells and eosinophils were 15.95% (95% CI=11.6920.20%) and 91.18% (95% CI=88.7193.65%) respectively. Overall comparisons showed that the expression of CD193 was significantly higher on CD19+CD23+B cells than CD19+B cells, P<0.0001. The expression of CD193 was also shown to be significantly higher on B cells than on T cells (P<0.0001), but significantly lower than on eosinophils (P<0.0001). Similar findings were observed in the *S. mansoni* infected and uninfected groups. However, comparisons between *S. mansoni* infected and uninfected groups, and among children with different infection intensity levels did not show significant differences in the expression of CD193 on B cells. No correlation was observed between CD193 expression by B cells with the expression of CD193 on eosinophils and T cells. We show that CD193 expression is evident on CD19+B cells and that the expression is neither associated with *S. mansoni* infection status nor infection intensity. We are currently investigating the functionality of the CD193 expressed on B cells.

### IPSE, A UROGENITAL PARASITE-DERIVED HOST MODULATORY PROTEIN, INDUCES GENE EXPRESSION CRITICAL FOR HOST PATHOGENESIS AND PARASITE EGG SURVIVAL AND EXPULSION

Loc Le<sup>1</sup>, Christopher Bayne<sup>2</sup>, Evaristus Mbanefo<sup>1</sup>, Nirad Banskota<sup>1</sup>, Abdulaziz Alouffi<sup>3</sup>, Franco Falcone<sup>3</sup>, Michael Hsieh<sup>2</sup>

<sup>1</sup>Biomedical Research Institute, Rockville, MD, United States, <sup>2</sup>Division of Pediatric Urology, Children's National Health System, Washington, DC, United States, <sup>3</sup>University of Nottingham, Nottingham, United Kingdom

Schistosomiasis continues to be a burden of disease for over 260 million people. *Schistosoma haematobium* and *S. mansoni*, the two most prevalent human-specific species, cause urogenital and hepatoenteric schistosomiasis, respectively. Eggs laid by *S. haematobium* worms cause the immunopathology associated with urogenital schistosomiasis, which include pronounced bladder fibrosis, urothelial hyperplasia, and

is associated in increased risk of bladder cancer; egg-associated lesions caused by *S. mansoni* infection can lead to portal hypertension and liver failure. Egg secreted proteins have been identified to play a large role in balancing host pathogenesis with egg passage through the urine and feces to continue the parasite life cycle. Interleukin-4 inducing Principle of *S. mansoni* Eggs (IPSE) is the most abundant egg secreted protein and has three important functions: 1) bind immunoglobulins, 2) sequester chemokines, 3) translocate into the host cell nucleus to modulate gene expression. Preliminary work has shown that the *S. haematobium* homolog of IPSE, or H-IPSE, has species-specific host modulatory functions. To elucidate the potential of H-IPSE for therapeutic exploitation or its conceivable role in carcinogenesis, we studied H-IPSE in two formulations: 1) intravenous administration and 2) delivered in a suspension of Matrigel. Effects on bladder gene expression were assayed through RNA-Seq, revealing upregulation and downregulation of several critical pathways, such as genes related to cell cycle, immune signaling, and tissue repair. These findings hint at the roles of H-IPSE in host pathogenesis and parasite egg survival and expulsion.

## 591

### A STUDY OF SALMONELLA PREVALENCE IN FROZEN MEATS AND CORRELATION IN TESTS USED FOR SURVEILLANCE TO ASSIST IN A MORE EFFECTIVE FOOD INSPECTION GUIDELINES AT THE FOOD AND ENVIRONMENT LABORATORY IN AJMAN, UAE

Nishi Singh<sup>1</sup>, Bashayer A. Al Marzooqi<sup>2</sup>, Mohammed Zaman<sup>2</sup>, Ban Altoumah<sup>2</sup>

<sup>1</sup>Dubai Women's College, Dubai, United Arab Emirates, <sup>2</sup>Sharjah Women's College, Sharjah, United Arab Emirates

Foodborne diseases continue to be a major problem despite advances in detection and prevention measures due to ingestion of food contaminated with microorganisms. *Salmonella enterica* tops the list of causative organisms that can cause foodborne disease. *Salmonella* outbreaks are commonly associated with eggs, meat and poultry. This study was undertaken to estimate the prevalence of *Salmonella* in the meat products for the first time in the emirate of Ajman. Meat products form the main stay of the regions' food intake, so it is of crucial importance to ensure it is free of *Salmonella* and other related pathogens. The aim of this study is to determine the presence of *Salmonella* in the meat products and find if there is correlation between detection by culture, rapid tests and PCR analysis. This study is a prospective study conducted in the Food and Environment laboratory Ajman in 2015 to investigate the prevalence of *Salmonella* in frozen meats. A total of 133 samples of frozen meat samples were collected randomly. From each sample, 25 g was separated and treated with 225 mL of buffered peptone water, homogenized and incubated at 37°C for 24 hours. Three different methods were used to detect *Salmonella*, namely; manual method by routine culture, BAX system- Ready Reference for Standard PCR Assays method and RapidChek Select for *Salmonella* By PCR assay, 8 out of 133 frozen meat samples (6%) were found to be contaminated with *Salmonella*. By manual culture result 6 out of 121 (4.5%) were positive. This is a high rate of contamination and samples were declared unfit for consumption as per the UAE standards. In conclusion, these results indicate that the prevalence of the *Salmonella* sp. is of concern in the samples obtained by the Food and Environment laboratory in Ajman. The regions high ambient temperatures throughout the year, questionable storage facilities at small outlets and transport conditions in hot and humid conditions can be a potential source of bacterial growth and food borne diseases. The study also confirms that routine culture techniques cannot be relied upon alone to ensure food free of *Salmonella* contamination

## 592

### ABERRATION IN IRON AND MEAN CORPUSCULAR HEMOGLOBIN METABOLISM CAUSED BY LAMBDA CYHALOTHRIN AND AFLATOXINS IN FISH DIET FROM SELECTED AQUATIC SOURCES IN KENYA

Faith O. Onyangore

University of Kabianga, Kericho, Kenya

Fish is high in iron that the human body needs to stay healthy. Excess or deficiency of minerals like iron may seriously disturb biochemical processes and upset internal homeostasis, leading to various diseases and disorders. This is occurred in organisms of various fish species due to deficiency or excess of micro and macro elements which are caused by improper nutrition, avitaminosis or poisoning. The specific objectives of the study were to determine the iron levels and mean corpuscular hemoglobin affected by lambda cyhalothrin and aflatoxins in fish diet from selected aquatic sources in Kenya. The *Oreochromis niloticus* and *Clarias gariepinus* used were bred in Kenya marine and fisheries research institute at Sagana whereas other fish were obtained from River Nyando. Laboratory procedures for fish from both sources to determine iron levels were carried out at Kenya Industrial Research and Development Institute and measured using atomic absorption spectrophotometer (AAS) analyst 800 (Parkin Elmer Instrument, USA). Mean Corpuscular Hemoglobin measurements were done at Moi Teaching and Referral Hospital laboratory. The results showed that iron availability was lower on treatment with aflatoxin compared to lambda cyhalothrin with a mean of  $3.66 \pm 0.84$  mg/kg. The mean corpuscular hemoglobin (MCH) levels was higher in both fish species obtained from Sagana with a mean of  $42.9 \pm 10.28$  (SEM 1.98 n=27) in *Clarias gariepinus*. The MCH on treatment with lambda cyhalothrin were elevated at 53.21 pg with both having means higher than in the control group. The iron levels were lower than the normal values in both treatments but aflatoxins caused lower iron levels. The reverse was true for MCH. Natural occurring toxins as well as synthetic toxicants affect the nutritional value of food and food quality tests be conducted from farms before and after processing to prevent disease transmission through diets.

## 593

### DRINKING WATER-SPECIFIC RISK FACTORS FOR MODERATE-TO-SEVERE DIARRHEA IN YOUNG CHILDREN IN THE GLOBAL ENTERIC MULTICENTER STUDY — SUB-SAHARAN AFRICA AND SOUTH ASIA, 2007-2012

Pediatrics, University of Virginia School of Medicine, Charlottesville, VA, United States

Diarrhea is a leading cause of childhood illness in developing countries; waterborne diseases are important contributors. We examined associations between drinking water practices and moderate-to-severe diarrhea (MSD) in children <5 years old participating in the Global Enteric Multicenter Study (GEMS) in rural (The Gambia, Kenya, Mozambique, Bangladesh), urban (Mali, India), and peri-urban (Pakistan) sites. Cases seeking care for MSD (defined as  $\geq 3$  loose stools in 24 hrs with one or more of the following: sunken eyes, skin tenting, dysentery, IV rehydration, or hospitalization) were enrolled at health facilities. Age-, gender- and community-matched controls were enrolled at home. Site-specific conditional logistic regression models were used to explore associations between water practices and MSD; proportions in cases and controls respectively, matched Odds Ratios (mOR) and 95% Confidence Intervals are reported. From Dec, 2007 to Nov, 2012, 12,109 cases and 17,290 matched controls were enrolled. Urban (Mali: 86% v. 88%; India: 98% v. 98%) and peri-urban (Pakistan: 61% v. 64%) sites predominantly used piped water as their main source. Recent use of an unimproved main drinking water source [Kenya: 42% v. 36%; mOR 1.3 (1.1-1.5); Bangladesh: 48% v. 41%; mOR 1.4 (1.2-1.7); Pakistan: 36% v. 32%; mOR 1.3 (1.1-1.7)], and recently giving the child stored drinking water [Gambia: 84% v. 63%; mOR 5.7 (4.5-7.2); Mozambique: 94% v. 87%; mOR 3.5 (2.7-4.4); Kenya: 91% v. 89%; mOR 1.8 (1.4-2.4)] were associated with MSD. Recent intermittent daily water availability was a risk factor for MSD in Mali [3% v. <1%; mOR 4.3 (2.6-7.4)] and Pakistan [32% v. 26%; mOR 1.4 (1.2-1.7)]. Round-trip water fetching times >30 min were associated with MSD in Gambia [10% v. 6%; mOR 1.8 (1.4-2.4)] Mali [3% v. 1%; mOR 3.0 (2.0-4.7)] and Kenya [26% v. 16%; mOR 1.9 (1.6-2.3)]. Reported household chlorination was <3% at all sites and confirmed use rare, with the exception of Kenya (48%), where confirmed use was not associated with MSD [16% v. 17%; mOR 1.1 (0.7-1.6)]. Water practices were highly variable across sites, however the impacts on MSD were relatively consistent across rural sites.

## 594

### SANITATION, WATER AND INSTRUCTION IN FACE-WASHING FOR TRACHOMA (SWIFT): THE CLUSTER-RANDOMIZED CONTROLLED TRIAL'S PROTOCOL AND RATIONALE

Solomon A. Wondimkun<sup>1</sup>, Zerihun Tadesse<sup>1</sup>, Kelly Callahan<sup>2</sup>, Paul M. Emerson<sup>3</sup>, Wondimu Gebeyehu<sup>4</sup>, Matthew C. Freeman<sup>5</sup>, Dionna M. Fry<sup>6</sup>, Vicky Cevallos<sup>6</sup>, Travis C. Porco<sup>6</sup>, Jeremy D. Keenan<sup>6</sup>

<sup>1</sup>Carter Center Ethiopia, Addis Ababa, Ethiopia, <sup>2</sup>Carter Center, Atlanta, GA, United States, <sup>3</sup>International Trachoma Initiative, Atlanta, GA, United States, <sup>4</sup>Bahir Dar Regional Health and Research Laboratory, Bahir Dar, Ethiopia, <sup>5</sup>Emory University, Atlanta, GA, United States, <sup>6</sup>Francis I. Proctor Foundation for Research in Ophthalmology, University of California San Francisco, San Francisco, CA, United States

Trachoma is the leading infectious cause of blindness worldwide and a focus of elimination efforts. The WHO recommends the SAFE strategy for the elimination of trachoma. Numerous randomized clinical trials have demonstrated the efficacy of mass azithromycin distributions, but in areas with hyper-endemic trachoma antibiotics alone do not appear to be sufficient for elimination. Many believe that the "F" and "E" components of SAFE are crucial for preventing the return of trachoma after mass azithromycin distributions have ended. However, the evidence base suggesting efficacy of non-antibiotic measures for trachoma is extremely weak. The objective of SWIFT study is to determine the efficacy of non-antibiotic measures for trachoma control. SWIFT is a series of 3 cluster-randomized trials designed to assess several alternative strategies for trachoma control in Ethiopia. The first trial (named WUHA) compares 20 clusters that receive a comprehensive WASH package to those that receive no intervention in the other 20 clusters. The second trial (TAITU-A) compares 16 clusters randomized to targeted antibiotic treatment versus

those 16 clusters randomized to mass antibiotics for trachoma, and the third trial (TAITU-B) compares 16 clusters randomized to targeted antibiotics versus those 16 clusters randomized to delayed antibiotics. Our primary outcome is the prevalence of ocular chlamydia in 0-5 year old children at 36 months. We will also monitor for several secondary outcomes, including facial cleanliness, anthropometry, nasopharyngeal pneumococcus, and soil-transmitted helminths. We will perform an intention-to-treat analysis.

## 595

### HANDWASHING WITH SOAP PRACTICES AMONG CHOLERA PATIENTS AND THEIR ACCOMPANYING FAMILY MEMBERS IN A HOSPITAL SETTING

**Fatema Zohura**

*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh*

There are estimated to be 3 to 5 million cases of cholera annually. Without treatment the case fatality rate for cholera can be higher than 50%. For severely dehydrated cholera cases hospitalization is required with intravenous and oral rehydration solution. A hospital setting is a high risk environment for the transmission of enteric infections. The objective of our study was to observe the hand washing practices of patients and their accompanying family members in a Dhaka hospital, Bangladesh which is treating more than 140,000 patients a year. Informed consent was obtained from participants. Trained assistants conducted three hours structured observation and administered a questionnaire to patients and their accompanying family members at hospital. It focused on observing hand washing with soap at the following key events: during food preparation, before eating and feeding, after toileting, after cleaning the child anus and removing child feces. In addition spot checks were performed of the presence of soap at the bathroom area. There were a total of 55 cholera patients and 93 household contacts observed during the 3 hour structured observation period. There were 17 male and 38 female patients and 34 male and 59 female household contacts. There were different age categories cholera patients and attendants (less than 5 years to older than 14 years old) under this observation study. Overall, 4% (4/103) of key times involved handwashing with soap among patients and household contacts during the structured observation period. This was 3% (1/37) among patients, and 5% (3/66) for household contacts. For toileting events, this was 7% (3/46), and 7% (1/14) for patients and 6% (2/32) for household contacts. For food related, overall this was 2% (2/93) for patients and 3% (2/59) for household contacts. During spot checks, 7% (4/55) of observations had soap present at handwashing station. Observed handwashing with soap at key times among patients and accompanying family members was very low (4%). These findings highlight the urgent need for intervention to target this high risk population of Bangladesh.

## 596

### IMPACT OF INDUSTRIAL FOOD PROCESSING EFFLUENT ON MAJOR DRINKING WATER SOURCES IN TECHIMAN MUNICIPALITY, GHANA: WATER POLLUTION AND POTENTIAL HUMAN HEALTH RISKS

**Napoleon Jackson Mensah**

*WA Polytechnic, Kumasi, Ghana*

Many water bodies are losing their capacity to host aquatic fauna and flora because of the alarming extent of pollution. Due to the possible human and aquatic health risks associated with untreated industrial effluent discharges, we assessed the microbiological and physicochemical impacts of effluent discharges from a major Ghanaian nut processing factory (Ghana Nut Limited (GNL)) on nearby water body, Tano River (TR). Six sampling stations (the GNL effluent discharge point, two upstream, two downstream sites and the point where the effluent joins the river)

were studied monthly for four consecutive months in terms of their physico-chemical quality (pH, Alkalinity, Turbidity, Total Dissolved Solids (TDS), Total Soluble Solids (TSS), Biological Oxygen Demand (BOD), Oil and Grease, Chemical Oxygen Demand (COD), phosphorus and nitrate) and microbiological quality (Total Coliforms (TC), Faecal Coliforms (FC) and *Escherichia coli* (*E.coli*)). These parameters of the effluent were compared to standards of the Environmental Protection Agency of Ghana (EPA-Ghana) to determine suitability for surface-water discharge. Whilst those of the stream and river samples were compared to the WHO drinking water quality guidelines. The BOD, COD, TSS, Fe and Oil and Grease values for the effluent were significantly above EPA Ghana standards with 1292.00 mg/l, 3156.00mg/l, 1242.00 mg/l, 13.38 mg/l and 6.31mg/l respectively. The BOD, COD, Fe and Turbidity values for the midpoint which was the tributary of the river and the effluent exceeded the WHO water quality guideline as 24.93mg/l, 75.83mg/l, 6.15mg/l and 43.08mg/l respectively. The tributary of the river and the effluent on the TR recorded significant values of TC, FC, and *E.coli* which were above the WHO guidelines of 0cfu as 29 x 10<sup>4</sup> cfu, 4.70 x 10<sup>1</sup> cfu, and 1.3 x 10<sup>1</sup> cfu. The contaminant levels reduced as the river flowed from the effluent discharge point to the downstream sites. This suggests that industrial effluent discharges were causes of pollution of drinking water sources and could pose waterborne health risks. Thus, industrial effluents must be properly treated before discharge.

### HIGH THROUGHPUT DETECTION OF 37 ENTERIC PATHOGENS WITH TAQMAN ARRAY CARDS IN ENVIRONMENTAL SPECIMENS

**Tahmina Ahmed<sup>1</sup>**, Tania Ferdousi<sup>1</sup>, Jie Liu<sup>2</sup>, Rashidul Haque<sup>1</sup>, James A. Platts-Mills<sup>2</sup>, Eric R. Houpt<sup>2</sup>, Mami Taniuchi<sup>2</sup>

*<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>University of Virginia, Charlottesville, VA, United States*

Diarrhea is one of the leading causes of mortality in children under five years of age in low-income countries. Prior studies of diarrhea etiology using our custom developed enteric Taqman Array Cards (TAC) have shown that multiple enteric pathogens are often present from the first months of life not only in diarrhea specimens but also in asymptomatic stool specimens. This suggested that early exposure was the norm but the route of exposure to these pathogens in these infants who are mostly exclusively breastfed is unknown. We conducted a pilot study testing drinking water, stored water, tap water, sewer, and soil in and around the households for a range of 37 enteric viruses, bacteria, helminthes, and parasites by TAC molecular method in Mirpur, Bangladesh. On average 2 pathogens (range 0 to 4 enteropathogens) were found in water used for drinking, bathing, and washing including *Aeromonas*, *Blastocystis*, *Campylobacter*, *Entamoeba histolytica*, and pan-*Entamoeba*. A broad range of pathogens (average 10 pathogens; range 5-13) including *E. coli*, bacteria, viruses, and protozoa were detected at a high burden level in the samples from the open sewer near the households. Soil samples on average had 9 pathogens (range 5 to 15) with included similar pathogens found in sewer samples with additional detections of helminthes such as *Ancylostoma duodenale*, *Ascaris lumbricoides*, and *Trichuris trichiura*. This study confirms the presence of ubiquitous enteric pathogens in the environment in and around the households in the urban slums of Dhaka. Further studies are needed to understand the route of transmission and infection from the environment to infants living in this low-income setting.

## ASSESSMENT OF WATER, SANITATION, HYGIENE AND INFECTION, PREVENTION AND CONTROL CONDITIONS IN FIFTY TWO HEALTHCARE FACILITIES IN HOIMA DISTRICT OF UGANDA

Habib Yakubu<sup>1</sup>, Richard K. Mugambe<sup>2</sup>, John Bosco Isunju<sup>2</sup>, James Michiel<sup>1</sup>, Constance Bwire<sup>3</sup>, Fred Owera-Odom<sup>3</sup>, Lindsay Denny<sup>1</sup>, Emmanuel Opoki<sup>4</sup>, Joanne McGriff<sup>1</sup>, Christine L. Moe<sup>1</sup>

<sup>1</sup>Emory University, Rollins School of Public Health, Center for Global Safe WASH, Atlanta, GA, United States, <sup>2</sup>Makerere University School of Public Health, Department of Disease Control and Environment, Kampala, Uganda, <sup>3</sup>CARE International Uganda, Kampala, Uganda, <sup>4</sup>World Vision Uganda, Kampala, Uganda

There is a dearth of knowledge of water, sanitation, hygiene (WASH) and infection prevention and control (IPC) conditions in healthcare facilities of developing countries. Absence of these services or conditions are associated with healthcare associated infections that disproportionately burden neonates and their mothers. A 2015 WHO/UNICEF report states that about 38% of healthcare facilities in lower and middle income countries do not have safe supply of water and 19% lack adequate toilets. The sustainable development goal six calls for a concerted effort to identify and improve these conditions. The aim of the study was to conduct an assessment of water, sanitation, hygiene and infection, prevention and control conditions in 52 healthcare facilities in Hoima District of Uganda to identify priority areas for improvement, guide plans for interventions and advocate for action. In November 2016, an assessment tool was deployed in 52 healthcare facilities in 10 sub counties of Hoima District. The tool consists of interviews with directors and administrative staff of the facilities, observation and water quality sampling and analysis of key wards. The data was collected on a mobile device and analyzed in SAS software program. A score card for each facility was produced based on whether the facility provides a basic, improved or unimproved or no service. Overall, only about 15% met basic standards for managing waste, about 8% met the basic standards for sanitation, about 10% had basic water supply systems and approximately 11% had handwashing with soap and water facilities at the time of visit. In addition, only about 29% carried out regular cleaning routines. Approximately 69% and 4% of the sampled water from all the healthcare facilities met the national standards for drinking water for *Escherichia coli* and free chlorine respectively. The study shows that majority of the healthcare facilities have poor IPC conditions and do not provide basic WASH services. These results have dire implications for healthcare associated infections. The results from this work is being used to inform interventions and advocate for action.

## DETECTION AND QUANTIFICATION OF ROTAVIRUS IN SEWAGE USING DROPLET DIGITAL PCR

Nicholas Kiulia, Joan Rose

Michigan State University, East Lansing, MI, United States

Globally rotavirus (RV) causes severe diarrhea in children < 5 years of age. The detection and quantification of RV in environmental samples is cumbersome and its recovery requires collection and concentration of a large volume sample. Molecular detection methods such as quantitative polymerase chain reaction (qPCR) and conventional reverse transcriptase (RT-PCR) have been used to detect and characterize RV in environmental samples. The goal of this study was; i) to evaluate droplet digital PCR (ddPCR) as a tool to detect and quantify RV in untreated sewage, ii) to optimize the sampling preparation method that can be able to quantify RNA viruses in untreated sewage. Untreated sewage samples were collected from a Kenyan lagoon (5 L, n=10), a US lagoon (10 L, n=10) and influent samples in the US (2 L, n=18) from a wastewater treatment plant (WWTP). The samples collected from Kenya lagoon (5 L) and from the US lagoon (7.5 L) were concentrated using an adsorption-elution

method (ViroCap), while 2 L of the US lagoon and 2 L of WWTP samples were concentrated using polyethylene glycol (PEG)/sodium chloride (NaCl) precipitation. Nucleic acid for RV (dsRNA) was extracted using commercially available kit (QIAamp Viral RNA Mini Kit) and RV was detected and quantified using ddPCR. Rotavirus was detected in 100% (10/10) in the Kenya, 100% (10/10) in the US lagoon and 100% (18/18) in the US WWTP samples. In the Kenya lagoon RV was detected at a mean concentration of  $1.09E+05 \pm 1.90E+05$  genome copies/L. In the US lagoon, the samples concentrated using ViroCap had a mean of  $7.68E+02 \pm 9.41E+02$  genome copies/L, while the one concentrated using PEG had a mean of  $1.48E+04 \pm 8.97E+03$  genome copies/L. The mean difference of RV concentration between the 2 viral concentration methods (ViroCap Vs PEG) in the US lagoon samples were statistically significant  $p < 0.05$ . The US WWTP had a mean concentration of  $4.92E+05 \pm 8.19E+05$  genome copies/L. In conclusion, the droplet digital PCR is an easy and promising technology for detection, identification and quantitation of RV in untreated sewage and the method was easily used with PEG or ViroCap concentrates.

## EFFECT OF SANITATION ON PHYSICO CHEMICAL QUALITY OF GROUNDWATER

Forgive A. Norvivor<sup>1</sup>, Chris Gordon<sup>2</sup>, Kwasi Appeaning-Addo<sup>3</sup>

<sup>1</sup>University of Health and Allied Sciences, Ho, Ghana, <sup>2</sup>University of Ghana, Institute for Environmental Science and Sanitation Studies, Legon-Accra, Ghana, <sup>3</sup>University of Ghana, Department of Marine and Fisheries Science, Legon-Accra, Ghana

The paper investigated physico-chemical quality of groundwater, considering the relative proximity of hand dug wells to coastal environment, but most importantly close to insanitary facilities like refuse dumps, septic tanks and pit latrines; this was done in selected coastal communities in the Keta. Thirty vials of water samples from selected hand dug wells in two seasons were tested for pH, Total Dissolved Solids (TDS), Conductivity, Turbidity, Calcium, Magnesium, Nitrate, Sulphate, and Phosphate; WHO standards of drinking water were adopted to validate the results obtained and statistical analysis run. Statistical analysis of results showed a statistical significance in Turbidity, Nitrate, Phosphate, Calcium and Magnesium values at  $p < 0.05$ , between the two seasons. There was a weak but significant correlation between Calcium and distance ( $r=0.398$ ) and a strong correlation between Magnesium and distance ( $r=0.763$ ). The study revealed that all the hand dug wells sampled recorded relatively high concentration of conductivity, turbidity, TDS, Calcium, Magnesium and Phosphates, irrespective of their proximity to the insanitary facilities and coastal environment, apart from nitrates when compared to WHO standards of drinking water.

## ASSESSING THE EFFECT OF A NOVEL HOUSEHOLD WATER PASTEURIZATION INTERVENTION ON CHILD DIARRHEA: EVIDENCE FROM A RANDOMIZED CONTROLLED TRIAL IN THE PERUVIAN AMAZON

Kristen Heitzinger<sup>1</sup>, Claudio A. Rocha<sup>2</sup>, Robert H. Gilman<sup>1</sup>, Stephen E. Hawes<sup>3</sup>, Carlos A. Alvarez<sup>4</sup>, Carlton A. Evans<sup>1</sup>

<sup>1</sup>A. B. Prisma, Lima, Peru, <sup>2</sup>U.S. Medical Research Unit No. 6, Callao, Peru, <sup>3</sup>University of Washington, Seattle, WA, United States, <sup>4</sup>Loreto Regional Ministry of Health, Iquitos, Peru

In low- and middle-income countries, diarrheal disease is a leading cause of morbidity and mortality among children under 5. Household water treatment generally reduces childhood diarrhea risk, but water boiling is the only method of household treatment to have reached scale in any country. Barriers to effective boiling such as time and indoor air pollution may be addressed by the use of a water pasteurization indicator (WAPI). We conducted a randomized controlled trial to evaluate the effect of a low-cost WAPI on diarrhea in children <5 and fecal contamination of

household drinking water in the Peruvian Amazon. In the intervention arm, 141 households received a water pasteurization indicator to treat their drinking water. All households received a 20 liter water storage container. Twelve weekly follow-up visits were conducted to measure the longitudinal prevalence of health outcomes and the prevalence of *Escherichia coli* contamination in household drinking water. We deployed temperature data loggers in a random subset of households to assess intervention use. Follow-up data from 377 children <5 (183 control group; 194 intervention group) were analyzed in an intention to treat analysis. The water pasteurization intervention did not reduce the longitudinal prevalence of diarrhea among children <5 (LPR=0.99, 95% CI=0.72, 1.38) or reduce the prevalence of *E. coli* contamination of household drinking water (PR=0.94, 95% CI=0.75, 1.18). Among intervention households monitored with a data logger, 7% used the indicator at least twice a week during the follow-up period. A water pasteurization intervention did not reduce diarrhea among children <5 or fecal contamination of household drinking water, consistent with low adherence to the intervention. Future research aimed at understanding the factors influencing the adoption of this treatment method would be valuable to inform the design of interventions.

## 602

### PSYCHOSOCIAL FACTORS MEDIATING THE EFFECT OF A HEALTH FACILITY BASED HANDWASHING WITH SOAP AND WATER TREATMENT INTERVENTION IN BANGLADESH (CHOBI7 TRIAL)

**Christine Marie George**<sup>1</sup>, Shwapon Biswas<sup>2</sup>, Jamie Perin<sup>1</sup>, Robert Dreifelbis<sup>3</sup>, Danielle Jung<sup>1</sup>, Tahmina Parvin<sup>2</sup>, Shirajum Monira<sup>2</sup>, Mahamud-ur Rashid<sup>2</sup>, K.m. Saif-Ur-Rahman<sup>2</sup>, Sazzadul Islam Bhuyian<sup>2</sup>, Elizabeth Thomas<sup>1</sup>, Elli Leontsini<sup>1</sup>, Fatema Zohura<sup>2</sup>, Xiaotong Zhang<sup>1</sup>, David Sack<sup>1</sup>, Munirul Alam<sup>2</sup>, R. Bradley Sack<sup>1</sup>, Peter J Winch<sup>1</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Inadequate hand hygiene is estimated to result in nearly 300,000 deaths annually, with the majority of deaths being among children younger than 5 years. In an effort to promote handwashing with soap and water treatment behaviors among highly susceptible household members of cholera patients, we recently developed the Cholera-Hospital-Based Intervention-for-7-Days (CHoBI7); chobi means picture in Bengali. This 1-week handwashing with soap and water treatment intervention is delivered by a promoter in the hospital and the home to cholera patients and their household members. In our randomized controlled trial of this intervention, we observed a significant reduction in symptomatic cholera infections during the 1-week intervention period compared to the control arm and sustained high uptake of observed handwashing with soap behaviors up to 12 months post-intervention. The aim of the present study was to assess the underlying mechanism of change that led to the high handwashing with soap behavior observed among participants who received the CHoBI7 intervention. Handwashing with soap was measured using 5-hour structured observation, and psychosocial factors were assessed using a structured questionnaire among 170 intervention and 174 control household members enrolled in the CHoBI7 trial. To investigate potential mediators of the CHoBI7 intervention effect, mediation models were performed. Response efficacy was found to mediate the intervention's effect on habit formation for handwashing with soap at the 1-week follow-up, and disgust, convenience, and cholera awareness were mediators of habit maintenance at the 6- to 12-month follow-up. These results support the use of theory-driven approaches for the development and implementation of handwashing with soap interventions.

## 603

### RISK FACTORS FOR HOUSEHOLD TRANSMISSION OF *VIBRIO CHOLERAE* IN DHAKA, BANGLADESH (CHOBI7 TRIAL)

**Vanessa Burrowes**<sup>1</sup>, Jamie Perin<sup>1</sup>, Shirajum Monira<sup>2</sup>, David Sack<sup>1</sup>, Mahamud-ur Rashid<sup>2</sup>, Toslim Mahamud<sup>2</sup>, Zillur Rahman<sup>2</sup>, Munshi Mustafiz<sup>2</sup>, Sazzadul Bhuyian<sup>2</sup>, Farzana Begum<sup>2</sup>, Fatema Zohura<sup>2</sup>, Shwapon Biswas<sup>2</sup>, Tahmina Parvin<sup>2</sup>, Tasdik Hasan<sup>2</sup>, Xiaotong Zhang<sup>1</sup>, Bradley Sack<sup>1</sup>, K. M. Saif-Ur-Rahman<sup>2</sup>, Munirul Alam<sup>2</sup>, Christine Marie George<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>International Centre for Diarrheal Disease Research, Bangladesh, Dhaka, Bangladesh

Household contacts of cholera patients are at a 100-times higher risk of a *Vibrio cholerae* infection than the general population. To examine risk factors for *V. cholerae* infections and investigate intervention strategies among this population, we followed household contacts of cholera patients for the 1-week high-risk period after the index patient obtained care. This study was nested within a randomized controlled trial of the Cholera-Hospital-Based-Intervention-for-7-days (CHoBI7), a handwashing with soap and water treatment intervention in Dhaka, Bangladesh. Rectal swab results were available from 320 household contacts of cholera patients at five time points over a 1-week period. Fecal and water samples were analyzed for *V. cholerae* by culture. All analyses were stratified by study arm. Within the intervention arm, a household median free chlorine concentration below 0.5 mg/L was associated with a three times higher odds of a cholera infection (odds ratio [OR]: 3.0; 95 confidence interval [CI]: 1.32, 6.63). In the control arm, having *V. cholerae* in stored water was associated with a significantly higher odds of a symptomatic cholera infection (OR: 8.66; 95% CI: 2.11, 35.48). No association was found between observed handwashing with soap at food and stool-related events and *V. cholerae* infections. Household water quality and treatment practices were found to be important risk factors for cholera infection among household contacts of cholera patients. These findings emphasize the need for water treatment interventions targeting this high-risk population.

## 604

### NOVEL GAMETOCYTE BIOMARKERS FOR DETECTION OF THE *PLASMODIUM FALCIPARUM* INFECTIOUS RESERVOIRS

**Bryan Grabias**<sup>1</sup>, Edward Essuman<sup>1</sup>, Nitin Verma<sup>1</sup>, Hong Zheng<sup>1</sup>, Abhai K. Tripathi<sup>2</sup>, Godfree Mlambo<sup>2</sup>, Isabella Quakyi<sup>3</sup>, Miranda Oakley<sup>1</sup>, Sanjai Kumar<sup>1</sup>

<sup>1</sup>Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>University of Ghana, Legon, Ghana

Eradication efforts as well as the optimal use of transmission-reducing malaria interventions requires further knowledge of the submicroscopic infectious reservoirs among asymptomatic individuals. Even sub-microscopic levels of *Plasmodium falciparum* gametocytes can be infectious to mosquitos and promote onward transmission. Most efforts to identify gametocyte carriers rely upon PCR amplification of the gametocyte-specific transcript Pfs25, a sexual stage antigen. We have utilized gene expression profiling microarrays of blood stage and gametocyte stage *P. falciparum* parasites to identify potentially novel gametocyte-enriched transcripts that could be sensitive biomarkers for gametocyte detection in asymptomatic individuals. This has led to identification of over 200 molecules that are uniquely expressed in sexual parasite stages. One candidate in particular, Pfg17, exhibited superior analytical sensitivity against a reference panel of gametocyte-spiked whole blood detecting as few as 10 gametocytes/mL of blood; in comparison Pfs25 detected only 25.3 gametocytes/mL of blood. Pfg17 also exhibited superior clinical sensitivity; identifying 19.1% more samples among blood-film negative Ghanaian children and 40% more samples from asymptomatic adults as gametocyte positive. Cumulatively, our

results suggest that Pfg17 could serve as a novel biomarker to detect asymptomatic infectious reservoirs who would be otherwise missed by the most sensitive molecular method available. Our study has also improved the repertoire of transmission stage antigens available for evaluation as candidate vaccines.

## 605

### PERFORMANCE OF LOOP-MEDIATED ISOTHERMAL AMPLIFICATION FOR THE IDENTIFICATION OF SUBMICROSCOPIC *PLASMODIUM FALCIPARUM* INFECTION IN UGANDA

Shereen Katrak<sup>1</sup>, Maxwell Murphy<sup>1</sup>, Patience Nayebare<sup>2</sup>, John Rek<sup>2</sup>, Mary Smith<sup>1</sup>, Emmanuel Arinaitwe<sup>2</sup>, Joaniter Nankabirwa<sup>2</sup>, Moses Kamy<sup>2</sup>, Grant Dorsey<sup>1</sup>, Phil Rosenthal<sup>1</sup>, Bryan Greenhouse<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda

Accurately identifying and targeting the human reservoir of malaria parasitemia is critical for malaria control, and requires a reliable and sensitive diagnostic method. Loop-mediated isothermal amplification (LAMP) is increasingly used to diagnose submicroscopic parasitemia. Although most published studies report the sensitivity of LAMP as >80%, they have failed to use a consistent, sensitive diagnostic as a comparator. We utilized cross-sectional samples from children and adults in Tororo, Uganda, a region with high but declining transmission due to indoor residual spraying of insecticides to characterize the sensitivity and specificity of pan-*Plasmodium* LAMP. We compared results from LAMP using primers *PgMt19* targeting a mitochondrial DNA sequence conserved in all *Plasmodium* species, performed on DNA extracted from dried blood spots, to those of a gold standard quantitative PCR assay targeting the *var* gene acidic terminal sequence of *Plasmodium falciparum* (*varATS* qPCR), performed on DNA extracted from 200  $\mu$ L of whole blood. Using LAMP and *varATS* qPCR increased the detection of parasitemia 2- to 5-fold, compared to microscopy. The sensitivity of LAMP was 81.5% for detecting submicroscopic infection > 1 parasites/ $\mu$ L. However, low density infections were common, and LAMP failed to identify more than half of all infections diagnosed by *varATS* qPCR, performing with an overall sensitivity of 44.7% for detecting submicroscopic infections of > 0.01 parasites/ $\mu$ L. Thus, although the LAMP assay is more sensitive than microscopy, it missed a significant portion of the submicroscopic parasite reservoir. These findings have important implications for malaria control, particularly in settings where low-density infections predominate.

## 606

### INVESTIGATING THE KINETICS OF TRANSGENIC *PLASMODIUM FALCIPARUM* HRP2 PROTEIN PRODUCED BY *P. BERGHEI* IN A NOVEL MURINE MODEL

Kristin E. Poti<sup>1</sup>, Amanda Balaban<sup>1</sup>, Priya Pal<sup>2</sup>, Daniel Goldberg<sup>2</sup>, Photini Sinnis<sup>1</sup>, David Sullivan<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Washington University, St. Louis, MO, United States

There is an increasing need for improved diagnostics for subclinical malaria, as these cases act as transmission reservoirs. Low parasitemic, subclinical malaria is difficult to diagnose. One way to better diagnose these cases is increasing the sensitivity of the malaria rapid diagnostic test that detects the *Plasmodium falciparum* histidine-rich protein 2 (PfHRP2). To develop more sensitive diagnostics, we need an understanding of PfHRP2 kinetics *in vivo* during infection and after clearance. We must also determine primary localization of PfHRP2 and its clearance time in plasma and erythrocytes for better targeting and detecting in diagnostic tests. In mice, we determined the average plasma half life of PfHRP2 to be 2.1 hours after intraperitoneal injection of recombinant protein, with a total clearance time of 4 days. PfHRP2 persists in circulation for 1-4 weeks post parasite clearance, presenting an additional challenge to

extending the limit of assay detection for PfHRP2. We established a novel working murine model using a transgenic *P. berghei* parasite expressing PfHRP2 to study this phenomenon. The transgenic parasite produces PfHRP2 in the erythrocyte and exports it into the erythrocyte cytoplasm in a manner similar to *P. falciparum*, which naturally produces the protein. In our model, PfHRP2 persists 5-7 days in the plasma and 8-9 days in the erythrocytes following treatment with artemisinin-based combination therapy. The average plasma half life of PfHRP2 during infection was 8 hours. Parasites were absent by microscopy at day 3 and parasite DNA was absent by qPCR on day 7. Due to the significantly extended persistence of PfHRP2 in erythrocytes, persistence could result from slow clearance from the red blood cells, through the process of erythrocyte pitting, a consequence of increased rigidity of *P. falciparum* infected cells. Preliminary IFA data demonstrated PfHRP2 positive, DAPI negative erythrocytes, corroborating the pitting hypothesis, which will be further explored. In conclusion, we developed a novel murine model to investigate PfHRP2 dynamics *in vivo* to better inform the generation of more sensitive malaria diagnostics.

## 607

### COMPARISON OF SIMULTANEOUS CAPILLARY AND VENOUS PARASITEMIA AND GENOTYPING RESULTS FROM CHILDREN AND ADULTS WITH UNCOMPLICATED MALARIA

Aine Lehane<sup>1</sup>, Moses Were<sup>2</sup>, Musleehat Hamadu<sup>1</sup>, Sylvia Kiconco<sup>2</sup>, Richard Kajubi<sup>2</sup>, Francesca Aweeka<sup>3</sup>, Norah Mwebaza<sup>2</sup>, Sunil Parikh<sup>1</sup>

<sup>1</sup>Yale School of Public Health, New Haven, CT, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States

Light microscopy remains the gold standard for diagnosis and follow-up of malaria. In addition, drug efficacy studies rely on molecular genotyping of polymorphic markers to distinguish recrudescence from new infections. While capillary blood remains as the most commonly used matrix for parasite detection and genotyping, clinical trials use results interchangeably from venous and capillary matrices. Importantly, parasitized erythrocytes adhere to capillary endothelium, and several studies support differences in hematologic and chemistry parameters between venous and capillary blood. To our knowledge, there has been no systematic comparison of diagnostic results from these two matrices. We hypothesize that variation between parasitemia and/or molecular genotyping data from these two compartments could have important implications for the conduct of clinical trials. To address this, we conducted a prospective study of uncomplicated *Plasmodium falciparum* malaria in adults and children, with and without HIV infection, in a high transmission region of Uganda. All participants were treated with artemether-lumefantrine. Simultaneous capillary and venous samples for microscopy and molecular genotyping were obtained at various time points: at baseline, over the course of follow-up, and at time of recurrent malaria. Smears were prepared identically with 2% Giemsa, stained for 30 minutes, and were read by 2 expert microscopists, with discrepancies resolved by a third reader. In total, we have simultaneous measurements at baseline in 52 children and 36 adults, at the time of recurrence in 52 children and 6 adults, and additional simultaneous measurements in 186 children and 46 adults over the course of 42-day follow-up. Thus far, baseline parasitemia measurements from both matrices have been compared in 36 adults and 37 children. In addition, paired samples from baseline and the time of recurrent malaria are being compared for 6 polymorphic markers to assess how results could impact the determination of recrudescence versus new infection, and multiplicity of infection. Full results will be presented at the time of the meeting.

### BLUE-LASER TECHNOLOGY FOR RAPID SENSITIVE DETECTION OF *PLASMODIUM FALCIPARUM* PARASITEMIA AND GAMETOCYTEMIA

**Isaie J. Reuling**, Wouter A. van der Heijden, Quirijn de Mast, Rianne Siebelink-Stoter, Kjerstin Lanke, Lisanne van de Schans, Annelies Post, Teun Bousema, Robert W. Sauerwein, Andre J. van der Ven

*Radboud University Medical Center, Nijmegen, Netherlands*

Sensitive detection of low-density parasite carriers is a priority for malaria elimination efforts. The rapid detection of low-density malaria parasites and in particular the transmissible gametocytes is a challenge that is not met by the currently available diagnostics. Novel tools for rapid identification of gametocyte carriers may support the planning and evaluation of malaria elimination programs. The Sysmex XN-30 hematology analyzer is able to detect parasitized erythrocytes, as well as gametocytes, using a novel blue-laser technique combined with a specific surfactant and DNA fluorescence dye. This method is quantitative, with the ability to differentiate between parasite subpopulations. We tested the diagnostic performance of this analyzer *in vivo* using a controlled human malaria infection model (CHMI, n=16) where low densities of gametocytes were induced, and *in vitro* using cultured *Plasmodium falciparum* parasites and gametocytes. Blood smear microscopy, 18s qPCR (asexual parasites), and Pfs25 qRT-PCR (gametocytes) were used as reference standard. Quantitative data of the CHMI study showed a strong correlation between 18s qPCR and blue-laser technology for parasitemia ( $r=0.769$ ;  $p<0.0001$ ). *In vitro* experiments showed similar correlations ( $r>0.892$ ;  $p<0.0001$ ) between the blue-laser technology, microscopy, and PCR, using cultured asexual- and sexual parasites. The analyzer detected asexual parasites and gametocytes at densities as low as 10 parasites/ $\mu$ L. The stability of samples was confirmed for at least 6hrs at room temperature. Further work is currently performed to assess performance of the blue-laser in submicroscopic malaria. In conclusion, our analyses show that this high throughput method can detect microscopic malaria in a volume  $<100\mu$ L of whole blood within 60 seconds without any sample preparation. We will present evidence that this hematology analyzer can detect low level parasitemia and gametocytemia *in vivo*. Therefore, this analyzer may be useful for diagnosis of malaria parasitemia, treatment follow-up, detection of gametocyte carriers and mass screening campaigns to support elimination efforts.

### BREATHPRINTING REVEALS MALARIA-ASSOCIATED BIOMARKERS AND MOSQUITO ATTRACTANTS

**Chad Schaber**, Nalin Katta, Lucy Bollinger, Indi Trehan, Barani Raman, Audrey Odom John

*Washington University, St. Louis, MO, United States*

Evidence suggests that the malaria parasite manipulates host odors to augment *Anopheles* mosquito attraction to infected hosts. *In vitro* studies have shown that parasite-infected red blood cells release plant-like volatile organic compounds (VOCs) called terpenes, including the monoterpene alpha-pinene, which attract mosquitoes. We investigated whether the attractants found in cultured parasites were also produced during *in vivo* infection. We performed two independent studies of pediatric patients with and without uncomplicated *P. falciparum* malaria in Malawi to evaluate for malaria-induced volatile changes in a natural field setting. We collected breath samples onto sorbent tubes, prior to analysis by thermal desorption gas chromatography-mass spectrometry (TD/GC-MS). Sweat volatiles were also collected and analyzed using nylon sleeves and solid phase microextraction (SPME)/GC-MS. In both cohorts, the malaria-infected group displayed significantly elevated levels of the known mosquito attractants alpha-pinene and 3-carene. Each of these compounds proved to have high specificity for predicting malaria infection ( $>94\%$ ), and moderate sensitivity (41 - 53%). To improve diagnostic

sensitivity, we used an unbiased, correlation-based algorithm to identify a combination of six breath biomarkers that successfully classified infection status with 83% accuracy. Our findings confirm, for the first time, that natural human malaria infection increases levels of known mosquito attractants, providing a likely mechanism for preferential attraction of *Anopheles* mosquitoes towards malaria-infected hosts. Furthermore, we demonstrate a robust "breathprint" of infection and nominate candidate breath biomarkers of malaria in a typical African field setting. Our findings will inform future development of noninvasive malaria diagnostics, as well as advanced measures of mosquito control.

### THE USE OF SMALL PEPTIDE MICROARRAYS TO DETECT MALARIA EXPOSURE

**Andrew Pike**<sup>1</sup>, Jason A. Bailey<sup>1</sup>, Mark A. Travassos<sup>1</sup>, Amed Uttara<sup>1</sup>, Sonia Agrawal<sup>1</sup>, Antoine Dara<sup>1</sup>, Lauren M. Cohee<sup>1</sup>, Drissa Coulibaly<sup>2</sup>, Kirsten E. Lyke<sup>1</sup>, Matthew B. Laurens<sup>1</sup>, Matthew Adams<sup>1</sup>, Shannon Takala-Harrison<sup>1</sup>, Bourema Kouriba<sup>2</sup>, Abdoulaye K. Kone<sup>2</sup>, Ogobara K. Doumbo<sup>2</sup>, Mahamadou A. Thera<sup>2</sup>, Philip L. Felgner<sup>3</sup>, John C. Tan<sup>4</sup>, Jigar Patel<sup>4</sup>, Christopher V. Plowe<sup>1</sup>, Andrea A. Berry<sup>1</sup>

<sup>1</sup>University of Maryland, School of Medicine, Institute for Global Health, Baltimore, MD, United States, <sup>2</sup>Malaria Research and Training Center, University Sciences, Techniques and Technologies, Bamako, Mali, <sup>3</sup>Division of Infectious Diseases, Department of Medicine, University of California Irvine, Irvine, CA, United States, <sup>4</sup>Roche Sequencing Solutions, Madison, WI, United States

Highly sensitive diagnostics that measure asymptomatic malaria infections within a region are vital to malaria elimination efforts. Molecular tests that identify parasite nucleic acids enhance our ability to detect very low-density active infections, but they cannot identify people who have recently cleared infections or those with parasite levels below the limit of detection. Serological testing allows us to measure anti-Plasmodium antibodies present in patient sera and may provide measurements of current, recent, distant and cumulative infections. However, current serological tests are based on a few antigens and may miss parasites with variants of these proteins not represented by the reference strain used to create the tests. We designed a diversity-reflecting peptide array to measure antibody levels to variants of 41 malaria antigens. Our goal was to use serological data to determine whether malaria transmission is ongoing in a region and help prioritize targeted interventions to those areas. We probed the array with sera from 10 Malian children before, at the peak of, and after the malaria transmission season and 10 Malian adults before the malaria transmission season. Comparisons of children to adults show that adults with a long history of malaria exposure recognize a greater number of peptides from 22 proteins than from children with limited, recent exposure. Similarly, comparisons between children before the malaria transmission season to children at the peak of or following the transmission season demonstrates that we can differentiate between the seroprofiles of children throughout the course of a malaria transmission season. We used multivariate analysis to identify a set of peptides to represent the signature of an individual's age and malaria exposure history. Seroreactivity against these peptides represents a promising indicator of recent or current malaria exposure that can help prioritize malaria elimination efforts to areas with ongoing or recent transmission. In the future, we will evaluate this new tool's ability to identify *foci* of infection in low transmission setting such as Myanmar.

## 611

**NEW EVIDENCE OF MATING SWARMS OF THE MALARIA VECTOR, *ANOPHELES ARABIENSIS* IN TANZANIA**

Emanuel W. Kaindoa<sup>1</sup>, Gustav Mkandawile<sup>1</sup>, Japhet Kihonda<sup>1</sup>, Alex Limwagu<sup>1</sup>, John Paliga<sup>1</sup>, Emmanuel Mwanga<sup>1</sup>, Halfan Ngowo<sup>1</sup>, Abdoulaye Diabate<sup>2</sup>, Fredros Okumu<sup>1</sup>

<sup>1</sup>Ifakara Health Institute, Morogoro, United Republic of Tanzania, <sup>2</sup>IRSS, Bobo-Dioulasso, Burkina Faso

Malaria mosquito mating swarming phenomenon may offer new opportunities for controlling the mosquitoes, for example by targeting the swarms with insecticides. Unfortunately, studies of actual *Anopheles* swarms have been rare in East Africa, the last recorded field observations in Tanzania having been in 1983. Mosquito swarms were surveyed between September 2016 and February 2017, in rural villages south-eastern Tanzania. Identified *Anopheles* mosquito swarms were sampled using sweep nets, and collected mosquitoes killed by refrigeration and identified morphologically. A sub-sample of the *Anopheles* was further identified by PCR, and all females examined to assess mating status. Age of the mosquitoes was estimated by observing the coiling and unwinding of female ovarian tracheoles, and the rotation of male genitalia. A total of 202 *Anopheles* swarms were identified, characterized and mapped in the study villages. During the same period, 9,319 *An. gambiae* s.l and 13 *An. funestus* mosquitoes were collected in the swarms. The *An. gambiae* s.l were 99.6% males and 0.4% females, while all the *An. funestus* collected were males collected in mixed swarms. Of all the male *An. gambiae* s.l analysed by PCR, 86.7% were identified as *An. arabiensis*, while 13.3% were unidentifiable, due to non-amplification in the PCR assays. The median height of the swarms was 2- 4 m above ground. We identified 5 potential swarm markers, of which 90% had confirmed swarm occurrence at least once during the study period. Common types of confirmed swarm markers included rice field areas with heaps of dry grass (65%), open grassland (20), woodpiles (10%) and brick piles (5%). The median duration of swarms was (20-30). Minutes. Visual estimates of swarm sizes closely matched the actual sizes as determined by sweep net sampling (R=0.9402). The study also provides evidence that swarms of *Anopheles* mosquitoes can be identified, characterized and quantified in the field by trained community volunteers. This finding opens up new opportunities for targeting malaria mosquitoes, including targeting of male swarms as an approach to deplete vector densities and reduce disease transmission.

## 612

**THE EFFECTS OF METAPOPULATION STRUCTURE ON FINE-SCALE MOSQUITO POPULATION DYNAMICS AND POTENTIAL CONSEQUENCES FOR THE TRANSMISSION DYNAMICS OF DENGUE AND MALARIA**

Clare McCormack, Azra C. Ghani, Neil M. Ferguson  
Imperial College London, London, United Kingdom

Fine-scale spatial heterogeneity in the transmission intensity of dengue and malaria is primarily caused by variation in the density of female adult mosquitoes. Thus an understanding of the fine-scale dynamics of mosquito populations is needed to understand spatial heterogeneity in disease transmission and persistence at those scales. In any given environment, adult mosquito density is largely determined by the death rate of adult mosquitoes and the rate at which new adult mosquitoes emerge from larval breeding sites. Although larval breeding sites of both *Anopheles* and *Aedes aegypti* mosquitoes are often highly fragmented, mathematical models of dengue and malaria transmission, which consider larval population dynamics, do not generally take account of such fragmentation. Rather, the entire larval population is treated as a well-mixed population coming from a single large breeding site, and density dependent larval mortality is assumed to increase linearly with population size. Here, using a fine-scale stochastic metapopulation model of dengue and malaria transmission, which has been calibrated against

appropriate entomological and epidemiological data, we explore the impact of accounting for breeding site fragmentation when modelling the dynamics of mosquito populations. We observe that, when mosquito population densities are low, fragmentation can lead to a reduction in vector population density, with mosquito population persistence highly dependent on the dispersal behaviour of the adult mosquito and features of the underlying landscape. We show that our results have particular importance for novel vector control measures such as *Wolbachia*-infected *Aedes aegypti* or genetically modified mosquitoes with gene-drive, as by not accounting for fragmentation, existing models are likely to over-estimate the speed of spatial spread of such invasive technologies. Last, we show that landscape fragmentation may have an important impact on the dynamics and attack rate seen in invasions of novel arboviruses, such as Zika virus.

## 613

**CHANGES IN MOSQUITO BEHAVIORS ARE LIKELY TO IMPACT ON THE EFFECTIVENESS OF INDOOR-BASED MALARIA VECTOR CONTROL INTERVENTIONS IN CHIKWAWA, MALAWI**

Justin Kumala<sup>1</sup>, Themba Mzilahowa<sup>2</sup>, Lisa Reimer<sup>3</sup>

<sup>1</sup>Wits Research Institute for Malaria, Johannesburg, South Africa, <sup>2</sup>Malaria Alert Centre, College of Medicine, Blantyre, Malawi, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Malaria vector control interventions tend to exploit behaviors of mosquito vector populations. Reports from Tanzania and Kenya have indicated changes in behaviors of malaria vectors following the scale-up of insecticide-treated nets (ITNs) and indoor residual spraying (IRS) interventions in recent years. In Chikwawa district, southern Malawi, we studied mosquito biting and resting preferences in 20 randomly selected households in an area of high and perennial malaria transmission along the lower Shire River basin. Mosquitoes were sampled both indoors and outdoors using indoor aspiration, human landing catch and outdoor barrier-screening techniques in order to investigate the species diversity of the indoor-resting and host-seeking populations, and to understand when and where exposure takes place. In total, 1342 anophelines were collected in the study over one month of sampling out of which 44% were intercepted flying outdoors by barrier screening and an equal proportion of 25% each were caught biting indoors and outdoors. Only 6% of the vector population was found resting indoors. These results showed that the majority (69%) of the entire vector population was sampled outdoors (barrier screening, n=593 and outdoor-landing catch, n= 337). *Anopheles arabiensis* made up 80% of the human-landing collections while *Anopheles funestus* s.l and *Anopheles coustani* made up 18% and 2% of the total host-seeking, respectively. *Plasmodium falciparum* sporozoite rate was 1.2% (n=328) determined by quantitative polymerase chain reaction and all positive specimens were *Anopheles arabiensis* collected outdoors. These results indicated that interventions which mainly target indoor-biting and indoor-resting mosquitoes may not be offering adequate protection against this vector population.

