In Bangladesh, pneumonia has a higher mortality among malnourished children aged <5 years. Evaluating the etiology of pneumonia among these children might help providers develop empiric treatment guidelines. During April 2015 to April 2016, we enrolled children aged < 5 years admitted with severe malnutrition and clinical or radiological pneumonia in icddr,b's Dhaka hospital and followed them for 30 days from the day of admission. We collected nasopharyngeal wash samples and tested for respiratory syncytial virus (RSV), human metapneumovirus (HMPV), influenza viruses, human parainfluenza viruses (HPIV 1, 2, 3) and adenoviruses by real-time RT-PCR and tested for bacterial pathogen by blood culture. We enrolled 234 children. Their median age was 8 months (IQR: 5-13) and 149 (64%) were male. Their weight/age Z-score was -4.3 (SD 1.1), weight/length -2.9 (SD 1.4) and 33 (14%) had bipedal edema. Respiratory viruses were detected in 110 (47%) and bacteria in 10 (4%). The most frequently detected viruses were RSV (32; 29%) followed by adenoviruses (23; 21%), HPIV3 (17; 15%), influenza A virus (14; 13%), HMPV (10; 9%), HPIV2 (1; 1%) and co-detections (13; 12%). Six (5%) children had mixed infections (3 HPIV3 with *Staphylococcus aureus*, *Enterococcus*, *Pseudomonas*; 2 adenovirus with *Salmonella Typhi* and *Pseudomonas*; HMPV with *Klebsiella*). Recurrence of pneumonia occurred in 16/234 (7%) children of which 13 (81%) had viral pathogen and 4 (25%) bacterial pathogen (2 *Streptococcus pneumoniae*, *Pseudomonas*, coagulase-negative *Staphylococci*) and 3 mixed infection (19%). Of all the children with detectable viruses, at time of discharge 84/110 (76%) had improved, 6 (5%) died (2 HPIV3, 1 HPIV3+adenovirus, 1 HPIV3+RSV, 1 HMPV, and 1 adenovirus), 18 (16%) were recovering and 2 (2%) were lost to follow-up. Nine of 16 (56%) deceased children had no detectable pathogen while 3 (19%) had bacterial infection and 2 (13%) mixed infection; all died within 10 days of symptom onset. All the children were treated with antibiotics without any antiviral. In severely malnourished children with pneumonia in Dhaka hospital, viral pathogens were common with RSV predominance.

### PNEUMONIA ETIOLOGY INVESTIGATING LUNG ASPIRATE SAMPLES USING MULTI-PLEX PCR

Grant Mackenzie<sup>1</sup>, Eunice Machuka<sup>1</sup>, Philip Hill<sup>2</sup>, Brian Greenwood<sup>3</sup>

<sup>1</sup>Medical Research Council Unit, The Gambia, Fajara, Gambia, <sup>2</sup>University of Otago, Dunedin, New Zealand, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The etiology of pneumonia is difficult to determine but its pursuit is essential given pneumonia is the most common cause of child mortality. We conducted population-based surveillance for pneumonia, including the collection of lung aspirate samples, among those aged ≥2 months in a demographic surveillance area in rural Gambia between 20 March 2011 and 31 August 2012. 7-valent pneumococcal conjugate vaccine (PCV7) was introduced in September 2009 and replaced by PCV13 in May 2011. Standard samples were collected and microbiologic investigations

performed to guide treatment. A 33-plex real-time PCR assay was used to detect bacterial and viral pathogens. A standardized diagnosis of clinical pneumonia was made in 3262 patients, of whom 2291 were aged 2-23 months, 729 were aged 2-4 years, 242 were aged 5 years and greater and 55 died. Chest radiographs were taken for 3069 patients. Of 379 (12%) patients with, and 2690 (88%) without WHO-defined pneumonia with consolidation, 11 (2.9%) and 36 (1.3%) died respectively. Lung aspirates were collected and analysed from 165 patients. Pathogens were detected in 126 (76%) samples, one pathogen in 48 (29%) and two or more in 78 (47%). Bacteria only co-infections were detected in 55 (33%) samples and bacterial-viral co-infections in 18 (11%). Common pathogens were *S. pneumoniae* (n=59, 36%), *S. aureus* (n=23, 14%), *H. influenzae* non-type b (n=13, 8%), Bocavirus (n=14, 8%), Influenza virus (n=12, 7%), *H. influenzae* type b (n=10, 6%), Parainfluenza virus (n=9, 5%) and Respiratory syncytial virus (n=5, 3%). The proportion of children aged less than 5 years in whom *S. pneumoniae* was isolated was significantly less among those who had received ≥2 doses of PCV (17/69) compared to zero doses (16/30); risk ratio 0.57 (95% CI 0.35, 0.93). Soon after the introduction of PCV in The Gambia the predominant etiologic pathogens causing pneumonia with substantial consolidation were *S. pneumoniae*, *S. aureus* and *H. influenzae*. PCV effectively prevented pneumococcal pneumonia. Following the widespread use of PCV in high-mortality settings, robust studies of pneumonia etiology are needed, that include detection of co-infections.

### QUANTIFYING THE BURDEN OF LOWER RESPIRATORY INFECTIONS: RESULTS FROM THE GLOBAL BURDEN OF DISEASE STUDY 2016

Chris Troeger, Ibrahim Khalil, Puja Rao, Scott Swartz, Shijun Cao, Simon Hay, Robert Reiner

University of Washington, Seattle, WA, United States

The global burden of lower respiratory infections (LRIs) remains substantial despite tremendous decline over the last several decades. The Global Burden of Diseases, Injuries, and Risk Factors Study 2016 (GBD 2016) is a systematic, scientific effort to measure the burden LRIs. GBD 2016 estimates the morbidity and mortality due to LRIs and four etiologies for all countries, age groups, and both sexes from 1990-2016. Mortality is modeled in a Bayesian ensemble platform that uses verbal autopsy and vital registration data and country-level covariates. Morbidity is modeled using a meta-regression tool that employs surveys, hospital records, and scientific literature to produce estimates. Deaths, years of life lost (YLLs), years lived with disability (YLDs), and disability-adjusted life years (DALYs) are used to measure the burden of LRIs. LRIs were the second leading cause of death among children under 5 years old in 2016, responsible for 720,000 deaths (95% Uncertainty Interval: 651,600-801,700) in this age group, and the fifth leading cause among all ages, responsible for 2,718,000 deaths (95% UI: 2,478,000-2,869,000). About 75% of LRI deaths occurred in children under-5 and adults over-70. Despite growing populations, the number of LRI deaths decreased by 17% between 1990 and 2016. This reduction is due primarily to reductions in under-5 mortality (65% reduction). LRI mortality in adults 70+ years old increased 94% during this time period. The under-5 LRI mortality rate varied by region and was highest in the Sahel of sub-Saharan Africa. Nearly 50% of under-5 LRI deaths occurred in just five countries: India, Nigeria, Pakistan, DR Congo, and Ethiopia. While under-5 LRI mortality was concentrated in low-income countries, LRI mortality in adults 70+ years was highest in India, Japan, China, the United States, and Brazil and these five locations were responsible for nearly 50% of the deaths in this age group. Despite dramatic declines in under-5 LRI mortality, interventions that focus on preventing and treating LRI remain necessary to accelerate reductions in LRI mortality including those targeting both children and elderly adults.

### HANDHELD POINT-OF-CARE LACTATE MEASUREMENT PREDICTS MORTALITY IN UGANDAN CHILDREN HOSPITALIZED WITH PNEUMONIA

Cary Ma<sup>1</sup>, Austin Ericson<sup>1</sup>, Sophie Namasopo<sup>2</sup>, Robert Opoka<sup>3</sup>, Andrea Conroy<sup>4</sup>, Michael Hawkes<sup>1</sup>

<sup>1</sup>University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Jinja Regional Referral Hospital, Jinja, Uganda, <sup>3</sup>Makerere University, Kampala, Uganda, <sup>4</sup>Indiana University, Kampala, Uganda

Globally, pneumonia is the leading cause of death of children <5. Rapid bedside tools to triage and risk-stratify pneumonia patients may improve patient care and outcomes. We conducted a prospective cohort study of children <5 admitted for pneumonia in Uganda. Lactate was measured at admission and daily during hospitalization using a handheld point-of-care device, the Lactate Scout Analyzer. Clinical data and outcome (survival or death) were recorded and clinical risk scores were calculated. Statistical analysis employed receiver operator characteristic (ROC) curves, Kaplan-Meier curves, and linear mixed-effects models. From Sept 2013 to July 2015, we enrolled 155 children with pneumonia admitted to the Jinja Regional Referral Hospital and Kambuga District Hospital. In-hospital mortality was 22/155 (14%). Median [range] lactate level was 2.4 [0.9-25] mmol/L among children who survived versus 5.3 [1.6-20] mmol/L among children who died ( $p=0.0001$ ). Lactate was an informative prognostic marker of mortality, with area under the ROC curve (AUROC) greater than or equal to that of any single clinical sign or composite clinical risk score (AUROC 0.76, [95%CI 0.65-0.87],  $p=0.0001$ ). Lactate augmented the ability of the leading clinical risk score, Pediatric Early Death Index for Africa (PEDIA), to predict mortality (AUROC 0.82 [95%CI 0.69-0.94],  $p=0.001$ ). Lactate level at admission accurately risk-stratified children, with 5-day mortality of 2%, 11% and 26%, among children with lactate of <2.0, 2.0-4.0, and >4.0 mmol/L, respectively ( $p=0.001$ ). Lactate levels decreased over time in patients who recovered (estimated rate 1.1 [95%CI 0.62-1.5] mmol/L per day,  $p<0.0001$ ), and were higher overall in patients who died (estimated difference 2.2 [95%CI 0.98-3.4] mmol/L,  $p=0.0005$ ). Handheld point-of-care lactate measurement is a superior predictor of mortality than any clinical sign or risk score among hospitalized pediatric pneumonia patients. This may be a valuable, convenient tool for triage and risk stratification in resource-limited hospitals for pneumonia, the leading killer of children <5 worldwide.

### CHEST ULTRASOUND VERSUS X-RAY FOR PULMONARY TUBERCULOSIS IN SOUTH AFRICAN CHILDREN

Charlotte C. Heuvelings<sup>1</sup>, Sabine Bélard<sup>1</sup>, Savvas Andronikou<sup>2</sup>, Halvani Moodley<sup>3</sup>, Norme Jamieson-Luff<sup>4</sup>, Martin P. Grobusch<sup>1</sup>, Heather J. Zar<sup>4</sup>

<sup>1</sup>Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, <sup>2</sup>Bristol Royal Hospital for Children and University of Bristol, Bristol, United Kingdom, <sup>3</sup>University of Witwatersrand, Johannesburg, South Africa, <sup>4</sup>Red Cross War Memorial Children's Hospital, Cape Town, South Africa

Globally, around 1 million children develop tuberculosis (TB) annually. Chest X-ray (CXR) is a main diagnostic tool for diagnosis of pulmonary TB (PTB) but has poor inter-reader agreement. Chest ultrasound (US) is free of ionizing radiation and increasingly used by clinicians for pediatric lung diseases. We compared clinician-performed chest US with CXR in children with suspected PTB. Children <13 years with suspected PTB, presenting to a children's hospital in Cape Town between 2014-2015 were enrolled. A clinician, who had 4 days of US training, performed chest US using a grey-scale machine. The anterior, lateral and posterior chest was scanned using a linear transducer (5-10 MHz) and the mediastinum was scanned using a micro-convex array transducer (7.5 MHz). Two clinicians evaluated the US clips independently for consolidation, effusion or mediastinal lymphadenopathy; two independent radiologists reviewed the CXRs. Of

169 enrolled children (median age 27 months), consolidation occurred as commonly on US as on CXR (72.5% versus 73.1%,  $p < 0.01$ ), with moderate agreement between US and CXR ( $\kappa = 0.40$ ). Pleural effusion was more common on US (20.6% versus 14.3% on CXR,  $p < 0.01$ ) with substantial agreement between US and CXR,  $\kappa = 0.67$ . There was poor agreement for lymphadenopathy on CXR versus US ( $\kappa = 0.08$ ); lymphadenopathy was more common on CXR (68.0%) than US (51.7%,  $p = 0.58$ ). US had a higher inter-reader agreement for consolidation ( $\kappa = 0.89$ ) or effusion ( $\kappa = 0.85$ ) than CXR (respectively  $\kappa = 0.45$  and  $\kappa = 0.40$ ), while CXR had a higher inter-reader agreement for lymphadenopathy ( $\kappa = 0.38$  versus  $\kappa = 0.07$ ). In a subgroup of 39 microbiologically confirmed PTB cases, consolidation or effusion was more common on US (consolidation 86.5% versus 73.0%,  $p < 0.01$ ,  $\kappa = 0.43$ ; effusion 25.6% versus 15.4%,  $p = 0.04$ ,  $\kappa = 0.38$ ). Lymphadenopathy was more common on CXR (45.5% versus 36.4% on US,  $p = 0.69$ ,  $\kappa = 0.07$ ). This study shows that chest US is potentially a better imaging modality to identify consolidation or effusion in children with PTB with a higher inter-reader agreement than CXR. However, these findings are not exclusive for PTB; comparing PTB and pneumonia is needed.

### DENGUE VIRUS IGG ANTIBODIES AND ITS ASSOCIATION WITH CLIMATE VARIABLES. A COUNTRY-BASED STUDY (MÉXICO)

Mario Rojas-Rusell<sup>1</sup>, Irma Y Amaya Larios<sup>2</sup>, Elsa Sarti<sup>3</sup>, José Ramos Castañeda<sup>4</sup>, Laura Tirado-Gomez<sup>1</sup>, Esteban Puentes Rosas<sup>3</sup>, Liliana Castro-Porras<sup>1</sup>, Victoria Castro-Borbonio<sup>1</sup>, Gustavo Olaiz<sup>5</sup>

<sup>1</sup>Universidad Nacional Autónoma de México, Ciudad de México, Mexico, <sup>2</sup>Instituto Nacional de Salud Pública, Cuernavaca, Mexico, Mexico, <sup>3</sup>Sanofi Pasteur, Ciudad de México, Mexico, <sup>4</sup>Instituto Nacional de Salud Pública, Cuernavaca, México, Mexico, <sup>5</sup>Universidad Nacional Autónoma de México, Ciudad de Mexico, Mexico

The rapid expansion of dengue in the world is a major concern to health authorities. Forecasting the development from endemic to hyperendemic areas is a major goal to evaluate the burden of the disease and to considerate the application of public health interventions such as vaccination. Particularly, endemic regions are characterized by a continuous exposure of the population to Dengue virus, which in theory result in high levels of antibodies against the virus. However seroepidemiological studies are expensive and limited to communities well known as hyperendemic locations. It seems that environmental conditions optimal for vector breeding could be associated with a continuous exposure to the virus and as a consequence with high levels of anti DENV antibodies. Based on the results of a cross-sectional study conducted in Mexico to assess DENV antibodies seroprevalence, we analyzed the relationship between specific dengue seroprevalence at community level and environmental variables, as altitude, average annual temperature and average annual precipitation in each place where blood samples were taken. As the Primary Sampling Units were schools, we used as data source for environmental data the National System of School Information, of the Ministry of Education in Mexico. Through logistic models, the association between seroprevalence and environmental variables was assessed and confidence intervals were obtained. These analyses were done using software Stata V.14 and the complex design was taken into account in all the estimations. We found that average annual temperature is positively and significantly associated with seroprevalence (OR 2.66; CI95%: 1.68-4.24) while altitude is also significantly associated but in a negative direction (OR 0.91; CI95%: 0.86-0.96). No statistical association was identified in relation to annual precipitation (OR 1.0; CI95%: 0.99-1.01). As the study was cross-sectional, more information is needed to calibrate a model that helps to forecast dengue prevalence in areas where transmission is increasing and, also, to weigh up the effect of the global warming in dengue transmission.

**TRENDS IN DENGUE AMONG UNITED STATES TRAVELERS, 2010-2016**

Aidsa Rivera, Steve Waterman, Tyler Sharp

*Centers for Disease Control and Prevention Dengue Branch, San Juan, Puerto Rico*

Dengue is a tropical emerging arboviral disease that can result in life-threatening disease. Importation of the four dengue viruses (DENV-1-4) into the U.S. via travelers returning from the tropics has resulted in recent dengue outbreaks in Texas, Florida, and Hawaii. In 2010, dengue became a nationally reportable condition in the U.S. A descriptive analysis was performed using dengue cases reported from state and local health departments to ArboNET, a surveillance system used to monitor trends in arboviral diseases in the U.S. Laboratory-positive dengue cases were defined as clinically suspected cases with either (i) DENV nucleic acid detected by RT-PCR in a clinical specimen; or (ii) detection of anti-DENV IgM in serum. A total of 4,478 travel-associated, laboratory-positive dengue cases were reported to ArboNET during 2010-2016. DENV infection was defined by detection of nucleic acid identified in serum by RT-PCR in 28% of cases, and by detection of IgM antibody in 72% cases. Among RT-PCR-positive cases, the most common DENVs identified were DENV-1 (n= 106, 47%), DENV-2 (n=59, 26%), DENV-3 (n=37, 16%) and DENV-4 (n=25, 11%). The greatest number of dengue cases were reported in 2016 (n=835, 19%), followed by 2013 (n=793, 18%) and 2015 (n=746, 17%). Jurisdictions with the most reported cases were California (n = 681, 15%), Florida (n = 654, 15%), and New York City (n = 623, 14%). Median age of dengue case-patients was 41 years (range: 1-89 years), 90% were adults, and 50% were male. Among cases with a known destination of travel, the most common were Dominican Republic (n=438; 10%), India (n=437, 10%), and Mexico (n=411, 9.5%). The reported rate of hospitalization was 28% and 17 (0.4%) of all cases were fatal. ArboNET reporting of dengue cases among travelers has trended upward in recent years, reflecting the increase in incidence worldwide and an ongoing risk of DENV importation potentially leading to local transmission and outbreaks where competent *Aedes* vectors are present. Continued efforts to improve reporting will allow rapid detection of cases and response as well as messaging to at-risk travelers.

## 784

**ASSOCIATED FACTORS TO DENGUE INFECTION IN SUBJECTS FOLLOWED UP DURING 2.5 YEARS FROM AN ENDEMIC MEXICAN AREA**Ruth A. Martínez-Vega<sup>1</sup>, Irma Yvonne Amaya-Larios<sup>2</sup>, Fredi A. Díaz-Quijano<sup>3</sup>, José Ramos-Castañeda<sup>2</sup>*<sup>1</sup>Universidad de Santander, Bucaramanga, Colombia, <sup>2</sup>Instituto Nacional de Salud Pública, Cuernavaca, Mexico, <sup>3</sup>OLFIS, Colombia, Colombia*

The immunity and the mobility of subjects could be determinant factors for Dengue virus (DENV) infection. To determine associated factors to DENV infection in subjects followed up during 2.5 years from two Mexican endemic localities. Between August and November of 2014 we visited subjects from a cohort of older than 5 years old enrolled between June and November 2011, and they were followed until November of 2016. We interviewed and took blood sample every 6 months from subjects who accepted to participate. ELISA capture IgM and IgG and ELISA indirect IgG (Panbio) were performed to evaluate the incidence of DENV infection during this period. Binomial regression was performed to evaluate associated factors to DENV infection. An adjustment of standard errors was made considering the 75 sample clusters (houses in an area of 50 mt radio). 862 (72%) of 1197 subjects from original cohort and 104 subjects were new inclusions. 400 were selected for serology, of which 12 (9.6%) were primary infections, 17 (18.9%) were secondary infections and 17 (9.2%) were post-secondary infections. The associated factors were to live in Axochiapan compared with Tepalcingo (Risk Ratio [RR] 0.52; IC95% 0.29-0.93; p=0.028), previous immune status as secondary

infection compared with primary infection (RR 2.09; IC95% 1.01-4.32; p=0.046) and the different place to home where they spend the most time as staying in the house of relative compared with school or workplace (RR 3.89 IC95% 1.05-14.32, p=0.014), other places as church, markets were not associated. Other variables like age, gender and time spend at home were not associated. Dengue transmission in endemic settings seems to depend on specific life styles as suggested by the increase in risk to be infected in seropositive subjects and the mobility of subjects.

## 785

**DENGUE IN PREGNANT WOMEN: CHARACTERIZATION OF CASES IN BRAZIL, 2007-2015**Laura B. do Nascimento<sup>1</sup>, Cláudio M. Siqueira<sup>1</sup>, Giovanini E. Coelho<sup>2</sup>, João B. Siqueira, Jr.<sup>1</sup>*<sup>1</sup>Federal University of Goiás, Goiânia, Brazil, <sup>2</sup>Ministry of Health- Brazil, Brasília, Brazil*

This study was undertaken to characterize the probable cases of dengue in pregnant women reported in Brazil, from 2007 to 2015. A descriptive study was carried out of sociodemographic, epidemiological, clinical and laboratory characteristics, with data from the Sinan Information System. The annual incidence of dengue in pregnant women ranged from 3.3 (2009) to 816.6 (2010) cases per 100,000 live births; of the 43,772 probable cases of dengue in pregnant women residents of 3,218 municipalities in the five major regions of the country, 81.6% were investigated, 34.1% were laboratory confirmed, and 1.7% were severe; rates of hospitalization and lethality were 5.4% and 1.6%, respectively; the risk of death due to dengue was higher in the pregnancy than the population of non-pregnant women of childbearing age (ratio=3.95 [95%CI=3.07;5.08]), higher in the third trimester of pregnancy (ratio=8.55 [95%CI=6.08;12.02]). The results show the burden of dengue in pregnant women and their vulnerability to worsening of the disease and death.

## 786

**EVALUATION OF DENGUE ANTIBODIES IN SERONEGATIVE SUBJECTS FROM A PHASE III EFFICACY TRIAL DEMONSTRATES A POSITIVE CORRELATION IN GENERATION OF SEROTYPE-SPECIFIC AB WITH INCREASING AGE FOLLOWING VACCINATION**Anthony Byers<sup>1</sup>, Alina Munteanu<sup>1</sup>, Robert Small<sup>1</sup>, Lilibeth Lanza<sup>1</sup>, Del Leistritz-Edwards<sup>1</sup>, Michael Peredelchuk<sup>1</sup>, Matthew Bonaparte<sup>2</sup>, Aravinda de Silva<sup>3</sup>, Bruno Guy<sup>4</sup>, Janice Moser<sup>1</sup>*<sup>1</sup>Sanofi Pasteur, Orlando, FL, United States, <sup>2</sup>Sanofi Pasteur, Swiftwater, PA, United States, <sup>3</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>4</sup>Sanofi Pasteur, Marcy l'Etoile, France*

Sanofi Pasteur's tetravalent dengue vaccine (CYD-TDV) has shown efficacy against symptomatic dengue in endemic areas of Asia-Pacific and Latin America with subjects between the ages of 2-14 and 9-16 years (y), respectively. The vaccine showed efficacy of 60.3% (95% confidence interval [CI], 55.7;64.5) for all participants, but demonstrated differing efficacy based on age: 65.6% (95% CI, 60.7;69.9) for those aged 9y or older and 44.6% (95% CI, 31.6;55.0) for those younger than age 9 years. Based on this and other analyses, countries throughout Asia-Pacific and Latin America have approved the CYD-TDV vaccine for use in individuals 9-45y. To assess the impact of subject age independent of their dengue serostatus, we evaluated the specificity and affinity of the serum antibody (Ab) response in a subset of CYD-TDV vaccinated subjects from the Asia-Pacific phase III trial (NCT01373281) over 4 age ranges (2-5, 6-8, 9-11, 12-14y), who were confirmed seronegative at the onset of the trial by Vero PRNT50. Ab specificity was assessed via a combined dengue virus-depletion flow cytometry-based U937 DC-SIGN neutralization assay that qualitatively determined whether serum neutralizing Abs (nAbs) to each of the 4 dengue serotypes from these subjects were homotypic and/or heterotypic (cross-reactive). In agreement with previous studies, CYD-

TDV vaccination primed dominant homotypic nAb responses to serotype 4 while the nAb responses to the other 3 serotypes were mostly cross-reactive. To get sufficient data to compare between age groups, we then focused on anti-serotype 4 responses, and interestingly, we observed a significant positive correlation in the level of dengue serotype 4-specific homotypic nAb with the increase in the age of the subjects. Alternatively, evaluation of serum Ab affinity via a biolayer interferometry-based assay did not find any statistical differences in Ab affinity for any of the 4 serotypes across the age ranges tested. These data display a positive effect of increased age on the generation of CYD-TDV-induced serotype-specific homotypic nAb responses, not biased by pre-existing dengue antibodies at the time of vaccination.

## 787

### EVALUATION OF THE EFFECT OF PRE-EXISTING IMMUNITY AGAINST DENGUE ON NEUTRALIZING ANTIBODY RESPONSE INDUCED BY A LIVE ATTENUATED TETRAVALENT DENGUE VACCINE CANDIDATE, KD-382, IN CYNOMOLGUS MONKEYS

**Shota Takagi<sup>1</sup>**, Masaya Yoshimura<sup>1</sup>, Kazuhisa Kameyama<sup>1</sup>, Yasuhiko Shinmura<sup>1</sup>, Kengo Sonoda<sup>1</sup>, Yoichiro Kino<sup>1</sup>, Sutee Yoksan<sup>2</sup>, Takashi Fujii<sup>1</sup>

<sup>1</sup>The Chemo-Sero-Therapeutic Research Institute (KAKETSUKEN), Kumamoto-shi, Kumamoto, Japan, <sup>2</sup>Center for Vaccine Development, Institute of Molecular Biosciences, Mahidol University, Salaya, Nakhon Pathom, Thailand

One of the challenges in dengue vaccine development is inducing neutralizing antibody responses against all four serotypes simultaneously and ensuring that the induced neutralizing antibodies last for a long time. Our tetravalent dengue vaccine candidate currently under development, KD-382, is a live attenuated vaccine using a classical host range mutation strategy and thus is expected to induce a strong neutralizing antibody response similar to the antibody response induced by natural infection. To date, we have shown that dengue-naïve cynomolgus monkeys administered a single dose of KD-382 seroconverted for all four serotypes (Tetra-NAb response). However, when considering vaccine use in dengue endemic regions, it is thought that some vaccinees will be immune to dengue as a result of previous natural dengue infections. Therefore, it is important to evaluate the effect of pre-existing dengue immunity on neutralizing antibody responses induced by KD-382. We administered KD-382 (5, 5, 5, 5Log<sub>10</sub> PFU/dose) to 15 cynomolgus monkeys pre-administered with one of the monovalent parental wild-type strains (DENV3: 6Log<sub>10</sub> PFU/dose, DENV1, 2, 4: 5Log<sub>10</sub> PFU/dose) or vehicle 60 days before KD-382 vaccination (3 monkeys per group). Neutralizing antibody titers against each of the four parental wild-type strains were measured by a focus reduction assay 30 days after KD-382 administration. All 3 monkeys given the vehicle followed by KD-382 (not pre-immune/naïve) seroconverted (FRNT50=1:>10) against all four serotypes (Tetra-NAb response). Also, all 12 monkeys given one of the monovalent parental wild-type strains (pre-immune) followed by KD-382, regardless of the pre-immunized serotypes, showed a Tetra-NAb response. KD-382 successfully induced Tetra-NAb responses under both naïve and pre-immune conditions, suggesting that KD-382 could be a useful vaccine for both naïve vaccinees and vaccinees that are seropositive due to previous natural dengue infection at base-line.

## 788

### SINGLE ADMINISTRATION OF LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE CANDIDATE, KD-382, INDUCED LONG-LASTING (>2 YEARS) NEUTRALIZING ANTIBODY AGAINST ALL FOUR SEROTYPES IN CYNOMOLGUS MONKEYS

**Yasuhiko Shinmura<sup>1</sup>**, Shota Takagi<sup>1</sup>, Masaya Yoshimura<sup>1</sup>, Kazuhisa Kameyama<sup>1</sup>, Kengo Sonoda<sup>1</sup>, Yoichiro Kino<sup>1</sup>, Sutee Yoksan<sup>2</sup>, Takashi Fujii<sup>1</sup>

<sup>1</sup>The Chemo-Sero-Therapeutic Research Institute (KAKETSUKEN), Kumamoto-shi, Kumamoto, Japan, <sup>2</sup>Center for Vaccine Development, Institute of Molecular Biosciences, Mahidol University, Salaya, Nakhon Pathom, Thailand

One of the challenges in dengue vaccine development is inducing neutralizing antibody responses against all four serotypes simultaneously and ensuring that the induced neutralizing antibodies last for a long time. Our tetravalent dengue vaccine candidate currently under development, KD-382, is a live attenuated vaccine using a classical host range mutation strategy and thus is expected to induce a strong neutralizing antibody response similar to the antibody response induced by natural infection. To date, we have shown that dengue-naïve cynomolgus monkeys administered a single dose of KD-382 seroconverted for all four serotypes (Tetra-NAb response). However, it is important to show how long neutralizing antibodies induced by KD-382 can be expected to last. We administered a single dose of KD-382 (5, 5, 5, 5Log<sub>10</sub> PFU/dose) to 6 cynomolgus monkeys (male and female), and are measuring the neutralizing antibody titer against parent strains for each serotype over time. This study has currently been running for over two years, and we have confirmed that neutralizing antibody titers against all four serotypes (FRNT50=1:>10) persist for at least 25 months. The geometric mean neutralizing antibody titers at 25 months for serotype-1, serotype-2, serotype-3 and serotype-4 were 3.2, 2.6, 2.3 and 2.9 (Log<sub>10</sub> FRNT50), respectively. The persistence of neutralizing antibodies for over two years suggests that, in cynomolgus monkeys, KD-382 can induce a strong neutralizing antibody response against all four dengue serotypes simultaneously with only a single administration, and thus has high potential as a dengue vaccine. We will continue our observations, but as no decrease in neutralizing antibody titer has been observed so far, we expect that neutralizing antibodies will last for even longer.

## 789

### EFFECT OF EXPOSURE HISTORY ON DENGUE INFECTION AND DISEASE: A STATISTICAL APPROACH AND ITS APPLICATION TO THE DENGUE COHORT IN NICARAGUA

**Tim K. Tsang<sup>1</sup>**, Ira Longini<sup>1</sup>, M. Elizabeth Halloran<sup>2</sup>, Yang Yang<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>University of Washington, Seattle, WA, United States

A cohort of children has been established in Nicaragua since 2004 to study the epidemiology, virology and immunology of the dengue virus, an mosquito-borne arbovirus with four co-circulating serotypes. Each subject was bled annually and followed up for dengue-fever-like symptoms. Serum samples were tested by ELISA, and a subset of ELISA-positive samples were serotyped with other lab-methods. We proposed a novel statistical competing-risk framework to assess the infection risks of all four serotypes during the study years and the effects of exposure history on both infection and probability of disease given infection. This framework couples the cohort data with surveillance data to inform the model about the complete exposure history at the individual level both before and during the study years. The model is fitted with a data-augmented MCMC sampling algorithm. An efficient sampling approach for individual exposure history was also proposed. We demonstrated by extensive simulation studies that the proposed algorithm can provide unbiased estimation of key model parameters. By applying our method

to the Nicaragua pediatric cohort, we found that there were three outbreaks triggered by three different serotypes during the study years. The probability of disease given infection was much lower for DENV-4 than for other three serotypes. We found that the time since most recent infection (as a proxy of decay of immunity) showed different effects on the pathogenicity for younger and older children, suggesting age may play an important role on the immune response after dengue infection, which has important implications on dengue vaccine policy.

### GEOSPATIAL ANALYSIS OF DENGUE EMERGENCE IN RURAL AREAS IN THE SOUTHERN PROVINCE OF SRI LANKA: 2012-2013

Charmaine P. Mutucumarana<sup>1</sup>, Champica K. Bodinayake<sup>2</sup>, Ajith Nagahawatte<sup>2</sup>, Vasantha Devasiri<sup>2</sup>, Ruvini Kurukulasooriya<sup>2</sup>, Thamali Anuradha<sup>2</sup>, Aruna Dharshan De Silva<sup>3</sup>, Truls Østbye<sup>1</sup>, Christopher W. Woods<sup>1</sup>, Megan E. Reller<sup>1</sup>, L. Gayani Tillekeratne<sup>1</sup>, Paul M. Lantos<sup>1</sup>

Dengue is a major cause of acute febrile illness in Sri Lanka, historically considered an urban disease. In 2012-2013, we documented acute dengue surprisingly associated with self-reported rural residence in the Southern Province. In this analysis, we used geographic information systems (GIS) and spatial statistical analysis to assess this association among patients hospitalized with febrile illness in the Southern Province. Febrile patients were enrolled from June 2012-May 2013 in a cross-sectional surveillance study at the largest tertiary care hospital in the Southern Province. Acute dengue was diagnosed in a subset of febrile patients by paired serology and virologic testing. Patients' addresses were used to determine their grama niladhari (GN) divisions, the lowest administrative division in Sri Lanka. Each patient was geocoded to the geographic center of the GN division and placed randomly within a 10 km radius of that center. Geographic distribution of acute dengue infection was modeled using a spatial generalized additive model (GAM) predicted onto a grid of coordinate pairs covering the Southern Province to map spatial variation in odds of dengue infection. Permutation tests were applied to identify areas where local odds of dengue infection significantly differed from the average odds of dengue. Of 760 patients, 312 (41%) had laboratory-confirmed acute dengue. Dengue was highly spatially heterogeneous (local odds ratio (OR) 0.29-4.97 of acute dengue infection compared to the cohort average). There was a higher than average odds ( $p < 0.05$ ) in the rural northeast region of the Southern Province and a lower than average odds in the more urbanized southwest region of the Southern Province, including cities such as Galle and Matara. Our study further affirms the emergence of dengue in rural southern Sri Lanka. Increased travel, changes in land use or demographics, and favorable living conditions for mosquito vectors may account for these changes. Our study highlights the need for real-time, geospatial analyses to identify unrecognized clusters of dengue infection and to optimize public health surveillance and control activities.

## 791

### SPREAD OF DENGUE 1 AND 2 IN MACHALA, ECUADOR: EVIDENCE OF A DYNAMIC EPIDEMIC GENETICALLY RELATED TO THOSE OF SURROUNDING COUNTRIES OF COLOMBIA, VENEZUELA AND PERU

Irina Maljkovic Berry<sup>1</sup>, Anna M. Stewart-Ibarra<sup>2</sup>, Wiriya Rutvisuttinunt<sup>1</sup>, Efraín Beltrán-Ayala<sup>3</sup>, Washington B. Cárdenas<sup>4</sup>, Cinthya Cueva<sup>2</sup>, Mark Polhemus<sup>2</sup>, Sadie J. Ryan<sup>5</sup>, Timothy P. Endy<sup>2</sup>, Richard G. Jarman<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>SUNY Upstate Medical University, Syracuse, NY, United States,

<sup>3</sup>Universidad Técnica de Machala, Machala, Ecuador, <sup>4</sup>Escuela Superior Politécnica del Litoral (ESPOL), Guayaquil, Ecuador, <sup>5</sup>University of Florida, Gainesville, FL, United States

Dengue is one of the major public health concerns in Ecuador, where it is endemic and provides the greatest burden of all mosquito-borne febrile illnesses. A surveillance platform has been established in the city of Machala to identify and characterize disease caused by arboviruses. Here, samples are collected from febrile subjects at four sentinel clinics and the central hospital of the Ministry of Health. A total of 14 DENV1 and 35 DENV2 sequences were successfully obtained from these samples collected in 2014 (previously published) and 2015. The sequences were aligned together with other reference dengue sequences from the surrounding countries and phylogenetic trees of full genome and E gene were inferred. For DENV1, the trees indicated existence of two different lineages in 2014, suggesting at least two different introductions of this serotype into the city of Machala, one lineage most closely related with sequences from Colombia and the other one to sequences from Venezuela. In 2015, no samples belonging to the Venezuela lineage were collected, suggesting possible extinction of this lineage in Machala. For DENV2 all sequences belonged to the same lineage, indicating that the majority of this serotype in the city originates from the same introduction and that this lineage continues to persist in the city. DENV2 lineage, like DENV1, was closely related to sequences from Colombia and Venezuela, but also to sequences from Peru. Our results suggest frequent flow of DENV between Ecuador and surrounding countries and show an epidemic in the city of Machala that is dynamic, with introduction and persistence of multiple lineages, as well as lineage extinction. In addition, our results show the importance of continuous surveillance, where genetic information can be used to track epidemic dynamics and patterns of dengue movement in this region.

Dengue disease is a large public health problem that mainly afflicts tropical and subtropical regions. Understanding of the correlates of protection against dengue virus (DENV) is poor and hinders the development of a successful human vaccine. Here we map HLA DRB1 restricted DENV-specific epitopes in individuals previously exposed to dengue virus in the general population of Nicaragua and compare it to the breadth and specificity of CD4+ T cell responses previously investigated in Sri Lanka. The 22 DRB1 alleles analyzed to date cover 81.7% of alleles with phenotype frequency  $\geq 5\%$  worldwide and account these alleles combined afford 92% phenotypic coverage worldwide (92% of individuals express at least one of the alleles). The capsid protein followed by nonstructural NS3, NS2A, and NS5 proteins were the most targeted proteins. We further noticed a wide variation in magnitude of T cell responses as a function of the restricting DRB1 allele. Comparing these patterns to those in the general population of Sri Lanka, we found a general correlation between restricting HLA allele and magnitude of CD4+ T cell responses. Based on these results we devise a pool of epitopes that affords improved coverage worldwide at the level of CD4 T cells response, broadly covering different HLA DRB1\* alleles and different DENV serotypes. These results are of relevance for both vaccine design and the identification of robust correlates of protection in natural immunity.

## NEW BIOMARKERS OF LIVER INVOLVEMENT BY DENGUE INFECTION IN ADULT VIETNAMESE PATIENTS

Nguyen Thi Cam Huong<sup>1</sup>, Nguyen Phuong Hai<sup>2</sup>, Nguyen Van Vinh Chau<sup>3</sup>, Pham Thi Le Hoa<sup>4</sup>, Mohamed Gomaa Kamel<sup>5</sup>, Abdelrahman Tarek Mohammed<sup>6</sup>, Kenji Hirayama<sup>7</sup>, Nguyen Tien Huy<sup>8</sup>

<sup>1</sup>University of Medicine and Pharmacy of Ho Chi Minh city, Ho Chi Minh City, Vietnam, <sup>2</sup>Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Vietnam, <sup>3</sup>Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, <sup>4</sup>University of Medicine and Pharmacy of Ho Chi Minh City, Ho Chi Minh City, Vietnam, <sup>5</sup>Faculty of Medicine, Minia University, Minia, Egypt, <sup>6</sup>Faculty of Medicine, Al-Azhar University, Cairo, Egypt, <sup>7</sup>Department of Immunogenetics, Institute of Tropical Medicine (NEKKEN), Leading Graduate School Program, and Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, <sup>8</sup>Department of Clinical Product Development, Institute of Tropical Medicine (NEKKEN), Leading Graduate School Program, and Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Liver injury with marked elevation of aspartate amino transferase enzyme (AST) is common in dengue infection. New plasma biomarkers are reported in drug-induced liver injury mainly in the centrilobular area such as Glutamate Dehydrogenase (GLDH), Hydroxyphenylpyruvate dioxygenase (HPPD), and Glutathione S Transferase- $\alpha$  (GST). Arginase-1 (ARG-1) indicates liver injury mainly in the portal area. Paraoxonase-1 (PON-1), 4- and Gamma-glutamyl transferase (GGT) are other measurements to detect liver injuries. The cross sectional study was conducted in adult dengue patients from October 2015 to December 2016 at the Hospital for Tropical Diseases of Ho Chi Minh City, Vietnam. A total of 87 dengue patients were recruited into three equal groups according to plasma AST levels (lower 80, 80-400, higher 400 IU/ml). The new liver enzymes in the blood samples were measured from 4th to 6th day of their illness by commercial ELISA kits. Thirty nine patients (44.8%) had dengue without warning signs (D), 37 (42.5%) had dengue with warning signs (DWS), and 11 (12.6%) had severe dengue (SD) on the discharged day according to the 2009 WHO classification. Plasma AST level was significantly higher in SD group [mean:1192.4 (standard deviation: 416.3)] compared to the DWS group [322.6 (332)] and D group [(143.3 (165.0)]. Our univariate analysis revealed that ARG-1, HPPD, and GGT levels were significantly associated with dengue severity, whereas GLDH, GST, and PON-1 were not associated with disease severity. Additionally, multivariate logistic regression indicated that plasma ARG-1, HPPD, and GST levels were independently correlated with SD against DWS/D patients, while HPPD and GLDH were associated with SD/DWS against D patients. Dengue-induced liver injury is initiated in the centrilobular region towards the portal area during disease progress. Moreover, these new biomarkers can serve as good prognostic predictors.

## BRIDGING EFFICACY OF THE CYD-TDV TETRAVALENT DENGUE VACCINE FROM CHILDREN/ADOLESCENTS TO ADULTS IN HIGH ENDEMIC COUNTRIES BASED ON NEUTRALIZING ANTIBODY RESPONSE

Peter B. Gilbert<sup>1</sup>, Ying Huang<sup>1</sup>, Michal Juraska<sup>1</sup>, Zoe Moodie<sup>1</sup>, Youyi Fong<sup>1</sup>, Alexander Luedtke<sup>1</sup>, Yingying Zhuang<sup>2</sup>, Jason Shao<sup>2</sup>, Lindsay N. Carpp<sup>1</sup>, Nicholas Jackson<sup>3</sup>, Laurent Chambonneau<sup>3</sup>, Alain Bouckenooghe<sup>4</sup>, Betzana Zambrano<sup>5</sup>, Carina Frago<sup>4</sup>, Sophie Pallardy<sup>3</sup>, Fernando Noriega<sup>6</sup>

<sup>1</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>Sanofi Pasteur, Marcy-L'Etoile, France, <sup>4</sup>Sanofi Pasteur, Singapore, Singapore, <sup>5</sup>Sanofi

Pasteur, Montevideo, Uruguay, <sup>6</sup>Sanofi Pasteur, Swiftwater, PA, United States

The CYD-TDV dengue vaccine has recently been licensed in multiple endemic countries based on vaccine efficacy (VE) to prevent symptomatic, virologically-confirmed dengue (VCD) demonstrated in two placebo-controlled Phase 3 trials in 2–14 year olds (y.o) in Asia (CYD14 - NCT01373281) and 9–16 y.o in Latin America (CYD15 - NCT01374516). Neutralizing antibody titers at baseline and post-vaccination (Month 13) measured by the PRNT50 strongly correlated with VE. These titer data may be useful for predicting VE in adults, thus constituting a basis for bridging/extrapolation of VE. Two Phase 2 trials of CYD-TDV measured PRNT50 titers pre-vaccination (baseline) and one month post-vaccination (Month 13): CYD22 in Vietnam (n=32 9–16 y.o and n=18 18–45 y.o - NCT00875524) and CYD47 in India (n=115 18–45 y.o - NCT01550289). PRNT50 distributions were compared between age cohorts by geometric mean ratios. In addition, epidemiological bridging methods were applied to estimate VE against any serotype (DENV-Any) and against each DENV serotype over 25 months of follow-up post first vaccination in a hypothetical 18–45 y.o cohort in CYD14+CYD15 (Bridging Population 1) and in the 18–45 y.o CYD47 cohort (Bridging Population 2). Baseline and Month 13 geometric mean PRNT50 titers to each serotype were significantly greater in 18–45 than 9–16 y.o for all comparisons (CYD22 18–45 vs. CYD22 9–16 and vs. CYD14+CYD15 9–16; CYD47 18–45 vs. CYD14+CYD15 9–16) in these endemic regions. Based on the multiple bridging methods VE against DENV-Any was estimated to be 75.3–86.0% with 95% confidence intervals spanning 52.5–100% for Bridging Population 1 and 68.4–77.5% with 95% confidence intervals spanning 42.3–88.5% for Bridging Population 2. VE was estimated to be 56.9–76.9%, 68.3–85.8%, 91.4–95.0%, and 93.2–100% against serotype 1, 2, 3, 4 for Bridging Population 1 and 44.5–66.9%, 53.2–69.2%, 79.8–92.0%, and 90.6–95.0% against serotype 1, 2, 3, 4 for Bridging Population 2. In conclusion, VE to prevent dengue disease is predicted to be at least equal to or higher in 18–45 than 9–16 y.o in the above described endemic populations.

## ZIKA AND DENGUE VIRUS-SPECIFIC AND CROSS-REACTIVE MEMORY B CELL RESPONSES

Paulina Andrade<sup>1</sup>, Josefina Coloma<sup>1</sup>, Daniela Michlmayr<sup>1</sup>, Angel Balmaseda<sup>2</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Since 2015, Zika virus (ZIKV) has spread rapidly to many countries in the Americas, where it co-circulates with other flaviviruses that also cause human disease, such as dengue virus (DENV). DENV is comprised of four serotypes, where the amino acid sequence of the envelope is 65-70% conserved among the serotypes and 54-59% conserved with ZIKV. The antigenic similarity of ZIKV and DENV has raised important biological concerns regarding the effect of immunological cross-reactivity on protection and potential enhancement of ZIKV and DENV infections and vaccines. To date, the cross-reactivity of ZIKV and DENV B cell responses is not fully understood in the context of natural human infections. Here, we use a novel ELISPOT-based assay, designated the Quad-Color Fluorospot assay, that enables analysis of DENV serotype specificity vs. cross-reactivity of the memory B cell (MBC) population at a single-cell level, adding a fifth color to include ZIKV. We analyzed a unique set of peripheral blood mononuclear cells from the Nicaraguan Pediatric Dengue Cohort Study, ongoing since 2004, to which Zika was added in January 2016. Samples were collected 2 weeks and several months after RT-PCR-confirmed ZIKV infection (ZIKV+) from children who were documented to be previously DENV-immune or DENV-naïve. We also included a set of dengue patients who were ZIKV-naïve. Preliminary analysis of early convalescent samples (day 14-15) from 10 patients showed that despite the antigenic similarity between DENV and ZIKV and regardless of prior DENV exposure, MBCs

from ZIKV-infected subjects were highly reactive and specific to ZIKV, with lesser cross-reactivity to DENV. When analyzing total activated MBCs, DENV-naïve ZIKV+ patients displayed a higher frequency of ZIKV-specific MBC spots compared to DENV-immune ZIKV+ patients and as expected, DENV-naïve ZIKV+ patients displayed a lower frequency of DENV-specific MBC spots compared to DENV-immune ZIKV+ patients. Analysis of a larger set of patients at convalescence and 6 months post-illness is ongoing. These studies provide much-needed information on how the human memory B cell response reacts to ZIKV and DENV over time.

There are an increasing number of investigational dengue vaccines in clinical development that have the potential to be important tools to reduce the burden of dengue. Vaccine efficacy (VE) estimates obtained in late-phase field trials are crucial for assessing vaccine suitability for public health implementation. Various known heterogeneities in dengue virus (DENV) transmission, which typically are not measured or fully balanced by randomization during vaccine trials, have the potential to confound estimates of VE against clinical endpoints. We quantified the extent to which VE estimates may be sensitive to heterogeneities associated with DENV transmission and vaccine action by analyzing simulated results from “virtual” phase-III trials in Iquitos, Peru. To ensure that we captured all known heterogeneities, we simulated city-wide DENV transmission and vaccine trial protocols using an agent-based model calibrated with entomological and epidemiological data from long-term field studies. We simulated several scenarios, including a baseline scenario in which the trial was designed to have 90% power of detecting VE with a lower bound of the 95% confidence interval > 30% against virus-confirmed clinical disease. Assuming leaky protection, we found that estimates of overall VE were 5-10% lower than the per-exposure protection used in the simulation due solely to the fact that the number of exposures was not measured in the simulated trial. In scenarios with equal per-exposure protection by serotype, estimates of serotype-specific VE were capable of varying by as much as 10-15% due to heterogeneity in exposure by serotype. The extent of these and other sensitivities of VE estimates to unmeasured heterogeneities tended to be exacerbated when the simulated vaccine had a relatively short duration of protection, particularly in the presence of temporal heterogeneity in serotype-specific exposure. Our results highlight both the sensitivity of VE estimates to unmeasured heterogeneities and the potential for agent-based models to quantify the extent of that sensitivity for locations under consideration as possible vaccine trial sites.

## 797

### DISSECTING THE QUALITY OF NEUTRALIZING ANTIBODY RESPONSES INDUCED BY THE NIH LIVE ATTENUATED TETRAVALENT DENGUE VACCINE TV003

**Matthew J. Delacruz<sup>1</sup>**, Usha K. Nivarthi<sup>1</sup>, Bhumi Patel<sup>1</sup>, Jessica A. Swanstrom<sup>1</sup>, Anna P. Durbin<sup>2</sup>, Stephen S. Whitehead<sup>3</sup>, Ralph S. Baric<sup>1</sup>, Aravinda M. de Silva<sup>1</sup>

<sup>1</sup>Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, NC, United States, <sup>2</sup>Center for

Immunization Research, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Dengue virus (DENV) is responsible for about 390 million infections annually. A safe and effective vaccine against DENV should stimulate prolonged and balanced immune responses to all the four serotypes. Proper understanding of the correlates of protection using dengue human infection models (DHIM) prior to engaging in efficacy trials in endemic areas is crucial for accelerating effective vaccine development. The Laboratory of Infectious Diseases at the National Institutes of Health developed a live attenuated tetravalent DENV vaccine TV003 currently in Phase 2 and 3 evaluations. A randomized placebo-controlled trial in which TV003 or placebo recipients were challenged six months later with a DENV-2 Tonga 74 strain, (rDENV2Δ30) was conducted to better understand the protective efficacy of TV003. All the recipients were protected from dengue infection defined as rDENV2Δ30 viremia, rash, and neutropenia. In order to understand possible correlates of protection, we compared the properties of neutralizing antibody responses elicited by TV003 against all four DENV serotypes. We hypothesized that serotype-specific antibodies provide long-term protection based on natural infection studies. To test this hypothesis, we estimated the contribution of serotype cross-reactive and type-specific antibodies to neutralization, by depleting specific populations of DENV-reactive antibodies from 6 months post vaccinated immune sera. Most of the subjects developed neutralizing antibodies to all 4 serotypes of DENV. Depletion results demonstrated that greater than 50% of neutralization responses were mediated by type-specific antibodies against all 4 serotypes. Further, epitope specific mapping studies were performed using the recombinant chimeric viruses as tools to further predict the regions targeted by type-specific neutralizing antibodies. We discuss the implications of these results in terms of testing the vaccine in large efficacy clinical trials.

## 798

### A SINGLE GLYCOSYLATED AMINO ACID IN DENGUE VIRUS NS1 PROTEIN IS REQUIRED FOR TRIGGERING HUMAN ENDOTHELIAL CELL PERMEABILITY

**Chunling Wang**, Edwina B. Tran, Henry Puerta-Guardo, Carmel Malvar, Dustin Glasner, Eva Harris

Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States

Dengue virus (DENV) is a mosquito-borne flavivirus that causes up to 96 million dengue cases annually. Infection with any of the four serotypes (DENV-1-4) can result in inapparent infection, classic dengue, or severe forms of the disease associated with vascular leak leading to shock and death. We recently described a novel role for DENV nonstructural protein 1 (NS1) in triggering permeability of human endothelial cells *in vitro* and systemic vascular leak *in vivo*. We also showed that DENV NS1 disrupts the endothelial glycocalyx layer (EGL), resulting in hyperpermeability. However, the molecular determinants of NS1-induced endothelial permeability have not yet been identified. Unlike NS1 from most flaviviruses, DENV NS1 displays only two, rather than three, conserved N-linked glycans (Asn-130 and Asn-207), required for hexamer stability and secretion. We examined the importance of NS1 glycosylation status on endothelial barrier dysfunction *in vitro* and demonstrated that mutation of the N-glycosylation site 207 (N207Q) completely prevents (i) NS1-induced hyperpermeability (measured by transendothelial electrical resistance, TEER) and (ii) EGL disruption (measured by cleavage of sialic acid, a major component of the EGL) in human pulmonary microvascular endothelial cells, without affecting NS1 binding to the surface of endothelial cells or expression or secretion of the protein. In contrast, the N130Q mutation greatly reduced secretion of NS1. We are currently assessing the effect of the N207Q mutation on other pathogenic functions of NS1 *in vitro* as well as in our *in vivo* model of dermal endothelial permeability. We are also expanding the study to NS1 from other flaviviruses such as Zika virus and West Nile virus. In summary, we have identified a single amino acid,

N207, at one of the two glycosylation sites of DENV-2 NS1 as the key determinant required for NS1 to trigger endothelial permeability *in vitro*. This information is crucial for understanding DENV pathogenesis, as well as for developing antiviral therapies and NS1-based vaccines.

## 799

### BOOSTING EXPLAINS PATTERNS IN RATIOS OF INAPPARENT AND SYMPTOMATIC DENGUE VIRUS INFECTIONS

Rotem Ben-Shachar<sup>1</sup>, Leah Katzelnick<sup>1</sup>, Angel Balmaseda<sup>2</sup>, Michael Boots<sup>3</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States*, <sup>2</sup>*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua*, <sup>3</sup>*Department of Integrative Biology, University of California Berkeley, Berkeley, CA, United States*

Dengue is the most prevalent arthropod-borne viral disease worldwide, and the four dengue virus (DENV) serotypes circulate endemically in many tropical and subtropical regions worldwide. Numerous studies have shown that the majority of dengue virus (DENV) infections are inapparent and that the ratio of inapparent to symptomatic infections (*I/S*) fluctuates substantially year-to-year. In the Pediatric Dengue Cohort Study (PDCS) in Nicaragua, established in 2004 and as such the longest continuously running longitudinal dengue cohort study in the field, the *I/S* ratio has varied greatly, from 16.5:1 in 2006-7 to 1.2:1 in 2009-10. We hypothesize that in dengue-endemic areas, frequent boosting of the immune response can be protective against symptomatic disease and can explain fluctuating *I/S* ratios. We define boosts as exposures to homotypic or heterotypic DENV serotypes that do not lead to extensive viremia and result in a <4-fold rise in antibody titers (below the threshold of classification as an inapparent infection), thus leaving a modest trace on the immune response. Evidence for frequent boosting in endemic areas comes from studies that show that neutralizing antibody titers marginally increase between primary and secondary infections, even though traditionally, cross-reactive neutralizing antibodies are thought to wane following a primary infection, as observed in non-endemic settings. We formulate mechanistic, epidemiological models to examine the epidemiological effects of protective homologous and heterologous boosting of the antibody response in preventing subsequent symptomatic DENV infection. We fit these models to the PDCS dataset using Bayesian approaches and discriminate between models using Bayesian selection criteria. We show that models that assume that frequent boosts can protect against symptomatic disease can recover fluctuations in the *I/S* ratio, whereas a model without boosting cannot. These results have important implications for dengue vaccination policy, as effective vaccination has the potential to decrease the protective effects of boosting.

## 800

### CHANGES IN THE FORCE OF INFECTION OF DENGUE FROM 1994 TO 2015 IN A PEDIATRIC DENGUE COHORT STUDY IN NICARAGUA

Leah Katzelnick<sup>1</sup>, Rotem Ben-Shachar<sup>1</sup>, Aubree Gordon<sup>2</sup>, Angel Balmaseda<sup>3</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States*, <sup>2</sup>*Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States*, <sup>3</sup>*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua*

Dengue virus (DENV) is the most prevalent vector-borne disease of humans, infecting up to 400 million individuals annually. The force of infection, the rate at which susceptible individuals are infected in a population, is an important measure of the burden of disease and a critical metric for vaccination policy. We used age-stratified seroprevalence and case data from 12 years of the Pediatric Dengue Cohort Study in

Nicaragua to estimate the annual force of infection from 1994-2015. Seroprevalence data revealed a consistent decline in the rate at which children acquire DENV-specific immunity over time: in 2004, ~50% of children >5 years old were seropositive, but by 2014, children ≥11 were ≥50% seropositive. We estimated high force of infection in 1994-1995 and 1998-1999 and a gradual decline thereafter, with the exception of an uptick in 2009-2011. Two hypotheses proposed to explain changes in the force of infection are 1) transition from epidemic to endemic transmission and 2) population demographic transition. In 1994-1998, DENV3 was introduced for the first time into Nicaragua; in 2009-2011, DENV3 once again caused large epidemics. The age distribution of the Nicaraguan population has also shifted over this time period, with a decline in birthrate and increase in life expectancy. We used mathematical models to simulate these hypotheses and test the most likely determinants of changes in the force of infection in Nicaragua. We show that the initial large decline in the force of infection can be explained by the virgin-soil introduction of DENV3 in 1994-1998, in which high numbers of dengue cases were reported and a large fraction of the population was infected and became subsequently immune to DENV3. We show that the subsequent gradual decline in the force of infection can be attributed to changing demographics in Nicaragua, specifically lower birth rates. The decline in DENV transmission intensity in Nicaragua is consistent with trends seen globally. These results suggest that changes in immunity and demographics over time substantially impact dengue transmission intensity in Nicaragua. \*L. Katzelnick and R. Ben-Shachar contributed equally.

<sup>1</sup>*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*, <sup>2</sup>*Johns Hopkins School of Medicine, Baltimore, MD, United States*, <sup>3</sup>*LIDI/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States*

Over the past several decades dengue has become hyper-endemic in all tropical and sub-tropical regions of the world. Current estimates report nearly 100 million symptomatic and 300 million asymptomatic dengue infections annually. More recently, dengue and severe dengue are being reported in elderly populations in endemic regions, indicating a possible need for vaccination in these populations. For this reason, we sought to evaluate the safety and immunogenicity of the live attenuated tetravalent dengue vaccine TV005 in flavivirus-naïve adults 50 – 70 years of age in a placebo-controlled, double-blind study. Twenty-eight subjects were enrolled in the Baltimore/Washington area and randomly assigned to receive a single dose of TV005 (20) or placebo (8). The ages of enrolled subjects ranged from 51 – 70 years. Fifteen subjects were male (53%). Subjects were evaluated in the clinic approximately every other day for the first 16 days post-vaccination and again on days 21, 28, 58, 90, and 180. Adverse events were collected through day 28. Blood for safety assessment and viremia was collected through day 21. The vaccine was well-tolerated in this age group. The only adverse event that occurred significantly more frequently in TV005 recipients was an asymptomatic rash (65%). Thirteen subjects (65%) had vaccine virus recovered from the blood; 8 subjects had > 1 virus recovered. TV005 induced a tetravalent antibody response in 89% of vaccinees and a trivalent or better response in 95%. These data demonstrate that TV005 is well tolerated and highly immunogenic in an elderly population. TV005 will be further evaluated in a Phase 2 trial in an elderly population in Taiwan.

## 802

### FLAVIDOT: AN AUTOMATED VIRUS PLAQUE COUNTER FOR MEASUREMENT OF THE SEROLOGICAL NEUTRALIZATION RESPONSE AGAINST ZIKA AND DENGUE VIRUSES

Christian Chávez<sup>1</sup>, Leah Katzelnick<sup>1</sup>, Ana Coello Escoto<sup>1</sup>, Benjamin McElvany<sup>2</sup>, Wensheng Luo<sup>3</sup>, Henrik Salje<sup>3</sup>, Isabel Rodriguez-Barraquer<sup>3</sup>, Richard Jarman<sup>4</sup>, Sean Diehl<sup>2</sup>, Anna Durbin<sup>3</sup>, Derek Smith<sup>5</sup>, Derek Cummings<sup>1</sup>, Stephen Whitehead<sup>6</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>University of Vermont, Burlington, VT, United States, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>University of Cambridge, Cambridge, United Kingdom, <sup>6</sup>National Institutes of Health, Bethesda, MD, United States

Immunoassays, such as plaque reduction neutralization test (PRNT), allow us to quantify the neutralization capability of antisera. This assay is considered the gold standard for estimating the amount of infective viral particles in a sample but requires researchers to count individual plaques in each of the wells either by eye or utilizing expensive equipment and proprietary software. This process is time-consuming (even more so on 96-well plates), difficult to standardize among analysts, and not easy to customize when working with a wide variety of viruses. We report the development of a free, open-source, automated alternative, the Flavidot plaque counter. The Flavidot is capable of counting viral plaques from a variety of phenotypes, is easy to customize for different staining methods, and has a user-friendly interface. The counter was created using R statistical software, and Shiny to provide a user interface where different parameters may be adjusted. The counter was optimized by analyzing plaque images of 150+ DENV strains of all four serotypes. PRNT assays were performed on 96-well plates coated with C6/36 cells. The program's performance was tested on C6/36 and Vero cells infected with DENV and ZIKV. We compared the plaque counts obtained by unaided eye and the counts produced by the Flavidot. Counts obtained by Flavidot automatic settings were similar to those obtained by eye (Analyst 1, average plaque difference between methods: -1.89 [95%CI -4.00 - 0.22]; Analyst 2: -2.64 [95% CI -5.02 - 0.25]), which is consistent with the average plaque difference in counts by eye between analysts (-0.75 [95%CI -2.29 - 0.79]). The Flavidot plaque counter was developed as a tool to assist researchers using PRNTs on DENV and ZIKV to quantify protective antibodies. It is easy to install and requires no prior coding experience. With further improvements, this counter may be used in clinical settings, providing analysts with the speed and consistency needed to respond to emerging global health threats.

## 803

### DENGUE SEROTYPE AND DISEASE SEVERITY TRENDS AMONG INFANTS AND YOUNG CHILDREN IN INDIA, 2012-2015: IMPLICATIONS FOR DENGUE VACCINE STUDIES

Anita Shet<sup>1</sup>, Vivek Rosario<sup>2</sup>, Syed F. Ahamed<sup>2</sup>, Shalini Kotabagi<sup>2</sup>, Kaustav Nayak<sup>3</sup>, Murali K. Kaja<sup>3</sup>, Anmol Chandele<sup>3</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>St. Johns Research Institute, Bangalore, India, <sup>3</sup>International Center for Genetic Engineer and Biotechnology, New Delhi, India

India is a major epicenter for dengue. We aimed to provide baseline information for dengue vaccines by studying clinical and serotype patterns among children with dengue infection hospitalized at a tertiary-care center in southern India. Dengue was confirmed by positive NS1 and/or anti-dengue-IgM direct ELISA. Dengue severity was graded using the 2009 WHO classification. Dengue serotypes were determined by RT-PCR and sequencing. Between 2012-2015, among 1,064 children with suspected dengue, laboratory-confirmed dengue was seen in 726; 157 in the Nov 2012-Dec 2013 period, and 569 in Sept 2014-Dec 2015. The male:female ratio remained constant at 1.2:1. Mean age decreased over time: 9.1yrs

(2012-13) and 7.1yrs (2014-15). The proportion of infants (age<1yr) increased over time; 4.2% to 8.6% (p<0.01). Severe dengue occurred among 25.1% and 28.8% of children during the two time periods. Dengue severity increased with age (p<0.001); infants were more likely to have severe dengue than older children (62.2% vs 24.9%, p<0.001). Moderate-to-severe thrombocytopenia, present in 62.8%, was significantly associated with severe dengue (p<0.001) and DENV-1 serotype (p<0.05). In 2012-13 (PCR and sequencing-confirmed, n=113), serotype 3 (38.9%) and 2 (38.1%) predominated; DENV-1 was less common (19.5%). In 2014-15 (n=401), DENV-1 (64.6%) predominated, followed by DENV-2 (21.2%), DENV-3 (6.7%) and DENV-4 (2.0%). Co-infections with multiple serotypes were seen in 5.5% (n=22). There was no correlation between disease severity and multiple-serotype co-infection. Our results indicate a high burden of dengue among Indian children, particularly infants, and increasing disease severity with dynamic serotype replacement, highlighting the need for a safe vaccine for young children. Ongoing population-based epidemiological surveillance is critical for dengue vaccine studies.

## 804

### BURDEN OF DENGUE IN OUAGADOUGOU, BURKINA FASO

Jacqueline K. Lim<sup>1</sup>, Mabel Carabali<sup>1</sup>, Ahmed Barro<sup>2</sup>, Kang Sung Lee<sup>1</sup>, Desire Dahourou<sup>3</sup>, Suk Namkung<sup>1</sup>, Emmanuel Bonnet<sup>4</sup>, Jean E. Nikiema<sup>3</sup>, Losseni Kaba<sup>5</sup>, Paul-André Somé<sup>2</sup>, Valéry Ridde<sup>6</sup>, Seydou Yaro<sup>3</sup>, In-Kyu Yoon<sup>1</sup>

<sup>1</sup>International Vaccine Institute, Seoul, Republic of Korea, <sup>2</sup>AGIR, Ouagadougou, Burkina Faso, <sup>3</sup>Centre Muraz, Bobo-Dioulasso, Burkina Faso, <sup>4</sup>Institut de Recherche pour le Développement, Paris, France, <sup>5</sup>Centre National de Transfusion Sanguine, Ouagadougou, Burkina Faso, <sup>6</sup>Montreal School of Public Health, Montreal, QC, Canada

To address a gap in knowledge about dengue burden in Africa, the Dengue Vaccine Initiative conducted passive health care facility-based fever surveillance and seroprevalence study in Ouagadougou, Burkina Faso from Dec 2014 to Apr 2017. In the passive fever surveillance component, 3184 patients between 1-55 years of age, with current fever or history of fever ( $\leq 7$  days) with negative malaria rapid test, were enrolled at 5 health care centers; 505 were found to be positive either by dengue IgM ELISA or dengue rapid test (NS1 or IgM). Most of these cases occurred in the 15-29 year old age group. During the 26-month study period, dengue cases peaked in Sep-Dec 2015 and 2016. Selected acute serum samples, collected between Dec 2014 and June 2016, underwent further testing using Bioneer's DENV/ZIKV/CHIKV triplex PCR commercial kit. There were 157 acute samples selected for testing; 20 of these samples also had seroconversion by IgM ELISA between acute and convalescent visits; 17 were NS1 Ag positive by rapid test. Twelve (60%) of the 20 IgM seroconverters were dengue PCR positive; 14 (82%) of the 17 NS1 Ag positive patients were dengue PCR positive. In the seroprevalence component, blood samples were collected at 6 month intervals in a cohort aged 1-55 years, with 3 sets of blood samples collected in 3,066 subjects who were initially enrolled in June 2015. At enrollment, 66.4% of subjects were IgG ELISA positive. In the 2nd (n=2,473) and 3rd bleeds (n=2,248), 70.4% and 67.4% of subjects were IgG positive, respectively. The seroconversion rate was highest at 7.2% in 10-14 year olds, followed by 5-9 year olds (7.1%) and 30-34 year olds (6.9%). During the study period, a dengue outbreak was declared by WHO in Ouagadougou from Sep 2016 to Jan 2017. An additional seroprevalence blood collection was being performed in Mar/Apr 2017 on about 2,000 subjects who had participated in all three previous seroprevalence bleeds. Our study indicates that substantial endemic transmission of dengue is occurring in Burkina Faso.

## PERSISTENCE OF A NOVEL DENGUE VIRUS 2 COSMOPOLITAN GENOTYPE LINEAGE THAT EMERGED IN INDONESIA IN 2011, IDENTIFIED IN THE WESTERN AUSTRALIAN TRAVELLER COHORT

**Timo Ernst**<sup>1</sup>, Suzi McCarthy<sup>2</sup>, Edward C. Holmes<sup>3</sup>, David W. Smith<sup>2</sup>, Allison Imrie<sup>1</sup>

<sup>1</sup>University of Western Australia, Perth, Australia, <sup>2</sup>PathWest, Perth, Australia, <sup>3</sup>The University of Sydney, Sydney, Australia

Dengue virus (DENV) is found throughout the tropics. Over 70% of the global disease burden is borne by those living in Southeast Asia and the Western Pacific region. We have sequenced the Envelope gene of DENV-2 isolated from returning travellers entering Western Australia between 2011 and 2015, most of whom had visited Indonesia. A phylogenetic tree was estimated using maximum likelihood method. In previous studies we identified a novel lineage of DENV-2 Cosmopolitan genotype circulating in Indonesia, predominantly in Bali. The current study has found that this lineage emerged in Indonesia in early 2011 and has persisted into 2015, identified in travellers sampled between 2011-2013 and also 2015. A second lineage within the Cosmopolitan genotype that is most closely related to strains from Nepal, Malaysia and Singapore was found to have emerged in 2014 in Bali and continues to persist into 2015. Furthermore, other co-circulating lineages of DENV-2 were also identified, most of which are shown to be closely related to lineages known to have been circulating in Indonesia since at least 2008. The distribution and prevalence of these DENV-2 lineages should continue to be monitored. Febrile returning travellers can act as sentinels to provide timely data to identify circulating DENV genotypes and lineages, reveal epidemiological and evolutionary trends, and inform our understanding of epidemic virulence.

## DEVELOPMENT OF NOVEL SEROLOGICAL ASSAYS TO DISCRIMINATE BETWEEN DENGUE VIRUS AND ZIKA VIRUS ANTIBODY RESPONSES

**Valérie Martine Lecouturier**, Nathalie Mantel, Claire Fourlinnie, Elisabeth Marion, Florence Boudet, Matthew Bonaparte, Bruno Guy

*Sanofi Pasteur, Marcy l'etoile, France*

The recent emergence of Zika virus (ZIKV) in dengue-endemic regions/countries raises new challenges for dengue vaccine development and implementation. Cross-reactivity exists at the immunological level between these two related flaviviruses, which may bias the results of serological assays in areas where they co-circulate. In particular, analysis and follow up of dengue vaccine efficacy and effectiveness studies involves serological survey of anti-dengue responses, and such cross-reactivity may result in misleading interpretation. Therefore, easy, cheap, sensitive and specific assays are needed to discriminate between anti-dengue and anti-Zika responses. It is also important to differentiate these responses from those directed against yellow fever and Japanese encephalitis viruses, in Latin America and Asia respectively. Such specific assays would also be of benefit to the ongoing development of a Zika vaccine. Several assays are being evaluated; in particular, an ELISA aimed at measuring anti-NS1 antibody responses against these different flaviviruses is being developed, addressing both sensitivity and specificity. Sera from animals or humans obtained after infection by a single flavivirus or after multiple infections have been used in this regard, and preliminary data will be presented and discussed.

## DENGUE PREVALENCE IN A MILITARY VS CIVILIAN POPULATION

**John Mark Velasco**<sup>1</sup>, Ma. Theresa Valderama<sup>1</sup>, Ma. Nila Lopez<sup>2</sup>, Domingo Jr Chua<sup>3</sup>, Ma. Theresa Alera<sup>1</sup>, Paula Corazon Diones<sup>1</sup>, Kathyleen Nogrado<sup>1</sup>, Maribel Develos<sup>3</sup>, Elizabeth Sanchez<sup>3</sup>, Damon Ellison<sup>1</sup>, Alden Weg<sup>1</sup>, Louis Macareo<sup>1</sup>

<sup>1</sup>U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>AFPMSS, Manila, Philippines, <sup>3</sup>VLGH, AFPMC, Manila, Philippines

Dengue is the most common arbovirus infection in the world. In the Philippines, dengue is hyperendemic and high rates of the disease are reported (220,518 suspected cases of dengue in 2016). Newly available interventions can impact the force of transmission and may increase the average age of primary dengue infection and subsequently, occurrence of secondary dengue infection in adult populations. Though dengue has been described in the Philippine civilian population, the burden of disease among military personnel has not yet been characterized. Acute blood samples of patients presenting with dengue-like illness at the Armed Forces of the Philippines Medical Center, Manila were tested using DENV RT-PCR. Statistical tests of association were used to determine differences in demographic factors and logistic regression was used to determine signs or symptoms which can be predictors of dengue infection. From Nov 2012 to Nov 2016, 209/645 (32%) patients tested positive for DENV by RT-PCR, age-range for the confirmed dengue cases was 6 mos. – 55 yrs., male to female ratio 1.32; 129/209 had DENV serotype data: 54 (42%) DENV-3, 38 (29%) DENV-2, 25 (19%) DENV-1, and 12 (9%) DENV-4. We further analyzed the data according to age and military or civilian status. Our findings showed dengue as primarily affecting patients <18 y.o. and though the number of confirmed dengue cases was lower in the active duty military (OR 0.66) versus the civilian adult population, the disease burden in the military population was still substantial. Since only acute blood samples were tested and no serological testing of paired acute/ convalescent samples was done, this could lead to a lower rate of laboratory-confirmed dengue and underestimate the burden of infection.

## IMMUNOGENICITY AND SAFETY OF TAKEDA'S DENGUE VACCINE CANDIDATE IN CHILDREN AND ADOLESCENTS AGED 2-17 YEARS FROM PANAMA, THE DOMINICAN REPUBLIC AND THE PHILIPPINES: 18-MONTH RESULTS FROM A PHASE 2 RANDOMIZED PLACEBO-CONTROLLED TRIAL

**Vianney Tricou**<sup>1</sup>, Xavier Sáez-Llorens<sup>2</sup>, Delia Yu<sup>3</sup>, Luis Rivera<sup>4</sup>, Astrid Borkowski<sup>1</sup>, Derek Wallace<sup>1</sup>

<sup>1</sup>Takeda Pharmaceuticals International AG, Zurich, Switzerland, <sup>2</sup>Hospital del Niño Dr. José Renán Esquivel, Panama City, Panama, <sup>3</sup>De La Salle Health Sciences Institute, Dasmariñas, Philippines, <sup>4</sup>Hospital Maternidad Nuestra Señora de La Altagracia, Santo Domingo, Dominican Republic

Dengue is the most common mosquito-borne viral disease in humans. A dengue vaccine for those aged 9 years and older was licensed recently, but there remains urgent medical need for a vaccine that is safe and effective against all four dengue serotypes (DENV-1-4) in recipients of all ages. In December 2014, a phase 2, randomised, double-blind, placebo-controlled trial of Takeda's tetravalent dengue vaccine candidate (TDV) was initiated at three sites in dengue endemic countries (Panama, the Philippines, and the Dominican Republic) to determine its safety and immunogenicity in ~1800 healthy participants aged 2-17 years old. Participants were randomised to receive placebo or TDV in different dose schedules (either: one dose at 0 months and one dose at 3 months; one dose at 0 months; or one dose at 0 months and a booster dose at 12 months) (ClinicalTrials.gov: NCT02302066). The study is ongoing and all participants will be followed up for a 48 month period. The primary objective of this study is to assess geometric mean titres of neutralising antibodies to DENV-1-4 in

the per-protocol set at different time points. Secondary objectives include the analysis of the serious adverse events and the virologically confirmed dengue cases overall, and the analysis of the non-serious adverse events and seropositivity rates for one or more serotypes in the immunogenicity subset. Detailed safety and immunogenicity analyses following the administration of TDV in different schedules will be presented, with discussion on how these data support the continued development of this vaccine candidate.

## 809

### CIRCULATING DENGUE VIRUS AND CLINICAL CHARACTERISTICS IN PATIENTS WITH ACUTE FEBRILE ILLNESS FROM HUANUCO, PERU

Juana Mercedes del Valle-Mendoza<sup>1</sup>, Angela Cornejo Tapia<sup>1</sup>, Wilmer Silva-Caso<sup>1</sup>, Miguel Angel Aguilar-Luis<sup>1</sup>, Carlos Palomares-Reyes<sup>1</sup>, Fernando Vásquez-Achaya<sup>1</sup>, Pablo Weigl<sup>1</sup>, Joselyn Sacramento-Meléndez<sup>2</sup>, Beatriz Espejo-Evaristo<sup>2</sup>

<sup>1</sup>Universidad Peruana de Ciencias Aplicadas, Lima, Peru, <sup>2</sup>DIRESA Huanuco, Huanuco, Peru

Dengue infections are a major health problem and there is an increasing necessity to strength its epidemiological surveillance in Peru due to the low laboratory-confirmation rate (<50%). This study was undertaken to assess the frequency of Dengue virus (DENV) serotypes and describe its clinical presentation in patients with acute febrile illness from Huánuco, an endemic area in the center of Peru. A total of 268 serum samples from thirty five health care centers were studied for the presence of DENV via RT-PCR, NS1 antigen, IgM and IgG antibodies from November 2015 to July 2016. PCR positive samples were sent for commercial sequencing and serotype 1 to 4 identification. Physicians used a standardized questionnaire to collected the demographic and clinical symptoms information. Dengue virus RNA was detected in 25.0% (67/268) of samples via qPCR. For the anti-Dengue antibody tests, the NS1 antigen was detected in 19.03% (51/268), IgM antibodies were found in only 10.45% (28/268), and IgG antibodies were detected in 15.67% (42/268) of patients. The most common symptoms accompanying fever were: Headache (100.0%), Arthralgias (85.07%), Myalgias (94.03%), Headache (97.01%), retro-orbital pain (73.13%), Low back pain (53.73%), Skin rash (29.85%), hyporexia (52.24%), Sore throat (34.33%) and sickness (50.74%). In conclusion, Dengue is currently a predominant serotype in Huanuco, Peru. The clinic isn't sufficient to diagnose cases of DENV, for this reason it's necessary to have a laboratory diagnosis. Further investigations should be conducted to evaluate the use of RT-PCR as a reliable method for DENV detection as well as for serotype surveillance in Peru.

## 810

### HETEROGENEITY IN EVOLUTIONARY RATES MAY REFLECT ECOLOGICAL AND BIOLOGICAL DIFFERENCES BETWEEN DENGUE GENOTYPES

Simon Pollett<sup>1</sup>, Irina Maljokvic-Berry<sup>1</sup>, Melanie Melendrez<sup>1</sup>, Sebastian Duchene<sup>2</sup>, Richard Jarman<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>University of Melbourne, Melbourne, Australia

Dengue virus (DENV) evolutionary rates have not been comprehensively compared across all genotypes despite changes in global DENV incidence and the availability of DENV sequence data. Redressing this knowledge gap may have implications for the current understanding of DENV evolution. We obtained all unique complete envelope sequences for DENV serotypes 1 - 4 from GenBank comprising over 70 years of human DENV infections ( $n = 6784$ ). Sequences were genotyped by maximum likelihood phylogenies inferred by RAxML or PhyML packages using appropriate nucleotide substitution models informed by JModelTest2. 12 individual genotype datasets (DENV-1 I, IV, V; DENV-2 Asian-I, American, American-Asian and Cosmopolitan; DENV-3 I,II,III; DENV-4 I,II) then underwent evolutionary rate estimation by the BEAST package using comparative

clock and demographic models. To adjust for potential rate inflation by over-sampled focal epidemics, we repeated analyses after down-sampling to a maximum of 10 sequences by year. Under a strict clock and constant demographic model, the median genotype evolutionary rate was  $9.83 \times 10^{-4}$  substitutions/site/year (IQR 8.22 -  $10.24 \times 10^{-4}$ , range 4.38 -  $11.76 \times 10^{-4}$ ). There was striking heterogeneity between genotype evolutionary rates among the DENV-1, -2 & -4 serotypes, with as high as two-fold differences between genotype rates. While down-sampling reduced rate point estimates across all genotypes, DENV-2 and DENV-4 intra-serotype rate differences were robust after adjusting for sampling skew and comparative clock and demographic model analyses. In conclusion, There are substantial differences in the evolutionary rates of some DENV genotypes. We show that such differences are at least partially driven by skewed sampling of increasingly frequent epidemics, and may perhaps reflect intrinsic biological or ecological differences between DENV genotypes. Rate estimates for some genotypes were substantially higher than historical estimates in prior study and may reflect long term changes in the global epidemiology of DENV.

## 811

### CONGENITAL OCULAR PATHOLOGY IN RHESUS MACAQUES INFECTED WITH ZIKA VIRUS IN UTERO

Dawn M. Dudley, Sydney M. Nguyen, Kathleen M. Antony, Emma L. Mohr, David H. O'Connor, Thaddeus G. Golos, On Behalf of Project ZEST

University of Wisconsin Madison, Madison, WI, United States

Congenital Zika virus syndrome (CZS) continues to threaten women infected with Zika virus (ZIKV) during pregnancy with no known correlate to predict the severity of the syndrome, no treatment and no available vaccine. We developed the first rhesus macaque model of ZIKV infection during pregnancy to study the mechanisms of CZS pathogenesis and assess potential interventions. Five rhesus macaques were inoculated subcutaneously with 104 PFU of Asian-lineage ZIKV, to model mosquito transmission, during either the first ( $n=3$ ) or third ( $n=2$ ) trimester of pregnancy. All 5 animals were infected by 1 day post-inoculation (dpi). Notably, 3 animals infected in the first trimester exhibited a longer duration (24-70 dpi) of plasma viremia than seen in any non-pregnant animal (<17 dpi) infected with the same dose and virus, as also documented in human cases. One pregnancy resulted in a fetal demise at 49 dpi, when both the mother and fetus were euthanized and underwent necropsy. Fetuses from the other 4 pregnancies were surgically removed and necropsied at ~155 days of gestation. All 5 fetuses were vertically infected, with Zika viral RNA (vRNA) found in multiple tissues and evidence of inflammation in the placenta, decidua, fetal membranes, fetal lung, lymph nodes and spleen. Animals infected during the first trimester also showed moderate ocular pathology and inflammation of the fetal retina, choroid and optic nerve. The fetus that died *in utero* showed severe ocular pathology including a scleral and chorio-retinal coloboma as well as vRNA detected in 27/36 tissues tested by qRT-PCR and in 4/10 tissues tested by *in situ* hybridization (ISH). Maternal viral tissue distribution was also assessed in the fetal demise case. vRNA was present in 4 lymph nodes, spleen and uterus (6/63 tissues tested). The uterus and decidua was also positive for ZIKV by ISH. Altogether, these data suggest that ZIKV readily crosses the placental barrier leading to infection and pathology in the rhesus macaque that is similar to that seen in human infection.

## 812

### DECREASED TRANSMISSION OF ZIKA VIRUS IN Aedes Aegypti MOSQUITOES CO-INOCULATED WITH AN INSECT-SPECIFIC FLAVIVIRUS

Hannah E. Romo, Joan L. Kenney, Aaron C. Brault

Centers for Disease Control and Prevention, Fort Collins, CO, United States

Previous studies have demonstrated that an insect-specific flavivirus, Nhumirim virus (NHUV), can suppress the *in vitro* growth of West Nile

virus (WNV) and similarly decrease WNV transmission rates in NHUV/ WNV co-inoculated *Culex quinquefasciatus* mosquitoes. To assess whether NHUV might similarly interfere with flaviviruses that infect *Aedes aegypti*, the ability of NHUV to suppress *in vitro* viral growth of Zika virus (ZIKV), Dengue-2 virus (DENV2) and Chikungunya (CHIKV) was assessed. *Aedes albopictus* (C6/36) cells were concurrently inoculated with ZIKV, DENV2 or CHIKV and NHUV or infected with NHUV 1-5 days prior to ZIKV, DENV or CHIKV infection. Results demonstrated that ZIKV titers were reduced 100,000-fold in cultures either pre- or concurrently inoculated with NHUV/ ZIKV as compared to only ZIKV. A 1,000-fold reduction in DENV2 titer was observed for concurrent infections with NHUV/ DENV compared to DENV alone. Interestingly, DENV2 virus was not detected in C6/36 cells infected with NHUV 3 days prior to DENV2 (<1.8 log<sub>10</sub> PFU/mL). In contrast, the alphavirus, CHIKV, exhibited only a 10-fold reduction in titer observed only when cells were pre-inoculated with NHUV 3 days prior to CHIKV infection that was short-lived with titers rebounding within 72 hours, indicating a potential low-level non-specific interference. To assess whether NHUV could impact ZIKV transmission, *Ae. aegypti* mosquitoes were intrathoracically inoculated with ZIKV alone or NHUV/ZIKV and the resulting ZIKV infection and transmission rates assessed. Infection rates of 100% were observed in both groups; however, the transmission rate for mosquitoes from the NHUV/ZIKV dually-inoculated group was 41% compared to 78% for ZIKV-only inoculated mosquitoes ( $p < 0.0001$ ). Differences in ZIKV titers from bodies or saliva were not observed. These results indicate NHUV mosquito infection could be used as a model to assess superinfection exclusion mechanisms and to study the potential for the mosquito virome to impact vector competence of medically important flaviviruses.

## 813

### ZIKA VIRUS INFECTION AMONG A POPULATION-BASED AMONG A POPULATION BASED COHORT OF PREGNANT WOMEN IN PANAMA CITY, PANAMA, 2016-2017

Juan M. Pascale<sup>1</sup>, Arlene Calvo<sup>2</sup>, Rosalba Gonzalez<sup>1</sup>, Morgan Hess-Holtz<sup>2</sup>, Susan Hills<sup>3</sup>, Susan Kaydos-Daniels<sup>4</sup>, Eduardo Azziz-Baumgartner<sup>5</sup>, Nestor Sosa<sup>1</sup>

<sup>1</sup>Gorgas Memorial Institute for Health Studies, Panama, Panama, <sup>2</sup>University of South Florida, USF Health Panama Program, City of Knowledge, Panama, Panama, <sup>3</sup>Centers for Disease Control and Prevention, Fort Collins, CO, United States, <sup>4</sup>Centers for Disease Control and Prevention, Guatemala City, Guatemala, <sup>5</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Zika virus (ZIKV) infection during pregnancy has been recognized as a cause of microcephaly and other adverse outcomes. Because a high proportion of infected persons experience mild or no symptoms, and access to testing is often limited, it has been difficult to estimate the complete burden of ZIKV infection. We are conducting a cohort study of pregnant women in Panama to estimate the incidence of ZIKV symptomatic and asymptomatic infection, and assess birth outcomes and cognitive and psychological development up to two years of age. Participants have been recruited from two peri-urban health centers and are being followed throughout pregnancy. Blood samples are collected at recruitment, 28 weeks' gestation, and at one week post-partum. We are conducting active surveillance for ZIKV disease symptoms via weekly telephone calls, and collecting blood and urine samples from symptomatic patients who report fever or history of fever >38°C, rash, or conjunctivitis. Laboratory testing is conducted using serological and molecular methods, including IgM and neutralizing antibody testing and rRT-PCR. To date, 488 women have been recruited at a median gestational age of 16 weeks (IQR: 11-23). Overall, 735 blood samples have been collected. Among the 488 women, 411 (84.2%) have no evidence of ZIKV infection and 13 (2.7%) had a probable ZIKV infection (Zika IgM positive, dengue IgM negative). Among the remainder, both Zika and dengue IgM antibodies were detected or results were inconclusive. Additional confirmatory testing is pending. Eight of the 488 women reported symptoms but testing was negative. Our study demonstrates that probable asymptomatic ZIKV

infections have been identified among pregnant women in Panama. Study participants are being followed to determine the overall risk for ZIKV infection during pregnancy and to assess outcomes and child development following infection.

## 814

### PERFORMANCE OF THE CDC TRIOPLEX REAL TIME RT-PCR DURING THE 2016 ZIKA EPIDEMIC IN PUERTO RICO

Gilberto A. Santiago, Jesus Vazquez, Jorge L. Muñoz-Jordan  
Centers for Disease Control and Prevention, San Juan, PR, United States

The emergence of Zika virus in 2015 presented a challenge to diagnostics in areas where transmission of dengue and chikungunya viruses has been detected. In response to this public health emergency, the Centers for Disease Control and Prevention developed the Trioplex Real Time RT-PCR Assay designed for the simultaneous detection of dengue, chikungunya and Zika virus RNA in a variety of human clinical specimen types. We determined the analytical and clinical performance characteristics of the Trioplex in detecting each target virus serum, urine and whole blood-EDTA specimens. The assay was adapted to RNA extraction, PCR equipment and procedures commonly found in US and international public health laboratories. To determine the limit of detection (LoD) of the Trioplex for each target virus on each these modalities, inactivated dengue, chikungunya and Zika viruses were suspended in human serum, urine or whole blood and diluted to undetectable levels. The overall LoD for the assay was determined to approximate 103 genome copy equivalents per milliliter of specimen for every target virus. The assay modality that achieved the highest sensitivity included RNA extraction from 1 mL of specimen. Independent studies confirmed that the sensitivity of Trioplex is similar to other CDC and non-CDC tests; and that the Trioplex modality with the highest sensitivity compares to the most sensitive commercial tests. In order to determine the clinical sensitivity of Trioplex during the first 6 days of illness, 373 concurrently collected serum, urine and whole blood samples from patients with positive Zika IgM after 7 days were tested. In 373 confirmed cases in Puerto Rico, the Trioplex detected 85% (317/373) in serum, 55% (206/373) in urine and 70% (243/345) in whole blood. Testing simultaneously collected serum and urine provides an additional 3% sensitivity over serum alone; whereas the value of testing serum-whole blood provides an additional 5% over serum alone. The high sensitivity of the Trioplex demonstrates the utility of the assay resolving Zika cases in endemic areas. More than 30 thousand Zika cases in Puerto Rico have been confirmed with the Trioplex.

## 815

### EXPERIMENTAL INFECTION OF JAMAICAN FRUIT BATS (*ARTIBEUS JAMAICENSIS*) WITH ZIKA VIRUS

Ashley Malmlov, Kaitlyn Miedema, Tawfik Aboellail, Corey Rosenberg, Miles Eckley, Nunya Chotiwan, Rebekah Gullberg, Rushika Perera, Tony Schountz  
Colorado State University, Fort Collins, CO, United States

Zika virus (ZIKV) emerged in the New World with the 2014 outbreak in Brazil. It has spread to much of South America, Central America, Mexico and the Caribbean, with thousands of cases. While disease presentation may be subclinical to mild and include symptoms of maculopapular rash, conjunctivitis, and arthralgia, infection of pregnant women can lead to fetal microcephaly. Additionally ZIKV infection can induce Guillain-Barre syndrome. In the 1950s and 1960s bat species were investigated as possible reservoirs for ZIKV. In total, five different species of bats were found to be susceptible to the virus. Bats seroconverted, had viremia, and, in one experimental infection study bats developed fatal neurological disease. This warranted further investigation of ZIKV in bats to determine their use as an animal-model, and to better understand the potential role of bats in viral ecology. Nine Jamaican fruit bats (*Artibeus jamaicensis*) were subcutaneously inoculated with 7.5x10<sup>5</sup> pfu of ZIKV strain PRVABC59 and monitored over the course of 28 days, during which

there were no conspicuous signs of disease. Bats were euthanized at 2, 5, 10 and 28 days post-inoculation to assess the course of infection and antibody responses. Bats seroconverted by day 28 by ELISA with ZIKV-infected, fixed Vero E6 cells. Low levels of viral RNA were detected in one brain and one urine sample. IHC detected ZIKV antigen in lung and testes of one bat, and brains and salivary gland of two others. Pathology was consistently observed in the lungs, heart, testes and brain. Pneumonia was observed in four bats, cardiomyocyte necrosis in three bats, degeneration and lymphocyte infiltration in the testes of two bats, and neuronal degeneration in the hypothalamus and cerebellum in three bats. These results provide evidence that Jamaican fruit bats are susceptible to ZIKV and may serve as an animal model to study neurological components and sexual transmission of the virus. Low viral load in urine and tissues suggests the role of bats in viral ecology may be minimal.

## 816

### ANALYSIS OF THE EFFECT OF ZIKA VIRUS INFECTION DURING PREGNANCY ON PLACENTAL DEVELOPMENT AND BIRTH OUTCOMES

**Anna Gajewski**<sup>1</sup>, Raquel Burger-Calderon<sup>2</sup>, Liliam Llufrío<sup>1</sup>, Matthew Petitt<sup>3</sup>, Elsa Videá<sup>1</sup>, Guillermina Kuan<sup>4</sup>, Douglas Elizondo<sup>1</sup>, Juan Carlos Mercado<sup>5</sup>, José Víctor Zambrana<sup>1</sup>, Anna Urbina<sup>1</sup>, Jesslie Barrera<sup>1</sup>, Carlos Saenz<sup>6</sup>, Lenore Pereira<sup>3</sup>, Nestor Pavon<sup>7</sup>, Angel Balmaseda<sup>5</sup>, Eva Harris<sup>2</sup>

<sup>1</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>2</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>3</sup>Department of Cell and Tissue Biology, School of Dentistry, University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>Health Center Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, <sup>5</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, <sup>6</sup>Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, <sup>7</sup>Hospital de la Mujer Bertha Calderon Roque, Ministry of Health, Managua, Nicaragua

Since its recent emergence and pandemic spread in the Americas, Zika virus (ZIKV) infection during pregnancy has been associated with microcephaly and other congenital birth defects. Despite these devastating effects, the full extent of the impact of Congenital Zika Syndrome is yet unknown. ZIKV was first detected in Nicaragua in January 2016, and ZIKV transmission peaked in Managua from July 25 to August 14, 2016. ZIKV RT-PCR testing was performed for national surveillance on all pregnant women who presented to government health centers with Zika-like symptoms. Nicaragua began enrollment in the Zika in Infants and Pregnancy (ZIP) study, a multi-site study that enrolls pregnant women in their first trimester, in November 2016. The Nicaraguan Zika Positives (NZP) study began in January 2017 as a complementary study to include women infected during the peak of the epidemic. The NZP enrolls pregnant women confirmed as rRT-PCR ZIKV+ by the Ministry of Health or with a history of Zika-like symptoms during their pregnancy. For those who displayed Zika-like symptoms but did not have a ZIKV+ rRT-PCR result, recent ZIKV infection was confirmed via the NS1 Blockade-of-Binding ELISA (BOB) assay. Women complete questionnaires on demographics and risk factors and provide blood, urine, and vaginal secretion samples upon enrollment. At birth, additional samples, including placental tissue and cord blood, are collected. Infants are evaluated at birth, 3, 6, and 12 months by pediatric specialists to assess their overall health, hearing, vision, and neurological development. Biological samples (blood, urine) are collected at each infant visit and are assessed for evidence of ZIKV infection (IgM ELISA, BOB ELISA) and for possible confounding infections such as syphilis, CMV, toxoplasmosis, and HSV. Placental and amniotic membrane tissues have been analyzed to evaluate placental development and pathology and identify sites of ZIKV replication. To date, 26 women have been enrolled and 19 have given birth. This study is providing important information regarding the impact of ZIKV infection during pregnancy on placental, fetal, and infant development.

## 817

### INFLAMMATORY MONOCYTES ARE THE MAIN TARGET OF ZIKA VIRUS INFECTION IN PERIPHERAL BLOOD MONONUCLEAR CELLS FROM PEDIATRIC PATIENTS IN NICARAGUA

**Daniela Michlmayr**<sup>1</sup>, Paulina Andrade<sup>1</sup>, Karla González<sup>2</sup>, Chunling Wang<sup>1</sup>, Angel Balmaseda<sup>2</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

The ongoing Zika pandemic in the Americas is linked to congenital birth defects and Guillain Barré Syndrome. Leukocytes play an important role in host immune responses early in flaviviral infection, including dengue virus (DENV), where monocytes and dendritic cells are the main target of infection in humans. However, the targets of Zika virus (ZIKV) infection in peripheral blood mononuclear cells (PBMCs) are not known. Therefore, we infected PBMCs with ZIKV *in vitro* and characterized cell targets and phenotypic changes 24, 48 and 72 hours post-infection. To phenotype cells, we used markers for monocytes (CD16, CD14, CCR2, HLA-DR), dendritic cells (CD11c, CD123, CD1a, CD1c), T cells (CD4, CD8, CD45RA, CD45RO), and NK cells (CD56). ZIKV infection was detected using monoclonal antibodies against nonstructural protein 3 (NS3) and envelope protein (E). Analysis by flow cytometry and immunofluorescence microscopy revealed that monocytes are the main target of ZIKV infection, with many monocytes acquiring an intermediate phenotype (CD14+CD16+). Next, we analyzed by flow cytometry PBMCs collected on days 3, 4, and 5 post-onset of symptoms from ZIKV-infected pediatric patients in a hospital-based study in Nicaragua. Viral load was measured by qRT-PCR in serum and PBMCs. Patients with confirmed acute dengue virus (DENV) infection were used for comparison. Similar to *in vitro* experiments, we found that inflammatory and intermediate monocytes (CD14+CD16-CCR2+ and CD14+CD16+) are the main target for ZIKV infection in humans, but we also detected a few infected dendritic cells. In comparison to DENV infection, the frequency of ZIKV-infected cells was lower but the percentage of CD14+CD16+ cells was significantly higher. To characterize the immune response genes in ZIKV-infected monocytes, we isolated monocytes from healthy blood donors, infected them with ZIKV *in vitro*, and analyzed gene expression 48 hours post-infection. Many inflammatory chemokines and cytokines were upregulated after infection, suggesting that monocytes play an important role in orchestrating the innate immune response to ZIKV upon infection.

## 818

### LONGITUDINAL ANALYSIS OF CROSS-NEUTRALIZATION BETWEEN DENGUE AND ZIKA VIRUSES IN TWO PEDIATRIC STUDIES IN NICARAGUA

**Magelda Montoya**<sup>1</sup>, Henry Puerta-Guardo<sup>1</sup>, Leah Katzelnick<sup>1</sup>, Samuel Schildhauer<sup>1</sup>, Angel Balmaseda<sup>2</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, CA, United States

The four dengue virus serotypes (DENV1-4) and Zika virus (ZIKV) are antigenically related mosquito-borne flaviviruses that cause human diseases of major medical and public health importance worldwide. The cross-reactivity between DENV and ZIKV has raised questions about cross-protection and concerns of cross-enhancement of disease, yet few data exist characterizing the long-term antibody response. Here, we studied the extent of cross-neutralization between DENV and ZIKV using samples from two long-term studies in Nicaragua: a hospital-based study with a longitudinal arm extending for 18 months and a 13-year ongoing community-based cohort study with annual healthy blood samples. We

selected confirmed dengue cases, stratified by serotype (DENV1, 2, 3) and immune status (primary, secondary) (n=5/group), and analyzed plasma samples collected at acute, convalescent, 3-, 6-, 12- and 18-month time-points from the hospital study, as well as 1-3 years post-infection from the cohort study, using a Vero cell-based focus reduction neutralization assay. We also analyzed samples at convalescence and 3 months post-ZIKV infection. We found that ZIKV infections in both DENV-naïve and previously DENV-exposed individuals induce high levels of neutralizing antibodies to ZIKV, with much lower cross-neutralization of DENV1-4. We also found that in both primary and secondary DENV infections, neutralizing antibody titers to ZIKV were ~10-fold lower than to the homologous infecting DENV, and also lower than to heterologous DENV serotypes. We noted differences by serotype, with less cross-neutralization of ZIKV by DENV1-immune plasma. However, for all DENV infection antisera, cross-neutralizing antibody titers against ZIKV were consistently maintained over time, both 0-18 months and 1-3 years post-DENV infection. DENV/ZIKV-naïve samples used as controls did not neutralize (<10) DENV1-4 or ZIKV in our assay, demonstrating that we are not observing background signal. These findings improve our understanding of cross-neutralization over time between DENV and ZIKV, with implications for natural immunity and vaccines.

<sup>1</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, <sup>2</sup>Humabs BioMed SA, Bellinzona, Switzerland, <sup>3</sup>National Institute for Health Research Health Protection Research Unit in Emerging and Zoonotic Infections, University of Liverpool, Liverpool, United Kingdom, <sup>4</sup>Molecular Virology Unit, Microbiology and Virology Department, Fondazione Istituto di Ricovero e Cura a Carattere Scientifico, Policlinico San Matteo, Pavia, Italy, <sup>5</sup>Transfusion Microbiology, National Health Service Blood and Transplant, London, United Kingdom, <sup>6</sup>Department of Molecular Medicine, University of Padova, Padova, Italy, <sup>7</sup>Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, <sup>8</sup>Microbiology Services Colindale, Public Health England, London, United Kingdom, <sup>9</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States

Zika virus (ZIKV) is a mosquito-borne flavivirus that emerged recently as a global health threat, causing a pandemic in the Americas. ZIKV infection mostly causes mild disease, but is linked to devastating congenital birth defects and Guillain-Barré syndrome in adults. The high level of cross-reactivity among flaviviruses and their co-circulation has complicated the use of serological assays to differentially detect clinical and subclinical ZIKV and dengue virus (DENV) infections, accentuating the urgent need for a specific and sensitive serological test. We previously generated a ZIKV NS1-specific human monoclonal antibody, which we used to develop an NS1-based competition ELISA. Well-characterized samples from RT-PCR-confirmed Zika patients and individuals exposed to other flavivirus infections or vaccination were used in a comprehensive analysis to determine the sensitivity and specificity of the NS1 blockade-of-binding (BOB) assay, which was established in laboratories in 5 countries (Nicaragua, Brazil, Italy, United Kingdom and Switzerland). Of 158 sera/plasma from RT-PCR-confirmed ZIKV infections, 145 (91.8%) yielded greater than 50% inhibition. Of 171 patients with primary or secondary DENV infections, 152 (88.9%) scored negative. When the control group was extended to patients infected by other flaviviruses, other viruses, or healthy donors (n=540), the specificity was 95.9%. We also analyzed longitudinal samples from DENV-immune and DENV-naïve ZIKV infections and found inhibition was achieved within 10 days post-onset of illness and maintained over time for many months post-infection. We have used the

NS1 BOB ELISA to evaluate potential ZIKV infections in pregnant women months after exposure, to determine the rate of infection in our pediatric cohort study in Nicaragua, to perform age-stratified serosurveys in children and adults, and to investigate circulation of ZIKV in other parts of the world. Thus, the Zika NS1 BOB assay is a simple, robust, sensitive, specific, and low-cost solution for Zika surveillance programs, sero-prevalence studies, and intervention trials in flavivirus-endemic areas.

## 820

### PASSIVE TRANSFER OF ZIKA VIRUS-LIKE-PARTICLE-INDUCED IMMUNE SERA TO AG129 MICE PROTECTS AGAINST LETHAL ZIKA VIRUS CHALLENGE

**Jeffery Alexander<sup>1</sup>**, Diego Espinosa<sup>2</sup>, Darly Manayani<sup>1</sup>, Lo Vang<sup>1</sup>, Peggy Farness<sup>1</sup>, Tiffany Richard<sup>1</sup>, Jayavani Aruri<sup>1</sup>, Ben Guenther<sup>1</sup>, Jenny Avanzini<sup>1</sup>, Fermin Garduno<sup>1</sup>, Jonathan Smith<sup>1</sup>, Eva Harris<sup>2</sup>, Jason Mendy<sup>1</sup>

<sup>1</sup>PaxVax, San Diego, CA, United States, <sup>2</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States

Zika virus (ZIKV) infection poses a serious public health threat due to its association with neurological complications, including birth defects in developing fetuses and Guillain-Barre Syndrome in adults. We sought to develop a ZIKV vaccine based on virus-like-particles (VLPs) generated in transiently transfected HEK293 mammalian cells. The genetic construct consists of the structural protein genes of ZIKV placed downstream from a heterologous signal sequence. To better understand the humoral responses and potential correlates of protection (CoP) afforded by the VLP vaccine, a dose response study was first carried out in immune-competent mice (C57Bl6 x Balb/c) using a dose titration of VLPs formulated with and without aluminum hydroxide as an adjuvant. Serum samples from VLP-immunized mice were tested in neutralization assays using reporter virus particles (RVPs), where alum was observed to provide a significant dose-sparing effect of approximately 25-fold. Further, to assess the protective capacity of the immune sera, we performed passive transfer experiments in AG129 mice which are susceptible to ZIKV infection and pathogenesis. Of note, mice that received the immune sera prior to ZIKV infection demonstrated significantly reduced viral replication (greater than 99%) as measured by RNA genome equivalents in the blood, and remained healthy, as measured by weight maintenance and survival. Control mice succumbed to infection. These results underscore the significant protective effect of the antibody responses elicited by this VLP vaccine candidate. Additionally, these studies will help define optimal vaccine formulations, contribute to translational efforts in developing a ZIKV VLP vaccine for clinical development, and address immunologic CoP.

## 821

### KNOWLEDGE, PERCEPTIONS AND SOCIOECONOMIC STATUS DRIVING DENGUE PREVENTION PRACTICES IN URBAN COASTAL ECUADOR

**Ivayla I. Geneva<sup>1</sup>**, Aileen Kenneson<sup>1</sup>, Christina D. Lupone<sup>1</sup>, Sadie J. Ryan<sup>2</sup>, Mercy J. Borbor-Cordova<sup>3</sup>, Efrain Beltran-Ayala<sup>4</sup>, Mark Polhemus<sup>1</sup>, Timothy P. Endy<sup>1</sup>, Anna M. Stewart-Ibarra<sup>1</sup>

<sup>1</sup>State University of New York Upstate Medical University, Syracuse, NY, United States, <sup>2</sup>University of Florida, Gainesville, FL, United States, <sup>3</sup>Escuela Superior Politecnica del Littoral, Guayaquil, Ecuador, <sup>4</sup>Universidad Tecnica de Machala, Machala, Ecuador

Dengue is a major mosquito-borne febrile illness in the tropical and subtropical regions with dengue virus (DENV) infection ranging from asymptomatic to life-threatening hemorrhagic fever and shock. Since household-level vector control remains the primary means of controlling the disease, it is important to identify local social and behavioral factors that affect dengue prevention actions at the household-level. Our study measured the impact of socioeconomic factors and perceptions about dengue on the implementation of dengue prevention actions at

the household level in the city of Machala, Ecuador, which features a high incidence of DENV. From January 2014 to September 2016, we investigated 416 households. Households were identified through an active dengue surveillance study and included homes with people who had confirmed dengue disease (identified through Ministry of Health sentinel clinics), and neighboring homes within 200 meters. Each head of household completed a questionnaire that included demographics and questions about dengue knowledge, attitudes, and prevention. The data was evaluated using descriptive statistics (significance when  $p < 0.05$ ). We found that the total number of implemented dengue preventions increased during the three years of the study and positively correlated with knowledge of dengue transmission. Individual prevention measures positively correlated with perceiving dengue as a serious problem in the community, having attained higher education level, being of older age, owning the house, and having received dengue training. Fewer preventions were implemented by those who perceived dengue prevention as difficult or impossible. We conclude that socioeconomic status, the level of awareness about and attitude towards dengue, as well as dengue prevention training strongly influence the implementation of dengue prevention on the household level. These results will inform public health interventions in the region.

## 822

### AUSTRALIAN ARBOVIRUSES ASSOCIATED WITH UNDIAGNOSED UNDIFFERENTIATED FEBRILE ILLNESS

Narayan Gyawali<sup>1</sup>, Andrew W. Taylor-Robinson<sup>1</sup>, Richard S. Bradbury<sup>1</sup>, John G. Aaskov<sup>2</sup>

<sup>1</sup>School of Health, Medical and Applied Sciences, Central Queensland University, North Rockhampton, Australia, <sup>2</sup>Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia

There are at least 13 Australian arboviruses that have been associated with human infection but routine tests are not available to diagnose infection with most of these and their role in human pathology, undifferentiated febrile illness (UFI) or other serious diseases is unknown. Following the development of a commercial ELISA to diagnose Ross River virus infections, the number of cases in Australia rose from 20-50 per year to more than 9000 in 2016. The aim of this study was to determine how prevalent infection of humans with these "orphan" viruses was and whether any of them are the cause of UFI. Screening of 1000 age and gender stratified plasma samples from healthy blood donors for IgG antibodies against, Ross River, Barmah Forest, Alfuy, Kokobera, Stratford, Kunjin and Edge Hill viruses by indirect ELISA produced a large number of non-specific reactions so, an age and gender stratified sub-sample from the plasma panel was tested in plaque reduction neutralisation tests. Additionally, 492 UFIs samples from patients in northern Australia were screened by indirect immunofluorescence for the presence of IgM antibodies against these viruses. There was a linear increase in the prevalence of neutralising antibodies against these viruses with annual seroconversion rates of Ross River virus, 1.4% ( $r^2=0.7$ ); Barmah Forest virus, 0.5% ( $r^2=0.7$ ); Kunjin virus, 0.4% ( $r^2=0.7$ ); Edge Hill virus, 0.4% ( $r^2=0.5$ ); Kokobera virus, 0.3% ( $r^2=0.9$ ); Alfuy virus 0.2% ( $r^2=0.5$ ); Murray valley encephalitis virus, 0.1% ( $r^2=0.3$ ) and Stratford virus 0.6% ( $r^2=0.9$ ). Of the 492 samples from UFI patients 5.2% contained IgM antibodies against one or more of these Australian arboviruses: RRV (0.8%); BFV (0.4%); ALF (1.4%); EHV (1.8%); KOK (1.4%); KUNV (2.4%); MVE (1%); STRV (1.2%). These results suggest that a number of the "orphan" Australian arboviruses have been infecting humans at a regular rate for decades and some of them may be associated with UFIs. There should be ongoing, and systematic, testing of UFI patients for evidence of recent infection with these orphan arboviruses to determine how significant the burden of the disease they cause is.

## 823

### POLICI: AN ONLINE TOOL FOR VISUALIZATION OF POPULATION-LEVEL YELLOW FEVER IMMUNIZATION COVERAGE IN AFRICA

Arran Hamlet<sup>1</sup>, Kévin Jean<sup>1</sup>, Neil Ferguson<sup>1</sup>, Maria Van Kerkhove<sup>2</sup>, Sergio Yactayo<sup>3</sup>, William Perea<sup>3</sup>, Joseph Biey<sup>4</sup>, Amadou Sall<sup>5</sup>, Tini Garske<sup>1</sup>

<sup>1</sup>MRC Centre for Outbreak Analysis and Modelling, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, <sup>2</sup>Centre for Global Health, Institut Pasteur, Paris, France, <sup>3</sup>World Health Organization, Geneva, Switzerland, <sup>4</sup>World Health Organization-AFRO, Ouagadougou, Burkina Faso, <sup>5</sup>Institut Pasteur, Dakar, Senegal

Yellow fever (YF) is a vector-borne viral haemorrhagic fever found in Africa and Latin America, primarily spread by *Aedes* species in Africa. Despite the existence of an effective, life-long and safe vaccine since the 1930's, YF is still a major cause of mortality in Africa. Decades of inconsistent and incomplete vaccination have left the endemic region of Africa a patchwork mosaic of population level vaccination coverages both within and between countries, making outbreak risk assessments and planning of efficient vaccination campaigns difficult. Population level vaccination coverages at the first administrative level were previously calculated as part of a model calculating the burden of YF in R, but despite the usefulness of this information the necessity of specialist programming knowledge limited its accessibility. Through integrating this information with the R web-based graphical user interface (GUI), Shiny, we are able to present this pertinent information online and in an interactive way without the need of specialist information or software, making it accessible to relevant stakeholders in global health.

## 824

### A COHORT STUDY TO DETERMINE THE INCIDENCE OF ZIKA VIRUS INFECTION AMONG NEWBORNS, SANTOS, BRAZIL, 2016-2017

Expedito J. Luna<sup>1</sup>, Camila M. Romano<sup>1</sup>, Evaldo S. Araujo<sup>2</sup>, Jose E. Levi<sup>1</sup>, Olimpia N. Oliveira<sup>2</sup>, Luis R. Fernandes<sup>2</sup>, Alvina C. Felix<sup>1</sup>, Nathalia S. Souza<sup>1</sup>, Joao H. Fernandes<sup>2</sup>, Sergio R. Campos<sup>1</sup>, Danielli B. Fragoso<sup>2</sup>, Claudio S. Pannuti<sup>1</sup>

<sup>1</sup>Universidade de Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Hospital Ana Costa, Santos, Brazil

Zika virus has been recognized as a teratogenic infection since its emergence in Brazil in 2015, being implicated in severe neurological anomalies of the fetus and newborn. In order to assess the risk of transmission from an infected mother to the newborn, the risk of congenital anomalies among the infected newborns, and their relation to the timing of infection during pregnancy, a cohort study of mothers and their newborn babies was set up in Santos, state of Sao Paulo, Brazil. Data from a concurrent study has shown that Zika emerged in Santos in September, 2015. Enrollment in the cohort started in June, 2016. All women that come to the study's hospital for delivery are being invited to participate. The ones who agreed to participate signed an Informed Consent Form. Since November, 2016, recruitment has been extended to the antenatal clinic. Participants respond to a structured questionnaire, and have a blood sample collected for Zika IgG serology (Euroimmun), or PCR (when presenting Zika suggestive symptoms). A cord blood and an urine sample are being collected for PCR and serology of the newborns. From June, 2016 until February, 2017, 730 mothers and their 743 babies were enrolled. 15.1% of the mothers presented a positive IgG serology for ZIKV, while 5.6% had an inconclusive result. PCR and IgM serology of their babies were all negative. No ZIKV related congenital anomalies were reported in the study's hospital. The pattern of severe congenital anomalies occurring after a ZIKV outbreak, as previously seen in other sites in Brazil and elsewhere, has not been observed in this study's sample so far. The limitations on the specificity of serologic assays for ZIKV diagnosis have to

be considered in the interpretation of these results. The full spectrum of ZIKV infections of pregnant women and the congenital infection of the fetus and newborn are yet to be fully understood.

## 825

### PERSISTENCE OF ZIKA VIRUS IN SEMEN OF MEN LIVING IN AN ENDEMIC AREA

**Ralph Huits<sup>1</sup>**, Natalie Jess<sup>2</sup>, Devon Dickson<sup>2</sup>, Sonja Makee-Sookram<sup>2</sup>, Kaat Eggermont<sup>1</sup>, Johan Michiels<sup>1</sup>, Kevin Ariën<sup>1</sup>, Samuel Ramsewak<sup>2</sup>, Marjan Van Esbroeck<sup>1</sup>, Emmanuel Bottieau<sup>1</sup>, Catherine Minto-Bain<sup>2</sup>, Lieselotte Cnops<sup>1</sup>

<sup>1</sup>*Institute of Tropical Medicine, Antwerpen, Belgium*, <sup>2</sup>*Trinidad IVF Fertility Centre, Trinidad, West Indies, Trinidad and Tobago*

Zika virus (ZIKV) jeopardizes sexual health and reproductive health services. Sexual transmission of ZIKV is associated with viral persistence in semen after acute infection. Therefore, gamete preservation programs have been suspended in areas with active vector-borne transmission, like Trinidad and Tobago. However, data on ZIKV persistence in semen are scarce. We conducted a prospective observational study to assess the proportion of men living in an endemic area, who had persistent shedding of ZIKV in semen after confirmed infection. Symptomatic men with confirmed ZIKV infection and age  $\geq 18$  years, were recruited at Trinidad IVF Fertility Centre from June to October 2016. Clinical data and serial semen samples were collected. ZIKV infection was confirmed at the Institute of Tropical Medicine in Antwerp, Belgium, by ZIKV-specific real-time reverse transcriptase polymerase chain reaction (RT-PCR) on urine or semen samples, or by a virus neutralization test on serum. Follow-up of ZIKV shedding in semen was continued until ZIKV RNA could no longer be detected by RT-PCR in 2 consecutive samples. Cycle threshold (Ct-) values were used as a semi-quantitative measure of viral loads. Isolation of ZIKV from semen in culture (as a proxy for infectivity) was attempted in samples with low threshold Ct-values. Twenty-three men with confirmed ZIKV infection were recruited, mean age 36 years (range 25-53). The initial semen was collected at median 13 days post-infection (dpi) (range 2-25). ZIKV RNA was detected in 9/23 men (39.1%, 95%-CI [22.2-59.2]). ZIKV was isolated from three semen samples collected at 9, 12 and 17 dpi, with respective Ct-values 19, 21 and 18. Loss of ZIKV RNA detection had occurred in 4/9 men by 61 dpi, and in all men by 103 dpi. After acute infection, ZIKV-RNA was frequently detected in semen from men in Trinidad and Tobago. Our data suggest that clearance of ZIKV from semen occurred in 9/9 men. Testing of semen from ZIKV-infected men might assist in reducing the individual risk for sexual transmission of ZIKV.

Friedrich<sup>1</sup>, David H. O'Connor<sup>1</sup>

<sup>1</sup>*University of Wisconsin Madison, Madison, WI, United States*, <sup>2</sup>*Wisconsin National Primate Research Center, Madison, WI, United States*

Antibody dependent enhancement (ADE) is an antibody-mediated enhancement of disease that occurs with secondary infections of heterologous serotypes of dengue virus (DENV). The emergence of Zika virus (ZIKV) in the Americas, a close DENV relative, has led to the question of whether ZIKV might function as a "fifth serotype" of DENV, causing enhanced pathology in persons with previous DENV exposure. An important question related to ADE is whether it also contributes to significant fetal injury following congenital ZIKV infection. We recently developed a rhesus macaque model to study ZIKV. To examine whether exposure to DENV enhances ZIKV infection, we infected 3 Indian-origin

rhesus macaques, previously infected with DENV serotype 3 (DENV-3) with an Asian lineage ZIKV isolate from French Polynesia (ZIKV-FP). We compared infection of these 3 animals with 2 animals that were infected with ZIKV-FP alone and 3 animals that were mock-infected using quantitative RT-PCR to assess viral burden, complete blood counts (CBC) to assess blood count responses to ZIKV infection, and blood chemistry panels to evaluate changes in blood biochemical parameters throughout infection. We observed no significant difference in ZIKV vRNA burden between the animals previously infected with DENV-3 compared to ZIKV alone or controls. We also did not detect rash, fever, significant weight loss, nor any significant changes in CBC values for any animals. Chemistry panels showed increases in LDH and SGOT in animals that were infected with ZIKV alone and decreases in blood glucose in DENV/ZIKV and ZIKV alone animals. Overall, our results were not indicative of enhanced ZIKV infection. Longitudinal analysis of cytokine and chemokine profiles from plasma samples of these animals are in progress with results expected in early summer.

## 827

### GAPS ON RISK COMMUNICATIONS APPROACH OF NATIONAL ZIKA VIRUS OUTBREAK RESPONSE IN COLOMBIA, BRAZIL, EL SALVADOR, GUATEMALA, HONDURAS AND DOMINICAN REPUBLIC

**Alfonso C. Rosales**

*World Vision U.S., Washington, DC, United States*

To explore the needs, attitudes and practices of women, men, and youth related to Zika virus prevention. A cross-sectional survey using a mobile-technology-based structured questionnaire was administered to 3361 inhabitants of 6 countries (Brazil, Colombia, Dominican Republic, Guatemala, Honduras and El Salvador) during July-September 2016. The study used a 2-stage, 30-cluster sampling method. The study found that two-thirds of respondents attributed ZIKAV transmission to mosquito bites and contaminated water, only 4 and 1 percent respectively were aware that Zika can be spread by sexual intercourse and from a pregnant woman to her fetus. Four out of 10 respondents knew that there is a causal relationship between Zika and microcephaly in newborns. Most respondents agreed that Zika virus represents high or moderate risk in their communities and that it is a disease than can be prevented. However, participants' opinions were divided almost equally when asked if Zika virus infection could be treated. Participant responses on the use of preventive measures showed variation among the six countries. Participants in Guatemala, the Dominican Republic and El Salvador displayed a preference to adopt individual protective measures (mosquito net and mosquito repellent), while participants in Honduras and Colombia exhibited a preference towards water management. Participants in Brazil were evenly divided between protective measures (29%) and water management (29%). Aligned with the general lack of awareness on sexual transmission, there was no practice of sexual-related protection among participants in all six countries. Zika-related risk communication process in the six Latin American countries included in the study have been mostly focused on vector control. These findings clearly identify information priority gaps that need urgently to be addressed by regional and national stakeholder involved in public health activities to protect the most vulnerable population against Zika disease and its complications.

## 828

### DECIPHERING DURABLE NEUTRALIZING ANTIBODY RESPONSES TO ZIKA VIRUS

**Matthew Collins<sup>1</sup>**, Huy Tu<sup>2</sup>, Alice Liou<sup>1</sup>, Ramesh Jadi<sup>1</sup>, Sean Diehl<sup>2</sup>, Aravinda de Silva<sup>1</sup>

<sup>1</sup>*University of North Carolina, Chapel Hill, NC, United States*, <sup>2</sup>*University of Vermont, Burlington, VT, United States*

In 2015, Zika virus (ZIKV) became a global health emergency as it spread throughout Latin America causing thousands of cases of birth defects.

ZIKV is a flavivirus closely related dengue, and is presumably amenable to vaccine-mediated prevention. However, a greater understanding of humoral immunity to this virus is needed to design interventions that are optimally protective and do not enhance disease with ZIKV or dengue infection. To address these issues, we aim to study long term humoral immunity that is attributable to memory B cells (Bmem) and create tools for assessing ZIKV vaccine-induced immune responses. We identified travelers with prior ZIKV exposure (2 dengue-naïve, 2 dengue-immune), immortalized and cloned Bmem for recombinant monoclonal antibody (mAb) expression. Screening of polyclonal culture supernatants revealed a ZIKV-reactive Bmem frequencies ranging 0.2-1.0%. Bmem from primary ZIKV cases produce mAb that are almost entirely type-specific. Interestingly, ZIKV type-specific clones are also readily detected on a dengue-immune background, which means that ZIKV immunity in secondary flavivirus infection is not dominated by cross-reactive Bmem clones in contrast to what is observed in heterologous secondary dengue infection. We are further characterizing neutralizing mAb derived from a primary ZIKV case to determine epitope specificity, ability to protect against *in vivo* challenge, and representation in large panels of ZIKV-immune human serum. As with dengue, our data indicates that ZIKV-specific neutralizing antibodies recognize complex structural epitopes present on the intact virion but not recombinant E protein monomers.

829

### ZIKA VIRUS INFECTION OF RHESUS MACAQUES VIA MOSQUITO BITE

**Matthew T. Aliota**, Dawn M. Dudley, Christina M. Newman, Jorge E. Osorio, Shelby L. O'Connor, Thomas C. Friedrich, David H. O'Connor, On Behalf of the Zika Experimental Science Team  
*University of Wisconsin Madison, Madison, WI, United States*

Zika virus (ZIKV) is primarily transmitted by *Aedes aegypti* mosquitoes, but animal models of ZIKV pathogenesis rely on needle inoculations. Saliva delivered to the host by a biting mosquito may have a critical impact on the initial infection of the skin and may modulate the local innate and adaptive immune response, so needle inoculation may fail to fully recapitulate important biological aspects of natural ZIKV infection. We previously established a rhesus macaque model of ZIKV infection using subcutaneous (sc) inoculation to initiate infection. Here, we show that *Ae. aegypti* can be used to initiate systemic ZIKV infections in rhesus macaques. To assess differences in ZIKV replication between virus delivery by needle versus mosquito vector, we infected rhesus macaques with the Puerto Rican ZIKV isolate PRVABC59 by either sc inoculation (n=3) or by exposure to infected mosquitoes (n=4). All three sc-inoculated macaques were productively infected, with viral load dynamics similar to what we have reported previously. Four of four animals also were productively infected by mosquito bite, with noticeable differences in peak viral load and the time to peak viral load. In addition, we used *in vitro* methods to estimate the ZIKV dose inoculated by mosquitoes and found that *Ae. aegypti* saliva titers ranged from 101.5 to 103.2 PFU. Analysis of ZIKV tissue distribution is ongoing, but preliminary analyses demonstrate the presence of viral RNA in multiple lymphoid tissues of those animals infected via mosquito bite at 14 days post feeding. Data on ZIKV tissue distribution in sc-inoculated animals, as well as a characterization of the ZIKV variant repertoire present in mosquito saliva compared to needle inoculated virus, is anticipated later this spring and can be accessed in real-time at: <https://zika.labkey.com/project/OConnor/ZIKV-023/begin.view>. This tractable laboratory model demonstrates the feasibility of using direct mosquito feeding on nonhuman primates to better understand ZIKV transmission, systemic spread, and factors that influence disease outcomes in natural infections.

### LOW PREVALENCE OF ANTIBODY PERSISTENCE 10 YEARS AFTER HEPATITIS E VIRUS INFECTION AMONG PREGNANT WOMEN IN NORTHERN BANGLADESH

**Brittany L. Kmush**<sup>1</sup>, Saijuddin Shaikh<sup>2</sup>, Sucheta Mehra<sup>1</sup>, Hasmat Ali<sup>2</sup>, Kenrad E. Nelson<sup>1</sup>, Kieth P. West<sup>1</sup>, Alain B. Labrique<sup>1</sup>

<sup>1</sup>*Johns Hopkins School of Public Health, Baltimore, MD, United States*,  
<sup>2</sup>*JiVitA Project, Johns Hopkins University, Gaibandha, Bangladesh*

Hepatitis E Virus (HEV) is a major cause of viral hepatitis in developing countries with up to 30% case fatality among pregnant women. HEV is vaccine preventable yet is responsible for over 10% of all maternal mortality in Bangladesh. In South East Asia, HEV causes yearly outbreaks despite being highly endemic, suggesting that antibody persistence after infection is low. From 2001-2010, 103 pregnant women from Gaibandha, Bangladesh experienced an asymptomatic HEV infection. In 2016 (6 to 15 years after the infection), these women were revisited to examine long-term antibody persistence. We were able to revisit 86 of the 103 (83.5%) women. Antibody loss was high; 88.4% (95% CI: 80.0-94.3%) did not have detectable antibodies at follow-up. 30.3% of those who lost antibodies owned goats compared to 0% with persistent antibodies (X2 p=0.04). A higher percentage of those with persistent antibodies reported taking medicine for gastric illness (50% positive versus 19.7% negative, X2 p=0.03). None of the other demographic or exposure risk factors examined were associated with antibody persistence, including time since infection. Only a few years after infection, 88.4% of pregnant women no longer had detectable antibodies. This was much higher than previous findings of 20.0% (95% CI: 12.0, 28.0) antibody loss 10 years after HEV infection in the general population in Southern Bangladesh. It is unclear why the antibody persistence is so different in these two rural populations with similar health indicators but may highlight the importance of environmental re-exposures. In the less flood-prone Gaibandha, in Northern Bangladesh, environmental re-exposure to HEV may not occur frequently, whereas in Southern Bangladesh, an area surrounded by rivers and highly prone to severe floods, re-exposure to HEV may provide immune-boosts, preventing antibody loss. Since antibody titres waned quickly after infection in this population, adolescent immunization and frequent booster doses may be necessary to protect pregnant women from the severe consequences of HEV infection.

### ARBOVIRUS SURVEILLANCE

**Samuel V. Scarpino**<sup>1</sup>, Lauren Ancel Meyers<sup>2</sup>, Michael A. Johansson<sup>3</sup>

<sup>1</sup>*University of Vermont, Burlington, VT, United States*, <sup>2</sup>*University of Texas, Austin, TX, United States*, <sup>3</sup>*U.S. Centers for Disease Control and Prevention, San Juan, PR, United States*

Arboviral diseases affect hundreds of millions of people every year. Yellow fever, West Nile, dengue, chikungunya, and Zika are persistent threats globally to people living in or visiting affected areas. Timely and accurate surveillance of arboviruses at multiple geopolitical scales is critical to prevention and control. However, surveillance systems are often shaped by historical and practical considerations rather than specific public health objectives. We developed a method to leverage 15 years of dengue clinical data and laboratory testing data from Puerto Rico to design an efficient arbovirus surveillance system that is expected to provide timely, accurate, and efficient situational awareness of island-wide, regional, and serotype-specific dengue activity. Among 105 healthcare providers reporting in the Puerto Rico dengue surveillance system, we identified a set of 22 providers that are as informative as all 105 with respect to the specified public health awareness goals. Out-of-sample comparisons with historical data suggest that this streamlined system will perform robustly. We also identified an alternative strategy for targeting surveillance efforts for emerging threats when historical information is unavailable. As public health agencies throughout the Americas strive to track and

respond to the evolving threats of dengue, chikungunya and Zika, timely and accurate surveillance is paramount. A carefully targeted surveillance system can streamline data collection, improve situational awareness, and guide allocations of surveillance resources for dengue and other arbovirus threats. This data-driven design process can be easily and broadly applied to establish and improve arbovirus surveillance, and its data-free alternative provides a valuable tool for rapid implementation in response to emerging threats.

### SENTINEL SURVEILLANCE OF INFLUENZA VIRUS IN MALI

**Seydou Diarra**<sup>1</sup>, Boubou Tamboura<sup>1</sup>, Adama Mamby Keita<sup>1</sup>, Chaca T. Diallo<sup>1</sup>, Oumou Y. Coulibaly<sup>2</sup>, Mahamadou Keita<sup>1</sup>, Oumarou A. Traoré<sup>1</sup>, Doh Sanogo<sup>1</sup>, Hamidou Diallo<sup>1</sup>, Mamadou Sylla<sup>1</sup>, Nana Kourouma<sup>1</sup>, Seydou Sissoko<sup>1</sup>, Mamadou Farka Maiga<sup>2</sup>, Milagritos D. Tapia<sup>3</sup>, Kathleen Neuzil<sup>3</sup>, Karen Kotloff<sup>3</sup>, Samba O. Sow<sup>1</sup>

<sup>1</sup>Center for Vaccine Development, CVD-Mali, Bamako, Mali, <sup>2</sup>Direction Nationale de la Santé, Mali, Bamako, Mali, <sup>3</sup>University of Maryland, School of Medicine, Baltimore, MD, United States

To better define the burden of influenza in developing countries, the Center for Vaccine Development of MALI (CVD-Mali), Minister of Health Mali instituted national influenza sentinel surveillance in 2014 in both rural and urban sites. A total of five Influenza like Illness (ILI) sites and three Serious Acute Respiratory Infection (SARI) sites have been activated respectively in 5 Reference Health Center and 3 Hospitals. Samples were collected at all sites four days a week by following the WHO case definition, and delivered to the laboratory. Samples were transported in VTM at 2-4°C and delivered within 72 hours. The samples were processed at the laboratory approximately every 48 hours. The RNA extraction was performed per CDC standard methods (QIAamp @ viral RNA kit) and tested immediately by real-time RT-PCR CDC protocol for the detection and characterization of influenza virus. Data analysis was performed using the Biosystems™ software applied to the system ABI7500 real-time PCR. Possible outcomes include influenza A, B, H1N1 (swine flu) and H5N1 (bird flu). A weekly report is sent to all sites and the Ministry of Health, CDC, WHO country office and WHO Influenza Network. From November 24th, 2014 to December 29th, 2016, 2313 samples were received in the laboratory from 1988 ILI and 325 SARI cases. The diagnostic confirmed 162 Influenza B, 237 Influenza A (80 A (H1N1) pmd2009, 157 Influenza A (H3N2) and 1914 were negative to Influenza. Among SARI cases, 22 were positive to influenza (5 influenza B, 6 Influenza A (H1N1) pmd2009 and 11 Influenza A (H3N2)). Seasonal peaks of Influenza are observed in the year: from November to March with predominant of Influenza B and H1N1pmd2009 and from July to September with most H3N2 cases. The year round of surveillance shown that young children from 2-15 years old are most vulnerable. Two years of surveillance data have demonstrated that influenza is a public health problem. Vaccination would be a useful control strategy.

## 833

### ASSOCIATION BETWEEN SECRETOR STATUS AND NOROVIRUS INFECTIONS IN A BIRTH COHORT IN SOUTH INDIA

**Sidhartha Giri**<sup>1</sup>, Nirmal Kumar<sup>2</sup>, Ben Lopman<sup>3</sup>, Jan Vinje<sup>4</sup>, Gagandeep Kang<sup>2</sup>

<sup>4</sup>Wellcome Trust Research Laboratory, Department of Gastrointestinal Sciences, <sup>1</sup>Christian Medical College, Vellore, Vellore, India, <sup>2</sup>Emory University, Atlanta, GA, United States, <sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Noroviruses bind to histo blood group antigens (HBGA) found on the surface of gut epithelial cells, as well in saliva and other secretions. Expression of the HBGA antigen is in part controlled by *FUT2* gene; individuals who express the HBGA antigens on the gut epithelial cells are

known as “secretors”. In this study, we evaluated the rate of norovirus infections in the first 3 years of life in 10 secretor positive and 5 secretor negative children. These 15 children were part of a birth cohort study conducted in Vellore, India, involving 373 children who were followed up to the age of 3 years. The 373 children had 1856 diarrheal episodes which were tested for norovirus GI and GII, rotavirus and other common enteropathogens. Of the 10 secretor positive children, 5 had at least 1 episode of norovirus diarrhea during the 3 years of follow-up. The 5 secretor negative children had no norovirus diarrhea in 3 years. All surveillance stool samples collected every 2 weeks from birth till 3 years of age from the 15 children (approximately 70-80/child) were tested by quantitative multiplex real-time PCR for detecting norovirus genogroups GI and GII. Overall, 14.7% (63/428) of surveillance samples from the 5 secretor positive children who had norovirus diarrhea were positive for noroviruses (16 GI, 45 GII, 2 mixed), 15.2% (71/468) surveillance samples from 5 secretor positive children without norovirus diarrhea were positive for noroviruses (23 GI, 46 GII, 2 mixed), and 13.5% (47/349) of samples from the 5 secretor negative children who had no norovirus diarrhea, were positive for noroviruses (11 GI, 36 GII). In conclusion, there was no significant difference in the rate of norovirus infections between the secretor positive and secretor negative children, suggesting that noroviruses do infect secretor negative children.

## 834

### DETECTION OF HUMAN ANELLOVIRUSES (TORQUE TENO VIRUS, TORQUE TENO MIDI VIRUS, AND TORQUE TENO MINI VIRUS) FROM THE ACUTE RESPIRATORY INFECTION CONSORTIUM (ARIC) NATURAL HISTORY STUDY

**Robin H. Miller**<sup>1</sup>, Peng Fei Zhang<sup>1</sup>, Kimberly A. Bishop-Lilly<sup>2</sup>, Kenneth Frey<sup>2</sup>, Cassie Redden<sup>2</sup>, Theron Hamilton<sup>3</sup>, Christian L. Coles<sup>4</sup>, Wei-Ju Chen<sup>4</sup>, V. Ann Stewart<sup>5</sup>, Timothy Burgess<sup>6</sup>, Gerald Quinnan<sup>5</sup>

<sup>1</sup>Henry M. Jackson Foundation for the Advancement of Military Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Henry M. Jackson Foundation for the Advancement of Military Medicine, Naval Medical Research Center, Biological Defense Research Directorate, Fort Detrick, MD, United States, <sup>3</sup>Naval Medical Research Center, Biological Defense Research Directorate, Fort Detrick, MD, United States, <sup>4</sup>Henry M. Jackson Foundation for the Advancement of Military Medicine, Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>5</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>6</sup>Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Human anelloviruses are a recently discovered virus family and include torque teno virus (TTV), torque teno midi virus (TTMDV) and torque teno mini virus (TTMV). Human anelloviruses are genetically diverse, cause chronic infections in humans, and are highly prevalent worldwide with epidemiology studies reporting infection prevalence above 75% in adults in several countries. The link between human anellovirus infection and clinical disease or pathology in humans is unclear, however studies have suggested the possible association of anellovirus infection and a variety of conditions including cancers, hepatitis, autoimmune disorders, and respiratory diseases. Using patient samples collected as part of the Acute Respiratory Infection Consortium (ARIC) Natural History Study at U.S. military treatment facilities in which otherwise healthy subjects were enrolled within three days after influenza-like illness (ILI) onset, we 1) determined the prevalence of human anelloviruses from nasopharyngeal swabs collected from patients with both etiologically diagnosed and undiagnosed acute respiratory infections using conventional PCR and targeted deep sequencing and 2) report progress on a real-time PCR (qPCR) assay to detect and quantify torque teno virus from patient samples during the acute and convalescent phases of acute respiratory infection. Overall, we report high prevalence of all three human anelloviruses (TTV, TTMDV, TTMV) from ILI patient samples and describe a qPCR assay that

can be used in future studies to investigate the prevalence of TTV and improve our understanding of the clinical relevance of TTV as an emerging viral diagnosis in humans.

### 835

#### SECRETOR STATUS AND ITS ASSOCIATION WITH THE ROTAVIRUS DIARRHEA AND ANTIBODY RESPONSE IN A BIRTH COHORT FROM SOUTH INDIA

**Arun S. Karthikeyan**, Sidhartha Giri, Jayaprakash Muliyl, Gagandeep Kang

*Christian Medical College, Vellore, India, Vellore, India*

Individuals expressing the histo blood group antigen (HBGA) on the gut epithelial cells, which is in part controlled by the *FUT2* (*fucosyl transferase 2*) gene, are called secretors. The relation between HBGA functionality and rotavirus infection is not well documented. This study investigates the association between the *FUT2* secretor status and rotavirus diarrhea among a birth cohort from an Indian slum. The cohort of 373 children was followed up to the age of 3 years to understand the natural history of rotavirus infection and disease. Genomic DNA was isolated from buccal epithelial cells or blood by amplification of a region of the *FUT2* gene and genotyping for two single nucleotide polymorphisms (G428 and G385) was carried out. All the diarrheal and surveillance stool samples (collected every two weeks) were tested for rotavirus G and P types by a hemi-nested multiplex PCR. Of the 373 children, secretor status was assessed for 305 kids, of which 200 (65.6%) kids were secretor positive while 105 (34.4%) were secretor negatives. Of the 305 children with known secretor status, 232 (76.1%) had at least 1 episode of rotavirus diarrhea during the 3 years, and there was no significant difference between secretors and non-secretors ( $p=0.418$ ). However, Children with G428 homozygous mutation for inactivation of the *FUT2* (se428 se428) were at a significantly lower risk (43/232) of rotavirus diarrhea ( $p=0.04$ ). No significant association between secretor status and the number of rotavirus infections during the 3 years of follow-up was observed. The rotavirus genotype distribution was similar among the secretors and non-secretors, with G2P[4], G1P[8], G10P[11], G1P[4] and G9P[8] being the common circulating strains. However, both IgG and IgA antibody response to rotavirus infection was significantly lower among secretor negative children ( $p<0.001$ ) when compared to secretor positive children. To conclude, although secretor status does not significantly affect the rate of rotavirus infection in children followed up to 3 years of age, the secretor positive children mount a substantially higher immune response to rotavirus infection than secretor negatives.

### 836

#### EFFECT OF AGE AT VACCINATION ON ROTAVIRUS VACCINE EFFECTIVENESS IN BOLIVIAN INFANTS

**Rachel M. Burke**, Jacqueline E. Tate, Kimberly D. Pringle, Manish Patel, Umesh D. Parashar

*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Efficacy of rotavirus vaccines is lower in developing countries versus developed countries. One hypothesis is that higher levels of maternal antibodies in developing countries could interfere with vaccine response, suggesting that delayed dosing could be beneficial. The present analysis aims to assess whether rotavirus vaccine effectiveness (VE) varies by age at vaccination during routine use in Bolivia. Data were merged from two post-licensure evaluations of monovalent rotavirus vaccine (RV1) in Bolivia, where RV1 is recommended at two and four months of age. For each dose, children were classified as receiving each dose "early," "on-time," or "late." Stratified unconditional logistic models were used to estimate VE, using unvaccinated children as the referent. VE was calculated as  $(1 - \text{odds ratio}) \times 100\%$ . Models were adjusted for hospital, age, and time since RV1 introduction (via including terms for month and year of birth). VE for two doses of RV1 tended to be higher in infants receiving the first dose early (VE 90%; 95% confidence interval [CI] [67%, 98%]), when compared to

infants receiving their first dose on time (62% [48%, 72%]) or late (53% [32%, 66%]). Estimates of RV1 VE for two doses were not substantially different when comparing children by age at second dose. We found high effectiveness of RV1 when given at an early age, supporting the current WHO recommendations for administration of rotavirus vaccines.

### 837

#### ROLE OF MAMMALIAN IMMUNE RESPONSES IN VECTOR-ENHANCED ORBIVIRAL TRANSMISSION

**Barbara Drolet<sup>1</sup>**, Christopher Lehiy<sup>1</sup>, Lindsey Reister-Hendricks<sup>1</sup>, Mark Ruder<sup>2</sup>, Scott McVey<sup>1</sup>

<sup>1</sup>*Arthropod-Borne Animal Diseases Research Unit, Manhattan, KS, United States*, <sup>2</sup>*University of Georgia, Athens, GA, United States*

*Culicoides sonorensis* biting midges are vectors of several emerging and re-emerging orbiviruses including bluetongue, epizootic hemorrhagic disease, and African horse sickness viruses. They feed primarily on domestic sheep and cattle, but opportunistically feed on a variety of wildlife and on humans. The ability to obtain blood meals from this wide host range speaks to the versatility of midge salivary components, 45 of which we recently identified including anti-hemostatic factors and protease inhibitors, as well as proteins to immunomodulate host defenses. The extreme efficiency with which *Culicoides* midges can transmit orbiviruses, and the basis of anecdotal evidence for vector-enhanced orbivirus transmission by midge feeding, are unclear. One reason is that very little is known about the natural effects of *Culicoides* bites on mammalian hosts, particularly in the initial hours post feeding; a critical time for transmitted viral particles to establish infection. To gain insight as to why *C. sonorensis* are such efficient vectors for orbiviruses, we used a mouse model to characterize immune responses in the first three days after midge feeding. Analysis of skin, lymph node cell populations and cytokines by histology, flow cytometry, and real time PCR indicated a Th-mediated cellular response with significant mast cell activation, hemorrhaging, edema and vasodilation, as well as rapid dermal infiltration of CD16/32+ granulocytes, known infection targets of orbiviruses. In contrast to the hostile mammalian immunological environment we hypothesized would confront any bite-transmitted virus particles, effects on the dermal vasculature and lymphoid tissues in response to midge feeding led to a local, then systemic immunological state highly favorable for orbivirus infection and dissemination. The interactions of these beneficial innate immune responses with bite-transmitted virus is likely key to the transmission competency of this vector and play an important role in vector-enhanced transmission. These beneficial elicited responses may well extrapolate to other competent vector - arboviral disease associations.

### 838

#### CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS OF ONCOLOGICAL PATIENTS INFECTED WITH HUMAN T-CELL LYMPHOTROPIC VIRUS (HTLV-1) AT THE NATIONAL CANCER CENTER OF PERU, 2010-2015

Luis E. Cuéllar, Marco Zúñiga-Ninaquispe, **Andrea Anampa-Guzmán**, Juan Velarde, Alexis Holguin, Diana Portillo, Esther Reyes

*Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru*

Peru is a country where Human T-cell lymphotropic virus type 1 (HTLV-1) is endemic. The objective of the study is to describe clinical-epidemiological characteristics of HTLV-1 infected patients at the national cancer center of Peru, Instituto Nacional de Enfermedades Neoplásicas (INEN) during the period 2010-2015. This is an observational study of HTLV-1 cases diagnosed by positive confirmatory test in cancer patients. Clinical and sociodemographic information was obtained from medical records. 205 oncological cases with HTLV-1 infection were collected. The average age was 57.11 years and the male-female ratio was 0.38. The highland of Peru was the most common place of birth (58.5%). The most common neoplasms were non-Hodgkin's lymphoma (13.7%) for hematologic

malignancies and cancer of the cervix (56.1%) for solid tumors. 41.9% of patients had HLTV-1 associated disease: onychomycosis (24.4%), pulmonary tuberculosis (9.8%) and scabies (4.4%). ( $P < 0.01$ ). Have been breastfeeding was the most common risk factor of infection ( $P < 0.01$ ). The clinical-epidemiological characteristics of HTLV1-infected patients are similar to those reported in the Peruvian population. The high frequency of HTLV-1 infection in patients with cervical cancer could be related to either the immunosuppression by the retrovirus.

### 839

#### SEASONALITY AND GEOGRAPHIC DISTRIBUTION OF ROTAVIRUS DIARRHEA IN CHILDREN <5 YEARS FROM A NATIONAL SURVEILLANCE STUDY

**Nayana P. Nair**<sup>1</sup>, Sowmiya V. S<sup>1</sup>, Sidhartha Giri<sup>1</sup>, Sudhir Babji<sup>1</sup>, Girish Kumar<sup>2</sup>, Venkatasubramaniam S<sup>2</sup>, Rashmi Arora<sup>3</sup>, Gagandeep Kang<sup>1</sup>

<sup>1</sup>Christian Medical College, Vellore, India, <sup>2</sup>National Institute of Epidemiology, Chennai, India, <sup>3</sup>Indian Council of Medical Research, New Delhi, India

Rotavirus is the leading cause of diarrhea related hospitalization among infants and young children worldwide. In India, rotavirus diarrhea accounts for over half a million hospitalizations among under five children annually. We did a prospective, multi-center hospital based surveillance to investigate the seasonality and geographic distribution of rotavirus gastroenteritis among under five children in India. The seven sites included Vellore and Trichy (Tamil Nadu), Kolenchery (Kerala), Tirupati (Andhra Pradesh), and Hyderabad (Telangana) which are from the southern part of India while Ludhiana (Punjab), and New Delhi are from the north. During the surveillance period from July 2012 to June 2016, 6935 children with acute gastroenteritis were enrolled into the study and stool samples were collected from 6550 children. All the samples were tested for rotavirus positivity using EIA and the overall positivity was (34.9%). During the study period, the maximum number of rotavirus related hospitalizations were reported from December 2013 through February 2014 (241 [10.5%]). Overall, a seasonal variation in rotavirus diarrhea was observed, with the maximum number of cases (791 [31.5%]) seen during winter season (December-February), which was followed by summer season (March - May) (634 [27.6%]), and rainy season (September-November) (516 [22.5%]). The pattern was similar between the northern and southern sites of India. There is a high burden of rotavirus gastroenteritis among under five children in India which shows a seasonal variation with higher positivity rates during the winter months.

Middle East Respiratory Syndrome (MERS) is a novel viral respiratory disease caused by MERS-Coronavirus (MERS-CoV), and the first reported case was in Saudi Arabia in 2012. There is no specific treatment for MERS, and it ranges from supportive treatment to antiviral treatment like interferon (IFN) a 1a, IFN b 1a, and ribavirin. We conducted a systematic search on ten databases Studies published after 1/1/2012 and reporting information about treatment of MERS-CoV infection were included in our review. We used Mann-Whitney U, Chi2 and Fisher's exact tests to investigate the relation between the mortality outcome and independent variables. Classification tree model was used to find the best predictors of the mortality. We included 16 papers including ten case reports, two case series, and four observational studies. Despite receiving treatment with ribavirin plus IFN, the mortality rate was as high as 71% of 68 patients in IFN-treatment group and exactly the same (71% of 48 patients) in patients who received supportive treatment only. There was a significant difference between died and survived patients in chronic respiratory disease (CRD), diabetes mellitus (DM), hypertension, renal replacement therapy and ventilation. Indicating that having CRD, hypertension or DM and being ventilated increase the risk of mortality (for all of these factors). While there was no significant difference between died and survived patients in gender, ribavirin, corticosteroid, oseltamivir, IFN beta 1a, IFN alpha 2b, IFN alpha 2a, congestive heart failure (CHF), other comorbidities (p less than 0.05). There was a significant difference between died and survived patient in age, being older in died patients, and time from admission to antiviral treatment start being larger in died patients as well (p less than 0.05). The IFN treatment has shown no efficacy over supportive treatment only. Antiviral treatment delay, older age group, and co-morbidities pre-existence (hypertension, diabetes mellitus, chronic kidney disease, dialysis dependent) were associated with worse outcome.

### 841

#### OROPUCHE VIRUS IDENTIFICATION AS AN EMERGING ETIOLOGICAL AGENT RESPONSIBLE FOR ACUTE FEBRILE DISEASE IN A EASTERN MIDDLE REGION OF THE PERUVIAN JUNGLE

**Wilmer Silva-Caso**<sup>1</sup>, Carlos Palomares-Reyes<sup>1</sup>, Miguel Angel Aguilar-Luis<sup>1</sup>, Joselyn Sacramento-Meléndez<sup>2</sup>, Beatriz Espejo-Evaristo<sup>3</sup>, Fernando Soto-Febres<sup>4</sup>, Angela Cornejo Tapia<sup>1</sup>, Juana del Valle-Mendoza<sup>1</sup>

<sup>1</sup>Universidad Peruana de Ciencias Aplicadas, Lima, Peru, <sup>2</sup>Hospital de Tingo Maria-Ministerio de Salud, Huanuco, Peru, <sup>3</sup>Red de Salud Leoncio Prado-Huanuco, Huanuco, Peru, <sup>4</sup>Puesto de Salud Alto Pendencia-Red de Salud Leoncio Prado, Huanuco, Peru

Oropuche virus (OROV) is a member of the Bunyaviridae family from the Orthobunyaviridae genus, this viral RNA genus has more than 170 agents distributed in 18 different serogroups. OROV has been identified as a causal agent of the "Fiebre Oropuche", a febrile/tropical disease transmitted by arthropod vectors. Currently, the only notified cases of Fiebre Oropuche have been reported in Brazil, Panama, Peru and Trinidad y Tobago with a high incidence during the periods with increased precipitations as it favors the vector reproduction. This study was undertaken to assess the frequency of Oropuche (OROV) and describe its clinical presentation in patients with acute febrile illness from Huánuco, Peruvian Jungle, Peru. A total of 268 serum samples from thirty five health care centers were studied for the presence of OROV via RT-PCR

from November 2015 to July 2016. PCR positive samples were sent for commercial sequencing. Physicians used a standardized questionnaire to collect the demographic and clinical symptoms information. OROV virus RNA was detected in 17.35% (46/268) of samples via qPCR. The most common symptoms accompanying fever were: Arthralgias 65.22% (30/46), Myalgias 76.09.0% (35/46), Headache 86.96% (40/46), retro-orbital pain 60.87% (28/46), Low back pain 34.78% (16/46), Skin rash 32.61% (15/46), hyporexia 50.0% (23/46), Sore throat 34.78% (16/46) and sickness 47.83%(22/46). In conclusion, OROV is currently a predominant virus in Huanuco, Peruvian Jungle, Peru. The clinic isn't sufficient to diagnose cases of ORV, for This reason it's necessary to have a laboratory diagnosis. Further investigations should be conducted to evaluate the use of RT-PCR as a reliable method for OROV and for surveillance the other arbovirus in Peru.

## 842

### ANALYSIS OF THE *BABESIA MICROTI* PROTEOME IN INFECTED RED BLOOD CELLS BY A COMBINATION OF NANOTECHNOLOGY AND MASS SPECTROMETRY

Robert E. Molestina<sup>1</sup>, Alessandra Luchini<sup>2</sup>, Lance Liotta<sup>2</sup>

<sup>1</sup>ATCC, Manassas, VA, United States, <sup>2</sup>Center for Applied Proteomics and Molecular Medicine, George Mason University, Manassas, VA, United States

Babesiosis has been recognized in recent years as an emerging infectious disease in humans. The disease is caused by red blood cell (RBC)-infecting protozoan parasites of the genus *Babesia*. Transmission occurs primarily by ticks or less frequently through blood transfusion. There is an increased need to develop better tools for the design of drugs, vaccines, and biomarkers of infection for babesiosis. Here, we used a combination of nanotechnology and mass spectrometry (MS) to describe the proteome profile of *Babesia microti* in infected RBCs. Protein extracts were obtained from whole blood samples of 14-day infected hamsters showing 30% parasitemia. Proteins were captured from the extracts in bait-loaded nanoparticles, eluted, and analyzed by reverse-phase liquid chromatography-MS. The identification of tandem mass spectra was performed by searching against the NCBI *B. microti* database using the SEQUEST software. Using this approach, we identified ~500 proteins that shared homology with known and putative proteins of the genome-sequenced *B. microti* R1 strain. Ascribed functions of *B. microti* proteins identified in infected RBCs include intracellular signaling, protein translation and modification, protein transport, DNA replication, cytoskeleton support, and lipid and glucose metabolism. We also identified surface antigens shown to play critical functions in the immunopathogenesis of Apicomplexan parasites, such as GPI-anchored proteins and members of the *B. microti* sero-reactive surface antigen family. By applying recent advances in nanotechnology and proteomics, we successfully captured and identified proteins of *B. microti* from whole blood. Moreover, ours is the first evaluation of the proteome of *B. microti* in infected RBCs, information that could be relevant to the study of intracellular parasite survival, discovery of anti-parasitic compounds, and development of diagnostic tests.

## 843

### SEQUENCE CONSERVATION IN THE IMMUNODOMINANT *BABESIA MICROTI* ANTIGENS

Ankit Puri<sup>1</sup>, Nitin Verma<sup>1</sup>, Hong Zheng<sup>1</sup>, Peter J. Krause<sup>2</sup>, Sanjai Kumar<sup>1</sup>

<sup>1</sup>Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>Yale School of Public Health and Yale School of Medicine, New Haven, CT, United States

The Apicomplexa tick-borne hemoprotozoan parasite *Babesia microti* is responsible for human babesiosis in the Northeast and upper Midwest regions of the United States and globally. Most healthy adults infected with *B. microti* experience mild to moderate illness; however, the disease

can be fatal in immunocompromised individuals and those who acquire the disease through blood transfusion. Through genome-wide immunoscreening, we have identified over 50 immunodominant *B. microti* antigens that are reactive against plasma/serum from babesiosis patients. Among these, the top 3 ranking antigens - *Babesia*  $\alpha$ -helical cell surface domain (BmBAHCS), Serine Repeat Antigen (BmSERA) and Epidermal Growth Factor (BmEGF) are being pursued as diagnostic and vaccine antigens with promising results. In order to investigate the antigenic polymorphism among these antigens, we have determined the nucleotide sequence and deduced amino acid sequences by PCR-amplification of the full length gene of each molecule from 7 human samples isolated from *B. microti*-infected individuals. This analysis showed that the nucleotide and amino acid sequences were identical for BmBAHCS and BmSERA, but BmEGF showed alterations at two amino acid positions, Lys135 to Asn135 and Gly168 to Ile168. The biological significance of these mutations is not known, although these changes did not influence the reactivity of recombinant BmEGF protein to the serum samples from babesiosis patients. Our data suggest lack of immune pressure among immuno-dominant *B. microti* antigens. Bioinformatics analysis is underway to understand the impact of these mutations on the function of this molecule. The significance of limited or absent antigenic polymorphism in immuno-dominant *B. microti* antigens in parasites in endemic areas will be discussed.

## 844

### IDENTIFICATION OF PROTEIN PROFILES OF *BARTONELLA BACILLIFORMIS* STRAINS FROM ENDEMIC DEPARTMENTS OF PERU

Giovanna Mendoza, Yanina Zarate Sulca

Instituto Nacional de Salud-Perú, Lima, Peru

*Bartonella bacilliformis* is the etiologic agent of Carrion's disease, endemic in andean valleys of Peru, Ecuador and Colombia. In extreme poverty areas of Perú, it constitutes a serious public health problem, affecting mainly the child population. The aim of this research was to determine the variants of the protein profiles of *Bartonella bacilliformis* strains from endemic regions of Perú. For the research, bacterial colonies were collected from strains subcultures from the departments of Ancash, Cusco, Cajamarca, La Libertad, Lima and Piura; which were lysed by sonication to obtain total soluble proteins. The protein components of the bacteria were separated by vertical electrophoresis in 8% sodium dodecyl sulfate gels (SDS-PAGE), for the visualization of the bands the gel was dyed with silver nitrate. The determination of the fractionation Ranges and molecular weights was performed on the ChemiDocXRS+Image Lab software for PC or Mac (Bio-Rad) gels. The strains from Piura, Cajamarca and Lima presented the highest number of bands from 31.30 to 297.93 kDa, with fractionation ranges between 0.98 and 0.04; the highest concentrations were observed between 32 and 41 kDa present in strains from Piura, Cajamarca and Cusco. In strains from La Libertad, Ancash and Lima the 32 kDa protein was not visualized. The knowledge of the antigenic profiles of *Bartonella bacilliformis* circulating strains in endemic Peruvian departments has made possible that the National Institute of Health develop and implement confirmatory, sensitive and specific Western Blot diagnostic method, that recognises specific epitopes for IgM and IgG antibodies, showing four antigenic bands: 136.60 kDa, 122.70 kDa, 60.95 kDa y 56.60 kDa. The test could allow the early and accurate diagnosis of Carrion's disease cases that occur in high and extreme poverty Peruvian endemic areas, for the immediate antimicrobial treatment, having a high impact on the affected population health.

## 845

### MOLECULAR CHARACTERIZATION BY MULTI-LOCUS SEQUENCE TYPING OF *RICKETTSIA ASEMBONENSIS* AND OTHER *RICKETTSIA FELIS*-LIKE ORGANISMS, PERU

Steev Loyola<sup>1</sup>, Carmen Flores<sup>1</sup>, Armando Torre<sup>1</sup>, Claudine Kocher<sup>1</sup>, Gabriela Salmon-Mulanovich<sup>1</sup>, Christopher Mores<sup>1</sup>, Allen L. Richards<sup>2</sup>, Mariana Leguia<sup>1</sup>

<sup>1</sup>U.S. Naval Medical Research Unit-6, Lima, Peru, <sup>2</sup>Viral and Rickettsial Diseases Department, Naval Medical Research Center, Silver Spring, MD, United States

*Rickettsia asembonensis* and Candidatus *Rickettsia senegalensis* are *R. felis*-like organisms (RFLOs). Although it is unclear if these RFLOs are pathogenic to humans, their closest known relative *R. felis* does cause human disease, and thus, it is possible that these potential pathogens are an emergent threat in rural areas of Peru, where rickettsial infections are common and frequently go under-diagnosed and under-reported. *R. asembonensis* was first discovered in Kenya. Since then, multiple *R. asembonensis* strains have been reported worldwide. Candidatus *R. senegalensis* is a novel member of the RFLO group that so far has been reported in African countries, India and the USA. Despite these reports, there is limited genomic information on these strains, which hinders evolution and phylogenetic studies aimed at understanding the relationships among multiple RFLOs around the world. Recently we identified fleas and ticks that were positive for *R. asembonensis* and other RFLOs. Interestingly, no *R. felis* was detected. Here we report multi-locus sequence typing (MLST) characterization of nine diverse RFLO isolates collected in Iquitos and Puerto Maldonado, in Peru. We used genomic information derived from next-generation sequencing data to generate complete open reading frames (ORFs) for two conserved genes (*17-KDa* and *gltA*), and three variable genes (*ompA*, *ompB*, and *sca4*). The sequence information was also used to infer phylogenetic relationships among rickettsial strains. We find that RFLO strains collected in Peru are distinct from other isolates described thus far. This work will help to better understand the epidemiology of rickettsial infections in Peru and in Latin America, where novel rickettsial strains have potential as new emergent human pathogens.

## 846

### THE DETECTION OF SPOTTED FEVER GROUP *RICKETTSIA* DNA IN TICKS AND HUMAN SAMPLES FROM PASTORAL COMMUNITIES IN KENYA

Hellen S. Koka<sup>1</sup>, Rosemary Sang<sup>2</sup>, Lydia H. Kutima<sup>3</sup>, Lillian Musila<sup>1</sup>

<sup>1</sup>U.S. Army Medical Research Directorate-Kenya, Nairobi, Kenya, <sup>2</sup>Kenya Medical Research Institute, Nairobi, Kenya, <sup>3</sup>Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Undiagnosed febrile diseases are common in Kenya. This study tested the significance of *Rickettsia* spp. infections as a cause of febrile illness in humans living in pastoral communities where the presence of arboviruses in vectors and humans had previously been reported. Human blood and tick samples collected from several geographically dispersed pastoral communities in Kenya were tested for acute infections of *Rickettsia* spp. bacteria by conventional PCR using three primer sets targeting *gltA*, *ompA* and *ompB* followed by sequencing. *Rickettsia* spp. DNA was detected in 14% (39/278) of human blood samples tested using the *gltA* primer set. The human samples were negative on testing with the *ompA* and *ompB* primers. *Rickettsia africae*, *R. raoultii* and *R. aeschlimannii* DNA were detected in the subset of positive blood samples that were sequenced using the *gltA* primer. Of all the tick pools screened, 25% were positive for *Rickettsia* spp. DNA using the *gltA* primer set. The *Rickettsia* spp. identified by sequencing of forty one tick PCR amplicons were *R. aeschlimannii*, *R. africae*, *R. monglotimonae*, *R. raoultii*, *R. montanensis* and *R. parkeri*. The findings in this study suggest that rickettsioses also contribute to cases of

febrile illness in pastoral communities in Kenya. The high percentage of ticks from camels infected with *Rickettsia* suggests that camels may be involved in the maintenance of SFG *Rickettsia* in Kenya. *R. aeschlimannii* DNA was detected in human blood samples - the first time this has been reported in Kenya.

## 847

### INHIBITION OF B-TRYPTASE BY MOSQUITO SERPINS IS MEDIATED BY DISSOCIATION OF THE ACTIVE TETRAMER

Eric Calvo, Ines Martin-Martin, Andrezza C. Chagas, Jose M. Ribeiro

National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Saliva of mosquito and other blood-sucking arthropods contains a complex mixture of anti-hemostatic, anti-inflammatory, and immunomodulatory compounds that facilitate blood feeding and pathogen transmission. We previously showed that the main anticoagulant of *Aedes albopictus* (Alboserpin) mosquitoes belong to the serpin superfamily of protease inhibitors targeting the coagulation factor Xa. In addition to its anticoagulant activity, we discovered that Alboserpin also inhibits b-tryptase, the most abundant secretory serine protease in human mast cells. The inhibition of b-tryptase by Alboserpin appeared to be reversible, since excess heparin resulted in reactivation of the catalytic activity of this enzyme. These results indicate that Alboserpin inhibition of b-tryptase is mediated by destabilization of active tetramer rather than direct inhibition of the catalytic sites of the enzyme. Alboserpin also showed a potent anti-inflammatory effect on paw edema formation. This anti-inflammatory activity was also confirmed in cultured endothelial cells. Inhibition of the mast cells b-tryptase could attenuate the inflammation and vasoconstriction at the mosquito biting site and represent a strong adaptive evolution in hematophagy.

## 848

### MATRIX-ASSISTED LASER DESORPTION/IONIZATION TIME-OF-FLIGHT MASS SPECTROMETRY FOR RAPID IDENTIFICATION OF MEDICALLY IMPORTANT MOSQUITOES

Abhishek Mewara, Megha Sharma, Taruna Kaura, Kamran Zaman, Rakesh Yadav, Amit Sharma, Rakesh Sehgal

PGIMER, Chandigarh, India

Accurate and rapid identification of vectors is vital for the success of control programs. Conventionally, vector identification is done on the basis of morphological keys. Detection of the internal transcribed spacer (ITS2) of the rDNA has also been commonly used. Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) is now widely used for bacteria and fungi, but less explored for insects. We used MALDI-TOF MS for protein-profiling of the mosquito species from Chandigarh (North India) with the aim of creating their database. Mosquito larvae were collected from different rural and urban areas and reared to adult stages. Using the morphological keys, ITS2 PCR and species confirmation by sequencing, ten species were found, viz. *Anopheles stephensi*, *An. culicifacies*, *An. annularis*, *An. lindesayi*, *Aedes aegypti*, *Ae. albopictus*, *Culex quinquefasciatus*, *Cx. vishnui*, *Cx. tritaenorrhynchus*, *Armigeres subalbatus*. Cephalo-thorax part of the mosquitoes was selected for MALDI-TOF MS analysis on Microflex MALDI-TOF MS (Bruker Daltonics, Germany). The spectra so obtained were then processed using the Biotyper v3.0 and Flex Analysis v3.3. Five specimens of each species were processed in this way and the average spectral profiles so obtained were selected for database creation. Sixty coded mosquito specimens (six from each species) were then subjected to blind-testing. A score of >1.8 was used to denote reliable genus and species identification. The average number of peaks produced by different mosquitoes were 55-60 peaks for *Anopheles*, 80-100 for *Aedes*, 30-60 for *Culex* and 45-50 for *Armigeres* species, and a specific protein signature was obtained for these species. It was found that 58/60 (96.7%) were correctly identified with a score

of >1.8. *E. coli* ATCC 25922 gave a reliable score (>2) every time, when matched against the in-built database of Biotyper. Thus, MALDI-TOF MS appears to be a pragmatic technique for accurate and rapid identification of mosquito species. The database can be further expanded to include larvae and pupae stages and also species from different geographical regions.

## 849

### WANGA IN CELL CULTURE: TOOLS FOR STUDYING ASSOCIATIONS BETWEEN *ANOPHELES* AND *WOLBACHIA*

**Kelsey L. Adams<sup>1</sup>**, Jorge M. Santos<sup>2</sup>, Flaminia Catteruccia<sup>2</sup>

<sup>1</sup>Harvard University, Boston, MA, United States, <sup>2</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States

*wAnga* is to date the first and only strain of *Wolbachia* that has been identified in natural populations of *Anopheles gambiae* mosquitoes, the principle vectors of malaria (Baldini et al., (2014) Nat. Comm. 5:3985). *wAnga* is negatively associated with natural *Plasmodium falciparum* coinfection (Shaw et al., (2016), Nat. Commun. 7:11772), but there is no evidence that it can cause cytoplasmic incompatibility, limiting its potential use in vector control. Moreover, *wAnga* is also found at very low densities in the sister species *An. coluzzii*. We hypothesize that *wAnga*'s low titers may limit its ability to cause reproductive phenotypes in its host. We have established *wAnga* infections in *An. coluzzii* Mos55 cells and *Drosophila melanogaster* S2 cells, and are using cell culture to facilitate the study of this bacterium. We will make comparisons between *wAnga*'s ability to grow in *An. coluzzii* Mos55 cells and *D. melanogaster* S2 cells, which could provide valuable insight regarding the hospitability of the anopheline environment for *Wolbachia*. We are also working to transfer the *wAnga* strain via cell culture into other anopheline species. We hypothesize that an *Anopheles*-specific strain is more likely to be successfully transferred and stably maintained in other anophelines than *Aedes*- or *Drosophila*- specific *Wolbachia* strains, which have been met with recalcitrance in *Anopheles* thus far. Furthermore, we are striving to manipulate titers of *wAnga* using cell culture systems, with the goal of translating these findings into *in vivo* tools for the study of *wAnga*-induced host phenotypes. We are also taking advantage of the ability of cell culture to facilitate whole genome sequencing efforts by improving the capacity to obtain high purity DNA in higher ratios. This research will provide new knowledge to the field of innovative vector control against *Anopheles* mosquitoes, specifically towards assessing the potential of *Wolbachia* as a vector control agent for malaria transmission.

## 850

### THE ADULT *Aedes aegypti* MOSQUITO MIDGUT PERITROPHIC MATRIX PROTEOME

**Shavonn R. Whiten<sup>1</sup>**, Richard Helm<sup>2</sup>, Keith Ray<sup>2</sup>, Zach N. Adelman<sup>1</sup>

<sup>1</sup>Texas A&M University, College Station, TX, United States, <sup>2</sup>Virginia Tech, Blacksburg, VA, United States

The *Aedes aegypti* mosquito is the principle vector of arboviruses such as dengue, chikungunya, yellow fever and Zika virus. These arboviruses are transmitted during adult female mosquito blood feeding. While these viruses must transverse the midgut to be transmitted, the blood meal must also reach the midgut to be digested and subsequently used for egg development. However, this is a high-risk, high-reward process, as aggregation of blood meal metabolites can be toxic to the female mosquito midgut. Understanding the mechanisms that allow for midgut protection may provide novel molecular-based control strategies for mosquitoes and mosquito-borne diseases. The midgut peritrophic matrix (PM), a semipermeable extracellular layer that forms in response to blood feeding and separates midgut epithelial cells from the blood bolus, may serve as one such mechanism. While previous studies suggest the PM is comprised of 20-40 major proteins, only two have been identified to date. We conducted a mass spectrometry based proteomic analysis to identify

proteins that comprise the adult female *Ae. aegypti* midgut peritrophic matrix. Altogether, 474 unique proteins were identified, with 115 predicted secreted proteins. Of these, 57 were associated with catalytic activity, 20 were conserved hypothetical proteins, 8 were hypothetical proteins and 17 were of salivary gland origin. Most interestingly, we identified a conserved hypothetical protein of unknown function with characteristics similar to known peritrophic matrix proteins. This protein may be integral for midgut protection from blood meal derived toxicity, and serve as a novel target for vector control.

## 851

### ELUCIDATING THE ROLE OF LIPOLYTIC PATHWAY IN MOSQUITO REPRODUCTION AND *PLASMODIUM FALCIPARUM* TRANSMISSION

**Maurice A. Itoe<sup>1</sup>**, Kristine Werling<sup>1</sup>, Amy Deik<sup>2</sup>, Clary Clish<sup>2</sup>, Flaminia Catteruccia<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States,

<sup>2</sup>Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, MA, United States

Female *Anopheles* mosquitoes undergo a number of blood feeding cycles on a vertebrate host in order to produce multiple egg batches during their life span, and these obligatory steps are exploited by *Plasmodium* parasites for their own transmission. Blood feeding is therefore a critical step for both mosquito reproduction and parasite transmission that could be exploited to impact malaria dynamics in endemic areas, especially as these two processes are temporally and physiologically coupled. Previous studies revealed a correlation between blood meal digestion and major changes in transcriptional profiles of metabolic genes involved in lipid biosynthesis, transport, and breakdown, suggesting the occurrence of *de novo* lipid synthesis triggered by blood feeding and followed by lipid mobilization. Here, we aim to elucidate the specific role of blood meal-derived lipids (and/or of lipids synthesized *de novo* after a blood meal) in *Anopheles gambiae* reproduction and *Plasmodium falciparum* parasite development in mosquito stages. To address this, we initially performed targeted lipidomic analyses of various mosquito tissues after a blood meal. Our analyses reveal a coordinated accumulation and depletion of major lipid classes across key mosquito tissues during blood meal digestion, reflective of an engagement of lipogenic and lipolytic pathways. RNA interference (RNAi) against triglyceride (TAG) lipase and associated proteins, involved in lipolytic breakdown of TAGs to yield free fatty acids and diacylglycerol (DAG) identifies lipid mobilization as central in determining reproductive success of the main malaria vector. Specifically, TAG-lipase inhibition, significantly impairs egg development and abolishes fertility, and upon a *P. falciparum* infectious feed had no apparent impact on the number of oocysts per midgut. While further characterization is underway, this study identifies the regulation of TAG/DAG equilibrium as critical for achieving reproductive success of *Anopheles* mosquitoes that could be exploited to control mosquito population and reduce malaria transmission.

## 852

### A FEMALE REPRODUCTIVE PROTEIN AFFECTS THE INTERACTION BETWEEN *ANOPHELES GAMBIAE* MOSQUITOES AND *PLASMODIUM FALCIPARUM* PARASITES

**Perrine Marcenac<sup>1</sup>**, W. Robert Shaw<sup>1</sup>, Adam South<sup>1</sup>, Evdokia Kakani<sup>1</sup>, Sara N. Mitchell<sup>1</sup>, Abdoulaye Diabate<sup>2</sup>, Rakiswende S. Yerbanga<sup>2</sup>, Thierry Lefevre<sup>3</sup>, Flaminia Catteruccia<sup>1</sup>

<sup>1</sup>Harvard T. H. Chan School of Public Health, Boston, MA, United States,

<sup>2</sup>Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso, <sup>3</sup>Institut de Recherche pour le Developpement, Montpellier, France

In *Anopheles gambiae*, male-female molecular interactions following mating are important determinants of female reproductive fitness. *Anopheles* oogenesis and *Plasmodium* parasite development are both temporally and physiologically tied, and an increasing amount of evidence points to reproductive processes playing an important role in

*Plasmodium falciparum* development. Transfer of the steroid hormone 20-hydroxyecdysone (20E) from males to females during mating induces the expression of the gene *Mating-Induced Stimulator of Oogenesis* (*MISO*) in a number of *Anopheles* species and forms a complex with this factor. We find that species that have evolved this mating system have high tolerance to *P. falciparum* infection, and that depletion of *MISO* via RNA interference induces a significant fecundity cost in infected females. We hypothesize that *MISO* has evolved as a key factor to maintain female fitness in the face of *Plasmodium* infection. Our studies suggest male-transferred 20E may modulate aspects of female mosquito biology that are relevant to anopheline vector competence, which could have immense implications for *P. falciparum* transmission. Understanding how male-female molecular interactions following mating affect *P. falciparum* infection in the mosquito vector is key to the development of future vector control tools.

## 853

### HIGHLY CONSERVED PATTERN OF INTERGENOMIC SEQUENCE VARIATION IN INTERNAL TRANSCRIBED SPACER 2 (ITS2) IN ANOPHELES SUBPICIUS SPECIES A ACROSS WIDELY DISTRIBUTED POPULATIONS

Gunjan Sharma<sup>1</sup>, Ankita Sindhanian<sup>1</sup>, Manoj K. Das<sup>2</sup>, Om P. Singh<sup>1</sup>

<sup>1</sup>National Institute of Malaria Research, Delhi, India, <sup>2</sup>National Institute of Malaria Research, Field Unit, Ranchi, India

*Anopheles subpictus* s.l. has emerged as a malaria vector in India and Sri Lanka which consists of at least four cryptic species. Ribosomal DNA (rDNA) is extensively used for discrimination of cryptic species that is considered as a gold standard marker for taxonomic resolution of closely related species. Ribosomal DNA is considered highly conserved within an interbreeding population due to concerted evolution acting on this mutigene family and therefore has been extensively used for identification of closely related species especially for the discrimination of cryptic species that are morphologically indistinguishable. It is assumed that all copies of rDNA within an individual are identical, however there are some reports of presence of intergenomic sequence variation in rDNA. This phenomenon may affect the species diagnostic value of rDNA. We sequenced internal transcribed spacer rDNA (ITS2) of *Anopheles subpictus* species A from different geographical populations from Indian subcontinent (Alwar 27.5° N, 76.6° E; Jodhpur 26.2° N, 73.0° E; Delhi 28.7° N, 77.1° E; Kheda 22.9° N, 72.9° E; Ranchi 23.3° N, 85.3° E; Chilka Lake 19.8° N, 85.4° E; Jaffna, Sri Lanka 9.6° N, 80.0° E) and discovered constant pattern of intergenomic variation in rDNA of *An. subpictus* species A with presence of two types of sequences. Cloning and sequencing of ITS2 from individual mosquitoes revealed presence of two types of sequences differing by indel of 12 bases. However, all populations showed identical intergenomic sequence variation with presence of these two types of sequences. We infer that intergenomic sequence variation will not affect species diagnostic value of ribosomal DNA.

## 854

### DISCOVERY OF A NOVEL MOSQUITO JUVENILE HORMONE BINDING PROTEIN ISOLATED FROM THE YELLOW FEVER MOSQUITO, Aedes Aegypti

Il-Hwan Kim<sup>1</sup>, Van Pham<sup>1</sup>, Willy Jablonka<sup>1</sup>, Walter Goodman<sup>2</sup>, Jose Ribeiro<sup>1</sup>, John Andersen<sup>1</sup>

<sup>1</sup>National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>2</sup>University of Wisconsin Madison, Madison, WI, United States

Juvenile hormone (JH) is a key regulator of insect metamorphosis and reproductive development. JH binding protein (JHBP) is responsible for transporting JH to target tissues while protecting it from degradation and regulating its bound concentration. Although JHBP has been identified and physically characterized in agricultural pest insects (Lepidoptera), specific function and structure of JHBP remains unknown in medically-important

insects including mosquitoes. Here, we are the first to describe a new type of JHBP isolated from the yellow fever mosquito, *Aedes aegypti* (nJHBP). nJHBP is a member of the odorant-binding protein family (OBP) and is related to the D7 proteins found in mosquito saliva. Unlike Lepidoptera JHBP which is found in all life stages, Western blot analysis revealed that nJHBP circulates only in the hemolymph of pupal and adult mosquitoes. Binding studies using isothermal titration calorimetry showed that nJHBP binds JH II and JH III with high affinity. However, nJHBP did not interact with the eicosanoid fatty acid ligands of the D7 proteins or JH analogues lacking the epoxide group such as methoprene. nJHBP was crystallized in the presence of JH III and found to have a two OBP domain structure. A single molecule of JH III was found in the N-terminal domain binding pocket that is enclosed by a cap structure derived from the C-terminal domain. The lack of clear structural path to the binding site suggests that its binding mechanism is analogous to unrelated Lepidoptera JHBP. Relative quantification of nJHBP mRNA in female mosquitoes indicated nJHBP expression reaches its highest level at 12 hour post-eclosion, corresponding to a reported peak of JHIII synthesis. nJHBP expression level declines after 12 hours and remains low after blood-feeding, which also follows the expression pattern of JHIII. Altogether, these results document a discovery of a novel JHBP in mosquitoes. This finding has a major implication for understanding how JH is regulated in mosquitoes and future studies will aim to further understand the role of nJHBP in regulating JH and its mechanism of action in delivering JH to target sites.

### VECTORBASE: DATABASE FOR POPULATION BIOLOGY AND OMICS DATA QUERY, BROWSE AND ANALYSES

Gloria I. Giraldo-Calderon<sup>1</sup>, Scott J. Emrich<sup>1</sup>, Daniel Lawson<sup>2</sup>, Frank H. Collins<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Imperial College London, London, United Kingdom

VectorBase ([www.vectorbase.org](http://www.vectorbase.org)) is a free, web-based bioinformatics resource center (BRC) for invertebrate vectors of human pathogens, funded by NIAID/NIH. This database is the 'home' of genomes of arthropod vectors and pests (e.g., *Anopheles gambiae*, *Aedes aegypti* and *Culex quinquefasciatus* among other species in Diptera, Hemiptera, Phthiraptera, and Acari), phylogenetically related species, and one intermediate host (the snail, *Biomphalaria glabrata*). In addition to these 40 genomes, it also has transcriptomes, proteomes and population data for an even wider list of species. The population biology data includes lab and field collected information, both from genotypes and phenotypes, covering any biology, ecology, or behavior trait, and even insecticide resistance and population abundance. In addition to the data imported from external databases or directly submitted by users, VectorBase also generates and computes primary data. Over its 13 years of existence, the discovery and interpretation of hosted data has been used for basic and translational research, as expressed in numerous scientific publications, using data in new or re-purpose analyses, descriptions and hypotheses testing. Raw and process data can be exported or download in a variety of different formats, visualized, browsed, queried and analyzed with the site tools or any other external tools. Because VectorBase data, tools and resources are updated every two months, this presentation will highlight this last year major additions. The website has extensive documentation resources for new and experienced users including tutorials, video tutorials (YouTube/youku), practice exercises, answer keys and sample files. In addition to our standard (in-person) workshops, this year we started to offer live webinars. Thesis or publications using this database, are kindly ask to reference the paper or papers where the data was originally published and VectorBase most recent paper, as explained in the website under the "Help" navigation tab. To contact us send a message to [info@vectorbase.org](mailto:info@vectorbase.org).

### CHOLESTEROL-MODULATED IMMUNE SIGNALLING MEDIATES *WOLBACHIA*-INDUCED INHIBITION OF O'NYONG NYONG VIRUS IN *ANOPHELES* MOSQUITOES

Sujit Pujhari<sup>1</sup>, Grant L. Hughes<sup>2</sup>, Jason L. Rasgon<sup>1</sup>

<sup>1</sup>Pennsylvania State University, University Park, PA, United States, <sup>2</sup>University of Texas Medical Branch, Galveston, TX, United States

*Wolbachia* is an intracellular bacterium that infects numerous arthropods. *Wolbachia* has gained considerable attention as a potential disease control agent due to its ability to inhibit pathogen infection when introduced into naturally uninfected mosquito hosts. Field releases of *Wolbachia*-infected *Aedes aegypti* are currently underway to control Dengue and Zika viruses in multiple countries. We used the O'nyong nyong virus (ONNV) model to understand the molecular mechanism of *Wolbachia*-mediated virus interference in *Anopheles* mosquitoes. Enhanced host immunity and competition for metabolic resources are two competing hypotheses for the mechanism of *Wolbachia*-mediated pathogen inhibition in insects. Here we establish that 1) *Wolbachia*-mediated virus inhibition is the result of up-regulation of the Toll innate immune pathway, and 2) cholesterol inhibits *Wolbachia*-induced virus blocking by modulation of Toll signaling rather than competition for cholesterol between *Wolbachia* and virus. *Wolbachia* and cholesterol influence Toll immune signaling in *Anopheles* mosquitoes in a complex manner and provide a functional link between host immunity and metabolism in *Wolbachia*-mediated pathogen interference in mosquitoes.

### NATIONWIDE INSECTICIDE RESISTANCE STATUS AND BITING BEHAVIOR OF MALARIA VECTOR SPECIES IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC) 2013-2016

Francis Wat'senga<sup>1</sup>, Emile Manzambi<sup>1</sup>, Andre Lunkula<sup>2</sup>, Roger Mulumbu<sup>1</sup>, Tania Mampangulu<sup>1</sup>, Djenan Jacob<sup>3</sup>, Christen Fornadel<sup>4</sup>, Mame Niang<sup>5</sup>, Ferdinand Ntoya<sup>6</sup>, Tamfum Muyembe<sup>1</sup>, Joris Likwela<sup>2</sup>, Richard M. Oxborough<sup>7</sup>, Seth R. Irish<sup>8</sup>

<sup>1</sup>Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>National Malaria Control Program, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, Bethesda, MD, United States, <sup>4</sup>U.S. President's Malaria Initiative, US Agency for International Development, Washington, DC, United States, <sup>5</sup>U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Kinshasa, Democratic Republic of the Congo, <sup>6</sup>U.S. Agency for International Development, Kinshasa, Democratic Republic of the Congo, <sup>7</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, London, United Kingdom, <sup>8</sup>Entomology Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States

WHO estimates that malaria incidence and deaths in DRC reduced by >40% from 2010-2015, partly due to increased ownership of LLINs. Entomological data was collected nationwide in 7 Provinces between 2013-2016. Human landing catches (HLC) between 18:00 and 06:00 were used to assess mosquito biting times and behavior. HLC was conducted indoors and outdoors in two houses for four consecutive nights per trimester. HLC was conducted monthly in Sankuru and Haut Katanga during 2016. WHO insecticide susceptibility testing of adult *Anopheles gambiae* s.l. was conducted annually using diagnostic concentrations of deltamethrin (0.05%) and permethrin (0.75%). Pre-exposure to the synergist PBO followed by permethrin was done to determine resistance mechanisms. *Anopheles gambiae* s.l. were resistant to permethrin in six of seven Provinces. Conversely, five of seven sites reported susceptibility to deltamethrin. In bioassays with PBO and permethrin the mean increase in mortality was 24%, indicating involvement of metabolic resistance mechanisms. The *kdr*-1014F mutation was present at high frequency (>70%) in Tshopo and Kinshasa and low frequency (<20%) in Sankuru

and Haut Katanga in 2015. In Sankuru, *An. gambiae* s.l. biting rates were consistently high at more than 10 bites/person/night every month. While in Haut Katanga peak *An. gambiae* s.l. biting rates coincided with the rainy season between October and March and *An. funestus* s.l. biting continued through the dry season with 5-15 bites/person/night. *An. gambiae* s.l. biting times were similar in Tshopo, Kinshasa and Sankuru, with the majority of biting occurring late at night between 22:00 and 04:00. In Haut Katanga, considerable *An. gambiae* s.l. biting occurred before 19:00, while *An. paludis* was predominantly an outdoor biter with a large biting peak between 19:00 and 22:00. Malaria vector biting rates remain high in some Provinces of DRC despite increased LLIN coverage. The majority of biting was late at night; therefore LLINs should provide some personal protection. However, the finding of widespread permethrin resistance is concerning and alternative insecticides may be needed.

858

### INSECTICIDE RESISTANCE STATUS, INTENSITY AND MECHANISMS OF *ANOPHELES GAMBIAE* S.L. IN SOUTHERN AND CENTRAL MALI BETWEEN 2014 AND 2016

Arthur Sovi<sup>1</sup>, Chitan Keita<sup>1</sup>, Abdourhamane Dicko<sup>2</sup>, Dereje Dengela<sup>3</sup>, Elie Bankineza<sup>1</sup>, Jules Mihigo<sup>4</sup>, Kristen George<sup>5</sup>, Laura Norris<sup>5</sup>, Richard Oxborough<sup>6</sup>, Raymond Beach<sup>7</sup>

<sup>1</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, Bamako, Mali, <sup>2</sup>National Malaria Control Program, Bamako, Mali, <sup>3</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, Bethesda, MD, United States, <sup>4</sup>U.S. Centers for Disease Control and Prevention, Bamako, Mali, <sup>5</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States, <sup>6</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, London, United Kingdom, <sup>7</sup>Entomology Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

There is growing concern that insecticide resistance may jeopardize the effectiveness of long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS). Between 2014 and 2016, PMI supported annual IRS in Barouéli and Koulikoro, with Fana District added in 2016. Resistance testing was conducted annually in 14 sites covering southern and central Mali. *An. gambiae* s.l. were collected from larval sites and adult mosquitoes exposed in WHO tube tests to diagnostic doses of permethrin, deltamethrin, bendiocarb and pirimiphos-methyl. Pyrethroid resistance intensity tests were conducted using CDC bottle bioassays at 1x, 2x, 5x, and 10x the diagnostic concentration. Bottle bioassays with pre-exposure to the synergist PBO followed by permethrin were conducted to determine the contribution of mixed function oxidases. PCR was performed to identify species and frequency of *Ace1<sup>R</sup>*, *kdr* 1014F and *kdr* 1014S mutations. WHO tube tests revealed full susceptibility to pirimiphos-methyl in all sites and full susceptibility to bendiocarb except in Niono and Bougouni where possible resistance was recorded. Resistance to permethrin and deltamethrin was widespread with a mean mortality of 38% to permethrin and 64% deltamethrin across all 14 sites in 2016. There were survivors at all sites when permethrin and deltamethrin were tested at 10X the diagnostic dose. No significant difference in pyrethroid resistance intensity was observed between 2014, 2015 and 2016. There was a high frequency of *kdr* 1014F in *An. gambiae* and *An. coluzzii* but a low frequency in the secondary vector *An. arabiensis*. The *Ace1<sup>R</sup>* and *kdr* 1014S mutations were present at very low frequency. Strong phenotypic resistance to pyrethroids and partial implication of MFOs indicated that additional mechanisms may be important. Widespread high intensity pyrethroid resistance may threaten the effectiveness of LLINs in Mali. However, contrary to predictions, the intensity of resistance has not increased between 2014 and 2016 despite mass LLIN distribution. IRS with pirimiphos-methyl should continue to be an important complementary vector control tool due to continued susceptibility.

### INDOOR RESIDUAL SPRAYING WITH FLUDORA FUSION (A CLOTHIANIDIN AND DELTAMETHRIN INSECTICIDE MIXTURE) PROVIDES IMPROVED CONTROL AND LONG RESIDUAL ACTIVITY AGAINST PYRETHROID RESISTANT *ANOPHELES GAMBIAE* SL IN SOUTHERN BENIN

Corine A. Ngufor<sup>1</sup>, Augustin Fongnikin<sup>2</sup>, Raphael N'Guessan<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

There is an urgent need for new insecticides for indoor residual spraying (IRS) which can provide improved and prolonged control of malaria vectors that have developed resistance to existing insecticides. The neonicotinoid, clothianidin represents a class of chemistry new to public health. Clothianidin acts as an agonist on nicotinic acetyl choline receptors. IRS with a mixture of Clothianidin and another WHO approved insecticide such as deltamethrin could provide improved control of insecticide resistant malaria vector populations and serve as a tool for insecticide resistance management. The efficacy and residual activity of Fludora Fusion, a novel IRS mixture of deltamethrin and clothianidin was evaluated against wild pyrethroid resistant *An. gambiae* sl in semi-field experimental hut trials in Cote d'Ivoire, Benin. Comparison was made with clothianidin and deltamethrin applied alone. To assess the residual efficacy of the treatments on different local wall substrates, the inner walls of the experimental huts were covered with either cement or mud. Clothianidin demonstrated a clear delayed expression in mortality of wild pyrethroid resistant *An. gambiae* sl in the experimental huts which reached its full effect 120 hours after exposure. Overall mortality over the 12-month hut trial was 4% in the control hut and 12-16% in the deltamethrin-treated huts. Fludora induced high overall hut mortality rates of wild free-flying pyrethroid resistant malaria vectors that entered the experimental huts (72% on mud walls, 70% on cement walls) largely due to the clothianidin component and high hut exiting rates (55-60%) mostly due to the deltamethrin component. Mortality rates remained >60% for 5-7 months on mud and cement walls. The residual activity trend was confirmed by results from cone bioassays with laboratory-maintained resistant and susceptible *An. gambiae* strains. IRS campaigns with the mixture of clothianidin plus deltamethrin have the potential to provide prolonged control of malaria transmitted by pyrethroid resistant mosquito populations.

### MECHANISMS OF PYRETHROID RESISTANCE IN *AEDES AEGYPTI* FROM DENGUE ENDEMIC AREAS OF SAUDI ARABIA: A PRIMARY ROLE FOR TARGET SITE MUTATIONS

Ashwaq M. Alnazawi, Philip J. McCall, David Weetman

Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Control of *Aedes aegypti* using insecticides is the main method to reduce the prevalence of dengue in the disease-foci cities of Makkah and Jeddah. Despite potential impacts on control, little is known about insecticide resistance in the Middle Eastern Region, and nothing about underlying mechanisms. We characterized insecticide resistance in *Ae. aegypti* from Jeddah and Makkah and investigated the role of the two main resistance mechanisms, target site mutations and metabolic detoxification. WHO bioassays were performed on adult *Ae. aegypti* collected in Jeddah and Makkah. Portions of the voltage-gated sodium channel (*Vgsc*) gene were sequenced to identify target site mutations. Microarray analyses were performed to identify transcriptome variation potentially linked to deltamethrin resistance and qPCR of candidate genes applied to investigate mechanistic cross-resistance in lines selected for other insecticides. Adults bioassays revealed resistance/suspected resistance to all insecticides tested in *Ae. aegypti* with significantly higher levels of deltamethrin resistance in Makkah compared to a reference resistant Cayman strain. Three *kdr* mutations (S989P, V1016G, F1534C)

were detected for the first time in the Middle Eastern region, with S989P and V1016G markers in perfect linkage disequilibrium (LD) and strongly predicting deltamethrin resistance. The synergist PBO, which is applied to block the action of P450 enzymes, caused a moderate increase in deltamethrin mortality in Jeddah but had a non-significant effect on Makkah mortality. Transcriptional analysis identified multiple differentially expressed genes, numerically dominated by P450s, most more highly expressed in Jeddah than Makkah, consistent with the synergist test results. *Ae. aegypti* mosquitoes are highly resistant to pyrethroids in the two regions. *Vgsc* mutations are strongly associated with deltamethrin resistance and, whilst P450 enzymes appear to be the dominant metabolic mechanism, our data suggest a greater importance of target site mutations; however further investigation is required to determine the importance of other resistance mechanisms.

### COMMERCIAL AEROSOLIZED INSECTICIDES CAN SERVE AS A STRONG SELECTION FORCE FOR PYRETHROID-RESISTANCE IN *AEDES AEGYPTI*

Lyndsey Gray<sup>1</sup>, Sergio Dzib Flores<sup>2</sup>, Anuar Medina Barreiro<sup>3</sup>, Manuel Vadillo Sánchez<sup>4</sup>, Audrey Lenhart<sup>5</sup>, Pablo Manrique Saide<sup>4</sup>, Gonzalo Vazquez-Prokopec<sup>6</sup>

<sup>1</sup>Department of Epidemiology, Emory University, Decatur, GA, United States, <sup>2</sup>Unidad Colaborativa para Bioensayos Entomológicos, Universidad Autónoma de Yucatán, Mérida, Mexico, <sup>3</sup>Unidad Colaborativa para Bioensayos Entomológicos, Mérida, Mexico, <sup>4</sup>Unidad Colaborativa para Bioensayos Entomológicos, Universidad Autónoma de Yucatán, Mérida, Mexico, <sup>5</sup>CGH, Division of Parasitic Diseases and Malaria, Entomology Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>6</sup>Department of Environmental Sciences, Emory University, Atlanta, GA, United States

Long term use of pyrethroids, poor efficacy and sub-optimal insecticide doses are considered the main drivers of the high prevalence of insecticide resistance currently observed among *Ae. aegypti* populations in the Americas. Commercial aerosolized insecticides may be an additional, yet unproven, source of pyrethroid resistance. This study experimentally quantified the biological efficacy of household products commonly used among households in Mérida, Mexico against pyrethroid-resistant (field strain) and pyrethroid-susceptible (New Orleans strain) *Ae. aegypti*. The bioefficacy and residual action of the two most commonly used pyrethroid aerosols, designated P1 (tetramethrin, allethrin, and d-phenothrin) and P2 (imiprothrin and cypermethrin), were tested against the two *Ae. aegypti* strains. Field strain mosquitoes originated from eggs collected in three sites outside of Mérida known for high levels of pyrethroid resistance (and treated as resistant colonies, labeled C1, C2, and C3) and use of P1 and P2 insecticides. Mortality among female, 2-5 day-old *Ae. aegypti* was measured after exposure to P1 and P2 as an aerial space spray and a residual surface sprayer and surface sprays. Detection of the I1016 allele through PCR was used as an indicator of resistance. GLMM modeling showed that all three resistant colonies had lower mortality rates than the control (C1 OR: 0.04, C2 OR: 0.11, C3 OR: 0.34). Similarly, I1016 homozygous mutant genotype conferred the greatest resistance to both insecticides (OR: 0.06, 95CI: 0.03, 0.12). While I1016 allele frequency was associated with increased survivorship in the aerial spray trials (all p-values <0.05), no such association was made in the residual spray trials. Our results suggest that household insecticides act as a strong force of pyrethroid selection pressure and that household use of insecticides can contribute to observed increasing trends in pyrethroid resistance in *Ae. aegypti*.

### CONTRIBUTION OF TWO SYMPATRIC SIBLING SPECIES, *ANOPHELES COLUZZII* AND *AN. GAMBIAE*, TO MALARIA TRANSMISSION IN NORTH BENIN

Martin C. Akogbeto<sup>1</sup>, Albert Salako<sup>1</sup>, Fortuné Dagnon<sup>2</sup>, Michel Sezonlin<sup>3</sup>, Fiacre R. Agossa<sup>1</sup>, Harriet Ahokpossi<sup>2</sup>, Michelle Kouletio<sup>2</sup>, Raymond Beach<sup>4</sup>

<sup>1</sup>Centre de Recherche entomologique de Cotonou (CREC), Benin, Cotonou, Benin, <sup>2</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Cotonou, Benin, <sup>3</sup>Faculty of Sciences and Technology, University of Abomey-Calavi, Benin, Calavi, Benin, <sup>4</sup>President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

*Anopheles gambiae* s.l. is an 8-species taxonomic complex. These include *An. gambiae* s.s. Giles and *An. coluzzii* Coetzee & Wilkerson, formerly referred to as the S form and the M form, respectively. The members of the complex display different bio-ecological characteristics, for example: feeding on humans versus cattle, or resting indoors versus outdoors. Additionally, there are differences in the suitability of each for development of *Plasmodium falciparum* sporozoites. The Departments of Alibori and Donga, Benin, have been targeted by the National Malaria Control Program for indoor residual spraying (IRS) in 2017. Pre-IRS vector assessments indicated that two species of the *An. gambiae* complex are present: *An. coluzzii* and *An. gambiae* s.s. The goal of this study was to measure and compare IRS-related entomological measures of transmission for each species. Human landing capture (HLC), inside and outside households, and pyrethrum spray capture (PSC) were used to sample vector populations in 6 districts targeted for IRS. Captured *An. gambiae* s.l. mosquitoes were dissected to assess parity; tested by enzyme-linked immunosorbent assay (ELISA) to determine circumsporozoite antigen positivity; and identified to species by polymerase chain reaction (PCR). In addition, PCR was used to estimate the human blood index and the frequency of the *Kdr L1014F* mutation in the sodium channel which has been associated with resistance to pyrethroid insecticides. There were no significant differences between the two species in the rates of anthropophily, blood meal indices, indoor and outdoor biting rates, or sporozoite rates ( $p > 0.05$  all comparisons). However, monitoring data revealed two differences that could affect the impact of IRS: *An. coluzzii* is characterized by a lower *Kdr L1014F* frequency than *An. gambiae* s.s., and the ratio of *An. coluzzi* to *An. gambiae* s.s. was significantly greater in Donga than in Alibori ( $p < 0.05$ ). These results suggest that the presence of more *An. coluzzii*, with a lower frequency of *Kdr L1014F* (compared with *An. gambiae*), could result in better control of malaria by IRS in Alibori compared to Donga.

863

### TRANSCRIPTOME ANALYSIS OF GENES ASSOCIATED WITH PYRETHROID RESISTANCE IN SOUTH AND CENTRAL AMERICAN *ANOPHELES ALBIMANUS*

Lucy Mackenzie Impoinvil<sup>1</sup>, Gareth Weedall<sup>2</sup>, Nicole Dzuris<sup>1</sup>, Juan C. Lol<sup>3</sup>, Jesús A. Pinto<sup>4</sup>, Lucrecia Vizcaino<sup>1</sup>, Jacob Riveron<sup>2</sup>, Norma Padilla<sup>3</sup>, Charles Wondji<sup>2</sup>, Audrey Lenhart<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Liverpool School of Tropical Medicine Liverpool, Liverpool, United Kingdom, <sup>3</sup>Universidad del Valle de Guatemala, Guatemala, Guatemala, <sup>4</sup>Instituto Nacional de Salud, Lima, Peru

Decades of unmanaged insecticide use and routine exposure to agrochemicals have left many populations of malaria vectors in the Americas resistant to multiple classes of insecticides, including pyrethroids. Using a transcriptome-wide approach, we characterized the mechanisms of deltamethrin and alpha-cypermethrin resistance in *Anopheles albimanus* from sites in Peru and Guatemala. Field collected *An. albimanus* were phenotyped as either deltamethrin or alpha-

cypermethrin resistant using the CDC bottle bioassay. RNA from 1) field-collected resistant, 2) field-collected unexposed, and 3) a susceptible laboratory strain of *An. albimanus* was sequenced and analyzed using RNA-Seq. The expression profiles of the three groups were compared based on the current annotation of *An. albimanus* reference genome sequence. Several candidate genes associated with pyrethroid resistance in other malaria vectors were found to be over-expressed in resistant *An. albimanus* mosquitoes. The cytochrome P450 monooxygenase CYP9K1 was overexpressed in both Guatemala and Peru, relative to a susceptible laboratory colony (Sanarate), but to a much greater extent in Peru (14x) than Guatemala (2x). CYP6P5 was over-expressed in Peru (68x) but not in Guatemala. The results suggest different mechanisms may mediate pyrethroid resistance in different populations of *An. albimanus*. Differences were also noted in the voltage-gated sodium channel between Peruvian alpha-cypermethrin-resistant and deltamethrin-resistant samples. In deltamethrin resistant samples, the knockdown resistance mutation (*kdr*) variant alleles at position 1014 were rare, with approximately 5% frequency but in the alpha-cypermethrin resistant samples the frequency of these alleles was approximately 15-30%. Validation of select candidate genes and the *kdr* mutation as a resistance marker for alpha-cypermethrin will provide key information for the development of mechanism-specific assays.

### COI BARCODING OF *ANOPHELES COLUZZII* AND INSECTICIDE RESISTANCE MONITORING IN DEMOCRATIC REPUBLIC OF SAO TOME AND PRINCIPE

Ying An Chen<sup>1</sup>, Lien-Fen Tseng<sup>2</sup>, Chien-Fu Cheng<sup>2</sup>, Jih-Ching Lien<sup>2</sup>, Kun-Hsien Tsai<sup>1</sup>

<sup>1</sup>Institute of Environmental Health, National Taiwan University, Taipei, Taiwan, <sup>2</sup>Taiwan Anti-Malaria Advisory Mission, Sao Tome, Sao Tome and Principe

Democratic Republic of Sao Tome and Principe (DRSTP) is an island nation located in the central west Africa. The malaria vector in DRSTP is *Anopheles coluzzii* which was formerly named *Anopheles gambiae* M form. This study sequenced and analyzed the gene of mitochondrial cytochrome oxidase subunit I (COI) of *Anopheles coluzzii* from different locations and time slots in DRSTP. Results showed that the COI sequences of *Anopheles coluzzii* were similar in DRSTP, but different from the voucher specimen (Accession No. KT382819) with an identity cut-off of 99.4%. On the other hand, there were differences in knockdown resistance (*kdr*) between *Anopheles coluzzii* (M form) and *Anopheles gambiae* Giles (S form). *Anopheles coluzzii* in DRSTP was found no *kdr* resistant type before 2004. However, intensive anti-vector interventions including indoor residual spraying (IRS) and long-lasting insecticidal nets (LLINs) has conducted from 2004 in DRSTP. Therefore, this study performed a monitoring on *kdr* 1014 locus associated with pyrethroid resistance from 2010 to 2015. Results showed that after 2-3 years of yearly IRS and LLINs with pyrethroid insecticides in DRSTP, the *kdr* L1014F allele frequency was detected in 2010 (6.39%), and had dramatically increased to 73.5% in 2013. The province Agua Grande with the highest population had no *kdr* L1014F frequency in 2010, but increased to 73.85% in 2013. Followed by the change of IRS insecticide from alphacypermethrin to bendiocarb at the end of 2013, the *kdr* L1014F frequency had decreased to 38.1% in 2015. *Ace-1* G119S resistant type to carbamate had not been detected until 2015.

865

### MALARIA VECTORS IN ASIA: A COMPOSITE SET OF APPROACHES FOR IMPROVING THEIR CONTROL

Sylvie Manguin

Institute of Research for Development (IRD), France, Montpellier, France

The current goals of WHO to achieve the 2020 milestones of a 40% reduction in case incidence and mortality, and malaria elimination by

2030, rely for a large part on vector control interventions. Then, updated knowledge on *Anopheles* vectors is important to obtain for developing malaria surveillance plan and risk assessment. In Asia, the biodiversity of *Anopheles* mosquitoes is particularly rich compared to the other continents. The vector system is composite as each malaria vector belongs to a species complex with morphologically indistinguishable sibling species that may present different trophic behaviors and vectorial capacities. Recent advances in molecular systematics have allowed reliable species identification for their precise study. Another specific trait in Asia is that most malaria endemic areas occur in foci distributed along forested international borders with population movement maintaining the endemicity. The main aim of this work is to obtain information on the human-vector system, which is of primordial importance for applying appropriate vector control programs targeting the correct vector species and protecting the human population. Several approaches are being developed, in collaboration with Asian partners (Cambodia, China, Thailand, Vietnam), for answering crucial questions and improving vector control strategies. Do we know all the vectors, even secondary ones that may play a role in transmission? What is the role of the mosquito microbiota in its vectorial capacity? Can we evaluate human antibody responses to *Anopheles* saliva to evaluate the efficacy of vector control methods? Are there alternatives to synthetic insecticides capable of protecting the human population and less harmful to the environment? These joint studies are providing reliable data on *Anopheles* mosquitoes throughout Asia highlighting also the gaps to fill up. Today, there is an urgent need to extend this network at the regional scale as malaria vectors do not know boundaries and their control will be a lot more efficient if an international taskforce is identified which will increase the chance to meet the goal of malaria elimination by 2030.

## 866

### INSECTICIDE-TREATED COW-BAITED TENTS AS A TOOL TO CONTROL OUTDOOR BITING MALARIA VECTORS

Brandyce St. Laurent<sup>1</sup>, Nicholas Deason<sup>1</sup>, Kolthida Oy<sup>2</sup>, Siv Sovannaroth<sup>2</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Insecticide-treated cow-baited tents were tested in Cambodia over one year as an outdoor-biting mosquito control and monitoring tool. Insecticide-treated cow-baited tents exploit the animal feeding tendencies of outdoor vectors and could potentially target and eliminate large numbers of different anopheline species that contribute to outdoor, or residual, malaria transmission. The potential success of this strategy is that anophelines with a successful bloodmeal may linger on treated tent walls, increasing their rate of contact with insecticide treated or impregnated netting. Even if the mosquitoes are not knocked down directly, this exposure could drastically reduce the number of surviving females that are able to transmit, thus reducing malaria transmission. Since many outdoor biting mosquitoes carry other diseases, this type of approach could target not only vectors of residual malaria, but also those of filariasis and other zoonoses. Large tents fitted with deltamethrin-impregnated panels with a cow in the center were compared to untreated control tents every three months during 2016 in Pursat and Preah Vihear, Cambodia, provinces with emerging artemisinin-resistant malaria parasite populations. Mosquitoes were collected hourly from 6pm to 6am and were tested for knockdown effects exactly two hours after collection. The same diverse set of more than 25 *Anopheles* species were captured in treated versus untreated tents, hundreds of anophelines were entering treated tents every night, and some of those mosquitoes were carrying malaria parasites with Kelch-13 mutations, a marker that is linked to artemisinin-resistance. These results show that insecticide-treated cow-baited tents could be a valuable tool for targeting outdoor vector species.

### CROSS-RESISTANCE INVOLVING THREE CLASSES OF INSECTICIDES AND TWO MAJOR MALARIA VECTOR SPECIES IMPACTING MALARIA CONTROL IN NCHELENGE, A HIGH MALARIA TRANSMISSION REGION IN NORTHERN ZAMBIA

Chilusu<sup>1</sup>, Nelius Venter<sup>5</sup>, Davis Mwewa<sup>6</sup>, Modest Mulenga<sup>1</sup>, Maureen Coetzee<sup>5</sup>, Douglas E. Norris for the Southern African ICEMR<sup>7</sup>

<sup>1</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>2</sup>World Health Organization Country Office, Lusaka, Zambia, <sup>3</sup>Macha Research Trust, Choma, Zambia, <sup>4</sup>Department of Biological Sciences, School of Natural Sciences, the University of Zambia, Lusaka, Zambia, <sup>5</sup>Wits Malaria Research Institute, School of Pathology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, <sup>6</sup>District Health Office, Nchelenge, Zambia, <sup>7</sup>Johns Hopkins Malaria Research Institute, Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

For over a decade insecticide-treated bed nets (ITNs) and indoor residual spraying (IRS) have been the vector control tools in Nchelenge District, northern Zambia, although prevalence of malaria remains high. Some areas, particularly the islands, have only received ITNs. Studies carried out in the district provided insight into the problem of malaria on the mainland. We included islands in Lake Mweru with no history of IRS and determined the status of insecticide resistance and the intensity of this resistance using the World Health Organization (WHO) standard assays. We tested field-collected and F1 mosquitoes on five insecticides representing four classes between 2014 and 2016. Ninety-seven percent of the collections were *Anopheles funestus* group and 3% *An. gambiae sensu lato*. *An. funestus* from all the sites were resistant to pyrethroids and carbamates but susceptible to organophosphates and DDT. *An. gambiae* was resistant to pyrethroids and DDT but susceptible to organophosphates and bendiocarb. The intensity of resistance in *An. funestus* from all collection sites was high against bendiocarb and deltamethrin. On the mainland there was a significant increase in resistance intensity to bendiocarb between 2014 and 2016 (ANOVA F = 93, p-value < 0.001). We recorded 10% mortality in *An. gambiae* to DDT, an insecticide that has never been used before in the district. We recorded cross-resistance between pyrethroids and carbamates in *An. funestus* and between pyrethroids and DDT in *An. gambiae*. We detected cytochrome p450 resistance mechanism in *An. funestus* and knockdown resistance (kdr) in *An. gambiae*. Insecticide resistance may explain why control efforts have not made an appreciable impact on the transmission of malaria in Nchelenge. Well thought out integrated vector control and resistance management strategies are required, as options for vector control in Nchelenge are very limited. The use of new innovations such as ITNs incorporated with an insecticide synergist on the islands may be helpful. Alternative insecticides are needed in this area and Nchelenge could provide a good field site for evaluating efficacy of new vector control tools.

### PYRETHROID RESISTANCE INTENSITY AND MECHANISMS OF INSECTICIDE RESISTANCE IN THE MALARIA VECTOR *ANOPHELES GAMBIAE* S.L. IN SELECTED DISTRICTS IN NORTHERN GHANA

Sylvester Coleman<sup>1</sup>, Samuel Dadzie<sup>2</sup>, Yemane Yihdego<sup>1</sup>, Aklilu Seyoum<sup>1</sup>, Dereje Dengela<sup>3</sup>, Kristen George<sup>4</sup>, Kristen Fornadel<sup>5</sup>, Daniel Szumlas<sup>5</sup>, Maxwell Appawu<sup>2</sup>, Daniel Boakye<sup>2</sup>

<sup>1</sup>U.S. Agency for International Development President's Malaria Initiative Africa Indoor Residual Spraying Project, Accra, Ghana, <sup>2</sup>Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, <sup>3</sup>U.S. Agency for International Development President's Malaria Initiative Africa Indoor Residual Spraying Project, Abt Associates Inc., Bethesda, MD,

United States, <sup>4</sup>President's Malaria Initiative/U.S. Agency for International Development, Pennsylvania, WA, United States, <sup>5</sup>President's Malaria Initiative/U.S. Agency for International Development, Washington, DC, United States, <sup>6</sup>Armed Forces Pest Management Board, Montgomery, MD, United States

Insecticide susceptibility tests and resistance mechanism assays are conducted annually across selected sentinel sites for the President's Malaria Initiative (PMI) supported indoor residual spraying (IRS) Ghana project, to guide the selection of insecticides for the spray campaign. In 2016, WHO tube tests were conducted on the malaria vector *Anopheles gambiae* s.l. using selected insecticides recommended for IRS. Follow-up resistance intensity tests were also conducted to determine the pyrethroid resistance intensity among *Anopheles gambiae* s.l. in two IRS sites. Synergist assays with detoxification enzyme inhibitors (PBO and DEF), and biochemical tests were conducted to determine the presence and level of metabolic resistance. The insecticide susceptibility test results indicated that *An. gambiae* s.l. from all the sites tested are resistant to pyrethroids (alphacypermethrin 0.5% and deltamethrin 0.05%). The *An. gambiae* s.l. from Gbullung and Kumbungu showed high frequency of insecticide resistance to deltamethrin (0-5% mortality). However, the frequency of phenotypic resistance to deltamethrin is mainly of low intensity, because the vector was only resistant to the 1x and 2x diagnostic doses of deltamethrin, but susceptible to the 5x and 10x doses. The vectors from Gbullung were also resistant to bendiocarb (89% mortality). In contrast, vectors from all the IRS communities were susceptible to pirimiphos-methyl (98% -100% mortality). Synergist assays with PBO resulted in a significant increase in vector susceptibility to deltamethrin (from 67% to 95%;  $p < 0.0001$ ), assays with DEF increased the vector susceptibility only marginally, from 66% to 71% ( $p = 0.447$ ), suggesting that mono-oxygenases play a significant role in the resistance detected in Gbullung. Confirmatory biochemical assays showed significantly elevated activities of cytochrome P450 mono-oxygenases, and  $\alpha$  and  $\beta$ -esterases in samples collected from Gbullung ( $p < 0.0001$ ). Organophosphates remain the only insecticide to which no confirmed resistance has been reported. Insecticide resistance monitoring is crucial in maintaining the efficacy of IRS in the area.

### LANDSCAPE STRUCTURE AND *ANOPHELES* (DIPTERA: CULICIDAE) COMMUNITIES IN THE URABÁ AND BAJO CAUCA, COLOMBIA

Juan D. Sánchez-Rodríguez<sup>1</sup>, Juan C. Hernández<sup>1</sup>, Nelson Naranjo-Díaz<sup>1</sup>, Mariano Altamiranda-Saavedra<sup>1</sup>, Stiven Quintero<sup>1</sup>, Santiago Suárez<sup>2</sup>, Alba L. Marín Valencia<sup>2</sup>, **Margarita M. Correa<sup>1</sup>**

<sup>1</sup>Grupo de Microbiología Molecular, Universidad de Antioquia, Medellín, Colombia, <sup>2</sup>Espacio Vivo Ingeniería S.A.S., Medellín, Colombia

Landscape structure and composition greatly influences inhabitant insect communities and it is an aspect of importance for understanding malaria vector ecology. This work aimed to evaluate the influence of landscape coverages on the composition and diversity of *Anopheles* mosquitoes collected in localities of two Colombian malaria endemic regions, the Urabá and Bajo Cauca. Land cover types were characterized using orthorectified aerial photographs, in areas within 1.5 km radius of the collection site. In general, eight main coverage types were detected; forest, water bodies, grass, stubble, bare soil, crops, wetland and crop mosaics with natural areas; but the predominant coverages were forest, bare soil and crops. A total of 2,543 mosquitoes were collected corresponding to 13 species, being the most abundant, *Anopheles braziliensis* (33%), *Anopheles nuneztovari* (24%) and *Anopheles darlingi* (20%). *Anopheles darlingi* and *An. nuneztovari* showed higher densities in forest predominant landscapes, and *An. braziliensis* in grass and bare soil landscapes. There was no relationship between landscape diversity and anopheline community diversity. Studies on landscape structure

and anopheline communities for important malaria endemic regions of Colombia help to elucidate the malaria vector species spatial distribution which constitutes useful information for vector control interventions.

## 870

### DECIPHERING THE IMPACT OF *PLASMODIUM* AND *TRYPANOSOMA* COINFECTIONS ON THE VECTORIAL CAPACITY OF *ANOPHELES* MOSQUITOES

**Constantin Dieme**, Kenneth Vernick, Brice Rotureau, Christian Mitri

Institut Pasteur, Paris, France

Malaria and African trypanosomiasis (AT) are two parasitic diseases prevalent in African tropics, transmitted to humans and other mammals by the bite of competent female *Anopheles* mosquitoes for the malaria parasite *Plasmodium*, and male and female tsetse flies (*Glossina*) for *Trypanosoma*. In some sub-Saharan Africa areas, these two parasites are sympatric, thus competent *Anopheles* or *Glossina* vectors could feed directly on a co-infected host, or more likely, on two successive hosts respectively infected with one parasite and the other. This study aims at understanding how the ingestion of *Trypanosoma* could impact the development and the transmission of *Plasmodium* by *Anopheles*. Both concomitant co-infection and successive co-infection scenarios were assessed on *Anopheles coluzzi* using *Trypanosoma brucei brucei* and *Plasmodium spp* (*yoelii* or *falciparum*). In both concomitant and successive co-infection scenarios, our results showed that mosquitoes co-infected with *T. b. brucei* bloodstream forms are more susceptible to *P. yoelii* or *P. falciparum* as compared to the batch of mosquitoes mono-infected with *Plasmodium*. A transcriptomic approach will help us at identifying mosquito factors that could impact on *Plasmodium* development in co-infected *Anopheles* mosquitoes. These results emphasize the need for considering co-endemic areas for designing vector control strategies.

## 871

### A MOSQUITO ASSOCIATED *CHROMOBACTERIUM* CAUSES LETHALITY IN *ANOPHELES GAMBIAE* LARVAE THROUGH PRODUCTION OF HYDROGEN CYANIDE

**Sarah M. Short<sup>1</sup>**, Sarah Van Tol<sup>2</sup>, Hannah J. MacLeod<sup>1</sup>, Emmanuel Mongodin<sup>3</sup>, George Dimopoulos<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>University of Texas Medical Branch, Galveston, TX, United States, <sup>3</sup>University of Maryland School of Medicine, Baltimore, MD, United States

Malaria and other vector borne diseases account for hundreds of millions of disease cases each year and hundreds of thousands of deaths, and novel vector control strategies are a critical component of preventing disease transmission. In previous work, we have shown that a soil-derived bacterium *Chromobacterium species Panama* (*Csp\_P*), has insecticidal properties against *Anopheles gambiae* mosquitoes at both the larval and adult stages of development. In the current work, we dissected the mechanism of larval killing by *Csp\_P* when the bacterium is present in suspension in the breeding water. We determined that *Csp\_P* produces a larvicidal factor that persists after removal of live bacteria via filtration and that larval killing activity increases during log phase of bacterial growth, peaking near the end of log phase. Further, we determined that the larvicidal factor is a heat-stable and volatile small molecule (< 3 kDa). Upon sequencing the genome of *Csp\_P*, we discovered that the bacterium's genome encodes a hydrogen cyanide (HCN) synthase, as is the case for other species of *Chromobacterium*. We then determined that *Csp\_P* produces hydrogen cyanide when present in larval rearing water, reaching a concentration of approximately 0.51 mg/L, which is sufficient to kill the larvae. The HCN persisted in the larval water for less than 24 hours. We also determined that HCN production by *Csp\_P* occurs during the log phase of bacteria growth, and peaks at the end of log phase, mirroring the pattern of *Csp\_P*-mediated larval killing. Finally, we successfully eliminated larval mortality through treatment of the larval rearing water with

hydroxocobalamin, an HCN antidote. Taken together, these data strongly suggest that *Csp\_P*'s larvicidal activity is derived from its production of HCN in the larval breeding water.

## 872

### ANALYSIS OF CELLULAR INTERACTIONS BETWEEN *PLASMODIUM* PARASITES AND *ANOPHELES* SALIVARY GLANDS

**Michael B. Wells**, Jordan Villamor, Deborah J. Andrew  
*Johns Hopkins University, Baltimore, MD, United States*

*Plasmodium* parasites are the causal agent of malaria, a mosquito-borne disease still with hundreds of millions of infections and around 500,000 deaths each year. Parasites are acquired by female mosquitoes that blood feed on an infected individual. *Plasmodium* undergoes reproduction and development in and on the midgut. Sporozoites are subsequently released into the mosquito hemocoel, where they locate and specifically invade the salivary glands (SGs). During subsequent blood meals, the SGs provide the gateway for *Plasmodium* transmission to a new host. We sought to characterize interactions between sporozoites and SG cells using confocal immunofluorescence microscopy to better understand this stage of malaria transmission. *Plasmodium berghei* parasite- (either ANKA or GFP-tagged ANKA) infected *Anopheles stephensi* SGs were dissected at time points between 18 and 30 days post-infection and stained for features including SG secreted saliva proteins, cytoskeletal markers, organelle markers, dyes (lipids, chitin/O-GlcNAcylation), and antibodies to parasite-expressed GFP or *P. berghei* circumsporozoite protein (CSP). Using this strategy on a large sample size, we confirmed many of the described features of invaded SGs, including SG distal lateral lobe-focused invasion, SG cell stress and/or death, possible SG basal membrane repair after invasion, parasite bundling, and the presence of transient parasitophorous vacuoles. We have also uncovered novel preliminary information regarding SG infections, such as sites of subcellular SG localization of parasite CSP, very few parasites in the salivary duct (in the absence of a second blood meal), emergence from the parasitophorous vacuole, parasite maturation in the SG, cell traversal strategies, and the effects of infection on SG structure/function. Interactions between SG cells and the parasites are likely to be critical factors on parasite transmission rates. A better understanding of these interactions will inform future strategies to block parasite transmission at the SGs.

## 873

### COMPETITIVE MATING CHALLENGES OF TRANSGENIC *Aedes Aegypti* AGAINST WILD-TYPE STRAINS REARED UNDER LABORATORY AND SIMULATED FIELD CONDITIONS

**David S. Kang**, Joanne M. Cunningham, Diane D. Lovin, David W. Severson  
*University of Notre Dame, South Bend, IN, United States*

Population replacement and suppression as a means of mosquito control is a paradigm heavily reliant on the release of genetically altered strains into the wild. The ability of these transgenic mosquitoes to competitively interbreed with wild populations is critical to the success of such strategies, but has not been well studied. Here we performed mating challenges of transgenic and recent Trinidadian field isolates of *Aedes aegypti*. We subjected larvae to either standard optimum laboratory regimes or conditions simulating environmental stress found in the field, and determined that larval crowding and nutritional deprivation negatively influenced the competitiveness and reproductive success of Trinidad males. Specifically, in individual head-to-head challenges against optimally reared transgenic males, Trinidad males raised under stressed conditions were less likely to successfully inseminate females. Further, females were more likely to mate with multiple partners in challenges that included stress-reared Trinidad males. Here we provide evidence that upon release, transgenic *A. aegypti* males raised under optimal laboratory conditions are likely to have a competitive mating advantage over wild males in the field.

## 874

### BLOOD MEAL PREFERENCE OF MAIN MALARIA PARASITE VECTOR SPECIES AFTER AN INTENSIVE USE OF INSECTICIDE ON MALARIA VECTOR CONTROL IN MADAGASCAR

**Alice Zilera Suzanantsoa**<sup>1</sup>, Jacquelin Randriamihaja<sup>1</sup>, Maxime Ratovonjara<sup>1</sup>, Raharimanga Rakotoson<sup>1</sup>, Jocelyn Ratovonjato<sup>2</sup>, Arsène Ratsimbasoa<sup>1</sup>

<sup>1</sup>National Malaria Control Program, Antananarivo, Madagascar, <sup>2</sup>National Malaria Control Program Madagascar, Antananarivo, Madagascar

The detection of a high proportion of human blood meals in the vector population increases the risk of the spread of malaria parasite through the community. Since 2010, the National Malaria Control Programme of Madagascar has undertaken an intensive use of insecticides inside homes through the use of insecticide impregnated Nets or the indoor residual insecticide spraying. This study aimed to identify the origin of blood meals taken by the main malaria parasite vectors in Madagascar. Blood fed mosquito population tested were collected using pyrethrum spray catch technique conducted from 2010 to 2016 in 9 villages. All mosquito collected was morphologically identified and then abdomen of blood fed of vector species were crushed on a filter paper for blood meal analysis using a direct ELISA assay. Overall, 760 *Anopheles* blood fed were tested. Morphological identification showed that of 760 blood fed *Anopheles* vectors collected: 196 are *Anopheles funestus*, 548 *An. gambiae* s.l. and 15 *An. mascarensis*. The blood meal analysis revealed that 82.8% of *An. gambiae* s.l. fed on bovine and 7.7 % on human. However, 40.6% of blood meals from *An. funestus* were taken on human and 40.1% on bovine. As for blood meals of *An. mascarensis*, 20% were taken on human and 60% on bovine. Also, mixed blood meals (human and bovine) and blood meals from other domestic animals were identified. This study showed that *An. gambiae* s.l. and *An. mascarensis* are highly zoophilic, while *An. funestus* is both anthropophilic and zoophilic. The result of this study is one of important information needed for an effective vector control measures to be implemented in the country.

## 875

### INFLITE\*: A BEHAVIORAL SIMULATION PACKAGE FOR THE RAPID EVALUATION OF LLINS, CHEMISTRIES AND OTHER VECTOR CONTROL TOOLS (\*INDIVIDUAL FLYING INSECT TESTING ENVIRONMENT)

**Jeff Jones**<sup>1</sup>, Josephine E. Parker<sup>1</sup>, Natalia Angarita Jaimes<sup>2</sup>, Christian Kroner<sup>2</sup>, Vitaly Voloshin<sup>2</sup>, Catherine E. Towers<sup>2</sup>, David E. Towers<sup>2</sup>, Philip J. McCall<sup>1</sup>, Gregory P. Murray<sup>1</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>University of Warwick, Coventry, United Kingdom

Whether to combat insecticide resistance, exploit new knowledge of vector biology or to accommodate changes in abiotic conditions, disease vector control methods are under constant pressure to innovate, iterate and improve. Novel tools are constantly sought in order to increase cost-effectiveness and to improve community acceptance and sustainability of vector control programs. However, testing new tools is a highly risky, expensive and time-consuming process, facing numerous challenges and tasks ranging from the technical to the research ethics review process. Recent advancements in video-tracking and behavioral analysis research conducted by the authors, has enabled the accurate recording and quantification of multiple parameters associated with mosquito flight, host-seeking, resting and other behaviors. This enables the development of Individual (agent) Based Models operating at much finer spatial and temporal scales than was previously possible. The behavioral parameters of *Anopheles gambiae* and other mosquitoes interacting with bed nets during host-seeking have now been exploited to create a novel virtual testing simulation, allowing a wide range of innovative vector control ideas, both actual and theoretical, to be rapidly and easily assessed at marginal cost. The resulting model being presented here, represents an

easy to use computer software package, capable of simulating vector behavior. It allows the end user to compare, quantitatively and visually, alternative designs of vector control tools or systems, individually or in combination. The model parameters and validation presented are based on data collected during laboratory and field tests with *An. gambiae* and *An. arabiensis* interacting with different bed net designs, with or without human hosts. However, this *in silico* virtual testing model has been designed from the ground up to incorporate flexibility and ease of use to allow its adaptation for a wide range of control tools or vector families.

## 876

### SOCIAL-ECOLOGICAL FACTORS INFLUENCING RECEPTIVITY TO ZIKA VIRUS AND THE EFFICACY OF INTERVENTIONS IN COMMUNITIES ALONG THE TEXAS-MEXICO BORDER

Estelle M. Martin<sup>1</sup>, Monica Borucki<sup>2</sup>, Ismael Badillo-Vargas<sup>3</sup>, Rudy Bueno<sup>1</sup>, Matthew Medeiros<sup>4</sup>, Matthias Frank<sup>2</sup>, Gabriel L. Hamer<sup>1</sup>

<sup>1</sup>Texas A&M, College Station, TX, United States, <sup>2</sup>Lawrence Livermore National Laboratory, Livermore, CA, United States, <sup>3</sup>Texas A&M, Weslaco, TX, United States, <sup>4</sup>University of Hawaii, Oahu, HI, United States

The emergence and re-emergence of mosquito-borne diseases such as Zika, chikungunya and dengue fever remains a global public health challenge that threatens many communities in the continental United States. We are conducting studies along the Texas-Mexico border assessing the environmental receptivity to these mosquito borne viruses and evaluating different forms of vector control interventions. From September, 2016 to present, we have been gathering data on the abundance of the three primary mosquito vector species: *Aedes aegypti*, *Aedes albopictus*, and *Culex quinquefasciatus* in multiple communities that represent variable socio-economic conditions. We are using the CDC Sentinel Autocidal Gravid Ovitrap (SAGO traps) to estimate the relative abundance of vector species indoors and outdoors. The mosquito communities in these neighborhoods in South Texas are dominated by *Ae. aegypti* and *Cx. quinquefasciatus* with only a few *Ae. albopictus* specimens recorded. Our preliminary results show the mean number of female *Ae. aegypti* per SAGO trap per week to be  $0.3952 \pm 0.05742$  ( $n=377$ ) indoor and  $1.774 \pm 0.1262$  ( $n=384$ ) outdoor. The outdoor abundance of *Ae. aegypti* was higher in low income communities both indoor and outdoor. Ongoing surveys of the households with traps aims to identify risk factors for increased human-mosquito contact indoors. The testing of these mosquitoes for Zika virus has not revealed any positives although the pan-Flavivirus assays are documenting infection with insect-specific viruses. These baseline mosquito data are the foundation for a large-scale mosquito control intervention using CDC AGO traps that will begin in the summer of 2017.

## 877

### RESOLVING TEMPERATURE-DRIVEN MALARIA TRANSMISSION MODELS

Kerri Miazgowiec, Jack Owen, Temi Alandowa, Courtney Murdock

University of Georgia, Athens, GA, United States

Predicting current and future vector-borne disease (VBD) transmission is a significant challenge. While many factors influence VBD, recent work in a variety of transmission systems highlights the importance of climatic factors in shaping vector-borne disease transmission. In particular, temperature has strong effects on many aspects of mosquito biology involved in transmission including bite rate, mortality rate, fecundity, as well as, the rate of pathogen development within the mosquito vector. These trait by temperature relationships are non-linear, unimodal, and asymmetric. However, the resolution of these trait by temperature relationships is poor as few studies have investigated the variation in these life history traits across the full thermal breadth for a single mosquito species, or how age and temperature integrate to influence trait performance. Transmission models which incorporate these poorly

defined relationships with temperature and age can have significant impacts on disease risk predictions, the implementation of intervention strategies, and the evaluation of interventions. To address these gaps, we conducted a study which observed individual *Anopheles stephensi* mosquitoes, the primary malaria vector in India, across six temperature treatments (16°C, 20°C, 24°C, 28°C, 32°C, 36°C) over the duration of their lifespan. We provided a bloodmeal daily and directly measured bite rate, mortality rate, and fecundity for each individually-housed mosquito across our temperature treatments. Temperature effects were observed for each trait, with mosquito age affecting a subset of traits. We also observed interactions between temperature and age for some of these traits, suggesting that warming temperature can accelerate the effects of mosquito age on these traits. These data were used to parameterize a temperature-dependent R0 and compared to malaria models generated from coarser mix-species data. This study highlights that mosquito thermal performance is likely to vary with mosquito species, temperature, and age suggesting that current transmission models likely fail to capture important variation.

## 878

### SPATIAL PATTERNING AND FINE-SCALE HETEROGENEITY OF MALARIA RISK ALONG AN URBAN-RURAL CONTINUUM IN BLANTYRE, MALAWI

Nicole F. Dear<sup>1</sup>, Chifundo Kadangwe<sup>2</sup>, Themba Mzilahowa<sup>2</sup>, Andy Bauleni<sup>2</sup>, Don P. Mathanga<sup>2</sup>, Karl Seydel<sup>3</sup>, Terrie E. Taylor<sup>3</sup>, Edward D. Walker<sup>3</sup>, Mark L. Wilson<sup>1</sup>

<sup>1</sup>University of Michigan, Ann Arbor, MI, United States, <sup>2</sup>Malaria Alert Centre, University of Malawi College of Medicine, Blantyre, Malawi, <sup>3</sup>College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States

Malaria risk in urban and peri-urban environments is of increasing concern in highly-endemic settings undergoing urbanization. Understanding drivers of urban transmission is hampered by inconsistencies in how "urban" contexts are defined. A dichotomized "urban-rural" approach may misclassify environments or fail to capture fine-scale heterogeneity across time and space. We analyzed household-level *Anopheles* abundance patterns in and around Malawi's commercial capital of Blantyre (~1.1M pop.). Mosquito densities and distribution were measured inside houses using CDC light traps during rainy and dry seasons of 2015 and 2016. Clusters (N=64) of five houses each located at 2.5km intervals along eight transects radiating out from Blantyre city center were sampled. Multivariate mixed models for negative binomial distributions were used to evaluate abundances of *Anopheles funestus* (N= 3,367) and *An. arabiensis* (N= 1,177) separately. *Anopheles funestus* and *An. arabiensis* females were significantly more abundant in "rural" vs. "urban" Blantyre, as defined by governmental city boundary, increasing with distance from the urban center. Abundances were higher and more varied during rainy seasons. At the neighborhood level, lower elevation and lower household density significantly predicted higher *Anopheles* abundance. At the household level, peri-domestic agriculture, few rooms, few or no ITNs, and unscreened windows were significantly positively associated with *An. funestus* and *An. arabiensis* abundances. Among houses with peri-domestic agriculture, *Anopheles* were more abundant than among houses lacking crops, even after adjusting for potential confounders (e.g. house construction, nearby household density, elevation). Significant interactions of agriculture and unscreened windows with household density suggested that peri-domestic agriculture and house structure influence *Anopheles* abundance differently based on degree of urbanicity. A closer look at household- and peri-domestic-level factors should improve understanding and prevention of malaria transmission in urban and peri-urban settings such as Blantyre.

## THE LANDSCAPE OF METAGENOMES IN WILD POPULATIONS OF ANOPHELES GAMBIAE, AN. SINENSIS, AEDES ALBOPICTUS AND AE. AEGYPTI

Giannong Xu<sup>1</sup>, Dong Pei<sup>1</sup>, Jinjin Jiang<sup>1</sup>, Aditi Kulkarni<sup>1</sup>, Qing Xia<sup>1</sup>, Zebib Abraha<sup>1</sup>, Jesus Barba<sup>1</sup>, Wanqin Yu<sup>1</sup>, Yajun Ma<sup>2</sup>, Ruide Xue<sup>3</sup>, Mara Lawniczak<sup>4</sup>

<sup>1</sup>New Mexico State University, Las Cruces, NM, United States, <sup>2</sup>Second Military Medical University, Shanghai, China, <sup>3</sup>Anastasia Mosquito Control District, St. Augustine, FL, United States, <sup>4</sup>Sanger Institute, Hinxton, Cambridge, United Kingdom

Mosquito associated microbiome contributes to various life traits of host mosquitoes. 16S rDNA based profiling has revealed bacterial composition and community structure in major vector species. To further understand the microbial genetic repertoire and their functional impact on host physiology, we developed a pipeline to characterize microbiome using NGS shotgun sequencing data. Genomic DNA of wild caught mosquito specimens of *Anopheles sinensis* from Shandong, China, *Aedes albopictus* from Hainan, China and Florida, USA were sequenced using Illumina paired end platform. The clean sequence reads were mapped against corresponding mosquito genomes to separate mosquito reads from non-mosquito reads. Non-mosquito reads were *de novo* assembled into contigs. The contigs in size of 5kb-889.8kb were annotated. The taxonomic assignment was based on Blastn against available complete bacterial genomes. The functions of predicted genes were assigned using subsystems approach. The pipeline was also used for data mining from the Ag1000G project. Sequencing data from 150 *An. gambiae* individuals from Burkina Faso and 75 *An. gambiae* individuals from Gabon were analyzed. The assembled bacterial metagenome was 77.4Mb in *Ae. albopictus* from China, 16.7Mb in *Ae. albopictus* from Florida, 2.7Mb in *Ae. aegypti* from Florida, 4.1Mb in *An. sinensis* from China, 45.7Mb in *Ag. gambiae* from Burkina Faso and 9.4Mb in *Ag. gambiae* from Gabon. More than 100 genera/families were identified. Proteobacteria are predominant in the microbiome of all mosquito species, represented largely by taxa in Enterobacteriales. *Wolbachia pipientis* wAlbA and wAlbB strains were identified in *Ae. albopictus* from both Florida and China. The draft genomes of both *Wolbachia* strains was assembled. The *Wolbachia* contigs were present in *Ae. aegypti* from Florida, which is consistent with the report by Coon et al. that *Ae. aegypti* has natural infection of *Wolbachia* in the same region. Gene catalogues were compiled from the metagenomes. Characterization of fungal contigs is underway. The metagenome reference will facilitate to study interactions of mosquitoes and microbial symbionts.

## FIVE YEARS OF MALARIA PARASITE VECTOR SPECIES SURVEILLANCE IN MADAGASCAR

Raharimanga Rakotoson, Alice Zilera Suzanantsoa, Jacquelin Randriamihaja, Jocelyn Ratovonjato, Arsène Ratsimbaoa  
National Malaria Control Program, Antananarivo, Madagascar

Understanding the species composition of malaria parasite vector species is a component key for an effective malaria vector control in an endemic area. Since 2012 to 2016, an entomological survey was conducted in 10 sentinel sites belonging to different Malagasy malaria epidemiological "facies" by the entomological team of the National Malaria Control Program of Madagascar. Adult mosquito collection inside and outside homes was performed using human landing catch. Then collected mosquitoes were morphologically and molecularly identified. Results of the five years of entomological survey showed that 18 189 potential malaria vector species were collected: 21.8% *An. funestus*, 49.9% *An. arabiensis*, 13.6% *An.gambiae* s.s., 13.5% *An. mascarensis* and 1.2% *An. coustani*. The data collected revealed the changing on the behavior of *An. funestus* and *An. arabiensis*. Also, collected data demonstrated the spreading of *An. gambiae* s.s. to the high altitude of Central Highlands of Madagascar.

The results of the current entomological survey in Madagascar confirm the necessity of an intensive survey of the malaria vector species in an endemic country.

## MOSQUITO-MICROBE INTERACTIONS IN CONTAINER HABITATS: EFFECTS OF DETRITUS CONDITION ON MOSQUITO PRODUCTION AND MICROBIAL COMMUNITIES

Beth C. Norman<sup>1</sup>, Edward D. Walker<sup>2</sup>

<sup>1</sup>Michigan State University, East Lansing, MI, United States, <sup>2</sup>Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, United States

Many medically important mosquito species use natural or artificial containers as larval habitats. Factors controlling production of adult mosquitoes from these habitats are important to population dynamics of these disease vectors. Food webs in these habitats, forming the basis for larval growth and adult mosquito production, are driven by carbon and nutrient subsidies to tree holes, such as senesced plant parts, animal carcasses, or organic matter dissolved in stemflow water. These subsidies support the production of heterotrophic microbes which are consumed by mosquito larvae. Microbes colonizing detrital surfaces are an important component of the diets of *Aedes* species. Larvae have access to detritus in various stages of microbial conditioning, ranging from poorly conditioned, fresh detritus to detritus with well-established communities in later stages of development. Reciprocally, microbial communities in various stages of succession are exposed to larval predation. We simulated water-filled tree holes in the laboratory to explore the effects of poorly and well-conditioned detritus on *Aedes triseriatus* production and the reciprocal effects of larval predation on microbial communities. We used a 2 x 2 x 3 full factorial design with poorly or well-conditioned detritus, low or high detritus ration, and larval density as experimental factors. Detrital condition was an important driver of ration-density interactions. Larvae fed poorly conditioned leaves showed evidence of density-dependent resource limitation, with emerged female adults over 6x heavier in high ration, low density treatments than in low ration, high density treatments. Well-conditioned detritus alleviated this limitation: adult female mosquito mass was similar across density and ration treatments when larvae were provided well-conditioned leaves. Larval feeding affected bacterial and fungal communities differently, constraining bacterial diversity while promoting fungal diversity associated with the detritus. Overall, our results demonstrate that detrital conditioning affects mosquito production.

## THE PRESENCE OF CIBARIAL ARMATURE IN MOSQUITOES AND IMPACT ON THE TRANSMISSION OF LYMPHATIC FILARIASIS IN GHANA

Sellase A. Pi-Bansa<sup>1</sup>, Worlasi D. Kartey-Attipoe<sup>2</sup>, Joseph H. Osei<sup>2</sup>, Samuel Dadzie<sup>2</sup>, Benjamin Koudou<sup>3</sup>, Maxwell Appawu<sup>2</sup>, Michael D. Wilson<sup>2</sup>, Juerg Utzinger<sup>1</sup>, Dziedzorm K. de Souza<sup>2</sup>, Daniel A. Boakye<sup>2</sup>

<sup>1</sup>Swiss Tropical Institute for Public Health, Basel, Switzerland, <sup>2</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>3</sup>Liverpool Centre for Neglected Tropical Diseases, Liverpool, United Kingdom

The success of MDA programmes in eliminating LF depends on density dependent processes exhibited by existing and novel vectors. This may be attributed to role played by their cibarial armatures. This study investigated mosquito composition from Western and Upper East regions of Ghana, and vectorial competencies of mosquito species based on their cibarial armatures. Samples were collected from Mpohor, Ahanta West (AW), Kassena Nankana West (KNW) and Bongo districts with a total of 22,584, 4,784, 2,191 and 1,505 mosquitoes respectively. *An. gambiae* (25,548), *An. pharoensis* (54), *An. coustani* (22) *Aedes* (22), *Mansonia* (2,531) and *Culex* (2,807) were sampled from all districts. *An. coluzzii* and S form identification from subsamples of *An. gambiae* s.s revealed respectively:

Mpohor (125:60), AW (9:3), KNW (124:24) and Bongo (90:46). Observed teeth numbers for mounted mosquitoes was significantly different between *An. pharoensis/Culex*, *An. gambiae s.s./An. pharoensis*, *Culex/An. gambiae s.s.*, *An. melas/An. pharoensis*, *An. melas/Culex*, *An. arabiensis/Culex* ( $P<0.001$ ) and between *An. melas/An. gambiae s.s.*, *An. pharoensis/An. arabiensis* ( $P=0.001$ ) but not *An. arabiensis/An. gambiae s.s.* ( $P>0.05$ ) and *An. arabiensis/An. melas* ( $P=0.162$ ). *Aedes* and *Mansonia* had no cibarial teeth. Mean number of teeth was: *An. pharoensis* (21.00), *Culex* (25.69), *An. gambiae s.s.* (15.82), *An. melas* (13.25) and *An. arabiensis* (16.00). From Western and Upper East Regions, there was no significant differences in teeth numbers among *Culex* ( $P=0.079$ ) as in *An. gambiae* ( $P=0.726$ ). Cibarial teeth are sharp, pointed and long in *An. gambiae s.l.* though few in *An. melas*. However, it was less developed in *Culex* and absent in *Aedes/Mansonia*. *An. melas* was found only in AW district. Transmission of LF in Ghana might be due to few or no teeth seen in mosquito species coupled with their refractoriness. Where vectors, *An. melas* and *Mansonia* exhibit limitation, MDA must be complemented with vector control. *Culex* with less developed cibarial armature not being vectors in Ghana indicate other possible mechanisms preventing their capability to transmit LF in this area.

## 883

### IMMUNOMODULATORY ROLE OF ARYL-HYDROCARBON RECEPTOR IN *ANOPHELES GAMBIAE*

Aditi Kulkarni<sup>1</sup>, Jainder Chhilar, Wanqin Yu, Jiannong Xu  
New Mexico State University, Las Cruces, NM, United States

Mosquitoes have developed an efficient immune system during the evolutionary interactions with microbes, which includes Toll, Imd, JAK/STAT and RNAi pathways to defend against various microbial pathogens. The immune homeostasis is well maintained by different negative feedback mechanisms. In vertebrates, the aryl hydrocarbon receptor (AhR) pathway has been shown to operate xenobiotic detoxification and immunosuppression functions upon sensing endogenous and exogenous ligands. Upon activation, AhR is translocated into nucleus and transcribe genes for immune regulation or detoxification. In this study, we examined the role of mosquito AhR signaling in immune regulation. Kynurenine is an endogenous ligand of AhR, which is generated during tryptophan oxidation, mediated by tryptophan-2,3-dioxygenase (TDO) in mosquitoes. We used the TDO inhibitor 680C91 to reduce the production of kynurenine, which would decrease AhR activation. We also used two AhR antagonists, CH233191 and StemRegenin 1 (SR1), which inhibit AhR translocation and DNA binding. After feeding with these compounds for three days, the mosquitoes were challenged with a systemic infection by injection with a midgut bacterium *Serratia* sp. S1. The inhibition of AhR significantly increased the survival from 49.8% in the naïve control to 80.6% in the treated mosquitoes ( $P<0.01$ ). Furthermore, the interrogation of transcriptome of before and after infections in AhR manipulated mosquitoes revealed various genes that may be involved in AhR mediated immune regulation and xenobiotic metabolism. The data indicate that mosquito AhR may be a part of immune regulatory networks.

## 884

### INTERACTIVE VOICE BASED MOBILE PHONE TECHNOLOGY IN ANTENATAL AND INFANT MONITORING (AIM): A PROOF OF CONCEPT STUDY

Rajan Srinivasan<sup>1</sup>, Sharon Pandian<sup>1</sup>, Deapica Ravindran<sup>2</sup>, Sabari Rasan<sup>3</sup>, Venkat Raghava Mohan<sup>1</sup>, Ashok Jhunjhunwala<sup>4</sup>, Gagandeep Kang<sup>1</sup>

<sup>1</sup>Christian Medical College, Vellore, India, <sup>2</sup>Rural Technology Business Incubator, Chennai, India, <sup>3</sup>Uniphore Technologies, Chennai, India, <sup>4</sup>Indian Institute of Technology Madras, Chennai, India

Vaccine safety is integral to immunization program acceptance and success. Current Adverse Events Following Immunization (AEFI) reporting in India has been found suboptimal. With more than one billion

subscribers, mobile technology offers opportunities for mobile Health (mHealth) services overcoming literacy and geographical barriers. The automated interactive voice technology used in AIM provided antenatal and postnatal support and monitoring for 837 mothers (62% urban, 37% rural) through 130 interactive voice messages over 19 months (till the end of primary infant immunization) while capturing AEFIs directly from mothers. It also documented antenatal visits, Iron and Folic Acid (IFA) compliance, danger signs, high-risk mothers, maternal (Tetanus toxoid) and infant (Pentavalent) immunization and AEFIs at 24 hrs and 7 days post-immunization by converting verbal responses to data and sending alerts to health staff in real-time. Of the 837, 746 (89.1%) mothers completed the 19 month follow-up, 83% (619) reported timely antenatal visits and 5% (139) danger signs (reduced fetal movements, headaches and associated vomiting) while 10.6% (80) reported being diagnosed as hypertensive and 19% missed timely maternal immunization. AIM documented timely infant immunization as 86%, 72.8% and 56.8% for Penta 1, 2 and 3 respectively of 329 AEFIs reported 254 (77.2%) were validated to be true, of those reported all but 2 were non-serious. Few instances of wrong reports were due to voice data capture and data transfer, continuous modifications enabled the AIM system to capture a majority of data and its flexibility to choose time of message, changing registered phone numbers, re-listening health messages, speak to health supervisors, identified danger signs, immunization reminders while identifying those missing immunization schedules and confirming those reporting AEFI made it convenient, effective and acceptable. The AIM system was found to be an ideal to support antenatal and immunization program monitoring by grass-root level health workers, medical officers and program managers while capturing AEFI from mothers directly.

## 885

### STRENGTHENING CASE MANAGEMENT SKILLS OF FACILITY-BASED HEALTH PROVIDERS FOR THE MANAGEMENT OF CHILDHOOD DIARRHEA AND PNEUMONIA IN UTTAR PRADESH: KEY TO REDUCING UNDER-5 MORTALITY

Ashutosh Mishra<sup>1</sup>, Prince Bhandari<sup>1</sup>, Punit Kumar Mishra<sup>1</sup>, Animesh Rai<sup>1</sup>, Laura Lambert<sup>2</sup>, Lorine Pelly<sup>3</sup>, Maryanne Crockett<sup>3</sup>, John Kraemer<sup>4</sup>, Margaret Baker<sup>5</sup>

<sup>1</sup>RTI Global India Private Limited, New Delhi, India, <sup>2</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States, <sup>3</sup>University of Manitoba, Manitoba, MB, Canada, <sup>4</sup>Georgetown University, Washington, DC, United States, <sup>5</sup>RTI International, Washington, DC, United States

In India, diarrhea and pneumonia contribute to 12% and 23% of all under-5 deaths respectively. Most of these deaths are preventable with correct diagnoses and treatment. To inform an intervention focused on the appropriate management of childhood diarrhea and pneumonia, we conducted a survey to assess adherence of facility providers to World Health Organization guidelines for facility based integrated management of neonatal and childhood illnesses (F-IMNCI). We assessed 251 suspected diarrhea and 141 suspected pneumonia under-5 cases in 15 health facilities of Uttar Pradesh. While trained observers assessed provider skills, their knowledge was tested using case studies on diarrhea and pneumonia. Of 251 suspected diarrhea children, 101 were diagnosed with diarrhea, 1 with some and 3 with severe dehydration by the providers, and of 141 children with suspected pneumonia, 9 were diagnosed with pneumonia. While assessing adherence to F-IMNCI guidelines, observers concluded that providers asked about diarrhea in 16% of suspected diarrhea cases; 51% were asked about frequency; 38% about stool consistency; 29% about duration; 4% for blood in stools; and 28% were administered skin pinch test, to assess severity of dehydration. Of all suspected pneumonia cases, 26% were asked about cough; 13% about difficulty in breathing; 20% were assessed for chest in-drawing; and 9% each were assessed for fast breathing, peripheral and central cyanosis. Only 7 of the diagnosed diarrhea cases were recommended both ORS and zinc, while 4 of the diagnosed pneumonia cases were recommended Amoxicillin. None of the severe dehydration cases received intravenous drip. Mean score on diarrhea and pneumonia test was 1.6 (maximum

score: 11, SD:2.9) and 1.4 (maximum score: 14, SD:2.5) respectively. Fidelity to evidence based clinical practice was low with facility providers displaying low knowledge and practice skills for the diagnosis and management of childhood diarrhea and pneumonia. Future programs should promote the use of F-IMNCI based clinical algorithms to distinguish non-severe from severe illnesses and strengthen case management skills of facility providers.

## 886

### A SLAUGHTER OF THE INNOCENTS: PEDIATRIC MORTALITY AMONG BOER CIVILIANS IN SOUTH AFRICAN CONCENTRATION CAMPS, 1901-1902

David P. Adams<sup>1</sup>, Femi Taiwo<sup>1</sup>, Kali Neil<sup>2</sup>, Valerie Adams<sup>3</sup>, Joseph Miller<sup>3</sup>

<sup>1</sup>Point University, Savannah, GA, United States, <sup>2</sup>Baltimore County, Public Health, Baltimore, MD, United States, <sup>3</sup>Armstrong State University, Savannah, GA, United State

The Second Boer War began in the fall of 1899 and ended in the spring of 1902. (The first had been fought two decades earlier.) Utilizing guerrilla tactics, Boer forces fought a bloody and costly campaign—particularly for the British—that lasted roughly two and half years. By the end of hostilities in May 1902, the conflict had cost the British some £200000 and roughly 55,000 deaths and casualties—nearly the number of men who were killed or wounded on the first day of the Somme (July 1915) or total American dead during the Vietnam War a half-century later.

The British commander, Kitchener, countered the Boer tactics in a brutal attempt to subdue the Boer population, combatants or not. As farms smoldered in the wake of this scorched-earth strategy, however, thousands of Boer civilians were sent to British-run “concentration camps.” (Similarly squalid camps had been established by the Spanish during the 1890s in an attempt to quell a grassroots independence movement.)

Camp-based infectious diseases rates among children quickly skyrocketed due to chronic malnutrition and, most of all, an ongoing lack of proper sanitation and potable water. This presentation will offer an analysis of concentration camp mortality among children and adolescents between 1901 and 1902, focusing particular attention on the wide differences across more than 40 camps in which Boer civilians were held.

## 887

### INDIVIDUAL CONSENT PROCESS IN CLINICAL RESEARCH IN SUB-SAHARA AFRICA, BAMAKO, MALI

Youssouf Traore<sup>1</sup>, Fadima Cheick Haidara<sup>1</sup>, Fatoumata Diallo<sup>1</sup>, Flanon Coulibaly<sup>1</sup>, Moussa Doumbia<sup>1</sup>, Milagritos Tapia<sup>2</sup>, Karen Kotloff<sup>2</sup>, Samba O. Sow<sup>1</sup>

<sup>1</sup>Center for Vaccine Development, Mali, Bamako, Mali, <sup>2</sup>Center for Vaccine Development, University of Maryland Baltimore, Baltimore, MD, United States

Individual consent process is important to carried-out a vaccine trial in the world. This process should be understood by the study subjects to follow and complete all the study procedures. In Mali, only 33.5% of the population is literate, to facilitate understanding of the consent process, the center for vaccine development of Mali make a translation of the inform consent into the national language and records on the audiotape. Individual inform consent procedure and obtaining are carried out by a trained CVD-Mali doctor with mature adult parent or gardien with witness as needed and respecting confidentiality. For non-literate parent or participant we translate the consent form in local language and play on audio tape and use an impartial witness from the community. From 2003 to 2017 we have conducted 16 clinical studies at CVD-Mali and administered individual consent to 19842 participants aged from 9 months to 85 years old including pregnant women. Among them 18861 have been vaccinated 95%. The most common questions and comments

were made by participant parents or gardien. Understanding of certain participants in relation to the technical terms used during obtaining consent, vaccine test or trial, Antibody; Randomization; Placebo; Why should blood be taken before and after vaccination, some participants are impatient, which leads them to want to sign a consent form without understanding its content, signing a consent form would be an act that could have other intentions beyond the scope of clinical research such as prosecution this is why they often ask the investigator to sign in his place, the participants did not understand why a signature? Informed consent is a complex process and can be an element of protection for those involved in research studies. A good understanding of parents is a better partnership and may generate less anxiety for parents or investigators.

## 888

### CONDUCTING CLINICAL TRIALS IN CRISIS SETTINGS, 2012 MILITARY COUP IN MALI AND THE EBOLA VIRUS OUTBREAK IN 2014 IN WEST AFRICA

Flanon Coulibaly<sup>1</sup>, Fadima Cheick Haidara<sup>1</sup>, Fatoumata Diallo<sup>1</sup>, Moussa Doumbia<sup>1</sup>, Youssouf Traore<sup>1</sup>, Milagritos Tapia<sup>2</sup>, Karen Kotloff<sup>2</sup>, Samba O. Sow<sup>1</sup>

<sup>1</sup>Center for Vaccine Development, Mali, Bamako, Mali, <sup>2</sup>Center for Vaccine Development, University of Maryland Baltimore, Baltimore, MD, United States

Clinical research in epidemic, political and economic crises is a complex challenge in countries with limited resources including Mali. In a crisis, an experienced and pragmatic approach to implementing clinical trials is essential. Mali experienced a military coup and a counter coup in 2012 and the Ebola Outbreak in 2014. Challenges reported by investigators, field workers, community members and study participants were recorded in different study documents including individual case report forms and field registers. We have gathered and analyzed these challenges. During the period of military political crisis, following the curfew in Mali in 2012, the priority in conducting clinical trials was the safety of CVD Mali staff and participants, recruitment of participants and their follow-up at home. Obtaining community leaders commitment, training community relays on the protocol for adverse events and serious adverse events detection, involving clinics and health centers in the area for receiving and guiding participants, home visits where conditions could permit and the alternative of using mobile phones allowed CVD staff ethical concerns around research methods, and field operational challenges such as cold chain management and effective communication with those affected. During the 2014 Ebola Virus Disease outbreak caused panic in the general population, many rumors and negative attitudes towards health activities and Response Teams. The development of a strong communication plan focusing on positive behavior changes, Mobilization of community leaders, religious and traditions healers allowed the continuation of activities in accordance with the rules of ethics and to reassure the health workers and the general population. Clinical studies are difficult to perform and follow during crisis. Team spirit and performance of the staff in the conduct of clinical trials allow obtaining good results. However, researchers, sponsors and authorities must work together to better manage these crisis in order to achieve good results.

### COLLABORATION IS CRUCIAL; DELIVERING RESEARCH SKILLS TRAINING TO THOSE WHO NEED IT THE MOST

Liam Boggs, Alex Segrt, Tamzin Furtado, Amelie Julie, Trudie Lang

*The Global Health Network - University of Oxford, Oxford, United Kingdom*

Everyone working in global health research should have access to effective and appropriate research skills training and this is particularly important in resource-poor settings where the need for locally applicable research findings is so important. There are initiatives providing research skills

training in resource-poor settings; but the majority of this training is face to face, cannot be accessed widely enough and often focus on a specific protocol or disease area. The Global Health Network has collaborated with multiple organisations and institutions to share training materials and produce 24 high-quality, peer reviewed online training courses across a wide range of research topic areas which are free, easily accessible and available to all. Courses range from individual module short courses that can take up to 2 hours to complete to much more in-depth multi-module courses that can take anywhere up to 8 hours to complete. These courses are hosted within the Global Health Training Centre, which is a trusted and well-regarded centralised training hub within the Network, and each course is designed to be accessible from areas with low bandwidth internet connection, which can often be a barrier to accessing online training from resource-poor settings. By the end of March 2017, over 214,000 modules on the Training Centre had been taken by over 32,000 individuals. In 2016, on average 1644 modules were taken per week by an average of 226 individuals. This equates to an average of 32 individuals taking a course daily. Over 2500 individuals provided feedback on the courses they had taken and over 96% stated they would recommend the course to a friend or colleague. The majority of individuals accessing the courses are from Africa. There is a clear demand for free, easily accessible, high quality online research skills training. Increased collaboration and sharing of training materials between organisations and institutions is required to produce further online training resources to support research staff and develop capacity to conduct research in some of the world's poorest areas.

## 890

### APPLICATION OF EVENT-BASED SURVEILLANCE FOR EMERGING INFECTIOUS DISEASE PREPAREDNESS IN U.S. EUROPEAN COMMAND HEADQUARTERS

**Koya C. Allen**, Jennifer A. Steele

*U.S. European Command Headquarters, Stuttgart, Germany*

Event-based surveillance can be a reliable tool to fill gaps in surveillance information from traditional programs. For vector-borne diseases (VBD) and zoonoses, event-based surveillance permits monitoring of outbreaks, invasive vector species, reservoir hosts and imported disease cases. Collation of disparate information sources grants a comprehensive view of emerging VBD diseases and informs mitigation strategies in areas at risk. The US European Command (EUCOM) of the Department of Defense utilizes the Counter Biothreats Cell (CBC) for monitoring of infectious diseases of operational concern. The CBC conducts event-based biosurveillance in the EUCOM area of operation to mitigate risks associated with disease and ensure force health protection. By applying conceptual epidemiology principles for biopreparedness and bioresponsiveness, the CBC can discern disease trends, conduct rapid risk assessments and provide recommendations that inform decision-makers about potential risks and impacts of VBD emergence or outbreaks. Three examples of CBC assessments for diseases with differing epidemiological risk include Hantavirus, Crimean-Congo Hemorrhagic Fever (CCHF) and Zika virus. The CBC program successfully monitored the potential spread and impact of the Zika epidemic in 2015-16, emergence of CCHF in Western Europe and increased seasonal Hantavirus risk in Germany. Rapid analytics highlighted the timeliness and broad scope of biosurveillance when compared with traditional surveillance programs and allows for prompt information dissemination on prevention protocols and risk mitigation strategies. The CBC poses a unique opportunity to interpret disease surveillance data and determine operational impact. Biosurveillance programs can also provide documentation of risk likelihood for disease introduction and movement in lieu of traditional surveillance where resources are limited or overwhelmed. Application of surveillance information to military operations helps increase prevention efforts to ensure EUCOM is maintaining strategies for risk mitigation in disease movement.

## 891

### IMPACT OF COMMUNITY PERMISSION MEETING IN A LOW LITERACY SETTING IN SUB-SAHARAN AFRICA

**Fatoumata Diallo**<sup>1</sup>, Fadima Cheick Haidara<sup>2</sup>, Flanon Coulibaly<sup>2</sup>, Moussa Doumbia<sup>2</sup>, Youssouf Traore<sup>2</sup>, Adama Coulibaly<sup>2</sup>, Sekou Doumbia<sup>2</sup>, Milagritos Tapia<sup>3</sup>, Karen Kotloff<sup>3</sup>, Samba O. Sow<sup>1</sup>

*<sup>1</sup>Center for Vaccine Development-Mali, Bamako, Mali, <sup>2</sup>CVD-Mali, Bamako, Mali, <sup>3</sup>Center for Vaccine Development, University of Maryland Baltimore, Baltimore, MD, United States*

Clinical trials are recent activities in Malian culture. Community permission to implementation in research study search as epidemiological studies or vaccine trials in low income, low literacy settings (sub-Saharan Africa) play a key role in an understanding the study protocol in the study population. In developing countries like Mali where populations do not have much knowledge about vaccine research, community consent meeting is a prerequisite for the success of a research study. As an attempt to ensure an accurate understanding of the study risks and benefits, The National Translation Office translates the approved individual information consent and assent forms into the local languages and have it recorded on audiotapes. Community meetings are organized in collaboration with local religious and socio-cultural leaders and the community members. In addition to the public criers, invitations letters are distributed widely in the community. During the meeting, the audiotape is listened first by the audience; then the study investigators explain all study procedures, risks, benefits, and compensation. Community members are encouraged to ask questions. The community permission is obtained upon community satisfaction. The community permission allows to initiate and facilitate the process of individual informed consent/assent. From January 2006 to December 2017, we were able to observe the impact of community permission on screening in 10 clinical trials that CVD Mali has successfully conducted in the Malian communities, specifically in Bamako. A total of 25924 were registered among those 18094 were screening and 17163 were enrolled and vaccinated, with a retention rate of 94.9%. The success of a study depends on the degree of understanding of the community. For the population's comprehension of research studies, it is necessary to hold community permission meetings. Given the low literacy rate in the communities, it is important to develop strategies allowing them to better understand various aspects of the studies, and this can only be done by holding of community meetings before, during and after clinical studies.

## 892

### HIGHLIGHTING THE SUCCESSES AND CHALLENGES OF INTEGRATION OF SELF-CARE FOR PEOPLE AFFECTED BY FILARIAL LYMPHOEDEMA INTO EXISTING COMMUNITY LEPROSY SELF-HELP GROUPS IN NEPAL

**Hayley E. Mableson**<sup>1</sup>, Ramesh Choudhury<sup>2</sup>, Basu Dev Pandey<sup>3</sup>, Dambar Aley<sup>2</sup>, Hannah Betts<sup>1</sup>, Joseph Pryce<sup>4</sup>, Charles D. Mackenzie<sup>1</sup>, Louise A. Kelly-Hope<sup>1</sup>, Hugh Cross<sup>5</sup>

*<sup>1</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Nepal Leprosy Trust, Kathmandu, Nepal, <sup>3</sup>Department of Health Services, Ministry of Health, Kathmandu, Nepal, <sup>4</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>American Leprosy Missions, Greenville, SC, United States*

Lymphatic filariasis (LF) and leprosy are neglected tropical diseases endemic in Nepal. LF infection can lead to lymphoedema and hydrocele, while secondary effects of leprosy infection include impairments to hands, eyes and feet. The disabling effects of both conditions can be managed through self-care and the supportive effects of self-help groups (SHG). A network of SHGs exists for people affected by leprosy (PAL) in four districts in Nepal's Central Development Region, however no such service was available for people affected by LF (PALF). This study assessed the

success of integrating PALF into SHGs for PAL in this area, and documents challenges to achieving integration. A questionnaire was conducted pre-integration and six months post-integration with selected PALF and PAL to elicit information and changes on: (i) participant characteristics; disease burden; uptake of integrated services; (ii) participant knowledge of self-care for their condition; access to services; (iii) participant knowledge and perception of the alternate condition (PALFs' knowledge of leprosy and vice versa); attitudes towards integration. Community supervisors and SHG facilitators were interviewed to document experiences and improvements to integration. Comparison of 52 PALF and 53 PAL pre-integration showed that PAL had greater knowledge and practice of self-care compared to PALF ( $p < 0.001$ ). Perceived stigma of both PALF and PAL towards the other condition was high, but did not differ significantly between groups ( $p = 0.47$ ). Six months into the integrated programme, 18% of PALF surveyed reported joining a SHG, and 38% had received self-care training in a SHG. The stigma of both PAL and PALF towards the other condition reduced significantly ( $p < 0.005$ ), however stigma was reported by supervisors as a challenge. A lack of trust in the effectiveness of self-care by PALF was also cited as a reason for slow uptake of SHGs. Facilitators reported making home visits to PALF to encourage attendance, but also cited self-stigma of PALF as a challenge. Peer-support and community education were frequently suggested ways to improve uptake. Full results will be presented.

## 893

### DETERMINATION OF CAUSES OF DEATH IN STILLBORN BABIES AND NEONATES. VALIDITY OF A MINIMALLY INVASIVE AUTOPSY METHOD: AN OBSERVATIONAL STUDY

Clara Menéndez<sup>1</sup>, Paola Castillo<sup>2</sup>, Juan Carlos Hurtado<sup>2</sup>, Miguel J. Martínez<sup>2</sup>, Mamudo R. Ismail<sup>3</sup>, Carla Carrilho<sup>3</sup>, Khátia Munguambe<sup>4</sup>, Jaume Ordi<sup>2</sup>, Quique Bassat<sup>5</sup>

<sup>1</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhiça; CIBERESP, Barcelona, Spain, <sup>2</sup>Barcelona Institute for Global Health; Hospital Clínic de Barcelona, Barcelona, Spain, <sup>3</sup>Hospital Central de Maputo; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>4</sup>Centro de Investigação em Saúde de Manhiça; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>5</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhiça; ICREA, Barcelona, Spain

Over 5 million stillbirths and neonatal deaths occur annually. Limited and imprecise information on the cause of these deaths hampers progress in achieving global health targets. Complete diagnostic autopsies (CDA) -gold standard for cause of death determination-, are difficult to perform in most high burden settings. Therefore, validation of simpler and more feasible methods is needed. We aimed to compare the performance of a standardized minimally invasive autopsy (MIA) approach with the CDA in a series of stillbirths and neonatal deaths at Maputo Central Hospital in Mozambique. In this observational study the validity of a MIA in determining the cause of death was assessed in 18 stillbirths and 41 neonatal deaths by comparing the results of the MIA with those of the CDA. Concordance between the categories of diseases obtained by the two methods was assessed by the Kappa statistic and the sensitivity, specificity, positive and negative predictive values of the MIA diagnoses were calculated. A cause of death was identified in 89% and 83% stillborn babies in the CDA and the MIA, respectively. Fetal growth restriction accounted for 39%, infectious diseases for 22%, intrapartum hypoxia for 17% and intrauterine hypoxia for 11% of stillborn babies. Overall, the MIA showed in this group a substantial concordance with the CDA [Kappa=0.78, 95%CI (0.56, 0.99)]. A cause of death was identified in all (CDA) and 85% (MIA) of neonatal deaths. In this group, the majority of deaths were due to infectious diseases (66%). The overall concordance of the MIA with the CDA in neonates was moderate [Kappa=0.40, 95%CI (0.18, 0.63)]. A high percentage of accuracy was observed for the MIA in all the diagnostic categories in both stillbirths and neonates (>75%). The MIA could be a useful tool for cause of death determination in stillbirths and neonatal deaths. These findings may help to accelerate progress

towards meeting global health targets by obtaining more accurate information on the causes of death in these age groups, which is essential in guiding the design of new interventions and increasing the effectiveness of those already implemented.

## 894

### VALIDITY OF A MINIMALLY INVASIVE AUTOPSY TOOL FOR CAUSE OF DEATH DETERMINATION IN MATERNAL DEATHS FROM MOZAMBIQUE

Paola Castillo<sup>1</sup>, Juan Carlos Hurtado<sup>1</sup>, Miguel J. Martínez<sup>1</sup>, Mamudo R. Ismail<sup>2</sup>, Carla Carrilho<sup>2</sup>, Khátia Munguambe<sup>3</sup>, Quique Bassat<sup>4</sup>, Jaume Ordi<sup>1</sup>, Clara Menéndez<sup>5</sup>

<sup>1</sup>Barcelona Institute for Global Health; Hospital Clínic de Barcelona, Barcelona, Spain, <sup>2</sup>Hospital Central de Maputo; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>3</sup>Centro de Investigação em Saúde de Manhiça; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>4</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhiça; ICREA, Barcelona, Spain, <sup>5</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhiça; CIBERESP, Barcelona, Spain

Despite global health efforts to reduce maternal mortality, rates continue unacceptably high in large parts of the world. A reliable knowledge of the causes of maternal deaths is a condition to reduce them through adequate health planning. Accurate and feasible tools for cause of death determination are needed for decision-making on interventions to reduce this burden. The validity of a minimally invasive autopsy method (MIA) in determining the cause of death in 57 maternal deaths was assessed in an observational study by comparing the results of the MIA with those of the complete diagnostic autopsy (CDA). Concordance between the categories of diseases obtained by the two methods was assessed by the Kappa statistic and the sensitivity, specificity, positive and negative predictive values of the MIA diagnoses were calculated. Most deaths (82.5%) occurred postpartum. A cause of death was identified in the CDA in 98.2% (56/57) of cases, with indirect obstetric conditions accounting for 56.1% of deaths while direct obstetric complications accounted for 42.1% of deaths. Infectious diseases (68.8%) and obstetric hemorrhage (50.0%) were the commonest causes of death among indirect and direct obstetric conditions, respectively. The MIA identified the cause of death in 84.2% of cases. The overall concordance of the MIA with the CDA was moderate (Kappa= 0.521, p-value<0.0001) and both methods agreed in 70.2% of the diagnostic categories. The agreement was higher for indirect (90.6%) than for direct obstetric causes (41.7%). Thirty-six women were HIV-positive and HIV-related conditions accounted for 28% of deaths. Cerebral malaria accounted for 7% of deaths being all cases identified both in the CDA and the MIA. The MIA procedure could be a valuable tool to determine the cause of maternal deaths especially in those due to indirect obstetric conditions most of which are infectious diseases. This information is required for decision-making on health planning and prioritisation of interventions to reduce maternal mortality, and for monitoring progress towards achieving global health targets.

## 895

### UTILITY OF SPATIAL INTERPOLATION FOR GENERATING DHS INDICATORS AT SUB-NATIONAL ADMINISTRATIVE LEVELS

Clara R. Burgert-Brucker<sup>1</sup>, Peter Gething<sup>2</sup>

<sup>1</sup>The DHS Program, ICF, Rockville, MD, United States, <sup>2</sup>Oxford Big Data Institute, University of Oxford, Oxford, United Kingdom

Improved understanding of geographic variation and inequity in health status, wealth, and access to resources within countries is central to meeting sustainable development goals (SDGs). Furthermore, as national governments decentralize and policy decisions are made at the local level, there is a growing need to utilize existing data to accurately target, monitor, and evaluate the impact of programs in smaller geographic areas. The Demographic and Health Surveys (DHS) Program's spatially

interpolated maps for 15 standard development indicators contribute to this need of the development community without increasing survey sample size, cost, or time. This analysis used the Kenya 2014 DHS survey data to focus on the utility of these spatially interpolated map products in generating indicator estimates at lower sub-national administrative levels. The Kenya survey has a sampling density substantially higher than usual, which allows for directly estimating indicators at the county level. Multiple artificially thinned survey samples were created from the original sample to replicate a more traditional DHS sampling density. Geospatial modelling of the original sample and the artificially-thinned samples were used to generate new interpolated surfaces using conditional simulation to allow for county-level indicator estimates and uncertainty intervals. Systematic comparisons were performed on the county-level indicator estimate accuracy among the (1) full survey sample, (2) thinned survey samples, and (3) the final DHS report data estimate (gold standard). Results show that the geospatial methods perform well in predicting the “true” county-level estimate for many indicators. Variations in predictive ability depended on both specific indicators as well as density of sampled locations. This work contributes to a better understanding of the ability of spatial interpolation to estimate DHS indicators at sub-national administrative levels and also provides some basic guidance on how interpolation methods, as well as DHS surveys, can be adapted to improve modeling of development indicators.

### ASSESSMENT OF QUALITY INDICATORS OF INTENSIVE CARE UNIT IN A TERTIARY CARE HOSPITAL IN NORTH INDIA

**Neeru Sahni**, Kamlesh Kumari, Lakshmi Narayana Yaddanapudi  
*Postgraduate Institute of Medical Education and Research, Chandigarh, India*

Several countries have developed quality indicators (QI) for intensive care units (ICU) for the auditing the performance of ICU. The Indian Society of Critical Care Medicine identified QIs for ICUs in India to help them judge performance levels and compare with the national data base. Very common parameters mainly focusing on the outcome, process, infection, communication, human resource and safety were selected. We did an objective audit at Post graduate institute of medical education and research (PGIMER), a tertiary care academic centre in North India as per these parameters. After the approval of institute ethics committee (NK/2762/study/922), data was collected from May 2015 to October 2015. All the patients admitted to ICU were included which is a 12 bedded mixed ICU with a patient staff nurse ratio of 2:3. Out of total of 241 patients in ICU (129 males and 112 females) 36 patients were less than 18 years of age, 187 patients were between 19-65 years of age and 18 more than 65 years old. The average length of stay in ICU was 10.14 days and the average duration of mechanical ventilation was 8.63 days. The incidence of acute kidney injury was 11.2%. The incidence of iatrogenic pneumothorax was 12.4% and that of decubitus ulcer was also same. The incidence of patient falling off the bed was 0.40%. The reintubation rate was 7.14% and the readmission rate was 3.32. The incidence of medication error was 1.63. The incidence of ventilator-associated pneumonia was 14.43 per 1000 ventilator days and incidence of central line associated blood stream infection was 14.06 per 1000 catheter days. The incidence of catheter associated urinary tract infection was 3.96 per 1000 catheter days. A total of 38 patients died in six months and the observed mortality rate was 32.49. APACHE II within 24 hours of admission was recorded, 38 was the highest score and 5 minimum. 49 patients admitted to ICU had a 24 hour admission APACHE II score of 15. The formulation of set of parameters as QI for Indian ICUs is an attempt to judge performance of ICUs in resource constrained settings. Acceptability and utility of these parameters in the Indian scenario will have to be assessed over a period of time.