## 614

**A NOVEL HIGH-THROUGHPUT SEQUENCING ASSAY TO IDENTIFY AND CHARACTERIZE ALL EUKARYOTIC PARASITES PRESENT IN HUMAN STOOLS AND DISEASE VECTORS**

Matthew V. Cannon, David Serre

University of Maryland, Baltimore, Baltimore, MD, United States

Eukaryotic parasites cause many human infectious diseases - including malaria, schistosomiasis, leishmaniasis and Chagas disease - and are responsible for more than one billion cases and over one million deaths worldwide every year. These parasites also cause many animal diseases, that sometimes lead to poorly-characterized zoonoses. Unfortunately, the detection of these parasites and screening of clinical or entomological samples is challenging, time-consuming and expensive, which limits researchers and public health officials to monitoring only a few specific

parasites. Early identification and comprehensive characterization of (potential) parasites in vectors or clinical samples would greatly improve patient treatment and rapid implementation of specific control measures. To address this need, we developed a rapid and cost-efficient screening technique to detect and identify both known and potential parasites present in human stool samples and vectors. We designed several sets of PCR primers, each targeting a different taxon of eukaryotic parasites and use massively-parallel sequencing to obtain the taxonomic information for any positive amplification. Our preliminary data demonstrates that this approach can efficiently recover and identify DNA from Apicomplexa, Platyhelminthes, Nematodes (Spirurida and Trichocephalida), Parabasalia, Kinetoplastida and Blastocystis parasites. This enables screening hundreds of samples simultaneously for all these taxa. Our assay can also easily be modified to provide, in a single sequencing run, information about the vector's species and the composition of its previous bloodmeals. We believe that this approach could complement the efforts of clinicians and entomologists to monitor the presence and spread of diseases and could lead to significant improvement in public health in a variety of settings.

## 615

### NOVEL VECTORS OF THE ZONOTIC MALARIA PARASITE, *PLASMODIUM KNOWLESI*, IN TWO DISTRICTS OF SARAWAK, MALAYSIAN BORNEO

Joshua Ang Xin De<sup>1</sup>, Khamisah Abdul Kadir<sup>1</sup>, Dayang Shuaisah Awang Mohamad<sup>1</sup>, Asmad Matusop<sup>2</sup>, Khatijah Yaman<sup>1</sup>, Balbir Singh<sup>1</sup>

<sup>1</sup>Universiti Malaysia Sarawak, Sarawak, Malaysia, <sup>2</sup>Sarawak Department of Health, Sarawak, Malaysia

The zoonotic malaria parasite, *Plasmodium knowlesi*, is the most common cause of human malaria in Sarawak, Malaysian Borneo. It accounted for over 80% of hospitalised malaria cases from 2014-2016. Previously identified vectors of the parasite in nature in Malaysia and Vietnam all belong to the Leucosphyrus Group. Only one study on vectors of *P. knowlesi* has been conducted in Sarawak that incriminated *Anopheles latens* as the vector in the Kapit District. This project was therefore undertaken to identify malaria vectors in other districts of Sarawak. Human landing catches were conducted in forested sites of the Betong and Lawas Districts. The salivary glands of anophelines were removed, DNA was extracted and screened with nested PCR assays for *Plasmodium* and species of *Plasmodium*. The sequences of the small sub-unit ribosomal RNA (SSUrRNA) genes of *Plasmodium* spp. and the internal transcribed spacer 2 (ITS2) and mitochondrial cytochrome c oxidase subunit 1 (CO1) sequences of the mosquitoes were derived from the *Plasmodium*-positive samples. Collectively, 238 anophelines and 2,127 culicines were caught. *An. letifer* (44.5%, n=173) and *An. balabacensis* (47.7%, n=65) were found to be the predominant anophelines in Betong and Lawas districts, respectively. By PCR, 15 anophelines were found to be infected with only *P. knowlesi*, while 8 others were infected with two or more simian *Plasmodium* species (*P. coatneyi*, *P. cynomolgi*, *P. fieldi* and *P. inui*). Phylogenetic analysis of the SSUrRNA genes confirmed the presence of *P. knowlesi* and other simian malaria parasites in 3 *An. barbirostris*, 6 *An. balabacensis*, 1 *An. latens* and 1 *An. letifer*. Phylogenies inferred from the ITS2 and CO1 sequences of *An. balabacensis* and *An. barbirostris* indicate that the former is genetically indistinguishable from *An. balabacensis* in Borneo while the latter is a sibling species of the Barbirostris Subgroup. In conclusion, new vectors of *P. knowlesi* were identified in Betong (*An. barbirostris* and *An. balabacensis*) and Lawas (*An. latens* and *An. letifer*), including 2 species (*An. barbirostris* and *An. letifer*) which do not belong to the Leucosphyrus Group.

## 616

### DIFFERENTIAL EFFECTS OF TIRE LEACHATE ON *Aedes* MOSQUITOES MAY FACILITATE INVASION SUCCESS

Paul T. Leisnham

University of Maryland, College Park, MD, United States

Discarded vehicle tire casings are an important habitat for the developmental stages of numerous vector mosquitoes. The rubber of the tire casings degrade under ultraviolet light and leaches numerous soluble metals (e.g., barium, cadmium, zinc) and organic substances (e.g., benzothiazole and its derivatives, polyaromatic hydrocarbons) that could affect any mosquito larvae inhabiting rainwater that collects within the tire casing. This study examined relationships between Zn, as a marker of tire leachate, and other environmental correlates on mosquito densities in discarded tires in the field and tested the effects of tire leachate concentration on the survival and development of newly hatched *Aedes albopictus* and *Aedes triseriatus* larvae in a controlled laboratory dose-response experiment. *Aedes albopictus* and *Ae. triseriatus* co-occurred in over half (22/42, 52.4%) of tires in the field, and *Ae. triseriatus* was only collected without *Ae. albopictus* in one tire. *Ae. triseriatus* was more strongly negatively associated with zinc concentration than *Ae. albopictus* and another common mosquito, *Cx. pipiens*. *Ae. albopictus* was the most widespread species, being collected in 88.1% (37/42), and was correlated with detritus amount, while *Ae. triseriatus* (23/42, 54.8%) and *Cx. pipiens* (17/42, 40.5%) were less widespread and both were correlated with *Ae. albopictus*. In the laboratory experiment, *Ae. albopictus* and survival steeply declined to zero from 10,000 to 100,000 mg/L leachate. In contrast, *Ae. triseriatus* and survival declined at the lower concentration of 100 mg/L leachate, and was zero at 500, 10,000, and 100,000 mg/L. These results suggest that the invasive *Aedes albopictus* has superior tolerance to tire leachate than the native *Aedes triseriatus*, and that this tolerance may contribute to its success and displacement of *Ae. triseriatus* in urban areas and resultant disease risk.

### INFLUENCE OF RUBBER AND PALM CULTIVATIONS ON HUMAN EXPOSURE TO *Aedes aegypti* EVALUATED BY USING AN IMMUNO EPIDEMIOLOGICAL BIOMARKER

Céline M. Yobo<sup>1</sup>, Agnimou M. Sadia-Kacou<sup>2</sup>, Akre M. Adja<sup>2</sup>, Emmanuel Eilanga-Ndile<sup>3</sup>, André B. Sagna<sup>4</sup>, Négnorogo Guindo-Coulibaly<sup>2</sup>, Anne Poinson<sup>4</sup>, Franck Remoue<sup>4</sup>, Benjamin G. Koudou<sup>1</sup>

<sup>1</sup>Nangui Abrogoua University, Abidjan, Côte D'Ivoire, <sup>2</sup>Felix Houphouët Boigny University, Abidjan, Côte D'Ivoire, <sup>3</sup>Malaria Research Laboratory, Yaoundé, Cameroon, <sup>4</sup>IRD, Montpellier, France

In recent decades, numerous cases of arbovirus infections have been reported in Africa, mainly transmitted through infected *Aedes aegypti* bites. Their control is primarily based on anti-vector strategy and its efficient implementation requires an understanding of factors of risk of transmission linked to specific ecological settings. Environmental changes related to agricultural practices can impact upon arbovirus transmission, by influencing the vector species composition and their density which could, in turn, have an effect on the human-vector contact. The present study aims to assess the influence of oil palm and rubber plantations on a human exposure to *Ae. aegypti* bites, by using a new immunological tool which quantifies human IgG antibody (Ab) response to the *Aedes* Nterm-34kDa salivary peptide. Human IgG responses to the salivary peptide was assessed in 582 children living in different agro-ecosystem villages in Côte d'Ivoire: N'Zikro (rubber cultivation), Ehania-V5 (palm oil exploitation) and Ayébo (control village without plantations), in the dry and rainy seasons. In the dry season, specific IgG responses were significantly different between villages (P = 0.0089). The specific IgG level was significantly lower in Ayébo compared to Ehania-V5 (P = 0.0067) and N'Zikro (P = 0.0110). In contrast, specific IgG levels were similar between villages in the rainy season. As a consequence, specific IgG responses remained high in villages associated

with intensive agricultural during both seasons whereas, in the control village, a significant increase of the specific IgG response was observed ( $P = 0.0017$ ) in the rainy season compared to dry season. The present study indicated that rubber and oil palm plantations could maintain a high level of human exposure to *Ae aegypti* bites during both dry and rainy seasons. These agricultural activities could, therefore, represent a permanent factor of transmission risk of arboviruses.

## 618

### MAPPING GLOBAL VARIATION IN DENGUE TRANSMISSION INTENSITY AND ASSESSING THE IMPACT OF CONTROL STRATEGIES

Lorenzo Cattarino<sup>1</sup>, Isabel Rodríguez-Barraquer<sup>2</sup>, Derek Cummings<sup>3</sup>, Natsuko Imai<sup>1</sup>, Neil Ferguson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>University of Florida, Gainesville, FL, United States

Reliable local estimates of the intensity of dengue transmission (as characterised by the reproduction number,  $R_0$ ) are required for evaluating the potential impact of control measures and informing public health policy. Published global dengue maps give estimates of the burden of disease but not of transmission intensity. Using age-stratified seroprevalence and incidence data, combined with a geostatistical machine-learning model based on environmental factors which drive suitability of *Aedes aegypti*'s habitat, we have produced the first 1km resolution map of global dengue force of infection. Our force of infection predictions allowed us to also derive local estimates of the reproduction number and number of yearly dengue infections and cases. We predict high transmission rates in South America (Colombia, Venezuela and Brazil), Democratic Republic of Congo and south Asia (India, Indonesia and the Philippines). We estimated ~170 million infections annually, approximately half that of Bhatt et al. (2013). We also estimated an annual incidence of 80 million symptomatic infections. We then assessed the likely impact of two new control measures on dengue transmission intensity and disease burden: release of Wolbachia-infected mosquitoes, and introduction of childhood vaccination with the Sanofi dengue vaccine. The impact of both control measures varies as a function of local transmission intensity. Under the most pessimistic scenario examined, large scale release of Wolbachia might lead to a long-term reduction in dengue disease burden of 95%, rising to almost 100% reduction in more optimistic scenarios. We estimate that wide scale and near optimal use of the Sanofi dengue vaccine in line with WHO recommendations could reduce the global burden of dengue by approximately 20%. The high spatial resolution at which we have quantified dengue transmission intensity will help target and assess the potential impact of control measures.

## 619

### MAPPING THE GLOBAL ESTIMATES OF DENGUE SEROPREVALENCE AND TRANSMISSION INTENSITY

Natsuko Imai<sup>1</sup>, Isabel Rodriguez-Barraquer<sup>2</sup>, Wesley Hinsley<sup>1</sup>, Derek A. Cummings<sup>3</sup>, Neil M. Ferguson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>University of Florida, Gainesville, FL, United States

The first dengue vaccine (CYD-TDV) has been licensed for use in children >9 years of age in several countries. The World Health Organization recommends countries consider vaccination only in areas (national or subnational) with high endemicity corresponding to a seroprevalence of  $\geq 70\%$  in the target age group. Vaccination is not recommended where seroprevalence is  $< 50\%$ . Given these recommendations and the observed safety signal of the vaccine in seronegative recipients, it is important to know the proportion of potential vaccine recipients who might be seronegative. We have previously published work showing that the force of infection can be inferred by fitting catalytic models to age-stratified

seroprevalence and incidence data, and that estimates derived from the two data types are largely comparable. In order to present available estimates and provide some guidance to countries considering introducing the vaccine, a web tool was developed. The web tool maps currently available estimates of dengue transmission intensity at subnational levels, derived from age-stratified data on dengue: i) seroprevalence and ii) incidence, as well as the expected seroprevalence for several countries. The uncertainty around each estimate is also presented. The interactive web tool allows the user to explore how the transmission intensity relates to the expected seroprevalence at the target vaccination age group, or the expected age at which e.g. 70% seroprevalence is reached. The target age group or target seroprevalence can also be determined by the user. Users are also able to export all the estimates visualised on the website. Since the map only presents estimates for regions where data are available, it can also help to identify countries, regions, and sub-regions lacking dengue data which may inform surveillance systems. Although there are limitations such as the spatial heterogeneity observed in dengue transmission even at very small scales, having a baseline estimate of transmission intensity and seroprevalence at subnational level will be an important consideration for vaccine programmes deciding where to deploy the vaccine and who to target.

## 620

### A MULTI-COUNTRY STUDY OF THE ECONOMIC BURDEN OF DENGUE FEVER IN SIX COUNTRIES OF DVI FIELD STUDIES: VIETNAM, THAILAND, COLOMBIA, CAMBODIA, BURKINA FASO AND KENYA

<sup>1</sup>International Vaccine Institute, Seoul, Republic of Korea, <sup>2</sup>Mahidol University, Bangkok, Thailand, <sup>3</sup>AGIR, Ouagadougou, Burkina Faso, <sup>4</sup>Institut Pasteur Cambodia, Phnom Penh, Cambodia, <sup>5</sup>Ministry of Health, Nairobi, Kenya, <sup>6</sup>Clinical Epidemiology Unit, Universidad Industrial de Santander, Bucaramanga, Colombia, <sup>7</sup>National Institute of Hygiene and Epidemiology, Hanoi, Vietnam, <sup>8</sup>Kenya Medical Research Institute, Nairobi, Kenya, <sup>9</sup>Centre Muraz, Bobo-Dioulasso, Burkina Faso, <sup>10</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>11</sup>University of Oxford, Oxford, United Kingdom

Dengue is a major public health concern in the tropics and subtropics. With the first dengue vaccine licensed in several countries, it is critical to understand the economic burden of dengue fever to set health policy priorities for effective use of the vaccine. Dengue Vaccine Initiative (DVI) has conducted cost-of-illness studies in six countries: Vietnam, Thailand, Colombia, Cambodia, Burkina Faso, and Kenya. In order to capture all costs during the entire period of illness, patients were followed up on multiple interviews, after confirmation of dengue on rapid diagnostic tests on the first day of clinical visit, until the patients recovered from the current illness. Various cost items were collected such as direct medical and non-medical costs, indirect costs, and non-out-of-pocket costs. These cost components were presented as private, non-private, and societal perspectives. In addition, socio-economic factors affecting disease severity were also identified by adopting a logit model. We found that direct medical costs as patients' private expenditure were the highest in Vietnam and the lowest in Thailand where the universal healthcare system was implemented. The average direct medical costs in Burkina Faso (\$10) and Kenya (\$15) lied in between Vietnam and Thailand. In terms of direct non-medical costs, the two African countries were lower than the other four countries showing less than \$1 and \$3 in Burkina Faso and Kenya respectively. Among the first three countries, total cost per episode ranges from \$141 to \$385 for inpatient and from \$40 to \$158 outpatient, with Colombia having the highest and Thailand having the lowest. The percentage of the private economic burden of dengue fever was highest

in the low-income group and lowest in the high-income group. The logit analyses showed that early treatment, higher education, and better knowledge of dengue disease would reduce the probability of developing more severe illness. Our study indicates that substantial economic burden is caused by dengue and the findings can be used to consider vaccine introduction and prioritize alternative health interventions among competing health problems.

## 621

### THE ROLE OF HETEROTYPIC NEUTRALIZING ANTIBODY IN PROTECTION FOLLOWING TRIVALENT DENGUE VIRUS VACCINATION AND CHALLENGE

Sabundayo<sup>3</sup>, Cathy Larsson<sup>2</sup>, Yolanda Eby<sup>3</sup>, Helen He<sup>3</sup>, Sean Diehl<sup>2</sup>, Cassandra Ventrone<sup>2</sup>, Marya Carmolli<sup>2</sup>, Anna P. Durbin<sup>3</sup>

<sup>1</sup>Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>University of Vermont College of Medicine, Burlington, VT, United States, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

There are four dengue virus (DENV) serotypes, each capable of causing the full spectrum of illness ranging from an asymptomatic or mild infection to life-threatening disease. Typically, infection with one DENV serotype confers long-lived protection against symptomatic re-infection with the same serotype but only short-lived protection against a heterotypic serotype. However, following sequential infection with a second heterotypic DENV, cross-reactive immunity often provides protection against all four serotypes. Is a similar level of cross-protection elicited when multiple serotypes are encountered simultaneously, as would occur during live multivalent DENV vaccination, rather than sequentially, as occurs in nature? We sought to test this paradigm using our controlled human infection model (CHIM) developed for DENV-2. Twenty-four flavivirus-naïve adults were enrolled in a randomized, placebo-controlled trial. Eighteen subjects received a trivalent mixture of the live attenuated candidate DENV vaccines rDEN1Δ30, rDEN3Δ30/31, and rDEN4Δ30 (no DENV-2). Eight subjects received placebo. Six months later, all returning subjects were challenged with our DENV-2 CHIM strain. Following receipt of the trivalent admixture, all subjects seroconverted to DENV serotypes 1, 3, and 4, however, less than 40% of the subjects had evidence of cross-reactive neutralizing antibody to DENV-2. Twenty-one subjects returned for challenge (15 trivalent and 6 placebo recipients). Following challenge with DENV-2, four (27%) of those subjects who had received the trivalent mixture showed signs of breakthrough viremia and all subjects showed a significant boost in DENV-2 neutralizing antibody titer. All placebo recipients were viremic following challenge. Whereas efficacy against DENV-2 challenge viremia following tetravalent vaccination has been shown to be 100%, efficacy provided by the trivalent vaccination was only 73%. The complete clinical, virologic, and serologic responses following trivalent vaccination and challenge will be presented. The role of heterotypic antibody and cellular immune responses will be discussed.

## 622

### VIRAL GENETIC DIVERSITY AND PROTECTIVE EFFICACY OF A CYD-TDV TETRAVALENT DENGUE VACCINE IN A PHASE 3 TRIAL IN ASIA

**Craig A. Magaret<sup>1</sup>**, Michal Juraska<sup>1</sup>, Jason Shao<sup>2</sup>, Lindsay N. Carpp<sup>1</sup>, Andrew J. Fiore-Gartland<sup>1</sup>, David Benkeser<sup>3</sup>, Yves Girerd-Chambaz<sup>4</sup>, Edith Langevin<sup>5</sup>, Carina Frago<sup>6</sup>, Bruno Guy<sup>5</sup>, Paul T. Edlefsen<sup>1</sup>, Peter B. Gilbert<sup>1</sup>

<sup>1</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>University of California Berkeley, Berkeley, CA, United States, <sup>4</sup>Sanofi Pasteur, Marcy-

*L'Etoile, France, <sup>5</sup>Sanofi Pasteur, Lyon, France, <sup>6</sup>Sanofi Pasteur, Swiftwater, PA, United States*

CYD14 (NCT01373281) was a Phase 3 placebo-controlled efficacy trial of a tetravalent dengue vaccine (CYD-TDV) evaluated in children aged 2 to 14 years in Asia. It demonstrated a vaccine efficacy (VE) of 56.5% to prevent symptomatic, virologically confirmed dengue (VCD) of any severity during one-year post-vaccination follow-up. We conducted sieve analyses to evaluate variation in the level of VE with genomic features of breakthrough dengue sequences. Nucleotide sequences of the dengue virus (DENV) prM/E region were obtained from VCD endpoint cases via 454 sequencing, translated into proteins, and aligned with the four serotype-specific insert sequences of CYD-TDV. Extensions of the proportional hazards model were used to assess variation in VE with phylogenetic genotypes, amino acid (AA) patterns, and distances of breakthrough sequences to the vaccine strains. Of the four DENV serotype endpoints, VE significantly differed by DENV genetics only for DENV4, with differences restricted to 2–8 year-olds. In this age group, VE was significantly greater against the vaccine-matched DENV4-II (76.3%) than the vaccine-mismatched DENV4-I genotype (23.9%). Correspondingly, VE was significantly greater against DENV4 with a vaccine-matched residue at any of nine signature AA sites (pr73, M65, E46, E120, E160, E203, E329, E461, E478). The VE against DENV4 significantly decreased with an increasing percentage of vaccine-mismatched residues. We hypothesize that greater prior DENV exposure in 9–14 vs. 2–8 year-olds and their resultant broader specificity of immune responses to DENV sequences helped maintain VE against vaccine-mismatched DENV4 at a level that was comparable to that against vaccine-matched DENV4. This finding underscores the importance of improving vaccine-induced immune responses in younger children to achieve broader protection against DENV4. In addition, the similarity of the inserts to circulating viruses may partially explain how CYD-TDV's VE was greater against DENV3 and DENV4 than DENV1 and DENV2. Further investigation of the identified signature sites could increase knowledge of protective epitopes.

## 623

### PROGRESS IN DEVELOPMENT OF TAKEDA'S TETRAVALENT DENGUE VACCINE CANDIDATE

**Vianney Tricou<sup>1</sup>**, Xavier Sáez-Llorens<sup>2</sup>, Delia Yu<sup>3</sup>, Luis Rivera<sup>4</sup>, Astrid Borkowski<sup>1</sup>, Derek Wallace<sup>1</sup>

<sup>1</sup>Takeda Pharmaceuticals International AG, Zurich, Switzerland, <sup>2</sup>Hospital del Niño Dr. José Renán Esquivel, Panama City, Panama, <sup>3</sup>De La Salle Health Sciences Institute, Dasmariñas, Philippines, <sup>4</sup>Hospital Maternidad Nuestra Señora de La Altagracia, Santo Domingo, Dominican Republic

Takeda's live attenuated tetravalent dengue vaccine candidate (TDV) contains a molecularly characterized dengue serotype 2 virus (TDV-2), and three recombinant viruses expressing the pre-membrane (prM) and envelope (E) structural genes for serotypes 1, 3, and 4 in the attenuated TDV-2 backbone. Following the WHO guidelines for dengue vaccine development, Takeda has investigated different formulations, routes of administration, dosage schedules, and vaccine presentations, in several phase 1 and phase 2 studies in adults and children in dengue endemic and non-endemic countries. In an ongoing phase II placebo-controlled, multi-centre trial (ClinicalTrials.gov: NCT02302066), the safety and immunogenicity of different TDV vaccination schedules is being evaluated in ~1800 subjects from 2 to <18 years of age, living in dengue endemic areas of the Dominican Republic, Panama, and the Philippines. Here we present 18-month safety and immunogenicity results, including febrile illness surveillance, in which all reported febrile illnesses were investigated and DENV infections were laboratory-confirmed by serotype-specific RT-PCR and non-structural protein 1 ELISA. Progress of the phase 3 pivotal efficacy trial (TIDES) will also be presented.

Identifying a correlate of protection (CoP) is a major goal of vaccine research as it can predict vaccine efficacy in a new setting without the need to follow participants for the efficacy endpoint. However, very few CoPs have been identified recently. In Phase 3 efficacy trials of the CYD-TDV dengue vaccine in 2-14 year olds in Asia (NCT01373281) and in 9-16 year olds in Latin America (NCT01374516), estimated vaccine efficacy (VE) against symptomatic, virologically-confirmed dengue (VCD) between Months 13 and 25 post dose one was 57% and 61%, respectively. Case-cohort analyses assessed how dengue incidence and VE against VCD varied with dengue neutralizing antibody titers measured one month post-vaccination (Month 13) in 2848 vaccine and 1574 placebo recipients. Month 13 titers were assessed as correlates of risk using Cox regression accounting for the case-cohort sampling design, and assessed as CoPs using the principal stratification framework that studies how VE varies over vaccinated subgroups defined by Month 13 titers. For vaccine recipients in each trial, risk of dengue of each serotype significantly decreased with Month 13 homologous serotype titer (hazard ratios 0.19–0.43 per 10-fold increase); VE against dengue of any serotype significantly increased with average titer to the four serotypes (P values < 0.001). For 9–16 year olds pooled across trials ( $\geq 9$  is the licensed indication), VE estimates were 34.6%, 50%, 80%, and 97.5% for vaccine recipients with average titer of < 10 (below the assay limit), 82, 500, and 10,000, respectively. Month 13 neutralizing antibody titers positively correlate with vaccine efficacy to prevent dengue. The VE curve analysis concluded that high Month 13 titers predict high VE for all serotypes, pre-vaccination serostatus groups, age groups, and both trials. Other factors, however, may influence vaccine efficacy, especially at lower titers post third vaccination.

**LOW LOA LOA BLOOD MICROFILARIA DENSITY IN HYPO-ENDEMIC ONCHOCERCIASIS AREAS IN NIGERIA: USING THE NEW LOASCOPE TECHNOLOGY TO DETERMINE WHERE IT IS SAFE TO TREAT WITH IVERMECTIN**

Lindsay J. Rakers<sup>1</sup>, Emmanuel Emukah<sup>2</sup>, Barminas Kahansim<sup>2</sup>, Bertram E. Nwoke<sup>3</sup>, Emmanuel S. Miri<sup>2</sup>, Emily Griswold<sup>1</sup>, Yisa Saka<sup>4</sup>, Ifeoma Anagbogu<sup>4</sup>, Emmanuel Davies<sup>4</sup>, Cephas Ityonzughul<sup>2</sup>, Michael D'Ambrosio<sup>5</sup>, Matthew Bakalar<sup>5</sup>, Daniel A. Fletcher<sup>5</sup>, Thomas Nutman<sup>6</sup>, Frank O. Richards<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Jos, Nigeria, <sup>3</sup>Imo State University, Owerri, Nigeria, <sup>4</sup>Federal Ministry of Health, Abuja, Nigeria, <sup>5</sup>University of California Berkeley, Berkeley, CA, United States, <sup>6</sup>National Institutes of Health, Bethesda, MD, United States

Ivermectin treatment can rarely result in serious adverse events (encephalopathy and death) in persons with high *Loa loa* microfilariaemia (>30,000 mf/ml). In five states of southern Nigeria we conducted a study to determine whether it is safe to provide ivermectin MDA in onchocerciasis hypoendemic areas that are also *Loa loa* coendemic. Previous RAPLOA (a non-invasive rapid questionnaire assessment to determine history of eye worm) surveys conducted in this area showed many villages with a prevalence >40%, which should correlate with a prevalence of high intensity infections of >2% that would represent unacceptable risk for MDA. Our survey was conducted in 2016 in 110 ivermectin naïve villages located in districts likely to be hypoendemic for

onchocerciasis since they bordered districts currently receiving ivermectin MDA. Of the villages surveyed using RAPLOA prevalences, 28 had a prevalence of 40-60%, 57 had prevalences of 20%-39%, and 25 with prevalences of 10%-19%. We examined 10,605 residents of these villages aged 5 years and above using the "LoaScope" an innovative cellphone-based imaging device for rapidly determining the density of *Loa loa* infections at the point of contact. We found a mean village *Loa loa* prevalence of 8.4% (median 5.8%, 0 – 46.7% range). The maximum individual mf count was 11,429 mf/ml (mean individual mf count 20.1 mf/ml). Of the 2,756 persons sampled from the 28 villages with >40% RAPLOA, we were able to exclude the 2% threshold of high *Loa loa* intensity with high statistical confidence (p<0.0001). These findings indicate that ivermectin MDA can be delivered in these ivermectin naïve areas with low risk of *Loa loa*-related SAEs. We also concluded that in Nigeria the RAPLOA survey methodology is not predictive of high prevalence (>2%) of high density *Loa loa* microfilariaemia.

## 626

**QUANTIFICATION OF VECTOR INFECTION THRESHOLD FOR MAKING PROGRAMMATIC DECISION ON STOPPING OR CONTINUING THE PROGRAM TO ELIMINATE LYMPHATIC FILARIASIS**

Subramanian Swaminathan, Sadanandane Candasamy, Vasuki Venkatesan, Jambulingam Purushothaman

Vector Control Research Centre (ICMR), Puducherry, India

Transmission Assessment Survey (TAS) is the recommended strategy for deciding to stop mass drug administration (MDA) and post-MDA surveillance until certification of lymphatic filariasis (LF) elimination. TAS is based on detecting filarial antigen in children to verify absence of transmission in an evaluation unit (EU). The currently available antigen assays, the immuno-chromatographic card test (ICT) or filarial test strip (FTS), are expensive, besides issues on the size of the EU. Molecular xenomonitoring (MX) could be a potential alternative to TAS especially when human infection levels are very low. However, application of MX, as an alternative to TAS requires a valid sampling strategy and an estimate of the vector infection threshold below which transmission ceases to occur. Parallel data on *W. bancrofti* infection in human and its vector *Culex quinquefasciatus* from 33 villages/wards (sites) from one of the primary health centres, in Thanjavur district, Tamil Nadu, India was used to quantify the relationship between human and vector infection. The study area has undergone 8 MDAs, and stopped MDA after a mass screening survey results showed that the Mf-prevalence is <lt> 1% and Ag-prevalence in children is <lt> 2%. The vector infection prevalence was assessed by detecting parasite DNA in pools of gravids collected from each site. Logistic regression analysis was done to quantify the relationship of Ag-prevalence in community or children with community Mf-prevalence and to derive an estimate of the vector infection threshold. A significant linear relationship was observed between prevalence of vector infection and the Ag-prevalence in children (r=0.44, P<lt>0.01). The value of the intercept, 0.9% (95CI: 0.5-1.3%) provides an estimate of the vector infection threshold below which transmission would cease to occur ('zero' Ag-prevalence in children). The lower 95% CI of 0.5% could be a safe threshold for stopping / continuing MDA. The estimated vector infection threshold of 0.5% indicates that the currently recommended Ag-prevalence threshold of 2% in children for stopping MDA needs reconsideration to prevent the risk of LF-resurgence.

## A SIGNIFICANT STEP TO WARDS LYMPHATIC FILARIASIS ELIMINATION IN CAMEROON: THE DISEASE IS NOT ENDEMIC IN 31 HEALTH DISTRICTS CO-ENDEMIC WITH LOA LOA AND HYPOENDEMIC FOR ONCHOCERCIASIS

Benjamin Didier Biholong<sup>1</sup>, Patrick Mbia<sup>2</sup>, Julie Akame<sup>2</sup>, Henri C. Mougou<sup>2</sup>, Georges N. Ayissi<sup>1</sup>, Samuel Wanji<sup>3</sup>, Michel Paradis<sup>2</sup>, Steven D. Reid<sup>4</sup>, Yaobi Zhang<sup>5</sup>

<sup>1</sup>Ministry of Public Health, Cameroon, Yaoundé, Cameroon, <sup>2</sup>Helen Keller International, Yaoundé, Cameroon, <sup>3</sup>University of Buea, Buea, Cameroon, <sup>4</sup>Helen Keller International, New York, NY, United States, <sup>5</sup>Helen Keller International, Dakar, Senegal

Mapping conducted in 2010-2012 using immunochromatographic tests (ICT) showed 156 health districts (HDs) are endemic for lymphatic filariasis (LF) in all ten regions of Cameroon. Mass drug administration (MDA) using ivermectin and albendazole (ALB) was launched in endemic districts to eliminate LF with funding from the USAID. However, due to co-endemicity with *Loa loa*, entire or part of 31 HDs highly endemic for loiasis were not included in the MDA. This hinders the LF elimination process in the country. In view of cross-reactivity of ICT cards with other non-LF filarial antigens and in preparation for implementing a biannual ALB MDA for LF elimination, a confirmation survey was conducted in 2016 in 31 HDs (13 HDs in East, 10 HDs in Center, 4 HDs in South and 4 HDs in the Littoral) using Filariasis Test Strips (FTS) and thick blood films (TBF) were used to detect microfilaria (mf) for the FTS positive cases. The survey was conducted in line with the WHO LF mapping recommendations, but four sites/villages each HD were purposefully selected to give better geographical representation. In total, 14,577 participants were selected and tested with 40% of them between 9-14 years and 60% ≥ 15 years old. The results showed that 5 HDs had <1% FTS positives in all sites and are not considered LF endemic. 26 HDs had at least one site with ≥1% FTS positives (site prevalence range: 0-11%): 12 HDs in East, 9 HDs in Center, 4 HDs in South and 1 HD in Littoral. Among a total of 235 FTS positives, 210 were tested by day TBF and 185 by night TBF. No LF microfilaria (mf) was identified in any FTS positive cases, while *Loa loa* or *Mansonella perstans* mf was found from 135 and 28 cases respectively in day TBF, and from 113 and 30 cases in night TBF. The results suggests that there is no indication of LF endemicity in these 31 HDs, as the FTS positives may have been mainly due to cross-reactivity with *L. loa* or *M. perstans*. There is no need of LF MDA in these HDs. This takes Cameroon a great step forward towards LF elimination by the year 2020.

## PHARMACOKINETICS OF TRIPLE DRUG THERAPY IN PATIENTS WITH AND WITHOUT WUCHERERIA BANCROFTI INFECTION

Edi Constant<sup>1</sup>, Yashpal S. Chhonker<sup>2</sup>, Catherine Bjerum<sup>3</sup>, Allassane F. Ouattara<sup>4</sup>, Benjamin G. Koudou<sup>5</sup>, Abdoulaye Meïté<sup>6</sup>, Gary J. Weil<sup>7</sup>, Christopher L. King<sup>8</sup>, Daryl J. Murry<sup>2</sup>

<sup>1</sup>Centre Suisse de Recherche Scientifique en Côte d'Ivoire, Abidjan, Côte D'Ivoire, <sup>2</sup>UNMC, Omaha, NE, United States, <sup>3</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>4</sup>Centre Suisse de Recherche Scientifique en Côte d'Ivoire and Université Nangui Abrogoua, Abidjan, Côte D'Ivoire, <sup>5</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>6</sup>Programme national de la lutte contre la schistosomiase, les geohelminthiases et la filariose lymphatique, Abidjan, Côte D'Ivoire, <sup>7</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>8</sup>Center for Global Health and Diseases, Case Western Reserve University and Veterans Affairs Research Service, Cleveland, OH, United States

Recently we have shown a single co-administered dose of diethylcarbamazine (DEC), albendazole (ABZ) and ivermectin (IVM) is much more effective in sustained elimination of *Wuchereria bancrofti* microfilariae (Mf) compared to DEC+ABZ or IVM+ABZ currently used for

mass drug therapy for lymphatic filariasis (LF). However, the effect of active LF infection on the pharmacokinetics of this triple drug regimen are not known. The primary objective of the present analysis was to evaluate the pharmacokinetics of DEC, IVM and ABZ when administered to patients with and without LF infection. A total of 56 participants (32 infected and 24 non-infected) were enrolled in the study. Twelve plasma samples per subject were collected from 0 - 168 hours post-dose of DEC (6mg/kg), ABZ (400mg) and IVM (0.2mg/kg). Plasma samples of DEC, ABZ, albendazole sulfoxide (ABZ-OX), and albendazole sulfone (ABZ-ON) were measured simultaneously using liquid chromatography-mass spectroscopy. Ivermectin was measured separately using an established liquid chromatography method with fluorescence detection. Pharmacokinetic parameters were determined using standard non-compartmental analysis methods. Statistical analysis was performed using JMP software. The maximum concentration (C<sub>max</sub>) mean (range) values in LF infected patients for DEC, IVM, ABZ, ABZ-OX and ABZ-ON were 2602 (1728-3367), 87 (25-173), 56 (2-263), 407 (118-1256) and 24 (7-114) ng/mL, respectively. The mean (range) values of AUC<sub>0-∞</sub> for DEC, IVM, ABZ, ABZ-OX and ABZ-ON were 41930 (22749-69500), 2395 (693-6469), 250 (12-1196), 5584 (1352-18108), and 346 (80-1343) hr\*ng/ml, respectively. The mean AUC<sub>0-∞</sub> and C<sub>max</sub> for each drug was not different between patients with and without LF infection. Although all patients with parasitemia at diagnosis were clear of infection by 39 hours post treatment there was significant variation in AUC<sub>0-∞</sub>. The relationship between drug levels and clearance of Mf and adult worm one-year post-treatment will be reported. In conclusion, LF infection does not alter the pharmacokinetics of this three drug regimen.

## HYDROCOELE SURGERY FOR LYMPHATIC FILARIASIS: MEASURING THE IMPACT ON PATIENT CAREGIVERS IN MALAWI

Sarah Martindale<sup>1</sup>, John Chipwanya<sup>2</sup>, Dorothy Emmie Matipula<sup>2</sup>, Paul Ndhlovu<sup>2</sup>, Hannah Betts<sup>1</sup>, Louise Kelly-Hope<sup>1</sup>

<sup>1</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Ministry of Health, Lilongwe, Malawi

Lymphatic filariasis (LF) is a neglected tropical disease (NTD) targeted for elimination as a public health problem by 2020. Hydrocoele is the most common clinical manifestation, which affects approximately 19.4 million men worldwide and can be cured by surgery. Whilst surgery has been shown to positively impact men's lives by improving their physical and socio-economic outcome; there has been no research on how this may impact the people who care for them (caregivers). To explore this further, the main caregivers of hydrocoele patients in Malawi were surveyed pre- and post-surgery. A semi-structured questionnaire quantified differences in the level and type of assistance required, the number of days off work or school necessary to care for patients, and their own socio-economic wellbeing based on a scoring method (1=no problem, 2=mild, 3=moderate, 4=severe). In total, 40 caregivers were surveyed: mean age 36 years, majority female (75%; predominately wives), and approximately half illiterate (55%). Pre-surgery, 29 caregivers (72.5%) assisted men with at least one activity, which reduced to nine caregivers (22.5%) post-surgery, and most commonly was helping with the farm. Pre-surgery, caregivers were unable to work or attend school on average for 8.2 days per month, which reduced to zero days' post-surgery. Furthermore, positive significant differences were found when comparing caregivers pre- and post-surgery scores (p<0.05) in relation to their own usual living activities (ability to do their own job, household activities and leisure activities), social issues (joining in regular social activities in and outside the home, and romantic relationships), and psychological health (worried about their own health, their own future, feeling neglected from friends or family, and the ability to plan for the future). This study highlights the wider burden of filarial hydrocoele, and that both the patient and their caregivers can significantly benefit physically, economically, educationally, socially and psychologically from the outcome of surgery.

### LYMPHATIC FILARIASIS TRANSMISSION VARIATION WITHIN AN IMPLEMENTATION UNIT - THE CASE OF THE LIMBE COMMUNE IN THE NORTH DEPARTMENT OF HAITI

Alain Javel<sup>1</sup>, Carl Renand Fayette<sup>1</sup>, Franck Monestime<sup>1</sup>, Cudjoe Bennett<sup>2</sup>, Sarah Craciunoiu<sup>2</sup>, Abdel Direny<sup>3</sup>, Kim Won<sup>4</sup>, Caitlin Worrell<sup>4</sup>, Katherine Gass<sup>5</sup>, Jean-Frantz Lemoine<sup>6</sup>

<sup>1</sup>IMA World Health, Port au Prince, Haiti, <sup>2</sup>IMA World Health, Washington, DC, United States, <sup>3</sup>RTI International, Washington, DC, United States, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>Task Force for Global Health, Atlanta, GA, United States, <sup>6</sup>Ministry of Public Health and Population, Port au Prince, Haiti

Lymphatic Filariasis (LF) was determined to be endemic in all communes in Haiti in 2000-2001 after an extensive mapping exercise. The Haiti Neglected Tropical Diseases (NTD) Control Program, in line with the global goal, aims to eliminate LF as public health problem by 2020. There has been considerable progress to date; mass drug administration (MDA) has been conducted in all 140 communes, and 85% of communes have stopped MDA and are in the post-MDA surveillance phase. However, LF transmission persists in 21 communes, including Limbé commune in the North Department. Limbé passed a school-based transmission assessment survey (TAS) in 2015 in which 12 of 1,411 6-7 year old children tested were LF-antigen-positive (critical cutoff for antigen positives was 16). Of note, most of the positive individuals were geographically concentrated in schools around downtown Limbé. In a community-based TAS conducted in Limbé in the last quarter of 2016, 4,237 people were tested including 1,412 6-7 year old children from randomly selected households throughout the commune. In total 117 positives were found, including 25 6-7 year old children. The majority (n=93; 79%) of those who tested positive lived within a 5km radius of the downtown Limbé area and more than 50% (n=59) were within 1km of downtown Limbé; although the latter radius represents less than 3% of all the Limbé commune area. This pattern suggests a concentrated transmission area around the urban center. The NTD Control Program strategy of MDA and TAS is uniformly applied throughout implementation units (IU) and MDA coverage is calculated for whole IUs, but TAS results are applied across a widespread area. Our data demonstrate the need for revised strategies for evaluating disease prevalence that address areas with heterogeneous disease patterns, as in Limbé.

## 631

### MODELLING THE ROLE OF LONG LASTING INSECTICIDE-TREATED BEDNETS IN THE REDUCTION OF LYMPHATIC FILARIASIS PREVALENCE ACROSS A RANGE OF SETTINGS

Emma L. Davis, Deirdre Hollingsworth, Matt J. Keeling  
University of Warwick, Coventry, United Kingdom

Since being marked for elimination by 2020 by the World Health Organization (WHO) six countries have been confirmed to have eliminated lymphatic filariasis (LF) as a public health problem; another 13 have completed 4-6 rounds of annual mass treatment and are in surveillance to confirm interrupted transmission. However, 29 of the 54 countries that still need to complete treatment by 2020 will need enhanced strategies. Long lasting insecticide-treated bednets (LLINs) have long been a vital tool in malaria control, but have only recently started being used against LF. Following interrupted transmission in The Gambia, despite no antifilarial distribution, there is evidence to suggest that LLINs could play a significant role in achieving the 2020 goals in areas with anophelene mosquitoes. We combine a standard model of LF infection with methods of modelling LLIN-influenced vector dynamics adapted from the malaria literature. Firstly we demonstrate that low prevalence, as in The Gambia, can plausibly be achieved using bednets over these timescales; secondly we explore LLIN coverage in a variety of settings. Model results predict LLINs to have more impact than previous studies suggest, with coverage of 40-60%

sufficient in low endemicity settings to achieve the 1% microfilaria (mf) prevalence WHO threshold for cessation of drug programs. In the 29 countries requiring additional measures LLINs could play an important role in achieving the 2020 goals and avoid a scale up drug usage. Introducing MDA to the model shows that implementation of LLINs could force mf prevalence to below the targeted 1% in settings where MDA alone would be insufficient. This highlights the need for further data-driven analysis into the impact of LLINs and indicates a scale-up in the worldwide use of LLINs could be vital in tackling LF transmission.

## 632

### ATTENUATED VARIANT OF LEISHMANIA DONOVANI CAUSES CUTANEOUS LEISHMANIASIS IN SRI LANKA

Udeshika L. Kariyawasam<sup>1</sup>, Angamuthu Selvapandian<sup>2</sup>, Panduka Karunanayake<sup>3</sup>, Yamuna Siriwardena<sup>1</sup>, Hira L. Nakhasi<sup>4</sup>, Nadira D. Karunaweera<sup>1</sup>

<sup>1</sup>Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, <sup>2</sup>JH-Institute of Molecular Medicine, Jamia Hamdard, New Delhi, India, <sup>3</sup>Department of Clinical Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, <sup>4</sup>Laboratory of Emerging Pathogens, Division of Emerging and Transfusion Transmitted Diseases, Center for Biologics Evaluation and Research, Food and Drug Administration, Silver Spring, MD, United States

*Leishmania donovani* is the etiological agent of visceral leishmaniasis in the Indian subcontinent. However, it almost exclusively causes cutaneous leishmaniasis (CL) in Sri Lanka with over 6000 cases reported during the past decade. Visceralization potential of *L. donovani* in Sri Lanka (*L. donovani*-SL) is yet unknown. This study aimed to investigate the disease sequelae of CL patients through long-term follow-up and virulence of parasites through *in vitro* experiment. Patients (n=250) were recruited via passive case detection, after laboratory confirmation of diagnosis and were treated with weekly intra-lesional sodium stibogluconate up to 10 doses (IL-SSG) and followed up weekly for 3 months and bi-annually thereafter, up to 4 years. Patients were examined by a Physician at each follow up, to assess healing and to detect sign(s) of visceralization. Patients' serum samples were tested for anti-*L. donovani* antibodies (rK39 dip stick assay). Macrophage cultures were infected with *L. donovani*-SL(10:1, parasite: macrophage) and with *L. donovani*-1S as a positive control. Measures of infection efficiency, intracellular growth and parasite survival in infected macrophages were recorded. The age range of patients was 1-70 years (median=40); male to female ratio was 3:1 (179:71). There were no signs of systemic infection and no evidence for the presence of anti-*L. donovani* antibodies observed during the follow up period. Treatment success of IL-SSG was 76.4% and the remaining patients (23.6%) were cured following extra 4-9 doses. Recurrence of lesions was observed in 9 patients. In the *in vitro* study, infection efficiency and intra-cellular growth of *L. donovani*-SL was significantly lower at 48 hrs post-infection when compared to *L. donovani*-1S. The survival rate of *L. donovani*-1S was as twice as that of *L. donovani*-SL, at 48 and 72 hr post-infection. Sri Lankan *L. donovani* appears to be essentially dermatotropic. Diminished infection efficiency, intracellular growth and survival of *L. donovani*-SL suggest a natural attenuation of virulence of *L. donovani*-SL strain(s), which is likely to contribute to the resultant atypical clinical picture.

## 633

### FROM DECIPHERING THE SPECIFIC IMMUNE RESPONSE TO A NOVEL BIOMARKER FOR MONITORING CHAGAS DISEASE

Maan Zrein<sup>1</sup>, Ester C. Sabino<sup>2</sup>

<sup>1</sup>Infynity Biomarkers, Lyon, France, <sup>2</sup>University of Sao Paulo, Sao Paulo, Brazil

One of the fundamental medical needs for Chagas disease is a qualified test to assess treatment efficacy, and spontaneous cure, in *T. cruzi*-infected patients. The current consensus for parasitological cure is to monitor conversion to negative serology. However, seroreversion by standard tests

can take many years and up to decades. Hence, the current strategy, for investigational settings, is to use PCR to measure parasitemia as primary endpoint. PCR, especially qPCR, is costly and can still fail to detect parasites because parasitemia is extremely low and fluctuating over time in chronic patients. This is an important concern not only for the development of novel drugs but also for evaluation of clinical trials and the clinical management of Chagas disease patients. In this study we devised an innovative multi-parametric screening technology to identify surrogate antibody biomarker(s) that can be instrumental to monitor parasite persistence regardless of PCR results. We analyzed the diversity of antibody response against 15 well-selected *T. cruzi* peptide and protein antigens in a large sample collection from chronic Chagas patients (SaMi-Trop cohort), either BZN-treated or untreated, and revealed reliable changes in these responses that are associated to therapy. Using an interdisciplinary approach, we explored our experimental data with different mathematical models and were able to show that one unique and novel antibody (Ab3) is considerably more meaningful than PCR to monitor *T. cruzi* parasite persistence (information derived from PCR positive data). Importantly, the dynamic decline of the antibody titer, upon drug treatment, also seems to perform well in longitudinal studies (Gates-Slim, McGill-HUG). The performance of Ab3 has, so far, been tested and validated on over 2000 patients and four independent cohorts i.e. SaMi-Trop, REDS II, Gates-Slim, McGill-HUG. A simple immunoassay measurement of Ab3 has not only the potential to act as a treatment efficacy indicator but could also serve as a flag which guides the medical decision prior to therapy.

### 634

#### **PERSISTENCE OF *TRYPANOSOMA CRUZI* DNA COPIES BY QUANTITATIVE REAL TIME PCR 12 MONTHS AFTER TREATMENT WITH BENZNIDAZOLE AMONG CHILDREN AGED 4-15 YEARS OLD IN BOLIVIA**

**Clara Vasquez Velasquez**<sup>1</sup>, Kota Mochizuki<sup>1</sup>, Yelin Roca<sup>2</sup>, Jimmy Revollo<sup>2</sup>, Angelica Guzman<sup>2</sup>, Benjamín Quiroga<sup>3</sup>, Alberto Zambrana Ortega<sup>4</sup>, Eida Espinoza<sup>4</sup>, Mihoko Kikuchi<sup>1</sup>, Shusaku Mizukami<sup>1</sup>, Graciela Russomando<sup>5</sup>, Kenji Hirayama<sup>1</sup>

<sup>1</sup>Institute of Tropical Medicine, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, <sup>2</sup>Centro Nacional de Enfermedades Infecciosas CENETROP, Santa Cruz, Plurinational State of Bolivia, <sup>3</sup>Programa Departamental de Control de Chagas del Ministerio de Salud, Santa Cruz, Plurinational State of Bolivia, <sup>4</sup>Hospital Municipal Warnes "Nuestra Señora del Rosario", Santa Cruz, Plurinational State of Bolivia, <sup>5</sup>Departamento de Biología Molecular y Biotecnología, Investigaciones en Ciencias de la Salud, Universidad Nacional de Asunción, Asunción, Paraguay

Chagas disease is a parasitic infection caused by *Trypanosoma cruzi* that remains endemic in Latin American countries. In Bolivia, the National Program for Chagas has been implemented for 10 years and the natural infection is greatly reduced in number. Therefore, the program moved to initiate a treatment regimen of Benznidazole (5mg/kg/day) for 60 days in seropositive children aged 4-15 years living in areas certified as vector controlled areas. The efficacy and complications of the treatment for chronic Chagas remains controversial. We performed a 12 month follow-up study in collaboration with the departmental program of Chagas Control in Santa Cruz, Bolivia. From 2012 to 2015, 90 seropositive children were recruited from six regional hospitals and performed 60 days treatment. 3 ml of blood samples were collected 7 times as follows: (1) before treatment, (2) 30 days after the initiation of treatment, (3) 60 days, (4) 4 months, (5) 6 months, (6) 8 months and (7) 12 months. The quantitative real-time PCR assay (qPCR) with a dual-labeled TaqMan Probes was performed in each specific time points. The median age was 9 years, and 13 children experienced a side effect of treatment with one case being diagnosed as Stevens-Johnson syndrome. 17 children out of 46 participants from whom samples collected 12 months after initiation of therapy were available showed qPCR positive results though parasitemia levels were lowered when compared with initial sample results collected before start of the treatment. Because natural infection never occurred

in this area, this study indicates 37% of treatment failure 1 year after treatment. However, further follow-up should be done to clarify the meaning of this persistence of DNA copies in the peripheral blood.

### 635

#### **BENZINIDAZOLE TREATMENT IS ASSOCIATED WITH *TRYPANOSOMA CRUZI* BLOOD PCR NEGATIVITY AND LESS CARDIAC LESIONS IN CHAGAS DISEASE: NIH SAMITROP STUDY**

**Clareci S. Cardoso**<sup>1</sup>, Ester C. Sabino<sup>2</sup>, Claudia D. Oliveira<sup>1</sup>, Lea C. Oliveira<sup>2</sup>, Enrico A. Colosimo<sup>3</sup>, Ana L. Bierrenbach<sup>2</sup>, J. L. Silva<sup>4</sup>, Ariela M. Ferreira<sup>5</sup>, T. H. Lee<sup>6</sup>, Marcio Oikawa<sup>7</sup>, Michael Busch<sup>6</sup>, Antonio L. Ribeiro<sup>4</sup>

<sup>1</sup>Federal University of São João del-Rei, Public Health, Divinópolis, Brazil, <sup>2</sup>University of Sao Paulo, São Paulo, Brazil, <sup>3</sup>Federal University of Santa Maria, Santa Maria, Brazil, <sup>4</sup>Federal University of Minas Gerais, Belo Horizonte, Brazil, <sup>5</sup>State University of Montes Claros, Montes Claros, Brazil, <sup>6</sup>Blood Systems Research Institute, San Francisco, CA, United States, <sup>7</sup>Federal University of ABC, Sao Bernardo, Brazil

Chagas Disease (ChD) remains an important cause of cardiomyopathy in Latin America. Although persistence of tissue parasitism seems to play a role in the pathogenesis ChD, the efficacy of anti-parasite treatment with Benznidazole (BZN) in chronic phase remains unclear. The purpose was to evaluate if previous treatment with BZN is associated with less advanced cardiac disease and lower parasitemia positivity in patients with chronic ChD. The study was conducted using baseline data of the NIH-sponsored SaMi-Trop cohort, established in a highly endemic region of Brazil in which the vectorial transmission has been interrupted. Patients with reported ChD were submitted to interview, reporting previous use of BZN, NT-ProBNP measurement and ECG. ChD subjects that received at least one course of treatment with BZN were classified as treated group (TrG) and we used a pairing method (genetic matching) to select a comparison group (CG) of patients with similar characteristics, using gender, age, income, literacy, time of known ChD and hypertension as covariates. Clinical outcomes were: presence of major ECG abnormalities typical for ChD, age-adjusted NT-ProBNP levels suggestive of heart failure or both, and the parasitological outcome was PCR positivity for *Trypanosoma cruzi* in blood. Results of this paired analysis were compared with logistic regression and generalized estimating equations. From 1,959 patients with positive serology (EIA), 1803 with NT-proBNP results were studied (mean age: 59 years, 68% female). A total of 493 patients reported previous use of BZN (TrG) (average time of use: 90 days, 75% treated > 5 years before). Matched CG had frequencies of covariates similar to the TrG. Parasitological and clinical outcomes were worse in CG. A similar effect size was observed for whole sample using conventional multivariate analysis. When compared with a similar control group, patients previously treated with BZN had significantly reduced parasitemia positivity and lower frequency of markers of cardiomyopathy severity in ChD. Use of BZN may be related to better clinical and parasitological outcomes, if used in the early phases of the disease.

#### **POTENTIAL IMPROVEMENT IN THE DIAGNOSIS OF CANINE VISCERAL LEISHMANIASIS IN BRAZIL BY IMPLEMENTATION OF AN ELISA TEST USING RECOMBINANT PROTEINS OF *LEISHMANIA***

**Lairton S. Borja**<sup>1</sup>, Matheus S. Jesus<sup>1</sup>, Lívia B. Coelho<sup>1</sup>, Edmilson D. Silva<sup>2</sup>, Antonio G. Ferreira<sup>2</sup>, Deborah B. Fraga<sup>1</sup>, Patrícia S. Veras<sup>1</sup>

<sup>1</sup>FIOCRUZ/IBA - Instituto Gonçalo Moniz, Salvador, Brazil, <sup>2</sup>Instituto de Tecnologia em Imunobiológicos, Bio-Manguinhos, Rio de Janeiro, Brazil

Visceral Leishmaniasis (VL) caused by *Leishmania infantum*, is a serious neglected tropical disease and a public health problem worldwide distributed, being dogs the main urban reservoir of the disease.

Identification and euthanasia of infected dogs are one of the main strategies for VL control recommended by the Brazilian Ministry of Health. Thereby, make the accurate diagnosis is crucial to correctly identify animals infected with *L. infantum*. Twelve recombinant antigens were selected from a cDNA library of *Leishmania infantum* due to their strong potential as candidates in diagnostic testing. From the 12 recombinant antigens, 1 was selected using the antigen trial techniques of Multiple Antigen Print Immuno Assay (MAPIA) and ELISA immunoassay. The present study aimed to compare the accuracy of the commercial ELISA (EIE Bio-Manguinhos), actual confirmatory test recommended by Minister of Health in Brazil, and an ELISA using the selected antigen (rLci5). The accuracy was evaluated using sera obtained from 153 infected dogs (108 symptomatic and 45 asymptomatic) and from 117 negative dogs. All the samples were selected according to the results of culture and real-time PCR using splenic aspirate of dogs, evaluated in an endemic area of canine VL (CVL) in Brazil. Sensitivity obtained were 80%, 73%, and 64%, respectively for ELISA Lci5, DPP CVL, and EIE Bio-Manguinhos. Specificity was 92% for ELISA Lci5, 96% for DPP CVL and 90% for EIE Bio-Manguinhos. The accuracy was 85%, 83%, and 75%, respectively for ELISA Lci5, DPP CVL, and EIE Bio-Manguinhos. Then we compared the performance of the actual protocol of CVL diagnosis, recommended by Brazilian Minister of Health, using DPP CVL as screening test and EIE Bio-Manguinhos as confirmatory test, and the altered protocol, replacing the EIE Bio-Manguinhos by ELISA Lci5. The actual protocol presented sensitivity of 58%, specificity of 97% and accuracy of 75%, while the altered protocol presented a higher sensitivity (68%), specificity (99%) and accuracy (81%). We concluded that ELISA rLci5 is a promising test that could replace the EIE Bio-Manguinhos and improve the diagnostic of the CVL in Brazil.