## 897

### HEALTH RISKS FROM EXPOSURE TO UNTREATED WASTEWATER USED FOR IRRIGATION IN THE MEZQUITAL VALLEY, MEXICO: A 25-YEAR UPDATE

**Jesse D. Contreras**<sup>1</sup>, Rafael Meza<sup>1</sup>, Christina Siebe<sup>2</sup>, Sandra Rodríguez-Dozal<sup>3</sup>, Miguel A. Silva-Magaña<sup>2</sup>, Nallely Vázquez-Salvador<sup>2</sup>, Yolanda A. López-Vidal<sup>2</sup>, Marisa Mazari-Hiriart<sup>2</sup>, Irma Rosas Pérez<sup>2</sup>, Horacio Riojas-Rodríguez<sup>3</sup>, Joseph N. Eisenberg<sup>1</sup>

<sup>1</sup>University of Michigan, Ann Arbor, MI, United States, <sup>2</sup>Universidad Nacional Autónoma de México, Mexico City, Mexico, <sup>3</sup>Instituto Nacional de Salud Pública, Cuernavaca, Mexico

Wastewater reuse for agriculture is a common practice worldwide. Wastewater treatment, however, is rare in many countries, leading to high possibility for exposure to harmful pathogens. The Mexico City-Mezquital Valley reuse system is one of the largest wastewater reuse systems worldwide and was the site of key epidemiologic studies on wastewater conducted in the 1990s. We conducted a cross-sectional study of diarrheal disease and wastewater contamination in the Mezquital Valley to provide an updated assessment of the health risks associated with wastewater and to inform an upcoming update of the 2006 World Health Organization guidelines on safe wastewater reuse. We surveyed 314 households among communities that use wastewater for irrigation and communities that irrigate with well water to compare the prevalence of self-reported diarrheal disease in children under five years old. Wastewater, well water, household environmental samples, and stool samples were collected and analyzed for the presence of potential pathogens. Communities exposed to wastewater had a higher one-week prevalence of diarrhea (10%) compared to unexposed communities (5%). This association remained in an adjusted modified Poisson regression model (PR = 2.31, 95% CI 1.00, 5.31), but the association was not as strong when limited to households engaged in agriculture. Water quality indicators document differences between irrigation water from the two community groups. While overall diarrheal prevalence has declined when compared to studies conducted over 25 years ago in the same region, the association between diarrheal disease and wastewater exposure has remained and possibly increased. With rising urbanization worldwide, attention to the health risks of wastewater reuse and the impact of treatment is becoming increasingly important.

## 898

### CONTRIBUTION OF THE CLINICAL INFORMATION TO THE MINIMALLY INVASIVE AUTOPSY IN DEATHS FROM SUB-SAHARAN AFRICA

**Carla Carrilho**<sup>1</sup>, Paola Castillo<sup>2</sup>, Juan Carlos Hurtado<sup>2</sup>, Miguel J. Martínez<sup>2</sup>, Mamudo R. Ismail<sup>1</sup>, Llorenç Quintó<sup>3</sup>, Khátia Munguambe<sup>4</sup>, Quique Bassat<sup>5</sup>, Clara Menéndez<sup>6</sup>, Jaume Ordi<sup>2</sup>

<sup>1</sup>Hospital Central de Maputo; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>2</sup>Barcelona Institute for Global Health; Hospital Clinic de Barcelona, Barcelona, Spain, <sup>3</sup>Barcelona Institute for Global Health, Barcelona, Spain, <sup>4</sup>Centro de Investigação em Saúde de Manhiça; Faculdade de Medicina da Universidade Eduardo Mondlane, Maputo, Mozambique, <sup>5</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhiça; ICREA, Barcelona, Spain, <sup>6</sup>Barcelona Institute for Global Health; Centro de Investigação em Saúde de Manhiça; CIBERESP, Barcelona, Spain

There is a need to refine the existing tools of cause of death attribution in low- and middle-income regions. The minimally invasive autopsy (MIA), a simple method based on needle sampling of key organs followed by histological and microbiological analysis has shown an acceptable performance for cause of death identification in all age groups in Mozambique, when compared with complete diagnostic autopsy (CDA). This study aims to determine whether the addition of clinical data can improve the performance of MIA. Coupled MIAs and CDAs, the latter

considered as the gold standard, were performed blindly to 264 deaths (112 adults, 57 maternal deaths, 54 children and 41 neonates) conducted in a referral hospital of Mozambique. Kappa value was used to compare the agreement between the gold standard and the MIA diagnosis blind to any clinical data and with MIA enriched by clinical information. The addition of clinical data improved the results of MIA in all age groups. The improvement was particularly high in maternal deaths (kappa value increasing from 0.521, moderate agreement, to 0.838, almost perfect agreement,  $p < 0.001$ ), in neonates (kappa value increasing from 0.404, moderate agreement, to 0.618, substantial agreement,  $p = 0.025$ ), and in adults (kappa value increasing from 0.732, substantial agreement, to 0.813, almost perfect agreement,  $p = 0.021$ ). The improvement was also evident in children (kappa value increase from 0.704, substantial agreement to 0.802, almost agreement), although did not reach statistical significance ( $p = 0.173$ ). The addition of clinical data to the pathological and microbiological analyses performed in the MIA significantly improves its diagnostic performance. The improvement is higher in the maternal deaths, neonates and other adults. Clinical data or, in its absence, verbal autopsy data may improve the cause of death diagnosis by minimally invasive autopsy.

## 899

### INFORMED CONSENT ISSUES IN CLINICAL TRIALS INVOLVING CHILDREN WITH MINOR PARENTS IN SUB-SAHARAN AFRICA: A SYSTEMATIC REVIEW

Angela Lazarova<sup>1</sup>, Domnita Oana Badarau<sup>2</sup>, Christian Burri<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland, University of Aston, Birmingham, United Kingdom

Before participating in clinical trials (CT), international guidelines recommend potential research subjects to provide a fully informed and voluntary consent. The validity of informed consent (IC) depends on a subject's legal competence and decision-making capacity (DMC). In CT involving children, IC has to be provided by legally acceptable representatives. Additionally, children can assent in accordance with their DMC (i.e. intellectual maturity). In certain cases, however, adolescents can be considered mature or emancipated and provide autonomous consent. Emancipation status is defined by statute or case law and may include pregnant or underage parents. International guidelines remain vague about these aspects or refer to national legislation. Large variability in handling this topic in different countries complicates the implementation of IC procedures. Challenges arise in CT conducted with children in sub-Saharan Africa (SSA) where a higher proportion of CT involves children compared to European countries. In SAA, the population under 24 years is almost twice as high as in Europe and the mean age of mothers at first birth is 20 versus nearly 29 in Europe. Considering these facts, it is probable for children involved in clinical research in SSA to have minor parents and, therefore, guidance on the determination of DMC and legal competence is needed. We are currently conducting a literature search following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement for evidence and appropriate solutions to this sensitive issue. The following databases: PubMed, Embase, Medline, and Google Scholar, will be mined to identify information about CT with child participants whose parents are minors and examine IC procedures and issues, child subject protection measures and ethical review. This study has the potential to contribute to an improvement in quality and efficiency of CT by laying the foundation for recommendations for guidance on clinical research conducted in children in resource-limited settings.

## 900

### USING MHEALTH TO PROMOTE HAND WASHING WITH SOAP: HOW DO TANZANIAN YOUTH PERCEIVE TEXT MESSAGE INTERVENTIONS FOR HAND HYGIENE?

Carolyn A. Henry

Schistosomiasis Control Initiative, Imperial College London, London, United Kingdom

Over 1 million deaths a year could be prevented if effective hand hygiene was practiced throughout the world. With the application of mobile technology in health, there are now new opportunities to trigger motive based behaviour change through a Text Message Intervention (TMI) to enable cost effective, efficient and repeatable interventions, delivered at an individual level. This study produced formative research describing the preferences of youth towards an intervention using text messages, to increase hand washing with soap in rural Tanzania. Three main areas were investigated: 1. the text content to optimise behaviour change to increase hand hygiene, 2. the acceptability of text messages for health promotion, and 3. the preferences on the communication style to convey health promotion messages. A cross-sectional sample design was used and both a self-administered survey and focus group discussions were undertaken in a sample of 60 youth (18-25 years) from Mbeya region. A comparison of proportions and analysed weighted rankings were used for statistical analysis. For qualitative data a Thematic Analysis approach was used. In the inductive phase of analysis, a coding framework enabled themes to emerge then the deductive phase aligned these with identified motives. The results showed that text messages is a popular method of communication with 91.7% of the study sample both sending and receiving texts. There was a 100% willingness to receive health promotion text messages and the optimum time to receive them was found to be directly before or after school/work hours. The themes that emerged from the study on preferred motives were safety, protection and comfort that drive this youth group to increase hand hygiene. The study found that the messages should be clear, specific and action based, adopting the preferred language of the target population rather than losing clarity to accommodate humour or story telling communication styles.

## 901

### DATA-DRIVEN DECISION-MAKING FOR MALARIA ELIMINATION IN NAMIBIA: DESIGN AND IMPLEMENTATION OF CUSTOMIZED DASHBOARDS IN DHIS2

Mwalenga Nghipumbwa<sup>1</sup>, Bradley Didier<sup>2</sup>, Deepa Pindolia<sup>2</sup>, Lakshmi Balachandran<sup>2</sup>, Laura Gast<sup>2</sup>, Rangarirai Matavire<sup>3</sup>, Petrina Uusiku<sup>1</sup>, Anne-Marie Nitschke<sup>1</sup>

<sup>1</sup>National Vector-Borne Diseases Control Programme, Windhoek, Namibia,

<sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>ITINORDIC, Oslo, Norway

While Namibia has reduced malaria incidence by 97% since 2004, its 2020 national elimination goal has required re-orientation of surveillance systems to rapidly identify areas of continuing transmission and make data-driven decisions about targeting interventions. Paper-based case-reporting forms were simplified and moved to the DHIS2 Tracker system in early 2017, allowing for real-time capture of and access to decision-critical information. The DHIS2 platform also serves as an integrated central database, collating case-based and aggregate data. The integrated electronic information system has allowed for the creation of customized dashboards for decision makers. Each dashboard provides overviews of malaria cases and deaths, socio-demographic profiles of cases, and case management performance at each level of the health system, based on user interest in surveillance data. Key informant interviews and interactive sessions with national, regional, district, and health facility users during surveillance trainings informed the dashboard designs. These sessions provided overviews of current data review and analyses, priorities for indicators, and visualization preferences. Further reviews of surveillance

data, users' technical capacity, and existing digital infrastructure contributed to the design process. At health facilities, the dashboard facilitates immediate corrective action in testing and case management, and to improve quality and timeliness of data reporting. District-level users may use the dashboard to identify underperforming facilities and guide case investigations. Senior managers and users at the National Vector-Borne Diseases Control Programme plan to use the dashboard to design targeted interventions and generate evidence for policy change. The dashboards are undergoing testing with select users at each level for feedback on ease of access, appropriateness of visuals and data, and use in decision making, with the intention of developing a culture of data use. They will be rolled out to all users in April 2017 and closely monitored for use and further feedback.

## 902

### UNDER-FIVE MORTALITY REPORTING FOLLOWING THE EBOLA VIRUS DISEASE EPIDEMIC — BOMBALI DISTRICT, SIERRA LEONE, 2015-2016

**Amanda Wilkinson<sup>1</sup>**, Nathaniel Houston-Suluk<sup>2</sup>, Alpha Kamara<sup>3</sup>, Umaru Kamara<sup>3</sup>, Mohamad F. Jalloh<sup>1</sup>, John Redd<sup>4</sup>, Sara Hersey<sup>4</sup>, Pratima L. Raghunathan<sup>1</sup>, Dianna M. Blau<sup>1</sup>, Brima Osaio-Kamara<sup>2</sup>, Amara Jambai<sup>2</sup>, Reinhard Kaiser<sup>4</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Ministry of Health and Sanitation, Freetown, Sierra Leone, <sup>3</sup>eHealth Africa, Freetown, Sierra Leone, <sup>4</sup>CDC, Freetown, Sierra Leone

Sierra Leone has an estimated under-five (U5) child mortality rate (120 per 1,000 live births) that ranks among the highest globally. National mortality surveillance and vital registration are limited. The 2014-2015 Ebola Virus Disease (EVD) epidemic response rapidly established death reporting mechanisms that have continued post-outbreak, including a community-based toll-free phone alert system. We assessed under-5 (U5) death reporting in Sierra Leone to prepare for implementation of Child Health and Mortality Prevention Surveillance (CHAMPS) - a network aimed at determining child mortality etiology to guide prevention. Documented U5 deaths between January 2015 and November 2016 were retrospectively reviewed in Bombali Seborra chiefdom, Bombali District, Sierra Leone. The catchment area included approximately 161,383 persons with 1,269 expected U5 deaths calculated from published estimates. Data were abstracted into Excel spreadsheets from three sources: records from eight health facilities, district vital records, and a phone alert system established during the EVD epidemic. Data sources were consolidated and de-duplicated. Overall, 930 unique U5 deaths (73% of expected) were documented. Data sources were minimally overlapping; 65% of deaths were reported by telephone alert only, 20% by health facilities only, 5% by vital records only, and 9% through >1 source. Reporting patterns changed over time. Documented deaths were 92% of expected in 2015, compared to 53% in 2016, and the proportion of cases reported by telephone alert declined from 81% to 65% from 2015-2016. Periods of incomplete and/or inconsistent documentation were evident in all sources. Health facilities and vital records incompletely captured U5 mortality in Bombali Seborra. The phone alert system captured community-based deaths not recorded through other sources and can be used to improve completeness of mortality surveillance in Bombali Seborra; however, strategies are needed to promote post-EVD community participation and ensure the sustainability of the phone alert system.

## 903

### A COMPARISON OF THREE STATISTICAL THRESHOLDS TO TRIGGER A PUBLIC HEALTH RESPONSE TO MONKEYPOX — DEMOCRATIC REPUBLIC OF THE CONGO, 2011-13

**Sarah Anne Guagliardo<sup>1</sup>**, Mary Reynolds<sup>1</sup>, Robert L. Shongo<sup>2</sup>, Okitolonda Wemakoy<sup>3</sup>, Andrea McCollum<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Ministry of Health, Kinshasa, Democratic Republic of the Congo,

<sup>3</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Endemic to the Democratic Republic of the Congo (DRC), monkeypox is a zoonotic disease that causes smallpox-like illness in humans. Observed fluctuations in the number of reported cases over time raises questions about when it is appropriate to mount a public health response, and what specific actions should be taken. Here, we evaluate three different thresholds to differentiate between baseline and heightened incidence of disease, and propose a tiered approach to public health action. Both suspected and confirmed monkeypox cases occurring in Tshuapa Province from 2011-13 were used to calculate three different statistical thresholds (Cullen, C-sum, and a World Health Organization method) based on monthly case counts. When the observed cases exceeded the threshold for a given month, that month was considered to be an 'aberrant' month. The number of aberrant months detected was summed by year for each approach. There was notable variation in the number of aberrant months for each method. The Cullen approach, based on the mean incidence + 2\*standard deviation, did not detect any aberrant signals over the period of consideration (0/36 months). The C-sum method, calculated as the ratio of past to present cases, was the most sensitive, resulting in 18/36 aberrant months. The WHO method, involving the upper 3rd quartile of data from past cases, resulted in 11/36 aberrant months. A single threshold for triggering public health action may be insufficient for monkeypox and other diseases that are endemic yet relatively rare. We propose instead that multiple thresholds be considered to allow responses of varying intensity: 1) an alert threshold prompting further investigation/intervention beyond routine surveillance, and 2) an epidemic threshold, which may entail contact tracing and community education.

## 904

### #GLOBALHEALTH ON TWITTER: ANALYSIS OF TWEETS ON #MALARIA, #HIV, #TB, #NCDS AND #NTDS

Isaac Chun-Hai Fung<sup>1</sup>, **Ashley M. Jackson<sup>1</sup>**, Jennifer O. Ahweyevu<sup>1</sup>, Jordan Grizzle<sup>1</sup>, Jingjing Yin<sup>1</sup>, Zion Tsz Ho Tse<sup>2</sup>, Hai Liang<sup>3</sup>, Juliet N. Sekandi<sup>2</sup>, King-Wa Fu<sup>4</sup>

<sup>1</sup>Georgia Southern University, Statesboro, GA, United States, <sup>2</sup>University of Georgia, Athens, GA, United States, <sup>3</sup>The Chinese University of Hong Kong, Hong Kong, Hong Kong, <sup>4</sup>University of Hong Kong, Hong Kong, Hong Kong

Social media enables users to connect globally and engage in conversations on global health issues. Global health advocates use the hashtag #GlobalHealth on Twitter to draw users' attention to prominent themes on global health, to harness their support, and to advocate for change. Through analyzing five subcorpora within a #GlobalHealth Twitter corpus, we aim to summarize the Twitter global health conversations pertinent to 5 high burden diseases or groups of diseases into 4 major themes. Tweets containing the hashtag #GlobalHealth (n=157,951) from January 1, 2014, to April 30, 2015 were purchased from GNIP Inc. We extracted 5 sub-corpora of tweets, each with one of the top 5 co-occurring disease-specific hashtags (#Malaria, #HIV, #TB, #NCDS, and #NTDS) for further analysis. Unsupervised machine learning (Latent Dirichlet Allocation) was applied to each sub-corpus to categorize the tweets by their underlying topics and obtain the representative tweets of each topic. The topics were grouped into 4 themes (advocacy; epidemiological information; prevention, control and treatment; societal impact) and miscellaneous. In the entire #GlobalHealth corpus (N=157,951), there were 40,266 unique users, 85,168 retweets, and 13,107 unique co-occurring hashtags. Of the 13087 tweets across the 5 subcorpora with co-occurring hashtag #malaria (n=3640), #HIV (n=3557), #NCDS (n=2373), #TB (n=1781) and #NTDS (n=1736), the most prevalent theme was prevention, control and treatment (4339, 33.16%), followed by advocacy (3706, 28.32%), epidemiological information (1803, 13.78%), and societal impact (1617, 12.36%). The rest were miscellaneous (1622, 12.39%). This study highlighted the specific #GlobalHealth Twitter conversation pertinent to malaria, HIV, tuberculosis, non-communicable diseases, and neglected tropical diseases. These

conversations reflect the priorities of advocates, funders, policy-makers and practitioners of global health on these high burden diseases as they presented their views and information on Twitter to their followers.

## 905

### USING NOVEL ESOURCE EDC SYSTEM FOR CLINICAL RESEARCH STUDY IN MULTIPLE COUNTRIES WITH LIMITED INTERNET CONNECTIVITY

**Katuscia O'Brian<sup>1</sup>**, Joshua Bogus<sup>1</sup>, Avik Pal<sup>2</sup>, Amy Rigney<sup>3</sup>, Yerramalli Subramaniam<sup>2</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>CliniOps, Inc., Fremont, CA, United States, <sup>3</sup>SPRI Clinical Trials, Pittsboro, NC, United States

A community-based mass drug administration study for filariasis required collection of drug safety data from some 24,000 participants in 4 countries. The electronic data collection system (EDC) needed to collect data securely (per ICH and CDASH standards) in resource-poor areas with limited internet availability. After evaluating multiple options, we selected an eSource system developed by CliniOps. eSource is a next generation electronic data capture approach where data is entered directly into a tablet via a mobile application ("App"). Electronic case report forms for the study were designed to ensure compliance with country regulations and industry standards and to be used by ground teams with varying levels of technology expertise. The CliniOps eSource technology allowed near real-time data visibility that allowed safety review and oversight by multiple stakeholders around the world. Over a period of five months, 165 users using 4 different languages entered data from approximately 190,000 visits for 24,000 participants generating more than 4,500,000 data points in a database with 3,000 variables. Data was synced regularly through a secured AWS cloud server either using 3G local Enterprise internet providers (DigiCel in Haiti; Airtail in India) or satellite wifi (IndoSat in Indonesia; Northern Axxess in PNG). Strengths included remote monitoring of data management, high quality data with edit checks and query management built into the system, real time data access for all participating groups, minimal paper, offline capability, and guided workflow based data collection, which minimized errors. Limitations are that the system requires at least intermittent wifi for syncing and a cost that is higher than REDCap. In summary, this eSource EDC system allowed supported data collection with real-time analytics and enhanced data quality. This leapfrogging of technology for data collection in research trials provided increased data quality and remote oversight in parts of the world previously considered to be off the beaten digital track.

## 906

### ETHICS OF PREVENTIVE CHEMOTHERAPY FOR NEGLECTED TROPICAL DISEASES

**David G. Addiss**

*Task Force for Global Health, Decatur, GA, United States*

Preventive chemotherapy (PC) - periodic single-dose drug treatment of all eligible persons in endemic areas regardless of individual infection status - is a key strategy to control or eliminate seven neglected tropical diseases (NTDs). The World Health Organization estimates that ~1 billion persons received PC for NTDs in 2015. Advocates regard PC as an ethical mandate to alleviate immense NTD-related suffering of neglected populations. Critics have raised ethical concerns around informed consent, safety of drug combinations, and lack of benefit for uninfected individuals. However, comprehensive, systematic analyses of the ethics of PC are lacking. I analyzed the ethics of PC using standard principles of bioethics (beneficence, non-maleficence, autonomy, justice), public health ethics principles (proportionality, reciprocity, least infringement, transparency), and the social justice approach of Bailey et al., which considers impact on 'clusters of disadvantage.' In general, PC programs provide massive benefits to disadvantaged populations, minimize maleficence, and adequately respect autonomy; they also serve to dismantle 'clusters

of disadvantage' and promote social justice. However, patterns vary. For example, community-directed treatment with ivermectin (CDTI) for onchocerciasis control likely provided greater autonomy to communities than do some global NTD programs currently focused on interrupting transmission. Factors affecting the ethical dimensions of PC include: the target NTD; the drug or drugs used; frequency and severity of adverse reactions (AEs); the degree to which PC benefits individuals with clinical disease; the intent or goal (control or elimination); evidence of effectiveness; and degree to which programs adhere to public health ethics principles. Further attention is warranted regarding consent for minors ('opt-in' vs. 'opt-out'); AE prevention; outcome measurement; ensuring that PC reaches those at highest risk; and the role of apology. Systematic ethical analyses can help inform global health policy and improve program adherence to ethical principles.

## 907

### FOLLOW-UP OF TRICHIASIS SURGEONS TRAINED ON THE HEAD START SURGICAL SIMULATION DEVICE IN NIGER: WERE SURGEONS ABLE TO MAINTAIN THEIR COMPETENCY ONE YEAR FOLLOWING THE TRAINING?

Mahamane Abdou<sup>1</sup>, Chano Hamiden<sup>1</sup>, **Hadiara R. Adamou<sup>2</sup>**, Stephanie L. Palmer<sup>3</sup>, Kadri Boubacar<sup>1</sup>, Tchouloum Toudja<sup>2</sup>, Josette Vignon<sup>2</sup>, Thierno Faye<sup>2</sup>, Abdou Amza<sup>1</sup>

<sup>1</sup>Programme National de Santé Oculaire, Ministère de la Santé Niger, Niamey, Niger, <sup>2</sup>Helen Keller International, Niamey, Niger, <sup>3</sup>Helen Keller International, New York, NY, United States

Trachoma is targeted for elimination as a public health problem by the year 2020. Providing quality surgical services for trichiasis (TT) patients is necessary to reach the elimination targets, and maintaining surgeons' skills of quality surgery is crucial. In Niger, a study was carried out from September 2015 to February 2016 to determine whether a surgical simulation device, HEAD START, can help experienced surgeons improve their skills. Twenty-three surgeons from the Maradi region took part in this study, 22 completed. Results indicated that a half-day training on HEAD START improved these surgeons' skills, particularly placing traction sutures, suture spacing and correct incisions. In January 2017, we re-evaluated these surgeons on the same skills to determine whether their competency had been maintained. Each surgeon operated on one TT patient under observation of a HEAD START trainer, who evaluated the surgeon on 11 skills on a scale of 1 (poor) to 5 (excellent). If the surgeon had a grade of  $\leq 3$  on one skill, the trainer provided refresher training on HEAD START for that skill; if the surgeon had a grade of  $\leq 3$  on 2 or more skills, then the trainer provided a complete refresher training on HEAD START. In the follow-up, 20 of the 22 surgeons were re-evaluated (two had moved). Nineteen of these surgeons had continued to operate TT patients; their output varied from 7 to 155 cases in the last year. Sixteen of the surgeons received grades of 3 or above on all skills and did not require further refresher training. In almost all skills, the mean composite change for all skills was -0.26 points; individually, all skills were slightly lower at follow-up. Individual surgeons lost a mean of 0.24 points from their score one year ago. There was no correlation between number of surgeries conducted over the past year and score at one year following the training. These results indicate that to maintain skills, ongoing training and supportive supervision is necessary.

## 908

### ACADEMIC HEALTH SYSTEM PARTNERSHIPS MOUNTCREST UNIVERSITY (GHANA), EASTERN REGIONAL HOSPITAL (GHANA) AND PENN STATE COLLEGE OF MEDICINE (USA)

**Parvathi Kumar<sup>1</sup>**, Haley Spagnola<sup>2</sup>, Micheal Malone<sup>3</sup>, Benjamin Frederick<sup>3</sup>

<sup>1</sup>Pennsylvania State Hershey Children's Hospital, Hershey, PA, United States, <sup>2</sup>Pennsylvania State Health St. Joseph Hospital, Reading, PA, United States

States, <sup>3</sup>Pennsylvania State Hershey Medical Center, Hershey, PA, United States

Founded in 2008 and accredited in 2011, Mountcrest University College (MCUC) is based in Accra, Ghana. MCUC signed a Memorandum of Understanding in July 2014 with the leadership at Penn State College of Medicine (PSCOM) based in Hershey, PA. This collaboration is aimed at opening doors of opportunity for the two campuses to collaborate and support one another as they train the next generation of physicians in their respective countries. The founders of MCUC value higher education and are establishing a new medical school in rural Larteh. This will be the first rural medical school in Ghana and will begin accepting students in September 2017. The multi institutional collaboration has 3 overlapping realms of interaction: an international health systems collaboration between MCUC, PSCOM and Eastern Regional Medical Center (ERMC, the academic center for training interns and residents); global health education for residents in training and medical students at PSCOM and ERMC; and global health research/innovation for faculty at MCUC, ERMC and MCUC. A multitude of endeavors have been initiated between the 3 institutions. Research efforts include external grant funding applications and groundwork to develop a Population Health Research Institute, quality improvement projects, and medical students' community health research projects. On an educational front, a simulation (sim) center at MCUC is being explored through a grant proposal at USAID's Office of American Schools and Hospitals Abroad (USAID/ASHA) to be managed by a MCUCU faculty who was hosted for a 6 month fellowship at PSCOM sim center. On a clinical front, medical students and residents in training at PSCOM (pediatrics, family medicine, med- peds) work in both the inpatient and outpatient clinics alongside residents in training at ERMC. This enhances their ability at maneuvering and adapting medicine learned in a resource abundant environment to work efficiently in a resource limited setting. Additionally the PSCOM residents enhance their fund of knowledge as it pertains to infectious diseases and illness not commonly encountered in central PA.

## 909

### REPORT FROM THE WORLD HEALTH ORGANIZATION'S ADVISORY COMMITTEES ON INNOVATIVE PERSONAL PROTECTIVE EQUIPMENT FOR FRONT LINE HEALTH WORKERS

**May Chu**<sup>1</sup>, Daniel Bausch<sup>2</sup>, Adriana Velazquez-Berumen<sup>2</sup>, Constanza Vallenaz<sup>2</sup>, Advisory Committees<sup>2</sup>

<sup>1</sup>Colorado School of Public Health, Aurora, CO, United States, <sup>2</sup>World Health Organization, Geneva, Switzerland

The West Africa epidemic of Ebola virus disease (EVD) resulted in 28,646 cases with 11,323 recorded fatalities. The World Health Organization (WHO) documented 815 confirmed and probable cases of Ebola amongst the frontline health workers (FHW). This estimate represents 21 to 32 times greater than the general adult population in the affected West African countries. Preliminary findings of a WHO report found it very difficult to identify the precise risk factors and situations in which FHW were infected. Protection of the health worker was paramount to ensure a safe and conducive working environment. The use of personal protective equipment (PPE), infection prevention control practices and environment and administrative engineering were critical to reduce Ebola infections. In hot, humid settings this was challenging with the use of a full cover PPE which allowed for an average wear time of 45 minutes. Problems with PPE were identified as the key likely contributor to acquiring EVD in FHW. WHO during the height of the Ebola epidemic, reviewed PPE standards, design, material and social acceptance in order to find science-based evidence and innovative ideas to overcome the problems with inconsistent guidance, types of PPE and training. There are no international standards for PPE that protect health workers in the frontline for Ebola and very few systematic designed studies to show PPE use and protection for the health worker. Since October 2014, WHO has convened 4 consultations and workshops and set up 4 Advisory Committees for Innovative PPE to

define the technical and preferred characteristics of PPE for the future. These characteristics would incorporate existing published evidence on PPE effectiveness, the technical specifications, innovative designs, new materials, test standards and cultural aspects to create a PPE for FHW treating high consequence pathogens like Ebola and other filoviruses. We will report on the deliberative process, findings and recommendations of the WHO Advisory Committees.

## 910

### DO PERFORMANCE-BASED MONETARY INCENTIVES FOR REFERRALS BY TRADITIONAL BIRTH ATTENDANTS INCREASE POSTNATAL CARE USE? EVIDENCE FROM A NIGERIAN FIELD EXPERIMENT

**Adanna Chukwuma**<sup>1</sup>, Chinyere Mbachu<sup>2</sup>, Margaret McConnell<sup>1</sup>, Thomas Bossert<sup>1</sup>, Jessica Cohen<sup>1</sup>

<sup>1</sup>Harvard T. H. Chan School of Public Health, Boston, MA, United States,

<sup>2</sup>University of Nigeria, Enugu, Nigeria

In Nigeria, only 16 percent of mothers who deliver outside facilities receive postnatal care within the 48 hours of delivery. These mothers have a higher risk of mortality from preventable delivery complications. Qualitative evaluations suggest that monetary incentives for performance may motivate referrals of mothers to skilled providers by traditional birth attendants or TBAs. Using data collected through a field experiment in Ebonyi State, Nigeria, this study estimates the impact of monetary incentives for referrals by TBAs to maternal postnatal care within 48 hours of delivery. We recruited 207 TBAs and conducted an individually randomized controlled trial between August and December 2016 in Ebonyi State, South-Eastern Nigeria. TBAs were randomly assigned with 50-50 probability either to receive \$2.00 for every maternal client that attended postnatal care within 48 hours of delivery (treatment group) or to receive no monetary incentive for referrals (control group). We found that the intervention increased the proportion of maternal clients that attended postnatal care within 48 hours of delivery by 15.4 percentage points, and the proportion of neonatal clients that attended postnatal care within 48 hours of delivery by 12.6 percentage points. However, surveys of mothers revealed that in many cases health care providers did not address the issues that may have led to postnatal complications during their consultations. To our knowledge, this is the first field experiment examining the impact of performance-based monetary incentives on referrals by TBAs for maternal and neonatal postnatal care attendance in Africa. We show that motivating TBAs using monetary incentives can increase postnatal care demand among their clients, who have a higher risk of maternal and neonatal complications because of their exposure to unskilled birth attendance. Policy aimed at improving postnatal care uptake using performance-based monetary incentives directed at TBAs should also address improvements in the quality of postnatal care provision so that increases in postnatal care demand can translate to maternal and neonatal health gains.

## 911

### INTEGRATION OF MALARIA ROUTINE AND SURVEILLANCE INFORMATION SYSTEMS IN MALI'S HEALTH MANAGEMENT INFORMATION SYSTEM: BEST PRACTICES AND LESSONS LEARNED

**Diadier A. Diallo**<sup>1</sup>, Edem K. Kossi<sup>1</sup>, Ignace Traore<sup>1</sup>, Issiaka Dembele<sup>1</sup>, Madina Konate<sup>2</sup>, Diakalidia Kone<sup>2</sup>, Jules Mihigo<sup>3</sup>, Aminata Traore<sup>1</sup>, Ramine Bahrambegi<sup>1</sup>, Jean-Marie N'Gbichi<sup>1</sup>, Erin Eckert<sup>2</sup>, Alimou M. Barry<sup>1</sup>, Yazoume Ye<sup>1</sup>

<sup>1</sup>U.S. Agency for International Development-funded MEASURE Evaluation, University of North Carolina, ICF and John Snow Inc., Chapel Hill, NC, United States, <sup>2</sup>National Malaria Control Program, Bamako, Mali, <sup>3</sup>United

States Agency for International Development/President's Malaria Initiative, Washington, DC, United States

Until 2010, the platform for Mali's health management information system (HMIS) was Microsoft Access. Due to several challenges with that platform, MEASURE Evaluation helped the National Malaria Control Program (NMCP) to develop and implement an application for routine malaria data reporting using mobile phones in selected regions. However, Mali's interest in an integrated HMIS that could better collect and analyze all health data for quick action, strategic planning, and policy development led the country to adoption of District Health Information Software 2 (DHIS 2). Integration of Mali's HMIS using DHIS 2 started in 2015. The process involved consensus building among national and international partners, development of a DHIS 2 implementation road map, and creation of a budget aligned with development partners. The system was developed in a participative manner with direct involvement of users. Implementation began with the revision of indicators and data collection tools, followed by development of data entry screens and dashboards, and finally, cascade training for users across the health pyramid. To date, the collaborative effort between MEASURE Evaluation and key stakeholders to integrate HMIS has achieved impressive milestones. All 65 districts and 90% of the 1,340 *centres de santé communautaire* (CSCoM) have been equipped with laptop computers and Internet access, and a few CSCoM are equipped with a power source. Additionally, all data managers and malaria focal persons have been trained to use DHIS 2. Successful rollout and deployment of DHIS 2 in Mali relied on oversight committees, good coordination, and trust among partners. The commitment of health facilities to support Internet fees and to use the system was also key. Among the challenges encountered were initial reluctance of national counterparts to switch to DHIS 2, coordinating heterogeneous partners, harmonization of data collection tools, and poor Internet coverage. Ultimately, integration on a web-based platform has empowered the NMCP, as it now has full access to its own data while benefiting from data from other programs.

## 912

### HOW RUMORS OF PLACENTA SELLERS LED TO THE DECLINE OF A MALARIA IN PREGNANCY TRIAL IN BENIN: AN ETHNOGRAPHIC STUDY

**Adelaide Compaore<sup>1</sup>**, Susan Dierickx<sup>2</sup>, Fatou Jaiteh<sup>3</sup>, Alain Nahum<sup>4</sup>, Umberto D'Alessandro<sup>3</sup>, Halidou Tinto<sup>1</sup>, Henk Schallig<sup>5</sup>, Koen P. Grietens<sup>6</sup>

<sup>1</sup>Clinical Research Unit of Nanoro, Institute for Research in Health Sciences, Ouagadougou, Burkina Faso, <sup>2</sup>Research Center on Gender, Diversity and Intersectionality (RHEA), Vrije Universiteit, Brussels, Belgium, <sup>3</sup>Medical Research Council Unit, Fajara, Gambia, <sup>4</sup>Centre de Recherches Entomologiques de Cotonou, Cotonou, Benin, <sup>5</sup>Department of Medical Microbiology, Academic Medical Centre, Amsterdam, Netherlands, <sup>6</sup>Medical Anthropology Unit, Department of Public Health, Institute of Tropical Medicine, Belgium, Antwerp, Belgium

A multi-country community-based trial on scheduled screening and treatment (SST) for malaria in pregnancy (MiP) was conducted in Benin, The Gambia and Burkina Faso. Despite similar design and procedures, trial participation proved to be problematic in Benin where the study became the subject of "rumours". Ethnographic research was carried out in Benin, Burkina Faso and the Gambia on the effectiveness of SST for MiP with a specific emphasis in Benin on factors leading to the deterioration of the trial. Data from group discussions, semi-structured interviews, and participant observation were triangulated and analyzed with NVivo 10 qualitative analysis software. After rumours started of placentas being sold by the trial research team, community members refused to participate or continue in the trial. In Benin, the placenta is considered sacred and is object of several rituals that aim at assuring the new-born's general well-being later on in life. Cultural conceptions on the placenta, however, were similar in all three trial countries and could therefore not be a sufficient condition to have generated trial refusal and drop-out rates. Instead, the

rumors were set in motion by a confluence of factors initiating after a trial-related adverse event and caused by the historical distrust in governmental organizations, socio-economic inequality, sociocultural beliefs in the sacred nature of the afterbirth, and challenges in communication during the informed consent procedures. An improved understanding of study participants' concerns and of historical and geo-political factors can be decisive for a trial's efficacy.

## 913

### ENHANCING CORE COMPETENCIES AND IMPROVING MIDWIFERY QUALITY OF CARE IN LAKE ZONE, TANZANIA

**Annamagreth Mukwenda<sup>1</sup>**, John George George<sup>1</sup>, Mary Rose Giatas<sup>1</sup>, Agrey Mbilinyi<sup>1</sup>, Gustav Moyo<sup>2</sup>, Justine Ngenda<sup>3</sup>

<sup>1</sup>Jhpiego, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Ministry of Health Community Development Gender Elderly and Children, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Mwanza Zonal Health Resource Center, Mwanza, United Republic of Tanzania

In sub-Saharan Africa, maternal mortality is unacceptably high accounting for 56% of all maternal deaths. Tanzania is not different. It is estimated that five in every 100 children die before their first birthdays and that four women out of 1000 live births die due to pregnancy related causes. With prompt recognition and timely intervention most maternal and neonatal deaths can be avoided. Access to skilled care at these critical times save lives. A new initiative is working to improve midwifery care by building capacity of training institutions to prepare highly skilled nurse-midwives to enhance on job live saving skills. In 2014 A collaboration between the Tanzania Ministry of Health, Jhpiego through Maternal child survival program (MCSP), conducted a baseline assessment to assess the quality of midwifery pre-service education to adequately prepare students with the clinical skills to provide competent nursing and midwifery care. Four nursing and midwifery schools from two regions of Lake Zone were assessed to identify issues affecting the schools' ability to produce clinically competent graduates in nursing and midwifery. Among things, the assessment focused on tutors and recent graduates, with findings showing critical deficit on content/skill competencies. To address these challenges, midwifery tutors from 9 schools (100%) were updated in high impact midwifery interventions through trainings and supportive supervision including coaching and mentorship. Skills labs were also equipped with all mannequins necessary for midwifery training. The program is in the third year of implementation with tremendous improvement in midwifery training as evidenced by students final examination results as well as tutors' and students' testimonies. Experience of MCSP approach to strengthen competencies of graduates has contributed to improve midwifery quality of care to reduce maternal deaths in Tanzania.

## 914

### CENTERS OF EXCELLENCE IN MONITORING AND EVALUATION: AN APPROACH TO IMPROVING DATA QUALITY FOR EFFECTIVE DECISION MAKING IN THE DEMOCRATIC REPUBLIC OF THE CONGO

**Johanna N. Karemere**

MEASURE Evaluation, UNC and ICF, Kinshasa, Democratic Republic of the Congo

Malaria remains a major public health problem in the Democratic Republic of the Congo (DRC). High-quality data are important to effectively allocate resources, measure achievement, and ultimately, improve malaria control efforts. Data quality, however, remains a challenge in health facilities. The USAID-funded MEASURE Evaluation project supported the Ministry of Health in DRC to set up centers of excellence (COE) to document best practices and improve data quality and use at the health facility level. The establishment of COE included selection of health facilities in targeted health zones, collection of baseline data, and training of providers in fundamentals of monitoring and evaluation (M&E). The training curriculum reviewed concepts related to health information systems and tools for

data collection and transmission. It also reviewed routine supervision and the implementation of data quality assessments. In the original four health facilities selected in 2015, healthcare workers were equipped with data-management tools for health information systems, and they received technical support through supervision visits. Preliminary assessment findings show that data analysis meetings are held regularly, data are validated by the COE team, dashboards are well displayed, and indicators are documented. The findings also indicate that data completeness and timeliness have improved. Data use, however, remains limited, so a data demand and use plan is under development, to increase engagement of healthcare workers. Among this approach's requirements are increasing M&E skills among healthcare workers, improving Internet connection, boosting technical support, and ensuring adequate funding. The COE model has now been scaled up to 22 health facilities, with a further expansion planned to all health facilities in the targeted health zones by 2018. COE are contributing to improvements in data quality and evidence-informed decision making to reduce malaria burden in the DRC.

## 915

### COVERAGE GAPS IN EARLY INITIATION OF BREASTFEEDING AMONG NEWBORNS, SUB-SAHARAN AFRICA, 2010 - 2015

Pavani Kalluri Ram<sup>1</sup>, Susan Niermeyer<sup>2</sup>, Lily Kak<sup>3</sup>

<sup>1</sup>University at Buffalo, Buffalo, NY, United States, <sup>2</sup>University of Colorado, Denver, CO, United States, <sup>3</sup>U.S. Agency for International Development, Washington, DC, United States

The neonatal mortality rate in sub-Saharan Africa is estimated at 28 deaths per 1000 live births. Early initiation of breastfeeding is associated with a reduced risk of newborn mortality. We examined data from recent Demographic and Health Surveys (DHS) in sub-Saharan Africa to evaluate early initiation of breastfeeding (breastfeeding within the first hour after birth), as reported by mothers of children < 5 years old. We assessed differences in early initiation of breastfeeding by delivery at home vs at a health facility. In sub-Saharan Africa, 31 countries conducted DHS during 2010 to 2015. Delivery of the neonate at health facilities was reported in greater than 50% of births in 26 of the 31 countries. The median prevalence of reported early breastfeeding was 53% (IQR 37% - 62%). The lowest reported prevalence (16.6%) was observed in Guinea and the highest (81%) in Rwanda. In Ethiopia, 90% of births during the 5 years preceding survey took place at home; no difference was observed in early breastfeeding based on place of birth (52% of births in facilities and at home). Home deliveries were reported in 63% of births in Nigeria; early breastfeeding was reported in a minority of births (29% of home births and 40% of facility births). The three countries with the highest reported prevalences of early breastfeeding (Namibia, 71%; Malawi, 77%; Rwanda, 81%) all had facility delivery rates exceeding 80%. However, other countries with > 80% of births occurring in health facilities had low - moderate prevalence of early breastfeeding (Congo, 24%; Gabon, 32%; Democratic Republic of Congo, 54%). Despite its importance for neonatal mortality and morbidity prevention, early initiation of breastfeeding is not being offered to sizable proportions of newborns in sub-Saharan Africa. Coverage gaps exist even among newborns born in health facilities in many countries, underscoring the pressing need to improve the quality of care during delivery and in the postnatal period in order to achieve the Sustainable Development goal target of reducing neonatal mortality to as low as 12 per 1,000 live births by 2030.

## 916

### READINESS OF PUBLIC HEALTH FACILITIES TO TREAT UNDER-5 DIARRHEA AND PNEUMONIA: OBSERVATION OF PRIMARY HEALTH CARE FACILITIES IN UTTAR PRADESH

Punit K. Mishra<sup>1</sup>, Prince Bhandari<sup>1</sup>, Ashutosh Mishra<sup>1</sup>, Animesh Rai<sup>1</sup>, Margaret Baker<sup>2</sup>

<sup>1</sup>RTI Global India Private Limited, New Delhi, India, <sup>2</sup>RTI International, Washington, DC, United States

Although the Integrated Management of Neonatal and Childhood Illness (IMNCI) strategy was introduced in India in 2005, in Uttar Pradesh, one of the states with high under-5 mortality rates, the number of children seeking care at government health facilities for pneumonia and diarrhea remains low. This indicates a strong need of improving the quality of care at lower-level public health facilities that may lead to better outcomes, including increased care seeking at government facilities and reduced under-5 mortality. We conducted a survey of 15 government block facilities with multiple different methods to assess the quality of care delivered to sick children: direct observation of the health provider's examination of the child; exit interview with the caregiver; inventory of equipment and supplies; a self-administered assessment of health providers' knowledge and attitudes; a follow-up interview at the sick child's home 15 days after the facility visit; and a follow-up telephone interview with the caregiver after 60 days since the facility visit for a subset of children. Though care seeking for diarrhea and pneumonia is high among the caregivers, majority of the cases end up consulting rural medical practitioners not the government block facilities. The basic equipment and supplies are available but not used at these facilities. The providers at the block level lack knowledge and assessment skills to manage childhood diarrhea and pneumonia. Treatment of severe cases at these facilities is poor with practically no inpatient admission.

## 917

### USING TASK SHIFTING TO EASE THE MENTAL HEALTH BURDEN OF NON-COMMUNICABLE DISEASES

Annie Njenga, Karthik Subbaraman, Albert Orwa

Philips Research Africa, Nairobi, Kenya

Depression is the leading cause of ill health and disability worldwide. According to the latest estimates from WHO more than 300 million people are now living with depression. However, robust mental healthcare is nearly non-existent in most emerging markets. Depression is often comorbid with other chronic diseases and can worsen their associated health outcomes. The largest treatment gap for mental disorders is found in sub-Saharan Africa where the ratio of psychiatrists to population is estimated at 1: 1 million. Even when they are available they are often expensive and there is a lot of stigma associated with seeking mental care. Yet depression and anxiety disorders can be chronic, severely impair quality of life, increase mortality and societal costs. In Kenya, mild-moderate depression rates in primary care have been estimated at between 11-42%. Evidence from large RCTs in primary care across low resource settings show that ordinary people with limited training on a specific form of cognitive behavioral therapy (CBT) - problem solving therapy (PST) can deliver effective therapy for people with common mental disorders. PST is universally applicable, avoids stigma and effective for a wide range of issues. CBT therapy via computer has also been shown to be as effective as regular face to face treatment with medication and increases access to care as anonymous access allows to circumvent stigma. Inuka (Swahili for "rise up") is an online coaching chat platform that is used to deliver PST through ordinary lay people trained as coaches. Preliminary testing of the Inuka prototype through interviews, online tests, focus group discussions and two pilots (n=13 and n=12) resulted in positive feedback that provided sufficient evidence to proceed with additional development. A pilot study aimed at assessing whether lay workers can be trained to provide counselling via chat and the associated clinical outcomes on clients is ongoing. These results will contribute to the evidence on whether

depression can effectively be managed by task-shifting in order to reduce the disease burden and disability and improve the overall health of populations.

## 918

### FROM NEW BIOMARKERS TO DIAGNOSTIC TOOLS FOR THE MANAGEMENT OF FEVER IN LOW- AND MIDDLE-INCOME COUNTRIES: AN OVERVIEW OF THE CHALLENGES

Camille Escadafal, Christian Nzansabana, Julie Archer, Violet Chihota, William Rodriguez, Sabine Dittrich

*FINN, Geneva, Switzerland*

During the past two decades, the incidence of malaria has been decreasing in low- and middle-income countries (LMICs) but acute febrile illnesses are still a major cause of mortality and morbidity. A lack of simple, cheap and rapid tests for febrile illnesses other than malaria is resulting in overtreatment with antibiotics for those who test negative for malaria, contributing to the global rise in antimicrobial resistance. New tests for the detection of host biomarkers provide promising tools to differentiate bacterial from non-bacterial infections in febrile patients. However, most biomarker tests are not designed for use in LMICs and do not exist in rapid test format. Moreover, very few evaluation studies have been performed in the overall non-severe febrile population of LMICs, resulting in poor knowledge on the performance of these biomarker tests in a context of high prevalence of infectious and poverty-related diseases such as malaria, HIV, malnutrition, intestinal parasites. To address the public health challenge of fever management in LMICs, it is important to view the problem holistically, with the goal of an approved test in mind. This review presents some of the many challenges faced during the process of getting to an approved test, including difficulties in selecting the most appropriate fever biomarkers, and suitable study design and sites for test evaluations; lack of reference tests available to evaluate the performance of new tests; lack of interest from *in vitro* diagnostic companies to invest in products with uncertain markets; and lack of clear national and international guidelines for regulatory pathways to introduce such tests. Understanding the difficulties on the product development pathway will enable partners working in this area to address them ahead of time and in collaboration with national and international stakeholders. Improved fever management will have direct impact on patient care but will also influence public and global health as well as outbreak response activities. Product development is a key piece of the puzzle.

## 919

### GIVES: A COLLABORATIVE EFFORT FOR GIS CAPACITY BUILDING IN VECTOR SURVEILLANCE

Dabney P. Evans<sup>1</sup>, Michelle C. Stanton<sup>2</sup>, Sophie Dunkley<sup>2</sup>, Andrew South<sup>2</sup>, Olivia C. Manders<sup>1</sup>, Lara S. Martin<sup>1</sup>, Rebecca S. Levine<sup>3</sup>, Michael Coleman<sup>2</sup>, Audrey Lenhart<sup>3</sup>

<sup>1</sup>Center for Humanitarian Emergencies, Atlanta, GA, United States,

<sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom,

<sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

The 2016 Zika virus outbreak highlighted challenges inherent in the surveillance and control of its primary vector, *Aedes aegypti*, particularly with respect to the use of Geographic Information Systems (GIS). The capacity to use GIS platforms for *Aedes aegypti* surveillance/control data greatly increases vector control program efficiency. To address these gaps, Emory University's Center for Humanitarian Emergencies, the Liverpool School of Tropical Medicine, and the Integrated Vector Management Team of the U.S. Centers for Disease Control and Prevention developed and implemented the Geographic Information for Vector Surveillance (GIveS) program. GIveS undertook a needs assessment of 37 countries in the Americas, determining individual learning needs and system capacity. Most countries had partially or fully functioning vector control systems; high-level map making skills were not present in the region. The GIveS curriculum is a five-day training utilizing free QGIS mapping software,

available in both Spanish/English. It introduces GIS concepts, guides participants on using tools from mapping basics through the creation of maps using their own spatial data. National/regional-level entomologists and key decision makers engaged in four GIveS workshops. Monitoring and evaluation activities consisted of pre/posttests, daily skills-based assessments, quantitative course evaluation, and two focus group discussions (FGD) per training. Key FGD themes included a perceived need for GIS mapping tools with real-time data; the need for data quality improvement and advanced training. By course-end, participants produced quality maps from their own vector surveillance data. Evaluation data will identify further learning needs and systemic challenges for improved vector surveillance.

## 920

### KNOWLEDGE IS POWER, BY INVESTING IN TRAINING WE ARE SECURING A STRONG AND POWERFUL NATION AND DEVELOPING FUTURE LEADERS

Teresa Eduarda Machai<sup>1</sup>, Nuria Casamitjana<sup>2</sup>

<sup>1</sup>Manhica Health Research Center, Maputo, Mozambique, <sup>2</sup>Institute for Global Health, Barcelona, Spain

The Manhica Health Research Center-“Centro de Investigação em Saúde da Manhica - CISM” aims to promote and conduct biomedical research in health priority areas to safeguard the health of the most vulnerable populations in Mozambique. CISM is located in Manhica Village, in southern Mozambique, approximately 80 km north Maputo province. The Village is located in the western margin of Inkomati River. Manhica district has a total area of 2,500 km<sup>2</sup> with near 178,000 people. Since the creation of the CISM in 1996, the training of researchers has been one of its strategic areas, while retaining talent has been a key aspect. The center invests in a training fellowship program, which has been one of the most successful training programs of the Centre in recent years. Based on this program, Mozambican and Southern African candidates with a licentiate or honours degree, with the potential to develop a professional career as researchers are trained in health-related areas. The program ensures that the participants acquire direct experience in research methodology focussed on research projects within the Centre and within the scope of post-graduate training at Master and/or PhD level at internationally recognized universities, and it allows the opportunity to participate in research stays at international universities, research centers and organisations. At the end of this program, researchers are prepared to apply for competitive grants at international level, therefore boost research capacity by the design and implementation of research projects. The training fellowship program contributes to scientific development and to the creation of a critical mass of personnel qualified to assume the management and leadership of research centers in Mozambique and around the world. The centre has trained almost 40 people, 15 of which are women. Almost all of these are now in management and leadership positions at the center or other institutions, such as dean of the school of medicine, national program directors, principal investigators; members of national scientific committees, or members of international boards.

## 921

### ECONOMIC COSTS AND BENEFITS OF MORBIDITY MANAGEMENT AND DISABILITY PREVENTION FOR LYMPHATIC FILARIASIS IN INDIA

Eileen Stillwaggon<sup>1</sup>, Larry Sawers<sup>2</sup>

<sup>1</sup>Gettysburg College, Gettysburg, PA, United States, <sup>2</sup>American University, Washington, DC, United States

Lymphatic filariasis afflicts 68 million people in 73 countries, with 17 million persons living with chronic lymphedema. The two objectives of the Global Programme to Eliminate Lymphatic Filariasis (GPELF) are to stop new infections and to prevent disability in persons already affected, but morbidity management and disability prevention (MMDP) programs have been initiated in only 24 endemic countries. India is the country

with the most people affected by lymphatic filariasis. We examined the economic costs and benefits of alleviating chronic lymphedema and its effects in India through a simple limb-care program at the community level that includes instruction in limb washing and provision of soap, topical antibiotics, and antifungals. Such a program can reduce ADL and slow progression of lymphedema, attenuating disability and productivity loss. Modeling costs and benefits of this community-based program in the Khurda district of Odisha state in India, we found that such a program would reduce economic costs of lymphedema and ADLA over the lifetimes of affected persons by 55%. Per-person savings are more than 130 times the per-person cost of the program. Building on the study in Khurda, we scaled up the analysis to the level of India as a whole. Most of the parameter values in the Khurda study are specific to that district. Scaling up the community-based program to all-India requires determining new values for the country as a whole, including average daily wage rates used to measure the opportunity cost of lost productivity, lifetime out-of-pocket medical costs for ADLA treatment, and lifetime costs for treatment of chronic lymphedema. The new study demonstrates the lifetime savings from simple limb-care management for reducing disability in all-India through community-based programs. This strengthens the economic rationale for MMDP, which has an ethical mandate as the second pillar of GPELF.

## 922

### USING SHORT MESSAGE SERVICE (SMS) TO REMIND PREGNANT WOMEN OF ANTENATAL APPOINTMENTS IN GUINEA

Rajeev Colaco<sup>1</sup>, Rebecca M. Flueckiger<sup>1</sup>, Molly Chen<sup>2</sup>

<sup>1</sup>RTI International, Washington, DC, United States, <sup>2</sup>RTI International, Durham, NC, United States

The Millennium Development Goals (MDG) 4 and 5 adopted in 2000 aim to reduce child mortality and improve maternal health. The targets for these aims are 1) the reduction of under-five mortality rate by two-thirds, 2) the reduction of maternal mortality by three quarters and 3) universal access to reproductive health. Great strides have been made towards reaching these goals. However, Sub-Saharan Africa continues to report the highest child and maternal mortality rates in the world. The World Health Organization (WHO) recommends four antenatal care (ANC) visits where women receive identification and management of complications, preventive treatment for malaria, identification and management of infection, information to promote the use of skilled attendance at birth and education on healthy behaviors postnatal. 82% of pregnant women in Guinea attend a minimum of one ANC visit while only 49% attend the recommended four visits. Increasing the percent of women attending four ANC visits will improve maternal and infant health in Guinea. The USAID/ Guinea StopPalu project will pilot test the use of short message service (SMS) using Frontline as an alerting system to remind patients of upcoming ANC appointments. RTI International will conduct a formative evaluation that aims to determine if pregnant women who receive SMS reminders are more likely to attend follow-up ANC appointments than those who do not receive SMS reminders and to determine the perception of receiving SMS reminders among patients and the cost benefit of using SMS reminder program. As a result of analyzing the StopPalu's intervention outcomes, RTI International proposed to integrate technology to accelerate the development outcomes of the project. The integration of technology into a project intervention is a new area that is being explored across USAID and other donor-funded projects as the rapid spread of mobile technologies to developing countries continues. The findings of this evaluation can serve as a base for similar project interventions.

## 923

### TIME SERIES ANALYSIS OF THE INTEGRATED DISEASE SURVEILLANCE AS AN INTEGRATED ACTIVITY IN THE DRC

Nicole A. Hoff<sup>1</sup>, Reena H. Doshi<sup>1</sup>, Brain Colwell<sup>2</sup>, Mathias Massoko<sup>3</sup>, Beniot Kebela-Ilunga<sup>3</sup>, Emile Okitolonda-Wemakoy<sup>4</sup>, Jean-Jacques Muyembe-Tamfum<sup>5</sup>, Anne W. Rimoin<sup>1</sup>

<sup>1</sup>University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, <sup>2</sup>Texas A&M, College Station, TX, United States, <sup>3</sup>Direction de lutte contre la maladie-Ministère de la santé Publique, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Kinshasa School of Public Health, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo

Classic disease surveillance programs have generally focused on a single disease or group of symptoms. More recently, national programs and organizations have worked to develop integrated platforms where information on multiple diseases and symptoms are collected in parallel to improve the quality of data, especially in limited resource areas. In the Democratic Republic of Congo (DRC), the Integrated Disease Surveillance and Response (IDSR) unit has been implemented to collect information on multiple diseases. Using polio as a case study, we studied existing passive surveillance and laboratory test confirmation data to explore the association between these two components of the integrated system. Using available case counts from the IDSR and lab data from the National Institute of Biomedical Research (INRB) from 2008 to 2013, we explored factors that could be associated with disease reporting. We performed a time series analysis to determine if there are trends in confirmed polio cases and reporting for passively reported diseases as a result of increased activities in zones after confirmation of a case. During the study period, confirmed polio cases in a health zone had a negative association with MPX, measles and tetanus reporting, but had a positive association with acute flaccid paralysis (AFP) reporting. Additionally, health zones with confirmed cases of MPX had a positive association with MPX reporting, but a negative association with AFP, measles and tetanus reporting. The IDSR was implemented to integrate disease identification and confirmation, and improve the overall detection of all reportable diseases. The analyses indicate that the specific individual disease components may currently only work to strengthen individual disease detection. Further research should be done to learn how the system could be better integrated for improved utilization of already limited resources.

Protein glycosylation is one of the largest and most diverse classes of post-translational modifications (PTM). Of these modifications, O-fucosylation represents a relatively small but important glycosylation modality that plays a role in protein trafficking, cell movement/adhesion, and protein secretion. In Eukaryotes, the enzyme O-fucosyltransferase 2 (PoFUT2) is responsible for the specific O-fucosylation of a serine/threonine residue on thrombospondin type I repeat (TSR) protein domains. The TSR domains of several key proteins of the malarial parasite facilitate attachment to mammalian and mosquito host cells, and it was recently shown that *Plasmodium* sporozoite surface proteins containing TSR domains are

fucosylated. We hypothesize that *Plasmodium* modifies these domains via the putatively identified parasite PoFUT2 homolog and that this PTM influences ookinete and sporozoite invasion of mosquito and human host cells. We describe biochemically the activity of PfPoFUT2 in modifying TSR-domain containing proteins, such as the circumsporozoite protein (CSP), and evaluate its biological significance during parasite transmission through the mosquito. We characterized by mass spectrometry (MS) the TSR domain of CSP, as well as full length CSP, and show that both can be fucosylated by human and *Plasmodium* PoFUT2 enzymes. We generated a PoFUT2 null mutant of *P. falciparum* and *P. berghei* and compared the growth and survival of parasites throughout the life cycle. We observed that the PoFUT2 null mutant is viable, without any notable defects during development in blood-stage culture and mosquitoes; but *P. falciparum* salivary gland sporozoites are compromised in their motility in the null mutant compared to wild-type, potentially affecting hepatocyte invasion. Our MS data indicate that CSP lacks this fucose residue in the PoFUT2 null mutant sporozoites. We further compared introduction of null-mutant and wild-type sporozoites to mice by IV inoculation and mosquito bite by monitoring liver and blood stage infection. Finally, we examined the immunogenicity of O-fucosylation on full length PfCSP in mouse immunization studies.

## 925

### ANALYSIS PIPELINE FOR PFEMP1S IN PARASITES ISOLATED FROM CHILDREN PRESENTING WITH MALARIA

Patricia A. Gonzales Hurtado<sup>1</sup>, Robert Morrison<sup>1</sup>, Jose Ribeiro<sup>2</sup>, Alassane Dicko<sup>3</sup>, Patrick Duffy<sup>1</sup>, Michal Fried<sup>1</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>2</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>3</sup>Malaria Research and Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Science Techniques and Technologies of Bamako, Bamako, Mali

One of the major challenges in *Plasmodium falciparum* proteomics studies is identifying PfEMP1s at the protein level due to antigenic variation. To overcome this technical limitation, we developed a pipeline that combines high resolution mass spectrometry with bioinformatics tools including RNAseq on a subset of parasite isolates, *de novo* sequencing of proteins and sequence alignment to identify PfEMP1 expressed by clinical parasite isolates. Parasites from thirty-five *P. falciparum* infected Malian children were grown in culture for 14 to 20 hours in culture, membrane proteins were extracted and electrophoresed followed by in-gel digestion with trypsin. Peptides were analyzed by LC-MS/MS using the LTQ Orbitrap Velos. Acquired spectra were analyzed with PEAKS Studio using a combined database which includes RNAseq constructs. The peptides were then analyzed with the in-house Local Peptide Alignment (LAX) algorithm to match to a protein. The PfEMP1-matched peptides were placed in matrices to understand the relationship amongst the PfEMP1 protein matches. Peptides were then assigned to PfEMP1s with the most coverage and highest match score. Using this strategy, we doubled the total number of peptides that can be assigned to PfEMP1s. We will present the analysis pipeline for PfEMP1 proteins.

## 926

### SEEKING CARE AT A DRUG SHOP AS THE INITIAL RESPONSE TO ILLNESS WAS A RISK FACTOR FOR SEVERE MALARIA IN UGANDAN CHILDREN

Arthur Mpimbaza<sup>1</sup>, Grace Ndeez<sup>2</sup>, Anne Katahoire<sup>1</sup>, Philip J. Rosenthal<sup>3</sup>, Charles Karamagi<sup>2</sup>

<sup>1</sup>Child Health and Development Centre, Makerere University, College of Health Sciences, Kampala, Uganda, <sup>2</sup>Department of Paediatrics and Child Health, Makerere University, College of Health Sciences, Kampala,

Uganda, <sup>3</sup>Department of Medicine, University of California San Francisco, California, CA, United States

We studied associations between delayed care seeking, demographic, socioeconomic and geographic factors, and risk of severe malaria in Ugandan children. A case-control study was based at Jinja Hospital, Uganda. We enrolled 325 severe malaria cases and 325 uncomplicated malaria controls matched by age and residence. Patient details, an itinerary of events in response to illness, household information and location of participants' residences were captured. Conditional logistic regression was used to determine risk factors for severe malaria and delayed care seeking. Delayed care seeking (> 24 hours after fever onset; OR 5.88; 95%CI 2.75, 12.5), seeking care at a drug shop as the initial response to illness (OR 3.37; 95% CI 1.66, 6.83) and increasing distance from place of residence to the nearest health center (OR 1.52; 95% CI 1.21, 1.91) were independent risk factors for severe malaria. On sub-group analysis, delayed care seeking was a significant risk factor in children with severe malaria attributable to severe anemia (OR 11.5; 95%CI 2.78, 48.2), but not unconsciousness (OR 1.12; 95%CI 0.29, 4.19). Seeking care at a drug shop (OR 3.85, 95% CI 1.19, 12.3) and increasing distance to the nearest health center (OR 1.93, 95%CI 1.21, 3.08) were independent risk factors for delayed care seeking. Delayed care seeking and seeking care at a drug shop were risk factors for severe malaria. Seeking care at a drug shop was also a predictor of delayed care seeking. The role of drug shops in contributing to delayed care and risk of severe malaria requires further study.

## 927

### ALTERED GUT MICROBIOTA COMPOSITION IN PLASMODIUM FALCIPARUM PATIENTS IN UGANDA

Tomoyo Taniguchi<sup>1</sup>, Eiji Miyauchi<sup>2</sup>, Alex Olia<sup>1</sup>, Eiji Nagayasu<sup>3</sup>, Katuru Osbert<sup>4</sup>, Kazutomo Suzue<sup>1</sup>, Takashi Imai<sup>1</sup>, Chikako Shimokawa<sup>1</sup>, Risa Onishi<sup>1</sup>, Emmanuel I. <sup>1</sup>Gunma University, Maebashi, Japan, <sup>2</sup>RIKEN Center for Integrative Medical Sciences, Yokohama, Japan, <sup>3</sup>University of Miyazaki, Miyazaki, Japan, <sup>4</sup>Gulu University, Gulu, Uganda, <sup>5</sup>Osaka University, Suita, Japan, <sup>6</sup>Juntendo University, Tokyo, Japan

Malaria caused by protozoa of the genus *Plasmodium* is the most prevalent infectious disease in tropical and subtropical regions. Gastrointestinal symptoms such as abdominal pain, vomiting and diarrhea are frequently observed in malaria patients in addition to the malarial triad of fever, anemia, and splenomegaly. However, the association between intestinal microbiota and malaria pathology is poorly understood. We previously reported that mice infected with *P. berghei* ANKA suffer from intestinal pathology associated with remarkable changes in microbiota. In this study, we investigated the influence of falciparum malaria on microbiota in Ugandan patients. We collected stool samples from *P. falciparum* patients who were recruited from outpatients and inpatients in hospital during illness and convalescence. 16S rRNA metagenome analyses of stool samples revealed that patients have a different microbiota composition compared with healthy children, and the recovery from infection leads to different changes in gut microbiota composition between inpatients and outpatients. We also found that fecal microbiota of Ugandan children could be clustered into two enterotypes, *Bacteroides*/*UC\_Lachnospiraceae* and *Prevotella*, and the main changes in microbiota structure during illness was associated with a shift in enterotypes. Further investigations of the relationship between intestinal microbiota and malarial pathogenesis will add to our understanding of the mechanisms involved in intestinal pathology in malaria patients.

928

### PYGM75, A PROTEIN IN OSMIOPHILIC BODIES, IS DISPENSABLE FOR EGRESS OF MALE GAMETOCYTES BUT IMPORTANT FOR EXFLAGELLATION OF MICROGAMETES

Mayumi Tachibana<sup>1</sup>, Motomi Torii<sup>1</sup>, Takafumi Tsuboi<sup>2</sup>, Tomoko Ishino<sup>1</sup>

<sup>1</sup>Ehime university, Toon, Japan, <sup>2</sup>Ehime university, Matsuyama, Japan

*Plasmodium* transmission via mosquitoes requires sexual stage parasite development and fertilization in mosquito midguts. Once gametocytes are taken up by mosquitoes, gametogenesis is initiated by the temperature shift and chemical factors in mosquito midguts. Parasite egress from erythrocytes is one of the essential steps during gametogenesis, which requires lysis of parasitophorous vacuole membrane (PVM) and erythrocytic membrane (EM). Gametocytes retain unique vesicle structure, named osmiophilic body (OB), which contains several secretory proteins such as GEST, MDV1/Peg3, involved in PVM break down. Previously, we identified a novel male specific OB protein PyGM75 required for the transmission in *Plasmodium yoelii*. Here, we examined in which steps, PyGM75 has an important role during transmission by using *pygm75* gene disrupted parasites. To demonstrate whether PyGM75 is involved in egress of male gametocytes, *pygm75* disrupted gametocytes were activated to initiate gametogenesis for 15 min, and then incubated with  $\alpha$ tubulin antibodies and TER-119 antibodies to stain male parasites surrounding EM. Approximately 70% of *pygm75* disrupted male parasites did not retain the EM, which was comparable to wild type. In addition to EM breakdown, loss of PVM was observed by electron microscopy. On the other hand, although axoneme were formed in *pygm75* disrupted male parasites, release of flagella was affected. These results indicate that PyGM75 is dispensable for parasite egress from erythrocytes and flagella formation, but it plays a role in the process of exflagellation.

929

### DEVELOPMENT OF RELIABLE MOSQUITO INFECTIONS WITH NON-3D7 PLASMODIUM FALCIPARUM STRAINS FOR HETEROLOGOUS CONTROLLED HUMAN MALARIA INFECTION (CHMI)

Tatyana Savransky<sup>1</sup>, J. Kathleen Moch<sup>1</sup>, Megan Dowler<sup>1</sup>, Lucia Gerena<sup>1</sup>, Hoseah Akala<sup>2</sup>, Edwin Kamau<sup>3</sup>, Paul Howell<sup>4</sup>, Jorge Lopez<sup>1</sup>, Norman Waters<sup>1</sup>, Lindsey Garver<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>United States Army Medical Research Unit, Kenya, Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>United States Army Medical Research Unit--Kenya, Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Since 1985, the Walter Reed Army Institute of Research has produced *Plasmodium falciparum*-infected mosquitoes for use in clinical trials to evaluate anti-malarial vaccines, drugs, and immunity. The vast majority of those > 110 experimental malaria challenges used Pf3D7 and its parent strain, PfnF54, but the recent progression of candidate anti-malarial products has necessitated development of *P. falciparum* strains that are heterologous to Pf3D7. However, attaining strains that are culture-adapted and produce reliable, robust sporozoite infections in mosquitoes is difficult and laborious. Here, we describe the optimization of an existing clonal strain (Pf7G8) from Brazil and the development of new strains from Kenyan clinical isolates. For Pf7G8, we used parallel membrane feeding assays to evaluate the ability of three different *Anopheles* species to sustain CHMI-worthy sporozoite infections. These species differentially give low, medium, and high infection rates, indicating the vector species is a primary determinate of Pf7G8 success. For development of new strains, we received clonal parasite lines derived from parasitemic patient collections at hospitals or centers within the USAMRU-K Surveillance Network. We processed these lines for adaptation to our blood-stage culture methods, optimization for gametocyte production, and ability to

infect mosquitoes. We are currently evaluating CHMI suitability of 4 lines that were prioritized based on circumsporozoite protein (CSP) sequencing data; over 30 additional lines could be subsequently evaluated.

930

### FUNCTIONAL CHARACTERIZATION OF A PUTATIVE SEX SPECIFIC BIOMARKER IN PLASMODIUM FALCIPARUM

Zavana Schmit<sup>1</sup>, Garima Verma<sup>1</sup>, Krithika Rajaram<sup>2</sup>, Timothy Hamerly<sup>1</sup>, Rhoel R. Dinglasan<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

*Plasmodium falciparum* is an obligate parasite that completes its asexual and sexual life cycles in vertebrate and invertebrate hosts. Mature gametocytes are the sexual stages of the parasite present in the vertebrate microvasculature that are ingested by *Anopheles* mosquitoes during blood meal. The mature gametocytes are responsible for parasite transmission to the *Anopheles* vector where gametogenesis, fertilization, and reproduction occur. While the male and female gametocytes are morphologically distinguishable in Giemsa-stained thin blood smears, little is known about the mechanism and key players of sexual dimorphism in *P. falciparum*. Identification and functional characterization of sex-specific biomarkers would aid in exploring their biology and help differentiate the parasite "gender". Our previous systematic subtractive bioinformatic analyses compared the sex partitioned proteins in *P. berghei* and *P. falciparum*. This study led to the identification of conserved putative female and male specific gametocyte protein biomarkers, but the function of these putative sex specific proteins remains unknown. This study focuses on the functional characterization of a putative conserved protein that may serve as a biomarker for mature female gametocytes and play a role in sex partitioning in *P. falciparum*. This putative female-specific gene was cloned and expressed using a heterologous bacterial expression system. The spatio-temporal expression profile of this gene over a 12 day development period was determined by immunofluorescence, real time PCR and quantitative Single Reaction Monitoring Mass Spectrometry. Furthermore, antibodies against this sex-specific protein were assessed for their potential to block the parasite transmission to the mosquitoes by standard membrane feeding assays. Our body of work has shed light on a novel gene in the context of gametocyte development biology and hints at the utility of such a target for transmission-blocking interventions.

931

### A MECHANISTIC APPROACH TO UNDERSTANDING THE EFFECTS OF HIV-RELATED INFLAMMATION ON PLASMODIUM FALCIPARUM GAMETOCYTE DEVELOPMENT

Deborah Stiffler<sup>1</sup>, Shirley Luckhart<sup>2</sup>, V. Ann Stewart<sup>1</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>University of Idaho, Moscow, ID, United States

Co-infection with HIV-1 infection and *Plasmodium falciparum* has been associated with more frequent and severe episodes of clinical malaria. The effect of co-infection on malaria transmission is less well understood, although a previous study of SIV and *Plasmodium fragile* in rhesus macaques showed increased transmission potential due to much higher numbers of gametocytes in co-infected animals. We therefore hypothesize that people who are infected with both diseases may be carrying higher numbers of gametocytes, even during asymptomatic infections. We further hypothesize that an increase in inflammatory cytokines due to HIV infection is contributing to an increase in soluble adhesion molecules, including VCAMs and ICAMs, which are then binding to parasitized red blood cells (iRBCs), reducing the ability of iRBCs to sequester in the vasculature. It is possible that an inability to sequester may, in turn, serve as a signal for gametocytogenesis as the parasite attempts to move to a more suitable host environment. In humans, this is particularly difficult to study due to both the natural variations in gametocyte levels over time in asymptotically infected individuals, and the presence of potential

confounders that can dampen or interfere with the effects of increased inflammatory cytokines. To better understand the mechanism of this interaction, we are taking a multifaceted approach to analyze the effects of inflammatory cytokines on gametocyte adhesion and sequestration in a more simplified *in vitro* system of *P. falciparum* and endothelial cell co-culture. We look at the effects of cytokines on several outcomes, including the production of soluble adhesion molecules, *P. falciparum* gametocyte gene expression, and the ability of parasitized red blood cells to adhere to the vasculature. We hope to recapitulate the results of these *in vitro* studies using serum from HIV positive individuals. A better understanding of the specific triggers of gametocyte formation will help reduce transmission and aid in the movement to eradicate malaria worldwide.

### 932

#### EXPLOITING MECHANISMS OF GLYCOLYTIC REGULATION IN MALARIA PARASITES

Andrew J. Jezewski<sup>1</sup>, Audrey R. Odom John<sup>2</sup>

<sup>1</sup>Washington University in St. Louis, St. Louis, MO, United States,

<sup>2</sup>Washington University in St. Louis, St. Louis, MO, United States

Malaria is estimated to be responsible for over half of all deaths throughout human history. Pregnant mothers, young children, and the immune compromised are at the highest risk for infection. Unfortunately, the treatment and prevention of malaria remains an up-hill battle despite major advances in modern healthcare. Resistance has developed to every available antimalarial highlighting the importance of early stage drug target discovery in addition to late stage drug development. To address this problem, we investigate novel metabolic control mechanisms that are common in malaria parasites but distinct from the human host. In humans and malaria parasites glycolysis serves as a central point for controlling carbon for energy production and essential biomolecules such as lipids, nucleotides, and amino acids. A long history of studying glycolysis in model organisms has shown that phosphofructokinases (PFKs) serve an important role in overall metabolism via strong glycolytic control. Interestingly, malaria parasites contain a biochemically and phylogenetically unique PFK, which differs from the PFK found in the human host. Understanding the unique biochemical, structural, and regulatory functions of the malaria parasite PFK will provide a strong foundation for rational drug development strategies for the next generation of antimalarials. Additionally, the unique phylogeny of the malaria PFK matches other apicomplexan parasites and will likely translate our understanding to other important pathogens including *Cryptosporidium* spp.

### 933

#### PROTEOMIC CHARACTERIZATION OF *PLASMODIUM BERGHEI* LIVER STAGE MEROZOITES

Melanie J. Shears<sup>1</sup>, Raja Nirujogi<sup>2</sup>, Kristian Swearingen<sup>3</sup>, Santosh Renuse<sup>1</sup>, Satish Mishra<sup>2</sup>, Robert Moritz<sup>3</sup>, Akhilesh Pandey<sup>1</sup>, Photini Sinnis<sup>1</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>formerly Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>Institute for Systems Biology, Seattle, WA, United States

Malaria parasites must replicate in the liver before initiating the symptomatic blood stage of infection. Liver stage replication yields tens of thousands of liver stage merozoites, which are released into the bloodstream in packets called 'merosomes' that are enclosed within a host-derived membrane. Liver stage merozoites have structural and functional overlap with blood stage merozoites as both invade red blood cells, but data suggest they also have unique biology. However, little is known about the molecular events involved in merozoite formation, liver stage merozoite release, and red blood cell invasion. In this study, we use the *Plasmodium berghei* rodent malaria model to perform the first proteomic characterization of mature liver stage merozoites. We optimized large-scale *in vitro* culture of *P. berghei* liver stages and use high-resolution

Orbitrap mass spectrometry to perform untargeted proteomic analysis of isolated merosomes. We identify 1188 liver stage merozoite proteins with high confidence, including proteins involved in motility, egress and invasion, metabolism and housekeeping processes. Furthermore, we identify N-terminally processed peptides from several proteins that contain PEXEL protein export sequences, indicating these proteins are exported into the host liver cell during merozoite formation. This study reveals new insight into the biology of this elusive life cycle stage and identifies intriguing candidates for future study.

### 934

#### EVALUATING NEW METHODS FOR *PLASMODIUM VIVAX* IN VITRO CULTURE FROM FROZEN SAMPLES

D'Arbra Blankenship, Rajeev K. Mehlotra, Peter A. Zimmerman, Brian T. Grimberg

Case Western Reserve University, Cleveland, OH, United States

Historically, *Plasmodium vivax* (Pv) cultures have encountered significant challenges that have limited the ability to perform laboratory-based studies on this important human malaria parasite species. A growing number of approaches have now begun to report conditions that support short-term Pv *in vitro* cultures, however, little progress has been made toward developing long-term culture. Past studies have used standard medias supplemented with human AB serum and a variety of additives with varying degrees of success. The majority of these studies made further efforts to supplement cultures with reticulocytes, given the well-known Pv reference for these cells. Here we have compared long-term growth and propagation of the Pv monkey-adapted strain, Vietnam IV/ Palo Alto in *Saimiri* blood in published culture conditions as well as the newly developed AIM V media. All data shown are the results from flow cytometry which counted the number of DNA positive cells from triplicate culture conditions, 144 hrs after thawing. We demonstrated that AIM V had double the number of parasites compared to other medias (AIM V +10% human AB serum= 16,687 (± 92) parasitized (pRBC)/uL, RPMI 1640 + Waymouths +15% serum= 8,487 (±54) pRBC/uL, McCoys 5A + 25% serum = 8,137 (±19) pRBC/uL, and RPMI 1640 + 25% serum = 2,900 (±6) pRBC/uL). We further improved AIM V media by supplementing with between 10% up to 25% human AB Serum. With 10% Serum yielding 25,350 (±18,793) pRBC/uL, 15% = 28,133 (±21,418) pRBC/uL, 20%= 18,117 (±553) pRBC/uL, and 25%=24,875 (±672) pRBC/uL. Finally, we compared how variation in the atmospheric conditions influenced Pv *in vitro* propagation in AIM V with 10% AB Serum by varying the CO<sub>2</sub> concentration from 5% to 10%. In 5% CO<sub>2</sub> there were 12,683 (±769) pRBC/uL but when increasing the CO<sub>2</sub> to 10% we saw a marked increase in the number of parasites up to 51,767 (±6,804) pRBC/uL. Through this work, we identified AIM V with 10% AB Serum in 10% CO<sub>2</sub> as the conditions that best supported Pv *in vitro* culture and with this we were able to show 4 expansion cycles of the Vietnam IV strain of Pv over 40 days in *Saimiri* blood with parasites continuously visible by light microscopy using Giemsa stain.

### 935

#### EFFICACY OF ARTEMETHER LUMEFANTRINE AND DIHYDROARTEMISININ PIPERAQUIN FOR THE TREATMENT OF UNCOMPLICATED MALARIA IN KISUMU, WESTERN KENYA

Ben Andagalu<sup>1</sup>, Irene Onyango<sup>1</sup>, Hoseah Akala<sup>1</sup>, Dennis Juma<sup>1</sup>, Agnes Cheruiyot<sup>1</sup>, Lorna Chebon<sup>1</sup>, Charles Okudo<sup>1</sup>, Redemptah Yeda<sup>1</sup>, Edwin Kamau<sup>2</sup>, Matthew Brown<sup>3</sup>

<sup>1</sup>Kenya Medical Research Institute/ Walter Reed Project, Kisumu, Kenya,

<sup>2</sup>Walter Reed National Military Medical Center, Bethesda, MD, United States,

<sup>3</sup>United States Army Medical Research Directorate, Kisumu, Kenya

*Plasmodium falciparum* (Pf) resistance to artemisinin is prevalent in Southeast Asia (SEA) and is a threat to malaria control efforts. Africa is currently spared, but this observation is evocative of the emergence of

chloroquine and sulphadoxine-pyrimethamine resistance that was first observed in SEA and later in Africa. More comprehensive monitoring is required in malaria endemic areas. In 2014-2015, we conducted an efficacy study of artemether lumefantrine (AL) and dihydroartemisinin piperazine (DHA-PPQ) for the treatment of uncomplicated *Pf* malaria in Kisumu, western Kenya - an area with high malaria transmission. A total of 118 subjects were randomized in a 1:1 ratio to receive either AL or DHA-PPQ. Treatment was directly observed. Blood draws for malaria tests were performed at hours 0, 4, 8, 12, 18, 24 and 6 hourly thereafter until 2 consecutive negative malaria blood films (MBFs) were obtained. Blood samples for MBFs were also collected during weekly follow-up visits from day 7 to 42. Hour 0 samples were tested for *ex vivo* sensitivity to antimalarial drugs, as well as for the presence of genetic markers of drug resistance. The geometric mean parasitemia at presentation was 36928 parasites/ $\mu$ L and 38653 parasites/ $\mu$ L for the AL and DHA-PPQ arms respectively. There were no cases of early treatment failure. After PCR correction, 100% of the subjects in both arms had 28 and 42 day ACPR. The median parasite clearance slope half-life was 2.3 hours (IQR 2.0 - 2.9) and 2.2 hours (interquartile range (IQR) 1.9 - 2.5) for the AL and DHA-PPQ arms respectively. The time taken to clear 99% of parasites was 20.1 hours (IQR 17.5 - 22.1) and 16.8 hours (IQR 14.6 - 19.5) for the AL and DHA-PPQ arms respectively. At least 20% of the parasites had the wild type genotype in respect to K13. Hour 0 drug sensitivity IC50 median values for artemether, dihydroartemisinin and lumefantrine were all within the threshold for sensitivity. AL efficacy for the treatment of uncomplicated malaria in Kisumu is still high. None of the K13 mutations reported in SEA. This study provides baseline malaria parasite clearance profiles that must continuously be monitored.

### 936

#### INTERMITTENT PREVENTIVE TREATMENT WITH DIHYDROARTEMISININ-PIPERAZINE IN YOUNG UGANDAN CHILDREN IN THE SETTING OF INDOOR RESIDUAL SPRAYING OF INSECTICIDE

**Mary Kakuru Muhindo**<sup>1</sup>, Abel Kakuru<sup>1</sup>, Patricia Awori<sup>1</sup>, Paul Natureeba<sup>1</sup>, Bishop Opira<sup>1</sup>, Micheal Amailuk<sup>1</sup>, Peter Olwoch<sup>1</sup>, Noeline Nalugo<sup>1</sup>, Jaffer Okiring<sup>1</sup>, Leonard Opio<sup>1</sup>, Theodore Reul<sup>2</sup>, Tamara Clark<sup>2</sup>, Edwin Charlebois<sup>2</sup>, Diane Havlir<sup>2</sup>, Prasanna Jagannathan<sup>3</sup>, Grant Dorsey<sup>2</sup>, Moses Kamya<sup>4</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Tororo, Uganda, <sup>2</sup>University of California, San Francisco, CA, United States, <sup>3</sup>Stanford University, Stanford, CA, United States, <sup>4</sup>Makerere University College of Health sciences, Kampala, Uganda

Intermittent preventive treatment (IPT) is a promising strategy for the prevention of malaria in young children living in Africa. Dihydroartemisinin-piperazine (DP) is safe and highly efficacious when used for the treatment of malaria and is an excellent candidate for IPT because of its prolonged post-treatment prophylaxis. However, the optimal dosing strategy for DP as IPT in young children is unclear. We are conducting a double blinded randomized controlled trial (NCT02163447) to evaluate different IPT dosing strategies using DP in a birth cohort of children born to HIV uninfected pregnant women in Tororo district. Tororo is an area with historically high transmission intensity with an incidence of malaria of ~ 5 episodes per year in children 6-24 months of age based on previous cohort studies. In December 2014, indoor residual spraying of insecticide (IRS) was implemented in Tororo and ~ 90% of children from this study were born after IRS was implemented. Pregnant women were randomized to receive DP every 4 or 8 weeks during pregnancy and children were randomized to DP every 4 or 12 weeks between 8 and 104 weeks of age. Children are followed for all their health care needs and malaria diagnosed when a child presents with fever and the detection of malaria parasites by microscopy. Routine blood samples are collected every 4 weeks to estimate parasite prevalence by microscopy and loop mediated isothermal amplification (LAMP). Of 191 live births, 183 have reached 8 weeks of age and were initiated on study drugs. As of March 2017, 149 had reached 104 weeks of age, 17 had been withdrawn from the study and 17 were

still taking study drugs. There have been 65 episodes of malaria during 324.3 person years of follow-up giving an overall incidence of 0.20 episodes per person years. During routine visits, the prevalence of malaria parasitemia, as determined by microscopy and LAMP, has been 1.6% and 2.2% respectively. It is anticipated that the final un-blinded results stratified by children's IPT regimen will be available before November 2017. Compared to historical controls, the burden of malaria has been very low in this birth cohort in the setting of IRS and IPT.

### 937

#### ACTIVE MONITORING OF ARTEMISININ COMBINATIONS THERAPY ACT USE FOR TREATMENT OF UNCOMPLICATED MALARIA AMONG PREGNANT WOMEN IN SENEGAL

**Ibrahima Diallo**, Alioune Badara Gueye, Mamadou Lamine Diouf, Medoune Ndiop, Seynabou Gaye Faye, Fatou Ba Fall, Moustapha Cissé, Omar Sarr

Senegal National Malaria Control Program, Dakar Fann, Senegal

Since 2010, the World Health Organization (WHO) recommends the use of ACTs in pregnant women for treatment of uncomplicated malaria from the second trimester of pregnancy. In May 2013, the NMCP in Senegal revised its case management guidelines to incorporate this recommendation. ACT has the singularity of having a rapid action, but its large scale use in pregnant women has to be supported by active pharmacovigilance in order to monitor its safety and tolerance. Accordingly, 12 health facilities of the districts of Mbao, Pikine, Guediawaye and Kedougou. were purposively selected for the implementation of this approach, taking into account their capacity for recruiting cases of malaria in pregnant women. From January to December 2016, the NMCP recorded 7044 cases of malaria in pregnant women nationwide and a single malaria-associated death, according to routine data. In the same period, a total of 210 cases of uncomplicated malaria were confirmed among pregnant women in their 2nd or 3rd trimester of pregnancy at the 12 monitoring sites. Among these 208 women, 208 (100.0%) were treated and cured using ACTs. No cases of therapeutic failure were identified among pregnant women treated with ACT during the monitoring period. 21 (10.1%) of these women were followed at 4 health centers and had laboratory testing (diagnostic microscopy and blood count) performed on days 0 and 28 to monitor their response to treatment, which confirmed their full recovery. Of all the 208 cases treated with ACT, only 2 pregnant women had adverse effects identified thru active follow-up. The first woman presented minors effects like vomiting, asthenia and heavy legs on Day 3, and the second had side effects of tinnitus, Gastralgia and paleness on Day 7. Nonetheless, these two cases suffering of minor adverse effects were treated and cured of malaria after 3 days of ACT treatment. In conclusion, ACTs are effective and well tolerated in pregnant women, but the biggest limitation is the contraindication of usage during the first trimester of pregnancy due to the medication's teratogenic effects.

### 938

#### IMPROVING HEALTH CARE WORKER PERFORMANCE IN ADHERENCE TO TESTING AND TEST RESULTS FOR MALARIA IN EIGHT SUB-SAHARAN AFRICAN COUNTRIES

**James Eliades**<sup>1</sup>, Troy Martin<sup>2</sup>, Kelly Davis<sup>1</sup>, Jolene Wun<sup>1</sup>, Zahra Mkomwa<sup>3</sup>, Boubacar Guindo<sup>4</sup>, Samwel Onditi<sup>5</sup>

<sup>1</sup>President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States, <sup>2</sup>President's Malaria Initiative MalariaCare Project, PATH, Seattle, WA, United States, <sup>3</sup>President's Malaria Initiative MalariaCare Project, PATH, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>President's Malaria Initiative MalariaCare Project, PATH, Bamako, Mali, <sup>5</sup>President's Malaria Initiative MalariaCare Project, PATH, Kisumu, Kenya

Adherence to malaria diagnostic test results is crucial to ensure effective treatment of malaria and other febrile conditions, and to decrease irrational use of artemisinin-combination therapies (ACT). Reasons for lack of adherence may include lack of knowledge of guidelines, lack of

confidence in the diagnostic test or laboratory, stock-outs of ACTs or other drugs, and satisfying patient demands for treatment. The MalariaCare project has worked with National Malaria Control Programs to train a cadre of laboratory and clinical experts as on-site supervisors. They then work with local staff at health facility level to perform on-site outreach training and supportive supervision (OTSS). During OTSS, adherence is measured in two ways. First, is through direct observation of clinical encounters, where adherence is recorded as 'correct prescription per test result and diagnosis'. In 4,451 clinical observations in 7 sub-Saharan African countries, 93% were adherent with this measure. The second method, a register review, evaluates 3 measures: identifies 10 patients who received ACTs and records if they received a test prior to treatment (TPT), and starting from the diagnostic side identifies 10 tested patients (5 RDT, 5 microscopy) each with negative and positive test results (NTR & PTR) and recording if they received an ACT. The project strives for 90% adherence for these measures: TPT, withholding ACTs for NTR and treating with ACTs for PTR. The proportion of facilities meeting this standard for all 3 indicators in 8 countries during the most recent OTSS visit was 81%. Steady improvement in performance for each measure in facilities receiving at least 3 OTSS visits has been seen by 13, 18, and 10 percentage points respectively for TPT, NTR and PTR. No improvement or a decrease in performance for PTR was seen in 3 countries and were associated with ACT stock-outs and/or ongoing use of quinine. Findings indicate that OTSS may improve test adherence in areas where diagnostic and ACT stock-outs are minimal and national guidelines are in line with global standards.

In 2016, a therapeutic efficacy study (TES) was conducted at 4 sentinel sites (Kibaha, Mkuzi, Mlimba and Ujiji) in Tanzania. This single-arm prospective study evaluated artemether-lumefantrine (AL) for the treatment of uncomplicated malaria in children aged six months to 10 years. Follow-up was done for 28 days with scheduled and unscheduled visits (if symptoms reoccurred) for clinical and laboratory assessments. A total of 344 patients were enrolled in the study and 332 completed follow-up or had a pre-defined study outcome. Of these, 67(20.2%) demonstrated asexual parasitaemia after day 3 and none had early treatment failure. After PCR correction to distinguish recrudescence from new infections, only one patient from Mkuzi had late clinical failure

with a recrudescence infection on day 28, yielding a corrected adequate clinical and parasitological response rate of >99%. Sequencing of *k13* gene was successful for 395 samples (327 and 68 samples from day zero and recurrent infections, respectively) and revealed non-synonymous mutations in 6 samples: I416V, E433D, R471R, and A578S each in 1 sample; Q613E in 2 samples. However, none of these *k13* mutations have been associated with artemisinin resistance. For the *Pfmdr1* gene, 409 were successfully sequenced (334 and 75 samples from day zero and recurrent infections, respectively) and 178 (44.1%) samples possessed non-synonymous mutations: 2 with N86Y, 1 with N86I, 168 with Y184F, 1 with Y184N, 2 with S1050F, 1 with D1111N, and 3 with D1246Y. All samples analysed for *Pfmdr1* copy number (n=184; 149 from patients with recurrent parasitemia during follow up and 35 additional day zero samples) had a single copy of the gene. The one patient with recrudescence infection had wild type *k13* and *Pfmdr1* genes in both the initial and recrudescence samples. In summary, we observed no *k13* mutations associated with artemisinin resistance and high efficacy of AL treatment. Continued monitoring of molecular markers of resistance to artemisinin-based combination therapies is critical in supporting TESS and providing evidence-based malaria treatment policies.

### 940

#### COMPLEXITY OF INFECTION AND PARASITE RELATEDNESS OF PLASMODIUM FALCIPARUM PARASITE POPULATIONS IN PATIENTS ADMINISTERED ARTEMETHER-LUMEFANTRINE (AL) IN KENYA

**Lorna J. Chebon**<sup>1</sup>, Peninnah Muiruri<sup>2</sup>, Dennis Juma<sup>3</sup>, Hosea M. Akala<sup>3</sup>, Ben Andagalu<sup>3</sup>, Edwin Kamau<sup>4</sup>, Matthew Brown<sup>3</sup>

<sup>1</sup>JKUAT/Institute of Tropical Medicine and Infectious Diseases (ITROMID)/Walter Reed Project, Kisumu, Kenya, <sup>2</sup>Africa Biosystems Limited, Nairobi-Kenya, Nairobi, Kenya, <sup>3</sup>KEMRI/USAMRD-K/Walter Reed Project, Kisumu, Kenya, <sup>4</sup>Walter Reed National Medical Military Center, Bethesda, MD, United States

Molecular barcode of twenty-four unlinked single nucleotide polymorphisms (SNPs) have been used to characterize *Plasmodium falciparum* parasite. Complexity of infection (COI) is the average number of infections within human host that influences malaria clinical outcome and transmission of resistant strains. Owing to the wide range of disease endemicities, data on molecular barcode characterization of Kenyan parasites from all transmission zones is still inconclusive. This study sought to identify and track specific *Plasmodium falciparum* parasites in patients administered artemether-lumefantrine (AL) in different malaria endemic regions in Kenya. DNA from 71 blood samples collected from the various malaria transmission zones in Kenya in the year 2014 were isolated prior to target amplification and high resolution melting for SNP discrimination. Each sample was genotyped using a molecular barcode of 24 SNPs distributed across *P. falciparum* genome which have a high minor allele frequency (average MAF > 35%). Clustering was done in comparison with Asian, South American and African isolates. The highest COI value was 2, reported in 8% of all samples which represented presence of poly-genomic infections while the rest had COI of 1 representing isolate with mono-genomic infections. Poly-genomic infections showed evidence of high genetic diversity and malaria transmission among Kenyan parasites. All isolates from Asia, South America and Africa clustered geographically. More specific, clustering of Kenyan parasites showed presence of distinct (similar-genotype) parasite profile. Eight samples (11%) with posterior probability value of < 0.95 were eliminated from subsequent network analysis. These findings are important in evaluating reduced response to anti-malarial therapy which its findings pose a threat of artemisinin resistance emergence thus hampering malaria control and elimination efforts. Studies clustering COI and Poly-genomic samples with treatment outcome are warranted for detecting effect of current treatment in infection composition and parasite evolution.

## 941

### MOLECULAR CHARACTERIZATION OF IMPORTED MALARIA PARASITES DIAGNOSED IN THE UNITED STATES BETWEEN 2014 AND 2016

Naomi W. Lucchi<sup>1</sup>, Dragan Ljolje<sup>2</sup>, Luciana Silva-Flannery<sup>1</sup>, Julia Kelley<sup>2</sup>, Henry Bishop<sup>1</sup>, Kimberly E. Mace<sup>1</sup>, Paul M. Arguin<sup>1</sup>, Richard Bradbury<sup>1</sup>, Venkatachalam Udhayakumar<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Atlanta Research and Education Foundation, Atlanta, GA, United States

Malaria continues to be a significant disease in returning travelers from endemic countries. In 2012, the Centers for Disease Control and Prevention (CDC) expanded its malaria surveillance activities to detect molecular markers of antimalarial drug resistance in malaria parasites imported into the United States. Approximately 1,500 cases of imported malaria are reported in the United States annually and, blood samples are sent to the CDC Malaria Branch Laboratory for about 10%-15% of these. Between 2014 and 2016, a total of 683 samples were received. The majority of these specimens were from patients who had travelled to Africa and the bulk of the infections were caused by *Plasmodium falciparum* (70.5%). Infections with the other species were less frequent: 11.0% *Plasmodium vivax*, 9.3% *P. ovale* and 3% *P. malariae*. The *P. falciparum* positive specimens were evaluated by sequencing for known molecular markers of antimalarial drug resistance in *Pfcr*, *Pfdhfr*, *Pfdhps*, *Pfmdr-1* and *PfK13* genes. Copy number variation (CNV) in the *Pfmdr-1* gene was also evaluated. Mutations in the *PfK13* gene were observed in 4 of 439 successfully sequenced samples (all acquired in Africa): two had the 578S mutation, commonly observed in Africa and two had a synonymous mutation at codon 493 (TAC to TAT). Of the 391 samples tested for *Pfmdr-1* CNV, 12 (3.1%) had more than one copy of the *pfmdr-1* gene, associated with mefloquine resistance. Mutations in all the genes investigated reflected patterns similar to what is commonly observed in parasites from the countries where the infections were acquired. CDC will continue to track drug resistance markers in malaria samples and these data will contribute to chemoprophylaxis guidelines for United States travelers to malaria endemic countries and appropriate treatment guidelines for malaria in the United States.

## 942

### PREVALENCE OF K13 MUTATION AND DAY-3 POSITIVE PARASITEMIA IN AN ARTEMISININ-RESISTANT MALARIA ENDEMIC AREA OF CAMBODIA: A CROSS-SECTIONAL STUDY

Soy Ty Kheang<sup>1</sup>, Sovannaroth Siv<sup>2</sup>, Sovann Ek<sup>1</sup>, Say Chy<sup>1</sup>, Phally Chhun<sup>1</sup>, Sokkieng Mao<sup>1</sup>, Sokomar Nguon<sup>1</sup>, Neeraj Kak<sup>1</sup>, Soley Lek<sup>2</sup>, Didier Menard<sup>3</sup>

<sup>1</sup>University Research Co., LLC, Chevy Chase, MD, United States, <sup>2</sup>Cambodia National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>3</sup>Institut Pasteur du Cambodge, Phnom Penh, Cambodia

Artemisinin-resistant malaria was confirmed in western Cambodia in 2009. In 2013, mutations in the propeller domain of the kelch protein K13 "K13-propeller" was found to be associated with artemisinin resistance. From June-July 2014, a cross-sectional study was conducted at one private clinic to determine the prevalence of Day-3 parasitemia (no further follow up was conducted), estimate the frequency of K13 molecular marker and assess their relationship. Blood smears and filter paper blood spots were collected from febrile patients in Kravanh District, Pursat Province. The blood smears were examined by microscopy, and blood spots by a K13 mutation assay. Data from 92 patients were analyzed. Only one was positive for Day-3 parasitemia. Results of the K13 assay were interpretable for 76 of the 92 samples. All positive patients were treated as per 2012 national treatment guidelines with DHA-PPQ. The results showed that 9 (12%) were wild type, 64 (84%) were C580Y, and 3(4%) were Y493H. Therefore, despite the high prevalence of K13 mutants (67/76 - 88%), only one of the 92 patients remained blood smear positive for *P. falciparum* on

Day-3. There was weak correlation between presence of K13 mutations and delayed parasite clearance times on Day 3 in the sample. Further investigation is needed in order to confirm if the results are generalizable.

## 943

### DRUG COMBINATION THERAPY FOR ARTEMISININ RESISTANT *PLASMODIUM FALCIPARUM*

Amila C. Siriwardana, Kalpana Iyengar, Paul D. Roepe

Departments of Chemistry, and of Biochemistry and Cell and Molecular Biology, Georgetown University, Washington, DC, United States

Resistance to artemisinin combination therapy (ACT) is a growing problem. Current ACTs were discovered empirically without determination of drug mode(s) of action or drug-drug interactions. New ACTs that circumvent evolving ACT resistance mechanisms are needed. Recently our group found that while some malarial parasites are cross-resistant to many different artemisinin-like compounds, the synthetic, endoperoxide-containing ozonide, OZ439, is equally potent against both artemisinin resistant and sensitive *P. falciparum* strains. Other work from our group in collaboration with scientists at the National Center for Advancing Translational Sciences suggests that phosphatidylinositol 3'-kinase (PI3K) inhibitors are quite potent antimalarial compounds, including against drug resistant strains. Perhaps not coincidentally then, we found that *P. falciparum* parasites exhibit an autophagy-like pathway triggered in response to cytotoxic (or cell-kill) drug treatment. Additionally, class III PI3K enzymes are known to be important regulators of autophagy, which could potentially serve as a novel drug target. For these reasons, we have investigated the effects of PI3K inhibitors on the parasite autophagy-like response and have explored their utility as "partner" drugs in the design of second generation ACTs. Significant drug combination synergy, at both cytostatic (growth inhibitory) and cytotoxic (cell-kill) levels of activity, was found for various drug combinations involving OZ439 and PI3K inhibitors, including impressive cytotoxic synergy at the ring-stage of parasite development. This is an important, clinically relevant finding as ACT resistance is primarily distinguished at the parasite ring-stage under cell-kill concentrations of drugs. Based on these data, we suggest a novel strategy for the development of endoperoxide-based drug combination therapies to treat ACT resistant malarial parasites.

## 944

### ACT PARTNER DRUG EROSION: EVIDENCE OF PIPERAQUINE-RESISTANT *PLASMODIUM FALCIPARUM* IN CAMBODIA

Selina Bopp<sup>1</sup>, Pamela A. Magistrado<sup>1</sup>, Wesley Wong<sup>1</sup>, Angana Mukherjee<sup>1</sup>, Pharath Lim<sup>2</sup>, Charles J. Woodrow<sup>3</sup>, Elizabeth Ashley<sup>3</sup>, Nicolas White<sup>3</sup>, Arjen Dondrop<sup>3</sup>, Rick M. Fairhurst<sup>2</sup>, Frederic Ariey<sup>4</sup>, Didier Menard<sup>5</sup>, Dyann F. Wirth<sup>1</sup>, Sarah K. Volkman<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>National Institutes of Health, Rockville, MD, United States, <sup>3</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>4</sup>Institut Pasteur, Paris, France, <sup>5</sup>Institut Pasteur, Phnom Penh, Cambodia

With the emergence and spread of artemisinin (ART) resistance, partner drugs used in ART Combination Therapies (ACTs) are themselves more vulnerable to emerging drug resistance. Recent evidence indicates not only emergence of ART resistance, but also loss of partner drug efficacy, with indications that piperazine (PPQ) resistance has emerged in Southeast Asia (Cambodia, Vietnam and eastern Thailand). To assess whether ART-resistant parasites are also PPQ-resistant, we tested previously-adapted *Plasmodium falciparum* isolates from Pursat and Pailin, Cambodia, as part of the Tracking Resistance to Artemisinin Collaboration (TRAC). Among parasites with delayed clearance and high Ring-stage Survival Assay (RSA) values as evidence of ART resistance, we observed a bimodal growth response to increasing PPQ concentrations. This bimodal response was not due to the presence of mixed parasite populations within these isolates, as daughter lines retained the phenotype after subcloning. To better quantify this bimodal response, we chose the area under the curve (AUC) instead

of the conventional half-maximal effective concentration (EC50) used in drug assays. The AUC data correlated well with Piperaquine Survival Assay (PSA) values. Exposure of parasites to PPQ at consecutive 12-h intervals throughout the life cycle showed that late-stage schizonts are less susceptible than earlier-stage parasites. Sequencing data revealed that PPQ resistance is independent of ART resistance, as parasites with mutations in the *kelch13* gene showed a range of PPQ susceptibilities. We confirmed a general association of PPQ resistance with increased *plasmepsin II* copy number as recently reported. However, we found that some isolates harbor PPQ resistance in the absence of amplification or increased expression of *plasmepsin II*, suggesting additional *loci* may modulate PPQ resistance. Our results confirm the existence of PPQ-resistant parasites in Cambodia, identify PPQ-resistant parasites that lack *plasmepsin II* amplification, and provide a fast and easy method to measure PPQ resistance.

## 945

### IMPROVING HEALTH CARE WORKER PERFORMANCE IN CLINICAL CASE MANAGEMENT OF MALARIA AND OTHER FEBRILE ILLNESSES IN SEVEN SUB-SAHARAN AFRICAN COUNTRIES

Fozo Alombah<sup>1</sup>, James Eliades<sup>1</sup>, Troy Martin<sup>2</sup>, Kelly Davis<sup>1</sup>, McPherson Gondwe<sup>3</sup>, Chimika Phiri<sup>4</sup>, Goodluck Tesha<sup>5</sup>

<sup>1</sup>President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States, <sup>2</sup>President's Malaria Initiative MalariaCare Project, PATH, Seattle, WA, United States, <sup>3</sup>President's Malaria Initiative MalariaCare Project, PATH, Lilongwe, Malawi, <sup>4</sup>President's Malaria Initiative MalariaCare Project, PATH, Lusaka, Zambia, <sup>5</sup>President's Malaria Initiative MalariaCare Project, PATH, Dar es Salaam, United Republic of Tanzania

Averting morbidity and mortality from malaria and other febrile illnesses requires a clinician to be competent in performing differential diagnosis, recognizing the need for diagnostic testing, and adhering to test results with proper treatment. To build and maintain health care worker (HCW) performance in clinical case management, the President's Malaria Initiative (PMI)-funded, PATH-led MalariaCare partnership has supported national programs implement a system of quality assurance. We report here the results of over 6,000 observations of HCWs performing clinical consultations at all levels of the health care system. The power of this multi-country monitoring data is in its large numbers measuring performance in the challenges of the work place. MalariaCare works with national programs to train clinical supervisors in diagnosis, treatment, and referral of malaria and improve skills at differential diagnosis who then work with clinical staff at health facility level to perform on-site outreach training and supportive supervision (OTSS). The OTSS visits focus on skills observation using a checklist and on the spot problem solving. Data measuring performance in 7 focus countries in sub-Saharan Africa that received between 2-5 rounds of OTSS have shown an average 18 percentage point improvement in overall score. Clinical indicators measured include recognizing the need for a malaria diagnostic test, adherence to results, treating per national guidelines, recognition of severe disease, history and physical exam skills, and patient counseling. At the most recent OTSS visit in 7 countries that included 6,178 observations, the supervisor agreed with the clinician's final diagnosis and severity assessment 94% of the time, indicated the correct prescription was given per test result and diagnosis 93% of the time, and indicated the HCW checked for at least one sign of severe malaria 83% of the time. Areas in need of improvement include performing a focused physical examination to elicit other causes of fever. Findings suggest that clinical case management refresher training and OTSS can improve management of malaria and febrile illness.

## 946

### PLASMODIUM FALCIPARUM IN AFRICA: CHANGES IN DRUG EFFICACY AND THE RATIONALE FOR EXTENDED ACT REGIMENS

Colin Sutherland

London School of Hygiene & Tropical Medicine, London, United Kingdom

Recent evidence suggests that combination therapies such as artemether-lumefantrine are less effective against *Plasmodium falciparum* of African origin than when first widely deployed on the continent. In vivo data from clinical trials, case histories from imported malaria cases in Europe and Asia and results of *in vitro* studies will be considered in producing a current "bill of health" for ACT in Africa. As one of the options for extending the useful life of current drugs, a case for extended-duration ACT regimens will be argued on parasitological and pharmacokinetic grounds. A study design for evaluation of safety and efficacy of such regimens in African children will be proposed.

## 947

### HEME ACTIVATION OF ARTEMISININ ANTIMALARIAL DRUGS

Laura E. Heller, Eibhlin Goggins, Paul D. Roepe

Georgetown University, Washington, DC, United States

The current standard of care for *Plasmodium falciparum* malaria is one of several currently available Artemisinin (ART) combination therapies. Artemisinin, derived from the Chinese herb *Artemisia annua*, contains a highly reactive 1,2,4 trioxane ring. In its reduced form, free ferriprotoporphyrin IX heme is known to catalyze endoperoxide cleavage for artemisinin drugs. The activated drug likely proceeds from an oxy radical form to a carbon centered radical form that is then capable of alkylating a variety of drug targets within malarial parasites. It has been proposed for some time that heme liberated upon hemoglobin catabolism is one such target, a hypothesis that is supported by direct evidence for heme-ART adducts in artemisinin-treated mice infected with *Plasmodium vinckei petteri*. Using optimized extraction procedures and mass spectrometry, we have quantified the abundance of heme, hemozoin, and artemisinin drug - heme adducts at various stages of the *P. falciparum* life cycle. These data are important for defining the molecular pharmacology of artemisinin antimalarial drugs.

## 948

### HETEROLOGOUS EXPRESSION, PURIFICATION, AND FUNCTIONAL ANALYSIS OF PLASMODIUM FALCIPARUM PHOSPHATIDYLINOSITOL 3'-KINASE

Matthew R. Hassett<sup>1</sup>, Anna R. Sternberg<sup>1</sup>, Bryce E. Riegel<sup>1</sup>, Craig J. Thomas<sup>2</sup>, Paul D. Roepe<sup>1</sup>

<sup>1</sup>Georgetown University, Washington, DC, United States, <sup>2</sup>National Center for Advancing Translational Sciences, Bethesda, MD, United States

Recent high-throughput screening efforts have identified PI3K inhibitors as very potent antimalarial drugs (Mott B.T. *et al.* (2015) *Scientific Reports* 5:13891). The *Plasmodium falciparum* malarial parasite genome appears to encode one and only one phosphatidylinositol 3'-kinase (PI3K) and sequence analysis suggests that the enzyme is a "class III" or "Vps34" type PI3K. Recent work (Mbengue A. *et al.* (2015) *Nature* 520:683-7) suggests that this enzyme may be a target for artemisinin - based antimalarial drugs, which are critical components of current antimalarial drug therapy. For these reasons, we have optimized the *PfVps34* gene for heterologous expression in yeast, have purified the protein to homogeneity, and have used a recently validated quantitative assay for PI3P production from PI to characterize enzyme activity and to quantify drug inhibition of that activity. We have investigated whether key residues in the enzyme's catalytic and "N-lobe" domains influence drug - enzyme interaction. Data show that PfVps34 is indeed a "class III" PI3K, that helical domain segments are

not essential for function, and that PfVps34 is inhibited by artemisinin and related drugs, but only under conditions that cleave the drugs' endoperoxide bridge to generate reactive alkylating agents.

## 949

### ASSESSMENT AND IMPACT OF THE NEW INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY WITH SULPHADOXINE-PYRIMETHAMINE (IPTP-SP) IMPLEMENTATION STRATEGY ON MATERNAL, FETUS AND NEONATAL OUTCOME IN GHANA

**Bernard Torniyigah**

*1UMR216-Institut de Recherche pour le Développement and Université Paris Descartes, France, Paris, France*

On the back of wide spread sulphadoxine-pyrimethamine resistance across Africa and its implication to malaria prevention among pregnant women and also the dose dependent beneficial effect of SP against malaria in pregnancy, WHO reviewed their guideline to a monthly SP administration. Ghana adopted this amendment and the new policy is currently being implemented. To assess the implication of the new IPTp strategy to maternal and neonatal outcomes, 1,000 pregnant women visiting health facilities from a peri-urban (Kpone-on-sea) and urban (Maamobi) setting in the Greater Accra Region, for their first antenatal care (ANC) and another 1,000 for delivery were recruited. Plasma levels of antimalarial drugs including SP and artemisinin derivatives were measured using an HPLC/MS/MS method. Parasitemia was also determined using microscopy and real-time PCR. Of the 1,000 women recruited from the first ANC visit, the mean  $\pm$  sd gestational age was 17  $\pm$  7 weeks at Kpone-on-sea and 18  $\pm$  7 weeks at Maamobi. At Kpone-on-sea 41% of participants at ANC were PCR positive compared to 39% from Maamobi. Also, 4.2% of participants at delivery were PCR positive compared to 24% from Maamobi. At delivery, 96 % of the women reported at least one SP uptake in Kpone-On-Sea while 78% did in Maamobi. These results will be discussed in detail during the congress in relation to SP plasma levels at each visit, maternal anemia, G6PD deficiency, and the condition of the newborn.

## 950

### NO EVIDENCE OF AMPLIFIED *PLASMODIUM FALCIPARUM* *PLASMEPSIN II* GENE COPY NUMBER IN AN AREA WITH ARTEMISININ-RESISTANT MALARIA ALONG THE CHINA-MYANMAR BORDER

**Fang Huang<sup>1</sup>**, Biraj Shrestha<sup>1</sup>, Matthew Adams<sup>1</sup>, Hui Liu<sup>2</sup>, Shui-Sen Zhou<sup>3</sup>, Xiao-Nong Zhou<sup>3</sup>, Pascal Ringwald<sup>4</sup>, Myaing M. Nyunt<sup>1</sup>, Christopher V. Plowe<sup>1</sup>, Shannon Takala-Harrison<sup>1</sup>

*<sup>1</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Yunnan Institute of Parasitic Diseases, Puer, China, <sup>3</sup>National Institute of Parasitic Diseases, Chinese Centre for Disease Control and Prevention, Shanghai, China, <sup>4</sup>World Health Organization, Geneva, Switzerland*

The emergence and spread of artemisinin resistance in *Plasmodium falciparum* poses a significant risk to malaria control and eradication goals, including China's plan to eliminate malaria within its borders by 2020. In addition, piperazine resistance has also emerged in Cambodia, compromising an important partner drug that is widely used in China in the form of dihydroartemisinin-piperazine. Mutations in a *P. falciparum* gene encoding a kelch protein on chromosome 13 (*kelch13*) are associated with artemisinin resistance and have arisen from multiple times and spread in the Great Mekong Subregion, including the China-Myanmar border. Multiple copies of the *plasmepsin III/III* genes, located on Chromosome 14, have recently been shown to be associated with piperazine resistance in Cambodia. In this study, we investigated *plasmepsin II* amplification in relation to the presence of *kelch13* mutations from samples collected from 200 clinical trial participants from field sites along the China-Myanmar border as part of therapeutic efficacy studies conducted from 2009 to 2014. Polymorphisms within *kelch13* were genotyped by capillary

sequencing of *P. falciparum* DNA extracted from dried blood spots. *Plasmepsin II* copy number was quantified by relative-quantitative real time PCR. The preliminary data showed only a single copy variants of *plasmepsin II* within samples from the China-Myanmar border, including both parasites with and without *kelch13* mutations. The therapeutic efficacy of dihydroartemisinin-piperazine was more than 90% along the China-Myanmar border, consistent with the lack of amplification of *plasmepsin II*. Continued monitoring of the parasite population using molecular markers of both artemisinin and piperazine will be important to track emergence and spread of resistance in this geographic region.

## 951

### ARTESUNATE-AMODIAQUINE: EFFICACIOUS AFTER 10 YEARS OF USE AS TREATMENT FOR UNCOMPLICATED *P. FALCIPARUM* MALARIA IN ERITREA

**Selam Mihreteab<sup>1</sup>**, Assefash Zehaie Kassahun<sup>2</sup>, Araia Berhane<sup>1</sup>, Josephine Namboze<sup>2</sup>, Afewerki Araya<sup>3</sup>, Luul Banteyirga<sup>3</sup>, Marian Warsame<sup>4</sup>, Peter Ouma<sup>5</sup>

*<sup>1</sup>Ministry of Health, Asmara, Eritrea, <sup>2</sup>World Health Organization, Asmara, Eritrea, <sup>3</sup>Ministry of Health Gash Barka Region, Asmara, Eritrea, <sup>4</sup>World Health Organization Headquarters, Geneva, Switzerland, <sup>5</sup>World Health Organization (consultant), Asmara, Eritrea*

Despite the dramatic decline in malaria morbidity and mortality, malaria still remains an important public health problem in many regions of Eritrea. After the first therapeutic efficacy tests showed 97% adequate clinical and parasitological response (ACPR) in 2007, Artesunate-Amodiaquine (AS-AQ) continues to remain as the first line treatment for uncomplicated *P. falciparum* malaria in Eritrea. In this study we report efficacy of AS-AQ after 10 years of continuous use. During September to December 2016, children aged  $\geq$  6 months and adults with microscopy-confirmed uncomplicated *P. falciparum* malaria (200–200,000 parasites/ $\mu$ L) and meeting other study criteria participated in a 28-day one-arm *in-vivo* efficacy trial in 4 sentinel sites of Gash Barka region: Tokombia, Goluj, Shambuko and Akordat. The study was powered to estimate overall AS-AQ efficacy of 95%. Blood was collected for malaria microscopy and molecular testing on days 0, 2, 3, 7, 14, 21, and 28. The primary outcome was the PCR-uncorrected day 28 Kaplan-Meier cumulative success rate. A total of 281 children and adults were enrolled and out of these 270 (96%) reached a study endpoint and out of these 256 responded to the treatment making the day 28 uncorrected cumulative success rate (ACPR) at 94.8% [95% CI: 91.5%, 97.1%]. There was no early treatment failure but a total of 14 late treatment failures occurred after day 7. The proportion of ACPR may change after polymerase chain reaction (PCR) correction. The findings indicate that AS-AQ still remains efficacious for the treatment of uncomplicated malaria in Eritrea after almost 10 years of use. However, continued monitoring of efficacy levels of AS-AQ is recommended to ascertain its efficacy remains well above the 90% cut-off point.

## 952

### THE EFFICACY OF ARTEMISININ COMBINATION THERAPY IN KENYA; THE STATUS AT MSABWENI, NYANDO AND BUSIA MALARIA ENDEMIC STUDY SITES

**Francis T. Kimani<sup>1</sup>**, Omar Sabah<sup>1</sup>, Edwin K. Too<sup>1</sup>, Moreen S. Otinga<sup>1</sup>, Stephen Kaniaru<sup>1</sup>, Moses Ngari<sup>2</sup>

*<sup>1</sup>Kenya Medical Research Institute, Nairobi, Kenya, <sup>2</sup>Kenya Medical Research Institute, Kilifi, Kenya*

Artemisinin-based combination therapies (ACTs) and its derivatives are the most rapidly acting of all the current antimalarial drugs and recognition of their potential role as a component of combination therapy have led to several large trials aimed at assessing different combinations of existing drugs and to the specific development of new combination drugs. The Study Objective was to evaluate the efficacy of fixed dose combinations, Artemether-lumefantrine and dihydroartemisinin-piperazine in

uncomplicated malaria patients in Kenya with an aim to inform malaria treatment policy and practice in the country. The study was a multi-site two arm blinded randomized clinical trial. In this are the preliminary results of three study sites evaluated for the efficacy of two artemisinin-based anti-malarial combination drugs, AL and DP, in Kwale, Kisumu and Busia counties in Kenya. The *in-vivo* (clinical microscopy) treatment outcome was evaluated. Parasitological response at day 28 and 42, cure ratios in the two treatment arms, Fever Clearance Time (FCT), Asexual parasite clearance time (PCT), Gametocyte carrier rates and Adverse events were evaluated. A total of 352 children in Kwale, 315 in Kisumu and 334 in Busia, aged between 6 months and 12 years were randomized and treated with either AL or DP. For Kwale and Kisumu cumulatively, in the Intention to treat (ITT) analysis, at day 42, 483 participants had ACPR, ACPR rate of 72% (95% CI 69-76%), 268 participants in arm A (ACPR rate of 77% (95% CI 72-81%)) and 215 in arm B (ACPR rate of 68% (95% CI 62-73%)); P-value 0.008. By day 28, participants with ACPR were 542, ACPR rate of 81% (95% CI 78-84%), 293 in arm A (ACPR rate of 84% (95% CI 80-88%)) and 249 in arm B (ACPR rate of 78% (73-82%)); P-value=0.06. The results from these study sites indicate a note worth trend of the ACT efficacy in the regions and calls for further monitoring on the same for appropriate policy measures.

## 953

### EX VIVO SUSCEPTIBILITY OF *PLASMODIUM FALCIPARUM* TO DIHYDROARTEMISININ AND PIPERAQUINE BY NOVEL PHENOTYPIC ASSAYS (RSA AND PSA) IN BINH PHUOC PROVINCE, VIETNAM

**Tong Thanh Nguyen**, Thuy-Nhien Nguyen, Guy Thwaites, Hien Tinh Tran

Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam

Artemisinin based combination therapies (ACTs), the most effective antimalarial medicines against *Plasmodium falciparum* have contributed in the substantial reduction of malaria burden worldwide over the last decades. Like previously used antimalarial drugs, parasite resistance to artemisinin and its derivatives has emerged and spread in Southeast Asia. Moreover, the partner drug efficacy has gradually declined recently due to increasingly recrudescence cases in late treatment failure. This indicates that parasite resistance to both artemisinin and piperazine is prevalent. To provide supporting evidence of the resistant *P. falciparum*, *ex vivo* susceptibility of *P. falciparum* to dihydroartemisinin and piperazine has been investigated by ring-stage survival assay (RSA) and piperazine survival assay (PSA). In this study, 54 blood samples were collected from patients with uncomplicated falciparum malaria in Binh Phuoc province from 2016 to 2017. The parasites were exposed to drugs followed published procedure in order to assess the percentage of viable parasites as well as identify the resistant *P. falciparum*. The results showed that 98 % (53/54) of parasites was resistant to dihydroartemisinin with a median 7.88 % (IQR: 4.21 - 15.77 %) and 89 % (48/54) of parasites was resistant to piperazine with a median 52.08 % (IQR: 29.44 - 79.57 %). Additionally, RSA and PSA survival rates from recrudescence patients were higher than non-recrudescence patients (9.89% compared to 6.47% by RSA and 77.57% compared to 36% by PSA, respectively). The high survival rate of parasite exposed to antimalarial drugs could threaten to malaria elimination targets in areas where dihydroartemisinin - piperazine was used commonly. Our findings suggest that monitoring of drug resistance with phenotypic *ex vivo* / *in vitro* assays such as RSA and PSA is necessary to evaluate drug efficacy as well as useful in elucidating the molecular mechanism of resistance.

## 954

### PREVALENCE OF CYP2D6 POLYMORPHISMS IN A CAMBODIAN POPULATION AND RELATIONSHIP TO *PLASMODIUM VIVAX* RECURRENCE RATE AND HEMOLYTIC TOXICITY

**Michele Spring**<sup>1</sup>, Chanthap Lon<sup>1</sup>, Mariusz Wojnarski<sup>1</sup>, Somethy Sok<sup>2</sup>, Darapiseth Sea<sup>2</sup>, Soklyda Chann<sup>2</sup>, Sabaithip Sriwichai<sup>1</sup>, Samon Nou<sup>2</sup>, Mali Ittiverakul<sup>1</sup>, Worachet Kuntawunginn<sup>1</sup>, Montri Arsanok<sup>1</sup>, Pattarporn Vanachayangkul<sup>1</sup>, Mary So<sup>3</sup>, Satharath Prom<sup>3</sup>, Rekol Huy<sup>4</sup>, Mark Fukuda<sup>1</sup>, David Saunders<sup>5</sup>, Philip Smith<sup>1</sup>

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand,

<sup>2</sup>Armed Forces Research Institute of Medical Sciences, Phnom Penh,

Cambodia, <sup>3</sup>Ministry of National Defense, Department of Health, Phnom

Penh, Cambodia, <sup>4</sup>National Center for Parasitology, Entomology and

Malaria Control, Phnom Penh, Cambodia, <sup>5</sup>U.S. Army Medical Materiel Development Activity, Fort Detrick, MD, United States

With the large burden of *Plasmodium vivax* malaria in Cambodia, elimination efforts will require widespread administration of the 2-week course of oral primaquine (PQ) for radical cure, in an environment with 13-17% G6PD deficiency. Another host genetic factor which affects primaquine efficacy is polymorphisms in the hepatic cytochrome P450 2D6 enzyme. Clinical failure of PQ has been demonstrated in people with CYP2D6 genetic polymorphisms which result in reduced or no enzyme activity (Intermediate Metabolizer [IM] and Poor Metabolizer [PM] phenotypes, respectively), and a recent pharmacokinetic study demonstrated that IMs and PMs have significantly lower production of the PQ phenolic metabolites which may be responsible for anti-hypnozoite activity. The distribution of CYP2D6 genotypes/phenotypes in the Cambodian population is not well described. Other studies conducted in Asia have shown an approximate 50% prevalence of the IM phenotype, which could translate into increased risk of PQ radical cure failure, continued relapses with ongoing community transmission, as well as potential morbidity from repeated dosing of PQ. Here we report on the CYP2D6 genotypes from a group of 106 volunteers taking part in two malaria therapeutic efficacy studies conducted during 2010 and 2013 in Anlong Veng District in Cambodia, which represents the largest collection of CYP2D6 information in this country to date. Genotypes were assigned by using the Luminex xTag® CYP2D6 Kit v3 (Austin, TX), a cytometric bead detection assay detecting 17 different CYP2D6 alleles, on archived buffy coat samples. Phenotypes were predicted based on a published 2D6 activity score (AS-A). The 2010 study included both *P. vivax* and *P. falciparum* patients, which will enable comparison of CYP2D6 genotypes to *P. vivax* relapse frequency reported by volunteers after radical cure with PQ as well as the degree of anemia post treatment. Plans are also underway to conduct a pharmacokinetic study of primaquine in cohort of volunteers from the 2013 study in order to determine the effect of CYP2D6 polymorphisms on generation of the phenolic metabolites necessary to clear hypnozoites.

## 955

### A POINT-OF-CARE ASSAY TO DETECT ANTIMALARIAL DRUGS FROM FINGER STICK BLOOD SAMPLES

**Erin Coonahan**<sup>1</sup>, Rick Fairhurst<sup>1</sup>, Maarten De Vos<sup>2</sup>, Joel Tarning<sup>3</sup>, Tom Wellem's<sup>1</sup>, Carole Long<sup>1</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Oxford

Institute of Biomedical Engineering, Oxford, United Kingdom, <sup>3</sup>Mahidol

Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Artemisinin-based combination therapies (ACTs) have begun to fail as first-line therapies for the treatment of *Plasmodium falciparum* malaria in Southeast Asia. Preventing the spread of drug-resistant parasites to Africa is a top priority for global malaria elimination campaigns. The ability to detect small molecule antimalarial drugs in a patient's blood at the point-of-care could enable healthcare workers to identify a previously failed

treatment and adjust the patient's new treatment to improve its efficacy and thus reduce the spread of resistant parasites. A simple assay to detect these drugs in patient samples would also facilitate real-time mapping of drug use and compliance as well as provide an inexpensive tool for testing drug quality. The goal of this research is to develop a low-cost, field-based test to detect several slow-clearing ACT drug compounds from unprocessed finger stick blood samples. The test will detect drugs through the binding of target-specific aptamers and provide a colorimetric readout of drug levels. Our research is currently focused on optimizing selection protocols to identify ssDNA aptamers that bind target antimalarial drugs with improved sensitivity and specificity.

## 956

### ABSENCE OF ASSOCIATION BETWEEN *EX VIVO* SUSCEPTIBILITY TO PIPERAQUINE AND POLYMORPHISMS IN EXONUCLEASE GENE AND COPY NUMBERS IN PLASMEPSIN 2 GENE IN AFRICAN *PLASMODIUM FALCIPARUM* ISOLATES

Marylin Madamet, Mathieu Gendrot, Francis Foguim, Gladys Robert, Nicolas Benoit, Rémy Amalvict, Joel Mosnier, **Bruno Pradines**

*Institut de Médecine Tropicale du Service de Santé des Armées, Marseille, France*

Since 2005, the World Health Organization (WHO) has recommended artemisinin combination therapy (ACT) as the first-line treatment against malaria. The emergence of resistance to artemisinins, manifested by delayed parasite clearance after monotherapy with artesunate or ACT, was described in Southeast Asia. Dihydroartemisinin-piperazine is the most recent ACT to be commercialized. However, multidrug resistance to dihydroartemisinin-piperazine is currently emerging in Cambodia. The duplication of the gene coding the plasmepsin 2 was associated with decreased dihydroartemisinin-piperazine efficacy in Cambodia and *in vitro* resistance to piperazine. Additionally, the mutation E415G in the exonuclease gene (*exo-E415G*) was associated with high inhibitory concentrations 50% (IC50) of piperazine in 297 isolates from Cambodia obtained from 2011 to 2013. This E415G mutation was associated with parasite recrudescence following dihydroartemisinin-piperazine treatment. We evaluated the copy number of plasmepsin 2 in 81 isolates from Dakar, Senegal and 250 African isolates. None of the African samples harbored more than one copy. None of the African isolates harbored the E415G mutation in the exonuclease gene, although three other mutations were detected in this gene, including S114C, N419H and T435A. However, the E415G mutation and more generally polymorphisms in the exonuclease gene and copy number of plasmepsin 2 were not associated with *in vitro* reduced susceptibility to piperazine in African parasites.

## 957

### EVALUATION OF NOVEL PET-PCR PRIMERS FOR THE DETECTION OF *PLASMODIUM MALARIAE* IN CLINICAL SPECIMENS *MALARIAE* IN CLINICAL SPECIMENS

**Dragan Ljolje**<sup>1</sup>, David Akerele<sup>2</sup>, Eldin Talundzic<sup>3</sup>, Venkatachalam Udhayakumar<sup>3</sup>, Naomi Lucchi<sup>3</sup>

<sup>1</sup>Atlanta Research and Education Foundation, Decatur, GA, United States, <sup>2</sup>Division of Pediatric Infectious Disease, Emory University Medical Center, Atlanta, GA, United States, <sup>3</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

Molecular methods are useful for the detection of low density *Plasmodium* sp. infections that cannot be detected by microscopy. In reference laboratory settings, results of molecular testing complement results of microscopy and rapid diagnostic tests (RDTs). Moreover, molecular diagnostic tools allow for rapid large scale screening with high sensitivity and specificity and can be applied to control, pre-elimination and elimination settings for confirming submicroscopic infections. We have

demonstrated this capability with our previously described genus-specific photo-induced electron transfer polymerase chain reaction (PET-PCR), a relatively easy assay to implement in endemic countries and in the species-specific PET-PCR assays for *P. falciparum* and *P. ovale*, capable of detecting *P. falciparum* and *P. ovale* respectively. Here we report on the evaluation of a *P. malariae*-specific PET-PCR assay for the accurate and sensitive detection of *P. malariae*. Using a total of 138 clinical samples, the sensitivity and specificity of this assay at detecting *P. malariae* infections were both determined to be 100%, using a nested-PCR as a reference test. The limit of detection of the assay was found to be 2-8 parasites/μl. Further field evaluation of this method especially in endemic country setting will be valuable to confirm the sensitivity and specificity of this test.

## 958

### DOES THE EXPERIENCE OF MALARIA TESTING INCREASE TRUST IN THE TEST? EVIDENCE FROM WESTERN KENYA

**Indrani Saran**<sup>1</sup>, Elisa Maffioli<sup>1</sup>, Diana Menya<sup>2</sup>, Jeremiah Laktabai<sup>3</sup>, Elizabeth Turner<sup>1</sup>, Wendy P. O'Meara<sup>1</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>Moi University, Eldoret, Kenya, <sup>3</sup>Moi University, Eldoret, Kenya

Malaria diagnostic testing is a key tool for malaria control efforts. However, patients who test negative are often still treated with anti-malarial medications. This practice increases the risk of parasite resistance to the drug and limits the benefit of malaria treatment subsidies. We used data from a study conducted in Western Kenya to examine how the experience of malaria testing (either microscopy or rapid diagnostic tests) influences patients' trust in the test. Between July 2014 and June 2015, 444 individuals with a malaria-like illness, who had not yet sought any testing or treatment, were surveyed at study enrollment and at a follow-up visit one week later. At both time points, we collected individuals' beliefs about the probability that their illness was malaria, as well as their perceived probabilities that a hypothetical negative and positive malaria test result were correct. We elicited these probabilities using a visual scale ranging from 0%-100%, displayed on an interactive touchscreen tablet. Approximately 62% of patients were tested for malaria in the week between the two surveys. At the follow-up visit, patients had, on average, a 71% probability of believing that a negative malaria test result was correct, and a 76% probability of believing a positive test result was correct. Compared to those who were not tested, patients who were tested for malaria had a 6.8 percentage point (95% CI [0.005 0.131], P=0.035) greater probability of believing that a hypothetical negative test result was correct. Testing also had a positive, but statistically non-significant effect, on the perceived probability that a hypothetical positive test result was correct. (β=0.042, 95% CI [-0.019 0.102], P=0.178). Results are very similar when we control for patients' baseline beliefs about their illness and baseline trust in the test. We find no evidence that adherence to the test result is associated with patients' trust at follow-up in either a positive or negative test result. Our results suggest that greater experience with malaria diagnostic testing can increase patients' trust in the test, particularly when the test result is negative.

## 959

### PREPARATION OF A UNIFORM MONOLAYER OF GIEMSA-STAINED RED BLOOD CELLS ON HYDROPHILIC-TREATED PLASTIC PLATES FOR MALARIA DIAGNOSIS

**Muneaki Hashimoto**, Shohei Yamamura, Masato Tanaka, Hirokazu Sakamoto, Yusuke Ido, Kazuaki Kajimoto, Shouki Yatsushiro, Masatoshi Kataoka

*National Institute of Advanced Industrial Science and Technology (AIST), Kagawa, Japan*

Microscopic evaluation of Giemsa-stained thin blood smear on glass slides has been the gold standard for malaria diagnosis for more than 100 years. However, only a small area of the blood smear would provide a monolayer of red blood cells (RBCs) suitable for microscopic evaluation, thereby

limiting the number of cells that can be examined for the *Plasmodium* infection rate (parasitemia) and parasite species. This is one of the major reasons for the low parasite detection rate of this method. Herein, we established a method that allows microscopic examination of Giemsa-stained cells spread in a monolayer over the entire surface of hydrophilic-treated plastic plates. The method may enable more reliable diagnosis of malaria in patients with low parasitemia.

## 960

### COMPETENCE IN MALARIA RAPID DIAGNOSTIC TESTS (MRDTS) PERFORMANCE TWELVE MONTHS POST TRAINING: EVALUATION OF MALARIA TESTING BY UNITY HEALTH WORKERS (CHWS)

Jeremiah Laktabai<sup>1</sup>, Matthew Boyce<sup>2</sup>, Diana Menya<sup>3</sup>, Lucy Abel<sup>4</sup>, Indrani Saran<sup>2</sup>, Joseph Kurui<sup>4</sup>, Elizabeth Turner<sup>2</sup>, Wendy O'Meara<sup>2</sup>

<sup>1</sup>Moi University/AMPATH, Eldoret, Kenya, <sup>2</sup>Duke Global Health Institute, Durham, NC, United States, <sup>3</sup>Moi University, Eldoret, Kenya, <sup>4</sup>AMPATH, Eldoret, Kenya

Task shifting in malaria diagnosis is a potential strategy towards improving access to diagnostic testing in rural communities. With appropriate training and supervision, community health workers (CHWs) can bridge the access gap by offering malaria rapid diagnostic tests (mRDTs) in the community. However there are concerns about the ability of lay health workers to achieve and maintain competence in performing the mRDTs. As part of a larger study of CHWs using RDTs, we evaluated their performance in using malaria RDTs 12 months post-training. A total of 271 CHWs were trained on use of RDTs using a 3 day validated Ministry of Health curriculum. A post training evaluation test was administered to assess their grasp of the content. A practical competency assessment using a standardized 22 step checklist was also conducted. The CHWs were equipped with supplies to offer RDT testing. At 12 months post training, a sample of 102 CHWs underwent a repeat assessment using the checklist to evaluate whether their skills were maintained. The mean age of the CHWs was 43.6 years, with 68.9% being females and 82.5% married. The mean duration of CHW experience in their role was 4.1 years. About a third had previous training in malaria case management. At least 80% of CHWs completed 18 of the 22 steps correctly, with median number of steps completed correctly being 19 at baseline and 20 at 12 months (the difference was not statistically significant). The lowest average scores involved failure to check the expiry date on the cassette with the CHWs scoring 53% at baseline and 52.4% at 12 months. Using the investigators' interpretation as the gold standard, the sensitivity and specificity of CHW interpretation of mRDTs were 92.0% and 97.3% respectively, with the commonest error occurring when there were faint positive test lines. Using multivariate regression, factors associated with fewer error counts at 12 months post training were prior RDT experience (-0.74, p value 0.002) and age below 50 years (0.03, p value 0.00). CHWs can safely and accurately use mRDTs, with their competence maintained at 12 months post training.