### 637

#### PROGNOSTIC MARKERS OF DEATH FOR CHAGAS DISEASE IN REMOTE AREAS OF BRAZIL

**Claudia D. Oliveira<sup>1</sup>**, Ester C. Sabino<sup>2</sup>, Clareci S. Cardoso<sup>1</sup>, Lea C. Oliveira<sup>2</sup>, Ariela M. Ferreira<sup>3</sup>, Ana L. Bierrenbach<sup>2</sup>, Enrico Colosimo<sup>4</sup>, Carlos H. Moreira<sup>5</sup>, Marcio Oikawa<sup>6</sup>, Edecio C. Neto<sup>2</sup>, Antonio L. Ribeiro<sup>7</sup>

<sup>1</sup>Federal University of São João del-Rei, Public Health, Divinópolis, Brazil, Sao Joao Del Rei, Brazil, <sup>2</sup>University of Sao Paulo, São Paulo, Brazil, <sup>3</sup>State University of Montes Claros, Montes Claros, Brazil, <sup>4</sup>Federal University of Santa Maria, Santa Maria, Brazil, <sup>5</sup>Institute of Tropical Medicine, São Paulo, Brazil, <sup>6</sup>Federal University of ABC, São Paulo, Brazil, <sup>7</sup>Federal University of Minas Gerais, Belo Horizonte, Brazil

Chagas Disease (ChD) is an important cause of death in Latin America. Impaired left ventricular function is the most consistent predictive marker of death in longitudinal studies. However, in remote areas, where echocardiogram is not available, there is a need for alternative markers to evaluate risk of death. We have established a large cohort (SaMi-Trop) to evaluate markers of disease progression in a highly endemic region of Brazil. Twenty-two small municipalities in which vectorial transmission was interrupted, were included in the study. Inclusion criteria were individuals with confirmed seropositive for ChD and ECG abnormalities at baseline. The participants were submitted to an interview, sample collection, ECG, and followed for two years. Cox proportional-hazard model including sex, age, New York Heart Association (NYHA) class, Nt-ProBNP, number of major abnormalities on ECG and self-reported health state was used to access the risk for death. We included in this analysis 1,584 patients, 537 man (33.9%), and Nt-ProBNP values were  $\geq 300$  pg/mL in 550 (34.7%), and 3 or more ECG major abnormalities were detected in 89 (5.6%) of them. During the two years of follow-up 125 patients (7.9%) died. Age (HR: 1.01[1.002-1.03]), 3 or more major abnormalities in ECG (HR: 2.09[1.001-4.37]) and Nt-Pro-BNP  $\geq 300$ (HR 5.28[3.25-8.58]) were significantly associated with death. Our data suggest that Nt-Pro-BNP could be used as an alternative marker of risk of death when echocardiogram is not available.

### 638

#### MAXIMIZING THE UTILITY OF VL CLINICAL TRIAL DATA WITHIN AN ETHICAL DATA-SHARING FRAMEWORK

**Philippe J. Guerin<sup>1</sup>**, Michael Otieno<sup>2</sup>

<sup>1</sup>Infectious Diseases Data Observatory, Oxford, United Kingdom, <sup>2</sup>Drugs for Neglected Diseases initiative, Nairobi, Kenya

Over the last decades a substantial amount of trials measuring the efficacy of antileishmanial drugs have been carried out, but these data are scattered across geographical regions and published trial reports lack detailed information. Data on more than 35,000 patients enrolled to clinical trials internationally have never been pooled or standardised to allow for meta-analysis. These data could provide the necessary evidence to fill knowledge gaps, optimise treatment and guide future research. A variety of factors should be taken into account when considering the best therapeutic options to cure VL patients, including geographical area, drug resistance, and co-morbidities such as malnutrition or HIV co-infection. It is currently impossible to compare the efficacy of differing drugs, regimens and regions, since only summary statistics of VL clinical trials are available, and trial reports lack standardisation. A central database populated with individual patient data from clinical trials would improve our understanding of the clinical outcomes of VL treatments by enabling the pooling and comparison of the existing, diverse clinical trial datasets. Engaging the VL research community in developing a data platform, identifying relevant scientific questions and analysing the data would be critical to the success of such an enterprise. The involvement of policy-makers would also be critical in setting the research agenda and adapting treatment policy to reflect the resulting evidence. A partnership between the Infectious Diseases Data Observatory and the Drugs for Neglected Diseases initiative has engaged investigators in the planning and design of a VL data repository. An initial pilot project and systematic search of published and unpublished literature has assessed the feasibility of a VL data-sharing platform to facilitate the amalgamation and standardisation of available data. A VL data-sharing platform would maximise the utility of existing resources and enable researchers to address priority questions in VL treatment within a framework that recognises the contributions of data contributors and clinical trial participants.

### 639

#### EFFECTS OF HABITAT PERTURBATION ON RODENT ASSEMBLAGES AND THEIR GEOGRAPHIC DISTRIBUTIONS ALONG THE INTER-OCEANIC HIGHWAY IN MADRE DE DIOS, PERU

**Maria C. Guezala<sup>1</sup>**, Tatiana P. Quevedo<sup>2</sup>, J. Catherine Dupont-Turkowsky<sup>1</sup>, Christian B. Albuja<sup>1</sup>, Victor Pacheco<sup>3</sup>, Xiangming Xiao<sup>4</sup>, Yuanwei Qin<sup>4</sup>, A. Townsend Peterson<sup>5</sup>, James Mills<sup>6</sup>, Gabriela Salmon-Mulanovich<sup>7</sup>, Daniel G. Bausch<sup>8</sup>

<sup>1</sup>Naval Medical Research Unit-6, Bellavista, Peru, <sup>2</sup>RAICES, Lima, Peru, <sup>3</sup>Museo de Historia Natural, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>4</sup>Department of Microbiology and Plant Biology, Center for Spatial Analysis, College of Atmospheric and Geographic Sciences, University of Oklahoma, Norman, OK, United States, <sup>5</sup>Department of Ecology and Evolutionary Biology, University of Kansas, Kansas, KS, United States, <sup>6</sup>Population Biology, Ecology and Evolution Program, Emory University, Atlanta, GA, United States, <sup>7</sup>Unidad de Desarrollo Integral Ambiente y Salud, Facultad de Salud Pública, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>8</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Human development results in migration into previously uninhabited natural environments with consequent habitat perturbation including changes in land use and cover. Migration increases contact between humans and animals with the potential transmission of zoonotic pathogens. As part of a multidisciplinary network of investigators from Peru, Bolivia, Ecuador and the United States, we studied the influence

of human habitat perturbation on the risk of rodent-borne diseases. We studied habitat perturbation caused by the construction of roads through forests in Peru, Bolivia, and Ecuador. We worked along the inter-oceanic highway (IOH) through the southern Peruvian Amazon, in the Madre de Dios Region, bringing growth in human settlements and forest disturbance. To explore longitudinal changes in rodent populations, we trapped small mammals every 4 months for 4 years at 4 sites along the IOH. Permanent trapping grids were set on gradients from unperturbed to highly perturbed habitats. Rodents were caught, marked, and released with exception of terminal captures at the end of each trapping trip. Landscape changes were recorded in-situ using GPS photography and satellite images. We captured 1130 animals (14 species) with a 3% recapture rate. Rodents of the species *Oligoryzomys microtis* (522/46%) were caught in the greatest numbers followed by *Necomys lenguarum* (153/ 14%) and *Euryoryzomys nitidus* (123/11%). Three of the species captured, *O. microtis*, *N. lenguarum*, and *Necomys spinosus* (47/4%) have been shown to be reservoirs of Rio Mamoré and Andes hantaviruses, causative agents of hantavirus pulmonary syndrome. The majority of animals were trapped in dry (479) and dry-to-rainy (378) seasons. Changes in land use and land cover were obvious and happened faster than expected; preliminary analysis of remote sensing data show 26% forest loss from 2001-15, mainly due to forest conversion into cropland, etc. Analyses of associations between rodent assemblages, species distribution and habitat perturbation, as well as pathogen testing on rodents are ongoing and will be presented at the meeting.

## 640

### PARASITES IN THE PARK PART 2: AN EPIDEMIOLOGIC STUDY OF *TOXOCARA SP.* IN NYC PLAYGROUNDS AND USE OF A NOVEL SOIL-TRANSMITTED HELMINTH IDENTIFICATION TOOL

Donna L. Tyungu

University of Texas McGovern Medical School, Houston, TX, United States

*Toxocara* species are common pet parasites that can be found in the stool of dogs and cats. Eggs released in the stool, subsequently become infective in soil, where they survive for many years, and can be ingested by children who encounter them on playgrounds. *Toxocarasis* is listed by the CDC as one of five neglected parasitic infections in the US. It is considered a neglected disease of poverty, remaining largely underdiagnosed. Infection in humans can lead to visceral or ocular larva migrans, blindness, and silent brain infection that can diminish neurological cognition. It has been suggested that certain NYC neighborhoods may pose a higher risk for *Toxocara* infection, particularly in lower socioeconomic communities. The specific goals of the study are to: 1) determine the burden of *Toxocara* in parks 2) species determination. Soil is obtained and samples are analyzed by modified soil flotation method and standard microscopy. Speciation is achieved by multi-parallel quantitative real-time PCR (qPCR) and a novel DNA extraction method using specific primers to *T. cati* and *cani*. Preliminary results from 80 sites spanning NYC, identify eggs in 34% of sites, with considerable variation between the different boroughs. For example, 55% of samples from the Bronx were positive, compared to 41% in Staten Island, 31% in Queens, 27% in Brooklyn and only 25% of Manhattan samples. 75% of the *Toxocara* in Bronx samples were noted to be in infective stages, compared to none of the other sites tested thus far. qPCR data shows a Spearman value of 0.900 ( $p=0.08$ ), with a trend toward significance identifying *Toxocara cati* as the only contaminating species. This data strongly indicate that (i) *Toxocara* is common in play areas, (ii) prevalence of eggs is likely secondary to feline contamination, and (iii) a substantial health risk exists, particularly in poorer areas. Other parasites were noted during microscopy and qPCR will be used to identify these species using a novel soil-transmitted helminth identification tool for zoonotic infections especially looking to identify *Ancylostoma sp.* and *Baylisascaris* species.

### INVASIVE *POMACEA* SNAILS AS NEW HOST OF *ANGIOSTRONGYLUS ANTONENSIS* IN LAOS, CAMBODIA AND VIETNAM: IMPLICATION FOR OUTBREAKS OF EOSINOPHILIC MENINGITIS

Shan Lu<sup>1</sup>, Yunhai Guo<sup>2</sup>, Hung Manh Nguyen<sup>3</sup>, Muth Sinuon<sup>4</sup>, Somphou Sayasone<sup>5</sup>, Nathan C. Lo<sup>1</sup>, Xiaonong Zhou<sup>2</sup>, Jason Andrews<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States,

<sup>2</sup>National Institute of Parasitic Diseases, China CDC, Shanghai, China,

<sup>3</sup>Institute of Ecology and Biological Resources, Vietnam Academy of Science and Technology, Hanoi, Vietnam, <sup>4</sup>National Centre for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>5</sup>National Institute of Public Health, Vientiane, Lao People's Democratic Republic

Angiostrongyliasis, caused by infection with the rat lungworm, *Angiostrongylus cantonensis*, is a major cause of eosinophilic meningitis in tropical and subtropical regions. While *A. cantonensis* completes its lifecycle between rats and mollusks, humans become incidental hosts through consumption of infected snails. Due to limited diagnostic infrastructure in tropical settings, the geographic distribution of *A. cantonensis* is poorly understood. Although eosinophilic meningitis is commonly reported in Thailand and China, there are fewer reports in the interjacent continent, including Laos, Cambodia and Vietnam. We conducted a multi-country survey to investigate the prevalence *A. cantonensis* infection among freshwater snails in the region. We selected 17 sites along the Mekong river and eastern coast, collected at least 50 snails from each site, and examined them for the presence of *A. cantonensis* by microscopy. We confirmed the species and examined genetic diversity by sequencing the complete cytochrome c oxidase subunit I (*cox1*) gene, and assembling a Bayesian phylogenetic tree incorporating all published *Angiostrongylus cox1* sequences. Among the 17 study site, 15 sites were infested by *Pomacea spp.* snails, a known host for *A. cantonensis*. Among these, we detected *Angiostrongylus* in 7 sites, all in Cambodia and Vietnam. The prevalence in *Pomacea* snails ranged from 1% to 16% between the sites. Further genetic identification confirmed that all specimens were *A. cantonensis* and were closely related genetically. These findings indicate that *A. cantonensis* is widely distributed in Southeast Asia, particularly along the lower Mekong river and the eastern coast of Vietnam. Surveillance studies among snails may represent a powerful tool for risk-mapping of Angiostrongyliasis. This approach could assist targeting of public health campaigns to avert outbreaks of eosinophilic meningitis in this region.

## 642

### RISK FACTORS FOR MIDDLE EAST RESPIRATORY SYNDROME CORONAVIRUS (MERS-COV) SEROPOSITIVITY AMONG ANIMAL MARKET AND SLAUGHTERHOUSE WORKERS IN ABU DHABI, UNITED ARAB EMIRATES (UAE), 2014-2016

Marie E. Killerby<sup>1</sup>, Ahmed Khudhair<sup>2</sup>, Mariam Al Mulla<sup>2</sup>, Kheir Abou Elkheir<sup>2</sup>, Wassim Ternanni<sup>2</sup>, Zyada Bandar<sup>2</sup>, Stefan Weber<sup>3</sup>, Mary Khoury<sup>3</sup>, George Donnelly<sup>3</sup>, Salama Al Muhairi<sup>4</sup>, Abdelmalik Khalafalli<sup>4</sup>, Yassir Eltahir<sup>4</sup>, Nathalie Thornburg<sup>1</sup>, Suvang Trivedi<sup>1</sup>, Azaibi Tamin<sup>1</sup>, John Watson<sup>1</sup>, Susan Gerber<sup>1</sup>, Aron Hall<sup>1</sup>, Farida Al Hosani<sup>2</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Abu Dhabi Health Authority, Abu Dhabi, United Arab Emirates, <sup>3</sup>Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates, <sup>4</sup>Abu Dhabi Food Control Authority, Abu Dhabi, United Arab Emirates

Population seroprevalence of MERS-CoV is low in countries with active MERS-CoV transmission, with higher seroprevalence in workers with regular camel contact. Camel contact has been shown as a risk factor for MERS-CoV infection but exposures associated with MERS-CoV seroprevalence in camel workers are not fully understood. In this study,

seroprevalence was assessed in animal market and slaughterhouse workers, alongside a survey detailing duration, intensity, and types of contact with camels, and other risk factors, e.g. chronic medical conditions. Seroprevalence surveys were performed in 2014, 2015, and 2016, and an epidemiologic survey in 2016. Workers were recruited from two slaughterhouses and one live animal market on a shared site in the Eastern Region of Abu Dhabi Emirate. All facilities worked with sheep, goats, cattle and camels. Human sera were tested for anti-MERS-CoV antibodies using indirect ELISAs for nucleocapsid (N) and spike (S) proteins followed by a confirmatory microneutralization test. Samples were considered positive if either positive on (1) both N and S ELISA, or (2) N or S ELISA and microneutralization. Logistic regression was used to identify factors associated with seropositivity. During 2014-2016, 44/298 (14.8%) workers were seropositive. Seroprevalence was highest in camel salesmen (19/46, 41.3%) and butchers (16/99, 16.2%) relative to other occupations. Of 46 re-tested seronegative workers, two seroconverted. On univariate analysis, handling camels, feeding camels, cleaning camel housing, and contact with ill camels were associated with seropositivity. On multivariate analysis no specific exposures were associated with seropositivity. All significant risk behaviors were performed predominantly by salesmen, the occupation with the highest odds of seropositivity (odds ratio 6.5, confidence interval 1.2-32.9). Workers in this study showed higher seroprevalence than previous studies. Camel salesmen had higher seroprevalence compared to other occupational groups and performed many daily tasks involving direct camel contact. These results are important for communicating infection risk.

## 643

### EMERGING BAT PATHOGENS IN MYANMAR: A ROAD MAP FOR SURVEILLANCE OF POTENTIAL SPILLOVER RELATED TO CAVE UTILIZATION

Heather S. Davies<sup>1</sup>, Megan E. Vodzak<sup>2</sup>, Ohnmar Aung<sup>2</sup>, Kyaw Yan Naing Tun<sup>2</sup>, Marc Valitutto<sup>2</sup>, Suzan Murray<sup>2</sup>, Dawn Zimmerman<sup>2</sup>, Michael E. von Fricken<sup>1</sup>

<sup>1</sup>George Mason University, Department of Global and Community Health, Fairfax, VA, United States, <sup>2</sup>Global Health Program, Smithsonian Biological Conservation Institute, Washington, DC, United States

Cave-dwelling bats are a potentially significant reservoir of emerging viral threats across Southeast Asia. In Myanmar, cave activities like ecotourism and religious shrine visitation increase the likelihood of bat-human interactions, and, thus, the possibility for zoonotic disease exposure. There are seventy-two identified species of cave-dwelling bats present in Myanmar; however, research on the infection status of these bats is limited. This study attempts to delineate potential high-contact zones, based on spatial analysis of bat habitat, cave utilization, and detection of viruses that pose high risk of morbidity and mortality. With tens of thousands of Buddhist sacred sites across Myanmar, tourism to cave shrines is rapidly increasing, as are the number of commercial guide outfitters that advertise cave-tours and exploration, making these sites more accessible. Guano extraction from caves is a source of revenue for small family operations, while large-scale limestone extraction operations also exist. Published and informal data sources regarding human use of caves were compiled, as well as published detections of filo-, corona-, paramyxo-, or lyssa- viruses presented in proximity to Myanmar. Using bat species range data maintained by the International Union for the Conservation of Nature (IUCN), the range extent for each species was refined with sensitivity to elevation suitability, and then used to map the density of species linked to each viral family of import. Spatial analysis indicated regions with dense presence of bat species identified as possible reservoirs with known high-traffic cave locations. These "high contact potential zones" provide a spatial roadmap for future investigations and priority areas for outbreak surveillance.

## 644

### MEAT AND FISH AS A SOURCE OF EXPOSURE TO ANTIBIOTIC-RESISTANT ENTEROBACTERIACEAE IN PHNOM PENH, CAMBODIA

Maya Nadimpalli<sup>1</sup>, Kruey Sun Lay<sup>2</sup>, Yith Vuthy<sup>2</sup>, Malika Gouali<sup>2</sup>, Agathe De Lauzanne<sup>2</sup>, Laurence Borand<sup>2</sup>, Simon Le Hello<sup>1</sup>, Laëtitia Fabre<sup>1</sup>, Bich-tram Huynh<sup>1</sup>, Elisabeth Delarocque-Astagneau<sup>1</sup>

<sup>1</sup>Pasteur Institute, Paris, France, <sup>2</sup>Pasteur Institute of Cambodia, Phnom Penh, Cambodia

Extended spectrum  $\beta$ -lactamase (ESBL) genes encode resistance to penicillins and cephalosporins and can be horizontally transferred among Enterobacteriaceae. More than 60% of healthy humans living in southeast Asia are faecal carriers of ESBL-producing Enterobacteriaceae (ESBL-PE), compared to <10% in Western Europe, suggesting diverse exposure routes. In Cambodia, meat and fish consumption is relatively high, antibiotic use in animal agriculture is unmonitored, and food safety is poorly enforced. We hypothesized that meat and fish could be a reservoir for community exposure to ESBL-PE. From September-November, 2016, we conducted a meat sampling study in Phnom Penh in collaboration with the BIRDY program (<http://www.birdyprogram.org/>), an ongoing study of neonatal health in low-income countries. We evaluated ESBL-PE contamination among pork, fish, and chicken from two markets in the neighbourhood where healthy mothers participating in BIRDY reside. We used logistic regression to evaluate whether stall hygiene, meat storage practices, and reported animal antibiotic use were associated with ESBL-PE contamination of meat and fish. We performed whole genome sequencing on ESBL-PE recovered from meat and fish and from BIRDY mothers who provided faecal swabs less than one year prior. Among 150 pork, fish, and chicken samples, 75% were positive for ESBL-PE. Pork was most commonly contaminated ( $p < 0.01$ ). ESBL-PE from 8/150 samples demonstrated *mcr-1*-mediated colistin resistance, and *E. coli* from 2/150 samples were carbapenem-resistant. Pork and chicken fed medicine even when healthy versus those not were 2.8 times as likely (95% CI: 1.1, 7.3) to be contaminated with multidrug-resistant ESBL-PE. ESBLs belonging to the CTX-M-3 group (e.g. CTX-M-3, M-15, M-55) predominated across all hosts. Genomic comparisons between ESBL-PE from meat and humans are ongoing. A high proportion of meat and fish in Phnom Penh are contaminated with ESBL-PE, and similar ESBL-types can be detected among healthy humans. This work highlights the need for improved regulation of food-animal farming in Southeast Asia in order to protect public health.

## 645

### USING GPS TRACKERS TO EXPLORE FINE-SCALE HUMAN AND LIVESTOCK MOVEMENT IN BUSIA COUNTY, KENYA AND ITS IMPLICATIONS FOR ZOOSES

Jessica R. Floyd<sup>1</sup>, Nick W. Ruktanonchai<sup>1</sup>, Nicola Wardrop<sup>1</sup>, Andrew J. Tatem<sup>1</sup>, Eric M. Fèvre<sup>2</sup>

<sup>1</sup>WorldPop Project, University of Southampton, Southampton, United Kingdom, <sup>2</sup>Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom

Human and livestock mobility are key factors in the transmission of several high-burden zoonoses, yet our knowledge of them is relatively poor due to difficulty in quantifying population-level movement patterns. Significant variation in the movement patterns of individual hosts means it is necessary to capture their fine-scale mobility in order to gain useful knowledge at a population level. Here we explore how the movements of people and their livestock and their trips to various types of land cover correlate with livestock ownership, which could affect individual exposure to zoonoses. The study was conducted in Busia County, western Kenya, where the population are mostly subsistence farmers operating a mixed crop/livestock farming system. GPS trackers were fitted to one human and one cattle or other ruminant from each of the 27 households in the

study for a duration of one week. Households without livestock were also included for comparison. A total of 47 human and livestock individuals were tracked in July/August 2016, and the study was repeated at the end of the same year to compare movement patterns across these seasons. Although lengths of trips taken outside the household did not vary significantly by the type of livestock kept or by season, the maximum distance travelled did. We explored the association between the numbers and types of livestock kept, the relative wealth of the households, and the time spent by the people and livestock living there in different types of land cover. Significant differences were found in the amount of time people and livestock spent in swampy and woodland areas, with those keeping more livestock tending to spend more time in these areas. Finally, we looked at the home ranges of people and their livestock and found that people from less wealthy households had significantly larger home ranges. These results indicate that some individual-level mobility may be predicted by household characteristics such as livestock ownership and household wealth, which could have practical uses for assessing individual risk of exposure to some zoonoses and for future modelling studies of zoonosis transmission in similar rural areas.

## 646

### GENE EDITING OF OMEGA-1 OF SCHISTOSOMA MANSONI BY CRISPR-CAS MODIFIES DENDRITIC CELL INFLAMMATORY RESPONSE

Wannaporn Ittiprasert<sup>1</sup>, Victoria H. Mann<sup>1</sup>, Shannon E. Karinshak<sup>1</sup>, Apisit Chaidee<sup>2</sup>, Christina J. Cochran<sup>1</sup>, Paul J. Brindley<sup>1</sup>

<sup>1</sup>The George Washington University, Washington, DC, United States,

<sup>2</sup>The George Washington University, and Khon Kaen University, Thailand, Washington, DC, United States

A key goal of functional genomics for parasitic helminths involves lentiviral based gene editing in schistosomes; delivery by lentivirus can be expected to provide a 'hands-free' approach to enable scaling of gene editing and increase accessibility to less accessible cells. The egg stage of the blood fluke *Schistosoma mansoni* plays central roles in pathogenesis and in disease transmission. The T2 ribonuclease *omega-1* is a powerful Th2-inducing glycoprotein secreted by the eggs of this schistosome. We investigated knockout and tagging of the *omega-1* gene; this gene was targeted both as a representative, model schistosome gene to establish facile gene editing but also because of the pivotal role of this antigen in immunopathogenesis. Approaches including delivery of the editing components, including guide RNA and Cas9 nuclease by electroporation and as delivered by pseudotyped lentiviral virions were investigated, with the latter providing more efficient performance. Furthermore, the target locus was further modified by knocking-in (KI) a six-stop codon tag by providing *in trans* single-stranded oligodeoxynucleotide DNA (ssODN) bearing micro-homology arms to mediate homology directed repair following Cas9 double stranded cleavage at *omega-1* ( $\omega-1$ ). Efficiency of the latter approach targeted at cultured eggs was >11%, while from 45 to 83% reduction in specific transcript levels were seen within 48 hours of treatment. When dendritic cells (JAWSII) were pulsed with soluble egg antigen from gene-edited (KI) eggs or wild type soluble egg antigen, marked differences in expression of anti-inflammatory cytokines were apparent, including marked upregulation of DC-SIGN and IL-10. These findings revealed not only that Crispr-Cas9 based gene editing including donor directed homology directed repair was functional in schistosomes, and that gene editing will facilitate deeper investigation of the physiology and pathogenesis of these major neglected tropical disease pathogens including the function of the ribonuclease *omega-1*. 1

## 647

### DETERMINING THE MECHANISM OF ENDOSYMBIOSIS BETWEEN FILARIAL NEMATODES AND WOLBACHIA

Alexandra Grote<sup>1</sup>, Denis Voronin<sup>2</sup>, Swapna Sheshadri<sup>3</sup>, Dave Curran<sup>3</sup>, Sara Lustigman<sup>2</sup>, John Parkinson<sup>3</sup>, Elodie Ghedin<sup>1</sup>

<sup>1</sup>New York University, New York, NY, United States, <sup>2</sup>New York Blood Center, New York, NY, United States, <sup>3</sup>University of Toronto, Toronto, ON, Canada

Filarial nematodes represent one of the leading causes of disability in the developing world. Many filarial worm species, including *Brugia malayi*, one of the causative agents of lymphatic filariasis, have an obligate endosymbiotic relationship with the alpha-proteobacteria *Wolbachia*. To better understand the molecular interplay between these two organisms, we profiled the transcriptomes of *B. malayi* and *Wolbachia* across the life cycle of the parasite using dual RNA-seq. With these data, we built a co-expression network for the two organisms using weighted gene correlation network analysis (WGCNA). WGCNA is a well-established method by which expression data and trait data are integrated to identify co-expressed pathways. This allowed us to pinpoint functional pathways involved in this essential symbiotic relationship provided by the co-expression of nematode and bacterial genes. Using new transcriptional data from both the bacteria and worm, we have identified co-expressed pathways required for molting of the worm from L3 to L4. This molt is of particular importance as it marks the establishment of infection in the human host and is characterized by a 1000X expansion in *Wolbachia* population over the course of the molt. We found *Wolbachia* genes involved in heme, riboflavin, and purine/pyrimidine biosynthesis to be significantly upregulated during molting. These pathways are of interest as they are present in the *Wolbachia* genome but incomplete in the *B. malayi* genome. We also found genes involved in DNA replication, cellular respiration, chaperone function, and cell wall synthesis to be differentially expressed during molting. In parallel efforts, we are using these data to characterize the endosymbiotic relationship at the metabolic level using Flux Balance Analysis, identifying choke points that could be exploited for therapy. By creating a draft metabolic network for *B. malayi* and *Wolbachia*, and using *in silico* knockouts, we will determine the necessary pathways for growth and virulence and how these pathways are influenced by the presence of *Wolbachia*.

## 648

### GLOBAL TRANSCRIPTOME ANALYSIS OF WOLBACHIA STRAIN WOO UNDER ANTIBIOTIC PRESSURE IN VIVO

Germanus S. Bah<sup>1</sup>, Dong Xia<sup>2</sup>, Ritesh Krishna<sup>2</sup>, Vincent N. Tanya<sup>3</sup>, Alistair C. Darby<sup>2</sup>, Ben Makepeace<sup>2</sup>

<sup>1</sup>Institut de Recherche Agricole pour le Développement, Ngaoundéré,

Cameroon, <sup>2</sup>University of Liverpool, Liverpool, United Kingdom,

<sup>3</sup>Cameroon Academy of Sciences, Yaoundé, Cameroon

The potential use of antibiotics targeting the bacterial endosymbiont, *Wolbachia*, as macrofilaricidal drugs remains a major focus of research in the filarial field. In a previous *in vitro* study using *Wolbachia* strain wMelPop in a mosquito cell line, we reported global changes in symbiont RNA and protein expression following a brief exposure to doxycycline. We showed that *Wolbachia* is capable of regulating expression of transporters, energy metabolism and outer membrane proteins during doxycycline treatment and these changes may contribute to antibiotic tolerance. Here, we extend our analysis to *Wolbachia* strain wOo from *Onchocerca ochengi* during oxytetracycline treatment of cattle. In this system, a short intensive oxytetracycline regimen (SIR) leads to a transient depletion of *Wolbachia* followed by symbiont recrudescence and survival of the nematode host; whereas prolonged intermittent therapy (PIR) suppresses *Wolbachia* densities long-term, resulting in death of most adult worms. During these treatments, bovine intradermal nodules containing *O. ochengi* were removed sequentially, and total RNA was subjected to RNA-Seq. Reads were mapped to the bovine, *O. ochengi*, and wOo genomes

and significant differential expression of wOo genes with a fold-change  $\geq 2$  ( $P \leq 0.01$ ) was calculated. We compared gene expression at the critical time-point of 8 weeks post-treatment, when *Wolbachia* density reaches a minimum in both treatment groups, but symbionts in the SIR group are capable of recrudescence. At this stage, stationary-phase morphogene *boIA*, involved in adaptation to stress and changes in cell morphology, was upregulated in the SIR group relative to the PIR group. Surprisingly, one year after SIR treatment had terminated, >30 genes remained downregulated in wOo from treated animals relative to untreated controls, including several membrane protein genes and other transcripts involved in translation and secretion. These findings highlight the adaptability of *Wolbachia* during antibiotic stress and may help to explain why the identification of short, effective antibiotic regimens for filarial infections has posed special challenges.

## 649

### **SCHISTOSOMA HAEMATOBIIUM IPSE INDUCES CELLULAR PROLIFERATION, CELL CYCLE ALTERATIONS, ANGIOGENESIS, AND TRANSCRIPTIONAL PROFILES CONSISTENT WITH PRO-CARCINOGENIC EFFECTS**

Evaristus Mbanefo<sup>1</sup>, Irina V. Saltykova<sup>2</sup>, Luke Pennington<sup>3</sup>, Theodore Jardetzky<sup>3</sup>, Burcu Ayoglu<sup>3</sup>, P. J. Utz<sup>3</sup>, Abdulaziz Alouffi<sup>4</sup>, Franco H. Falcone<sup>4</sup>, Paul J. Brindley<sup>2</sup>, **Michael Hsieh**<sup>1</sup>

<sup>1</sup>Biomedical Research Institute, Rockville, MD, United States, <sup>2</sup>Department of Microbiology, Immunology and Tropical Medicine, and Research Center for Neglected Diseases of Poverty, George Washington University, Washington, DC, United States, <sup>3</sup>Stanford University, Stanford, CA, United States, <sup>4</sup>School of Pharmacy, Division of Molecular Therapeutics and Formulation, University of Nottingham, Nottingham, United Kingdom

*Schistosoma haematobium* infection, also known as urogenital schistosomiasis (UGS), affects over 112 million people globally. *S. haematobium* worms live in host pelvic veins and deposit eggs in the bladder [FF1]. The eggs secrete antigens that induce granuloma formation, in turn provoking urothelial hyperplasia and carcinogenesis. The IL-4-inducing principle of *Schistosoma mansoni* eggs (IPSE) is an abundant antigen released by schistosome eggs. IPSE binds immunoglobulins and chemokines, translocates into host cell nuclei and modulates gene transcription, and induces basophils and mast cells to release IL-4, thereby orchestrating a dominant Th2 response. Given that IPSE genes are only found in *Schistosoma*, their protein products may be pro-carcinogenic factors in schistosomal bladder cancer. We hypothesize that the *S. haematobium* homolog of IPSE (H-IPSE) plays a role in driving urothelial proliferation and bladder carcinogenesis in UGS. After cloning H-IPSE through RACE PCR and expressing it in recombinant form using a mammalian expression system, H-IPSE proteins were co-cultured with urothelial bladder cell lines derived from primary and transformed tissues, representing diverse species of origin and stages of carcinogenesis: HTB-9 (Grade II human bladder carcinoma), HCV-29 (normal human bladder urothelium) and MB49 (mouse urothelial carcinoma). Readouts included CFSE proliferation assays, cell cycle analysis, xCELLigence real-time monitoring of cell proliferation, and RNA-Seq. H-IPSE protein was also screened for its ability to bind cytokines and nuclear proteins in a 288-plex array. Across assays, H-IPSE induced proliferation of HCV-29 and MB49, but not HTB-9 cells. H-IPSE also altered cell cycle status of both HCV-29 and MB49 cells. Data also suggest that H-IPSE promotes angiogenesis, and alters transcription of many genes potentially relevant to carcinogenesis. H-IPSE bound multiple cytokines and nuclear proteins previously implicated in oncogenesis. These findings indicate that H-IPSE might contribute to bladder carcinogenesis in the context of UGS. Ongoing work aims to define the associated mechanisms.

## 650

### **INFILTRINS AS A NEW CLASS OF PATHOGEN-SECRETED, HOST NUCLEUS INFILTRATING PROTEINS IN TREMATODES**

Abdulaziz Alouffi<sup>1</sup>, Luke F. Pennington<sup>2</sup>, Nigel Mongan<sup>1</sup>, Robin J. Flynn<sup>3</sup>, David M. Heery<sup>1</sup>, Ted Jardetzky<sup>2</sup>, Evaristus C. Mbanefo<sup>4</sup>, Michael H. Hsieh<sup>4</sup>, **Franco H. Falcone**<sup>1</sup>

<sup>1</sup>University of Nottingham, Nottingham, United Kingdom, <sup>2</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>3</sup>University of Liverpool, Liverpool, United Kingdom, <sup>4</sup>Biomedical Research Institute, Rockville, MD, United States

Infiltrins (short for pathogen-secreted host nucleus infiltrating proteins) are proteins secreted by specific stages of trematode parasites, which are in close contact with host tissues. Such infiltrins have the ability to enter host cells by yet to be described mechanisms, and from there rapidly translocate to the nucleus. The archetypal infiltrin is M-IPSE (a.k.a. IPSE/alpha-1), a glycoprotein secreted by *Schistosoma mansoni* eggs, characterised by the simultaneous presence of a classical secretory and a nuclear localisation signal (CSS/NLS) signal. Within minutes following uptake by mammalian host cells, M-IPSE translocates to the nucleus and binds to DNA. This suggests that infiltrins, by acting e.g. as transcription factors, might play a central role in controlling the host-parasite relationship at the molecular level. Together with their secretory status, this role makes infiltrins interesting targets for vaccination. Here, we demonstrate similar properties for H-IPSE, the homologue of M-IPSE in *Schistosoma haematobium*. We first generated a series of truncated constructs fused with AcGFP1, which were transfected into mammalian cells. Nuclear localisation of fluorescence confirmed the existence of a single, monopartite NLS located near the C-term of H-IPSE. The predicted H-IPSE 'SKRRRKY' NLS motif, inserted into Tetra-EGFP, but not an Alanine NLS mutant, redirected the encoded approx. 100 kDa protein entirely to the nucleus. More importantly, wildtype recombinant H-IPSE, added exogenously to HTB-9 bladder carcinoma cells, fully translocated to the nucleus, whereas the Alanine NLS mutant remained in the cytoplasm. Similarly, *Fasciola hepatica* proteins H2A and GST-sigma were able to enter Huh7 hepatocarcinoma cells and translocate to the nucleus. We have scanned the *F. hepatica* genome with a stringent approach designed to detect genes encoding dual CSS/NLS functionality and identified several other potential infiltrins. Overall, the existence of infiltrins in *S. mansoni*, *S. haematobium* and *F. hepatica* suggests that these proteins may represent a more general regulatory principle operating in parasitic trematodes.

## 651

### **IDENTIFICATION OF ANTHELMINTIC DRUGS BY HIGH THROUGHPUT SCREENING OF A SCHISTOSOME SEROTONIN RECEPTOR**

**John D. Chan**, Jonathan S. Marchant

University of Minnesota, Minneapolis, MN, United States

The need to discover new anti-schistosomal targets and lead compounds is driven by the fact that the current frontline drug, praziquantel, does not kill all stages of parasite infection and there are no broad spectrum schistocidal alternatives. Serotonergic G-protein coupled receptors (GpCRs) are attractive drug targets given that serotonin (5-HT) controls schistosome neuromuscular function. While GpCRs are privileged targets, accounting for >1/3rd of all approved drugs, target based screens have been slowed by the fact that no flatworm G-protein coupled receptor has been functionally expressed in a high throughput assay. Here, we have screened a 5-HT receptor cloned from the predominant *Schistosoma* species responsible for human infection (*S. mansoni*, *S. japonicum*, *S. haematobium*) - advancing hits identified *in vitro* against recombinantly expressed receptors to validation against parasites cultured *ex vivo* and finally *in vivo* animal infections. Libraries of natural products were screened against *Schistosoma* 5-HT receptors stably expressed alongside a cAMP reporter in HEK293 cells. Hit compounds clustered into groups containing either tryptamine or benzyloisoquinoline ring systems, and structure-

activity profiling of these pharmacophores identified potent agonists ( $EC_{50} < 100\text{nM}$ ) and antagonists ( $K_i < 100\text{nM}$ ) active against receptors from all three species. 5-HT receptor agonists stimulated movement in cultured adult schistosomes, with some compounds demonstrating ~1000x higher potency than serotonin. Similarly, 5-HT receptor antagonists blocked parasite movement. Drugs prioritized from *in vitro* screens proved effective *in vivo*. Injection of compounds into infected mice resulted in a rapid shift of parasites from the mesenteries to the liver, and a 65% reduction in worm burden when dosed over one week. Oogram analysis revealed a 97% reduction in schistosome egg burden- a crucial outcome given that schistosomiasis pathology is driven by the immune response to parasite eggs. These data provide the first high throughput screen of a schistosome GPCR and validate serotonergic signaling as an anti-schistosomal target.

## 652

### MINIMIZING THE COST OF CONGENITAL CHAGAS DISEASE IN THE UNITED STATES THROUGH MATERNAL SCREENING

Eileen Stillwaggon<sup>1</sup>, Victoria Perez-Zetune<sup>2</sup>, Larry Sawers<sup>3</sup>

<sup>1</sup>Gettysburg College, Gettysburg, PA, United States, <sup>2</sup>Federal Reserve Board, Washington, DC, United States, <sup>3</sup>American University, Washington, DC, United States

Chagas disease, caused by *Trypanosoma cruzi*, is transmitted by insect vectors, as well as through blood transfusion, organ transplant, consumption of insect feces in food and water, and from mother to child during gestation. Programs of vector control and screening of blood products and transplant organs have been successful in reducing transmission. Congenital infection, however, could perpetuate Chagas indefinitely, even in countries with no or almost no autochthonous vector transmission. Even mothers who themselves have been infected congenitally and who are not symptomatic can transmit to their babies. About 30% of infected persons will develop lifelong cardiac or digestive complications that can be fatal. Treatment of infants with benznidazole has close to 100% cure rate, and efficacy in adults is estimated between 40% and 70%. This is the first study of the costs of screening and treatment for Chagas in the United States. We constructed a decision-analytic model to find the cost-minimizing option, comparing the costs of testing and treatment, as indicated, for mothers and infants with the lifetime societal costs of no testing and consequent morbidity and mortality due to lack of treatment or late treatment. We find that a protocol of screening and treatment is cost-minimizing for all rates of congenital transmission, even as low as 0.1%, and all levels of maternal prevalence, as low as 0.1%. Lifetime societal savings due to screening and treatment are more than \$1,300 per birth to Hispanic women from endemic areas. There are more than 480,000 births to Hispanic women from endemic areas in the United States per year, resulting in a saving of more than \$600 million in lifetime savings per birth-year cohort. Educating obstetricians to offer prenatal or cord blood serologic screening to Hispanic mothers makes it possible to treat mothers, infants, siblings, and other family members at risk of serious Chagas morbidity.

## 653

### RISK FACTORS FOR ACUTE MESOAMERICAN NEPHROPATHY IN NICARAGUAN SUGAR WORKERS

Rebecca S. Fischer<sup>1</sup>, Kaila A. Fagerstrom<sup>1</sup>, Denis Chavarria<sup>2</sup>, Sreedhar Mandayam<sup>1</sup>, Melissa N. Garcia<sup>1</sup>, Linda L. Garcia<sup>1</sup>, Ruth Montenegro<sup>2</sup>, Kristy O. Murray<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Gerencia de Salud Ocupacional, Nicaragua Sugar Estates Limited, Chichigalpa, Nicaragua

An epidemic of kidney disease of unknown etiology is unrelenting among primarily young agricultural workers in Central America. Patients with Mesoamerican nephropathy (MeN) lack traditional risk factors for kidney disease. Until recently, MeN was defined only as a chronic kidney disease (CKD), but we recently documented acute kidney injury (AKI) associated

with MeN. In order to shed light on the most likely etiology and gain a better understanding of factors contributing to acute MeN, we conducted a prospective study at a large sugar estate in Nicaragua, an area heavily affected by MeN. Physicians conducted case surveillance in patients presenting for care, and controls were recruited during health screening visits. Using structured interviews, we documented demographic, medical, occupational and behavioral data. In this univariate case-control analysis, we compare data from workers with acute MeN to that from healthy control workers in order to determine occupational risk factors for acute MeN. Interview data was available on 225 cases and 167 controls, mostly male (90%). Cases were older than controls (median 31 yrs vs 28 yrs;  $p=0.025$ ) and more likely to live in the village adjacent to the sugar fields ( $p=0.012$ ). Case patients were more likely to work in direct contact with the sugar fields ( $p<0.001$ ) but not with water, compared to controls. We also found that controls more often wore protective gear on the job: gloves ( $p<0.001$ ); glasses ( $p<0.001$ ); mouth cover ( $p=0.001$ ); nose cover ( $p=0.041$ ); and boots ( $p<0.001$ ). Cases were more likely to drink well water ( $p=0.002$ ) and less likely to drink from fountains ( $p=0.001$ ). Controls had a higher frequency of handwashing before eating lunch on the job ( $p=0.010$ ). Interestingly, cases reported having a family member with MeN ( $p<0.001$ ) more frequently than controls did. This is the first analysis to explore work-related risk factors of acute MeN. These data suggest an environmental source of MeN to which workers are exposed. Our ongoing analysis and predictive modeling will further elucidate which exposures are the most important and may inform where preventive measures could be used to prevent disease.

## 654

### BARRIERS TO PEDIATRIC INPATIENT CARE GUIDELINE ADHERENCE: A MIXED METHOD ASSESSMENT OF EIGHT HOSPITALS IN ASIA AND AFRICA

Kirkby D. Tickell<sup>1</sup>, Dorothy I. Mangale<sup>1</sup>, Stephanie N. Tornberg-Belanger<sup>1</sup>, Johnstone Thitiri<sup>2</sup>, Molly Timbwa<sup>3</sup>, Jenala Njiramadzi<sup>4</sup>, Md. Jobayer Chisti<sup>5</sup>, Tahmeed Ahmed<sup>5</sup>, Md. Al Fazal Khan<sup>6</sup>, Ali F. Saleem<sup>7</sup>, Zaubina Kazi<sup>7</sup>, Ezekiel Mupere<sup>8</sup>, John Mukisa<sup>8</sup>, Priya Sukhtankar<sup>9</sup>, James A. Berkley<sup>9</sup>, Judd L. Walson<sup>1</sup>, Donna M. Denno<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, <sup>3</sup>KEMRI-Wellcome Trust Research Programme, Nairobi, Kenya, <sup>4</sup>Queen Elizabeth Central Hospital, Blantyre, Malawi, <sup>5</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>6</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Matlab, Bangladesh, <sup>7</sup>Aga Khan University, Karachi, Pakistan, <sup>8</sup>Makerere University, Kampala, Uganda, <sup>9</sup>University of Oxford, Oxford, United Kingdom

Difficulty adhering to evidence-based guidelines is an important driver of inpatient child mortality. A mixed method assessment was conducted in eight district or national referral hospitals in Bangladesh (2), Kenya (3), Malawi (1), Pakistan (1) and Uganda (1) between July and November 2016. Key informants (administrators, clinicians, nurses, nutritionists, pharmacists) were interviewed and essential hospital infrastructure, equipment and medicines was assessed by direct observation. The clinical notes of 240 children aged 2-23 months were reviewed and indicators of adherence to guidelines for common pediatric conditions, including severe acute malnutrition (SAM), pneumonia, diarrhea, and anemia were abstracted. All facilities had local guidelines adapted from WHO recommendations. Staffing levels varied between 2.4-16.1 nurses, 0.0-11.9 nursing assistants and 2.6-12.4 clinicians per 1000 pediatric admissions. Equipment, medicines and infrastructure were generally adequate for guideline implementation, but the notes review demonstrated variable adherence. Prescribed antibiotics corresponded with recommended regimens for 79% (n: 174) of cases with a documented antimicrobial indication. Universal malnutrition screening was not implemented in four sites. Recommended SAM feeding volumes were followed in 83% (n: 72) of cases but relactation was not offered at four sites. Pulse oximetry was noted in 80% (n: 88) of pneumonia cases and

oxygen therapy was documented for 74% (n: 19) of hypoxemic children. Hemoglobin results were recorded in 70% of reviewed notes, but only 14% (n: 63) with mild or moderate anemia had documented diagnoses of anemia. Key informants reported inadequate human resources, frequent rotation of junior clinicians and difficulty providing senior supervision as key barriers to guideline adherence. Adherence to guidelines remains a challenge across a range of childhood conditions even when access to recommendations and the materials necessary for implementation are in good supply. Facility staff perceive inadequate human resources as the primary constraint to consistent guideline adherence.

## 655

### THE PREVALENCE AND DETERMINANTS OF DISCLOSURE OF SEXUAL PRACTICES TO OTHER FAMILY MEMBERS AMONG MEN WHO HAVE SEX WITH MEN IN LOME AND KARA, TOGO

**Horacio Ruiseñor-Escudero**<sup>1</sup>, Carrie Lyons<sup>2</sup>, Sosthenes Ketende<sup>2</sup>, Vincent Pitchen<sup>3</sup>, Simplicie Anato<sup>4</sup>, Jules Tshala<sup>5</sup>, Dometo Sodji<sup>6</sup>, Stefan Baral<sup>2</sup>

<sup>1</sup>Michigan State University, East Lansing, MI, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Conseil National de Lutte contre le SIDA, Lome, Togo, <sup>4</sup>Arc en Ciel, Lome, Togo, <sup>5</sup>Espoir Vie, Lome, Togo, <sup>6</sup>FAMME, Lome, Togo

Supporting HIV prevention and treatment among people at risk/living with HIV necessitates understanding their specific HIV acquisition/transmission risk. Disclosure of sexual practices facilitates improved service provision. However, in settings of higher HIV prevalence, disclosure of sexual practices may lead to stigma and discrimination. This study aims to characterize the prevalence and determinants of disclosure of sexual practices to a family member (DFM) among MSM in 2 cities in Togo. 683 MSM ≥18 years of age were recruited using respondent driven sampling for a cross-sectional survey (354/683 in Lomé and 329/683 in Kara). Participants completed a structured questionnaire and biological testing for HIV and syphilis. Statistical analyses included t-test, RDS-weighted (RDS-w) proportions, bootstrapped confidence intervals and logistic regression models. Overall median age was 23.9 years. Most participants reported a weekly income of 2001-12,000 CFA (RDS-w Lomé= 46.5% vs. Kara=48.7%,  $p<0.01$ ), and reported their sexual identity as gay/homosexual (RDS-w Lomé=61.2% vs. Kara: 62.6%,  $p=0.59$ ). In total, 62/683 (9.1%) MSM were living with HIV (RDS-w Lomé=10.4% vs. Kara: 0.2%,  $p<0.01$ ). Difficulties accessing health services and blackmail as a result of having sex with men were reported by less than 20% of participants. Overall, 26.8% (183/683) participants had DFM, 24.0% (85/354) in Lomé and 29.8% (98/329) in Kara. MSM living in Kara (aOR=2.05, 95% CI=1.35, 3.14) showed an increased odds of DFM compared to MSM living in Lomé. DFM was associated with income level (aOR=1.68, 95% CI=1.11, 2.56), gender (aOR=2.16, 95% CI=1.12, 4.16), living with HIV (aOR=2.03, 95% CI=1.08, 3.81). MSM who have DFM demonstrated increased odds of experiencing difficulties accessing health services (aOR=1.93, 95% CI=1.15, 3.24) and increased odds of blackmail (aOR=2.43, 95% CI=1.45, 4.07). These results highlight the individual, social, and community level determinants of DFM among MSM in Togo. Moving forward necessitates studying the temporality of disclosure in relation to other factors in order to better inform HIV treatment and prevention programs.

## 656

### SEASONAL FOOD INSECURITY IN HAYDOM, TANZANIA IS ASSOCIATED WITH LOW BIRTH WEIGHT AND ACUTE MALNUTRITION: RESULTS FROM THE MAL-ED STUDY

**Elizabeth T. Rogawski**<sup>1</sup>, Stephen Clark<sup>1</sup>, Crystal Patil<sup>2</sup>, Jean Gratz<sup>1</sup>, Eric R. Houpt<sup>1</sup>, Erling Svensen<sup>3</sup>, Esto Mduma<sup>4</sup>, James A. Platts-Mills<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>University of Illinois Chicago College of Nursing, Chicago, IL, United States, <sup>3</sup>Haukeland University Hospital, Bergen, Norway, <sup>4</sup>Haydom Lutheran Hospital, Haydom, United Republic of Tanzania

In rural agricultural communities, the pre-harvest “hunger” season is a particularly vulnerable period that may cause increased food insecurity and have lasting impact on child growth. We assessed seasonal patterns of food insecurity and related health outcomes among children in the MAL-ED birth cohort study at the rural Haydom, Tanzania site. Children were followed twice-weekly to document food intake and monthly for anthropometry until two years of age. Household food insecurity was reported by caregivers every 6 months. We modelled the seasonality of food insecurity, intake of foods, birth weight, and acute malnutrition to estimate the impact of the high food insecurity season on these outcomes. We assessed severe outcomes from pediatric admissions with acute malnutrition at Haydom Lutheran Hospital in 2010-2015. Of 262 enrolled children, 158 (60.3%) of their caregivers reported food insecurity at least once. Food insecurity was highly seasonal with peak insecurity from December to February. Children born during these 3 months had an average 0.35 z-score (95% CI: 0.12, 0.58) lower enrollment weight (within 17 days of birth) compared to children born in other months. In addition, weight-for-length z-scores measured in these months were on average 0.15 z-scores lower (95% CI: 0.10, 0.20) compared to other months, adjusting for enrollment weight, and this disparity was sustained up to two years of age. These associations corresponded to the seasonal availability of foods. Consumption of animal milk was 9% lower (95% CI: 5, 12) and consumption of root vegetables was 77% lower (95% CI 71, 81) during the high food insecurity months. Correspondingly, the number of admissions with acute malnutrition at the local hospital was highest at this time, with twice as many cases in December-February compared to July-September. We identified seasonal trends of malnutrition in Haydom, Tanzania that correspond to both caregiver reports of food insecurity and child food intake. Targeting of prenatal care and child feeding interventions during high food insecurity months would likely have the greatest impact on reducing child malnutrition in this community.

## 657

### MOVING BEYOND PRIMARY HEALTH BENEFITS: EVALUATING THE IMPACT OF DRAINAGE INFRASTRUCTURE IMPROVEMENT PROJECT ON BUSINESSES AND TRAFFIC FLOW IN LUSAKA, ZAMBIA

**Manjunath B. Shankar**<sup>1</sup>, Bishwa B. Adhikari<sup>1</sup>, Sydney C. Hubbard<sup>1</sup>, Warren Malambo<sup>2</sup>, Sunkyoung Kim<sup>1</sup>, Joan M. Brunkard<sup>1</sup>, Martin I. Meltzer<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Lusaka, Zambia

Impact evaluations of health intervention projects often fail to consider secondary potential benefits, possibly undervaluing the true value of the intervention. The Government of Zambia is upgrading drainage infrastructure in Lusaka, with one goal to reduce the impact of infectious diseases associated with seasonal flooding. To assess additional benefits, we collected, as part of a comprehensive evaluation of the drainage improvement project, baseline measurements of potential impact on households, businesses and traffic flow. We conducted business and traffic studies to evaluate the impact of flooding on travel time and business operations. We surveyed 587 randomly selected businesses located in a

main market within the drainage catchment area. The survey collected information on business closings and operations, property damage, revenue generation, and commute time of workers during rainy season. We conducted traffic and pedestrian flow assessments by counting the number of vehicles and pedestrians in 15-minute time intervals at major intersections located in close proximity to the drain and measured round trip travel times along 11 routes passing through the intersections. Eighty-one percent of businesses experienced flooding in the 2015-16 rainy season; 28% of businesses reported shutting down their shops due to flooding for one to two days in the rainy season. Number of goods-containing vehicles being loaded or unloaded in the business area was significantly lower during flooding ( $p < 0.01$ ) and about 50% of businesses reported that flooding also affected punctuality at work; 30% of workers were late to work for an average of 62 minutes. Property damage was reported by 147 businesses and the average value of damage was \$567 (SD: \$139) per business. Mean (SD) business revenues decreased by \$600 (\$1,058) per business due to floods. The number of vehicles passing through intersections increased by 3.6% due to rain or floods. On average, it took 1.66 minutes (3%) longer per round trip during flooding. Business and traffic components are essential components of the financial rationale for this public health intervention.

## 658

### REDUCTION IN CASE FATALITY RATE DUE TO ACUTE ENCEPHALITIS SYNDROME THROUGH INTEGRATED APPROACHES

**Akshay C. Dhariwal<sup>1</sup>**, Rajiv Tandon<sup>2</sup>, Shalini Khare<sup>2</sup>, Padmalochan Biswal<sup>2</sup>, Bhupendra Tripathi<sup>3</sup>, Soumya Swaminathan<sup>4</sup>

<sup>1</sup>National Vector Borne Diseases Control Programme (NVBDCP) of Ministry of Health, Government of India, New Delhi, India, <sup>2</sup>PATH, New Delhi, India, <sup>3</sup>Bill & Melinda Gates Foundation, New Delhi, India, <sup>4</sup>Indian Council of Medical Research, Government of India, New Delhi, India

Acute encephalitis syndrome (AES) is a major public health problem in India. It is estimated that approximately 375 million people are at risk of developing AES in India, with an incidence rate of 0.46 per 100,000 population. Following a massive outbreak of Japanese encephalitis (JE) in 2005, claiming 1600 lives, the government of India introduced JE vaccination for the age group of 1-15 years in the endemic districts which resulted in significant reduction of JE positivity. Considering the complex etiology of AES, in 2012 the government of India initiated a policy around integrated approach for prevention and control of AES/JE which involved interventions on improving water, sanitation, social justice and empowerment, animal husbandry, rural development, housing and poverty alleviation and education. However, the two most populous states, Uttar Pradesh (UP) and Bihar continue to grapple with AES outbreaks due to unknown etiologies. To address this problem, PATH initiated a project in Bihar and UP to support the governments in AES prevention and control. New sustainable initiatives were introduced which included upgradation of the primary and secondary health facilities to function as Encephalitis Treatment Centers (ETCs). By 2016, 49.5% AES cases were treated at the ETCs with a case fatality rate of 6%; Over 60,000 health personnel were trained on management of AES cases; 2092 AES cases were followed up from onset of symptoms to referral, management, rehabilitation and epidemiological information. For the first time, 19 etiologies of AES were identified. Mass awareness campaigns were conducted through wherein 16.4 million people were sensitized. Over 175,000 people were sensitized through village level community awareness; standardized/innovative tools were introduced for data management; a technical advisory group on AES was introduced at the national and state levels; based on the recommendations, government of UP has decided to pilot evidence based integrated control measures in high risk villages by leveraging on government-funded schemes to improve health, water, sanitation and environmental contributors to combat AES.

## 659

### USING G6PD TESTS TO ENABLE THE SAFE TREATMENT OF *PLASMODIUM VIVAX* INFECTIONS WITH PRIMAQUINE ON THE THAILAND-MYANMAR BORDER: A COST-EFFECTIVENESS ANALYSIS

**Angela Devine<sup>1</sup>**, Minnie Parmiter<sup>2</sup>, Cindy S. Chu<sup>3</sup>, Germana Bancone<sup>3</sup>, François Nosten<sup>1</sup>, Ric Price<sup>4</sup>, Yoel Lubell<sup>1</sup>, Shunmay Yeung<sup>5</sup>

<sup>1</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>Boyd Orr Centre, University of Glasgow, Glasgow, United Kingdom, <sup>3</sup>Shoklo Malaria Research Unit, Mae Sot, Thailand, <sup>4</sup>Global and Tropical Health Division, Menzies School of Health Research and Charles Darwin University, Darwin, Australia, <sup>5</sup>Mahidol Faculty of Infectious and Tropical Disease, The London School of Hygiene & Tropical Medicine-Oxford Tropical Medicine Research Unit, London, United Kingdom

Primaquine is the only licensed antimalarial for the radical cure of *Plasmodium vivax* infections. Many countries, however, do not administer primaquine due to fear of hemolysis in those with glucose-6-phosphate dehydrogenase (G6PD) deficiency. In other settings, primaquine is given without G6PD testing, putting patients at risk of hemolysis. New rapid diagnostic tests (RDTs) offer the opportunity to screen for G6PD deficiency prior to treatment with primaquine. We assessed the cost-effectiveness of using G6PD RDTs on the Thailand-Myanmar border and developed an online model to examine the validity of these findings in other settings. Decision tree models for the management of *P. vivax* malaria evaluated the costs and disability-adjusted life-years (DALYs) associated with recurrences and primaquine-induced hemolysis from a health care provider perspective. Screening with G6PD RDTs before primaquine use was compared to (1) giving chloroquine alone and (2) giving primaquine without screening. Data were taken from a recent study on the impact of primaquine on *P. vivax* recurrences and a literature review. Compared to the use of chloroquine alone, the screening strategy had similar costs while averting 0.026 and 0.024 DALYs per primary infection in males and females respectively. Compared to primaquine administered without screening, the screening strategy provided modest cost savings while averting 0.011 and 0.004 DALYs in males and females respectively. The probabilistic sensitivity analyses resulted in a greater than 75% certainty that the screening strategy was cost-effective at a willingness to pay threshold of US\$500, which is well below the common benchmark of per capita gross domestic product for Myanmar. In this setting G6PD RDTs could avert DALYs by reducing recurrences and reducing hemolytic risk in G6PD deficient patients at low costs or cost savings.

### DEVELOPMENT OF THE WHO INTERNATIONAL EXTERNAL QUALITY ASSURANCE SCHEME FOR MALARIA NUCLEIC ACID AMPLIFICATION TECHNIQUES

**Jaya Shrivastava<sup>1</sup>**, Jane Cunningham<sup>2</sup>, Sandra Incardona<sup>3</sup>, Agatha C. Saez<sup>1</sup>, Peter L. Chiodini<sup>4</sup>

<sup>1</sup>Public Health England, London, United Kingdom, <sup>2</sup>World Health Organization, Geneva, Switzerland, <sup>3</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland, <sup>4</sup>Hospital for Tropical Diseases, London, United Kingdom

With expansion of molecular methods for malaria detection and renewed emphasis on malaria elimination; in 2014, the WHO recommended establishing an international external quality assessment (EQA) scheme for nucleic acid amplification (NAA) assays to ensure that data generated by these methods is reliable and comparable and can support policy development. WHO and UKNEQAS, with support of FIND, have collaborated to launch the WHO Malaria NAA EQA scheme targeting public health and research laboratories in endemic and non-endemic settings. A repository of EQA materials sufficient to allow for biannual distributions to 60 laboratories over a minimum of two years was

established. The repository was prepared from *in vitro* cultures of *P. falciparum* (Pf) and *P. knowlesi* (Pk) and redundant clinical samples of Pf, *P. vivax* (Pv), *P. ovale* (Po) and *P. malariae* (Pm) and negative blood. Positive samples range in parasitaemia from a maximum of 2x10<sup>6</sup> p/mL to a minimum of 10p/mL. Specimens are stored as 500µL aliquots of lyophilized (LY) samples and as 50µL dried blood spots (DBS). First distribution was sent to 53 participating labs in January, 2017 and 41 labs returned results within the allotted timeframe. Initial analysis of data from 41 labs showed that labs performing assays on LY specimens performed better compared with DBS specimens: (% correct: LY 78.8% vs. DBS 62.5%; % incorrect: LY 15.8% vs. DBS 37.5%). A higher percentage of laboratories correctly identified Pf and Pv (average 66%) compared to Pk (55%). A higher rate of incorrect results was observed when parasitaemia was lower [Pf- 62.5% (50 p/µL) vs 28% (2,000 p/µL)]; Pv- [35.1% (18 p/µL) vs 9.8% (180 p/µL)]. False negatives were observed in all samples: [DBS (45.8%) compared to LY(18.9%)]. False positives were observed in all samples [DBS (17.2%) compared to LY (13.4%)]. Conclusions: WHO has established an EQA Scheme for Malaria NAA assays. Initial results illustrate problems with false positives and false negatives particularly when assaying specimens containing low parasitaemias; specimens containing non *P. falciparum* species (especially *P. knowlesi*) and with DBS compared to LY source material.

## 661

### CLINICAL AND LABORATORY PREDICTORS OF SEVERE KNOWLESI MALARIA: IMPLICATIONS FOR INITIATION OF PARENTERAL ARTESUNATE TREATMENT AND HOSPITAL REFERRAL

**Matthew J. Grigg**

*Menzies School of Health Research and Charles Darwin University, Darwin, Australia*

*Plasmodium knowlesi* is increasingly reported in Southeast Asia and can cause severe and fatal disease. Over 3.5 years, we prospectively assessed patients of any age with PCR-confirmed *Plasmodium* mono-infection presenting to 3 district hospitals in Sabah, Malaysia. Clinical and laboratory predictors of severe disease (WHO 2014 criteria) were evaluated using multivariate logistic regression and receiver operating characteristic analysis. 481 *P. knowlesi* (44[9%] children ≤12 years), 172 *P. vivax* (71[41%] children), and 96 *P. falciparum* (31[32%] children) malaria cases were enrolled. In *P. knowlesi*, severe malaria occurred in 6.4% (95%CI:3.9-8.3) of adults but not in children. The commonest *P. knowlesi* severity criteria were acute kidney injury, hyperparasitaemia, jaundice and anaemia. No patients had coma. Independent predictors of severe *knowlesi* malaria included age overall or age ≥45 years, parasite count, chronic comorbidities and abdominal pain. A parasite threshold of 15,000/µL had the best-combined sensitivity (74%) and specificity (87%) for predicting severe *knowlesi* malaria, with an AUC of 0.80 (95%CI 0.71-0.90) and a negative predictive value of 98.5%. Age ≥45 years in addition to parasitaemia >15,000/µL gave an adjusted OR for severe disease of 23.1 (95%CI 7.1-76.1; p<0.001), with a sensitivity of 65%, specificity of 96% (AUC 0.81; 95%CI 0.71-0.91), and a negative predictive value of 98%. Age ≥45 years was the best predictor of hyperparasitaemia (parasite count >100,000/µL) when controlling for other variables (AOR 4.9; 95%CI 1.0-23.9; p=0.048). Adults with *knowlesi* malaria had a higher risk of severe disease compared to adult *vivax* malaria patients (OR 3.4; 95%CI 0.8-14.5; p=0.098), and a comparable risk to *falciparum* malaria. Parasitaemia independently predicted *knowlesi* disease severity: intravenous artesunate is warranted initially for those with parasitaemia >15,000/µL given the potential delay or inability to evaluate other laboratory markers of severe disease in most primary care settings. Age and parasitaemia guide the initial clinical evaluation for hospital admission or tertiary hospital referral.

## 662

### BUILDING AND MAINTAINING HEALTH CARE WORKER PERFORMANCE OF MALARIA RAPID DIAGNOSTIC TESTS IN EIGHT SUB-SAHARAN AFRICAN COUNTRIES

**James Eliades<sup>1</sup>**, Victoria Longa Kalota<sup>2</sup>, Arune Estavela<sup>3</sup>, Fofo Alombah<sup>1</sup>, Kelly Davis<sup>1</sup>, Jolene Wun<sup>1</sup>

<sup>1</sup>President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States, <sup>2</sup>President's Malaria Initiative MalariaCare Project, Medical Care Development International, Lusaka, Zambia, <sup>3</sup>President's Malaria Initiative MalariaCare Project, PATH, Maputo, Mozambique

Relative ease of use and decreasing cost have led to a rapid expansion of rapid diagnostic tests (RDT) for parasitological confirmation of suspected cases of malaria at both facility and community level in countries in sub-Saharan Africa. Errors in key performance steps can reduce the specificity and sensitivity of RDTs. The President's Malaria Initiative (PMI) through the PATH-led MalariaCare partnership has supported National Malaria Control Programs (NMCP) to develop and implement a system of quality assured malaria diagnostics to build and maintain performance of health care workers (HCW) to conduct RDTs. We report here the results of 8,000 observations in 8 countries of HCW RDT performance in field settings at all levels of the health care system. The power of this multi-country monitoring data is in its large numbers measuring changes in performance in the challenges of the work place. MalariaCare works with NMCPs to train laboratory and clinical experts in quality RDT performance, including proper steps, benefits and limitations of the test, and common reasons for false positives and negatives. Best performers are trained as on-site supervisors who work with local laboratory and clinical staff at health facility level to perform on-site outreach training and supportive supervision (OTSS). The OTSS visits focus on observation of RDT conduction using a 13-point checklist and on the spot problem solving. Data from facilities receiving between 2 and 5 OTSS visits have shown steady improvements, averaging 7 percentage points in the performance of RDTs across all cadres of HCWs at all levels of health facilities. Across countries, an average of 96% of steps in the checklist were being performed correctly. Steps most commonly performed incorrectly include labeling of the cassette and checking of the expiry date, but key steps such as waiting the correct amount of time to declare a test negative and using the correct amount of blood and buffer were performed correctly by 89%, 90% and 92% respectively. Findings suggest a system of training and supervision supports strong RDT performance at all levels that improves access to effective case management.

## 663

### USING OUTREACH TRAINING AND SUPPORTIVE SUPERVISION TO MAINTAIN MICROSCOPY COMPETENCY IN SEVEN SUB-SAHARAN AFRICAN COUNTRIES

**Troy Martin<sup>1</sup>**, Nicole Whitehurst<sup>2</sup>, Rodgers Dena Mwinga<sup>3</sup>, Séraphine Kutumbakana<sup>4</sup>, Petros Chirambo<sup>5</sup>, Kelly Davis<sup>6</sup>, Jolene Wun<sup>6</sup>

<sup>1</sup>President's Malaria Initiative MalariaCare Project, PATH, Seattle, WA, United States, <sup>2</sup>President's Malaria Initiative MalariaCare Project, Medical Care Development International, Silver Spring, MD, United States, <sup>3</sup>President's Malaria Initiative MalariaCare Project, PATH, Nairobi, Kenya, <sup>4</sup>President's Malaria Initiative MalariaCare Project, PATH, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>President's Malaria Initiative MalariaCare Project, PATH, Lilongwe, Malawi, <sup>6</sup>President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States

Parasitological confirmation of suspected malaria is performed through the use of rapid diagnostic tests (RDT) or microscopy. The President's Malaria Initiative (PMI) through the PATH-led MalariaCare partnership supports National Malaria Control Programs (NMCP) to implement a system of quality assured malaria diagnostics. Relative to RDT use, microscopy requires more supplies, functioning equipment, extensive specialized

training, and requires regular use of skills to maintain competency - opportunities for which are decreasing with the increasing use of RDTs. MalariaCare works with NMCPs and national laboratories to train diagnostics experts in microscopy. Best performers - from central and sub-national reference laboratories - are then trained as on-site supervisors who work with laboratory staff at health facility level to perform on-site outreach training and supportive supervision (OTSS). The OTSS visits focus on skills observation and on the spot problem solving. The primary goal is to improve skills in preparation and accuracy of malaria slide reading guided by a 3-part checklist: preparation, staining and reading. In 966 laboratory observations across 7 sub-Saharan African countries during the most recent OTSS visit, 88% of hospitals, 82% in health centers, and 84% at health posts (in 2 countries where microscopy is performed at this level) are performing microscopy at a minimally acceptable level - measured as obtaining a score of 75% or higher on a competency weighted checklist. MalariaCare has noted an average improvement of 14 percentage points in performance in facilities receiving 4 rounds of OTSS. Change in performance is more variable in facilities receiving 3 or fewer rounds. Additional observed problems include 26% of facilities without functioning microscopes, 42% without electricity, 72% with stock-outs of pH paper, and 29% with stock-outs of other key commodities. Findings indicate training and at least 4 OTSS visits can significantly improve microscopy competency.

## 664

### PERFORMANCE ASSESSMENT OF LABORATORY TECHNICIANS ON MALARIA MICROSCOPY IN FIVE HIGH ENDEMIC DISTRICTS OF RWANDA

Noella Umulisa<sup>1</sup>, Angelique Mugirente<sup>1</sup>, Tharcisse Munyaneza<sup>2</sup>, Aniceth Rucogoza<sup>2</sup>, Aline Uwimana<sup>3</sup>, Beata Mukarugwiro<sup>1</sup>, Stephen Mutwiwa<sup>1</sup>, Aimable Mbituyumuremyi<sup>3</sup>

<sup>1</sup>Maternal and Child Survival Program/Jhpiego Rwanda, Kigali, Rwanda, <sup>2</sup>National Reference Laboratory (NRL), Rwanda Biomedical Centre (RBC), Kigali, Rwanda, <sup>3</sup>Malaria and Other Parasitic Diseases Division (Mal & OPDD), Kigali, Rwanda

Accurate malaria diagnostics help to establish the true prevalence of each *Plasmodium* species and can ensure appropriate treatment. Light microscopy is the gold standard for malaria diagnosis and sufficient training of laboratory staff is paramount for the correct microscopy diagnosis of malaria. In Rwanda each of about 400 health centers has a laboratory able to perform malaria microscopy, at least 2 trained lab technicians and 1 to 2 functioning microscopes. The objective of the study is to evaluate the performance of laboratory technicians in detecting and quantifying malaria parasites in 81 health centers from 5 highly endemic districts (Huye, Nyanza, Ngoma, Kirehe, Kayanza, Gatsibo). In October 2015 the Rwanda Biomedical Center and partners trained 1 lab technician per health center from these districts in malaria microscopy. The training emphasized determining parasite density and detection of malaria species. From August to September 2016 a follow-up assessment was conducted. Of the 81 technicians trained, 30 were randomly chosen and assessed at their health facilities. A standardized pre-validated slide panel of 5 slides was distributed, a comprehensive checklist used to collect information and conduct visual inspection and maneuvers used in routine malaria diagnosis. During the training a significant increase was found between pre and post tests with median scores improving from 47% to 85%. As part of the assessment 150 lab tech-prepared slides were analyzed to evaluate the quality of thick and thin blood smears. There was a significant increase in quality of both blood smear types. The sensitivity and specificity of participants in detection of malaria parasites were 100% and 86% respectively, while species identification and parasite quantification accuracy were 79% and 75% respectively. The findings of this assessment support the need for continuous capacity building for laboratory staff to ensure accurate malaria diagnosis for appropriate treatment and suggest that District hospitals may benefit from conducting regular malaria microscopy diagnosis quality control/assurance activities at health center laboratories.

## 665

### IMPLEMENTATION OF A QUALITY IMPROVEMENT APPROACH FOR MALARIA SERVICE DELIVERY IN ZAMBEZIA PROVINCE, MOZAMBIQUE

Baltazar Candrinho<sup>1</sup>, Armindo Tiago<sup>2</sup>, Custodio Cruz<sup>2</sup>, Mercino Ombe<sup>2</sup>, Katherine Wolf<sup>3</sup>, Maria da Luz Vaz<sup>2</sup>, Connie Lee<sup>3</sup>

<sup>1</sup>National Malaria Control Program, Ministry of Health, Maputo, Mozambique, <sup>2</sup>Maternal and Child Survival Program/Jhpiego, Maputo, Mozambique, <sup>3</sup>Jhpiego, Baltimore, MD, United States

In Mozambique, malaria in pregnancy (MIP) is one of the leading causes of maternal and newborn morbidity and mortality. Malaria also accounts for over 40% of deaths in children less than five years old. With provincial and facility-level commitment, a simple and comprehensive quality improvement (QI) system has been established in 10 of 16 districts in Zambezia Province. Since 2016, the Mozambique Ministry of Health (MOH) and Zambezia Provincial Health Directorate, in collaboration with partners, have implemented a malaria QI effort based on the Standards-Based Management and Recognition (SBM-R) approach. A standards-based approach to improving quality of malaria care engages both management and service providers to work together to assess the current performance, address gaps to ensure that all patients receive a minimum (standardized / evidence-based) package of care, and ultimately improve patient outcomes and facility performance. Thirty-one performance standards in five content areas (MIP, Case Management, Laboratory, Pharmacy, and Management of Human Resources and Malaria Commodities) were developed and adopted by the MOH in 2016. With support from partners, 40 health workers, including managers, clinicians and lab technicians, received training on SBM-R, and facility QI teams were established. These teams use checklists based on standards to conduct quarterly assessments that identify performance gaps, and then develop action plans to address areas of improvement. The MOH antenatal care and child health registers also contain information on coverage of key malaria interventions, including IPTp, and malaria diagnosis and treatment during pregnancy and for children under five with fever. Average attainment of standards at baseline in 20 health facilities was 30%, and is expected to improve as implementation progresses with quarterly application of the checklist (data will be available before November). Improvements in key malaria indicators for pregnant women and children under five years old are expected as the percentage of standards attained increases.

## 666

### A LARGE NON-HIV OUTBREAK OF AFRICAN HISTOPLASMOSIS IN RURAL COMMUNITY IN KIMPESE CITY, DEMOCRATIC REPUBLIC OF CONGO

Nestor Muyulu Pakasa<sup>1</sup>, Asaf Biber<sup>2</sup>, Samuel Zele Nsiangana<sup>3</sup>, Désiré H. Imposo<sup>3</sup>, Ernest Kiswaya Sumaili<sup>1</sup>, Hypolite Muhindo Mavoko<sup>1</sup>, Ali Mapatano<sup>4</sup>, Iris Barshack<sup>2</sup>, Eli Schwartz<sup>2</sup>

<sup>1</sup>University of Kinshasa Hospital, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>The Chaim Sheba Medical Center, Ramat Gan, Israel, <sup>3</sup>IME Kimpese, Kimpese, Democratic Republic of the Congo, <sup>4</sup>University of Kinshasa, Kinshasa, Democratic Republic of the Congo

African histoplasmosis due to *Histoplasma capsulatum* var *duboisii* is a rare chronic mycotic disease, endemic in several parts of equatorial Africa. Only incidental cases have been documented in humans. Herein we report the first large outbreak of African-Histoplasmosis in non-HIV patients from Kimpese in the Kongo-Central Western province of DR Congo. An observational study was conducted, based on consecutive routine biopsies done between July 2011 - January 2014 at Kimpese hospital. All biopsies were accessioned and diagnosed as *H. duboisii* by histopathology. Gomori methenamine silver staining was performed in Israel confirming initial observations. Immunohistochemistry (IHC) was done at the Pasteur Institute, Paris. A specific real-time polymerase chain reaction (RT-PCR) assay was done in Madrid, Spain. Finally, a field survey was conducted with

interviews and household visits. Altogether 36 patients were histologically diagnosed with Histoplasmosis. Patients originated from the city of Kimpese and its vicinity. The mean age was  $25 \pm 19$  (range 3- 67) years, with sex ratio F/M 1.7:1. The clinical picture included skin, bone and lymph node disorders. No pertinent laboratory abnormalities were noted. All HIV serologies were negative. Histology and histochemistry disclosed florid granulomatous inflammation with a myriad of thick double-walled yeasts consistent with *H. duboisii*. Ancillary IHC and RT-PCR assays confirmed the findings. The search for a putative natural reservoir of the pathogen pointed to *Chaeperon pumilus* cellar bats and guano fertilizer exploitation. All but two patients received and responded well to Ketoconazole therapy whereas the remaining 2 died from lack of medication and poverty. In conclusion, an unusual outbreak of non-HIV African histoplasmosis was encountered in a community setting in a novel hyperendemic location not hitherto identified in DRC. This observation might indicate a much larger public health threat, yet unrecognized. This opens new research perspectives for a better understanding of this neglected tropical disease.

## 667

### EFFECT OF ANTI-MYCOBACTERIUM TUBERCULOSIS THERAPY ON MORTALITY AMONG HIV-INFECTED PATIENTS ADMITTED WITH SEVERE SEPSIS TO A REGIONAL REFERRAL HOSPITAL IN UGANDA

Riley H. Hazard<sup>1</sup>, Sumit Agarwal<sup>1</sup>, Christopher C. Moore<sup>1</sup>, Abdallah Amir<sup>2</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>Mbarara Regional Referral Hospital, Mbarara, Uganda

Mycobacterium tuberculosis (MTb) is a common cause of severe sepsis among HIV-infected patients in sub-Saharan Africa. However, initial empiric treatment of severe sepsis does not frequently include anti-MTb therapy. We conducted a retrospective study at Mbarara Regional Referral Hospital (MRRH) in Uganda to 1) measure the proportion of severely septic patients who received anti-MTb therapy and 2) determine the relationship between initiation and timing of anti-MTb therapy administration and in-hospital mortality. We defined sepsis as clinical suspicion of infection plus  $\geq 2$  out of 3 systemic inflammatory response syndrome criteria (white blood cell count was excluded due to lack of availability) and severe sepsis as sepsis with systolic blood pressure  $<90$ mmHg, mean arterial pressure  $<60$ mmHg, or Glasgow coma scale score  $<15$ . We used the first clinical observation carried backward to impute missing admission vital signs and logistic regression to determine the association between anti-MTb therapy and in-hospital mortality. Of the 150 patients with HIV infection admitted to MRRH between January 2014 and December 2015 with sepsis, 87 (58.0%) had severe sepsis. There were 29 (19.3%) patients with severe sepsis that received anti-MTb therapy. Patients with severe sepsis were not more likely to receive anti-MTb therapy than patients without severe sepsis (odds ratio [OR]: 0.67, 95% confidence interval [CI]: 0.34-1.30,  $p=0.24$ ). Among patients with severe sepsis, 34 (39.1%) died, and there was no relationship between receiving anti-MTb therapy and in-hospital mortality (OR: 0.59, CI: 0.22-1.50,  $p=0.28$ ). There was also no relationship between the timing of administration of anti-MTb therapy and in-hospital mortality for patients with severe sepsis (OR: 1.14, CI: 0.94-1.45,  $p=0.22$ ). For patients with severe sepsis in a setting with a high prevalence of HIV and MTb in Uganda, the initiation and timing of anti-MTb did not affect in-hospital mortality.

## 668

### IMMUNE RESPONSE FOLLOWING REACTIVE VACCINATION CAMPAIGN USING FRACTIONAL DOSE YELLOW FEVER VACCINE — KINSHASA, DEMOCRATIC REPUBLIC OF CONGO, 2016

Rebecca M. Casey<sup>1</sup>, Meredith Dixon<sup>2</sup>, Steve Ahuka-Mundeke<sup>3</sup>, Jennifer Harris<sup>2</sup>, Kizito Mbunusu<sup>3</sup>, Pierre Mutantu<sup>3</sup>, Janeen Laven<sup>4</sup>, Gilson Paluku<sup>2</sup>, Abdou Salam Gueye<sup>5</sup>, Terri B. Hyde<sup>2</sup>, J. Erin Staples<sup>4</sup>, Jean-Jacques Muyembe-Tamfum<sup>3</sup>

<sup>1</sup>Epidemic Intelligence Service, Global Immunization Division, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Global Immunization Division, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Institut National de Recherche Biomédicale, Laboratoire de virologie, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, <sup>5</sup>Division of Global Health Protection, Centers for Disease Control and Prevention, Kinshasa, Democratic Republic of the Congo

In 2016, several large outbreaks of yellow fever (YF) led to a global YF vaccine shortage. To vaccinate 7.6 million people in Kinshasa in an outbreak response campaign, fractional (1/5; 0.1ml) dose of 17DD YF vaccine was provided to children age  $\geq 2$  years and non-pregnant adults via subcutaneous injection. We assessed the effectiveness of this novel control strategy. Participants were recruited in four age strata at six vaccination sites. We assessed the presence of YF virus-specific neutralizing antibodies from blood samples collected pre-vaccination and 28 days post-vaccination using the plaque reduction neutralization test (PRNT50). Participants with PRNT50 titers  $\geq 10$  were defined as seropositive. The study criteria for immune response were seroconversion (seronegative on pre-vaccination blood to titer  $\geq 10$  at follow-up), or  $\geq 4$ -fold increase in titer. 764 participants were enrolled. Of the 716 participants (94% that completed follow-up, 705 (98%; 95% confidence interval: 98%-99%) participants were seropositive for YF antibody. Of these, 630 (89%) met criteria for immune response and 75 (11%) had preexisting immunity and did not meet criteria. Stratified by age, the proportion seropositive at follow-up was 98% (157/161) in 2-5 year olds; 100% (189/189) in 6-12 year olds; 97% (182/187) in 13-49 year olds; and 99% (177/179) in those 50 or older. For the same age groups, the proportions meeting immune response criteria were 80%, 93%, 92% and 85% respectively. There was a significant association between lower baseline titers and developing an immune response ( $p<0.0001$ ). Among baseline seronegative participants, no significant difference in seroconversion rate (range 95%-100%) was observed by age; there was a small but significant difference by sex (male 99%, female 96%,  $p=0.03$ ). In this cohort, fractional dose YF vaccine was highly effective at eliciting an immune response among those without preexisting immunity. These findings support the use of fractional dose vaccination for outbreak control, an important approach in the context of ongoing YF vaccine shortage. Additional studies are needed to assess the duration of immune response.

## 669

### CEREBROSPINAL FLUID MARKERS TO DISTINGUISH BACTERIAL MENINGITIS FROM CEREBRAL MALARIA IN CHILDREN

James M. Njunge

KEMRI-Wellcome Trust Programme, Kilifi, Kenya

Acute bacterial meningitis (ABM) and cerebral malaria (CM) are common causes of acute non-traumatic coma, an important cause of morbidity and mortality among paediatric hospital admissions in Africa. Clinically distinguishing children with ABM from CM in high malarious areas is challenging, and both may be present. Few hospitals have diagnostic capacity for distinguishing the two syndromes resulting in broader antibiotic cover than necessary. A biochemical marker of ABM would

facilitate precise clinical diagnosis and management of these infections. We used Label-free protein quantification by mass spectrometry to identify cerebrospinal fluid (CSF) markers that distinguish ABM from CM in Kenyan children. Biomarker extraction combined differential protein expression and assignment of biomarker importance using random forests. Receiver operator characteristic (ROC) curves evaluated diagnostic characteristics of the biomarkers. The host CSF proteome response to ABM (*Haemophilus influenzae* and *Streptococcus pneumoniae*) is significantly different to CM. Among the differentially expressed proteins (FDR<0.01, Log FC≥2), Myeloperoxidase and Lactotransferrin were present in 37(100%) and 36(97%) of ABM cases respectively but absent in CM (n=22). Area under the ROC curve (AUC), sensitivity, and specificity were for Myeloperoxidase (1, 1, and 1; 95% CI, 1-1) and Lactotransferrin (0.98, 0.97, and 1; 95% CI, 0.96-1). Myeloperoxidase and Lactotransferrin have high potential to distinguish ABM from CM and thereby improve clinical management. Their validation requires a larger cohort of samples that includes other bacterial aetiologies of ABM.

## 670

### CONTRIBUTING FACTORS FOR ANEMIA IN YOUNG CHILDREN IN COASTAL KENYA

Julia Kao<sup>1</sup>, Francis Mutuku<sup>2</sup>, Shanique Martin<sup>1</sup>, Justin Lee<sup>1</sup>, Jackson Muinde<sup>3</sup>, Dunstan Mukoko<sup>4</sup>, Indu Malhotra<sup>5</sup>, Charles King<sup>5</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford School of Medicine, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Ministry of Health Kwale, Mombasa, Kenya, <sup>4</sup>Ministry of Health, Nairobi, Kenya, <sup>5</sup>Case Western Reserve University, Cleveland, OH, United States

This study measured prevalence of anemia in conjunction with parasitic infection and nutritional status in a child cohort in rural Kenya. In a project where children have been followed biannually with stool, urine, and blood testing for parasitic infections, this 6-week sub-study in 2016 involved in depth testing for anemia and its risk factors using complete blood counts, nutritional assessment, and linkage to mother's and children's parasitic infection data for 244 children 0.5 to 3 years old. CBC showed 76% of infants were anemic (Hb < 11g/dL) at the 2016 visit. Longitudinal data indicated that one infant was anemia-free for her entire 20-month life and 11 had a lifetime average hemoglobin (Hb) that was non-anemic; however, 95% of children had an average lifetime Hb that was anemic, with younger infants more likely to be anemic at the 2016 visit. Anthropometric analysis showed that 26.5% of the currently anemic group were growth stunted, compared to 18.6% in the currently non-anemic group. Of note, maternal Hb at delivery was significantly lower for the currently anemic group, so analysis of the impact of parasitic infections included both antenatal maternal infections and infant infections during the postnatal period. Multivariable analysis, correcting for age and gender, indicated that antenatal malaria, as well as current infection with hookworm, *Trichuris*, *Strongyloides*, *Ascaris*, or malaria, were significantly associated with decreased current Hb. The nutritional assessment revealed that infants with a decline in Hb ate less vitamin A-rich vegetables and eggs, more milk and bread, and lived in a household that experienced significant food shortage in the past year. Maternal slate chewing during pregnancy and infant pica were also more frequent in the group with a decline in Hb. This study calls attention to the extremely high prevalence of anemia among vulnerable infants in a rural Kenyan population. Given that the anemia in this cohort appears to be multifactorial in origin, interventions need to address both diet and parasitic infections in pregnant women and their infants to effectively combat this priority public health threat.

## 671

### CAUSES OF NON-TRAUMATIC PARAPLEGIA IN MALAWI

Eduard E. Zijlstra<sup>1</sup>, Jaap van Hellemond<sup>2</sup>, Nyengo Mkandawire<sup>3</sup>, Juri Katchanov<sup>4</sup>, Camilla Rothe<sup>5</sup>

<sup>1</sup>Rotterdam Centre for Tropical Medicine, Rotterdam, Netherlands, <sup>2</sup>Erasmus Medical Center, Rotterdam, Netherlands, <sup>3</sup>College of Medicine, Blantyre, Malawi, <sup>4</sup>University Hospital Hamburg-Eppendorf, Hamburg, Germany, <sup>5</sup>University Medical Center Hamburg Eppendorf, Hamburg, Germany

Non-traumatic paraplegia is neglected tropical syndrome. It is not uncommon in Malawi; however there are only scanty reports on its pathogenesis. This study was undertaken to study the most common causes of paraplegia and make recommendations for treatment. We studied 50 sequential patients with paraplegia of < 6 months duration. A full neurological assessment was made using the American Spinal Injury Association (ASIA) scale. An MRI scan and a lumbar puncture was done as clinically indicated. Serum samples and CSF were screened for viral infections, schistosomiasis, tuberculosis and syphilis. Tuberculosis was the most common diagnosis (36%), followed by malignancy (20%) and transverse myelitis (10%); 3 cases were diagnosed as presumed neuroschistosomiasis. The diagnosis of tuberculosis was based on clinical and radiological evidence; in none of the CSF samples *M. tuberculosis* could be demonstrated by PCR. Four patients had evidence of neurosyphilis. A novel cyclovirus was found 10% of 40 CSF samples examined; other viruses found in the CSF included HIV, EBV, HSV and hepatitis B virus. In conclusion, tuberculosis was the most common cause of non-traumatic paraplegia; the contribution of schistosomiasis was lower than expected. The role of cyclovirus needs to be confirmed. The current policy of empirical treatment for schistosomiasis seems still justified; evidence for tuberculosis should be sought in all patients.

## 672

### ACUTE KIDNEY INJURY FOLLOWING MULTIPLE WASP STINGS - A CLINICOPATHOLOGICAL STUDY FROM A MOUNTAINOUS STATE OF INDIA

Sanjay Vikrant

Indira Gandhi Medical College, Shimla (Himachal Pradesh), India

Acute kidney injury (AKI) after multiple wasp stings is well known, but still a rare phenomenon. A retrospective study of clinicopathological spectrum AKI following multiple wasp stings patients admitted at Indira Gandhi Medical College Hospital, Shimla over 13 years (July 2003 to June 2016). 32 patients were diagnosed with AKI due to multiple wasp stings. Mean age was 42.7±16.7 years and majority (62.5%) were male. The mean number of stings was 44±23 with a range of 15-100 stings. 26 (81.3%) of the patients had oliguria and 19 (59.4%) of the patients had history of hematuria or having passed cola-colored urine. Hemoglobin was 8.8±2.4 g/dL and white blood cell (WBC) count was 14±7.3 (x103/mm<sup>3</sup>). Peak serum urea and creatinine were 252±113 mg/dL and 11±5.7 mg/dL respectively. The hematological and biochemical laboratory abnormalities were: anemia (96.9%), leucocytosis (53.1%), hyperkalemia (71.9%), severe metabolic acidosis (56.3%), hepatic dysfunction (71.9%), hemolysis (90.6%) and rhabdomyolysis (59.4%). Main complications were acute respiratory distress syndrome (ARDS) and encephalopathy 4 (12.5%) patients each, gastrointestinal bleed, hypertension and eosinophilic panniculitis 2 (6.3%) patients each and one (3.1%) patient each developed intra abdominal bleed, stroke and polyserositis. 29 (91%) patients required dialysis. 10 (31.3%) patients died. The proportion of patients with laboratory abnormalities of leucocytosis (p=0.06), severe metabolic acidosis (p=0.019) and the complications of ARDS and encephalopathy (p=0.006) were significantly higher in patients who died. Kidney biopsy was done in 13 patients. Acute tubular necrosis (ATN) with or without pigmented granular cast was seen in 10 (77%); four (30.8%) severe ATN and other six (46.2%) ATN associated with mild to moderate acute interstitial nephritis (AIN). Three (23%) had only moderate

AIN with overall AIN in nine (69.2%) kidney biopsies. The kidney functions normalized at  $5.6 \pm 2.6$  weeks. AKI due to multiple wasp stings is severe and is associated with high mortality. ATN and AIN are common findings on renal histology.

### EFFECT OF HUMAN C5A PROTEIN ON MOSQUITO CELLS AND ITS IMPLICATIONS IN ZIKA VIRUS TRANSMISSION

Donghun Kim<sup>1</sup>, Seokyoung Kang<sup>2</sup>, Crystal Gripping<sup>3</sup>, Mauricio Figueroa-Lozano<sup>4</sup>, Tonya M. Colpitts<sup>5</sup>, George Dimopoulos<sup>2</sup>, Yoonseong Park<sup>1</sup>, Berlin L. Londono-Renteria<sup>1</sup>

<sup>1</sup>Kansas State University, Manhattan, KS, United States, <sup>2</sup>Department of Molecular Microbiology and Immunology, Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>Department of Tropical Medicine, Tulane University, New Orleans, LA, United States, <sup>4</sup>Universidad de Pamplona, Pamplona, Colombia, <sup>5</sup>University of South Carolina, Columbia, SC, United States

After ingesting blood from an infected host, the mosquito midgut becomes the first place where the pathogen, the mosquito, and vector factors are in close contact. The interactions occurring at this stage and site have profound implications in pathogen transmission and vector survival. Our previous research suggests that human complement interacts with mosquito proteins, modulating gene expression and defense against pathogens. To test the effect of the human complement on Zika virus (ZIKV) infection of mosquito cells, we treated Aag2 cells with recombinant C5a prior to ZIKV (MR-766 strain) exposure. We found that cells treated with C5a presented lower ZIKV infective particles than the untreated control cells. The effect was abrogated mosquitoes after knock-down of two mosquito trans-membrane proteins suspected to directly interact with C5a. In addition, RNAseq data showed that AAEL009292 (involved in protein-protein interaction) and a CLIPB serine protease protein were significantly up-regulated in cells treated with C5a while AAEL018103 (involved in lipid transport) was significantly downregulated. Our data suggest that human complement may play an important role in modulating the immune response mounted against arboviruses by the arthropod vector.

### ZIKA-AEDES MOLECULAR INTERACTIONS AND MOSQUITO IMMUNITY-MEDIATED VIRAL SUPPRESSION

Yesseinia I. Anglero-Rodriguez, Hannah MacLeod, Seokyoung Kang, Jenny Carlson, Natapong Jupatanakul, George Dimopoulos  
Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Zika virus (ZIKV) is an emerging arbovirus that recently became a public health threat. ZIKV is transmitted between humans through *Aedes* mosquitoes. However, the molecular interactions between the vector and the virus remain largely unknown. Using RNA sequencing analysis of mosquito's midguts infected with ZIKV or Dengue virus (DENV), we demonstrate that 40% of the mosquito's infection-responsive transcriptome is virus-specific. Regulated genes included key factors of the mosquito's anti-viral immunity. Comparison of ZIKV and DENV infection-responsive transcriptome data to those for Yellow fever virus and West Nile virus identified 26 genes likely to play key roles in arboviral infection of *Aedes* mosquitoes. Through reverse genetic analyses, we show that the Toll and the Jak/Stat innate immune pathways mediate increased resistance to ZIKV infection, and the conserved DENV host factors vATPase and inosine-5'-monophosphate dehydrogenase are also utilized for ZIKV infection. Here, we describe a comprehensive study on the *Ae. aegypti* molecular responses to ZIKV infection, and the implication of mosquito immune system in suppressing virus infection.

### CHEMICAL DEPLETION OF GRANULOCYTES REVEALS CONTRIBUTIONS OF HEMOCYTES TO ANTI-PLASMODIUM IMMUNITY

Hyeogsun Kwon, Ryan C. Smith

Department of Entomology, Iowa State University, Ames, IA, United States

Malaria, caused by *Plasmodium* parasites, is one of the most devastating human diseases, resulting in half a million deaths every year. The interaction between *Anopheles* mosquito vectors and malaria parasites is a key determinant of vector competence. Therefore, an understanding of immune molecules that influence parasite development in the mosquito host can provide opportunities to disrupt disease transmission. Immune cells known as hemocytes play critical roles in killing invading pathogens by phagocytosis, encapsulation and nodulation. However, little is known about hemocyte-mediated immune responses to malaria parasite infection. To address the immune responses mediated by phagocytic granulocytes on bacterial infections and parasite development, we depleted *An. gambiae* granulocyte populations using a chemical-based approach. In subsequent experiments, granulocyte depletion impeded immune defenses to bacterial and malaria parasite infections, causing high mortality and increased parasite survival. Furthermore, we establish that immune responses mediated by granulocytes shortly after parasite infection (<24h) are critical to both early- and late-phase immune responses that limit malaria parasite survival. To our knowledge, this study provides the first definitive insight into the temporal function of cellular immune responses in mosquitoes to malaria parasite infection, and serves as an important advancement to study of phagocytic cells in other insect vectors.

676

### LOSS-OF-FUNCTION STUDIES WITH KNOCK OUT AEDES AEGYPTI LINES GENERATED BY CRISPR/CAS9 HIGHLIGHT THE PHYSIOLOGICAL RELEVANCE OF SALIVARY D7 PROTEINS IN BLOOD FEEDING AND PARASITE TRANSMISSION

Ines Martin-Martin<sup>1</sup>, Azadeh Aryan<sup>2</sup>, Jose M. Ribeiro<sup>1</sup>, Zach Adelman<sup>3</sup>, Eric Calvo<sup>1</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Virginia Tech University, Blacksburg, VA, United States, <sup>3</sup>Texas A&M University, College Station, TX, United States

*Aedes aegypti* saliva facilitates blood meal acquisition through pharmacologically active compounds that prevent host haemostatic and immune responses. The D7 salivary proteins are one of the most abundant, accounting for 30% of the total salivary protein content. The D7 salivary family of proteins are encoded by a multigene family related to the arthropod odorant-binding protein superfamily and have been shown to act as scavengers of biogenic amines and eicosanoids. Our goal was to generate *Ae. aegypti* D7 knock out (KO) lines by CRISPR/Cas9 system to further characterize the biological function of these proteins by loss-of-function studies. We generated 2 homozygous mosquito lines for the salivary proteins AeD7L1 and AeD7L2. Global transcriptome and proteomics changes were analyzed by RNAseq and LC/MS/MS, confirming the absence of D7 protein expression in the KO mosquitoes. Lack of these proteins was also observed by confocal microscopy of the salivary glands with D7 specific antibodies raised in rabbits. KO mosquitoes took longer to locate blood vessels when feeding on C57BL6 mice and, therefore, had significantly longer probing times (17-300 s,  $P < 0.0001$ ) when compared with parental mosquitoes (18-80 s). These differences in probing time were abolished when B6.129S2-Alox5tm1Fun mutant mice were used instead. Mutant mice do not produce leukotrienes due to the lack of arachidonate 5-lipoxygenase, confirming the role of D7 proteins as leukotrienes scavengers. We also investigated the role of D7 salivary proteins in *Plasmodium gallinaceum* infection and transmission. Our results show that both KO lines carried significantly less oocysts per midgut and a 5-fold reduction in sporozoites number in salivary glands. *Ae. aegypti* KO

lines were successfully produced by CRISPR/Cas9 technology and allowed us to better understand the role of D7 salivary proteins in preventing host hemostatic and immune responses. The information generated by this work highlights the biological functionality of salivary gene products in blood feeding and pathogen transmission.

## 677

### IDENTIFICATION OF A RECEPTOR FOR *PLASMODIUM FALCIPARUM* Pfs47 IN THE *ANOPHELES GAMBIAE* MIDGUT

**Alvaro Molina-Cruz**, Gaspar Canepa, Simardeep Nagyal, Smith Agyingi, Thiago Silva, Nathanie Trisnadi, Eric Calvo, Carolina Barillas-Mury

National Institutes of Health, Rockville, MD, United States

We have found that *Plasmodium falciparum*, a human malaria parasite, requires its Pfs47 protein to evade the mosquito immune system in order to infect the vector midgut. We have also obtained evidence that the mosquito immune system can be an important barrier for adaptation of the parasite to evolutionarily distant vectors, through natural selection of Pfs47 haplotypes that are compatible with a given vector. Pfs47 is a member of the 6-cys (s48/47 domain) protein family. It is a polymorphic gene that has signatures of selection with its haplotypes presenting a strong population structure at continental level, consistent with selection by the vector. Here we present evidence for a Pfs47-receptor protein in the *An. gambiae* midgut. The presence of specific binding to Pfs47 by *An. gambiae* midguts was detected by ELISA. Using far-western blotting of midgut proteins probed with recombinant Pfs47, we were able to identify and sequence a specific midgut protein that binds Pfs47. The Pfs47-receptor in *An. gambiae* is a gene of unknown function that has orthologues in other anophelines. dsRNA based knock down of the Pfs47-receptor led to a decrease in *P. falciparum* infection in the midgut, suggesting that it may be a negative regulator of the midgut immune response against the parasite. Binding analysis showed that a recombinant Pfs47 haplotype prevalent in Africa interacts with recombinant Pfs47-receptor from *An. gambiae* (Africa) and *An. dirus* (Asia) while it does not interact with an *An. albimanus* (Americas) Pfs47-receptor. The differences in binding specificity of Pfs47 with its receptors recapitulate the infection compatibility of tested African *P. falciparum* lines with the 3 vectors. This gives more evidence for the "lock and key" model of compatibility between *P. falciparum* and its vectors, in which selection of compatible Pfs47 by the different vectors has determined the adaptation of *P. falciparum* to different vectors around the world.

## 678

### FACTORS TRIGGERING *PLASMODIUM* DEVELOPMENT FOLLOWING *ANOPHELES* SALIVARY GLAND INVASION

**Mai I. Hussein**<sup>1</sup>, Belal A. Soliman<sup>1</sup>, Maha K. Tewfik<sup>1</sup>, Kristina Pilitt<sup>2</sup>, David A. O'Brochta<sup>2</sup>

<sup>1</sup>Department of Zoology, Faculty of Science, Suez University, Suez, Egypt,

<sup>2</sup>Institute for Bioscience and Biotechnology Research, University of Maryland-College Park, Rockville, MD, United States

Using an *in vitro* sporozoite development assay mimicking salivary gland invasion we report the results of efforts to identify and characterize insect factors triggering essential changes in *Plasmodium berghei* that are associated with the invasion of mosquito salivary glands and that result in sporozoites competent to infect their mammalian host. Plasmodium parasites undergo a sequential series of developmental changes as they traverse and invade various tissues of both vertebrate and invertebrate hosts. These developmental changes are reflected in the parasites' morphology and/or changes in levels and patterns of gene expression. In *Anopheles* mosquitoes, sporozoites from oocysts and hemolymph differ from sporozoites in salivary glands in that they are less capable of infecting their hosts and are less motility. Following salivary gland invasion sporozoites become competent to infect their mammalian hosts and lose their capacity to reinvade salivary glands. These developmental changes

are reflected in changes in gene expression including up-regulation of some 30 genes. The factors associated with salivary glands that trigger developmental changes during and after salivary gland invasion are largely unknown. Using a UIS4:mCherry-containing line of *P. berghei* (RMgm-1339) that only has visible mCherry expression following salivary gland invasion, we show that UIS4:mCherry up-regulation can occur *in vitro* following exposure to adult female *Anopheles stephensi* salivary gland homogenates and fractions. Treated sporozoites have a transcription profile like that of post-invasion sporozoites. Here we report on results aimed at addressing the nature of the factors associated with salivary glands responsible for triggering this major developmental transition in *Anopheles* mosquitoes.

## 679

### THE ROLE OF TWO FEMALE ATRIAL PROTEASES IN THE REFRACTORINESS OF *ANOPHELES GAMBIAE* MOSQUITOES TO FURTHER MATINGS

**Priscila Bascuñan**<sup>1</sup>, Paolo Gabrieli<sup>2</sup>, Enzo Mameli<sup>1</sup>, Robert Shaw<sup>3</sup>, Matthew Peirce<sup>2</sup>, Flaminia Catteruccia<sup>1</sup>

<sup>1</sup>University of Perugia/Harvard School of Public Health, Boston, MA, United States, <sup>2</sup>University of Perugia, Perugia, Italy, <sup>3</sup>Harvard School of Public Health, Boston, MA, United States

Although the reproductive rate of *Anopheles gambiae* mosquitoes is a key aspect of their capacity to transmit malaria, fertility of these vectors depends on a single copulation event as females become refractory to mating after a first copulation. Interfering with mating is therefore a promising alternative to control mosquito populations in endemic areas, potentially reducing malaria morbidity and mortality. In this study, we show the involvement of two female atrial serine proteases in shaping the mating receptivity of *An. gambiae* females. These two proteolytic enzymes ensure correct processing of the mating plug, a gelatinous structure composed of male seminal secretions that is transferred to the female reproductive tract during mating. We show that correct processing of the plug by these proteases is necessary to trigger a series of events that lead to the reduction of mating receptivity experienced by females after a first copulation. Moreover, these proteases are associated with, and possibly contribute to the formation of a peritrophic matrix-like structure secreted by female atrial cells, which surrounds the plug after mating and may be critical for its function. These results shed new light on the mechanisms regulating female receptivity to mating in *An. gambiae*, with possible implications for reducing the reproductive output of these mosquitoes.

## 680

### EFFECTIVENESS OF HAND SANITIZER WITH HAND AND RESPIRATORY HYGIENE EDUCATION IN REDUCING INFLUENZA-LIKE ILLNESS AND LABORATORY CONFIRMED INFLUENZA AMONG SCHOOL CHILDREN IN BANGLADESH, 2015

**Debashish Biswas**<sup>1</sup>, Fahmida Chowdhury<sup>1</sup>, Katherine Roguski<sup>2</sup>, Makhdum Ahmed<sup>3</sup>, Fosiul A. Nizame<sup>1</sup>, Shahana Parveen<sup>1</sup>, Probir K. Ghosh<sup>1</sup>, Sazzad H. Khan<sup>1</sup>, A. Danielle Iuliano<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>University of Texas M.D. Anderson Cancer Center and University of Texas Health Science Center, Houston, TX, United States

School children are important vectors for transmitting influenza. High infection rates among children and overcrowding at schools in many low-income countries make children more susceptible to exposure and spread of influenza viruses at school. Common measures to prevent transmission include non-pharmaceutical interventions such as handwashing and self-isolation. Handwashing is often a challenge in places like Bangladesh, because of limited availability of soap and water. Evaluations of alternative hygiene options, such as hand sanitizer, in reducing influenza virus

infection are needed. For three months during the 2015 influenza season in Bangladesh (May-September), we conducted a cluster randomized control trial in 24 primary schools in Dhaka city to assess the effectiveness of hand sanitizer with hygiene education to reduce influenza-like illness (ILI) and laboratory confirmed influenza. Twelve randomly selected schools received hand sanitizer with an educational intervention and students were encouraged to use the hand sanitizer at specific times at school. In addition, we taught children to cover their mouth and nose with their upper arm while coughing and sneezing. The 12 control schools received no intervention. We conducted daily follow-up at schools through visits and by phone if a child was absent to identify new ILI cases (cough with fever) and collect nasal swabs to test for influenza viruses. After controlling for cluster level effects and adjusting for classroom and household factors, ILI was 36% lower in the intervention schools compared to the control schools, but this was not statistically significant (Intervention: 22%, Controls: 27%,  $p=0.07$ ). Laboratory confirmed influenza was 55% lower in the intervention schools compared to the control schools after adjusting for gender (Intervention: 3%, Controls: 6%,  $p=0.008$ ). Hand sanitizer with hygiene education was associated with a reduction in ILI and laboratory confirmed influenza among school children. Future influenza prevention strategies in Bangladesh could explore the feasibility of including hand sanitizer and hygiene education in schools.

## 681

### **SPILLOVER EFFECTS OF A COMBINED WATER, SANITATION AND HANDWASHING INTERVENTION IN RURAL BANGLADESH: A RANDOMIZED CONTROLLED TRIAL**

**Jade Benjamin-Chung**<sup>1</sup>, Nuhu Amin<sup>2</sup>, Ayse Ercumen<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>, Alan Hubbard<sup>1</sup>, Leanne Unicomb<sup>2</sup>, Mahbubur Rahman<sup>2</sup>, Stephen P. Luby<sup>3</sup>, John M. Colford, Jr.<sup>1</sup>

<sup>1</sup>University of California Berkeley, Berkeley, CA, United States,

<sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>Stanford University, Stanford, CA, United States

Water, sanitation, and handwashing (WSH) interventions may confer indirect benefits on neighbors of recipients by interrupting pathogen transmission; prior trials have not measured such "spillover effects". We measured spillovers in WASH Benefits, a large, cluster-randomized trial in rural Bangladesh, by comparing outcomes among neighbors of intervention vs. control participants. WASH Benefits had randomly allocated geographically-defined clusters to a compound-level intervention (chlorinated drinking water, upgraded sanitation, and handwashing promotion) or control and followed children for 2 years. We enrolled neighboring children age-matched to trial participants (within ~ 22 months) that would have been eligible for WASH Benefits had they been conceived slightly earlier or later. After 28 months of intervention, we quantified fecal indicator bacteria in toy rinse and drinking water samples, measured soil-transmitted helminth infections, and recorded caregiver-reported diarrhoea and respiratory illness. Neither fieldworkers nor participants were masked. Analysis was intention-to-treat. Registration: ClinicalTrials.gov #NCT02396407. We enrolled neighbors of the main trial participants in 90 control (N=900) and 90 intervention clusters (N=899). Neighbors' characteristics were balanced across arms. Detectable *E. coli* in tubewell samples was significantly lower among neighbors of intervention compounds (55%) vs. neighbors of control compounds (66%) (prevalence ratio=0.84; 0.73, 0.96). There was no difference in *E. coli* or coliform prevalence between arms for other environmental samples. Neighbors' disease prevalence was similar in intervention vs. control: *Ascaris* (prevalence difference [PD]=0.02; -0.09, 0.05), hookworm (PD=-0.01; -0.01, 0.04), *Trichuris* (PD=-0.01; -0.04, 0.02), diarrhoea (PD=-0.01; -0.03, 0.02), respiratory illness (PD=0.02; -0.01, 0.06). In this randomized trial, we found a compound-level combined WSH intervention improved neighbors' tubewell water quality but did not improve child health outcomes in neighboring compounds.

## 682

### **THE ROLE OF THE ENVIRONMENT IN ROTAVIRUS TRANSMISSION: TEMPERATURE AND HYDROLOGIC FACTORS**

**Alicia N. Kraay**<sup>1</sup>, Nan Lin<sup>1</sup>, Andrew F. Brouwer<sup>1</sup>, Justin V. Remais<sup>2</sup>, Phillip A. Collender<sup>2</sup>, Joseph N. Eisenberg<sup>1</sup>

<sup>1</sup>University of Michigan Ann Arbor, Ann Arbor, MI, United States,

<sup>2</sup>University of California Berkeley, Berkeley, CA, United States

Rotavirus is known to persist in water sources and its incidence has been shown to vary with temperature. At the same time, studies generally do not assert that its incidence can be reduced by targeting water and sanitation pathways. Here we use compartmental models to examine the potential environmental mechanisms more in detail. We conducted a meta-analysis to estimate the effect of temperature on the rotavirus decay rate in water and examined mechanistic relationships between temperature and incidence using a two-community rotavirus transmission model that accounted for both human-to-human and water-mediated transmission. Pathogen decay rates are significantly related to temperature ( $N=39$ ,  $p<.0001$ ) when modeled with an exponential relationship (fitted equation: ). For temperatures below 20°C, each 1°C increase in temperature results in a 0.004 unit increase in decay rate compared with a 0.016 increase at 25°C. Water acted as an effective disseminator of disease between the upstream and downstream communities for all temperatures, whereas direct transmission was more important for disease amplification within communities. For standing water, this increase in decay led to decreased risk of disease, with every 1°C increase in temperature leading to a 2.5% decrease in risk. Consistent with prior meta-analytic work and time series analyses of climate and rotavirus, our models suggest that water could be an important source of risk for rotavirus that is often overlooked by conventional epidemiologic studies. This environmental transmission of rotavirus is likely to be most important in cooler seasons (resulting in increased persistence) and in larger communities with a standing water source. In these situations, joint interventions that target both direct and indirect pathways are needed to interrupt transmission and the critical coverage to interrupt this pathway is temperature dependent. In contrast, in communities with flowing water systems, targeting direct transmission alone is likely to be sufficient to stop the spread of disease unless the size of the reservoir is small.