## 961

### MALARIA DIAGNOSTIC TESTING ASSOCIATED WITH SIGNIFICANT INCREASES IN COST OF CARE FOR FAMILIES IN RURAL WESTERN KENYA

Diana C. Menya<sup>1</sup>, Indrani Saran<sup>2</sup>, Jeremiah Laktabai<sup>1</sup>, Joseph Kirui<sup>3</sup>, Wendy P. O'Meara<sup>2</sup>

<sup>1</sup>Moi University, Eldoret, Kenya, <sup>2</sup>Duke University, Durham, NC, United States, <sup>3</sup>Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya

Although malaria cases have decreased in Kenya over the past decade, there are still areas of high incidence in western Kenya. Optimum management of malaria involves prompt diagnosis and treatment. These actions have associated costs which are often borne by community members themselves rather than the government. We used a population

based household survey, conducted in 2015 in 34 community clusters in western Kenya, to examine how malaria testing is associated with overall treatment costs. Households in which a malaria like illness was reported in the past four weeks were enrolled. Adults and caregivers of children under 18 years in 2,065 households were interviewed and asked about the treatment the patient sought, whether the patient was tested for malaria, their expenditures on malaria testing, and overall expenditures on the illness. Approximately 44% of patients in the survey received a malaria diagnostic test. Both the median and mean cost of a malaria test was 50 Kenya shillings (Kshs) (approximately \$0.50) and was similar whether the patient was tested with a rapid diagnostic test (RDT) or with microscopy. The cost of a malaria test was lower for children under the age of 5 and was higher if the patient was tested in the private sector. Total treatment costs were on average Kshs 380 (median was Kshs 150). Controlling for patient age, household wealth, distance to a health facility, and location of care, malaria testing was associated with a Kes 460 (95% CI [128.8, 790.3],  $P < 0.01$ ) increase in total treatment costs. Patients who ever visited a private health facility or who were from the richest wealth quintile also had higher overall treatment costs. The difference in treatment costs between those tested and not is much higher than the cost of the test which suggests that the test cost itself may not be the major barrier to testing but that testing decisions may be affected by associated fees such as additional laboratory tests, registration and other costs that may result from seeking care in a place that offers testing.

## 962

### ASSESSMENT OF RDT PERFORMANCE IN ENDEMIC AREA IN SAKARAH, MADAGASCAR

Rason Marie Ange, Raobela Omega, Franchard Thierry, Rakotomanga Tovonahary, Rasoarilalao Noeline, Ralaiseheno Yvon, Ratsimbaoa Arsene

National Malaria Control Program, Antananarivo, Madagascar

Malaria remains a major public health problem in Madagascar. The National Strategic Plan requires biological diagnostic confirmation before treatment of malaria cases. Rapid Diagnostic Test (RDT) is used at based health center and coupled with microscopy in hospital center. Assessment of performance of RDT is important to improve the quality diagnosis and treatment. The aim of the study is to evaluate the performance of RDT. The data was collected during an outbreak investigation in March 2016 in Antsokay, Ankida and Andoharotsy villages. All patients presenting fever or history of fever were recruited. Each patient was tested systematically with RDT (SD Bioline Malaria *Pf/Pan*), thick drip/thin smear and blood spots. All patients with positive RDT and uncomplicated malaria were treated with Artesunate - Amodiaquine (ASAQ). The slides were read at NMCP laboratory by the WHO-accredited experts. A total of 245 patients were recruited. Sex ratio (M / F) was at 0.9. Only *Plasmodium falciparum* has been identified in this study. The results showed that the RDT positivity rates in all 3 sites were 53.9%. The smear positivity rates were 32.7%. There is a difference between RDT results and microscopy. Respectively, sensibility, specificity, VPP and VPN of RDT was 97.5%, 67.3%, 59.1% and 98.2%. The geometric mean of parasitaemia was 3405,9 parasites/ $\mu$ L. In summary, SD Bioline Malaria *Pf/Pan* is sensitive but less specific diagnostic test there is. The parasite reservoir for malaria transmission was found in Sakaraha.

## LESSONS LEARNED: MALARIA DIAGNOSTIC REFRESHER TRAINING IN AFRICA FRANCOPHONE COUNTRIES

**Pharath Lim**<sup>1</sup>, Renion Saye<sup>2</sup>, Abdoulaye Ouologuem<sup>3</sup>, Séraphine Kutumbakana<sup>3</sup>, Nestor Niyizompa<sup>4</sup>, Boubacar Gunido<sup>2</sup>, Moza Seleman<sup>4</sup>, Arsene Ratsimbaoa<sup>5</sup>, Jules Mihigo<sup>6</sup>, Erin Eckert<sup>7</sup>, Lee Yellott<sup>8</sup>, Julie Heinsen<sup>9</sup>, Troy Martin<sup>10</sup>, Paul Hamilton<sup>9</sup>, Daouda Ndiaye<sup>11</sup>, Chris Schwabe<sup>8</sup>

<sup>1</sup>President's Malaria Initiative MalariaCare Project, Medical Care Development International, Washington, DC, United States, <sup>2</sup>President's Malaria Initiative MalariaCare Project, PATH, Bamako, Mali, <sup>3</sup>President's Malaria Initiative MalariaCare Project, PATH, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>President's Malaria Initiative MalariaCare Project, PATH, Bujumbura, Kenya, <sup>5</sup>National Malaria Control Program, Antananarivo, Madagascar, <sup>6</sup>President's Malaria Initiative, United States Agency for International Development, Bamako, Mali, <sup>7</sup>President's Malaria Initiative, United States Agency for International Development, Washington, DC, United States, <sup>8</sup>President's Malaria Initiative MalariaCare Project, Medical Care Development International, Silver Spring, MD, United States, <sup>9</sup>President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States, <sup>10</sup>President's Malaria Initiative MalariaCare Project, PATH, Seattle, WA, United States, <sup>11</sup>Department of Parasitology and Mycology, University Cheikh Anta Diop, Dakar, Senegal

Since 2010, WHO has recommended that testing all suspected malaria cases with a parasitological test and high quality malaria microscopy remains the diagnostic standard. The USAID-funded MalariaCare project assists program countries to improve their accuracy of malaria diagnostic testing. We report MalariaCare's experience in implementing five-day malaria diagnostic refresher training (MDRT) for laboratory supervisors and staff in five francophone countries: Burundi, the Democratic Republic of the Congo (DRC), Guinea, Madagascar and Mali. The 377 MDRT participants were selected from central and peripheral reference facilities and were trained on parasite detection (PD), species identification (ID) and parasite counting (PC); practice on slide preparation and staining; use of malaria RDTs; and improving quality assurance measures according to WHO guidelines. The knowledge and competency of participants was evaluated through written pre- and post-tests and practical skills assessments, with their final outcome scores classifying them into one of four performance levels based on a WHO grading scale. Of the total 377 participants trained on basic MDRT, 97 were in Burundi, 84 in the DRC, 20 in Guinea, 59 in Madagascar and 117 in Mali. In addition, 63 participants (30 in Burundi and 33 in the DRC) were trained in an advanced course. Overall, significant improvements were made in slide reading for PD, ID and PC with average post-test scores at 93, 64 and 37 percent, respectively, representing improvements by 16, 15 and 21 percentage points; 19.9% obtained national expert level 1 or 2 status. Among these high performers, 11 were selected for a WHO francophone external competency accreditation malaria microscopy course in Dakar, Senegal, with six receiving WHO level 1 and three level 2 accreditation. These outcomes suggest that five day MDRTs are an effective way of administering WHO's recommendation for regular refresher training of reference level laboratory staff, while at the same time highlighting that more training needs to be done to bring all reference microscopists to a quality level of performance.

## AN OFFLINE VIRTUAL MICROSCOPE-BASED MALARIA MICROSCOPY COURSE TO IMPROVE PERFORMANCE IN THE MICROSCOPIC DIAGNOSIS OF MALARIA

**Matthew P. Horning**<sup>1</sup>, Jane Y. Carter<sup>2</sup>, Ken Lilley<sup>3</sup>, Earl G. Long<sup>4</sup>, David Ocheng<sup>5</sup>, Anderson Chinorumba<sup>6</sup>, David Aganyo Isaboke<sup>2</sup>, Bernard Kikechi<sup>2</sup>, Vikas Agrawal<sup>7</sup>, Adam Askew<sup>8</sup>, Stephen D. Johnston<sup>8</sup>, Travis Ostbye<sup>1</sup>, Peter Mwatha<sup>9</sup>, Rachel Achilla<sup>10</sup>, Dionicia Gamboa<sup>11</sup>, Christine Bachman<sup>1</sup>, David Bell<sup>1</sup>

<sup>1</sup>Intellectual Ventures Laboratory, Bellevue, WA, United States, <sup>2</sup>Amref Health Africa, Nairobi, Kenya, <sup>3</sup>Australian Army Malaria Institute, Brisbane, Australia, <sup>4</sup>Retired, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>Amref Health Africa Tanzania, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>World Health Organization - Malaria Inter Country Support Team for East and Southern Africa, Harare, Zimbabwe, <sup>7</sup>Vestige Systems LLC, Wilmington, DE, United States, <sup>8</sup>Philips Digital Pathology Solutions, Belfast, United Kingdom, <sup>9</sup>Kenyatta National Hospital, Nairobi, Kenya, <sup>10</sup>U.S. Army Medical Research Directorate-Kenya, Nairobi, Kenya, <sup>11</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

We developed an in-service malaria microscopy e-learning course that utilizes virtual microscopy and is consistent with World Health Organization standard operating procedures. A key feature of the course is that it can be taken without Internet access—the entire course is stored on a USB drive, making it accessible to malaria microscopists even in remote locations. The course is based on Amref Health Africa's workshop-based course and incorporates instructional content in five modules. A large bank of detailed blood film images can be viewed and navigated on-screen with the virtual microscopy software. The course systematically guides the participant through a process of self-learning, concentrating on specific areas of expertise. Post-module tests and pre- and post-tests allow the user to assess and improve their background knowledge and skills in interpreting blood films. A final assessment is linked to certification, in which the user submits an encrypted code containing their responses to the course organizer. While the course can stand alone as an introduction to malaria microscopy, we envision its primary role as refresher training, including preparation for the external competency assessment of malaria microscopists (ECAMM). Pre-ECAMM refresher training has been shown to increase competency levels. Expanding access to such training may decrease the burden of training during ECAMM and improve outcomes. A late-2015 pilot of a partially completed course received positive and constructive feedback which was used to guide further development. A pilot of the full course was distributed to over 300 participants in 24 countries, covering a broad range of experience, in April 2017. Initial feedback indicates that the course addresses a significant gap in malaria microscopy refresher training, and we are planning to roll out of the complete course later in 2017. A summary of the course, full results of both pilots, including a summary of pre- and post-test results and participant evaluations, and the plan for roll out will be presented.

## EFFECTIVENESS OF URINE-BASED RDT AND BLOOD-BASED RDT IN MALARIA DIAGNOSIS

Chukwudi M. Egbuche<sup>1</sup>, **Chikaodili B. Ukonze**<sup>1</sup>, Tobechukwu Okafor<sup>1</sup>, Ifreke J. Udofia<sup>2</sup>, Obinna A. Chukwuzoba<sup>3</sup>

<sup>1</sup>Nnamdi Azikiwe University Awka, Anambra, Nigeria, <sup>2</sup>Victory Medical Laboratories Onitsha, Anambra, Nigeria, <sup>3</sup>Society For Family Health, Enugu, Nigeria

Management of malaria requires prompt diagnosis by Microscopy and Rapid Diagnostic Test (RDT) kits. The aim of this study was to compare the performance of Blood-based RDT and Urine-based RDT with Microscopy results in malaria diagnosis. This study was conducted using blood and urine specimens collected from 100 human subjects that attended the Community Health center Amansea, Awka-North Local Government Area. Giemsa stained thick and thin films were used for microscopic

examination. Care-start® Blood-based RDT Cassette and Fyodor® Urine Malaria test kit were used for rapid diagnosis of malaria. The prevalence of the malaria as recorded by microscopy was 37%. This was significantly higher than 21% prevalence obtained with blood based RDT and 5% prevalence obtained with urine based RDT. The intensity of malaria and 14% recorded by microscopy was 23% for one plus (+) of malaria and 14% for two pluses (++) of malaria. Malaria intensity as recorded by blood based RDT was 4% for faint line and 17% for thick line. Malaria intensity as recorded by urine based RDT was 3% for faint line and 2% for thick line. Blood-based RDT recorded 52.2% of malaria cases that had one plus of malaria parasite and 57.1% of cases that had two pluses (++) of malaria. Urine based RDT recorded 4.4% of malaria cases that had one plus (+) of malaria and 21.4% of malaria cases that had two pluses (++) of malaria. There was only one positive case of both urine and blood based RDT that had a negative microscopy result. However, there was no significant difference in both urine -based RDT positive cases and Blood-based RDT positive cases that had one plus and two pluses of malaria. The Urine-based RDT recorded a low sensitivity (10.8%) when compared to Blood-based RDT (54.0%). Malaria is still a problem in the study area. The RDT used in the diagnosis is parasite density dependence and may show low or poor performance in low infected population.

## 966

### CONTRIBUTION OF RAPID DIAGNOSIS TEST IN MALARIA CASE MANAGEMENT STRATEGY IN SENEGAL

**Mamadou L. Diouf**

*Ministry of Health, Dakar, Senegal*

According to WHO recommendations issued in 2004 for RDT use to improve quality and accuracy of the diagnosis, Senegal had introduced RDT (based on the detection of the antigen Histidin Rich Protein-2/HRP-2 specific for *Plasmodium falciparum*) in October, 2007. This diagnosis tool was supposed to: allow rational use of CTA, reduce the risk of CTA resistance development in the parasite, increase accuracy and reliability of morbidity data, avoid useless care-costs. In 2015, Senegal recorded 929,010 suspected cases (tested negative), all these cases should have been treated with an antimalarial if RDT was not conducted. Thus, by considering the cost of a CTA treatment at one US dollar, NMCP has realized almost 929,010 USD savings. RDT introduction into malaria case management was a realistic alternative to no functionality of the laboratories in the peripheral structures and to operational issues in the realization of the microscopic diagnosis. Before RDT introduction, the confirmation cases rate by microscopy was just around 10%. In 2007, at the beginning, RDT realization was around 15%, it jumps to 99, 31% in 2015. This was possible as RDT contributed to increase access to biological diagnostic to end users within the community by the mean of community health workers, due to easy use and rapidity in result delivery. Moreover, RDT was accepted by caregivers at any level as it allowed rational use of time, credibility for the health system and increased confidence of the populations. RDT had largely contributed to the decrease of morbidity and mortality due to malaria, since it made possible detecting earlier and accurately malaria cases, treating its with rapidity and by reducing the risks of transmission and evolution of cases to severe ones.

## 967

### A NEW HIGH SENSITIVITY RAPID DIAGNOSTIC TEST FOR *PLASMODIUM FALCIPARUM* DETECTION IN AN ELIMINATION SETTING: INDIVIDUAL DIAGNOSIS OF INFECTION AND MEASUREMENT OF PREVALENCE

**Jordi Landier**<sup>1</sup>, Armon Santirad<sup>1</sup>, Chode Wanachaloemlap<sup>1</sup>, Saw B'let<sup>1</sup>, Keerati Kittitawee<sup>1</sup>, Kamonchanok Konghahong<sup>1</sup>, Peter Christensen<sup>1</sup>, Warat Haohankhunnatham<sup>1</sup>, Laypaw Archasuksan<sup>1</sup>, Mueanfan Wongaeka<sup>1</sup>, Jathee Raksuansak<sup>1</sup>, Smita Das<sup>2</sup>, Iln Kyung Jang<sup>2</sup>, Jacher Wiladphaingern<sup>1</sup>, Daniel M. Parker<sup>1</sup>, Aung Myint Thu<sup>1</sup>, Clare Ling<sup>1</sup>, Stéphane Proux<sup>1</sup>, Gonzalo J. Domingo<sup>2</sup>, Gilles Delmas<sup>1</sup>, François Nosten<sup>1</sup>

<sup>1</sup>Shoklo Malaria Research Unit - Mahidol Oxford Tropical Medicine Unit, Mae Sot, Thailand, <sup>2</sup>PATH, Seattle, WA, United States

The role of asymptomatic carriage of parasites in the persistence of falciparum malaria is increasingly described in low transmission settings where ultrasensitive molecular methods allowed to fully measure the extent of parasite reservoir. However, no point of care test is currently available to detect the parasite densities commonly found in asymptomatic carriers, thus limiting the options to identify and target all parasites as required for active elimination strategies. This is necessary in the Greater Mekong Subregion where rapid elimination of *P. falciparum* has been undertaken to prevent the spread of artemisinin-resistant parasites and the emergence of multi-drug resistant parasites. We tested the Malaria Ag Pf high sensitive RDT (hsRDT) developed by Standard Diagnostics/Alere aiming at a 10-fold increase in sensitivity of PfHRP2 detection compared to standard RDT. From June 2016 to January 2017, prevalence surveys were conducted in 39 villages from Eastern Myanmar by the Malaria Elimination Task Force. In each village, a RDT and hsRDT were performed on site to all participants who provided informed consent. A 2-mL venous sample was collected from a random sub-sample of adults to allow laboratory tests to compare *P. falciparum* detection by RDT, hsRDT, microscopy, ultrasensitive qPCR assay (uPCR) and highly sensitive quantitative HRP2 assay (Quansys). Overall 1730 samples were analyzed with all methods in the laboratory. Preliminary results indicated that laboratory-performed hsRDT could detect 62% (151/243) of all uPCR PF-positive samples, and over 56% (116/208) when restricting the analysis to asymptomatic individuals. In contrast, RDT detected 40% (97/243) of all uPCR PF-positive, and 31% (67/208) of asymptomatics. The specificity was 99.3% compared to uPCR, awaiting confirmatory HRP2 results. The correlation between hsRDT- and uPCR-measured prevalence was 0.955 (compared to 0.822 for RDT). Comparison with results of field hsRDT and RDT is ongoing. The hsRDT significantly increased the sensitivity of the individual diagnostic of asymptomatic infection and provided reliable estimates of community-level prevalence.

## 968

### MAXIMIZED DIAGNOSTIC SENSITIVITY REVEALS UNEXPECTED RESERVOIR OF MALARIA INFECTIONS

**Natalie E. Hofmann**<sup>1</sup>, Daniela Rodriguez-Rodriguez<sup>1</sup>, Elma Nate<sup>2</sup>, Ivo Mueller<sup>3</sup>, Moses Laman<sup>2</sup>, Leanne J. Robinson<sup>3</sup>, Ingrid Felger<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>PNG Institute for Medical Research, Madang, Papua New Guinea, <sup>3</sup>The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Sub-microscopic malaria infections are prevalent particularly in low-endemic settings and are considered an important reservoir for mosquito infection. Ultra-low density infections below the detection limit even of standard PCR present a challenge for malaria diagnosis, which is limited mainly by the volume of blood analyzed, and thus their relevance for malaria transmission and control remains unclear. In Papua New Guinea (PNG), where intensified control efforts during 2004 to 2014 had reduced malaria prevalence drastically, venous blood samples were collected from 302 participants from Madang province during the wet season of 2016/17 and aliquoted to clarify the proportion of infections missed by standard

molecular diagnosis. Malaria prevalence in the study area by standard molecular diagnosis procedures, i.e. 18S rRNA qPCR on finger-prick blood volumes (200 µL), has tripled between 2014 and 2017 for *P. falciparum* (2014, 11%; 2017, 30%) but remained constant for *P. vivax* (2014, 21%; 2017, 20%). Preliminary data suggests that in 2017 one third of *P. falciparum* and *P. vivax* infections are missed when using small volumes (200 µL) and standard 18S rRNA qPCR compared to high volumes (2 mL) combined with ultra-sensitive qPCR. However, finger-pricking is more feasible for routine surveillance studies. 40% of those samples positive in high blood volumes only can also be detected by ultra-sensitive qPCR done in small-volume blood samples. The proportion of ultra-low density *P. falciparum* and *P. vivax* infections is comparable between villages, age groups, men and women, with the exception of children <10 years. In this young age group *P. falciparum* densities, but not *P. vivax* densities, are well detected by standard 18S rRNA qPCR. The high proportion of ultra-low density infections and rapid resurgence of *P. falciparum* between 2014 and 2017 in PNG raises the possibility that sub-microscopic malaria infections even of ultra-low parasite density may constitute an important reservoir for malaria transmission. RNA work for investigation of gametocyte prevalence in these ultra-low density infections was on-going at time of abstract submission.

### ESTABLISHING NATIONAL MALARIA SLIDE BANK: IN ETHIOPIA

**Abeba G. Reda**<sup>1</sup>, Gonfa Ayana Ayana<sup>1</sup>, Abnet Abebe Abebe<sup>1</sup>, Bereket Alemayehu Alemayehu<sup>2</sup>, Mekonnen Tadesse Tadesse<sup>3</sup>, Tesfay Abreha Abreha<sup>3</sup>, Nicole Whitehurst Whitehurst Whitehurst<sup>4</sup>, Hiwot Teka Tekas<sup>5</sup>

<sup>1</sup>EHNRI, Addis Ababa, Ethiopia, <sup>2</sup>Columbia University - ICAP, New York, NY, United States, <sup>3</sup>Columbia University - ICAP in Ethiopia, Addis Ababa, Ethiopia, <sup>4</sup>U.S. Agency for International Development MalariaCare Project, Medical Care Development International, Silver Spring, MD, United States, <sup>5</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Addis Ababa, Ethiopia

Despite the provision of microscopy trainings for health workers and implementation of proficiency testing (PT) external quality assurance (EQA) programs implemented in most countries, few countries have the capacity to produce and use validated blood film slides to ensure the sustained reliability of the trainings and EQA programs. Public Health Institute (EPHI), with support from the U.S. President's Malaria Initiative (PMI), has partnered with the ICAP and Malaria Care for mass production of validated malaria blood film slides with the aim of establishing the nation's first malaria slide bank. *Plasmodium falciparum* and *Plasmodium vivax* positive slides and dry blood spots were prepared at Adama Malaria Control Center from blood specimens collected from consented adult patients. Negative slides were prepared from blood collected from volunteer visitors from non-malaria endemic countries with no history of malaria and travel to malarious areas. Between 200-400 blood film slides were prepared from each donor. The blood film slides were examined by WHO-certified expert microscopists for species identification, for MSP typing and characterized and validated by Polymerase Chain Reaction (PCR). The slides were archived using a custom-made slide bank database and storage cabinets with capacity for 10,000 slides. A total of 10,742 (7,042 *Plasmodium falciparum* and 3,700 *Plasmodium vivax* positive; 1,697 negative) validated blood film slides were collected from 35 donors. Validated malaria slides sets containing blood films slides of negative, mixed from 35 samples for MSP typing 28 were 3D7 and 3 were Dd2 the rest 4 were unknown. Establishment of the slide bank enabled the national malaria program to use standardized and validated slides for quality in-service and pre-service malaria microscopy trainings, competency assessment of microscopists, laboratory mentorship programs, and regional malaria microscopy proficiency testing EQA programs.

## 970

### ANTIBIOTIC PRESCRIPTION PRACTICE FOLLOWING INTRODUCTION OF THE MALARIA 'TEST AND TREAT' POLICY IN UGANDA

**Jane Frances Namuganga**, James Kapisi, Arthur Mpimbaza, Asadu Sserwanga, Ruth Kigozi, Yeka Adoke, Moses Kiggundu, Sam Lubwama Nsohya, Jimmy Opigo, Moses Robert Kamyas

*Infectious Diseases Research Collaboration, Kampala, Uganda*

The WHO recommends parasitological confirmation of all suspected malaria cases before antimalarial treatment. Where malaria testing facilities are lacking, health workers treat suspected malaria cases presumptively with an antimalarial, antibiotic, or both. The malaria 'Test and Treat' policy adopted by Uganda in 2011 contributed to rational antimalarial prescription, however its impact on antibiotic use among those with negative malaria tests is not known. Misuse of antibiotics may contribute to the development of Antimicrobial Resistance since bacterial infections are not routinely confirmed. We assessed antibiotic prescription practices among patients attending Malaria Reference Health Centers (MRCs) in Uganda following the introduction of the malaria 'Test and Treat' policy. We analyzed antibiotic prescription data from the Outpatient Department (OPD) Registers (HMIS Form 031) at 21 MRCs covering 5 years (2012 - 2017). Of 2,417,772 patients who attended OPD, 1,042,263 (43%) had a malaria test done of which 525,154 (50%) tested positive. Antibiotics were prescribed to 163,100/525,154 (31%) patients with a positive test result for malaria and to 338,776/517,107 (66%) with a negative test result. Patients with positive malaria test results were less likely to receive an antibiotic prescription compared to those with a negative test result (OR = 0.211, 95% CI = 0.209 - 0.213). Among patients with a negative test result, those who were not prescribed antimalarials were more likely to receive an antibiotic compared to those who were prescribed an antimalarial (OR = 3.93, 95% CI = 3.84-4.03). Achieving high testing rates for malaria to reduce unnecessary use of antimalarials could significantly increase empirical use of antibiotics. More studies are needed to examine antibiotic prescription practices among patients with acute febrile non malaria illness and the potential drivers of such practices.

## 971

### ULTRASENSITIVE DETECTION OF HISTIDINE-RICH PROTEIN 2 (HRP2) AS A ROBUST METRIC IN ESTIMATING ACTIVE OR RECENT *PLASMODIUM FALCIPARUM* INFECTION IN HAITI

**Eric Rogier**<sup>1</sup>, Camelia Herman<sup>1</sup>, John Williamson<sup>1</sup>, Jean F. Lemoine<sup>2</sup>, Patrick Lammie<sup>1</sup>, Venkatchalam Udhayakumar<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti

Estimating residual malaria transmission becomes increasingly difficult as parasite prevalence is decreased. Increases in proportion of infections with subpatent characteristics and low parasite densities cause field diagnostics of microscopy and rapid diagnostic tests (RDT), as well as lab-based nucleic acid amplification assays, to become more unreliable. Histidine-rich protein 2 (HRP2) is produced exclusively by only one of the human malarial, *Plasmodium falciparum*, and has been an effective diagnostic marker utilized for decades due to its high expression levels and species specificity. Recently, development of a novel laboratory assay for detecting HRP2 allows picogram detection of the antigen in human biospecimens. We employed this assay to a school-based survey in a concentrated sampling area in the low-endemic nation of Haiti (n=1,230 students in 52 schools), where all participants were given a HRP2-based RDT test, and provided a dried blood spot (DBS) for later testing by PET-PCR, ultrasensitive HRP2 assay, and serology assay for IgG against *P. falciparum* antigens. Of all students sampled, 7 (0.57%) tested positive by RDT, 9 (0.73%) positive by PET-PCR, and 26 (2.11%) positive by the HRP2 assay. Discordance was noted among these three assays, with just 4 children testing positive for all, 3 RDT only positives, 3 PET-PCR only positives, and 20 HRP2 only

positives. Children only positive for the HRP2 lab assay consistently had lower concentrations of the antigen, indicating a very low-density infection (below PET-PCR limit of detection), or lingering antigen in the blood from a previously-resolved infection. Regardless of the assay used, similar geospatial clustering was observed to estimate regions of active or recent malaria exposure. Serological data for IgG prevalence to *P. falciparum* antigens corroborated these findings, showing higher percentage of children with malaria antibodies in clustered regions. Direct comparisons of estimates provided by each of these assays provides evidence of HRP2 detection and quantification as a potentially useful metric for population-based malaria surveillance purposes.

### IMPROVING QUALITY OF BLOOD SMEAR MALARIA MICROSCOPY THROUGH A DISTRICT-BASED EXTERNAL QUALITY ASSURANCE SCHEME IN UGANDA, 2014-2016

**Bosco B. Agaba**<sup>1</sup>, Jimmy Opigo<sup>1</sup>, Umaru Sekabira<sup>2</sup>, Ruth Nabwire<sup>1</sup>, Charles Katureebe<sup>3</sup>, Gloria Sebikaari<sup>4</sup>, Joel Kisubi<sup>4</sup>, Ruth Kigozi<sup>5</sup>, Hope Ninsiima<sup>6</sup>, Paul Mbaka<sup>3</sup>, Bayo Fatunmbi<sup>3</sup>, Belay Kassa<sup>4</sup>

<sup>1</sup>Department of Disease Control, Malaria Program, Kampala, Uganda, <sup>2</sup>Infectious Diseases Institute, Kampala, Uganda, <sup>3</sup>World Health Organization, Kampala, Uganda, <sup>4</sup>President's Malaria Initiative, Kampala, Uganda, <sup>5</sup>Malaria Consortium, Kampala, Uganda, <sup>6</sup>Mulago National Referral Hospital, Kampala, Uganda

World Health Organization (WHO) recommends Microscopic examination of blood smears as the gold standard method for malaria diagnosis. However, its quality in most malaria endemic and resource limited settings remains modest. To improve the quality of malaria microscopy, we conducted refresher training before a WHO recommended External Quality Assurance (EQA) system was implemented in Uganda. We report on findings of a district-based slide cross-checking program that aimed at improving the quality of malaria microscopy in 21 districts of Uganda. From 2014 to 2016, 54 health facilities located across 21 districts were selected to participate in an EQA program. Each health facility randomly selected and stored two blood slides (positive and negative) from routinely examined slides per day. On a monthly basis, a district laboratory coordinator randomly selected and transported 10 positive and 10 negative slides to the district hospital for cross-checking in an independent and blinded manner. Ability to correctly classify blood smears as positive or negative was compared for parasite detection with those at the district hospital. Discordant slides were tie broken by WHO certified expert slide readers whose decision was final. Blinding of readers was done at all levels. The Kappa statistic was used to measure accuracy and level of agreement between the slide readers. Between January 2014 and November 2016, a total of 18,000 blood slides were collected, of these, 5200 (28%) were discordant after cross-checking at the district level. Overall, the proportion of laboratories with accurate parasite detection increased from 49% (26) in 2014 [Kappa=0.66] to 78% (42) in 2016 [Kappa=0.88]. Improvement in accuracy varied across districts with the highest and lowest being 67% in 2014 to 82% in 2016, [p<0.02] and 67% in 2014 to 77% in 2016 [p<0.04] respectively. Implementation and maintenance of an external Quality assurance system can potentially improve quality of malaria microscopy in support of malaria case management and surveillance systems.

## 973

### CLINICAL PERFORMANCE OF A HIGH-SENSITIVITY HISTIDINE-RICH PROTEIN 2 (HRP2)-BASED ELISA FOR DETECTION OF *PLASMODIUM FALCIPARUM* MALARIA

Roger Peck<sup>1</sup>, Ihn Kyung Jang<sup>1</sup>, Becky Barney<sup>1</sup>, **Smita Das**<sup>1</sup>, Bryan Greenhouse<sup>2</sup>, Francois Nosten<sup>3</sup>, Gonzalo Domingo<sup>1</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Shoklo Malaria Research Unit, Mae Sot, Thailand

Detection of individuals harboring low-density *Plasmodium falciparum* (*Pf*) infections is critical for assessing malaria intervention efforts, as well as *Pf* vaccine efficacy and drug sensitivity studies. The gold standard, microscopy, lacks reproducibility and has high false-positive rates and low sensitivity at submicroscopic parasitemias (200 parasites/ $\mu$ L). As a result, biomarkers such as HRP2 that are abundant throughout the parasite asexual stage are increasingly being used as a surrogate for *Pf* detection. Current commercial enzyme-linked immunosorbent assays (ELISAs) are used because they have higher sensitivity than current diagnostics, but they have only a 400 pg/mL HRP2 limit of detection (LOD) and are therefore unable to detect and quantify HRP2 at low parasitemias. Recently, Alere™ developed the high-sensitivity Malaria Ag P.f ELISA (HS ELISA) with an LOD of 25 pg/mL HRP2. As part of the PATH Diagnostics for Malaria Elimination Toward Eradication (DIAMETER) project, a performance evaluation of the Alere HS ELISA was conducted using field-collected whole blood specimens from malaria-endemic areas. The HS ELISA study used 300 whole blood specimens, of which 100 were from Nagongera, Tororo District, Uganda, and 200 were from Karen Village, Myanmar. The Uganda specimens were collected from May through September 2015 in a high-transmission area, and the Myanmar specimens were collected from April through May 2015 in a low-transmission area. All 100 specimens from Uganda were *Pf* positive by both microscopy and qRT-PCR, and the 200 specimens from Myanmar were *Pf* negative by both microscopy and qRT-PCR. The results showed an HS ELISA sensitivity of 100% (96.4-100) and a specificity of 97.9% (94.8-99.4) compared to concordant microscopy and qRT-PCR results. The findings suggest that the Alere™ HS ELISA has excellent sensitivity and specificity against clinical specimens when compared to gold standard assays, making it a promising tool for successful malaria programs.

## 974

### A RETROSPECTIVE CLINICAL RECORD REVIEW OF MALARIA DIAGNOSES IN HAITI: 2008-2016

**Caroline J. Stephenson**<sup>1</sup>, Michael E. von Fricken<sup>1</sup>, Nuhira Ahm Masthan Ahmed<sup>1</sup>, Marie Y. Remy<sup>2</sup>, Robert Nicolas<sup>2</sup>

<sup>1</sup>George Mason University, Fairfax, VA, United States, <sup>2</sup>African Methodist Episcopal Church Service and Development Agency, Inc., Washington, DC, United States

The national policy for malaria diagnosis in Haiti changed in 2012, switching from microscopy to rapid diagnostic tests (RDTs). This study aims to examine the temporal trends of malaria diagnosis among five clinics in the Ouest Department that captures the impact of this change in policy on reporting. Monthly clinic records from 2008 to 2016 were acquired from the African Methodist Episcopal Church Service and Development Agency, Inc. (AME-SADA) for five different clinics within the Ouest Department of Haiti. Data was dichotomized between "microscopy only" for the years 2008 to 2011 and "RDT" for the years 2012 to 2016. Descriptive statistics and logistic regression were used to analyze data. From 2008 to 2016, the percentage of malaria positive samples out of the total number tested was approximately 9% overall. The microscopy group was found to have 533 malaria positives out of 1678 suspected cases (31.8%), while the RDT group had 92 malaria positives out of 5272 suspected cases (1.7%). After adjusting for the number of people tested, patients examined by microscopy were approximately 1.8 times more likely to have a malaria positive diagnosis than patients examined by RDTs (OR = 1.79 95% CI:

1.44-2.24). The significant difference between percentages of confirmed cases before and after the implementation of RDTs in Haiti may be evidence of improved diagnostics with the switch to RDTs and possible previous over diagnosis with microscopy. However, a plausible reason for this could be differences in thresholds of detection or that microscopy was identifying asymptomatic gametocytemia while RDTs identified the acute clinical phase. Regardless, 98% of suspected malaria cases tested negative, warranting further investigations into the underlying cause of undifferentiated febrile illness in Haiti.

## 975

### EXPLORING THE ANTIMALARIAL POTENTIAL OF WHOLE PLANT *CYMOPOGON CITRATUS*

**Uchechukwu M. Chukwuocha**, Ikechukwu N. Dozie  
Federal University of Technology, Owerri, Nigeria

Malaria is a health problem concentrated in the poorest Sub-Saharan African countries. Because of the development of resistance and adverse reactions to common antimalarials as well as their limited affordability and accessibility, it is important to investigate other options for malaria therapy. Plants have been used as therapeutics for centuries and as source of pharmaceutical antimalarial drugs. In this study, the antimalarial activity of the dried whole plant (WP) *Cymbopogon citratus* (Lemon Grass) was evaluated. This plant has been used as herbal infusion against fever and malaria. The antimalarial activity of the whole plant was assessed in two rodent malaria models, *Plasmodium chabaudi* AS, which generates a self-cured infection, and *P. berghei* ANKA, which is lethal. Results showed that the WP *C. citratus* treatment produced prolonged antimalarial activity against both parasites. In addition, two whole plant doses of 1600mg/kg and 3200mg/kg were respectively tested. The low dose elicited higher antimalarial activity than the high dose, indicating a potential saturation of receptors with the high dose. As a prophylactic treatment, the whole plant displayed higher antimalarial activity than chloroquine as well as the plant's infusion. These findings provide evidence of the antimalarial effectiveness of the dried whole plant *C. citratus* and supports continued efforts towards developing whole plant therapies for the management of malaria and other infectious diseases in resource poor settings.

## 976

### PYRIDO[1,2-A]BENZIMIDAZOLES: A NOVEL NON-QUINOLINE B-HAEMATIN INHIBITING ANTIMALARIAL CHEMOTYPE

**John Okombo**, Kawaljit Singh, Timothy J. Egan, Kelly Chibale  
University of Cape Town, Cape Town, South Africa

The emergence of *Plasmodium falciparum* strains tolerant to artemisinin combination therapies underscores the urgent need to expand the antimalarial drug arsenal. One approach to this involves exploring novel compound classes, preferably with multistage activity, good safety profiles and targeting critical pathways within the parasite. Pyrido[1,2-a]benzimidazoles (PBIs), which possess a chloroquine (CQ)-like planar heterocyclic moiety, are likely to interact through  $\pi$ - $\pi$  stacking with ferriprotoporphyrin IX - a toxic byproduct of haemoglobin degradation by *P. falciparum*, leading to inhibition of haemozoin (Hz) formation and consequent parasite death. The aim was to profile a series of PBIs using *in vitro* analyses to determine their activity against various stages of *P. falciparum* lifecycle and, as mechanistic evaluation, test their ability to inhibit *in vitro*  $\beta$ -haematin and with-in cell Hz formation as well as *in vivo* efficacy in a mouse model. Characterization of the antiplasmodial potency, cytotoxicity,  $\beta$ -haematin/Hz inhibition activity and metabolic profiles of each compound was performed using established *in vitro* and *in vivo* assays. All test compounds had nanomolar activity against CQ-sensitive and -resistant *P. falciparum* strains and displayed favourable toxicity indices. Representative analogues in the series were effective against liver and gametocytic stages, and showed *in vivo* oral efficacy in the *P. berghei* mouse model. Most of the compounds tested inhibited  $\beta$ -haematin formation in the same range as the standard inhibitor, amodiaquine and

further showed dose-dependent Hz inhibition signatures similar to CQ in trophozoites. These PBIs are therefore potential candidates for pre-clinical development and inhibition of Hz formation is a likely mechanism of action contributing to their activity in *P. falciparum*.

## 977

### BOOSTING IVERMECTIN FOR VECTOR CONTROL: CYTOCHROME-P-450/ABC-TRANSPORTER INHIBITION SYNERGIZES IVERMECTIN AND INCREASES THE MORTALITY OF *ANOPHELES GAMBIAE*

**Carlos J. Chaccour**<sup>1</sup>, Marta Alustiza<sup>2</sup>, Brian B. Tarimo<sup>3</sup>, Helena Martí<sup>1</sup>, José L. Del Pozo<sup>4</sup>, Marta Maia<sup>5</sup>

<sup>1</sup>ISGlobal Barcelona Institute for Global Health, Barcelona, Spain, <sup>2</sup>Universidad de Navarra, Pamplona, Spain, <sup>3</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>4</sup>Clinica Universidad de Navarra, Pamplona, Spain, <sup>5</sup>KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

Insecticide resistance and mosquito behavioural adaptations that allow avoidance of home-centred vector control measures are two of the major challenges faced by the malaria community today. In this context, the mass use of drugs that can kill mosquitoes feeding on treated subjects has potential to become a new paradigm for vector control. Ivermectin is one of the leading candidates given its excellent safety profile. In the phase of the challenge posed by insecticide resistance, a thorough understanding of the mosquito metabolic pathways and potential defence mechanisms from ivermectin is of paramount importance for vigilance purposes and early assessment if this novel strategy is to be used in the field. Simple synergistic bioassays have been previously used to identify metabolic resistance in *Anopheles* adults and larvae. We have conducted a synergistic bioassay to evaluate the potential involvement of ABC transporters and cytochrome P450 in the metabolism of ivermectin in *Anopheles gambiae*. Mosquitoes were membrane fed with matched pairs of blood samples containing the same ivermectin concentration with or without Ketoconazole (a dual cytochrome-P450/ABC-transporter inhibitor). Mosquitoes in the ivermectin plus ketoconazole group had a significantly reduced mean survival and time to median mortality as assessed by Kaplan-Meier analysis. Our results show that pharmacological inhibition of P450 and ABC transporters could further improve the efficacy of ivermectin as a vector control tool and extend the spectrum towards less susceptible vectors.

## 978

### ANTIMALARIAL THIOTRIAZOLES: DISCOVERY OF A NOVEL PRECLINICAL CANDIDATE WITH CLINICALLY VALIDATED MODE OF ACTION

**Laura M. Sanz**, Cristina De Cózar, Benigno Crespo, Noemi Bahamontes, Maria Jesús Almela, Virginia Franco, Fernando Neria, Jose Luis Llargo, Maria José Lafuente, Maria De Gómez, Janneth Rodrigues, Beatriz Díaz, Francisco Javier Gamo  
GlaxoSmithKline, Tres Cantos (Madrid), Spain

Malaria continues to be a major global disease still causing impermissible number of deaths. The effectiveness of current antimalarial therapy is under continuous threat through the spread of resistance. Consequently, there is an urgent need to replace those drugs compromised by resistance, as well as identifying potential novel therapies that offer significant advantages over the current standard of care. Within the TCAM set of phenotypic hits identified at GSK, a thiothiazole chemical series was selected because its chemical novelty offering exciting properties as antimalarial. Thiothiazole molecules are dual acting antimalarials with demonstrated activity against both asexual and sexual intra-erythrocytic *Plasmodium* stages, with nanomolar *in vitro* potency in sensitive and MDR strains (including clinical isolates). Potential to block disease transmission has been validated using a standard membrane feeding assay (SMFA)

with *Anopheles* mosquitoes. These properties are accompanied by an oral efficacy characterized by a rapid parasite clearance in the *P. falciparum* mouse model. Thiotriazole series displays a novel mechanism of action and its parasitological profile and genetic studies point at compounds targeting the PfATP4 pathway. Lead optimization efforts within the series led to the identification of GSK3212030 molecule as a new preclinical candidate that will offer opportunities linked to its rapid antimalarial mode of action expected to maximize efficacy, achieving fast clinical resolution, and minimizing the in-patient window of opportunity for resistant parasite selection and dissemination. The overall properties of GSK3212030 constitute a promising profile supporting further development to provide novel antimalarial therapeutic opportunities.

## 299

### DISCOVERY OF NOVEL ANTI-MALARIALS BY HIGH THROUGHPUT SCREENING AND COMBINATORIAL CHEMISTRY

**Farhana Mosaddeque**<sup>1</sup>, Shusaku Mizukami<sup>2</sup>, Awet Alem Teklemichael<sup>1</sup>, Satoshi Mizuta<sup>3</sup>, Yoshimasa Tanaka<sup>4</sup>, Nguyen Tien Huy<sup>2</sup>, Kenji Hirayama<sup>1</sup>

<sup>1</sup>Department of Immunogenetics, Institute of Tropical Medicine (NEKKEN), Nagasaki University, Nagasaki, Japan, <sup>2</sup>Department of Clinical Product Development, Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, <sup>3</sup>Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan, <sup>4</sup>Center for Therapeutic Innovation, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Malaria has been a major global health concern for many years. Despite some reduction in mortality, malaria still have a hideous impact on people's health, especially on children. Swift spread of drug resistant malaria parasites and limited available drugs - accelerate the necessity of novel anti-malarial compound development. In our previous study (doi:10.1128/AAC.01607-16), core 9600 compounds assigned with various structural diversity of >200,000 compounds from the University of Tokyo chemical library were screened. 224 compounds among 9600, were identified as potential hemozoin inhibitors after an initial *in vitro* anti-hemozoin high throughput screening (HTS). In our current study, an *in vitro* erythrocytic anti-malarial assay was performed at 10  $\mu$ M to screen positive compounds exhibiting anti-malarial activity using Chloroquine/Mefloquine sensitive *Plasmodium falciparum* (Pf) strain, 3D7. Subsequently, dose-response assay was done at ten different dilutions ranged between 0.5 nM and 10  $\mu$ M to measure the 50% inhibitory concentration (IC<sub>50</sub>). Each experiment was conducted twice. Eventually, an *in vitro* anti-malarial assay followed by dose-response assay were performed using Chloroquine/Mefloquine resistant *P. falciparum* strain, Dd2, at similar condition as mentioned above. SYBR Green-I was used for the staining and detection of parasite. Cytotoxicity was measured using human liver carcinoma (HepG2) and adult mouse brain (AMB) cells at 20  $\mu$ M concentration. A total of 22 compounds were identified to exhibit anti-malarial activity against 3D7 strain with IC<sub>50</sub>  $\leq$  10  $\mu$ M. Out of 22, only six compounds possessed IC<sub>50</sub> < 7  $\mu$ M for both *Plasmodium falciparum* (Pf) strains, 3D7 and Dd2. However, five compounds demonstrated anti-malarial activity at IC<sub>50</sub> < 7  $\mu$ M for both Pf strains and CC<sub>50</sub> > 20  $\mu$ M. Among them, 3 compounds showed IC<sub>50</sub> < 0.8  $\mu$ M. In conclusion, 5 compounds have selected as potential "Hit compounds". Based on the chemical similarity scores using "Tanimoto similarity measure", all the available analogues (>1500) of the five hit compounds were purchased from University of Tokyo for further analysis.

### OPTIMIZATION OF POLYMERIC BLENDS-ARTESUNATE-AMODIAQUINE HCL MICROPARTICLES USING DESIGN EXPERT SOFTWARE

**John D. Ogbonna**, Anthony A. Attama, Kenneth C. Ofokansi  
University of Nigeria, Nsukka, Nigeria

A 23 Factorial design of cissus-gelatin B polymer blends was developed to formulate amodiaquine HCl-artesunate microparticles by varying the polymer blend concentration (2 %w/v, 5 %w/v), crosslinking time (0.5 h, 1 h) and glutaraldehyde volume (0.5 ml, 1 ml). The formulations were evaluated using drug entrapment efficiency (EE), particle size, polydispersity index, thermal behaviour with differential scanning calorimetry, crystallinity with powder X-ray diffraction, morphology with scanning electron microscope and *in vitro* release using combination of simulated gastric fluid (SGF, pH= 7.4, 95 %) and methanol (5 %). The expected responses, EE and *in vitro* release were fitted into Design Expert®. The polymer blends exhibited pseudoplastic behavior and there was no marked change in rheology behaviour of 2 % w/v dispersion at 55 oC. The amodiaquine HCl-artesunate formulated microparticles were dark brownish discrete mass, physically stabilized, irregular shape, polydisperse, and semi-amorphous system. An optimal formulation comprising polymer blend (5%w/v), glutaraldehyde (1 ml) and cross-linking time (0.5 h) was identified to provide desired values for EE, amodiaquine HCl (47.41%), artesunate (36.42%) and *in vitro* release. This study proposes the best opportunity for selection of factors required for optimum microparticles formulation using the polymer blends and the drugs.

**Keywords:** microparticles, crystallinity, entrapment efficiency, polymer blend, *in vitro* release.

## 981

### EVALUATION OF THE ANTIOXIDANT POWER AND THE EFFECT OF POTENTIATION AND STUDY OF TOXICITY PARAMETERS OF 2 EXTRACTS OF PLANTS WITH STRONG ANTIMALARIAL ACTIVITY

**Dominique K. Tano**<sup>1</sup>, William Yavo<sup>1</sup>, Joseph A. Djama<sup>2</sup>, Hervé E. Menan<sup>3</sup>

<sup>1</sup>National Institute of Public Health (NIPH - Côte d'Ivoire), Abidjan, Côte D'Ivoire, <sup>2</sup>Pharmacodynamics Biochemical Laboratory, UFR of Biosciences - University Félix Houphouët Boigny, Abidjan, Côte D'Ivoire, <sup>3</sup>Département of Parasitology and Mycology, Faculty of Pharmaceutical and Biological Sciences - University Félix Houphouët Boigny/Center for Diagnosis and Research on AIDS and Other Infectious Diseases (CeDRes), Abidjan, Côte D'Ivoire

In the aim to seek an alternative face to the *Plasmodium falciparum* resistance to known antimalarials, especially artemisinin derivatives, and as part of the promotion of African traditional pharmacopoeia by the development of ITM, we have in this study evaluated *ex vivo* and *in vitro* antiparasmodial activity of several extracts from two plants traditionally used as antimalarials in Ivory Coast: *Erigeron floribundus* and *Terminalia glaucescens*. Then we explored the chemical composition of active and promising extracts, assessed their antioxidant activity and studied their toxicological profile. After this work, we noted that the methanol extracts of the leaves and roots bark of *T. glaucescens* showed the best activities with respective IC<sub>50</sub>s of 2.20  $\mu$ g/mL and 1.40  $\mu$ g/mL on chloroquine-sensitive isolates and 3.65  $\mu$ g/mL and 1.38  $\mu$ g/mL on chloroquine-resistant isolates. These extracts have been more active on chloroquine-sensitive and chloroquine-resistant reference strains and also showed a high potentiating power over chloroquine. The evaluation of the antioxidant activity of these extracts showed their wealth in polyphenols, tannins and flavonoids. In addition, we determined that methanol extracts of *T. glaucescens* leaves and roots bark have nearly three times the reducing power of vitamin C on the DPPH radical. On the toxicological aspect, we noted that these extracts showed no immediate toxicity

by oral administration. From the experience of repeated doses, rather we noted several beneficial effects of these extracts on body weight, hemoglobin, blood levels of cholesterol and triglycerides, and a remarkable hepatoprotective action. The signs of toxicity appeared only at very high doses. Thus the traditional therapeutic dose of 13.90 mg/kg body weight of methanol extracts of *T. glaucescens* leaves and root bark is not toxic and may be admixable in human. NOAEL have been determined below or close to 1390 mg / kg body weight.

## 982

### MECHANISTIC AND SAR EVALUATION OF HEMOZOIN-INHIBITING COMPOUNDS IDENTIFIED VIA HTS ACTIVE AGAINST PLASMODIUM FALCIPARUM

Kathryn J. Wicht<sup>1</sup>, Jill M. Combrinck<sup>2</sup>, Peter J. Smith<sup>2</sup>, Roger Hunter<sup>1</sup>, Timothy J. Egan<sup>1</sup>

<sup>1</sup>Department of Chemistry, University of Cape Town, Cape Town, South Africa, <sup>2</sup>Division of Pharmacology, Department of Medicine, University of Cape Town, Cape Town, South Africa

Quinoline antimalarials target hemozoin (Hz) formation causing a cytotoxic accumulation of ferriprotoporphyrin IX (Fe(III)PPIX). Well-developed SAR models exist for  $\beta$ -hematin ( $\beta$ H); synthetic Hz) inhibition, parasite activity and cellular mechanisms for this compound class, but no comparably detailed investigations exist for other Hz-inhibiting chemotypes. In a previous study, target based screening was carried out for inhibitors of  $\beta$ H formation and series of benzimidazoles and triarylimidazoles were identified as active against *Plasmodium falciparum*. Here we report the subsequent synthesis and testing of derivatives with varying substituents for these series. The results indicated that only benzamide derivatives containing an electron deficient aromatic ring and capable of adopting flat conformations, optimal for  $\pi$ - $\pi$  interactions with Fe(III)PPIX, can inhibit  $\beta$ H formation. In contrast to quinolines, introduction of amine side chains for pH trapping did not lead to benzamide accumulation in the parasite. Furthermore, a 2-hydroxy-1,3-dimethoxy substitution pattern on the 2-phenyl ring of the triarylimidazoles is required for submicromolar parasite activity. The two most potent analogues showed nanomolar IC50s, with little CQ cross-resistance, low cytotoxicity and high *in vitro* microsomal stability. Selected  $\beta$ H inhibiting analogues were shown to dose-dependently inhibit Hz formation and parasite survival in parasitized red blood cells causing unprecedented levels of intracellular exchangeable (free) heme at their relative IC50. In contrast, active compounds which do not inhibit  $\beta$ H formation, did not show this effect *in vitro*, suggesting an alternative mechanism of action. These data reveal complex relationships between heme binding, free heme levels, cellular accumulation and *in vitro* activity of potential novel antimalarials.

## 983

### IDENTIFICATION OF APPROVED DRUGS THAT HAVE ACTIVITY AGAINST PLASMODIUM FALCIPARUM USING IN SILICO AND IN VITRO APPROACHES

Reagan M. Mogire<sup>1</sup>, Hoseah M. Akala<sup>2</sup>, Dennis W. Juma<sup>2</sup>, Agnes C. Cheruiyot<sup>2</sup>, Rosaline W. Macharia<sup>3</sup>, Hans A. Elshemy<sup>4</sup>, Ben Andagalu<sup>2</sup>, Matthew L. Brown<sup>2</sup>, Steven G. Nyanjom<sup>5</sup>

<sup>1</sup>Pan African University, Nairobi, Kenya, <sup>2</sup>United States Army Medical Research Directorate – Kenya (The Walter Reed Project), Kisumu, Kenya, <sup>3</sup>University of Nairobi Centre for Biotechnology and Bioinformatics, Kenya Medical Research Institute/U.S., Kenya, <sup>4</sup>Cairo University, Cairo, Egypt, <sup>5</sup>Jom Kenyatta University of Agriculture and Technology, Kenya Medical Research Institute/U.S., Kenya

Recent reports of artemisinin resistance in South-East Asia warrant urgent discovery of novel drugs for treatment of malaria. Unfortunately, the success rate of bringing new drugs to the market is low. This is mainly because most bioactive compounds don't get approved due to safety concerns and the prohibitive cost and time involved in drug discovery and development. Therefore, repositioning of already approved drugs

can be sustainable since these have passed safety tests in the treatment of some diseases. This study screened approved drugs for antiparasmodial activity using *in silico* chemogenomics approach and *in vitro* assays. All *Plasmodium falciparum* proteins available at NCBI RefSeq database were retrieved in FASTA format. Sequence similarity search was performed against these proteins and putative target proteins of approved drugs in Therapeutic Target Database, DrugBank and STITCH databases. Functional residues of the drug targets were determined using ConSurf server which were used to fine tune the similarity search. Druggability of the *P. falciparum* proteins were also obtained from TDR targets database. Of the drugs predicted to have antiparasmodial activity, those that have been previously tested against malaria were identified by doing a published literature search. Finally, drug susceptibility assays using SYBR Green I method were done to validate their antimalarial activity. Preliminary results showed 133 approved drugs could target specific *Plasmodium* proteins. Though, published literature showed that only 34 out of 133 drugs not to have been tested. Interestingly, most of those tested did show significant antimalarial activity. We did *in vitro* tests on 12 out of the 34 drugs, 10 had IC50 below 100  $\mu$ M while 3 had less than 10  $\mu$ M. This study validates the use of target-similarity in identifying approved drugs that have activity against the *Plasmodium* parasite and hence reposition them for antimalarial treatment. This approach would circumvent many challenges involved in preliminary stages of drug discovery and development hence could save on cost and time spent in introducing new drugs into the market.

## 984

### HIGH THROUGHPUT DISCOVERY OF NEW DRUGS TARGETING MALARIA PARASITE TRANSMISSION - TOWARDS THE ALTRUISTIC ANTIMALARIAL

Michael J. Delves<sup>1</sup>, Celia Miguel-Blanco<sup>2</sup>, Holly Matthews<sup>1</sup>, Andrea Ruecker<sup>1</sup>, Irene Molina<sup>2</sup>, Ursula Straschil<sup>1</sup>, Esperanza Herreros-Aviles<sup>2</sup>, Francisco J. Gamo<sup>2</sup>, Jake Baum<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>GlaxoSmithKline, Madrid, Spain

Growing evidence of resistance to artemisinin threatens the shelf-life of the current frontline antimalarial combination therapies and underscores the need for the discovery of novel drug targets with new modes of action. Historically, antimalarial chemotherapy has been an arms race between drug-development and resistance acquisition of asexual parasites. Multi-stage targeted approaches are therefore a necessity if future gains are to be made and held. Since only 0.2-1 % of asexual parasites differentiate into gametocytes, targeting this natural bottleneck provides a tangible route to interrupt transmission whilst avoiding resistance selection. In recent years, development of high-throughput antimalarial assays has permitted access to previously unexplored chemical space. Towards discovery of transmission blocking antimalarials and novel targets, a Dual Gamete Formation Assay (DGFA) has been developed as a high-throughput alternative to the Standard Membrane Feeding Assay (SMFA). The DGFA determines viability of male and female gametocytes independently, using different readouts of the same well, following drug exposure. Here we present the results from a large-scale high-throughput screen of the Global Health Chemical Diversity Library, with nearly 70,000 different chemical scaffolds, identifying several classes of novel drug hits. The screening campaign has uncovered compounds with different activity profiles (male-specific activity, dual male-female activity or dual-asexual-sexual activity), providing new options to target parasite transmission. We present results from ongoing work aimed at validating *in vivo* activity of each compound along with efforts to determine their precise mode of action. The discovery of novel antimalarials targeting transmission sets the groundwork for future therapeutics that would prevent transmission of parasites through the population, altruistically blocking the spread of malaria in communities. Combined with schizonticides, we believe dual-stage combination therapies envisaged this way would become key assets for future global eradication campaigns.

## TRANSLATIONAL PRECLINICAL PLATFORM FOR EVALUATION OF ANTIMALARIAL COMBINATION THERAPY

Maria J. Lafuente<sup>1</sup>, Laura Sanz<sup>1</sup>, Didier Leroy<sup>2</sup>, John Haselden<sup>1</sup>, Francisco Javier Gamo<sup>1</sup>

<sup>1</sup>Tres Cantos Medicines Development Campus. Diseases of the Developing World. GlaxoSmithKline, Severo Ochoa 2, 28760 Tres Cantos, Spain,

<sup>2</sup>Medicines for Malaria Venture (MMV), Geneva, Switzerland

Malaria is a global health problem that causes significant mortality and morbidity in many developing countries, where young children and pregnant women are the groups most affected. Most antimalarial drugs face decreased efficacy due to the spread of resistance. The past decade has seen a transformation of the portfolio of malaria medicines, with new chemical entities, that act through novel mechanisms of action, entering clinical development. The challenge in drug discovery and development is to show that a medicine is effective in the clinical setting. Drug combinations are essential for optimal control of malaria, as they should delay the selection of anti-malarial drug resistance and could offer additional advantages if the separate agents are active against different parasite stages. A translational preclinical platform aimed at identifying novel and optimal combinations to optimize efficacy and avoid selection of resistance has been established. This platform is supported by the Bill and Melinda Gates Foundation and encompasses a complete profiling which involves several phases: a/ To map the compatibility of a range of current and new antimalarials based on its different Mode of Action (MoA) and establishment of quantitative *in vitro* and *in vivo* assays to analyze combination interactions. b/ To conduct *in vitro/in vivo* efficacy analysis of selected pairs of antimalarials c/ To provide a detailed PK/PD analysis of selected drug combinations for Human Dose Prediction. d/To analyse the effect of antimalarial combinations on resistance selection. The combinations that are to be thoroughly investigated will be selected by a joint Steering Committee of both MMV and GSK members. Novel combinations will be studied extensively with the main aim of identifying key parameters that will assist the design of future clinical trials. "The human biological samples were sourced ethically and their research use was in accord with the terms of the informed consents" "All animal studies were ethically reviewed and carried out in accordance with European Directive 86/609/EEC and the GSK Policy on the Care, Welfare and Treatment of Animals."

## MEPICIDES: POTENT INHIBITORS OF ISOPRENOID METABOLISM IN *PLASMODIUM FALCIPARUM*

Rachel L. Edwards<sup>1</sup>, Robert C. Brothers<sup>2</sup>, T. R. S. Kumar<sup>3</sup>, Xu Wang<sup>2</sup>, Maxim I. Maron<sup>4</sup>, Peter D. Ziniel<sup>5</sup>, Patricia S. Tsang<sup>6</sup>, Kim C. Williamson<sup>5</sup>, David A. Fidock<sup>3</sup>, Cynthia S. Dowd<sup>2</sup>, Audrey R. Odom John<sup>7</sup>

<sup>1</sup>Washington University, St. Louis, MO, United States, <sup>2</sup>George Washington University, Washington, DC, United States, <sup>3</sup>Columbia University, New York, NY, United States, <sup>4</sup>Loyola University Chicago, Chicago, IL, United States, <sup>5</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>6</sup>National Institutes of Health, Bethesda, MD, United States, <sup>7</sup>Washington University, St. Louis, MO, United States

The emergence of *Plasmodium falciparum* strains resistant to current antimalarial therapies has prompted efforts to identify and validate agents with novel mechanisms of action. The enzymes of the methylerythritol phosphate (MEP) pathway of isoprenoid biosynthesis are promising drug targets, as pathway enzymes are essential, conserved, and lack mammalian homologues. We specifically targeted the first dedicated enzyme of the MEP pathway, deoxyxylulose phosphate reductoisomerase (Dxr), and have both genetically and chemically validated the enzyme as an antimalarial target. The ultrastructural changes that occur when Dxr is disrupted were characterized by transmission electron microscopy. Our data indicate that Dxr function is essential for maintaining normal

cellular morphology. Further, we identified a new series of Dxr inhibitors, termed MEPicides, which have low nM potency against asexual blood stage parasites. Targeted metabolite analysis demonstrated that MEP pathway metabolites are substantially reduced in *P. falciparum* following treatment with the inhibitors. In addition, isoprenoid precursors rescued growth of MEPicide-treated parasites, and *P. falciparum* mutants that produce higher levels of the Dxr substrate were resistant to MEPicide treatment. Importantly, multidrug-resistant parasites were sensitive to the inhibitors, and there was no observable toxicity to human cell lines. While the MEPicides lacked activity against mature gametocytes, the compounds effectively killed parasites committed to gametocytogenesis, suggesting that the Dxr inhibitors may reduce transmission. Finally, our data indicate that this novel class of compounds is both safe and efficacious in malaria-infected mice. Collectively, our findings demonstrate that the MEPicides are promising antimalarial agents, and likewise, are candidates for further drug development.

## SCREENING THE PATHOGEN BOX FOR HITS AGAINST ARTEMISININ-RESISTANT *PLASMODIUM FALCIPARUM* MALARIA

Maha Alharbi<sup>1</sup>, Abu Naser Mohon<sup>1</sup>, Benoit Laleu<sup>2</sup>, Dylan R. Pillai<sup>1</sup>

<sup>1</sup>University of Calgary, Calgary, AB, Canada, <sup>2</sup>MMV, Geneva, Switzerland

The Pathogen Box contains 400 diverse, drug-like molecules active against neglected diseases of interest and is available free of charge from Medicines for Malaria Venture. A dramatic increase in artemisinin and partner drug resistance in SE Asia has forced the need for new drugs against *P. falciparum* malaria. In an effort to identify new anti-malarials with such activity, we screened n=80 compounds from The Pathogen Box against artemisinin-resistant *Plasmodium falciparum* malaria strains MRA-1236 (*Plasmodium falciparum* IPC3445 Pailin Cambodia 2010) and MRA-1240 (*Plasmodium falciparum* IPC 5202 Battambang Cambodia 2011) using the standard erythrocyte stage assay. Both strains harbour mutations in the kelch 13 gene which confers resistance to artemisinin. *P. falciparum* was cultured under standard conditions, synchronized, and tested using the histidine-rich protein ELISA assay. Drugs were screened at 10uM in order to identify hits. Our results confirm that 4 out of 80 compounds have significant activity (>65% inhibition versus control, triplicate experiments performed twice) against both strains MRA-1236 and MRA-1240 in our screen. Of the 4 molecules, 3 were known to have activity against malaria previously, whereas 1 had previously only shown activity against tuberculosis. While these data are preliminary, we will present the final screening results on all 400 compounds together with their 50% inhibitory concentration, known DMPK data, and chemical structures. We anticipate uncovering further novel agents against artemisinin-resistant *P. falciparum* malaria in this collection which may be repurposed as leads in drug development.

## A PHASE IB STUDY TO INVESTIGATE THE ANTIMALARIAL ACTIVITY OF (+)-SJ000557733 (SJ733) IN INDUCED BLOOD STAGE *PLASMODIUM FALCIPARUM* MALARIA

James S. McCarthy<sup>1</sup>, John Woodford<sup>1</sup>, R. Kip Guy<sup>2</sup>, Aditya H. Gaur<sup>3</sup>, Louise Marquart<sup>1</sup>, John C. Panetta<sup>3</sup>, Burgess B. Freeman<sup>3</sup>, Heike Huegel-Koerpert<sup>4</sup>, Jörg J. Möhrle<sup>4</sup>, Lidiya Bebrevska<sup>4</sup>, Stephan Chalou<sup>4</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Herston, Australia, <sup>2</sup>College of Pharmacy, University of Kentucky, Lexington, KY, United States, <sup>3</sup>St. Jude Children's Research Hospital, Memphis, TN, United States, <sup>4</sup>Medicines for Malaria Venture, Geneva, Switzerland

SJ733 is a new oral antimalarial that targets the ATPase 4 ion transporter of plasmodia. A two cohort single-dose study was undertaken to define its antimalarial activity in the induced blood-stage malaria (IBSM) system. A dose of 150 mg was selected for the first cohort by combining the

minimal parasitocidal concentration (MPC) predicted from preclinical data (0.1-0.2 µg/mL) with the emerging human PK, aiming to observe parasite clearance kinetics, including recrudescence. Testing of 150 mg in 6 healthy volunteers resulted in transient antimalarial activity over 24 hrs, with a parasite clearance half-life of 6.5 hrs (95%CI: 5.9 - 7.2 hrs). However, rapid recrudescence occurred with all subjects, requiring artemether-lumefantrine rescue 2 days post SJ733 dosing. In the second cohort where 8 subjects were administered 600 mg, clearance of parasitemia was quicker, with a parasite clearance half-life of 3.6 hrs (95%CI: 3.3 - 3.9 hrs); a longer duration of action (~30hrs), as well as a longer interval to recrudescence (days 2 [2], 3, 5, 6 [2], 7, and 11). SJ733 pharmacokinetic parameters in this IBMS study were similar to the ones previously observed in the First-In-Man study. Although no SJ733-related adverse events were reported, transient inoculum-related moderate clinical and laboratory adverse effects were observed. Laboratory changes included significant elevations in ALT in 3 subjects (>5xULN) only in the first cohort where early and rapid recrudescence occurred. Clinical and laboratory adverse events were less common in cohort 2, with only 1 subject experiencing ALT >3xULN. A population PK/PD model led to an estimate of the human MPC of 0.3 µg/mL. These data suggest that SJ733 shows promise as a component of a new combination 3 day treatment for malaria.

## 989

### TARGETED-REACTIVE CASE DETECTION AT SLEEPING SITES TO INTERRUPT MALARIA TRANSMISSION IN VIETNAM II: REPORTED AND OBSERVED MALARIA PREVENTION, TREATMENT AND RISK BEHAVIORS

**Thuan H. Vo<sup>1</sup>**, Sara E. Canavati<sup>2</sup>, Cesia E. Quintero<sup>2</sup>, Long Khanh Tran<sup>3</sup>, Colin Ohrt<sup>4</sup>, Thang Duc Ngo<sup>5</sup>, Duong Thanh Tran<sup>5</sup>, Nicholas J. Martin<sup>6</sup>

<sup>1</sup>Vysnova Partners Inc.; Faculty of Social Sciences, University of Tampere, Tampere, Finland, <sup>2</sup>Ha Noi, Vietnam, <sup>3</sup>Vysnova Partners Inc.; Center for Biomedical Research, Burnet Institute, Melbourne, Australia, <sup>4</sup>Ha Noi, Vietnam, <sup>5</sup>Vysnova Partners Inc.; Department of Environmental Health, Ha Noi School of Public Health, Ha Noi, Vietnam, <sup>6</sup>Vysnova Partners, Inc., Ha Noi, Vietnam, <sup>5</sup>National Institute of Malariology, Parasitology and Entomology (NIMPE), Ha Noi, Vietnam, <sup>6</sup>Naval Medical Research Center-Asia, Singapore, Singapore

Reactive case detection (RACD) has limited impact and high costs in low endemicity areas where malaria cases sleep outside of their homes. In Vietnam, over 60% of malaria cases sleep in forests or on farms. We applied a targeted-RACD approach to collect information from participants at their sleeping sites and identify risk behaviors associated with malaria cases in a low malaria transmission setting. A cross-sectional study was conducted in three mountainous communes in Phu Yen province, 2016. An index case was defined as someone who routinely slept in the forest or farm and tested positive for malaria using rapid diagnostic test or microscopy at a community health facility, between 2014 and 2016. A list of 110 index cases was obtained from three commune health centers. Index cases came from 71 huts (referred to as an "index hut"). We found 109 neighbor huts, located within 500m of the index hut. Participants were interviewed face-to-face using a standardized questionnaire and a tool for direct observation. Logistic regression models were used to calculate prevalence odds ratios (PORs) and 95% confidence interval (CI) for risk factors, after adjusting for socio-demographic characteristics. The respondents lived in 180 huts: 21 huts had two or more malaria cases per hut, 50 had one case, and 109 had no cases. Neighbor huts were significantly closer to their official homes than the index huts—they were 3.10 times more likely to be within a 30 minute motorbike ride (95% CI 1.87-5.13). Significantly more index huts than neighbour huts had more than three occupants (POR=4.63; 95% CI 2.74-7.81), and were surrounded by more than 3 huts (POR=2.48; 95% CI 1.28-2.79). Access to a cell phone network was significantly higher among the neighbour huts (POR = 6.33; 95% CI 3.11-12.90). Direct observation showed low ownership of treated nets in both groups (13.8% vs 5.6% among the

index huts). Targeted education and malaria prevention strategies can be developed to address the specific risk factors identified for those primarily sleeping in farms and forests.

## 990

### IMPACT OF BIOLARVICIDES ON THE MALARIA MORBIDITY IN SCHOOLCHILDREN LIVING IN OUAGADOUGOU, BURKINA FASO

**Alphonse Ouedraogo**, Amidou Diarra, Désiré Kargougou, Aissata Barry, Nébié Issa Ouédraogo, Alfred Tiono, Sodiomon Bienvenu Sirima

Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso

Larval source management is considered as one of the major strategies to reduce malaria transmission in endemic countries. A pilot study was conducted in the urban area of Ouagadougou, Burkina Faso to evaluate to what extent using biolarvicide (Griselesf® + Bactivec®) to treat mosquitoes breeding sites will reduce malaria vectors population density, and hence the transmission. To complement the entomological evaluations, a parallel study was conducted to measure potential reduction of malaria morbidity indicators. The intervention consisted of weekly applications of the biolarvicides in the main Anopheles larval habitats during the year. Two cross sectional surveys were conducted in parallel to measure malaria morbidity indicators before (first survey) and after (second survey) the intervention in randomized schools and children. Clinical and biological data were collected. A total of 4190 children aged 5 to 14 years were randomly included during the two surveys. Prevalence of *Plasmodium falciparum* infection was 16.5% (ic95% [14.8%-18.0%]) and 15.2% (ic95% [13.7%-16.8%]) respectively during the first and second surveys. The risk to present febrile episode was 1.26 (1.1<OR<1.7) during the second survey compare to the first survey. Clinical malaria prevalence was 18.8% (ic95% [13.9%-24.6%]) at the first survey and 27.6% (ic95% [22.4%-33.4%]) at the end of season. Parasite density was 281.80 ic95% [204.08-330.78] vs. 946.12 ic95% [776.92-1152.17]. Mean haemoglobin level was 11.7±2.2 g/dL (first survey) vs. 11.6±1.2 g/dL (second survey) (p<< 0.0001). This study has not shown any efficacy of the intervention in reducing malaria burden in this age category.

## 991

### CHALLENGES IN LLIN INTERVENTION AMONG MOBILE MIGRANT POPULATIONS ALONG THE SURINAME-FRENCH GUIANA BORDER

Marieke Heemskerk<sup>1</sup>, Celine Duijves<sup>1</sup>, Hedley Cairo<sup>2</sup>, Loretta Hardjopawiro<sup>2</sup>, **Helene Hiwat<sup>2</sup>**

<sup>1</sup>Social Solutions Consultancy, Paramaribo, Suriname, <sup>2</sup>Malaria Program Ministry of Health, Paramaribo, Suriname

In the past decade, Suriname has rapidly decreased its malaria burden. The Malaria Elimination program in Suriname currently focuses on the last remaining foci of transmission in small-scale gold mining (SSM) sites along the Suriname-French Guiana border. The border also is a crossing point for migrant mobile populations working in French Guiana SSM areas, where they have no access to malaria diagnosis and treatment. For the past decade, the distribution of Long Lasting Insecticide-treated Nets (LLIN) has been a key component of the National Strategic Plan. In 2016, LLINs were mass-distributed among inhabitants of high malaria risk areas. To assess the effectiveness of this strategy, interviews were conducted with gold miners and mining service providers in two border-crossing points, who had suffered from (suspected) malaria in the 18 months preceding the interview, both prior to (N=141) and after (N=152) distribution of LLINs. Results suggest that both knowledge of LLIN as an effective way to protect oneself against malaria (from 69.5% to 82.2%) and LLIN possession (10.6% to 36.8%) significantly increased in the project period (X<sup>2</sup>, p<0.001; p<0.001). Nevertheless, 3 months after LLIN distribution, only 36.8% of interviewees reported possession of an LLIN. Moreover,

only 11.8% of respondents slept under an LLIN in the night prior to the interview. The low LLIN coverage is partly due to the high mobility of the target population, which results in high population turn-over and loss or abandonment of LLIN. Another factor is the French repressive policy towards clandestine SSM, which includes the burning of mining camps -including bed nets. Reported factors discouraging LLIN use included absence of mosquitoes, low malaria prevalence, discomfort, and the nets hinder quick fleeing in case of French military raids. We conclude that the distribution of LLINs to at-risk gold mining populations in the border region has not achieved the desired results (80% LLIN usage). Reaching and engaging the members of this highly mobile, superfluous SSM community remains challenging, and will require regional cooperation.

## 992

### QUALITATIVE FINDINGS FROM A CROSS-SECTIONAL MALARIA RISK FACTOR AND PARASITEMIA SURVEY, NORTHERN LAO PDR

**Emily Dantzer<sup>1</sup>**, Andrew A. Lover<sup>1</sup>, Bouasy Hongvanthong<sup>2</sup>, Keobuphaphone Chindavongsa<sup>2</sup>, Susie Welty<sup>1</sup>, Tania Reza<sup>1</sup>, Vatthana Nanthana<sup>1</sup>, Sophia Hocini<sup>1</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Center for Malariaology, Parasitology and Entomology; Ministry of Health, Vientiane, Lao People's Democratic Republic

Northern Laos has experienced large reductions in reported malaria cases in recent years despite limited changes in interventional coverage. In Sept-Oct 2016, a mixed-methods study was conducted in four northern districts to measure parasite prevalence, intervention coverage, and risk factors, and to improve understanding of the observed changes in malaria epidemiology. Semi-structured qualitative interviews with local health staff and high-risk populations were conducted to triangulate quantitative survey data. Four focus group discussions and six key informant interviews were conducted in each of the four study districts. Focus groups were separately comprised of health center staff, village malaria workers, forest-goers, and recently diagnosed malaria patients, while key informants included provincial and district malaria staff and other government officials. Interview topics included malaria risk factors, temporal changes in malaria burden, care-seeking behaviors, access to treatment, travel patterns, and any recent changes in employment patterns. A total of 145 respondents were interviewed across 16 focus groups and 24 in-depth interviews. Preliminary analyses suggest that overnight stays in forests or rice fields, work-related travel to higher-burden areas, ethnic minority status, failure to use bednets, and poor food hygiene were all perceived as malaria risk factors. Changes in labor and land use patterns varied by district, with some citing increased mobility among adult men for work and shifts from rice to other crops (including tea, and *Jatropha curcas* for biodiesel). Commonly cited challenges among malaria staff included RDT and ACT stock-outs and limited capacity for supervision due to resource constraints and poor road access. While the malaria burden in northern Lao PDR has declined in recent years, further studies are needed to validate these changes to inform elimination policies nationally and mitigate the potential for resurgence. Increasing population mobility and weak supply chain and supervision structures should be addressed to strengthen systems for sustainable malaria elimination.

### MALARIA ELIMINATION PLANNING TOOL: AN OPERATIONAL CAPACITY ASSESSMENT FOR MALARIA ELIMINATION EFFORTS IN ETHIOPIA

**Anisa Saleh<sup>1</sup>**, Hiwot Solomon<sup>2</sup>, Ayele Zewde<sup>3</sup>, Honelgn Nehusenay<sup>3</sup>, Firehiwot Workneh<sup>3</sup>, Semira Abdel-Menan<sup>3</sup>, Dereje Dillu<sup>2</sup>, Degu Mehari<sup>2</sup>, Gudisa Asefa<sup>2</sup>, Gezahegn Tesfaye<sup>2</sup>, Hiwot Teka<sup>4</sup>, Sheleme Chibsa<sup>4</sup>, Tsion Demissie<sup>4</sup>, Jessica K. Butts<sup>1</sup>, Matthew W. Murphy<sup>5</sup>

<sup>1</sup>U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>National Malaria Control Program, Ethiopian Ministry of Health, Addis Ababa, Ethiopia, <sup>3</sup>Addis Continental Institute of Public Health, Addis Ababa, Ethiopia, <sup>4</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Addis Ababa, Ethiopia, <sup>5</sup>U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Addis Ababa, Ethiopia

The Ethiopian National Malaria Control Program (NMCP) has set a goal to eliminate malaria by 2030. Malaria elimination readiness is often assessed using epidemiological criteria. However, a country's operational capacity to implement malaria elimination efforts is a factor that also needs consideration. To assist the Ethiopia NMCP to achieve its goal, a Malaria Elimination Planning Tool (EPT) was developed to assess the operational capacity of woredas (districts) to implement critical surveillance, vector control, and case management activities required to achieve and sustain malaria elimination. The approach used to develop the tool included consulting WHO guidance, the NMCP's malaria elimination strategy guideline, and technical experts from the NMCP and other malaria partners. The EPT contains 9 capacity assessment categories: (1) human resource, (2) governance and political support, (3) financial resource, (4) technical resource, (5) malaria case management, (6) surveillance, monitoring and evaluation, (7) vector control, (8) social and behavior change communication, and (9) malaria commodities. The tool is designed to assess various health facility levels including the Woreda Health Office (WoHO), Health Centers (HCs) and Health Posts (HPs). Interviews using the tool will be conducted with WoHO heads, malaria focal persons (WoHO), HMIS focal persons (WoHO; HC), PHEM focal persons (WoHO; HC), pharmacy personnel (WoHO; HC), laboratory staff (HC), clinical staff (HC) and Health Extension Workers (HP). With Ethiopia's NMCP officially declaring the start of malaria elimination activities in March 2017, the EPT is a key component to assess operational capacity in the 239 woredas targeted for elimination. The EPT is easily adaptable to be used by other countries aspiring to eliminate malaria.

## 994

### DATA-DRIVEN APPROACHES FOR FINER TEMPORAL AND SPATIAL RESOLUTION COVERAGE AND PROGRESS ESTIMATES FOR INDOOR RESIDUAL SPRAYING (IRS) CAMPAIGNS IN CHOBE DISTRICT, BOTSWANA

**Ayokunle Abogan**

Clinton Health Access Initiative, Gaborone, Botswana

As Botswana approaches its 2018 malaria elimination target, evidence-based operational planning is important to target malaria interventions. Indoor Residual Spraying (IRS) is a cornerstone of the National Malaria Programme's (NMP) vector control program, with a goal to achieve 80% target coverage nationally. Historically, coverage has been evaluated by the total number of rooms sprayed compared to rooms seen, aggregated by village at the end of the season from paper spray forms. In 2016, the NMP collaborated with the Clinton Health Access Initiative (CHAI) to implement a novel, data-driven approach in Chobe district that would allow better estimations at finer spatial and temporal resolutions. A remote enumeration of structures (13,466 buildings in Chobe) was conducted to build a household footprint database for what appears to be a building on freely available satellite imagery. An electronic data collection solution,

including collection of GPS points of each household, was implemented for real-time data collection during IRS implementation. The electronic data was automatically fed into a web-based dashboard, which was used to visualize key decision indicators for progress of field teams. Post-season data analysis was conducted to compare completeness and quality between the paper and electronic data, and assess coverage of the intervention. Approximately 9,514 (71%) buildings were targeted for IRS, given some areas will receive bed nets. Assuming 2 buildings and an average of 4 rooms per household, a total of 38,056 rooms were targeted for IRS. Based on electronically collected data, 7188 (19%) of the targeted rooms were visited for IRS and 4947 (13%) were sprayed. However, using the paper aggregated data, 7,871 (21%) were visited and 5,744 (15%) were sprayed. Comparing the electronic and paper-based system, 91% of rooms reported by the paper-based spray card system (N=7871) were collected in the electronic system (N=7188). The introduction of electronic data collection provided a detailed understanding of IRS coverage and progress in real-time via web, informing improvements required for future IRS seasons.

### GENOMIC METHODS OF SURVEILLANCE REVEAL MARKED PATTERNS IN *PLASMODIUM FALCIPARUM* PARASITE POPULATIONS ACROSS THE TRANSMISSION GRADIENT IN SENEGAL

**Rachel Fath Daniels<sup>1</sup>**, Katelyn Durfee<sup>1</sup>, Awa B. Deme<sup>2</sup>, Yaye Die Ndiaye<sup>2</sup>, Amy K. Bei<sup>1</sup>, Baba Dieye<sup>2</sup>, Fatou B. Fall<sup>3</sup>, Medoune Ndiop<sup>3</sup>, Alioune B. Gueye<sup>3</sup>, Yakou Dieye<sup>4</sup>, Gnagna Dieng<sup>4</sup>, Michael Hainsworth<sup>4</sup>, Kalidou Kone<sup>5</sup>, Algaye Ngom<sup>5</sup>, Moustapha Cissé<sup>3</sup>, Oumar Sarr<sup>3</sup>, Duncan Earle<sup>4</sup>, Philippe Guinot<sup>4</sup>, Caterina Guinovart<sup>6</sup>, Richard W. Steketee<sup>4</sup>, Dyann F. Wirth<sup>1</sup>, Daouda Ndiaye<sup>2</sup>, Sarah K. Volkman<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Cheikh Anta Diop University and LeDantec Teaching Hospital, Dakar, Senegal, <sup>3</sup>Senegal National Malaria Control Program, Dakar, Senegal, <sup>4</sup>Malaria Control and Elimination Partnership in Africa (MACEPA) at PATH, Seattle, WA, United States, <sup>5</sup>Richard Toll Medical District/St. Louis Medical Region, St. Louis, Senegal, <sup>6</sup>PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain

Senegal is characterized by three broad transmission zones from low transmission in the northern, moderate transmission in the central, and relatively high transmission in the southern regions of the country. To better assess patterns of transmission, we deployed a molecular barcode to genotype 24 independent single nucleotide polymorphisms (SNPs) utilizing discarded rapid diagnostic tests at multiple clinics across these transmission zones. Based on the hypothesis that the general patterns related to the proportion of monogenomic infections and the frequency of clonal parasites within these monogenomic infections may reveal distinct patterns of transmission and migration, we analyzed samples from multiple clinics across these transmission zones in Senegal, including extensive collections from the northern Richard Toll district, which is moving toward elimination. This study assessed nearly 750 cases positive for *Plasmodium falciparum* infection in Richard Toll and more than 1000 samples collected from surveillance sites nationwide from 2012 to 2015. These data reveal patterns of changing indicators related to the proportion of monogenomic infections and clonality among these monogenomic infections, as well indicate several parasite genetic signatures that were shared across transmission zones, suggesting that human migration may be an important factor with regard to sustaining transmission in low transmission settings such as Richard Toll. Delineation of these parasite signatures inform sites of ongoing transmission and those dominated by imported parasites which may inform actionable responses to malaria infections and stratify regions according to the optimal intervention based on their genomic characteristics. Evaluation of the genetic relatedness and population characteristics using simple tools may offer new insight for policy decision-makers for malaria control and elimination.

## 996

### THE LONG-TERM DURABILITY OF MASS DRUG ADMINISTRATION USING DIHYDROARTEMISININ-PIPERAQUINE AS PART OF A COMPREHENSIVE MALARIA ELIMINATION STRATEGY IN SOUTHERN PROVINCE ZAMBIA

**Thomas P. Eisele<sup>1</sup>**, Adam Bennett<sup>2</sup>, Kafula Silumbe<sup>3</sup>, Travis Porter<sup>1</sup>, Timothy P. Finn<sup>1</sup>, Victor Chalwe<sup>4</sup>, Busiku Hamainza<sup>5</sup>, Hawela Moonga<sup>5</sup>, Emmanuel Kooma<sup>6</sup>, Elizabeth Chizema Kawesha<sup>7</sup>, Josh Yukich<sup>1</sup>, Joseph Keating<sup>1</sup>, Ruben O. Conner<sup>8</sup>, Duncan Earle<sup>3</sup>, Laurence Slutsker<sup>8</sup>, Richard W. Steketee<sup>8</sup>, John M. Miller<sup>3</sup>

<sup>1</sup>Tulane University, New Orleans, LA, United States, <sup>2</sup>Malaria Elimination Initiative, Global Health Group, University of California San Francisco, Seattle, WA, United States, <sup>3</sup>PATH-MACEPA, Lusaka, Zambia, <sup>4</sup>Institute for Medical Research and Training, University Teaching Hospital, Lusaka, Zambia, <sup>5</sup>Zambia National Malaria Elimination Centre, Lusaka, Zambia, <sup>6</sup>Zambia Ministry of Health, Southern Provincial Health Office, Choma, Zambia, <sup>7</sup>Zambia Ministry of Health, Lusaka, Zambia, <sup>8</sup>PATH-MACEPA, Seattle, WA, United States

A community randomized controlled trial in a population of ~300,000 people in 60 health facility catchment areas (HFCA) in Southern Province Zambia was conducted to assess the impact of 4 rounds of community-wide (MDA) and household-level mass treatment (focal MDA) with dihydroartemisinin-piperazine from 2014-2016. The entire study area received a standard of care of sustained high vector control coverage and improved access to facility and community case management. Across all treatment groups, child malaria parasite prevalence declined from 31% at baseline to 4% after 4 MDA rounds. MDA reduced child infection prevalence in low transmission areas by a further 72% [adjusted odds ratio 0.28 (95% CI 0.09 - 0.87)] compared to the control of no MDA measured 3-months after the 4th MDA round. Following the trial, the Zambia national program implemented an additional 2 rounds of MDA in 2016-17 in 'high transmission' HFCA that included 35 from the previous trial areas with the highest malaria cases. As a result there were 12 HFCA that received 6 rounds of MDA, 8 HFCA that received the initial 4 MDA rounds only, and 6 control HFCA that never received MDA. In the HFCA that received no additional MDA after the trial, the sustained impact of the initial 4 MDA rounds (14 months since the last round) will be compared to control HFCA that never received any MDA, using a parasite survey in April-May 2017. Facility-based confirmed malaria case incidence will serve as a secondary endpoint. Among the facilities that received no additional MDA, confirmed malaria incidence was 0.56 and 2.11 per 1,000 in the previous MDA and control HFCA, respectively, during the peak malaria season (January-March) at the end of the trial in 2016. Preliminary results show confirmed malaria incidence was 0.82 and 3.48 per 1,000 in MDA and control HFCA, respectively, in January-March 2017, about a year after the last MDA round. However, confirmed incidence is still well below 2014 and 2015 levels during this period. These results will be critical in understanding the long-term durability of MDA when implemented as part of a comprehensive elimination strategy in this context of Southern Africa.

## 997

### ASSESSING BIAS AND IMPACT ON DECISION-MAKING FOR MALARIA ELIMINATION WHEN RELYING ON RISK MAPS DERIVED USING CONVENIENCE BASED SAMPLING STRATEGIES IN HAITI

**Gillian H. Stresman<sup>1</sup>**, Thom Druetz<sup>2</sup>, Ruth Ashton<sup>2</sup>, Leonel Philibert<sup>3</sup>, Lotus Van den Hoogen<sup>1</sup>, Jean Frantz Lemoine<sup>4</sup>, Thomas P. Eisele<sup>2</sup>, Chris Drakeley<sup>1</sup>

<sup>1</sup>London School of Hygiene and Tropical Medicine, London, United Kingdom, <sup>2</sup>Tulane School of Public Health and Tropical Medicine, New

Orleans, LA, United States, <sup>3</sup>IMA, Port au Prince, Haiti, <sup>4</sup>Programme National Contre la Malaria, Port au Prince, Haiti

One of the challenges with controlling and eliminating malaria transmission is being able to estimate where transmission is actually occurring. The gold standard for determining transmission intensity is to use household surveys. However, these are time and cost intensive and are not a viable option as a tool for routine data collection. The use of easy access groups (EAG) such as health facilities, schools, or churches provide a convenient option to quickly collect data on malaria. However, due to issues with selection bias such as access and differing age profiles than the target population present in the EAGs, the resulting estimates of malaria may be biased. Generating malaria risk maps using data collected as part of convenience sampling can be done but how the predicted risk surface compares with those generated using data generated as part of a gold-standard household survey is not known. Data from 6300 participants in 10 health facilities, 25 schools, and 8 churches from the Artibonite valley in Haiti will be integrated into risk maps using Bayesian geostatistical models and compared to risk maps generated using a contemporaneous household survey. Malaria prevalence surfaces according to the convenience and household data are then compared to determine the concordance between the estimates. There is considerable heterogeneity in malaria infection in this area with RDT positivity in health facilities ranging from very low to over 10%. Preliminary evidence suggests that maps generated using an intensive household survey provided a more granular picture compared to the EAG surveys. However, risk surfaces based on all three venue types led to a similar stratification of burden. The ability to quantify these biases and validate the use of EAG surveys to generate malaria risk maps has important implications for malaria control and elimination decision-making.

### THE IMPACT OF PRIMAQUINE (PQ) DEPLOYMENT AND INSECTICIDE TREATED UNIFORMS ON *PLASMODIUM VIVAX* INCIDENCE IN A PILOT MALARIA ELIMINATION STUDY IN CAMBODIA

Mariusz Wojnarski<sup>1</sup>, Somethy Sok<sup>2</sup>, Chanthap Lon<sup>1</sup>, Soklyda Chann<sup>1</sup>, Rathvicheth Bun<sup>1</sup>, Michele Spring<sup>1</sup>, Threechada Boonchan<sup>1</sup>, Panita Gosi<sup>1</sup>, Kin Soveasna<sup>2</sup>, Nillawan Buathong<sup>1</sup>, Mali Ittiverakul<sup>1</sup>, Sabaithip Sriwichai<sup>1</sup>, Worachet Kuntawunginn<sup>1</sup>, Huy Rekol<sup>3</sup>, Muth Sinoun<sup>3</sup>, Khengheng Thay<sup>3</sup>, Mary So<sup>2</sup>, Jessica Lin<sup>4</sup>, Jessica Manning<sup>1</sup>, Prom Satharath<sup>2</sup>, Kong Saly<sup>2</sup>, David Saunders<sup>5</sup>, Philip Smith<sup>1</sup>, Mark Fukuda<sup>1</sup>

<sup>1</sup>U.S. Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Ministry of National Defense, Department of Health, Phnom Penh, Cambodia, <sup>3</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>4</sup>University of North Carolina School of Medicine, Chapel Hill, NC, United States, <sup>5</sup>U.S. Army Medical Materiel Development Activity, Fort Detrick, MD, United States

Elimination strategies targeting *Plasmodium vivax* (Pv) and its hidden hypnozoite reservoir remain elusive. We conducted a two-arm, cluster-randomized, open-label malaria elimination study, to determine the effectiveness of monthly malaria prophylaxis (MMP) with dihydroartemisinin-piperazine (DP) and weekly primaquine (PQ), against PCR-based monthly screening and treatment (FSAT), over a 6-month period. In the MMP arm (n=534), all volunteers over 12 years old were treated with weekly PQ of 22.5 mg for 12 weeks. In the FSAT arm (n=516), volunteers received radical cure with PQ only if Pv positive. Half of volunteers had permethrin treatment of uniforms (ITU), while the other half had sham treatment (sITU). Overall Pv failure risk during 6 months of follow up was 19%, 8%, 8%, and 12% in FSAT+sITU, FSAT+ITU, MMP+sITU and MMP+ITU, respectively. The MMP group had a PCR-corrected Pv prevalence of 9% on D0 which was highest in the MMP+ITU, high transmission area (12%). At the 6 month follow up, Pv prevalence decreased to 5%, further stratified to 3%, 3%, 10%, and 4% for MMP+ITU (low endemic), MMP+sITU (low endemic), MMP+ITU

(high endemic), and MMP+sITU (high endemic) interventions, respectively. Volunteers in MMP group who were less than 13 years old and not treated with PQ (n=57) had Pv prevalence of 7% on D0 and 4% on month 6. In the MMP arm, Pv failure risk was 30% (95% CI: 17-43%) and 7.1% (95% CI: 4.9-10%) in volunteers with and without Pv on enrollment, respectively. In FSAT arm, risk of Pv infection in children under 18 years old (n=55) was low during 6 months of follow up, with only 3 cases reported. Interventions in FSAT+ITU, MMP+sITU, and MMP+ITU all showed benefit over FSAT+sITU with ARR of 11% (95% CI 5-18%), 11% (95% CI 5-18%), and 8% (95% CI 1-15%), respectively. However, effectiveness of presumptive antirelapse therapy was lower than expected despite the 3 months of weekly PQ in MMP arm. There was no benefit of ITU over drug therapy in MMP arm. In the FSAT arm, the additional benefit of insecticide-treated uniforms was only observed in high endemic area. Multidisciplinary approach is needed for targeting vivax malaria elimination.

## 999

### MOSQUITO DIRECT MEMBRANE FEEDING ASSAY: OVERCOME THE FIELD CONSTRAINTS AND ADAPT THE METHOD FOR THE EVALUATION OF MALARIA TRANSMISSION-BLOCKING INTERVENTIONS

Dari F. Da<sup>1</sup>, Thierry Lefevre<sup>2</sup>, R. Serge Yerbanga<sup>1</sup>, Franck A. Yao<sup>1</sup>, Bienvenue K. Yameogo<sup>1</sup>, Roch K. Dabire<sup>1</sup>, Jean Bosco Ouedraogo<sup>1</sup>, Anna Cohuet<sup>2</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Santé (IRSS/DRO), Bobo-Dioulasso, Burkina Faso, <sup>2</sup>MIVEGEC IRD-CNRS-Université, Montpellier, France

The Direct Membrane Feeding Assay (DMFA) is one of the main methods for measuring human to mosquito malaria transmission. This method is routinely used to evaluate the transmission blocking interventions (TBIs) for malaria control. However, DMFA can be limited by some field and lab constraints. It is usually considered that gametocyte containing blood must be provided to mosquitoes as fast as possible after withdrawal to insure infectivity. This imposes that the volunteers come to the lab which can be distant from their living location. This constitutes a logistic challenge or even an obstacle in some cases. Here we aimed at determining the timeframe between withdrawal of gametocyte containing blood and mosquito blood meal that allows relevant mosquito infection for subsequent experiments. We also tested the effect of blood transportation on *Plasmodium* infectivity in mosquitoes. For each replicate, blood was collected from a gametocyte carrier in heparinized tubes and assigned to one of 5 treatments: immediately used for mosquito feeding (0H) or; kept at 37°C in the lab and provided to mosquitoes 2H, 4H, 6H or 8H afterwards. Fully fed mosquitoes were dissected 7 days-post feeding and oocysts were counted to compare infection levels in the mosquito's groups. Moreover, the effect of blood transportation was tested by comparing infectivity of gametocyte-infected blood either kept at 37°C in the lab or placed in a moving car for 1 to 3 hours before mosquito blood feeding. We found a significant time effect on both the proportion of successfully infected mosquitoes (infection prevalence: X24=73.5, P<0.001) and on the number of oocyst (infection density: X24=42, P<0.001). The relationship of these two traits with time followed a bell-shaped curve with maximal infectivity at 2 to 4h post blood drawing. Also, we detected no blood transportation effect on the gametocyte infectivity (X22=3, P= 0.2176). These findings suggest that delaying and transporting blood for few hours before mosquito blood meal may not prevent the infectivity. Further studies are required to confirm this pattern and explore the proximate mechanisms.

## 1000

**QUANTITATIVE POINT OF CARE G6PD TESTS FOR RADICAL CURE OF VIVAX MALARIA**

**Sampa Pal**, Nicole LaRue, Sevan Hrutkay, Barney Becky, Maria Kahn, Pooja Bansil, Michael Kalnoky, Troy Leader, Gonzalo J. Domingo

*PATH, Seattle, WA, United States*

Currently, the only drugs that can completely cure a patient of *Plasmodium (P.) vivax* parasites (radical cure), thus reducing the risk of relapse, are those in the 8-aminoquinoline family, such as the registered drug primaquine. This class of drugs presents a safety risk to subjects with glucose-6-phosphate dehydrogenase (G6PD) deficiency. G6PD deficiency is an X-linked disorder that affects more than 400 million people worldwide. Moderate to severe life-threatening hemolytic anemia episodes can develop if G6PD-deficient individuals are treated with 8-aminoquinoline drugs. This risk represents a major barrier to wide-scale adoption of radical cure. Therefore, determination of a malaria patient's G6PD activity level is critically important before 8-aminoquinoline drug therapy. We have evaluated novel G6PD-Hb integrated quantitative test prototypes that simultaneously measure red blood cell G6PD and hemoglobin (Hb) in whole blood in a point-of-care setting with results available in 2 to 5 minutes; we have also evaluated qualitative tests. Analytical performance of the tests has been evaluated following the criteria of the target product profile. Analytical sensitivity and accuracy have been measured against the reference assay over the critical G6PD activity dynamic range.

## 1001

**TARGETED-REACTIVE CASE DETECTION AT SLEEPING SITES TO INTERRUPT MALARIA TRANSMISSION IN VIETNAM I. RISK BEHAVIORS ASSOCIATED WITH MALARIA CASES SLEEPING IN A FARM OR FOREST**

**Sara E. Canavati**<sup>1</sup>, Thuan H. Vo<sup>2</sup>, Cesia E. Quintero<sup>1</sup>, Long Tran Khanh<sup>3</sup>, Colin Ohrt<sup>4</sup>, Thang Duc Ngo<sup>5</sup>, Duong Thanh Tran<sup>5</sup>, Nicholas J. Martin<sup>6</sup>

<sup>1</sup>Vysnova Partners Inc.; Center for Biomedical Research, Burnet Institute, Melbourne, Australia, Hanoi, Vietnam, <sup>2</sup>Vysnova Partners Inc.; Faculty of Social Sciences, University of Tampere, Tampere, Finland, Hanoi, Vietnam, <sup>3</sup>Vysnova Partners Inc.; Department of Environmental Health, Ha Noi School of Public Health, Hanoi, Vietnam, <sup>4</sup>Vysnova Partners Inc., Hanoi, Vietnam, <sup>5</sup>National Institute of Malariology, Parasitology and Entomology (NIMPE), Hanoi, Vietnam, <sup>6</sup>Naval Medical Research Center, Singapore, Singapore

Reactive case detection (RACD) has limited impact and high costs to identify malaria cases in low endemicity areas where cases sleep outside their home. In Vietnam, over 60% of malaria cases sleep either in forests or on farms. We piloted a targeted-RACD approach to collect information from participants at their sleeping sites and identify risk behaviors associated with malaria cases in a low malaria transmission setting. A cross-sectional study was conducted in three mountainous communes in Phu Yen province, 2016. An index case was defined as someone who routinely slept in forest or farm and positive for malaria using rapid diagnostic test or microscopy. A list of index cases was obtained from three commune health centers. All index cases and neighbors from huts within 500m were interviewed face-to-face at their sleeping sites. Logistic regression models were used to calculate prevalence odds ratios (PORs) and 95% confidence interval (CI) for risk factors after adjusting for socio-demographic characteristics. Of 110 index cases, 82% were males with a mean age of 36.6 years; illiteracy proportion was 23%. Among 93 participants who slept in the forest, index cases were less likely to use treated bed nets (adjusted-POR=0.10; 95% CI 0.02–0.58), and more likely not to use any net when sleeping (POR=2.95; 95% CI 1.26–6.92). Index cases were also more likely than neighbors to sleep in huts without walls or outdoors (POR=44.0; 95% CI 13.0–148), and to work after dark

(adjusted POR=6.33; 95% CI 1.92–20.9). A significantly higher proportion of forest-based index cases worked in natural resource occupations (hunting, trapping) (POR=11.7; 95% CI 4.37–31.2), than did neighbors. Among 204 respondents who slept on a farm, the proportion using treated nets and no nets were not significantly different between index cases and neighbors. A significantly higher proportion of index cases were involved in planting or logging on farms (POR=2.74; 95% CI 1.27–5.91), than were neighbors. Targeted education and malaria prevention strategies can be developed to address the specific risk factors identified for forest and farm workers, particularly for illiterate group.

## 1002

**MALARIA PARASITEMIA AND SEROLOGICAL PREVALENCE IN NEAR-ZERO TRANSMISSION SETTINGS IN SENEGAL**

Steketee<sup>3</sup>, Chris Drakeley<sup>8</sup>, Caterina Guinovart<sup>9</sup>

<sup>1</sup>PATH MACEPA, Dakar, Senegal, <sup>2</sup>Universite Cheikh Anta Diop, Dakar, Senegal, <sup>3</sup>PATH MACEPA, Seattle, WA, United States, <sup>4</sup>Richard Toll Medical District, Dakar, Senegal, <sup>5</sup>National de Lutte contre le Paludisme, Dakar, Senegal, <sup>6</sup>PATH MACEPA, Lusaka, Zambia, <sup>7</sup>PATH, Seattle, WA, United States, <sup>8</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>9</sup>PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain

Senegal has made enormous progress in the fight against malaria and is close to elimination in certain regions. Passive incidence of malaria cases is the only metric available in near-zero transmission settings, and other methods to assess potential interruption of transmission at the sub-national level are needed. In Richard Toll, Northern Senegal, four health post catchment areas with zero or very low malaria incidence ( $\leq 3$  confirmed, locally-acquired malaria cases in the last two years) were selected. A community-based cross-sectional study was conducted in 1,200 randomly selected individuals (400 aged 1-4 years old, 400 aged 5-9 years old, and 400  $\geq 10$  years old) to estimate prevalence of *Plasmodium falciparum* infection by rapid diagnostic test (RDT), microscopy and PCR, sero-prevalence of anti-AMA-1 and MSP-1 antibodies, and serological conversion rate. To assess whether an operationally easier convenience survey could be used instead, a survey in a convenience sample of 400 children 1-4 years old (recruited at health facilities and during community health outreach activities in the same areas) was also conducted, and prevalence of infection and sero-prevalence results were compared. Prevalence of *P. falciparum* by RDT and microscopy was zero in both the community and the convenience surveys. PCR analysis is ongoing and results will be available by mid-2017. Preliminary data from the community survey show that respective MSP-1 and AMA-1 sero-prevalence increased with age, being 0.8% and 0.5% in 1-4 years of age, 3.1% and 3.3% in 5-9 years, 3.5% and 7.9% in 10-19 years old, and 32.2% and 40.8% in  $\geq 20$  years old. In the convenience survey the sero-prevalence in 1-4 years old was 2.1% both for MSP-1 and AMA-1. Serological conversion rates will also be estimated. Preliminary results suggest that there is almost zero transmission in the study areas—mirroring the passively-detected malaria incidence—and that transmission intensity decreased around 20 years ago, and has remained low since that time.

## 1003

### ZAMBIAN MALARIA RAPID REPORTING SYSTEM: VARIATIONS IN DATA QUALITY ACROSS HEALTH FACILITIES IN SOUTHERN PROVINCE

Travis Porter<sup>1</sup>, Marie-Reine I. Rutagwera<sup>2</sup>, Prudence M. Malama<sup>2</sup>, Chris Lungu<sup>2</sup>, Busiku Hamainza<sup>3</sup>, Japhet Chiwaula<sup>3</sup>, Mercy Mwanza Ingwe<sup>3</sup>, Thomas P. Eisele<sup>1</sup>, John M. Miller<sup>2</sup>, Jeff Bernson<sup>4</sup>, Michael Hainsworth<sup>4</sup>

<sup>1</sup>Tulane University, New Orleans, LA, United States, <sup>2</sup>PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, <sup>3</sup>National Malaria Elimination Centre, Ministry of Health, Lusaka, Zambia, <sup>4</sup>PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States

As part of increased investment in surveillance, Zambia's National Malaria Elimination Centre has implemented strategies designed to improve the timeliness with which malaria incidence is communicated to the national level. The Malaria Rapid Reporting (MRR) system uses inexpensive mobile phones to transmit malaria indicator data from health facilities on a weekly basis. To understand how well information transmitted through this system reflects what is captured in health facility registers, audits were conducted reviewing 24-week periods in both 2014 and 2015 among 172 and 165 health facilities, respectively, in Southern Province. Program review of audits described data quality across 4 dimensions—completeness, timeliness, reporting, and accuracy—aggregated at the district level. Further insight can be gained from this information by understanding how data quality indicators vary at a more granular scale—i.e., at the health facility level—and what factors are associated with reporting data quality. To this end, this analysis aims to describe the variation in MRR data accuracy, completeness, and reporting rates across health facilities, assess the degree of spatial clustering of poorly performing facilities, and determine associations of other non-spatial characteristics with data quality. Accuracy of reports varied from 100% to 0% (med: 87.5%, IQR: 65.3% - 94.6%) across facilities. Facility reporting ranged from 100% to 0% (med: 97.9%, IQR: 91.7% - 100%). Analysis of variance demonstrated significant differences in average facility reporting accuracy between districts ( $F=1.77$ ,  $p<0.05$ ), and initial review of the spatial distribution of reporting accuracy suggests clear spatial clustering. Further analysis will describe spatial clustering of MRR data quality and assess characteristics of health facilities—such as distance from the district health office, facility type, facility case load, and total malaria incidence—associated with individual indicator and overall accuracy, reporting rates, and completeness of data reported through the MRR system, and thereby help direct efforts to improve malaria surveillance.

## 1004

### MALARIA CONTROL IN MIGRANT LABORERS WORKING IN AGRICULTURAL FARMS IN METEMA REGION, ETHIOPIA: CURRENT PRACTICES, FEASIBILITY AND ACCEPTABILITY OF NEW MALARIA INTERVENTIONS

Steffanie Chritz<sup>1</sup>, Asnakew K. Yeshiwondim<sup>2</sup>, Pooja Bansil<sup>1</sup>, Worku M. Workie<sup>2</sup>, Adem A. Agmas<sup>2</sup>, Melkamu T. Zeleke<sup>2</sup>, Girma S. Guesses<sup>2</sup>, Belendia A. Serda<sup>2</sup>, Berhane H. Tesfay<sup>2</sup>, Teklehaimanot G. Kidanemariam<sup>3</sup>, Nicole Salisbury<sup>1</sup>, Duncan Earle<sup>4</sup>, Richard W. Steketee<sup>1</sup>, Caterina Guinovart<sup>5</sup>, Asefaw Getachew<sup>2</sup>

<sup>1</sup>PATH MACEPA, Seattle, WA, United States, <sup>2</sup>PATH MACEPA, Addis Ababa, Ethiopia, <sup>3</sup>Amhara National Regional State Health Bureau, Addis Ababa, Ethiopia, <sup>4</sup>PATH MACEPA, Lusaka, Zambia, <sup>5</sup>PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain

Every year, an estimated 400,000 seasonal migrant workers move to large-scale agricultural farms in western Amhara—where malaria transmission is moderate—and then return home, mostly to lower-transmission areas. They represent a high-risk group for malaria infection during their stay at the farms, and risk bringing malaria back to their home villages (20% were

infected upon return in a pilot study). To design malaria control strategies, we conducted a mixed methods evaluation to describe the current malaria control interventions at farms, and assess the feasibility and acceptability of implementing other strategies at the farms and upon workers' return. All 285 agricultural farms in Metema district were mapped and a survey was conducted in a subset of 102 farms randomly selected to collect information on farm operations, malaria risk-related behaviors, and current malaria control. Focus group discussions with laborers and key informant interviews with farm managers and health stakeholders were also conducted. Migrants begin arriving in the region in July-August and most stay through November-December. The living conditions are poor and the majority sleep outdoors or in thatched shelters. Only 25% of the farms use malaria control strategies (18% in smaller farms and 67% in larger farms), of which 80% provide bednets, 8% spray sleeping quarters with insecticide, 36% conduct source reduction activities, and 4% offer traditional repellents. Formal onsite or offsite healthcare is available at 30% of the farms (15-33% in smaller farms and 67% in larger farms), but most ill laborers seek presumptive antimalarial treatment from the farm managers instead. Most stakeholders indicated the need to provide healthcare at the farms either through mobile or stationary clinics. Most of the migrants and farm managers would be willing to use other control tools (such as bednets) if they were distributed for free, or would participate in drug-based interventions (such as mass test and treat) at the farms or upon arrival at their home village. Thus, with appropriate funding, malaria control could greatly improve the laborers' and their families' health.

## 1005

### DATA USE FOR DECISION-MAKING THROUGH DATA MONITORING POSTERS IN KRIBI CAMEROON

Kodjo Morgah<sup>1</sup>, Eric M. Tchinda<sup>2</sup>, Naibei Mbaïbardoum<sup>1</sup>

<sup>1</sup>Jhpiego, N'Djamena, Chad, <sup>2</sup>Jhpiego, Kribi, Cameroon

Malaria is the leading cause of morbidity and mortality in Cameroon, where an estimated 500,000 cases occur every year and led to 55% of hospitalizations and 241 deaths among pregnant women in 2010. In order to measure the long-term impact of malaria prevention and treatment interventions at the facility level through outcome indicators, Jhpiego developed a data analysis process using an *affiche de monitoring* or data monitoring poster, which includes indicators on case management, suspected cases tested, intermittent preventive treatment for pregnant women (IPTp) and use of long-lasting insecticide-treated net (LLINs). Jhpiego and the National Malaria Control Program (NMCP) identified inadequate and irregular data collection and data use as a systemic problem throughout Kribi district. In response, Jhpiego developed and implemented training sessions on the data posters that focused on: the context and rationale for this type of data visualization; techniques for data collection, analysis, and interpretation for decision-making; and practical sessions enabling health providers to practice mapping data onto the posters. In September 2015, Jhpiego introduced the posters in 26 health facilities in Kribi that were already trained in malaria prevention and case management interventions. Jhpiego then provided blank copies of the data posters and supported sites via biannual supervision visits during which they reviewed data posters for accuracy against facility registers. Furthermore, supervisors assessed facility's progress on their objectives, identified gaps and their causes, and discussed corrective actions. As a result of Jhpiego's efforts by June 2017, 61% of the trained facilities use the data poster for decision-making. With the introduction of the posters, the percentage of health facilities that did not experience stock shortages increased by 17 percentage points, from 21% in October 2016 to 38% in March 2017. Additionally, the Ministry of Health requested Jhpiego to lead a training of 181 health administrators and providers aimed at scaling-up the use of the data posters across all 9 districts of the South Region of Cameroon.

## 1006

### PREVALENCE OF MALARIA AND ANEMIA AMONG PATIENTS ATTENDING REFERENCE HEALTH CENTER IN NIORO DU SAHEL, MALI, WEST AFRICA

Ibrahim Sanogo<sup>1</sup>, Ismaïla Coulibaly<sup>1</sup>, Merepen dite Agnes Guindo<sup>1</sup>, Drissa S. Konate<sup>1</sup>, Seidina A.S. Diakite<sup>1</sup>, Sory Ibrahima Diawara<sup>1</sup>, Gordon A. Awandare<sup>2</sup>, David J. Conway<sup>3</sup>, **Mahamadou Diakite<sup>1</sup>**

<sup>1</sup>USTTB, Bamako, Mali, <sup>2</sup>University of Ghana, Accra, Ghana, <sup>3</sup>Pathogen Molecular Biology Department, London School of Hygiene & Tropical Medicine, London, United Kingdom

Despite several studies on malaria in the south of Mali where its transmission is seasonal from June to October, there is scarcity of data on malaria prevalence in the Sahelian part of the country, where its transmission is short and seasonal. We carried out this study during three annual transmission seasons (specify months and years) in order to assess both malaria and anemia in NiORO-du-Sahel located in the Sahelian area in the north-west of Mali. We conducted a cross-sectional study at the Reference Health Centre of NiORO-du-Sahel, where 1090 all-cause, patients selected randomly of any age were seen during medical visit and enrolled after obtaining consent. Capillary blood was collected for determination of malaria parasitemia and hemoglobin levels. Malaria infection and anemia proportion (Hb<11g/dL) among all patients examined was 45.3% and 38.6%, respectively. Fever was the main reason for medical visit, accounting for 61.8%. Self-reported ITN use was 83.3%. Participants with parasitemia  $\geq 10,000$  Parasites/ $\mu$ L represented 16.8%. Severe anemia (Hb < 7g/dL with parasitemia >0) was observed in 12.3% of study participants. Both malaria (61.2%) and anemia (55.6%) frequencies were higher in patients <18 years old compared to those  $\geq 18$  years old (35% and 25%, respectively,  $p < 0.05$ ). The lowest malaria infection prevalence was found among adults >37 years (32%;  $P < 0.05$ ). Anemia was significantly higher among children less than 5 years compared to adults aged 28 – 37 years ( $P < 0.05$ ). Malaria prevalence among ITN users was 43.8% compared to 56.4% observed in non-ITN users ( $P = 0.003$ ). Malaria infection peak was observed in October (56.1%;  $p < 0.001$ ) while the peak of anemia was in November (58.8%;  $P < 0.001$ ). Malaria infection was significantly associated with anemia among patients presenting in NiORO du Sahel ( $r_2 = 0.83$ ;  $P = 0.043$ ). In conclusion, despite high ITN coverage, malaria infection remains common among patients presenting to the main health centre in NiORO-du-Sahel. Anemia was also prevalent, particularly in children below 5 years, and was significantly associated with malaria infection.

## 1007

### HAS SEASONAL MALARIA CHEMOPREVENTION DECREASED THE MALARIA BURDEN AMONG CHILDREN UNDER FIVE YEARS IN SENEGAL?

Medoune Ndiop<sup>1</sup>, Julie I. Thwing<sup>2</sup>, Mamadou L. Diouf<sup>1</sup>, Moustapha Cisse<sup>1</sup>, Alioune B. Gueye<sup>1</sup>, Ibrahima Diallo<sup>1</sup>, Seynabou Gaye<sup>1</sup>, Oumar Sarr<sup>1</sup>

<sup>1</sup>Senegal National Malaria Control Program, Dakar, Senegal, <sup>2</sup>Centers for Disease Control and Prevention and U.S. President's Malaria Initiative, Atlanta, GA, United States

Senegal, a West African country, has made great strides in malaria control during the last decade, but its four southeastern regions continue to suffer a high malaria burden. In 2014, Senegal introduced seasonal malaria chemoprevention (SMC) - treatment with sulfadoxine-pyrimethamine and amodiaquine monthly during rainy season, for children aged 3 -120 months in the four high transmission regions, reaching  $\geq 95\%$  of the approximately 625,000 eligible children annually. The Ministry of Health also increased access to care, particularly for children under five years, through a variety of initiatives, and increased access to malaria diagnostic testing beginning in 2014. We analyzed routine malaria information system data, provided by all publicly supported health facilities, for the three regions that received SMC and for which completeness of

reporting was at least 95%, for the period from 2013 (the year before introduction) to 2016. Data were analyzed for children under 5 years and for non-pregnant patients 5 years and older. From 2013 to 2016, the reported annual incidence of malaria among children < 5 years increased 6%; however, total curative outpatient consultations for children < 5 years increased 63%, the number tested for malaria increased 117%, the proportion of all outpatient curative consultations associated with confirmed malaria (proportional morbidity) decreased from 15% to 10%, and the test positivity rate decreased from 66% to 32%. Among non-pregnant patients 5 years and older, reported annual incidence increased 48% from 2013 to 2016; however, total curative outpatient consultations increased 40%, the number tested for malaria increased 90%, the proportional morbidity did not change (18% to 19%), and the test positivity rate decreased from 72% to 56%. While assessment of SMC results based on reported annual incidence is complicated by increasing care seeking and diagnostic testing, particularly among children under 5 years, proportional morbidity and test positivity rate have declined substantially among children under 5 years compared to older patients, suggesting decreased malaria burden among this age group.

## 1008

### PREVALENCE OF PARASITEMIA DURING TWO SEASONS IN AN AREA RECEIVING SEASONAL MALARIA CHEMOPREVENTION (SMC) IN NIGER

Matthew E. Coldiron<sup>1</sup>, Bachir Assao<sup>2</sup>, Alena Koscalova<sup>3</sup>, Michel Quere<sup>3</sup>, Céline Langendorf<sup>1</sup>, Rebecca F. Grais<sup>1</sup>

<sup>1</sup>Epicentre, Paris, France, <sup>2</sup>Epicentre, Maradi, Niger, <sup>3</sup>Médecins Sans Frontières, Geneva, Switzerland

Seasonal malaria chemoprevention (SMC) is recommended in the Sahel: monthly courses of sulfadoxine-pyrimethamine and amodiaquine (SPAQ) are given to children aged 3-59 months during the high transmission season. In some areas, SMC has been expanded to include children up to 10 years old. We performed two malaria prevalence surveys to evaluate the burden of parasitemia in the expanded SMC target age group in Niger, aiming to estimate the prevalence of parasitemia during two different transmission seasons in among those 3-59m, 5-9y, and  $\geq 10y$ . We performed household-based surveys in October and December 2016 in Magaria District, Niger. (October is traditionally the end of the high season, and late December is traditionally the beginning of the low season.) The target sample size was 396 households in October and 266 households in December, because of the expected lower prevalence of parasitemia in December. Households were randomly selected with probability proportional to population size of the village. One household member in each age group was selected randomly for participation. Thick and thin smears were prepared, and slides were read by two microscopists. Overall prevalence of parasitemia was 43% [95%CI: 39-48] in October and 40% [37-44] in December. In both surveys, prevalence was higher among 5-9y than among 3-59m: 66% [58-74] vs. 52% [45-59],  $p = 0.005$ , in October; 64% [56-71] vs. 48% [41-55],  $p = 0.002$ , in December. Among  $\geq 10y$ , prevalence was 24% [19-29] and 21% [17-26], respectively. Gametocytemia was present in 19% [15-24] of children <10 in October and 13% [9-17] in December, with no difference between age groups ( $p = 0.81$  in October,  $p = 0.83$  in December). Parasite burden was higher in 3-59m than in 5-9y (geometric mean 4663 [3123-6962] vs 1404 [989-1995] ( $p = 0.001$ ) in October; and 1545 [1061-2250] vs 614 [453-832] ( $p = 0.001$ ) in December). In conclusion, prevalence of parasitemia among 3-59m was elevated despite SMC. Children aged 5-9 years in this area have a high prevalence of parasitemia and gametocytemia, though their overall parasite burden is lower than in younger children. They would potentially benefit from receiving SMC.

### GEOGRAPHICAL, TEMPORAL AND SEASONAL TRENDS IN *PLASMODIUM OVALE* AND *P. MALARIAE* INFECTIONS IMPORTED TO THE UK BETWEEN 1987 AND 2015

Laura Nabarro<sup>1</sup>, Claire Broderick<sup>1</sup>, Behzad Nadjm<sup>1</sup>, Valerie Smith<sup>2</sup>, Marie Blaze<sup>2</sup>, Anna Checkley<sup>1</sup>, Colin Sutherland<sup>2</sup>, Peter L. Chiodini<sup>2</sup>, Christopher J. Whitty<sup>2</sup>

<sup>1</sup>The Hospital for Tropical Diseases, London, United Kingdom, <sup>2</sup>Malarial Reference Laboratory, Public Health England, London, United Kingdom

*Plasmodium ovale* and *P. malariae* are less common than *P. falciparum* and *P. vivax* and cause milder clinical infection. Nevertheless, they are both important causes of febrile illness in endemic regions and in returning travellers. Using national surveillance data collected between 1st January 1987 and 31st December 2015 by Public Health England's Malaria Reference Laboratory (MRL), we describe the epidemiology of *P. ovale* and *P. malariae* infections imported to the UK. By collating this with data from the International Passenger Survey and climatic data from East and West Africa, we describe geographical, temporal and seasonal trends over this period. 52,242 cases of malaria were notified to the MRL during this period of which 6.04% (3157) were caused by *P. ovale* and 1.61% (841) by *P. malariae*. Most affected travellers had acquired infection in West or East Africa; those infected in West Africa had principally visited friends and family whilst those infected in East Africa had travelled for holidaying purposes. Mortality was rare at just 0.03% (1) and 0.12% (1) in patients with *P. ovale* and *P. malariae* respectively compared to 0.62% in those with *P. falciparum* infection. The time between arrival in the UK and onset of symptoms (latency) was 76 days for *P. ovale* and 18 days for *P. malariae*, reflecting the existence of hypnozoites in the former. Interestingly, there was seasonal variation in latency of *P. ovale* infections imported from West Africa with shorter latent periods in those arriving in the UK during the West African monsoon season (July to November, 49 days) than in those arriving at other times of the year (December to June, 92 days,  $P=0.0001$ ). This trend was not seen in *P. ovale* imported from East Africa or in patients with *P. malariae* infection. Between 1987 and 2015, infection rate fell five fold, from 0.62 to 0.13/1000 travellers to West Africa and 0.19 to 0.038/1000 travellers to East Africa. These data suggest that West African *P. ovale* is adapted to relapse during the West African monsoon. This is of evolutionary benefit to the parasite, offering the greatest chance of onward transmission to a new host in the period of maximal mosquito density.

### 1010

### A LONGITUDINAL STUDY OVER THREE YEARS LEADS TO THE IDENTIFICATION OF *PLASMODIUM VIVAX* INFECTIONS IN DUFFY BLOOD GROUP NEGATIVE CHILDREN IN BANDIAGARA, MALI

Karthigayan Gunalan<sup>1</sup>, Amadou Niangaly<sup>2</sup>, Amed Ouattara<sup>3</sup>, Drissa Coulibaly<sup>2</sup>, Juliana M. Sá<sup>1</sup>, Matthew Adams<sup>3</sup>, Mark A. Travassos<sup>3</sup>, Jennifer Ferrero<sup>3</sup>, Matthew B. Laurens<sup>3</sup>, Abdoulaye K. Koné<sup>2</sup>, Mahamadou A. Thera<sup>2</sup>, Christopher V. Plowe<sup>3</sup>, Louis H. Miller<sup>1</sup>, Ogobara K. Doumbo<sup>2</sup>

<sup>1</sup>Laboratory of Malaria and Vector Research and National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Malaria Research and Training Center, International Center for Excellence in Research, University of Sciences, Techniques and Technology of Bamako, Bamako, Mali, <sup>3</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

*Plasmodium vivax* was thought to only infect the red blood cells of Duffy blood group positive people particularly in Asia and South America. In the last decade, *P. vivax* has appeared in Africa in areas such as Madagascar and Ethiopia, where Duffy positive and negative people live side-by-side. We sought evidence of *P. vivax* infections in a cohort of 300 children in

Bandiagara, Mali, West Africa (a Sahelian area of Mali where people are primarily Duffy negative) from the beginning of one transmission season through a second season and into the beginning of a third season.

We used quantitative PCR of blood samples dried onto filter paper to determine the prevalence of *P. vivax* and *P. falciparum*. We observed the occurrence of *P. vivax* in 25 children in Bandiagara, Mali. Duffy negativity was confirmed in all 25 children by Sanger sequencing the single point mutation (T to C) in the GATA1 binding region 5' prime of the Duffy blood group antigen open reading frame. The prevalence of *P. vivax* infection was 2.0-2.5% at every time point (June 2009 to June 2010). While experiencing *P. vivax* infections, none of the children had a history of fever, chills, headache or muscle ache, which are symptoms that may be associated with malaria. The parasite densities were extremely low between 8 and 157 parasites per microliter. The present data indicate that at some time in the past, *P. vivax* has adapted to infect Duffy-negative people in Africa which could become a burden to sub-Saharan Africa in future. Hence, the evidence of *P. vivax* existence needs to be taken into consideration in designing malaria control and elimination strategies in Africa.

### 1011

### GROWTH TRAJECTORIES OF CHILDREN IN SEASONAL AND PERENNIAL MALARIA TRANSMISSION SETTINGS

Jennifer L. Kwan<sup>1</sup>, Barry Amadou<sup>2</sup>, Gaoussou Santara<sup>2</sup>, Moussa Traore<sup>2</sup>, Djibrilla Issiaka<sup>2</sup>, Rathy Mohan<sup>1</sup>, Andrew Teo<sup>1</sup>, Edward Kabymela<sup>3</sup>, Michal Fried<sup>1</sup>, Alassane Dicko<sup>2</sup>, Patrick Duffy<sup>1</sup>

<sup>1</sup>National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, <sup>2</sup>Malaria Research and Training Center, Department of Epidemiology of Parasitic Diseases, Faculty of Medicine and Odontostomatology and Faculty of Pharmacy, University of Sciences, Techniques and Technologies of Bamako, Mali, Bamako, Mali, <sup>3</sup>Muheza Designated District Hospital, Muheza, United Republic of Tanzania

Pediatric growth curves and velocities can provide an overall clinical impression at the individual level, but little is known about variation in individual z scores related to malaria infection. To determine whether there was an impact of malaria infection on the z score we used the anthropometric measurements in the Immuno-Epidemiology cohort in Oulessebouyou, Mali. We contrast these data with measurements from the previously described Mother-Offspring Malaria Study (MOMS) cohort data from Muheza, Tanzania, to compare growth trajectories in both seasonal and perennial transmission settings. In the Immuno-Epidemiology cohort 1,764 children were followed from birth to 5 years from 2011-2016, with an average of 26 measurements per child over the study period. The sex distribution of the cohort was 49.6% males and 50.3% females. Anthropometric measures of weight, length, height, head and arm circumference for both cohorts were compared with the WHO Child Growth Standards using the WHO Anthro macro version 3.2.2 for SAS, published January 2011, to define growth velocity and z scores by age and sex for each individual in the cohort. Head circumference was directly comparable between the cohorts. In the seasonal malaria transmission setting of Oulessebouyou head circumference for age mean z scores was 0.03 (SD 1.19) for 0-5 month olds, -0.12 (SD 1.10) for 6-11 month olds, -0.23 (SD 1.09) for 12-23 month olds, -0.31 (SD 1.05) for 24-35 month olds, -0.31 (SD 1.04) for 36-47 month olds, and -0.24 (SD 0.99) for 48-60 month olds. In the MOMS cohort head circumference for age mean z scores were 0.47 (SD 1.20) for 0-5 month olds, 0.76 (SD 1.02) for 6-11 month olds, 0.63 (SD 0.97) for 12-23 month olds, 0.61 (SD 0.94) for 24-35 months, and 0.83 (SD 0.90) for 36-74 month olds. The findings of this study highlight the differences in anthropometric measures between the two cohorts and describe differences in growth trajectory related to malaria infection.

## 1012

**DETERMINANTS OF MALARIA PARASITEMIA AMONG CHILDREN UNDER 5 IN NIGERIA: AN ANALYSIS OF THE DRIVING FORCES THAT INFLUENCE PARASITEMIA**

Ibrahim K. Maikore<sup>1</sup>, Taiwo D. Orimogunje<sup>2</sup>, Abimbola G. Olayemi<sup>3</sup>, Perpetua E. Uhomoibhi<sup>2</sup>, Mohammed B. Audu<sup>2</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>National Malaria Elimination Programme, Abuja, Nigeria, <sup>3</sup>Maternal and Child Survival Program, John Snow Inc., Abuja, Nigeria

Results from 2015 Nigeria malaria indicator survey (MIS) showed a drop in prevalence of malaria in reference to the 2010 survey. The survey showed regions with high levels of Parasitaemia also have high levels of ownership and use of Insecticide Treated Nets (ITN). This brought about the question, what could be the cause of the high levels of Parasitaemia in the face of high utilisation of preventive methods, especially the ITN? Could there be other factors? A secondary data analysis of the 2015 Nigeria MIS was carried out among children aged between 6 to 59 months (n=5,766) tested for Parasitaemia using microscopy. Multivariate logistic regression was used to compare odds of having malaria among children who slept under ITN the night before the survey while controlling for other determinants like children's age in months, residence, mother's educational status, wealth quintile. Sleeping under an ITN has weak evidence of association on the odds of having malaria (OR=1.2, CI: 0.99-1.44). However, children living in the rural residence were faced with over 4 times the odds of having malaria (OR=4.3, CI: 3.18-5.83). Similarly, mother's educational level and household's wealth quintile showed decrease odds of having malaria with increasing educational level (OR=0.53, CI: 0.47-0.60) and wealth quintile (OR=0.56, CI: 0.51-0.61). After adjusting for Age in months, ITN Use among children Under 5, Mother's education in years and Wealth quintile, there was still strong evidence of association among children living in the rural residence and the risk of having malaria (OR=1.62, CI: 1.2-2.2). It can therefore be concluded that the use of ITN is not the main driver of malaria Parasitaemia in Children under 5. Low mother's educational level, low household's wealth quintile and living in rural areas have presented to be the main drivers of malaria Parasitaemia in Nigeria. These factors can be seen to be indicators of development, stressing the position that malaria is a disease of poverty and lack of general human development. The regions in Nigeria with high ITN ownership and use but still have high Parasitaemia qualify as the areas with these factors as described.

## 1013

**DISTRIBUTION OF MALARIA BURDEN BY TRANSMISSION STRATUM SENEGAL, 2016**

Medoune Ndiop<sup>1</sup>, Julie Thwing<sup>2</sup>, Ibrahima Diallo<sup>1</sup>, Alioune Badara Gueye<sup>1</sup>, Seynabou Gaye<sup>1</sup>, Moustapha Cisse<sup>1</sup>, Omar Sarr<sup>1</sup>, Mamadou Lamine Diouf<sup>1</sup>, Katharine Sturm Ramirez<sup>3</sup>, Mame Birame Diouf<sup>3</sup>

<sup>1</sup>National Malaria Control Programme, Dakar, Senegal, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>U.S. Agency for International Development, Dakar, Senegal

Senegal, a West African country, scaled up malaria control interventions aggressively over the past decade, aiming for universal coverage with long lasting insecticidal nets and case management with rapid diagnostic tests and artemisinin-based combination therapy in health facilities and at the community level. Parasite prevalence in children under 5 years of age fell from 6% in 2008 to 1.2% in 2014. Malaria transmission varies greatly, increasing in intensity from north to south, and starting in 2014, Senegal introduced additional interventions targeted according to transmission intensity, implementing seasonal malaria chemoprevention and proactive community case management in high transmission zones, and reactive case detection in low transmission zones. We analyzed data reported in 2016 from every publicly supported health facility in all 76 health districts, including 35 hospitals, categorizing them by reported annual malaria

incidence, to assess the malaria burden in each transmission zone and to improve intervention targeting. Completeness of reporting was 99%; nationwide, the incidence was 23.6 cases / 1,000 residents (349,540 cases). Thirty three districts with malaria incidence less than 5 / 1,000 comprise 47% of the population and accounted for 6% of cases (20,390). Nineteen districts with incidence of 5 to 15 / 1,000 residents comprise 23% of the population and accounted for 9% of cases (30,488). Twenty-four districts with incidence more than 15 / 1000 residents comprise 30% of the population but accounted 85% of cases (298,682); among these are ten districts in which incidence was more than 100 / 1,000 residents, comprising only 8% of the population but 55% of cases (191,342). Almost half the nation lives in districts at pre-elimination status in 2016, highlighting the need for expansion of active case detection activities in all these districts. However, incidence remains high among a small population that accounts for the majority of cases despite high coverage of a package of interventions, requiring a better understanding of the local epidemiological context and more aggressive approaches to reduce the malaria burden.

## 1014

**STUDY OF PREGNANCY OUTCOMES IN ASSOCIATION WITH MALARIA AND CO-INFECTION WITHIN MYANMAR'S PUBLIC HEALTH SYSTEM**

Janie Anne Zuber<sup>1</sup>, Kay Thwe Han<sup>2</sup>, Zaw Win Thein<sup>1</sup>, Yuanyuan Liang<sup>1</sup>, Christopher V. Plowe<sup>1</sup>, Poe Poe Aung<sup>1</sup>, Myaing Myaing Nyunt<sup>1</sup>

<sup>1</sup>Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Department of Medical Research, Myanmar Ministry of Health, Yangon, Myanmar

In Myanmar, no specific intervention for malaria prevention is recommended for pregnant women, primarily due to a lack of sufficient data on how malaria impacts maternal or newborn health in areas of low or unstable malaria transmission. To measure the incidence of adverse pregnancy outcomes and their association with malaria and intestinal parasitic infections, a prospective, multi-center, longitudinal study was embedded into the existing structure of public healthcare services for pregnant women in 12 villages of two rural townships in Myanmar. From these historically malaria endemic areas, eligible and consenting pregnant women were enrolled and followed throughout the perinatal period. Demographic and clinical data, including reproductive health history, were collected. Blood was obtained for hemoglobin measurement and malaria evaluation. Stool was tested for intestinal parasites. Pregnancy outcome data were analyzed for the prevalence of adverse events. 752 pregnant women were enrolled, among whom were detected 137 (18.2%) intestinal parasitic infections and 43 (5.7%) asymptomatic malaria infections; these contributed to 10 (1.3%) co-infections. 670 (89.1%) birth events were recorded; 161 (24%) mothers were noted to be anemic (hemoglobin concentration <10 g/dL) during pregnancy. There were 657 (98.1%) live births, 7 (1%) stillbirths, 72 (10.7%) preterm births, 68 (10.1%) operative deliveries, 15 (2.2%) low birth weight infants, and 10 (1.5%) small size for gestational age infants. There were no statistically significant associations between infections and adverse pregnancy outcomes, likely owing to insufficient statistical power to detect associations between low frequency events. We conclude that treatable infections and potentially correctable anemia are common during pregnancy in rural Myanmar, and that more expansive studies would be needed to characterize the contribution of malaria and co-existing parasitic infections to poor maternal or newborn health. Our experience also demonstrated that long-term research integrated into Myanmar's maternal-newborn public healthcare system is feasible.

## 1015

**THE HIGHLY VARIABLE EPIDEMIOLOGY OF BLACKWATER FEVER****G. Dennis Shanks***Australian Army Malaria Institute, Enoggera, Australia*

Blackwater fever is a massive hemolytic event usually occurring in the context of repeated falciparum malaria infections and intermittent quinine use. Its aetiology is poorly understood and it is rarely seen today. Historical epidemiological observations from the 20th century demonstrated a very wide range of blackwater fever in prisoners in Andaman Islands, refugees in Macedonia, canal workers in Panama, expatriates in Rhodesia and Second World War soldiers in New Guinea and West Africa. Rates of blackwater fever (BWF) per 1000 malaria cases varied over two orders of magnitude. Islands such as the Andaman Islands (0.5 BWF cases / 1000 malaria cases) and New Guinea (0.2 BWF cases / 1000 malaria cases) had lower blackwater fever rates than continental areas such as Macedonia (36.8 BWF cases / 1000 malaria cases) and Rhodesia (74.6 BWF cases / 1000 malaria cases). Panama Canal workers (6.4 BWF cases / 1000 malaria cases) and British soldiers in West Africa (8.3 BWF cases / 1000 malaria cases) had intermediate rates. During the Second World War, blackwater fever rates in British soldiers in West Africa and Australian soldiers in New Guinea differed by a factor of forty despite similar treatment regimens and falciparum transmission risks. Fifteen of the 25 blackwater fever cases reported by the US Army from the Southwest Pacific during the Second World War were in black soldiers suggesting a role for G6PD deficiency. Blackwater fever is a complex interaction between host erythrocyte, falciparum malaria and antimalarial drugs which only occasionally combines to cause massive intravascular hemolysis for reasons that remain obscure.

## 1016

**APPROPRIATENESS OF MALARIA DIAGNOSIS AND TREATMENT OF FEVER EPISODE ACCORDING TO PATIENT HISTORY AND ANTIMALARIAL BLOOD MEASUREMENT****Joanna Gallay<sup>1</sup>**, Emilie Pothin<sup>1</sup>, Dominic Mosha<sup>2</sup>, Martin Zuakulu<sup>2</sup>, Erick Lutahakana<sup>2</sup>, Laurent Decosterd<sup>3</sup>, Blaise Genton<sup>4</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, Basel, Switzerland, <sup>2</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Division and Laboratory of Clinical Pharmacology, Department of Laboratories, University Hospital, Lausanne, Switzerland, <sup>4</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Monitoring the impact of case management strategies in terms of use and compliance to RDT result as well as drug use is essential to evaluate the public health benefit they confer. Methodologies that rely on objective and standardized endpoints such as drug levels in the blood should be used. We evaluated diagnosis and treatment appropriateness in case of fever according to patient history and antimalarials blood concentration. The survey took place in 2015 in three regions of Tanzania with different levels of malaria endemicity. Community surveys were conducted to collect information on demographics, health seeking behavior and case management in case of fever. Blood samples were collected as dried blood spots for further antimalarials measurements by LC-MS/MS. Health facility surveys collected information on diagnosis and treatment practices. Appropriate testing was defined as a patient with history of fever being tested for malaria and appropriate treatment as having antimalarial in the blood if the test result was positive or if the person was not tested. In total, 6485 individuals were surveyed and 1344 (21%) had antimalarials detected in the blood. 1021 reported a febrile episode in the previous 2 weeks but only 664 (65%) of them sought care. 69% (172/248) of the individuals who sought care in health facilities were tested and 52% (130/248) appropriately treated. When other providers were sought, 6% (23/382) of persons were appropriately tested and 44% (169/382) appropriately treated. Results obtained through exit interviews in health facilities were close with 67% (151/226) of individuals tested and 66%

(149/226) appropriately treated. Overall, the proportion of individuals treated was larger than that being tested (45% (301/664) treated, 30% (196/664) tested). Only about half of individuals with detectable levels of antimalarials in the blood were those having a test result positive or not being tested. These results show that treatments are often not targeted to individuals that are sick with malaria. Efforts should be made to better follow WHO recommendations of systematic diagnostic testing and treatment upon result.

## 1017

**LONGITUDINAL SEROLOGICAL EVALUATION OF MALARIA TRANSMISSION PATTERNS IN BIKO ISLAND, EQUATORIAL GUINEA****Jackie Cook<sup>1</sup>**, Joseph Biggs<sup>1</sup>, Catherine Mair<sup>1</sup>, Dianna Hergott<sup>2</sup>, Aveika Akum<sup>3</sup>, Lou Herman<sup>1</sup>, Julie Niemczura de Carvalho<sup>2</sup>, Guillermo Garcia<sup>2</sup>, Christopher Schwabe<sup>2</sup>, Immo Kleinschmidt<sup>1</sup>, Chris J. Drakeley<sup>1</sup><sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,<sup>2</sup>Medical Care Development International, Silver Spring, MD, United States,<sup>3</sup>Medical Care Development International, Malabo, Equatorial Guinea

Monitoring and evaluation of malaria control programmes is a key element of refining intervention strategies. Alongside parasitological measures, serological markers of malaria transmission have been utilised to investigate impact, as well as to identify heterogeneities in effect. Three cross-sectional serological surveys have taken in place in 18 sentinel sites in Bioko Island, Equatorial Guinea, in 2008, 2012 and 2015, encompassing a period when the island was experiencing a decrease in transmission, due to extensive roll-out of indoor residual spraying (IRS) and insecticide treated nets (ITN). There was a sharp reduction in seropositivity to AMA-1 between 2008 and 2012 (from 52% to 35%) which remained similar between 2012 and 2015 (33%). Estimated seroconversion rates correlates strongly with parasitological data in all three years and the method was able to highlight differential impact of interventions between regions on the island, with several sites appearing close to elimination in 2015. Modelling of serological data can help to reconstruct historical transmission patterns and these three repeated surveys highlight the integrity of the method in an area undergoing changes in transmission patterns.

## 1018

**TRENDS AND SEASONALITY OF SEVERE MALARIA DEATHS IN RWANDA, 2007-2016****Jean Pierre Habimana<sup>1</sup>**, Alphonse Rukundo<sup>1</sup>, Nsengiyumva Divine<sup>2</sup><sup>1</sup>Private Firm working with Rwanda BioMedical Center, Kigali, Rwanda,<sup>2</sup>Kabgayi District Hospital, Muhanga/South Province, Rwanda

Malaria remains one of the most important parasitic disease causes of death, accounting for nearly three million annual globally. In Rwanda, 5% of deaths are due to severe malaria. We did this study to determine the trend in malaria deaths and to describe the weather seasonal patterns of severe malaria deaths during a ten-year period. Rwanda Health Information System (RHMS) contains monthly reports from District and referral hospitals. Severe malaria death was defined as death occurred in hospital with diagnostic of confirmed severe malaria. We used STATA for data analysis. Descriptive analysis was used to assess the trend in malaria deaths and a negative log-binomial regression was done to assess the relationship between weather seasons and malaria deaths. Relative Risks (RR) and 95% confidence intervals (CI) were calculated. A total of 5,880 patients died with a diagnosis of severe malaria from 2007 to 2016. Of the severe malaria deaths, 29% (1,696) were children less than five years. The total number of malaria deaths was 2,593 during 2007-2011 and 2,287 during 2012-2016, representing a decline of 11.8%. Comparing malaria deaths in children under-five for the years 2007-2011 and 2012-2016, malaria deaths declined by 37% (1042 to 654). Our study has shown also a relationship between seasonality in weather patterns. The short dry

season indicated the relative risk of all malaria deaths (RR=1.16, 95%CI: 1.04-1.29). In addition, the short dry season indicated the highest relative risk of malaria deaths in fewer than five years (RR=1.35, 95%CI: 1.17-1.60). In conclusion, Slight increase in malaria deaths was observed in five and above patients during the period of our study. A decline of mortality among children fewer than five years was observed during the same period of study. Results showed a correlation between malaria deaths and weather season. We recommend targeted early malaria case management interventions.

## 1019

### ASSESSMENT OF THE DYNAMICS OF *PLASMODIUM FALCIPARUM* PARASITEMIA REGARDING THREE ARTEMINININ COMBINATION REGIMENS FOR ACUTE UNCOMPLICATED MALARIA TREATMENT, BANFORA, BURKINA FASO

**Issiaka Soulama**, Aboubacar Sam Coulibaly, Jean Moïse Kaboré, Maurice San Ouattara, Edith C. Bougouma, Souleymane Sanon, Noélie Henry Béré, Amidou Diarra, Daouda Ouattara, Alphonse Ouédraogo, Amidou Ouédraogo, Benjamin S. Sombié, Issa Nébidi Ouédraogo, Alfred B. Tiono, Sodiomon B. Sirima

*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso*

The two recommended Artemisinin Combination based Therapy (ACTs: ) for the uncomplicated malaria treatment in Burkina Faso are suffering from the mass used from the Seasonal Malaria Chemoprevention strategy (Amodiaquine) and from the high frequency of the new infections cases with the Artemether-Lumefantrine Combination. Therefore the assessment of alternative effective combination treatment is highly recommended. In that context, a comparative, randomized, open label longitudinal clinical trial involving children and adults with uncomplicated *Plasmodium* sp. malaria was carried out. The study was a two years follow up involving 2 new ACT, Artesunate-pyronaridine (PYR) and Dihydroartemisinin-piperazine (DHA-PQ) compared to Artesunate-Amodiaquine (ASAQ) in the treatment of the uncomplicated acute *Plasmodium falciparum* malaria cases in Banfora, located at the southern part of Burkina Faso. Each of participant enrolled received during their subsequent episodes the same drug and went through the same trial procedures as for the initial episode. Sexual and asexual parasite prevalence were evaluated during 42-days follow-up to assess the dynamics of *Plasmodium falciparum* regarding each of the 3 ACTs. All treatment doses were supervised and administered according to patients' weight. A total of 763 persons aged from 6 month and above (mean  $\pm$  SD age = 7.3  $\pm$  5.9 years, median age = 5.5 years) were included in the study; 50.3% were female. The mean  $\pm$  SD number of malarial episodes occurring in a person's during the two years follow up was 2.9  $\pm$  2.1 episodes. The therapeutic efficacy rates (PCR-non corrected) were 93% for ASAQ, 97.3% for DHA-PQ, and 93.3% for PYR. Sexual and asexual parasitemia dynamics of each treatment regimen showed no statistically significant differences between the three Artemisinin Combination based Therapy (by log-rank test).

## 1020

### THE ECONOMIC BURDEN OF MALARIA CASES IMPORTED FROM HISPANIOLA TO OTHER NON-ENDEMIC COUNTRIES IN THE WESTERN HEMISPHERE (2007- 2013)

**Hani M. Mohamed**, Ann S. Goldman, Mimi Ghosh

*The George Washington University, Washington, DC, United States*

Hispaniola is the only island endemic for malaria in the Caribbean region. Widening income disparity and natural disasters have hindered malaria control. Routine travel between Hispaniola and other non- endemic countries in the Western Hemisphere could pose a risk for the re-introduction of malaria in non- endemic countries. Given the paucity of

information on the cost of imported cases to non-endemic countries in the Americas, this study sought to estimate the cost and evaluate the economic burden of malaria cases imported from Hispaniola to non-endemic countries in Americas. Epidemiologic data on imported malaria cases came from reports from the US Centers for Disease Control and Prevention, Public Health Agency of Canada, the Canadian Malaria Network, the World Health Organization and the Pan American Health Organization. Calculation of costs per disability adjusted life-year (DALY), were based upon the WHO burden of disease estimates of DALY loss due to malaria in non- endemic countries in Americas, and the costs of diagnosis and treatment of malaria. During 2007-2013, the estimated number of malaria cases, imported from Hispaniola, to non-endemic countries in North America ranged between 30 and 192. Disease management costs varied between \$100,018 and \$1,229,320; the Cost/DALY range was \$121,377 to \$1,079,557. Between 2011 and 2013, 24 cases from Haiti reported in non-endemic Caribbean Islands; they cost \$53,076, with no loss of DALY reported. Understanding the economic and human impact of malaria on endemic countries as well as on their non-endemic neighbors helps strengthen the case for worldwide malaria elimination.

## 1021

### DIVIDE AND CONQUER: PARTITIONING MOSQUITO BITING HETEROGENEITY AND IDENTIFYING MALARIA HOTSPOTS FOR INTERVENTION

**Su Yun Kang**<sup>1</sup>, Donal Bisanzio<sup>1</sup>, David L. Smith<sup>2</sup>

<sup>1</sup>*University of Oxford, Oxford, United Kingdom*, <sup>2</sup>*Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States*

Heterogeneity in malaria transmission varies with the intensity of transmission. A large portion of heterogeneity in transmission over time and space can be attributed to seasonality, individual household attractiveness, and environmental noise. With the ability to identify households which act as hotspots for sustaining a major portion of malaria transmission we can increase the efficiency of control interventions. This study focuses on mosquito count data from entomological surveillance conducted between October 2011 and September 2016 at three study sites in Uganda. A total of 330 households were involved in the surveillance. The intensity of malaria transmission varies considerably across the three sites. Using a Bayesian zero-inflated negative binomial model and a prior distribution for seasonal signals, we partitioned the heterogeneity in mosquito abundance into household biting propensities, seasonality, and environmental noise. For each study site, we contrasted household biting propensities in different scenarios - dry vs. rainy seasons; before the enrolment of indoor residual spraying vs. after; during the first half period of the surveillance vs. the second half period of the surveillance. We also conducted hotspot analysis using the Getis-Ord (Gi\*) statistic for all three sites to identify hotspots of malaria risk. This work provides an understanding of heterogeneity in malaria exposure and offers a critical appraisal of the possibility of targeting interventions at households with the most mosquitoes, which differ depending on various environments and various levels of endemicity. Once transmission in an area has decreased but is maintained in hotspots of malaria transmission, such targeted interventions are likely to become increasingly important tools in malaria elimination efforts. Focusing malaria interventions on households which contribute disproportionately to malaria transmission could achieve community protection by eliminating transmission in a relatively small fraction of human hosts.

### TRACKING MALARIA SLIDE POSITIVITY RATES IN 30 SENTINEL SITES ACROSS GHANA

**Benjamin Abuaku**<sup>1</sup>, Nana Yaw Peprah<sup>2</sup>, Collins Ahorlu<sup>1</sup>, Wahjib Mohammed<sup>2</sup>, Nancy Quashie<sup>1</sup>, Alexander Asamoah<sup>2</sup>, Neils Quashie<sup>1</sup>, Christabel Addo<sup>1</sup>, Eunice Obeng Amoako<sup>1</sup>, Keziah Malm<sup>2</sup>, Constance Bart-Plange<sup>2</sup>, Kwadwo Koram<sup>1</sup>

<sup>1</sup>Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Accra, Ghana, <sup>2</sup>National Malaria Control Programme, Public Health Division, Ghana Health Service, Accra, Ghana

In Ghana, effective case management remains one of the main interventions for the achievement of the primary goal of malaria control, which is to reduce malaria-related morbidity and mortality. Key to the provision of effective malaria case management is adequate diagnosis, which is vital for assessing the impact of preventive strategies such as deployment and use of long lasting insecticide-treated Nets (LLINs), indoor residual spraying (IRS), intermittent preventive treatment in pregnancy (IPTp), and seasonal malaria chemoprevention (SMC). Over the years malaria diagnosis has largely been presumptive leading to poor case management and poor data on malaria parasite positivity rates, which is necessary for the assessment of the country's progress along the control-elimination continuum. It is in this light that the National Malaria Control Programme (NMCP), in collaboration with the Noguchi Memorial Institute for Medical Research (NMIMR), established sentinel sites across the country to generate data for monitoring malaria slide positivity rates (mSPRs). The surveillance activity aims at tracking mSPRs in 30 sentinel health care facilities across Ghana with 2014 as baseline. Thick and thin blood smears for microscopy are prepared for all 3rd suspected malaria cases attending the health care facility. Blood smears are stained with 10% Giemsa stain, dried and stored in plastic slide boxes for reading by experienced microscopists from NMIMR and the Ghana Health Service (GHS). Data generated over the past 3 years show a significant decline in the overall mSPR from 23.7% (95% CI: 23.3-24.1) in 2014 to 18.8% (95% CI: 18.5-19.1) in 2016 with regional variations. *Plasmodium falciparum* mono-infection remains the most prevalent infection-type in the country: 97.5% (95% CI: 97.2-97.8). The majority of slide-positive patients were under 5 years old: 37.5% (95% CI: 36.7-38.4). We conclude that malaria interventions over the years have had a significant positive impact on mSPR in Ghana.

### 1023

#### PREVALENCE OF ASYMPTOMATIC MALARIA INFECTION AND GLUCOSE-6-PHOSPHATE (G6PD) DEFICIENCY IN A *PLASMODIUM VIVAX*-ENDEMIC SETTING, LAO PDR: IMPLICATIONS FOR SUB-NATIONAL ELIMINATION GOALS

**Andrew A. Lover**<sup>1</sup>, Emily Dantzer<sup>1</sup>, Bouasy Hongvanthong<sup>2</sup>, Keobuphaphone Chindavongsa<sup>2</sup>, Susie Welty<sup>1</sup>, Tania Reza<sup>1</sup>, Nimol Khim<sup>3</sup>, Didier Menard<sup>3</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Center for Malariology, Parasitology and Entomology; Ministry of Health, Vientiane, Lao People's Democratic Republic, <sup>3</sup>Institute Pasteur, Phnom Penh, Cambodia

Confirmed malaria case incidence reported through the health system in Northern Laos has declined rapidly over the past 5 years, and *Plasmodium vivax* now accounts for the majority of cases. As a result, the national malaria program is aiming for sub-national elimination of *P. falciparum* by 2020, and *P. vivax* by 2025. A cross-sectional survey was conducted in four districts of Northern Laos in Sept-Oct 2016 to determine the remaining prevalence of malaria parasite infection and the prevalence of genotypic G6PD deficiency. 1,500 households across 100 villages were selected using two-stage cluster sampling, and household heads interviewed using a demographic and risk factor survey. Rapid diagnostic tests (RDTs) and dried

blood spots were collected for all consenting individuals > 18 months. All blood samples were tested via PCR for parasitemia and a random subset of males genotyped for G6PDd. Out of a total sample of 5,082 individuals, zero infections were detected by RDTs; 39 infections were detected by PCR (weighted prevalence 0.77%; 95% CI: 0.40-1.47%), with 3 *P. falciparum*, 28 *P. vivax*, 2 *P. malariae*, 5 *P. falciparum/P. vivax*, and 1 *P. vivax/P. malariae* infections. Infection prevalence was greatest in adolescents and young adults, and similar by gender, with substantial clustering within households and villages. In preliminary analyses, lack of household bednet ownership [odds ratio= 31.9; (95% CI: 4.3 - 234.1),  $p = 0.001$ ] and any household members sleeping overnight in forest or rice field areas [OR= 3.4; (95 %CI: 1.1 - 10.2),  $p = 0.03$ ] were associated with PCR-positivity; G6PD genotyping is ongoing. The very low parasite prevalence suggests subnational elimination goals in Northern Laos are feasible, and case-based surveillance should be rapidly scaled-up to target interventions to remaining transmission foci. The higher prevalence of *P. vivax* infections highlights the critical need for G6PDd data for safe and efficacious deployment of primaquine towards elimination goals.

### 1024

#### GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY GENETIC VARIANTS IN MALARIA PATIENTS IN SOUTHWESTERN ETHIOPIA

**Tamar E. Carter**<sup>1</sup>, Seleshi K. Mekonnen<sup>2</sup>, Karen Lopez<sup>1</sup>, Victoria Bonnell<sup>1</sup>, Lambodhar Damodaran<sup>1</sup>, Abraham Aseffa<sup>3</sup>, Daniel A. Janies<sup>1</sup>

<sup>1</sup>University of North Carolina at Charlotte, Charlotte, NC, United States, <sup>2</sup>Jimma University, Jimma, Ethiopia, <sup>3</sup>Armauer Hansen Research Institute, Addis Abba, Ethiopia

Malaria remains a major public health concern in Ethiopia, affecting over five million individuals each year. *Plasmodium vivax* infections underlie a third of malaria cases and are often treated with primaquine. One disadvantage to primaquine use is the risk for hemolytic anemia in patients with the X-linked enzymatic disorder, glucose-6-phosphate dehydrogenase (G6PD) deficiency. This risk is increased when treating *P. vivax* infections, as these pathogens require a high primaquine dose. As primaquine becomes more widely used in Ethiopia, it is important to identify G6PD deficiency mutations in the population. In the present study, mutations in the *G6PD* gene are identified in a sample of patients with malaria in Jimma town in southwest Ethiopia. Polymerase chain reaction (PCR) and gel electrophoresis were used to detect *Plasmodium* species of infection from blood spot samples collected from malaria patients. For G6PD deficiency, PCR and Sanger sequencing were performed to observe a portion of the *G6PD* gene where the common G6PD mutations, A376G and G202A, are found. The majority of the samples were identified as single *P. vivax* infections (83.7%). For G6PD genotyping, A376G (rs1050829, A>G) was frequent in this study sample set (23.26%) while G202A (rs1050828, G>A) was absent. Three mutations were also identified at *G6PD* locations that have not yet been characterized for their association with G6PD enzyme activity. One mutation occurs in the coding region (rs782669677, G>A,) and two mutations occur in non-coding regions (rs370658483, G>T and a new mutation at chrX:154535443, C>T). Analysis of the functional properties of the three additional mutations are on-going. The data presented here add to the growing literature on the diversity of the *G6PD* gene in Ethiopia needed to inform policy on appropriate primaquine use in malaria control programs.

## 1025

**HIGH PREVALENCE OF CLINICAL MALARIA IN A POPULATION OF PREGNANT WOMEN LIVING IN LIBREVILLE, GABON**

**Marie Louise Tshibola Mbuyi**<sup>1</sup>, Denise Patricia Mawili-Mboumba<sup>1</sup>, Tanguy de Dieu Tchanchou<sup>2</sup>, Noé Patrick M'bondoukwe<sup>1</sup>, Michelle Marrion Ntsame Owono<sup>1</sup>, Michelle Marrion Ntsame Owono<sup>1</sup>, Marielle Karine Bouyou-Akotet<sup>1</sup>

<sup>1</sup>Département de Parasitologie-Mycologie, Libreville, Gabon, <sup>2</sup>Département de Gynécologie, Hôpital d'Instruction des Armées Omar Bongo Ondimba, Libreville, Gabon, Libreville, Gabon

Pregnant women in malaria endemic areas are at high risk of *Plasmodium falciparum* infection and its complications. This study investigated for the first time in Libreville, the prevalence and risk factors for *P. falciparum* infection among pregnant women. We conducted a cross-sectional study from May and November 2015 at gynecological services of l'Hôpital d'Instruction des Armées Omar Bongo Ondimba (HIABO) of Libreville. For each pregnant women who was hospitalized for fever and non febrile ones seen during their antenatal care visit, socio-demographic, obstetrical and clinical data, history of fever and antimalarial treatment, use of IPTp-SP, and delivery outcome were recorded. Peripheral blood was collected for *falciparum* malaria detection by thick and thin blood smears and for hemoglobin concentration measurements. The association between the studied variables and malaria were analyzed by logistic regression. A total of 179 pregnant women were included in the study, 94 were febrile and hospitalized, 85 non-febrile and non-hospitalized. Nearly half, 47.5% were seen before the third antenatal care visit, 56.4% received IPTp-SP and 38.5% used bed net. The preliminary analysis shows that the prevalence of confirmed clinical malaria was 60.6% among the hospitalized pregnant women. The factors associated with malaria infection were a maternal age below 25 years old (71% vs. 52.9%), a high education level, a low number of ANC visits (93%), being at the second trimester of pregnancy (78%) ( $p < 0.01$ ). The median number of IPTp-SP doses was significantly low ( $p = 0.02$ ) and the frequency of women who did not used IPTp-SP ( $p = 0.02$ ) or bednet ( $p = 0.04$ ) were significantly high among infected women compared to those without malaria. In conclusion, the frequency of clinical malaria is high in febrile hospitalized pregnant women. It is associated with an infrequent use of preventive measures.

## 1026

**PROXIMITY OF HUMAN RESIDENCE TO IRRIGATION DETERMINES MALARIA RISK AT AN IRRIGATED AGRO-ECOSYSTEM IN MALAWI**

**Charles Mangani**<sup>1</sup>, Edward D. Walker<sup>2</sup>, Terrie E. Taylor<sup>2</sup>, Themba Mzilahowa<sup>1</sup>, Leo Zulu<sup>2</sup>, Don Mathanga<sup>1</sup>

<sup>1</sup>University of Malawi, Blantyre, Malawi, <sup>2</sup>Michigan State University, East Lansing, MI, United States

Although malaria control interventions have led to a decline in transmission intensity, the disease continues to be a major public health problem in Malawi. Proximity of vector breeding sites to human residences affects malaria risk. Irrigation plays an increasingly important role in Malawi to improve food security and the rural economy. However, land transformation for irrigated agriculture could increase malaria vulnerability for those residing in proximity to irrigation schemes, negatively impacting the anticipated improvements in rural life. Therefore, we aimed to determine the effect of irrigated agriculture on variation in malaria risk in villages around Bwanje Valley rice irrigation Scheme. Two cross-sectional surveys were conducted at the end of the rainy seasons of April 2016 and 2017. Demographic and health information was collected for household members. Blood samples were obtained for malaria rapid test and microscopic identification of *Plasmodium falciparum*. Malaria risk was assessed by village clusters, defined by distance of village from irrigation scheme; within 3km or 3-6 km radius. Among 2,709 individuals aged greater than six months, prevalence of infection by microscopy was 33.2 % and was significantly in residents of villages within a 3 km

radius of the scheme (40.1%) compared to 3-6 km from the scheme (28.4%). Prevalence estimates by rapid diagnostic test were higher. Study participants living within 3 km radius from the boundary of the scheme were at significantly higher risk of malaria infection than were those living further away (aOR=1.7; 95% CI, 1.4-2.2). Most (90%) infected people were asymptomatic. Compared with the younger and older age groups, children aged 6-15 years had higher risk of malaria infection (aOR=3.2; 95% CI, 2.4-4.2), higher parasite densities, higher gametocytemia, and reported less frequent use of bed nets. We conclude that proximity of human residence to irrigation in Malawi increases malaria risk. Additionally, among the community members, school-age children share the greater burden to malaria infection.

## 1027

**EVALUATING THREE YEARS OF A TARGETED INDOOR RESIDUAL SPRAYING (IRS) CAMPAIGN IN A HIGH TRANSMISSION AREA OF NORTHERN ZAMBIA**

**Marisa Hast**<sup>1</sup>, Mike Chaponda<sup>2</sup>, James Lupiya<sup>2</sup>, Mbanga Muleba<sup>2</sup>, Jean-Bertin B. Kabuya<sup>2</sup>, Tamaki Kobayashi<sup>1</sup>, Timothy M. Shields<sup>1</sup>, Frank C. Curriero<sup>1</sup>, Justin Lessler<sup>1</sup>, Modest Mulenga<sup>2</sup>, Jennifer C. Stevenson<sup>1</sup>, Douglas E. Norris<sup>1</sup>, William J. Moss<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia

Evidence-based approaches are needed to meet malaria control and elimination goals in endemic countries. The World Health Organization has identified vector control as a key strategy to reduce transmission, however limited resources and surveillance capacity remain a challenge in regions with the greatest need. An increase in malaria cases has been reported in Luapula Province, northern Zambia since 2007 despite consistent reductions nationwide. In response, a large-scale indoor residual spraying (IRS) campaign was conducted using novel methodology to target high-transmission areas through household satellite mapping and health center malaria reports. Annual targeted spraying was done prior to the rainy season in 11 districts in Luapula Province starting in 2014 using the organophosphate insecticide Actellic. A multi-year evaluation of the IRS campaign was conducted in Nchelenge District, Luapula Province using active malaria surveillance data collected by the Southern Africa ICEMR project. From April 2012-March 2017, 3,345 participants from 1,030 households participated in cross-sectional surveys in sprayed and unsprayed areas, with an overall parasite prevalence by RDT of 50%. Fifty five percent of households within IRS-targeted areas reported being sprayed with Actellic. In multivariate regression analyses controlling for demographics, weather, and geographic factors, there was a 25% reduction in rainy season malaria prevalence by RDT within the IRS-targeted area compared with the same geographical area pre-intervention ( $P < 0.001$ ) but no decrease in dry season malaria prevalence. However, malaria prevalence in adjacent unsprayed areas increased each year throughout the period of surveillance, and a difference-in-differences analysis to compare pre- vs. post-intervention malaria prevalence between sprayed and unsprayed areas revealed a significant effect of IRS for both rainy and dry seasons ( $P = 0.02$  for each). Targeted IRS using Actellic had a moderate but measurable impact on parasite prevalence in Nchelenge District, but more intensive interventions are needed to achieve Zambia's malaria elimination goals.

### A SITUATIONAL ASSESSMENT OF THE DRIVERS OF MALARIA IN COMMUNITIES ALONG THE ZIMBABWE-MOZAMBIQUE BORDER OF MANICALAND PROVINCE

Rose Kambarami<sup>1</sup>, John Mandisarisa<sup>1</sup>, Frank Chikhata<sup>1</sup>, Simon Nyadundu<sup>2</sup>, Simba Mashizha<sup>2</sup>, Patron Mafaune<sup>2</sup>, Joseph Mberikunashe<sup>3</sup>, **Fadzai Mutseyekwa**<sup>1</sup>, Rugare G. Mandigo<sup>1</sup>, Kate Gilroy<sup>4</sup>

<sup>1</sup>Maternal Child Integrated Program (MCHIP), Harare, Zimbabwe,

<sup>2</sup>Manicaland Provincial Medical Directorate, Manicaland, Zimbabwe,

<sup>3</sup>Zimbabwe National Malaria Control Programme, Harare, Zimbabwe,

<sup>4</sup>Maternal Child Survival Program (MCSP), Washington, DC, United States

In Zimbabwe (ZIM), the 3 provinces bordering Mozambique (MOZ) reported 86% of malaria cases and 60% of malaria deaths. The President's Malaria Initiative supported the Government of Zimbabwe's National Malaria Control Program (NMCP) to assess the potential drivers of malaria transmission in Manicaland on the ZIM-MOZ border. Methods included a household (HH) survey (n=522), interviews with individuals (n=850), key informants (n=55), cross-border travelers and traders (n=106), MOZ patients seeking care in ZIM (n=138) and facility and community medical records review (n=2,331). Findings indicate that neighboring Manica (MOZ) and Manicaland (ZIM) Provinces are not equally prioritized to receive malaria interventions. Interviews suggest that cross-border collaboration efforts initiated by the leadership from the two provinces over the years have not progressed to concrete implementation steps. Just over 50% of the 850 individuals interviewed reported hearing messages on malaria prevention during the preceding 6 months. About 64% of HHs surveyed had long-lasting insecticide nets (LLIN), although only 38% reported using LLINs the previous night, and the number of nets per HH was insufficient for sleeping spaces. About 65% of HHs surveyed reported indoor residual spraying in the previous year. 37% of the border population reported regular cross-border travel. Less than 20% of travelers reported using personal protection when crossing the border. Outpatient registers do not collect travel history, so the extent of imported malaria cases wasn't determined. ZIM cross-border travelers with malaria often seek care at ZIM health facilities; as do MOZ nationals (4% of malaria cases reviewed). The assessment illuminated intervention coverage gaps on the ZIM side. Communities on both sides of the border are dynamic and interactive, thus the ZIM NMCP should continue coordinate and collaborate with MOZ counterparts. Enhanced social and behavior change communication would benefit border communities on both sides. Cross border traders and travelers form a significant group at risk and should be deliberately targeted for malaria interventions.

### 1029

#### THE EFFECT OF DROUGHT ASSOCIATED INDICATORS ON MALARIA IN SOUTHERN ZAMBIA

**Anton Kvit**<sup>1</sup>, Harry Hamapumbu<sup>2</sup>, Clive Shiff<sup>1</sup>, Douglas E. Norris<sup>1</sup>, Tim Shields<sup>1</sup>, Jennifer C. Stevenson<sup>1</sup>, Philip E. Thuma<sup>2</sup>, William J. Moss<sup>1</sup>, Frank C. Curriero<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Macha Research Trust, Macha, Zambia

Malaria is an infectious disease endemic to Zambia transmitted by anopheline mosquitoes. Due to their key role in transmission, malaria incidence is strongly influenced by environmental variables (e.g. vegetation and elevation) and climatic variables (e.g. rainfall and temperature). Drought strongly affects most of these variables. While previous studies have examined associations between climatic factors and malaria, few have considered drought measures such as soil moisture or drought index as predictors of malaria. Furthermore, when considering the lag effects of weather-related variables on malaria incidence, most studies assumed lagged weather at one time. However, weather occurring over an interval of time within a lag might better correlate with the biology and ecology of vector mosquitoes and hence have a stronger association with malaria

incidence. Diagnosed weekly malaria incident cases from 14 rural health centers (RHCs) in Southern Province, Zambia were recorded between 2012 and 2016. All predictor parameters were remotely sensed except relative humidity and daily rainfall, which were recorded using a weather station. Weekly data from all 14 RHCs were aggregated for analysis. Optimal point temporal lags and interval lags were determined using cross correlation maps. Univariate and multivariate negative binomial regressions were performed to determine the best predictors of malaria counts. To account for nonlinear relationships between malaria counts and predictor variables, models using splines were also considered. Drought index and soil moisture were significantly associated with malaria counts; however, the best predictors were rainfall, night temperature, and normalized difference vegetation index. These three variables could be used in future studies of the impact of drought on malaria transmission. Point lag and lag interval models resulted in similar prediction quality. Accounting for the nonlinear association of night temperature and malaria counts improved prediction quality but an increase in malaria counts in 2016 remained underestimated, due to suspected differences in rainfall effects.

### 1030

#### OUTBREAK OF MALARIA IN UBON RATCHATHANI, THAILAND (2012-2015)

**Chris Erwin G. Mercado**<sup>1</sup>, Saranath Lawpoolsri<sup>2</sup>, Jeeraphat Sirichaisinthop<sup>3</sup>, Prayuth Sudathip<sup>3</sup>, Jaranit Kaewkungwa<sup>4</sup>, Annat Khamsirivatchara<sup>4</sup>, Nattwut Ekapirat<sup>1</sup>, Vilasinee Yuwaree<sup>1</sup>, Nicholas P. Day<sup>1</sup>, Arjen M. Dondorp<sup>1</sup>, Chatree Rasribut<sup>5</sup>, Richard J. Maude<sup>1</sup>

<sup>1</sup>Mahidol Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, <sup>2</sup>Department of Tropical Hygiene, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, <sup>3</sup>Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, <sup>4</sup>Center of Excellence for Biomedical and Public Health Informatics, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, <sup>5</sup>Bureau of Vector-borne Diseases, Ministry of Public Health, Ubon Ratchathani, Thailand

Thailand has made significant progress reducing its malaria cases by 85% between 2000 and 2015, but the burden of disease remains a challenge in areas along the country's borders. Moreover, evidence of anti-malarial resistance has been observed on the Thai-Cambodian border, making prevention and control efforts for malaria less effective. As Thailand aims to eliminate malaria by 2024, it is necessary to have a detailed and up to date understanding of local disease patterns and possible drivers of transmission. In 2014, there was a large outbreak of malaria in Ubon Ratchathani Province in northeast Thailand. This outbreak has not been studied in detail but could have important implications for other malaria eliminating countries. A detailed analysis of routine incidence data over space and time was conducted to examine the spatial and temporal epidemiology of malaria in this province. Malaria surveillance data were obtained from the Thai Ministry of Public Health from 2012 to 2015. Subdistrict-level analyses of numbers of confirmed malaria cases by species and annual parasite index were produced. Data were explored for any relationships between numbers of cases and other factors such as temperature and rainfall. There were 15,459 malaria cases of all species reported between 2012 and 2015. The majority were men (92%), and of Thai nationality (96%). In 2014, a 6.8-fold increase in both *Plasmodium falciparum* and *Plasmodium vivax* cases was observed compared to the previous year from 2.6% of the national total in 2013 to 22.9% in 2014. Peak incidence was in June and May 2014, with most of the increase being in three neighboring districts of Buntharik, Na Chaluai and Nam Yuen, all geographically sharing borders with southern Lao PDR and northern Cambodia. This large outbreak was very focal, and although it was not possible to determine a definite cause from available data, cross-border importation and travel into the forest may have played a role. Field studies are underway to examine the current situation in more detail.

## 1031

### DEMOGRAPHIC AND REGIONAL RISK FACTORS FOR MALARIA-ASSOCIATED HOSPITALIZATIONS IN WESTERN AND COASTAL KENYA

Priyanka Suresh<sup>1</sup>, Amy Krystosik<sup>1</sup>, David M. Vu<sup>1</sup>, Cornelius Kiptoo<sup>2</sup>, John Vulule<sup>2</sup>, Dunstan Mukoko<sup>3</sup>, Uriel Kitron<sup>4</sup>, Charles H. King<sup>5</sup>, Bryson Ndenga<sup>2</sup>, Francis M. Mutuku<sup>6</sup>, **A. Desiree LaBeaud**<sup>1</sup>

<sup>1</sup>Stanford University, Department of Pediatrics, Stanford, CA, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Ministry of Public Health and Sanitation, Nairobi, Kenya, <sup>4</sup>Emory University, Atlanta, GA, United States, <sup>5</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>6</sup>Technical University of Mombasa, Mombasa, Kenya

Malaria is a major cause of morbidity and mortality in Kenya. Children can present with diverse clinical manifestations ranging from asymptomatic parasitemia to severe malaria and death. It is unclear why some individuals progress to severe disease. Risk factors for severe malaria could be linked to the host, parasite, socio-economic status and/or environmental factors. We enrolled children aged 1 to 17 years who presented with fever (Jan 2014- present) at each of four Kenyan study sites: Chulaimbo (rural) and Kisumu (urban) in Western Kenya, and Msambweni (rural) and Ukunda (urban) on the coast. All patients were tested for malaria by light microscopic examination of peripheral blood smears and detailed questionnaire data were collected on demographics, education level, socioeconomic status, and household environment, along with full clinical history and physical examination. "Severe" malaria cases, defined as those requiring hospitalization due to malaria, were compared to "mild" malaria cases, defined as those sent home after the clinic visit. Incidence of malaria in the cohort by blood smear was 42.1% (1,393/3,310). The majority of cases (98.0%) were due to *P. falciparum*, and the remaining were due to *P. ovale* (0.6%) and *P. malariae* (1.3%). Of the 1,393 cases, 94 (6.75%) were classified as having severe malaria. Severe cases were significantly more common in western Kenya (59.6% vs. 40.4%  $p < 0.001$ ), were younger (median age=4 vs. 5 years;  $p < 0.001$ ) and were more likely to have a history of prior malaria (95.7% vs. 71.0%;  $p < 0.001$ ) than "mild" malaria cases. No association was found between risk of severe malaria and family wealth, maternal education level, hygiene, or mosquito prevention indices. This study highlights the remaining large burden of malaria in young children, especially in western Kenya, and the critical need for more vector-borne disease control and prevention resources targeting this vulnerable population for severe malaria.

## 1032

### SPATIOTEMPORAL EPIDEMIOLOGY OF MALARIA IN THAILAND 2012-2015

Nattwut Ekapirat<sup>1</sup>, Prayuth Sudathip<sup>2</sup>, Nipon Chinanonwait<sup>2</sup>, Chris E. Mercado<sup>1</sup>, Steeve Ebener<sup>3</sup>, **Richard J. Maude**<sup>1</sup>

<sup>1</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>Bureau of Vector Borne Disease, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, <sup>3</sup>AeHIN GIS Lab, Manila, Philippines

Thailand has a plan to eliminate malaria by 2024 and has made significant progress reducing the number of cases from around 150,000 in 2000 to 25,000 in 2015. Over the past few years, most malaria cases were found along the borders with Myanmar, Lao PDR and Cambodia with many cases thought to be imported. In addition, resistance to first-line antimalarial drugs has been identified in different parts of Thailand and there is concern that this could derail efforts to reaching elimination by 2024. To support these elimination efforts, it is essential to have a highly effective surveillance system to provide a detailed understanding of the disease patterns over space and time, as well as information on risk factors and groups at higher risk of malaria. Working in partnership with the Ministry of Public Health (MOPH), detailed routine malaria surveillance data from the whole of Thailand from 2012 to 2015 were analysed and mapped at subdistrict level including calculation of annual parasite index (API) using data on population, identification of areas of highest risk and

the stability of these risk areas over time. In addition, detailed climate data from the Thai government to assess the relationship between climate and incidence. The primary goal was to generate results to support elimination efforts by the MOPH. Malaria incidence was found to be highest in four provinces (59% of total cases during 2012-2015) along international borders: Tak, Kanchanaburi, Yala (Thai-Burmese border) and Ubon Ratchathani (Thai-Cambodia-Lao PDR border). *Plasmodium vivax* was the predominant species in three of these provinces, with falciparum being commoner in Yala. The majority were male (42%), aged 5 to 19 years and of Thai (66%) or Burmese nationality (25%). The incidence and risk maps produced will be combined with population movement data from travel surveys and analysis of anonymized aggregated mobile phone call detail records to determine the effect of population movement on the distribution of malaria in the country and internationally.

## 1033

### PROACTIVE COMMUNITY TREATMENT OF CHILDREN UNDER-5: RESULTS OF A PILOT PROJECT IN NORTHERN BENIN

Sierra Petrosky<sup>1</sup>, **Mathew DeLeonardis**<sup>1</sup>, Christian Alokpo<sup>1</sup>, Boniface Denakpo<sup>2</sup>, Fortune Dagnon<sup>3</sup>, Michelle Kouletio<sup>3</sup>, Peter E. Thomas<sup>4</sup>

<sup>1</sup>United States Peace Corps, Cotonou, Benin, <sup>2</sup>National Malaria Control Program, Cotonou, Benin, <sup>3</sup>United States Agency for International Development, Washington, DC, United States, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

The ProActive Community Treatment (ProACT) model uses weekly household visits by community health workers (CHWs) to detect and treat illnesses like malaria in children. ProACT had not been tested in a year-round high malaria transmission country like Benin. The National Malaria Control Program worked with Peace Corps volunteers and the US President's Malaria Initiative to implement a ProACT pilot in four villages in Northern Benin. The villages were economically, demographically, and culturally similar; all were located  $\geq 5$  km from a health center. CHWs identified children with malaria or diarrhea during "sweeps" conducted weekly (two villages) or intermittently (at 0, 8, and 16 weeks; two villages). Children were evaluated and treated or referred for treatment per existing CHW protocols. During the pilot, CHWs diagnostically confirmed and treated 95 malaria cases among the 440 children under 5 years of age living in the four villages. Sixty-five cases were identified during sweeps (43 in villages with weekly sweeps, 22 in villages with intermittent sweeps). Illness identified during sweeps accounted for 64% of the total care provided. Weekly active detection identified substantial numbers of children with malaria and may have led to earlier treatment and/or treatment of cases that would have otherwise gone untreated. More rigorous evaluation is needed to determine ProACT's ability to reduce morbidity during high malaria transmission periods in Benin.

## 1034

### A TLR1 POLYMORPHISM INCREASES THE RISK OF VIVAX MALARIA IN SOUTHERN INDIA

**Prabhanjan P. Gai**<sup>1</sup>, Suyamindra Kulkarni<sup>2</sup>, Konrad Siegert<sup>1</sup>, Jakob Wedam<sup>1</sup>, Rashmi Rasalkar<sup>2</sup>, Costanza Tacoli<sup>1</sup>, Animesh Jain<sup>3</sup>, Chakrapani Mahabala<sup>3</sup>, Shantharam Baliga<sup>3</sup>, Rajeshwari Devi<sup>4</sup>, Damodara Shenoy<sup>3</sup>, Pramod Gai<sup>2</sup>, Frank P. Mockenhaupt<sup>1</sup>

<sup>1</sup>Charité-Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Karnataka Institute for DNA Research, Dharwad-Hubli, India, <sup>3</sup>Kasturba Medical College, Manipal University, Mangalore, India, <sup>4</sup>Wenlock Hospital, Mangalore, India

Malaria is considered the single most important selective force in the history of the human genome but the extent to which this notion applies to *Plasmodium vivax* is not well established. In Mangalore, Karnataka, southern India, we conducted an unmatched case-control study among malaria patients attending the largest governmental hospital and representatively selected community controls, and genotyped Toll-like

receptor 1 (TLR1) I602S and the MBL -221 X/Y promoter polymorphisms as exemplary members of the innate immune response. 960 patients with PCR-confirmed malaria (*P. vivax*, 69.4%; *P. falciparum*, 9.0%; mixed species, 21.4%) as well as 1017 community controls were included in analysis. The *TLR1* 602S variant was present in 13.3% of patients and 11.1% of controls. Adjusting for significant differences in age, sex, and migration status between cases and controls, the odds of malaria *per se* tended to be increased in *TLR1* 602S carriers (aOR, 1.32; 95%CI, 0.96-1.81), and it was significantly increased with respect to *P. vivax* mono-infection (aOR, 1.49; 95%CI, 1.05-2.09). MBL -221 X/Y had no such impact. We show that TLR1 is involved in the risk of vivax malaria in India. Ongoing work will show whether this applies to further members of the TLR and the innate immune system. Geographical variation of innate immunity polymorphisms may contribute to differing risks and manifestation patterns of malaria in India.

### VARIATION AT THE VAR2CSA LOCUS: RESULTS FROM A CROSS-SECTIONAL STUDY IN DEMOCRATIC REPUBLIC OF CONGO

Robert Verity<sup>1</sup>, Oliver Watson<sup>1</sup>, Stephanie Doctor<sup>2</sup>, Nicholas Hathaway<sup>3</sup>, Jeffrey Bailey<sup>3</sup>, Jonathan Juliano<sup>2</sup>, Melchior Kashamuka<sup>4</sup>, Antoinette Tshetu<sup>5</sup>, Joris Likwela<sup>6</sup>, Azra Ghani<sup>1</sup>, Steven Meshnick<sup>2</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>3</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>4</sup>Hopital General Provincial de Reference de Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>6</sup>Programme National de Lutte Contre le Paludisme, Kinshasa, Democratic Republic of the Congo

*P.falciparum* affects over 1 million pregnancies in Democratic Republic of Congo (DRC) each year, placing both pregnant women and newborns at risk. The adverse effects of pregnancy associated malaria (PAM) are mediated by the binding of infected erythrocytes to the placental microvasculature via the VAR2CSA surface antigen. Using next generation deep sequencing, we categorized the diversity of the *var2csa* gene in 120 survey cluster sites from the 2013-4 Demographic and Health Survey in DRC. We found that *var2csa* is highly variable. We identified 583 different haplotypes, only about 1/3 of which were found in 2 or more clusters. Our results indicate that there is extensive connectivity and gene flow across large parts of DRC, combined with balancing selection maintaining diversity at this locus. These results impact on how we perceive and manage parasite populations within DRC, and ultimately our ability to develop an effective vaccine against PAM.

## 1036

### WITHIN-VECTOR PARASITE DIVERSITY: INSIGHTS FROM PLASMODIUM FALCIPARUM DEEP WHOLE-GENOME SEQUENCING FROM FIELD-CAUGHT MOSQUITOES IN NORTHERN ZAMBIA

Giovanna Carpi<sup>1</sup>, Julia C. Pringle<sup>1</sup>, Mbanga Muleba<sup>2</sup>, Jennifer C. Stevenson<sup>1</sup>, Mike Chaponda<sup>2</sup>, Modest Mulenga<sup>2</sup>, William J. Moss<sup>3</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Johns Hopkins Malaria Research Institute, Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Center, Ndola, Zambia, <sup>3</sup>Johns Hopkins Malaria Research Institute, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In regions of moderate and high malaria transmission where infectious mosquito bites occur frequently, human infections with *Plasmodium falciparum* typically comprise multiple clones. Because parasites undergo

sexual recombination within the mosquito, cross-fertilization between genetically distinct parasite gametes may occur more frequently than inbreeding, possibly contributing to the observed genetic diversity of the parasite population. Most parasite genomics studies have focused on monoclonal infections in human samples to characterize transmission intensity and model the impact of interventions, and few empirical studies characterizing parasite diversity and relatedness within mosquitoes exist. Better understanding of the extent of within-vector parasite diversity, genetic relatedness, and which parasite clone(s) are transmitted to humans, may aid reconstruction of transmission chains and inform vector control strategies targeted to disrupt malaria transmission. To gain insights into parasite diversity within mosquitoes, we used a multiplexed hybrid capture technique to selectively enrich and deep sequence 20 whole genomes (WGS) of *P. falciparum* directly from field-caught mosquitoes from a high transmission setting in Nchelenge District in northern Zambia. Using WGS and genome-wide SNPs, we will infer parasite diversity and genetic relatedness resulting from recombination and different bottleneck and expansion events across these *P. falciparum* samples from mosquitoes. We anticipate that population genomic studies of mosquito-derived *P. falciparum* samples, coupled with spatially and temporally paired human samples, could greatly aid understanding of transmission dynamics in malaria endemic regions by identifying hotspots of parasite diversity and clarifying the role of mosquitoes in modulating parasite diversity at the population level.

## 1037

### MATCHED PLACENTAL AND PERIPHERAL BLOOD PARASITES ARE GENETICALLY HOMOLOGOUS AT THE VAR2CSA ID1-DBL2X LOCUS BY DEEP SEQUENCING

Andreea Waltmann<sup>1</sup>, Jaymin C. Patel<sup>1</sup>, Kyaw L. Thwai<sup>1</sup>, Nicholas J. Hathaway<sup>2</sup>, Christian M. Parobek<sup>1</sup>, Achille Massougbojji<sup>3</sup>, Nadine Fievet<sup>4</sup>, Jeffery A. Bailey<sup>2</sup>, Philippe Deloron<sup>4</sup>, Jonathan J. Juliano<sup>1</sup>, Nicaise T. Ndam<sup>4</sup>, Steven R. Meshnick<sup>1</sup>

<sup>1</sup>University of North Carolina Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>University of Massachusetts, Worcester, MA, United States, <sup>3</sup>Université d'Abomey-Calavi, Cotonou, Benin, <sup>4</sup>Université Paris Descartes, Paris, France

In pregnancy-associated malaria (PAM), infected erythrocytes (IEs) accumulate in the placenta. It is unclear if in polyclonal infections, which are common in natural infections, placental sequestration of IEs results in distinct peripheral and placental parasite populations. We used long amplicon deep sequencing of *Plasmodium falciparum* *var2csa*-ID1-DBL2X, the 1.6kb region encoding the minimal binding epitope to human CSA, in 15 matched peripheral and placental samples at delivery (i.e. a total of 30 samples from 15 women) in a high transmission area of Benin. We aimed to determine the within-patient genetic homology between sample pairs. Despite substantial sequence diversity (580 variable sites of 1738 total nucleotide sites, including INDELS) and within-host allele frequencies as low as 1%, the majority of infections (28/30, 93.3%) were monoclonal or had a predominant haplotype. The mean multiplicity of infection (MOI) in peripheral and placental samples was 1.4 (range = 1-2) and 1.6 (range = 1-5), respectively. Pairs mostly contained the same genetic variants, with 11/15 pairs sharing 100% of their haplotypes, while other pairs showed some heterogeneity. These findings suggest that at the time of delivery, placental parasites are not a selected subset of those in the periphery, and the parasites in the two compartments appear to intermix. Whether this intermixing reflects that cytoadherent variants are at a selective advantage over non-cytoadherent genotypes will be discussed. In conclusion, these data show that the placental population can be inferred through peripheral blood sampling.

## 1038

**EVALUATING CROSS-BORDER MALARIA TRANSMISSION BETWEEN ZAMBIA AND THE DEMOCRATIC REPUBLIC OF CONGO: A PARASITE GENETICS APPROACH**

Julia C. Pringle<sup>1</sup>, Tamaki Kobayashi<sup>2</sup>, Giovanna Carpi<sup>1</sup>, Steven Meshnick<sup>3</sup>, Jonathan Juliano<sup>3</sup>, Modest Mulenga<sup>4</sup>, Mbanga Muleba<sup>4</sup>, Mike Chaponda<sup>4</sup>, Thierry Bobanga<sup>5</sup>, William J. Moss<sup>2</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Johns Hopkins Malaria Research Institute, Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Johns Hopkins Malaria Research Institute, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, United States, <sup>4</sup>Tropical Diseases Research Center, Ndola, Zambia, <sup>5</sup>Universite Protestante au Congo, Kinshasa, Democratic Republic of the Congo

In Zambia, the national goal to eliminate malaria by 2020 is threatened by potential carriage of parasites across borders in human or mosquito hosts. Cross-border malaria transmission was evaluated using parasite genetics between Nchelenge District, Luapula Province (malaria RDT+ prevalence 30-50%) in northwest Zambia and two villages, Kilwa and Kashobwe, across the border from Nchelenge District in the Democratic Republic of Congo (DRC) (malaria RDT+ prevalence 47%). Randomly selected households in Nchelenge, Kilwa, and Kashobwe were visited in June and July 2016 and consenting individuals provided a dried blood spot (DBS) for detection of *Plasmodium falciparum* by PCR and genetic analysis. Among the DBS which tested positive for *P. falciparum* by PCR, 41 samples from Nchelenge, 39 from DRC, and 15 positive controls (spiked with known concentrations and varying ratios of laboratory *P. falciparum* strains NF54, 3d7, and 7g8) were extracted and prepared for amplicon deep sequencing at the CSP, var2csa, and AMA1 loci. By analyzing haplotype diversity and genetic relatedness between human-derived samples from Nchelenge District and the DRC, the extent of gene flow between parasite populations will be estimated to indicate the extent of cross-border malaria transmission. This research will inform regional control programs on the need to coordinate malaria elimination efforts, particularly along border regions.

**EUPATHDB: POWERFUL DATA-MINING TOOLS FOR EXPLORING THE BIOLOGY OF HOST-PATHOGEN INTERACTIONS**

Susanne Warnefeltz<sup>1</sup>, Brian Brunk<sup>2</sup>, Omar S. Harb<sup>2</sup>, Jessica C. Kissinger<sup>1</sup>, David S. Roos<sup>2</sup>

<sup>1</sup>University of Georgia, Athens, GA, United States, <sup>2</sup>University of Pennsylvania, Philadelphia, PA, United States

The Eukaryotic Pathogen Database (EuPathDB, <http://EuPathDB.org>) is a free, online data mining resource facilitating the discovery of meaningful biological and clinical relationships from large volumes of genomic and epidemiological data. This platform places the power of bioinformatic analysis in the hands of the scientific community, supporting hypothesis-driven discovery research by providing guided queries and powerful tools for data mapping and analysis in a graphical web-interface. EuPathDB supports 170+ species including pathogenic protists (*Amoebae*, *Cryptosporidium*, *Giardia*, *Leishmania*, *Plasmodium*, *Trypanosoma*, etc), fungi (*Aspergillus*, *Cryptococcus*, *Candida*, etc), and related non-pathogenic species. EuPathDB integrates a wide range of omics-scale data types, applies standard bioinformatics workflows, and creates orthology profiles and domain predictions. Data exploration and interrogation proceed via direct examination of record pages representing genes, pathways, study subjects, etc; dynamic visualization of sequence-based data aligned to the genome; analyses such as functional enrichment or Galaxy workflows; and a sophisticated Search Strategy system with

>100 pre-configured searches that can associate diverse evidence with specific hypotheses. EuPathDB makes it easy to interrogate biological questions relating to stage-specific expression, gene model integrity or alternative splice variants, etc, and to compile lists of genes that share multiple biological characteristics (e.g. kinases secreted at a particular time, where they may affect host responses). This platform has recently expanded to incorporate data from Systems Biology programs (including the Malaria Host-Pathogen Interactions project) and clinical studies (e.g. the International Centers of Excellence in Malaria Research, and the GEMS and MAL-ED projects supported by the Gates Fdn Enteric and Diarrheal Diseases program). Active user support includes an email help desk (Help@EuPathDB.org), social media, YouTube tutorials, and a global program of workshops. Please visit our poster or exhibitor hall booth for a demonstration.

**A LARGE-SCALE GENETIC SCREEN OF PLASMODIUM FALCIPARUM IDENTIFIES GENOTYPY-PHENOTYPE MUTATIONS AFFECTING TOLERANCE TO FEBRILE TEMPERATURES**

Min Zhang<sup>1</sup>, Chengqi Wang<sup>1</sup>, Phaedra Thomas<sup>1</sup>, Jenna Oberstaller<sup>1</sup>, Thomas D. Otto<sup>2</sup>, Xiangyun Liao<sup>1</sup>, Suzanne Li<sup>1</sup>, Kenneth Udenze<sup>1</sup>, Swamy R. Adapa<sup>1</sup>, Katrina Button-Simons<sup>3</sup>, Michael T. Ferdig<sup>3</sup>, Julian C. Rayner<sup>2</sup>, Rays H. Y. Jiang<sup>1</sup>, John H. Adams<sup>1</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Wellcome Trust Sanger Institute, Hinxton Cambridgeshire, United Kingdom, <sup>3</sup>University of Notre Dame, Notre Dame, IN, United States

Intermittent fever is a characteristic clinical feature of malaria that reflects the synchronized cyclical development of blood-stage parasites. Importantly, malarial fever is lethal to blood-stage *Plasmodium falciparum*, except for early intraerythrocytic ring stages that can tolerate febrile temperatures. Because parasite survival of febrile temperatures represents an essential adaptive mechanism, we seek to understand the pathways and processes associated with parasite tolerance of febrile temperatures through a forward-genetic approach using ~1000 unique *piggYbac* (*pB*) mutants of *P. falciparum* NF54. Our experimental and computational approaches rely on Quantitative Insertion-site Sequencing (QISeq) to quantify differences in growth of *pB* mutants before and after phenotype selection. QISeq is a next-generation sequencing method that counts each *pB* insertion within a mutant pool and in this study enabled tracking of individual *P. falciparum* mutations affecting sensitivity to heat-shock stress. The *in vitro* phenotypic selection was a heat-shock stress assay used to simulate malarial fever by exposing mutant parasites to 41C for 8 hours. First, we optimized the heat-shock screen SOP with a pilot clone library of 128 extensively characterized unique *pB* mutant clones and then scaled up to a library containing ~ 1000 unique *pB* mutants. We identified ~100 *pB* mutants that have strong positive phenotypes adversely affected by heat-shock stress. Analysis of genes linked to the heat-shock mutants and RNAseq of febrile-sensitive mutants indicated that genes associated with protein folding, unfolded protein binding, and protein trafficking were the most dysregulated in response to febrile temperatures. Additionally, these data suggest that terpenoid biosynthesis in the apicoplast coupled with thiamine synthesis might be a uniquely required process of primate malaria parasites to cope with febrile stress. Large-scale application of the approach used in this study offers the potential for broader functional annotation of the *P. falciparum* genome for the genetic factors associated with other important phenotypes.

## G6PD DEFICIENCY IN CHILDREN IN AN AREA ENDEMIC FOR MALARIA IN BENGO PROVINCE, ANGOLA

Miguel Brito<sup>1</sup>, Chissengo Tchonihi<sup>2</sup>

<sup>1</sup>CISA - Health Research Centre in Angola AND ESTESL-IPL, Caxito, Angola,

<sup>2</sup>CISA - Health Research Centre in Angola, Caxito, Angola

Glucose 6-phosphate dehydrogenase (G6PD) is the rate-limiting enzyme of the pentose phosphate pathway, important in the protection of cells against oxidative stress. The G6PD deficiency is the most common enzymopathy X linked worldwide. The majority of the G6PD deficient do not manifest any symptoms, however, acute hemolytic anemia may be triggered by several agents, such as primaquine. Current WHO guidelines state that in elimination areas a single 0.25 mg base/kg primaquine dose should be given, as a gametocytocide, to all patients with parasitological-confirmed *P. falciparum* malaria on the first day of treatment in addition to an ACT. In face of this recommendation, endemic malaria countries should be informed of the prevalence G6PD deficiency, in order to make safe and appropriate decisions regarding the use of potentially unsafe drugs for G6PD deficient individuals. The aim of this study is to determine the prevalence of G6PD deficiency in an holoendemic region in Africa for *P. falciparum*, evaluating the genotype and the phenotype of the enzyme. This is a longitudinal prospective cohort study, involving 1692 children. The G202A, A376G genotypes were determined through Real Time PCR methods. For the enzyme activity NeolISA kit was used for Neonatal screening of G6PD deficiency. The prevalence of the G6PD A- allele was 19.4%, with 19% of hemizygous males and 4.5 % of homozygous females. Moreover 22.2% and 8,2% of heterozygous B/A- and A/A- heterozygous females respectively were observed. The enzyme activity was low in G6PD deficient in both sexes and with statistical significance from A and B alleles respectively for boys (1, 66U/gHb [0.55 -2.76] p < 0.001) and for girls (0, 97U/gHb [0.32 -1.62] p < 0.003). There seems to be a protection against malaria in heterozygous girls, since the lowest number of confirmed cases (7.7%) was observed in the class B/A- in a 18 months period. The prevalence of G6PD deficiency among children in Bengo is considerable and is similar to that found in other parts of Africa. This data, can be used by MoH in order to make safe and appropriate decisions regarding the use of potentially unsafe drugs for G6PD deficient individuals.

## EFFECT OF PLASMODIUM FALCIPARUM CRT SINGLE NUCLEOTIDE POLYMORPHISM AND PLASMEPSIN 2-3 COPY NUMBER INCREASE ON EX VIVO PIPERAQUINE RESISTANCE IN P. FALCIPARUM ISOLATES FROM NORTHWESTERN CAMBODIA, 2012-2015

*Plasmodium falciparum* resistance to piperazine (PPQ) emerged rapidly across western Cambodia over the last 5 years, leading to high rates of dihydroartemisinin-piperazine (DHA-PPQ) treatment failure. Molecular correlates of PPQ resistance would allow timely surveillance, important for monitoring the efficacy of DHA-PPQ outside Southeast Asia and helping to determine if and when DHA-PPQ could be reintroduced in the region. We are investigating the relationship of *ex vivo* PPQ susceptibility amongst 162 Cambodian isolates collected in Anlong Veng, northwestern Cambodia, to copy number variation of the *plasmepsin 2-3* gene and single nucleotide polymorphisms in the *Pfcrtr* gene, including a *Pfcrtr* F145I mutation recently implicated in DHA-PPQ treatment failure. Isolates were collected pre-treatment from two cohorts, the first enrolled in Dec 2012-Feb 2014, the second between Dec 2014-Sep 2015. Median PPQ IC90, measured using an HRP2-based assay on fresh isolates, rose from 104 nM (IQR: 65 – 368) in the earlier cohort to 837 nM (IQR: 113 - 12050) in the later cohort. Thus far, real-time PCR and whole genome sequencing of 78 isolates from the earlier cohort show that 38 (49%) have multiple copies of *plasmepsin 2-3*, 11 (14%) contain the F145I mutation, and 8 (10%) have both the mutation and increased *plasmepsin* copy number. When PPQ IC90 is dichotomized at a cut point of 200uM, a previously determined pharmacologically relevant dose, increased *plasmepsin 2-3* copy number is associated with an odds of increased IC90 more than six times that of the odds in those with only one copy (OR = 6.6, 95% CI = 2.2 - 22.8, p = 0.001). Preliminary SNP analysis suggests the presence of the F145I mutation is also associated with increased mean IC90 (6513 nM vs. 258 nM). This study confirms the previously described association between increased *plasmepsin 2-3* copy number and increased IC90, and supports an additional role for the *crt* F145I mutation in PPQ resistance. Future analyses will define the independent and joint effects of these molecular correlates on PPQ resistance.

## QUANTIFYING VAR GENE EXPRESSION IN UNCOMPLICATED MALARIA INFECTIONS USING WHOLE GENOME SEQUENCE DATA

*Plasmodium falciparum* erythrocyte membrane protein-1s (PfEMP1s), expressed on the surface of infected erythrocytes, play a critical role in immune evasion by mediating cytoadhesion and sequestration in host capillaries. PfEMP1s are encoded by *var* genes, with each parasite genome containing ~40-60 copies. Sequencing and assembling these genes has been a challenge due to extreme sequence diversity and motif repetition. Full *var* repertoires are known for only a few reference genomes and clinical isolates, and this lack of knowledge has posed a challenge for studying *var* gene expression, particularly in clinical samples. We previously sequenced *var* gene repertoires from symptomatic uncomplicated malaria infections in 12 Malian children. To measure *var* expression in these samples, we first evaluated the ability of published degenerate primer sets targeting the hypervariable DBL $\alpha$  region to optimally capture these repertoires. We complemented this primer set with additional degenerate primers predicted *in silico* to maximize the number of *vars* amplified from the total pool of ~1092 available *var* sequences. To identify predominantly

expressed *vars* in these uncomplicated malaria infections, we extracted RNA from all 12 samples, generated cDNA via reverse transcription, and amplified *vars* from each sample using our comprehensive primer set, barcoded by sample. The resulting amplicons were pooled in equimolar amounts and deep-sequenced via Illumina to measure the abundance of *var* transcripts identified by this degenerate primer set. We report the identity of *vars* and relative proportions in each sample. In addition, classes of *var* genes expressed in these uncomplicated infections were identified and compared to results from previous *var* expression profiles in different clinical presentations in this population. This approach provides an in-depth analysis of *var* expression in clinical infections using a fully sequenced *var* repertoire and may provide insights into further use of next generation sequencing to better understand parasite variant surface antigen expression.

## 1044

### GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM* BASED ON *MSP-1* BLOCK2 GENEPOLYMORPHISM ANALYSIS IN ISOLATES FROM TSARATANANA COMMUNE, IFANADINA DISTRICT, SOUTHEAST OF MADAGASCAR

Fanomezantsoa Ralinoro<sup>1</sup>, Omega Raobela<sup>1</sup>, Tiavina Rakotomanjaka<sup>1</sup>, Michel Marolahy<sup>1</sup>, Noeline Rasoarialao<sup>1</sup>, Brunette Razanadrazanina<sup>1</sup>, Tovonahary Rakotomanga<sup>1</sup>, Miarimbola Raharizo<sup>2</sup>, Arsene Ratsimbasa<sup>1</sup>

<sup>1</sup>National Malaria Control Program, Antananarivo, Madagascar, <sup>2</sup>Faculty of Medicine, Antananarivo, Madagascar

Malaria drug efficacy tests are indispensable for malaria control in endemic countries. In Madagascar, ASAQ is the antimalarial therapeutic recommended by the National Malaria Control Program (NMCP). In contrast to Asia and Africa, no resistance to Artesunate + Amodiaquine (ACT) so far has been detected proving for ACT to be an efficient treatment. In this study, we were interested in the *Plasmodium falciparum* merozoite surface protein 1 (*mSP1*) genetic diversity among symptomatic patients enrolled during a therapeutic efficacy test in the southeast of Madagascar in April 2016. The genetic diversity was analysed in 65 isolates from Tsaratanana commune in the Ifanadina district. Children between six months to fifteen year-old and only *P. falciparum* infected were included. After DNA extraction from blood spot, allele frequency and diversity of *mSP1* block2 genes within this population were investigated by nested polymerase chain reaction. Over the 65 samples, 89.23% were identified with *mSP1* genes including 49.23% and 40% of single and multiple infections respectively. The multiplicity of infection (MOI) was 1.5. A same MOI value of 1.4 was found for patients between 6 months and 5 year-old and from 6 to 15 year-old. Among the single infections, 33.84%, 9.23% and 6.15% corresponded respectively to K1, MAD20 and RO33 allelic types. As observed worldwide, the K1 allele is always present in single infections but also in the mixed infections among the 65 Malagasy isolates. Within the mixed infections, the K1+MAD20 allelic types were preponderant with 15.38% followed by the K1+RO33 genotype with 12.30%, MAD20+RO33 genotype with 7.69% and K1+Mad20+RO33 genotype with 4.61%. This genetic diversity study showed the presence of seven allelic *mSP1* block2 types in total in this malaria endemic area with the K1 dominant genotype. K1 genotype has been found to be the major one in Africa. Based on antigenic marker, this study illustrates the presence of 7 parasitic strains circulating in this endemic area.

## 1045

### GENOME-WIDE SCAN OF GENE LOCI UNDER POSITIVE SELECTION IN IMPORTED *PLASMODIUM VIVAX* FROM CHINA-MYANMAR BORDER AREA

Hai-Mo Shen, Shen-Bo Chen, Jun-Hu Chen

National Institute of Parasitic Diseases at the Chinese Centre for Disease Control and Prevention, Shanghai, China

High importation risk from Myanmar and wide distribution of malaria vectors in the China-Myanmar border region sustain risk for secondary infections among local populations. High recombination rates of *Plasmodium vivax* populations associated with varied transmission intensity might cause distinct local selective pressures. The information on the genetic variability of *P. vivax* in this area is scant. Our study assessed the genetic diversity of *P. vivax* genome sequence in CMB area aim to provide information on the positive selection of new gene locus. Blood samples were collected from 6 clinical malaria cases that are microscopically positive for *P. vivax* and PCR confirmed for single infection. Our sequencing generated an average of 120M paired-end reads of 125 bp and 188,757 SNPs after filtering. We found that considerable genetic diversity and mean pair-wise divergence among the sequenced *P. vivax* isolates are higher in some important gene families. Using the standardized integrated haplotype score (IiHS) for all SNPs in chromosomal regions with SNPs above the top 1% distribution, it was observed that the top score locus involved 356 genes and most of them are associated with red blood cell invasion and immune evasion. The XP-EHH test was also applied and some important genes associated with anti-malarial drug resistance were observed in high positive scores list. This result suggest that *P. vivax* in CMB area is facing high pressure and this has led to the strong positive selection of genes that are associated with host-parasite interactions. Our study suggests that greater genetic diversity in *P. vivax* from CMB area and the positive selection signals in invasion and drug resistance genes are consistent with the history of drug use during malaria elimination programme. Furthermore, our work also demonstrates that haplotype-based detecting selection can assist the genome-wide methods to identify the determinants of *P. vivax* diversity.

### COMPLEX GENOMIC EVOLUTION OF INSECTICIDE RESISTANCE IN THE MAJOR AFRICAN MALARIA VECTOR *ANOPHELES FUNESTUS*

Gareth Weedall, Jacob Riveron, Murielle Wondji, Helen Irving, Charles S. Wondji

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Insecticide resistance in malaria vectors such as *Anopheles funestus* is hindering malaria prevention throughout Africa. To help design suitable insecticide resistance management (IRM) strategies, we elucidated the dynamics and genetic basis of resistance across Africa revealing a complex genomic evolution of resistance Africa-wide. Susceptibility surveys showed that resistance including against pyrethroids, the only class recommended for bed nets, is spreading with increasing cases of multiple resistance and higher resistance intensity. Lab and field studies revealed that increased resistance is reducing the efficacy of control tools with PBO-based nets providing better efficacy. Significant contrast in the gene RNAseq expression profiles of resistant mosquitoes is observed between African regions suggesting differences in the molecular basis of resistance. For example, the P450s CYP6P9a/b are dominant in southern Africa but not in other regions where other genes operate. This variation correlates with high genetic differentiation between regions and the distribution patterns of resistance markers suggesting that barriers to gene flow impact the spread of resistance. Whole genome sequencing detected signatures of selective sweeps but these varied by regions as for gene expression. Fine-scale analysis of key resistance genomic regions revealed a complex evolution of resistance mechanisms with evidences of various copy number

variations suggesting independent selective events across the continent. Analysis of pre and post-intervention samples reveals that selective sweep is likely caused by the scale up of control tools which are selecting alleles the most metabolically efficient in conferring resistance. The near fixation of such alleles in populations would limit options for IRM.

## 1047

### STUDY ON MOLECULAR MARKERS ASSOCIATED WITH DIHYDROARTEMISIN-PIPERAQUINE AND OTHER DRUG RESISTANCE IN *PLASMODIUM FALCIPARUM* POPULATION IN BINH PHUOC PROVINCE, VIETNAM 2015-2016

**Nguyen T. Tuyen**, Truong Nhi, Tran Tinh Hien, Nguyen Thuy-Nhien

Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam

Artemisinin-based combination therapies (ACT) have been recommended by WHO as first-line treatment for uncomplicated *Plasmodium falciparum* infections in all malaria endemic areas. Recently, there were the worrying sign that the efficacy of ACT have been declined in Mekong Delta regions especially in Binh Phuoc, Vietnam. Artemisinin-resistance in *P. falciparum* has been proved that associated with mutations in K13-propeller gene. There were new molecular markers related to piperazine resistance: (a) plasmepsin 2 gene copy number variation (CNV) and (b) mutation E415G in exonuclease encoding gene (Exo-E415G). (c) the chloroquine (CQ), sulphadoxine and pyrimethamine (SP) resistance associated with multidrug resistance gene 1 (pfmdr1), dihydrofolate reductase gene (pfdhfr) and dihydropteroate synthetase gene (pfdhps). An understanding of those genetic factors that determine how resistant parasite emerges and spreads is necessary. From 2015 to 2016, 84 blood samples were collected from uncomplicated *P. falciparum* patients in Binh Phuoc province. Mutations of K13 propeller domain gene, exonuclease gene are detected by sequencing method and plasmepsin 2 gene copy number is determined by qPCR. Among the samples, C580Y mutation in the K13 propeller domain showed the highest frequency with 71.4% (60/84). Multicopy of plasmepsin 2 gene was detected in 25% (21/84) of the samples, while single copy was found in 36.9% (31/84) of them. The Exo-E415G mutant was found 67.8% (57/84). The others were the frequency of the single mutant Y184F in pfmdr1 gene was 65.78% (25/38) and there are no mutations detected at N86Y and D1246Y. The prevalence of IRNL quadruple-mutant haplotype accounted for 74% (27/38) and was more popular than IRNI triple-mutant, 26% (10/38) in pfdhfr. The triple-mutant GNGA haplotype was much more common (61%) than the double mutant GEAA (39%) in pfdhps gene. Identification of those marker genes and its frequency in population of *P. falciparum* in Vietnam will support surveillance efforts to contain, prevent the artemisinin resistance and facilitate the development of effective strategy to combat drug resistance.

## 1048

### MALARIA IN HAITI: A GENOMIC APPROACH TO ITS EPIDEMIOLOGY AND BIOLOGY

**Massimiliano S. Tagliamonte**<sup>1</sup>, Charles A. Yowell<sup>1</sup>, Maha A. Elbadry<sup>2</sup>, Bernard A. Okech<sup>2</sup>, Marco Salemi<sup>3</sup>, John B. Dame<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases and Pathology, University of Florida, Gainesville, FL, United States, <sup>2</sup>Department of Environmental and Global Health, University of Florida, Gainesville, FL, United States, <sup>3</sup>Department of Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL, United States

The malaria parasite (*Plasmodium falciparum*) was introduced into Hispaniola through the slave trade when, during a 300 year period ending in the early 1800s, ~10 million Africans were brought to the Caribbean. It is likely that a substantial percentage of these individuals carried the parasite, since malaria is holoendemic in West Africa. Hispaniola is now the only island in the Caribbean where malaria is still actively transmitted. Haiti occupies the western half of the island and has the bulk of malaria cases with epidemics occurring during rainy seasons. We hypothesize

that in establishing transmission through its new vector, *Anopheles albimanus*, the parasite population underwent several bottlenecks driven by powerful selection pressures. Timing the founder events of the parasite, and understanding its underlying population dynamic in Hispaniola, represents a unique opportunity to examine the evolution of *P. falciparum*. We have undertaken a detailed study of the genetics of the parasite population utilizing whole genome sequencing. Principal component and phylogenetic analyses based upon single nucleotide polymorphisms (SNPs) indicate that the Haitian parasites have, as expected, an ancestral relationship with parasites from Africa, but they clearly belong to a phylogenetic lineage distinct from the ones found in South America. Loci under selection, representing mutations allowing *P. falciparum* to adapt to its novel vector and environmental conditions on Hispaniola, were mapped using maximum likelihood and Bayesian algorithms that take into account evolutionary relationships. Mutations in drug resistance loci and vaccine antigens, as well as those suited to tracking the movement of the parasite between countries, are under study and may be useful in support of elimination plans.

## 1049

### POPULATION STRUCTURE OF *PLASMODIUM FALCIPARUM* IS DETECTABLE AT SMALL SPATIAL SCALES IN KIHIFI, UGANDA

**Alison Kuchta**<sup>1</sup>, Maxwell Murphy<sup>1</sup>, Emmanuel Arinaitwe<sup>2</sup>, John Rek<sup>2</sup>, Anna Chen<sup>1</sup>, Jordan Wilhelm<sup>1</sup>, Sofonias K. Tessema<sup>1</sup>, Teun Bousema<sup>3</sup>, Moses Kamya<sup>2</sup>, Sarah Staedke<sup>2</sup>, Grant Dorsey<sup>1</sup>, Philip J. Rosenthal<sup>1</sup>, Bryan Greenhouse<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Makerere University, Kampala, Uganda, <sup>3</sup>Radboud University Medical Centre, Nijmegen, Netherlands

Clustering of malaria incidence is apparent over various spatial scales. Evaluation of genetic relatedness of malaria parasites may be a useful tool for understanding transmission patterns, but may not be easily detectable in areas with moderate-high transmission. To evaluate the potential to detect genetic relatedness within a community with moderate-high malaria transmission, we measured relatedness of isolates from cohort participants recruited from 100 randomly selected households in the Kihifi sub-county of Uganda (annual EIR=27 infectious bites per person; area ~12x24 km). All infections detected via microscopy or *Plasmodium* specific loop mediated isothermal amplification from passive and active case detection during the first 6 months of the study were genotyped at 26 microsatellite loci, providing data for 301 samples from 267 participants living in 89 households. As expected, genetic diversity was high (mean He=0.73), and 85% of samples were polyclonal. Despite the high diversity, spatiotemporal structure in genotypes was detectable. Identical haplotypes were observed in 3 pairs of monoclonal infections; 1 pair was from a single household on the same day, and the other 2 were pairs living ~7km apart and detected within 2 weeks of each other. Pairwise genetic distance, identity by state (IBS), was calculated using the number of non-shared alleles at each locus weighted by the total number of alleles detected. Pairs of infections which were closely related genetically (IBS 0-0.2) were significantly more likely to have been collected from nearby locations than those with moderately (IBS 0.2-0.4) and more distantly related (mean distances of 4.6 km, 6.4 km, and 8.4 km, respectively, p=0.04 and <0.001) infections. Household members were more likely to have closely or moderately related infections (with IBS <0.4) vs. comparisons to other community members (5% vs. 0.15%, p<0.001). These data suggest malaria transmission within a household or small spacial scale, which could be targeted by interventions such as reactive case detection with treatment or IRS. Additional genotyping and analyses on samples from this cohort are ongoing.

## 1050

### PATTERNS OF INFLAMMATORY RESPONSES AND PARASITE TOLERANCE VARY WITH MALARIA TRANSMISSION INTENSITY

**Temitope W. Ademolue**, Yaw Aniweh, Asamoah K. Kusi, Gordon A. Awandare

*University of Ghana, Accra, Ghana*

In individuals living in malaria-endemic regions, parasitaemia thresholds for the onset of clinical symptoms vary with transmission intensity. The mechanisms that mediate this relationship are however, unclear. Since inflammatory responses to parasite infection contribute to the clinical manifestation of malaria, this study investigated inflammatory cytokine responses in children with malaria from areas of different transmission intensities (ranging from low to high). Blood samples were obtained from children presenting with clinical signs of malaria (at clinic) from sites of distinct transmission intensities. Cytokine levels were assessed using the Luminex® based magnetic-bead array system, and levels were compared across sites using appropriate statistical tests. A multivariate analysis was used to determine the influence of age, gender, parasitaemia and transmission intensity on cytokine levels. Parasite density increased with increasing transmission intensity in children presenting to hospital with symptomatic malaria, indicating that the parasitaemia threshold for clinical malaria increases with increasing transmission intensity. Furthermore, levels of pro-inflammatory cytokines, including tumour necrosis factor (TNF)- $\alpha$ , interferon (IFN)- $\gamma$ , interleukin (IL)-1b, IL-2, IL-6, IL-8, and IL-12, decreased with increasing transmission intensity, and correlated significantly with parasitaemia levels in the low transmission area but not in high transmission areas. Similarly, levels of anti-inflammatory cytokines, including IL-4, IL-7, IL-10 and IL-13, decreased with increasing transmission intensity, with IL-10 showing strong correlation with parasitaemia levels in the low transmission area. Multiple linear regression analyses revealed that transmission intensity was a stronger predictor of cytokine levels than age, gender and parasitaemia. Taken together, the data demonstrate a strong relationship between the prevailing transmission intensity, parasitaemia levels and the magnitude of inflammatory responses induced during clinical malaria.

## 1051

### CHARACTERIZATION OF B CELL SUBSETS OVER THE COURSE OF *PLASMODIUM YOELII* INFECTION AND ROLE OF CD73+ B CELLS IN PROTECTION

**Marcela Parra**, Steven Derrick, Xia Liu, Amy Yang, Sheldon Morris

*Food and Drug Administration, Silver Spring, MD, United States*

Despite the critical importance of humoral and B cell mediated immunity in protecting against malaria, the biological nature of anti-malaria memory B cells (MBC) has not been sufficiently delineated. In this study, we used the *Plasmodium yoelii* 17XNL (PyNL) mouse model of malaria to confirm the importance of anti-malarial B-cell immunity and identified subsets of B cells as critical components of protective immunity against malaria. MBC subsets were identified using flow cytometry by quantification of PD-L2, CD80, and CD73 markers on splenic B cells. Evaluations were done at days 0, 6, 13 and 22 over the course of a primary PyNL self-resolving infection and from mice which had recovered from the primary infection and were protected against a second infection. When compared to naïve mice, we found that the frequencies of PD-L2<sup>lo</sup>CD80<sup>lo</sup>CD73<sup>hi</sup> cells during a primary infection significantly increased from 2.1 $\pm$ 0.1% at day 6 to 39.1 $\pm$ 1.2% at day 22 post-infection. Interestingly, significantly increased relative frequencies of PD-L2<sup>hi</sup>CD80<sup>hi</sup>CD73<sup>lo</sup> cells (4.6 $\pm$ 0.3% and 5.2 $\pm$ 0.6%) and of PDL2<sup>hi</sup>CD80<sup>hi</sup>CD73<sup>hi</sup> (1.2 $\pm$ 0.1; 3.6 $\pm$ 0.3 and 1.8 $\pm$ 0.1%) B cells at days 6, 13 and 22 post Py NL infection were detected for both cell types, and the profile of the mean percentage B cell curve was similar to the Py NL infection parasitemia curve with maximal cell frequencies seen at the

day of peak parasitemia. Mice that were challenged with PyNL (malaria immune) had a rapid increase in the frequencies in PD-L2<sup>lo</sup>CD80<sup>lo</sup>CD73<sup>hi</sup> and PDL2<sup>hi</sup>CD80<sup>hi</sup>CD73<sup>hi</sup> cell subsets at 4 days post-infection. Most importantly, passively transfer of CD73+ B-cells from mice that had recovered from a primary PyNL infection protected naïve mice from a PyNL challenge. In conclusion, in these studies we characterized immune B cell subsets using PD-L2, CD80, and CD73 surface markers over the course of a primary infection and showed that passive transfer of CD73+ B cells generated nearly sterilizing immunity against a PyNL re-challenge.

## 1052

### NATURALLY ACQUIRED IMMUNITY TO *PLASMODIUM FALCIPARUM* GAMETOCYTE ANTIGENS

**Jo-Anne Chan**<sup>1</sup>, Linda Reiling<sup>1</sup>, James Kazura<sup>2</sup>, Arlene Dent<sup>2</sup>, Takafumi Tsuboi<sup>3</sup>, James G. Beeson<sup>1</sup>

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Ehime University, Matsuyama, Japan

The recent emergence and spread of drug-resistant malaria has accelerated the need for an effective vaccine, including vaccines that block malaria transmission. However, exceptionally little is known about host immune responses to gametocytes to reduce transmission. We have evaluated acquired antibodies to gametocytes, gametocyte-infected erythrocytes (gam-IEs) of different stages, and transmission-blocking vaccine candidates. We also assessed the functional activity of antibodies to fix complement, believed to be important in transmission-blocking immunity. We used genetically-modified parasites with suppressed PfEMP1 expression, the major surface antigen of asexual-stage IEs. We found little antibody response to the surface of gam-IEs, similar to that seen for asexual-stage IEs lacking PfEMP1. Significant antibody reactivity to the surface of gametocytes (without the host erythrocyte membrane) was also observed, including antibodies to the major gametocyte antigen and vaccine candidate, Pfs230. Some individuals had functional antibodies that fix complement, which may contribute to transmission-blocking immunity. Our findings suggest that effective immunity to gam-IEs is limited and do not effectively target these stages to mediate transmission-blocking immunity. In contrast, antibodies are acquired to gametocyte antigens, which likely contribute to transmission-blocking immunity. These insights will help inform vaccine development and the assessment of transmission-blocking immunity in endemic populations.

## 1053

### GLUCOSE AND IRON METABOLISM IN MONOCYTES EXPOSED TO MALARIA

**Ricardo Ataíde**, Isobel Walker, Clovis S. Palmer, Freya J. Fowkes  
*Burnet Institute, Melbourne, Australia*

Malaria parasites are still one of the world's most significant infectious agents. Both the morbidity and mortality of malaria is in great measure a consequence of inflammation. Monocytes/macrophages are well-recognized sources of inflammation as they are amongst the most effective cells that can find and eliminate parasites. As such monocytes are key players in the development of malaria pathogenesis. We propose that a deeper understanding of the metabolic responses in monocytes during malaria can pave a new way to comprehend how the immune response against the parasite is generated and can be therapeutically targeted. The aims of this study were to expose blood-monocytes from naïve donors (n=10) to malaria parasites and measure changes in glucose metabolism (glucose transporter 1 (Glut1) levels, glucose uptake ability), and iron metabolism (levels of surface Ferroportin and intracellular Ferritin). Surface expression of Glut1 and cellular uptake of the fluorescent glucose analog 2-(N-(7-nitrobenz-2-oxa-1, 3-diazol-4-yl) amino)-2 deoxyglucose were analyzed by flow cytometry, using a method previously validated by us on samples from HIV-positive individuals, and coupled with immunofluorescence, and western blots to measure the levels of the iron metabolism proteins Ferroportin and Ferritin in the monocyte

compartment after co-culture with malaria parasites. Additionally we related these levels to the functional ability of the monocytes. Preliminary data shows that upon exposure to malaria parasites monocytes increase their expression of surface Glut1, which suggests a switch from oxidative to glycolytic metabolism. We discuss our results in the context of what are the known clinical outcomes observed in malaria-exposed individuals. Understanding the balance between the beneficial and harmful effects of monocyte-induced inflammation in malaria infection is key to successful clinical outcomes and reducing the global illness and death due to malaria.

## 1054

### A SINGLE NUCLEOTIDE POLYMORPHISM IN AN AP2 TRANSCRIPTION FACTOR ENCODED IN THE MALARIA CAUSING *PLASMODIUM BERGHEI* ALTERS THE DEVELOPMENT OF HOST IMMUNITY

**Munir Akkaya**, Patrick W. Sheehan, Abhisheka Bansal, Gunjan Arora, Alvaro Molina-Cruz, Mirna Pena, Takele B. Yazew, Chen-Feng Qi, Jeff Skinner, Louis Miller, Susan K. Pierce

*National Institutes of Health, Rockville, MD, United States*

The Apetela2 (AP2) family of transcription factors is a major regulator of Plasmodium parasite gene expression. Twenty seven members of this family have been identified since their discovery in 2005. However, our understanding which AP2 members regulate key features of Plasmodium biology is incomplete. Here we describe the impact of a single nucleotide polymorphism (SNP) in the active site of the AP2 protein, PBANKA\_011210, on the outcome of infection in mice. *Plasmodium berghei* Anka (PbA), the only rodent parasite that causes experimental cerebral malaria (ECM), codes for a phenylalanine at position 1823 whereas all other Plasmodium parasite strains, none of which cause ECM in mice, including PbNK65, have a serine in this position. Using CRISPR, we modified the PbNK65 parasite (PbNK65-WT) to encode the PbA SNP (PbNK65-PbA). The course of infection with PbNK65-WT or PbNK65-PbA were similar and showed no ECM pathology indicating that the PbA AP2 SNP is not sufficient to cause ECM. However, mice infected with PbNK65-PbA had dramatically higher serum levels of IFN-gamma and TNF alpha and they generated more persistent, stronger germinal center responses as well as higher titers of parasite-specific antibodies. When infected mice were treated with sub-therapeutic doses of the anti-malarial, chloroquine, to lower the parasitemias PbNK65-PbA-infected mice cleared the infection whereas mice infected with PbNK65-WT were unable to control the infection resulting severe anemia and death. These results reveal a novel role of AP2 proteins in controlling host immunity to Plasmodium infections.

### LIVER-RESIDENT MEMORY T CELLS CAN BE HARNESSSED FOR UNPRECEDENTED PROTECTION AGAINST MALARIA

**Daniel Fernandez-Ruiz**<sup>1</sup>, Wei Yi Ng<sup>1</sup>, Lauren Holz<sup>1</sup>, Anton Cozijnsen<sup>2</sup>, Vanessa Mollard<sup>2</sup>, Roghieh Skandari<sup>3</sup>, Jonathan H. Manton<sup>3</sup>, Szun Szun Tay<sup>4</sup>, David G. Bowen<sup>4</sup>, Friedrich Koch-Nolte<sup>5</sup>, Bjorn Rissiek<sup>5</sup>, Francis R. Carbone<sup>1</sup>, Brendan S. Crabb<sup>6</sup>, Scott N. Mueller<sup>1</sup>, Patrick Bertolino<sup>4</sup>, Geoffrey I. McFadden<sup>2</sup>, Irina Caminschi<sup>7</sup>, William R. Heath<sup>1</sup>

<sup>1</sup>The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, <sup>2</sup>The School of Biosciences, The University of Melbourne, Melbourne, Australia, <sup>3</sup>Department of Electrical and Electronic Engineering, The University of Melbourne, Melbourne, Australia, <sup>4</sup>Liver Immunology Program, University of Sydney, Sydney, Australia, <sup>5</sup>Institute of Immunology, University of Hamburg, Hamburg, Germany, <sup>6</sup>Macfarlane Burnet Institute for Medical Research & Public Health, Melbourne, Australia, <sup>7</sup>Monash Biomedicine Discovery Institute, Melbourne, Australia

T cell memory allows for the rapid generation of effective immune responses to previously encountered pathogens. Although most memory T cells recirculate through the body, a recently discovered subset, the

tissue resident memory T cells (TRM), remains in the affected tissue after infection is cleared. By staying in the organ most likely targeted by the pathogen in subsequent reinfections, TRM have the potential to elicit faster, more focused responses than circulating memory T cell subsets. We found that following vaccination with radiation-attenuated *Plasmodium berghei* ANKA sporozoites (RAS), a population of TRM cells formed in the liver. These cells constantly surveyed the hepatic sinusoids and were essential for protection, as their depletion rendered vaccinated mice fully susceptible to sporozoite infection. Based on these results, we hypothesized that an immunization strategy aimed at maximizing liver TRM formation might be highly protective. By combining dendritic cell priming and antigen recognition on hepatocytes we were able to induce the formation of vast numbers of liver TRM and achieve high levels of sterile protection against live sporozoite challenge. Vaccination aimed at the induction of liver TRM cells may be a more effective way to control liver-stage malaria than traditional strategies generating circulating memory T cells.

## 1056

### IMMUNOBIOLOGY OF THE KUPFFER CELL-SPOROZOITE INTERACTION

**Rebecca E. Tweedell**<sup>1</sup>, Henry C. Law<sup>2</sup>, Timothy Hamerly<sup>2</sup>, Zhaoli Sun<sup>1</sup>, Rhoel R. Dinglasan<sup>2</sup>

<sup>2</sup>University of Florida, Gainesville, FL, United States

Malaria is a devastating disease, causing over 400,000 deaths annually. The *Plasmodium* parasite responsible is transmitted from the mosquito vector to the vertebrate host during a blood meal. After *Plasmodium* sporozoites are inoculated into the skin, the sporozoites make their way to the liver and traverse the sinusoidal barrier, which contains Kupffer cells (KCs) (liver-resident macrophages), before invading hepatocytes. The job of KCs during a typical infection is to detect, phagocytose, and present foreign antigens, while producing cytokines to activate an immune response. It has been shown that sporozoites are able to traverse KCs without being phagocytosed or killed, suggesting that sporozoites are altering the normal KC response to pathogens. However, the mechanism by which this occurs is not understood. It is well-documented that the parasite can evade the immune system during the blood stages through various mechanisms, including direct suppression of immune responses. To test whether similar phenomena occur in the liver stage, we analyzed the primary rat KC cytokine response to *P. berghei* sporozoites *in vitro*. We hypothesized that KC responses would be skewed towards a tolerant, or anti-inflammatory, phenotype. Here, we report that KCs up-regulate cytokines of both the M1 (pro-inflammatory/classically activated) and M2 (alternatively activated) variety in response to live sporozoites, but not in response to sporozoite lysate. The cytokine response is rapid and short-lived, with cytokines found in the supernatant just 10 minutes after exposure, and levels dropping below the limit of detection after 2 hours, suggesting sporozoite silencing of KC cytokine secretions. Additional work focuses on the interaction of KCs with a sporozoite secreted protein, the *P. berghei* homolog of macrophage migration inhibitory factor, which is involved with the disruption of immunological memory during the blood stages and may play a similar immune evasion role during the liver stage. Taken together, our work sheds new light on the mechanism by which sporozoites modulate KC activity to remain hidden from the host immune system during traversal.

## 1057

**INFLAMMATORY CYTOKINE RESPONSES IN MALARIAL ANAEMIA AMONG MANGALORE RESIDENTS, INDIA**

**N. Suchetha Kumari**<sup>1</sup>, Punnath Kishore<sup>1</sup>, Valleesha Chandrashekar<sup>2</sup>, Kiran Kumar<sup>1</sup>, Shiny Joy<sup>1</sup>, Rajeshwara N. Achur<sup>3</sup>, D. Channe Gowda<sup>4</sup>, Satheesh Kumar Bhandary<sup>1</sup>

<sup>1</sup>Kshema, Nitte University, Mangalore, India, <sup>2</sup>Kshema, Nitte University, Shimoga, India, <sup>3</sup>Kuvempu University, Shimoga, India, <sup>4</sup>Pennsylvania State University College of Medicine, Hershey, PA, United States

In 2016, Mangalore alone accounted for malaria 6404 number of cases. Anaemia is a common complication, yet its severe form i.e, severe malarial anaemia (SMA) is of a major concern due to its high mortality rate. The present work aimed to evaluate the degree of anaemia (Haemoglobin levels, Hb) and levels of Pro and anti-inflammatory cytokines (TNF- $\alpha$ , IL-6, IL-10, IL-12 and IFN- $\gamma$ ) during malarial anaemia among residents of Mangalore, Karnataka, India during 2013 to 2015. Among 692 individuals, 138 were healthy controls (HC) while 351 patients suffered from *P.vivax*, 149 from *Plasmodium falciparum* and 54 with mixed infections. 63 patients with *Pv*, 37 with *Pf* and 15 patients with mixed infections had severe malaria. 70.1% were Non-anemic (NA) where as 20.2% had Mild anaemia, 5.1% with moderate and 4.6% have SMA. Among patients with SMA, *Pv* infections were the highest (56.3%), *Pf* (34.4%) and mixed infections (9.4%). The levels of Hb fell in mixed (11.19 g/dL), *Pf* (11.22 g/dL), *Pv* (12 g/dL) in comparison with HC (12.35 g/dL). Hb levels between NA and Anaemic (A) groups fell significantly across various infection types, mixed infections (13.28 vs 8.141), *Pf* (13.11 vs 8.252) *Pv* (13.02 vs 8.585) g/dL. The parasitemia (%) increased between NA and A groups in patients with *Pv* and *Pf* infections. With an increase in parasitemia(%), the levels of cytokines such as TNF- $\alpha$  increased in *Pv* ( $r=0.1708$ ,  $p=0.0040$ ) and *Pf* ( $r=0.3931$ ,  $p<0.0001$ ), where as IL-12 ( $r=0.1933$ ,  $p<0.0027$ ) and IFN- $\gamma$  levels ( $r=0.1624$ ,  $p<0.0154$ ) increased in only *Pv* groups. The plasmatic cytokines levels were significantly higher in infected patients compared to HC. In comparison with NA and A groups, TNF- $\alpha$  increased in *Pv* ( $P=0.030$ ), and *Pf* ( $P=0.0189$ ); IL-10 levels increased in *Pv* ( $P=0.076$ ); IFN- $\gamma$  increased in *Pv* and *Pf* ( $P=0.0095$ ); A non-significant increase in IL-12 levels was observed in all groups where as IL-6 levels remained same across all infection groups. In conclusion, the present study reveals that an imbalanced inflammatory response such as TNF- $\alpha$ , IL-12 and IFN- $\gamma$  levels may lead to malarial anaemia.

## 1058

**IDENTIFYING RIFIN AND STEVOR EPITOPES ASSOCIATED WITH MALARIA EXPOSURE USING PEPTIDE AND PROTEIN MICROARRAYS**

<sup>1</sup>Division of Malaria Research, Institutes of Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Malaria Research and Training Center, University Science, Techniques and Technologies, Bamako, Mali, <sup>3</sup>Division of Infectious Diseases, Department of Medicine, University of California, Irvine, CA, United States, <sup>4</sup>Centre for Immunity, Infection and Evolution, Institute of Immunology and Infection Research, School of Biological Sciences, University of Edinburgh, Edinburgh, United Kingdom, <sup>5</sup>Roche NimbleGen Inc., Madison, WI, United States

An erythrocyte infected with *Plasmodium falciparum* expresses adhesive variant surface antigens (VSAs) on its surface that play a critical role in sequestration and evasion of host immune responses. These VSAs possess

extraordinary genetic diversity, posing a challenge to understanding their role in immunity and designing an effective vaccine. In regions with high malaria transmission, adults and older children develop immunity to clinical disease, which is believed to be associated with the development of antibodies to particular VSAs. The best studied and largest VSA family is comprised of *P. falciparum* erythrocyte membrane protein-1s. The other major VSA families, the repetitive interspersed family of polypeptides (RIFINs) and subtelomeric variable open reading frame (STEVORs), have also been implicated in malaria pathogenesis, but their genetic diversity and role in immunity have not been well characterized. We aimed to identify RIFIN and STEVOR epitopes involved in protective natural immunity by using protein and ultra-dense peptide microarrays based on VSAs in the *P. falciparum* reference genome 3D7. Using sera from malaria-exposed Malian children and adults before, during, and following a malaria season, we determined seroreactivity against three RIFINs and six STEVORs, with each VSA expressed on an array as a single protein, and divided into 16-amino acid (aa) peptides, with 12-aa overlap. All three RIFINs and six STEVORs were recognized by sera from Malian adults and children as compared to sera from malaria-naïve controls. In addition, sera from malaria-exposed adults reacted more intensely to four STEVORs than sera from malaria-exposed children. Although protein array results did not demonstrate overall differential seroreactivity of RIFINs in adults versus children, adult sera reacted more intensely than pediatric sera to a subset of RIFIN peptides that spanned the length of the PF07\_0134 RIFIN, predominantly in the variable domain. Using this approach, we plan to map critical RIFIN and STEVOR epitopes associated with short-term and long-term protective immunity to clinical manifestations of malaria.

## 1059

**UNDERSTANDING THE DECLINE AND REBOUND IN IMMUNITY TO SYMPTOMATIC MALARIA DUE TO INTERVENTION DISRUPTION IN MALARIA TRANSMISSION**

Smith<sup>2</sup>, Isabel Rodriguez-Barrquer<sup>3</sup>, Moses Kanya<sup>4</sup>, Joaniter Nankabirwa<sup>4</sup>, Grant Dorsey<sup>3</sup>, John Rek<sup>5</sup>, Sarah Staedke<sup>6</sup>, Isaac Ssewanyana<sup>6</sup>, Bryan Greenhouse<sup>3</sup>, Edward A. Wenger<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>Makerere University College of Health Sciences, Kampala, Uganda, <sup>5</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>6</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

High-level parasitaemia by *Plasmodium falciparum* is associated with the onset of symptomatic malarial disease and mortality. Individuals build partial immunity to symptomatic malaria with increasing age as a direct result of exposure to *P. falciparum* parasite. This immunity results in a subpopulation of asymptomatic carriers that remain a barrier to establishing and maintaining elimination. What happens to individual and population immunity to malaria when transmission decreases due to long-duration targeted interventions? Little is known about how immunity wanes as transmission decreases, and understanding the dynamics of immunity is critical to informing effective surveillance systems needed for elimination. Strong and long-lasting immunity may help populations reach elimination more rapidly; conversely, rapid return of symptomatic malaria after interruption could make elimination a "sticky" state where outbreaks can be quickly detected and addressed. We use longitudinal data from two distinct settings where malaria transmission was temporarily interrupted and subsequently reestablished: a high-transmission site in Tororo, Uganda subject to three rounds of indoor residual spraying with carbamate over 14 months; and a high-transmission site in Garki, Nigeria, with highly seasonal transmission subject to spraying over 18 months. We use an agent-based mathematical model and statistical methods to describe the effects of disrupted transmission on susceptibility to symptomatic disease among individuals in these sites. We demonstrate the dynamics of

individual-level acquired immunity during shifting transmission intensities among both child and adult cohorts to help guide strategies for resurgent epidemics of malaria amidst campaigns towards elimination.

## 1060

### ANTIBODY IN THE SKIN: DO ANTIBODIES HAVE THEIR GREATEST IMPACT AT THE INOCULATION SITE?

Gibbs Nasir, Fidel Zavala, Photini Sinnis

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Malaria-causing *Plasmodium* parasites are deposited into host skin as infected *Anopheles* mosquitoes search for blood. In order for *Plasmodium* to establish infection in the liver, sporozoites need to exit the inoculation site, which they do by moving in the skin to find blood vessels and enter the circulation. This stage of the *Plasmodium* lifecycle (the pre-erythrocytic stage), at which parasite numbers are the lowest, has been recognized as a bottleneck for the parasite. RTS,S, the only vaccine candidate to have shown efficacy in Phase III clinical trials, targets the pre-erythrocytic stages of the parasite. Indeed further studies have shown that antibodies targeting the major surface protein of sporozoites (circumsporozoite protein or CSP) are critical for RTS,S-mediated immunity. We hypothesized that since sporozoites are extracellular for a significant period of time at the inoculation site, that antibodies in the skin could contribute significantly to decreasing sporozoite infectivity. Using rodent malaria parasite *Plasmodium berghei*, we standardized the dose of sporozoites delivered intravenously and by mosquito bite that result in comparable liver infection. We then compared the efficacy of two different doses of a monoclonal antibody (mAb) specific for the P. berghei CSP repeats (50 µg & 25 µg mAb 3D11; IgG1) in their ability to inhibit infection when sporozoites were inoculated intravenously versus by mosquito bite. Our data shows that both concentrations of antibody have greater efficacy when sporozoites are inoculated by mosquito bite. These results have important implications for malaria vaccine development, and provide further insight into host-pathogen interactions in the skin.

## 1061

### MEMORY IL-4<sup>+</sup> CD4 T CELL RESPONSES AS A POTENTIAL SURROGATE OF PROTECTION INDUCED BY *PLASMODIUM FALCIPARUM* RADIATION ATTENUATED SPOROZOITES

Stasya Zarling, Urszula Krzych

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Immunization with radiation attenuated sporozoites (RAS) is considered the gold standard of protection against malaria. Various immune responses including proliferating and cytokine producing CD4 and CD8 T cells, increased prevalence of TCRγδ<sup>+</sup> cells and circumsporozoite protein-specific antibodies have been observed in RAS-immunized subjects. Despite the recent successful induction of lasting protection by intravenous delivery of *Plasmodium falciparum* (Pf) RAS, we still do not have complete understanding as to which of these immune responses underlie Pf RAS-induced lasting sterile protection. Previously, we have observed that subjects protected by exposure to Pf RAS delivered by a bite from an infected mosquito have increased numbers of peripheral memory (CD45RO<sup>+</sup>) CD4 T cells, that upon *in vitro* stimulation with parasitized red blood cells (pRBC) undergo further differentiation into CD4<sup>+</sup>CD27<sup>-</sup> T cells and secrete IL-4, a cytokine required for B cell maturation including Ig isotype switching, as well as memory CD8 T cell maintenance. We have also demonstrated induction of CD4 T cells expressing memory phenotype and producing IL-2 in persons protected by vaccination with RTS,S against homologous controlled human malaria infection (CHMI). A recently conducted study based on Pf RAS delivery by a mosquito bite, IMRAS, was designed to achieve sterile protection in 50% of the enrolled subjects against homologous CHMI. The availability of PBMCs from a cohort of protected and non-protected subjects prompted us to investigate whether pRBC-responding CD4 T cells that express memory phenotype and

produce IL-14 could distinguish protective from non-protective subjects. On the basis of the available evidence we are currently evaluating the possibility that memory IL-4<sup>+</sup>CD4 T cells may be considered as surrogate markers for lasting protective immunity against malaria.

## 1062

### ENHANCEMENT OF THE IMMUNE RESPONSE TO *PLASMODIUM YOELII* CIRCUMSPOROZOITE PROTEIN BY PD-1 INHIBITORS

Timothy W. Phares<sup>1</sup>, Vinayaka Kotraiah<sup>1</sup>, Cristina Fernandez<sup>2</sup>, Amir Horowitz Horowitz<sup>2</sup>, Moriya Tsuji<sup>2</sup>, Susan Youll<sup>3</sup>, Lorraine Soisson<sup>3</sup>, Carter Diggs<sup>3</sup>, Amy R. Noe<sup>1</sup>, Gabe M. Gutierrez<sup>1</sup>

<sup>1</sup>Leidos Life Sciences, Frederick, MD, United States, <sup>2</sup>HIV and Malaria Vaccine Program, Aaron Diamond AIDS Research Center, Affiliate of The Rockefeller University, New York, NY, United States, <sup>3</sup>Malaria Vaccine Development Program, United States Agency for International Development, Washington, DC, United States

In malaria-infected individuals, PD-1 is highly elevated on CD4<sup>+</sup> T cells suggesting that PD-1-mediated immune dysfunction may limit protective immunity against the parasite. Further, in a rodent malaria model, PD-1 was shown to severely dampen CD8<sup>+</sup> T cell proliferation and prolong chronic infection. These data argue that blocking PD-1 inhibition may enhance protection from malaria after immunization. We identified several PD-1 peptides that bind both human and mouse PD-1. Their effect on the immunogenicity of a recombinant replication-defective adenovirus expressing *P. yoelii* circumsporozoite protein (AdPyCSP) was determined using a rodent malaria model. BALB/c mice were immunized with AdPyCSP and then injected with either PD-1 peptide blockers or anti-PD-L1 monoclonal antibody (mAb) on days 1, 3, 5 and 7. At day 12, a 3-fold increase in splenic PyCSP-specific, IFN-γ<sup>+</sup> CD8<sup>+</sup> T cells was seen in mice treated with PD-1 peptide blockers as compared to AdPyCSP only. Comparable splenic PyCSP-specific, IFN-γ<sup>+</sup> CD8<sup>+</sup> T cells numbers were detected between mice treated with PD-1 peptide blockers and anti-PD-L1 mAb. Similar studies are ongoing in preclinical challenge models to assess the immunomodulatory efficacy of the identified PD-1 peptide inhibitors with other malaria immunogens.

### USING MULTI CRITERIA EVALUATION TO IDENTIFY PRIORITY AREA FOR INDOOR RESIDUAL SPRAYING, MADAGASCAR

Antonio H. Rakotoarison<sup>1</sup>, Mampionona Rasamimalala<sup>1</sup>, Jean-Marius Rakotontramanga<sup>1</sup>, Brune Ramiranirina<sup>2</sup>, Thierry Brinchar<sup>2</sup>, Laurent Kapesa<sup>3</sup>, Jocelyn Razafindrakoto<sup>3</sup>, Laurence Baril<sup>1</sup>, Patrice Piola<sup>4</sup>, Fanjasoa Rakotomanana<sup>1</sup>

<sup>1</sup>Epidemiology Unit, Pasteur Institute, Antananarivo, Madagascar, <sup>2</sup>National Malaria Control Program, Ministry of Health, Antananarivo, Madagascar, <sup>3</sup>U.S. Agency for International Development Madagascar, Health Population and Nutrition Office (HPN), Antananarivo, Madagascar, <sup>4</sup>Epidemiology Unit, Pasteur Institute, Phnom Penh, Cambodia

Despite sustained efforts to control malaria in Madagascar, the Central Highlands remain threatened by unstable malaria transmission. Indoor Residual Spraying (IRS) for malaria vector control mostly depends on external funding and relies on costly logistical implementation. We aimed to map malaria risk gradients using a multi-criteria evaluation (MCE) decision tool to help the Malagasy Ministry of Public Health (MPH) to prioritize areas for indoor residual spraying. We completed annual risk modeling for inhabited locations using MCE by weighted linear combination method. We performed multiple comparisons to assess area changes according to malaria risks using data per two consecutive years during the 2014 to 2016 period. A semi-automatic workflow combining risk modeling processes was developed. To estimate a best-fit risk magnitude probability per commune (administrative entity), we used per-pixel values for inhabited locations, and calculated an adjusted mean. The Jenks Natural Breaks algorithm was used to classify the

obtained malaria risk gradient. Risk models were obtained for 2014, 2015 and 2016. Between 2014 and 2015, we observed areas of malaria transmission risk changes as follows: a decrease in 35.3%, an increase in 29.1% and no change in 35.6%, respectively. Between 2015 and 2016, area changes were as follows: a decrease in 61.9%, an increase in 26.9% and no change in 11.2%, respectively. Environmental and climatic factors determined the changes in the models. The malaria risk maps per commune showed the priority areas for selective IRS. A plugin named "Full Multi Criteria Evaluation for Public Health" is currently available and works on the open-source program QGIS. Malaria epidemiological and intervention data will be integrated in the models for the annual IRS decision-making of the MPH. Running the process is cost- and time- saving for low income countries such as Madagascar. Prioritizing the interventions will optimize the IRS implementation and management. The tool may complement existing surveillance systems. It could be valuable for other infectious diseases of Integrated Disease Surveillance and Response system.

## 1064

### ARE PLANTATIONS A HOTSPOT OF MALARIA TRANSMISSION IN CAMBODIA? AN ECOLOGICAL STUDY AND MATHEMATICAL MODEL

Simon C. Mendelsohn<sup>1</sup>, Abigail Pratt<sup>2</sup>, Panharith Nou<sup>2</sup>, Laura Merson<sup>3</sup>, Chea Nguon<sup>4</sup>, Pengby Ngor<sup>5</sup>, Richard J. Maude<sup>5</sup>, Lisa J. White<sup>5</sup>

<sup>1</sup>Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Population Services Khmer, Phnom Penh, Cambodia, <sup>3</sup>WorldWide Antimalarial Resistance Network, Oxford, United Kingdom, <sup>4</sup>The National Centre for Parasitology, Entomology and Malaria Control, Ministry of Health, Phnom Penh, Cambodia, <sup>5</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Malaria is a leading cause of morbidity in Cambodia with an estimated incidence of 120,000 cases in 2015 according to the WHO. Transmission is highest in rural areas where a large proportion of the population live and work. Plantations are hypothesised to be "hotspots" of malaria transmission due to the proximity of forests and the vectors therein. To assess this hypothesis, malaria incidence data collected by plantation malaria workers from August 2013 to March 2016 in north-eastern Cambodia was compared with incidence data from health facilities and village malaria workers in surrounding villages. A deterministic compartmental model was developed based on the malaria life cycle and interaction of plantation workers with the ecosystem to explore malaria transmission dynamics on plantations. Plantation malaria incidence was found to follow a seasonal pattern with a peak in cases at the end of the wet season. The mean annual incidences of cases reported by plantation malaria workers in Monduliri and Stung Treng provinces were 15.8 and 13.9 cases per 1,000 population respectively, consistent with a hypoendemic transmission setting. There was no statistical difference in malaria incidence between plantation and village settings which is probably due to similar risk factors and proximity to mosquito breeding sites. The model predicted that importation of malaria by migrant workers was not a contributing factor to its transmission on plantations. Plantation workers with immunity and asymptomatic malaria were predicted to act as a reservoir enhancing malaria transmission and thus need to be targeted in elimination efforts. As the plantations approach elimination, the transmission pattern will shift from a stable endemic to unstable epidemic pattern with declining immunity which may result in an increase in clinical and severe malaria cases. Plantation workers are often mobile, migrant, and hard to reach, rendering provision of healthcare services challenging. The results highlight the role ministry of health and civil society have in improving access to and uptake of mobile malaria worker services in order that malaria cases are treated early.

## 1065

### MODELLING THE POTENTIAL OF IVERMECTIN TREATED CATTLE AS A NOVEL MALARIA VECTOR CONTROL TOOL: IMPLICATIONS OF KILLING ZOOPHILIC MOSQUITOES

Amy Dighe, Azra Ghani, Hannah Slater

MRC Centre for Outbreak Analysis and Modelling, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom

Current malaria vector control interventions target anthropophilic, indoor-biting mosquitoes, leaving zoophilic, exophilic vectors to sustain residual transmission of malaria, even in areas with high vector control coverage. It has been suggested that targeting zoophilic vectors by injecting cattle with the multi-purpose mosquitocidal drug ivermectin (IVM) could ameliorate this. However, applying such a strong selection pressure against zoophilic vectors could shift vector populations towards being more anthropophilic which would increase the human biting rate. Here, a mathematical model of vector dynamics and malaria transmission are linked with an existing ecological larval model and extended to simulate administration of IVM to cattle. When this framework is used to investigate the effects of this intervention in a homogenous vector population of mosquitoes with identical Human Biting Indexes (HBIs), the administration of an annual dose of IVM to cattle is predicted to considerably reduce malaria infection, particularly when given immediately prior to the peak of the rainy season in a seasonal transmission setting. However, if two competing species with different HBIs are present, the intervention may cause an increase in annual malaria infections by changing the composition of the vector population to include a larger proportion of anthropophilic mosquitoes. If the two vector species occupy entirely overlapping breeding sites (complete competition), a single dose of IVM is predicted to cause a permanent increase in malaria prevalence. In reality, competition is more likely to be partial, in which case a single dose of IVM is predicted to only increase malaria prevalence temporarily when the level of competition is above a certain threshold. These findings highlight the importance of considering the local vector species before planning administration of IVM to cattle.

## 1066

### ESTIMATING THE MALARIA ATTRIBUTABLE FEVER FRACTION ACCOUNTING FOR PARASITES BEING KILLED BY FEVER AND MEASUREMENT ERROR

Kwonsang Lee, Dylan Small

University of Pennsylvania, Philadelphia, PA, United States

A characteristic symptom of malaria is fever. The fraction of fevers that are attributable to malaria, the malaria attributable fever fraction (MAFF), is an important public health measure for assessing the effect of malaria control programs and other purposes. Estimating the MAFF is not straightforward because there is no gold standard diagnosis of a malaria attributable fever; an individual can have malaria parasites in her blood and a fever, but the individual may have developed partial immunity that allows her to tolerate the parasites and the fever is being caused by another infection. We develop a causal inference perspective on the MAFF by defining the MAFF using the potential outcome framework for causal inference and show what assumptions underlie current estimation methods. Current MAFF estimation methods rely on an assumption that the parasite density is correctly measured. However, this assumption does not generally hold because (i) fever kills some parasites and (ii) the measurement of parasite density has measurement error. In the presence of these problems, we show current estimation methods do not perform well. We propose a novel maximum likelihood estimation method based on exponential family g-modeling. Under the assumption that the measurement error mechanism and the magnitude of the fever killing effect are known, we show that our proposed method provides approximately unbiased estimates of the MAFF in simulation studies. A sensitivity analysis can be

used to assess the impact of different magnitudes of fever killing and different measurement error mechanisms. We apply our proposed method to estimate the MAFF in a study in Kilombero, Tanzania.

## 1067

### UNDERSTANDING THE MALARIA TRANSMISSION PROCESS IN NEAR-ELIMINATION SETTINGS

**Isobel Routledge<sup>1</sup>**, José Eduardo Romero Chévez<sup>2</sup>, Zulma Cucunubá<sup>1</sup>, Caterina Guinovart<sup>3</sup>, Kammerle Schneider<sup>3</sup>, Patrick Walker<sup>1</sup>, Azra Ghani<sup>1</sup>, Samir Bhatt<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Ministerio de Salud (MINSAL), San Salvador, El Salvador, <sup>3</sup>PATH, Seattle, WA, United States

In 2016 the WHO identified 21 countries for whom it would be realistic to eliminate Malaria within the next five years. However, as countries approach elimination targets, changes in geographic clustering, the influence of imported cases, *Plasmodium vivax* relapse dynamics, and the shifting demographics of infected individuals pose major challenges to reaching zero cases. An in-depth understanding of these changes is essential to design optimal elimination strategies. For outbreaks of numerous other diseases, surveillance data is used to reconstruct transmission chains and estimate transmission dynamics, providing useful information for decisions about disease control and intervention. These methods are difficult to apply to endemic malaria, which has long generation times, complexities in immunity and large numbers of unobserved cases. In near elimination countries, with strong surveillance systems, these complexities are mitigated and such methods can be applied to understand the malaria transmission process. We analysed novel health surveillance data from El Salvador. This dataset contains detailed geographic, epidemiological, and demographic information about all reported and confirmed cases from 2010 to 2015, (87 cases, of which 29 were imported). We apply a continuous diffusion process on discrete networks to reconstruct the most likely transmission chains between 2010 and 2015 and quantified heterogeneities in transmission over time, space and between individuals. Our results suggest that between 2010-2015 transmission intensity waned, however importation continues to sustain transmission in border regions. We found the mean value of  $R_c$  is below 1 between 2010 and 2015 suggesting that, in isolation, El Salvador would be likely to sustain elimination. However, following importation from neighbouring countries, time varying reproduction numbers often surpassed 1. This highlights the need for cross-border collaboration to achieve elimination and the potential value of the Elimination of Malaria in Mesoamerica and Espanola Initiative (EMMIE).

## 1068

### MODELING THE RELATIVE ABUNDANCE OF MAJOR MALARIA ANOPHELES SPP. ACROSS GHANA USING A BAYESIAN APPROACH

**Punam Amratia**, Denis Valle

University of Florida, Gainesville, FL, United States

Understanding the ecology and spatial distribution of dominant malaria vectors is essential to the design of effective and sustainable strategies for malaria control and elimination. However, rarely is spatial distribution of the dominant vectors used in planning at country-level and there have been fewer attempts to understand the link between spatial composition and behavioral bionomics. Previous studies have tried to define ecological niches and vector bionomics, but at larger-scales. These have been important for general understanding of vector dominance and distribution at the continental scale, but they lack the ability to define the density of each species at a finer resolution. In this study, we aim to build on these earlier approaches and assess the determinants of vector abundance, so as to produce better predictive maps of the relative abundance of major vectors of malaria in Ghana. Vector count data were modeled using an over-dispersed Poisson model within a Bayesian framework to evaluate key environmental drivers and to predict spatial distribution.

Environmental variables were derived from remote sensing applications. A total of 334 survey sites were collated for the species *Anopheles gambiae* and *An. funestus*. Model validation was done on 10% of these locations prior to final predictions. We find that, although mapping of these vector abundance patterns shows promise, there still the need for more systematic and consistent data to be able to help with vector management.

### PREDICTING NEW YORK CITY COMMUNITIES AT RISK FOR IMPORTED MALARIA: METHODS AND APPLICATIONS

**Elizabeth H. Lee<sup>1</sup>**, Robin H. Miller<sup>2</sup>, Penny Masuoka<sup>2</sup>, Danushka Wanduragala<sup>3</sup>, Lucretia Jones<sup>4</sup>, Christina M. Coyle<sup>5</sup>, Stephen Dunlop<sup>6</sup>, William Stauffer<sup>6</sup>, Patrick Hickey<sup>1</sup>

<sup>1</sup>The Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, <sup>3</sup>Minnesota Department of Health, Minneapolis, MN, United States, <sup>4</sup>New York City Department of Health and Mental Hygiene, New York, NY, United States, <sup>5</sup>Albert Einstein College of Medicine, New York, NY, United States, <sup>6</sup>University of Minnesota, Minneapolis, MN, United States

In the United States, most malaria cases are acquired by immigrants visiting friends and relatives (VFRs). Methods for identifying, mapping, and predicting communities at risk for imported malaria now and in the future, can help inform intervention strategies and focus resources. Building upon previous work and using census and routine surveillance data for 2010-2014, our objective was to build and validate a model which could be used to accurately predict the distribution and case burden of imported malaria in New York City over a five-year period. To this end, we: 1) adapted and applied a multivariable negative binomial regression model previously derived from a study of Minnesota data to census data for New York City to predict number and location of malaria cases for ZIP Codes as a proxy for communities, and 2) attempted to validate and improve upon this model for the New York metropolitan area based on actual case data obtained from the New York City Department of Health. Our initial model for NYC census data from 2010-2014 suggested that, when compared to a similar map for the overlapping 2004-2012 period, findings were qualitatively similar in terms of the geographic distribution, but that even if doubled to reflect a longer reporting period, expected case counts (0 to 7) for a five-year period were substantially lower than actual cases (0 to >22) over a nine-year period. Testing our model with NYC case data for 2010-2014 resulted in a better fit and improved ability to predict case burden. Combined analysis of routine surveillance and census data can improve understanding of where and which communities may be at risk for imported malaria. Our methods can be extended to other reportable emerging infectious diseases to inform targeted interventions, as well as to predict malaria case distribution and burden for an expanded geographic area. Potential impacts include increased coverage of travel medicine services and improved pre- and post-travel care for high-risk communities.

## 1070

### COSTING MALARIA ELIMINATION IN THE ASIA-PACIFIC

**Sheetal Prakash Silal<sup>1</sup>**, Rima Shretta<sup>2</sup>, Olivier Celhay<sup>3</sup>, Lisa J. White<sup>4</sup>

<sup>1</sup>University of Cape Town, Cape Town, South Africa, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Mahidol University, Bangkok, Thailand, <sup>4</sup>Oxford University, Oxford, United Kingdom

The Asia Pacific region has attracted between 12-21 percent of global malaria funding from 2006-2010. However, since 2009, there has been steady decline in external financing for malaria particularly in the low-burden and eliminating countries. In order to achieve the goal of a malaria-free Asia Pacific, financial resources will need to be increased and sustained over the medium to long-term. Without intensive support and evidence to understand and articulate the cost requirements to help

mobilize adequate and sustained resources, and/or reprogram existing funds to be spent as efficiently as possible, these countries will be unable to reach their elimination goals. The study aims to use mathematical modelling to project rates of decline to elimination by 2030 and determine the costs for (and maintaining) elimination in the Asia Pacific region. Non-linear differential equations were used to develop a mathematical model to capture the dynamics of *Plasmodium falciparum* and *Plasmodium vivax* malaria for the 22 countries in the Asia-Pacific region. The models accounted for health system interventions, immunity, G6PD deficiency and mobility. All 22 countries are predicted to achieve malaria elimination by 2030 through a mixture of interventions such as universal coverage of bednets and drug therapy, increased surveillance, indoor residual spraying and mass drug administration. Economic costing for elimination was conducted to assess the potential for efficiency savings on the path to malaria elimination by 2030. A web-based application was created for the users of the model.

## 1071

### THE RELATIONSHIP BETWEEN *PLASMODIUM FALCIPARUM* PARASITEMIA FROM MIS DATA AMONG PREGNANT WOMEN AND CHILDREN AND ASSESSING THE USE OF ANC DATA FOR ESTIMATING MALARIA PREVALENCE

**Kenneth Charles Murray**<sup>1</sup>, Aveika Akum<sup>1</sup>, Jordan Smith<sup>1</sup>, Wonder Philip Phiri<sup>1</sup>, Megan Perry<sup>2</sup>, Julie Niemczura de Carvalho<sup>2</sup>, Guillermo Garcia<sup>2</sup>, Christopher Schwabe<sup>2</sup>, Jackie Cook<sup>3</sup>, Immo Kleinschmidt<sup>3</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Malaria control programs often target vulnerable populations such as children and pregnant women. The Bioko Island Malaria Control Project (BIMCP) has implemented population specific control programs with aim of reducing the burden of malaria among such groups on Bioko Island, Equatorial Guinea. Through the annual Malaria Indicator Survey (MIS), the BIMCP is able to monitor malaria prevalence, but as most surveys this is an intensive and time-consuming process. Although the BIMCP has observed significant reductions in *P. falciparum* prevalence among children ages 2-14 years (From 45% in 2004 [95% CI, 40%-50%] to 12.1% in 2016 [95% CI, 11.2%-13.3%]), more efficient and timely methods of monitoring malaria prevalence will be needed to continue its progress. During antenatal care (ANC) visits, pregnant women are routinely screened for parasitemia, thus providing monthly variation of malaria incidence among this sub-population. If a relationship exists between malaria prevalence among pregnant women and children, monthly monitoring of ANC data could prove effective and efficient in estimating malaria trends in other subpopulations, such as children. The Pearson's product-moment correlation (PPMCC) will be used to assess the linear correlation between parasitemia prevalence among pregnant women and children using MIS data from 2008-2016 at a sentinel site level and island wide data from 2015-2016. Previous results indicate a strong relationship between the two groups. This study will continue to monitor the strength of the association of parasitemia between the two sub-populations, and therefore, the ability to use prenatal care attendees as an indicator for malaria prevalence estimation on Bioko Island.

## 1072

### USING MODELED *PLASMODIUM VIVAX* PREVALENCE DATA TO ESTIMATE THE MARKET SIZE FOR GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY TESTS TO SUPPORT DECISION-MAKING ON SERVICE DELIVERY MODELS

**Michael Kalnoky**<sup>1</sup>, Nick Luter<sup>1</sup>, Spike Nowak<sup>1</sup>, Mutsumi Metzler<sup>1</sup>, Gonzalo Domingo<sup>1</sup>, Rosiland Howes<sup>2</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>Malaria Atlas Project at Oxford University, Seattle, WA, United States

*Plasmodium vivax* is estimated to be responsible for over 100 million clinical infections annually. Drugs in the 8-aminoquinoline family, such as primaquine and tafenoquine, can completely clear *P. vivax* parasites by killing malaria gametocytes and thus blocking vector-borne transmission. For patients with reduced activity of the G6PD enzyme, however, 8-aminoquinoline drugs can cause severe hemolysis, and the World Health Organization therefore recommends identifying the G6PD status of patients infected with *P. vivax* malaria prior to administering these drugs. Point-of-care (POC) tests that can rapidly and affordably identify G6PD status are needed to support safer and wider use of the 8-aminoquinoline family of drugs. During the time that PATH has been supporting development and market entry of POC G6PD quantitative and qualitative tests, we also developed a computer program, GeoDX model, to estimate *P. vivax* burden per health facility (i.e., the number of patients positive for *P. vivax* who visit each health facility) in selected countries. GeoDX is a computer program written in an open-source programming language, R. Inputs to this model are *P. vivax* prevalence and population per geographic area, geospatial facility data, and certain assumptions around facility catchment. Outputs from GeoDX are ported to a secondary program geared toward leveraging GeoDX data to estimate G6PD diagnostic demand. Calculating diagnostic demand is achieved by considering different treatment algorithms, country diagnostic adoption characteristics, malaria elimination scenarios, and product costs as well as product shelf life and shipping characteristics. The output of the diagnostic demand software is a ten-year demand forecast of the total number of qualitative and quantitative G6PD diagnostics and their associated aggregate and unit costs. National malaria control programs and other program implementers can use the outputs of our model to evaluate which use-case scenario would most likely attain the desired target coverage in the most effective manner.

## 1073

### A CLUSTER-RANDOMIZED TRIAL TO TARGET SUBSIDIZED ARTEMISININ COMBINATION THERAPY (ACT) IN THE RETAIL SECTOR USING A COMMUNITY-BASED TESTING AND VOUCHER SCHEME

**Wendy Prudhomme O'Meara**<sup>1</sup>, Jeremiah Laktabai<sup>2</sup>, Manoj Mohanan<sup>1</sup>, Alyssa Platt<sup>1</sup>, Elisa Maffioli<sup>1</sup>, Joseph Kirui<sup>3</sup>, Lucy Abel<sup>3</sup>, Paige Meier<sup>1</sup>, Elizabeth Turner<sup>1</sup>, Diana Menya<sup>2</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>Moi University College of Health Sciences, Eldoret, Kenya, <sup>3</sup>Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya

Private drug retailers are a major source of antimalarials in malaria-endemic areas and yet dispensing in these shops is largely divorced from diagnostic testing. This leads to poor targeting of antimalarials; both under-consumption among those with malaria and over-consumption among those without. Several countries, including Kenya, offer publicly subsidized ACTs through the private sector. Poor targeting reduces the public health effectiveness of these subsidies. The objective of this study is to evaluate the impact of targeting an antimalarial subsidy through a partnership between Community Health Workers (CHWs) and private drug shops. Free, community-based malaria diagnostic testing was made available through CHWs. The subsidy is offered in the form of a voucher

from the CHW conditional upon a positive malaria rapid diagnostic test (RDT). The voucher is redeemed for a WHO-qualified ACT at a reduced price at a participating shop. We randomized 32 clusters in western Kenya between intervention (CHW testing&vouchers) and comparison arms (normal CHW activities). In the intervention arm, we trained 275 CHWs serving approximately 100,000 people to offer RDTs in their communities. 36 shops in intervention areas agreed to redeem vouchers. ACT cost for voucher-holders was \$0.10-0.40 compared to \$1.20 without a voucher. Over 15 months, >26,000 participants sought testing and 30% were RDT-positive (2.5% - 47%, by cluster). 90% of the vouchers issued were redeemed at shops. Community-based surveys of households with a malaria-like illness in the preceding four weeks were used to estimate the impact of the intervention. Surveys were conducted prior to the intervention and at six-month intervals during the 18 month intervention period. >7,000 households participated in the surveys. The primary outcome is the percent of fevers captured by the survey that received a malaria diagnostic test. Secondary outcomes include the proportion of ACTs consumed by individuals with a positive test, a negative test, no test, and the proportion of patients receiving an adequate dose of ACT. Primary and secondary outcomes will be compared between the study arms.

## 1074

### CONTRIBUTION OF COMMUNITY-BASED HEALTH WORKERS (CBHWS) TO IMPROVING PREVENTION OF MALARIA IN PREGNANCY: PROCESS FOR IMPLEMENTING A FEASIBILITY STUDY

Justin Tiendrebeogo<sup>1</sup>, Ousmane Badolo<sup>1</sup>, Mathurin Dodo<sup>1</sup>, Danielle Burke<sup>2</sup>, William Brieger<sup>3</sup>

<sup>1</sup>Jhpiego/Improving Malaria Care Project, Ouagadougou, Burkina Faso, <sup>2</sup>Jhpiego, Baltimore, MD, United States, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The Ministry of Health of Burkina Faso with the support of its partners initiated a study on the feasibility of increasing provision of Intermittent Preventive Malaria Treatment in pregnant women (IPTp) with sulfadoxine-pyrimethamine (SP) by involving existing community-based health workers (CBHWS). As Burkina Faso adopted the WHO recommendations for more doses of IPTp during pregnancy, it was proposed that the challenge of achieving coverage of third, fourth and additional doses could be met using CBHWS. The approved protocol calls for CBHWS to refer pregnant women to antenatal care (ANC) to receive their first IPTp dose. Subsequent doses at one-month intervals would be provided by trained CBHWS, who would report back to supervising midwives at the ANC clinics. Several steps were taken to gain approval and set up the intervention. First, IPTp data from the health information system was gathered. IPTp coverage based on ANC registration in the 6 intervention clinics was 69% IPTp1, 68% IPTp2, 56% IPTp3, and 1% IPTp4. Similar information was obtained from the 6 control clinic catchment areas. Situation analysis found that while CBHW curriculum stresses the importance of ANC, it does not address IPTp at community level. In response updated training materials have been developed. The study team also collected information on village size and availability of CBHWS, especially females. Among the villages in the catchment of the 6 intervention ANC clinics, 33 were found to lack female CBHWS. As a result, the team needed to recruit additional female CBHWS, as revised national recruitment guidance stressed attainment of primary school certificate over gender, meaning mainly men had been hired previously. Two institutional review boards were involved and suggested the need to address the potential rare side effects of SP and concerns that community IPTp would not detract from ANC clinic attendance. Since district and clinic level health staff will be involved in implementing the program using the national CBHW program, lessons learned from this effort to expand the work of CBHWS in preventing malaria in pregnancy should be applicable/adaptable nationwide.

## 1075

### STRENGTHENING MALARIA SUPPLY CHAINS LEADS TO IMPROVED MALARIA CASE MANAGEMENT

Chris Warren

JSI Research and Training Institute, Inc., Arlington, VA, United States

Strong supply chains help ensure crucial access to malaria diagnostics and medicines. The significant progress that has been made towards Significant progress achieving the global targets of reducing malaria-related morbidity and mortality. would not have been possible without the strengthening of the supply chains that manage and move malaria products, improving product availability which support improvements in malaria case management and outcomes. Analyses of data on malaria product availability and malaria case management demonstrate the importance of product availability. In Burkina Faso, the percentage of health facilities with ACTs available improved from 15% to 85% between 2012 and 2015. During the same time period, the malaria mortality rate in children under 5 decreased by 50%. Facilities stocked out of RDTs decreased from >90% to less than 5%. In Ghana, in 2010 only 15% of the malaria cases were diagnosed with an RDT or microscopy. By mid-2016, this had improved to almost 90%. During this time, the percent of facilities stocked out of RDTs declined by 50%. In Malawi, in 2011 around 50% of facilities were stocked out of ACTs; by 2016, less than 10% of facilities were stocked out of ACTs. From 2010 to 2015, the percent of children under 5 that received an ACT increased by 42%. Also in Malawi, analysis of survey data and supply chain data showed that the peak of stockouts of sulfadoxine-pyrimethamine (SP) resulted in the lowest percentage of eligible pregnant woman who received any SP, a critical intervention to preventing malaria in pregnancy. In Zambia, the decline in stockout rates over the last five years, from more than 30% to less than 5% have been accompanied by significant increases in the percent of children under 5 that received an ACT (more than a 50% increase). Despite these positive country examples, there are still an estimated 212 million cases of malaria worldwide. Investments in supply chain strengthening contribute to greater product availability, to preventing, diagnosing, and treating malaria, and ultimately in malaria case outcomes. Supply chain strengthening remains a critical component to the global malaria agenda.

## 1076

### CLINICAL CONSEQUENCES OF SUBMICROSCOPIC MALARIA PARASITEMIA IN UGANDAN CHILDREN

Shereen Katrak<sup>1</sup>, Patience Nayebare<sup>2</sup>, John Rek<sup>2</sup>, Emmanuel Arinaitwe<sup>2</sup>, Joaniter I. Nankabirwa<sup>2</sup>, Moses Kamya<sup>2</sup>, Grant Dorsey<sup>1</sup>, Philip Rosenthal<sup>1</sup>, Bryan Greenhouse<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda

Submicroscopic malaria parasitemia remains common in both high- and low-endemicity settings in Africa. Submicroscopic parasitemia impacts mosquito infectivity and disease transmission, but its clinical consequences are unclear. We performed repeated cross-sectional surveys measuring parasite prevalence from August 2011 – June 2016 in a cohort of children (n=364) and adults (n=106) in Tororo District, Uganda, where malaria transmission intensity has historically been high, but has declined after implementation of indoor residual spraying (IRS) in December 2014. Participants were followed using active and passive surveillance. Those who presented with fever (tympanic temperature > 38.0°C or history of fever in the previous 24 hours) and a positive blood smear were treated for malaria. Participants also presented to the clinic every 90 days for routine visits (n=9,075); a subset of patients was followed every 30 days. Blood smears and dried blood spots (DBS) were collected at every routine visit, and all patients with a negative blood smear had loop-mediated isothermal amplification (LAMP) performed to test for submicroscopic parasitemia. Submicroscopic parasitemia was common, with an overall prevalence of 25.8% and 39.2% in children and adults, respectively. In children, but not adults, having submicroscopic parasitemia at a routine

visit, compared to having no detectable parasitemia, was associated with increased risk of fever (adjusted risk ratio [CI], 1.67 [1.37 – 2.03]) and an increased risk of clinical illness, a composite outcome comprised of eleven signs and symptoms (1.32 [1.15 – 1.51]). The risk of fever in children with submicroscopic infection was maintained after excluding individuals with a malaria episode within the preceding or following 14 days, to limit effects of recent symptomatic malaria, and after adjusting for other variables that may be associated with fever, including age, housing type, and socio-economic status (1.68 [1.39–2.03]). Although we cannot establish causation, our analyses suggest that submicroscopic malaria infection has clinical consequences in children.

## 1077

### IMPROVING QUALITY OF DATA TO ADVANCE MALARIA IN PREGNANCY INDICATOR COVERAGE IN EBONYI STATE, NIGERIA

**Bright Orji**, Gladys Olisaakee, Onyinye Udenze, Enobong Umoekeyo, Chika Nwankwo, Boniface Onwe, Chibugo Okoli, Emmanuel Otolorin

*Jhpiego, Baltimore, MD, United States*

Quality data are crucial for informed decision-making to address health challenges and improve malaria service delivery among countries on the pathway to malaria elimination. This emphasis on better data quality was reflected in the World Malaria Day theme of “Counting Malaria Out” in 2009 and 2010. In Nigeria, improving malaria data quality has been difficult due to critical health system challenges including poor coordination across different departments, institutional complexities, and a shortage of medical record officers and service providers sufficiently trained in data visualization and use of data for decision-making. In response, the Maternal and Child Health Survival Program (MCSP) in Nigeria embarked on the implementation of key activities to improve quality of malaria data in Ebonyi State. These activities included training on record keeping and use of data for decision-making; post training follow-up; dash boards at the frontline for better data visualization; monthly data collation meetings; improved synergy among service departments; and quarterly data quality assurance visits. As a result, more than 75% of facilities graphed malaria indicators thereby increasing data visualization and use of data for decision-making. An example of data improvements leading to service increases was Intermittent Preventive Treatment for malaria in pregnancy (IPTp). IPTp1 service statistics in MCSP-supported facilities improved from 54.1% in Oct-Dec 2015 to 81.3% by Jul-Sept 2016 compared to 54.7% to 67.8% in the same periods for non-MCSP facilities. Similarly, IPTp2 service statistics in MCSP-supported facilities improved from 52.8% to 70.5% compared to 46.5% to 58.0% in the same period for non-MCSP facilities. Data quality improvement interventions such as monthly data collation and validation meetings prior uploading data to DHIS can contribute to improved quality of malaria performance indicators, better coordination between antenatal care, outpatient and pharmacy departments and increased IPTp coverage.