## 683

### **IDENTIFICATION OF SPECIFIC ENTEROPATHOGENS AS PREDICTORS OF LINEAR DECLINE IN ENVIRONMENTAL ENTERIC DYSFUNCTION**

**Sana Syed**<sup>1</sup>, Najeeha T. Iqbal<sup>2</sup>, Furqan Kabir<sup>2</sup>, Tauseef Akhund<sup>2</sup>, Shahida Qureshi<sup>2</sup>, Jie Liu<sup>3</sup>, Jennie Z. Ma<sup>3</sup>, Shan Guleria<sup>3</sup>, Molly A. Hughes<sup>3</sup>, Kamran Sadiq<sup>2</sup>, S. Asad Ali<sup>2</sup>

<sup>1</sup>University of Virginia/Aga Khan University, Charlottesville, VA, USA/ Karachi, Pakistan, <sup>2</sup>Aga Khan University, Karachi, Pakistan, <sup>3</sup>University of Virginia, Charlottesville, VA, United States

Environmental enteric dysfunction (EED) is an acquired small intestinal inflammatory condition underlying high rates of stunting in children <5yrs in low- and middle-income countries. EED is hypothesized to be due to chronic exposure to enteropathogens, resulting in malabsorption. We aimed to characterize the association between enteropathogenic infection, EED biomarkers and linear growth in a prospective birth cohort in rural Pakistan. Growth was measured monthly for 18 mo. Length-for-age-Z (LAZ) scores were calculated according to WHO 2006 guidelines. Stool and serum samples were collected at 6 and 9 mo for biomarkers of systemic/ enteric inflammation, enterocyte regeneration and bacterial translocation. Molecular screening tests for an array of > 40 enteropathogens were conducted using PCR-based TaqMan cards. Linear regression was used to study the effect of specific enteropathogen infection on change in linear growth  $\Delta LAZ(18mo-birth)$  of  $n=272$  children. Subjects with  $\geq 1$

identified enteropathogens had similar  $\Delta$ LAZ(18mo-birth) scores at six and nine mo, compared to those with no identified pathogens. Increasing numbers of any identified enteropathogen correlated with serum flagellin Ig A (6mo,  $r=0.19$ ,  $p=0.002$ ), fecal Reg1b (6mo,  $r=0.16$ ,  $p=0.01$ ; 9mo,  $r=0.16$ ,  $p=0.008$ ) and serum Reg1b (6mo,  $r=0.26$ ,  $p<0.0001$ ; 9mo,  $r=0.16$ ,  $p=0.008$ ). At 6 mo of age, *Astrovirus* ( $\beta$ (SE)-0.38(0.19),  $p=0.046$ ), *Campylobacter jejuni/coli* ( $\beta$ (SE)-0.36(0.16),  $p=0.03$ ), *Cryptosporidium spp* ( $\beta$  (SE)-0.45(0.20),  $p=0.03$ ) and *Giardia* ( $\beta$ (SE)-0.57(0.23),  $p=0.01$ ) were associated with a trend of negative  $\Delta$ LAZ scores over 18 mo (implying higher LAZ scores at the end of follow-up). At 9 mo this was true of *Norovirus* ( $\beta$  (SE) -0.29 (0.15),  $p=0.049$ ) only. These results showed multiple enteropathogen infections (potential therapeutic targets) occurred early on in life, which is consistent with our hypothesis that EED secondary to enteric infections, is a mediating factor for growth decline in children in low-income countries. The relationship between enteropathogen infection and intestinal pathophysiological changes associated with EED require further study.

## 684

### ANTIBIOTIC RESISTANCE IN DENSE, LOW-INCOME NEIGHBORHOODS: THE ROLE OF SANITATION IN GENE DISPERSION

David Berendes<sup>1</sup>, David Holcomb<sup>2</sup>, Jackie Knee<sup>1</sup>, Trent Sumner<sup>1</sup>, Rassul Nala<sup>3</sup>, Joe Brown<sup>1</sup>

<sup>1</sup>Georgia Institute of Technology, Atlanta, GA, United States, <sup>2</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>3</sup>Ministerio da Saude, Maputo, Mozambique

Antibiotic resistance (AbR) threatens global public health, yet there has been little focus outside the clinical realm to the role environmental improvements may play in mitigating AbR, particularly in enteric bacterial pathogens. The goal of this study was to understand how sanitation infrastructure may act as a source of or containment strategy against AbR gene dispersion. We aimed to 1) describe the diversity and concentrations of AbR genes circulating in families and young children specifically; and 2) evaluate whether children born into compounds with improved, shared sanitation infrastructure had less diversity and lower prevalence of AbR genes compared to children born into control compounds. We examined the prevalence and diversity of AbR genes in households enrolled in a controlled before-and-after urban sanitation trial. We sampled household latrines (a proxy for family-level measures) and children's stool in intervention and control compounds before and after the implementation of a sanitation intervention with improved containment in Maputo, Mozambique. Samples are being analyzed for AbR genes and gene origins by metagenomic techniques, and tested against a panel of gene targets by qPCR. Subsequently, AbR gene concentrations will be assessed by droplet digital PCR and analyzed for differences by intervention status using regression modelling. Before the intervention, latrine waste had high prevalence and diversity of AbR genes—9/10 latrines were positive for at least one resistance gene target, and 8/10 were positive for 15 or more—and prevalence of enteric infection, measured in children's stool, was high (~90%). Post-intervention latrine waste, and also children's stool specimens, are currently being evaluated for AbR gene content (results by summer). This study will be the first to characterize AbR gene prevalence and diversity in the context of a sanitation intervention, yielding new evidence for environmental approaches to mitigate AbR in dense, highly-contaminated, low-income urban areas with high antibiotic use.

## 685

### EVALUATION OF WATER, SANITATION, AND HYGIENE INFRASTRUCTURE IN RURAL HEALTHCARE FACILITIES — KAMWENGE DISTRICT, UGANDA, 2017

Jarred Mcateer<sup>1</sup>, Sae-Rom Chae<sup>1</sup>, Emily Atuheire<sup>2</sup>, Daniel Kadobera<sup>2</sup>, Alex R. Ario<sup>2</sup>, Rob Quick<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Uganda Public Health Fellowship Program, Kampala, Uganda

Lack of access to safe water, sanitation, and hygiene (WASH) in healthcare facilities (HCFs) poses health risks to patients and health workers. Universal WASH coverage in HCFs is included among Sustainable Development Goals (SDGs). We evaluated access to handwashing facilities and safe drinking water, and adequacy of waste management in HCFs in Kamwenge District, Uganda. Our HCF assessments included water sources and treatment, the availability of hand washing and drinking water stations, and tests of water from HCF sources and a sample of drinking and handwashing stations for *Escherichia coli*. Of 62 HCFs surveyed, 30 (48%) were public and 32 (52%) were private. Outpatient services were provided by all HCFs and inpatient services by 42 (67%), including 30 (94%) private HCFs. The main water source was classified as improved for 53 (85%) HCFs; water sources were on premises in 32 (52%) HCFs. Water was unavailable from the main source for  $\geq 3$  months per year in 16 (26%) HCFs. Water was always available in patient care areas in 19 (31%) HCFs. Hand washing stations were observed in 56 (92%) of 62 HCFs. These 56 HCFs had a total of 159 patient care areas, and 99 (62%) usable handwashing stations (defined as having water and soap present, and no broken parts). While 32 (51%) of 62 HCFs reported usually having drinking water for staff and patients, 23 (38%) had drinking water available on interview day. Regular drinking water treatment was reported by 30 (48%) of 62 HCFs, with 16 (53%) reporting chlorination and 14 (47%) boiling. *E. coli* contamination was found in water samples from 17 (39%) of 44 accessible water sources, 2 (13%) of 16 drinking water stations, and 16 of 72 (22%) handwashing stations. Of 62 HCFs, 33 (53%) separated infectious and noninfectious waste, and 10 (16%) disposed of sharps securely. All HCFs burned at least some waste, with 2% using a lined pit for disposal. Most HCFs lacked access to reliable supplies of water for handwashing and drinking, and had inadequate waste management practices. Achievement of the SDG for HCFs in Kamwenge District will require substantial WASH investments.

## 686

### EVALUATION OF A LARGE-SCALE DISTRIBUTION OF WATER FILTERS IN WESTERN PROVINCE, RWANDA

Miles A. Kirby<sup>1</sup>, Corey Nagel<sup>2</sup>, Ghislaine Rosa<sup>3</sup>, Laura Zambrano<sup>1</sup>, Marie Mediatrice Umupfasoni<sup>4</sup>, Florian Ndagijimana<sup>4</sup>, Evan Thomas<sup>5</sup>, Thomas Clasen<sup>1</sup>

<sup>1</sup>Emory Rollins School of Public Health, Atlanta, GA, United States, <sup>2</sup>Oregon Health & Science University, Portland, OR, United States, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>DelAgua Health, Kigali, Rwanda, <sup>5</sup>Portland State University, Portland, OR, United States

Unsafe drinking water is a major cause of death and disease in low-income countries, and interventions to improve water quality within the household can reduce the risks associated with high exposures. However, little is known about the effectiveness of these interventions delivered programmatically at scale. In late 2014, a public-private partnership between the Rwanda Ministry of Health and DelAgua Health, a private social enterprise, distributed and promoted the use of tabletop Lifestraw Family 2.0 water filters in Western Province. Filters were delivered free to the poorest 25% of households (N=101,000) within randomly allocated sectors (administrative units), with the remaining sectors serving as controls. Using two-stage random sampling, we selected 1582 households from 199 villages to assess household-level filter uptake and impacts on water quality and diarrhea in children under 5 years of age. Households

were visited every 4 months over a 12-month period; 94.9% were followed up at visit 1, 91.6% at visit 2, and 89.1% at visit 3. At visits 1, 2, and 3, 94.0%, 93.8%, and 91.7% of households had the filter, and of these, 69.8%, 66.9%, and 58.7% had water respectively. Using a random intercept mixed effects negative binomial model accounting for clustering within villages and households, we found a 77% reduction in thermotolerant coliform contamination in the intervention arm (IRR .23, 95% CI 0.15-0.36,  $p < .001$ ). Using a random intercept mixed effects logistic model adjusting for clustering at village, household, and child levels, caregiver-reported child diarrhea within the previous 7 days was also significantly reduced in the intervention arm (OR 0.60, 95% CI 0.47- 0.76,  $p < .001$ ,  $n = 2345$  children contributing 5925 observations). The results of this trial, the first of a large-scale programmatic household water filter intervention, demonstrate positive household environmental and child health improvements as delivered. However, declining filter usage over the study period suggests continued programmatic engagement and behavior change is necessary to maintain and maximize health benefits.

## 687

### THE EFFECT OF CHRONIC HELMINTH INFECTION ON IGE-MEDIATED ANAPHYLAXIS IN SENSITIZED MICE

Laura E. Kropp, Edward Mitre

Uniformed Services University, Bethesda, MD, United States

Numerous animal studies have reported that helminths can prevent allergic sensitization, yet few have evaluated the effects of infection on pre-existing allergy. We hypothesized that chronic infection would protect against the clinical symptoms of IgE-mediated anaphylaxis in previously sensitized mice. Mice were sensitized by weekly intraperitoneal (IP) injection of either ovalbumin (OVA)/alum or PBS/alum for 3 weeks. At 4 weeks, mice were infected with *Litomosoides sigmodontis* (*L.s.*), a rodent filarial parasite, or mock infected. Mice were challenged IP with OVA during the twelfth week of infection. Following challenge, serum levels of murine mast cell protease 1 (mMCP-1) were significantly lower in sensitized mice that were *L.s.*-infected as compared to mock infected. Additionally, *L.s.*-infected mice that had been previously sensitized exhibited an average drop in core body temperature of 3.5 °C after 30 min, which was significantly less than the 5.0 °C drop observed in sensitized controls. Anaphylaxis was IgE and mast-cell dependent, as mice deficient in FcεRI or mast cells released little to no mMCP-1 and exhibited minimal drops in core body temperature in response to challenge. Experiments suggest that changes in mast cell functionality were central to the protective effect. First, serum levels of OVA-IgE were not altered by *L. sigmodontis* infection. Second, purified mast cells from OVA-sensitized and infected mice released less histamine than OVA-sensitized and mock-infected mice in response to stimulation with anti-IgE. These results suggest that chronic helminth infection protects against anaphylaxis by decreasing allergen-driven mast cell degranulation. Interestingly, 7 weeks of infection with *L. sigmodontis* did not protect against clinical symptoms of anaphylaxis in sensitized mice. Studies are underway to determine the effect of chronicity of infection on anaphylaxis. Last, IL-10 was investigated as a potential mechanism for protection against anaphylaxis at 12 weeks post-infection. IL-10 was not required for protection as IL-10 knockout mice were protected against hypothermia.

## 688

### INTERLEUKIN 13 AND HEDGEHOG SIGNALING PATHWAYS REGULATE FIBROSIS COLLABORATIVELY IN SCHISTOSOMIASIS MANSONI

Thiago de Almeida Pereira<sup>1</sup>, Lee Borthwick<sup>2</sup>, Mariana Verdelho Machado<sup>3</sup>, Guanhua Xie<sup>4</sup>, Paula Vidigal<sup>5</sup>, Izabela Voieta<sup>5</sup>, Vivian Resende<sup>5</sup>, Rafal Witek<sup>6</sup>, José Roberto Lambertucci<sup>5</sup>, Anna Mae Diehl<sup>4</sup>, Thomas A. Wynn<sup>1</sup>

<sup>1</sup>National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Newcastle University, Newcastle,

United Kingdom, <sup>3</sup>Hospital Universitário de Santa Maria, Lisbon, Portugal, <sup>4</sup>Division of Gastroenterology, Duke University Medical Center, Durham, NC, United States, <sup>5</sup>Faculdade de Medicina, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, <sup>6</sup>Thermo Fisher Scientific, Frederick, MD, United States

IL13 and Hedgehog (Hh) signaling pathways have both been implicated in the pathogenesis of schistosomiasis. In this study, we investigated if there is cross-talk between IL13 and Hh pathways in schistosomiasis liver fibrosis. Hh and IL13 signaling were investigated in uninfected healthy transplant donors, hepatointestinal and hepatosplenic patients by qRT-PCR, immunohistochemistry and ELISA. To confirm the association between Hh and IL13 pathways, we investigate the levels of Hh pathway activation in *Schistosoma mansoni* infected wild-type mice, IL13Rα1-/- mice lacking IL13 signaling and TKO (IL-10-/-, IL12p40-/-, IL13Rα2-/-) mice exhibiting enhanced IL13 activity. To investigate the role of IL13 in Hh pathway, primary murine and human Kupffer cells and human hepatic stellate cells were stimulated with recombinant IL13 *in vitro*. To elucidate the role of IL-13 in Hh pathway activation *in vivo*, wild-type mice were injected with GFP or IL13 overexpressing plasmid. Infected mice treated with isotype control or anti-IL13 neutralizing antibody were included to confirm if Hh ligands/transcription factors are dependent on IL13. Patients with severe schistosomiasis had increased IL13 and Hh pathway activity and both pathways correlate with each other and with collagen deposition, fibrosis staging by ultrasound and severity of portal hypertension. Infected TKO mice had more collagen, myofibroblasts, M2 macrophages and Hh pathway activity than infected wild-type mice, infected IL13Rα1-/- mice, and non-infected controls. Infected IL13Rα1-/- mice had lower expression of Ihh, Shh, Dhh, Gli1 and Gli2 than uninfected controls, suggesting that IL13 promotes Hh signaling. IL13 directly induced Hh ligand production by Kupffer cells and induced Gli2 expression in hepatic stellate cells. Overexpression of IL13 *in vivo* demonstrates that Ihh and Dhh are target genes of IL13 signaling. Neutralization of IL13 abrogates Hh ligand production/ activation of Hh pathway and reduced fibrogenesis. IL13-mediated activation of Hedgehog pathway promotes liver fibrosis in schistosomiasis and could be a novel therapeutic target.

## 689

### TRANSCRIPTOMIC-BASED FUNCTIONAL CHARACTERIZATION OF HOST SYSTEMIC ADVERSE EVENTS FOLLOWING LYMPHATIC FILARIASIS TREATMENT

Britt Andersen<sup>1</sup>, Bruce Rosa<sup>1</sup>, Abdoulaye Meité<sup>2</sup>, Christopher King<sup>3</sup>, Makedonka Mitreva<sup>1</sup>, Peter Fischer<sup>1</sup>, Gary Weil<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>Programme national de la lutte contre la schistosomiase, les geohelminthiases et la filariose lymphatique, Abidjan, Côte D'Ivoire, <sup>3</sup>Case Western Reserve University, Cleveland, OH, United States

Lymphatic filariasis (LF) is a neglected tropical disease caused by the nematode parasite *Wuchereria bancrofti*. The primary tool used by the Global Program to Eliminate LF is mass drug administration (MDA), and some 500 million people take the medications each year. Mild to moderate adverse events (AEs) are common after LF treatment, and these pose a challenge for the LF elimination program. To better understand the pathogenesis of AEs, we studied patients from a LF treatment trial in Côte d'Ivoire. Total RNA was extracted from peripheral blood leukocytes collected before and 24h after treatment (when AEs peak). Global RNA sequencing was performed for 9 individuals with systemic AEs and for 9 matched controls without AEs. Differential gene expression analysis (DESeq) identified transcriptional signatures (TS) associated with post-treatment AEs. Out of the 36 sequenced samples, the 9 post-treatment samples from subjects with AEs had a distinct TS ( $P = 0.006$  by clustering analysis); 744 genes were significantly upregulated in this group (post vs pre-treatment, paired). These genes were enriched for many biological pathways that included pro-inflammatory pathways such as TLR and NF-kappa B signaling. Genes upregulated in AEs were also significantly enriched for having STAT1/2/3 transcription factor binding sites indicating

the importance for interferons in the AEs pathogenesis. A computational method to infer leucocyte proportions (CIBERSORT) identified that neutrophil numbers increase while lymphocytes decrease more post-treatment in individuals with AEs compared to people with no AEs, suggesting an AEs stress response. Additionally, a method to compare transcriptional signatures to existing datasets (GeneQuery) matched the AE TS to endotoxin exposure signatures, indicating a possibility for *Wolbachia* lipoprotein to be involved in AE development. This was supported by significant post-treatment increases in plasma LPS Binding Protein (LBP) in individuals with AEs. Improved understanding of the pathogenesis of AEs may lead to improved management or prevention that could increase MDA compliance and hasten LF elimination.

## 690

### PROTECTIVE IMMUNITY WITH HUMANS IS CONSISTENT WITH A DEFINED IMMUNE RESPONSE AGAINST THE TWO LEAD *ONCHOCERCA VOLVULUS* VACCINE CANDIDATES, OV-103 AND OV-RAL-2

Jovvian G. Parakkal<sup>1</sup>, Sonia Jain<sup>1</sup>, Nancy Tricoche<sup>1</sup>, David Abraham<sup>2</sup>, Sara Lustigman<sup>1</sup>

<sup>1</sup>New York Blood Center-The Lindsley F. Kimball Research Institute, New York, NY, United States, <sup>2</sup>Thomas Jefferson University, Philadelphia, PA, United States

*Onchocerca volvulus*, a filarial nematode is an etiologic agent of river blindness that infects approximately 17 million people, mostly in Africa. The current strategy for elimination of *O. volvulus* focuses on controlling transmission through ivermectin-based mass drug administration (MDA) programs. Due to potential ivermectin resistance, the lack of macrofilaricidal activity by ivermectin and the prolonged time line (>20 years) needed for transmission interruption, additional tools are critically needed including the need for a vaccine against onchocerciasis. Ov-103 and Ov-RAL-2 are presently the most promising vaccine candidates for a prophylactic vaccine. The mechanism of protective immunity induced in mice by the adjuvanted Ov-103 and Ov-RAL-2 vaccines appear to be multifactorial with roles for cytokines, chemokines, antibody and specific effector cells. However, the involvement of immune responses against these two larval proteins in the development of protective immunity in humans has not been yet studied. The role of Ov-103 and Ov-RAL2 specific antibodies was determined in two human populations in Cameroon; the putatively immune (PI: Mf- over 5 years) and the infected (INF; Mf+). Both populations have significant cytophilic antibody (IgG1, IgG3) responses to both antigens as measured by ELISA. Moreover, the IgG3 response to both antigens was significantly increased with age (concomitant immunity). Secondly, we analyzed the systemic levels of cytokines/chemokines in plasma of both populations using milliplex magnetic bead assay. We found that cytokines and chemokines associated with monocyte recruitment such as TNF- $\alpha$ , IL-10, IP-10, MCP-1 and MIP-1 $\beta$  were elevated in the plasma of both INF and PI individuals. Finally, we have shown that human mono-specific Ov-103 and Ov-RAL-2 antibodies inhibited 70-80% of molting of L3 larvae *in vitro* (but did not kill) when cultured in the presence of naive human monocytes, suggesting that monocytes and their soluble factors may be associated with protective immunity also in humans.

## 691

### A NOVEL MECHANISM FOR IMMUNE EVASION BY A HUMAN FILARIAL PARASITE

Michael Andrew Kron

Medical College of Wisconsin, Milwaukee, WI, United States

A hallmark of chronic infection with many different species of human parasitic helminths is the development of a relative degree of immunosuppression in the infected host. This phenomenon is believed to represent an evolutionary adaptation of the parasite to promote its survival. Cytokine orthologues have been reported in many different

helminths however until recently, there were no examples of a parasite-derived chemotactic factor that had structural similarity to human chemokines. Herein we report an overview of our research on the first reported example of a parasite "physiocrine" an asparaginyl-tRNA synthetase (BmAsnRS) that has one function intracellularly (aminoacylation of tRNA) and a second novel role in signal transduction when it is transported extracellularly via interaction with interleukin-8 receptors. We have developed a hypothesis of how this enzyme can exert two diverse biological activities based on comparative structural studies of the filarial BmAsnRS. This hypothesis suggests that the mechanism of action of BmAsnRS is different from the physiocrine activities reported in human tRNA synthetase splice variants that are known to exhibit diverse and novel biological activities with the ability to specifically bind to CCR5, CCR3 or IL-8 chemokine receptors.

## 692

### CORD BLOOD ANTI-PARASITE IL-10 AS RISK MARKER FOR COMPROMISED VACCINE IMMUNOGENICITY IN EARLY CHILDHOOD

Indu Malhotra<sup>1</sup>, A. Desiree LaBeaud<sup>2</sup>, Nathan Morris<sup>1</sup>, Maxim McKibben<sup>1</sup>, Peter L. Mungai<sup>1</sup>, Eric Muchiri<sup>3</sup>, Christopher L. King<sup>1</sup>, Charles H. King<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Stanford University, Stanford, CA, United States, <sup>3</sup>Division of Vector Borne and Neglected Tropical Diseases, Nairobi, Kenya

Previous studies have established a significant impact of maternal parasitic infections during pregnancy on infants' subsequent responses to vaccination. The present study investigated how prenatal infections and lymphocyte cytokine profiles at birth relate to antibody responses to standard vaccination against *Haemophilus influenzae* (Hib), diphtheria toxoid (DT), hepatitis B (Hep B) and tetanus toxoid (TT) during infancy. 450 Kenyan women were tested for malaria, schistosomiasis, lymphatic filariasis (LF), and intestinal helminths during pregnancy. Their newborns' responses to malaria blood-stage antigens, soluble *Schistosoma haematobium* worm antigen, and filaria antigens were assessed in cord blood (CB) lymphocytes collected at delivery. The cohort children were then followed biannually to age 36 months after receiving three rounds of standard vaccination given at 6, 10 and 14 weeks of age. Cohort children were tested for absolute levels of IgG against Hib, DT, Hep B, and TT at each visit. In extended analysis of the time series of post-vaccination IgG levels, we noted 4 types of anti-vaccine response profiles among children: Dimension reduction by functional principal component analysis defined two quantitative components that could be used to quantify each child's pattern: PC1, reflecting height of response over time (high versus low), and PC2, reflecting the tendency to cross over from high to low or from low to high. In linking our observed CB cytokine responses to parasite antigens at birth, a highly significant association ( $P < 0.001$ ) was found between augmented anti-helminth IL-10 response to *Schistosoma* and filaria and downward shifts in antibody response, particularly to DT. Overall diminished response (PC1) was seen for DT ( $P = 0.04$  for prenatal *Schistosoma* exposure) and Hep B ( $P = 0.03$  for prenatal filarial exposure), whereas a late decline (PC2) was seen for anti-Hib responses after prenatal helminth exposure ( $P = 0.02$  for LF and  $P = 0.09$  for *Schistosoma*). Further studies are warranted to document whether treatment of these infections during pregnancy can alleviate prenatal parasitic exposure impact on vaccine responses.

**THE IMPORTANCE OF US FOREIGN AID FOR GLOBAL MALARIA CONTROL AND ELIMINATION**

Peter Winskill<sup>1</sup>, Hannah C. Slater<sup>1</sup>, Jamie T. Griffin<sup>2</sup>, Azra C. Ghani<sup>1</sup>, Patrick G. Walker<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Queen Mary University of London, London, United Kingdom

The President's Malaria Initiative is a leading global funder of malaria control interventions. In the period 2005-2015 PMI contributed over \$4.4 billion dollars to malaria control in 21 countries. This constitutes a significant proportion of the global malaria budgetary envelope. We present a case study detailing the past impact and future projected impact that PMI has had on malaria control and the potential synergies that have arisen due to PMI investment. Using an established malaria transmission model we have estimated the past and future global trajectories for malaria under different funding scenarios. We estimate that, since its inception in 2005 PMI has prevented 150 million malaria cases and saved 838 thousand lives. Ongoing investment could avert an extra 131 million cases saving a further 614 thousand lives over the next four years. PMI investments are highly cost effective. Our estimate of \$124 (\$69 - \$775 range across African countries) per DALY averted is significantly below the WHO threshold for cost-effectiveness in those countries. We highlight the impact that any reduction in future PMI funding could have both in terms of the reduction in direct prevention of malaria, but also on the capacity of health systems to respond to increased caseloads. Reduced caseloads due to interventions funded by PMI has knock-on beneficial effects for country health systems, saving an estimated further \$145 million over the period 2017-2020.

## 694

**ESTIMATING THE EFFECT OF HEALTH SYSTEMS ON CHILDHOOD MORTALITY IN SUB-SAHARAN AFRICA FROM 1996-2013**

Rebecca Anthopolos<sup>1</sup>, Ryan Simmons<sup>2</sup>, Wendy Prudhomme O'Meara<sup>2</sup>

<sup>1</sup>Rice University, Houston, TX, United States, <sup>2</sup>Duke University, Durham, NC, United States

Approximately 6 million children die each year before their fifth birthday. The majority of post-neonatal deaths are due to infectious causes such as diarrhea, malaria, and pneumonia, all of which can be effectively prevented or treated with cost-effective interventions delivered through even very basic health facilities. We hypothesize that access to these life-saving interventions may be limited by the health systems that deliver them and therefore sought to understand the role of supply-side factors on childhood mortality. First, we examine the relationship between survival beyond 59 months of age in Kenya and three domains of health services; geographic distribution of health facilities, quality of services, and cost of services. Using birth history data from nearly 2 decades, we assembled a retrospective cohort of 81,000 children and describe the health systems context of each child using Service Provision Assessments representative of the province at the time of a child's birth. We find significant geographic heterogeneity in survival; children in Nyanza experience double the average risk of death while residence in Central and Nairobi conferred a survival advantage. These differences can be partially explained by differences in distribution of health facilities and fees for sick child visits. Higher per capita density of health facilities resulted in a 25% reduction in the risk of death (HRR=0.73, 95%CI:0.58 to 0.91) and accounted for 30% of the between-province heterogeneity in survival. User fees for sick-child visits increased risk by 30% (HRR=1.30, 95%CI:1.11 to 1.53). We did not find an effect of the number and training of clinical staff on survival, perhaps indicating that personnel are not the limiting factor in delivering adequate care. We extend this investigation to describe the relationship between health services and child survival in seven countries in sub-Saharan Africa. Our preliminary results implicate health systems

constraints in child mortality, quantify the contribution of specific domains of health services, and suggest priority areas for improvement to accelerate reductions in child mortality.

## 695

**INFLUENZA VACCINE KNOWLEDGE AND ACCEPTABILITY**

Arlene Calvo<sup>1</sup>, Rosalba Gonzalez<sup>2</sup>, Juan Miguel Pascale<sup>2</sup>, Morgan Hess-Holtz<sup>1</sup>, SC Kaydos-Daniels<sup>3</sup>, Eduardo Azziz-Baumgartner<sup>4</sup>, Wilfrido Clara<sup>4</sup>, Julio Armero<sup>5</sup>, Nestor Sosa<sup>2</sup>

<sup>1</sup>University of South Florida, Panama, Panama, <sup>2</sup>Gorgas Memorial Institute, Panama, Panama, <sup>3</sup>Centers for Disease Control and Prevention, Guatemala, GA, United States, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>Instituto Nacional de Salud, El Salvador, El Salvador

Vaccination against seasonal influenza has been associated with a decrease in the risk of adverse pregnancy outcomes. Vaccination of pregnant women offers secondary protection to infants under 6 months of age from influenza illness. In 2012, the WHO Strategic Group of Experts recommended influenza vaccination to pregnant women. We administered a knowledge, attitudes, beliefs, and behaviors (KABB) questionnaire to assess the acceptability of this recommendation to a cohort of pregnant women from 2 peri-urban health centers in Panama and El Salvador. From October 2014 - March 2017, 1708 participants completed the questionnaire at the time of survey administration, 75% (n=1281; 95%CI: 0.73 - 0.77) of participants reported they had received the influenza vaccine for the current season. Interview takes place usually at the beginning of enrolment. Coverage was 81% (n=1391 95%CI: 0.80-0.83) at the end of pregnancy. More than half (60%; n=1026; 95%CI: 0.58-0.62) of participants had heard of influenza; 60% (n= 1035; 95% CI: 0.58-0.63) believed they were at risk for influenza; and, 90% (n=1545; 95% CI: 0.89 - 0.92) agreed pregnant women should be vaccinated against influenza. The majority considered vaccines to be safe (81%, n=1389 95% CI: 0.79-0.83) and without harmful long-term effects (58%, n=993; 95% CI: 0.56-0.60). When asked, "During your pregnancy, what would be the main reason why you would not get vaccinated against influenza" participants who did not receive the influenza vaccine before giving birth responded: lack of doctor or nurse recommendation (48%, n=148), concern about the safety and side effects of the vaccine (12%; n=39), "don't know" (8%; n=26), not knowing where to get the vaccine (5%, n=16), never getting sick (4%, n=14), and other reasons (23%, n=74). Influenza vaccination coverage among health center attendees and KABB results suggest the acceptability among pregnant women in Panama and El Salvador. Public health officials may be able to further protect pregnant women and their babies by ensuring physicians consistently recommend and educate about influenza vaccine, and building-on the existing culture of vaccination.

## 696

**ARE ORAL CHOLERA VACCINES COST-EFFECTIVE AND AFFORDABLE IN DHAKA, BANGLADESH? COST-EFFECTIVENESS OF ORAL CHOLERA VACCINE INTRODUCTION IN DHAKA, BANGLADESH**

Ann Levin<sup>1</sup>, Denise DeRoeck<sup>2</sup>, Dennis Chao<sup>3</sup>, Jahangir Khan<sup>4</sup>, Abdur R. Sarker<sup>5</sup>, Mohammed Ali<sup>6</sup>, Firdausi Qadri<sup>5</sup>

<sup>1</sup>Levin and Morgan LLC, Bethesda, MD, United States, <sup>2</sup>Independent, Waltham, MA, United States, <sup>3</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>6</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Cholera remains a serious public health problem in developing countries, and can be either endemic or epidemic. Cholera epidemics are often associated with humanitarian crises such as floods, other epidemics, population displacement or armed conflict. Vaccination with oral cholera

vaccine (OCV) has been shown to be an effective intervention to prevent cholera in areas with endemic and epidemic cholera in the short- and medium term until improvements in access to clean water and sanitation can be ensured. The cost-effectiveness of introducing oral cholera vaccine in populations at high-risk of cholera in Dhaka in Bangladesh from 2016-2025 is estimated in this presentation. The effectiveness of introducing oral cholera vaccination in Dhaka City was estimated through modeling the number of cases of cholera that would be averted with and without vaccination. To identify areas in Dhaka at high risk of cholera, we analyzed data from the laboratory surveillance of 2% of hospitalized ICDDR,B diarrhea patients in Dhaka from 2011 to 2015. To estimate the impact of different vaccination targeting strategies on the incidence of cholera in this population over ten years, we used a mathematical model that simulates the dynamics of cholera transmission. To estimate the cost of vaccination, we used data from the pilot ICDDR,B OCV introduction in Mirpur, Dhaka. We estimated the net cost of introducing the vaccine through subtracting the cost of treating the disease from the cost of implementation for three age groups: 1-4 years, 1-14 years and all persons greater than 1 year. We estimated the cost per case averted, cost per death averted and cost per DALY averted for each age group. We also conducted univariate sensitivity analysis. In Bangladesh, the results of dividing the net vaccination costs by DALYs averted for each vaccination strategy and vaccine vial size was estimated. The option of vaccinating 1-14 year olds is the most cost-effective, with a cost per DALY averted of \$479 and \$674 for one and ten-dose vial sizes, respectively. The study shows that introduction of oral cholera vaccine is cost-effective and affordable in high risk areas of Dhaka.

## 697

#### VALIDITY OF A MINIMALLY INVASIVE AUTOPSY TOOL FOR CAUSE OF DEATH DETERMINATION IN PEDIATRIC DEATHS FROM SUB-SAHARAN AFRICA

Quique Bassat<sup>1</sup>, Paola Castillo<sup>2</sup>, Juan Carlos Hurtado<sup>2</sup>, Miguel J. Martínez<sup>3</sup>, Mamudo R. Ismail<sup>4</sup>, Carla Carrilho<sup>4</sup>, Khátia Munguambe<sup>5</sup>, Clara Menéndez<sup>6</sup>, Jaume Ordi<sup>3</sup>

<sup>1</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhica; ICREA, Barcelona, Spain, <sup>2</sup>Barcelona Institute for Global Health, Barcelona, Spain, <sup>3</sup>Barcelona Institute for Global Health; Hospital Clínic de Barcelona, Barcelona, Spain, <sup>4</sup>Hospital Central de Maputo; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>5</sup>Centro de Investigação em Saúde de Manhica; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>6</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhica; CIBERESP, Barcelona, Spain

In recent decades, the world has witnessed unprecedented progresses in child survival. However, our knowledge of what is killing nearly six million children annually in low and middle income countries remains poor, partly because of the inadequacy and reduced precision of the methods currently utilized in these settings to investigate causes of death. The minimally invasive autopsy (MIA) approach has been proposed as an adequate and more acceptable substitute to the complete diagnostic autopsy (CDA) for cause of death investigation in poor settings. The validity of the MIA approach in determining the cause of death was assessed in 54 post-neonatal pediatric deaths in a referral hospital of Mozambique by comparing the results of the MIA with those of the CDA. Concordance between the categories of diseases obtained by the two methods was evaluated by the Kappa statistic and the sensitivity, specificity, positive and negative predictive values of the MIA diagnoses were calculated. A cause of death was identified in all cases in the CDA and in 52/54 (96%) of the cases in the MIA, with infections and malignant tumors accounting for the majority of diagnoses. The MIA categorization of disease showed a substantial concordance with the CDA categorization (Kappa = 0.70, p-value < 0.0001) and sensitivity, specificity and overall accuracy were high. The ICD-10 diagnoses were coincident in up to 75% (36/48) of the cases. The MIA allowed the identification of the specific pathogens deemed responsible for the death in 25/32 (78%) of all deaths of infectious origin. Discrepancies between the MIA and the CDA regarding

individual diagnosis could be minimized with the addition of some basic clinical information such as those ascertainable through a verbal autopsy or clinical record. The MIA showed a substantial performance for cause of death identification in this series of pediatric deaths in Mozambique. This minimally invasive approach, simpler and more readily acceptable than the disfiguring CDA could provide robust data for CoD surveillance specially in resource-limited settings, which can be helpful to guide child survival strategies in the future.

## 698

#### EMPIRICAL ESTIMATES OF DISABILITY BURDEN OF A SYMPTOMATIC DENGUE EPISODE

Donald S. Shepard<sup>1</sup>, Yara A. Halasa<sup>1</sup>, Wu Zeng<sup>1</sup>, Laure Durand<sup>2</sup>, Laurent Coudeville<sup>2</sup>

<sup>1</sup>Brandeis University, Waltham, MA, United States, <sup>2</sup>Sanofi Pasteur, Lyon, France

Disability weights are critical to assess the cost-effectiveness of dengue control interventions, but existing estimates are few and variable. To generate robust estimates, we combined a meta-analysis and original data from Puerto Rico for acute episodes, and a model for chronic (persistent) dengue, which leads to depression, fatigue and other symptoms. The meta-analysis searched major data bases for empirical studies through 2016 with "dengue" combined with "quality of life," "disability," or similar terms in 4 languages. The Puerto Rico study was based on detailed retrospective interviews with 101 (69 hospitalized and 32 ambulatory) patients with laboratory-confirmed dengue across the island. To compute the disability-adjusted life year (DALY) burden for acute episodes, we fit the extent of disability by day of illness (where 0 denoted no disability and 1 disability equivalent to death) to reported data and computed the area under this disability curve. The model for chronic dengue was based on a prevalence regression (C Tiga et al, AJTMH, 2016) and the disability weight for "major depressive disorder, mild episode" (J Salomon et al, Lancet, 2015). The meta-analysis found 5 published studies. Results are presented as means ± standard errors. The Puerto Rico study found: durations (in days) 15.31±0.99 (all cases), 12.13±1.26 (ambulatory cases), 16.80±1.30 (hospitalized cases); DALY per episode 0.0174±0.0012 (all cases), 0.0150±0.0017 (ambulatory cases), 0.0185±0.0016 (hospitalized cases); disability weights per day 0.4105±0.0145 (all cases), 0.4292±0.0275 (ambulatory cases), 0.4018±0.0170 (hospitalized cases). The model for persistent dengue found 0.092 person years and a DALY burden of 0.0133±0.0026 per dengue episode. Combining all studies, ambulatory and hospitalized episodes have average DALY burdens per episode of 0.0116±0.0026 and 0.0148±0.0053, respectively (acute phase) and 0.0249 ±0.0037 and 0.0281±0.0034, respectively (both phases). These results are within the broad range of previous estimates, but offer more systematic estimates of burden for cost-effectiveness analyses and burden of disease estimates.

## 699

#### SATELLITE AND IN SITU CLIMATE DATA MEASUREMENTS AT CHIKUNGUNYA AND DENGUE STUDY SITES IN KENYA

Assaf Anyamba<sup>1</sup>, Richard Damoah<sup>2</sup>, Bryson A. Ndenga<sup>3</sup>, Francis M. Mutuku<sup>4</sup>, Angelle Desiree LaBeaud<sup>5</sup>

<sup>1</sup>Universities Space Research Association/GESTAR and NASA Goddard Space Flight Center, Greenbelt, MD, United States, <sup>2</sup>Morgan State University/GESTAR and NASA Goddard Space Flight Center, Greenbelt, MD, United States, <sup>3</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Nairobi, Kenya, <sup>4</sup>Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya, <sup>5</sup>Department of Pediatrics, Division of Infectious Diseases, Stanford University School of Medicine, Stanford, CA, United States

Understanding climate and ecological conditions associated with the emergence and propagation of vectors of chikungunya and dengue fever is critical to managing and diminishing the burden of these diseases to

populations at risk. As part of the study of the burden of chikungunya and dengue in Kenya, we have been monitoring various climate variables (including rainfall and temperature) by satellite remote sensing and *in situ* measurements at four study locations in Kenya: inland near Lake Victoria and at the south coast of Kenya. The *in situ* measurements are to inform proximate conditions at the study locations while satellite measurements provide a broader regional view of the conditions. We compare the two sets of measurements and find a good temporal correspondence in the evolution of monthly and daily time series especially over the coastal locations. However, we find that in some instances satellite measurements may overestimate rainfall amounts at inland locations and “underestimate” over the coastal locations. This can be attributed to (a) the different rainfall types: orographic vs convective, (b) area (satellite) versus *in situ* (point) measurements and (c) the random nature of daily rainfall. When aggregated at the monthly time scale, we find a high correlation ( $r = \sim 0.9$ ) overall for between satellite estimates of rainfall and *in situ* rainfall measurements at all sites. We also compare these measurements to vector collections and find a good agreement between rainfall and vector population peaks at all locations; however, there is a time lag ( $\sim 1$  month) between peak rainfall and the peak in vectors numbers collected. We conclude for large area surveillance, satellite derived rainfall measurements can be used to monitor conditions for vector emergence especially areas without surface observations.

The development of malaria parasite sexual stages is critical for transmission, yet much remains unknown about how this process is regulated. Recently, epigenetic repression and expression of the transcription factor AP2-G have been shown to play important roles in regulating sexual commitment. However, the mechanisms that release repression and consequently allow gametocyte production are still a mystery. Our previous work demonstrated that *Pfgdv1* is required for gametocyte production. Here, we investigate the temporal relationship between PFGDV1 protein expression and gametocyte production by tagging the 3' end of the endogenous *Pfgdv1* gene with green fluorescent protein (GFP) and a ligand (Shield-1)-stabilized degradation domain (DD). Growing tightly synchronized PFGDV1-GFP-DD parasite in the presence of the stabilizing ligand, GFP expression was observed in a majority of parasites from  $\sim 33$ -42 hours post invasion, while in the ligand's absence no GFP expression was observed along with a drastic reduction in gametocyte production and lower transcript levels for AP2-G. To determine when PFGDV1 expression is required for sexual commitment and gametocyte production, PFGDV1-GFP-DD expression was stabilized for discrete time periods and gametocyte production evaluated. Expression was only required during schizogony for optimal gametocyte production following the next cycle of RBC invasion. To evaluate PFGDV1-conditional transcriptional responses during sexual commitment, single cell RNA-seq of developing late asexual blood-stages in the presence or absence of Shield-1 ligand was performed. Using single cell resolution, we identified transcript levels of 27 genes that were significantly up-regulated upon PFGDV1 stabilization. Only two, AP2-G and MSP7-like protein (MSRP1) have previously been associated with gametocytogenesis, while five are predicted to localize to the nucleus, including ALBA1 and DNA-binding chaperone, PF3D7\_1216900. Together these data suggest that PFGDV1 acts upstream of the regulation of AP2-G, prior to the release of gametocyte-committed merozoites.

### LONG-TERM *IN VITRO* CULTURE OF *PLASMODIUM VIVAX* ISOLATES FROM MADAGASCAR MAINTAINED IN *SAIMIRI BOLIVIENSIS* BLOOD

Rajeev K. Mehlotra<sup>1</sup>, D'Arbra Blankenship<sup>1</sup>, Rosalind E. Howes<sup>2</sup>, Tovonahary A. Rakotomanga<sup>3</sup>, Thierry Franchard<sup>3</sup>, Brune Ramiranirina<sup>3</sup>, Stephanie Ramboarina<sup>3</sup>, Marlin Linger<sup>3</sup>, Melinda Zikursh<sup>1</sup>, Arsène Ratsimbasa<sup>3</sup>, Peter A. Zimmerman<sup>1</sup>, Brian T. Grimberg<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States,

<sup>2</sup>University of Oxford, Oxford, United Kingdom, <sup>3</sup>National Malaria Control Programme, Antananarivo, Madagascar

*Plasmodium vivax* is the most prevalent human malaria parasite and is likely to increase proportionally as malaria control efforts reduce the impact and prevalence of *P. falciparum*. Despite the prominence of *P. vivax* as a major human pathogen, vivax malaria qualifies as a neglected and under-studied tropical disease. Significant challenges bringing *P. vivax* into the laboratory have limited the study of this parasite's red blood cell (RBC) invasion mechanism, blood stage development, gene expression and genetic manipulation. Patient isolates of *P. vivax* have been collected and cryopreserved in the rural community of Ampasimpotsy, located in the Tsiroanomandidy Health District of Madagascar. Periodic, these cryopreserved isolates are transported to the country's National Malaria Control Program laboratory in Antananarivo preceded onward sample transfer to laboratories at Case Western Reserve University, USA. There, the *P. vivax* isolates have been cultured through propagation in RBCs of *Saimiri boliviensis*. For the four patient isolates studied to-date the average time interval between sample collection and *in vitro* culture has been 509 days (range 166 to 961 days). The average time in culture, continuously documented by light microscopy, has been 111 days; Pv AMP2014.01 was continuously propagated for 233 days. Further studies show that the *P. vivax* parasites propagated in Saimiri RBC retain their ability to invade human RBCs. Long-term culture of *P. vivax* is possible in RBCs of *Saimiri boliviensis*. These studies provide an alternative to propagation of *P. vivax* in live animals that are becoming more restricted. *In vitro* culture of *P. vivax* in Saimiri RBC provide new strategies for investigating the molecular and cellular biology of this important malaria parasite.

## 702

### AN EX VIVO GAMETOCYTE CULTURE METHOD TO DETERMINE *PLASMODIUM FALCIPARUM* GAMETOCYTE COMMITMENT IN THE PATIENT'S PERIPHERAL BLOOD

Surendra K. Prajapati<sup>1</sup>, Ruth Ayanful-Torgby<sup>2</sup>, Fetsus K. Acquah<sup>2</sup>, Elizabeth Cudjoe<sup>2</sup>, Courage Kakaney<sup>2</sup>, Jones A. Amponsah<sup>2</sup>, Evans Obboh<sup>3</sup>, Andrea Arku<sup>2</sup>, Benjamin K. Abuaku<sup>2</sup>, Linda E. Amoah<sup>2</sup>, Kim C. Williamson<sup>1</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Noguchi Memorial Institute for Medical Research (NMIMR), University of Ghana, Accra, Ghana, <sup>3</sup>University of Cape Coast, Cape Coast, Ghana

Malaria transmission via mosquito is vital to spread the disease, however the factors influencing the production of the sexual stage parasites required have been challenging to define. *In vitro*, commitment to sexual differentiation in *P. falciparum* begins during the trophozoite to schizont transition and leads to the production of gametocyte-committed merozoites. However, distinct gametocyte-specific morphological differences are not apparent for 4-5 days after red blood cell (RBC) invasion. By this time in the human host the early gametocyte stages have already sequestered and cannot be observed in the peripheral blood. Consequently, currently there is no way to monitor gametocyte production until 10-12 days after invasion when mature stage V gametocytes are released into the circulation. To begin to investigate this hidden stage and identify early gametocyte specific biomarkers, we developed an ex

vivo gametocyte culture method to quantify gametocyte-committed parasites circulating in malaria patients' blood. Blood samples were obtained from uncomplicated malaria patients in Ghana (n=170) just prior to treatment and cultured for 8 days in the presence or absence of N-acetyl glucosamine (NAG) to track gametocyte development by counting Giemsa-stained slides (~20,000 RBCs/slide). As seen *in vitro* with strain NF54 parasites, stage II-III gametocytes were observed by Day(D) 4 and continued to mature to stages III-V by D8 in 66% of the samples (n=112). There was good correlation between the D4 and D8 gametocytemias as well as D8 gametocytemia and D8 transcript levels of mature gametocyte marker, Pfs25. Based on the D0 parasitemia, the gametocyte conversion rate ranged from (0.02% to 88%) with a median of 1.72%. Preliminary data suggest that conversion is not related to age, hematocrit or WBC cell count. The gametocyte densities detected were all 100 times higher than the theoretical limit of ~2 gametocyte/ $\mu$ l needed to infect mosquitoes indicating the robust infectious production of the parasite. This assay provides an important tool to directly evaluate both the host and parasite factors that contribute to gametocyte production.

### 703

#### NOT1-G IS A NOVEL MEMBER OF THE CAF1/CCR4/NOT COMPLEX THAT IS ESSENTIAL FOR HOST TO VECTOR MALARIAL TRANSMISSION

Kevin J. Hart, Michael P. Walker, Scott E. Lindner

The Pennsylvania State University, University Park, PA, United States

The transmission of the malaria parasite between mosquitoes and mammals requires translational repression to ensure that only the proper proteins are expressed at the right time, while still allowing the parasite to prepare the mRNAs it will need for the next developmental stage. With relatively few known specific transcription factors (ApiAP2 family) that may specifically initiate gene transcription, *Plasmodium* parasites also regulate the stability and turnover of transcripts to provide more comprehensive gene regulation. We and others have demonstrated that members of the CAF1/CCR4/NOT complex have specific and important functions in both the development of the parasite (CAF1) and in its host-to-vector transmission (CCR4-1). In model eukaryotes, this large multi-functional complex uses its largest component, NOT1, as a scaffold for its effector proteins, such as CAF1 and CCR4-1. Here, in stark contrast to most other eukaryotes, we have bioinformatically identified that *Plasmodium* species encode two putative NOT1 proteins. These are only detectable in *Plasmodium* and in the related *Theileria* parasite genome, but are absent in all others, indicating that specific functions may be restricted to this clade of apicomplexans. We find that in *Plasmodium* NOT1 is essential as it is in model organisms, but that *not1-g* parasites produce male gametocytes that cannot activate nor be transmitted to mosquitoes. Interestingly, both NOT1 proteins are expressed throughout the life cycle and yet do not appear to have redundant functions. We hypothesize that NOT1 and NOT1-G associate with distinct accessory factors that determine their function and are now determining this using a proximity based biotinylation approach. Ultimately the NOT1-G complex likely affects mRNAs important to gametocytogenesis and/or gametocyte activation, and we are currently investigating this using comparative transcriptomics. Thus, *Plasmodium* has evolved a paralog of NOT1 that is essential for transmission and plays an important role in the parasites utilization of RNA regulation for this critical process.

### 704

#### PB102, A NOVEL GENE ESSENTIAL FOR FEMALE FERTILITY OR OOKINETE MATURATION OF MURINE MALARIA PARASITE, PLASMODIUM BERGHEI

Akimasa Maeta, Makoto Hirai, Toshiyuki Mori, Toshihiro Mita

Juntendo University, Tokyo, Japan

A portion of blood stage malaria parasites (~10%) differentiates into male and female gametocytes. Both sex gametocytes fertilize and then

differentiate into ookinetes in the *Anopheles* mosquito midgut. However, the mechanisms of these processes have only been partially clarified. The aim of our present study is to elucidate the molecular mechanisms of *Plasmodium* sexual reproduction. We first screened a set of genes expressed in gametocytes using microarray data of the rodent malaria parasite *P. berghei*. We then produced a series of knockout (KO) parasites for each gene candidate and found a potential candidate gene, *Pb102*, for the regulation of sexual reproduction. Database search revealed that *Pb102* is a novel gene and its orthologue is exclusively conserved in *Plasmodium*, suggesting an indispensable function in the genus. *Pb102*-KO parasites were able to grow and differentiate into morphologically normal gametocytes. However, no mature ookinete was produced *in vitro* fertilization assay, very likely to be involved in gamete fusion or ookinete maturation. To test sex-specific function of *Pb102*, we performed cross-fertilization assay between *Pb102*-KO and *Nek4*-KO (female sterile) or *CDPK4*-KO (male sterile). *Pb102*-KO gametes were able to fertilize with the male sterile gametes and develop into ookinetes. In contrast, no ookinete was produced in cross-fertilization assay with the female sterile gametes. These findings indicate that *Pb102* has female-specific function related to gamete fusion or ookinete maturation. Since *Pb102* contains several potential functional domains, we are producing *P. berghei* parasites expressing a series of truncated *Pb102*s to clarify the role of these domains. We are also generating a transgenic parasite having a *Pb102* with C-terminal GFP to further elucidate subcellular localization. These results will be presented at the Annual meeting.

#### A LONGITUDINAL COHORT STUDY OF MALARIA EXPOSURE AND CHANGING SEROSTATUS IN A MALARIA ENDEMIC AREA OF RURAL TANZANIA

Ryan Simmons<sup>1</sup>, Leonard Mboera<sup>2</sup>, Marie Lynn Miranda<sup>3</sup>, Alison Rand<sup>4</sup>, Gillian Stresman<sup>4</sup>, Elizabeth Turner<sup>1</sup>, Randall Kramer<sup>1</sup>, Chris Drakeley<sup>4</sup>, Wendy Prudhomme O'Meara<sup>1</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Rice University, Houston, TX, United States, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Measurements of antimalarial antibodies are increasingly used as a proxy for transmission intensity. Most serological surveys are based on the use of cross-sectional data that, when age-stratified, approximates historical patterns of transmission within a population. Comparatively few studies leverage longitudinal data to explicitly relate individual infection events with subsequent antibody responses. We examined the incidence of seroconversion and seroreversion events for two *Plasmodium falciparum* asexual stage antigens (MSP-1, AMA-1), using 3 annual measurements of 691 individuals from a cohort in a malaria endemic area of rural east-central Tanzania, in a mixed-effects logistic regression model. We also modeled the respective antibody titer distributions directly using mixed-effects linear regression models. While we found the expected population-level relationship between seroprevalence and infection incidence, on an individual level the relationship between detected infections and the antibody response was complex. Changes in serostatus for each antigen were correlated, but a seropositive status for one does not increase the odds of converting for the other. There was no evidence of an age effect on the odds of a conversion or reversion event. In the titer models, MSP-1 antibody responses were more dynamic in response to the occurrence and resolution of infection events than AMA-1, while the latter was more correlated with consecutive infections. The MSP-1 antibody response to an observed infection seemed to decay faster over time than the corresponding AMA-1 response. While our population-level results concur with previously published seroepidemiological surveys, our individual-level results highlight the more complex relationship between detected infections and antibody dynamics than can be observed using cross-sectional data alone. The longitudinal analysis of serological data may

provide a powerful tool for examining the relationship between infection events and the corresponding immune response, thereby improving our ability to rapidly assess the success or failure of malaria control programs.

## 706

### SEASONALITY AND TRENDS OF MALARIA EPIDEMIC IN UNDER-FIVE-YEAR CHILDREN IN LAKESHORE COMPARED TO HIGHLAND AREAS IN ZOMBA DISTRICT, MALAWI

Precious L. Hajison<sup>1</sup>, Bonex W. Mwakikunga<sup>2</sup>, Don P. Mathanga<sup>3</sup>, Shingairai A. Feresu<sup>4</sup>

<sup>1</sup>*Invest in Knowledge, Zomba, Malawi*, <sup>2</sup>*Council for Scientific and Industrial Research, Pretoria, South Africa*, <sup>3</sup>*College of Medicine, University of Malawi, Blantyre, Malawi*, <sup>4</sup>*University of Pretoria, School of Health Systems and Public Health, Pretoria, South Africa*

Malaria infection was seasonal and varies according to geographic location in Malawi, this may influence the number of reported malaria cases among children in different hospitals and areas. This study assessed the seasonality, trends and risk factors of malaria in under-five-year-children originating from highlands compared to those from lakeshore in Zomba district, Malawi. A cross section study was done and secondary monthly data on outpatient hospital visitation for n=550206 under five children were extracted from Zomba health management information system for the period of 2010 to 2015. Meteorological data on Temperature, Rainfall and Humidity was collected for the same period. Risk factor variables for malaria were drawn from exit interviews. Guardians for eligible under five children from 4 randomly selected health facilities, 2 from highland and lakeshore respectively were interviewed. Grouped data logistic regression test was done to come up with malaria risk factors. STATA 13 was used for data analysis. Outpatient malaria cases accounted for 61.4% prevalence and 88% morbidity for Zomba district. Malaria transmission was observed throughout the year with minimal difference between the seasons in both lakeshore and highlands. Malaria diagnosis in the under-five children was less likely if caregiver had knowledge on anti-malaria prescription [adjusted odds ratio (AOR) =0.71, 95% CI 0.64 to 0.80]; if caregiver owned a bed net AOR=0.33 95% CI 0.15 to 0.72; and if the caregiver attended health talks on malaria prevention AOR= 0.45, 95% CI 0.25 to 0.79. People who did not clear weeds regularly, were more likely to have their children diagnosed with malaria, AOR= 1.78, 95% CI 1.20 to 2.63. Annually, malaria was more common in February, (which is spring) in Zomba district, while lowest infections were in the month of August. Intensifying health education on malaria preventive measures will reduce the malarial burden in Malawi. This study affirms that malaria in Zomba district is perennial and does not follow rainfall seasonality both in highlands and lakeshore areas.

## 707

### ONE HUNDRED YEARS OF MALARIA IN PREGNANCY SURVEYS: A SYSTEMATIC REVIEW OF SURVEYS CONDUCTED BETWEEN 1915 AND 2015

Anna M. van Eijk, Jenny Hill, Feiko O. Ter Kuile  
*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

In 1915, Clark published the first survey of malaria (placental) in Panama and the first articles to report on differences in malaria prevalence by gravidity appeared in the 1950s. To examine changes in epidemiology of malaria during pregnancy, we extracted survey data on malaria infection during pregnancy collected by blood smear published over the last century. We used random effects meta-analysis to examine pooled prevalence (PP) during pregnancy by region, over time, by trimester, and gravidity where data were available. Malaria prevalence during pregnancy varied widely and was lowest in South and Central America (PP 0%, 95% CI 0-1%, N=3 studies, 1973-2013), and highest in Nigeria, the country with the highest number of surveys (PP 42%, 36-49, N=112, 1957-2015). In some locations with more than one survey a decrease in malaria prevalence was seen over time (e.g. Lagos, Nigeria: 73% in 1997 to 6% in 2013; Madang Province, Papua New Guinea: 30% in 1986 to 7% in 2011; Mangochi

district, Malawi: 44% in 1988 to 11% in 2012). The prevalence among pregnant women was 1.76 times higher (95% 1.54-2.01, N=29 studies) than among non-pregnant women, 1.60 times (1.51 -1.70) higher among primigravidae compared to multigravidae (N=146) and 1.35 times (1.26-1.45) higher compared to secundigravidae (N=82). Factors associated with the increased risk among primigravidae using meta-regression included study region (less in Asia and the Pacific), and time period (highest in studies before 1990). The prevalence was similar in the first and second trimester (prevalence ratio 0.98, 0.91-1.06, N=76), and higher in the second compared to third trimester (prevalence ratio 1.16, 1.09-1.23, N=80). Further analyses will be presented at the meeting.