## 1078

### ASSESSMENT OF BEHAVIOR CHANGE COMMUNICATION (BCC) INTERVENTIONS IN SUPPORT OF MALARIA CONTROL ACTIVITIES CONDUCTED IN BENIN BY PMI'S ARM3 PROJECT

Boniface Denakpo<sup>1</sup>, Jeanne Togbenou<sup>2</sup>, **Jean Fortuné Dagnon**<sup>3</sup>, Désiré Ekué Amegnikou<sup>2</sup>, Saka I. Amoussou<sup>1</sup>, Bella Hounkpe<sup>1</sup>, Adrien Hessavi<sup>1</sup>, Alexis Yemalin Tchevoede<sup>1</sup>, Adicatou-Lai Adeothy<sup>1</sup>, Mariam Oke Sopoh<sup>1</sup>, Gilbert Andrianandrasana<sup>2</sup>, Michelle Kouletio<sup>3</sup>, Pablo Aguilar<sup>4</sup>, Christopher Schwabe<sup>4</sup>

<sup>1</sup>National Malaria Control Program (NMCP), Cotonou, Benin, <sup>2</sup>PMI ARM3 Project, Cotonou, Benin, <sup>3</sup>United States President's Malaria Initiative/U.S.

*Agency for International Development-Benin, Cotonou, Benin, <sup>4</sup>Medical Care Development International, Silver Spring, MD, United States*

In Benin, from 2012 to 2014, PMI ARM3 project conducted Behavior Change Communication (BCC) activities in 28 of 34 health zones (HZs). In 2015, we assessed the project's BCC contributions to improving malaria preventive and treatment-seeking attitudes and behaviors among pregnant women and children <5. We selected two HZs in Oueme-Plateau region as the intervention group and two HZs in Mono-Couffo region as the control group. Both groups shared similar socio-economic characteristics. We sampled 16 health centers, 528 women (321 pregnant and 207 mothers of children <5) and assessed in both areas using the Roll Back Malaria 2014, Malaria BCC Indicator Reference Guide. Associations among variables were tested at the 5% threshold using the ANOVA *F*-test. Dissemination of malaria messages was mainly conducted through social mobilization (34% of women recalled participating in the intervention group vs. 9% in the control group), community radio spots (32% of participants in the intervention group reached/recalled having heard a message versus 14% control group,  $p < 0.001$ ) and flyers distribution through household visits (76% intervention group recognize an image from a flyer vs. 54% control group). 93% of the women in the intervention group knew what to do (use mosquito nets, preventive medication taken during pregnancy) to prevent malaria compared with 84% in the control group ( $p < 0.05$ ). 90% of children <5 in the intervention group had slept under an LLIN the night before the assessment compared to 82% in the control group ( $p < 0.01$ ). The level of LLIN use by pregnant women in the intervention group was higher compared to the control group (87% against 76%,  $p < 0.05$ ). 66% of women in the intervention group who had a live birth during the past two years received two or more doses of sulfadoxin/pyramethamin during antenatal care visits versus 42% in the control group ( $p < 0.01$ ). 48% of women in the intervention group stated that ACT is the most effective drug against malaria compared to 28% in the control group ( $p < 0.01$ ). BCC activities had a positive effect in improving behaviors related to the prevention of malaria in pregnant women and children <5.

## 1079

### IMPROVEMENTS IN QUALITY OF MALARIA CASE MANAGEMENT THROUGH COUNTY REFERRAL HOSPITAL MEDICINES AND THERAPEUTICS COMMITTEES IN KENYA: THE MIGORI COUNTY EXPERIENCE

**Elizabeth Marube**<sup>1</sup>, Tony Chahale<sup>1</sup>, Beatrice Onyando<sup>2</sup>, Samwel Onditi<sup>1</sup>, Tiffany Clark<sup>3</sup>, Illah Evance<sup>2</sup>, Rodgers Dena Mwinga<sup>4</sup>, Troy Martin<sup>5</sup>, Chester Kolek<sup>6</sup>

<sup>1</sup>President's Malaria Initiative MalariaCare Project, PATH, Kisumu, Kenya, <sup>2</sup>President's Malaria Initiative MalariaCare Project, PATH, Nairobi, Kenya, <sup>3</sup>President's Malaria Initiative MalariaCare Project, PATH, Washington, DC, United States, <sup>4</sup>President's Malaria Initiative MalariaCare Project, Medical Care Development International, Kisumu, Kenya, <sup>5</sup>President's Malaria Initiative MalariaCare Project, PATH, Seattle, WA, United States, <sup>6</sup>Ministry of Health, Migori County, Kenya

Hospital medicines and therapeutics committees (HMTc) are used to assure administrative and departmental coordination of clinical hospital outcomes in the developing world. MalariaCare has supported revival of HMTcs in several counties in western Kenya in order to strengthen implementation of high quality malaria case management services. This report focuses on improvements in malaria case management indicators in Migori County Referral Hospital (MCRH), after initiation of an HMTc in April 2016. The MCRH HMTc held four meetings between May and December 2016. Participants included the hospital superintendent, pharmacist, surgeon, pediatrician, gynecologist, laboratory in charge, clinicians, MalariaCare regional coordinator and technical advisors. Meetings focused on reviewing gaps identified during the most recent malaria case management supervision visit, conducted by MalariaCare in coordination with the National Malaria Control Program and Ministry of Health (MOH). The HMTc developed actions plans for implementation

by various responsible departments to address these gaps which included several activities: dissemination of national guidelines for the diagnosis, treatment and prevention of malaria in Kenya to all hospital departments; developing facility specific clinical flow charts for malaria case management; organizing continuing medical education (CME) sessions for relevant hospital staff; and sharing of feedback to all key departments on supervision performance indicators. The hospital has seen a dramatic improvement in key indicators assessed during three supervision visits from the first visit in November 2015 to the most recent in December 2016. The overall clinical performance score improved from 83% to 96%, the percentage of suspected malaria cases with a corresponding test improved from 85% to 100% (20 records sampled), and percentage confirmed malaria cases treated with ACTs increased from 50% to 100% (10 records sampled). Given these successes, MalariaCare is working with the MOH to continue reviving HMTCs in one referral hospital in each of the eight MalariaCare-supported counties in Kenya.

## 1080

### INCREASING CARE SEEKING BEHAVIOR AMONG CAREGIVERS OF CHILDREN UNDER FIVE YEARS OF AGE WITH FEVER IN BENIN USING BEHAVIOR CHANGE COMMUNICATION: RANDOMIZED TRIAL

**Damien Georgia**<sup>1</sup>, Eve Amoussouga<sup>1</sup>, Paul Perrin<sup>2</sup>, Mohamed Keita<sup>3</sup>, Ellenite Zinsou Kpavodé<sup>1</sup>, Jacques Saizonou<sup>4</sup>, Moussiliou Paraiso<sup>4</sup>, Ghislain Sopoh<sup>4</sup>, Fortune Dagnon<sup>5</sup>, Boniface Denakpo<sup>6</sup>

<sup>1</sup>Catholic Relief Services, Cotonou, Benin, <sup>2</sup>Catholic Relief Services, Baltimore, Benin, <sup>3</sup>Catholic Relief Services, Regional RTA MEAL CARO, Guinea, <sup>4</sup>Regional Institut of Public Health, Ouidah, Benin, <sup>5</sup>U.S. Agency for International Development, Cotonou, Benin, <sup>6</sup>National Malaria Control program, Cotonou, Benin

Increasing the utilization of malaria prevention and control efforts in Benin is challenging although simple and effective diagnosis and medicines for malaria exist. We investigated whether an effective behavior change communication (BCC) strategy and related trainings for caregivers can increase the proportion of children less than five years of age suffering from fever or illness for whom care is sought by the caregiver at the community level. We conducted operational research using a randomized trial in Benin, West Africa. We compared care seeking behavior of two groups: the reference group used integrated management of childhood illness plus rapid diagnostic tests (IMCI+RDT) and the intervention group applied IMCI+RDT+BCC. Eighteen arrondissements (in the north and the south) were assigned in two groups by block randomization, based on preliminary surveys. Within those 18 arrondissements, there were 46 intervention and 54 control villages. The primary endpoint was the proportion of children less than five years of age suffering from fever or illness for whom care is sought by the caregiver at the community level. Information was obtained using cross-sectional household surveys from May 2015 to July 2016. During 14 months of observation, 2,691 households were considered for data collection and 67% met the three inclusion criteria of (1) consenting to the survey, (2) having the caregiver at home and able to answer the questions, and (3) having a child less than five years of age, who had fever or illness in the previous two weeks. With a power of 80%, there was no statistically significant difference between intervention and comparison groups at baseline (27% versus 22% respectively), ( $p=0.112$ ). At the end line, the care seeking behavior was significantly higher in the intervention group (22%) compared to control (14%), ( $p<0.001$ ). So, although the intervention group is higher than the control group, both are worse. The lessons learned from this study can be used to refine as well as inform the national BCC strategy within the National Malaria Control Program and could serve as a foundation to improve BCC message that influences care seeking.

## 1081

### USING RAPID TASK ANALYSIS TO STRENGTHEN PRE-SERVICE EDUCATION (PSE) LEARNING AND PERFORMANCE OF CRITICAL MALARIA INTERVENTIONS BY REGISTERED MIDWIVES (RMS) AND MEDICAL LAB TECHNICIANS (MLTS) IN LIBERIA

**Marion Subah**

*Johns Hopkins University, Baltimore, MD, United States*

Health worker task analysis helps human resource planners and managers update pre-service education (PSE) curricula and plan needed in-service training. In Liberia, a task analysis was conducted focusing on Liberia's midwives' and Medical Laboratory Technicians' (MLT) work practices. Task lists were developed using curricula, job descriptions and professional scope of practice, and validated by key stakeholders for each cadre. Responses from 25 MLTs and 26 midwives were examined that addressed the following questions: How often do you do the task (frequency)? 2) Where did you learn to do the task (location)? 3) How well do you think you are able to perform the task (performance)? 4) How critical is the task in terms of patient and/or public health outcomes (criticality). Eligibility criteria included those currently practicing between 6 months and 5.5 years following graduation. Midwives were assessed for five tasks relating to malaria service provision, including provision of preventive treatment for malaria in pregnancy, management of vector borne diseases, diagnosis and management uncomplicated malaria in adults and children (respectively), and provision of malaria preventive services. Lab technicians were assessed for one malaria task, performance of parasitological tests. On average 61% of midwives learned these malaria tasks in PSE, 74% said they performed these tasks daily, 80% felt proficient in performing the tasks, and 82% rated the tasks moderate to high in criticality. For MLTs, 88% learned malaria testing in pre-service education, 100% performed this task daily, 77% felt they were proficient and 93% said the task was of moderate to high criticality. The results from this rapid task analysis are being applied to the current curricula review. Courses that could be updated or strengthened have been identified. Malaria Case Management Technical Update and Effective Teaching Skills Training are being organized for tutors at the training schools. Finally, integrated supportive supervision tools are being strengthened to improve performance of these malaria tasks by midwives and lab technicians.

## 1082

### UNDERSTANDING THE ENVIRONMENT OF MALARIA-RELATED BEHAVIORS ON BIKO ISLAND, EQUATORIAL GUINEA

**Megan Perry**<sup>1</sup>, Julie Niemczura de Carvalho<sup>1</sup>, Guillermo Garcia<sup>1</sup>, Christopher Schwabe<sup>1</sup>, Dianna E.B. Hergott<sup>1</sup>, Jackie Cook<sup>2</sup>, Immo Kleinschmidt<sup>2</sup>

<sup>1</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Indoor Residual Spraying (IRS) and Long Lasting Insecticide Treated Nets (LLIN) are the two largest vector control interventions used by the Bioko Island Malaria Control Project (BIMCP) on Bioko Island, Equatorial Guinea. The BIMCP has been successful in achieving optimal coverage with IRS in targeted communities and completed a mass distribution of LLINs in 2015, with targeted top-off campaigns in 2016 and 2017. In 2016, the BIMCP conducted a malaria indicator survey (MIS) in a representative sample of households. The MIS collects data regarding malaria prevention methods practiced at home, socio-economic status, and general health, and LLINs observed in use in household sleeping spaces were recorded. Additionally, participants were asked a series of knowledge-based questions related to malaria transmission, symptoms, and treatment methods. Clustering, linear regression, and association techniques will be used to determine how malaria knowledge, socio-economic status, and geographical location correlate with behaviors at the household level. Dependent variables

used in the analyses are: whether the survey participant slept under a net the night before, ratio of people to LLINs, whether a household desires to participate in upcoming IRS spray rounds, and if the household has participated in past rounds of IRS. Explanatory variables will be used to find data patterns to help better understand the household environment of the 38.4 % of individuals that slept under a net the night before versus the 55% who did not, the 38.5% of household that have sufficient bed nets for members versus 61.5% that did not, or the 81.9% of households that want to receive in IRS versus the 10.8% who do not. These explanatory variables will include a household malaria knowledge score, a socio-economic score, and geographical clusters. Scatter plots, classification trees and maps will be used to visually explain the correlation of the dependent and explanatory variables, and will shed light on which factors may be most influential in the uptake of key malaria control interventions.

## 1083

### USE OF CAP380 AS A MARKER FOR *PLASMODIUM FALCIPARUM* OOCYST DEVELOPMENT IN VIVO AND IN VITRO

Leslie S. Itsara<sup>1</sup>, Yaxian Zhou<sup>1</sup>, Julie Do<sup>1</sup>, Samrita Dungal<sup>1</sup>, Matthew Fishbaugher<sup>2</sup>, William Betz<sup>2</sup>, Thao Nguyen<sup>2</sup>, Mary Jane Navarro<sup>2</sup>, Erika L. Flannery<sup>2</sup>, Ashley M. Vaughan<sup>2</sup>, Stefan H. Kappe<sup>2</sup>, Anil K. Ghosh<sup>1</sup>

<sup>1</sup>MalarVx, Seattle, WA, United States, <sup>2</sup>Center for Infectious Disease Research, Seattle, WA, United States

The sporozoite stage of *Plasmodium* first develops inside the oocyst; then, sporozoites invade and mature in mosquito salivary glands before transmission to humans. Oocysts develop in between the midgut epithelial cell plasma membrane (PM) and the basal lamina of the mosquito. The outside of the oocyst is composed of two parts, including the oocyst capsule, which is the outermost layer comprised of mosquito-derived and parasite components, including laminin from the mosquito and the parasite capsule protein, CAP380. Directly under the oocyst capsule is the PM, which contains the parasite-derived circumsporozoite protein (CSP). Both CAP380 and CSP are essential for normal oocyst development in the mosquito. To study *Plasmodium falciparum* (*Pf*) oocyst development of mosquito-derived (*in vivo*) and culture-derived (*in vitro*) oocysts, we raised an antibody against *Pf*CAP380. We monitored *in vivo* oocyst development, by performing immunofluorescence assays (IFAs) on *Pf*-infected midguts using anti-*Pf*CAP380 to detect oocysts. To study *in vitro* oocyst development, we first cultured gametocytes, and then promoted *in vitro* mosquito stage development through the following stages: gamete → zygote → ookinete → oocyst. For *in vivo* oocysts, we found that *Pf*CAP380 is expressed as early as 2 days after mosquito infection and persists through day 11. We also found that CSP is expressed ~6 days after mosquito infection. Using *in vitro* methods to produce mosquito stages, we achieved high conversion of gametocyte → ookinete (24%) and ookinete → early oocyst (85%). After screening basal lamina components, we found that the combination of collagen IV, entactin, and laminin allows for greatest conversion to early oocysts. Similar to the IFA results using *in vivo*-derived oocysts, we detect *Pf*CAP380 from *in vitro*-derived oocysts as early as day 2 and persistence up to day 11. We conclude that we can produce mosquito stages of *Pf* using *in vitro* methods through the oocyst stage as determined by oocyst marker expression of *Pf*CAP380. Further *in vitro* studies focused on sporozoite production will support manufacturing of live-attenuated sporozoites for malaria vaccines.

## 1084

### ASSESSING THE IMPACT OF MALARIA AND MALARIA CONTROL INTERVENTIONS ON THE WELFARE OF THE POPULATION ON BIKO ISLAND, EQUATORIAL GUINEA

Guillermo Garcia<sup>1</sup>, Wonder Philip Phiri<sup>2</sup>, John Bradley<sup>3</sup>, Jackie Cook<sup>3</sup>, Immo Kleinschmidt<sup>3</sup>, Julie Niemczura de Carvalho<sup>1</sup>, Edward Aldrich<sup>1</sup>, Christopher Schwabe<sup>1</sup>

<sup>1</sup>Medical Care Development International, Silver Spring, MD, United States,

<sup>2</sup>Medical Care Development International, Malabo, Equatorial Guinea,

<sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The Bioko Island Malaria Control Project (BIMCP) has conducted intensive malaria control interventions on Bioko Island, Equatorial Guinea since 2005. The BIMCP has had significant success in reducing *P. falciparum* parasite prevalence in 2-14 year olds from 45% (95% CI 40%-50%) in 2004 (baseline) to 12.1% (95% CI: 11.2%-13.3%) in 2016 based on annual Malaria Indicator Survey (MIS) data. During MIS surveys, the BIMCP assessed, every 5 years, the impact of malaria and malaria control interventions on the welfare of the island's population and its effect on the poor, as measured by socio-economic status (SES) indicators. Most often, SES is calculated as a proxy using principal components assessment (PCA) which enables ranking of surveyed households. However, using PCA to measure SES provides several limitations such as: the inability to measure the absolute level of poverty in a community or changes in poverty level over time (20% of houses always remain the poorest without any knowledge of how vulnerable they are). Inter-country and inter-temporal analysis is only possible if SES indices are derived from the same asset combination (which may depend on context). Using data on expenditure and savings questions on a subset of households from 2004, 2009, and 2013 MIS data, regression analysis will be used to impute incomes for all surveyed households which also provided information on assets and ownership. Per capita income will be calculated as a proxy for household welfare, and used to rank the households into deciles. This study will examine self-reported incidence of malaria and prevalence of infection across welfare groups, and establish whether the malaria control interventions have an effect on health improvement, as well as welfare-enhancing (pro-poor), on the population of Bioko Island in Equatorial Guinea.

## 1085

### IMPLEMENTING THE GLOBAL TECHNICAL STRATEGY AT THE DISTRICT LEVEL: INDIVIDUAL CAPACITY BUILDING IN MALARIA SURVEILLANCE IN SENEGAL

Ashley Garley<sup>1</sup>, Medoune N'Diop<sup>2</sup>, Moustapha Cisse<sup>2</sup>, Yakou Dieye<sup>3</sup>, Mayassine Diongue<sup>4</sup>, El Hadj Ba<sup>5</sup>, Yazoume Ye<sup>1</sup>

<sup>1</sup>MEASURE Evaluation, ICF, Rockville, MD, United States, <sup>2</sup>National Malaria Control Program, Dakar, Senegal, <sup>3</sup>PATH Malaria Control and Elimination Partnership of Africa, Dakar, Senegal, <sup>4</sup>Institut Santé et Développement, Dakar, Senegal, <sup>5</sup>Institut de Recherche pour le Développement, Dakar, Senegal

Malaria surveillance is now a globally recognized intervention strategy to achieve pre-elimination and elimination. Senegal has adopted this strategy and recently intensified its malaria surveillance system by strengthening the capacity of the National Malaria Control Program (NMCP) to conduct surveillance supervision, case detection, case investigation, and response. In 2015, the NMCP, with support from MEASURE Evaluation, conducted a national surveillance and monitoring and evaluation (M&E) workshop to train subnational NMCP personnel in fundamental M&E concepts and practical surveillance approaches. As more districts in Senegal move toward pre-elimination and elimination, a robust malaria surveillance system, and personnel to lead it, will be essential. To date, 49 NMCP staff have completed this three-week training, learned to develop M&E plans, conducted surveillance supervision, and led case investigations. Surveillance supervisions and case detection took place in four health

facilities in the Niakhar and Fatick regions, followed by case investigations at the household level, using the focal test-and-treat and focal screening test-and-treat methods. In the coming years, the NMCP plans to train all relevant surveillance and M&E staff from the 76 health districts in malaria surveillance best practices. The NMCP anticipates leading five sessions, with two sessions per year. Success from this program may inform scale-up of capacity for malaria surveillance systems in other countries in low-transmission settings where malaria surveillance as an intervention would be beneficial.

## 1086

### CONCORDANCE OF QPCR AND MICROSCOPY FOR ENDPOINT ANALYSIS IN CLINICAL TRIALS OF ANTIMALARIAL DRUGS AND VACCINES

Emma Ballard<sup>1</sup>, Claire Wang<sup>2</sup>, Jane Gaydon<sup>2</sup>, Tran Hien<sup>3</sup>, Joel Tarning<sup>4</sup>, Louise Marquart<sup>1</sup>, Peter O'Rourke<sup>1</sup>, James McCarthy<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Herston, Australia, <sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, <sup>4</sup>Mahidol Oxford Tropical Medicine Research Unit, Mahidol University, Bangkok, Thailand

While microscopy remains the gold standard for diagnosis of malaria and for quantitation of parasite counts, it is well recognised to be less sensitive compared to qPCR (limit of detection (LOD) of ~10 vs 0.02-0.10 parasites/μL). Low sensitivity is particularly problematic in studies where the key endpoints for evaluation of candidate blood stage vaccines and antimalarial drugs are the parasite growth and clearance curves respectively, as many of the values are typically below the LOD of microscopy. Using two 18s rDNA qPCR assays, both of which had undergone external validation, we compared the equivalence of parasite counts for 357 blood samples analysed by thick film microscopy in a previously published trial undertaken in Vietnam, where parallel laboratory analyses by qPCR had been independently undertaken in Vietnam and Australia. The median and interquartile range for parasite counts by microscopy were 813 and 40-10,715 parasites/μL. Excellent intra-class correlation (>0.97) of log-transformed parasite counts for microscopy and qPCR were observed and no systematic or proportional differences by Passing-Bablok regression were observed, indicating equivalence of microscopy and the two qPCR methods. Intercepts were close to zero [0.06 (95%CI -0.18, 0.28) and -0.01 (95%CI -0.27, 0.23)] and slopes close to one [1.01 (95%CI 0.97, 1.04) and 0.97 (95%CI 0.93, 1.00)] for Vietnamese and Australian qPCR, respectively. There was a tendency for higher discrepancies between methods at low counts, where microscopy is known to be less reliable. There was close agreement in mean log-transformed parasite counts by paired t-test (difference 0.04, 95%CI -0.01, 0.10, p=0.09) between microscopy and Vietnamese qPCR, but disagreement (difference -0.25, 95%CI -0.30, -0.20, p<0.001) between microscopy and Australian qPCR, indicating lower mean parasite counts by Australian qPCR after storage, transport and additional processing of samples. We conclude that qPCR gives equivalent parasite counts and is a viable alternative method to quantitate malaria parasite counts and to estimate parasite growth and clearance rates.

## 1087

### CAPACITY BUILDING FOR VECTOR BORNE DISEASE CONTROL PROGRAM FOR THE SUB DISTRICT LEVEL SURVEILLANCE AND RAPID RESPONSE TEAM (SRRT) IN KRABI PROVINCE, THAILAND

Supawadee Pongsombat<sup>1</sup>, Nopparat Mongklangkul<sup>2</sup>, Chamnan Pinna<sup>3</sup>, James Hopkins<sup>4</sup>, Piyaporn Wangroongsarb<sup>1</sup>, Karuna Nasom<sup>5</sup>, Preecha Prempre<sup>1</sup>

<sup>1</sup>Bureau of Vector Borne Disease, Department of Disease Control, Ministry of Public Health, Thailand, <sup>2</sup>Bureau of Emerging Diseases, Ministry of Public Health, Thailand, <sup>3</sup>Tak Provincial Health Office, Tak, Thailand,

<sup>4</sup>Kenan Institute Asia, Kenan Institute Asia, Thailand, <sup>5</sup>Krabi Provincial Health Office, Krabi, Thailand

Vector borne diseases are illnesses caused by pathogens and parasites in human populations such as malaria, dengue and chikungunya fever, etc. The Bureau of Vector Borne Disease works together with partners and many different government sectors in Koh Lanta District, Krabi Province to strengthen and enhance the capacity building in the proactive surveillance system including case detection, case investigation and vector control measures for the sub district health officers called as Surveillance and Rapid Response Team (SRRT) which includes 3 sub district health promoting hospitals, 2 sub district municipality administrative organizations, 10 village health volunteers, 5 village malaria volunteers and 5 NGO workers in the sub district areas. The objective of the surveillance training program is to provide basic knowledge on malaria and vector borne diseases and to enable health personnel at sub district level to do malaria and vector borne disease surveillance, investigation, prevention and control. The results have shown that knowledge of malaria and vector borne diseases among 25 observations were in moderate level having the good practice and attitude about the vector borne disease prevention and control. The capacity building for SRRT team at sub district level is very helpful for malaria elimination and vector borne disease control program. This will be useful for the SRRT to do case investigation and control diseases effectively and also transfer the knowledge to health personnel and villagers for effective prevention and control of vector borne diseases in the near future.

## 1088

### LESSONS LEARNED: MALARIA CASE MANAGEMENT TRAINING COMMUNITY IN MADAGASCAR

Razanakotomalala Voahangy

National Malaria Control Program, Antananarivo, Madagascar

In Madagascar the scaling up of malaria management through the IMCI approach, complementary to that applied in health facilities, stipulated in the National Strategic Plan, was effective in 2012. Community health workers have been trained. To help improve the quality of service and care at the community level, the Malaria Control Branch with the support of OMS to upgrade these community workers in district of Vatomandry in 2017. A training day for community health workers on the management of malaria cases was conducted in the six targeted communes: Tsiangina, Ifasina, Niarovana, Ilaka East, Ambodivoananto and Ampasamadinika. The training focused on the quality of diagnosis with the practice of TDR and treatment with Artesunate-Amodiaquine. Participants were assessed using pretests and posttests to assess knowledge gains on case management. Of the 134 participants, 66.5% were women and 33.5% were men. Overall, 89% of participants stated that the training met their expectations. 72% of participants in Tsiangina improved their knowledge and skills after training - with an average increase of 13 percentage points between pretest and posttest. Similarly, 70% of participants in Ifasina increased their scores by an average of 8 percentage points, 50% of participants in Niarovana increased their scores by an average of 6 percentage points, 50% of participants in Ilaka Est increased their scores by an average of 6 increased their scores by an average, 71% of participants in Ambodivoananto increased their scores by an average of 11 percentage points and 40% of participants in Ampasamadinika increased their scores by an average of 4 percentage points. Average pre and posttest scores were 54% à 67% pour Tsiangina, 56% à 64% for Ifasina; 58% à 64% for Niarovana et 58% à 64% for Ilaka Est. 53% à 64% for Ambodivoananto. 62% à 66% for Ampasamadinika. Participants will use the knowledge gained from this training to improve the quality of diagnostic and treatment in their communities, aimed at reducing malaria related morbidity and mortality rate in remote areas of Madagascar.

## 1089

### CLINICAL AND LABORATORY PREDICTORS OF DEATH IN AFRICAN CHILDREN WITH FEATURES OF SEVERE MALARIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Paulina Sypniewska<sup>1</sup>, Jose Duda<sup>2</sup>, Isabella Locatelli<sup>1</sup>, Clotilde Rambaud Althaus<sup>3</sup>, Fabrice Althaus<sup>2</sup>, Blaise Genton<sup>1</sup>

<sup>1</sup>University of Lausanne, Lausanne, Switzerland, <sup>2</sup>International Committee of the Red Cross, Geneva, Switzerland, <sup>3</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

The criteria for defining severe malaria have evolved over the last 20 years. We aimed at assessing the strength of association of death with features currently characterizing severe malaria by using a systematic review and meta-analysis. Electronic databases (Medline, Embase, Cochrane Database of Systematic Reviews, Thomson Reuters Web of Knowledge) were searched to identify publications including African children with severe malaria. PRISMA guidelines were followed. Selection was based on: design (epidemiological, clinical and treatment studies), setting (Africa), participants (children <15 years with severe malaria), outcome (survival/death rate), and prognostic indicators (clinical and laboratory features). Quality assessment was performed following the criteria of the 2011 Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2). Odds ratios (ORs) were calculated for each study and prognostic indicator, and when a test was assessed in at least two studies, pooled estimates of ORs were computed using fixed- or random-effects meta-analysis. 601 articles were identified and screened and 30 publications were retained. Features with the highest pooled ORs were: renal failure (5.96 [2.93-12.11]), coma score (4.83 [3.11-7.5]), hypoglycemia (4.59 [2.68-7.89]), shock (4.31 [2.15-8.64]), and deep breathing (3.8 [3.29-4.39]). Only half of the criteria had an OR > 2. Features with the lowest pooled ORs were: impaired consciousness (0.58 [0.25-1.37]), severe anemia (0.76 [0.5-1.13]), and prostration (1.12 [0.45-2.82]). The findings of this meta-analysis show that the strength of association between the criteria defining severe malaria and death is quite variable from one to the other clinical and/or laboratory features (OR ranging from 0.58-5.96). This ranking allowed identifying features weakly associated with death, such as impaired consciousness and prostration, which could assist in refining case definitions, and hence optimize antimalarial treatment.

## 1090

### POVERTY CONSTRAINS BED NET USE AMONG ETHNIC MINORITIES IN CENTRAL VIETNAM

Ikumi Sawada<sup>1</sup>, Melanie Bannister-Tyrell<sup>2</sup>, Nguyen Xuan Xa<sup>3</sup>, Joan Muela<sup>4</sup>, Susanna Hausmann-Muela<sup>5</sup>, Pham Vinh Thanh<sup>3</sup>, Nguyen Van Hong<sup>3</sup>, Nguyen Van Van<sup>6</sup>, Tran Thanh Duong<sup>3</sup>, Charlotte Gryseels<sup>7</sup>, Umberto D'Alessandro<sup>8</sup>, Annette Erhart<sup>7</sup>, Koen Peeters Grietens<sup>7</sup>

<sup>1</sup>Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, <sup>2</sup>Department of Public Health, Institute of Tropical Medicine, Antwerp, Belgium, <sup>3</sup>National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, <sup>4</sup>University Ramon i Virgili, Tarragona, Spain, <sup>5</sup>Partners for Applied Social Sciences, PASS International, Tessenlo, Belgium, <sup>6</sup>Provincial Malaria Station, Quang Nam, Vietnam, <sup>7</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>8</sup>Medical Research Council Unit, Fajala, Gambia

Malaria in impoverished ethnic groups in remote forested areas is a challenge for malaria elimination in Vietnam. It is important to understand what factors influence their actual usage of long-lasting insecticidal nets (LLINs). This study aimed to assess constraints to LLIN use in an ethnic minority. Between April 2009 and January 2011, an anthropological study, using a mixed-method exploratory design, was carried out in four remote villages of the M'nonng and Ca Dong ethnic minority in central Vietnam. The qualitative strand was carried out to assess structural socio-cultural factors impacting on the bed net use and exposure to malaria. The quantitative strand was administered in one of the four villages to quantify

the ownership and the utilization of LLINs. One-hundred-forty-one people from 80 households participated in the quantitative strand. Poverty and the related harsh living conditions were the important constraints to the regular use of LLINs. (i) Residence patterns. 71% of households had multiple residences, consisting of a village house and a plot hut on their farmland. Homes located at farms in the forest are not taken into consideration in the LLIN distribution program, leading the reported shortage of LLINs. (ii) Housing and the social use of space. LLINs get easily torn due to bamboo construction materials, children using them to play and chickens kept indoors. Due to harsh climate conditions and poor housing structure, they traditionally sleep around the kitchen fire (60% of households), leading to low use of LLINs as nets can catch fire. The humid cold and the lack of good support to hang nets led to the use of nets as blankets (92%) especially during the rainy season despite 83% stating to use the nets. Perceived etiology. Effective bed net use was further limited by a lack of understanding of malaria etiology. In addition to the relevance of knowledge on malaria etiology and other sociocultural factors, poverty-related factors were the main constraints to bed net use. They cannot be overcome by traditional campaigns and require more trans-disciplinary approaches to health care.

## 1091

### ANALYSIS OF LLIN USE IN INFORMAL KORANIC RESIDENTIAL SCHOOLS OF DAROU MOUSTY HEALTH DISTRICT, SENEGAL

Adama Faye<sup>1</sup>, Mamadou Diongue<sup>2</sup>, Seynabou Gaye<sup>3</sup>, Anta Tal Dia<sup>1</sup>

<sup>1</sup>Health and Development Institute, Cheikh Anta Diop University, Dakar, Senegal, <sup>2</sup>Darou Mousty Health District, Ministry of Health and Social Action, Dakar, Senegal, <sup>3</sup>National Malaria Control Program, Dakar, Senegal

The use of long lasting insecticidal nets (LLIN) has not achieved targets in Senegal despite the efforts made by the Government through National Malaria Control Program (NMCP) and partners to ensure availability, including campaigns of mass distribution to target every sleeping space, availability through routine channels, and communication campaigns. Students (talibés) of the residential Koranic schools (dahras) are a population at high risk for severe malaria, and have particularly poor LLIN access and use. The living conditions in dahras are often favorable to malaria transmission. We studied the determinants associated with the use of LLIN in the dahras of one health district. A cross-sectional, descriptive and analytical study of talibés and their teachers (marabouts) was conducted in the health district of Darou Mousty, in the North, which hosts many dahras. The data were collected at the level of the dahras using a questionnaire for individual interview after informed consent, for both talibés and marabouts. The data included socio-demographic, environmental, knowledge of malaria, LLINs, and other protective measures. They were entered and analyzed using EPI INFO software version 3.5.3. A total of 400 talibés and 40 marabouts were enrolled. The mean age of the talibés was 10.7 +/- 2.6 years; males outnumbered females by 15.7 fold. The proportion of talibés not schooled in french was 90.2%. The rate of utilization of the LLIN of 33.9%. The use of the LLIN was positively correlated to knowledge of the talibés of the utility of LLIN (OR = 2.7, CI = [1.5 - 4.6]), knowledge of the mode of malaria transmission (OR = 1.8; CI = [1.0 - 3.3]), the age of the talibés in the dahra (p = 0.03) and female sex (OR = 10, CI = [1.4-25], P = 0.0029), and negatively correlated with the number of talibés per sleeping space (OR = 0.5; CI = [0.3 - 0.8]). The use of LLIN in dahras requires improving the knowledge of the talibés and marabouts on malaria and LLIN, ensuring that dahras are included in mass LLIN distributions for equitable access throughout Senegal. This strategy require the support of all partners intervening with the vulnerable population.

## ASSESSMENT OF DATA USE FOR MALARIA PROGRAM DECISION MAKING IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Olivier M. Kakesa

*MEASURE Evaluation, Kinshasa, Democratic Republic of the Congo*

The use of data and information to guide policy and program implementation is critical to successfully reaching intervention targets. However, most national malaria control programs and departments of health information systems in malaria endemic countries face challenges to data use, particularly at the subnational level. The USAID-funded MEASURE Evaluation project conducted an assessment in the Democratic Republic of the Congo (DRC) to identify how data are being used for decision making and how future interventions can be designed to promote data demand and use for decision making. The assessment was conducted at the national level and at the provincial level in Haut Katanga, Kinshasa, and Lualaba. The methodology comprised individual interviews, a group assessment, and a site visit checklist to look at technical, organizational, and behavioral determinants of data use. The assessment gave insight into the main barriers preventing data use for decision making among the national and provincial teams. For example, most of the 38 participants acknowledged that they are not using data for decision making, because of data quality concerns. These findings paved the process for strategic action planning to overcome these barriers and, ultimately, to improve the culture of data use. Participants prioritized three key programmatic questions to answer with data in the two months following the assessment. They were also encouraged to use action plans to delegate tasks and responsibilities and to produce timelines for these activities to ensure completion. The assessment process increased participants' commitment to the data use cycle—in which data use improves quality, which in turn leads to further use. These activities will launch the data use cycle in the DRC and are anticipated to lead to better quality data.

## CYP2D6 POLYMORPHISMS INVOLVED IN PRIMAQUINE TREATMENT OUTCOME OF MALARIA PATIENTS

Vy Tuong Nguyen, Quyen Than Nguyen, Hien Tinh Tran, Thuy-Nhien Nguyen

*Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam*

Malaria is life-threatening disease caused by *Plasmodium* parasites. *Plasmodium vivax* is the second common cause of malaria after *Plasmodium falciparum*. The presence of hypnozoites is reported to cause relapse after the initial attack for up to about 2 years. Primaquine, which is the FDA approved drug, has been used for treatment relapse and against hypnozoite. However, relapse of *P.vivax* due to drug failure still occurs. Human cytochrome P450 isoenzyme 2D6 (CYP2D6) is a highly polymorphic gene involved in the metabolism of numerous drugs. Common CYP2D6 genetic variants affect enzymatic function resulting in a wide range of enzyme activity from ultrarapid to no metabolism. Recent reports have shown that CYP2D6 may be a key enzyme involved in metabolizing primaquine into redox-active metabolites to against hypnozoite. To determine the relationship between CYP2D6 genotypes and relapse of *P. vivax* in patients in Vietnam, the CYP2D6 genotypes were determined by Luminex assay and using the activity score to predict CYP2D6 phenotypes. Data was available on 92 patients treated with primaquine, in which there were 28 recurrent cases. Preliminary results have shown that CYP2D6\*10, which is a reduced function allele, have a high frequency at about 52.6%, and frequency of the non-functional alleles represent about 8% with CYP2D6\*4, \*5. Among the 92 patients, 38 (41.3%) were classified as intermediate metabolizer (IM), 47 (51.1%) as extensive metabolizer (EM), 1 (1.1%) as poor metabolizer and the last one was ultra-rapid extensive metabolizer. Out of 28 recurrent patients, CYP2D6 phenotype was observed at frequency with 42.9% IM and 50% EM. However, the sample size in the clinical trial was limited. So there

was not significantly different between non-relapsed group and relapsed group with the level of the CYP2D6 enzyme activity on primaquine treatment. Larger sample size is necessary to explain primaquine treatment failure cases. The CYP2D6-Primaquine interaction will help to understand the rates of primaquine failures and to improve the overall effect of anti-relapse therapies such as the different primaquine dosages and combination of other drugs.

## FACTORS INFLUENCING UTILIZATION OF ANTIMALARIALS IN NIGERIA

Chinazo N. Ujuju<sup>1</sup>, Adekunle Akerele<sup>2</sup>, Olufemi Ajumobi<sup>2</sup>

<sup>1</sup>*Society for Family Health, Abuja, Nigeria*, <sup>2</sup>*African Field Epidemiology Network, Abuja, Nigeria*

Globally, the use of artemisinin - based combination therapy (ACT) has contributed significantly to the reduction in malaria-related morbidity and mortality. In 2005, Nigeria adopted ACT as the first line treatment for uncomplicated malaria and the availability of ACTs in both public and private sectors has increased over time. It is assumed that the effectiveness of ACTs coupled with its increased availability would result in reduced utilisation of non-recommended antimalarials (NRA). This outcome is most desired as NRA act as potential triggers for development and spread of antimalarial drug resistance. As mothers and health providers play a crucial role in the treatment provided to children under- five (U5), this paper seeks to determine mothers' individual factors, influence of source of antimalarials and information on the use of ACTs and NRA in Nigeria. Secondary data analysis of 2013 Nigeria Demographic Health Survey was conducted. The outcomes were use of ACTs and NRA for malaria treatment in U5 in both public and private sectors. Explanatory variables include mother's age, marital status, education, and residence. Overall, 49.1% of mother sought antimalarial treatment from the private sector, 39.9% in public sector while 9.9% administered antimalarials without seeking treatment. Overall, 27.8%, 25.6% and 17.8% of mothers administered Chloroquine (CQ), Sulphadoxine-pyrimethamine (SP) and ACTs respectively. Mother of U5 living in the rural area, married and younger mothers were less likely to use ACTs in the public sector while mothers with secondary (OR: 2.1; 95% CI: 1.5-5.0) and higher level of education (OR:4.3; 95% CI: 1.4-13.0) were more likely to use ACTs in the private sector. Watching television was significantly associated with use of ACT in the private sector (OR:2.3;95% CI:1.2-4.3). This study revealed low use of ACTs especially in rural areas, and increased use of CQ and SP. Ensuring availability of affordable ACTs for rural populace and phasing out NRA in Nigeria are recommended. Mothers who do not seek care before antimalarial treatment should be targeted for media messages on ACT.

## REAL-TIME COMMUNITY SURVEILLANCE FOR MALARIA CONTROL IN MADAGASCAR

John Yanulis<sup>1</sup>, Andritiana Tsarafihavy<sup>1</sup>, Mamy Tiana Andrianarilala<sup>1</sup>, Aishling Thurow<sup>2</sup>, Jocelyn Razafindrakoto<sup>3</sup>, Laurent Kapesa<sup>3</sup>, Brune Estelle Ramiranirina<sup>4</sup>, Elke Konings<sup>2</sup>

<sup>1</sup>*U.S. Agency for International Development Mikolo, Antananarivo, Madagascar*, <sup>2</sup>*Management Sciences for Health, Medford, MA, United States*, <sup>3</sup>*President's Malaria Initiative, Antananarivo, Madagascar*, <sup>4</sup>*National Malaria Control Program, Antananarivo, Madagascar*

While malaria is endemic in Madagascar, the potential for outbreaks is high. Early identification of these outbreaks is critical for initiating an effective response, including case management and supply forecasting to prevent shortages of commodities for diagnosing and treating cases. However, the traditional surveillance system relies on hand-written reports, which results in delays. In order to improve timely reporting, the USAID Mikolo Project created a real-time community surveillance tool. Beginning in 2014, the Project customized District Health Information System (DHIS2) database software for epidemiological surveillance data collected

by Community Health Volunteers (CHVs). Technical assistants support CHVs in the 8 project regions to collect their monthly paper reports, and enter their data into DHIS2 using tablets. Data includes case information (location, demographics, rapid diagnostic test [RDT] results) and the availability of RDTs and artemisinin-based combination therapy (ACT). The data is reviewed by Project staff monthly; when a surge in malaria cases, or shortages of RDT and/or ACT are observed, the Ministry of Health's (MOH) malaria unit is notified. In March 2016, the tool enabled Project staff to identify a surge of confirmed (RDT-positive) cases in children under 5 (CU5)-- from 14,410 in December 2015 to 18,340 in March 2016 across 8 regions. MOH staff were notified, and resources were mobilized. As a result, the number of confirmed malaria cases treated with ACTs by CHVs increased from 71% in March 2016 to 82% by September 2016, and stock-outs of ACTs decreased from 23% to 9% during the same time period. There were 202,520 confirmed malaria cases in CU5 throughout 2015, compared with 109,028 cases in 2016, which represents a 45% decrease in malaria cases. USAID Mikolo's DHIS-2 data collection system allowed for real-time community surveillance which was used to alert the MOH about an increase in malaria cases, enabling them to mobilize partners and respond to the outbreak. Rapid response facilitated stock management, and may have resulted in more rapid treatment of confirmed cases and limiting of the outbreak impact.

## 1096

### REPORTED COMMUNITY-LEVEL INDOOR RESIDUAL SPRAY COVERAGE FROM 2-STAGE CLUSTER SURVEYS IN SUB-SAHARAN AFRICA

**David A. Larsen**, Lauren Borrill, Ryan Patel, Lauren Fregosi  
*Syracuse University, Syracuse, NY, United States*

Malaria is an important cause of morbidity and mortality in malaria-endemic areas. Indoor residual spray (IRS) is an effective intervention to control malaria, but high community-level coverage is needed to maximize its impact. We used lot quality assurance sampling to estimate IRS coverage at the enumeration level across sub-Saharan Africa since 2010. Thirty-four 2-stage cluster surveys were identified and included in the analysis. IRS coverage was defined as <50%, 50-75%, 75-85% and >85%. For enumeration areas receiving IRS a logistic regression predicted whether enumeration-area coverage exceeded 50% or not. Household-level coverage with IRS was equitable both in terms of wealth and urban/rural, with poorer and rural houses more likely to be sprayed than richer and urban houses. Coverage of indoor residual spray at the community level, however, was poor across the continent, with 54% of enumeration areas reportedly receiving the intervention not reaching 50% coverage threshold. Having > 50% coverage at the enumeration area was not associated with increased number of houses sprayed in the country. Implementation and monitoring of indoor residual coverage at small geographical scales need to improve greatly to receive maximum benefit of this costly intervention.

## 1097

### PROVIDER ORIENTATION TO MALARIA CASE MANAGEMENT GUIDELINES IN REGIONAL HOSPITALS

**Moumouni Bonkougou**, Ousmane Badolo, Thierry Ouedraogo  
*Jhpiego/Improving Malaria Care (IMC) Project, Ouagadougou, Burkina Faso*

Malaria remains the leading cause of consultations, hospitalization and death in health facilities in Burkina Faso. In 2015, 23,634 cases of severe malaria were recorded in hospitals with 1,634 deaths, a mortality rate of 7% at this level compared to 1% nationally. Since April 2014, 1,819 providers from 49 districts have been trained in malaria case management, specifically at the first level (health center - CSPS). Conversely, at referral centers - medical centers with surgical units (CMA), regional hospitals (CHR) and university hospitals (CHU) - providers are not well educated on the new WHO guidelines for malaria prevention and case management. This situation led the United States Agency for International Development-

supported Improving Malaria Care (IMC) project and the National Malaria Control Program (NMCP) to organize orientation sessions for providers in 8 CHR in September 2016. The sessions were conducted by trainers at the national level, supported by clinicians from hospitals including pediatricians and gynecologists. A total of 298 health workers were oriented, including 24 physicians, 157 nurses, 56 midwives, as well as pharmacists and laboratory technicians. 39% of participants were female and 43% have less than 5 years of service in these hospitals. The sessions have provided participants with an opportunity to familiarize themselves with the new guidelines for malaria prevention and case management. The orientations have also made it possible to identify the difficulties encountered by referral structures in malaria case management, which include: insufficient staff, inadequate capacity building, no blood bank in some hospitals, reagent stock-outs, inadequacies in the referral system, and insufficient equipment. To address these difficulties, staff redeployment, internal supervision, development of tools to monitor reagents stocks have been proposed. To move forward, response plans for the period of high malaria transmission is expected to be developed for these referral facilities.

PfSPZ Vaccine is a candidate pre-erythrocytic malaria vaccine composed of radiation-attenuated, aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) NF54 sporozoites (SPZ). In trials in the U.S. and Africa, PfSPZ Vaccine administered by direct venous inoculation (DVI) provided durable protection against heterologous strains and heterogeneous populations of Pf for at least 24 to 33 wks. A second PfSPZ-based vaccine approach - administration of low doses of non-irradiated, infectious NF54 PfSPZ (PfSPZ Challenge) under chloroquine chemoprophylaxis (PfSPZ-CVac) - protected against homologous strains of Pf in the U.S. and Europe for at least 10 wks, but had not been tested in Africa. We conducted a randomized, double blind placebo-controlled trial comparing tolerability, safety, immunogenicity and efficacy against controlled human malaria infection (CHMI) of PfSPZ Vaccine versus PfSPZ-CVac in healthy malaria-exposed Equatoguinean 18 to 35-year-old men and women. We randomized 26 subjects to receive 3 doses of 2.7x10<sup>6</sup> PfSPZ (PfSPZ Vaccine) or placebo at 0, 8 and 16 wks, and 24 subjects to receive 3 doses of 1x10<sup>5</sup> PfSPZ (PfSPZ Challenge) or placebo at 0, 4 and 8 wks after an oral dose of chloroquine (CQ) 600 mg base then CQ 300 mg base weekly (PfSPZ-CVac), followed in both groups by homologous CHMI at 10-13 wks post final vaccine dose. Adverse events (AEs) were solicited for 7 days and surveillance for unsolicited AEs done for 28 days after each vaccination. Monitoring for serious AEs was done throughout. Hematologic, renal and hepatic tests were done at baseline, 2 and 14 days after each vaccination, and prior to CHMI. Blood samples for humoral and cellular immunology were taken at

baseline and 14 days after each vaccination. Both vaccine approaches were well-tolerated, and DVI was typically straightforward with only mild pain associated with injection. Safety, immunogenicity and efficacy data will be presented. This comparison of PfSPZ Vaccine and PfSPZ-CVac will provide more information as to which product could be used in mass vaccination programs aimed at regional elimination of malaria. (ClinicalTrials.gov number, NCT02859350)

## 1099

### SAFETY, TOLERABILITY AND IMMUNOGENICITY OF PFSPZ VACCINE IN EQUATOGUINEAN CHILDREN AND OLDER ADULTS

<sup>1</sup>Ministry of Health, Equatorial Guinea, Malabo, Equatorial Guinea, <sup>2</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>3</sup>Sanaria Inc., Malabo, Equatorial Guinea, <sup>4</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>5</sup>Sanaria Inc., Rockville, MD, United States, <sup>6</sup>Medical Care Development International, Bath, ME, United States, <sup>7</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>8</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

PfSPZ Vaccine is a candidate pre-erythrocytic malaria vaccine composed of aseptic, purified, live (metabolically active), radiation-attenuated, cryopreserved *Plasmodium falciparum* (Pf) NF54 sporozoites (SPZ). In trials in the U.S. and Africa, PfSPZ Vaccine administered by direct venous inoculation (DVI) to young adults proved safe and well-tolerated, and provided durable protection against homologous and heterogenous populations of Pf for at least 24 to 33 weeks. PfSPZ Vaccine has undergone limited testing in children in Tanzania and an ongoing trial in Kenya, but has not previously been tested in older adults. Since the eventual goal is to use PfSPZ Vaccine in mass vaccination programs for malaria elimination in specified geographical areas, it is necessary to test the vaccine in all age groups. As part of a larger randomized, double blind placebo-controlled trial, we evaluated the safety, tolerability, and immunogenicity of PfSPZ Vaccine in 62 healthy malaria-exposed Equatoguinean children and older adults. We randomized 15 adults age 36-65 years to receive 3 doses of 2.7x10<sup>6</sup> PfSPZ of PfSPZ Vaccine, and 16 children age 11-17 years, 16 children age 6-10 years, and 15 children age 1-5 years to receive 3 doses of 1.8x10<sup>6</sup> PfSPZ, or placebo at 0, 8 and 16 weeks. A sentinel group of 3 subjects was vaccinated one day prior to the rest of each age cohort. Age de-escalation was done sequentially in children, with safety data evaluated by an external data and safety monitoring board before progressing to the youngest group. Adverse events (AEs) were solicited for 7 days and surveillance for unsolicited AEs done for 28 days after each vaccination. Monitoring for serious AEs was done throughout. Hematologic, renal and hepatic tests were done at baseline, 2 and 14 days after each vaccine dose. Blood samples for immunologic assays were taken prior to and 14 days after each vaccine dose, and at 4 and 20-24 weeks after the final vaccine dose. The vaccine was well-tolerated in all age groups, and DVI was generally straightforward with only mild pain associated with injection. Safety and immunogenicity data will be presented. (ClinicalTrials.gov number, NCT02859350)

### SAFETY, FEASIBILITY AND TOLERABILITY OF RADIATION ATTENUATED *PLASMODIUM FALCIPARUM* SPOOROZOITE (PFSPZ) VACCINE ADMINISTERED BY DIRECT VENOUS INOCULATION TO HEALTHY CHILDREN AND INFANTS 5 MONTHS THROUGH 9 YEARS OF AGE IN WESTERN KENYA

**Martina Oneko**<sup>1</sup>, Yego R. Cherop<sup>1</sup>, Kephas Otieno<sup>1</sup>, Tony Sang<sup>1</sup>, Dorcas Akach<sup>1</sup>, Mary J. Hamel<sup>2</sup>, Aaron M. Samuels<sup>2</sup>, Simon Kariuki<sup>1</sup>, Julie Gutman<sup>2</sup>, Ginnie Abarbanell<sup>3</sup>, Kim B. Lee Sim<sup>4</sup>, Peter F. Billingsley<sup>4</sup>, Thomas L. Richie<sup>4</sup>, Stephen L. Hoffman<sup>4</sup>, Robert A. Seder<sup>5</sup>, Laura Steinhart<sup>2</sup>

<sup>1</sup>KEMRI/ICGHR, Kisumu, Kenya, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Children's Healthcare of Atlanta, Atlanta, GA, United States, <sup>4</sup>Sanaria, Rockville, MD, United States, <sup>5</sup>National Institutes of Health, Bethesda, MD, United States

A highly effective vaccine is needed to reduce the burden of malaria among African children. PfSPZ Vaccine is a pre-erythrocytic vaccine candidate composed of radiation-attenuated, aseptic, purified, cryopreserved *Plasmodium falciparum* sporozoites administered by direct venous inoculation (DVI). We conducted an age de-escalating, dose escalating, randomized, double-blind, placebo-controlled trial to assess safety, tolerability, and feasibility of one or two doses of PfSPZ Vaccine in children residing in Siaya County, western Kenya. From July to November 2016, we enrolled children in three age groups (5-9 years, 13-59 months, 5-12 months), and vaccinated with doses of 1.35/2.7/4.5/9.0/18.0 x 10<sup>5</sup> PfSPZ or placebo. Each age-dose group consisted of 8 vaccine and 4 placebo recipients. Two vaccinations, 8 weeks apart, were administered to those receiving the two highest doses. DVI success rate was recorded. Safety and tolerability were evaluated through daily visits for 5 days post vaccination and on days 8 and 29. We performed 233 vaccinations on 165 participants, including 9 partial vaccinations in children <5 years. There were no Grade 3 related adverse events (AEs), laboratory abnormalities, or significant electrocardiogram changes post vaccination. We noted possibly to definitely related solicited local and systemic AEs (Grade 1/2) during 7 days post vaccination in 20.6% and 10.3% of participants, respectively, and possibly related unsolicited AEs (Grade 1) during 28 days in 6.1% of participants; all resolved. All new day 8 post-vaccination Grade 1/2 laboratory abnormalities resolved. Three serious AEs were related to incident malaria infection, and one grade 3 AE to a blood draw; all resolved. 156 children received the full vaccine dose: 91.5%, 81.6%, and 75.3% in the 5-9 year, 13-59 month, and 5-12 month age groups, respectively, were vaccinated on first injection. Unblinded data will be presented. DVI with PfSPZ Vaccine was tolerable, safe and feasible in children and infants. These data provided the foundation for an ongoing phase 2 trial of PfSPZ Vaccine to assess safety, immunogenicity, and efficacy in 5-12-month-olds in Siaya.

Direct venous injection (DVI) of aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) NF54 sporozoites (SPZ) (Sanaria® PfSPZ

Challenge (NF54) mimics controlled human malaria infection (CHMI) by mosquito bite. Development of additional strains for CHMI by DVI would facilitate vaccine and therapeutics testing against representative parasitic strains circulating in nature that are heterologous to vaccine strains. Pf7G8 is a Brazilian clone with a divergent genomic sequence from PfNF54. We conducted a double blind, randomized, dose escalation study to assess the infectivity PfSPZ Challenge (7G8) administered by DVI. We randomized 30 malaria-naïve adults to five groups. Four groups received escalating doses of PfSPZ Challenge (7G8) (800, 1600, 3200 and 4800 PfSPZ) and one group received standard dose PfSPZ Challenge (NF54) that infects 100% of malaria-naïve individuals (3200 PfSPZ). We monitored participants daily for symptoms. Daily quantitative polymerase chain reaction (qPCR) testing for parasite RNA and DNA determined malaria patency. Participants tolerated injections well. Only mild local post-injection reactogenicity was recorded (12/30 participants), and only one participant (NF54 group) experienced fever due to malaria before diagnosis and treatment initiation with atovaquone/proguanil. Infectivity of PfSPZ Challenge (7G8) was dose-dependent: 43% (800 PfSPZ; n=7; 95% CI 10-82); 57% (1600 PfSPZ; n=7; 95% CI 18-90); 89% (3200 PfSPZ; n=9; 95% CI 52-100); and 100% (4800 PfSPZ; n=2; 95% CI 48-100); Pearson correlation coefficient = 0.98. All five participants who received PfSPZ Challenge (NF54) developed Pf parasitemia. PfSPZ Challenge (7G8) administered by DVI was well tolerated by malaria-naïve adults. Higher doses of PfSPZ may be required to ensure 100% infectivity of Pf7G8 compared to PfNF54. Additional studies of other Pf strains are needed to confirm the infective dose for each. The availability of multiple Pf strains of diverse geographic origin will greatly aid clinical development of candidate malaria vaccines to inform heterologous efficacy and dose optimization.

## 1102

### SAFETY AND TOLERABILITY OF A METABOLICALLY ACTIVE, NON-REPLICATING, WHOLE ORGANISM MALARIA VACCINE IN MALARIA-EXPERIENCED ADULTS IN BURKINA FASO

**Matthew B. Laurens**<sup>1</sup>, Alphonse Ouédraogo<sup>2</sup>, Alfred B. Tiono<sup>2</sup>, J. M. Kaboré<sup>2</sup>, Edith C. Bougouma<sup>2</sup>, N. I. Ouédraogo<sup>2</sup>, Peter F. Billingsley<sup>3</sup>, Anita Mano<sup>3</sup>, Yonas Abebe<sup>3</sup>, Thomas L. Richie<sup>3</sup>, Eric R. James<sup>3</sup>, Kirsten E. Lyke<sup>1</sup>, Christopher V. Plowe<sup>1</sup>, B. K. Sim<sup>3</sup>, Stephen L. Hoffman<sup>3</sup>

<sup>1</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>3</sup>Sanaria, Inc., Rockville, MD, United States

*Plasmodium falciparum* sporozoite (PfSPZ) Vaccine is a metabolically active, non-replicating, whole malaria sporozoite vaccine with an extremely favorable safety profile that is protective against *P. falciparum* controlled human malaria infection in malaria-naïve individuals. A recent clinical trial demonstrated 52% protection by time to event and 29% protection by proportional analysis against naturally occurring infection in Malian adults receiving five doses of 2.7 x 10<sup>5</sup> PfSPZ. We aimed to assess the safety and protective efficacy of higher doses of PfSPZ Vaccine against naturally acquired Pf in malaria-experienced adults in Burkina Faso. We conducted an open-label dose escalation study in four cohorts of eight participants who received two vaccinations at 12-14 week intervals. Vaccine dose increased from 4.5 x 10<sup>5</sup> to 9 x 10<sup>5</sup> to 1.8 x 10<sup>6</sup> to 2.7 x 10<sup>6</sup> PfSPZ in a step-wise manner after safety and tolerability assessments. Data Safety and Monitoring Board (DSMB) members conducted reviews after the first dose of 2.7 x 10<sup>6</sup> PfSPZ, and after the first four cohorts received dose two. All 32 participants received two vaccinations except for one participant in the 1.8 x 10<sup>6</sup> PfSPZ dose group who was lost to follow-up. No participant experienced local solicited symptoms after either vaccination. Only two clinical laboratory abnormalities were noted after vaccination, both deemed related to other causes—mild ALT elevation in one participant and moderate anemia in another. No related grade two or three adverse events were recorded through Day 56 following second vaccination, and only eight mild grade 1 adverse events were noted. The vaccine demonstrated a favorable safety and tolerability profile at all doses tested. At the DSMB's

astmh.org

recommendation, recruitment and vaccination of a fifth cohort of 80 individuals occurred in early 2017. This double-blinded part of the study randomized participants to receive three doses of either 2.7 x 10<sup>6</sup> PfSPZ Vaccine or normal saline placebo. We will assess overall and strain-specific efficacy against malaria infection during the malaria transmission seasons in 2017 and 2018.

## 1103

### HOMOLOGOUS AND HETEROLOGOUS PRIME BOOST VACCINATIONS WITH DISTINCT VARIANTS OF PLASMODIUM VIVAX CIRCUMSPOROZOITE PROTEIN (CSP) PROTECTS MICE AGAINST TRANSGENIC PB/PV SPOOROZOITE CHALLENGE

Françoise<sup>1</sup>, Oscar Bruna-Romero<sup>3</sup>, Hildegund C. Ertl<sup>4</sup>, Ruth S. Nussenzweig<sup>5</sup>, Victor Nussenzweig<sup>5</sup>, Maurício M. Rodrigues<sup>2</sup>, Arturo Reyes-Sandoval<sup>6</sup>, **Irene S. Soares**<sup>1</sup>

<sup>1</sup>University of São Paulo, Sao Paulo, Brazil, <sup>2</sup>Federal University of São Paulo, Sao Paulo, Brazil, <sup>3</sup>Federal University of Santa Catarina, Florianópolis, Brazil, <sup>4</sup>The Wistar Institute, Philadelphia, PA, United States, <sup>5</sup>New York University School of Medicine, New York, NY, United States, <sup>6</sup>University of Oxford, Oxford, United Kingdom

Vaccine development against *Plasmodium vivax* malaria lags behind that for *Plasmodium falciparum*. To narrow this gap, we administered recombinant antigens based on *P. vivax* circumsporozoite protein (CSP) to mice. We expressed two novel soluble chimeric proteins by merging the three central repeat regions of different CSP alleles (VK210, VK247, and *P. vivax*-like). The first construct (yPvCSP-AllFL) contained the fused repeat regions flanked by N- and C-terminal regions. The second construct (yPvCSP-AllCT) contained the fused repeat regions and the C-terminal domain only. We generated replication-defective adenovirus vectors expressing CSP of human serotype 5 (AdHu5) and chimpanzee serotype 68 (AdC68). Mice were vaccinated with three doses of yPvCSP in adjuvants Poly (I:C) or Montanide ISA720, or with a regimen of a primary AdHu5 or AdC68 immunization followed by two immunizations with yPvCSP in adjuvant. Regardless of the adjuvant used, mice immunized with yPvCSP-AllFL or yPvCSP-AllCT generated high IgG titres specific to all CSP alleles. After challenge with *P. berghei* ANKA transgenic parasites expressing Pb/PvVK210 or Pb/PvVK247 sporozoites, significant time delays for parasitemia were observed in all vaccinated mice. These vaccine formulations should be clinically tried for their potential as protective universal vaccine against *P. vivax* malaria.

## 1104

### PFSPZ VACCINE INDUCES T CELL RESPONSES TO SPOOROZOITES AND FOUR MALARIA ANTIGENS

**Harini Ganeshan**<sup>1</sup>, Maria Belmonte<sup>1</sup>, Jun Huang<sup>1</sup>, Arnel Belmonte<sup>1</sup>, Sandra Inoue<sup>1</sup>, Rachel Velasco<sup>1</sup>, Michael Hollingdale<sup>1</sup>, B. Kim Lee Sim<sup>2</sup>, Eileen Villasant<sup>1</sup>, Judith Epstein<sup>1</sup>, Stephen L. Hoffman<sup>2</sup>, Martha Sedegah<sup>1</sup>

<sup>1</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>2</sup>Sanaria, Inc., Rockville, MD, United States

T cell responses to multiple *Plasmodium falciparum* (Pf) antigens are thought to mediate protection induced by PfSPZ Vaccine. PBMCs from subjects immunized with 3- and 5-doses of PfSPZ Vaccine were tested in a FLUOROSpot assay to measure single IFN- $\gamma$ , single IL2, and double (IFN- $\gamma$  + IL2) responses to NF54 Pf sporozoites (PfSPZ) and PfCSP, PfAMA1, PfTRAP/SSP2 and PfCeITOS peptide pools. The 5-dose regimen induced 92% protection against homologous (Pf3D7) controlled human malaria infection (CHMI) and 80% protection against heterologous (Pf7G8) CHMI 3 weeks after final immunization; the 3-dose regimen induced 87% efficacy to homologous CHMI. At 24 weeks after final immunization, the 5-dose regimen induced 70% efficacy against homologous CHMI but only 10% against heterologous CHMI; the 3-dose regimen induced

57% efficacy to homologous CHMI. Responses to PfSPZ peaked post-1st, and occurred in all subjects. In the 5-dose regimen, IFN- $\gamma$  and IL2 responses dropped significantly post-3rd and post-4th and rose post-5th. In the 3-dose regimen, IFN- $\gamma$  and IL2 responses were similar to those induced by the 5-dose regimen post-1st, significantly dropped post-2nd and remained unchanged post-3rd. IFN- $\gamma$ +IL2 responses were lower than IFN- $\gamma$  and IL2 but had similar kinetics. While the kinetics of IFN- $\gamma$  and IL2 activities against peptide pools was similar to PfSPZ, the magnitude of response was lower compared to PfSPZ responses (peptides range: 1-319 sfc/m; PfSPZ range: 1-1344 sfc/m). In both regimens, IFN- $\gamma$ +IL2 response against any peptide was rare. The most frequent activity was against PfTRAP/SSP2. Most subjects were positive to one or two antigens but 25% were negative to all antigens, consistent with MHC-restriction, and with the concept that other antigens may contribute to protection. Responses to PfCSP, PfCeITOS and PfTRAP/SSP2 were more frequent in protected subjects at the 3-week CHMI and were largely absent at the 24-week CHMI. Responses to PfAMA1 increased at the 24-week CHMI; the significance of this is not clear. Overall, these results show that the Pf specific T cell responses in subjects immunized with the 3- and 5-dose regimens were similar.

## 1105

### PROTECTIVE EFFICACY OF DIRECT VENOUS INOCULATION OF ESCALATING DOSES OF PFSZ VACCINE AGAINST CHMI BY DIRECT VENOUS INOCULATION OF PFSZ CHALLENGE IN TANZANIAN ADULTS

<sup>1</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Sanaria Inc., Rockville, MD, United States, <sup>3</sup>Swiss TPH, Basel, Switzerland

*Plasmodium falciparum* (Pf) Pf sporozoite (SPZ) Vaccine administered by direct venous inoculation (DVI) has been extremely well tolerated and safe in studies with volunteers from malaria naïve and endemic populations. PfSPZ Vaccine induces durable, sterile protection against homologous and heterologous controlled human malaria infection (CHMI) with Pf in naïve volunteers (U.S.), and durable protection against heterogeneous Pf parasites in the field. Previously available data indicated a dose response relationship between increasing the numbers of PfSPZ/dose and improving protective efficacy, and an indication that the vaccine could be administered in 3 doses as opposed to 5 doses. This relationship has not been assessed in malaria-exposed volunteers from endemic areas. To address this deficit, between 2014 and 2017, we conducted two double blind, normal saline placebo-controlled trials at the Bagamoyo Clinical Trials Unit of the Ifakara Health Institute in a total of 94 male and female Tanzanian adults aged 18 to 45 years. These trials, in addition to determining the tolerability and safety, were aimed at demonstrating dose response immunogenicity and protective efficacy against CHMI at 3 and 24 weeks, following either 5 doses (each with  $1.35 \times 10^5$  PfSPZ or  $2.7 \times 10^5$  PfSPZ given at 4 week intervals with last dose at 8 weeks) or 3 doses (each with  $9.0 \times 10^5$  PfSPZ or  $1.8 \times 10^6$  PfSPZ given at 8 week intervals). The last CHMI was administered in March 2017. Preliminary results indicate that the two 3-dose regimens with a higher total number of PfSPZ gave better protection against CHMI at 3-11 weeks after last dose (8/12=67%) as compared to the 5-dose regimens with a lower total number of PfSPZ (5/39=13%) ( $p=0.006$ , Fisher's exact test-2 tailed), but still have not achieved significant long term (24 weeks) protection against CHMI. The complete un-blinded results of immunogenicity and protective efficacy through this spectrum of PfSPZ doses will be presented, as will plans for the next IHI study designed to determine the safety and protective efficacy of an accelerated regimen with a single boost in Tanzanian adults including HIV infected individuals.

### A PHASE 1, BLINDED, RANDOMIZED, DOSE ESCALATION TRIAL OF PFSZ CHEMOPROPHYLAXIS VACCINATION (PFSZ-CVAC) ON AN ACCELERATED SCHEDULE IN HEALTHY MALARIA-NAÏVE ADULTS IN THE UNITED STATES

**Sean C. Murphy**<sup>1</sup>, Annette M. Seilie<sup>1</sup>, Ming Chang<sup>1</sup>, James G. Kublin<sup>2</sup>, B. Kim Lee Sim<sup>3</sup>, Thomas L. Richie<sup>3</sup>, Stephen L. Hoffman<sup>3</sup>, Lisa A. Jackson<sup>4</sup>

<sup>1</sup>University of Washington Medical Center, Seattle, WA, United States, <sup>2</sup>Seattle Malaria Clinical Trials Center, Fred Hutch Cancer Research Center, Seattle, WA, United States, <sup>3</sup>Sanaria Inc., Rockville, MD, United States, <sup>4</sup>Kaiser Permanente Washington Health Research Institute, Seattle, WA, United States

A highly effective malaria vaccine is urgently needed to protect at-risk populations, travelers and the military. Such a vaccine could accelerate efforts to eliminate malaria globally. Direct venous inoculation (DVI) of PfSPZ Vaccine (radiation attenuated aseptically, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ)) protects volunteers against short and long term homologous and heterologous controlled human malaria infection (CHMI) and natural exposure to Pf in Mali. For the PfSPZ-CVAc (chemoprophylaxis vaccine) approach, subjects taking antimalarial chemoprophylaxis are administered aseptically, purified, cryopreserved infectious PfSPZ (PfSPZ Challenge). Three doses at 28-day intervals of  $5.12 \times 10^4$  PfSPZ administered to volunteers taking chloroquine (CQ) chemoprophylaxis protected 100% (9/9) against CHMI with homologous PfSPZ 10 weeks after last dose of PfSPZ. When the vaccine was administered at 5-day intervals protection was reduced to 63%. To further define an optimal dose and dosing interval for PfSPZ-CVAc, we are assessing the safety, tolerability, immunogenicity and protective efficacy of PfSPZ-CVAc with CQ chemoprophylaxis administered 3 times at 7 day intervals. There are 3 dose escalation cohorts ( $5.12 \times 10^4$ ,  $1.0 \times 10^5$  or  $2.0 \times 10^5$  of PfSPZ Challenge) with 12 subjects per cohort (9 vaccinees and 3 placebo controls each). Subjects will undergo CHMI with PfSPZ Challenge by DVI 10 weeks after last dose of vaccine. A *Plasmodium* 18S rRNA qRT-PCR is being used to detect blood-stage infections and initiate treatment in unprotected subjects. Adverse events, safety laboratory data, parasite growth kinetics, pharmacokinetics of CQ and humoral and cellular immune responses to PfSPZ will be assessed. The first cohort has undergone CHMI, and the next cohort is being enrolled. Data from all cohorts will be presented.

## 1107

### EXCEPTIONAL TOLERABILITY OF CHLOROQUINE WHEN ADMINISTERED AS CHEMOPROPHYLAXIS WITH ASEPTIC, LIVE, CRYOPRESERVED NON-ATTENUATED WHOLE PLASMODIUM FALCIPARUM SPOOROZOITES (PFSZ-CVAC) IN HEALTHY EQUATOGUINEAN YOUNG ADULTS

**Vicente Urbano**<sup>1</sup>, Ally Olotu<sup>2</sup>, Ali Hamad<sup>2</sup>, Ali Mtoro<sup>2</sup>, Mwajuma Chemba<sup>2</sup>, Stephen R. Manock<sup>3</sup>, Esther Eburu<sup>4</sup>, Martin Eka Ondo Mangué<sup>1</sup>, Genaro Nsue Nguema Okomo<sup>1</sup>, Beltrán Ekua Ntutum Pasialo<sup>1</sup>, Yonas Abebe<sup>5</sup>, Salomón Nguema Owono<sup>1</sup>, Matilde Riloha Rivas<sup>1</sup>, Julie Niemczura de Carvalho<sup>6</sup>, Peter F. Billingsley<sup>5</sup>, B. Kim Lee Sim<sup>5</sup>, Thomas Richie<sup>5</sup>, Salim Abdulla<sup>2</sup>, Stephen L. Hoffman<sup>5</sup>

<sup>1</sup>Ministry of Health, Equatorial Guinea, Malabo, Equatorial Guinea, <sup>2</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>3</sup>Sanaria Inc., Malabo, Equatorial Guinea, <sup>4</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>5</sup>Sanaria Inc., Rockville, MD, United States, <sup>6</sup>Medical Care Development International, Silver Spring, MD, United States

PfSPZ-CVAc is a candidate pre-erythrocytic malaria vaccine which involves the direct venous inoculation of aseptically, purified, live, cryopreserved, chloroquine (CQ)-sensitive *Plasmodium falciparum* (Pf) NF54 sporozoites (PfSPZ Challenge) under antimalarial chemoprophylaxis. Using CQ as the partner drug, this approach provided high levels of protection against

homologous strains of Pf in the U.S. and Europe, but had not been tested in Africa. Among the known side effects of CQ, pruritus has been reported in up to 52% of dark-skinned individuals, and can be severe. The viability of CQ as a partner drug for use in PfSPZ-CVac in Africa will depend on its tolerability. As part of a larger double blind placebo-controlled trial, 24 healthy malaria-exposed Equatoguinean 18 to 35-year-old men and women were randomized to receive 3 doses of 1x10<sup>5</sup> PfSPZ (PfSPZ Challenge) or placebo at 0, 4 and 8 weeks. All subjects were given CQ diphosphate 1000 mg (620 mg CQ base) orally 2 days prior to PfSPZ Challenge, followed by 500 mg CQ diphosphate (310 mg CQ base) orally weekly. CQ administration was directly observed. Previous testing had verified the quality of the CQ, and whole blood drawn 2 days after the initial CQ dose contained >15 ng/mL in all subjects. Malaria parasitemia was ruled out by blood smear and qPCR prior to each vaccination. Fifteen potentially CQ-related adverse events (AEs) (GI symptoms, neurologic and psychiatric symptoms, pruritus, fatigue, and myalgia) plus 10 general AEs were solicited daily for 12 days, then at 14, 19 and 26 days post-vaccination. Surveillance for unsolicited AEs was done for 26 days after the vaccine dose. After the first four weeks, 1 (4.2%) subject had nausea, 1 (4.2%) had tinnitus, 1 (4.2%) had myalgia, 2 (8.3%) had fatigue, 2 (8.3%) had pruritus, and 4 (16.7%) had headache and/or dizziness. All symptoms were mild, transient and required no treatment. There were no related unsolicited AEs. The extremely low incidence of pruritus was unexpected and encouraging; it may be related to the chemoprophylaxis versus treatment dose of CQ used. (ClinicalTrials.gov number, NCT02859350)

## 1108

### IMMUNIZATION OF NON-HUMAN PRIMATES WITH A *PLASMODIUM FALCIPARUM* WHOLE PARASITE VACCINE INCLUDING PARASITE SEXUAL AND MOSQUITO STAGES INDUCES ANTIBODIES THAT BLOCKS PARASITE TRANSMISSION TO MOSQUITOES

Tao Li<sup>1</sup>, Minglin Li<sup>2</sup>, Sumana Chakravarty<sup>1</sup>, Abraham G. Eappen<sup>1</sup>, Yun Wu<sup>2</sup>, Chris Fox<sup>3</sup>, Steve Reed<sup>3</sup>, B. Kim Sim<sup>2</sup>, Stephen L. Hoffman<sup>1</sup>, Peter F. Billingsley<sup>1</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Protein Potential LLC, Rockville, MD, United States, <sup>3</sup>Infectious Disease Research Institute, Seattle, WA, United States

A vaccine that interrupts malaria transmission (VIMT) would be a valuable tool for malaria control and elimination. Sanaria is exploiting its capacity to manufacture *Plasmodium falciparum* (Pf) whole parasite vaccines by producing sexual and mosquito stage (SMS) parasites under cGMP conditions. Compared to subunit vaccine approaches, a whole parasite (WP) Pf SMS-WP-VIMT would increase the diversity of antigens presented to the immune system and negate the need for complex post-translational processing of recombinant antigens. Starting with mature stage V gametocyte cultures, Pf SMS parasite development was initiated by a decrease in temperature and exchange into an exflagellation medium for 2 hours. The parasites were then introduced into ookinete medium for 1 or 22 hours to obtain parasites of different stages. The parasites were then purified using a magnetic column to eliminate uninfected erythrocytes and non-parasite material. Non-human primates (NHPs) (rhesus macaques) were immunized intramuscularly on days 0, 21, and 42 with 1.5 × 10<sup>7</sup> purified Pf SMS/dose in GLA-LSQ (glucopyranosyl lipid adjuvant in liposomes with QS-21), and boosted on day 85 with 3.0 × 10<sup>7</sup> purified Pf SMS. Anti-sera from immunized NHPs were collected 2 weeks after the third and fourth immunizations and fed with mature Pf NF54 gametocytes in a standard membrane feeding assay. Transmission blocking activity at a 1:9 dilution was equivalent to that of an anti-Pfs25 monoclonal antibody (a leading transmission blocking vaccine candidate antigen) at 125 µg/mL concentration. A Pf SMS-WP-VIMT will be an ideal complement to Sanaria's PfSPZ-based vaccines to dramatically reduce transmission by preventing blood stage infection with the pre-erythrocytic stage vaccine and preventing transmission of any breakthrough parasites with the SMS vaccine.

## 1109

### BETWEEN FILL-FINISH AND THE CLINIC: THE SUPPLY CHAIN FOR DISTRIBUTION OF PFSPZ VACCINES

Eric Robert James, Adam Ruben, Aderonke O. Awe, Henry Huang, Victoria Laney, Ching Lam, B. Kim Lee Sim, Stephen L. Hoffman

Sanaria, Rockville, MD, United States

The PfSPZ platform products' (PfSPZ Vaccine, PfSPZ-CVac, PfSPZ-GA1 Vaccine) immunogen is *Plasmodium falciparum* (Pf) sporozoites (SPZ), which are eukaryotic organisms, ergo stabilization is by cryopreservation. Distribution uses a liquid nitrogen (LN2) vapor phase (LNVP) cold chain that maintains temperature below -150 oC. Critical to distribution is the product container. Standard cryovials have screw-cap with O-ring or gasket seal closures and are not suitable for many reasons, most importantly because upon opening, product sterility is compromised. We have created a new cryovial with co-molded septum for access by needle/syringe, enabling use in any location in a manner similar to typical pharmaceutical vials. During manufacture, 96-place SBS array boxes of cryovials are filled using an automated 12-channel filling machine, caps are pressure-applied forming an impervious vial-cap seal and the caps' tops are protected by applying a mat of individual heat-annealed foil seals. Boxes of cryovials are batch cryopreserved and placed into LNVP storage. For distribution, boxes are loaded into LNVP cryoshippers and air/road freighted to clinical sites. Each cryoshipper remains on-site up to one month as the vaccine store. The cryoshipper returns to base for LN2 recharging and vaccine re-stocking. Cryoshipper temperature is continuously monitored. For immunizations, vaccine vials are retrieved, thawed using an automated dry thawing device, the foil seal removed and a syringe/needle injects diluent and withdraws mixed diluted vaccine for injection. Over 380 shipments supplying >30 trials have used this LNVP cold chain to date and experience gained is being translated into expanded distribution network designs for Phase 3 clinical trials and into post-launch distribution models for travelers and focal elimination campaigns.

### CONSISTENCY OF INFECTION AFTER CONTROLLED HUMAN MALARIA INFECTION WITH PFSPZ CHALLENGE OF DIFFERENT AGE AND LOTS

B. Kim Lee Sim<sup>1</sup>, Eric R. James<sup>1</sup>, Benjamin Mordmüller<sup>2</sup>, Peter G. Kremsner<sup>2</sup>, Adam J. Ruben<sup>1</sup>, Yonas Abebe<sup>1</sup>, Aderonke Awe<sup>1</sup>, Henry Huang<sup>1</sup>, Jonathan Jackson<sup>1</sup>, Pedro L. Alonso<sup>3</sup>, Sara A. Healy<sup>4</sup>, Patrick E. Duffy<sup>4</sup>, Sean C. Murphy<sup>5</sup>, James G. Kublin<sup>6</sup>, Matthew B. Laurens<sup>7</sup>, Peter F. Billingsley<sup>1</sup>, Anita Manoj<sup>1</sup>, Thomas L. Richie<sup>1</sup>, Stephen L. Hoffman<sup>1</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Institute of Tropical Medicine, University of Tübingen, Tübingen, Germany, <sup>3</sup>Barcelona Institute for Global Health, Universitat de Barcelona, Barcelona, Spain, <sup>4</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>5</sup>University of Washington Medical Center, Seattle, WA, United States, <sup>6</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>7</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Sanaria® PfSPZ Challenge is composed of aseptic, purified, cryopreserved infectious *Plasmodium falciparum* (Pf) sporozoites (SPZ) that are used to conduct controlled human malaria infection (CHMI) studies to assess anti-malarial vaccines and drugs, and naturally acquired immunity. Thus far, 661 volunteers in the USA, the Netherlands, Germany, Spain, the UK, Tanzania, Kenya, Gabon, and Mali have undergone CHMI with PfSPZ Challenge. Three hundred fifty of those volunteers were in Africa. An additional 134 volunteers have undergone immunization with a total of 390 doses of PfSPZ Challenge as part of Sanaria® PfSPZ-CVac. PfSPZ Challenge is stored in liquid nitrogen vapor phase (LNVP) at below -150 degrees C, and the stability of PfSPZ Challenge is assessed at Sanaria by

PfSPZ cell membrane integrity tests (viability assay) and *in vitro* growth and development in hepatocytes (potency assay). However, the most powerful indicator of the stability of PfSPZ Challenge over time has been the infectivity of PfSPZ Challenge held in LNVP for different periods of time. For the majority of studies, volunteers are injected by direct venous inoculation (DVI) with 3,200 PfSPZ derived from the NF54 strain of Pf. The infection rates and time to parasitemia vary considerably from country to country in Africa depending on the levels of naturally acquired and innate immunity in recipients. However, they are similar in non-immune subjects in the USA and Europe. To assess the potential for changes in infectivity from lot to lot and over time, we used the results of CHMI in 54 non-immune, non-immunized control volunteers in the USA, Germany, and Spain who were injected with 3,200 PfSPZ (NF54) from two different lots of PfSPZ Challenge that had been manufactured from 9 to 33 months previously. All 55 subjects developed parasitemia (100% infection rate), and the pre-patent periods after CHMI were similar over time and between lots. CHMI has been an enormously important tool to establish the lot to lot consistency and stability of infectivity of PfSPZ Challenge and by analogy of all of Sanaria's PfSPZ-based products.

## 1111

### DEVELOPMENT AND EXECUTION OF A REGULATORY PROGRAM FOR A MALARIA VACCINE TO BE LICENSED ON THREE CONTINENTS

**Tooba Murshedkar**, Anusha Gunasekera, Thomas L. Richie, Asqual Getachew, Anita Manoj, Kim Lee Sim, Stephen L. Hoffman  
*Sanaria Inc., Rockville, MD, United States*

Sanaria's mission is to develop highly effective malaria vaccines that can be used to immunize the entire population, including pregnant women, in geographically defined areas to halt transmission and eliminate malaria, and to prevent malaria infection in individuals. In collaboration with partners, Sanaria has conducted 32 clinical trials of its *Plasmodium falciparum* (Pf) sporozoite (SPZ)-based products in the USA, the Netherlands, Germany, Spain, the UK, Tanzania, Kenya, Mali, Burkina Faso, Gabon, and Equatorial Guinea, and anticipates initiating trials in Ghana and Indonesia within a year. All of these clinical trials are conducted under Investigational New Drug (IND) applications with the U.S. FDA (n=10 INDs) and with the appropriate regulatory filings in each of the other countries internationally. The regulatory process generally starts with a pre-IND meeting with FDA at which specific questions are asked of the FDA, the responses to which facilitate successful IND preparation. In addition, the IND submission is generally preceded by submission of a Biologics Master File (BMF) to FDA on a specific PfSPZ-based product that provides critically important information that supports the specific IND. The PfSPZ-based products are all aseptic, purified, and cryopreserved in liquid nitrogen vapor phase (LNVP). They include Sanaria® PfSPZ Challenge (fully infectious), Sanaria® PfSPZ Vaccine (radiation attenuated), Sanaria® PfSPZ-CVac (PfSPZ Challenge administered under chemoprophylaxis) and PfSPZ-GA1 Vaccine (genetically attenuated). Sanaria has moved from conducting pre-clinical IND-enabling studies to phase 1 and now phase 2 clinical trials. The goal is to initiate phase 3 clinical trials in next few years. Sanaria's leading and most advanced product, PfSPZ Vaccine, was granted FDA's Fast Track Designation in 2016. The specifics and pitfalls of this complicated regulatory process, including plans for submission of a Biologics License Application (BLA) and the equivalent internationally will be presented.

## 1112

### PERIPHERAL CELLULAR RESPONSES OF HUMAN SUBJECTS IMMUNIZED VIA MOSQUITOES WITH RADIATION ATTENUATED SPOOROZOITES (IMRAS)

**Emily C. Smith**<sup>1</sup>, Jessica S. Bolton<sup>1</sup>, Mengyan Du<sup>1</sup>, Sharina Reyes<sup>1</sup>, Jo Glenna Banania<sup>1</sup>, Harini Ganeshan<sup>1</sup>, Jun Huang<sup>1</sup>, Maria Belmonte<sup>1</sup>, Arnel Belmonte<sup>1</sup>, Joanne M. Epstein<sup>2</sup>, The WRAIR/NMRC IMRAS Team<sup>3</sup>

<sup>1</sup>The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, <sup>2</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>3</sup>Walter Reed Army Institute of Research/ Naval Medical Research Center, Silver Spring, MD, United States

Protection from malaria following immunization with radiation attenuated sporozoites (RAS) is well established, yet our understanding of the immune mechanisms of protection is incomplete. To facilitate further understanding of protective immunity induced by RAS, a phase I clinical trial was recently completed (IMRAS). Two consecutive cohorts, consisting of twelve true- and four mock-immunized subjects, received approximately 1000 infectious mosquito bites over five sessions four weeks apart, followed by controlled human malaria infection (CHMI). Protection was 55% and 90% respectively in the two cohorts. Peripheral blood mononuclear cells (PBMCs) were collected by leukapheresis at several time points throughout the study, including pre-immunization, day 14 post 3rd immunization, day 5-6 post-CHMI, and day 112 post-CHMI. A subset of four subjects received a second set of immunizations (hyper-immunization) and PBMCs were collected after the boost immunizations and second CHMI. PBMCs were stimulated for 18h with *P. falciparum* sporozoites and infected red blood cells (PfRBCs). Surface and intracellular staining were performed, and data were acquired by flow cytometry. Responding populations of CD4 and CD8 T cells, NK cells, and gamma-delta T cells were identified and production of IFN- $\gamma$ , TNF, IL-2, MIP1 $\beta$ , CD154, granzyme B, and CD107a was evaluated in response to parasite stimulation. We will present a comprehensive analysis of these cellular responses, including a comparison of responses to sporozoites and PfRBCs, and association with protection.

## 1113

### ANALYSIS OF LIVER PARASITE BURDEN FOLLOWING IMMUNIZATION WITH NOVEL MALARIA ANTIGEN PYE140 AND PLASMODIUM YOELII SPOOROZOITE CHALLENGE

**Emily C. Smith**<sup>1</sup>, **Jessica S. Bolton**<sup>1</sup>, Nonenipha Rangel<sup>2</sup>, Kyosuke Oda<sup>2</sup>, Jianyang Wang<sup>2</sup>, Arnel Belmonte<sup>1</sup>, Rachel Velasco<sup>1</sup>, Mengyan Du<sup>1</sup>, Kalpana Gowda<sup>3</sup>, Joanne M. Lumsden<sup>1</sup>, Martha Sedegah<sup>3</sup>, Noelle B. Patterson<sup>1</sup>, Thomas L. Richie<sup>3</sup>, Eileen F. Villasante<sup>3</sup>, Robert V. Gerbasi<sup>3</sup>, Keith J. Limbach<sup>1</sup>, Joao C. Aguiar<sup>2</sup>

<sup>1</sup>The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, <sup>2</sup>CAMRIS International, Bethesda, MD, United States, <sup>3</sup>Naval Medical Research Center, Silver Spring, MD, United States

Recently we identified a novel *Plasmodium yoelii* antigen, PyE140, which induces a high level of sterile protection following immunization, as measured by the emergence of blood-stage parasites on daily thin smears. Mice immunized by DNA-prime/adenovirus serotype 5 (Ad5)-boost expressing PyE140 develop high titer antibodies which correlate with sterile protection from sporozoite challenge. High frequency CD8+ T cells were also detected in both spleen and liver following immunization, but depletion of neither CD8+ nor CD4+ T cells had any effect on sterile protection. PyE140 and its *P. falciparum* ortholog PfE140 are expressed in pre-erythrocytic (sporozoite and liver) as well as blood-stage parasites. Therefore, it is not known at which stage the parasite is targeted by E140 antigen-specific immunity. In the present study, mice were immunized against PyE140 by DNA-prime/Ad5-boost, and separate groups of mice

were challenged with 100 and 10,000 sporozoites. Livers were harvest 42 hours after sporozoite challenge, homogenized, and total RNA was isolated. RT-qPCR was performed to measure the copies of Py18S and murine GAPDH RNA. The resulting data improve our understanding of the mechanism of protection conferred by the PyE140 antigen, and will guide subsequent vaccine development approaches to develop a PFE140-based subunit vaccine against *P. falciparum* malaria.

## 1114

### REMOTE AND OBJECTIVE MONITORING OF ANTI-MALARIAL BEDNET USE IN RURAL UGANDA: INSIGHTS FROM A PILOT STUDY

Paul Joseph Krezanoski<sup>1</sup>, Santorino Data<sup>2</sup>, Ryan Carroll<sup>3</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>Mbarara University of Science and Technology, Mbarara, Uganda,

<sup>3</sup>Massachusetts General Hospital, Boston, MA, United States

Insecticide-treated bednets (ITNs) are a mainstay of malaria prevention, recommended by the World Health Organization (WHO) for nightly use by over 3 billion people worldwide. ITNs are accepted as a cost-effective means of preventing malaria, but our tools for measuring ITN use limit our ability to examine exactly how ITNs are used. The most common tool for assessing ITN use is based on inquiring into a household's self-reported use the prior night. While effective for obtaining a general sense of ITN coverage, these measures are inadequate for relating specific ITN use behaviors to important malaria outcomes. SmartNet is a remote ITN-use monitoring system designed to provide objective measures of ITN use over time. SmartNet is integrated into a WHO-approved ITN and uses battery power to log at 15 minute intervals the use of that ITN on a memory card for later analysis. To date, we have performed lab testing, a proof of concept study among volunteers in the United States and a pre-deployment acceptability study in Uganda. SmartNet is currently undergoing a pilot study in 10 Ugandan households over six weeks to demonstrate the feasibility of objective remote ITN use monitoring. The results provide novel insights into ITN use behaviors in households at risk of malaria infection, including exact quantification of ITN coverage, daily records of the times of unfurling, and the ability to capture identifiable episodes of interruptions in use. We also relate ITN use behaviors to perceptions of malaria risk and detailed household and individual characteristics that increase the risk of malaria infection, such as night work or early rising. Remote objective ITN use monitors, such as SmartNet, provide precise measures of ITN use over extended periods of time at a far greater resolution than current methods. These tools improve our understanding of how ITNs are used in practice and greatly enhance our ability to quantify how actual ITN use relates to the risk of malaria infection.

## 1115

### URBAN LONG LASTING INSECTICIDAL NETS MASS CAMPAIGN DISTRIBUTION IN MADAGASCAR

Nambinisoa Mauricette Andriamananjara, Claude Arsene Ratsimbaoa

Ministry of Health, Antananarivo, Madagascar

The Madagascar National Strategy 2013-2017 is sharing by the facies epidemiological. In the high area transmission, there are the LLIN distributions. In the otherwise, there are the localized IRS and the daily epidemiological surveillance of the low transmission. In the LLIN mass campaign 2015, we have 85% of the population so 19 112 163; 3 981 826 households and 46 217 community health workers. By the LLIN geographic coverage, the 92 districts is divided in 17 urban, 85 rural. We have distributed 10 600 750 LLINs. The universal coverage with mass free distribution of LLINs by the end of 2015 is doing in the 92 per 112 health districts targeted in LLIN. The objective is 1 LLINs to 2 persons. Involving the LLIN Mass Campaign Distribution in Urban Cities, Tamatave city is a town that is located on the east coast of Madagascar

astmh.org

and 298 000 populations. Most people work on Port is related activities and big mining company. 75% of the population lives below the poverty line. The climate is subequatorial type and the city is exposed frequent to cyclone disaster and high malaria transmission. The LLIN distributed are 146 750. The successes in campaign methodology, which is being improved in urban city based on 2013 lessons learned, have improved the training of local distribution teams, standardized guidelines and training materials, developed guidelines on waste management for urban cities, extended campaign period for 2 weeks instead of one. Then, we improved the supervision teams participation to resolve problems with the local authorities. We have emphasized BBC by the community health workers with NMCP. We have produced communication plans, mass media in the different dialects. The logistic tools are simplified. In the end, the challenges are the household registration, the late registration completion in some villages and health center caused by confused messages from other health activities taking place at the same period, some people not at home during the household registration or not willing to have their house visited. For the hang up, some people refused CHW's visit and the CHW are not recognized by the urban population.

## 1116

### FEASIBILITY ASSESSMENTS FOR ITN CONTINUOUS DISTRIBUTION IN TWO SETTINGS: KENYA AND GUINEA

Sean C. Blaufuss, Richmond Ato Selby, Hannah Koenker, Sara Berthe

Johns Hopkins Center for Communication Programs, Baltimore, MD, United States

Recent pilots of continuous distribution of insecticide-treated nets (ITNs) through the education sector, health facilities, and community mechanisms show that ITN access can be sustained between universal coverage campaigns, and potentially function in lieu of mass campaigns. Kenya and Guinea provide two disparate environments to demonstrate how aspects of health systems, education systems or social structures can affect feasibility and potential effectiveness of implementation. VectorWorks conducted feasibility assessments in both countries, consisting of four weeks of interviews with stakeholders from health, education and community sectors to discern factors impacting the success of currently implemented continuous distribution channels and to examine what structures could be used to optimize new channel implementation. Kenya possesses a reliable supply chain that ensures ITNs reach health facilities as needed, making community ITN distribution by community health workers connected to health facilities feasible in endemic areas. In contrast, health facility distribution in Guinea is currently transitioning to a data driven requisition system that must be improved before community-distribution is possible. Guinea's Ebola response created a strong collaboration between health and education sectors that could serve as an effective backbone for school distribution. Both countries have strong cross-sectoral partnership between health and education offices, but due to factors like quality of roads and available human resources, would need to approach school distribution in a slightly different manner. Contextual, structural, and logistical considerations must be paired with modeling tools to determine which channel or combination of channels is ideal in a given context to provide adequate population access. This case study demonstrates that these factors determine which continuous distribution channels are viable, and explores how these nuances would shape planning and implementation of distribution.

## STREAMLINING OPERATIONS AND REDUCING COSTS IN SCHOOL ITN DISTRIBUTION IN TANZANIA: 2013-2017

**Waziri Nyoni**<sup>1</sup>, David Dadi<sup>1</sup>, Noela Kisoka<sup>1</sup>, Dismas Mwalimu<sup>2</sup>, Renata Mandike<sup>2</sup>, Ally Mohamed<sup>2</sup>, George Greer<sup>3</sup>, Naomi Kaspar<sup>3</sup>, Ikupa Akim<sup>2</sup>, Bongo Mgeni<sup>4</sup>, Eric Filemyr<sup>5</sup>, Matt Lynch<sup>5</sup>, Hannah Koenker<sup>5</sup>

<sup>1</sup>VectorWorks Project, Johns Hopkins Center for Communication Programs, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>National Malaria Control Programme, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>President's Malaria Initiative Tanzania, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>VectorWorks Project, Population Services International, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>VectorWorks Project, Johns Hopkins Center for Communication Programs, Baltimore, MD, United States

In 2011, the Ministry of Health and National Malaria Control Program of Tanzania developed a Keep Up Strategy with the goal of maintaining the population's access to an ITN at or above 80%, by using school-based distribution as an innovative distribution channel. Over the last five years, improved coordination between government offices has streamlined operations, and this has led to significant cost-savings for implementation. School distribution of ITNs was first piloted in the Southern Zone in 2013, when the NMCP and the Tanzanian Red Cross Society distributed ITNs in 2,302 schools in 19 districts in Lindi, Mtwara, and Ruvuma, a total of 421,285 ITNs, to classes 1,3,5,7 in primary school and Form 2 and 4 in secondary schools. SNP2 was implemented in 2014 by NMCP and Research Triangle Institute, delivering 489,099 ITNs to school children, and adding classes 2 and 4 in Lindi. In the third round in 2015, NMCP with JHUCCP's VectorWorks project delivered 494,407 ITNs to 1,919 schools in the 19 districts, targeting classes 1-3, 5, and 7 in primary school in Ruvuma and Mtwara, and classes 1-5 and 7 in Lindi. In 2016, SNP4 expanded to four additional regions in the Lake Zone; 1,152,715 ITNs were delivered to 5,242 schools in a total of seven regions. SNP5 in 2017 will expand to 14 regions in total. The President's Office of Regional Administration and Local Government now coordinates the majority of activities at the regional level and below. Over the last five years, enrolment data collection has been streamlined and digitized, using the Basic Education Monitoring Information System. Training requirements have been reduced (Ward Education Coordinators and teachers will no longer receive training in SNP5), and transport and storage have been optimized in collaboration with the private-sector logistics partner, who will deliver nets from the port directly to the school level. The improvements in operations have resulted in significant cost-savings, allowing scale up from 9 to 14 regions within the original budget envelope. Cost analysis is underway, and will be discussed in further detail.

## 1118

### EXPLORING MELANIN-BASED ANOPHELES GAMBIAE IMMUNE RESPONSE TO MALARIA PARASITE

**Emma Camacho**, Yesseinia I. Anglero-Rodriguez, Yuemei Dong, Maggie Wear, George Dimopoulos, Arturo Casadevall

Johns Hopkins University, Baltimore, MD, United States

Malaria parasite transmission is dependent on the survival of *Plasmodium* during its cycle in the mosquito. The major bottleneck for parasite development occurs during traversal of the midgut epithelium, where it is exposed to human-blood derived factors, mosquito immune defenses, and gut microbiota. Indeed, melanin-based cellular immune response and midgut microbiota are responsible for the refractoriness of certain mosquito strains to *Plasmodium* infection. Several studies have suggested that parasite killing precedes the melanization step; nonetheless, molecular mechanisms that govern these processes are poorly understood. We hypothesize that key mosquito factors that associate with the parasite to

mediate killing and melanization will be trapped in the melanotic capsules. Thus, *An. gambiae* L3-5 refractory line was infected with *P. berghei* to enrich the melanotic capsules for proteomics. Melanotic capsules were successfully recovered using a protocol for fungal melanin isolation. We identified a subset of *Anopheles* proteins associated with the melanin matrix by performing a pilot proteomic analysis using a filter-aided sample preparation (FASP) procedure followed by tandem MS/MS. In parallel, a confrontational assay between *Cryptococcus neoformans* (fungal biosensor) and mosquito midgut-derived bacteria was performed to detect melanin-precursors released by the bacteria. We identified dopaminergic bacterial strains that induced fungal melanization. Accumulative evidence has shown that catecholamines regulate the crosstalk between microbes and the immune system. Currently, we are validating *Anopheles* proteins implication in parasite killing, encapsulation, and association with the parasite, as well as identifying melanin-precursors released by mosquito intestinal microbiota. This project will provide mechanistic insights on the vector-parasite interactions while enhancing our knowledge of mosquito vectorial capacity and malaria parasite transmission, possible contributing to the development of potential novel malaria control strategies to make these mosquitoes more resistance to *Plasmodium*.

## 1119

### CAN AGE AND GENDER DIFFERENCES IN THE RISK OF MALARIA BE EXPLAINED BY BEHAVIOR RELATED TO MOSQUITO EXPOSURE?

**Anna M. van Eijk**<sup>1</sup>, Sandhya Choubey<sup>2</sup>, Punam Barla<sup>2</sup>, Subrata Acharya<sup>2</sup>, Rajashri Rani Oraon<sup>2</sup>, Mohammed A. Haque<sup>2</sup>, Steven A. Sullivan<sup>1</sup>, Sanjib Mohanty<sup>3</sup>, Sanghamithra Satpathi<sup>3</sup>, Jane M. Carlton<sup>1</sup>

<sup>1</sup>Center for Genomics and Systems Biology, Department of Biology, New York University, New York, NY, United States, <sup>2</sup>Jigyansha, International Center of Excellence for Malaria Research, Raurkela, India, <sup>3</sup>Molecular and Immunology Laboratory, Ispat General Hospital, Raurkela, India

In our studies in rural Odisha, India, as part of an NIH-funded International Center of Excellence in Malaria Research, children and men were found to be at higher risk of malaria than older people and women. Using surveys of individuals and households in the same villages, we examined if **behavior** could be identified that may impact on malaria acquisition by gender and age. Adjusting for clustering at the household level, preliminary analysis of 171 participants from 73 households shows that there were no differences by age and gender in bedtime (median 9 pm, range 5.30 pm to 11 pm); however, adults were up earlier (median 5 am, range 3-8 am) than children (<18 years, median 6 am, range 4-7 am,  $p < 0.001$ ), and females (median 5 am, range 3-7) were up earlier than males (median 5 am, range 3-8,  $p = 0.004$ ). Adult males were more likely to be outside in the evening (26%), when sleeping (21%), and in the early morning (81%), compared to adult women (7%, 1%, and 13%, respectively,  $p < 0.01$  for all comparisons) and children (9%, 2%, and 10%, respectively,  $p < 0.05$  for all comparisons). Insecticide treated net use in the previous night was lower among adults (33%) compared to children (51%,  $p = 0.005$ ), but not different by gender ( $p = 0.9$ ). More women (21%) than men (10%) said they tried to cover up exposed skin during morning and evening hours ( $p = 0.03$ ). There were no differences in time before health unit visits for fever by gender or age (median 1 day, range 0-6 days). At the household level, coils (5%), mats (1%), vaporizers (10%), insecticide spray (12%) and window screening (4%) were infrequently used. Clearing bushes (64%) and stagnating water (59%) around the house, burning leaves or dung (26%), and keeping doors/windows closed in the evening (70%) were common methods to decrease mosquito burden, and bedrooms in 26% of households were reported to have been sprayed with insecticide the year before. Outdoor **behavior** may play a role in gender differences in malaria prevalence in rural Odisha, where exophilic early biting mosquitoes are more common than in Africa. Additional protection methods to reduce outdoor exposure to mosquitoes in early morning and evening may be useful.

## 1120

**QUANTIFYING GAPS IN ITN USE TO BETTER PLAN AND TARGET MALARIA INTERVENTIONS IN MADAGASCAR**

Jean-Marie N'Gbichi<sup>1</sup>, Maurice Ye<sup>1</sup>, Laurent Kapesa<sup>2</sup>, Claude Arsène Ratsimbaoa<sup>3</sup>, Yazoume Ye<sup>1</sup>

<sup>1</sup>U.S. Agency for International Development-funded MEASURE Evaluation, University of North Carolina and ICF, Chapel Hill, NC, United States, <sup>2</sup>U.S. Agency for International Development, Health Population and Nutrition Office, Antananarivo, Madagascar, <sup>3</sup>NMCP (MOH) and University of Antananarivo, Antananarivo, Madagascar

Though Madagascar is experiencing a significant scale-up of key malaria interventions, intervention coverage remains below the targets set by the National Malaria Control Program (NMCP). There is a need to quantify these gaps in coverage and identify specific populations with low coverage to better target interventions, particularly as Madagascar considers subnational pre-elimination strategies. Data from the 2016 Malaria Indicator Survey (MIS) were compared to the NMCP's 2016 targets for selected indicators. The target for use of insecticide-treated nets (ITNs) among children under the age of five years (U5) was 90%, and the target for pregnant women (PW) was 88%. The overall gaps between the targets and ITN use were 17 percentage points among U5 and 19 percentage points among PW. In an analysis of subgroups among U5, the gaps in ITN use for place of residence were 17 percentage points in rural areas and 10 percentage points in urban areas. Similarly, the gaps in ITN use among PW vary between rural areas (20 percentage points) and urban ones (12 percentage points). Regarding socioeconomic status, the gaps in ITN use among U5 ranged from 8 percentage points in the lowest wealth quintile to 15 percentage points in the highest. Among PW, the gap in ITN use was also lower for the lowest quintile (3 percentage points) compared to the highest wealth quintile (26 percentage points). There were additional variations by malaria epidemiological zones in ITN use among both U5 and PW. Overall, substantial progress has been made in reducing the gaps in ITN use among U5 and PW; however, there are significant variations in subpopulations. Identifying groups with large gaps allows the NMCP to target resources better during program planning and implementation. Further analyses could identify factors driving these gaps in coverage of malaria control interventions and improve program performance.

## 1121

**EMPOWERMENT EVALUATION TO ENGAGE COMMUNITY FOR MALARIA PREVENTION AND TREATMENT IN ETHNIC MINORITY POPULATIONS ALONG THE THAI MYANMAR BORDER**

Piyaporn Wangroongsarb, Supawadee Pongsombat, Duangkamon Hathawee, Precha Prempree

Bureau of Vector Borne Disease, Nanthaburi, Thailand

In moving toward global malaria elimination, community engagement is one important strategy to achieve a malaria free zone. The ethnic minority populations who are at higher risk of malaria need to be equipped with appropriate tools in activities related to their socio-ecological situation and lifestyle. Empowerment evaluation is an evaluation approach designed to help communities monitor. The objectives were to explore the socio-ecological situation among ethnic populations and empower the community to identify the gaps in their way of life and find solutions in preventing malaria. We conducted the study in malaria endemic villages of selected provinces in the western part of Thailand. A variety of qualitative methods were used as appropriate. The results obtained were as follows: the ethnic communities' livelihood activities were the same as before which was related to the time of malaria peak season. Some elderly villagers experienced malaria infection over 10 times in the past 10 years. But nowadays occurrence of malaria cases have slowed down. On the other hand, some aspects of their lifestyle changed from the past due to the availability of solar cells and television. Because the

electricity was limited, but they preferred to watch at night time without using neon lights which coincides with the anopheles mosquitoes biting time. Most of ladies and children watched Thai drama without protection against mosquitos. After receiving feedback, we gave 3 suggestions and empowered them to decide on the suggestions. Some villagers volunteered to use Insecticide Treated Clothes (ITC) for covering the exposed parts of their bodies. After using for 6 months, it was found that acceptability to the use of ITC was high, and they mostly preferred to cover their lower part of body. But for children, ITC was used as a blanket to cover their bodies and they also preferred for other activities. No side effects were detected. In conclusion, the empowerment evaluation will be useful for increasing and reaching the community engagement in preventing malaria outdoor transmission in the remote areas of border communities in Thailand.

## 1122

**COMPARISON BETWEEN AGE ESTIMATES OF WILD ANOPHELES ARABIENSIS USING NIRS CLASSIFICATION MODEL AND OVARY DISSECTION (DETINOVA'S METHOD)**

Masabho P. Milali<sup>1</sup>, Samson S. Kiware<sup>1</sup>, Richard J. Povinelli<sup>2</sup>, George F. Corliss<sup>2</sup>, Maggy Sikulu-Lord<sup>3</sup>

<sup>1</sup>Ifakara Health Institute, Ifakara-Morogoro, United Republic of Tanzania, <sup>2</sup>Marquette University, Milwaukee, WI, United States, <sup>3</sup>Queensland Alliance of Agriculture and Food Innovation, The University of Queensland, Brisbane, Australia, Australia

Different studies have demonstrated that near-infrared spectroscopy (NIRS) accurately classifies the age of lab-reared mosquitoes with accuracy greater than 80%. Despite the ability of near-infrared spectrometry to classify the age of lab-reared mosquitoes, it is unknown if NIRS can classify the age of wild mosquitoes because we lack age-labeled wild mosquitoes with which to train a model. Training a model using labels from ovary dissection yields a model with poor accuracy. Applying a model trained on spectra from lab-reared mosquitoes to estimate the age of wild mosquitoes was unjustifiable until Milali study ran a cluster analysis on a mixture of spectra collected from lab-reared and wild mosquitoes of the same species. They found no clear difference between spectra collected from lab-reared mosquitoes and those collected from wild mosquitoes. Referring to the Milali study, we applied a classification model trained on lab-reared *Anopheles arabiensis* to classify the ages of wild *An. arabiensis*. Because we lack age labels of wild *Anopheles arabiensis*, we cannot directly validate the accuracy of the model. Alternatively, we indirectly validated our model by comparing the number of mosquitoes in each age class obtained when classification was done using our model and when done using Detinova ovary dissection. Our model classified 86% of the total 927 wild mosquitoes as young (less than seven days old) and 14% as old (greater or equal to seven days old). Detinova ovary dissection classified 72% of the same number (927) of mosquitoes as young (not laid eggs) and 28% as old (laid eggs). A Jaccard similarity analysis comparing Detinova ovary dissection and our model trained on lab-reared mosquitoes shows there is a 67% chance that the two methods will classify a mosquito into the same age class and a 33% chance they will classify a mosquito into different age classes. Hence, a classification model trained on lab-reared mosquitoes and Detinova ovary dissection are more similar than they are different.

## 1123

**"SLEEP IS LEISURE FOR THE POOR" - UNDERSTANDING PERCEPTIONS, BARRIERS AND MOTIVATORS TO NET CARE AND REPAIR IN SOUTHERN TANZANIA**

Zawadi D. Mageni<sup>1</sup>, Angel Dillip<sup>1</sup>, Christina Makungu<sup>1</sup>, Karen Kramer<sup>2</sup>, George Greer<sup>3</sup>, Lena M. Lorenz<sup>4</sup>

<sup>1</sup>Ifakara Health Institute, Dar-es-Salaam, United Republic of Tanzania, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>3</sup>U.S. Agency for International Development/PMI Tanzania, Dar-es-Salaam, United

Republic of Tanzania, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The Government of Tanzania has made substantial effort in achieving universal coverage of Long-Lasting Insecticidal Nets to its population. Personal responsibility to maintain nets provided is crucial to sustain gains in the fight against malaria. Therefore, this study aimed to understand local perceptions, barriers and motivators of net care and repair in Ruangwa district. Qualitative research methods were applied in Kilimahewa and Makanjiro villages to three groups of people; men, women, and women with children under five. We also conducted an assessment of the physical status of nets currently in use by the study participants. Most of the study participants reported to have received nets from the School Net Programme while others purchased theirs from local stores. Continued protection from mosquitoes and in turn malaria was the main motivation to net care. Net care also ensured cleanliness which prevented other dirt-related symptoms such as sneezing. Barriers to net care included it not being a priority in the day-to-day activities, lack of education and understanding of the importance of net care. Net repair was reported necessary as soon as a hole was identified; however, during the net assessment and participatory activity, most of the nets with smaller holes were less likely to be repaired than to be left as is for continued use. Protection against mosquitoes, malaria and cost saving were identified as motivators to net repair. Barriers to net repair included it not being a priority especially as holes at the bottom could be tucked under the mattress, lack of education on the how and the importance of repairing nets. Some participants also reported they did not have tools for net repair. In southern Tanzania, there seems to be readiness to care and repair for mosquito nets, especially among women who are the primary caretakers in the households. Targeted education through health facilities and community change agents were reported as potential means to overcome barriers to net care and repair that could be reinforced for implementation by the National Malaria Control Program.

## 1124

### MISSED OPPORTUNITIES FOR UPTAKE OF INTERMITTENT PREVENTATIVE TREATMENT FOR MALARIA IN PREGNANCY (IPTP): A CASE OF TANZANIA

Jasmine Chadewa<sup>1</sup>, Yusuph Kulindwa<sup>1</sup>, Dunstan Bishanga<sup>1</sup>, Mary Drake<sup>1</sup>, Jeremie Zoungrana<sup>1</sup>, Elaine Roman<sup>2</sup>, Hussein Kidanto<sup>3</sup>, Naomi Kaspar<sup>4</sup>, Kristen Vibbert<sup>2</sup>, Lauren Borsas<sup>2</sup>

<sup>1</sup>Jhpiego Corporation, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Jhpiego Corporation, Baltimore, MD, United States, <sup>3</sup>Tanzania Ministry of Health, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>President's Malaria Initiative, Dar es Salaam, United Republic of Tanzania

About 35 million people in Tanzania are at risk of malaria, with pregnant women and under five children being the most vulnerable. The Tanzania National Malaria Control Program's (NMCP) Strategic Plan for 2007–2012 reports that malaria accounts for 30% of the national disease burden, with about 1.7 million cases per year among pregnant women. To prevent the effect of malaria in pregnancy, the Tanzania Government adopted IPTp3+ therapy for pregnant women per the WHO recommendations for IPTp-SP. This study explores missed opportunities to deliver IPT by looking at predictors causing the drop between coverage of IPTp2 (34%) and IPTp3+ (7%). The study examined Tanzania Demographic and Health Survey (TDHS) 2015/2016 data on women aged 15–49 with a live birth in the two years preceding the survey and at least 2 doses or more of IPTp during ANC (n=4219) to identify factors associated with differences in IPTp uptake. Variables of interest were identified, recoded and generated as required. Data was analyzed using STATA v14, whereby frequency distributions were calculated and cross-tabs and logistic regressions were done comparing dependent and independent variables. The analysis shows the factors contributing to the drop of IPTp uptake include wealth (the richest people are 2.5 times more likely to take at least three doses of IPTp) and education (those with no education are less likely to take more doses of IPTp compared to those who are educated). Residency is

the largest contributing factor: 50% of pregnant mothers in rural areas are less likely to take three or more doses of SP. Clients living within 5 km of health facilities have higher uptake of IPTp3+ compared to their counterparts who live further from the health facilities (33% less likely). However, our analysis shows that there is no correlation between IPTp3+ uptake and number of ANC visits, health insurance or number of children. Based on these results, it is important to strategize to make health services and education more accessible to the population in order to increase IPTp uptake among pregnant women.

## 1125

### IMPLEMENTATION OF MOSQUITO-PROOF HOUSING: LESSONS LEARNED ON OPERATIONAL FEASIBILITY, COST AND COMMUNITY ENGAGEMENT IN NAMIBIA

Bradley Didier<sup>1</sup>, litula litula<sup>2</sup>, Hans Angula<sup>2</sup>, Inessa Ba<sup>1</sup>, Tara Seethaler<sup>1</sup>, Deepa Pindolia<sup>1</sup>, Katelyn Woolheater<sup>1</sup>, Peter Williams<sup>3</sup>, Riksum Kazi<sup>3</sup>, Taylor Klinke<sup>3</sup>, Claire Weil<sup>3</sup>, Wayne Norbeck<sup>4</sup>, Jordan Rogove<sup>4</sup>, Charlotte Dolenz<sup>1</sup>, Petrina Uusiku<sup>2</sup>, Anne-Marie Nitschke<sup>2</sup>

<sup>1</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>2</sup>Namibia National Vector-Borne Disease Control Programme - Ministry of Health and Social Services, Windhoek, Namibia, <sup>3</sup>ARCHIVE Global, New York, NY, United States, <sup>4</sup>DXA Studio, New York, NY, United States

As Namibia works toward its 2020 elimination goal, the country strives to identify and operationalize effective interventions as part of an integrated malaria elimination strategy. The program conducted a small-scale implementation of housing improvements to assess operational feasibility and inform potential scale up. Communities were selected based on malaria risk, acceptability and need, diversity of housing type, number of structures and operational feasibility. Types of improvements include screening windows, eaves, and doors; sealing gaps in the wall; and patching roofs. Planning included a literature review, community surveys and focus groups, material selection, and household assessments. Local contractors were recruited from the National Youth Service and received a two-week technical training. Community health workers and local headmen were also trained on the project and maintenance for two days. Six communities were selected to receive housing improvements, targeting approximately 1,540 structures. Implementation is complete, and basic epidemiological and entomological indicators will be collected as indication of directional effect for impact, while additional questionnaires will capture data on maintenance and durability. The delivery of the project on budget and on time was supported by a comprehensive protocol and technical manual; piloting which allowed for recalibration of the designs; direct lines of communication with the implementers and regular supervision visits. It was found that early and frequent touch points with the community and recruitment of local labor resulted in high community acceptance. Careful planning around materials helped with maximizing effectiveness and efficiencies, with early estimates for cost per structure being \$38, \$31, \$29 for a modern, traditional and metal structure, respectively. Early results show that there is good uptake, and that with careful planning, local ownership, regular supervision and cross-ministerial engagement, housing improvement has the potential of becoming a cost-effective intervention for elimination.

## 1126

### SAFE INDOORS: CHEAP, SUSTAINABLE SPATIAL REPELLENTS TO COMBAT RESISTANCE AND KEEP MALARIA VECTORS OUT OF HOMES

Penelope A. Lynch<sup>1</sup>, Mike Boots<sup>2</sup>

<sup>1</sup>University of Exeter, Penryn, United Kingdom, <sup>2</sup>University of California, Berkeley, CA, United States

While there is increasing interest in the role of housing for malaria prevention, economic realities mean that neither ideal buildings, nor retrofit measures such as screening and eave-tubes, will likely be universally available over the short term. A reappraisal of the repellent

action of DDT in historic malaria control programs is generating interest in the use of spatial repellents as an alternative means to keep vector mosquitoes out of homes. We have suggested generating cheap, effective new spatial repellents by harnessing the same evolutionary processes which drive the spread of insecticide resistance. Combining existing IRS programs with use of an indoor repellent initially effective against only part of the vector population can generate selection for vectors susceptible to the repellent, modifying the target vector population and hence increasing efficacy of the repellent. In turn, the repellent protects the IRS insecticide against the rapid spread of insecticide resistance. We formalised this idea using models which explore vector population genetics and associated disease transmission metrics, and have now extended our analysis to consider location-specific scenarios and to explore how evolved repellence might contribute to protection of the crucial pyrethroid insecticides used on bed nets.

## 1127

### INCREASING THE TIME BETWEEN INCIDENT MALARIA EPISODES IN UGANDAN CHILDREN: REPEATED APPLICATION OF IRS

**Kate Zinszer**<sup>1</sup>, Kathryn Morrison<sup>1</sup>, Jon Rek<sup>2</sup>, Emmanuel Arinaitwe<sup>2</sup>, Joaniter Nankabirwa<sup>2</sup>, Moses R. Kamyua<sup>2</sup>, Grant Dorsey<sup>3</sup>  
<sup>1</sup>University of Montreal, Montreal, QC, Canada, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>Department of Medicine, University of California San Francisco, CA, United States

Malaria is the leading cause of morbidity and mortality in Uganda, with some of the highest levels of malaria transmission intensity in the world. Indoor residual spraying of insecticide (IRS) is one control intervention that is used in targeted areas in Uganda. The goal of the study was to estimate the time between incident malaria episodes in individual children before and after several rounds of IRS application. A dynamic cohort of children was enrolled in Nagongera, Uganda starting in 2011. Household were randomly selection from enumeration surveys and all eligible children aged 0.5-10 yr were enrolled from 107 households. Cohort study participants received all medical care free of charge at a designated study clinic open every day. Malaria was diagnosed using passive surveillance and defined as a fever and the detection of parasites by microscopy. The first 3 rounds of IRS (December 2014-February 2015, June-July 2015, and November-December 2015) utilized a carbamate (bendiocarb) and a fourth round (June-July 2016) utilized an organophosphate (pirimphos-methyl). The analysis included data through December 2016 and involved using a multiple Poisson regression, with factor variables to represent the IRS rounds, to estimate the mean time between episodes of incident malaria. There were 376 children enrolled. In total, there were 2,857 cases of incident malaria. The mean number of malaria episodes per child was 9, with a range of 1 to 32. In the pre-IRS treatment period, there was an average of 100 days between malaria infections for each child. After IRS round 1, IRS round 2, IRS round 3, and IRS round 4, the average time between infections was 159 days, 224 days, 438 days, and 507 days, respectively. There was a consistent increase in time between malaria episodes post-IRS applications, with the largest increase in time occurring after rounds 3 and 4 of IRS. This suggests that IRS is effective at reducing the burden of malaria episodes these children experienced by increasing the time between each episode. Future work will include estimating the longevity of effect post-IRS application to determine the optimal timing for IRS application.

## 1128

### AN OBSERVATIONAL ANALYSIS OF THE IMPACT OF INDOOR RESIDUAL SPRAYING IN THE NORTHERN, UPPER EAST AND UPPER WEST REGIONS OF GHANA: 2011-2016

**Christelle Gogue**<sup>1</sup>, Joseph Wagman<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Jason Richardson<sup>2</sup>, Andrew Saibu<sup>3</sup>, Yemane Yihdego<sup>3</sup>, Sylvester Coleman<sup>3</sup>, Constance Bart-Plange<sup>4</sup>, Wahjib Mohamed<sup>4</sup>, Anthony Ofosu<sup>5</sup>, Richard Steketee<sup>1</sup>, Molly Robertson<sup>1</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>IVCC, Washington, DC, United States, <sup>3</sup>Abt Associates, Accra, Ghana, <sup>4</sup>National Malaria Control Program, Accra, Ghana, <sup>5</sup>Ghana Health Services, Accra, Ghana

The indoor residual spraying (IRS) of insecticides has contributed substantially to recent successes in malaria control, leaving IRS as one of the key components of vector control strategies moving forward. Ghana has seen a decline in malaria prevalence nationally since 2011, particularly in the northern Savannah where IRS has been implemented in a number of districts. Demographic and Health Survey and Multiple Indicators Cluster Survey data show consistent decreases in malaria prevalence from 2011 to 2016. In 2011, Northern, Upper East and Upper West regions presented high parasite prevalence in children under 5 (48%, 44%, and 51% respectively), but all were below 40% in 2016. Entomological surveillance has tracked the effect of IRS and the introduction of new IRS products on vector indicators, but there is a need for evidence demonstrating epidemiological impact as well. We conducted a retrospective, observational analysis of the epidemiological impact of IRS with varying insecticide classes, using routine surveillance data comparing malaria incidence from IRS and comparable non-IRS districts in the Northern, Upper East and Upper West regions. Preliminary results of district-level analysis in the Northern Region show that in districts that received IRS in 2016, rapid diagnosis test (RDT)-confirmed incidence rates fell 18% during the three months immediately after the spray campaign; incidence rates in non-IRS districts increased by 98% in the same timeframe. In addition, US President's Malaria Initiative (PMI)/Africa Indoor Residual Spraying (AIRS) project's entomological surveillance has shown lower indoor resting vector densities between IRS and non-IRS sentinel sites as well as overall lower entomological inoculation rates. These analyses illustrate the positive contribution of IRS in malaria control programs in the north of Ghana and the value of using routine surveillance and implementation data to help rapidly assess the impact of vector control interventions in operational settings. Further analysis will examine monthly trends in incidence over several years following IRS with pyrethroid and carbamate insecticides.

## 1129

### AN OBSERVATIONAL ANALYSIS OF THE IMPACT OF IRS IN THE SÉGOU REGION OF MALI: 2011-2014

**Joseph Wagman**<sup>1</sup>, Christelle Gogue<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Jules Mihigo<sup>2</sup>, Diadier Diallo<sup>3</sup>, Elie Bankineza<sup>4</sup>, Mamadou Bah<sup>4</sup>, Andrew Saibu<sup>5</sup>, Jason Richardson<sup>6</sup>, Diakalia Kone<sup>7</sup>, Seydou Fomba<sup>7</sup>, Laurence Slutsker<sup>1</sup>, Molly Robertson<sup>1</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>U.S. President's Malaria Initiative, Bamako, Mali, <sup>3</sup>MEASURE Evaluation, Bamako, Mali, <sup>4</sup>Abt Associates, Bamako, Mali, <sup>5</sup>Abt Associates, Accra, Ghana, <sup>6</sup>IVCC, Washington, DC, United States, <sup>7</sup>Programme National de Lutte contre le Paludisme, Bamako, Mali

The widespread adoption of new products for indoor residual spraying (IRS) is hampered by gaps in the evidence used to evaluate their public health impact and cost-effectiveness across various malaria transmission settings. To help address this gap, and to foster evidence-based decision making, we present a retrospective, observational analysis of the epidemiological and entomological impact of IRS with two different non-pyrethroid insecticides, using routine indicators of malaria transmission in the Ségou Region of Mali. Ségou has had high access to and use of insecticide treated nets, documented pyrethroid and organochloride resistance, and a scale-up of seasonal malaria chemoprevention that began

in 2013. District level analysis of routine passive surveillance data shows substantial decreases in the number of rapid diagnostic test-confirmed symptomatic malaria cases following IRS campaigns from 2011 - 2014. In 2012 and 2013, in the Ségou Region, two districts (Bla and Barouéli) were sprayed with the carbamate bendiocarb and, together, reported 321 (2012) and 289 (2013) fewer malaria cases/10,000 person-months than those districts that did not receive IRS. Results were similar in 2014, when houses in both districts were sprayed with the organophosphate pirimiphos-methyl and subsequently reported 473 fewer cases/10,000 person-months than did non-IRS districts. In addition, data from the US President's Malaria Initiative Africa Indoor Residual Spraying project routine entomological surveillance show that reduced malaria incidence following each IRS campaign correspond to reductions in *An. gambiae* s.l. indoor biting rates (73% reduction post-spray in 2014, from 3.75 bites/night to 1.0 bites/night). This work shows the utility and importance of using quality assured and validated routine surveillance and implementation data to help rapidly assess the impact of vector control interventions in operational settings, even in complex implementation environments. Further evaluations of various malaria control interventions in different settings will develop a more robust evidence-base to help guide decision making.

### 1131

#### **TYPHOID FEVER CASE FATALITY RATE IN PATIENTS PRESENTING TO A LABORATORY NETWORK IN DHAKA, BANGLADESH**

**Alexander T. Yu<sup>1</sup>**, Nuhu Amin<sup>2</sup>, Muhammad W. Rahman<sup>2</sup>, Stephen Luby<sup>1</sup>

<sup>1</sup>Stanford University, Palo Alto, CA, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Case fatality rate estimates for typhoid fever are central to estimating disease burden, but are scarce. Estimates range widely from 0-15%, with active population based surveillance reporting lower rates presumably due to early detection and hospital based surveillance with higher estimates given their sicker patients. We measured the case fatality rate among patients who had blood culture confirmed typhoid in Dhaka Bangladesh. Between January and December 2010, we prospectively followed patients with blood cultures positive for *Salmonella typhi*, identified from six private laboratories utilized by both hospitals and outpatient private practitioners throughout Dhaka, Bangladesh. We collected antibiotic resistance information from the laboratories. 1425 patients were enrolled; 59% were male, 41% were female, with a median age of 14. 98% experienced fever, 26% required hospitalization and 4 patients died from *S. typhi* (0.3%, 95% CI 0.28-0.32%). There were no significant differences in demographics between patients who were hospitalized and those not hospitalized with typhoid. The four patients who died were all female and had ages ranging from 32-65 years old. 26% of isolates were resistant to chloramphenicol, ampicillin and co-trimoxazole; 38% were resistant to azithromycin. 47% started antibiotics prior to blood cultures, with another 17% starting antibiotics after cultures but before results were reported. Culture results caused 55% to switch antibiotics. This study found a 0.3% case fatality rate for blood culture confirmed typhoid fever among a mixed population of sicker, hospitalized patients and healthier outpatients in urban Bangladesh. This assessment did not capture the experience of people too poor to secure a blood culture, but offers a low-cost strategy to generate an empirical estimate and explore case fatality in other contexts. Future studies should track antimicrobial resistance and its impact on patient outcomes.

### 1132

#### **SALMONELLA BACTEREMIA IN HOSPITALIZED UGANDAN CHILDREN WITH FEBRILE ILLNESS**

*Salmonella* is a known cause of acute febrile illness (AFI) among children in sub-Saharan Africa; however its contribution to bacterial blood stream infections is poorly defined due to limited diagnostic capacity. To address this gap and to inform accurate patient diagnosis and treatment, improved AFI surveillance and expanded diagnostic testing is needed. The Uganda AFI project conducts sentinel surveillance for causes of AFI in children <1 to 14 years old hospitalized at six regional hospitals. We evaluated preliminary demographic data, blood culture and antimicrobial susceptibility results of children hospitalized with a history of fever or documented temperature  $\geq 37.5^{\circ}\text{C}$  from the first three sentinel AFI sites during the first seven months of this ongoing surveillance project (July 1, 2016 – January 31, 2017). Over a combined total of 585 days at the three sites, blood cultures were performed and results were available for 1,169 (26%) of 4,545 hospitalized children. Overall, 1,059 (93%) yielded no growth; 21 (2%) yielded a likely contaminant, and 53 (5%) yielded a pathogen. Among positive blood cultures, *Salmonella* was found in 21 (48%) samples, including 10 (24%) identified as non-Typhi *Salmonella*, 5 (12%) as *Salmonella Typhi*, and 5 (12%) *Salmonella* whose serotypes are pending. *Salmonella* isolates were resistant to ampicillin (58%) and cotrimoxazole (37%), but all were fully susceptible to ciprofloxacin and ceftriaxone. Six (29%) of the children whose blood cultures yielded *Salmonella* had a positive malaria rapid diagnostic test (RDT) (2) or a positive blood smear (4), and one had both a positive malaria RDT and blood smear. The majority (86%) of *Salmonella* isolates were identified from the site with the highest malaria transmission intensity. *Salmonella* was an important cause of bacteremia in children hospitalized with fever, including those with a positive malaria RDT or blood smear. To improve detection and treatment, evaluation of sentinel AFI surveillance is ongoing to better characterize the serotypes of *Salmonella* causing bacteremia and their associated drug resistance patterns.

Moderate-to severe diarrhea (MSD) in infants is caused by a myriad of enteric pathogens. In resource limited areas, rapid diagnostics are often not available to identify causative agents, thus complicating treatment decisions. We identified clinical profiles to distinguish rotavirus from other diarrheal agents in children <5 years old in Kenya (prior to introduction of rotavirus vaccination) participating in the Global Enterics Multicenter Study (GEMS). Demographic and clinical features were collected from caretaker interviews, and clinician assessment of children seeking medical care for MSD. Stool specimens were collected and tested for viral, bacterial and parasitic etiologies of diarrhea. Variables collected were considered as predictors of viral versus other enteric etiologies in tree-based classification models. Complementary logistic regression models were applied for validation. GEMS enrolled 1,778 children with MSD in rural western Kenya from Jan 31, 2008 to Sep 30, 2012. Enteric pathogens were identified in 1,436 (81%) children of which 719 (50%) had a single pathogen identified. Of those with a single pathogen, 90 (13%) had rotavirus, 54 (8%) had another virus, 412 (57%) had a bacterial and 163 (23%) a parasitic pathogen identified. The rotavirus weighted tree models partitioned rotavirus-positive children into groups based on four main predictors: age <18 months; vomiting  $\geq 3$  times/24 h; onset in warm-dry month; skin tenting. The largest group of children with MSD identified with <1% rotavirus positive (n=174) were  $\geq 18$  months without skin tenting. No rotavirus cases were identified in young children <18 months, without vomiting present, and without skin tenting. These results were supported by logistic regression models that identified age (Odds Ratio= 5.63; 95% confidence interval (CI): 2.78-11.41), vomiting  $\geq 3$  times/24 h (OR= 2.98; 1.85-4.81), and onset in warm-dry month (OR= 2.37; 95% CI: 1.45-3.87) as significantly associated with rotavirus. Tree-based models highlighted the order of clinical variable importance in predicting rotavirus infection in children and can assist in guiding treatment at point of care.

## 1134

### FEASIBILITY OF A COMPREHENSIVE TARGETED CHOLERA INTERVENTION IN KATHMANDU VALLEY, NEPAL

Mellisa Roskosky

Johns Hopkins University, Baltimore, MD, United States

Studies have demonstrated a much higher risk of cholera in the immediate area around a case and that this increased risk persists for about 2 to

3 weeks. A Comprehensive Targeted Intervention (CTI) was designed and deployed in the neighborhoods of cholera cases in the Kathmandu Valley during 2016 with the intent to reduce rates among neighbors of the case. This was a feasibility study to determine if clinical centers, laboratories and field teams were able to cooperate and coordinate a response within 48 hours of hospital admission. Daily line listings were requested from the 12 participating hospitals, and a single case initiated the CTI. Rapid diagnostic tests and culture were used for confirmation. The strategy included hospital and household investigation of cases, water testing, WASH intervention, and health education. A single-dose of oral cholera vaccine using a reactive ring strategy was included in the plan, but vaccine could not be obtained in time for the summer 2016 outbreak. An intervention coverage survey was conducted 8 months post-monsoon season. Between June 1 and December 1, 2016, 169 cases of *V. cholerae* O1 were confirmed by culture. Average time to result of hospital culture was 2.4 days. On average, the CTI Rapid Response Team (RRT) was able to visit the household 2 days after the culture result was received from the hospital. 90.4% of household water samples were found unsuitable for drinking and 3 sources were positive for cholera. Coverage of WASH and health behavior messaging campaigns was 30.2% in the target areas. Recipients were 2.3 times more likely to have knowledge of cholera symptoms, treatment, and prevention. This attempt at implementing CTI was successful in raising awareness and engaging stakeholders in both government and private sectors. While the RRT were able to investigate cases at the household within 48 hours of a positive culture result, the study identified several constraints which limited a truly rapid response. Using the information from this first year, we identified pathways that will be useful for future implementation of CTI which have been included in the country's national cholera control strategy.

## 1135

### ENTEROPATHOGENS AND GUT INFLAMMATION IN ASYMPTOMATIC INFANTS AND CHILDREN IN DIFFERENT ENVIRONMENTS IN SOUTHERN INDIA

Ira Praharaj<sup>1</sup>, R. Revathy<sup>1</sup>, Blossom Benny<sup>1</sup>, Mohammad K. Azharuddin<sup>1</sup>, Rini Bandyopadhyay<sup>1</sup>, Jie Liu<sup>2</sup>, Eric Houpt<sup>2</sup>, Gagandeep Kang<sup>1</sup>

<sup>1</sup>Christian Medical College, Vellore, India, <sup>2</sup>University of Virginia, Charlottesville, VA, United States

Children in poor environmental conditions are exposed early and often to enteric pathogens, but within developing countries heterogeneity is rarely addressed. We tested fecal samples from healthy infants and children from two different environments in the same Indian town for gut enteropathogens and biomarkers of gut inflammation. Fecal samples were collected from N=83 infants and children between 3 months to 4 years age residing in Chinnalapuram, a poor neighbourhood (formerly a slum) in Vellore town, south India and N=53 infants and children staying on the residential campus of the Christian Medical College, Vellore. Testing for gut enteropathogens was done using arrayed qPCR assays (Taqman array card assays) and levels of inflammatory biomarkers (fecal calprotectin and myeloperoxidase) were assessed using commercial ELISA assays. A significantly higher proportion of infants and children from the poor semi-urban neighborhood (93%) had one or more enteropathogens than those from a medical college campus (71.7%). Infants and children from the poor neighborhood had an average of 3.3 (95% confidence interval 2.9-3.7) enteropathogens compared to an average of 1.4 (95% confidence interval 1.0-1.7) enteropathogens in campus infants/children. Viral and bacterial infections, including enteroviruses, adenoviruses, *Campylobacter* spp and diarrheagenic *Escherichia coli* were more common and levels of fecal biomarkers of inflammation such as fecal calprotectin and myeloperoxidase were significantly higher among infants and children from the poor neighborhood, even after age-related adjustments. The findings demonstrate significant difference in the asymptomatic carriage of gut enteropathogens and gut inflammatory biomarker levels in infants and children from two different environments within the same town in

south India. Understanding this kind of heterogeneity within the same town enables measures for improvement and might have implications for environmental enteropathy and performance of oral vaccines.

## 1136

### A NOVEL MOUSE MODEL OF *CAMPYLOBACTER JEJUNI* ENTEROPATHY AND DIARRHEA

**David Bolick**, Solanka Ellen Ledwaba, Pedro H. Medeiros, Glynis L. Kolling, Richard L. Guerrant

*University of Virginia School of Medicine, Charlottesville, VA, United States*

*Campylobacter jejuni* is a gram-negative bacteria that is one of the leading recognized bacterial causes of food-borne illnesses worldwide. In the Global Enteric Multicenter Study (GEMS), *C. jejuni* was a leading bacterial cause of moderate to severe diarrhea burden at several South Asian sites. In addition, *Campylobacter* was the leading bacterial pathogen associated with diarrhea across all 8 sites in the MAL-ED study. Furthermore, "asymptomatic" *Campylobacter* infections (i.e. without overt diarrhea) were also the leading pathogen associated with significant growth failure, increased intestinal permeability, and inflammatory biomarkers. Lack of an inexpensive small animal model of enteric disease with *Campylobacter* has been a major limitation for understanding its pathogenesis, interventions or vaccine development. We describe a robust normal mouse model that can exhibit reproducible bloody diarrhea or growth failure as well as fecal biomarkers, depending on the zinc or protein deficient diet. Weaned C57BL/6 mice were fed a regular diet for 2 days, and then either standard rodent 'House Chow' (HC), a defined protein source diet without zinc (dZD), or protein (2%) deficient (dPD) diet. On day 10 of diet, mice were given 3 days on antibiotics to disrupt resident microbiota followed by 1 day on untreated water to clear antibiotics. *C. jejuni* (CVD 81-176) infected mice fed dZD diet had significantly greater weight loss than HC or dPD groups. While all HC or dZD fed mice developed diarrhea by day 3 post infection, all dZD mice had persistent bloody diarrhea for greater than 7 days post infection. Only dZD fed mice were colonized with *C. jejuni* for the duration of the experiment. The inflammatory biomarkers myeloperoxidase and lipocalin-2 measured in cecal contents at day 3 post infection were significantly elevated in dZD fed groups, with MPO being highest with dZD, while LCN-2 was also increased in HC and dPD groups as well. Finally, histology of mice infected with *C. jejuni* showed increased mucus secretion and flattened villi. This model opens new approaches to testing specific hypotheses regarding disease pathogenesis and vaccine development.

## 1137

### SYNERGISTIC AND ANTAGONISTIC EFFECTS OF DIARRHEAGENIC *E. COLI* CO-INFECTIONS IN A MURINE MODEL

**Solanka E. Ledwaba**<sup>1</sup>, David T. Bolick<sup>2</sup>, Pedro H. Medeiros<sup>2</sup>, Afsatou N. Traore<sup>1</sup>, Natasha Potgieter<sup>1</sup>, James P. Nataro<sup>2</sup>, Richard L. Guerrant<sup>2</sup>

<sup>1</sup>*University of Venda, Thohoyandou, South Africa*, <sup>2</sup>*University of Virginia, Charlottesville, VA, United States*

Diarrheal diseases are major causes of morbidity in children worldwide. Enteropathogenic *E. coli* (EPEC), Enteroaggregative *E. coli* (EAEC) and Enterotoxigenic *E. coli* (ETEC) are major causes of acute diarrhea; dual infections pathogens have been reported in different parts of the world. The goal of the study is to determine the role of diet and disease severity during single infections of EAEC, EPEC and ETEC and also during co-infections. Four-week old weaned C57BL/6 mice on standard chow diet were placed on antibiotic cocktail water for 3 days. These mice were administered orally (109 c.f.u./mouse) single infections (EAEC 042, EPEC E2348/69, ETEC H10407) and co-infections (EAEC/EPEC and EPEC/ETEC) (109 c.f.u./mouse per pathogen). During infection, mice were monitored for change in weight and stools were collected daily. At peak of infection; serum, intestinal tissue and cecum contents were collected. Bacterial DNA

was extracted from stools and tissue, and qPCR was used to determine shedding and tissue burden. Proteins lysates extracted from cecum contents and stools were used to determine inflammatory biomarkers myeloperoxidase (MPO) and lipocalin-2 (LCN-2). All mice developed diarrhea on the first day post-infection except EAEC/EPEC co-infections. There was significant weight loss on day 2 and 3 post-infection in mice infected with EPEC or ETEC alone or with EPEC/ETEC co-infections, but not for those infected with EAEC/EPEC. MPO and LCN-2 levels in EPEC/ETEC co-infections were significantly higher compared to EPEC or ETEC alone, while MPO levels were diminished during EAEC/EPEC co-infection. Disease outcome of EPEC/ETEC co-infection was worse compared to the single infections. In addition, EPEC/ETEC co-infection resulted in worse outcomes with mice experiencing severe disease outcome with increased weight loss, diarrhea and increased MPO and LCN-2. EAEC/EPEC co-infection resulted in antagonistic effects with no weight loss and reduced inflammatory LCN-2 and MPO. Future directions include assessing expression of virulence genes during co-infections to better understand these potentially important differences in outcomes.

## 1138

### PROTECTION INDUCED BY A SEROTYPE-INDEPENDENT VACCINE AGAINST SHIGELLOSIS: THE ROLE OF DENDRITIC CELLS

**Olivia Arizmendi**, Prashant Kumar, Jason P. Stewart, William D. Picking, Wendy L. Picking, Francisco J. Martinez-Becerra

*University of Kansas, Lawrence, KS, United States*

Diarrheal diseases are a major cause of morbidity and mortality worldwide and are common in settings where there is inadequate sanitation, poor hygiene and contaminated water. In a multicenter study conducted in Africa and Asia, it was observed that infections with rotavirus, *Shigella* spp., *Cryptosporidium* spp. and ST-ETEC (*E. coli*) accounted for the majority of cases of moderate-to-severe diarrhea in children. No commercially available vaccine exists against shigellosis, and immunity to the pathogen is commonly serotype-restricted. The variety of serotypes (over 50 serotypes across 4 different species of *Shigella*), along with the geographical overlap between them highlight the need for a broadly protective vaccine. This need drives our efforts on the development of a subunit vaccine against this enteric disease. Our research group has previously shown the Type Three Secretion System (T3SS) proteins IpaB and IpaD are protective antigens in mouse models of infection. These proteins are highly conserved among all *Shigella* serotypes and are essential to virulence and pathogenesis. In order to optimize vaccine formulation we generated a fusion protein (DBF) that includes IpaD and IpaB in the same polypeptide chain and used dmLT as an adjuvant. This formulation was protective against *Shigella flexneri*, *Shigella sonnei* and *Shigella dysenteriae*. Testing of different administration routes showed the degree of protection conferred by our vaccine formulation did not correlate with antibody titers. We subsequently have studied the cellular response to intranasal immunization and found dendritic cell activation at this site. Dendritic cell activation was further confirmed *in vitro* along with its effect on T cell differentiation and proliferation. We have proposed a mechanism of protection based on participation of the antigen portion of our vaccine along the adjuvant in activating antigen presenting cells of the immune system and subsequent presentation to T cells. This proposed mechanism would allow bacterial clearance in the gut upon infection with *Shigella* spp.

## 1139

### EARLY ENTEROPATHOGENIC *E. COLI* INFECTIONS ASSOCIATED WITH GROWTH FALTERING AT 24 MONTHS OF AGE IN URBAN BANGLADESH

Michael B. Arndt<sup>1</sup>, Patricia B. Pavlinac<sup>2</sup>, Barbra A. Richardson<sup>2</sup>, Tahmeed Ahmed<sup>3</sup>, Mustafa Mahfuz<sup>3</sup>, Rashidul Haque<sup>3</sup>, Grace C. John-Stewart<sup>2</sup>, Donna M. Denno<sup>2</sup>, Judd L. Walson<sup>2</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

*Escherichia coli* (*E. coli*) are among the first microbes to colonize the infant gut. *E. coli* pathotypes (heat labile (LT-) or heat stable (ST-) enterotoxigenic (ETEC), typical and atypical enteropathogenic (tEPEC, aEPEC), enteroaggregative (EAEC), enteroinvasive (EIEC), and Shiga-toxin producing (STEC)) are among the leading causes of child diarrhea globally. Early life enteropathogen exposure has been associated with child stunting in low-resource settings, however the contribution of pathogenic *E. coli* has not been well characterized. We sought to describe the frequency of pathogenic *E. coli* infection from birth to 6 months of age in urban Bangladesh, and to identify strains associated with linear growth at 24 months of age. Healthy newborns from Dhaka, Bangladesh enrolled in MAL-ED cohort were visited every other day for 2 years for morbidity and health behavior assessment. Length was measured monthly, and stools collected monthly through 1 year of age from children without diarrhea, and each time a child had diarrhea. *E. coli* spp. were identified using conventional stool culture, and virulence genes were detected by multiplex PCR. Linear regression was used to model the relationship between detection of *E. coli* pathotypes in the first 6 months and length for age z-score (LAZ) at 24 months of age, controlling for LAZ at birth, exclusive breastfeeding in the first 100 days, and number of diarrhea episodes before 6 months. Among 210 children enrolled, 89% had at least one *E. coli* pathotype identified in their stool in the first 6 months of life. The most commonly detected pathotypes were EAEC (79%) and tEPEC (22%). Accounting for potential confounders, the mean LAZ at 24 months was 0.37 lower in children with tEPEC detected in any stool (95% CI: -0.64, -0.09,  $p=0.009$ ) and 0.39 lower in children with LT-ETEC than those without (95% CI: -0.71, -0.06,  $p=0.022$ ). There were no associations among other pathotypes and linear growth at 24 months. Early tEPEC and LT-ETEC infections were significantly associated with growth faltering in children in urban Bangladesh. Early tEPEC infections may be influencing child growth even in the absence of diarrhea.

### LONGITUDINAL COHORT STUDY OF ACUTE GASTROENTERITIS AMONG U.S. MILITARY PERSONNEL DEPLOYED TO HONDURAS FROM 2014-2016

Mark P. Simons<sup>1</sup>, Giselle Soto<sup>2</sup>, Faviola Reyes<sup>3</sup>, Michael Goodson<sup>4</sup>, Nathaneal D. Reynolds<sup>1</sup>, Jamie Fraser<sup>5</sup>, Ricardo Aviles<sup>3</sup>, David Tribble<sup>6</sup>, Ramiro Gutierrez<sup>1</sup>, Mark S. Riddle<sup>1</sup>

<sup>1</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>2</sup>Naval Medical Research Unit-6, Callao, Peru, <sup>3</sup>U.S. Joint Task Force Bravo, Comayagua, Honduras, <sup>4</sup>Wright-Patterson Air Force Base, Dayton, OH, United States, <sup>5</sup>Henry M. Jackson Foundation and Infectious Disease Clinical Research Program, Department of Preventive Medicine and Biostatistics, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>6</sup>Infectious Disease Clinical Research Program, Department of Preventive Medicine and Biostatistics, Uniformed Services University of the Health Sciences, Bethesda, MD, United States

The need for field sites to monitor infectious disease burden among deployed military personnel and for evaluation of treatment and preventive interventions, including vaccines is a strategic need for the U.S. military. We established a field site at Soto Cano Air Base for clinical trials among military deployed to Honduras complete with an on-site laboratory

for stool cultures, in-house BioFire FilmArray GI pathogens panel, and reference capacity at NAMRU-6 in Peru for enhanced workup. With this framework, we developed a pilot longitudinal cohort study for acute gastroenteritis (AGE) during two deployment cycles from June 2015-March 2016 and March-November 2016. Participants were given a description of the study during their medical in-brief and allowed to individually meet with the civilian study coordinator for consent, completion of data forms, and submission of baseline stool samples. A total of 39 persons were enrolled with 1 loss to follow-up. Subjects were contacted weekly to track illness and if ill were asked to complete a case report form and submit a stool sample for testing. Additionally, 10 subjects were recruited into a nested gut microbiome study to explore changes associated with deployment and illness. In this subset, participants submitted stool samples weekly regardless of illness events and completion of a daily diet log. During this period there were 16 episodes of AGE over 316.6 months at risk for an incidence rate of 5.1 per 100 person-months as compared to the incidence of respiratory illness of 2.8 per 100 person-months. Stool culture yielded only 1/16 (6%) isolate of *Shigella sonnei*, whereas the FilmArray was positive in 12/16 (75%) of cases with 9/12 (75%) found positive for multiple pathogens versus only 3/12 (25%) with a single pathogen. Diarrheagenic *E. coli* was found in all 12 cases with 7/12 (58%) EPEC-positive, 7/12 (58%) ETEC, and 6/12 (50%) with EAEC. These findings illustrate the complex etiology of diarrhea in deployed settings. Gut microbiome analysis and correlations with dietary and illness is pending. This study provides a foundation for future clinical trials for treatment regimens and vaccines at this site.

The global burden of diarrhea is high, particularly among children in low- and middle-income countries. Despite global recommendation of continued feeding, prior studies have reported inadequate adherence to this recommendation during diarrheal episode treated at home. We hypothesized that continued feeding (offering usual or more than usual amount of food) during home treatment of moderate-to-severe diarrhea (MSD) will reduce case-fatality. Using data from the 7 sites of the Global Enteric Multicenter Study, we conducted secondary analyses to estimate prevalence of continued feeding during home treatment of MSD and exclusive breastfeeding among babies less than 6 months old. We also estimated risk ratios (RR) and 95% confidence intervals (CI) for death, in relation to continued feeding at home before seeking care for the MSD episode. Prevalence of exclusive breastfeeding among babies less than 6 months old was low across the sites, ranging from 9.5% to 52.2%. Prevalence of continued feeding during MSD varied across sites ranging from 19.3 to 88.9%, with low pooled prevalence of 43.6%. In multivariable pooled analyses adjusted for age, sex and socioeconomic status, continued feeding was inversely associated with extended case-fatality at follow up visits 50-90 days after MSD episodes (0.47, CI 0.22-1.03), but the association was borderline statistically significant. Further analyses that examine the role of factors such as nutritional status, maternal education and concomitant treatments (oral rehydration and zinc) in this association are still needed. Future studies should address a broader range of potential confounders and evaluate impact of interventions to facilitate uptake of continued feeding on case-fatality in low-income settings.

<sup>1</sup>Protein Potential LLC, Rockville, MD, United States, <sup>2</sup>Sanaria Inc., Rockville, MD, United States, <sup>3</sup>Kansas State University College of Veterinary Medicine, Manhattan, KS, United States, <sup>4</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Recent reports estimated that shigellosis, ETEC diarrhea, and typhoid fever caused a combined 448 million cases and close to 200,000 deaths annually. Sadly, there are no vaccines against shigellosis nor ETEC diarrheal disease and licensed vaccines against typhoid are only partially effective. We exploit the extensive safety and long-term efficacy record of the live, oral, attenuated Ty21a typhoid fever vaccine, which has been administered to more than 200 million individuals worldwide, by utilizing it as our vector for combination oral vaccines. We established an acid-stabilized Ty21a platform that carries stable, inducible expression of glutamate-glutamine based acid resistance genes and showed that this strain (Ty21a-AR) is acid resistant *in vitro*. This strategy allows for increased passage of vaccine organisms through the acid environment of the stomach, thereby optimizing immunogenicity and protective efficacy. Genes encoding serotype-specific O-antigens of *Shigella* spp. and a multi-epitope fusion

antigen (MEFA) of toxoided heat-labile toxin of ETEC were integrated into the chromosome of our innovative acid-stabilized Ty21a-AR strain. Our most advanced vaccine candidate, Ty21a-AR-Ss (TyOraSs), expressed *S. sonnei* form I O-antigen and *Salmonella* Typhi O-9,12-antigens simultaneously on the cell surface. Mice immunized with TyOraSs through a mucosal route produced IgG antibodies to both *S. sonnei* and *S. Typhi* O-antigens and were protected by a lethal infection of *S. sonnei* 53G. We have also constructed Ty21a-AR-Sf2a (TyOraSf2a) that expresses *S. flexneri* 2a O-antigen on Ty21a-AR cell surface and demonstrated immunogenicity of TyOraSf2a in mice. We have innovatively stabilized our Ty21a-vector platform at room temperature using foam dry technology. By proving the principle that our rTy21a shigellosis and ETEC vaccines are safe, well tolerated, and immunogenic and the shigellosis vaccine is protective, we will establish acid-stabilized rTy21a as a flexible, oral, rapidly administered (over 1 week), room temperature stable vector platform for rapid response to emerging and re-emerging infectious disease threats.

## 1143

### YERSINIA PESTIS SURVIVES AND REPLICATES IN PHAGOCYTOTIC AMOEBAS: THE CONTINUING SEARCH FOR AN ENVIRONMENTAL PLAGUE RESERVOIR

David W. Markman<sup>1</sup>, Michael F. Antolin<sup>1</sup>, Richard A. Bowen<sup>1</sup>, William H. Wheat<sup>1</sup>, Michael E. Woods<sup>2</sup>, Mary Jackson<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Centers for Disease Control, Fort Collins, CO, United States

Plague ecology is characterized by sporadic epizootics, followed by periods of cryptic dormancy. Building evidence suggests environmentally ubiquitous amoebae act as "feral macrophages" and permissive hosts to a wealth of competent intracellular pathogens. We performed environmental genetic surveys and laboratory co-culture infection experiments to assess whether plague bacteria were resistant to digestion by five common environmental amoeba species. We demonstrate: (1) *Yersinia pestis* is an amoeba-resistant microorganism, (2) *Y. pestis* survives and replicates intracellularly within the social amoeba, *Dictyostelium discoideum*, for at least 48h post-infection, (3) *Y. pestis* is transiently amoeba-resistant in four other free-living amoeba species, and (4) *Y. pestis* resides within amoeba structures visually synonymous to those found in infected human macrophages, for which *Y. pestis* is a competent intracellular pathogen. Evidence for the existence of plague reservoirs and these newly identified amoeba-resistance phenotypes in *Y. pestis* stress the importance of recognizing pathogen-harboring amoebae as potential threats to global health, agriculture, conservation, and biodefense.

## 1144

### PREVALENCE OF ACUTE CHORIOAMNIONITIS AMONG HIV INFECTED AND UNINFECTED PREGNANT UGANDAN WOMEN AND ITS ASSOCIATION WITH ADVERSE BIRTH OUTCOMES

John Ategeka<sup>1</sup>, Razack Wasswa<sup>1</sup>, Abel Kakuru<sup>1</sup>, Gabrielle Rizzuto<sup>2</sup>, Atis Muehlenbachs<sup>3</sup>, Moses R. Kamya<sup>4</sup>, Grant Dorsey<sup>5</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Department of Anatomic Pathology, University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Infectious Diseases Pathology Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>4</sup>School of Medicine, Makerere University, College of Health Sciences, Kampala, Uganda, <sup>5</sup>Department of Medicine, Division of Infectious Diseases, University of California San Francisco, San Francisco, CA, United States

Preterm birth (PTB) is a leading cause of neonatal mortality and longer-term morbidity. Acute chorioamnionitis (ACA) is a common cause of PTB, however, there are limited data on the prevalence of ACA and its association with PTB in resource limited settings. Data and samples came from clinical trials evaluating novel strategies for the prevention of malaria in HIV infected and uninfected pregnant women in Uganda. Women were enrolled between 12-28 weeks gestation and followed through

delivery. For each placenta delivered, 3 placental tissue types (placental membrane roll, umbilical cord and fetal plate) were collected. Slides were assessed for histologic diagnosis of maternal and fetal ACA by microscopic evaluation of neutrophilic infiltration of the placenta using a grading scale. The primary outcomes were preterm birth (< 37 weeks) and low birth weight (LBW, < 2500gm). Biopsies were collected from a total of 486 placentas, with 483 included in the analysis (40.4% HIV infected, 59.6% HIV uninfected). Evidence of maternal ACA was seen in 44.3% of samples (21.2% mild, 12.3% moderate, and 10.8% severe). Evidence of fetal ACA was seen in 26.1% of samples (15.5% mild, 8.9% moderate, and 1.7% severe). There were no significant associations between HIV status or gravidity and maternal or fetal ACA. HIV infected women with evidence of moderate-severe ACA had a significantly higher risk of preterm birth (25.0% vs. 6.0%; RR=3.97, 95% CI 1.68-9.36, p=0.002) and LBW (22.7% vs. 9.4%; RR=2.14, 95% CI 1.03-4.43, p=0.04) compared to those with mild or no ACA after adjusting gravidity and maternal age. There was no significant association between evidence of maternal ACA and adverse birth outcomes among HIV uninfected women or between fetal ACA and adverse birth outcomes regardless of HIV status. Histological evidence of maternal ACA was associated with an increased risk of preterm birth and LBW among HIV infected women but not HIV uninfected women.

## 1146

### CHARACTERIZATION OF ANTI-*HELICOBACTER PYLORI* PEPTIDES PRESENT IN THE HEMOLYMPH OF *HERMETIA ILLUCENS* LARVAE

Daniela Alvarez<sup>1</sup>, Kevin A. Wilkinson<sup>2</sup>, Michel Treillhou<sup>3</sup>, Nathan Téné<sup>3</sup>, Denis Castillo<sup>1</sup>, Michel Sauvain<sup>1</sup>, Michel Sauvain<sup>4</sup>

<sup>1</sup>Cayetano Heredia Peruvian University, Lima, Peru, <sup>2</sup>Antenor Orrego Private University, Trujillo, Peru, <sup>3</sup>Centre Universitaire de Formation et de Recherche Jean-François Champollion, Albi, France, <sup>4</sup>UMR 152 PHARMA-DEV, Université de Toulouse, IRD, UPS, Toulouse, France

More than half of the global population is infected by the gastric pathogen *Helicobacter pylori*, often since childhood. This waterborne bacteria is known to cause chronic gastritis, peptic ulcers, and is a risk factor for gastric adenocarcinoma development. It is highly prevalent in tropical developing nations. Chemotherapeutic eradication of *H. pylori* is necessary to treat the accompanying gastrointestinal disorders. However, resistance to first line antibiotics is increasing, especially for clarithromycin (17.5%) and metronidazole (34.9%). Therefore, we are searching for alternative chemotherapeutic agents, such as antimicrobial peptides (AMPs) from insects. AMPs are immune system molecules present in every living organism; indeed, some have been found with activity against multidrug resistant bacteria. Our research focuses on the Black Soldier Fly (*Hermetia illucens*), a saprophytic dipteran that can tolerate pathogen-rich environments, such as decomposed waste and manure. Due to its life cycle, we postulate that it is a rich source of useful AMPs. Hemolymph peptidome analysis of inoculated *H. illucens* larvae using centrifugal filtration and sequential reverse-phase preparative liquid chromatography revealed a fraction of 3-10 kDa that had a minimal inhibitory concentration of 31.3 µg/ml against *H. pylori* ATCC®43504. Mass spectrometry (MS) divulged that the active fraction contained four polycationic peptides with masses near 4.2 kDa (~36 aa). Production of these peptides is inducible, as their expression hardly occurred in uninoculated control larvae. These peptides have very similar sequences and no disulfide bridges. To our knowledge, this is the first time that an antibacterial effect against Gram-negative microorganisms has been demonstrated in *H. illucens*. We are now trying to elucidate the primary sequence of the active peptides using MS.

## 1147

### UTILIZING THE GENEEXPERT TESTING SYSTEM FOR SEXUALLY TRANSMITTED INFECTION DIAGNOSIS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Kamy K. Musene<sup>1</sup>, Gisèle M. Mvumbi<sup>2</sup>, Nicole A. Hoff<sup>3</sup>, Camille T. Dzogang<sup>1</sup>, Patrick K. Mukadi<sup>4</sup>, Maxime Masisa<sup>2</sup>, Daniel B. Mukadi<sup>4</sup>, Adva Gadoth<sup>3</sup>, Emile W. Okitolonda<sup>2</sup>, Pamina Gorbach<sup>3</sup>, Risa Hoffman<sup>5</sup>, Jeffery Klausner<sup>5</sup>, Anne W. Rimoin<sup>3</sup>

<sup>1</sup>University of California Los Angeles-DRC Research Program, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, <sup>4</sup>Institut National de Recherche Médicale, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA, United States

Sexually transmitted infections (STIs), excluding HIV, are the second most common cause of healthy life years lost by women 15 - 44 years old in Africa. More than one million STIs are acquired every day worldwide, and many are asymptomatic. In many resource-limited countries, including the Democratic Republic of the Congo (DRC), a syndromic approach for testing and treating STIs is used. This method is non-specific and often leads to misdiagnosis and mistreatment, which can generate serious reproductive health consequences and promote antibiotic resistance among vulnerable populations. From October 2016 to March 2017, we conducted a cross-sectional study in pregnant women receiving antenatal care in Kisantu, DRC to compare self-reported and clinically-observed syndromic diagnosis to a PCR-based GeneXpert® rapid testing technology (Cepheid, Sunnyvale, CA). Consenting participants were enrolled; completed a questionnaire on sociodemographic factors, sexual history, and STI symptoms; and had a vaginal swab collected during clinical observation of the genital area. Swab specimens were tested with the Xpert® CT/NG Assay and Xpert® TV Assay for *Chlamydia trachomatis*, *Neisseria gonorrhoea* and *Trichomonas vaginalis*, respectively. Among 352 pregnant women, 59 (16.8%) self reported vaginal symptoms (ulcer, vaginal discharge, genital warts). Of those women, 6.7% had clinically-observed symptoms or lesions, and 15.2% were found positive for an STI via GeneXpert®. Almost the same percentage of asymptomatic women (15.0%, n=44/293) were also found positive upon nucleic acid amplification testing, resulting in very low symptom reporting-based sensitivity and specificity (17.0% and 83.3%, respectively) when compared against the gold standard technology. These results suggest that syndromic STI management is insufficient, and that GeneXpert® technology may be appropriate for disease diagnosis in resource-limited areas. Rapid NAAT diagnosis allows for detection of STI-positive women who may have been missed by traditional syndromic testing and further identifies specific infective species to ensure proper and timely treatment.

## 1148

### FREQUENCY OF ANTIBIOTIC RESISTANCE AND ADHESION GENOTYPES IN *ESCHERICHIA COLI* STRAINS ISOLATED FROM VAGINAL INFECTIONS

Gloria Luz Paniagua-Contreras, Eric Monroy-Pérez, Areli Bautista-Cerón, José Rogelio Reyes-Solís, Susana González-Almazán, Patricia Sánchez-Yañez, Sergio Vaca  
UNAM FES Iztacala, Tlalnepantla, Mexico

The purpose of this work was to establish the frequency of the genes encoding adhesins (*fimH*, *papA*, *papC*, *papEF*, *papGI*, *papGII*, *papGIII*, *iha*, *afa*, *sfa*, *sfaE*, *bmaE*, *focG*, and *gafD*), and antibiotic resistance genes [*aac3-IV* (gentamicin), *CITM* (betalactams), *cmla* (chloramphenicol), *tet(A)* and *tet(B)* (tetracycline), *dfrA1* (trimethoprim) and *qnr* (quinolones)] in a group of cervicovaginal *Escherichia coli* strains (CVEC). We analyzed 200 strains of *E. coli* isolated from patients with cervicovaginal infections from the outpatient clinic of two IMSS clinics in the State of Mexico.

Identification of *E. coli* was performed by biochemical tests and by PCR amplification of the 16S rRNA gene. Adhesion and resistance genes to antibiotics were detected by conventional PCR and by multiplex PCR. Eighty-nine percent (n = 179) of the *E. coli* strains were carriers of the *fimH* gene, 11% (n=22) of *papA*, 41% (n=82) of *papC*, 26.5% (n=53) of *papEF*, 33.5% (n=67) of *papGII*, 3% (n=6) of *papGIII*, 51.5% (n=103) of *iha*, 9% (n=18) of *afa*, 14.5% (n=29) of *sfa*, and 9% (n=18) of *focG*. The *papGI*, *sfaS*, *bmaE* and *gafD* genotypes were not identified in any of the strains. A total of 36% (n = 72) of the strains were carriers of the *dfra1* gene, 14.5% (n = 29) of *CITM*, 3.5% (n = 7) of *cmla*, 49.5% (n=99) of *tet(A)*, 33.5% (n = 67) of *tet (B)*, and 4.5% (n = 9) of *aac(3)-IV*. The *qnr* gene was not identified in any strain. The results obtained in this study showed that strains of *E. coli* responsible for cervicovaginal infections were carriers of multiple genotypes of adhesion and resistance to antibiotics, which could increase the seriousness of infectious processes. This results may be used to orient the doctors to prescribe the appropriate treatment.

## 1149

### COLONIZATION WITH ESBL-PRODUCING ENTEROBACTERIACEAE OF HOUSEHOLD MEMBERS AND NEIGHBORS TWO MONTHS AFTER DISCHARGE OF COLONIZED PATIENTS FROM HOSPITAL IN RWANDA

Mathis S. Kurz<sup>1</sup>, Claude Bayingana<sup>2</sup>, Jules Ndoli<sup>2</sup>, Augustin Sendegeya<sup>2</sup>, Jean Bosco Gahutu<sup>2</sup>, **Frank P. Mockenhaupt**<sup>1</sup>

<sup>1</sup>Charité-Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>University Teaching Hospital of Butare, University of Rwanda, Butare, Rwanda

At the University Teaching Hospital of Butare, Rwanda, we recently observed two thirds of patients to be colonized with ESBL-producing Enterobacteriaceae (ESBL-PE) at discharge. Two months later, we visited the households of previously colonized patients, screened them for ESBL-PE carriage as well as each two household members and one household animal. In parallel, three household members and one animal of the neighboring dwelling were screened for each index patient (group sizes, 43 to 66) as well as >1000 schoolchildren in the study area. Rectal swab samples were screened on chromogenic agar, and bacterial species were determined using the API-20E system. Two months after discharge, approximately one third of the previous patients and of the household members were ESBL-PE carriers. Among members of the neighboring households, this figure was ten percent lower ( $P = 0.03$ ), similar to the difference on the level of household animals. *Escherichia coli* was the predominant ESBL-PE species. ESBL-PE carriage in patients' and neighbors' household was positively associated ( $P = 0.03$ ) in addition to other risk factors to be presented. The community prevalence of ESBL-PE (schoolchildren) was 4.9%. The observed gradient of ESBL-PE carriage from patients' households to neighbors and schoolchildren suggests transmission of highly resistant pathogens from hospital to community. Prevention of hospital-related acquisition of ESBL-PE and hygiene counselling of colonized patients may help to contain further spread.

## 1150

### A ROBUST INCUBATOR TO FACILITATE MORE WIDESPREAD BACTERIAL CULTURE FOR LOW RESOURCE ENVIRONMENTS IN DEVELOPING COUNTRIES

**Andrew K. Miller**<sup>1</sup>, Simon Ghionea<sup>1</sup>, Manivanh Vongsouvath<sup>2</sup>, Viengmon Davong<sup>2</sup>, Mayfong Mayxay<sup>2</sup>, Akos Somoskovi<sup>1</sup>, Paul N. Newton<sup>2</sup>, David Bell<sup>1</sup>, Michael Friend<sup>1</sup>

<sup>1</sup>Intellectual Ventures Laboratory, Bellevue, WA, United States, <sup>2</sup>Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (LOMWRU), Vientiane, Lao People's Democratic Republic

In order to address the limitations of operating currently available incubators in low resource environments, a new incubator design was developed and tested to meet the requirements of operation in laboratories without reliable power (power outages up to 12 hours) or

climate control (ambient indoor temperatures from 5°C to 45°C). This incubator is designed to broaden the reach of microbiological culture in poorly-resourced health systems, to guide case management and presumptive treatment of a community, and enable extension of antimicrobial resistance (AMR) and disease surveillance. The challenges of operation in low resource environments were met by a design that uses phase change materials (PCM) as a bi-directional thermal battery to maintain incubation temperature during prolonged power outages and periods of poorly regulated input power in ambient temperatures ranging from 5°C to 45°C. Five prototypes were built and tested in the laboratory using environmental test chambers and programmable power supplies. Three of the prototypes were then successfully field tested in Laos in conjunction with the Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (LOMWRU). The devices were operated for an extended period in representative target facilities by health technicians performing an interaction script designed to replicate the intended use of the device.

## 1151

### ADHESION AND FIBRIN CLOTTING INHIBITION BY LEPTOSPIRAL PROTEINS

**Ana L. Nascimento**<sup>1</sup>, Priscila Pereira<sup>1</sup>, Luis Fernandes<sup>1</sup>, Gisele Souza<sup>2</sup>, Silvio Vasconcelos<sup>2</sup>

<sup>1</sup>Instituto Butantan, Sao Paulo, Brazil, <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil

Leptospirosis is a global infectious disease of human and veterinary concern. The study of surface antigens may shed light to pathogen-host interactions and help the identification of serodiagnosis and vaccine targets. This study was undertaken to data mine the genome sequences of *L. interrogans* to identify proteins predicted to be located at cell surface. To characterize two membrane proteins, using *E. coli* as expression system. Binding of these proteins to human components was evaluated. Recognition of these proteins in leptospirosis human sera was performed. Extracts of different species of *Leptospira* were membrane-blotted and probed with antisera raise in mice against each recombinant protein. The interaction of recombinant proteins with human components was evaluated by ELISA. Confirmed leptospirosis human sera were set to interact with recombinant proteins, measuring total IgG antibodies; samples at the onset (MAT-) and convalescent (MAT+) phases of the diseases were employed, and reactivity was compared to commercial normal human serum samples, employed for cut-off calculation. In conclusion, the native proteins are conserved among the pathogenic strains of *Leptospira*. The interactions of the two recombinant proteins with plasminogen, fibrinogen and laminin are dependent on protein concentration, reaching saturation point. The binding of one of the proteins to fibrinogen inhibited the formation of fibrin clot. The plasminogen captured by both recombinant proteins could be converted into plasmin, a mechanism that could help bacterial penetration in the host. Both proteins are capable of inducing immune response in humans, suggesting that these proteins are expressed during infection and may participate in *Leptospira*-host interactions.

## 1152

### THIRTEEN GLOBALLY CONDUCTED PRE-CLINICAL STUDIES ON DNA VACCINES AGAINST LEPTOSPIRA: A SYSTEMATIC REVIEW

**Rathnabahu Mudiyansele I. Senavirathna**, Devarajan Rathish, Suneth B. Agampodi

Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka

DNA vaccines have gained a novel place in prevention of bacterial infections. This study systematically reviews pre-clinical studies on DNA vaccines against *Leptospira*. All articles in English, regardless of the country of evaluation, were included from the following databases: PubMed, Trip, Google-Scholar, Science-Direct, Cochrane-Library, Google, Open-Grey and

Grey-literature-report. Also, the reference lists of selected articles were screened for suitable studies. PRISMA 2009 guidelines were followed in conducting and reporting of this study results. Quality assessment of the selected studies was done using the SYRCEL's risk of bias tool for animal studies. Thirteen were included in the final analysis. The average quality assessment score was 6.7 (SD  $\pm$  1) out of 10. Thirty-nine percent (n=13) of the study was from Brazil, which was the highest. pTARGET plasmid (31%; n=13) and LipL32 (39%; n=13) were used as the commonest vector and target gene respectively. 31% (n=13) of the studies had *Leptospira interrogans* Copenhageni-Fiocruz-L1-130 as its main strain used in the construction of vaccine. The commonest expression system used was Prokaryotic-E.coli TOP 10 (31%; n=13). Golden Syrian hamster female and BALB/c mice were the commonest animal models used (39% each). Copenhageni Spool, Canicola Hond Utrecht and Pamona (Each 25% - 2/8) were the main strains used in challenging of DNA vaccine. Vector alone treatment (85%) was the commonest method among control groups. The humoral immune response was measured using ELISA in 85% of the studies. Hundred percent potential protective response and zero percent pathological events was seen with interventional DNA vaccines. Enhancement of the efficacy and safety of DNA vaccines against *Leptospira* relies on the finding of optimum vaccination schedule. This could be achieved only with further studies.

## 1153

### MLST ANALYSIS OF *BURKHOLDERIA PSEUDOMALLEI* ISOLATES FROM SRI LANKA

**Aruna Dharshan De Silva**<sup>1</sup>, Harindra D. Sathkumara<sup>1</sup>, Adam J. Merritt<sup>2</sup>, Enoka M. Corea<sup>3</sup>, Shivankari Krishnananthasivam<sup>1</sup>, Mohan Natesan<sup>4</sup>, Timothy J. Inglis<sup>5</sup>

<sup>1</sup>Genetech Research Institute, Colombo, Sri Lanka, <sup>2</sup>PathWest Laboratory Medicine, Nedlands, Australia, <sup>3</sup>University of Colombo, Colombo, Sri Lanka, <sup>4</sup>United States Army Medical Research Institute of Infectious Diseases, Frederick, MD, United States, <sup>5</sup>PathWest Laboratory Medicine, Nedlands, Australia

*Burkholderia pseudomallei* is a Gram-negative bacterium found in soil and water in tropical and subtropical regions worldwide. It causes melioidosis, a severe disease with a broad spectrum of clinical presentations endemic to Southeast Asia and northern Australia. Sri Lanka is situated in an endemic belt and over the last few years we started a project screening undifferentiated fever cases to identify potential melioidosis cases in Sri Lanka. As a result of this screening the number of culture confirmed cases have risen dramatically, with over 50 cases being reported each year in recent years. Genotyping via multi-locus sequence typing (MLST) was carried out to differentiate Sri Lankan isolates from others found worldwide and a large genetic diversity was seen. Sequence types (ST) and isolation data were submitted to the international *B. pseudomallei* database (<http://pubmlst.org/bpseudomallei/>) to aid in understanding the best representation of ST abundance. A total of 108 strains clinical isolates from 2006 until 2015 were genotyped. MLST analysis revealed that they belonged to 46 different STs in which 23 novel STs were found demonstrating great diversity in Sri Lanka. ST1137 is the commonest ST and there were five shared STs (10 isolates), of which three were exclusive to the Southeast Asian region (ST308, ST655 and ST912). Five isolates belonged to ST594 which has been seen among clinical and environmental isolates in both Australia and Thailand. Surprisingly, one of our isolates belonged to ST 132, an exclusive Australian ST which is seen among clinical, animal and environmental specimens. As of 2016, Sri Lanka has the largest representation on the MLST database of all the South Asian countries. We identified 46 STs representing a total of 108 clinical isolates, the commonest of which were STs 1137, 1135, 1132, 1136, 1434 and 1140. These six genotypes accounted for half the isolates and half the deaths. This work outlines our preliminary findings from an externally funded project to identify the strains and study the melioidosis disease burden in Sri Lanka.

## 1154

### EXAMINATION OF LABORATORY DATA FOR SURVEILLANCE OF ANTIMICROBIAL RESISTANCE IN OUTPATIENT URINARY TRACT INFECTIONS IN TAMIL NADU, INDIA — THE RATIONALE FOR CASE-BASED SURVEILLANCE

Kolandaswamy Karumanagounder<sup>1</sup>, **Mohan Kumar Raju**<sup>2</sup>, Aditya Sharma<sup>3</sup>, Premkumar Balasubramanian<sup>1</sup>, Raju Sivadas<sup>1</sup>, Neil Gupta<sup>3</sup>, Malar Nagamani<sup>4</sup>, Muthaiah Namasivayam<sup>5</sup>, Benjamin Park<sup>3</sup>, Kayla Laserson<sup>6</sup>, Jay Graham<sup>7</sup>, Padmini Srikantiah<sup>6</sup>

<sup>1</sup>Directorate of Public Health and Preventive Medicine, Chennai, Tamilnadu, India, <sup>2</sup>Public Health Institute, Chennai, India, <sup>3</sup>Centre For Disease Control, Atlanta, GA, United States, <sup>4</sup>District Public Health Laboratory, DPH&PM, Tenkasi, Tirunelveli Dt, Tamilnadu, India, <sup>5</sup>District Headquarters Hospital, DM&RHS, Tenkasi, Tirunelveli Dt, Tamilnadu, India, <sup>6</sup>U.S. Centers for Disease Control and Prevention, Global Disease Detection Program, New Delhi, India, <sup>7</sup>Public Health Institute, Oakland, CA, United States

The global spread of antimicrobial resistance (AR) is a serious public health threat that requires rigorous surveillance to guide interventions. Laboratory-based approaches, which summarize results of routine clinical specimens, are commonly used for AR surveillance. In India, most published reports describe AR in routine isolates from inpatients in tertiary-care facilities in metropolitan centers; few describe AR in outpatient infections in rural settings. We evaluated a laboratory-based approach to describe AR in isolates from outpatient urinary tract infections (UTIs) in a rural population in Tamil Nadu. Clinicians were interviewed to assess practices for referring outpatients for urine culture. All outpatients who provided a urine specimen for microbiological culture at a district hospital in Tamil Nadu during 2015 were included. Urine specimen results of 218 unique UTI episodes were reviewed. Of 82 (37.6%) culture-positive specimens, 63 (76.8%) had an Enterobacteriaceae isolate; most of these were *Escherichia coli* (52.4%) and *Klebsiella spp.* (20.7%). Of the 63 Enterobacteriaceae isolates assessed, 46 (73.0%) were resistant to third-generation cephalosporins. Twelve Enterobacteriaceae isolates were tested for carbapenem resistance; of these, 10 (85.7%) were resistant. Clinician interviews revealed that urine culture was not routinely performed for all outpatients with UTI symptoms; those who failed empiric UTI treatment were preferentially referred. Resistance to third-generation cephalosporins and carbapenems in tested Enterobacteriaceae isolates from urine specimens was common in rural Tamil Nadu. However, non-uniform microbiological referral practices limit measuring the true extent of AR in outpatient UTIs in this population. Surveillance based on routine clinical specimens might overestimate AR due to systematic bias in patients sampled. Case-based surveillance, which involves sampling and testing all patients with a defined clinical syndrome, would more accurately describe the magnitude of AR infections in a population to direct public health action, including data-driven antibiotic guidance.

## 1155

### UNEXPECTED PREVALENCE AND GEOGRAPHIC SPREAD OF SCRUB TYPHUS IN INDIA

**Govindakarnavar Arunkumar**<sup>1</sup>, Jayaram Anup<sup>1</sup>, Mohan Papanna<sup>2</sup>, Devadiga Santhosh<sup>1</sup>, Rao Chaitra<sup>1</sup>, Abdulmajeed Jazeel<sup>1</sup>, Sushama Aswathyraj<sup>1</sup>, Nittur Sudheesh<sup>1</sup>, A. Gokuldev<sup>3</sup>, S. Girish<sup>4</sup>, Prabhakar Gujjarappa<sup>4</sup>, Pradeep Khasnobis<sup>5</sup>, Srinivas Venkatesh<sup>5</sup>, Jagdish Prasad<sup>6</sup>, Kayla F. Laserson<sup>2</sup>

<sup>1</sup>Manipal University, UDUPI, Karnataka, India, <sup>2</sup>U.S. Centers for Disease Control and Prevention, India Office, New Delhi, India, <sup>3</sup>District Hospital, Mananthawady, Kerala, India, <sup>4</sup>Jayachamarajendra Hospital, Thirthahalli, Karnataka, India, <sup>5</sup>National Centre for Disease Control, Ministry of Health and Family Welfare, Government of India, Delhi, India, <sup>6</sup>Directorate

General of Health Services, Ministry of Health and Family Welfare, Government of India, New Delhi, India

Scrub typhus (*ST-Orientia tsutsugamushi*) has been recognized as a cause of acute febrile illness (AFI) in India since 1932; until recently, it was considered a rare disease. In 2014, as part of Global Health Security (GHS), we initiated a facility-based AFI surveillance platform. From June 2014-Sept 2016, we enrolled all admitted AFI patients with documented or reported fever <15 days duration from 29 district/sub-district hospitals in 10 states of India. We recorded demographic and clinical data, and tested for bacterial, viral and parasitic diseases, including leptospirosis, malaria, dengue, influenza, Kyasanur Forest Disease, chikungunya, typhoid, brucellosis, and scrub typhus. An optical density of  $\geq 0.5$  was considered probable ST using a serum IgM ELISA. We enrolled 12013 AFI patients; of these, 5942 (49.5%) were positive for any pathogen. Of those with a diagnosis, 577 (9.7%) were ST-positive: Odisha (1/7, 14.3%), Kerala (218/2226, 9.8%), Jharkhand (26/332, 7.8%), Tripura (26/424, 6.1%), Tamil Nadu (42/778, 5.4%), Karnataka (189/4878, 3.9%), Maharashtra (12/379, 3.2%), Assam (39/1458, 2.7%), Gujarat (7/324, 2.2%), Goa (17/1207, 1.4%). ST was the 4th most common pathogen, after influenza (35.5%), dengue (13.7%) and leptospirosis (10.2%). ST-positive patients ranged from 1-65 years (median age 35 years); 62% were male. 10% of patients (58/577) presented with neurological symptoms, and 2% had identified skin eschars. Low platelet counts ( $<150000/\mu\text{l}$ ) were observed in 37% (173) patients, elevated liver enzyme in 69% (227) patients, and raised C-reactive protein (above 6mg/dl) in 81% (119) patients. <1% of patients died. This study documents unexpected prevalence and large geographical spread of scrub typhus across India. As ST is more common than previously estimated, routine testing for ST at district or lower level facilities should be considered. AFI platforms, as are being built under GHS, are critical for the comprehensive detection, characterization, response, and control of known pathogens and may lead to detection of novel pathogens.

## 1156

### PREVALENCE OF BACTERIAL PATHOGENS IN WOUND INFECTIONS AND THEIR ANTIBIOTIC RESISTANCES ALONG THE RIVERS OF THE AMAZON BASIN

Ricardo E. Abadie<sup>1</sup>, Claudio Rocha<sup>1</sup>, Rosa Burga<sup>1</sup>, Melita Pizango<sup>1</sup>, Betty Rios<sup>2</sup>, James Regeimbal<sup>1</sup>, Nathanael Reynolds<sup>3</sup>

<sup>1</sup>U.S. Naval Medical Research Unit-6, Lima, Peru, <sup>2</sup>Dirección Regional de Salud Loreto, Iquitos, Peru, <sup>3</sup>U.S. Naval Medical Research Center, Silver Spring, MD, United States

Wound infections caused by antibiotic resistant bacterial pathogens are a growing problem in civilian and military populations. Very little is known about the prevalence and antimicrobial resistant profiles of bacterial pathogens isolated in remote regions. In order to characterize the causes of wound infections and their antibiotic resistances in remote regions, swabs of infected wounds were taken from patients who received medical care on board riverboats serving remote populations in the Amazonian region of Peru. The identification and antimicrobial susceptibility testing of bacteria isolated from the swabs were performed using standardized clinical laboratory procedures. Between November 2015 and September 2016, 52 wound samples from 51 participants  $\geq 18$  years old were taken (65% males, 35% females). In 44 of the 52 samples there was detectable bacterial growth (31 with only one pathogen and 13 with more than one); 1 sample grew yeast and in 7 samples there was no bacterial growth. A total of 60 bacterial strains were isolated. *Staphylococcus aureus* was the most common isolate with 27 isolates (27/60, 45%), followed by 7 isolates of *Aeromonas* spp. (12%), 5 of *Escherichia coli* (8%), 4 isolates of *Streptococcus pyogenes* (7%), 3 isolates of coagulase-negative *Staphylococcus* and 3 of *Pseudomonas stutzeri* (among others). It should be noted that from the 31 samples where only one pathogen was, 68% (21/31) were *S. aureus*. Of all *S. aureus* isolates, 81% (22/27) showed resistance to penicillin, 19% (5/27) were resistant to azithromycin and erythromycin each, 7% to clindamycin and 11% showed inducible

clindamycin resistance, and only one isolate (4%) was methicillin resistant. From the 5 *E. coli* 40% (2/5) were resistant to ciprofloxacin, and only one (20%) was ESBL-producing. *Staphylococcus aureus* was the pathogen most isolated in wound infections in the Amazon basin. The observed resistance profiles suggest that more remote areas, with presumably less antibiotic use, have lower incidences of antibiotic resistance. However, resistance was still detectable in each of these remote regions, exemplifying the far reaching problem of bacterial resistance.

## 1157

### THE CHANGING EPIDEMIOLOGY OF LEPTOSPIROSIS IN MAINLAND CHINA AND ITS IMPACT ON ANNUAL DISEASE BURDEN ESTIMATES

Pandji W. Dhewantara<sup>1</sup>, Abdullah A. Mamun<sup>2</sup>, Wen-Yi Zhang<sup>3</sup>, Danhuai Guo<sup>4</sup>, Wenbiao Hu<sup>5</sup>, Federico Costa<sup>6</sup>, Albert Ko<sup>7</sup>, Ricardo J. Soares-Magalhaes<sup>1</sup>

<sup>1</sup>School of Veterinary Science, University of Queensland, Gatton, Queensland, Australia, <sup>2</sup>Institute for Social Science Research, University of Queensland, Brisbane, Queensland, Australia, <sup>3</sup>Center for Disease Surveillance and Research, Institute of Disease Control and Prevention Academy of Military Medical Science, Beijing, China, <sup>4</sup>Scientific Data Center, Computer Network Information Center, Chinese Academy of Sciences, Beijing, China, <sup>5</sup>School of Public Health and Social Work, Queensland University of Technology, Brisbane, Australia, <sup>6</sup>Oswaldo Cruz Foundation, Brazilian Ministry of Health, Salvador, Bahia, Brazil, <sup>7</sup>Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States

Leptospirosis morbidity and mortality in China has significantly decreased since the 2000s. Evidence on the epidemiological changes occurring in the last decade and its implication on the burden are essential for formulating effective intervention strategies. We used time-series individual-level leptospirosis data from the Chinese National Disease Surveillance Reporting System (1st January 2005-31st December 2015) to analyze the epidemiological trend and estimate the burden over space and time and demographical groups. A total of 7,763 leptospirosis cases were reported during 2005-2015. Of which, 2,403 cases were laboratory confirmed. During 2005-2010, the incidence was gradually decreased ( $p\text{-trend}<0.001$ ), while from 2011-2015, it was relatively stable ( $p\text{-trend}>0.05$ ). Within the last 5-years, leptospirosis has emerged in the temperate region in northern China. We estimated approximately 10,313 Disability Adjusted Life Years (DALY) were lost due to leptospirosis during 2005-2015, comprising a total of 1,803 years of life with disability (YLD) and 8,509 years of life lost (YLL). The annual burden of leptospirosis was significantly reduced ( $p\text{-trend}<0.001$ ) with the greatest reduction occurred in the endemic provinces in southern China. Males were the most affected group (7,149 DALYs) compared to females (3,723 DALYs). The highest disease burden estimate was attributed to school-age children (10-19 years) living in less-developed provinces of China due to premature deaths. This age group has contributed to more than 30% of the total DALYs lost in the country. The dramatic reduction in the burden of leptospirosis in China observed in the past decade has been accompanied by an epidemiological change in the population most at risk and the geographical areas affected. Our study highlights that these changes reflect massive socio-demographic and ecological changes that China has undergone which their role deserves further investigation. Leptospirosis remains a public health threat in China. Hence, we recommend a strengthened targeted surveillance and control measures particularly in the identified endemic region in China.

## 1158

### DETECTION OF SCRUB TYPHUS IN A SUBSTANTIAL PROPORTION OF ACUTE ENCEPHALITIS SYNDROME PATIENTS IN INDIA: THE CASE FOR ROUTINE TESTING AND EVALUATION

Ravi Vasanthapuram<sup>1</sup>, Anoop Velayudhan<sup>2</sup>, Shafeeq Shahul Hameed<sup>1</sup>, Vijayalakshmi Reddy<sup>1</sup>, Reeta Subramanian Mani<sup>1</sup>, Anita Desai<sup>1</sup>, Amita Jain<sup>3</sup>, Lahari Saikia<sup>4</sup>, Bhaswathi Bandhopadhyay<sup>5</sup>, Ravi Yadav<sup>1</sup>, Sen PK<sup>6</sup>, Khasnobis P<sup>7</sup>, Dhariwal AC<sup>6</sup>, Venkatesh S<sup>7</sup>, Jagdish Prasad<sup>8</sup>, Kayla Laserson<sup>2</sup>, Padmini Srikantaiah<sup>2</sup>

<sup>1</sup>National Institute of Mental Health And Neuro Sciences, Bangalore, India, <sup>2</sup>Center for Disease Control, India Office, New Delhi, India, <sup>3</sup>King George Medical University, Lucknow, India, <sup>4</sup>Assam Medical College, Dibrugarh, India, <sup>5</sup>School of Tropical Medicine, Kolkata, India, <sup>6</sup>National Vector Borne Disease Control Program, New Delhi, India, <sup>7</sup>National Centre for Disease Control, New Delhi, India, <sup>8</sup>Director General of Health Services, New Delhi, India

In India, Japanese encephalitis virus (JE) is the most commonly recognized cause of acute encephalitis syndrome (AES). Recent reports suggest scrub typhus (ST; *Orientia tsutsugamushi* infection) may also contribute to AES burden, though ST testing is not routinely performed in AES patients. We conducted prospective facility-based AES surveillance, and systematically assessed all JE-negative patients for ST. Between January 2014–December 2016, serum and cerebrospinal fluid (CSF) were collected from each patient admitted with AES [fever (>38°C) and ≥1 of altered mental status or seizures] to selected district hospitals in Uttar Pradesh (UP), West Bengal (WB), and Assam. JE-negative patients were tested for seven pathogens according to a standard laboratory algorithm. ST testing was done by Inbios IgM ELISA using locally validated optical density cut-offs, which has shown strong correlation with gold standard assays (IFA). A case of probable ST was defined as a positive serum ST IgM in a patient who tested negative for all other pathogens. Standard clinical data were collected. Among 6770 AES patients enrolled, 5601 (83%) were JE-negative. Of these, 4314 (77%) were tested for ST; 1040 (24%) were positive. The proportion of AES patients with ST was 36% (745/2052) in UP, 26% (91/347) in WB, and 11% (204/1915) in Assam. The majority (69%) of ST cases were detected from July 1–October 31, when the majority (54%) of AES cases was reported. Of 305 ST patients with recorded CSF cytology, 232 (76%) had white blood cell count >10/μL. Of 141 ST patients with recorded data, 20 (14%) reported rash; none had an identified eschar. Of 563 ST patients with recorded outcomes, 34 (6%) died. ST was detected in a substantial proportion of JE-negative AES patients in high AES burden areas of India, though there was wide geographic variability in ST prevalence between UP, WB, and Assam. The overlapping seasonality of ST and JE transmission, the absence of eschar, and frequent detection of CSF pleocytosis in ST AES cases underscores the challenges of distinguishing ST from other AES causes by clinical signs alone, and highlights the need to routinely test AES patients for ST in India.

## 1159

### IN SILICO PREDICTION OF OUTER MEMBRANE PROTEINS FROM *BARTONELLA BACILLIFORMIS* AS CANDIDATE VACCINE

Carlos Padilla, Priscila Lope, Henry Bailon, Adolfo Marcelo, Jackeline Morales, Gladis Ventura  
Instituto Nacional de Salud Peru, Lima, Peru

Carrión's disease caused by *Bartonella bacilliformis* is a major public health problem in Peru. Currently, control of this disease is mainly based on case management and vector control. However, the availability of a vaccine against this disease would be very useful for its prevention. Outer membrane proteins are more promising vaccine candidates against this infection. The KC583 *B. bacilliformis* proteome was analyzed in

order to predict outer membrane proteins. The presence of helix-like transmembrane domains was determined using TMHMM 2.0 server. In addition, all *B. bacilliformis* proteins were analyzed with the pSORT software. Additionally, the presence of peptide signal was analyzed using SignalP, the candidates were compared with PEDANT, Pfam and COG databases. 112 proteins were predicted as outer membrane proteins: 3 autotransporters, 25 outer membrane proteins (5 of these was annotated as lipoproteins), 10 membrane-associated and 74 hypothetical proteins. Our results contribute to identifying outer membrane proteins that are promising vaccine candidates against Carrion's diseases.

## 1160

### THE EPIDEMIOLOGY OF SEVERE MALARIA IN RURAL UGANDA: A FRESH LOOK AT OLD PARADIGMS

Ross M. Boyce<sup>1</sup>, Raquel Reyes<sup>1</sup>, Moses Ntaro<sup>2</sup>, Michael Matte<sup>2</sup>, Edgar Mulogo<sup>2</sup>, Mark J. Siedner<sup>3</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Mbarara University of Science and Technology, Mbarara, Uganda, <sup>3</sup>Massachusetts General Hospital, Boston, MA, United States

Severe *Plasmodium falciparum* malaria is a leading cause of morbidity and mortality across sub-Saharan Africa. After more than a decade of investment in highly effective interventions, however, few studies have re-examined the epidemiology of severe malaria. We conducted a prospective, observational cohort study in order to describe the epidemiology of severe malaria among children and adults presenting to a rural health center in Uganda. Individuals presenting with a history of fever were screened with a malaria RDT. Those with a positive RDT result had blood collected for microscopy and measurement of hemoglobin and serum chemistries. Severe malaria was defined in accordance with the WHO guidelines for research and epidemiological studies. Ninety-eight of 1,462 (6.7%) of participants with confirmed parasitemia satisfied criteria for severe malaria. The incidence of severe malaria peaked between 2-3 years of age (IRR 17.1, 95% CI 8.4-34.9, p<0.001) and then declined steadily until age 10. However, we also found a second peak among patients ≥50 years of age (IRR 7.78, 95% CI 2.44-24.9, p=0.001). Severe anemia and cerebral malaria were infrequent complications of severe disease, detected in only 5.3% and 3.1% of cases respectively. Instead, lactic acidosis (19.4%) and hyperparasitemia (19.4%) were the most frequently encountered manifestations. Few participants with acidosis demonstrated acidotic breathing and the performance of clinical examination for identifying acidosis was quite low (Sn 15.4%, Sp 76.9%). In conclusion, we found that severe anemia and cerebral malaria were rarely observed among patients with severe malaria. Instead, acidosis was the most common manifestation of severe disease, although few patients demonstrated visible signs of acidotic breathing. Severe malaria was most common in young children, but an elevated risk persisted up to the age of 10, as well as among those >50 years of age. Together, these findings suggest that a reliance on traditional bedside criteria and targeting resources to young children may miss a significant proportion of cases.

## 1161

### THE 2009 WORLD HEALTH ORGANIZATION DENGUE CLASSIFICATION OVER-ESTIMATES DENGUE DISEASE SEVERITY IN SRI LANKA

Champica K. Bodinayake<sup>1</sup>, L. Gayani Tillekeratne<sup>2</sup>, Ajith Nagahawatte<sup>1</sup>, Charmaine Mutucumarana<sup>2</sup>, Vasantha Devasiri<sup>1</sup>, Ruvini Kurukulasooriya<sup>1</sup>, Truls Ostbye<sup>2</sup>, Megan E. Reller<sup>2</sup>, Christopher W. Woods<sup>2</sup>

<sup>1</sup>Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, <sup>2</sup>Duke University, Durham, NC, United States

Dengue is the most important arboviral disease in the world with a diverse clinical presentation. Accurate diagnosis is important for a favorable outcome. The revised 2009 World Health Organization (WHO) dengue classification was developed to improve sensitivity of diagnosis; the

performance of these criteria has not been widely assessed in Sri Lanka. A cross-sectional study was conducted at the largest tertiary care hospital in Southern Province, Sri Lanka in June 2013- Oct 2014. Children and adults with acute fever were enrolled. Epidemiological/ clinical data and blood samples were obtained at enrollment and 2-4 wks later. Dengue IgM capture ELISA was performed on convalescent sera. Acute sera NS1 antigen testing and paired IgG testing were performed in patients with IgM positivity. Of 366 enrolled patients, 248 (67.8%) were male and 243 (66.4%) were adults. A total of 67 (19.5%) had dengue, with 43.3% primary, 53.7% secondary, and 3.0% unclassified. Patients with dengue were older (26.7 years vs 22.1 years,  $p=0.004$ ) and more likely to report headache (83.6% versus 53.3%,  $p<0.001$ ), joint pains (71.2% versus 42.4%,  $p<0.001$ ), and muscle pains (74.6% versus 44.7%,  $p<0.001$ ). The severity of dengue was low, with no patients having effusions and 5 (7.5%) having signs of hemorrhage. No patients with dengue received intensive care management or died. The sensitivity and specificity of clinical diagnosis were 58.2% and 90.9%, respectively, on admission. Of patients with dengue, the 2009 WHO criteria classified 14 (20.9%) as dengue without warning signs, 42 (62.7%) as dengue with warning signs, and 0 as severe dengue. The sensitivity and specificity of the WHO 2009 criteria for diagnosis were 83.6% (95% CI 74.6- 92.6) and 64.5% (95% CI 58.8-70.2), respectively. The 2009 WHO criteria had high diagnostic sensitivity in Sri Lanka, but severity was greatly over-estimated. In dengue-endemic settings, universal application of the 2009 WHO criteria may result in unnecessary admissions and further strain of overburdened healthcare systems. Algorithms for appropriate triaging of patients to inpatient versus outpatient management are urgently needed.

## 1162

### SURVEILLANCE OF ADVERSE EVENTS AND SERIOUS ADVERSE EVENTS DURING VACCINE TRIAL: EXPERIENCE OF CVD MALI

**Moussa Doumbia**<sup>1</sup>, Fadima Cheick Haidara<sup>1</sup>, Fatoumata Diallo<sup>1</sup>, Flanon Coulibaly<sup>1</sup>, Adama Coulibaly<sup>1</sup>, Milagritos D Tapia<sup>2</sup>, Samba O Sow<sup>1</sup>, Karen Kotloff<sup>2</sup>, Myron M Levine<sup>2</sup>

<sup>1</sup>Center for Vaccine Development, Mali, Bamako, Mali, <sup>2</sup>University of Maryland, School of Medicine, Baltimore, MD, United States

Vaccine preventable diseases remain the major cause of mortality in developing world. During the past decade, the number of vaccine trial performed in developing countries is increasing importantly. The need to enroll healthy participants in vaccine trials to assess efficacy is not well understood by the community and adverse events are not accepted by the participants. CVD Mali performed several vaccine trials and has developed a strong strategy to monitor adverse events following immunization among participants. During vaccine trial and study procedures all the medical staff are trained and certified in ICH GCP. After vaccination, immediate AEs and SAEs are assessed for 30 to 60 minutes and the following days according to the study specific protocol. Participants are divided between field workers and community relays who will conduct home visits and remind participants about the clinic planned visits. The main pediatrics hospital, referral health centers and community health centers within the study area are informed about the trial. Participants also have the study ID card with phone contacts of keys study investigators and field supervisors in case of emergency. All AEs and SAEs are managed adequately by the study team. With this multicomponent strategy, site has been able to monitor AEs and SAEs. The number of completed visits has increase while the total lost to follow up go and missed events toward zero. Participants understand that AEs and SAEs are not necessarily linked to the study product and that their well-being is our goal. Community engagement is very strong and leaders are involved in crisis management. Community engagement and good communication between field workers and participants are required for AEs and SAEs follow up and may reduce the risk of lost to follow up in clinical trials.

## 1163

### REASON FOR REFUSAL TO ENROLL SICK BABIES INTO CVD-MALI HOSPITAL BASED SURVEILLANCE STUDY OF INVASIVE BACTERIAL DISEASES FROM 2012 TO 2016

**Nana Kourouma**<sup>1</sup>, Adama Mamby Keita<sup>1</sup>, Bintou Traoré<sup>1</sup>, Seydou Sissoko<sup>1</sup>, Mamadou Sylla<sup>1</sup>, Rokiatou Dembele<sup>1</sup>, Brehima Coulibaly<sup>1</sup>, Modibo Sidibé<sup>1</sup>, Mahamadou Fofana<sup>1</sup>, Diakaridia Sidibé<sup>1</sup>, Hamidou Diallo<sup>1</sup>, Abdoulaye Diakité<sup>1</sup>, Doh Sanogo<sup>1</sup>, Aliou Touré<sup>1</sup>, Karen Ball<sup>2</sup>, Milagritos D. Tapia<sup>2</sup>, Karen Kotloff<sup>2</sup>, Samba O. Sow<sup>1</sup>

<sup>1</sup>Center for Vaccine Development, CVD-Mali, Bamako, Mali, <sup>2</sup>University of Maryland, School of Medicine, Baltimore, MD, United States

Invasive bacterial diseases surveillance is essential in monitoring the impact of introduction of new vaccines and the trend of other pathogens. Since 2002, Center for Vaccine Development (CVD-Mali) is implementing a hospital based surveillance in the main pediatric hospital in Bamako, targeting children admitted or seen out as patient. We are describing here the consent process of parents. CVD-Mali Intern identifies eligible inpatient and outpatient, and after brief explanation send the child parent/guardian to the permanent office. Eligible inpatient is defined as children aged 0-15 year old admitted for fever  $\geq 39^{\circ}\text{C}$  and or suspicion of invasive bacterial infection (SIBI). Then the investigator introduce the consent process and provide parent/guardian with the consent form if literate for reading or listening the audio tape of the consent in local language for illiterate and an impartial witness must be present. Parent/guardian and witness will be given enough time and clarification will be provided. Assent is required for children aged from 13 years and above. Study procedure start after getting all required signatures on consent form. From January 2012 to December 2016, we approached legal representatives of 15245 eligible children and proposed participation of their babies in the surveillance. 509 (3.3%) refused to let their infants enrolled in the studies. Different reasons for refusal were: - Don't have money to stay at the hospital and pay for the care; - Don't have someone who can stay at the hospital next to the child; - Prefer immediate care rather than waiting for any kind of investigation; - Prefer to postpone study participant after assessment of initial treatment; - Think that taking blood sample may worsen the child fragile status; - Parent who is present cannot decide alone and propose to wait for someone else to decide child participation in the study. CVD-Mali hospital based surveillance is highly accepted by parents in general. However, refusal cases should not be neglected because of the reasons behind which are linked to poor socio-economics conditions.

## 1164

### ANTIMICROBIAL USE IN UNDER-FIVE CHILDREN WITH DIARRHEAL ILLNESS IN RURAL BANGLADESH

**Shahnawaz Ahmed**<sup>1</sup>, ASG Faruque<sup>1</sup>, Poonum Korpe<sup>2</sup>, Rashidul Haque<sup>1</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Johns Hopkins University School of Public Health, Baltimore, MD, United States

Unnecessary use of antimicrobials has the potential to increase the development of drug resistance. Due to the self-limiting course of most diarrheal illnesses, use of antimicrobials should be rational; however, antibiotic misuse and overuse use has been widely reported globally, and controlling this irrational use is a major public health challenge. From January 1, 2010 to December 31, 2012, a total of 3,570 under-5 children with diarrhea were enrolled in a tertiary level hospital in Mirzapur, a rural sub-district in Bangladesh, and constituted the study population. Diarrheal stools were collected and tested for enteric pathogens using culture and antigen detection methods. Data entry and statistical analyses were performed using SPSS, Chicago, IL version 20. Associations between antimicrobial use at home and at the hospital, socio-demographic characteristics and diarrheal etiology were evaluated using chi-square test. Finally, logistic regression analysis was performed with the enter method probability of exclusion at  $p=0.10$  to identify the factors significantly

associated with a dependent variable to document the most common underlying indications leading to the prescription of an antimicrobial in diarrheal illness of under-5 children. The rate of antimicrobial use at home was 39% among children aged 0-24 months as opposed to 84% among hospitalized children of a similar age. In a multivariate analysis, distance of facility >5 miles from residence, zinc and ORS use at home, vomiting, greater than 10 stools within 24 hours, greater than 3 days of diarrhea, and presence of rotavirus diarrhea were characteristics of children more likely to receive antimicrobials at home. Children with greater than 10 stools within 24 hours, greater than 3 days of diarrhea, use of antibiotics prior to hospital attendance, fever ( $\geq 37.8^{\circ}\text{C}$ ), rectal straining and *Shigella* infection were more likely to receive antimicrobials during hospitalization or out-patient visits. Antimicrobial use of diarrheal illness in under-5 children requires considerable attention. Education is needed for rational use of antimicrobials at home and in healthcare facilities.

## 1165

### REAL-WORLD ASSESSMENT OF THE WHO GUIDELINES FOR HEPATITIS B IN RESOURCE-LIMITED SETTINGS: A PROSPECTIVE COHORT STUDY IN UGANDA

Nicholas J. Easom<sup>1</sup>, Nicholas Laing<sup>2</sup>, Henry Tufton<sup>3</sup>, Emmanuel Ochola<sup>2</sup>, Ojok Godfrey P'Kingston<sup>2</sup>, Mala K. Maini<sup>1</sup>

<sup>1</sup>University College London, London, United Kingdom, <sup>2</sup>St. Mary's Hospital, Lacor, Uganda, <sup>3</sup>Peterborough and Stamford Hospitals NHS Foundation Trust, Peterborough, United Kingdom

Hepatitis B is a major cause of mortality worldwide, despite effective therapy. The cost and availability of investigations, particularly HBV DNA PCR is a major barrier to treatment. We aimed to validate WHO guidelines for identifying individuals requiring hepatitis B treatment in resource-limited settings, which include recommendations for making treatment decisions without the use of HBV DNA PCR. We compared treatment allocation with and without the use of HBV DNA in a cohort of predominantly hospital outpatients in Uganda, a low-middle income country. HBsAg positive, HIV negative, adults were recruited into a prospective cohort in Gulu Province, where HBsAg prevalence is high. Preliminary allocations into treatment and observation groups were made based on liver ultrasound and routine haematological and biochemical blood tests, and taking into account participant age. HBV DNA viral load PCR was performed for each participant and HBeAg testing for selected individuals and final treatment decisions made. Treatment decisions made with and without HBV DNA were compared. Full assessment was completed for 100 participants, treatment was indicated in 20 cases. Combining liver ultrasound, APRI and ALT identified patients for treatment with a positive predictive value of 88.2% and a negative predictive value of 94%, compared with assessment using HBV DNA viral load. Liver ultrasound identified 12/20 individuals requiring treatment. Addition of HBeAg testing as a marker for high viral replication resulted in modest improvements in allocation accuracy. Our data shows that where HBV DNA viral load PCR is unavailable, patients with hepatitis B can be assessed by liver ultrasound and routine laboratory tests alone. These findings will enable physicians in resource-limited settings to initiate treatment more readily. This has implications for the WHO target to reduce viral hepatitis deaths worldwide by 65% before 2030.

## 1166

### NON-OBSTETRIC DEATHS IN WOMEN OF REPRODUCTIVE AGE (12-49 YEARS) IN 12 RURAL COMMUNITIES FROM MAPUTO AND GAZA PROVINCE, SOUTHERN MOZAMBIQUE

Charfudin N. Saco<sup>1</sup>, Orvalho Joaquim Augusto<sup>1</sup>, Beth Payne<sup>2</sup>, Ariel Nhacolo<sup>1</sup>, Marianne Vidler<sup>2</sup>, Faustino Vilanculo<sup>1</sup>, Khatia Munguambe<sup>3</sup>, Tang Lee<sup>2</sup>, Peter Von Dadelszen<sup>4</sup>, Esperanca Sevens<sup>3</sup>

<sup>1</sup>Manhica Health and Research Centre, Manhica-Maputo, Mozambique, <sup>2</sup>University of British Columbia, Vancouver, BC, Canada, <sup>3</sup>Manhica Health and Research Centre and University Eduardo Mondlane, Manhica-Maputo,

Mozambique, <sup>4</sup>Department of Obstetrics and Gynaecology, St. George's University, London, United Kingdom

In Mozambique, data regarding death in women of reproductive age are scarce, particularly in rural areas, where the health system has limited coverage. The most recent comprehensive data comes from the post-census mortality survey from 2007-2008. The aim of this study is to estimate the mortality rate and identify non-obstetric causes of death among women of reproductive age. This is a descriptive study to assess mortality rates and causes of death in women 12-49 years using data from a census conducted in 2014 in 12 rural communities located in Gaza and Maputo Provinces, southern Mozambique. This census included household registration to identify women of reproductive age, death registration and verbal autopsy. Women were separated into three age groups: 12-19, 20-34 and 35-49 years, the cause of death was determined using InterVA4. All obstetric related cases of death were excluded because they were published elsewhere. A total of 80,483 women of reproductive age were identified for this study. Of the 246 (3.0 per 1000 women of reproductive age) deaths reported in the previous 12 months, 216 (87.8%) were non-maternal, 23 (9.35%) were maternal and 7 (2.8%) without verbal autopsy information. Communicable diseases, non-communicable disease and road traffic accidents/trauma were responsible for 68.9%, 14.7% and 8.7% of deaths, respectively. The top three causes of death were HIV/AIDS (41.6%), tuberculosis (14.1%), and road traffic accidents or trauma (7.1%). However, age-related differences in top-three causes were observed (malaria (7.7%) at age 20-34 and acute respiratory infection including pneumonia (4.7%) at age 35-49). This study shows that HIV/AIDS remains the most important cause of death in these rural communities. The study findings also reveal the contribution of non-communicable disease, road traffic accidents and trauma which is typical in urban areas suggesting a transition of diseases burden. Strategic public health interventions targeting poor and rural population including HIV care is crucial to save lives in rural Mozambique.

## 1167

### IMPACT OF INTEGRATING A PRE-REFERRAL TREATMENT OF SEVERE MALARIA WITH RECTAL ARTESUNATE AT THE COMMUNITY LEVEL: A NON-INFERIORITY TRIAL IN THE DEMOCRATIC REPUBLIC OF CONGO

Patrick M. Mvumbi<sup>1</sup>, Joris Likwela<sup>2</sup>, Jeanine Musau<sup>3</sup>, Emile Wemakoy Okitolonda<sup>1</sup>, Ousmane Faye<sup>3</sup>, Hortense Angoran-Benie<sup>3</sup>

<sup>1</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Malaria National Control Program, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Management Science for Health - Integrated Health Project, Kinshasa, Democratic Republic of the Congo

The Democratic Republic of Congo (DRC) adopted the strategy of using at the community level, a dose of rectal artesunate as a pre-referral treatment of severe malaria amongst under five children (CU5) who cannot reach quickly a health care facility and take oral medication. However, its feasibility and acceptability were unknown. To assess the impact of integrating the pre-referral rectal artesunate on the adherence to the referral advice provided by the community health workers (CHWs) and the CHWs and nurses' capacities to identify correctly the danger signs of malaria. A non-inferiority (NI) community trial with a pre- and post-intervention design and a mixed approach was conducted in 51 community care sites (CCS) in 4 provinces (Kasaï-Oriental, Kasaï-Central, Lomami, Lualaba) from August 2014 through June 2015. Surveys targeted at pre-test 387 mothers of CU5, 63 CHWs and 45 nurses; at post-test, 346 mothers, 41 CHWs and 37 nurses. Proportions at 95% confidence intervals were calculated for key indicators. A 15% threshold was considered for NI analyses due to the expected decrease of the adherence to the referral advice after the introduction of the strategy. Rectal route was often used (60.7%) and medicines given rectally were considered more effective (63.6%) and easily administrate (69.7%). Acceptability of the pre-referral strategy was relatively high: 79.4% (CI95: 75.4-83.3) among mothers, 90.3% (CI95: 82.3-96.8) among CHWs, and 97.8%

(CI95: 93.3-100) among nurses. In addition, 41.5% of CHWs and 32.4% of nurses could identify correctly the five danger signs of severe malaria at post-test compare to none at pre-test ( $p < 0.05$ ). The adherence to the referral advice at post-test [84.3% (CI95: 80.6-88.1)] was non-inferior to the pre-test adherence [94.1% (CI95: 91.7-96.4)]. Integration of the pre-referral strategy of severe malaria in the CCS in DRC is feasible and acceptable. It had positive impact on CHWs and nurses' capacities to identify correctly the dangers signs of malaria and on the adherence to the referral advice. However, more information, education and communication are needed for parents of CU5 and trainings for CHWs and nurses.

## 1168

### EVALUATING TRADEOFFS BETWEEN ORAL FLUID AND BLOOD SAMPLES FOR BIOMARKER DETECTION IN RESEARCH AND SURVEILLANCE PROGRAMS: A SIMULATION MODEL

**Kelly M. Searle**, William J. Moss, Kyla Hayford

*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Biological markers are integrated into population health surveys to obtain more accurate measures of disease outcomes and risk factors. Biomarkers can be measured using point-of-care-diagnostics or samples can be collected for subsequent analyses in the lab (e.g. enzyme immunoassays). The type of sample collected determines the type of assay that can be performed and the test sensitivity. Some sample types may be more easily collected in field settings, particularly during household surveys (e.g. oral fluid is considered more acceptable than blood). A common assumption is that the tradeoff in increased acceptability, and therefore test coverage, compensates for a loss in test sensitivity. In this analysis, a simulated population was constructed to determine the tradeoffs between assay sensitivity and acceptability. The first analysis determined what proportion of those with an outcome would be correctly identified by an assay of varying sensitivity and test coverage. The second analysis determined what degree of bias would be introduced into the prevalence estimate measured using an assay with varying sensitivity, specificity, and test coverage, as well as the degree of bias introduced when coverage is differential by the outcome of interest. Preliminary results showed for every increase in test coverage, the increase in identified individuals was proportional to the sensitivity of the assay. Thus, an assay with a 10% lower sensitivity would have to increase coverage by at least 10% to identify the same proportion of individuals. Under the assumption of less than perfect specificity, assays with higher sensitivity slightly overestimated the prevalence of the outcome while assays with lower sensitivities consistently underestimated the prevalence at all test coverage levels. These results suggest that there is a significant tradeoff in the ability to detect an outcome of interest with a lower sensitivity test that may have moderately higher acceptability levels. When the test is used to estimate prevalence, increased acceptability of a test with lower sensitivity can result in inaccurate and biased estimates.

## 1169

### DELIVERY MECHANISM OF INTERMITTENT PREVENTIVE THERAPY (SULFADOXINE PYRIMETHAMINE) AMONGST PREGNANT WOMEN IN FEDERAL MEDICAL CENTRE KEFFI, NASSARAWA STATE

**Oyindamola Coker**

*All Saints University School of Medicine, Roseau, Dominica*

Malaria is highly endemic in Nigeria and poses a major health challenge with attendant risk of morbidity and mortality contributing to loss of productivity and economic development. The most vulnerable groups are children below 5 years of age and pregnant women, particularly women in their first and second pregnancy. IPT is recommended in pregnancy to prevent malaria in pregnancy. The following are objectives for the research project:

To establish the mode of administration, frequency of administration and total dosage of IPT given to pregnant women and also to identify the challenges involved with administration and compliance.

Structured interviewer administered questionnaires will be used for data collection from pregnant women to find out their preferred mode of administration of IPT, frequency of administration and also the side effects of the therapy on the mother.

It is hoped that the findings of the proposed research will inform decisions on how to counsel pregnant women to use IPT.

## 1170

### HOW CAN WE KEEP IMMIGRANT TRAVELERS HEALTHY? HEALTH CHALLENGES EXPERIENCED BY CANADIAN SOUTH ASIAN TRAVELERS VISITING FRIENDS AND RELATIVES

**Rachel Savage**<sup>1</sup>, Laura Rosella<sup>1</sup>, Natasha Crowcroft<sup>2</sup>, Jasleen Arneja<sup>3</sup>, Eileen de Villa<sup>4</sup>, Maureen Horn<sup>4</sup>, Kamran Khan<sup>5</sup>, Monali Varia<sup>4</sup>

*<sup>1</sup>Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, <sup>2</sup>Public Health Ontario and Dalla Lana School of Public Health and Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, <sup>3</sup>University of Toronto, Toronto, ON, Canada, <sup>4</sup>Peel Public Health, Mississauga, ON, Canada, <sup>5</sup>Li Ka Shing Knowledge Institute at St. Michael's Hospital, and Department of Medicine, Division of Infectious Diseases, University of Toronto, Toronto, ON, Canada*

Immigrant travelers who visit friends and relatives (VFR) experience high rates of travel-related morbidity, which has been attributed in part to low uptake of pre-travel health advice. While several barriers to accessing advice have been identified, better characterization of these barriers is needed to inform strategies to overcome them. Consequently, we sought to understand how South Asian VFR travelers perceived and responded to travel-related health risks. We recruited participants and clients from community service organizations for four group interviews between November 2015 and January 2016. Participants were residents of Peel region in Ontario, Canada, who reported visiting friends and relatives in India or Pakistan within the past five years. Interviews were audio-recorded, transcribed, and analyzed thematically. Baxter et al's 'typologies of concern' was used as a framework to understand how participants conceptualized risk. We interviewed 32 travelers who described facing numerous health challenges, from contaminated water and food to pollution to their own personal health, among others. Participants expressed a moderate level of concern for most known risks, which triggered responses to mitigate or avoid the risk where possible or convenient to do so, consistent with Baxter's 'Wait and See' typology. While no participants visited a travel medicine clinic prior to departure, they were knowledgeable of key travel health risks and responded pragmatically with convenient and affordable strategies or behaviours (e.g. drinking bottled or boiled tap water). Responses to risks were context and value dependent. We found that planning a trip in rushed circumstances, a desire to preserve authentic experiences, familial duty to hosts, and financial constraints were competing concerns to travelers responding to health risks. As VFR travelers become knowledgeable of travel health risks, health promotion efforts should emphasize the added value of medical intervention (e.g. immunization and destination-specific health advice), and explore how to best support VFR travelers in light of unique competing concerns they face.

## 1171

### SAFETY AND IMMUNOGENICITY OF AGS-V, A MOSQUITO SALIVA PEPTIDE VACCINE: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 1 TRIAL

Jessica E. Manning<sup>1</sup>, Shaden Kamhawi<sup>2</sup>, Fabiano Oliveira<sup>2</sup>, Iliano V. Coutinho-Abreu<sup>2</sup>, Claudio Meneses<sup>2</sup>, Holly Ann Baus<sup>1</sup>, Alison Han<sup>1</sup>, Lindsay Czajkowski<sup>1</sup>, Amanda Donaldson<sup>1</sup>, Rani Athota<sup>1</sup>, Susan Reed<sup>1</sup>, Tyler Bristol<sup>1</sup>, Luz Angela Rosas<sup>1</sup>, Ana Fernandez<sup>2</sup>, Olga Pleguezuelos<sup>3</sup>, Gregory Stoloff<sup>3</sup>, Jesus Valenzuela<sup>2</sup>, Matt Memoli<sup>1</sup>

<sup>1</sup>Laboratory of Infectious Diseases Clinical Studies Unit, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>SEK, London, United Kingdom

Mosquito-borne diseases continue to cause significant morbidity and mortality worldwide despite on-going control efforts. A new approach to disease prevention focuses on the arthropod salivary-mediated transmission of pathogens. Parasites and viruses carried within mosquito saliva appear to initiate or enhance severity of host infection by taking advantage of saliva-human host interactions. This leads to alteration of the cutaneous environment and modulation of the host's innate and adaptive immune responses, thereby providing a rationale for creating vaccines against mosquito salivary proteins rather than the pathogens contained within the saliva. AGS-v is a vaccine composed of four salivary peptides that are common across a number of arthropods. In this ongoing first-in-human study, we are enrolling and randomizing 45 healthy adult participants to receive the AGS-v vaccine with and without adjuvant (Montanide ISA 51) versus placebo. Vaccinations occur on Day 0 and Day 21 followed by a clean mosquito feeding on Day 42. Primary objectives are: 1) to assess safety via incidence of adverse events and 2) to evaluate humoral and cellular immunity by respectively measuring total AGS-v specific immunoglobulins and Th1-associated cytokine release after incubation of peripheral blood mononuclear cells (PBMCs) with AGS-v antigens. Secondary objectives are post-mosquito feeding measures of AGS-v specific immunoglobulins and Th1-related cytokine release, mosquito survival and fecundity, as well as the effects of saliva-coated Zika virus on cytokine production by PBMCs from immunized individuals. This trial is in process with the plan to complete all vaccinations and mosquito feedings by August 2017. Of note, the data blind will still be in place at the time of the conference.

## 1172

### SAFETY AND FUNCTIONAL IMMUNOGENICITY OF PLASMODIUM FALCIPARUM TRANSMISSION BLOCKING VACCINES PFS230D1M-EPA/ALHYDROGEL AND PFS25M-EPA/ALHYDROGEL ALONE AND IN COMBINATION IN MALIAN ADULTS

<sup>1</sup>MRTC, University of Science, Techniques and Technologies, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>3</sup>PATH-MVI, Washington, DC, United States, <sup>4</sup>BRB/National

Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Malaria still is a public health problem. New approaches, such as transmission blocking vaccines (TBV) that prevent mosquito infections, are needed for malaria elimination. We recently reported that a TBV targeting sexual stage antigen Pfs25 induced functional antibodies in US volunteers when conjugated to the carrier protein ExoProtein A (EPA), and are now studying TBV responses in malaria-experienced volunteers in Mali. Before the malaria transmission season, 225 healthy volunteers aged 18-50 years old were enrolled in a dose-escalating, double blind, comparator-controlled study to assess the safety, tolerability, immunogenicity (by ELISA), and functional activity (by SMFA and DSF) of two transmission blocking vaccines (TBV) against *Plasmodium falciparum* malaria (Pfs230D1M-EPA/Alhydrogel® and Pfs25M-EPA/Alhydrogel®) in Bancoumana, Mali. We first assessed the safety of the vaccines administered alone or in combination in 25 participants. The larger cohort then enrolled volunteers to receive either Pfs25M and normal saline (NS) (n=50), Pfs230D1M and NS (n=50), Pfs25M + Pfs230D1M co-administered (n=50), or comparator and NS (n=50) at 0, 1, 6 months in 2015 with a booster vaccination at 18 months given in 2016. Vaccinations have been well tolerated, with most reported AEs being mild or moderate in severity. No serious adverse events related to vaccination were reported. Based on their ability to induce functional immune responses (SMFA, DSF), Pfs25M alone was inferior to Pfs230D1M alone or Pfs230D1M + Pfs25M, while the combination of Pfs230D1M + Pfs25M did not improve on Pfs230D1M alone. These findings will inform future TBV development, such as the trial to test Pfs230D1M-EPA alone with the adjuvant AS01 that started in Mali this year.

## 1173

### BIOMARKERS OF ENDOTHELIAL AND IMMUNE DYSFUNCTION PREDICT MORTALITY IN FEBRILE OUTPATIENT TANZANIAN ADULTS

Melissa Richard-Greenblatt<sup>1</sup>, Noémie Boillat-Blanco<sup>2</sup>, Kathleen Zhong<sup>1</sup>, Valérie D'Acremont<sup>2</sup>, Kevin C. Kain<sup>1</sup>

<sup>1</sup>Sandra Rotman Centre for Global Health, University Health Network, Toronto General Hospital, Toronto, ON, Canada, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Febrile syndromes are among the most common causes of illness globally, accounting for over 1 billion episodes annually. However, most infections are self-limited and few progress to life-threatening infections (LTIs). We currently lack tools to rapidly identify patients who have, or will progress to LTIs and this is a major barrier to rational triage and management of patients at both outpatient and inpatient levels. We hypothesized that measuring biomarkers of pathways implicated in the pathobiology of serious infections would permit the early recognition of LTIs due to multiple etiologies. In this study, we examined consecutive adults (>18 years of age) presenting with fever (>38.0C) to outpatient departments in Dar es Salaam, Tanzania. We quantified circulating levels of markers of endothelial (Ang-2, sFlt-1, sVCAM-1) and immune (sTREM-1, IL-6, IL-8, CHI3L1, sTNFR1, PCT, CRP) dysfunction at clinical presentation, using Luminex® multiplex platform or ELISA, to determine if they predicted disease severity and outcome in "all cause" fever syndromes (i.e. independent of etiology). Of the 519 febrile adults enrolled, 9 died within 48h of presentation and 32 by day 28. Single biomarkers variably predicted 48h mortality: CRP (AUROC 0.55), PCT (AUROC 0.73) versus sTREM-1 (AUROC 0.91) and Ang-2 (AUROC 0.90) which had the best predictive accuracy. By day 28, sTREM-1 remained a good predictor of mortality (AUROC 0.87). Combining a clinical score, qSOFA (quick Sepsis Related Organ Failure Assessment), with even a single biomarker significantly improved predictive accuracy at both day 2 (AUROC 0.94) and day 28 (AUROC 0.91) mortality. These findings validate sTREM-1 and Ang-2 as informative markers to identify individuals at risk of infection-related mortality. Since sTREM-1 and Ang-2 displayed superior performance

to qSOFA, point-of-care rapid diagnostic test versions of these markers could have clinical utility in triage and risk stratification of febrile patients, especially in low resource settings.

### OUTER MEMBRANE PROTEINS LSA46 AND LSA77 ARE POTENTIAL VACCINE CANDIDATES AGAINST LEPTOSPIROSIS PROTEINS LSA46 AND LSA77 ARE POTENTIAL VACCINE CANDIDATES AGAINST LEPTOSPIROSIS

**Aline F. Teixeira**<sup>1</sup>, Luis G. Fernandes<sup>1</sup>, Gisele O. Souza<sup>2</sup>, Antonio F. Filho<sup>2</sup>, Marcos B. Heinemann<sup>2</sup>, Silvio A. Vasconcelos<sup>2</sup>, Ana Lucia T. Nascimento<sup>1</sup>

<sup>1</sup>Instituto Butantan, Sao Paulo, Brazil, <sup>2</sup>USP, Sao Paulo, Brazil

Leptospirosis is a major public health problem caused by pathogenic spirochetes of the *Leptospira* genus. The available vaccine formulations induced short term-immunity and protect only against the serovars included in the preparation. Development of a universal, cost-effective vaccine is long being pursued. The aim of this study is to evaluate the immunoprotective potential of Lsa46 and Lsa77 proteins, individually or combined, with Alum adjuvant. The amplified gene sequences were cloned into the vector pAE for expression of recombinant proteins. The recombinant proteins Lsa46 and Lsa77 were purified by affinity chromatography under denaturing conditions. Hamsters were immunized with 50 µg of Lsa46 and Lsa77 or 25 µg of each protein mixed in 10% Alhydrogel, and antibodies against Lsa46 and Lsa77 evaluated. After immunization, hamsters were challenged with an intraperitoneal inoculum of virulent leptospires. The recombinant proteins were purified by affinity chromatography and confirmed by Western blottings probed with polyclonal antibodies raised in hamsters against the proteins. Lsa46 and Lsa77 were recognized by confirmed leptospirosis human serum samples. Furthermore, mouse anti-Lsa46 and anti-Lsa77 sera recognized the corresponding leptospiral Lsa46 and Lsa77 proteins in virulent Fiocruz L1-130 and pathogenic attenuated M20 whole cell lysates. The data showed that recombinant proteins are capable to stimulate antibody immune response in hamsters. Immunoprotection evaluation of recombinant proteins followed by challenge with virulent leptospires showed that both proteins conferred partial protection. However, only animals immunized with Lsa77 exhibited reduction in renal colonization when compared with Lsa46. Immunization with combined Lsa46+Lsa77 resulted in 90% protection after challenge. Although the death observed with PBS-control group were inconsistent, leptospiral burden among the survivors were lower than the control group. In conclusion, the results indicate that Lsa46 and Lsa77 are potential vaccine candidates against *Leptospira*.

Diseases/National Institutes of Health, Rockville, MD, United States,

<sup>4</sup>GlaxoSmithKline Vaccines, Rixensart, Belgium

Transmission blocking vaccines (TBV) prevent mosquito infections and could be critical tools for malaria elimination in Sub-Saharan Africa. NIAID scientists have enhanced TBV immunogenicity by conjugating recombinant forms of sexual stage antigens such as Pfs25 and Pfs230 to carrier proteins including ExoProtein A (EPA), and by formulating vaccines in more potent adjuvants. A phase 1 dose-escalating, double-blind, randomized, comparator-controlled trial (NCT02942277) of the safety, tolerability, and immunogenicity of the conjugated vaccines Pfs25M-EPA and Pfs230D1M-EPA formulated with AS01 adjuvant developed and contributed by GSK, is currently being conducted in healthy adult volunteers in Mali. The study started in January 2017 with the unblinded pilot safety cohort in Sotuba, a peri-urban area of Bamako, where 65 healthy adult volunteers aged 18-50 years old were enrolled and have thus far received two doses of the scheduled three vaccine series at 0, 1, and 6 months. Among the 45 participants receiving TBV in AS01 adjuvant, 15 received a low vaccine dose (16µg Pfs25, n=5; or 13µg Pfs230, n=5; or 16µg Pfs25 + 13µg Pfs230, n=5), while 30 received a high vaccine dose (47µg Pfs25, n=10; or 40µg Pfs230, n=10; or 47µg Pfs25 + 40µg Pfs230, n=10). 20 participants received the comparator vaccine Engerix-B. After initial review of the safety cohort, the main double-blind phase of the study started on March 30th, 2017 in Bancoumana and Donéguébougou, two rural villages outside of Bamako, Mali, where to date 196 out of the planned 240 healthy adult volunteers have received first vaccinations with either 40 µg Pfs230 or Engerix-B. To date, vaccinations have been well-tolerated with few related vaccine adverse events (AEs); most reported AEs have been local injection site reactivity, particularly mild injection site pain. Safety data will be presented from both the unblinded pilot safety cohort and blinded field cohort. Immunogenicity including functional serum activity post vaccination from the unblinded pilot safety cohort will be presented.

## 1176

### COMMON SCREENING FINDINGS AND EXCLUSION CRITERIA FOR ADULTS WILLING TO ENROLL IN A MALARIA TRANSMISSION BLOCKING VACCINE STUDY IN SOTUBA, MALI

**Mamady Kone**<sup>1</sup>, Issaka Sagara<sup>1</sup>, Sara A. Healy<sup>2</sup>, Mahamadou H. Assadou<sup>1</sup>, Mahamadou S. Sissoko<sup>1</sup>, Abdoulaye Katile<sup>1</sup>, Bouran Sidibe<sup>1</sup>, Mohamed Lamine Alhousseini<sup>1</sup>, Merepen A. Guindo<sup>1</sup>, Bruce Swihart<sup>3</sup>, Kourane Sissoko<sup>1</sup>, Souleymane Dama<sup>1</sup>, Bourama Kamate<sup>1</sup>, Sibiri Sissoko<sup>1</sup>, Amadou Bamadio<sup>1</sup>, Boubou Sangare<sup>1</sup>, Sintry Sanogo<sup>1</sup>, M'Bouye Doucoure<sup>1</sup>, Jen C. Hume<sup>2</sup>, Amagana Dolo<sup>1</sup>, Patrick E. Duffy<sup>2</sup>, Ogobara Doumbo<sup>1</sup>

<sup>1</sup>MRTC, University of Science, Techniques and Technologies, Bamako, Mali,

<sup>2</sup>Laboratory of Malaria Immunology and Vaccinology /National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>3</sup>BRB/National Institute of Allergy and Infectious Diseases/ National Institutes of Health, Rockville, MD, United States

For malaria vaccine testing, volunteers must be enrolled from a suitable site and population. Screening is a critical step to identify and enroll appropriate participants into early phase studies. We are conducting a malaria transmission blocking vaccine study among Malian adults in Sotuba, a peri-urban area of Bamako. Once informed consent was obtained, each individual underwent clinical and laboratory assessments. The screening aimed to assess inclusion and exclusion criteria that preclude the enrolment of adult subjects into a dose-escalating, open label, randomized, pilot phase 1 study. In January 2017, we screened 175 volunteers and enrolled 65 volunteers into the malaria vaccine study of Pfs25M-EPA/AS01 and Pfs230D1M-EPA/AS01. Of 175 screened, 114 (65.1%) were eligible for enrollment. Of the 61 (34.9 %) subjects not eligible for enrollment, the main reason was volunteer withdrawal of consent (23/61; 37.7%) before or at the time of enrollment. Of the remaining 38 subjects, 31 (81.6%) failed screening secondary to laboratory abnormalities. The most frequent reason for screen failure was

the hepatitis B surface antigen positivity (9.1%; 16/175), followed by high blood pressure (3.4%; 6/175). Hepatitis C (3.4%; 6/175) and HIV (1.7%; 3/175) frequency was low in this population. In this area, less than 35% of volunteers failed to be enrolled, with voluntary consent withdrawal being the primary reason followed by abnormal laboratory results and high blood pressure. Ratio of screened to enrolled (1.5:1) in Sotuba is lower than other vaccine trial sites in Mali in rural areas.

## 1177

### BURDEN OF COMMON ILLNESSES AND THE PROTECTIVE EFFECT OF BREASTFEEDING IN EARLY CHILDHOOD IN MAL-ED, AN EIGHT-SITE COHORT STUDY

**Stephanie Richard**<sup>1</sup>, Benjamin McCormick<sup>1</sup>, Zeba Rasmussen<sup>1</sup>, Margaret Kosek<sup>2</sup>, William Petri<sup>3</sup>, Liz Rogawski<sup>3</sup>, Anuradha Bose<sup>4</sup>, Estomih Mduma<sup>5</sup>, Bruna LL Maciel<sup>6</sup>, Ram K. Chandyo<sup>7</sup>, Zulfiqar Bhutta<sup>8</sup>, Ali Turab<sup>8</sup>, Pascal Besson<sup>9</sup>, Laura Caulfield<sup>2</sup>

<sup>1</sup>National Institutes of Health - Fogarty International Center, Bethesda, MD, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>University of Virginia, Charlottesville, VA, United States, <sup>4</sup>Christian Medical College, Vellore, India, <sup>5</sup>Haydom Lutheran Hospital, Haydom, United Republic of Tanzania, <sup>6</sup>Universidade Federal RGN, Natal, Brazil, <sup>7</sup>University of Bergen, Bergen, Norway, <sup>8</sup>Aga Khan University, Karachi, Pakistan, <sup>9</sup>University of Venda, Thohoyandou, South Africa

Children in low-income countries experience multiple episodes of illness in early childhood, and the relationships among these illnesses is not well understood. In the MAL-ED cohort study, 1,731 children were enrolled at or near birth and followed for two years in eight sites (in Bangladesh, Pakistan, India, Nepal, Brazil, Peru, South Africa, and Tanzania). Field workers visited households twice a week and inquired about symptoms the child experienced and their diet. Logistic regression was used to determine if history of illness (in the last 30 days) was associated with incidence of diarrhea or ALRI, accounting for exclusive breastfeeding. Exclusive breastfeeding in the first three months of life was protective against diarrhea. Children with history of diarrhea, fever, or ALRI who were also exclusively breastfed were half as likely to experience a new episode of diarrhea in the first three months of life (diarrhea: OR 0.44, 95% CI 0.31, 0.62; fever: OR 0.61, 95% CI 0.48, 0.77; ALRI: OR 0.50, 95% CI 0.29, 0.86). Fever was associated with greater odds of incident diarrhea between 3-5 months (OR 1.44, 95% CI 1.29, 1.61), and in children > 6 months, diarrhea and fever were both associated with higher odds of incident diarrhea (diarrhea: OR 1.15, 95% CI 1.07, 1.22; fever: OR 1.40, 95% CI 1.33, 1.48). Fever increased the chance of ALRI at all ages (0-2: OR 2.69, 95% CI 1.99, 3.62; 3-5: OR 2.70, 95% CI 1.81, 4.03; >6: OR 3.04, 95% CI 2.74, 3.38), and breastfeeding practices did not change that relationship. Exclusive breastfeeding in the first three months of life was protective against new episodes of diarrhea, which underscores the importance of exclusive breastfeeding in early childhood. Previous illness was associated with greater risk of new illness, indicating that public health programs would benefit from targeting those high morbidity children and households.

## 1178

### CHILDHOOD NEURODISABILITY: CHALLENGES FACED BY CHILDREN AND THEIR FAMILIES IN RURAL NEPAL

**Susan M. George**<sup>1</sup>, Prakash Poudel<sup>2</sup>

<sup>1</sup>University College London, London, United Kingdom, <sup>2</sup>BP Koirala Institute of Health Sciences, Dharan, Nepal

In Nepal, 1.94% of the population is reported to have disability (Nepal census data, 2011). The first National, representative household survey carried out in Nepal in 2014 - 2015 identified a lower score in most indicators of level of living, in households with a person with disability in both urban and rural Nepal. Nepal poses unique challenges due to poverty, a predominantly rural population, the challenging terrain and

strongly held cultural beliefs. Little is known about the prevalence and impact of childhood neuro-disability on families in Nepal. There is lack of data available from Nepal on this topic. We undertook qualitative research among the caregivers of 24 children from 23 families (18 boys, 6 girls; mean age 8.3y) in rural Nepal between 2013 and 2014. Focus group discussions and face to face interviews guided by structured questionnaire were employed. Thematic analysis was carried out to identify the key issues. The children had conditions ranging from cerebral palsy to genetic neuro-degenerative conditions. The key issues identified were difficulty in obtaining appropriate and timely medical advice, financial challenges, practical challenges with schooling, cultural beliefs and taboos that influence the child and the family, and the psychological impact of the illness on the children and caregivers. There is often a significant delay in confirming the diagnosis, and in many cases the diagnosis is not yet clear. Limited facilities for medical treatment and therapy makes it challenging to access these regularly. Among the group, 18 caregivers reported significant anxiety and fear about their child's future. Three children lived in single parent households. Alcohol addiction, domestic abuse and abandonment by a parent was reported in 4 families. Most of our families reported that children were treated differently by the community (19/23), but 3 caregivers reported that their children were positively supported and loved by the community due to their disability. Our data identified gaps in clinical service, educational support and psychological support of children with neuro-disability and their families in rural Nepal.

## 1179

### A NOVEL PUTATIVE LIPOPROTEIN OF *LEPTOSPIRA INTERROGANS* THAT INTERACTS WITH LAMININ, PLASMINOGEN AND COMPLEMENT COMPONENTS

**Maria Fernanda C. Pereira**<sup>1</sup>, Aline F. Teixeira<sup>1</sup>, Gisele O. Souza<sup>2</sup>, Silvio A. Vasconcelos<sup>2</sup>, Ana Lucia T. Nascimento<sup>1</sup>

<sup>1</sup>Instituto Butantan, São Paulo, Brazil, <sup>2</sup>USP, São Paulo, Brazil

Leptospirosis is a zoonosis globally disseminated caused by pathogenic spirochetes of the genus *Leptospira*. Rodents are the main reservoirs of the disease and constantly eliminate live leptospires in their urine, contaminating soil and water. Preventive measures to control leptospirosis are difficult to implement. Thus, understanding leptospiral pathogenic mechanisms is critical for the efficient development of vaccines and diagnostic tests. Our group has identified leptospiral surface proteins with the ability to bind extracellular matrix and plasma components, which could mediate adhesion and facilitate invasion through the hosts. This work aims to characterize the role of a probable lipoprotein encoded by the gene LIC13259 of *L. interrogans* serovar Copenhageni in pathogenesis. The gene LIC13259 was cloned into the expression vector pAE. The plasmid pAE-LIC13259 was employed to transform *E. coli* strains for protein expression studies. After purification of the recombinant proteins, mice were immunized for polyclonal antibody production. The ability of recombinant protein to interact with the extracellular matrix proteins, complement and human plasma components was evaluated. The coding sequence LIC13259 was cloned and expressed in their soluble form successfully. The recombinant protein was purified by nickel affinity chromatography and appeared as a single band after SDS-PAGE analysis. Mice immunized with the recombinant protein LIC13259 stimulated effectively antibody immune response. LIC13259 exhibited adhesion properties and was able to bind laminin. Studies with human plasma components demonstrated that LIC13259 interacts with plasminogen and in the presence of an activator could generate plasmin. Furthermore, LIC13259 was able to interact with vitronectin, C7, C8 and C9 complement components in a dose-dependent manner and could recruit them from normal human serum. Our data suggest that LIC13259 is a multifunctional protein that might be involved in invasion and complement immune evasion processes within the hosts.

### ASSESSMENT OF *LEPTOSPIRA INTERROGANS* PROTEINS LIC11711 AND LIC12587 AND THEIR INTERACTIONS WITH EXTRACELLULAR MATRIX AND PLASMA COMPONENTS

Leandro T. Kochi<sup>1</sup>, Luis G. Fernandes<sup>1</sup>, Antônio F. Filho<sup>2</sup>, Gisele O. Souza<sup>2</sup>, Sílvia A. Vasconcelos<sup>2</sup>, Ana Lucia T. Nascimento<sup>1</sup>

<sup>1</sup>Instituto Butantan, São Paulo, Brazil, <sup>2</sup>USP, São Paulo, Brazil

Leptospirosis is a worldwide zoonosis of endemic occurrence in tropical countries. In Brazil, *Leptospira interrogans* serovar Copenhageni is prevalent in urban centres, affecting several species of animals including humans. Therefore, the understanding of leptospiral interactions with host components and the immune system is important to elucidate pathogenicity mechanisms and to develop strategies to eliminate the microorganism. In this work, we aimed to express and to characterize two putative membrane proteins of *L. interrogans* serovar Copenhageni and assess their interactions with human components. Recombinant LIC11711 and LIC12587 proteins were expressed in *E. coli* DE3 Star pLysS strain and then purified by metal affinity chromatography. For native proteins localization assay, intact *L. interrogans* strain M-20 and saprophytic *L. biflexa* cells were immobilized and detected with homologous antiserum and secondary anti-mouse/HRP by ELISA; cytosolic protein LipL31 was used as negative control. The interaction of recombinant proteins with human extracellular matrix and plasma components was evaluated by ELISA. Recombinant proteins were obtained from the soluble fraction after cell lysis and purified by metal affinity chromatography. Protein purity was observed by SDS-PAGE. Both proteins were detected in intact *L. interrogans* but are absent in the saprophyte *L. biflexa* cells. LipL31, a cytosolic protein, was obtained only in basal level, suggesting that both proteins are probably located on the leptospiral surface. Binding interactions with host components laminin and plasminogen were dose-dependent, but didn't reach saturation for both recombinant proteins. In addition, when bound to PLG, the component was converted into its enzymatically active form, plasmin, in the presence of the plasminogen activator uPa. The proteins encoded by the genes LIC11711 and LIC12587 are probably located at bacterial surface and could mediate host-pathogen interactions.

### PLASMODIUM FALCIPARUM CONTROLLED HUMAN MALARIA INFECTION IN MALARIA EXPOSED VOLUNTEERS: CAN IT INFORM MALARIA VACCINE TRIALS IN THE FIELD

Sara A. Healy<sup>1</sup>, Mahamadou S. Sissoko<sup>2</sup>, Abdoulaye Katile<sup>2</sup>, Erin Gabriel<sup>3</sup>, Irfan Zaidi<sup>1</sup>, Bourama Kamate<sup>2</sup>, Yacouba Samake<sup>2</sup>, Kourane Sissoko<sup>2</sup>, Cheick O. Guindo<sup>2</sup>, Amagana Dolo<sup>2</sup>, Karamoko Niare<sup>2</sup>, Fanta Koita<sup>2</sup>, Amadou Niangaly<sup>2</sup>, Amatique Ziguime<sup>2</sup>, Merepen A. Guindo<sup>2</sup>, M'Bouye Doucoure<sup>2</sup>, Boucary Ouologuem<sup>2</sup>, Souleymane Traore<sup>2</sup>, Jillian Neal<sup>1</sup>, Eric R. James<sup>4</sup>, Anita Manoj<sup>4</sup>, B. Kim Lee Sim<sup>4</sup>, Peter F. Billingsley<sup>4</sup>, Thomas L. Richie<sup>4</sup>, Stephen L. Hoffman<sup>4</sup>, Ogobara Doumbo<sup>2</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>2</sup>MRTC, University of Science, Techniques and Technologies, Bamako, Mali, <sup>3</sup>BRB/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>4</sup>Sanaria Inc., Rockville, MD, United States

A clinical trial was conducted in Mali, West Africa to assess the safety, immunogenicity and protective efficacy of a 3-dose regimen of Sanaria® PfSPZ Vaccine (1.8x10<sup>6</sup> PfSPZ) administered by direct venous inoculation (DVI) against homologous controlled human malaria infection (CHMI) by DVI. 29/30 (96.7%) subjects enrolled to receive PfSPZ Vaccine during the dry season completed all 3-doses. ~6 weeks later, 15 infectivity controls and 29 vaccinees underwent CHMI with 3.2x10<sup>3</sup> PfSPZ Challenge. All 44 subjects received a full treatment course of artesunate/amodiaquine

(ASAQ) approximately 7 weeks prior to CHMI. Primary protective efficacy endpoint was detection of 1st positive blood smear (BS). All subjects were treated with artemether/lumefantrine when BS positive or at day 27 post CHMI. All 44 subjects completed CHMI follow-up. Reported AEs post CHMI were few, with vaccinees reporting 5 AEs (4/29 subjects; 13.8%) and infectivity controls 8 AEs (7/15 subjects; 46.7%). All reported AEs were mild to moderate. Only one AE, granulocyte decrease, was deemed related to CHMI. Of subjects undergoing CHMI, 0/29 vaccinees and 1/15 infectivity controls became BS positive. By qPCR, 0/29 vaccinees and 8/15 (53.3%) infectivity controls were positive. Most qPCR positive infectivity controls were positive only for a single timepoint (5/8; 62.5%). By qPCR vaccine efficacy was significant (p<0.001) by time-to-infection analysis and 100% (p<0.001, 95% CI 73-100%) by proportional analysis. In comparison, participants who underwent the same vaccination series and were assessed for protective efficacy against natural malaria infection during 24 weeks had a per-protocol vaccine efficacy of 51% (p=0.004, 95% CI 20-70) by time-to-infection analysis and 24% (p=0.031, 95% CI 2-41) by proportional analysis. Protective efficacy against homologous CHMI at 6 weeks exceeded vaccine efficacy against natural occurring infection measured over 24 weeks; given the incomplete infectivity achieved with 3.2x10<sup>3</sup> PfSPZ in the controls, higher doses of PfSPZ Challenge via DVI, or CHMI with heterologous parasite strains, should be assessed to increase the stringency.

### 1182

### CASE REPORT OF SIGNIFICANTLY ABNORMAL LIVER ENZYMES IN HEALTHY VOLUNTEERS ENROLLED IN A MALARIA VACCINE CLINICAL TRIAL: IMPACT OF EMPIRIC ANTIMALARIAL DRUG TREATMENT ON VACCINE SAFETY EVALUATIONS

Abdoulaye Katile<sup>1</sup>, Mahamadou S. Sissoko<sup>1</sup>, Sara A. Healy<sup>2</sup>, Bourama Kamate<sup>1</sup>, Yacouba Samake<sup>1</sup>, Kourane Sissoko<sup>1</sup>, Charles Anderson<sup>2</sup>, Puthupparampil Scaria<sup>2</sup>, Cheick O. Guindo<sup>1</sup>, Merepen A. Guindo<sup>1</sup>, M'Bouye Doucoure<sup>1</sup>, Boucary Ouologuem<sup>1</sup>, Souleymane Traore<sup>1</sup>, Boubacar Fomba<sup>1</sup>, Sidiki Perou<sup>1</sup>, Thomas L. Richie<sup>3</sup>, Stephen L. Hoffman<sup>3</sup>, Patrick E. Duffy<sup>2</sup>, Ogobara Doumbo<sup>1</sup>

<sup>1</sup>MRTC, University of Science, Techniques and Technologies, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>3</sup>Sanaria Inc., Rockville, MD, United States

A double blind, randomized clinical trial was conducted in Mali, West Africa to assess the safety, immunogenicity and protective efficacy against natural malaria exposure of a three-dose regimen of Sanaria® PfSPZ Vaccine (1.8x10<sup>6</sup>) administered via direct venous inoculation (DVI). All study volunteers (n=175) enrolled received at least one, and in some cases three, 3-day treatment regimens with artesunate/amodiaquine (ASAQ) for *Plasmodium falciparum* (Pf) clearance prior to immunization. During the execution of the vaccine trial we noted multiple unanticipated significantly elevated transaminases (Grade 3 to 4) in four participants (2 PfSPZ Vaccine, 2 placebo) at varying stages in the study (14 to 65 days post ASAQ). All four subjects were asymptomatic at presentation with no associated agranulocytosis. All laboratory abnormalities resolved without sequelae (duration 169 to 214 days). Testing for potential of other etiologies, through imaging, expanded laboratory testing, and serology, identified no other possible contributing causes, except a traditional medicine provided to the first subject presenting with liver enzymes derangements. Serum antibodies to AQ are pending at this time. AQ has previously been linked to severe serum aminotransferase elevations in a small proportion (1%) of recipients, but the impact of AQ may be underestimated if routine follow-up testing is not done, and if, as with all 4 volunteers in this study, the abnormalities remain asymptomatic.

**THE MANAGEMENT OF HYDROCELE IN THE HEALTH DISTRICT OF KOLLO****Adamou Bathiri A. Salissou**, Gnanadou G. Issa*Onchocerciasis and lymphatique filariasis programme manager, Niamey, Niger*

In Niger, more than half of the population lives in Areas with risk of lymphatique filariasis infection and the disease affect 1/5 of the people living in the 31 endemic districts. The debilitation effects of the disease like hydrocele aggravate the cycle of poverty, and those suffering are often unable to provide their families with everyday necessities. They are at the bottoms of society, away from school, and community life. In 2016, an active census of hydrocele cases have been conducted in 4 health centers of the district of Kollo. 156 suspected patients were actively diagnosed by community agent. After the confirmation, 71.16% of the presumed hydrocele were confirmed and the rest (28.84%) are hernias. A free hydrocele surgery camp was organized in March 2017 in the district and the technique used is a resection of the vaginal. A total of 187 interventions were carried out on the 127 patients operated. 87.4% of the patients operated came from the villages where the active census were conducted beforehand. 12.6% came by themselves because of the radio announcements. The hydrocele represents 63.3% of the interventions performed, 32.06% were hernias and the rest others. After one week, of postoperative follow-up and after two dressings were renewed, there were 0% complications and the patients returned home safe. After 3 week-end all the patients are cured and the wounds healed.

## 1184

**RECENT SUCCESSFUL CROSS-BORDER ONCHOCERCIASIS ELIMINATION ACTIVITIES - OUR EXPERIENCE****Moses N. Katarwa**<sup>1</sup>, Tom Lakwo<sup>2</sup>, Isam Zroug<sup>3</sup>, Biruck Kebede<sup>4</sup>, Peace Habomugisha<sup>5</sup>, Oumer Shafi<sup>6</sup>, Tony Ukety<sup>7</sup>, Edridah Tukahebwa<sup>8</sup>, Zerihun Tadasse<sup>8</sup>, Nabil Aziz<sup>9</sup>, Kamal Hashim<sup>3</sup>, Ismael Byaruhanga<sup>10</sup>, Leonard Lopay<sup>11</sup>, Uvon Awaca Pitchouna<sup>12</sup>, Makoy Yibi Logara<sup>13</sup>, Lauri Hudson-Davis<sup>1</sup>, Emily Griswold<sup>1</sup>, Frank Richards<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>Ministry of Health, Kampala, Uganda, <sup>3</sup>Federal Ministry of Health, Khartoum, Sudan, <sup>4</sup>Federal Ministry of Health, Addis Ababa, Ethiopia, <sup>5</sup>The Carter Center, Kampala, Uganda, <sup>6</sup>Emory University, Atlanta, GA, United States, <sup>7</sup>Consultant, Bunya, Democratic Republic of the Congo, <sup>8</sup>The Carter Center, Addis Ababa, Ethiopia, <sup>9</sup>The Carter Center, Khartoum, Sudan, <sup>10</sup>Ministry of Health, Aru, Democratic Republic of the Congo, <sup>11</sup>Federal Ministry of Health, Aru, Democratic Republic of the Congo, <sup>12</sup>Federal Ministry of Health, Kinshasa, Democratic Republic of the Congo, <sup>13</sup>Ministry of Health, Juba, Democratic Republic of the Congo

As the shift from control to elimination of onchocerciasis progresses in Ethiopia, Sudan and Uganda, cross-border transmission has become an increasingly apparent obstacle to success. Without a clear understanding of the situation on the other side of the border, part of a transmission zone cannot be verified for interruption of transmission. There are cross-border transmission zones between Ethiopia and Sudan; Ethiopia, Sudan and Republic of South Sudan (RSS); Uganda and Democratic Republic of Congo (DRC); and possibly Uganda and RSS. Since 2014, Ethiopia and Sudan have successfully coordinated activities in the Galabat/Metema cross border focus and ensured that co-endemicity with lymphatic filariasis is also tackled in the area. Health workers from DRC and Uganda have epidemiologically and entomologically assessed three of four transmission zones along their common border. It was not possible to tackle the fourth due to civil strife, but there is determination to do so as soon as possible. Other cross-border activities planned for and keenly awaited are between Uganda and RSS. Most of the necessary discussions and planning has been done, but insecurity and funding in RSS remains a stumbling block. The factors responsible for our success and the challenges we encountered

are critical to informing future cross-border operations for onchocerciasis elimination, and possibly other public health problems. These include: utilization of local knowledge and institutions; building trust; identifying trusted leaders, required resources, and cost containment; standardization of approaches; co-ordination between relevant government departments and partner institutions; addressing lymphatic filariasis co-endemicity; and operational flexibility.

## 1185

**THE SIGNIFICANT SCALE UP AND SUCCESS OF MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS IN ZAMBIA: ACCELERATING TOWARDS THE ELIMINATION GOAL OF 2020****Deborah R. Edwards**<sup>1</sup>, Elizabeth Chizema<sup>2</sup>, Caroline Phiri<sup>2</sup>, Namasiku Siyumbwa<sup>2</sup>, Tedious Sokesi<sup>3</sup>, Tina Chisenga<sup>2</sup>, Brent Thomas<sup>1</sup>, Sarah Martindale<sup>1</sup>, Hannah Betts<sup>1</sup>, Louise Kelly-Hope<sup>1</sup>, Chummy S. Sikasunge<sup>4</sup>, Mark Taylor<sup>1</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Government of Zambia Ministry of Health, Lusaka, Zambia, <sup>3</sup>Government of Zambia, Ministry of Health, Lusaka, Zambia, <sup>4</sup>University of Zambia, Lusaka, Zambia

Lymphatic filariasis (LF) is a mosquito-borne disease that is endemic in 85 districts of Zambia, and targeted for elimination through the implementation of mass drug administration (MDA) of albendazole (ALB) and diethylcarbamazine citrate (DEC) to at-risk populations. Prevalence mapping conducted between 2003-2010 using the rapid immunochromatographic test (ICT) card found an overall rate of 7.4% (range 0-54%). Pre-MDA sentinel site surveys conducted in 2012 and 2014 indicated a significant decline in LF prevalence with most districts reporting <1%, which has been associated with the scale-up of insecticide treated bed nets (ITNs). This suggests that MDA including ALB/DEC may further reduce LF transmission to critical elimination thresholds. This study highlights the success of nation-wide MDA since 2015, including the community mobilization strategy, reported and verified treatment coverage rates, reasons for non-compliance, challenges faced by community drug distributors (CDDs) and number of morbidity cases (i.e. hydrocele, lymphoedema) found in relation to district risk. In 2015, Prevalence mapping community mobilization helped to successfully implement the MDA campaign. Overall, high ALB/DEC rates were reported in 2015 (mean 106%; range 44%-136%), and 2016 (mean 101%; range 58% to 138%), and independently verified high coverage in 10 (79%-93 %) and 5 districts (83-94%), respectively. There was little non-compliance, with 'being away at the time' and/or 'unaware of the MDA activity' cited as main reasons. CDDs noted that problems with transport was the main challenge. Only 372 hydroceles and 255 lymphoedema cases were reported among the 10.2 million target population, with most cases found in previously highly endemic districts. This significant scale up and success of nationwide ALB and DEC distribution - the largest ever reported in sub-Saharan Africa - with high verified coverage, and minimal morbidity case reported together with large scale impact of ITNs, suggests that the Zambia LF Programme could swiftly move to a surveillance phase and accelerate towards the elimination goal of 2020.

## 1186

**THE IMPACT OF SEMI-ANNUAL MASS DRUG ADMINISTRATION FOR MULTI-SPECIES LYMPHATIC FILARIASIS IN INDONESIA: A MODELLING APPROACH****Suzanne Verver**<sup>1</sup>, Periklis Kontoroupi<sup>1</sup>, Taniawati Supali<sup>2</sup>, Peter U. Fischer<sup>3</sup>, Sake J. de Vlas<sup>1</sup>, Gary J. Weil<sup>3</sup>, Wilma A. Stolck<sup>1</sup>

<sup>1</sup>Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Universitas Indonesia, Jakarta, Indonesia, <sup>3</sup>Washington University School of Medicine, St. Louis, MO, United States

Many countries have achieved an enormous decrease in LF infection prevalence through implementation of annual mass drug administration (MDA), but a number of countries lag behind. Acceleration strategies are

needed to achieve the 2020 elimination goal worldwide. Mathematical modelling suggested that the required duration of interventions can be halved by switching from annual treatment to 6-monthly treatment. This needs confirmation by empirical data. We aim to refine model-based estimates of the required duration of annual versus semi-annual MDA for achieving LF elimination, by analyzing DOLF project data. These include a community intervention study in Sikka district, Flores, Indonesia that compared trends in brugian and bancroftian filariasis infection in 3 communities after 3 years of annual or biannual MDA with diethylcarbamazine and albendazole. We fitted the LYMFASIM simulation model to antigenaemia prevalence (*W. bancrofti*), antibody prevalence (*B. timori*), and microfilaraemia (mf) prevalence and intensity (both species) at baseline. Thereafter we assessed whether the model-predicted trends are in accordance with the observed data. Lastly we estimated the number of treatment rounds required to bring mf prevalence below 1%. The baseline prevalence in the community with biannual MDA was higher (8.7 and 10.3% for *W. bancrofti* and *B. timori*, respectively) than for the two communities with annual MDA (0 and 0.4% for *W. bancrofti* and 3.9 and 4.9% for *B. timori*). Our modeling approach accurately reproduced the observed trends. Because of the low baseline mf prevalence in the communities with annual MDA, these communities reached the 1% pre-TAS threshold faster than the community with annual MDA. Our modelling suggests that the target would have been achieved later than in the biannual village, if the baseline mf prevalence was equally high. The total required duration of MDA can be about halved by treating biannually instead of yearly, for both LF species, provided that good coverage levels are maintained. This is a useful strategy to accelerate MDA where biannual MDA can be implemented.

## 1187

### A COMPREHENSIVE ASSESSMENT OF PERSISTENT *WUCHERERIA BANCROFTI* IN HOTSPOTS IN GALLE COASTAL EVALUATION UNIT IN SRI LANKA 9 YEARS AFTER STOPPING MASS DRUG ADMINISTRATION

Ramakrishna U. Rao<sup>1</sup>, Sandhya D. Samarasekera<sup>2</sup>, Kumara C. Nagodavithana<sup>2</sup>, Manjula W. Punchihewa<sup>3</sup>, Devika Mendis<sup>2</sup>, Gary J. Weil<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>Antifilaria Campaign, Ministry of Health, Colombo, Sri Lanka, <sup>3</sup>Regional Antifilaria Unit, Galle, Sri Lanka

The Sri Lankan Anti-Filariasis Campaign (AFC) distributed 5 rounds of MDA (DEC plus ALB) according to WHO guidelines to some 10 million people in 8 endemic districts between 2002 and 2006. All districts met WHO criteria for verification of lymphatic filariasis (LF) elimination as a public health problem in 2016. We previously reported results from comprehensive post-MDA surveillance that was conducted in Galle district between 2013 and 2014. These results and a district wide molecular xenomonitoring study suggested that there were many hotspots in coastal EU in Galle district with ongoing transmission. One of these hot spots called Balapitiya PHI (Population: 17,500) had alarmingly high LF parameters: community CFA rate (3%, 1.8-4.8 CI), MF rate (1%, 0.4-2.2% CI); school children CFA rate (1.2%, 0.5-2.8% CI), Bm14 antibody rate (5.7%, 3.7-8.4% CI) and filarial DNA rate in *Culex* (5.2%, 4.2-6.3% CI). Microfilaraemia rates in this area ranged from 0.9% in 2013 and 0.6% in 2016 suggesting that 2 rounds of MDA in 2014 and 2015 may have had some effect. We reexamined 22 of 168 PHM areas in the Galle district coastal EU after 2 rounds of MDA, and 8 of these were drawn from Balapitiya. Approximately 660 *Culex* pools collected from 22 PHMs in Galle were tested for filarial DNA. 179/660 (27%) pools were positive for filarial DNA. Interestingly, a higher percentage of mosquito pools [107/240 pools (45%)] sampled from Balapitiya contained filarial DNA. This hotspot may require additional rounds of MDA with improved coverage or a test and treat program along with integrated vector management. Coastal Galle district and Balapitiya provide excellent opportunities for applied field research to compare different methods for erasing hotspots and for strengthening Transmission Assessment Surveys.

## 1188

### HYPO-ENDEMIC ONCHOCERCIASIS HOTSPOTS: CHARACTERIZING RISK, DEMOGRAPHY, INFRASTRUCTURE AND ENVIRONMENT TO FACILITATE THE SCALE UP OF ALTERNATIVE STRATEGIES FOR ELIMINATION IN CENTRAL AFRICA

Harriet J. Blundell<sup>1</sup>, Hannah Betts<sup>1</sup>, Thomas R. Unnasch<sup>2</sup>, David H. Molyneux<sup>1</sup>, Mark J. Taylor<sup>1</sup>, Louise A. Kelly-Hope<sup>1</sup>

<sup>1</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Department of Global Health, University of South Florida, Tampa, FL, United States

Community directed treatment with ivermectin (CDTi) has been successful in reducing and controlling the global prevalence of onchocerciasis, with elimination now targeted in all endemic countries. However, in Africa, severe adverse events (SAEs) from ivermectin treatment, including death, have been reported in some areas that are hyper-endemic for loiasis. We define 'hypo-endemic onchocerciasis hotspots' as areas of overlapping onchocerciasis hypo-endemicity and loiasis hyper-endemicity. In such hotspots, the potential risks of CDTi may outweigh the benefits to individual patients, and if left untreated, could contribute to on-going transmission and prevent meeting elimination targets for onchocerciasis. Alternative intervention strategies such as anti-*Wolbachia* therapy, vector control and/or the Test and (not) Treat need to be implemented in such hotspots to ensure safety and impact. It is important however to first understand the local risk, demography, infrastructure and environment that characterise the hotspots. This study, therefore, aimed to characterise five hypo-endemic hotspots across central Africa. Firstly, by using onchocerciasis and loiasis prevalence data to define the scale and spatial extent of risk; secondly, by examining key demographic factors including: age, sex, population density and distribution; thirdly, infrastructure factors including: health facilities, roads and nearest large town, and finally, environmental factors, including: rivers, forests and elevation. These key characteristics were summarised, mapped with key information and used to develop a simple algorithm/decision matrix to facilitate country programmes in identifying high-risk areas, target populations, available human resources, access to health infrastructure and logistical requirements to successfully implement alternative interventions. This study considers whether this pragmatic approach can bridge an existing gap between academic research and programme implementation in hypo-endemic hotspots, in countries currently falling behind in the WHO onchocerciasis elimination agenda.

## 1189

### MEASURING THE NUMBER OF REPRODUCTIVE ADULT FEMALES AND DEFINING TRANSMISSION ZONES FOR FILARIAL NEMATODES USING POPULATION GENETIC MEASURES

Warwick Grant<sup>1</sup>, Katie Crawford<sup>1</sup>, Shannon Hedtke<sup>1</sup>, Steven R. Doyle<sup>2</sup>, Catherine Bourguinat<sup>3</sup>, Roger Prichard<sup>3</sup>, Michel Boussinesq<sup>4</sup>, Joseph Kamgno<sup>5</sup>, Hugues Nana-Djeunga<sup>5</sup>, Samuel Wanji<sup>6</sup>, Mike Osei-Atweneboana<sup>7</sup>

<sup>1</sup>La Trobe University, Bundoora, Australia, <sup>2</sup>Wellcome Trust Sanger Institute, Cambridge, United Kingdom, <sup>3</sup>McGill University, Montreal, QC, Canada, <sup>4</sup>Institut de Recherche pour le Développement, Université Montpellier, Montpellier, France, <sup>5</sup>Centre for Research on Filariasis and other Tropical Diseases, Yaoundé, Cameroon, <sup>6</sup>Research Foundation in Tropical Diseases and the Environment, Buea, Cameroon, <sup>7</sup>Council for Scientific and Industrial Research, Accra, Ghana

For most organisms, there are limits to the distance over which mating can occur between any two individuals, giving rise to population structure in which genetic relatedness is correlated with distance: close together, more related (i.e. more likely to share common ancestors) and further

apart, less related. The result is that measures of genetic relatedness can be used to assign an individual to their population of origin, and that measures of population structure can define the boundaries within which mating between two individuals is likely to occur. For filarial nematodes, two individuals can only mate if they are transmitted to the same host, so measures of genetic relatedness in filarial parasites are an indirect measure of the distances over which transmission occurs within a given population. Consequently, measures of population structure define the boundary of a parasite transmission zone and estimate the probability that an individual parasite is a "resident" of that transmission zone or is an immigrant. Similarly, measures of population structure can be used to estimate the risk of parasite transmission between two locations (for example, across a border between countries/states/districts with differing degrees of success in parasite elimination). We have used a variety of genotyping tools (whole genome sequencing, whole and partial mitochondrial and *Wolbachia* sequencing, and single locus genotyping) to characterise population structure and hence transmission zones for *Onchocerca volvulus* in West Africa and have shown that we can resolve population structure and transmission zones over several spatial and temporal scales. These measures may provide objective tools with which to determine the boundaries of implementation and evaluation units for mass drug administration and cessation of treatment. We have also coincidentally used genotyping data to estimate the number of females contributing to the microfilarial population in the skin of an individual patient, providing a novel measure of parasite infection intensity, and to track the rate at which a parasite population declines under MDA.

### DEVELOPING THE FIRST NATIONAL DATABASE AND MAP OF LYMPHATIC FILARIASIS CLINICAL CASES IN MALAWI

John Chipwanya<sup>1</sup>, Sarah Martindale<sup>2</sup>, Square Mkwanda<sup>1</sup>, Dorothy Emmie Matipula<sup>1</sup>, Paul Ndhlovu<sup>1</sup>, Charles Mackenzie<sup>2</sup>, Michelle Stanton<sup>2</sup>, Kennedy Uadiale<sup>2</sup>, Hannah Betts<sup>2</sup>, Mark Taylor<sup>2</sup>, Louise Kelly-Hope<sup>2</sup>

<sup>1</sup>Ministry of Health, Lilongwe, Malawi, <sup>2</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The Lymphatic Filariasis (LF) Elimination Programme in Malawi is on track to meet the Global Programme to Eliminate Lymphatic Filariasis (GPELF) targets of 2020 by interrupting transmission with mass drug administration (MDA) and alleviating suffering by managing morbidity and preventing disability (MMDP). This study aimed to highlight the LF programme's approach to determining the number of people affected by lymphoedema and hydrocoele, and developing the first national database and morbidity map for targeted interventions across the 26 endemic districts. Such information is essential for certification of LF elimination as a public health problem. The first data on morbidity was collected during national MDA campaigns in 2009-2010 when community drug distributors (CDDs) reported the number of lymphoedema and hydrocoele cases at the health-centre-level. Once MDA was stopped in 2014, the three districts with the highest baseline prevalence and reported number of cases during MDA (Chikwawa, Nsanje and Karonga), were selected for intensive patient mapping using the mHealth tool *MeasureSMS-Morbidity* in which health surveillance assistants (HSAs) reported all cases in their communities by SMS. Each district reported approximately 350 lymphoedema and 800 hydrocoele cases, and provided specific village-level patient data on age, sex, condition and severity of condition (mild, moderate, severe) which could be used to further understand spatial-epidemiological patterns. Focal mapping is now planned for six to eight districts to help develop predictive maps in the remaining 23 districts. Each district will be strategically selected, considering its location, environment, baseline prevalence, and morbidity data reported by MDA. This will allow country-wide data and a map to be generated, highlighting and classifying areas of 'low', 'medium' and 'high' predicted prevalence/case numbers, which will then be verified.

This information will allow the Malawi LF Programme to appropriately plan and deliver a basic package of care to those suffering from the disabling and debilitating clinical manifestations of LF across the country.

## 1191

### FAMILIAL AGGREGATION AND HERITABILITY OF LOA LOA INFECTION

Serge Eyébé<sup>1</sup>, Audrey Sabbagh<sup>2</sup>, Sébastien D. Pion<sup>3</sup>, Joseph Kamgno<sup>4</sup>, Michel Boussinesq<sup>3</sup>, **Cédric B. Chesnais**<sup>3</sup>

<sup>1</sup>Centre for Reserch on Filariasis and other Tropical Diseases, Yaoundé, Cameroon, <sup>2</sup>Institut de Recherche pour le Développement UMR216, COMUE Sorbonne Paris Cité, Université Paris Descartes, Faculté des Sciences Pharmaceutiques et Biologiques, Paris, France, <sup>3</sup>IRD UMI 233-INSERM U1175-Montpellier University, Montpellier, France, <sup>4</sup>Centre for Reserch on Filariasis and other Tropical Diseases, Faculty of Medicine and Biomedical Sciences, University of Yaounde I, Yaoundé, Cameroon

Large scale treatment with ivermectin (IVM) against onchocerciasis needs to be expended to hypo-endemic areas to reach the elimination goal. In these areas, localities where community-directed treatment with IVM (CDTI) cannot be applied because of possible occurrence of *Loa*-related severe adverse events (SAE) have to be identified. At individual level, people at risk of SAE are those harboring >30,000 *Loa* microfilariae per mL of blood. For a given prevalence of microfilaremia, the proportion of people with such high densities varies significantly between communities. We hypothesized that the latter observation is related to the existence of familial clusters of hypermicrofilaremic individuals which would be the consequence of a genetic predisposition to present high *Loa* microfilarial densities. We tested this hypothesis in 10 villages in the Okola Health District of Cameroon. Intrafamilial correlation coefficients and heritability estimates were assessed for both *Loa* microfilaremia and individual microfilarial densities by controlling for age, sex, *Mansonella perstans* microfilaremia and household effects. Pedigree charts were constructed for 1,126 individuals. A significant familial susceptibility to be microfilaremic for *Loa* was found for first-degree relatives ( $p = 0.08$ ,  $P < 0.05$ ; heritability = 0.23). Regarding individual microfilarial densities, a significant familial aggregation was demonstrated ( $p = 0.36$  for first- and 0.27 for second-degree relatives). For first-degree relatives, the highest coefficients were found between mothers and daughters ( $p = 0.57$ ). Overall heritability estimate for intensity was 0.24. These results suggest that the *Loa* microfilaremic status is mainly driven by environmental factors and habits, while a genetic component governs the microfilarial density. These results support the hypothesis that a genetical predisposition to be hypermicrofilaremic exists, leading to the presence of familial clusters of individuals at risk for post-ivermectin SAE. This finding should be taken into account for developing sampling strategies to identify communities where CDTI cannot be applied.