## 708

### PREDICTORS OF DETECTING ANTIMALARIALS DRUGS IN THE BLOOD IN COMMUNITY SURVEYS IN TANZANIA

Joanna Gallay<sup>1</sup>, Emilie Pothin<sup>1</sup>, Dominic Mosha<sup>2</sup>, Martin Zuakulu<sup>2</sup>, Erick Lutahakana<sup>2</sup>, Laurent Decosterd<sup>3</sup>, Blaise Genton<sup>1</sup>

<sup>1</sup>*Swiss Tropical and Public Health Institute, Basel, Switzerland*, <sup>2</sup>*Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania*, <sup>3</sup>*Division and Laboratory of Clinical Pharmacology, Department of Laboratories, University Hospital, Lausanne, Switzerland*

Measuring antimalarials in the blood can provide accurate estimate of overall levels of circulating drugs, an important driver of emergence of parasite resistance. The aim of the study was to estimate the prevalence of individuals with antimalarials in their blood and to determine the predictors of detecting antimalarials in the blood. Community-based x-sectional surveys were conducted in 2015 in three regions of Tanzania with different levels of malaria endemicity. Information on demographics, history of fever and drug use were collected as well as dried blood spot samples for further antimalarial analysis by LC-MS/MS. Besides, RDT and treatment availability were investigated through health facility and drug stores surveys. Multilevel mixed effects logistic regression models were used to estimate odds ratios for having lumefantrine (LF), sulfadoxine-pyrimethamine (SP) or any antimalarial in the blood. The survey included 6485 individuals. Prevalence of antimalarials in the blood was 21% (1344/6485). In multivariate analysis, the significant predictors for having any antimalarials in the blood were living in places where a high proportion of drug shops had antimalarials in stock (OR=2.8), followed by living in highly endemic regions (OR=2.9 for Mwanza and 2.0 for Mtwara compared to Mbeya), having had a febrile episode in the previous 2 weeks (OR=2.1), living close to a health facility (p<0.01) and being of young age (p<0.05). The predictors for having LF in the blood were the same plus living in a rural district (OR=5.9) and sleeping under a bednet (OR=1.3). The predictors for having SP in the blood were being pregnant (OR =3.9), being of old age (p<0.001) and having had a febrile episode in the previous two weeks (OR=1.6). These data show that the amount of antimalarial drug pressure is high in the population. The main predictors of antimalarial detection in the blood were expected. Measuring drug concentrations in the blood could provide a new tool to monitor drug use, which should help better targeting specific interventions, and hence decrease drug pressure.

## 709

### EVALUATING THE IMPACT OF THE EXPANSION OF MALARIA CONTROL INTERVENTIONS IN KENYA, 2003-2015

Agneta Mbithi<sup>1</sup>, Rebecca Kiptui<sup>2</sup>, Hellen Gatakaa<sup>1</sup>, Abdisalan Noor<sup>3</sup>, Christie Hershey<sup>4</sup>, Ann Buff<sup>5</sup>, Waqo Erjesa<sup>2</sup>, Yazoume Yé<sup>6</sup>

<sup>1</sup>*MEASURE Evaluation PIMA, Nairobi, Kenya*, <sup>2</sup>*National Malaria Control Program, Nairobi, Kenya*, <sup>3</sup>*KEMRI-Wellcome Trust Programme, Nairobi, Kenya*, <sup>4</sup>*United States Agency for International Development, U.S. President's Malaria Initiative, Washington, DC, United States*, <sup>5</sup>*U.S. President's Malaria Initiative-Kenya, Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, U.S. Centers for Disease*

*Control and Prevention, Atlanta, GA, United States, <sup>6</sup>MEASURE Evaluation, Chapel Hill, NC and ICF, Rockville, MD, United States*

With more than \$700 million for malaria interventions in the past decade, Kenya has expanded key malaria interventions. Measuring the impact of these investments will help inform the policies, strategies and activities of Kenya's National Malaria Control Program and its partners. We assessed trends in all-cause childhood mortality (ACCM) against trends in coverage of key malaria interventions and trends in other factors likely to affect child survival. The evaluation included data from nationally representative household surveys conducted between 2003 and 2015 to estimate intervention coverage and malaria morbidity and mortality, stratified by malaria epidemiologic zones. Household ownership of at least one insecticide-treated net (ITN) increased from 6% in 2003 to 63% in 2015. In malaria-endemic and highland epidemic-prone areas, where ITN distribution has been concentrated, ownership over this period increased in the coast-endemic (13% to 73%), highland epidemic-prone (8% to 73%), and lake-endemic (12% to 87%) zones. Use of ITNs increased in the general population (21% to 61%), pregnant women (28% to 73%), and children under five (26% to 69%). The proportion of pregnant women receiving at least two doses of sulfadoxine-pyrimethamine for prevention of malaria in the malaria-endemic zones increased from 22% in 2010 to 56% in 2015. During the evaluation period, ACCM declined from 114 to 52 (54%) deaths per 1,000 live births. The decline was greatest among children living in the malaria-endemic zones: 213 to 64 (70%) deaths per 1,000 live births. Coverage and use of several non-malaria health interventions and socioeconomic factors also improved during the evaluation period. Given these patterns of improvement in key malaria interventions and declines in ACCM in the malaria epidemiological zones, malaria control interventions are likely to have contributed substantially to the decline in ACCM in Kenya.

## 710

### M-HEALTH INNOVATIONS < THEIR CHALLENGES TO MANAGE MALARIA SENTINEL SURVEILLANCE NETWORK IN MADAGASCAR

**Laurence Randrianasolo<sup>1</sup>**, Stephan Randrianasolo<sup>1</sup>, Florian Girond<sup>1</sup>, Léa Randriamampionona<sup>2</sup>, Jocelyn Razafindrakoto<sup>3</sup>, Toky Ramarokoto<sup>1</sup>, Fanjasoa Rakotomanana<sup>1</sup>, Rindra Randremanana<sup>1</sup>, Laurent Kapesa<sup>3</sup>, Arsène Ratsimbasa<sup>2</sup>, Laurence Baril<sup>1</sup>, Patrice Piola<sup>1</sup>

<sup>1</sup>Institut Pasteur de Madagascar, Antananarivo, Madagascar, <sup>2</sup>Ministry of Health Madagascar, Antananarivo, Madagascar, <sup>3</sup>U.S. Agency for International Development Madagascar, Health Population and Nutrition Office (HPN), Antananarivo, Madagascar

Madagascar is a predominantly rural country ranked among the lowest income countries. Access to community health care infrastructure is difficult. Since 2007, a Sentinel Surveillance Network (SSN) has been set up using mobile technology to transmit country-level health data (M-Health). The SSN collects data from community- to hospital structure (108 Community Health Workers, 54 primary health centers and 18 hospitals) to identify malaria and other epidemics. Daily, the integrated SSN system is analyzing reported febrile syndromes including malaria, influenza like illness, dengue like syndrome and diarrhea. In 2015, an Android platform was developed by Malagasy engineers. Short Message System-based applications were used to transmit data from sentinel sites to the Institut Pasteur in Madagascar. In-app text, graphs, and maps are weekly updated to provide feedback to the community- and hospital-based sentinel sites. In addition, a malaria early warning system is available through an interactive web-based system. A standardized multi-criteria alert threshold is used to promptly identify abnormal situations using semi-automatic analysis based on specific algorithms. When an abnormal situation is detected, a check is done by the SSN team (mostly by phone). The epidemic alert is promptly communicated from central (Ministry of Public Health) to district level to ensure a timely response. The SSN performance indicator analysis is regularly performed to ensure system improvement.

However, technological challenges are inherent to the system efficiency to maintain data quality: wireless network disturbance, slow internet speed, health care provider turn-over and need to replace materials. All efforts are made to ensure SSN data completeness and timeliness. From 2015 to 2016, 122/128 (95%) of alerts have been managed by the health district teams. This system is efficient and it will be complementary to the routine epidemiological electronic surveillance which is progressively deployed by the Malagasy Ministry of Health. Technical details on the sentinel surveillance information and communication system will be presented.

## 711

### MAPPING THE TRAVEL PATTERNS OF PEOPLE WITH MALARIA IN BANGLADESH

Chan School of Public Health, Harvard University, Boston, MA, United States, <sup>4</sup>Dev Care Foundation, Dhaka, Bangladesh, <sup>5</sup>Shaheed Suhrawardy Medical College, Dhaka, Bangladesh, <sup>6</sup>BRAC Centre, Dhaka, Bangladesh, <sup>7</sup>National Malaria Control Programme, Dhaka, Bangladesh, <sup>8</sup>Vector-Borne Disease Control, World Health Organization, Dhaka, Bangladesh, <sup>9</sup>Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh, <sup>10</sup>Wellcome Trust Sanger Institute, Hinxton, United Kingdom, <sup>11</sup>Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom

Elimination of malaria in Bangladesh is crucially dependent on effective surveillance, ongoing efficacy of available treatment and a detailed understanding of disease epidemiology. Being adjacent to the Greater Mekong Subregion, Bangladesh is high on the list of possible countries to which artemisinin resistance may spread next but there is little information on international and local movement of people with malaria. We hypothesize that dissemination of malaria and antimalarial resistance could occur through cross border movement and migration of individuals within Bangladesh between highly populated coastal areas around Chittagong and rural Hill Tracts where 90% of the cases are recorded. 2100 unselected patients with malaria of any species were recruited at 109 study sites in 2015-2016 and interviewed including about their travel patterns in the preceding 2 months. This was compared and combined with surveillance data from National Malaria Control Programme (NMCP) and census data. Blood spots were taken to study malaria parasite DNA. Forested hill tract areas in Bandarban District had the highest numbers of malaria cases. *Plasmodium falciparum*, *vivax* and mixed infection were at 74, 16 and 10% respectively. Median age was 20, with 8% children under 5 and 26% aged 5 to 15 years. Males were overrepresented (67%) compared to the census. Farmers (21%) and students (19%) were the top two occupations recorded, with 66 and 47% reporting travel to the forest respectively. 1811 patients reported having travelled, 17% to another district, 1% to another division and 1% to another country. Males aged 25-49 years accounted for 46% of cases visiting forests but only 14% of the study population. Travel patterns were mapped and analysed to identify population groups with high mobility, find nodes of high traffic and ultimately predict possible sources and routes of spread of malaria for targeting by NMCP. Later analyses will include parasite genetic data. Through working in close partnership with NMCP, this improved understanding of the impact of population movement on the spread of malaria and will directly inform malaria elimination strategy in Bangladesh.

### BAKER'S YEAST-BASED INTERFERING RNA LARVICIDES TARGETING *Aedes aegypti*

Limb K. Hapairai<sup>1</sup>, Keshava Mysore<sup>1</sup>, Ying-Ying Chen<sup>2</sup>, David W. Severson<sup>2</sup>, Na Wei<sup>1</sup>, Molly Duman Scheel<sup>1</sup>

<sup>1</sup>Indiana University, South Bend, IN, United States, <sup>2</sup>The University of Notre Dame, South Bend, IN, United States

Novel strategies are needed to control *Aedes aegypti*, a mosquito vector of infectious diseases including dengue, yellow fever, chikungunya, and Zika. RNA interference (RNAi) allows for silencing of gene expression in the target species, but not of genes in non-target species that lack the interfering RNA target sequence. This specificity allows for development of new biorational larvicides to address the increase of insecticide resistance and rising concern for the negative effects of current chemical larvicides on non-target organisms. Baker's yeast, *Saccharomyces cerevisiae*, was engineered to create several strains of yeast that produce short hairpin RNAs corresponding to larval lethal genes. Short hairpin RNAs were inexpensively propagated through yeast cultivation. Two strains that target nervous system development genes were characterized in detail. Feeding *A. aegypti* larvae with the engineered yeasts resulted in silenced target gene expression, disrupted neural development, and up to 100% larval mortality in laboratory trials. Heat inactivated yeasts that were dried into a granular formulation retained larvicidal activity and attracted gravid females to oviposit in lab assays. Field evaluation of these interfering RNA yeast larvicides will soon commence. The low cost of production, lure-and-kill species-specificity, and ease of use of inactivated granular tablet formulations supports the potential use of yeast-based larvicides in integrated mosquito control programs.

713

### FUNCTIONAL DIVERSITY OF *ANOPHELES ALBIMANUS* MICROBIOTA PROVIDES NEW INSIGHTS INTO INSECTICIDE RESISTANCE MECHANISMS

Nsa Dada<sup>1</sup>, Mili Sheth<sup>1</sup>, Kelly Liebman<sup>2</sup>, Jesus Pinto<sup>3</sup>, Audrey Lenhart<sup>1</sup>

<sup>1</sup>United States Centers for Diseases Control and Prevention, Atlanta, GA, United States, <sup>2</sup>California Department of Public Health, Richmond, CA, United States, <sup>3</sup>Instituto Nacional de Salud, Lima, Peru

An understanding of the selective forces leading to evolution of insecticide resistance (IR) is needed to mitigate its threat to malaria vector control. *Anopheles albimanus*, the main coastal malaria vector in Latin America, shows resistance to various insecticides, including organophosphates (OPs). Following evidence of endosymbiont-mediated IR in agricultural pests, and the identification of OP resistance in *An. albimanus*, we hypothesized that bacteria may be contributing to insecticide degradation in resistant mosquitoes. To test this, whole metagenome sequencing was used to characterize the microbiota and its functions in Peruvian *An. albimanus* with differing fenitrothion resistance profiles (resistant, FEN\_Res; susceptible, FEN\_Sus). Results showed higher ( $p < 0.01$ ) proportions of OP-degrading bacteria in FEN\_Res compared to FEN\_Sus, and nine enriched ( $p < 0.05$ ) microbial xenobiotic degradation pathways in FEN\_Res. Predominant bacterial species associated with these pathways in FEN\_Res were; *Klebsiella pneumoniae* (81.2%), *Acinetobacter baumannii* (4.2%), *A. pittii* (1.6%), and *Enterobacter cloacae* (0.7%), all known to degrade OPs. The proportion (%) of bacterial enzyme classes involved in these pathways in FEN\_Res & FEN\_Sus were, hydrolases: 20.1 & 16.3, transferases: 17.8 & 17.9, oxidoreductases: 19.6 & 22.9, lyases: 6.9 & 6.7, isomerases: 0.4 & 0.7, and others: 12.6 & 11.6. At  $p < 0.05$  and a difference in proportion between FEN\_Res & FEN\_Sus (Diff)  $\geq 0.2\%$ , hydrolases, the most enriched enzyme class in FEN\_Res, comprised: carboxymethylenebutenolidase (Diff 1.70%), gluconolactonase (Diff 1.46%), alkaline phosphatase (Diff 0.51%), and acid phosphatase (Diff 0.41%) in comparison to FEN\_Sus. These results show differential microbial functional profiles between FEN\_Res & FEN\_Sus, with significant enrichment of hydrolases - the

astmh.org

principal class of enzymes involved in biodegradation of OPs - in FEN\_Res. Our findings provide novel insights into IR mechanisms that should be considered in the development of new IR monitoring and management tools.

714

### EFFECT OF KNOCKDOWN RESISTANCE ON *PLASMODIUM FALCIPARUM* SPOROZOITE RATES IN MALARIA VECTORS SAMPLED FROM WESTERN KENYA

Isaiah Debrah<sup>1</sup>, Bernard Guyah<sup>1</sup>, Maurice Ombok<sup>2</sup>, Eric Ochomo<sup>2</sup>

<sup>1</sup>Maseno University, Kisumu, Kenya, <sup>2</sup>Center for Global Health Research, Kenya Medical Research Institute/Centers for Disease Control and Prevention, Kisumu, Kenya

Genetic mutations associated with knockdown resistance to pyrethroid insecticides have been well described. In western Kenya, both L1014S and L1014F mutations have been reported. We sought to determine whether these two mutations were correlated with increased sporozoite rates in *Anopheles* vectors of malaria in western Kenya. We sampled wild adult *Anopheles* resting indoors and exposed them to 0.05% deltamethrin. We then determined their species, kdr genotypes and sporozoite rates. Of 4,360 wild *Anopheles* sampled, 32.8% were *An. funestus* and the rest *An. gambiae s.l.* Independent t-test showed that *An. funestus* was more resistant than *An. gambiae s.l.* ( $P < 0.001$ ). *An. funestus* had higher sporozoite rate than *An. gambiae s.l.* ( $P < 0.001$ ). *Anopheles gambiae* mosquitoes that had higher resistance showed higher sporozoite rates than their susceptible counterparts ( $X_2 = 7.14$ ,  $P = 0.01$ ) but did not see the same trend in *An. funestus* ( $X_2 = 0.05$ ,  $P = 0.89$ ). The result also indicated that *An. gambiae s.s.* having L1014S mutation have higher sporozoite rate than those that do not have the mutation ( $X_2 = 5.49$ ,  $P = 0.032$ ). *An. arabiensis* that were phenotypically resistant had more sporozoite rate because they are likely to get more blood meal. The significant association between L1014S and sporozoite rate in *An. gambiae s.s.* which confirmed a previous study suggest the epidemiological importance of that marker; it could contribute to malaria transmission.

715

### THE *ANOPHELES GAMBIAE* 1000 GENOMES PROJECT PHASE 2: INSECTICIDE RESISTANCE, GENE DRIVE AND GENOME VARIATION IN 1,142 MALARIA MOSQUITOES

Chris S. Clarkson<sup>1</sup>, Alistair Miles<sup>2</sup>, Nicholas J. Harding<sup>2</sup>, Giordano Botta<sup>3</sup>, Mara K. Lawniczak<sup>1</sup>, Martin J. Donnelly<sup>4</sup>, Dominic Kwiatkowski<sup>2</sup>, The *Anopheles gambiae* 1000 Genomes Consortium<sup>2</sup>

<sup>1</sup>Wellcome Trust Sanger Institute, Hinxton, United Kingdom, <sup>2</sup>Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, <sup>3</sup>Universita di Roma - Sapienza, Rome, Italy, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The *Anopheles gambiae* 1000 Genomes Project (Ag1000G) is conducting whole-genome sequencing of wild-caught malaria vectors from populations across Africa with three core objectives: discover genetic variation, describe population structure/history, and to connect these with malaria epidemiology and vector control. Here we describe results from phase 2 of the Ag1000G project, which includes data on nucleotide variation from the whole genome sequencing of 1,142 individual mosquitoes collected from 13 African countries. The phase 2 cohort includes several new mainland populations representing the incipient species *An. gambiae* and *An. coluzzii* and introduces two new island populations, providing a rich resource for investigating speciation processes, patterns of gene flow, and genome regions under strong selective pressures. Within the cohort, we have discovered over 57 million SNPs, corresponding to a variant allele at every 1.9 accessible bases of the genome on average. We will present the results from analyses of genetic diversity, population structure and demographic history and also show the latest results from haplotype-based analyses of recent selection at genes

involved in insecticide resistance, including new information on the spread of insecticide resistance between different regions and new candidate resistance *loci*. We will discuss the applications of our data to the design of new vector control tools using genetic modification. Advances in CRISPR/Cas9 genome editing may allow efficient gene drive to suppress or replace populations, reducing malaria transmission, however, high genetic diversity could lead to rapid gene drive resistance. Of 12,502 genes in the *An. gambiae* genome, we found 4,303 genes that could be targeted for CRISPR/Cas9 gene drive after excluding target sites with natural variation, and 571 genes that contained multiple conserved targets, including 11 putative sterility genes that could be targeted for population suppression. The Ag1000G data resource has been publicly released and provides unique opportunities for the malaria research community to develop new approaches to vector control.

## 716

### SCIENCE AND NATURE: SUSCEPTIBILITY OF WILD CAUGHT ADULT ANOPHELES GAMBIAE S.S. TO INSECTICIDES MAY NOT DECREASE WITH AGE

**Kevin Ochieng' Opondo**<sup>1</sup>, Martin Donnelly<sup>2</sup>, Musa Jawara<sup>1</sup>, Amfaal Fofana<sup>1</sup>, Julia Mwesigwa<sup>1</sup>, Florence Crombe<sup>2</sup>, Umberto D'Alessandro<sup>1</sup>, David Weetman<sup>2</sup>

<sup>1</sup>Medical Research Council Unit The Gambia, Banjul, Gambia, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Insecticide resistance increases adult vector longevity and may increase intensity of malaria transmission as a larger proportion of individuals survive the extrinsic incubation period. Previous studies have shown that mosquitoes become more susceptible to insecticide with age, but this has not been studied in wild caught adults harbouring target site resistance. This study investigated the relationship between age and insecticide resistance in wild *Anopheles gambiae s.l.* populations from The Gambia where until 2014, DDT was used for Indoor Residual Spraying (IRS). Female adult mosquitoes were collected using Human Landing Catches; tested for DDT and bendiocarb susceptibility using WHO tube tests and then parity status, as a proxy of physiological age, determined. An alternative age related outcome, infection with *Plasmodium falciparum*, together with known resistance-associated molecular markers were also assessed. A total of 251 (167 exposed to DDT; 84 to bendiocarb) were successfully identified to species (*Anopheles gambiae s.s.* -69.3%; *An. coluzzii*-7.6%; *An. arabiensis*-23.1%). In contrast to earlier lab studies, there was not a significant increase in DDT susceptibility between nulliparous and parous mosquitoes  $\chi^2_{df=1} = 0$ ,  $p = 1$ . The proportion of mosquitoes carrying the *Vgsc*-1014F allele was higher in parous *An. gambiae s.s.* than in nulliparous ( $\chi^2_{df=1} = 4.1$ ,  $p = 0.04$ ). Irrespective of parity status, target site mutations conferred a strong survival advantage to DDT, from *Vgsc*-1014F (OR 18, 95% CI 2-557,  $p < 0.01$ ), and to bendiocarb, from *Ace-1*-119S (OR 41, 95% CI 4-1394,  $p < 0.01$ ). In conclusion, the *kdr Vgsc*-1014F mutation was associated with DDT resistance in mixed age populations of *An. gambiae s.s.* The significantly higher frequency of *Vgsc*-1014F in parous mosquitoes explains the lack of association between insecticide susceptibility and physiological age. This observation suggests that resistance mechanisms may partially counteract the senescence phenomenon commonly observed in laboratory reared mosquitoes which normally become more susceptible to insecticides with age.

## 717

### THE EVOLUTION OF METABOLIC INSECTICIDE RESISTANCE IN AFRICAN MALARIA VECTORS VIA COPY NUMBER VARIATION

**Eric Lucas**<sup>1</sup>, Alistair Miles<sup>2</sup>, David Weetman<sup>1</sup>, Dominic Kwiatkowski<sup>3</sup>, Martin Donnelly<sup>1</sup>, The Anopheles gambiae 1000 Genomes Consortium<sup>3</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom,

<sup>2</sup>Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom,

<sup>3</sup>Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Metabolic resistance via increased expression of detoxification genes underlies much of the insecticide resistance observed in mosquito populations, yet causal genetic variants remain poorly characterised, meaning that logistically-challenging measurements of expression are needed to monitor changes. One way in which changes in gene expression levels can be achieved is via copy number variation (CNV), with recent gene duplications of particular relevance to insecticide resistance. Using 1,142 genomes of *Anopheles gambiae s.s.* and *An. coluzzi* from 16 populations spanning continental Africa, sequenced in phases 1 and 2 of the *Anopheles gambiae* 1000 genomes (*Ag1000g*) project, we have identified CNVs across the genome and characterised duplications in three metabolic genes or gene clusters with known associations to insecticide resistance: *GSTE1-8*, *CYP9K1* and *CYP6P1-5*. All three regions showed multiple independent duplications of varying size, distribution and frequency. Most duplications were rare, being found in only a handful of individuals, and no duplications were detected that spanned all populations. No duplication was fixed in any population, but some were detected at local frequencies up to 50%. Interestingly, all ten of the duplications identified in the *GSTE* cluster encompassed *GSTE2*, a gene with known links to insecticide resistance. Our results point to a varied mosaic of duplications in key detoxification genes across Africa, and identify candidate duplications that have reached high local frequencies. Reads spanning the duplication breakpoints revealed the start and end points for each duplication, which were used to design duplication-diagnostic PCR assays to test the association of individual duplications with insecticide resistance in phenotyped mosquito collections.

### OXIDATIVE DEFENSE CAPACITY IS CRITICAL FOR FECUNDITY AND XENOBIOTIC METABOLISM IN ANOPHELES GAMBIAE

**Cody J. Champion**, Jiannong Xu

New Mexico State University, Las Cruces, NM, United States

Blood digestion in hematophagous insects results in elevated oxidative stress. Capacity for defense against oxidative stress is limited, and if unabated can lead to oxidation of cellular material resulting in a loss of function. Reducing power is often found in the form of NADPH which can be used to regenerate antioxidant molecules. We examined the dynamics of oxidative stress via induction by paraquat (PQ) and the inhibition of the NADPH regeneration by 6-aminonicotinamide (6AN). Important vector associated traits such as fecundity, longevity, and insecticide susceptibility were measured. Both PQ and 6AN feeding increased oxidative stress as measured by the ratio of reduced form vs. oxidized form of glutathione (GSH:GSSG ratio). Both pro-oxidants lowered fecundity. The basal level of reducing power varies in individuals, as measured by GSH:GSSG ratio. Low basal reducing capacity was positively correlated with low fecundity. Co-feeding with the antioxidant, lycopene, attenuated adverse effects on fecundity implying that oxidative stress was the cause of this phenotype. Low dosage (0.5 mM) PQ decreased longevity and pre-feeding with 6AN increased insecticide susceptibility. Both PQ and 6AN resulted in higher expression of gene *nrf2* (mediating oxidative response signaling) and repressed vitellogenin (a fecundity marker). These results indicate that redox homeostasis is critical for fecundity and xenobiotic detoxification. This knowledge can be used to design novel and effective vector control strategies which influence insecticide sensitivity, infection susceptibility, fecundity, and longevity.

## 719

### SAFETY/IMMUNOGENICITY OF A SINGLE INTRAMUSCULAR DOSE OF THE INVESTIGATIONAL RECOMBINANT CHIMPANZEE ADENOVIRUS TYPE 3-VECTORED EBOLA ZAIRE VACCINE (CHAD3-EBO-Z) IN CHILDREN IN AFRICA: A PHASE 2, RANDOMIZED, CONTROLLED STUDY

Milagritos D. Tapia<sup>1</sup>, Zaire Ebola Research Alliance (ZEBRA) Group

<sup>1</sup>University of Maryland School of Medicine, Baltimore, MD, United States

The West-African Zaire Ebola virus (EBOV) outbreak in 2014 accelerated vaccine development. This study assessed safety/immunogenicity of ChAd3-EBO-Z (GSK) in children. In this phase 2, multi-country study (NCT02548078) in Africa, 600 children (age strata: 13-17 years [Y], 6-12Y, 1-5Y) were 1:1 randomized to receive ChAd3-EBO-Z (1x10<sup>11</sup> particle units; EBO-Z group) or meningococcal conjugate vaccine (MenACWY-TT, GSK; Control group) at day 0 (D0), with crossover at month 6. 13-17Y were vaccinated first, younger strata followed after independent D0-6 safety data review for ≥50 older children. Solicited/unsolicited adverse events (AEs), serious AEs (SAEs), hematologic/biochemical outcomes (primary objectives) and immune responses were assessed. Results up to D30 are shown. The most frequent solicited AEs (D0-6) were injection site pain (13-17Y: 31% [EBO-Z, N=100] and 14% [Control, N=100]; 6-12Y: 41% [EBO-Z, N=99] and 24% [Control, N=101]; 1-5Y: 55% [EBO-Z, N=101] and 23% [Control, N=99]), headache (13-17Y: 36% and 11%; 6-12Y: 26% and 6%, 1-5Y: not collected per protocol) and fever (13-17Y: 20% and 4%; 6-12Y: 25% and 1%; 1-5Y: 50% and 23%); 8 children had severe solicited AE (all in EBO-Z groups). Unsolicited AEs (D0-29) were reported for 41/300 (14%) EBO-Z vaccinees and 24/300 (8%) controls; most were mild, none severe. SAEs were reported for a 4-year-old (EBO-Z, malaria) and 14-year-old (Control, hepatitis B and D); none were vaccine-related. No clinical impact on platelet function was observed. In the per-protocol cohort for immunogenicity, 17% of all children were seropositive for EBOV at D0. At D30, all EBO-Z vaccinees (except 2 of 1-5Y) were seropositive for anti-EBOV glycoprotein (GP); geometric mean concentrations of anti-GP EBOV antibodies increased to 1575 (95% CI: 1346-1843) in 13-17Y (N=98), 1379 (1165-1632) in 6-12Y (N=99) and 2372 (1915-2939) in 1-5Y (N=97). Polyfunctional ChAd3-EBOV-specific CD4+/CD8+ T-cell responses were observed at D30 in a subcohort of EBO-Z vaccinees of the 6-12Y and 1-5Y strata (13-17Y: data not available). ChAd3-EBO-Z was well tolerated and immunogenic 30 days after a single dose in African children.

## 720

### SAFETY AND IMMUNOGENICITY OF MONOVALENT AD26.ZEBOV AND MULTIVALENT MVA-BN-FILO HETEROLOGOUS PRIME-BOOST VACCINE REGIMENS AGAINST EBOLA IN AFRICAN HEALTHY ADULT VOLUNTEERS

Zacchaeus Anywaine<sup>1</sup>, George Praygod<sup>2</sup>, Omu Anzala<sup>3</sup>, Samuel Kalluvya<sup>4</sup>, Pontiano Kaleebu<sup>1</sup>, Gaudensia Mutua<sup>3</sup>, Hilary Whitworth<sup>5</sup>, Kerstin Luhn<sup>6</sup>, Cynthia Robinson<sup>6</sup>, Deborah Watson-Jones<sup>5</sup>, Macaya Douoguih<sup>6</sup>

<sup>1</sup>MRC/UUVRI Uganda Research Unit, Entebbe-Uganda, Uganda, <sup>2</sup>National Institute for Medical Research, Mwanza, United Republic of Tanzania, <sup>3</sup>KAVI - Institute of Clinical Research, College of Health Sciences, University of Nairobi, Nairobi, Kenya, <sup>4</sup>Bugando Medical Centre, Mwanza, United Republic of Tanzania, <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>6</sup>Janssen Vaccines & Prevention, Leiden, Netherlands

Ebola virus disease outbreaks with high fatality rates have been reported since the 1970s; by far the most deadly outbreak occurred in 2013–16 in West Africa. Safe and effective Ebola vaccines and prevention measures are needed to help manage and prevent future outbreaks. The safety and immunogenicity of various sequences and schedules of the Ad26.ZEBOV/

MVA-BN-Filo regimen (28-day and 56-day prime-boost interval) were assessed in two separate Phase 1 clinical studies in Africa (EBL1003: Kenya; EBL1004: Uganda & Tanzania). 144 participants (EBL1003: n=72; EBL1004: n=72) were randomised 5:1 (active:placebo). Adverse events (AEs) and serious adverse events (SAEs) were recorded until 21 days post-boost and 1 year post-prime, respectively. Humoral and cellular immune responses were evaluated over one year following vaccination. Post-prime and post-boost rates of solicited local AEs (pooled data) (Ad26: 66%; MVA: 77%) and systemic AEs (Ad26: 75%; MVA: 73%) were similar in both studies; most were mild-to-moderate and short-lived, with injection site pain and fatigue as most frequent local and systemic AEs. At 21 days post-boost, almost all Ad26/MVA recipients from both studies displayed robust binding and neutralizing antibody responses (100% and ≥93%, respectively), which were mostly sustained to Day 360 (EBL1003: 97% and 60% of recipients; EBL1004: 100% and 63%). Cellular responses to Ad26/MVA varied widely across individuals in both studies. In EBL1003, responses were observed 21 days post-boost for CD4+, CD8+ (ICS), and IFN-γ (ELISpot) in 60%, 27% and 62% of recipients, respectively. In EBL1004, responses were observed post-boost in 37%, 54% and 47% of recipients. Responses were sustained to Day 360 in 17%, 17% and 27% of recipients in EBL1003 and 11%, 31% and 24% in EBL1004. Consistent with previously reported UK data, Ad26.ZEBOV/MVA-BN-Filo vaccine regimens were well tolerated and immunogenic among healthy African adults, with antibody responses elicited early on and persisting to Day 360. The regimen may therefore be well-suited for vaccination strategies to counter future Ebola outbreaks and is currently under Phase 2/3 evaluation.

## 721

### SEROLOGIC PROFILING OF THE HUMORAL IMMUNE RESPONSE TO EBOLA VIRUS MINIMALLY OR ASYMPTOMATICALLY INFECTED SUBJECTS

Patrick K. Mukadi<sup>1</sup>, Nicole A. Hoff<sup>2</sup>, Daniel Mukadi<sup>1</sup>, Reena H. Doshi<sup>2</sup>, Emile W. Okitolonda<sup>3</sup>, Jean-Jacques T. Muyembe<sup>1</sup>, Benoit I. Kebela<sup>4</sup>, Russel Williams<sup>1</sup>, Matthew S. Bramble<sup>5</sup>, Brad Nicholson<sup>6</sup>, Anne W. Rimoin<sup>2</sup>

<sup>1</sup>National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, <sup>3</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Ministère de la Santé, Direction de Lutte Contre la Maladie, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>University of California Los Angeles David Geffen School of Medicine, Human Genetics, Los Angeles, CA, United States, <sup>6</sup>Duke University, Durham, NC, United States

Evaluation of antibody profiles can provide exposure history to human pathogens. Analyses of humoral responses against different infectious agents are critical for infectious disease diagnostics, understanding pathogenic mechanisms, and the development and monitoring of vaccines and therapeutics. Profiling antibody response in minimally or asymptomatic Ebola virus (EBOV) infection is limited. To better understand optimal antibodies and their targets, which might be important for protection from Ebola virus infection, we characterized the serologic profile of antibodies against multiple EBOV viral proteins in health care workers in the Tshuapa district, the site of the 2014 Ebola outbreak in the Democratic Republic of Congo (DRC). Serum samples from consenting health care workers (HCW) in Boende, DRC were collected one year post outbreak in November 2014. Samples were screened for the presence of EBOV antibodies. An enzyme-linked immunosorbent assay specific for viral proteins NP, GP1–649; VP40 was measured using a fluorescent immunoprecipitation assay and plaque reduction neutralization test (PRNT) was realized. In total, 616 HCW were enrolled. The largest proportion of HCW were seropositive for NP (31, 5%), followed by GP1–649 (27.2%), then VP40 (9%). Comparison of positive immunoreactivity between the viral proteins NP, GP, VP40 and PRNT demonstrated that 9 (1.4%) individual's immuno reactive to both GP and NP were more likely to be positive for PRNT. These findings suggest that different serological methods are needed

to generate complete antibody profiles for EBOV. Developing a better understanding of pathogenic mechanism utilizing multiple assays may aid in the development of vaccines and therapeutics.

## 722

### PREVALENCE AND PREDICTORS OF ROTAVIRUS SHEDDING AMONG A COHORT OF POST-VACCINATED INFANTS IN EL ALTO, BOLIVIA 2013 - 2015

**Shanon M. Smith<sup>1</sup>**, Paulina A. Rebolledo<sup>2</sup>, Jessica Prince-Guerra<sup>1</sup>, Juan S. Leon<sup>1</sup>, Leonarda Acha Alarcon<sup>3</sup>, Lucia Inchauste<sup>3</sup>, Rita Revollo<sup>4</sup>, Volga Iniguez<sup>3</sup>

<sup>1</sup>Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, <sup>2</sup>Emory School of Medicine, Atlanta, GA, United States, <sup>3</sup>Instituto de Biotecnología y Microbiología, Universidad Mayor de San Andrés, La Paz, Plurinational State of Bolivia, <sup>4</sup>Servicio Departamental de Salud, La Paz, Plurinational State of Bolivia

Historically, rotavirus (RV) associated mortality rates from diarrheal illness disproportionately affect children in low-income countries. Despite the global introduction of oral RV vaccines, reduced efficacy in low-income countries that are the most vulnerable to this disease has been observed. Further understanding barriers to vaccine performance in low-income settings is needed. We characterized the prevalence of RV shedding post-vaccination and identified factors associated with reduced viral shedding. During 2013 to 2015, 355 infants received both doses of the Rotarix® vaccine and were followed for 6 (n=325) and 18 (n=169) months. Of these, a subset (n=158) had stool shedding samples 5 or 7 days post-vaccination that were assayed by a real-time PCR that targets the NSP3 region (Ct ≤ 36 was considered positive). The following data was collected during the study: infant RV-specific IgA (2, 6 months), nutritional markers and anthropometrics (2 months) and demographics; maternal IgG (1 month). Infants with missing seroconversion or inconclusive shedding data (n=4) were excluded from analysis. Of the 154 infants, 38% were positive for RV viral shedding and 4% were positive by EIA (one discordant positive). RV shedding status was not significantly associated with seroconversion: (seroconverters [40% shedding] vs. non-seroconverters [36% shedding]), OR: 1.34, 95% CI: 0.68, 2.70 p = 0.20). RV shedding status was not significantly associated with age at vaccination, vaccine seasonality, preterm status, stunting, wasting, vitamin A or zinc deficiency. RV shedding status was significantly associated with maternal baseline IgG (OR: 0.29, 95% CI: 0.13, 0.62 p = 0.001). High maternal IgG titers were associated with the absence of viral shedding suggesting maternal IgG may have an inhibitory effect on RV vaccine uptake. Our study highlights the importance of utilizing a more sensitive method such as real-time PCR rather than EIA for detecting viral shedding. The low prevalence of RV shedding and the association with high levels of maternal IgG warrant further exploration as causes of vaccine underperformance.

## 723

### LEWIS ANTIGEN AND SECRETOR STATUS MEDIATE SUSCEPTIBILITY TO P-GENOTYPE SPECIFIC ROTAVIRUS INFECTIONS BUT DO NOT AFFECT ROTAVIRUS VACCINE PERFORMANCE AMONG INFANTS IN BANGLADESH

**Benjamin Lee<sup>1</sup>**, Sean A. Diehl<sup>1</sup>, E. Ross Colgate<sup>1</sup>, Dorothy M. Dickson<sup>1</sup>, Muhammad I. Uddin<sup>2</sup>, Salma Sharmin<sup>2</sup>, Shahidul Islam<sup>2</sup>, Taufiqur R. Bhuiyan<sup>2</sup>, Mami Taniuchi<sup>3</sup>, William A. Petri<sup>3</sup>, Firdausi Qadri<sup>2</sup>, Rashidul Haque<sup>2</sup>, Beth D. Kirkpatrick<sup>1</sup>

<sup>1</sup>University of Vermont, Burlington, VT, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>University of Virginia, Charlottesville, VA, United States

Rotavirus (RV) is the leading cause of diarrhea among children worldwide. Limited data suggest Lewis (Le) histoblood group antigen or secretor (Se) negative children may be resistant to genotype P[8] RV infection. Both globally-licensed RV vaccines contain P[8] RV, potentially rendering

Le- or Se- infants resistant to vaccination and thus unprotected against heterotypic RV strains. To investigate this, we performed a sub-study within PROVIDE, a randomized, controlled trial of Rotarix vaccine (RV1, GlaxoSmithKline) performed in urban Dhaka, Bangladesh. Infants were enrolled, randomized 1:1 to receive RV1 or no RV1 at 10 and 17 weeks, and underwent active diarrheal surveillance until 1 year of life. Saliva was collected for Le and Se typing by dot-blot assay and ELISA, respectively. RV diarrhea (RVD) was confirmed by stool ELISA and the P-type of each infecting strain was determined by sequencing. Among 562 eligible infants, 82 (14.6%) were Le- and 180 (32.2%) were Se-; 167 (29.7%) had ≥1 episode of RVD, of whom 21 (12.6%) were Le- and 37 (22.2%) were Se-. Among infected infants, Le- infants were less likely than Le+ infants to be infected with P[8] RV (OR 0.095, 95%CI 0.030-0.30) but more likely to be infected with P[6] RV (OR 306, 95%CI 52-1797). However, the overall risk of any RVD did not differ between the groups and Le status did not impact vaccine effect. In contrast, Se- infants were significantly protected from RVD compared to Se+ infants (OR 0.51, 95%CI 0.33-0.77), chiefly due to a protective effect of Se- status compared to Se+ status among unvaccinated infants (N=274, OR 0.355, 95% CI 0.20-0.64) that was not seen in vaccinated infants. Of note, Se- infants were not resistant to P[8] RV infection, with 28 (75.7%) infections in Se- infants due to P[8] RV. This finding suggests susceptibility to RV1 among Se- infants in this cohort. Surprisingly, Se- infants were completely protected against P[4] RV, with all 40 P[4] infections found only in Se+ infants (P<0.0001). In this Bangladeshi cohort, Le and Se status had distinct effects on susceptibility to P-genotype specific RV infections, but did not directly impact vaccine performance.

### IMPACT OF ROTAVIRUS VACCINE PERFORMANCE ON INFANT UNDERNUTRITION IN EL ALTO, BOLIVIA

**Jessica Prince-Guerra<sup>1</sup>**, Paulina A. Rebolledo<sup>2</sup>, Rachel Burke<sup>3</sup>, Anna Fabiszewski de Aceituno<sup>1</sup>, Parminder Suchdev<sup>1</sup>, Rita Revollo<sup>4</sup>, Volga Iniguez<sup>5</sup>, Juan S. Leon<sup>1</sup>

<sup>1</sup>Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, <sup>2</sup>Emory School of Medicine, Atlanta, GA, United States, <sup>3</sup>Department of Epidemiology, Rollins School of Public Health, Emory University, Atlanta, GA, United States, <sup>4</sup>Servicio Departamental de Salud, La Paz, Plurinational State of Bolivia, <sup>5</sup>Instituto de Biotecnología y Microbiología, Universidad Mayor de San Andrés, La Paz, Plurinational State of Bolivia

Rotavirus (RV) vaccination has the potential to reduce the burden of undernutrition - stunting and micronutrient deficiencies - caused by RV diarrhea, but in developing countries, oral RV vaccines have lower efficacy. This study sought to determine if impaired RV-specific immunity after vaccination is associated with stunting and micronutrient deficiency in Bolivian infants. In a prospective cohort study of 166 mother-infant pairs from El Alto, Bolivia, infants were followed from birth to 12-18 months of age. Data collected at each visit (2, 6, and 12-18 months) included: sociodemographics, self-reported morbidities (e.g. diarrheal episodes), anthropometry, micronutrients (hemoglobin, iron, vitamin A, zinc), and RV-specific IgA titers. RV-specific seroconversion was defined as a four-fold increase in RV-specific IgA titer between pre-immunization sera and 2 months post-second vaccine dose, stunting as per WHO Child Growth Standards, anemia as hemoglobin <13.7 g/dL (corrected for altitude), vitamin A deficiency (VAD) as retinol binding protein < 0.7 µmol/L, iron deficiency (ID) as ferritin < 12 µg/L, and zinc deficiency as < 65 or < 57 µg/dL, depending on sampling time. Logistic regression models, adjusted for sex, infant age, and inflammation status at the 12-18 month visit, assessed the impact of RV-specific seroconversion on infant nutrition. Only 63% of the 166 infants seroconverted, compared to high-income countries (96%). At 12-18 months, 20% of the infants were stunted, 82% were anemic, 66% were iron deficient, 15% had VAD, 57% were zinc deficient, and 19% of mothers reported infant diarrhea in the past 2 weeks. RV-specific seroconversion was not significantly associated with 12-18 month stunting, anemia, VAD, or self-reported diarrhea, but was significantly associated with zinc deficiency (OR: 2.4, 95% CI: 1.2, 4.7 p =

0.02). Among infants with RV-specific seroconversion, there was a trend towards protection from ID at 12-18 months (OR: 0.5, 95% CI: 0.23, 1.0  $p = 0.06$ ). In conclusion, these data suggest that RV-vaccine performance has a selective impact on certain infant nutritional markers.

## 725

### TRENDS IN CIRCULATING ROTAVIRUS STRAINS IN INDIA FROM 2012-2016: A MULTI-CENTER SURVEILLANCE DATA AMONG UNDER FIVE CHILDREN

Nayana P. Nair<sup>1</sup>, Sidhartha Giri<sup>1</sup>, Sudhir Babji<sup>1</sup>, Girish Kumar<sup>2</sup>, Venkatasubramaniam S<sup>2</sup>, Rashmi Arora<sup>3</sup>, Gagandeep Kang<sup>1</sup>

<sup>1</sup>Christian Medical College, Vellore, India, <sup>2</sup>National Institute of Epidemiology, Chennai, India, <sup>3</sup>Indian Council of Medical Research, New Delhi, India

Rotavirus is a leading cause of under-five diarrhea globally and accounts for about 39% of hospitalizations due to diarrhea in children <5 years of age in India. We conducted a multicenter hospital-based surveillance in seven sites, viz. Vellore and Trichy (Tamil Nadu), Kolenchery (Kerala), Tirupati (Andhra Pradesh), Hyderabad (Telangana), Ludhiana (Punjab), and New Delhi from July 2012 to June 2016 to generate information on rotavirus disease among Indian children, with the use of standardized protocols for enrollment and evaluation. All children aged less than 60 months who presented to a study hospital with acute gastroenteritis and required hospitalization with rehydration for at least 6 hours were enrolled in the study after obtaining informed consent from parent/guardian. A single stool specimen was collected from each child enrolled in the study along with clinical information. All samples were screened for by enzyme immunoassay (EIA) at a central laboratory. For the EIA positive samples, genotyping was performed for VP7 and VP4 by reverse-transcription polymerase chain reaction (RT-PCR). During the 4 years of surveillance, a total of 6935 eligible children were enrolled with diarrhea. Rotavirus was detected in 34.9% samples (2291 children). A total of 2207 rotavirus strains were genotyped. The most common types were G1P[8] (in 50.3% of infections), followed by G2P[4] (in 9.6%), G9P[4] (in 8.4%), and G12P[6] (in 5.3%). Mixed infections were approximately 8%. The G and P types could not be identified in 1.8% of infections. The G1P[8] strain increased from 37.6% in 2012 to 69.7% in 2015, and decreased to 24.3% by 2016. G9P[4] strains increased in prevalence from 6.4% in 2012 to 21.5% in 2016. Emergence of G3P[8] was noticed in 2015 and by 2016, the prevalence was 12%. There is a significant burden of rotavirus diarrhea among under five Indian children with a predominance of G1P[8] and G2P[4] strains, but circulation of strains varies in time and space.

## 726

### INTEGRATING A GEOGRAPHIC INFORMATION SYSTEM TO EXPLORE THE EFFECT OF WATER, SANITATION, AND HYGIENE ON TRACHOMA AT AGGREGATE SPATIAL SCALES

Forest M. Altherr<sup>1</sup>, Eshetu Sata<sup>2</sup>, Aisha E.P. Stewart<sup>1</sup>, Tigist Astale<sup>2</sup>, Mulat Zerihun<sup>2</sup>, Andrew Nute<sup>1</sup>, Demelash Gessesse<sup>2</sup>, Gedefaw Ayenew<sup>2</sup>, Melsew Chanyalew<sup>3</sup>, Berhanu Melak<sup>2</sup>, Zerihun Tadesse<sup>2</sup>, E. Kelly Callahan<sup>1</sup>, Scott D. Nash<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Addis Ababa, Ethiopia, <sup>3</sup>The Amhara Regional Health Bureau, Bahir Dar, Ethiopia

Trachoma is an infectious disease responsible for a large proportion of the global burden of preventable blindness. The WHO endorsed SAFE strategy (Surgery, Antibiotics, Facial cleanliness, and Environmental improvement) has been implemented at scale throughout Amhara National Regional State of Ethiopia since 2007. The effect of F&E on the prevalence of trachoma tends to be contextually dependent, exhibiting variability in prior studies. The aim of this research was to elucidate the relationships between water, sanitation, and hygiene (WASH) indicators and the spatial distribution of trachoma throughout Amhara. Through multi-stage cluster random impact surveys conducted in all districts from 2011 to 2016. Trachoma clinical outcomes were collected using the WHO simplified

grading scale, and WASH indicators were collected through household and individual level assessments. In the analysis, spatial methods corrected biases that arise from geographic relationships. Disease hotspots, defined as evaluation units with high trachomatous inflammation-follicular among children aged 1 to 9 (TF) in relation to a neighborhood, were identified using TF prevalence estimates and the Getis-Ord  $G_i^*(d)$  statistic. Socio-demographic, community, and environmental factors thought to promote the clustering of the disease were modeled with logistic regression. The district-level TF prevalence in Amhara ranged from 1.2% to 73.9%. Twelve districts and 325 villages were identified as statistically significant hotspots with 90% confidence. Percentage of children with clean face and household access to a water source in less than 30 minutes were significantly associated with a reduced odds of residence in a hotspot. The aforementioned variables as well as household access to a latrine were significant predictors in a spatial lag model of the prevalence of TF. This study demonstrated that water and hygiene are important factors in the clustering of trachoma within a hyperendemic area. Intensified promotion of structural and behavioral interventions to increase WASH coverage may be necessary to eliminate trachoma as a public health problem in Amhara.

## 727

### TRACHOMA PREVALENCE AFTER THREE ROUNDS OF MASS DRUG ADMINISTRATION IN KANKAN, MANDIANA AND SIGUIRI, THREE HEALTH DISTRICTS IN GUINEA

André Géopogui<sup>1</sup>, Sylvain Haba<sup>2</sup>, Mamadou S. Baldé<sup>1</sup>, Cece Nieba<sup>1</sup>, Lamah Lamine<sup>2</sup>, Christelly Badila Flore<sup>2</sup>, Bamba Fongotin Ibrahim<sup>2</sup>

<sup>1</sup>Ministry of Health, Conakry, Guinea, <sup>2</sup>Helen Keller International, Conakry, Guinea

Kankan region in Guinea is highly endemic with trachoma and mass drug administration (MDA) with azithromycin and tetracycline in the region started in 2014 targeting all the at-risk population, with financial support from the United States Agency for International Development (USAID)'s ENVISION Project. In 2016, Kankan, Mandiana and Siguiiri districts completed three annual rounds of MDA and three annual surgery campaigns for trachomatous trichiasis (TT) were also conducted in Kanakna and Siguiiri districts. An impact survey was conducted six months after the last MDA from December 2016 to January 2017. A cross-sectional survey using a cluster sampling method of 20 villages and 30 households randomly selected in each of the three districts were conducted to assess the prevalence of Trachomatous Inflammation - Follicular (TF) in children aged 1-9 years old and the prevalence of TT in adults aged 15 years and above. TF and TT were diagnosed by clinical examination using the World Health Organization (WHO) simplified grading system. Results of the impact survey were then compared to the baseline prevalence. A total of 5,790 children, and 4,624 adults from 1,877 households were screened for clinical signs of TF and TT respectively. Results showed a significant reduction from the baseline in TF prevalence: from 25.1% to 2.3% in Kankan, from 15.0% to 1.4% in Mandiana and from 16.8% to 1.2% in Siguiiri. Reductions were also found in TT prevalence in Kankan (1.5% to 0.6%) and in Siguiiri (5.1% to 1.0%) after three annual TT surgery campaigns, while TT prevalence increased in Mandiana from 0.6% to 0.9% without a TT surgery campaign, however this increase was not statistically significant. Three rounds of annual trachoma MDA with sufficient program coverage have significantly reduced TF prevalence in the three districts to below the threshold of 5%, reaching the criteria to stop MDA in these districts. The persistently elevated TT prevalence highlights the need of systematic TT surgical intervention in Guinea.

## LONGITUDINAL TRENDS IN TRACHOMA OVER EIGHT YEARS IN A HYPERENDEMIC SETTING UNDER THE SAFE STRATEGY: RESULTS FROM SERIAL IMPACT SURVEYS IN WEST GOJJAM ZONE, ETHIOPIA

Scott D. Nash<sup>1</sup>, Eshetu Sata<sup>2</sup>, Aisha E.P. Stewart<sup>1</sup>, Tigist Astale<sup>2</sup>, Mulat Zerihun<sup>2</sup>, Demelash Gessesse<sup>2</sup>, Gedefaw Ayenew<sup>2</sup>, Melsew Chanyalew<sup>3</sup>, Berhanu Melak<sup>2</sup>, Zerihun Tadesse<sup>2</sup>, E. Kelly Callahan<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Addis Ababa, Ethiopia, <sup>3</sup>Amhara Regional Health Bureau, Bahir Dar, Ethiopia

As part of the WHO recommended SAFE (Surgery, Antibiotics, Facial cleanliness, and Environmental improvement) strategy to control trachoma, annual community-wide mass drug administration (MDA) with antibiotics is warranted until district level prevalence of trachomatous inflammation-follicular (TF) among children ages 1-9 years falls below the elimination threshold of 5%. Impact surveys are conducted after 1-7 rounds of MDA depending on baseline prevalence, and are used to monitor progress towards the elimination threshold. West Gojjam zone in Amhara region, Ethiopia, is made up of 16 administrative districts with a population of about 2.7 million people, and had a baseline zonal level TF prevalence of 33.1% in 2006. Multi-stage cluster surveys were conducted in all districts throughout the zone first in 2012/2013 after 5 rounds of MDA and again in 2015/2016 after an additional 3 to 5 rounds to monitor the impact of the SAFE strategy. The 2012/2013 impact surveys (n=17,124) demonstrated a TF prevalence of 18.1% (95% confidence interval (CI): 15.8-20.7%), a 45.3% reduction from baseline. The prevalence of trachomatous inflammation-intense (TI) was 3.5% (95%CI:2.8-4.2%) and the prevalence of chlamydial infection in children ages 1-5 years was 2.5% (95%CI:0.0-5.0%) suggesting ongoing transmission. One district in this zone achieved the elimination threshold. Based on the first impact survey results, 15/16 districts in West Gojjam received 3 to 5 more rounds of MDA. Second impact surveys (n=20,134) in 2015/2016 demonstrated a TF prevalence of 13.9% (95%CI: 11.7-16.5%), and an additional district had reached the elimination threshold. The prevalence of TI and chlamydial infection, although lower than in the earlier impact survey, were still present in the zone. Data from 3 population-based surveys across 8 years in West Gojjam zone demonstrated that under the SAFE strategy, TF decreased by 58%, and that 2 districts no longer required MDA. Despite these successes, TF remained above 10% in 14 districts, requiring 3 to 5 additional rounds of MDA. Trachoma hyperendemic areas may require 10 or more rounds of MDA under current treatment guidelines.

## INSIGHTS AND COMPLEXITIES MODELLING SEROLOGICAL DATA FOR TRACHOMA SURVEILLANCE

Amy Pinsent

Monash University, Melbourne, Australia

Antibodies to the antigens PGP3 and CT694 are reported to have high sensitivity and specificity to detect infection with *Chlamydia trachomatis* (Ct). The seropositivity rates for these responses amongst children increase with age in trachoma-endemic communities, suggesting that age seroprevalence may be an indicator of cumulative exposure to ocular *C. trachomatis* infection within a population. Ct-specific antibody seroprevalence is therefore being investigated for a role in post-mass-drug administration surveillance in trachoma elimination programmes. Before suitable thresholds can be established, the antibody half-life and/or sero-reversion rate (SRR) needs to be estimated in order to understand how long individuals in the population remain sero-positive following elimination of trachoma. Here we analyse data from 5,368 participants aged between 1 and 90 years, collected from 6 different trachoma endemic countries: Nepal, The Gambia, Tanzania, Fiji, Solomon Islands and Kiribati. We use sero-catalytic and antibody acquisition models to investigate age-dependent sero-prevalence and to understand patterns

of transmission within each country. We highlight the challenge of cross-reactivity with urogenital chlamydia infection in different populations, and demonstrate how this can be accounted for to quantify the sero-conversion rate (SCR) for trachoma. We find a significant correlation—follicular (TF) within the population. Using data from regions for which 2 cross-sections are available, we estimate the median population-level half-life for sero-reversion to be 22 years (95% CrI: 17-30 years). Serology can be informative for assessing current and historical trachoma transmission intensity, but accurate understanding of the SRR is needed if estimates of the SCR are to be informative. Furthermore, work is needed to better understand the contribution of urogenital infection to age-specific sero-prevalence.

## TRACHOMATOUS TRICHIASIS SCREENING AND ACTIVE CASE FINDING, AN OPPORTUNITY FOR EYE HEALTH PROGRAMS: CASE STUDY OF THE MMDP PROJECT IN BURKINA FASO

Francois Drabo<sup>1</sup>, Martin Kabore<sup>1</sup>, Issouf Bamba<sup>2</sup>, Jean-Paul Djiatsa<sup>2</sup>, Fanny Yago-Wienne<sup>2</sup>, Yaobi Zhang<sup>3</sup>, Awa Dieng<sup>3</sup>, Emily Gower<sup>4</sup>, Zeina Sifri<sup>5</sup>

<sup>1</sup>Maladies Tropicales Negligees (MTN), Ministry of Health, Ouagadougou, Burkina Faso, <sup>2</sup>Helen Keller International, Ouagadougou, Burkina Faso,

<sup>3</sup>Helen Keller International, Dakar, Senegal, <sup>4</sup>University of North Carolina/Helen Keller International, Chapel Hill, NC, United States, <sup>5</sup>Helen Keller International, Washington, DC, United States

Trachoma is an ocular bacterial infection whose complications can lead to blindness. Trachoma elimination through the SAFE strategy is recommended to interrupt the transmission of infection. Burkina Faso is a trachoma-endemic country that recently, employed a fixed strategy for Trachomatous Trichiasis (TT) case finding. However, with new resources provided through the USAID-funded MMDP project, we have been able to evaluate another strategy: door-to-door screening. The goal of this research was to examine whether this new strategy improved case identification and surgery uptake and to characterize the prevalence of TT and other ocular pathologies in the region. We conducted two ten-day TT screening and surgery campaigns in two health districts (DS) in the Center North Region in June and October 2016. During the campaigns, we screened 18,902 persons and identified 439 TT cases. Of the persons examined, 4,408 (23.3%) had an ocular pathology. Among the diagnosed eye conditions, TT accounted for 10.1% of the cases (439 cases); pterygium for 28.6% (1259 cases); cataract for 15.18% (669 cases), corneal affections 10.3% (455 cases). To date, 295 of the 439 TT cases were operated, 14 were provided with epilation counseling and 8 were referred for surgery due to lower lid trichiasis. The door-to-door screening process resulted in screening of more people and finding more cases than the fixed strategy, in which 1,751 people were screened and 68 TT cases identified. Through the TT case-finding campaigns we are creating a record of the conditions found and contact information for the affected patients, which might contribute to increasing the likelihood that these patients will receive care for their non-TT ocular problems. Moving forward, we need to share the records with partners to ensure effective collaborations between eye health programs and eye care facilities in order to improve the eye health of patients. This project provides important opportunities to piggyback with other eye health programs to provide much needed services for patients being screened, while also reaching the country's targets for eliminating blinding trachoma.

## 731

### INFLUENCE OF INDIVIDUAL AND ENVIRONMENTAL FACTORS ON THE PREVALENCE OF TRACHOMA IN THE HEALTH DISTRICT OF MOKOLO, CAMEROON AFTER THREE YEARS OF MASS TREATMENT WITH ZITHROMAX AND TETRACYCLINE

**Assumpta Lucienne Bella**<sup>1</sup>, Emilienne Epée<sup>2</sup>, Armelle Ngomba<sup>3</sup>, Godefroy Koki<sup>4</sup>, Fabrice N. Djouma<sup>5</sup>, Georges Nko'o Ayissi<sup>2</sup>, Julie Akame<sup>6</sup>, Patrick Mbia<sup>6</sup>, Henri MOUNGUI<sup>6</sup>, Michel Paradis<sup>6</sup>, Yaobi Zhang<sup>7</sup>

<sup>1</sup>National Programme for the Prevention of Blindness, Yaoundé, Cameroon, <sup>2</sup>National NTD Coordination Unit Ministry of Public Health, Yaoundé, Cameroon, <sup>3</sup>Department of Public Health, Faculty of Medicine and Pharmaceutical Sciences, University of Douala, Douala, Cameroon, <sup>4</sup>Faculty of Medicine and Biomedical Sciences, University of Yaoundé, Yaoundé, Cameroon, <sup>5</sup>University of Dschang, Dschang, Cameroon, <sup>6</sup>Helen Keller International, Yaoundé, Cameroon, <sup>7</sup>Helen Keller International, Dakar, Senegal

It is commonly believed that personal hygiene and the state of cleanliness of the environment are significant factors in the spread of trachoma. The strategy for control is through SAFE (Surgery, Antibiotic treatment, Facial cleanliness and Environmental improvement). The health district of Mokolo in the Far-North Region of Cameroon, recognized as endemic with trachoma in 2010, benefited from the azithromycin and tetracycline mass distribution during three consecutive years, supported by HKI with funding from USAID's ENVISION Project, managed by RTI International. Rarely actions in F and E components were registered. We aimed at evaluating the influence of facial cleanliness and the environmental factors on the residual infection of trachoma after the treatment. We carried out a descriptive cross-sectional study based on a stratified random sampling in Mokolo in 2015. Selected were 20 communities representing clusters; with 25 households in each. After an interview with the households and ophthalmic assessments by trained trachoma graders, data were collected using the numerical tablets transferred to a central base, before being analyzed using Software SPSS. Among the 827 children aged 1 to 9 years examined, the prevalence of active trachoma (TF&TI) was 1.7% in 2015 against 18.1% in 2010. The proportion of children having dirty faces was 14.85%. A strong association was found between the facial uncleanness and active trachoma infections (OR = 14.79;  $p < 0.01$ ). Out of 91.6% of houses with cattle, 94.7% cohabited with the animals inside the homes. However 60.8% of the households were located within less than 30 min from a source of water. Despite drastic reduction of the disease prevalence to the threshold of the stopping MDA, the individual and environmental factors remain a strong influence. This could compromise the sustainable elimination of trachoma in this health district. More efforts on the F and E components of the SAFE strategy is needed.

## 732

### THE TRACHOMA END-GAME IN VIETNAM: SURVEYING TRACHOMA HOTSPOTS IN HÀ GIANG PROVINCE

**Tran Minh Dat**<sup>1</sup>, Nguyen Xuan Hiep<sup>1</sup>, Jeremiah Ngondi<sup>2</sup>, Ngoc Nguyen Viet My<sup>3</sup>, Long Nguyen Tien<sup>3</sup>, Joshua Sidwell<sup>4</sup>, Molly Brady<sup>4</sup>, Rob Henry<sup>5</sup>, Aryc Mosher<sup>5</sup>, Lisa Rotondo<sup>4</sup>, Anthony Solomon<sup>6</sup>

<sup>1</sup>Vietnam National Institute of Ophthalmology, Hanoi, Vietnam, <sup>2</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Fred Hollows Foundation, Da Nang, Vietnam, <sup>4</sup>RTI International, Washington, DC, United States, <sup>5</sup>U.S. Agency for International Development, Washington, DC, United States, <sup>6</sup>World Health Organization, Geneva, Switzerland

The Vietnam National Institute of Ophthalmology (VNIO) was established over 60 years ago as the National Trachoma Institute. Following launch of the World Health Organization (WHO) Alliance for Global Elimination of Trachoma by 2020 in 1996, the government of Vietnam and partners implemented the SAFE strategy. In 2000-2001, 67 district-based surveys

were undertaken in 27 trachoma-suspect provinces to identify need for SAFE. Impact surveys were done at four time periods in: 2003, 2004, 2005, and 2009-2011. Surveillance surveys done in 2014 revealed the prevalence of trachomatous inflammation—follicular (TF) in children aged 1-9 years was <5% in all 15 evaluation units. However, in one village in Yen Minh district of Hà Giang, the proportion of children with TF was 10.9%. In January 2015, VNIO investigated if trachoma was confined to that village or if it was more widespread by examining 388 children in the village with the highest proportion of children with TF and six surrounding villages. The proportion of children with TF was 8% and they were all offered antibiotic treatment. A follow-up investigation, in August 2015, examined children in the same seven villages, revealing the proportion of children with TF had doubled to 16%. In May 2016, a Trachoma Master Grader from the WHO investigated and confirmed the findings, and recommended population-based prevalence surveys in the entire Hà Giang province. Surveys are underway, with results expected in June 2017. The objectives of the surveys are to: 1) estimate the prevalence of TF among 1-9-year-olds; and 2) estimate the prevalence of trachomatous trichiasis (TT) among people aged ≥15 years. The surveys will be carried out across all 10 districts of Hà Giang combined into five evaluation units, powered to estimate prevalence of TF in 1-9-year-olds of 10% with an absolute precision of 3%, 95% confidence level, design effect of 2.65 and a non-response rate of 20%. Survey results will: 1) inform the next steps in the trachoma elimination process in Vietnam; and 2) help guide decision makers on investigation of trachoma hotspots in other areas.

## 733

### EXPERIMENTAL MALARIA IN PREGNANCY IS ASSOCIATED WITH ALTERED FETAL NEUROGENESIS AND NEUROPSYCHIATRIC DISORDERS IN OFFSPRING

**Andrea Weckman**<sup>1</sup>, Vanessa Tran<sup>2</sup>, Chloe McDonald<sup>2</sup>, Guang Yang<sup>3</sup>, David Kaplan<sup>3</sup>, Kevin C. Kain<sup>2</sup>

<sup>1</sup>Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Sandra Rotman Centre for Global Health, University Health Network-Toronto General Hospital, Tropical Disease Unit, Department of Medicine, University of Toronto, Toronto, ON, Canada, <sup>3</sup>Program in Neuroscience and Mental Health, Sick Kids Hospital, Toronto, ON, Canada

Each year ~125 million pregnant women are at risk for malaria infection. Malaria in pregnancy (MiP) has a profound impact on mother-child health, including delivery of low birth weight (LBW) infants. Even in the absence of LBW, epidemiological studies show a link between maternal infections during pregnancy and increased susceptibility of offspring to neuropsychiatric disorders later in life. Maternal immune activation can cause disruptions in embryonic neurodevelopment that could mechanistically underlie psychiatric outcomes. The impact of malaria exposure *in utero* on neurodevelopment and long-term vulnerability to psychiatric diseases has not been reported. We hypothesize that prenatal exposure to MiP will interfere with neurodevelopment via a host-mediated immune response and prime offspring to an increased risk of neuropsychiatric disorders. We used the established experimental mouse model of MiP (EMIP) with *Plasmodium berghei* ANKA (PbA). Uninfected adult offspring of dams infected with an inoculum of PbA that does not induce a LBW phenotype were subjected to a battery of standardized behavioural tests. Exposure to EMIP *in utero* induced increased anxiety-like behavior and hypersensitivity to amphetamine, and deficits in prepulse inhibition compared to unexposed offspring ( $p < 0.05$ ). The behavioural outcomes were associated with EMIP-mediated perturbations in embryonic neurogenesis including an altered distribution of embryonic cortical cells and a premature neurogenesis phenotype ( $p < 0.05$ ). Recent work by our lab showed that interrupting pathways of complement activation (i.e. C5a) improved fetal outcome in the EMIP model. Our future work will therefore compare the psychiatric and neurogenesis outcomes in malaria-infected  $\alpha$ -C5a treated and untreated offspring as a putative intervention. Our data implicate MiP as a modifiable risk factor for neurological injury and psychiatric disorders in exposed offspring. This concept represents a

paradigm shift in our understanding of risk factors for mental illness in malaria-endemic settings and may shift global health priorities from costly rehabilitation to prevention.

## 734

### TCR COMBINATORIAL IMMUNORECEPTOR EXPRESSION BY NEUTROPHILS CORRELATES WITH PARASITE BURDEN AND ENHANCED PHAGOCYTOSIS DURING A *PLASMODIUM BERGHEI* ANKA MALARIA INFECTION

**Miranda Oakley**, Joanna Chorazeczewski, Victoria Majam, Adovi Akue, Mark KuKuruga, Maya Aleshnick, Sanjai Kumar  
*Food and Drug Administration, Silver Spring, MD, United States*

Neutrophils are the first responders of the innate immune response to invading pathogens. During malaria, neutrophils play an important role in the regulation of parasite burden and the immunopathogenesis of disease. In this study, we report the presence and expansion of a novel population of TCR $\beta$ -expressing CD11b+Ly6G<sup>+</sup> neutrophils in the spleen during a *Plasmodium berghei* ANKA infection in mice. Measurement of TCR $\beta$  transcript and protein levels in neutrophils in wildtype versus nude (which lack T cells) and *Rag1* KO (which lack B and T cells) mice showed that the observed TCR expression is not a consequence of nonspecific antibody staining or passive receptor expression due to phagocytosis or trogocytosis of peripheral T cells. Remarkably, on day 3 post-infection, we observed a highly significant correlation between the proportion of neutrophils that express TCR and peripheral blood parasite burden. In addition, we demonstrate that TCR $\beta$ <sup>+</sup> neutrophils phagocytose parasitized erythrocytes four fold more efficiently than TCR $\beta$ <sup>-</sup> neutrophils. Together these results signify that TCR expression by the neutrophil may play an important role in the regulation of parasite burden by enhancing the phagocytic capacity of the neutrophil.

## 735

### SUBMICROSCOPIC MALARIA INFECTIONS ARE NOT ASSOCIATED WITH NEGATIVE BIRTH OUTCOMES IN PREGNANT WOMEN FROM COLOMBIA

**Kenneth Gavina**<sup>1</sup>, Sedami Gnidehou<sup>2</sup>, Eliana Arango<sup>3</sup>, Chloe Hamel-Martineau<sup>4</sup>, Catherine Mitran<sup>5</sup>, Aisha Karidio<sup>4</sup>, Shanna Banman<sup>5</sup>, Olga Agudelo<sup>3</sup>, Carolina Lopez<sup>3</sup>, Jaime Carmona-Fonseca<sup>3</sup>, Ali Salanti<sup>6</sup>, Nicaise Ndam<sup>7</sup>, Michael Hawkes<sup>8</sup>, Amanda Maestre<sup>3</sup>, Stephanie Yanow<sup>5</sup>

<sup>1</sup>Department of Medical Microbiology and Immunology, University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Campus Saint-Jean, University of Alberta, Edmonton, AB, Canada, <sup>3</sup>Universidad de Antioquia, Medellin, Colombia, <sup>4</sup>Campus Saint-Jean, University of Alberta, Edmonton, AB, Canada, <sup>5</sup>School of Public Health, University of Alberta, Edmonton, AB, Canada, <sup>6</sup>University of Copenhagen, Copenhagen, Denmark, <sup>7</sup>University of Ghana, Accra, Ghana, <sup>8</sup>Pediatrics, University of Alberta, Edmonton, AB, Canada

Most of our knowledge regarding malaria in pregnancy stems from research based in Africa, where *Plasmodium falciparum* is the predominant species. However, little is known about the effects of *Plasmodium falciparum* or *P. vivax* infection in pregnancy in other regions, particularly submicroscopic infections (SMI) that are common in areas with lower transmission. Here, we present our findings from the first longitudinal study of malaria in pregnancy in Colombia, with complete molecular diagnostic and clinical outcomes data. The study included 180 women recruited early in pregnancy (median=19 weeks) and followed during antenatal visits (median=3 visits) through to delivery. One quarter of women (n=45) had a SMI at least once during pregnancy. Twenty-one (47%) were caused by *P. falciparum*, 16 (36%) by *P. vivax*, and 8 (17%) by mixed spp. Low birth weight babies (n=10; 5.3%) and pre-term births (n=21; 11.2%) were observed in our cohort but were not associated with SMI during pregnancy. To test whether the positive birth outcomes were

due to protective antibodies, we measured anti-*VAR2CSA* antibodies at enrolment and delivery. Over 60% of women had antibodies to *VAR2CSA* at enrolment, regardless of parity. Antibody levels decreased during pregnancy and we did not observe boosting following *P.* exposure. Using the inhibition of binding assay, 38% of women with an SMI infection had functional antibodies at enrolment that inhibited binding of infected erythrocytes to chondroitin sulphate A, an *in vitro* correlate of protection from *P. falciparum* placental malaria. Among the primigravid women, 33% had inhibitory antibodies at enrolment. These results reveal a high frequency of SMI in this region. However, contrary to the findings from studies in Africa, these infections were not associated with negative birth outcomes. These findings suggest that SMI in pregnancy does not pose a significant risk to the mother and the fetus, and anti-*VAR2CSA* antibodies acquired outside of pregnancy may mediate protection from negative birth outcomes in this setting.

### PROBABILITY OF TRANSMISSION OF MALARIA FROM MOSQUITO TO HUMAN IS REGULATED BY PARASITE DENSITY IN NAIVE AND VACCINATED HOSTS

**Thomas S. Churcher**<sup>1</sup>, Robert E. Sinden<sup>1</sup>, Nick J. Edwards<sup>2</sup>, Ian Poulton<sup>2</sup>, Thomas W. Rampling<sup>2</sup>, Patrick M. Brock<sup>1</sup>, Jamie T. Griffin<sup>1</sup>, Leanna M. Upton<sup>1</sup>, Sara E. Zakutansky<sup>1</sup>, Katarzyna A. Sala<sup>1</sup>, Fiona Angrisano<sup>1</sup>, Adrian V. Hill<sup>2</sup>, Andrew M. Blagborough<sup>1</sup>  
<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>The Jenner Institute, Oxford, United Kingdom

Over a century since Ronald Ross discovered that malaria is caused by the bite of an infectious mosquito it is still unclear how the number of parasites injected influences disease transmission. Currently it is assumed that all mosquitoes with salivary gland sporozoites are equally infectious irrespective of the number of parasites they harbour, though this has never been rigorously tested. Here we analyse >1000 experimental infections of humans and mice and demonstrate a dose-dependency for probability of infection and the length of the host pre-patent period. Mosquitoes with a higher numbers of sporozoites in their salivary glands following blood-feeding are more likely to have caused infection (and have done so quicker) than mosquitoes with fewer parasites. A similar dose response for the probability of infection was seen for humans given a pre-erythrocytic vaccine candidate targeting circumsporozoite protein (CSP), and in mice with and without transfusion of anti-CSP antibodies. These interventions prevented infection more efficiently from bites made by mosquitoes with fewer parasites. The importance of parasite number has widespread implications across malariology, ranging from our basic understanding of the parasite, how vaccines are evaluated and the way in which transmission should be measured in the field. It also provides direct evidence for why the only registered malaria vaccine RTS,S was partially effective in recent clinical trials.

### CHARACTERIZING THE ROLE OF A UNIQUE PHISTB PROTEIN IN *VAR2CSA* ADHESION, PLACENTAL MALARIA PATHOGENESIS AND IMMUNITY

**Bethany J. Jenkins**<sup>1</sup>, Sanjay A. Desai<sup>2</sup>, Patrick E. Duffy<sup>1</sup>, Michal Fried<sup>1</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

*VAR2CSA* is a PfEMP1 variant surface protein that binds chondroitin sulfate A (CSA), allowing *Plasmodium falciparum* to sequester in the placenta, leading to severe pathologies. Antibodies against *VAR2CSA* increase with gravidity as women become resistant to placental malaria (PM), making *VAR2CSA* the leading PM vaccine candidate. Additional

parasite proteins are upregulated in CSA-binding parasites, but their specific contributions to PM pathogenesis and immunity are unknown. One of these, PFI1785w, is a member of the PHISTb family, several of which have been implicated in PM and other severe pathologies. Multiple studies on clinical samples from East and West Africa have demonstrated that transcript and protein expression of PFI1785w are upregulated in parasites from PM patients versus other populations, indicating that it may play a distinct role in PM pathogenesis. PFI1785w is part of a chromosome deletion found in several lab strains, including model strains for PM that retain strong expression of VAR2CSA and CSA binding. Further, additional lab strains contain a polymorphism encoding a nonsense mutation not present in most clinical isolates. While this indicates that PFI1785w is not essential for *in vitro* adhesion to CSA, the *in vivo* role of PFI1785w in PM is undefined. To better characterize this protein, we have epitope-tagged PFI1785w in several clinical isolates to define its expression and localization. Gene knockout parasites are currently being generated with CRISPR/Cas9, and the resulting phenotypes will be described, as will the patterns of antigenicity using immune sera from gravidae compared to other populations. Finally, recent studies have shown that PHIST proteins interact with the acidic terminus segment of PfEMP1 with differential affinities, suggesting that specific PHIST proteins may interact with specific PfEMP1 variants. Co-immunoprecipitation experiments to evaluate whether VAR2CSA interacts with PFI1785w or alternate PHIST proteins in null lines are in progress and will be reported.

#### TRAFFICKING AND TOPOLOGY IDENTIFICATION OF *PLASMODIUM FALCIPARUM* MAURER'S CLEFT TWO TRANSMEMBRANE PROTEIN

Raghavendra Yadavalli<sup>1</sup>, John W. Peterson<sup>2</sup>, Judith A. Drazba<sup>2</sup>, Tobili Yvonne Sam-Yellowe<sup>1</sup>

<sup>1</sup>Cleveland State University, Cleveland, OH, United States, <sup>2</sup>The Cleveland Clinic, Cleveland, OH, United States

*Plasmodium falciparum* Maurer's clefts (MC) proteins are potential vaccine and drug candidates. In this study, we investigated the trafficking and biochemical properties of *P. falciparum* Maurer's cleft two transmembrane protein (PfMC-2TM). Previous studies, showed PfMC-2TM is an integral membrane protein encoded by a 13-member multigene family. PfMC-2TM is associated with the parasitophorous vacuole (PV), MC and infected erythrocyte (IE) membranes. PfMC-2TM is transcriptionally upregulated in the trophozoite stage of *P. falciparum*. Based on these observations, we hypothesized that the protein is trafficked to the IE cytosol through the classical secretory pathway after which it associates with MC and IE membranes. To understand the stage specific expression and trafficking of PfMC-2TM, we treated tightly synchronized parasites with 10µg/ml brefeldin A. To detect the synthesis and export, PfMC-2TM was co-localized with the nascent MC resident protein ring export protein 1 (REX1) in all intraerythrocytic stages of the parasite starting from 4-hour post invasion (hpi) by immunofluorescence analysis. The results show that the protein PfMC-2TM is synthesized 4 hpi, co-localizes with REX1 and is actively trafficked by the classical secretory pathway in ring and trophozoite stages of the parasite. Further, to identify the solubility of PfMC-2TM associated with MC and IE membranes, differential carbonate and detergent extraction with protease digestion was performed on IE membrane ghosts. We show that PfMC-2TM retains integral membrane properties upon association with the IE membrane and is accessible to proteases. Additionally, permeabilization studies with streptolysin-O in combination with saponin and trypsin shown that PfMC-2TM associates with the MC with both N and C termini exposed to the erythrocyte cytosol. In conclusion, PfMC-2TM is an additional marker of the nascent MCs. PfMC-2TM is trafficked through the classical secretory pathway into the IE cytosol, associates with the MC membrane with both N and C termini facing the IE cytosol, and also associates with the IE membrane.

#### INTRA AND INTER-INDIVIDUAL RED BLOOD CELL VARIABILITY IN BIND TO *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN

Celia Dechavanne<sup>1</sup>, Sebastien Dechavanne<sup>1</sup>, Rich Fong<sup>1</sup>, Sushma Krishnan<sup>1</sup>, Lenore Carias<sup>1</sup>, Edwin Chen<sup>2</sup>, Nicole D. Salinas<sup>2</sup>, Anil Ghosh<sup>1</sup>, Niraj H. Tolia<sup>2</sup>, Christopher L. King<sup>1</sup>, Peter A. Zimmerman<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States,

<sup>2</sup>Washington University School of Medicine, St. Louis, MO, United States

*Plasmodium vivax* invasion of the red blood cell (RBC) is considered to require interaction between the Duffy Binding Protein (PvDBP) at the merozoite's apical end and the RBC Duffy blood group protein (Fy). A SNP in the Fy gene promoter underlies the "Fy erythrocyte silent" (FyES) phenotype. However, studies report *P. vivax* infections in FyES individuals from ≥8 malarious African countries where FyES approaches genetic fixation. At least two hypotheses arise to explain these observations. First, low level or periodic Fy expression may occur in FyES people. Second, PvDBP may not interact with Fy, exclusively. We studied Fy and PvDBP interaction with RBCs among Fy-positive (Fy+; n=2) and Fy-negative (Fy-; n=2) individuals over 4-months (6 time-points) to assess intra-individual variability. The relative range of recombinant PvDBP binding to RBC measured by flow cytometry (fold-increase over background) was 4.9-47.8 (mean=18.1) for Fy\*A/\*A, 11.0-110.9 (mean=34.3) for Fy\*B/\*B, 0.7-5.9 (mean=2.0) for one Fy\*B<sup>ES</sup>/\*B<sup>ES</sup> donor and 0.5-4.0 (mean=1.8) for a second Fy\*B<sup>ES</sup>/\*B<sup>ES</sup> donor. Interaction of unfolded PvDBP was 0.6-2.3 (mean=1.1) with Fy+ RBC; 0.5-1.4 (mean=0.9) with Fy- RBC. PvDBP binding to Fy RBCs was chymotrypsin sensitive. To further demonstrate binding specificity, PvDBP interaction with RBC was evaluated in inhibition experiments using the CA111, single domain camelid antibody that recognizes an epitope (Fy6) in the binding domain of Fy to PvDBP. Compared to unchallenged RBC binding, CA111 (60 µg/mL) inhibited PvDBP-RBC interaction by 91.83% for Fy\*A/\*A, 87.93% for Fy\*B/\*B, 69.23% for Fy\*B<sup>ES</sup>/\*B<sup>ES</sup> donor#1 and 65.55% for Fy\*B<sup>ES</sup>/\*B<sup>ES</sup> donor#2. These data show that PvDBP interacts specifically with Fy+ and Fy- RBCs; Fy+ > Fy-. PvDBP-specific binding varied within individuals across the 6 different study time points. Interestingly, PvDBP-specific binding for one Fy- individual was comparable to low-level binding by the Fy\*A/\*A donor at 3 of 6 study time points. It is unclear whether constitutive low level or periodic RBC expression of Fy in Fy\*B<sup>ES</sup>/\*B<sup>ES</sup>, or that PvDBP interacts with more than Fy could trigger *P. vivax* invasion of Fy- RBCs.

### 740

#### PREVALENCE AND INCIDENCE OF SCHISTOSOME INFECTION AND MORBIDITY IN PRE-SCHOOL CHILDREN AGED 6 MONTHS TO 5 YEARS

Derick N. Osakunor<sup>1</sup>, Takafira Mduluzza<sup>2</sup>, Nicholas Midzi<sup>2</sup>, Mark E. Woolhouse<sup>1</sup>, Francisca Mutapi<sup>1</sup>

<sup>1</sup>University of Edinburgh, Edinburgh, United Kingdom, <sup>2</sup>University of Zimbabwe, Harare, Zimbabwe

For a long time, pre-school children have been considered low-risk for schistosomiasis, received lower research focus and have been excluded from mass drug administration. Here, we describe the prevalence and incidence of first schistosome infection and morbidity in children aged 6 months to 5 years. This is part of a larger longitudinal study of schistosome infections in selected villages in Zimbabwe. A total of 1502 children were recruited in February 2016. Demographic and anthropometric measurements was gathered. Stool and urine samples were taken from each child for parasitological diagnosis of *Schistosoma haematobium* (urine-filtration) and to rule out *S. mansoni* and soil-transmitted helminths (Kato-Katz) respectively. Markers of morbidity including haematuria (macro, micro) and faecal occult blood (FOB) were assessed using reagent dipsticks and rapid tests. *S. haematobium* negative children were split into two groups, followed up quarterly and

annually. At baseline, prevalence of *S. haematobium* infection was 8.5% and infection prevalence/intensity increased significantly with age. FOB was positive in 2.5%, macrohaematuria in 0.7% and microhaematuria in 8.6% of children. Microhaematuria (Attributable fraction in infected–AFI:92.0%; Attributable fraction in population–AFP:40%), macrohaematuria (AFI:71.0%; AFP:1.2%), stunting–HAZ (AFI:38.0%; AFP:10.3%), malnutrition–MUACZ (AFI:34.0%; AFP:3.6%), Underweight–WAZ (AFI:29.0%; AFP:3.9%), and malnutrition–WHZ (AFI:9.0%; AFP:0.8%), showed significant associations with infection. Age (AOR: 1.4) and microhaematuria (AOR: 23.0) were independent predictors of *S. haematobium* infection. Mean quarterly incidence of *S. haematobium* infection was 4.7%, with an associated 5.6% microhaematuria. Annual incidence of *S. haematobium* was 1.8% with an associated 3.6% microhaematuria. We demonstrate for the first time, the incidence of schistosome infections with significant morbidity in pre-school children. Parasitology and haematuria are successful diagnostic and morbidity tools in this age group. Increased awareness, monitoring and treatment in this cohort is essential.

## 741

### DETECTION OF MULTI SCHISTOSOME PARASITES FROM SINGLE FILTERED URINE SAMPLES FROM SCHOOL CHILDREN AFTER MDA IN ZAMBIA

**Nilanjan Lodh<sup>1</sup>**, Mary Thao<sup>1</sup>, Megan J. Hessler<sup>1</sup>, Austin Cyrs<sup>1</sup>, Steven C. Krenzke<sup>1</sup>, El Shaimaa Mahmoud<sup>1</sup>, Chummy Sikasunge<sup>2</sup>, James Mwansa<sup>2</sup>

<sup>1</sup>Marquette University, Milwaukee, WI, United States, <sup>2</sup>The University of Zambia, Lusaka, Zambia

Schistosomiasis is one of the most important Neglected Tropical Diseases (NTDs). In sub-Saharan Africa two major human schistosomes namely *Schistosoma mansoni* and *S. haematobium* often occur sympatrically largely affecting children. In the age group of 6 - 15 year's infection prevalence and intensity peaks, which associated with growth delays, delayed cognition, poor school performance and a negative effect on the overall growth and quality of a child's life. World Health Organization (WHO) is urging member states to regularly treat at least 75% and up to 100%, of all school-aged children at risk of morbidity. We have detected *S. mansoni* and *S. haematobium* parasite specific small repeat DNA fragment from filtered urine on filter paper by Polymerase Chain Reaction (PCR). In this study we are testing urine samples obtained from Zambian school children after Mass Drug Administration (MDA) to compare between existing diagnostic tests and PCR amplification of parasite DNA from urine. We have assessed 111 samples for the above-mentioned schistosome species by amplifying species-specific DNA fragment from single urine sample. Our approach detected eight times more positive cases (total 77) than by Kato-Katz (KK: 9) for *S. mansoni* and six times more (total 72) than by hematuria (11) for *S. haematobium* and even more than urine filtration (77 compared to only 6). All of the samples were detected with 100% sensitivity and specificity devoid of any cross amplification. The same pattern was observed when stratified for age group and sex specific analysis. In addition, 69 individuals (62%) were co-infected by both parasites. We have demonstrated a significantly higher prevalence of both species than indicated by the classical examination of urine or stool and also the maintenance of infection reservoir after MDA. Our approach of detecting low prevalence multi schistosome infection is an effective means to detect low intensity infection and would enhance the effectiveness of surveillance and MDA control programs of schistosomiasis.

## 742

### ASSESSMENT OF MORBIDITY DUE TO *SCHISTOSOMA MANSONI* IN SCHOOL-AGED-CHILDREN IN MADAGASCAR

**Stephen Spencer<sup>1</sup>**, James Penney<sup>2</sup>, Cortland Linder<sup>2</sup>, Hannah Russell<sup>2</sup>, Stephanie Jokhan<sup>2</sup>, Sheena Cruickshank<sup>2</sup>, Amaya Bustinduy<sup>3</sup>, Alain Rahetilahy<sup>4</sup>

<sup>1</sup>Royal United Hospital, Bath, United Kingdom, <sup>2</sup>University of Manchester, Manchester, United Kingdom, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Madagascar Ministry of Public Health, Antananarivo, Madagascar

*Schistosoma mansoni* is a significant problem for children in eastern Madagascar. Chronic infection causes intestinal and hepatic disease, contributing to an enormous health burden. Madagascar Medical Expeditions (MADEX) is a student initiative involving schistosomiasis research in the Marolambo District of Madagascar. Across two research expeditions in 2015 and 2016 we have investigated schistosomiasis prevalence and morbidity in school-aged children and carried out educational and treatment programs for children in the district. Prevalence of *S. mansoni* was determined by Kato-Katz stool microscopy and urine circulating cathodic antigen tests. Children were interviewed using structured questionnaires on symptoms and water contact behaviour and the Pediatric Quality of Life Inventory (PedsQL). Anaemia and malaria were assessed using point-of-care tests and periportal fibrosis was investigated ultrasonographically. Preliminary results reveal 97% prevalence of schistosomiasis; nearly two-thirds of children complained of symptoms of infection; 78% children had regular interaction with the river, most commonly fetching water and washing clothes; 57% were anaemic. There were lower than average PedsQL scores in children within medium and high infection intensity subgroups. Results reveal alarming schistosomiasis prevalence and disease burden. A longitudinal approach via annual research, treatment and education based expeditions will provide information into any improvements on disease prevalence and morbidity. Qualitative behavioural studies will be a particular focus for 2017, alongside expansion of education efforts.

## 743

### IMPACT OF THREE YEARS' INTENSIVE, COMMUNITY-WIDE ANTHELMINTHIC TREATMENT ON ALLERGY-RELATED OUTCOMES, HELMINTH PREVALENCE AND HELMINTH-ASSOCIATED PATHOLOGY AMONG HIGH *SCHISTOSOMA MANSONI* TRANSMISSION ISLAND COMMUNITIES OF LAKE VICTORIA, UGANDA: RESULTS OF A CLUSTER-RANDOMIZED TRIAL

**Richard E. Sanya<sup>1</sup>**, Gyaviira Nkurunungi<sup>1</sup>, Remy Hoek Spaans<sup>1</sup>, Margaret Nampijja<sup>1</sup>, Moses Kiiza<sup>1</sup>, Joy Kabagenyi<sup>1</sup>, Edridah Tukahebwa<sup>2</sup>, Emily L. Webb<sup>3</sup>, Alison M. Elliott<sup>1</sup>

<sup>1</sup>Medical Research Council/Uganda Research Unit, Entebbe, Uganda, <sup>2</sup>Vector Control Division, Ministry of Health, Kampala, Uganda, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Parasitic helminths co-evolved with mammals. Helminth antigens and allergens have common structures and atopic (IgE-mediated) immune responses probably evolved to protect against helminths and ectoparasites, while helminths evolved strategies to down-regulate atopic processes. While strong inverse associations have been described between helminths (especially *Schistosoma*) and atopy, helminth infections are associated with some serious, and much subtle morbidity. We hypothesised that intensive anthelmintic mass drug administration (MDA) would increase atopic (skin prick test) reactions and allergy-related disease prevalence, while reducing prevalence of helminths and their associated pathology. We conducted a cluster-randomised trial of community-wide intensive MDA (quarterly single-dose praziquantel 40mg/kg plus albendazole 400mg for three days) versus standard, Uganda government intervention (annual praziquantel 40mg/kg; 6-monthly single-dose albendazole); 26 island fishing villages

were randomised, 13 per trial arm, for three years; outcomes were determined in a household survey of 3350 individuals. Intensive (compared to standard) MDA had no effect on wheeze, atopy or allergen-specific IgE levels. Intensive (compared to standard) MDA reduced *S. mansoni* infection intensity: by Kato Katz examination of 1 stool sample, prevalence fell to 23% vs 39% among all participants ( $p=0.003$ ); 36% vs 77% among 10-14 year-olds, but urine CCA remained positive in 85% of participants in both trial arms. Hookworm prevalence was reduced (8% vs 11%,  $p=0.05$ , by PCR) but there was no effect on *Trichuris* or *Strongyloides*. There were no differences in anaemia, growth, hepatosplenomegaly or abdominal ultrasound findings between trial arms. Thus, helminth infections, especially *S. mansoni*, remained almost universal in these high-transmission communities despite sustained, intensive MDA. Intensive MDA produced no clinical harm or benefit compared to standard MDA. While reassuring regarding allergy-related conditions, these results accentuate concern regarding the limitations of what can be achieved by anthelmintic MDA.

## 744

### A HIGH FIELD GRADIENT MAGNETIC PROBE FOR THE ISOLATION OF SCHISTOSOME EGGS FROM FECAL MATTER BASED ON THEIR INTERACTION WITH MAGNETIC PARTICLES

Renata Russo Frasca Candido<sup>1</sup>, Robert Charles Woodward<sup>1</sup>, Vivian Favero<sup>2</sup>, Catieli Lindholz<sup>2</sup>, Alessandra Morassutti<sup>2</sup>, Carlos Graeff-Teixeira<sup>2</sup>, Malcolm Kenneth Jones<sup>3</sup>, Timothy Guy St. Pierre<sup>1</sup>

<sup>1</sup>The University of Western Australia, Crawley, Australia, <sup>2</sup>Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil, <sup>3</sup>The University of Queensland, Brisbane, Australia

Schistosomiasis is a chronic parasitic infection caused by helminths of the genus *Schistosoma*. Most diagnostic methods, including the most widely used Kato Katz (KK) method, lack sensitivity when the egg burden in feces is low. The aim of this study was to test the sensitivity of a new method, a magnetic probe, for detecting schistosome eggs in fecal samples. A case-control study was carried out in 40 samples (20 KK +ve and 20 KK -ve) from a field study in an endemic area for *Schistosoma mansoni* in the Northeast of Brazil. Samples were processed according to a highly sensitive method called Helmintex, which starts with 30 g of feces and finishes with approximately 1 mL of sediment in an Eppendorf tube. The fecal samples in the tubes are then mixed with magnetic particles and submitted to a magnetic field, where the eggs interacted and attached to the particles, and were isolated when the magnetic field was applied. The suspension was stirred with the tip of a probe that produces a source of high magnetic field gradient for 20 seconds. Two 40- $\mu$ L droplets were extracted from the sediment by withdrawal of the probe. Each droplet was deposited on a microscope slide during demagnetization of the probe to enable inspection by optical microscopy. The remainder of the sediment was screened carefully for confirmatory results. For analysis of sensitivity, a composite reference standard was defined as follows: if any of KK, probe, or standard Helmintex screening identified an egg, the case is disease positive – otherwise negative. Eggs were detected in all 20 KK positive samples, and in the KK negative samples, the probe yielded positive results for 3 samples. Time needed to read the samples was around 3-5 minutes. Against the composite reference standard, following sensitivities with 95% CIs were observed: KK 83% (63-95%), POC CCA 79% (58-93%), probe 92% (73-99%), standard Helmintex 96% (79-100%). In conclusion, the high field gradient magnetic probe in conjunction with the Helmintex method can provide rapid and sensitive detection of *Schistosoma* eggs.

## 745

### POINT OF CARE DIAGNOSIS FOR MULTIPLE SCHISTOSOME PARASITES: SPECIES-SPECIFIC DNA DETECTION FROM SINGLE URINE SAMPLE BY LAMP AND PCR

Nilanjan Lodh<sup>1</sup>, Kei Mikita<sup>2</sup>, Kwabena M. Bosompem<sup>3</sup>, William K. Anyan<sup>3</sup>, Joseph K. Quartey<sup>3</sup>, Joseph Qtchere<sup>3</sup>, Miriam Price<sup>1</sup>, Clive J. Shiff<sup>4</sup>

<sup>1</sup>Marquette University, Milwaukee, WI, United States, <sup>2</sup>Keio University School of Medicine, Tokyo, Japan, <sup>3</sup>Noguchi Memorial Institute for Medical Research (NMIMR), Accra, Ghana, <sup>4</sup>Johns Hopkins University, Baltimore, MD, United States

Schistosomes are easily transmitted and multiply considerably so if control strategies based on targeted mass drug administration (MDA) are to succeed it is essential to have a test that is sensitive, accurate and simple to use. It is regularly demonstrated that praziquantel does not always eliminate an infection so in spite of the successes of control programs a residual of the reservoir will survive to re-infect snails. The issue of diagnostic sensitivity will become more critical in the assessment of program effectiveness. While serology or antigen capture tests might improve sensitivity, it has been shown that the presence of species-specific DNA fragment by amplification from urine residue captured on Whatman # 3 filter paper that is dried after filtration improves sensitivity significantly. It is simple to handle, transport and can be stored for several months without freezing. In the current study done in a low to moderate transmission area in Ghana, we assessed the efficacy of detection of either or both *Schistosoma mansoni* and *S. haematobium* specific DNA from 86 urine residues both by PCR and loop mediated isothermal amplification (LAMP). We also compared the DNA extraction techniques by standard extraction kit and field usable LAMP PURE kit and have evaluated these different extractions for species-specific DNA detection. With *S. haematobium* all three methods showed similar sensitivity and specificity when compared with PCR amplification (100%). For *S. mansoni* sensitivity was highest for LAMP amplification (100%) than PCR and LAMP PURE (99% and 94%). The LAMP PURE extraction produced false negatives, which require further investigation for this field usable extraction kit. Overall high positive and negative predictive values (90% - 100%) for both species demonstrated a highly robust approach. The LAMP approach is close to point of care use and more sensitive and equally specific to detection of parasite eggs in urine or stool showing that LAMP can be an effective means to detect low intensity infection and its simplicity and ease of sampling would enhance the effectiveness of surveillance and MDA control programs of schistosomiasis.

## 746

### TREATMENT EFFECTS ON EGG AND ANTIGEN DIAGNOSTICS OF SCHISTOSOMA MANSONI INFECTIONS

Joaquin M. Prada<sup>1</sup>, Poppy H. Lamberton<sup>2</sup>, Moses Adriko<sup>3</sup>, Moses Arinaitwe<sup>3</sup>, David W. Oguttu<sup>3</sup>, Panayiota Touloupou<sup>1</sup>, Deirdre Hollingsworth<sup>1</sup>

<sup>1</sup>University of Warwick, Coventry, United Kingdom, <sup>2</sup>University of Glasgow, Glasgow, United Kingdom, <sup>3</sup>Ministry of Health Uganda, Kampala, Uganda

Schistosomiasis is a major socio-economic and public-health problem in many sub-Saharan African countries. After large mass drug administration (MDA) campaigns, prevalence of infection rapidly returns to pre-treatment levels. The traditional egg-based diagnostic for schistosome infections, Kato-Katz, is being substituted in many settings by circulating antigen recognition based diagnostics, such as the point-of-care circulating cathodic antigen test (CCA). The relationship between these two diagnostics, particularly after treatment in drug-efficacy studies, is poorly understood. We created an inference model of schistosome infections to better understand and quantify the relationship between these two egg and adult worm antigen based diagnostics. Due to the semi-quantitative nature of CCA, we focused on the current major challenges of interpreting "trace" CCA results. Our analyses suggest that CCA is generally a better

predictor of prevalence, particularly after treatment, and that trace CCA results are typically associated with truly infected individuals. Even though prevalence rises to pre-treatment levels only a few months after MDAs, our model suggests that the average infection level is much lower, and is probably due to a smaller burden of surviving juveniles from when the treatment occurred. This work helps to better understand CCA diagnostics and the interpretation of post-treatment prevalence estimations.

## 747

### **BREAST MILK EPIDERMAL GROWTH FACTOR IS ASSOCIATED WITH GROWTH AND DIARRHEA IN BANGLADESHI CHILDREN**

**Jeffrey Donowitz**<sup>1</sup>, Masud Alam<sup>2</sup>, Rashidul Haque<sup>2</sup>, Beth D. Kirkpatrick<sup>3</sup>, Hafiz Kakon<sup>2</sup>, Bushra Zarin Islam<sup>2</sup>, Sajia Afreen<sup>2</sup>, E. Ross Colgate<sup>3</sup>, Marya P. Carmolli<sup>3</sup>, William A. Petri<sup>4</sup>

<sup>1</sup>Virginia Commonwealth University, Richmond, VA, United States,

<sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>The University of Vermont College of Medicine, Burlington, VT, United States, <sup>4</sup>University of Virginia, Charlottesville, VA, United States

Environmental enteropathy, an intestinal inflammatory condition, has been associated with poor linear growth in children from low-income countries. Diarrhea in this setting represents the second leading cause of mortality and a significant cause of morbidity in young children. Epidermal growth factor (EGF) is 6kDa protein that is known to have cellular proliferative and anti-inflammatory properties. EGF is known to be present in human breast milk. Thus, we decided to measure EGF levels in breast milk of new Bangladeshi mothers and investigate if EGF level was associated with growth and diarrheal disease. Breast milk was collected at 6 weeks postpartum. EGF was measured via commercial ELISA kit (Eagle Biosciences, Nashua, NH USA). Children were followed through 1 year of age with continuous diarrheal surveillance via twice weekly home visits. Anthropometrics data was also collected. Data was first analyzed via Pearson correlation for anthropometrics and univariate poisson regression for diarrhea. Multivariable linear regression models were constructed for change in length-for-age and weight-for-age Z score with EGF, income, postpartum day of milk collection, and maternal height as predictors. EGF was log transformed for analysis. In univariate analysis EGF was associated with improved linear growth at 18 weeks ( $r = 0.13$ ,  $p = 0.004$ ), 24 weeks ( $r = 0.11$ ,  $p = 0.02$ ), and 52 weeks of age ( $r = 0.12$ ,  $p = 0.007$ ). EGF was not associated with improved weight gain. This relationship remained significant when covariates were corrected for at 18 weeks (coefficient [95% CI]: 0.38 [0.12, 0.65],  $p = 0.004$ ), 24 weeks (0.37 [0.085, 0.66],  $p = 0.01$ ), and 52 weeks (0.48 [0.15, 0.83],  $p = 0.005$ ). EGF was also associated with decreased number of diarrheal episodes at 3 months (coefficient [95% CI]: -0.70 [-1.15, -0.25],  $p = 0.002$ ) and 6 months (-0.39 [-0.71, -0.08],  $p = 0.015$ ). This association was not significant at 1 year of age. Our analysis showed that EGF levels in breast milk are associated with improved linear growth through 1 year of age. Additionally, EGF levels are associated with decreased diarrheal episodes through 6 months of age but this effect wanes by 1 year.

## 748

### **VACCINE-INDUCED MUCOSAL IMMUNITY FROM IPV-BOPV AND IPV-ONLY IMMUNIZATION SCHEDULES: ANALYSIS OF AN OPEN-LABEL, RANDOMIZED CONTROLLED TRIAL IN CHILEAN INFANTS**

**Elizabeth B. Brickley**<sup>1</sup>, Wendy Wieland-Alter<sup>2</sup>, Ruth I. Connor<sup>1</sup>, Margaret E. Ackerman<sup>3</sup>, Austin W. Boesch<sup>3</sup>, Minetaro Arita<sup>4</sup>, Miguel G. O’Ryan<sup>5</sup>, Ananda S. Bandyopadhyay<sup>6</sup>, Peter F. Wright<sup>2</sup>

of Chile, Santiago, Chile, <sup>6</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States

A globally synchronized replacement of trivalent oral polio vaccine (OPV) with bivalent OPV (bOPV) lacking a type 2 poliovirus component was successfully implemented in early 2016. To mitigate risks of re-emergent type 2 poliomyelitis following the switch, the World Health Organization recommended the concomitant introduction of at least one dose of trivalent inactivated polio vaccine (IPV). Nevertheless, the capacity of IPV to elicit robust intestinal mucosal immunity against polio - and thereby block poliovirus replication and shedding - remains uncertain. In a Chilean clinical trial (NCT01841671), infants were randomized to receive IPV-bOPV-bOPV, IPV-IPV-bOPV, or IPV-IPV-IPV at 8, 16, and 24 weeks of age and then challenged with monovalent OPV type 2 (mOPV2) at 28 weeks. Using fecal samples collected at 28, 29, 30, 31, and 32 weeks, we investigated the extent to which the immunization schedules induced polio type-specific neutralization and immunoglobulin A at enteric sites. Despite receiving up to three doses of IPV ( $\pm$  bOPV), only 32% of the total 181 vaccinees had detectable type 2-specific stool neutralization after the primary vaccine series. In contrast, the mOPV2 challenge induced brisk type 2-specific intestinal responses in all vaccine groups, and significantly higher stool neutralization ( $p < 0.0001$ ) and immunoglobulin A concentrations ( $p < 0.0001$ ) were measured after two weeks. Overall, type 2-specific mucosal neutralization and immunoglobulin A levels were positively associated with sustained breastfeeding and inversely correlated with viral shedding. Although IPV-bOPV and IPV-only immunization schedules consistently elicit high rates of seroconversion against all three poliovirus types, these results suggest vaccine regimens lacking OPV2 may induce only modest intestinal mucosal immune responses against type 2 poliovirus.

### **IMMUNOGENICITY AND PROTECTIVE EFFICACY OF A LIVE ATTENUATED ETEC VACCINE CANDIDATE AGAINST VIRULENT ENTEROTOXIGENIC ESCHERICHIA COLI (ETEC) IN A HUMAN ETEC CHALLENGE MODEL**

**Subhra Chakraborty**<sup>1</sup>, Clayton Harro<sup>1</sup>, Jessica Brubaker<sup>1</sup>, Barbara DeNearing<sup>1</sup>, Nicole Bauers<sup>2</sup>, Len Dally<sup>3</sup>, Alan Fix<sup>2</sup>, Sachin Mani<sup>2</sup>, Louis Bourgeois<sup>2</sup>, David Sack<sup>1</sup>, Richard Walker<sup>2</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>PATH, Washington, DC, United States, <sup>3</sup>The EMMES Corporation, Rockville, MD, United States

ETEC is a common cause of bacterial diarrhea in children as well as in travelers and military personnel deploying to ETEC endemic countries. A licensed vaccine for ETEC is not currently available. We have previously demonstrated that an oral, live attenuated, three-strain recombinant ETEC vaccine, ACE527, was safe and well tolerated. However the protective efficacy (27%) against severe diarrhea was not statistically significant. We have extended these observations in a new phase 2b efficacy study where we added double mutant heat labile toxin (dmLT) as an adjuvant and also added a 3rd dose to the primary immunization series. Immunized subjects were challenged with the ETEC H10407 at 6-7 months after immunization. Serum IgA and IgG; antibody in lymphocyte supernatant (ALS); fecal IgA and memory B cell responses to LT-B, CFA/II, CS3, and CS6 following vaccination and challenge were evaluated to monitor vaccine immunogenicity and to identify immune correlates of protection. Functional assays such as, toxin neutralization and adherence blocking assays are currently getting evaluated. Results of this recent Ph2b study indicated that the adjuvanted group was significantly protected against severe diarrhea (PE=65.9%  $p=0.01$ ) and against diarrhea of any severity (PE=58.5%  $p=0.02$ ). Overall, the immune responses in the adjuvanted and vaccine alone groups were not significantly different. We found strong indications which suggests that CFA/II response may have contributed in protection. There were also measurable anti-LT, anti-CS3 responses in these subjects. Most of the subjects exhibited antigen-specific Memory B cell responses; however, the responses were short lived and there was no

significant association with protection. The apparent diminished responses to key antigens in the adjuvanted immune subjects following challenge with H10407 gave a further indication that colonization may be modified in this group. Further investigations looking at T cell responses, as well as expanded immune profiling using proteome arrays are underway to find novel ETEC antigens that might show clearer association with protection.

## 750

### WHEN IS A CONTROL NOT A CONTROL? —ANALYSIS OF DIARRHEA AND ENTERIC INFECTION AMONG CONTROLS IN THE GLOBAL ENTERIC MULTICENTER STUDY, KENYA, 2008-2012

**David M. Berendes<sup>1</sup>**, Ciara E. O'Reilly<sup>2</sup>, Sunkyung Kim<sup>2</sup>, Richard Omoro<sup>3</sup>, John B. Ochieng<sup>3</sup>, Tracy Ayers<sup>3</sup>, Kirsten Fagerli<sup>2</sup>, Tamer H. Farag<sup>4</sup>, Dilruba Nasrin<sup>5</sup>, Sandra Panchalingam<sup>5</sup>, James P. Nataro<sup>6</sup>, Karen L. Kotloff<sup>5</sup>, Myron M. Levine<sup>5</sup>, Joseph Oundo<sup>3</sup>, Kayla Laserson<sup>7</sup>, Robert F. Breiman<sup>8</sup>, Eric D. Mintz<sup>2</sup>

<sup>1</sup>Georgia Institute of Technology, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Kenya Medical Research Institute, Center for Global Health Research, Kisumu, Kenya, <sup>4</sup>Center for Vaccine Development, University of Maryland School of Medicine/Institute for Health Metrics and Evaluation, Baltimore, MD, United States, <sup>5</sup>Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>6</sup>Center for Vaccine Development, University of Maryland School of Medicine/Department of Pediatrics, University of Virginia School of Medicine, Baltimore, MD, United States, <sup>7</sup>KEMRI/Centers for Disease Control and Prevention, CDC India, Kisumu, Kenya, <sup>8</sup>Emory Global Health Institute, Atlanta, GA, United States

Most case-control studies of risk factors for diarrheal disease focus on cases and use eligibility criteria to ensure controls are diarrhea-free. However, growing attention to the impact of subclinical enteric infections in children suggests these controls may offer valuable insights into underlying rates of infection and disease. This study examined enteric infection, diarrhea, and health outcomes in control children (n=2,534) of the Global Enteric Multicenter Study (GEMS) Kenya site. Data were obtained from laboratory results of stool samples collected from controls at enrollment, a subsequent 14-day memory aid for diarrhea, and a 60-day follow-up visit. Controls reported being diarrhea-free for  $\geq 7$  days before GEMS enrollment, but 69% of stool samples from controls tested positive for  $\geq 1$  enteric pathogen, compared with 81% of samples from cases (p<0.001). Almost 39% of controls reported diarrhea within 14 days of enrollment; 459 (50%) of whom reported diarrhea within the first 5 days. Controls with and without diarrhea in the 14-day period did not differ significantly in detection of enteric pathogens in stool at enrollment, with the exception of typical enteropathogenic *E. coli* (6% in controls with diarrhea v. 4% in those without). At 60-day follow-up, controls who reported diarrhea in the 14-day period were more likely to have visited a health facility for diarrhea (28% v. 7%) or fever (23% v. 16%), and to have significantly lower height-for-age Z (HAZ) scores than controls without diarrhea during that period. Almost 20% of controls were negative for both diarrhea and enteric pathogens. These controls had significantly improved HAZ scores over both a) controls with diarrhea and enteric pathogens in stool (27%) and b) controls without diarrhea but with enteric pathogens in stool (42%). Overall, the high incidence of diarrhea after enrollment and of subclinical enteric infection in controls, and their links with poorer clinical outcomes at follow-up, highlight complexities in assessing diarrheal disease contributors with a single entry point for participants, relevant for design of future epidemiologic studies of diarrheal disease.

## 751

### IMPACT OF MENINGOCOCCAL SEROGROUP A CONJUGATE VACCINE ON MENINGITIS EPIDEMIOLOGY—BURKINA FASO, 2011-2015

**Alpha Oumar Diallo<sup>1</sup>**, Heidi M. Soeters<sup>1</sup>, Issaka Yameogo<sup>2</sup>, Guetawendé Sawadogo<sup>2</sup>, Flavien Aké<sup>3</sup>, Xin Wang<sup>1</sup>, Lassana Sangaré<sup>4</sup>, Rasmata Ouédraogo-Traoré<sup>5</sup>, Isaïe Medah<sup>2</sup>, Brice Bicaba<sup>2</sup>, Ryan T. Novak<sup>1</sup>

<sup>1</sup>U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Direction de la Lutte contre la Maladie, Ministère de la Santé, Ouagadougou, Burkina Faso, <sup>3</sup>Davycas International, Ouagadougou, Burkina Faso, <sup>4</sup>Centre Hospitalier Universitaire Yalgado Ouédraogo, Ouagadougou, Burkina Faso, <sup>5</sup>Centre Hospitalier Universitaire Pédiatrique Charles de Gaulle, Ouagadougou, Burkina Faso

Historically, *Neisseria meningitidis* serogroup A (NmA) caused large meningitis epidemics in sub-Saharan Africa. In 2010, Burkina Faso became the first country to implement a national meningococcal serogroup A conjugate vaccine (MACV) campaign. We examined nationwide laboratory-confirmed case-based meningitis surveillance data in Burkina Faso in the five years (2011-2015) following MACV introduction to evaluate vaccine impact on meningitis epidemiology. We calculated incidence (cases per 100,000 persons) and described reported NmA cases. In 2011-2015, Burkina Faso reported 18,538 cases of suspected meningitis with average annual incidence of 22.2, lower than the reported average annual incidence (81.2) in the 4 years prior to MACV introduction. Among reported cases, 98% received lumbar punctures (LPs); 62% of specimens were tested by at least one confirmatory test. Among 11,164 tested meningitis cases, 4,503 (40%) were laboratory-confirmed: *H. influenzae* (2%), *N. meningitidis* (40%), and *S. pneumoniae* (57%). Average annual incidence of meningococcal meningitis was 3.8 (range: 2.0-10.2 annually) and was highest among infants aged <1 year (8.4). *N. meningitidis* serogroup W caused the majority (64%) of meningococcal meningitis among all age groups. Only six confirmed NmA cases were reported in 2011-2015. Five cases were in children who were age ineligible (n=2) or otherwise not vaccinated (n=3) during the 2010 MACV mass vaccination campaign; one case had documented MACV receipt, representing the first documented MACV vaccine failure. Meningitis incidence in Burkina Faso remains relatively low following MACV introduction; however, data suggest a substantial burden remains and NmA transmission persists. MACV integration into Burkina Faso's routine immunization program is essential to provide continued protection. Sustained investment to strengthen meningitis surveillance will allow monitoring of evolving epidemiology and vaccine effectiveness.

Buruli ulcer disease (BUD), caused by *Mycobacterium ulcerans*, is a chronic debilitating disease of the skin causing necrotic lesions and ulcerations. The disease mainly affects children and adolescent and cases are reported in 33 tropical and subtropical countries with West Africa, including Ghana, being most affected. As for other mycobacterial infections, T cell mediated immune responses are important for protection and recovery during

treatment, but studies investigating antigen-specific immune responses and immune modulation in BUD patients are scarce. The aim of the study was to characterize *M. ulcerans* specific CD4+ T cell responses and analyze immune modulation in BUD patients. We performed a case-control study on children with BUD and compared them to healthy controls and a follow-up study on BUD patients before and after treatment with antibiotics. Whole blood was stimulated with antigens prepared from *M. ulcerans* and cytokine production by T cells was analyzed by intracellular flow cytometry. In addition, we evaluated markers of activation and inhibition on T cells to determine systemic immune modulation in BUD patients. Results were associated with disease severity and progression to *i.*) investigate potential biomarkers for the disease and *ii.*) to dissect mechanisms of *M. ulcerans*-specific protective immune responses. We show that TNF $\alpha$ -single cytokine producing CD4+ T cells are increased in BUD patients, are associated with severity and healing progress indicating a potential use as biomarker. We will further present results on the TH2 and regulatory cytokine profile of CD4+ T cells in BUD and on regulatory T cell responses. The presented results will provide a complex figure of the antigen-specific immune responses induced in BUD patients, it will provide insights in immune regulation and thereby help to dissect mechanisms of protection and immune pathology in BUD.

## 753

### IMMUNE RESPONSE TO RECOMBINANT PROTEINS OF MYCOBACTERIUM LEPRAE POTENTIAL APPLICATION FOR LEPROSY DIAGNOSIS

Pedro H. Marçal<sup>1</sup>, Lucia Alves Fraga<sup>2</sup>, Tom Ottenhoff<sup>3</sup>, Annemieke Geluk<sup>3</sup>, Malcon Duthie<sup>4</sup>, Henrique Couto Teixeira<sup>5</sup>

<sup>1</sup>Universidade Vale do Rio Doce, Governador Valadares, Brazil,

<sup>2</sup>Universidade Federal de Juiz de Fora - Campus GV, Governador Valadares, Brazil, <sup>3</sup>Leiden University Medical Center, Amsterdam, Netherlands,

<sup>4</sup>Infectious Disease Research Institute (IDRI), Seattle, WA, United States,

<sup>5</sup>Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil

Leprosy is a infectious disease, that remains a serious public health problem. Until now, the diagnosis of leprosy has been based on dermatoneurological examination complemented with smear microscopy and with histopathology. The development of a specific and sensitive serological test is of fundamental importance for early diagnosis. The purpose of this study was to evaluate serum samples from leprosy patients, household contacts and healthy subjects for reactivity against specific recombinant proteins of *M. leprae* (ML0405, ML2055, ML2331, Ag85B, NDO-LID, NDO-HAS and LID) using ELISA. 44 leprosy patients (PB and MB), 61 household contacts (MBC and PBC) and 16 healthy individuals (HC), participated of the study. The comparison between the groups was carried out through the non-parametric Mann-Whitney. The ROC curve was used for analysis of the accuracy values: area under the curve, sensitivity, specificity and likelihood ratios (LR+ and LR-). The group of MB patients had higher IgG production compared to HC and PB groups for all antigens. MBC group showed higher production of specific IgG antibodies to ML2055 and ML0405 in comparison with the HC group. IgM levels were higher in MB patients compared with the HC group only for the ML2331. IgM levels to ML2055 and Ag85B were higher in MBC compared to the HC group. The evaluation of sensitivity and specificity for the ROC curve of the MB group showed that the ML0405 antigen-specific IgG1 levels presented sensitivity of 73% and specificity of 93.8% with LR+ of 11.73 and LR- of 0.28. IgG4 levels to ML0405 presented sensitivity of 80% and specificity of 93.8%, with LR+ of 9.6 and LR- of 0.41. Serum levels of total IgG and IgG1 against LID-1, NDO-LID and NDO-HSA antigens were significantly higher in MB patients in comparison with all other groups. Our results suggest that a serological test using ML0405, ML2055 and LID-1 antigens could be developed as an additional test for the early diagnosis of leprosy. Serological reactivity against ML0405, ML2055 and Ag85B in MBC may represent an eligible strategy for active surveillance and preventive chemoprophylaxis seeking better control of leprosy.

## 754

### HERITABLE GENE EDITING BY TARGETED DELIVERY OF CAS9 NUCLEASE TO THE MOSQUITO GERMLINE

Jason L. Rasgon<sup>1</sup>, Duverney Chaverra Rodreguez<sup>1</sup>, Vanessa M. Macias<sup>1</sup>, Grant L. Hughes<sup>2</sup>, Yasutsugu Suzuki<sup>3</sup>, David R. Peterson<sup>1</sup>, Sujit Pujhari<sup>1</sup>

<sup>1</sup>Pennsylvania State University, University Park, PA, United States,

<sup>2</sup>University of Texas Medical Branch, Galveston, TX, United States, <sup>3</sup>Institut Pasteur, Paris, France

CRISPR/Cas9 gene editing is a powerful tool for addressing research questions in arthropods. Current approaches rely upon delivering Cas9 ribonucleoprotein complex (RNP) to arthropod eggs by embryonic microinjection. However, embryonic microinjection is challenging, is limited to a small number of species, and is inefficient even in optimized taxa. We have developed a technology called Receptor-Mediated Ovary Transduction of Cargo (ReMOT Control) to specifically deliver the Cas9 RNP to the insect germline by injection into adult females. After injection into the adult female hemolymph, ReMOT Control transduces Cas9 RNP to the developing germline, resulting in "in utero" editing of the offspring chromosomal sequence. In *Aedes aegypti*, ReMOT Control gene editing efficiency is as high as 17%. Once optimized for multiple species, the ReMOT Control technology will dramatically change the landscape of molecular entomology research, allowing easy, flexible genetic manipulation of a wide variety of vector arthropods and non-model species.

## 755

### CRISPR-CAS9 MEDITATED GENE KNOCKOUT OF PLASMODIUM AGONISTS IN ANOPHELES GAMBIAE ENHANCES MOSQUITOES' RESISTANCE TO THE HUMAN MALARIA PARASITE

Yuemei Dong<sup>1</sup>, Maria L. Simões<sup>1</sup>, Eric Marois<sup>2</sup>, George Dimopoulos<sup>1</sup>

<sup>1</sup>Johns Hopkins School of Public Health, Baltimore, MD, United States,

<sup>2</sup>Institut de Biologie Moléculaire et Cellulaire, UPR9022 CNRS, Strasbourg, France

In the malaria parasite's journey through the mosquito, *Plasmodium* engages in intimate interactions with the vector's midgut, hemolymph, and salivary glands, during which it relies on numerous mosquito-derived host factors. The mosquito's anti-*Plasmodium* immune responses are on the other hand targeting the parasite through a variety of immune proteins, or restriction factors. These crucial *Anopheles-Plasmodium* interactions represent powerful targets for transmission-blocking by either inhibiting parasite agonists (or host factors) that are required for infection, or over-expressing parasite antagonists (or restriction factors) that suppress infection. *Plasmodium* infection can be suppressed in the *Anopheles* vector by agonist deletion through gene editing. The recently developed CRISPR-Cas9 based genome editing tools for *Anopheles* mosquitoes provide new and promising opportunities for the study of agonist function through gene deletion. We have focused on several validated *Plasmodium falciparum* host factors as targets for CRISPR-Cas9 based germ-line targeted gene knockout (KO), to study their host factor biology, and evaluate them as transmission-blocking targets for the development of a novel malaria control strategy. We have selected three guide RNA (gRNA) target sequences for each gene of interest, and generated several U6::gRNA constructs for embryo microinjection of *A. gambiae*. Several gRNA-overexpressing transgenic lines were obtained and through the crossing with the Vasa::Cas9 strain and outcrossing with the wild type mosquitoes, a couple of KO mutants were generated. Our results have shown that, while some host factors play essential biological roles which are impossible to mutate because of lethality at pre-adult embryonic and larval stages in the KO mutants, other host factors mutants did develop into adults showing profound suppression of human malaria parasite

infection with a significant 82% reduction in oocysts load. Ongoing studies are investigating the biology of *Plasmodium* blocking through gene knockout of *Plasmodium* agonists, as well as the over-expression of anti-*Plasmodium* effectors.

756

### DEVELOPING EVOLUTIONARILY STABLE GENE DRIVES IN *ANOPHELES GAMBIAE*

Andrea L. Smidler

Harvard University, Boston, MA, United States

Gene drives are transgenes capable of biasing their own inheritance. By encoding CRISPR components targeting the homologous wild type locus in the germline, and subsequent repair by Homologous Recombination (HR), they enable super-Mendelian inheritance in the progeny of diploid species. As a result they are capable of spreading themselves - as well as any associated genetic cargo - to allelic fixation in wild populations. Among other possibilities, they promise to enable scientists to unilaterally engineer wild mosquito populations to be refractory to malaria. However research is emerging that 'classic' gene drives create mutations as they propagate, directly preventing further drive spread. These drive-resistant alleles render gene drives unable to copy by HR, and results in the gene drive being selected out of the population. To overcome this hurdle, we are developing evolutionarily stable gene drives that prevent drive-resistant alleles from being created. Here we will outline our progress towards developing evolutionarily stable CRISPR-based gene drives in the malaria mosquito *Anopheles gambiae*. Towards this end I will discuss a new method for gene knock-in into genetically-intractable *loci* as well as preliminary data on the stability and efficiency of these novel gene drive architectures.

757

### SI-RNA PESTICIDES TARGETING MULTIPLE MALARIA VECTOR MOSQUITO SPECIES

Molly Duman Scheel<sup>1</sup>, Keshava Mysore<sup>1</sup>, Limb Haparai<sup>1</sup>, Kathleen Eggleston<sup>1</sup>, Longhua Sun<sup>2</sup>, Elizabeth Harper<sup>1</sup>, Yingying Chen<sup>2</sup>, Na Wei<sup>2</sup>, David W. Severson<sup>2</sup>

<sup>1</sup>Indiana University School of Medicine, South Bend, IN, United States,

<sup>2</sup>University of Notre Dame, Notre Dame, IN, United States

Mosquito control is the primary means of preventing malaria and other mosquito-borne diseases. Due to the increase of reported insecticide resistance and rising concern for the negative effects of pesticides on non-target organisms, the current pesticide repertoire is faced with great challenges to sustainability. New biorational pesticides are vitally needed to address established and emerging arthropod-borne infectious diseases. RNAi, which is attracting attention in the agricultural pest control community, has facilitated functional genetic characterization of mosquito development in our laboratory. We are now examining the hypothesis that ingested siRNAs can be utilized as mosquito pesticides. A high-throughput screen conducted in *Anopheles gambiae* enriched for the selection of siRNA pesticides that generate high levels of mortality throughout the larval period, target multiple *Anopheles* species, are non-toxic to humans and other non-target organisms, and which will create an siRNA arsenal to combat resistance that arises from point mutations in any one target sequence. This successful screen identified 50 *Anopheles* siRNA larvicides. Of the 50 larvicidal siRNAs, 10 highly lethal siRNAs with target sequences that are conserved in multiple *Anopheles* mosquito species were prioritized. In silico assays demonstrated that the siRNAs pose little risk for humans or other non-target organisms. Potential field delivery systems for these interfering RNA molecules were then assessed. These studies identified larval soaking, chitosan nanoparticles, non-pathogenic bacteria, and *Saccharomyces cerevisiae* (baker's yeast) as potential delivery systems for *Anopheles* interfering RNA larvicides. Of the delivery mechanisms assessed, yeast interfering RNA larvicides, which can generate up to 100% larval death in laboratory trials even when the yeast are heat-inactivated,

are of particular interest. Future studies will pursue field-testing of these pesticides, as well as extension of our siRNA pesticide screens to adult mosquitoes.

758

### CYTOGENETIC MECHANISMS OF HYBRID MALE STERILITY IN THE *ANOPHELES GAMBIAE* COMPLEX

Jiangtao Liang, Michael Hodge, Igor V. Sharakhov

Virginia Tech, Blacksburg, VA, United States

The success of malaria transmission highly depends on the rate of mosquito reproduction. The development of novel approaches to control the reproductive output of mosquitoes must include the understanding of how reproduction is regulated. Studying the mechanisms of sterility of male hybrids between closely related species of mosquitoes can improve our knowledge of speciation and empower the sterile insect technique. Inter-species crosses in the *Anopheles gambiae* complex most often result in F1 hybrid male sterility confirming the Haldane's rule about sterility or inviability of the heterogametic sex. The genetic basis and mechanisms of hybrid male sterility in mosquitoes are unknown. To investigate them, we performed crosses between laboratory colonies of *An. merus* (MAF) and either *An. gambiae* s.s. (Zanu) or *An. coluzzii* (Mopti and Mali). Our results confirmed sterility of F1 hybrid males. Testes had a near normal morphology and size but produced very few sperms in hybrids between female *An. merus* and male *An. gambiae* or *An. coluzzii*. However, testes were severely underdeveloped in hybrid males from the reciprocal crosses. Using X-specific and Y-specific FISH probes, we followed the process of meiosis in individual species and their F1 hybrids. We discovered a novel sperm phenotype - X+Y bearing sperms - caused by abnormal chromosomal activities in meiosis of male hybrids. Compared with chromosomes in parental species, chromosomes in hybrid males showed various degrees of insufficient condensation indicating a malfunction of proteins associated in chromosome condensation. Moreover, sex chromosomes in hybrid males failed to pair and to enter anaphase I. We hypothesize that fixed differences in the molecular structure of sex chromosome heterochromatin may contribute to the abnormal progress of meiosis and hybrid male sterility in malaria mosquitoes.

759

### CHEMOSENSORY GENE EXPRESSION IN THE PROBOSCIS OF *ANOPHELES GAMBIAE* S.L. MOSQUITOES WITH VARYING HOST PREFERENCE

Zachary R. Popkin-Hall<sup>1</sup>, Luciano V. Cosme<sup>2</sup>, Giridhar Athrey<sup>1</sup>, Michel A. Slotman<sup>1</sup>

<sup>1</sup>Texas A&M University, College Station, TX, United States, <sup>2</sup>Yale University, New Haven, CT, United States

The *Anopheles gambiae* complex contains several of the primary vectors of malaria in sub-Saharan Africa. Within the complex, *Anopheles coluzzii* is highly anthropophilic, while *Anopheles quadriannulatus* prefers feeding on bovines. Mosquito host searching is modulated by the olfactory organs, and differential expression of chemosensory genes could play a significant role in determining host preference. Previous work has compared chemosensory expression in the antennae and palps of these species. The proboscis remains unstudied, even though olfactory genes are known to be expressed in *Aedes aegypti* proboscises. Five chemosensory gene families that interact directly with odorants may be relevant for host choice: olfactory receptors (*Ors*), ionotropic receptors (*Irs*), odorant binding proteins (*Obps*), chemosensory proteins (*Csps*) and gustatory receptors (*Grs*). We therefore used RNA-Seq to compare their expression in the proboscises of *An. coluzzii* and *An. quadriannulatus*. Overall chemosensory gene expression between the two species is highly correlated, but the expression of a number of genes is considerably enhanced in *An. coluzzii*. *Or6* stands out as the 2nd most highly expressed *Or* in both sexes of this species, while it is almost absent from *An. quadriannulatus*. In addition, several highly expressed *Irs* are between 2.0 and 7.1-fold enhanced in *An.*

*coluzzii*. *Ir7s* is the most highly expressed *Ir* in the proboscis of this species, and is 7.1-fold upregulated. Similarly, two of the most highly expressed *Obps* (*Obp54* and *Obp26*) are 5.0 and 8.4-fold upregulated in *An. coluzzii* proboscises, with *Obp26* being mostly specific to females. No *Csps* showed significantly different expression between the females of the two species. Finally, we detected a large number of *Grs*, although many were expressed at low levels. Several of the most highly expressed *Grs* (*Gr15*, *Gr48-52*) were significantly 1.7 to 12.6-fold higher expressed in the proboscis of *An. coluzzii* females. It is possible that some of the gene expression differences observed here are correlated to host preference in these mosquitoes.

## 760

### GENETIC ARCHITECTURE OF WOLBACHIA-MEDIATED DENGUE VIRUS BLOCKING IN Aedes Aegypti

Gerard Terradas<sup>1</sup>, Scott L. Allen<sup>2</sup>, Stephen F. Chenoweth<sup>2</sup>, Elizabeth A. McGraw<sup>1</sup>

<sup>1</sup>Monash University, Clayton, Vic, Australia, <sup>2</sup>The University of Queensland, Brisbane, Qld, Australia

The mosquito vector *Aedes aegypti* is responsible for transmitting a range of arboviruses including dengue (DENV) and Zika (ZIKV). The global reach of these viruses is increasing due to an expansion of the mosquito's geographic range and increasing urbanization and human travel. Vector control remains the primary means for limiting these diseases. *Wolbachia pipiensis* is an endosymbiotic bacterium of insects that has the ability to block the replication of pathogens, including flaviviruses such as DENV or ZIKV, inside the body of the vector. A strain of *Wolbachia* called *wMel* is currently being released into wild mosquito populations to test its potential to limit virus transmission to humans. The mechanism that underpins the virus blocking effect, however, remains elusive. Using a full-sib breeding design in conjunction with vector competence assays, we show the first evidence of genetic variation in *Wolbachia*-mediated blocking. We also demonstrate that the trait is highly heritable. In addition, we revealed a significant positive correlation between *Wolbachia* load and DENV copy number in whole mosquitoes. Finally, we used the phenotyped mosquito families to test for correlations between strength of blocking and expression level for several insect immunity genes with possible roles in blocking. Our findings indicate that *Wolbachia*-mediated blocking has the capacity to evolve and is likely to vary over geographic landscapes. The results also indicate that the application of genome wide association approaches should lead to the successful identification of mosquito genes that underpin blocking.

## 761

### ABBV-4083: A CLINICAL CANDIDATE FOR THE TREATMENT OF ONCHOCERCIASIS - EFFICACY IN THE LITOMOSOIDES SIGMODONTIS RODENT MODEL

Dominique Bloemker<sup>1</sup>, Marc P. Hübner<sup>1</sup>, Ivan Scandale<sup>2</sup>, Tom von Geldern<sup>3</sup>, Kennan Marsh<sup>3</sup>, Mark J. Taylor<sup>4</sup>, Dale Kempf<sup>3</sup>, Achim Hoerauf<sup>1</sup>

<sup>1</sup>University Hospital Bonn, Bonn, Germany, <sup>2</sup>Drugs for Neglected Diseases initiative, Geneva, Switzerland, <sup>3</sup>AbbVie, North Chicago, IL, United States, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

A collaboration between AbbVie, academia and DNDi identified ABBV-4083, a tylosin analog, as a clinical candidate for onchocerciasis. By targeting the *Wolbachia* endosymbionts of filariae and depleting them from filarial nematodes, the worms are sterilized and will eventually die. The prototype anti-wolbachial drug, doxycycline, is macrofilaricidal, but the long treatment regimen (4 weeks for onchocerciasis) and its contraindications have limited its broad use and spurred the search for drugs with the same mode of action, but with better safety and higher potency to achieve shortened treatment regimens. Preclinical efficacy studies with ABBV-4083 were performed using the filarial nematode *Litomosoides sigmodontis*. Effects on *Wolbachia* were analyzed one day post treatment in mice that received orally 75 mg/kg/d ABBV-4083

for 3, 7, 10, and 14 days. Depletion of *Wolbachia* from female adult worms was seen beginning with the 7 day treatment regime, reaching a reduction of 93.6% with the 14 day treatment regime in comparison to vehicle controls. Efficacy of ABBV-4083 was further evaluated in jirds with patent *L. sigmodontis* infection to assess long term efficacy on *Wolbachia* reduction and the impact on microfilaremia. 14 days of 100 mg/kg/d ABBV-4083 treatment reduced the *Wolbachia* by 99.7% in female adult worms and 98.1% in thoracic cavity microfilariae 16 weeks post treatment start. In contrast, the same treatment duration with the human bioequivalent dose of doxycycline was not sufficient to maintain *Wolbachia* depletion over time. Thus, blood microfilariae were not detected in ABBV-4083-treated jirds 10 weeks post treatment, while microfilariae levels had increased from their initial decrease in doxycycline treated controls. These results indicate that two weeks of ABBV-4083 treatment are superior to the bioequivalent dose of doxycycline, leading to a long-term *Wolbachia* reduction (>99%) and loss of peripheral microfilaremia. ABBV-4083 is a clinical candidate for onchocerciasis that leads to permanent sterilization of female adult worms, but lacks a strong microfilaricidal efficacy, thus reducing the risk for adverse events.

### DETERMINING THE OPTIMAL DOSE OF MOXIDECTIN FOR ONCHOCERCIASIS VIA PHARMACOKINETIC-PHARMACODYNAMIC (PK-PD) MODELLING OF DATA FROM HEALTHY VOLUNTEERS AND PATIENTS WITH ONCHOCERCIASIS

Kris Jansen<sup>1</sup>, Carl Kirkpatrick<sup>2</sup>, Nicholas O. Opoku<sup>3</sup>, Simon K. Attah<sup>3</sup>, Kwablah Awadzi (Deceased)<sup>3</sup>, Annette C. Kuesel<sup>4</sup>, Piero Olliaro<sup>4</sup>, George Oliph<sup>3</sup>, Victoria Ryg-Cornejo<sup>5</sup>, Beesan Tan<sup>6</sup>, Mark Sullivan<sup>5</sup>, Lawrence Fleckenstein<sup>6</sup>, Craig Rayner<sup>1</sup>

<sup>1</sup>d3 Medicine LLC – a Certara Company, Parsippany, NJ, United States, <sup>2</sup>Faculty of Pharmacy and Pharmaceutical Sciences, Centre for Medicine Use and Safety, Monash University, Parkville, Australia, <sup>3</sup>Onchocerciasis Chemotherapy Research Centre, Hohoe, Ghana, <sup>4</sup>UNICEF/UNDP/World Bank/World Health Organization Special Programme on Research and Training in Tropical Diseases (TDR), Geneva, Switzerland, <sup>5</sup>Medicines Development for Global Health, Southbank, Australia, <sup>6</sup>University of Iowa, Iowa City, IA, United States

Moxidectin, a second generation macrocyclic lactone, is an effective veterinary endectocide that is currently in development for onchocerciasis in humans. Moxidectin was well tolerated in 244 healthy adults (doses 3 - 36 mg) and 1,105 onchocerciasis patients in 8 clinical trials. Moxidectin's potential as a global health medicine is substantial: it is broadly active, has low intrinsic toxicity, is orally administered (PO), has extensive tissue distribution (Vd/F ~2000L), is minimally metabolised and has low drug interaction risk. Its terminal phase elimination half-life (T<sub>1/2</sub>) of ~23 days supports infrequent dose regimens. Population (pop) PK-PD analyses were performed to determine optimal dose. The pop PK-PD model was developed with data from 210 moxidectin recipients: 112 healthy volunteers (8 mg or 10 mg), and 98 onchocerciasis patients (2, 4 or 8 mg, n=33, 34 or 31, respectively) using NONMEM (7.3). Covariates evaluated included weight, BMI, gender, *O. volvulus* infection, study phase, food and formulation. Individual *post-hoc* estimates were used to compute the AUC<sub>0-∞</sub> in central and peripheral compartments in onchocerciasis patients. Using logistic or linear regression, AUC<sub>0-∞</sub> in central and peripheral compartments were assessed against achieving complete sustained microfilarial response (SMR, defined as achieving zero skin microfilariae at Month 1 sustained to Months 6 and/or 12) and against the ocular mf burden over 12 months. A 3-compartment pop-PK model with 2 transit compartment input was established with allometric weight, BMI, study phase, food and formulation (liquid vs. tablet) effect, and gender as covariates. Increasing moxidectin plasma AUC<sub>0-∞</sub> was associated with SMR for 6 and/or 12 months and increased probability of lower ocular mf burden over 12 months. Predicted peripheral compartment AUC<sub>0-∞</sub> yielded similar results. SMR at 6 months occurred in 95% of moxidectin 8 mg recipients, with a corresponding mean plasma exposure of 2709 ng/

mL.h. Together these results show that anti-mf efficacy is associated with systemic exposure to moxidectin and that an 8 mg PO dose provides a near-maximal complete response at 6 months.

## 763

### A MULTICENTER STUDY OF THE SAFETY OF TRIPLE DRUG MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS

**Gary J. Weil**<sup>1</sup>, Joshua Bogus<sup>1</sup>, Christine Dubray<sup>2</sup>, Peter U. Fischer<sup>1</sup>, P. Jambulingam<sup>3</sup>, Christopher L. King<sup>4</sup>, Jean Frantz Lemoine<sup>5</sup>, Katuscia O'Brian<sup>1</sup>, Leanne J. Robinson<sup>6</sup>, Taniawati Supali<sup>7</sup>

<sup>1</sup>Washington University, St. Louis, MO, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Vector Control and Research Centre, ICMR, Puducherry, India, <sup>4</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>5</sup>Ministry of Public Health and Population, Port-au-Prince, Haiti, <sup>6</sup>Burnet Institute, Melbourne, Australia, <sup>7</sup>Universitas Indonesia, Jakarta, Indonesia

Recent clinical trials have shown that a single dose of ivermectin, diethylcarbamazine (DEC), and albendazole (IDA) is dramatically superior to DEC plus albendazole (DA) or ivermectin plus albendazole for clearing *Wuchereria bancrofti* microfilaremia (Mf). Adverse events were more common but not more severe after IDA. We now report results of large community trials that compared the safety of IDA and DA. The trials were conducted in varied endemic settings including two areas with persistent lymphatic filariasis (LF) despite multiple rounds of mass drug administration (MDA, in Haiti and India), and two areas with no prior MDA (in Papua New Guinea and in Indonesia, whose study site is coendemic for *W. bancrofti* and *Brugia timori*). Treatment assignment was randomized by village/locality of residence, and treatment was offered to all residents who were >5 years of age and not pregnant. Participants were followed actively for 2 days and passively for an additional 5 days. More than 21,000 persons have been enrolled to date. 97% of participants were assessed on days 1 or 2 after treatment for adverse events (AEs). Rates of AEs were the same after IDA (10.5%) and DA (10.6%). Severity of AEs were also similar between both groups; 99.4% and 98.9% of AEs were mild or moderate (grade 1 or 2) in IDA and DA arms. There were 3 all-cause serious AEs, all after DA treatment. The most common AEs reported were headache, dizziness, abdominal pain, fever, nausea, and fatigue. AE rates varied by study site. They were significantly more common in persons with Mf, and also significantly more common after IDA than after DA in persons with Mf (40% vs. 24%). However, there was no excess of severe or serious AEs after IDA. IDA has the potential to significantly accelerate LF elimination in countries without co-endemic onchocerciasis or loiasis. Results from the current study suggest that IDA should be safe to use in MDA programs.

## 764

### COMMUNITY RANDOMIZED SAFETY TRIAL OF TRIPLE-DRUG MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS IN PAPUA NEW GUINEA

Livingstone Tavul<sup>1</sup>, Samuel Howard<sup>2</sup>, Moses Laman<sup>1</sup>, Steven Kumai<sup>3</sup>, Anna Samuel<sup>1</sup>, Bethuel Kotty<sup>1</sup>, Lina Lorry<sup>1</sup>, Leo Makita<sup>4</sup>, Mary Yohogu<sup>4</sup>, Lucy John<sup>4</sup>, Sibauk Bieb<sup>4</sup>, James Wangi<sup>5</sup>, Peter Siba<sup>6</sup>, Joshua Bogus<sup>7</sup>, Katuscia O'Brian<sup>7</sup>, James Kazura<sup>8</sup>, Gary J. Weil<sup>7</sup>, Daniel Tisch<sup>8</sup>, Christopher L. King<sup>8</sup>, **Leanne J. Robinson**<sup>9</sup>

<sup>1</sup>PNG Institute of Medical Research, Madang, Papua New Guinea, <sup>2</sup>Case Western Reserve University; PNG Institute of Medical Research, Cleveland, OH, United States, <sup>3</sup>Bogia District Health Administration, Bogia, Papua New Guinea, <sup>4</sup>PNG National Department of Health, Port Moresby, Papua New Guinea, <sup>5</sup>World Health Organisation - PNG, Port Moresby, Papua New Guinea, <sup>6</sup>PNG Institute of Medical Research, Goroka, Papua New Guinea, <sup>7</sup>University of Washington, St. Louis, MO, United States, <sup>8</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>9</sup>Burnet Institute; PNG

Institute of Medical Research; Walter & Eliza Hall Institute, Melbourne, Australia

Small studies in Papua New Guinea (PNG) have shown that a single co-administered dose of Ivermectin (IVM), Diethylcarbamazine (DEC), and Albendazole (ALB; IDA) is far more effective at eliminating *W. bancrofti* microfilaremia (Mf) than treatment with standard therapy of DEC plus ALB (DA) used for mass drug administration (MDA) for lymphatic filariasis (LF). Larger community-based studies were required to confirm that IDA has an acceptable safety profile in varying transmission regions that have not previously received MDA, such as many areas of PNG. In this open-label parallel group cluster randomized trial of 24 villages, all community members who were healthy, >5 years, and not pregnant were offered IDA or DA based on their village of residence. Following treatment, participants were actively followed for 2 days and then passively followed for 5 days to screen for adverse events (AEs). More than 2697 participants have been enrolled to date and 91% of these followed up on either day 1 or 2 after treatment. Overall infection rate was 23% (range 8-46% among villages) based on rapid filarial test strip (FTS) positive. Interim analysis on 2697 participants (IDA=1295, 29% FTS+, 6% Mf+; DA=1402, 20% FTS+, 4% Mf+) reveals 21% of participants experienced mild to moderate AEs, with no severe or serious AEs in either treatment group. AE rates were equivalent between sexes and higher among adults compared to children (15% 5-17yr versus 24% >18yr). Headache, nausea, fatigue, fever and dizziness were the most commonly reported AEs. These were more common in participants receiving IDA (23% [21-26, 95%CI]) compared to those receiving DA (19% [17-21, 95%CI, p=0.049]). AEs were also more common in Mf+ individuals particularly the IDA arm (41%) versus the DA arm (29%). Grade 2 AEs were similar in the two arms; 3% versus 2% in IDA and DA groups respectively. There were no differences in AE rates among FTS+/Mf- versus FTS-/Mf- participants for either group. IDA has the potential to significantly accelerate LF elimination in a country such as PNG and results from this study, as well as from other trial sites, suggests that the safety profile of IDA is suitable for use in MDA programs.

## 765

### IDENTIFICATION OF POTENTIAL CLINICAL CANDIDATES WITH MACROFILARICIDAL EFFICACY FOR THE TREATMENT OF ONCHOCERCIASIS

**Natalie Hawryluk**<sup>1</sup>, Marc Hubner<sup>2</sup>, Achim Hoerauf<sup>2</sup>, Dominique Blömker<sup>2</sup>, Simon Townson<sup>3</sup>, Suzanne Gokool<sup>3</sup>, Coralie Martin<sup>4</sup>, Nathalya Vallarino-Lhermitte<sup>4</sup>, Agnieszka Chojnowsk<sup>5</sup>, Tamara Kreiss<sup>5</sup>, Monika Prorok<sup>5</sup>, John Siekierka<sup>5</sup>, Ivan Scandale<sup>6</sup>, Stacie Canan<sup>1</sup>, Vikram Khetani<sup>7</sup>, Joseph Camardo<sup>7</sup>

<sup>1</sup>Celgene Global Health, San Diego, CA, United States, <sup>2</sup>Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, <sup>3</sup>Northwick Park Institute for Medical Research, London, United Kingdom, <sup>4</sup>Biodiversité et Adaptation des Microorganismes Eucaryotes à leur Environnement, Muséum National d'Histoire Naturelle, Paris, France, <sup>5</sup>Sokol Institute of Pharmaceutical Life Sciences, Montclair State University, Montclair, NJ, United States, <sup>6</sup>Drugs for Neglected Diseases initiative, Geneva, Switzerland, <sup>7</sup>Celgene Global Health, Summit, NJ, United States

Mass drug administrations that are currently used to control onchocerciasis are directed against the microfilarial stage blocking temporarily female worm embryogenesis and thus have to be given once to twice per year for the life span of the adult worms to prevent transmission. Identification of a macrofilaricidal compound would therefore reduce program time frames to control and eliminate onchocerciasis. In a joint collaboration with DNDi, academia and Celgene Global Health, we identified potential clinical candidates with such a macrofilaricidal effect. More than 400 compounds were tested *in vitro* against *Onchocerca gutturosa* adults as well as *Litomosoides sigmodontis*, *Brugia malayi*, and *Brugia pangi* microfilariae and adults, identifying 196 compounds with enhanced activity towards the adult stage parasites. 55 lead compounds with *O. gutturosa* EC50 <0.250µM and suitable pharmacokinetic profiles were further tested by oral gavage in mice harboring adult worms of the rodent filarial nematode

*L. sigmodontis*. Two direct-acting lead compounds were identified and assessed for their efficacy against microfilarial and adult stages in patently *L. sigmodontis* infected jirds (5 day treatment once per day and 10 days bi-daily) revealing complete elimination of adult worms 16 weeks post treatment (wpt) with continuous slow decline of microfilaremia until 16 wpt. Subsequently, three potential clinical candidates have been identified that significantly reduced the *L. sigmodontis* adult worm burden in mice by 96% (7d), 83% (7d) and 82% (5d) after bi-daily treatment within four weeks post treatment. These three clinical candidates are currently being evaluated for their impact on adult worm clearance, microfilaremia and embryogenesis in the *L. sigmodontis* jird model. The current study describes the discovery of three potential clinical candidates with macrofilaricidal efficacy that adhere to the current target product profile. Such macrofilaricidal compounds which lack a strong microfilaricidal effect are ideal candidates for the treatment of onchocerciasis, as they possess a reduced risk for microfilariae-driven adverse events.

## 766

### DEVELOPMENT OF ONCHOCERCA VOLVULUS IN HUMANIZED NSG MICE

John B. Patton<sup>1</sup>, Thomas Nutman<sup>2</sup>, Jessica A. Hess<sup>1</sup>, April Torigian<sup>1</sup>, Sasisekhar Bennuru<sup>2</sup>, Sara Lustigman<sup>3</sup>, David Abraham<sup>1</sup>

<sup>1</sup>Thomas Jefferson University, Philadelphia, PA, United States, <sup>2</sup>National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>New York Blood Center, New York, NY, United States

The study of *Onchocerca volvulus* has been limited by its host range, with only non-human primates shown to be susceptible to the infection. Small animal models that support the maturation of the parasite have not been identified. Initially, we screened 6 genetically diverse Collaborative Cross mouse strains for susceptibility to infection with *O. volvulus* infective third-stage larvae (L3). None of the Collaborative Cross mice were susceptible to the infection, suggesting that either the murine immune response controls the infection or that mice lack survival and growth factors essential for the parasite. We hypothesized that highly immunodeficient NSG mice would support the maturation of *O. volvulus* and alteration of the host microenvironment through the addition of various human cells and tissues would further enhance the level of maturation. Specifically, NSG mice were humanized with: (1) umbilical cord derived CD34+ stem cells, (2) fetal derived liver, thymus and CD34+ stem cells or (3) primary human skeletal muscle cells. NSG and humanized NSG mice were infected with 100 *O. volvulus* L3 for 4, 8, or 12 weeks. To confirm infection and determine distribution of *O. volvulus*, mice were dissected into 100 regions and qPCR specific to *O. volvulus* O-150 repeat was performed; parasites were found distributed throughout the animal suggesting that the worms survived and migrated in the mice. Necropsies of infected animals were performed and it was observed parasites survived and developed throughout the infection time course and were recovered from a wide range of tissue locations. In each of the different humanized mouse models it was observed that worms matured from L3 to advanced fourth stage larvae, with both male and female organ development. In addition, worms increased in length by up to 5 fold. These novel mouse models for onchocerciasis will enable the development of *O. volvulus* specific biomarkers, new therapeutic approaches and potentially the study of human immune responses to infection with *O. volvulus*.

## 767

### PRE-CLINICAL USE OF FDA-APPROVED SMALL MOLECULE INHIBITORS AS MACROFILARICIDES IN ONCHOCERCA VOLVULUS: A POST-GENOMIC APPROACH

Elise M. O'Connell<sup>1</sup>, Fidelis Cho-Nowa<sup>2</sup>, Nancy Tricoche<sup>3</sup>, Aaron Bell<sup>4</sup>, Gargi Pal<sup>3</sup>, Sara Lustigman<sup>3</sup>, Thomas B. Nutman<sup>1</sup>

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Biotechnology Unit, Faculty of Science, University of Buea, Buea, Cameroon, <sup>3</sup>Lindsley F.

Kimball Research Institute, New York Blood Center, New York, NY, United States, <sup>4</sup>National Institutes of Health, Lindsley F. Kimball Research Institute, New York Blood Center, New York, NY, United States

Post genomic analyses of the *Onchocerca volvulus*, *Brugia malayi*, and *Loa loa* genomes demonstrated that a number of parasite-encoded tyrosine kinases were found to have human homologues with FDA-approved inhibitors. Having previously shown that the tyrosine kinase inhibitor imatinib is microfilaricidal for *B. malayi* at pharmacologically achievable concentrations and affects embryonic development in adult female worms, we sought to find other protein kinase inhibitors that had macrofilaricidal activity. An *in vitro* screen of 8 PKIs against *Brugia malayi* adult parasites identified 3 that were filaricidal to adult females at <10  $\mu$ M. These drugs, sorafenib (b-Raf inhibitor), lapatinib (EGFR inhibitor), and temsirolimus (mTOR inhibitor) were then tested (at 30  $\mu$ M and 10  $\mu$ M) *in vitro* against adult *O. gutturosa* (Og) and *O. ochengi* (Oo) from cattle and against early Ov adults (L5) developed using a novel *in vitro* culturing system, where mobility and viability can be assessed periodically for 29 days. Against Oo adults, sorafenib and temsirolimus had the most macrofilaricidal activity whereas lapatinib had more active against Og. In the Ov L5 viability assay, whereas lapatinib achieved only 50% inhibition of motility and 50% killing at day 29 at 30 $\mu$ M, temsirolimus was highly active, and at 30 $\mu$ M caused 100% inhibition of motility by day 17, and at 10 $\mu$ M 100% inhibition of motility and viability by day 29. Electron microscopy confirmed extensive damage in the killed L5s. Proteomic data and 3-dimensional protein modeling revealed that stage-specific protein expression and computed degree of homology between the Ov and the human target proteins and were predictive of *in vitro* drug efficacies against Ov. Given these results, PKIs should continue to be investigated to assess *in vivo* efficacy as a macrofilaricide using doses approved and tolerable for humans.

## 768

### ALTERATIONS IN THE IL27 PATHWAY ARE CORRELATED WITH THE LOSS OF TRYPANOSOMA CRUZI-SPECIFIC T CELLS IN PATIENTS WITH CHRONIC CHAGAS DISEASE

Maria A. Natale<sup>1</sup>, Todd Minning<sup>2</sup>, Maria G. Alvarez<sup>3</sup>, Rodolfo Viotti<sup>3</sup>, Graciela Bertocchi<sup>3</sup>, Bruno Lococo<sup>3</sup>, Maria C. Albareda<sup>1</sup>, Rick L. Tarleton<sup>4</sup>, Susana A. Laucella<sup>1</sup>

<sup>1</sup>INP Dr. Mario Fatala Chaben, Ciudad Autonoma de Buenos Aires, Argentina, <sup>2</sup>Center for Tropical and Emerging Global Diseases, University of Georgia, Athens, GA, United States, <sup>3</sup>HIGA Eva Peron, San Martin, Argentina, <sup>4</sup>Center for Tropical and Emerging Global Diseases, University of Georgia, Athens, GA, United States

We have previously shown that chronically *T. cruzi*-infected subjects bear several features of a process of immune exhaustion including an inverse correlation between disease severity and the magnitude of T cell responses, and alterations in the signaling pathway of the IL-7R. Like IL-7, IL-27 also exerts its function through STAT5. In this study, we performed an analysis of the expression of the IL-27R components (CD130 and WSX1 chains) on CD4+ and CD8+ T cells, and evaluated IL-27-dependent signaling events in relation to T cell responses in patients at different clinical stage of chronic Chagas disease using polychromatic flow cytometry. Subjects with no signs of cardiac disease showed a decrease in CD130+WSX1+CD4+ T cells and an increase in CD130+WSX1+CD8+ T cells compared with either patients exhibiting heart disease or uninfected controls. *T. cruzi* infection *in vitro*, was able to stimulate the downregulation of the IL-27R on CD4+ T cells and the upregulation on CD8+ T cells. IL-27-induced phosphorylation of STAT1, STAT3 and STAT5 was lower in patients with heart disease compared with asymptomatic patients and inversely associated with the frequency of *T. cruzi*-specific IFN- $\gamma$ -producing T cells measured by ELISPOT assay. STAT5-downstream gene expression of *tbx21*, *eomes*, *gzmb* and *cxcl9* assessed by q-RT-PCR was also reduced in patients with cardiomyopathy. These findings support a possible role of the IL-27R signaling pathway in promoting *T. cruzi*-specific T cells responses.

769

### INHIBITORY LIGAND PD-L1 ON MHC CLASS II-EXPRESSING NEUTROPHILS AND MURINE LEISHMANIASIS IN HUMAN

Richard E. Davis<sup>1</sup>, Smriti Sharma<sup>2</sup>, Yani Chen<sup>1</sup>, Shyam Sundar<sup>2</sup>, Mary E. Wilson<sup>1</sup>

<sup>1</sup>University of Iowa, Iowa City, IA, United States, <sup>2</sup>Banaras Hindu University, Varanasi, India

Neutrophils (PMNs) are typically thought to be short-lived effector cells recruited to sites of acute infection by *Leishmania* spp. where they take up, but do not control, parasites. Additionally while neutrophils are highly recruited during early infection, they are present in areas of chronic parasite infection as well. Another long-standing observation from visceral leishmaniasis patients is that direct activation of low-density peripheral blood mononuclear cells (PBMCs) with *Leishmania* antigen does not result in IFN $\gamma$  production by CD4 T cells unless cultures contain anti-IL-10 antibodies. However, stimulation of whole blood (which has not been depleted of normal-density PMNs via density gradient) from these same patients does result in robust IFN $\gamma$  production. This may suggest that low-density PMNs, enriched in the PBMC layer, but not normal-density PMNs, might have an inhibitory effect on CD4 T cell responses. We have recently identified a unique phenotype of neutrophils in circulation and tissue of human patients with chronic cutaneous and visceral leishmaniasis (VL), specifically PMNs that express the molecule MHC class II, often associated with antigen-presentation. We found that MHC class II-expressing PMNs also show increased costimulatory molecules CD80 and CD86. Additionally, patients showed increased low-density neutrophils, which were significantly more likely to express MHC-II and CD80/CD86. However, *in vitro* experiments showed no evidence of direct antigen presentation to, or activation of, T cells by patient neutrophils. Interestingly, we found that MHC class II-expressing neutrophils, already increased in circulation of human VL patients, also show significant expression of the inhibitory molecule PD-L1. PD-L1 is known to bind to PD1 on T cells. MHC II and CD80/CD86 have also been shown to act as inhibitory, rather than activating ligands (binding T cell LAG3 and CTLA4 respectively). Employing a murine model of leishmaniasis, we found that tissue recruited PMNs show increased MHC class II+ PMNs that express PD-L1. These findings may point to a role for tissue-recruited PMNs in inhibiting CD4 T cell responses.

770

### TARGETING INHIBITORY RECEPTORS LAG3 AND TIM3 TO ENHANCE ANTI-PARASITIC CD4 T CELL RESPONSES IN VISCERAL LEISHMANIASIS

Rajiv Kumar<sup>1</sup>, Neetu Singh<sup>1</sup>, Bhavana Singh<sup>1</sup>, Shashi Bhushan Chauhan<sup>1</sup>, Christian Engwerda<sup>2</sup>, Shyam Sundar<sup>1</sup>

<sup>1</sup>Banaras Hindu University, Varanasi, India, <sup>2</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia

Visceral leishmaniasis (VL) caused by protozoan parasite *Leishmania donovani* remains a major public health problem in tropical countries. CD4+ T cells exhaustion is a common phenomenon during chronic leishmania infection which causes reduced IFN- $\gamma$  secretions, critical for controlling the parasite replication. This can be mediated by abnormal expression of immunosuppressive receptors LAG-3 and TIM-3 on the surface of CD4+ T cells. The present study aims to investigate the role of Lag-3 and Tim-3 in patients with VL. Peripheral blood mononuclear cells (PBMCs) were collected from VL patients before and after drug treatment as well as from endemic healthy control. CD4+ T cells were enriched using magnetic beads. Ex-vivo mRNA expression of TIM-3 and LAG-3 was measured in whole PBMCs as well as enriched CD4+ T cells by Real-Time PCR. Surface expression of TIM-3 and LAG-3 were examined by flow cytometry. To know the functional relevance of LAG-3 and TIM-3, whole blood cells of VL patients were stimulated for 24 hours with soluble leishmania antigen in presence of anti LAG-3 or anti TIM-3 antagonistic antibodies or isotype controls and IFN- $\gamma$  secretion was measured in culture

astmh.org

supernatant. We observed enhanced mRNA expression of TIM-3 and LAG-3 in whole PBMCs as well as CD4+ T cells of VL patients in pre treatment stage compared to post treatment and endemic controls. Similarly, CD4+ T cells showed enhanced surface expression of TIM-3 and LAG-3 as revealed by flow cytometry analysis. We observed an enhanced IFN- $\gamma$  secretion in whole blood culture after LAG-3 blockade compared to isotype controls but there was no any effect of TIM-3 blockade on IFN- $\gamma$  secretion. These results identify LAG-3 as an important immunotherapeutic target to enhance anti-parasitic CD4+ T cell response and treat VL patients.

771

### BACTERIAL CO-INFECTION IN MURINE CUTANEOUS LEISHMANIASIS

Tiffany Y. Borbón<sup>1</sup>, Gwendolyn Clay<sup>1</sup>, Breanna Scorza<sup>1</sup>, Alan Sariol<sup>1</sup>, Yani Chen<sup>1</sup>, Bayan Zhanbolat<sup>1</sup>, Fayyaz Sutterwala<sup>2</sup>, Mary E. Wilson<sup>1</sup>

<sup>1</sup>University of Iowa, Iowa City, IA, United States, <sup>2</sup>Cedars-Sinai Medical Center, Los Angeles, CA, United States

Cutaneous leishmaniasis (CL) is caused by *Leishmania* spp. protozoa leading to localized skin lesions and ulceration. In some human infections, response to treatment is best initiated after ulceration. Ulceration introduces bacteria into skin, and secondary bacterial infections are common in CL. The effects of ulceration-induced immune responses on CL are relatively unexplored. We hypothesized that bacteria present during development of CL activate inflammatory responses that contribute to outcome of parasitic infection. Because *Staphylococcus aureus* (Sa) is the most common bacterium in CL lesions, we used a model of Sa-*Leishmania major* (Lm) co-infection. We injected Lm, Sa, or both intradermally into ears of C57BL/6 mice. We monitored lesion volume, and analyzed inflammation by histology, microbial burden by qPCR, expression of immune mediators by qPCR, and ex vivo antigen stimulation of draining lymph nodes (LNs) by cytokine multiplex at 4 weeks post-infection. Through the course of infection, lesion sizes in co-infected ears were two-fold larger than ears injected with Sa or Lm alone ( $p < 0.0001$ ,  $p < 0.001$  at 3 days, 3 weeks of infection). At 4 weeks there were no significant differences in microbial burdens between co-infected vs. singly infected groups. Histology revealed greater neutrophils in co-infected ears (1.5-fold,  $p < 0.01$ ). TSLP transcripts were upregulated in Lm-infected but not co-infected ears ( $p < 0.01$ ). *Leishmania* antigen-stimulated lymph node cells from co-infected mice released over two-fold more IL-17A than cells from mice infected with Lm or Sa alone ( $p < 0.001$ ). These differences occurred although there was no detectable *S. aureus* DNA. These data suggest that co-infection with Sa leads to an increase in neutrophilic inflammation in Lm lesions, which does not alter parasite burden. These pathologic changes could be related to lower TSLP-induced Treg development and/or a more vigorous TH17 type response.

772

### TRANSCRIPTIONAL SIGNATURES ASSOCIATED WITH CD8+ T-CELLS RESPONSES DURING VISCERAL LEISHMANIASIS

Bhawana Singh<sup>1</sup>, Rajiv Kumar<sup>1</sup>, Shashi Bhushan Chauhan<sup>1</sup>, Christian Engwerda<sup>2</sup>, Shyam Sundar<sup>1</sup>

<sup>1</sup>Institute of Medical Sciences, Banaras Hindu University, Varanasi, India, <sup>2</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia

Visceral leishmaniasis is one of the major neglected tropical diseases where the role of CD8 has been poorly understood. Following infection, CD8+ T cell activation generates several effector mechanisms for killing the target cell. In addition to the naïve CD8+ T cells, effector/memory CD8+ T cells and CD8+ Treg cells employ different mechanisms for regulating immune responses. Given these various fates for CD8+ T cells in response to infection, there has been a lot of interest in the factors that regulate these processes. We hypothesize that CD8+ T cell function is compromised in VL patients and recovers following successful drug treatment. This has been tested by nanostrating technology for studying the transcriptional

profile of CD8+ T cells in VL patients, and compared after 30 days of drug treatment, as well as with endemic controls to measure mRNA species involved in T-cell development, activation, function and regulation. The results were analyzed for the differences in the expression levels in terms of adjusted p-values and subsequently IPA (Ingenuity Pathway Analysis) was done to uncover the alterations in the signaling pathways. We have found compromised effector and regulatory functions during the disease as compared to the healthy subjects which was further validated at protein level by flow cytometric analysis and functional studies. Moreover, correlational studies provided new avenue for the immunomodulatory roles of CD8+ T cells during chronic infectious diseases. Therefore, these results provide insight for identifying new strategies to manipulate this T cell subset for therapeutic advantage.

### IMUNIZATION WITH *LEISHMANIA DONOVANI* DOUBLE KNOCK-OUT PARASITES (*LdCen<sup>-/-</sup>MIF<sup>-/-</sup>*) INDUCES LONG TERM MEMORY AND PROTECTION AGAINST VISCERAL LEISHMANIASIS

Immunogenic potential of the vaccination against visceral leishmaniasis was extensively shown. However, data showing long term memory induced by different vaccine formulations is still scarce. In the current study, the immunogenicity and protection of a vaccine against leishmaniasis (based on *Leishmania donovani* gene deletion mutant strains deficient for centrin and MIF genes- *LdCen<sup>-/-</sup>MIF<sup>-/-</sup>*) were assessed. BALB/c mice were immunized with *LdCen<sup>-/-</sup>*, *LdMIF<sup>-/-</sup>* or *LdCen<sup>-/-</sup>MIF<sup>-/-</sup>* parasites, and the immune responses were compared to a control group (PBS). Our results showed that *LdCen<sup>-/-</sup>MIF<sup>-/-</sup>* immunized group presented higher percentage of CD4+ and CD8+ central memory T cells, increased CD8+ T cell proliferation after specific stimulation at 12wpc. Also, this group presented higher production of antibodies (IgG), and IFN-γ and TNF-α producing CD4+ T cells after challenge. In addition, *LdCen<sup>-/-</sup>MIF<sup>-/-</sup>* immunized group showed lower number of parasites in spleen and liver at 4 and 12 weeks post challenge with wild type strain of *L. infantum*. These data indicates that parasites manipulated to not express certain genes could improve long term and protection when used as vaccine for visceral leishmaniasis. More importantly, focusing on the mechanisms involved on protection and long term immunity could improve the development of vaccines against VL.

### RESPIRATORY VIRUS ASSOCIATED WITH WHEEZING IN EARLY LIFE: A BIRTH COHORT STUDY IN A LOW-INCOME URBAN COMMUNITY IN DHAKA, BANGLADESH

Wheezing in early life is associated with an increased risk of asthma and viral acute respiratory illnesses are primarily responsible for wheezing in young children. We estimated the incidence and impact of respiratory viruses in early childhood wheezing. From May 2015-February 2017, children in a low-income community in Dhaka were enrolled during the first week of life. Field staff visited households twice weekly and referred children with respiratory symptoms to the study clinic. Physicians collected nasal wash samples from children with acute respiratory infections (ARI), defined as cough and/or runny nose; or pneumonia, defined as cough with tachypnea, and identified wheezing on lung auscultation. Samples were tested for respiratory syncytial virus (RSV), humanmetapneumovirus (HMPV), influenza viruses, human parainfluenza viruses (HPIV) and adenoviruses by rRT-PCR. We used Cox's regression, adjusted for clustering at child level, to calculate hazard ratios (HR) to estimate the association between experiencing a viral respiratory illness before six months of age and subsequent episodes of wheezing. We followed 481 children for 527 child-years. Of 2114 respiratory illness episodes, 1824 (86%) were ARI, 290 (14%) were pneumonia. Wheezing was associated with 12% (248/2114) of episodes and of these 149 (60%) were ARI and 99 (40%) were pneumonia. Thirty-three percent (151/481) of children had at least one episode of wheezing; 10% (49/481) had at least two episodes. Respiratory viruses were detected in 50% (123/248) of wheezing episodes. RSV was detected in 19% (48/248) of episodes, HPIV in 15% (38/248), influenza viruses in 6% (15/248), adenovirus in 5% (13/248) and HMPV in 4% (9/248). Viral respiratory illness episodes were more likely than non-viral episodes to present with wheezing (16% vs. 9%, p<0.001). Children with at least one viral respiratory illness episode before six months of age were at increased risk of wheezing after six months of age (HR=2.3, 95% CI 1.2-4.4, p=.01). Young children in Dhaka frequently suffered from respiratory illnesses with wheezing and viral infections may increase the risk of wheezing.

Pneumonia and acute respiratory infections (ARIs) caused by bacteria and viruses and pneumonia is the most common cause of death in children under 5 years of age. While most etiologies of pneumonia and ARIs are unknown, multiple pneumonia and ARI-causing viruses circulate widely in South East Asia. However, the patterns and drivers of the seasonal and spatial transmission dynamics are unknown. Using hospital-based surveillance in children, we identify the seasonal patterns of multiple circulating viruses causing hospitalizations for ARIs and pneumonia in Nha Trang, Vietnam and examine clustering of hospitalizations over the study period. We find strong seasonal transmission of respiratory syncytial virus (RSV), peaking in the late summer months, and of WHO-confirmed pneumonia, peaking in the winter months. We examine the relationship of hospitalizations with rainfall, temperature, and dew point, and find significant associations between RSV and the previous mean 7 days rainfall and temperature (odd ratios: 1.98 [95% CI: 1.31, 2.99, p = 0.0013] and 1.23 [95% CI: 1.08, 1.4, p = 0.0015], respectively), and a significant out-of-phase relationship between human parainfluenza 3 and temperature and dew point. We find significant clustering of hospitalizations at local spatial scales (between 1 and 2 km). Influenza A, human metapneumo

virus, and human parainfluenza virus 3 exhibit the strongest clustering up to about 2 km. Our results are important for understanding the spatiotemporal risk associated with circulating pathogens in Southern Vietnam.