## 1192

### PREDICTIVE VALUE OF OV16 ANTIBODY PREVALENCE IN DIFFERENT AGE GROUPS FOR ELIMINATION OF AFRICAN ONCHOCERCIASIS

Luc E. Coffeng<sup>1</sup>, **Wilma A. Stolk**<sup>1</sup>, Sake J. de Vlas<sup>1</sup>, Allison Golden<sup>2</sup>, Tala de los Santos<sup>2</sup>, Gonzalo J. Domingo<sup>2</sup>

<sup>1</sup>Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>PATH, Seattle, WA, United States

Onchocerciasis is targeted for elimination in Africa by 2025 through mass drug administration (MDA) with ivermectin. Current WHO guidelines for stopping MDA and verifying elimination require that the Ov16 antibody prevalence in 0-9 year old children is brought below 0.1%, but the empirical evidence underlying the choice of age group and threshold is still limited. We assessed the predictive value of different Ov16 antibody prevalence thresholds for elimination of onchocerciasis, for various age groups, a variety of endemic settings and various MDA scenarios. We used the individual-based stochastic ONCHOSIM model to simulate trends in infection and Ov16 antibody prevalence levels during and after MDA. We

simulated 750 scenarios, varying with respect to pre-control endemicity level and MDA characteristics (frequency, coverage and duration of MDA). Each scenario was simulated 10,000 times, and each time we recorded the model-predicted Ov16 prevalence in various age groups (one year after the last MDA round) and the outcome in terms of ongoing transmission vs. elimination (non-zero vs. zero mf prevalence 50 years after the last MDA round). We found that the sensitivity and specificity of Ov16 antibody prevalence for predicting elimination highly depends on the pre-control epidemiological situation, history of MDA, the age group that is sampled, and the chosen Ov16 antibody prevalence threshold. Still, threshold values can be defined such that positive predictive values for elimination are close to 100% regardless of the history of MDA. Importantly, the Ov16 antibody prevalence in school-aged children (age-group 5-14) performs best in predicting elimination. Although exact estimation of thresholds remains difficult due to uncertainties regarding antibody response dynamics, our study indicates that 1) sampling school-age children instead of children under ten increases the accuracy of anti-Ov16 prevalence as a predictor for elimination; 2) the current threshold of 0-1% is too stringent except for the most highly endemic settings; and 3) a differentiated approach to defining thresholds based on pre-control endemicity is pertinent.

### 1193

#### EFFORT TOWARDS ELIMINATION OF LYMPHATIC FILARIASIS IN CAMEROON: RESULTS OF A TRANSMISSION ASSESSMENT SURVEY IN 31 HEALTH DISTRICTS IN NORTHERN REGIONS

**Benjamin Didier Biholong**<sup>1</sup>, Julie Akame<sup>2</sup>, Henri C. Mounqui<sup>2</sup>, Patrick Mbia<sup>2</sup>, Hugues Nana-Djeunga<sup>3</sup>, Georges N. Ayissi<sup>1</sup>, Steven D. Reid<sup>4</sup>, Yaobi Zhang<sup>5</sup>, Josph Kamgno<sup>6</sup>

<sup>1</sup>Ministry of Public Health, Cameroon, Yaoundé, Cameroon, <sup>2</sup>Helen Keller International, Yaoundé, Cameroon, <sup>3</sup>Center for Research on Filariasis and other Tropical Diseases (CRFILMT), Yaoundé, Cameroon, <sup>4</sup>Helen Keller International, New York, NY, United States, <sup>5</sup>Helen Keller International, Dakar, Senegal, <sup>6</sup>Center for Research on Filariasis and other Tropical Diseases (CRFILMT) and the Faculty of Medicine and Biomedical Sciences, University of Yaoundé, Yaoundé, Cameroon

Lymphatic filariasis (LF) is one of the major neglected tropical diseases in Cameroon. The northern regions (Far North and North) were classified by the Ministry of Public Health as LF endemic, based on historical and clinical data, and underwent mass drug administration (MDA) with ivermectin and albendazole in all the health districts (HDs) of the two regions, with financial support from the United States Agency for International Development. Following stopping MDA in 5 HDs that successfully passed their first transmission assessment survey (TAS 1) in 2014 after 6 rounds of effective MDA, a further 31 HDs completed 5 rounds of effective MDA and successfully passed their pre-TAS in 2014 and 2015. TAS 1 in these 31 HDs was subsequently conducted in 2016 using the Alere™ Filariasis Test Strip (FTS). The 31 HDs were grouped in 9 evaluation units (EUs). As the school enrolment rates are below 75% in the northern regions, the TAS 1 was carried out using a community-based cluster sampling according to the World Health Organization guidelines. A total of 13,957 children aged 6-7 years old were enrolled in 267 villages (clusters) and tested using FTS. Overall, 10 positive cases were found in the 9 EUs. No positive case was found in 3 EUs, and 1, 2 and 4 positive cases were found in 4, 1 and 1 EUs, respectively. According to the critical cut-off value for each of the 9 EUs (18 or 20), all EUs passed the TAS 1, suggesting that MDA can be stopped and surveillance organized in these HDs. The results showed that Cameroon has made significant progress in eliminating LF. However, the sample size in one EU was significantly lower than the sample size generated by the Survey Sample Builder because one HD in that EU was not surveyed due to insecurity issue. MDA in this EU may have to continue until further assessment.

#### WHERE ARE WE WITH ONCHOCERCIASIS IN MALI AFTER FORTY YEARS OF IMPLEMENTATION OF CONTROL ACTIVITIES?

**Mamadou Oumar Traoré**<sup>1</sup>, Benoit Dembélé<sup>2</sup>, Boubacar Guindo<sup>2</sup>, Seydou Goita<sup>2</sup>, Modibo Keita<sup>2</sup>, Konimba Doumbia<sup>1</sup>, Kalifa Mounkoro<sup>1</sup>, Mama Niele Keita<sup>3</sup>, Abdoulaye Guindo<sup>1</sup>, Abdoul Karim Sidibé<sup>1</sup>, Steven David Reid<sup>4</sup>, Marily Knieriemen<sup>2</sup>, Yaobi Zhang<sup>5</sup>

<sup>1</sup>Direction Nationale de la Santé, Ministère de la Santé et de l'Hygiène Publique, Bamko, Mali, <sup>2</sup>Helen Keller International, Bamko, Mali, <sup>3</sup>Institut National de la Recherche en Santé Publique au Mali (INRSP), Bamko, Mali, <sup>4</sup>Helen Keller International, New York, NY, United States, <sup>5</sup>Helen Keller International, Dakar, Senegal

Mapping carried out from 1971 to 1987 showed that 35 health districts (HDs) in Sikasso, Ségou, Mopti, Koulikoro and Kayes regions in Mali were endemic with onchocerciasis (OV). Mali began its OV program in 1974 through vector control with the support of the Onchocerciasis Control Program in West Africa (OCP). From 1988 onwards, community-directed treatment with ivermectin (CDTI) was conducted in hyper-endemic foci (20 HDs) to control morbidity. In 2007, OV treatment was integrated into the mass drug administration (MDA) for lymphatic filariasis elimination in the national integrated neglected tropical disease (NTD) program with effective treatment coverage, funded by the USAID. The aim was to consolidate previous achievements and contribute to OV elimination by 2025. The 1971-1987 baseline data gave a median prevalence of 42% (range: 10-73%), using cutaneous biopsy. During the vector control period with OCP, the median prevalence in 1987 after 12 years of control was 16.5% (range: 3-34%). Since the introduction of CDTI in 1988, surveys by cutaneous biopsy showed a gradual decline in prevalence: median prevalence of 2% (range: 0-7%) in 1998 (after ten years of CDTI) and 0% in 2008 for all the surveyed HDs. Since integrated MDA, the prevalence from surveys by biopsy in 2009-2015 has been 0%, which confirmed the previous prevalence obtained with CDTI. The first entomological surveys in 1976 and 1987 showed a median annual transmission potential (ATP) of 497 (0-2914). After 12 years of vector control the median ATP was 70 (29-1116) in 1987. In the last entomological surveys from 2009 to 2015, the infectivity rate was less than 0.5/1000 blackflies (*Simulium*), achieving the threshold biting rate of <100 per person per year. Currently, treatment for LF has stopped in all districts co-endemic with OV. The National Program plans to conduct serological assessment using OV16 in order to determine if treatment for OV can also be stopped in the 20 districts concerned. The country has created the National Committee for the Certification of Elimination of Onchocerciasis that will determine the way forward on the validation of OV elimination in Mali before 2025.

### 1195

#### ELIMINATION OF LYMPHATIC FILARIASIS AS A PUBLIC HEALTH PROBLEM IN NIGER: PROGRESS AND CHALLENGES TO REACHING THE TARGET BY 2020

Adamou Bathiri Salissou<sup>1</sup>, **Zeinabou Trapsida Koullou**<sup>2</sup>, Youssouf Yaye<sup>2</sup>, Aichatou Alfari<sup>1</sup>, Stephanie L. Palmer<sup>3</sup>, Thierno Faye<sup>2</sup>, Josette Vignon<sup>2</sup>, Yaobi Zhang<sup>4</sup>

<sup>1</sup>Ministry of Health, Niamey, Niger, <sup>2</sup>Helen Keller International, Niamey, Niger, <sup>3</sup>Helen Keller International, New York, NY, United States, <sup>4</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal

Lymphatic filariasis (LF) is endemic in 31/42 districts (HDs) across all regions of Niger with baseline microfilaria prevalence ranging from 1% to 52%. Niger aims to eliminate LF as a public health problem by 2020. The strategy is by annual mass drug administration (MDA) with ivermectin and albendazole. Niger began MDA in 2007 in 10 HDs, and progressively reached full geographical MDA coverage in 2014. By 2017, 30/31 endemic HDs have conducted 5 or more rounds of effective MDA

with epidemiological coverage of  $\geq 65\%$ . 17 HDs have undergone the first transmission assessment survey (TAS 1): 8 in 2013, 6 in 2014 and 3 in 2016. Of these, 11 HDs passed TAS 1 and stopped MDA (3 in 2013, 5 in 2014 and 3 in 2016); 6 HDs failed the TAS 1 (5 in 2013, 1 in 2014 and 0 in 2016). 7 other HDs will undergo TAS 1 in 2017. Other 6 HDs recently completed pre-TAS (and those that failed TAS 1 recently underwent re-pre-TAS) and will undergo TAS 1 in 2018 if results allow (pending). The remaining 1 HD finished mapping in 2014 and MDA is ongoing, but it is anticipated that it may be able to stop MDA in 2020. The reason for the continued high prevalence in certain locations and the failure of TAS 1 in some HDs may be due to a highly mobile population (nomadic populations and/or migrants for economic reasons for part of the year), which may have led to sub-optimal MDA coverage in certain sectors of the population, even if overall minimum coverage was met. In addition, the grouping of HDs into evaluation units (EUs) may also have been a factor (e.g. in two EUs that failed in 2013, all positive cases were found in only some of the districts in each EU). In order for Niger to reach its elimination targets, the National LF Program proposes twice-yearly MDA in areas with mobile populations to ensure a better chance to find nomadic groups and ensure at least one annual treatment for economic migrants. More intensive social mobilization and advocacy among leaders will be needed to ensure adherence to MDA. In addition, great care will be taken when deciding eligibility of HDs for TAS 1.

## 1196

### EFFICACY AND SAFETY OF MOXIDECTIN PLUS ALBENDAZOLE, MOXIDECTIN PLUS TRIBENDIMIDINE, AND MOXIDECTIN ALONE VERSUS ALBENDAZOLE PLUS OXANTEL PAMOATE AGAINST *TRICHURIS TRICHIURA* AND CONCOMITANT SOIL-TRANSMITTED HELMINTH INFECTIONS: A RANDOMIZED CONTROLLED TRIAL

Beatrice D. Barda<sup>1</sup>, Marco Albonico<sup>2</sup>, Ame Shaali<sup>3</sup>, Ali Said<sup>3</sup>, Maxim Puchkov<sup>4</sup>, Jorg Huwyler<sup>4</sup>, Jennifer Keiser<sup>1</sup>

<sup>1</sup>Department of Medical Parasitology and Infection Biology, Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Center for Tropical Diseases, Negrar Hospital, Verona, Italy, <sup>3</sup>Public Health Laboratory, Chake Chake, United Republic of Tanzania, <sup>4</sup>Department of Epidemiology and Public Health, Swiss Tropical and Public Health Institute, Basel, Switzerland

Hundreds of millions of people are affected by soil-transmitted helminth (STHs) that are represented by *Trichuris trichiura*, *Ascaris lumbricoides* and hookworms. Infection is most intense and debilitating in children and adolescents. However, their treatment relies on few drugs only. The benzimidazoles are the treatment of choice in preventive chemotherapy, hence most commonly used. However these drugs have a little effect against *Trichuris trichiura*. Moxidectin, in a preliminary study, has shown good activity against this infection. The aim of our study is to assess the efficacy of different combinations of drugs against *T. trichiura* infection and concomitant co-infections with other STHs. In addition, we aim to compare the sensitivity of Kato-Katz and PCR since the sensitivity of Kato-Katz is fairly low, despite being the recommended tool. We conducted a randomized single-blinded trial in *T. trichiura* infected adolescents on Pemba Island, Tanzania. We enrolled 640 adolescents (12-18 years old). At baseline each participant was asked to provide two stool samples, which were examined according to WHO standard procedures (Kato Katz method) and one subsample was shipped to Swiss TPH for PCR procedure. Each participant was randomly assigned to one of the four treatment arms: 1) moxidectin (8 mg), 2) moxidectin (8 mg)/tribendimidine (400 mg), 3) moxidectin (8 mg)/albendazole (400 mg) and 4) albendazole (400 mg)/oxantel pamoate (25 mg/kg). Adverse events were monitored at several time points post-treatment. The participants were asked to provide another two stool samples for follow-up 14-21 days after treatment. Stool samples were again analyzed with Kato-Katz and a sub-sample was shipped to the Swiss TPH for PCR examination. Cure and egg reduction rates of the different treatments will be presented. I will show how the drugs were tolerated by the adolescents, together with the diagnostic

performance of the two methods. Our results are of great importance as we will have elucidated the trichuricidal activity of novel treatments and drug combinations, which might serve as treatment alternative.

## 1197

### EVALUATION OF THE ANTHELMINTHIC ACTIVITY OF COMPOUNDS EXTRACTED FROM *DALEA PARRYI*, *D. POGONATHERA* AND *D. NANA* (PLANTAE, FABACEAE)

Blaise Dondji<sup>1</sup>, Lindsey Engels<sup>1</sup>, Kiah Jones<sup>1</sup>, Brendon Torrey<sup>1</sup>, Victoria McPherson<sup>1</sup>, Angel Coria<sup>1</sup>, Taylor Henne<sup>1</sup>, Katherine Nash<sup>2</sup>, Haley Wolhart<sup>2</sup>, Trevor Shultz<sup>2</sup>, Gil Belofsky<sup>2</sup>

<sup>1</sup>Laboratory of Cellular Immunology and Parasitology, Department of Biological Sciences, Central Washington University, Ellensburg, WA, United States, <sup>2</sup>Department of Chemistry, Central Washington University, Ellensburg, WA, United States

Hookworm infection is a major cause of iron-deficiency anemia, malnutrition, growth delay and cognitive defects in children in endemic countries where about a billion people are affected. Severe iron-deficiency anemia due to hookworm infection during pregnancy might lead to severe consequences for the mother, the unborn fetus and the neonate including impairment of milk production and low birth weight. Control strategies relying on mass distribution of benzimidazole drugs are hampered by frequent re-infections. In addition, reports from the field indicate increasing low efficacy of the current anthelmintics to treat hookworm and other soil-transmitted nematodes. In our quest to identify alternative therapeutic tools for the control of hookworm, we have tested compounds extracted from plants for their anthelmintic activity against the adult stage of the hookworm, *Ancylostoma ceylanicum*. We have reported that two compounds namely tephrosin and deguelin obtained from the plant species *Dalea ornata* can induce 100% mortality of adult hookworm *ex vivo* by 24 hours post-incubation. Consequently, we have rationally collected other plants of *Dalea* genus and evaluated their anthelmintic activity. Data from compounds isolated from *Dalea parryi*, *D. pogonathera* and *D. nana* will be presented. In preparation of our *in vivo* evaluation using our hamster laboratory model of hookworm infection, toxicity of these compounds to mammalian cells is being evaluated by flow cytometry and their effects on cell proliferation by BrdU, a colorimetric assay. Detailed results will be presented.

## 1198

### PREVALENCE OF SOIL TRANSMITTED HELMINTHIASIS AND SCHISTOSOMIASIS AMONG SCHOOL GOING CHILDREN IN SELECTED COUNTIES, KENYA, 2013-2015

Stephen Mwatha

Neglected Tropical Medicine, Nairobi, Kenya

Soil transmitted helminths (STHs) are the most common parasitic infection, infecting an estimated 2 billion people worldwide with over 600million School aged children living in intensive transmission areas. Kenya has been providing prophylactic chemical treatment (PCT) for STHs among school-going children over the past 5 years in 27 counties of which 19 did not have baseline data. Our objectives aimed to determine the prevalence and geographical distribution of STHs and Schistosomiasis (SCH) in Kenya. This was a cross sectional survey conducted using multistage stratified sampling within 19 counties located in Western, Central and Rift-valley region of Kenya. We randomly sampled five schools in each sub-counties and stool samples collected from 50 pupils in each school aged 5-14 years as per world Health Organization (WHO) guidelines. We analyzed stool samples using Kato-Katz technique to identify STH and *Schistosoma mansoni* eggs. We also collected Urine samples from 50 pupils in 5 randomly selected schools in sub-counties in Migori, Marsabit and Homa Bay counties and tested for Schistosomiasis hematobium by using filtration and microscopy. We analyzed data using Ms. Excel, Epi-Info and calculated summary statistics. A total of 18,054 stool samples and 2,950 urine samples were collected. Mean age of pupils were 10.7 years (standard deviation [SD]

2.1). Females constituted 50.6% (n=9,135). Overall STH prevalence in the 19 counties was 5.6%. Prevalence was highest in Narok county (21.2%), Migori 17%, and Homa Bay 12.1%. Overall Schistosomiasis prevalence was 5.6%, with *Schistosoma mansoni* at 4.1% and *Schistosoma hematobium* 1.5% with Migori having the highest prevalence (21.6%). In conclusion, there was still a high prevalence in some counties implementing PCT which would indicate a high transmutability or inadequate treatment. There is need to consider WHO guidelines on sanitation, midterm review of STH and SCH endemicity and effectiveness of intervention is recommended.

## 1199

### INVESTIGATING THE DIFFERENTIAL IMPACT OF SCHOOL AND COMMUNITY-BASED INTEGRATED CONTROL PROGRAMS FOR SOIL-TRANSMITTED HELMINTHS IN TIMOR-LESTE: THE (S)WASH-D FOR WORMS PILOT STUDY

Naomi E. Clarke<sup>1</sup>, Archie C. Clements<sup>1</sup>, James McCarthy<sup>2</sup>, Rebecca Traub<sup>3</sup>, Darren Gray<sup>1</sup>, **Susana Vaz Nery**<sup>1</sup>

<sup>1</sup>Australian National University, Canberra, Australia, <sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>University of Melbourne, Melbourne, Australia

Deworming programs for STH control are usually targeted to school-age children (SAC), through school-based delivery systems, in line with current World Health Organization guidelines. However, a recent meta-analysis shows greater reductions in STH prevalence in children following community-wide deworming, compared to child-targeted deworming. Furthermore, although water, sanitation and hygiene (WASH) interventions are thought to be important for sustainable STH control, alongside regular distribution of anthelmintic drugs, there has been limited research integrating deworming and WASH. The (S)WASH-D for WORMS pilot study aimed to compare the impact of school- and community-based integrated deworming and WASH programs on STH in SAC in six remote communities in Timor-Leste. STH prevalence and intensity were measured in SAC at baseline and six months after anthelmintic delivery, using quantitative PCR. All communities received a deworming and WASH program at the primary school (targeting SAC), and three communities additionally received a community-wide deworming and WASH program. The impact of the study intervention on STH infection rates was estimated. For hookworm, a greater reduction in prevalence at follow-up was seen in the intervention arm (62.5% reduction, 15.1% to 5.7%) compared to the control arm (33.2% reduction, 14.8% to 9.9%). Results of a mixed effects multivariable regression model, with hookworm infection at follow-up as the outcome, suggest that there is a trend towards reduced odds of infection in the intervention arm. The results of the pilot study demonstrate not only the feasibility and acceptability of both the study procedures and the deworming and WASH program, but more importantly provide proof of principle for our hypothesis that a community-wide approach to STH control will reduce STH infections in children more than an exclusively school-based approach.

## 1200

### HYGIENIC BEHAVIORS AND RISKS FOR ASCARIASIS AMONG COLLEGE STUDENTS IN KABUL AFGHANISTAN

**Mohammad Yousuf Mubarak**<sup>1</sup>, Abram L. Wagner<sup>2</sup>, Bradley F Carlson<sup>2</sup>, Matthew L. Boulton<sup>3</sup>

<sup>1</sup>Kabul Medical University, Kabul, Afghanistan, <sup>2</sup>Department of Epidemiology, University of Michigan, Ann Arbor, MI, United States, <sup>3</sup>Department of Internal Medicine, University of Michigan, Ann Arbor, MI, United States

The most at-risk group for ascariasis is older children and teenagers, but the mechanism by which they are at risk is poorly understood, particularly in developing countries. In this study, the proportion of university students in Kabul, Afghanistan, with ascariasis was estimated, along with the distribution of risk factors for infection. We stratified sampling of students

from Kabul Medical University between those who lived in a group hostel vs those who lived in a private home. Students were asked about risk factors with a questionnaire, and they provided a stool sample to test for presence of ascaris eggs. A total of 15.8% of students had ascariasis. Living in a hostel was a strong risk factor for ascariasis (21.2% vs 10.4% in houses). Prevalence of certain risk factors was higher for students in hostels vs homes, like eating street food (51.2% of those in hostels vs 45.8% of those in homes), and eating unwashed vegetables (17.3% vs 8.1%). In conclusion, living in a group hostel was shown to be a risk factor for ascariasis in this study, potentially because the students engaged in at-risk behaviors, like eating food outside of the home. Interventions looking to reduce ascariasis could focus on educating students in group hostels about healthy eating behaviors.

## 1201

### CHILD DEVELOPMENT CENTER-BASED SURVEILLANCE AND CONTROL OF SOIL-TRANSMITTED HELMINTH INFECTIONS IN PRESCHOOL-AGE CHILDREN IN SELECTED LOCAL GOVERNMENT UNITS IN THE PHILIPPINES

Vicente, Jr. Y. Belizario<sup>1</sup>, **John Paul Caesar R. delos Trinos**<sup>1</sup>, Olivia T. Sison<sup>2</sup>, Jonathan Neil Erasmo<sup>3</sup>, Marie Jocelyn Te<sup>4</sup>, Agapito Hornido<sup>5</sup>, Cathrel Nava<sup>6</sup>, Marie Cris Modequillo<sup>7</sup>

<sup>1</sup>University of the Philippines Manila-College of Public Health, Manila, Philippines, <sup>2</sup>University of the Philippines Manila-National Institutes of Health, Manila, Philippines, <sup>3</sup>Department of Health Region VII, Mandaue City, Philippines, <sup>4</sup>Department of Health Region VI, Iloilo City, Philippines, <sup>5</sup>Davao del Norte Provincial Health Office, Tagum City, Philippines, <sup>6</sup>Guimaras Provincial Health Office, Jordan, Guimaras, Philippines, <sup>7</sup>Department of Health Region XI, Davao City, Philippines

The study aimed to describe the parasitologic status of preschool-age children (PSAC) through child development center (CDC)-based sentinel surveillance methodology and to develop and evaluate a CDC-based mass drug administration (MDA) for soil-transmitted helminthiasis (STH) in PSAC in selected sites in the Philippines. For the sentinel surveillance, 30 PSAC in CDCs were targeted from each *barangay* (village). Stool samples were collected in CDCs and examined using the Kato-Katz technique in Cavite, Guimaras, Iloilo, Negros Occidental, Davao del Norte, and Iloilo and Lapu-Lapu cities in 2013-2015. A CDC-based MDA scheme in PSAC was implemented in Guimaras, Davao del Norte, and Lapu-Lapu City in July 2016. MDA coverage rates were obtained, while the implementation of the scheme was described using a monitoring form. Good practices and challenges in the implementation were described through interviews. The survey included 1,732 PSAC. The cumulative STH prevalence and moderate-heavy (M-H) intensity prevalence are 24.9% and 10.3%, respectively. Five schistosomiasis cases were found in Lapu-Lapu City and Davao del Norte. The WHO target for M-H intensity STH prevalence of less than 1% was not met, despite the program being implemented for almost a decade. Good practices included the active involvement of local stakeholders, while challenges included the low turnout for stool collection in some barangays. On the other hand, Lapu-Lapu City and Davao del Norte both reported 100% MDA coverage, while Guimaras reported 86.78% MDA coverage. Good practices included capacity building of health workers and child development workers, social media campaign, health promotion and education integrated in the CDCs, and directly observed deworming. Challenges included absentees and insufficient health workers. Biennial CDC-based sentinel surveillance and biannual CDC-based MDA may be considered to improve STH surveillance and control in PSAC.

## 1202

**CHARACTERISTICS AND OUTCOMES OF STRONGYLOIDIASIS IN SOUTHERN THAILAND**

**Thanaporn Hortiwakul**, Sarunyou Chusri, Kachornsakdi Silpapojakul

*Prince of Songkla University, Hat yai, Songkhla, Thailand*

Epidemiological study on strongyloidiasis in southern Thailand unclear. Even the incidence of helminthic infection in this area is relatively high. A cross-sectional study was conducted to determine the clinical characteristics and outcomes of *Strongyloides stercoralis* infection among inpatients of Songklanagarind Hospital, the tertiary care hospital and referral center in southern Thailand from 2005-2015. Samples of each isolate were examined with microscopy and conventional culture. Then molecular techniques were used to identify the phylogenetic tree of the isolatable strains. Results: Of the 470 inpatients with clinical suspicious of strongyloidiasis with routine laboratory report. Those aged ranged from 21 to 91 years with median of 60 years (interquartile [IQR] range from 45 to 68 years). Four hundred and four patients were male, accounting to 86 %. Most common medical underlying disease was systemic lupus erythematosus (SLE) (50%), solid organ malignancies (36%) and hematologic malignancy (19%), subsequently. Most of patients (70%) were plant gardeners and rice formers. Most common clinical manifestation were fever (90%), respiratory symptoms (70%) including dyspnea, pleuritic chest pain and cough. Routine laboratory showed significant eosinophilia (65%) while anemia and thrombocytopenia was rare. Mortality rate was 59 % and length of hospital stay after infection ranged from 14 to 123 days (IQR; 45 to 90 days). Time to identify the infection was 25 days (IQR; 9-21 days). With logistic regression analysis showed the delayed treatment > was associated with higher mortality. Culture for *S. stercoralis* was positive for 77 isolates from 56 patients. Most common positive-culture sample was sputum (57 samples) accounting to 74 %. Most strains fell into type 4, the common strain in Asian Pacific region, while based on published sequences for species, they cannot be distinguished from the strains were identified in this area. In conclusion, strongyloidiasis is one of the fatal causes of the patients with immunocompromised in southern Thailand and yielded high mortality. Early diagnosis is challenged.

## 1203

**SYSTEMATIC NON-ADHERENCE TO TREATMENT IN HELMINTH MASS DRUG ADMINISTRATION PROGRAMS: INTERACTIONS WITH DISEASE-SPECIFIC TRANSMISSION DYNAMICS**

**Sam Farrell**

*Imperial College London, London, United Kingdom*

In mass drug administration (MDA) aimed at elimination of disease, sufficient treatment coverage is essential for success. Non-adherence to treatment is a barrier to achieving adequate coverage. A critical question concerns the likelihood of non-adherence at one round of treatment predisposing to non-treatment at subsequent rounds. Transmission modelling indicates that the impact of non-adherence varies between helminth diseases. We examine the underlying reasons for this disease-specific heterogeneity through an individual-based stochastic computational model and discuss implications for targeting of MDA in treatment policy.

## 1204

**SOIL-TRANSMITTED HELMINTHIASIS IS UNDER CONTROL IN SEGOU, SIKASSO, KAYES, MOPTI AND KOULIKORO - FIVE REGIONS IN MALI**

**Mahamadou Traoré**<sup>1</sup>, Boubacar Guindo<sup>2</sup>, Benoit Dembélé<sup>2</sup>, Aly Landouré<sup>3</sup>, Seydou Goita<sup>2</sup>, Modibo Keita<sup>2</sup>, Moussa Sacko<sup>3</sup>, Zana Berthé<sup>2</sup>, Abdoul K. Sidibé<sup>1</sup>, Steven D. Reid<sup>4</sup>, Marily Knieriemé<sup>2</sup>, Yaobi Zhang<sup>5</sup>

<sup>1</sup>*Direction Nationale de la Santé, Ministère de la Santé et de l'Hygiène Publique, Bamako, Mali*, <sup>2</sup>*Helen Keller International, Bamako, Mali*,

<sup>3</sup>*Institut National de la Recherche en Santé Publique au Mali (INRSP), Bamako, Mali*, <sup>4</sup>*Helen Keller International, New York, NY, United States*,

<sup>5</sup>*Helen Keller International, Dakar, Senegal*

Segou, Sikasso, Kayes, Mopti and Koulikoro regions in Mali are endemic with soil-transmitted helminths (STH). Initial mapping conducted in 2004-5 showed that 28 of a total of 38 health districts (HDs) in the five regions had STH infections where the prevalence ranged 0.3-33.5% and 7 HDs had prevalence over 20%. The prevalence of hookworm was the highest of the three STH species in the 38 HDs: 19 HDs had hookworm prevalence of ≥1%, with the highest prevalence being 33.5%. Taking advantage of the integration of mass drug administration (MDA) against neglected tropical diseases (NTDs) in Mali, which started in 2007, STH treatment was integrated with that of lymphatic filariasis (LF) in all endemic HDs. Thus the entire population over five years old was targeted for treatment with albendazole. In addition, since 1999, deworming of children under five years has been conducted twice per year during vitamin A supplementation campaigns. To evaluate the impact of mass treatment, STH prevalence was assessed in 2014-16 in 84 sentinel sites in 38 HDs during schistosomiasis sentinel site survey in schools. A total of 5053 children aged 7 to 14 years were evaluated. The Kato-Katz method was used to diagnose STH infections using stool samples. STH infection was found in the sampled school children in only 4 of the 38 HDs surveyed (hookworm in three HDs and *Trichuris* in one), with prevalence ranging from 0.82% to 1.63%, and no heavy infection was found. According to the World Health Organization criteria, the current results showed that STH is successfully under control in all 38 HDs. The treatment of the entire population through deworming and the LF MDA campaign has been conducted in the country's all 65 HDs, and this may have successfully controlled STH throughout Mali. The NTD program plans to conduct further assessments to confirm the control of STH in Mali and will integrate STH assessments with LF transmission assessment surveys. With the LF MDA being gradually stopped in Mali, discussion is under way to integrate STH deworming with schistosomiasis MDA targeting mainly school age children in HDs where the baseline STH prevalence was over 20%.

## 1205

**ASSESSING BETWEEN-VILLAGE HETEROGENEITY OF HOOKWORM TRANSMISSION IN A LOW-INTENSITY SETTING**

**James E. Wright**<sup>1</sup>, James Truscott<sup>1</sup>, Marleen Werkman<sup>1</sup>, Rajiv Sarkar<sup>2</sup>, Gagandeep Kang<sup>2</sup>, Roy M. Anderson<sup>1</sup>

<sup>1</sup>*Imperial College London, London, United Kingdom*, <sup>2</sup>*Christian Medical College, Vellore, India*

Since the London Declaration on NTDs in 2012, the extent to which mathematical modelling has been used to inform public health policy within NTD research has increased markedly. Frequently, however, only cross-sectional data from specific areas within a country of interest are available, which are often collected for other goals rather than informing mathematical models. Data that are required to inform models are scarce as they are difficult and expensive to collect, especially true for high-quality longitudinal data. As such, an assumption may be required that results obtained from the models are applicable to not only the rest of country, but potentially to other countries as well. However, it is well known that prevalence differences are present both between and within

countries, and therefore differences in disease dynamics may also exist. In this study, we investigate whether heterogeneities in transmission dynamics of hookworm exist between villages and their impact on model predictions and policy recommendations. We apply a highly detailed, longitudinal dataset consisting of 45 villages collected from a study into soil-transmitted helminth control in Tamil Nadu, India. Although the mean prevalence across the 45 villages was 19%, the village-level prevalence ranged from 2% to 45%. The high degree of variation in hookworm prevalence, combined with the individual-level, longitudinal nature of the data, result in a dataset of great use in investigating our desired aims. Transmission parameters will be fitted to the age-prevalence profiles for each village separately using maximum-likelihood estimation. These parameters will then each be used within the mathematical models to investigate the impact of village-specific parameter estimates on policy recommendations.

## 1206

### MULTIPLEX POLYMERASE CHAIN REACTION FOR DETECTION OF HOOKWORMS AND *STRONGYLOIDES STERCORALIS*

**Pedro E. Fleitas<sup>1</sup>**, Alejandro Krolewiecki<sup>2</sup>, Julio Nasser<sup>1</sup>, Paola Vargas<sup>2</sup>, Nicolás Caro<sup>2</sup>, Marisa Juarez<sup>2</sup>, Pamela Cajal<sup>2</sup>, Ruben O. Cimino<sup>2</sup>

<sup>1</sup>Universidad Nacional de Salta, Facultad de Ciencias Biológicas, Cátedra de Química Biológica, Salta, Argentina, <sup>2</sup>Instituto de Investigaciones en Enfermedades Tropicales, Universidad Nacional de Salta, San Ramón de la Nueva Orán, Argentina

Diagnosis of gastrointestinal parasites has traditionally relied on stool microscopy, which has low diagnostic sensitivity; although relatively simple and low cost in terms of equipment, the main species of hookworms that infect humans, *Necator Americanus* and *Ancylostoma duodenale*, cannot be differentiated through microscopy of eggs. Moreover, *Strongyloides stercoralis* is the most difficult to diagnose, due to the intermittent nature of larval shedding in the stool as well as the relatively low numbers of larvae found in the stool. As an alternative technique, we developed a Multiplex PCR assay to identify and detect mixed infection with *Necator Americanus*, *Ancylostoma duodenale* and *Strongyloides stercoralis* in human's fecal samples. The multiplex PCR reaction system was established by optimizing the reaction conditions. Results showed that the three target fragments corresponding to the three species used in this work were specifically amplified. The detection limit was ten eggs for hookworms and one larval for *Strongyloides stercoralis*. To measure sensitivity and specificity three groups of fecal samples previously examined by five microscopy test were evaluated. Group 1: 5 patients without parasites; group 2: 10 patients with infection with other parasites (*Ascaris lumbricoides*, *Trichuris trichiura*, *Giardia intestinalis*, and *Hymenolepis nana*) and group 3: 40 patients with single and mixed infections with hookworms and *Strongyloides stercoralis*. No amplification occurred in any of the samples of groups 1 and 2. All the samples from group 3 were positive with single and mixed infection by multiplex PCR, and we could distinguish the species of hookworms. In conclusion, the established multiplex PCR assay is a convenient, rapid, and species-specific identification method for molecular detection and epidemiological investigation in regions of multiples soil-transmitted helminths.

## 1207

### OPERATIONAL CHALLENGES ON THE IMPLEMENTATION OF MASS TEST AND TREAT APPROACH FOR THE ACTIVE SCREENING AND TREATMENT OF HELMINTHS AND PROTOZOA IN PRE-SCHOOL CHILDREN FROM BONGO, ANGOLA

**Cláudia Fançony**, Ánia Soares, Joaquinito Firmino, Amélia Adão, Miguel Brito

Health Research Center of Angola, Lisboa, Portugal

Neglected Tropical Diseases impose a massive burden to health systems, especially in sub-Saharan Africa. The Health Research Center of Angola (CISA), have been investigating integrated interventional strategies willing to control helminths and protozoa in under 5 children, using mass test-and-treat approach. This study aim at documenting the main operational challenges on the implementation of this strategy. Data was collected from under 5 years old children between July and September 2016. It included the collection of stool samples for the diagnosis of intestinal helminth and protozoa (by ParasiTrap and Kato-katz), and the collection of urine for the diagnosis of urogenital schistosomiasis (by filtration technique). Praziquantel and albendazole were administered to infected children. A total of 657 children's were evaluated. From those, 83% delivered urine samples, collected mainly in the supplied container (64%) and in the chamber-pot (30%). On the other hand, a total of 78% stool samples were delivered, where 99.6% were successfully processed by ParasiTrap and 94.7% by Kato-katz. The stool samples were mainly collected from the chamber-pot (51%) and from the floor (27%). In total, 247 children were infected with at least one of the studied parasites, 31% needed Praziquantel, 54% needed Albendazole and 15% needed both drugs. From all infected children, only 222 individual treatment sheet (the main proof of treatment) were signed by the caretakers and 202 were signed by the technician. The main limitations observed here were failure in delivering samples, inadequate sample volume, collection of samples in/from inappropriate containers/locations, impossibility of performing katokatz in diarrheal samples, lack of compliance to treatment appointments or visits, non-supervision of all intakes (in the cases of multiple dosages/drugs) and inadequate filling of treatment records. It should be noticed that the adoption of mass drug administration, as a possible way to overcome these limitations, would entail the unnecessary treatment of uninfected children and limit the number of parasites species included on research studies.

## 1208

### ANTIBODY RESPONSES TO *PLASMODIUM FALCIPARUM* ANTIGENS IN HUMAN IMMUNODEFICIENCY VIRUS-INFECTED ADULTS IN BONDO SUB COUNTY HOSPITAL, WESTERN KENYA

**Eliud O. Odhiambo<sup>1</sup>**, Dibyadyuti Datta<sup>2</sup>, Bernard Guyah<sup>3</sup>, Bartholomew N. Ondigo<sup>1</sup>, George Ayodo<sup>1</sup>, Benard O. Abong'ō<sup>3</sup>, Chandy C. John<sup>2</sup>, Anne EP Frosch<sup>4</sup>

<sup>1</sup>Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States, <sup>3</sup>Department of Biomedical Science and Technology, Maseno University, Kisumu, Kenya, <sup>4</sup>Department of Medicine, University of Minnesota Medical School, Minneapolis, MN, United States

Malaria and human immunodeficiency virus (HIV) infections are co-endemic in sub-Saharan Africa. HIV infection has been associated with severe and frequent malaria episodes. The effect of HIV on malaria immunity is poorly understood but studies have shown altered malaria-specific antibody responses and B-cell phenotypes. Major alterations in CD4+ T cell populations, disruptions in lymphoid tissue and chronic inflammation may alter malaria-specific B cell responses beyond total antibody levels. However, the effect of HIV infection on malaria-specific

antibody isotypes and subclasses is unknown, including the influence of viral load (VL), CD4+ cells and CRP levels on these malaria-specific antibody responses. We enrolled 190 adult participants (52 HIV-uninfected and 138 infected) at Bondo sub-county hospital in western Kenya at the time of HIV testing. We measured antibody isotypes (IgM and total IgG) and subclasses (IgG1-4) in plasma against AMA-1 and GLURP-R0 antigens using ELISA. Quantification of CRP, CD4+ cells and VL was obtained using ELISA, FACSCount system and Abbott m2000 analyzer respectively. We compared malaria-specific antibodies in HIV-infected and uninfected subjects and also associate these measurements with CD4+ cells, VLs and CRP. IgM, IgG1 and IgG3 levels against AMA-1 and GLURP-R0 were higher in HIV-infected individuals ( $P<0.01$ ). Higher CD4+ cell counts were positively and negatively associated with total IgG and IgG1 responses to AMA-1 respectively ( $P<0.05$ ), VL was negatively associated with total IgG to AMA-1 and positively associated with both IgM to AMA-1 and IgG1 to AMA-1 and GLURP-R0 ( $P<0.05$ ) while IgM and IgG1 levels to AMA-1 and GLURP-R0 respectively were positively correlated with CRP levels of HIV-infected individuals ( $P<0.05$ ). In conclusion, in HIV-infected adults, antibodies associated with malaria protection in prior studies, specifically IgM, IgG1, and IgG3, were significantly increased, and often increased with increased viral load. Since HIV increases risk of clinical malaria, future studies should assess antibody affinity and function in these individuals.

## 1210

### LONGITUDINAL ASSESSMENT OF CD4 RECOVERY AFTER ART INITIATION IN ART-NAÏVE HIV-INFECTED ADULTS IN FOUR AFRICAN COUNTRIES

**Emmanuel C. Bahemana**<sup>1</sup>, Allahna Esber<sup>2</sup>, Kavitha Ganesan<sup>2</sup>, Lucas Maganga<sup>3</sup>, Samoel Khamadi<sup>1</sup>, John Owouth<sup>4</sup>, Jonah Maswai<sup>5</sup>, Francis Kiweewa<sup>6</sup>, Senate Amasu<sup>7</sup>, Julie Ake<sup>2</sup>, Trevor Crowell<sup>2</sup>, Christina Polyak<sup>2</sup>

<sup>1</sup>Henry Jackson Foundation Medical Research International/Walter Reed Program Tanzania, Mbeya, United Republic of Tanzania, <sup>2</sup>U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>3</sup>Mbeya Medical Research Center, National Institute for Medical Research, Mbeya, United Republic of Tanzania, <sup>4</sup>Walter Reed Project HIV Program, Kisumu, Kenya, <sup>5</sup>Walter Reed Project, Kericho, Kenya, <sup>6</sup>Makerere University-Walter Reed Project, Kampala, Uganda, <sup>7</sup>U.S. Military HIV Research Program, Abuja, Nigeria

With mortality rates decreasing from increasing use of combination antiretroviral therapy (cART), HIV infected adults are surviving longer. Characterizing the impact and efficacy of cART use in older adults can inform care strategies for this population in resource-limited settings where access to cART is now rapidly expanding. We examined changes in CD4 count after cART initiation, stratified by age, in a unique longitudinal African Cohort Study (AFRICOS) across 11 PEPFAR-supported facilities in four African countries; Tanzania, Uganda, Kenya and Nigeria. ART-naïve adults who started ART while in the cohort and underwent evaluations six and twelve months after ART initiation were included in the analyses among two age categories: <50 and >50 years based on the WHO definition for older age. We assessed the association between age group and population-averaged CD4 count using linear regression with generalized estimating equations and an independent working correlation to account for repeated observations in the same individual. Variables for time since ART initiation and the interaction between age group and time were included in the model to evaluate longitudinal changes in CD4 by age stratum. Between Jan 2013 and Jan 2017, 72 HIV-infected participants, eligible for inclusion in these analyses were enrolled. Participants had a median age of 38.6 years (IQR 30.3-46.1) and 48 (67%) were females. 61 (85%) participants were <50 years old and 11 (15%) were >50. At the time of ART initiation, participants who were >50 had a lower mean CD4 count than did participants <50 years old (199 vs 310 cells/mm<sup>3</sup>,  $p<0.001$ ). This disparity between the older and younger age groups persisted after 12 months of ART (256 vs. 361 cells/mm<sup>3</sup>,  $p<0.001$ ), representing a mean increase of 59 cells/mm<sup>3</sup> in the older group compared to 51 cells/mm<sup>3</sup> in the younger group. Despite the

fact that patients >50 years old in this cohort demonstrated similar CD4 responses to ART initiation as were observed among <50 years patients, and lower baseline CD4 counts and immune senescence that is inherent in aging, current case finding strategies are probably inadequate for older individuals.

## 1211

### EVALUATION OF MALARIA STATUS IN INDIVIDUALS WITH AND WITHOUT HIV INFECTION

**Carolyne M. Kifude**<sup>1</sup>, Deborah Stiffler<sup>2</sup>, Robin Miller<sup>2</sup>, Emily Parsons<sup>2</sup>, Claire Wortmann<sup>2</sup>, Stephen Ocholla<sup>1</sup>, John Waitumbi<sup>1</sup>, Shirley Luchhart<sup>3</sup>, Janet Oyieko<sup>1</sup>, V. Ann Stewart<sup>2</sup>

<sup>1</sup>U.S. Army Medical Research Directorate, USAMRD-Kenya, Kisumu, Kenya, <sup>2</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>3</sup>Medical Microbiology and Immunology, School of Medicine, University of California Davis, Davis, CA, United States

The public health crisis of malaria-HIV co-infection is rapidly expanding in sub-Saharan Africa. Lowland western Kenya in particular is holoendemic for malaria transmission and also has high rates of HIV/AIDS infection. Previous studies have shown that individuals infected with HIV experience more frequent and more severe episodes of clinical malaria and the risk increases with advancing HIV disease. However, the impact of HIV infection on asymptomatic malaria, which represents the majority of malaria infections in adults in high transmission areas, remains unclear. We hypothesize that there are high levels of asymptomatic malaria prevalence and malaria parasitemia in HIV-infected compared to HIV-uninfected persons. To address this question, we used sensitive molecular techniques to determine the point prevalence of malaria infection of malaria parasites in HIV-infected and HIV-uninfected participants. Using 700 samples collected in a HIV/malaria co-infection study in a malaria endemic region in western Kenya, the presence of any species of malaria was first determined using an improved assay based on genus-conserved sequences of the *Plasmodium* 18S ribosomal gene. All infections with  $\geq 1$  parasite per 50ul sample were detectable by our assay. Second, if positive for malaria, we utilized a panel of highly species-specific qPCR assays to determine the presence and quantity of mixed species infections including *P.falciparum*, *P.ovale* and *P.malariae*. We report the point prevalence and magnitude of asexual malaria parasitemia as well as the prevalence of infection with multiple species in HIV-infected versus HIV-uninfected persons. Preliminary results show that our quantitative PCR assays are highly sensitive and can be used on blood samples collected on filter paper from malaria endemic areas where high prevalence of sub-microscopic parasitaemia have been reported. The relevance of this study is that HIV-malaria co-infected individuals may be more efficient reservoirs of malaria and therefore there is need for higher public health priority of persons at risk for both diseases.

## 1212

### PREVALENCE OF MICROSCOPIC AND SUBMICROSCOPIC MALARIA INFECTION AMONG PATIENTS LIVING WITH HIV INFECTION AND HIV NEGATIVE INDIVIDUALS IN GABON

**Koumba Lengongo Jeanne Vanessa**, Mawili-Mboumba Denise Patricia, François Sandrine, M'Bondoukwe Noé Patrick, Mbang Nguema Ornela, Ondounda Magloire, Djoyi-Mbiguino Angélique, Bouyou Akotet Marielle Karine

University of Health Science, Libreville, Gabon

Malaria infection is frequent in endemic among asymptomatic individuals as well as submicroscopic infection who constitute the parasite reservoir. In Gabon, submicroscopic malaria infection has been frequently detected among febrile patients, but its prevalence has not been investigated in people living with HIV (PLHIV) most represented by adults where malaria susceptibility increasing this last year. The present study aims to determine the frequency of microscopic and submicroscopic infection among PLHIV compared to the seronegative patients in different areas of Gabon. A survey was conducted in rural (Koulamoutou and Oyem)

and urban (Lireville) areas of Gabon from March 2015 to June 2016. The microscopic malaria diagnosis was performed by blood smears. The gene encoding the 18S subunit of riosomal RNA was amplified to detect of submicroscopic malaria infection. In total, 339 samples were analysed, among them, 61,1% (n=207) were PLHIV. The prevalence of malaria infection was 31,8% (108/339). The parasite were detected in 27,7% (94/339) by microscopic and 5,7% (14/245) by submicroscopic. The largest proportion of malaria infected samples by microscopic was found among HIV seronegative patients compared to the PLHIV (45,5% vs 15,4%) (p <0.01). Contraste to submicroscopic malaria infection, the prevalence was higer among PLHIV compared to the seronegative patients (6,9% vs 2,7%). This profil of prevalence was comparable according to the fever, the asymptomatic PLHIV were the carried of submicroscopic infection (9,6%; n=12/125). Among PLHIV, frequency of malaria vary according to the use of cotrimoxazole (CTX). This frequency was low among patients with microscopic infection compared to the submicroscopic infections individuals (4,6% vs 12,1%). The present study highlight that submicroscopic and asymptomatic malaria infection not uncommon among HIV infected patients compared to the seronegative patients. The protective effect of CTX were observed. However, submicroscopic infection were frequente among PLHIV with taking CTX.

## 1213

### CHARACTERIZATION AND IDENTIFICATION OF CYP2B6 POLYMORPHISMS IN A CONGOLESE HIV-1 POSITIVE COHORT NAIVE TO TREATMENT

Simon Marie Peko<sup>1</sup>, Félix Koukouikila-Koussounda<sup>1</sup>, Simon Charles Kobawila<sup>2</sup>, Francine Ntoumi<sup>1</sup>

<sup>1</sup>Fondation Congolaise pour la Recherche Médicale, Brazzaville, Republic of the Congo, <sup>2</sup>Université Marien Ngouabi, Brazzaville, Republic of the Congo

Antiretroviral therapy has greatly improved the prognosis of AIDS. However, polymorphisms in genes involved in the enzymatic metabolism of drugs seem to be partly blamed for being responsible for the variability in responses to antiretroviral drugs including toxicity. Thus, genotyping of CYP2B6 G516T has been suggested to identify slow metabolizers for precision medicine. In Republic of Congo, highly active antiretroviral therapy (HAART) for HIV / AIDS consists of two nucleoside reverse transcriptase inhibitors (NRTIs) combined with a non-nucleoside reverse transcriptase inhibitor (NNRTI), Efavirenz or Nevapirine (EFV or Nvp), or with a protease inhibitor (PI). Unfortunately, no data are available on the variation of CYP2B6 in the Congolese population. ART (Antiretroviral Therapy) is initiated without a genetic test of the CYP2B6 G516T. Therefore, the aim of this study was to determine 1) the prevalence of the polymorphisms of the CYP2B6 gene at position 516 in Congolese population and 2) to predict the proportion of GG genotype (rapid metabolizer), GT genotype (intermediate metabolizer) and TT Genotype (slow metabolizer), and finally to show the importance of genetic testing in personalized medicine in the country. We collected blood samples from thirty-six HIV positive patients consulting the anti tuberculosis national Center in Brazzaville. Human DNA was extracted and CYP2B6 G516T genotyping was done using Polymerase Chain reaction-restriction fragment length polymorphisms (PCR-RFLP). Our results showed a distribution of 9/36 for the GG genotype (extensive metabolizer), 12/36 for the GT genotype (intermediate metabolizer) and 15/36 for the TT genotype (slow metabolizer). This study shows in a small sample size, the high presence of this mutation in the Congolese population and it would be of interest to conduct a larger study and to explore the possibility to incorporate this test in the national treatment algorithm to improve health care of HIV positive patients.

## 1214

### ART ADHERENCE

Faith Musvipwa

University of Virginia, Charlottesville, VA, United States

For diseases, such as human immunodeficiency virus (HIV), rural communities must often grapple with adopting a Western biomedical approach to treatment or use traditional healing methods rooted in generations of religious and cultural practice. Despite advocacy for a biomedical approach to treating HIV with antiretroviral therapy (ART) in South Africa, traditional healing preferences remain prominent. It is unknown what factors influence these preferences in rural Limpopo province and whether a better understanding of these health seeking behaviors could be utilized to improved ART uptake and adherence while maintaining a culturally important connection to traditional practices. A structured literature review was performed to identify rates of ART uptake and adherence based on levels of economic disadvantage. We then sought to identify at least five districts in Limpopo province representing the major ethnic groups living in communal settings, and whose belief systems are at least partly African traditional. Next, purposive and snowball sampling methods were designed to draw a sample of 30 participants evenly sampled from each district. Semi-structured interviews will be used to collect data. Data will be analyzed through grounded theory method. Structured literature review found that non-adherence to ART was more prevalent in communities which are economically disadvantaged, and was particularly common in areas characterized by communal subsistence farming lacking formal education and employment. Stigma and discrimination also resulted in patients on ART taking their medications in concealment to cover their HIV positive status or defaulting treatment rather than risk stigmatization. Participant enrollment for qualitative study has yet to begin. Economically disadvantaged populations in rural Limpopo are at major risk for lack of ART uptake or non-adherence but complimentary engagement of the traditional healing community may improve HIV outcomes. Ongoing qualitative study will elucidate the most promising community-based mechanisms.

## 1215

### RATES OF TUBERCULOSIS DIAGNOSIS AMONG AN HIV-POSITIVE COHORT IN 4 AFRICAN COUNTRIES

Kavitha Ganesan<sup>1</sup>, Christina Polyak<sup>1</sup>, Allahna Esber<sup>1</sup>, Emmanuel Bahemana<sup>2</sup>, Yakubu Adamu<sup>3</sup>, Francis Kiweewa<sup>4</sup>, Jonah Maswai<sup>5</sup>, John Owuoth<sup>6</sup>, Julie Ake<sup>7</sup>, Elizabeth Haraus<sup>1</sup>

<sup>1</sup>U.S. Military HIV Research Program, Henry M. Jackson Foundation, Bethesda, MD, United States, <sup>2</sup>Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, <sup>3</sup>Walter Reed Program-Nigeria, Abuja, Nigeria, <sup>4</sup>Makerere University-Walter Reed Project, Kampala, Uganda, <sup>5</sup>KEMRI/Walter Reed Project, Kericho, Kenya, <sup>6</sup>KEMRI/Walter Reed Project, Kisumu, Kenya, <sup>7</sup>U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Tuberculosis (TB) disproportionately affects people living with HIV (PLWH) but is underdiagnosed due to atypical signs and symptoms and the paucibacillary nature of the disease among HIV-positive people. Diagnosing TB is a challenge to health systems. For this analysis, we describe the rates of TB diagnosis among PLWH in an African cohort study. The African Cohort Study is an ongoing 15 year prospective observational HIV focused cohort that enrolls adults at 11 PEPFAR-supported health facilities in Uganda, Kenya, Tanzania, and Nigeria, all high burden HIV/TB countries. HIV and co-infection clinical parameters and laboratory assessments are obtained at enrollment and every 6 months. TB diagnosis is either bacteriologically confirmed (via GeneXpert® MTB/RIF or acid-fast bacilli smear) or clinically diagnosed on the basis of symptoms and history. We evaluated rates of TB diagnosis among PLWH in our cohort and described associated clinical and demographic characteristics. Between January 2013 and December 2016, 2,488 HIV-infected participants were enrolled. During this period, 111 (4.5%) subjects were diagnosed with TB; 64

(58%) of those cases were bacteriologically confirmed and 47 (42%) were clinically diagnosed. TB incidence was 2.4 cases/100 person years; with 1.4 cases/100 person years and 1 case/100 person years diagnosed among the bacteriologically confirmed and clinically diagnosed, respectively. Although incidence of active TB among PLWH is not well known, a systematic review of intensified TB case finding in HIV clinics in Sub-Saharan Africa found TB rates of 8.2% [Kranzer et al. Lancet 2010]. Among PLWH in South Africa, TB incidence was 5% among patients with comparable CD4 counts to our cohort (mean CD4 465.8 cells/mm<sup>3</sup>) [Lawn et al. JID 2011]. Therefore, our cohort's incidence of 2.4% may be under-diagnosing TB. Continued aggressive screening and diagnosis for TB is warranted.

## 1216

### TRENDS IN THE PREVALENCE OF HIV/AIDS IN THE STATE OF MISSISSIPPI: A FIVE YEAR REVIEW

Alex D. Acholonu

Alcorn State University, Alcorn State, MS, United States

Acquired immune deficiency syndrome (AIDS) is a disease of utmost concern all over the world. The etiology is the human immunodeficiency virus (HIV). It is one of the most serious sexually transmitted diseases (STDs). But it can also be transmitted by contact with infected blood from mother to child during pregnancy, childbirth, or breast feeding. There is no cure for it but there are available antiviral drugs that can be used to mitigate its severity. The signs and symptoms vary depending on the stage of infection. Mississippi with a population of 2.9 million, was said to have the 7th highest rate of HIV infection in the U.S. in 2011. The purpose of this study is to assess the trend in the prevalence of HIV/AIDS within the last five years (2011-2015). The study is based on the statistical analysis of the prevalence reports in literature and the Mississippi State Department of Health. The literature review showed that the prevalence of HIV/AIDS in the State of Mississippi in the five years under review appears to have been continuously increasing rather than decreasing. However, there is no significant difference on year to year basis from 2011 to 2015 ( $P > 0.05$ ). HIV infection by sex showed a preponderance of males infected as against females ( $P < 0.05$ ) for each of the five years reviewed. The study showed the highest prevalence in 2011 and the lowest, in 2012 and increased yearly from 2013-2015. But the increase was not very significant ( $P > 0.05$ ). African Americans had the highest number of diagnosed cases of all the races within the review period, even though they make up only 38% of the State's population. They represent 78% of people in Mississippi with HIV/AIDS. These results are very revealing. The trend show how the prevalence of HIV/AIDS is highest in African Americans and appear to be increasing and much less in the caucasians and appear to be decreasing. It is recommended that more efforts be made to reduce the prevalence of HIV/AIDS among African Americans in the State of Mississippi.

## 1217

### PROSPECTIVE VALUE OF QUANTIFERON TB GOLD FOR ACTIVE TUBERCULOSIS IN ART NAIVE HIV POSITIVE INDIVIDUALS IN THE AFRICAN COHORT STUDY

Inge Kroidl<sup>1</sup>, Michael Holscher<sup>2</sup>, Lucas Maganga<sup>3</sup>, Emmanuel Bahemana<sup>4</sup>, Jonah Maswai<sup>5</sup>, John Owuoth<sup>6</sup>, Yakubu Adamu<sup>7</sup>, Hannah Kibuuka<sup>8</sup>, Leigh Anne Eller<sup>9</sup>, Michelle Imbach<sup>9</sup>, Christina Polyak<sup>9</sup>, Julie Ake<sup>10</sup>

<sup>1</sup>Division of Infectious Diseases and Tropical Medicine, Medical Center of the University of Munich, Munich, Germany, <sup>2</sup>German Center for Infection Research, Munich, Germany, <sup>3</sup>Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, <sup>4</sup>Walter Reed Program-Tanzania, Mbeya, United Republic of Tanzania, <sup>5</sup>KEMRI/Walter Reed Project, Kericho, Kenya, <sup>6</sup>KEMRI/Walter Reed Project, Kisumu, Kenya, <sup>7</sup>Walter Reed Program-Nigeria, Abuja, Nigeria, <sup>8</sup>Makerere University-Walter Reed Project, Kampala, Uganda, <sup>9</sup>U.S. Military HIV Research Program, Henry M. Jackson Foundation, Bethesda, MD, United States, <sup>10</sup>U.S. Military HIV Research

Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Tuberculosis (TB) causes globally significant morbidity and mortality. Among people with HIV, the diagnosis of TB is difficult as the detection of acid-fast bacilli in sputum via smear, culture or PCR (TB Xpert) often fails. We evaluated whether immune response to TB, measured by Quantiferon TB Gold (QFT) could improve detection. The African Cohort Study (AFRICOS) prospectively enrolls adults at 11 PEPFAR-supported facilities in Uganda, Kenya, Tanzania, and Nigeria. HIV management history and laboratory assessments were obtained at entry and every 6 months. Clinical diagnosis of TB was determined by national guidelines. Baseline laboratory evaluation involved screening for TB using TB Xpert for all individuals and QFT for ART naïve participants. Between January 2013 and August 2016, 2263 HIV infected participants were enrolled, with a mean follow-up of 1.05 years (range 0 to 3.5 yrs). The mean age was 39.7 yrs and 58.9% were women. At enrollment, 1494 (66%) of participants were taking antiretroviral treatment (ART); 777 (34%) were ART-naïve. 233 (10.3%) of those on ART reported a previous episode of TB, in contrast to 20 (2.6%) of the ART-naïve. At enrollment, 15 of 2263 (0.7%) participants were newly diagnosed with active TB, 10 of them with a positive Xpert and 5 with clinical criteria. During follow-up (2381 person-yrs), a total of 44 cases of TB were clinically diagnosed (1.8 cases per 100 py), 25 among the ART naïve group (3.6 per 100py), compared to 19 (1.1 per 100 py) among the ART experienced. Of these 44 cases, all had a TB Xpert completed, of which 23 had a confirmed positive result. Of the 777 ART-naïve participants, QFT results are available for 549 of which 176 (32.1%) were positive. Out of the subgroup with a positive QFT result 7.8% had a positive Xpert compared with 1.69% of the QFT negative group. Our results suggest an increased risk for developing TB in ART-naïve individuals in a prospective cohort study. Individuals with a positive QFT among ART-naïves are at increased risk for developing active TB. For TB suspects for whom the microbiological proof of TB through Xpert or culture is difficult, testing with QFT can improve the management of patients.

## 1218

### PATTERNS OF HIV STATUS DISCLOSURE TO HOUSEHOLD MEMBERS IN AN AFRICAN COHORT

Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States

Persons living with HIV (PLWH) who do not disclose their status to members of their household may not seek out HIV care and treatment due to fear of stigma or discrimination. These analyses describe patterns of HIV status disclosure, including to household members, and evaluate associations between disclosure, stigma and outcomes such as ART use, and virologic suppression. The African Cohort Study (AFRICOS) prospectively enrolls participants at clinics in Kenya, Nigeria, Tanzania and Uganda. At enrolment of PLWH, a structured questionnaire is administered, a review of ARV medications performed, and blood samples collected. For these analyses, PLWH living with  $\geq 1$  person were categorized based on disclosure to household members. Categories of persons aware of each participant's HIV status were tallied based on self-report. Characteristics were compared between the two disclosure groups. Multivariable Poisson regression models with robust variance estimators were used to calculate risk ratios (RRs) and 95% confidence intervals (CIs) for associations between disclosure to household members and (1) ART use and (2) virologic suppression (HIV RNA  $< 50$  copies/mL). As of 31 December 2016, 2490 PLWH were enrolled and 2296 of them lived

with  $\geq 1$  person. Of these, 1813 (79%) had disclosed their HIV status to a child, 1748 (76%) to a household member, and 1346 (59%) to a spouse or partner. As compared to PLWH who had not disclosed, those who had disclosed to a household member were older (median 39.2 [interquartile range 32.5-46.4] vs 37.6 [30.8-45.6] years,  $p=0.007$ ), more likely to be male (45% vs 24%,  $p<0.001$ ), more likely to be married (72.4% vs 29.9%,  $p<0.001$ ), and more likely to be prescribed ART (70% vs 57%,  $p<0.001$ ). Most participants in both groups denied any experience of HIV-related stigma (88% vs 89%,  $p=0.32$ ). Adjusting for other factors, disclosure to household members was associated with increased likelihood of both ART use (RR 1.09 [95% CI 1.06-1.12]) and virologic suppression (RR 1.29 [95% CI 1.16-1.44]). Efforts to encourage disclosure—particularly among young, unmarried men—may improve ART adherence and clinical outcomes in PLWH.

### POPULATION LEVEL ANALYSES TO EXAMINE COMORBID HIV/AIDS INFECTION IN SUB-SAHARAN AFRICA AND TRANSMISSION OF DRUG RESISTANT MALARIA PARASITES

**Brandi K. Torrevillas<sup>1</sup>**, Nicholas Hathaway<sup>2</sup>, Ozkan Aydemir<sup>2</sup>, Carolyne Kifude<sup>3</sup>, Robin Miller<sup>3</sup>, Deborah Stiffler<sup>3</sup>, Mgrignayni Venkatesan<sup>3</sup>, Alida Gerritsen<sup>1</sup>, Dan New<sup>1</sup>, Jeffrey Bailey<sup>2</sup>, V. Ann Stewart<sup>3</sup>, Shirley Luckhart<sup>1</sup>

<sup>1</sup>University of Idaho, Moscow, ID, United States, <sup>2</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>3</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Modeling in previous studies showed that co-infection with HIV and malaria has the potential to amplify transmission of both diseases through immunosuppression and higher disease burden. However, few studies emphasize the impact of asymptomatic malaria on transmission dynamics. Antifolate prophylaxis for HIV-associated opportunistic infections can increase gametocyte burden, and also may increase parasite drug resistance. Accordingly, we seek to establish the prevalence of drug resistant genotypes within individual patients and at the population level as a prelude to investigate transmissibility of resistance alleles using paired patient and vector samples interrogated by targeted deep sequencing. For these studies, genomic DNA was extracted from dried blood spots obtained from patients in western Kenya. Because parasite DNA is present against a high background of human DNA from leukocytes in these samples, gene-specific targets are initially amplified using a hemi-nested PCR approach. A subsequent PCR further amplifies the targets while adding universal adapters to both 5' and 3' ends of the amplicons. Finally, PCR using primers complementary to the universal adapters adds molecular barcodes and Illumina sequencing adapters. This method allows a greater number of unique identifiers to be added to each library using fewer primers and enables pooling of libraries into a single lane for sequencing. Data are demultiplexed by dbcAmplicons and quality filtered using the SeekDeep analysis pipeline. Data from our validation study suggest that alleles conferring moderate to high resistance in the dihydropteroate synthetase (DHPS) and dihydrofolate reductase (DHFR) genes are approaching fixation in a region of high malaria transmission in Western Kenya. In the context of holoendemic malaria and HIV transmission, fixation of resistant genotypes significantly limits utility for sulfadoxine-pyrimethamine for intermittent preventative therapy. By quantifying and evaluating the transmissibility of drug resistant genotypes, we hope to inform better strategies for the control and treatment of HIV and malaria.

## 1220

### CO-INFECTION MALARIA-HELMINTHIASIS IN PREGNANT WOMEN AT THE GENERAL HOSPITAL OF KIMPESE, DEMOCRATIC REPUBLIC OF CONGO

**Solange E. Umesumbu<sup>1</sup>**, Dickens Mpembele<sup>2</sup>, Trésor Zola<sup>3</sup>, Thierry L. Bobanga<sup>3</sup>

<sup>1</sup>National Malaria Control program, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Universite Simon Kimbangu, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Universite de Kinshasa, Kinshasa, Democratic Republic of the Congo

Parasitic infections are a major cause of morbidity and mortality in pregnant women. Soil Transmitted Helminthiasis, Schistosomiasis and malaria have a negative impact on the woman and the child who is in gestation, especially by the anemia that they can cause during pregnancy. The objective of this study is to determine the prevalence of co infection malaria-helminthiasis during pregnancy. This is a preliminary cross-sectional descriptive study of 128 pregnant women attending antenatal clinics at IME / Kimpese hospital from January to May 2016. Biological examinations allowed diagnosis of malaria and intestinal helminthiasis and Dose hemoglobin. The frequency of malaria during pregnancy was 32%. In relation to malaria prevention, 64% of women received ITP and 89% were under LLIN. Helminth infection was found in 57% of pregnant women. Malaria co-infection with helminth infections was observed in 24% of pregnant women with 23% *Ascaris lumbricoides*, 16% *Schistosoma mansoni* and 8% hookworm. *A. lumbricoides*, *Schistosoma* spp and hookworm infection co-infected 3% of the pregnant women. However, 65% of the pregnant women had anemia. Malaria-helminth infections co-infected nearly one-quarter of the women receiving pre-natal consultations at the Kimpese HGR. More than 60% of these women had hemoglobin levels below 11g%.

## 1221

### UNUSUAL MORPHOLOGIES AND REPRODUCTION OF CRYPTOCOCCUS NEOFORMANS

**Rito Zepa<sup>1</sup>**, José María Guevara Granados<sup>2</sup>, Roberto Rojas<sup>3</sup>, Shivany Condor Montes<sup>4</sup>

<sup>1</sup>Instituto de Medicina Tropical "Daniel Alcides Carrión", Lima, Peru, <sup>2</sup>National Hospital Carrión, Callao, Peru, <sup>3</sup>Federico Villarreal National University, Lima, Peru, <sup>4</sup>University of California, Berkeley, CA, United States

Two cases of immunocompromised patients with cryptococcal meningitis were recorded in the year 2008. The aim of this report is to present unusual morphologies of *Cryptococcus neoformans*. The samples of cerebrospinal fluid obtained from a 7 year-old child, National Institute of Child Health, Lima, Peru, and an adult aged 47, National Hospital Carrión, Callao, Peru, were processed using the modified Chinese stain technique. Both samples showed unusual morphologies and reproduction of *Cryptococcus neoformans*: cells with pseudohyphae, hyphae, successive budding and germ tubes, presented here in two- and three-dimensional images. *Cryptococcus neoformans* was confirmed using culture and biochemical methods. In conclusion, unusual morphologies and reproduction of *Cryptococcus neoformans* have been found in cerebrospinal fluid of immunocompromised patients.

## 1222

**RETROSPECTIVE HOSPITAL REVIEW OF THE INCIDENCE HIV AND SYPHILIS IN HAITI FROM 2008-2016**

Nuhira A. Masthan<sup>1</sup>, Caroline J. Stephenson<sup>1</sup>, Marie Y. Remy<sup>2</sup>, Robert Nicolas<sup>2</sup>, Michael E. von Fricken<sup>1</sup>

<sup>1</sup>George Mason University, Department of Global and Community Health, Fairfax, VA, United States, <sup>2</sup>African Methodist Episcopal Church - Service and Development Agency Inc., Washington, DC, United States

Haiti is among the poorest countries in the Western Hemisphere and has the highest number of people living with Human Immunodeficiency Virus (HIV) in the Caribbean region. Damaged infrastructure following multiple natural disasters has led to an increase risk of HIV and syphilis transmission, due to limited access to health services. Retrospective clinical data focusing on HIV and syphilis was extracted from five African Methodist Episcopal Service and Developing Agency (AME-SADA) network clinics located in the Ouest department of Haiti, capturing data from 2008-2016. Monthly incidence and annual trends were then examined. All data was double entered to ensure accuracy. Between 2008 and 2012, 3.9% (263/6580) of those tested for HIV were found to be positive, while 3.02% (150/4966) number of patients were found to be infected with syphilis. Between 2013 and 2016, the HIV prevalence decreased to 3.4% (523/15331) and syphilis cases increased to 6.2% (996/15973). In 2016 alone, the prevalence of HIV was 3.67% (190/5169) while syphilis was 14.3% (189/1319). However, the 2016 HIV prevalence is relatively high compared to previous years, which may indicate surging transmission and requires monitoring. Studies in Haiti have shown that syphilis infection or having any other sexually transmitted infections (STI's) increases the risk of facilitating HIV transmission and acquisition. In addition, HIV/syphilis infection during pregnancy can lead to adverse birth outcomes, congenital syphilis and increases the risk of mother to child transmission of HIV. Ongoing efforts and funding are critical to reducing the ongoing epidemic of HIV and other STIs in Haiti.

## 1223

**CHARACTERIZATION OF THE POTENCIAL DIAGNOSTIC OF POLYANTIGENS FOR DETECTING *TRYPANOSOMA CRUZI* IN THE CHRONIC PHASE OF CHAGAS DISEASE**

Fred L. Santos<sup>1</sup>, Paola A. Celedon<sup>2</sup>, Nilson I. Zanchin<sup>3</sup>, Wayner V. Souza<sup>4</sup>, Edmilson D. Silva<sup>5</sup>, Leonardo Foti<sup>3</sup>, Mitermayer G. Reis<sup>1</sup>, Marco A. Krieger<sup>3</sup>, Yara M. Gomes<sup>4</sup>

<sup>1</sup>Gonçalo Moniz Institute (Fiocruz-BA), Salvador, Brazil, <sup>2</sup>Molecular Biology Institute of Paraná, Curitiba, Brazil, <sup>3</sup>Carlos Chagas Institute (Fiocruz-PR), Curitiba, Brazil, <sup>4</sup>Aggeu Magalhães Institute (Fiocruz-PE), Recife, Brazil, <sup>5</sup>Biomanguinhos (Fiocruz-RJ), Rio de Janeiro, Brazil

Chronic Chagas disease (CCD) diagnosis is based on serological methods employing crude, semipurified or recombinant antigens, which eventually may result in low sensitivity or cross-reactivity. An alternative method for solving this problem is the use of chimeric molecules composed by conserved and repetitive epitopes of distinct parasite structures. Our objective was to evaluate the use of chimeras in immunoassays for the diagnosis of CCD. The chimeras IBMP-8.1, IBMP-8.2, IBMP-8.3 and IBMP-8.4 were purified by chromatography and their purity assessed by SDS-PAGE. Circular dichroism (CD) and dynamic light scattering (DLS) were used to assess the hydrodynamic radius of the chimeras, to evaluate their stability and to select the buffering system that offers the lowest state of molecular aggregation. Serological tests for detection of anti-*Trypanosoma cruzi* were performed by ELISA and liquid bead microarray using a panel of 857 positive and 689 negative serum samples for CCD. Cross-reactivity was assessed by using 1079 serum samples from patients with unrelated diseases. The purification was efficient since SDS-PAGE indicated the absence of degradation of chimeric proteins. Analyses of CD and DLS showed that the four chimeras had low aggregation tendency in carbonate buffer, pH 9.6. Serological testing showed high values of sensitivity (Sen) and specificity (Spe) for IBMP-8.4 (Sen-99.3%; Spe-100%).

The performance of other molecules was satisfactory, being the Sen and Spe values above 94%. Cross-reaction was observed in 0.46%, 0.85%, 0.46% and 0.37% of the samples tested against IBMP-8.1, IBMP-8.2, IBMP-8.3 and IBMP-8.4, respectively. The results indicate that the chimeras can be safely used in diagnostic assays for CCD.

## 1224

**USE OF CHITOSAN MICROPARTICLES TO CAPTURE AND CONCENTRATE *TRYPANOSOMA CRUZI* DNA IN URINE OF EXPERIMENTALLY INFECTED GUINEA PIGS**

Martha Helena Jahuiria-Arias<sup>1</sup>, Alejandra Pando<sup>1</sup>, Janet Acosta<sup>1</sup>, Edith Arocutipá<sup>1</sup>, Ye Castro-Sesquen<sup>2</sup>, José Cconislla<sup>3</sup>, Ily Maza<sup>3</sup>, Christian Jacinto<sup>3</sup>, Ana Valderrama<sup>3</sup>, Holger Mayta<sup>4</sup>

<sup>1</sup>Infectious Diseases Research Laboratory, Department of Molecular and Cellular Sciences, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Department of International Health, Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Baltimore, MD, United States, <sup>3</sup>Universidad Nacional de Ingeniería, Lima, Peru, <sup>4</sup>Infectious Diseases Research Laboratory, Department of Molecular and Cellular Sciences, Universidad Peruana Cayetano Heredia, Department of International Health, Johns Hopkins University, Bloomberg School of Hygiene and Public Health, Lima, Peru

Chagas disease is a neglected tropical disease, caused by the protozoan *Trypanosoma cruzi*, which is a major public health problem in Latin America and a potentially serious emerging globally. Detection of *T. cruzi* DNA in urine has been demonstrated before but has low sensitivity due because of the dilution effect of molecules in urine, DNA degradation and presence of PCR inhibitors. In recent years, more practical and accurate diagnostic tools have been developed using non-invasive samples for rapid detection of cases using microparticle and nanoparticle platforms. The chitosan, a cationic biopolymer, obtained from the deacetylation of chitin can interact with anionic molecules included DNA. Here we synthesized microparticles of chitosan by cross-linking with 1% glutaraldehyde to concentrate small fragments of *T. cruzi* DNA in urine and detection of Transrenal DNA (Tr-DNA) of experimentally infected guinea pigs (*Cavia porcellus*). DNA detection was performed using real time PCR target in parasite satellite (166 bp) and kinetoplast DNA (118 bp) sequences. Our results showed that the detection limit of DNA in urine by qPCR was 0.1 parasites/ml for both target sequences. The specificity was 100 % and the sensitivity was 25 % using satellite DNA target and increase to 68 % using kinetoplast DNA target. In conclusion, chitosan microparticles could be used to capture and concentrate *T. cruzi* DNA in urine samples and can increase the sensitivity of qPCR. Detection of *T. cruzi* Tr-DNA could be used for diagnosis of Chagas disease and for the evaluation of treatment efficacy.

## 1225

**ANTI-LEISHMANIAL ACTIVITIES OF SYNTHETIC ENDOPEROXIDES, N-89 AND N-251**

Kofi D. Kwofie<sup>1</sup>, Sato Kai<sup>2</sup>, Akina Hino<sup>1</sup>, Sanjoba Chizu<sup>2</sup>, Shimogawara Rieko<sup>1</sup>, Irene Ayl<sup>3</sup>, Daniel Boakye<sup>3</sup>, Hye-Sook Kim<sup>4</sup>, Mitsuko Ohashi<sup>1</sup>, Yoshitsugu Matsumoto<sup>2</sup>, Nobuo Ohta<sup>1</sup>

<sup>1</sup>Tokyo Medical and Dental University, Tokyo, Japan, <sup>2</sup>The University of Tokyo, Tokyo, Japan, <sup>3</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>4</sup>Okayama University, Okayama, Japan

Leishmaniasis is a major problem worldwide which causes significant morbidity and mortality in cases of visceral leishmaniasis. New chemotherapeutics are urgently needed due to severe side effects and drug resistance plaguing current drugs. The new antimalarial synthetic organic compounds based on endoperoxide structure (N-89 and N-251) were found to possess strong antimalarial and antischistosomal properties, which suggested a broad spectrum of anti-parasitic activities. We therefore investigated the antileishmanial activities of both N-89 and N-251. N-89 exhibited inhibition activity against promastigote forms of 4 *Leishmania*

parasites *in vitro*; *L. major* (PM 2), *L. donovani* (Dd8 and BD38) *L. infantum* (EP173). N-251 also showed inhibition activity against all *Leishmania* spp promastigotes screened *in vitro* except *L. major* (Friedlin). In addition, N-251 induced parasite morphological change resulting in round-shaped *L. donovani* promastigotes mostly lacking nuclei and ability to divide. This was further confirmed when N-251 treatment resulted in parasites with fragmented DNA, a classical feature of apoptosis. Furthermore, 80/20 ratio combination of N-251/miltefosine enhanced activity with reduced toxicity resulting in improved selectivity against *L. donovani* promastigotes. Further *in vivo* studies showed N-251 to significantly reduce parasite burden in both pre-infection and post-infection orally treated BALB/c mice. Results therefore confirm the antileishmanial activities of N-89 and N-251 and also suggest the apoptotic effect of N-251. Further studies to investigate efficacy of N251/miltefosine combination therapy *in vivo* and elucidation of mechanisms of action of N-251 *in vitro* are ongoing.

## 1226

### CO-ENCAPSULATED HOST- AND PARASITE-DIRECTED THERAPIES TO TREAT VISCERAL LEISHMANIASIS

Erica N. Pino<sup>1</sup>, M. Shamim Hasan Zahid<sup>1</sup>, Sanjay Varikuti<sup>2</sup>, Abhay Satooskar<sup>2</sup>, Eric M. Bachelder<sup>1</sup>, Kristy M. Ainslie<sup>1</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,

<sup>2</sup>The Ohio State University, Columbus, OH, United States

Visceral leishmaniasis is the second deadliest parasitic disease worldwide, causing an estimated 200,000 to 400,000 new infections annually. Despite its far-reaching effects, there exist very few treatment options, all of which are associated with adverse side effects. Moreover, emerging resistant strains of *Leishmania donovani* limit options even further. It is estimated that nearly 60% of newly-diagnosed visceral leishmaniasis cases are caused by resistant strains of *L. donovani*. One strategy to circumvent resistance mechanisms is to deliver host-directed therapeutics in combination with parasite-directed therapeutics. Previous work in our lab has shown that resiquimod, an agonist for the intracellular toll-like receptor 7/8, can effectively clear *L. donovani* parasite loads, which reside within phagocytic cells. Furthermore, there is evidence for synergistic interactions between suboptimal doses of the parasite-directed amphotericin B and the host-directed resiquimod. Using an acid-sensitive biopolymer (Acetalated dextran (Ac-DEX)) microparticle (MP), we have co-encapsulated resiquimod and amphotericin B at a synergistic ratio capable of passively targeting macrophages and other phagocytic cells. The Ac-DEX MPs allows greater spatiotemporal control of therapeutic delivery, potentially requiring less drug and subsequently resulting in fewer off-target effects than traditional therapies. Furthermore, encapsulation in Ac-DEX MPs mitigates the need for cold-chain storage, rendering this treatment more accessible worldwide than current formulations, which often require administration at a healthcare facility. Ultimately, treatment with both host- and parasite-directed therapeutics could reduce the resistance of emergent strains while minimizing adverse side effects.

## 1227

### THE STRONG HEARTS PILOT: RESULTS OF A PRIMARY-CARE SCREENING PROGRAM FOR *TRYPANOSOMA CRUZI* IN EAST BOSTON, MASSACHUSETTS

Jen Manne-Goehler<sup>1</sup>, Juan Huanuco Perez<sup>2</sup>, Elizabeth Barnett<sup>3</sup>, Julia R. Köhler<sup>4</sup>

<sup>1</sup>Beth Israel Deaconess Medical Center, Boston, MA, United States, <sup>2</sup>East Boston Neighborhood Health Center, Boston, MA, United States, <sup>3</sup>Boston Medical Center, Boston, MA, United States, <sup>4</sup>Boston Children's Hospital, Boston, MA, United States

The United States is home to approximately 300,000 people who are infected with *Trypanosoma cruzi*, though less than 1% of those infected have been treated with benznidazole or nifurtimox. We designed and are implementing a screening program for Chagas disease in East Boston, Massachusetts. The aim of this study is to describe the results of a pilot to

integrate Chagas disease screening and referral for treatment into primary care for high-risk populations. This screening pilot is being implemented in the adult, pediatric and obstetrics departments of a large community health center. More than one third of people in this community are from a Chagas-endemic country. Prior to screening, at least one continuing education session about Chagas disease was offered to participating providers. The screening strategy recommends that all patients <50 years old who had lived in Mexico, Central or South America for at least 6 months be offered a one-time screening test. Country of origin was recorded in the electronic medical record with each test ordered. The health center laboratory stored a sample of serum for each patient screened to facilitate rapid confirmatory testing. The pilot established a referral process with a local infectious disease department to ensure close follow-up for infected patients. Community outreach to educate at-risk communities was simultaneously implemented. In the 3 months prior to the pilot, 7 screening tests were ordered across all departments. During the first 2 weeks of the pilot, providers from Adult Medicine ordered 60 screening tests and providers from other departments ordered an additional 2 screening tests. Of these 62 screening tests, only 10 were resulted to date (9 negatives and 1 positive) and 52 were still pending. The patients screened included 28 females (45%) and 34 males (55%). The leading countries of origin for these patients were El Salvador with 23 patients and Colombia with 14 patients. In conclusion, screening for Chagas disease is feasible and accepted by both providers and patients in primary care settings that serve large communities of high-risk patients.

## 1228

### HIGH RESOLUTION MELTING ANALYSIS TARGETING HSP70 AS A FAST AND EFFICIENT METHOD FOR THE DISCRIMINATION OF *LEISHMANIA* SPECIES

Ricardo R. Zampieri<sup>1</sup>, Maria F. Laranjeira-Silva<sup>2</sup>, Sandra M. Muxel<sup>1</sup>, Ana C. Stocco de Lima<sup>1</sup>, Jeffrey J. Shaw<sup>1</sup>, Lucile M. Floeter-Winter<sup>1</sup>

<sup>1</sup>São Paulo University, Sao Paulo, Brazil, <sup>2</sup>University of Maryland, College Park, MD, United States

Protozoan parasites of the genus *Leishmania* cause a large spectrum of clinical manifestations known as Leishmaniasis. These diseases are increasingly important public health problems in many countries both within and outside endemic regions. Thus, an accurate differential diagnosis is extremely relevant for understanding epidemiological profiles and for the administration of the best therapeutic protocol. Exploring the High Resolution Melting (HRM) dissociation profiles of two amplicons using real time polymerase chain reaction (real-time PCR) targeting heat-shock protein 70 coding gene (*hsp70*) revealed differences that allowed the discrimination of genomic DNA samples of eight *Leishmania* species found in the Americas, including *Leishmania (Leishmania) infantum chagasi*, *L. (L.) amazonensis*, *L. (L.) mexicana*, *L. (Viannia) lainsoni*, *L. (V.) braziliensis*, *L. (V.) guyanensis*, *L. (V.) naiffi* and *L. (V.) shawi*, and three species found in Eurasia and Africa, including *L. (L.) tropica*, *L. (L.) donovani* and *L. (L.) major*. In addition, we tested DNA samples obtained from standard promastigote culture, naturally infected phlebotomines, experimentally infected mice and clinical human samples to validate the proposed protocol. In conclusion, HRM analysis of *hsp70* amplicons is a fast and robust strategy that allowed for the detection and discrimination of all *Leishmania* species responsible for the Leishmaniasis in Brazil and Eurasia/Africa with high sensitivity and accuracy. This method could detect less than one parasite per reaction, even in the presence of host DNA.

## 1229

### TISSUE IMPRESSION SMEAR AS A SUPPLEMENTARY DIAGNOSTIC TEST FOR HISTOPATHOLOGY IN CUTANEOUS LEISHMANIASIS

Nuwani H. Manamperi<sup>1</sup>, Vipula C. de Silva<sup>2</sup>, Nishantha Pathirana<sup>3</sup>, Wimaladharm Abeyewickreme<sup>1</sup>, Nadira D. Karunaweera<sup>2</sup>

<sup>1</sup>University of Kelaniya, Ragama, Sri Lanka, <sup>2</sup>University of Colombo, Colombo, Sri Lanka, <sup>3</sup>Department of Dermatology, Army Hospital, Colombo, Sri Lanka

Diagnosis of cutaneous leishmaniasis is a new challenge faced by the dermatologists in Sri Lanka. Majority of patients are diagnosed clinically, due to lack of facilities in areas where the disease is highly endemic, and light microscopy of slit skin smears (SSS) is used to supplement the clinical diagnosis whenever possible. Histopathology of skin biopsy is used as a second line investigation if the SSS is negative or when the lesion is atypical. This study compares the tissue impression smears (TIS) with histopathology for diagnosis of CL in Sri Lanka. A total of 111 patients with clinically suspected CL were included and a single skin punch biopsy specimen was obtained from the active border under local anaesthesia. A TIS was prepared by gently rolling the biopsy on a glass slide. The biopsy specimen was then fixed in 10% neutral buffered formalin, processed routinely for histopathology and examined under a conference microscope for Leishman-Donovan bodies. Tissue impression smears were air dried, fixed in methanol, stained with Giemsa and examined under a light microscope for amastigotes. These two methods were compared by applying the z-test for difference between two proportions to discordant pairs. The study group consisted of 87 (78.4%) males and 24 (21.6%) females with a mean lesion duration of 6.2 months (SD=7.2, range: 1-48). Majority of lesions were either papules or nodules (66, 59.5%), and 32 (28.8%) presented as ulcerated lesions. Lesions were mainly found on the upper limb (63, 56.8%), followed by lower leg (22, 19.8%). Tissue impression smear was positive in 78 (70.3%) patients and histopathology was positive in 63 (56.8%) patients. Both TIS and histopathology were positive in 58 (52.2%) patients. In 20 (18%) patients amastigotes were seen only by TIS and in 5 (4.5%) patients amastigotes were seen only by histopathology. Amastigotes were more likely to be detected in TIS than histopathology ( $p = 0.001$ ). Considering the high positivity and ease of performance of TIS we recommend it as a supplementary diagnostic test in instances where a skin biopsy is performed on skin lesions suggestive of leishmaniasis.

## 1230

### IDENTIFICATION OF ANTI-*TRYPANOSOMA CRUZI* LEAD COMPOUNDS WITH PUTATIVE IMMUNOMODULATORY ACTIVITY

Isabela Natália P. do Vale<sup>1</sup>, Dayane A. Ottaa<sup>1</sup>, Fernanda F. Araújo<sup>1</sup>, Elaine M. Fagundes<sup>2</sup>, Vítor B. Rezende<sup>1</sup>, Matheus F. Silva<sup>1</sup>, Raiany A. Santos<sup>1</sup>, Heloísa A. Costa<sup>1</sup>, Silvana M. Elói-Santos<sup>3</sup>, James McKerrow<sup>4</sup>, Jair S. Neto<sup>4</sup>, Olindo A. Martins-Filho<sup>1</sup>, Andréa T. Carvalho<sup>1</sup>

<sup>1</sup>Grupo Integrado de Pesquisas em Biomarcadores, Centro de Pesquisas René Rachou, Fundação Oswaldo Cruz, Belo Horizonte, Minas Gerais, Brazil, Belo Horizonte, Brazil, <sup>2</sup>Departamento de Fisiologia e Biofísica, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, Belo Horizonte, Brazil, <sup>3</sup>Grupo Integrado de Pesquisas em Biomarcadores, Centro de Pesquisas René Rachou, Fundação Oswaldo Cruz, Belo Horizonte, Minas Gerais, Brazil e Departamento de Propeidética Complementar, Faculdade de Medicina, Universidade Federal de Minas Gerais, Belo Hori, Belo Horizonte, Brazil, <sup>4</sup>Skaggs School of Pharmacy and

Pharmaceutical Sciences, University of California, San Diego, USA, Belo Horizonte, Brazil

Chagas disease (CD) is an important public health problem not only in Latin America where it is endemic but it is increasingly spreading in other areas such as Europe, North America, Japan and Australia. Around 7 million people are affected worldwide and approximately 7,000 deaths occur annually. The current drugs used for the treatment of Chagas disease are not effective during the chronic phase and cause numerous toxic side effects. In this context, the balance of the host immune response seems to be a key element for therapeutic success, where a pro-inflammatory microenvironment modulated by IL-10 has shown to be relevant to potentiate anti-*Trypanosoma cruzi* drug activity. The present work aimed to identify the potential immunomodulatory activity of the new therapeutic candidates anti-*T. cruzi*, K777, Pyronaridine (PYR) and Furazolidone (FUR) in peripheral blood mononuclear cells (PBMC) from noninfected subjects (NI) and patients with chronic CD. Our results showed low toxicity of the compounds with IC<sub>50</sub>= 13.1 μM (K777); 5.9 μM (PYR) and greater than 20 μM (FUR) for PBMC. In addition, K777 showed no impact on the exposure index (EI=culture in the presence of the drug/culture with medium only) of phytohemagglutinin-stimulated PBMC, while PYR and FUR induced increased EI of monocytes and T lymphocytes at late stages of apoptosis in NI subjects. The analysis of the cytokine signatures in culture supernatants demonstrated a mixed pro-inflammatory profile, with expressive elevation of IL17, in all treatments employed from CD patients. Moreover, K777 induced a pro-inflammatory response (TNF-α+CD14+/IFN-γ+CD4+) modulated by IL-10 (+IL-10+CD4+/IL-10+CD8+), while PYR and FUR triggered a more inflammatory response by increasing TNF-α+CD14+ and reducing IL-10+ from CD4+/CD8+ T cells. Signature analysis of intracytoplasmic cytokines corroborated with the proinflammatory/modulated (K777) and pro-inflammatory (PYR/FUR) profiles found for these compounds. In conclusion, K777 lead compound may induce beneficial changes in the immunological profile of patients with chronic CD and may contribute to a more effective therapy against the disease.

## 1231

### CHAGAS DISEASE IN THE GRAN CHACO ECOREGION: FROM SURVEILLANCE AND CONTROL TO DIAGNOSIS AND TREATMENT

Diego Weinberg, Rosa G. Cejas, Favio G. Crudo, Marcelo C. Abril

Fundación Mundo Sano, Ciudad de Buenos Aires, Argentina

Approximately 1.6 million people in Argentina are infected with *Trypanosoma cruzi* (4% of the population) and 7.3 million are exposed to Chagas disease (CD). Less than 1% of them have access to diagnosis and etiological treatment and an estimated 1,300 children are infected annually due to congenital transmission. Mundo Sano (MS) develops surveillance and control (S&C) actions in Santiago del Estero (Gran Chaco Ecoregion) since 2002 as well as operational research on *Triatoma infestans*, main vector of CD in the region. In 2005, MS incorporated the component of Sanitary Improvement of Rural Housing to its S&C program as an innovative strategy to reduce vector transmission of CD. This program has currently covered 11 rural communities, covering 1587 inhabitants from 384 households. Moreover, since 2015, MS has also included the diagnosis and treatment of CD in rural areas in order to improve the situation of underdiagnosis and to aid in the access to etiological treatment. In this study, the data from one of these rural communities is presented. Pozo Herrera (General Taboada Department, Santiago del Estero - Argentina), a settlement of the southeast of the Gran Chaco Ecoregion, is inhabited by 120 people that are distributed in 39 households. This settlement was added to the program of vector S&C in 2010. S&C consists of intra and peridomestic inspection (animal pens, deposits, chicken coops) and its subsequent chemical control with 5% beta-cypermethrin at least once a year, as well as the improvement of housing. This improvement includes the waterproofing of roofs, whitening of walls, ceiling improvement, paint, animal pens and the construction

of water wells and latrines. After six years of implementation, there was a marked reduction in the household infestation rate of *T. infestans* from 31% to 2.7%. In this manner, what started as a purely S&C project has evolved into an integral project that has enabled Pozo Herrera to enter into the diagnosis and treatment phase of the program, allowing for the etiological treatment of CD with Benznidazol (ABARAX® - Elea) following national guidelines.

### CIRCULATING MIRNAS PROFILE AS POTENTIAL SIGNATURE OF BENZNIDAZOLE TREATMENT TOXICITY IN CHAGAS PATIENTS

Darlan da Silva Cândido<sup>1</sup>, Edecio Cunha-Neto<sup>1</sup>, Vagner O. Rigaud<sup>2</sup>, Lea C. de Oliveira<sup>3</sup>, Carlos Henrique V. Moreira<sup>3</sup>, Nelson G. Júnior<sup>3</sup>, Marcela de Souza<sup>3</sup>, Ester C. Sabino<sup>3</sup>, **Ludmila R. Ferreira<sup>2</sup>**

<sup>1</sup>Heart Institute of São Paulo (InCor) - Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, <sup>2</sup>Heart Institute of São Paulo (InCor) - Instituto de Medicina Tropical - Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil, <sup>3</sup>Instituto de Medicina Tropical - Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil

Chagas disease is an infectious disease caused by the protozoan parasite *Trypanosoma cruzi* (*T. cruzi*). It is endemic in Latin America where it currently affects around seven million people. Even after 100 years of its discovery by Carlos Chagas, there is still a lack of effective treatment for the chronic phase. In addition, the only two drugs available for its treatment, Benznidazole and Nifurtimox, are associated to a great amount of toxicity and no gold-standard biomarkers to assess treatment effectiveness have been described. Therefore, in light of the latest advances showing microRNAs (miRNAs), post-transcriptional regulators of gene expression, as potential biomarkers for drug treatment, we evaluated the effect of benznidazole treatment in Chagas' patients plasma microRNA expression. A group of 41 Chagas patients were enrolled in this study. Blood samples for *T. cruzi* qPCR were collected before, at 60, 180, and 360 days after Benznidazole treatment. Treatment was considered successful when no qPCR positive results were obtained after treatment. A MicroRNA profiling (754 miRNAs) was performed comparing before and 1 year after treatment samples. The comparison between post and pre-treatment samples resulted in 11 differentially expressed miRNAs: 9 upregulated (hsa-miR-181a, hsa-miR-130b, hsa-miR-660, hsa-miR-320, hsa-miR-29a, hsa-miR-29c, hsa-miR-93, hsa-miR-142-3p, hsa-miR-886-3p) and 3 downregulated (hsa-miR-340, hsa-miR-335, hsa-miR-197). Pathway analysis resulted in "Hepatic Fibrosis/ Hepatic stellate cell activation" as one of the most enriched pathways indicating that these benznidazole-induced miRNAs could be regulating targets related to liver damage.

## 1233

### THE POTENTIAL IMPACT OF VISCERAL LEISHMANIASIS VACCINES: EXPLORATIONS WITH DIFFERENT DETERMINISTIC AGE-STRUCTURED TRANSMISSION MODELS

**Epke A. Le Rutte**, Luc E. Coffeng, Sake J. de Vlas

Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

Current interventions to control visceral leishmaniasis (VL) focus on diagnosis and treatment of cases and on vector control. At this point there is no human vaccine available. However, vaccine development has been ongoing for decades and the results of various studies strongly support the possibility for immunoprophylaxis of VL in the future, suggesting vaccines to be of great additional benefit for individuals at risk. This study explores the potential health impact of different hypothetical vaccines at population level using two age-structured mathematical models that capture the VL transmission dynamics between humans and sandflies. The models differ regarding the main reservoir of infection; in symptomatic and asymptomatic individuals. We incorporate different types of vaccines that

1) lower the risk of infection, 2) lower the risk of developing clinical VL, 3) lower the risk of developing PKDL and 4) a vaccine after which susceptible individuals become immune. Other assumptions take into account different durations of the vaccines' effect and various population coverage levels. The vaccine protecting individuals from developing infection reaches the largest decrease in VL incidence, with the model with the main reservoir of infection in asymptomatic individuals. The vaccine that decreases the development of PKDL has the least impact, only causing a minor decrease in incidence after at least 10 years of an active vaccination programme. The same is true for the model with the main reservoir of infection in symptomatic individuals, however showing a slower decline in VL incidence. The vaccine target product profiles (TPP) are also identified for specific VL targets including the minimum required vaccine efficacy, duration of effect, coverage levels and which age groups best to include in a vaccine program would one become available. In conclusion, these new insights aid in guiding vaccine development and support policy makers with the development of potential future vaccination strategies for the elimination and control of VL.

### POTENTIATION OF BENZNIDAZOLE EFFECT BY COADMINISTRATION OF REPURPOSED DRUGS ACTING IN THE INVASION OF HOST CELLS BY *TRYPANOSOMA CRUZI*

Ramendra P. Pandey<sup>1</sup>, Marilda Savoia<sup>1</sup>, Ester Sabino<sup>1</sup>, Jorge Kalil<sup>1</sup>, **Edecio Cunha-Neto<sup>2</sup>**

<sup>1</sup>Universidade De São Paulo, São Paulo, Brazil, <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil

Benznidazole (BZN) treatment of chronically infected Chagas disease patients shows limited or no effectiveness, and the development of more effective drug regimens is one of the major challenges in the field. Host mechanisms involved in *Trypanosoma cruzi* cell invasion and replication offer novel therapeutic targets that have been little explored. We identified two drugs, used for other diseases, that inhibit host cell functions crucial for *T. cruzi* invasion. We hypothesized that treatment with these two drugs could synergize with BZN against *T. cruzi* infection of host cells *in vitro*. Different concentrations of BZN alone, each of the two drugs alone, or their combination were tested against the BZN-resistant Colombian strain of *T. cruzi*. We measured parasite release in the supernatant of cultures of human non-phagocytic HEK293T and phagocytic THP1 cell lines. The concentrations for half-maximal anti-*T. cruzi* activity (IC50) for BZN alone on HEK293T cells and THP-1 cells were 31 µM and 29 µM respectively. Combination of the two identified drugs with BZN reduced the BZN IC50 by 4 to 8-fold as compared to BZN alone. In addition, we analyzed the effect of treatment on the number of intracellular amastigotes after 48h and observed that the combination of the two drugs with a suboptimal concentration of BZN (25 µM) reduced intracellular parasites in THP1 cells by 4 to 10-fold as compared with BZN (25 µM) alone. The drugs had no direct effect on the viability of axenic epimastigotes and trypomastigotes. Results indicate that the combination of repurposed drugs that inhibit host cell functions crucial for *T. cruzi* invasion strongly synergized with BZN in the control of *in vitro* infection by the BZN-resistant Colombian strain of *T. cruzi*. The use of repurposed drugs acting on the host, to synergize with and increase the effect of Benznidazole even at lower - and probably less toxic - doses may have important implications for the treatment of benznidazole-resistant Chagas disease and chronic phase of infection, and animal experiments are under way.

## 1235

### BLOOD CLOT BASED QPCR FOR THE DIAGNOSIS OF CHAGAS DISEASE

**Holger Mayta<sup>1</sup>**, Yomara K. Romero<sup>1</sup>, Robert H. Gilman<sup>2</sup>, Lidabel M. Rios<sup>1</sup>, Caryn Bern<sup>3</sup>

<sup>1</sup>Infectious Diseases Research Laboratory, Department of Cellular and Molecular Sciences, Universidad Peruana Cayetano Heredia, San Martin de

Porres, Peru, <sup>2</sup>Department of International Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States

Chagas disease remains an important public health problem especially in endemic countries. The qPCR has become the most important tool for the diagnosis and monitor *Trypanosoma cruzi* load in peripheral blood samples. We have shown previously for qPCR that DNA extracted from clot yields greater sensitivity than DNA extracted from either buffy coat or whole blood samples. However, phenol-chloroform DNA extraction from clot samples is troublesome and toxic, DNA yield is highly variable and DNA stability is poor. The objective of the present study was to develop a better and more reliable DNA extraction method for clot samples. Whole blood – guanidine-EDTA (GEB) and clot samples were obtained from mothers in a previous study of congenital transmission of Chagas disease. We analyzed 100 match GEB and clot samples; 58 were from subjects positive to Chagas disease by serology. A new methodology was developed for blood clot samples based on a combination of the fast-prep technique and the standard method for GEB extraction. Detection of *T. cruzi* was performed by qPCR targeting the nuclear satellite sequences. Out of the 58 samples from Chagas positive individuals by serology, sixteen were positive by qPCR, when either DNA from GEB or clot was used while four samples were positive only in the clot samples. None of the 43 GEB or clot samples from serology negative subjects were positive by qPCR. The new methodology for DNA extraction from blood clot samples increases DNA yield and stability, thus largely improving the molecular diagnosis of Chagas disease.

## 1236

### DIAGNOSIS OF CHAGAS DISEASE BY QPCR IN DIFFERENT SAMPLES FROM NEWBORNS

Yomara K. Romero<sup>1</sup>, Alejandra Pando<sup>1</sup>, Holger Mayta<sup>1</sup>, Robert H. Gilman<sup>2</sup>, Caryn Bern<sup>3</sup>

<sup>1</sup>Infectious Diseases Research Laboratory, Department of Cellular and Molecular Sciences, Universidad Peruana Cayetano Heredia, San Martin de Porres, Peru, <sup>2</sup>Department of International Health, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, United States

Chagas disease, caused by *Trypanosoma cruzi*, affects 8 million people around the world. Congenital transmission has become an important public health concern. Early diagnosis in new born babies is important to implement an effective treatment, since treatment is best tolerated in young babies. The qPCR is an important diagnostic tool specially in new born babies, but sensitivity on the target sequence and on the sample used as source of DNA. In the present study, we compare the use of three different samples as source of DNA: clot, guanidine-EDTA whole blood (GEB) and tissue obtained from the umbilical cord. Archived matched samples (n=100) obtained in a previous study of congenital Chagas transmission were analyzed by qPCR targeting satellite sequences of the *T. cruzi* genome. GEB samples were DNA extracted using previously standardized methodology. DNA from blood clot and cord tissue were extracted using a new developed methodology based on a combination of the fast-prep technique and the standard method for GEB extraction. Three samples were positive when DNA extracted from either of the three sources was tested by qPCR. Two were positive only when DNA from GEB and cord tissue were employed and one sample was positive only when DNA from cord tissue was used, thus sensitivity for GEB, clot and cord tissue was 3; 6 and 7% respectively. We have developed a new DNA extraction technique for DNA extraction from umbilical cord tissue in addition we have shown that tissue from umbilical cord is an important DNA source for the diagnosis of Chagas disease.

## 1237

### DIAGNOSING LEISHMANIASIS BY TARGETING THE ARGININE PERMEASE (AAP3) CODING SEQUENCE

Karl E. Müller<sup>1</sup>, Ricardo A. Zampieri<sup>2</sup>, Juliana I. Aoki<sup>2</sup>, Sandra M. Muxel<sup>2</sup>, Audun H. Nerland<sup>1</sup>, Lucile M. Floeter Winter<sup>2</sup>

<sup>1</sup>University of Bergen, Bergen, Norway, <sup>2</sup>University of São Paulo, São Paulo, Brazil

The leishmaniasis are caused by around 20 different species of the protozoan parasite *Leishmania*. The clinical outcome of the disease and the effectiveness of the treatment protocols is partly dependent on the species, therefore species identification is paramount. Correct identification of *Leishmania* species generate important data for epidemiological and ecological studies. This study was undertaken to develop a rapid, specific and sensitive diagnostic assay for differentiation of *Leishmania* species targeting the *aap3* coding sequence. We designed four pairs of primers flanking polymorphic sites on the *aap3* coding sequence for amplification in real-time PCR and subsequent HRM analysis. Amplicon 1 was used to group the parasites into three main groups: (I) *L. (L.) donovani*, *L. (L.) infantum*, *L. (L.) tropica*, *L. (L.) major*; and (II) *L. (L.) mexicana*, *L. (L.) amazonensis*; and (III) *L. (V.) braziliensis*, *L. (V.) guyanensis*, *L. (V.) lainsoni*, *L. (V.) naiffi*, *L. (V.) shawi*, *L. (V.) panamensis*. For further distinction, three amplicons were designed to differentiate the species within the groups. The assay was able to distinguish all the species tested. Specificity was further investigated comparing the dissociation profiles of different strains of the same species. Further, the amplification profile for other trypanosomatids was distinct from the ones observed for *Leishmania* species. No amplification was detected for mouse, rat or human DNA. In conclusion, *aap3*-HRM analysis is a fast strategy for detection and discrimination of *Leishmania* species. Distinct profiles were found for phylogenetically close organisms and host DNA was negative. The limit of detection was about 0.5 parasites per reaction after a pre-amplification step. Our results indicate that the AAP3 coding sequence could also be a good target for species differentiation by sequencing.

## 1238

### SURROGATE MARKERS OF CURE FOR CHAGAS DISEASE IN CHILDREN TREATED WITH BENZNIDAZOLE DISEASE IN CHILDREN TREATED WITH BENZNIDAZOLE

Elizabeth Ruiz-Lancheros<sup>1</sup>, Eric Chatelain<sup>2</sup>, Facundo Bournissen<sup>3</sup>, Samanta Moroni<sup>3</sup>, Guillermo Moscatelli<sup>3</sup>, Jaime Altcheh<sup>3</sup>, Momar Ndao<sup>1</sup>

<sup>1</sup>McGill University, Montreal, QC, Canada, <sup>2</sup>Drugs for Neglected Diseases initiative, Geneva, Switzerland, <sup>3</sup>Parasitology Service, Hospital de Niños Ricardo Gutierrez, Buenos Aires, Argentina

Chagas disease (CD), caused by *Trypanosoma cruzi* is the most neglected tropical disease in Latin America. There are no reliable tests or validated biomarker(s) to ensure parasitological cure in chronically infected patients. In adults, seronegative conversion can take decades. However, seronegative conversion in children occurs in few months to a few years, which made children serum samples ideal for CD biomarkers validation. Thirty CD children mainly infected by vertical transmission and diagnosed *T. cruzi* positive by microscopy and PCR (time point S0) were treated with Benznidazole (BZ) 5-8 mg/kg/day for 60 days (time point S1). Treatment efficacy was assessed by serological tests at the end of BZ treatment and follow up until seronegative conversion with at least two serological tests (time point S2). Twenty children from the same range of age were used as healthy controls (HC). Immunoblot and a proteomic-based-assay were used to assess cure in these children using fragments of Apolipoprotein A-1 (ApoA1) and Fibronectin (FBN), biomarkers identified previously in our laboratory. Immunoblot evaluation of ApoA1 and FBN fragments shown gradual reduction or absent of fragments at S1, compared to fragments at diagnosis (S0), and their clearance at seroconversion (S2). Similar results were observed using mass spectrometry. In addition, using intact proteins analysis, a 28109 Da protein was detected in HC serum samples but not

in CD. MS/MS analysis confirmed the protein corresponds to ApoA1 full length. These new data suggest fragments of ApoA1 and FBN are valid biomarkers and demonstrate their better predictive capacity than serology. These biomarkers might be useful to predict cure in clinical settings as well as treatment efficacy in clinical trials of new drugs and drug regimen.

## 1239

### REGIONAL DIFFERENCES OF INFLUENZA LIKE-ILLNESS SYNDROME IN CHILDREN UNDER 5 YEARS, DEMOGRAPHIC AND HEALTH SURVEY (DHS) PERU 2010 - 2014

Jorge L. Maguiña<sup>1</sup>, Yeny Tinoco<sup>2</sup>, Cesar Munayco<sup>1</sup>, Andres G. Lescano<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>U.S. Naval Medical Research Unit-6, Callao, Peru

Acute respiratory diseases commonly present a seasonal pattern. However, due to its geographic diversity, it is thought that in Peru there may be seasonal differences at the regional level. We analyzed data from 2010 to 2014 of the Demographic and Health Survey (DHS) Peru. Our outcome variable was the variation of the average prevalence of influenza-like illness (ILI) in children under five years between March-December in the five years, defined by the report of the mother over the presence of cough and fever in the last two weeks. Following WHO guidelines, we defined an epidemic peak as 2 DS above the median. The co-variable of interest was the geographic region categorized in coast, highlands and amazon. We report complete data of 45,445 children. The average prevalence of ILI in the five years differed between the coast, highlands, and amazon (15.5%, 16.2% and 20.1% respectively,  $p < 0.001$ ). In March, the average prevalence of ILI was: coast (11.8%), highlands (12.2%) and amazon (16.1%). The median of the frequency of ILI in coast was 15.6%, highlands 16.4% and amazon 19.7%. Epidemic peaks for coast and highlands were presented between April-June (18.1%) and May-September (18.5%) and for amazon two peaks between May-July (26.1%) and October-November (20.1%). The prevalence in the coast decreased in July (13.4%) and had a slight increase in September (16.3%), while in the sierra and amazon decreased in November (15.9%) and December (16.1%). We observed regional differences in the seasonality of the influenza like-illness syndrome, with an earlier onset in the coast compared with the other regions, which could be due to the beginning of classes and greater population of children in schools. On the other hand, the high frequency of ILI in our amazon may be due to a high circulation of other respiratory viruses and bacteria, which have been reported for tropical areas. These findings will serve to design specific preventive actions by region.

## 1240

### IMMUNODETECTION OF PYRAZINE-2-CARBOXYLIC ACID

Edgar A. Florentini, Noelia Angulo, Roberto H. Alcantara, Elisa Roncal, Ricardo Antiparra, Emily Toscano, Katherine Vallejos, Mirko Zimic, Patricia Sheen

UPCH, Lima, Peru

Mycobacterium tuberculosis (Mtb) is globally associated to high morbimortality. Drug resistance is threatening the efforts to control this disease. Pyrazinamide (PZA) is a pro-drug integrated in both first and second line treatment schemes due to its unique ability to kill Mtb in its latent stage. Resistance to pyrazinamide is a predictor of poor prognosis, and a cause of treatment abandon and lengthening. Despite genetic polymorphisms in the *pncA* gene, explaining and predicting to a great extent PZA resistance, molecular analysis of clinical isolates is not feasible at great scale since its high costs and complexity, plus not every mutation causes enzyme malfunctioning and PZA resistance. Phenotypic analyses attempt to quantify the metabolite of PZA: pyrazinoic acid (POA). A resistant strain would not convert PZA in to POA at a critical required rate, whereas a susceptible strain will do, and would expel POA in the extracellular environment at a certain rate, allowing its quantification. The

Wayne Test, serves as a simple but not highly sensitive colorimetric test for PZA resistance. We have developed an indirect competitive ELISA test using rabbit serum against POA. POA was covalently linked to Keyhole Limpet Hemocyanine, and inoculated in rabbits. In this test, Bovine Serum Albumin linked to POA is fixed in a Maxisorp Microplate at 40 ng/well and incubated with rabbit antiserum diluted to 1:50000 and a solution of POA. POA positive samples (typical of the supernatant of a MODS liquid culture of a sputum sample of a PZA susceptible TB patient), will block the polyclonal antibodies from binding the BSA linked to POA, causing a decreased colorimetric signal in contrast to negative controls (supernatant of sputum culture of negative controls). The optical density ratios are proportional to the POA concentration in a negative sigmoidal curve fashion. We standardized this assay with serially diluted POA concentrations and found the limit of detection (LOD) at 80ug/mL, which is more sensitive than the Wayne test (500ug/mL). We expect to improve LOD by further diluting competitor agents and using chemiluminescence, which is usually 10x more sensitive.

## 1241

### EFFECT OF CARBOXY TERMINAL MUTATIONS OF RIBOSOMAL PROTEIN S1 OF MYCOBACTERIUM TUBERCULOSIS ON INTERACTION WITH PYRAZINOIC ACID

Katherine J. Vallejos

Universidad Peruana Cayetano Heredia, Lima, Peru

Pyrazinamide (PZA) is a first-line drug used in the treatment of tuberculosis. The importance of the study of this drug lies in that it acts mainly on microorganisms in a state of dormancy and yet its mechanism of action is little known. The ribosomal protein S1 (*rpsA*) has been reported as the target of pyrazinoic acid (POA), the active form of pyrazinamide. Thus, in this study we evaluate how a mutation recorded at the terminal carboxyl terminus of *rpsA* can confer resistance to the pyrazinamide strain despite not being at the site of interaction between the *rpsA* and the POA, but rather in a Highly flexible and distant region. Our first hypothesis proposes a loss of affinity of the *rpsA* for the POA due to steric hindrance since the mutation would generate that this highly flexible end more frequently visit the site of interaction and avoid the interaction between both. To evaluate our hypothesis we performed an in silico study, where it was evaluated by docking peptides generated from the carboxyl terminal end and its interaction with the binding site between *rpsA*-POA. Three recombinant proteins with truncated carboxyl terminal end were produced at sites proposed by the in silico study and also contained the mutation conferring resistance of the strain to the drug. The affinity for isothermal titration microcalorimetry was evaluated and our results show that the mechanism by which the mutation recorded at the carboxy terminal end of *rpsA*, which in turn changes the affinity of the *rpsA*-POA, is not generated by a steric hindrance, And that this mutation would be generating other interactions that would change their affinity. To assess what could be the interactions of the carboxy-terminal end and the *rpsA*-POA interaction site, site-directed mutagenesis was generated by *rpsA* recombinant proteins and affinity was determined. To assess what could be the interactions of the carboxyl-terminal end and the site of interaction *rpsA*-POA will be generated by site-directed mutagenesis directed recombinant proteins of *rpsA* with which it is intended to raise the explanation of how a mutation generates the change of affinity between *rpsA* and POA.

## 1242

**HIGH TUBERCULOSIS AND MULTIDRUG RESISTANT TUBERCULOSIS RATES IN A PERUVIAN COHORT**

**Rosio Isabel Guerra Gronerth**<sup>1</sup>, Claudio Rocha<sup>2</sup>, Giselle Soto<sup>2</sup>, Miguel Gonzales Aste<sup>3</sup>, Yenni Alberca<sup>3</sup>, Laner Ramirez<sup>2</sup>, Juan Cotera<sup>3</sup>, Miguel Gonzales Roca<sup>3</sup>

<sup>1</sup>Peruvian Navy Health Directorate, Callao, Peru, <sup>2</sup>Naval Medical Research Unit-6, Callao, Peru, <sup>3</sup>Peruvian Naval Medical Center, Callao, Peru

Tuberculosis and multidrug resistant *Mycobacterium tuberculosis* (TB & MDRTB) remain significant public health threats worldwide. Peru ranks the second highest in estimated number of new TB cases per year and first in MDR and extremely drug resistant (XDR) TB cases in the Americas; however TB rates in Peruvian military populations are unknown. Here we report results from a cohort under the Peruvian National TB Program (PNTBP) at the Peruvian Naval Medical Center serving active duty military, family members and Peruvian Navy civilians. All symptomatic patients at the military health units in Lima, Peru, received medical exams, smear microscopy and X-rays in accordance with PNTBP guidelines. TB positive patients were registered into the program (serving 16,490 active duty military), a first-line TB drug was started, and culture and sensitivity tests were performed according to PNTBP. Centralized Peruvian microbiology laboratories performed Ogawa and proportion tests to detect TB and MDR/XDRTB. In 2014, primary TB cases were detected in 79 patients; of these 55 (incidence: 33.4/10,000 persons/year) were active duty military, 5% were MDRTB, 78% were male, 85% were pulmonary TB, and 1 was HIV positive. All of these patients completed treatment and were cured. Conversely, in 2015, 93 primary TB cases were detected; 63 (incidence: 38.2/10,000 persons/year) were active duty military, 8% were MDRTB, 83% were male, 80% were pulmonary TB, 4 (4%) were HIV positive, and 4 (n=4) succumbed to the infection. However, no statistically significant differences between 2014 and 2015 were observed for these parameters. Of interest, a teenager in the study presented with XDRTB. High prevalence of TB and MDR/XDRTB has been found in active duty military personnel in this Peruvian Navy cohort; further analysis is required to elucidate risk factors. Control and preventive measures should be implemented to mitigate TB and MDR/XDRTB in military settings.

## 1243

**METHODS OF A STUDY EVALUATING THE IMPACT OF LUNG ULTRASOUND (LUS) ON MANAGEMENT OF PNEUMONIA IN LOW-RESOURCE SETTINGS**

**Jennifer L. Lenahan**<sup>1</sup>, Fyezah Jehan<sup>2</sup>, Quique Bassat<sup>3</sup>, Rasa Izadnegahdar<sup>4</sup>, Amy S. Ginsburg<sup>1</sup>

<sup>1</sup>Save the Children, Seattle, WA, United States, <sup>2</sup>Aga Khan University, Karachi, Pakistan, <sup>3</sup>Barcelona Institute for Global Health, Barcelona, Spain, <sup>4</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States

Pneumonia is the leading infectious cause of death in children worldwide. To address this mortality, it is critical to explore modalities to improve outcomes, such as improved diagnostics. In low-resource settings (LRS), pneumonia is diagnosed using World Health Organization (WHO) Integrated Management of Childhood Illness (IMCI) guidelines that rely on assessing variable and subjective clinical signs like respiratory rate and chest indrawing. Lung ultrasound (LUS) is a promising pneumonia diagnostic technology. There is evidence that indicates that LUS may be as sensitive and specific as chest radiography (CXR). Additional advantages of LUS include its portability, ease of use, lower cost, and absence of ionizing radiation. We will conduct a pilot study among 240 children aged 2 through 23 months presenting to sub-district hospitals in Mozambique and Pakistan (200 cases and 40 controls). Eligible cases will present with cough <14 days and/or difficult breathing and chest indrawing. Eligible controls will present with cough <14 days and/or difficult breathing with no chest indrawing, fast breathing or fever. Children will receive local standard of care including WHO IMCI assessment as well as CXR and LUS performed at enrollment. Physician panels will interpret the CXR and

LUS to ensure consistency and accuracy of interpretation. Respiratory specimens for viral and bacterial testing will be collected from children at enrollment, along with blood for disease screening. Enrolled children will be followed for 30 days post-enrollment; LUS will be performed on enrollment, and on days 2, 6, and 14. The primary outcome will be LUS findings at enrollment with secondary outcomes including patient outcomes, repeat LUS findings, viral and bacterial test results, and patient status after 14 and 30 days of follow-up. Qualitative data will also be collected to assess feasibility, usability and acceptability among healthcare providers and caregivers. By generating this evidence to accelerate LUS as a point-of-care device, a paradigm shift and advance over present-day approaches to the detection and diagnosis of pneumonia can be achieved in LRS.

## 1244

**MATERNAL VITAMIN D SUPPLEMENTATION DURING PREGNANCY AND LACTATION TO PREVENT ACUTE RESPIRATORY INFECTIONS IN INFANCY IN DHAKA, BANGLADESH (MDARI TRIAL): A PROSPECTIVE COHORT STUDY NESTED WITHIN A RANDOMIZED CONTROLLED TRIAL DURING PREGNANCY AND LACTATION TO PREVENT RESPIRATORY INFECTIONS IN INFANCY IN BANGLADESH (MDARI TRIAL)**

<sup>1</sup>Hospital for Sick Children, Toronto, ON, Canada, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>Public Health Ontario Laboratories, Public Health Ontario, Toronto, ON, Canada, <sup>4</sup>Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States

Infancy is a high-risk period for severe acute respiratory infections (ARI). Severe ARIs are often preceded by viral upper respiratory tract infections. Vitamin D status is a candidate modifiable early-life determinant of the host antiviral immune response that may influence the risk of ARI-associated morbidity in high-risk populations. The MDARI trial is a prospective cohort study nested within the Maternal Vitamin D for Infant Growth (MDIG) study in Dhaka, Bangladesh in which 1300 pregnant women were randomized to one of 5 groups of weekly vitamin D supplementation: placebo, 4200 IU, 16800 IU, or 28000 IU from 2nd trimester to delivery plus placebo from 0-6 months postpartum; or, 28000 IU prenatal and until 6-months postpartum. Infants consented into the MDARI sub-study underwent active home-based weekly surveillance during the first 6 months of life that included inquiry about ARI symptoms and a standardized clinical assessment. Additional surveillance visits were conducted when caregivers reported ARI symptoms. Infants meeting clinical ARI criteria had a mid-turbinate nasal swab performed and tested by reverse transcription polymerase chain reaction for 8 viruses (influenza A/B, parainfluenza 1/2/3, RSV, adenovirus, and human metapneumovirus (hMPV)). The primary outcome is incidence of microbiologically confirmed ARI. Secondary outcomes include incidence of ARI associated with specific pathogens (influenza A or B, RSV), clinical ARI, and hospitalized ARI. 1214 (94%) of MDIG participants consented to enrollment in the MDARI study. There were 8333 instances of possible ARI reported of which 3860 (46%) met the study definition of ARI and 3810 (99%) nasal swabs were performed. 4.4% of samples tested positive for RSV, 1.7% for influenza A, 1.0% for influenza B, 4.9% for hMPV, 3.8% for adenovirus, 7.1% for parainfluenza virus, and 1.1% tested positive for more than one viral pathogen. The dose-ranging effect of vitamin D supplementation during pregnancy and lactation on infant ARI in Bangladesh will be summarized and the significance of the findings for maternal vitamin D supplementation guidelines will be discussed.

## THE ASSOCIATION OF COUGH FREQUENCY WITH THE MICROBIOLOGICAL DYNAMICS OF TUBERCULOSIS IN PATIENTS WITH ACTIVE PULMONARY TUBERCULOSIS

Gilman<sup>8</sup>, Valerie Paz-Soldan<sup>2</sup>, Richard Oberhelman<sup>2</sup>

<sup>1</sup>University of Michigan, Ann Arbor, MI, United States, <sup>2</sup>Tulane University, New Orleans, LA, United States, <sup>3</sup>Virginia Commonwealth University, Richmond, VA, United States, <sup>4</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>5</sup>Hospital Nacional Dos de Mayo, Lima, Peru, <sup>6</sup>Hospital Nacional Cayetano Heredia, Lima, Peru, <sup>7</sup>Imperial College London, London, United Kingdom, <sup>8</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Prolonged cough is a signal feature of tuberculosis infection, and an assumed determinate of tuberculosis transmission. Among HIV-negative patients receiving appropriate therapy, it has been demonstrated that cough rates drop rapidly in the first 14 days of treatment, and that cough frequencies are associated with bacillary load as determined through the microscopic-observation drug-susceptibility (MODS) assay. To further evaluate the association between patient cough and microbiological results in patients with active pulmonary tuberculosis, we conducted a prospective cohort study of recently diagnosed tuberculosis patients in Lima, Peru, at Hospital Dos de Mayo, and Hospital Cayetano Heredia. Cough frequency was determined based on 4 hour recordings using a vibration-sensor based device with a semi-automated cough detection algorithm, and drug resistance was determined using the MODS assay. Paired sputum samples and cough recordings were taken at six time points: at days 0 (or pre-treatment), 3, 7, 14, 30, and 60. Our final cohort included 59 HIV-negative patients with drug-sensitive tuberculosis on appropriate therapy, 7 HIV-positive patients with drug-sensitive tuberculosis, 6 HIV-negative patients on first-line therapy whose disease was subsequently identified as mono- or multidrug resistant, and 1 HIV-positive patients with drug-resistant tuberculosis. Preliminary results confirm that cough detection based on a 4-hour vibration-sensing device and a semi-automated algorithm produced similar estimates of cough frequency compared to a 24-hour, audio-based device. Cough frequency decreased with treatment, patients with a positive MODS result coughed approximately twice as much as patients without cough. In conclusion, cough is associated with microbiological positivity in HIV positive and MDR patients as well as patients with drug-sensitive TB.

## WORLD PNEUMONIA DAY 2011-2016: TWITTER CONTENTS AND RETWEETS

Md Mohiuddin Adnan<sup>1</sup>, Ashley M. Jackson<sup>1</sup>, Jingjing Yin<sup>1</sup>, Zion Tsz Ho Tse<sup>2</sup>, Hai Liang<sup>3</sup>, King-Wa Fu<sup>4</sup>, Isaac Chun-Hai Fung<sup>1</sup>

<sup>1</sup>Georgia Southern University, Statesboro, GA, United States, <sup>2</sup>The University of Georgia, Athens, GA, United States, <sup>3</sup>The Chinese University of Hong Kong, Hong Kong, Hong Kong, <sup>4</sup>The University of Hong Kong, Hong Kong, Hong Kong

Pneumonia remains a major killer of children. In 2015, 703,900 children <5 years died of lower respiratory infection globally. World Pneumonia Day (Nov 12) is an annual event advocating for pneumonia awareness. Social media (e.g. Twitter) has become part of the health communication strategy adopted by the campaign. In this study, 28,181 original tweets with hashtag #pneumonia were retrieved on Nov 21, 2016. From this Twitter corpus, 6 sub-corpora of tweets, one month before and one month after the World Pneumonia Day from 2011 to 2016 were extracted (n=998, 1409, 1036, 1369, 1221, and 688 respectively, N=6721). The underlying topics of the 6 sub-corpora were identified via unsupervised machine learning (Latent Dirichlet Allocation). Topics were then manually coded if they belonged to the themes of Raising Awareness, Promoting

Intervention, and Call to Action. Given the overdispersion of retweet counts and inflated number of zeros, we used multivariable hurdle regression models to assess whether themes of Twitter contents were associated with number of retweets, controlling for hashtag count, URL presence, and the age of the tweet. We found that tweets that raised awareness, promoted interventions and called the audience to action were more likely to have retweets (adjOR=2.11, 95%CI 1.89, 2.35; 1.37, 95%CI 1.21, 1.55; 1.99, 95%CI 1.40, 2.85) and if retweeted, to have a higher retweet count by 188%, 122% and 78% respectively (adjPR=2.88, 95%CI 2.36, 2.51; 2.22, 95%CI 1.76, 2.79; 1.78, 95%CI, 1.03, 3.14). Tweets with URL links were also more likely to have retweets (adjOR=1.27, 95%CI 1.13, 1.42) and a 65% higher retweet count (adjPR=1.65, 95%CI 1.35, 2.02). We also described the Twitter topics on pneumonia and their changes over the years. In 2015 and 2016, price of vaccines occurred in the list of top 10 topics of highest number of original tweets and retweets. Our study suggests that among #pneumonia tweets, tweets raising awareness of pneumonia, promoting interventions, and calling their audience to action were more engaged by Twitter users and were likely to be retweeted than others (e.g. sharing personal experience with pneumonia).

## ASSOCIATION BETWEEN SELF-REPORTED SYMPTOMS WITH OBJECTIVE COUGH AND DYNAMIC MYCOBACTERIAL MICROBIOLOGY IN PATIENTS WITH ACTIVE PULMONARY TUBERCULOSIS

Nehal S. Naik<sup>1</sup>, Gwenyth O. Lee<sup>2</sup>, German Comina<sup>2</sup>, Gustavo Hernandez<sup>2</sup>, Jorge Coronel<sup>3</sup>, Oscar Gayoso<sup>3</sup>, Eduardo Ticona<sup>4</sup>, Robert Gilman<sup>5</sup>, Valerie A. Paz-Soldan<sup>2</sup>, Richard Oberhelman<sup>2</sup>

<sup>1</sup>Virginia Commonwealth University, Richmond, VA, United States, <sup>2</sup>Tulane University, New Orleans, LA, United States, <sup>3</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>Hospital Nacional Dos de Mayo, Lima, Peru, <sup>5</sup>Johns Hopkins University, Baltimore, MD, United States

Subjective cough measures have shown utility in assessing quality of life among patients with chronic cough and may also have applicability in patients with Tuberculosis (TB). With existing difficulties in quantitatively prognosticating TB patients, patient-reported of symptoms might also be used to aid in clinical management. Our study evaluated the association between patient-reported cough and objective cough frequency and the association of patient reported symptoms to sputum bacillary load determined by the microscopic-observation drug-susceptibility (MODS) assay. We conducted a prospective cohort study in Lima, Peru at Hospital Cayetano Heredia and Hospital Dos de Mayo on patients recently diagnosed with active pulmonary tuberculosis. The Leicester cough questionnaire and a questionnaire about other TB related symptoms were administered at six times points: at days 0 (or pre-treatment), 3, 7, 14, 30, and 60, with paired sputum samples and cough recordings at each point. 73 patients were enrolled in our study. Preliminary analysis of 47 patients revealed that patient-reported fatigue and difficulty breathing dropped most slowly with treatment, while fever dropped most quickly. The mean Leicester cough score was found to decrease over time from 18.1/40 at day 0 to 9.6/40 at day 60. Correlation between objective cough rate, in epochs or fits of coughing per hour, with Leicester Cough scale was 0.50. There was a notable relationship between reported improvements in symptoms in the first 3 days of treatment, and MODS positivity (OR: 0.84, 95% CI: 0.78 – 0.91, p < 0.001). Increasing self-reported cough frequency was also significantly related to less days to MODS positivity (each question option p < 0.05). In conjunction with other methods of quantifying TB symptoms, a self-reported symptom questionnaire could be a valuable tool for determining prognosis for patients with TB, especially in low resource settings.

**ASIA SURVEILLANCE FOR ACUTE NOVEL RESPIRATORY INFECTIONS**

**Tyler E. Warkentien**<sup>1</sup>, Tham Nguyen<sup>2</sup>, Khanh C. Nguyen<sup>3</sup>, Yen Le Hai<sup>4</sup>, Benjamin Anderson<sup>5</sup>, Gregory C. Gray<sup>5</sup>

<sup>1</sup>U.S. Naval Medical Research Center Asia, Singapore, Singapore, <sup>2</sup>Duke-National University Singapore, Singapore, Singapore, <sup>3</sup>National Institute of Hygiene and Epidemiology, Hanoi, Vietnam, <sup>4</sup>Military Institute of Preventive Medicine, Hanoi, Vietnam, <sup>5</sup>Duke University, Durham, NC, United States

Novel respiratory virus generation often occurs first among livestock, then infects man before adapting and causing epidemics. Viral groups prone to this include influenza viruses, coronaviruses, adenoviruses, and enteroviruses. In this work we are seeking to identify novel respiratory viruses causing morbidity in humans or emerging in domestic animals which have potential to infect humans. We ultimately seek to detect and characterize these viruses before they fully cross-over to humans and cause epidemics. To do this we have developed a multi-phase surveillance program beginning with severe acute respiratory infection (SARI) caused by these viral groups at four hospitals in Vietnam. The aim of this first phase is to develop a sustainable sentinel surveillance system that strengthens the ability to detect emerging infections. Four sentinel military and civilian hospitals will enroll 400-450 subjects annually. Duke-NUS and NMRC-A have trained local partners in employing molecular techniques using algorithms developed at Duke for evidence in nasopharyngeal samples of human adenovirus, influenza viruses, enterovirus, and coronavirus infections. When an algorithm indicates a patient may be suffering with a recognized human virus, the specimen will be shared with Duke-NUS for further culture and sequence-based study. Additionally, an aliquot of the specimens which screen negative for known pathogens will also be screened for veterinary viruses. Data analysis will include: Counts of SARI detection by month and by site, proportional etiology of likely viral etiology types, and risk factors for severe disease (hospitalization or death). In the preliminary results from the first two months of surveillance, 19 patients have been enrolled and 37% have had an etiology detected (5=influenza A, 1= influenza B, 1=enterovirus). Culture and sequence-based analyses are pending. We plan to expand the surveillance in 2017 to include domestic livestock surveillance (swabs and bioaerosol sampling) in Vietnam, and to begin similar novel respiratory pathogen surveillance at the human-animal nexus in Malaysia.

## 1249

**NON-TREATMENT OF FAST BREATHING PNEUMONIA - THE RETAPP TRIAL**

**Fyezah Jehan**<sup>1</sup>, Imran Nisar<sup>1</sup>, Salima Kerai<sup>1</sup>, Benazir Baloch<sup>1</sup>, Nick Brown<sup>2</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>University of Southampton, Southampton, United Kingdom

“World Health Organization (WHO) defined fast breathing pneumonia” among children 2-59 months of age in low resource settings mandates outpatient antibiotic therapy with high dose amoxicillin. WHO itself recognizes limitations of this approach-non-specificity of the clinical diagnosis, large proportion due to viral infections and giving antibiotics where they are not needed, resultant disruption in microbiome, consequent poor growth along with the increased burden on scarce health resources. To fill the evidence gap for giving amoxicillin in fast breathing pneumonia a double blind randomized placebo controlled non-inferiority trial using parallel assignment is conducted in low income squatter settlements of Karachi, Pakistan. Children 2-59 months old with fast breathing, without any WHO-defined danger signs and seeking care at primary health care center are randomized to receive either three days of placebo or amoxicillin. Primary outcome is difference in cumulative treatment failure between two groups (new clinical sign based on preset definitions indicating illness progression or mortality) on day 0, 1, 2 or 3

of therapy. From September 2014-November 2016, 62,442 children were triaged, 34934 (55.9%) presented with cough or difficulty in breathing. 5550 (15.8%) met the inclusion criteria i.e. having cough for less than two weeks with tachypnoea. Based on eligibility, 2755 were enrolled and received high dose amoxicillin or placebo. With per protocol rate of 96%, overall treatment failure is 3.5% with 1 death. Causes of treatment failure are hospitalization (2%), onset of chest indrawing (2%) and danger signs in 1% among others. Relapse are 66 (2.5%), 33 due to chest indrawing pneumonia. X-ray positivity among treatment failures/relapses is 17%. There were 2 serious adverse events (severe diarrhea). Thus overall rates of treatment failure in fast breathing pneumonia are low. Trial results will serve to support or refute use of antibiotics in this illness. Findings are generalizable to settings with low HIV and malaria prevalence and Hib/Pneumococcal vaccines in their national immunization plan.

## 1250

**ACQUISITION OF PROPER TREATMENT FOR EXTENSIVELY DRUG RESISTANT TUBERCULOSIS PATIENTS IN MALI: WHERE IS THE ISSUE?**

**Moumine Sanogo**<sup>1</sup>, Bassirou Diarra<sup>2</sup>, Yacouba Toloba<sup>3</sup>, Bakary Konate<sup>4</sup>, Antiémé Combo Georges Togo<sup>1</sup>, Gaoussou Berthe<sup>3</sup>, Diaguina Soumare<sup>3</sup>, Bocar Baya<sup>1</sup>, Drissa Goita<sup>1</sup>, Yeya dit Sadio Sarro<sup>1</sup>, Mamoudou Maiga<sup>5</sup>, Michael Belson<sup>6</sup>, Susan Orsega<sup>6</sup>, Sounkalo Dao<sup>1</sup>, Robert L. Murphy<sup>5</sup>, Sophia Siddiqui<sup>6</sup>, Bouke de Jong<sup>7</sup>, Seydou Doumbia<sup>1</sup>, Souleymane Diallo<sup>1</sup>

<sup>1</sup>University Clinical Research Center (UCRC)-SEREFO-Laboratory, University of Sciences, Techniques and Technologies of Bamako (USTTB), Bamako, Mali, <sup>2</sup>University Clinical Research Center (UCRC)-SEREFO-Laboratory, University of Sciences, Techniques and Technologies of Bamako (USTTB) - Institute of Tropical Medicine, Antwerp, Belgium, Bamako, Mali, <sup>3</sup>Service de Pneumo-physiologie du Centre Hospitalier Universitaire du Point-G, Bamako, Mali, <sup>4</sup>Programme National de Lutte contre la Tuberculose (PNLT), Ministère de la santé et de l'hygiène publique, Bamako, Mali, <sup>5</sup>Global Health, Northwestern University, Chicago, IL, United States, <sup>6</sup>Collaborative Clinical Research Branch, Division of Clinical Research, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, <sup>7</sup>Institute of Tropical Medicine, Department of Biomedical Sciences, Antwerp, Belgium

Extensively drug-resistant tuberculosis (XDR TB), defined as resistance to rifampin and isoniazid plus any fluoroquinolone and at least one injectable second-line drug, has been detected in Mali. This study presents the first three XDR TB patients identified in Mali and describes the barriers to treatment access currently faced in Mali's healthcare system. This alarming development of XDR-TB cases has not been entirely unexpected since resistant infections are the consequence of poor patient management and failure to follow drug treatment regimens established by international authorities. At a referral hospital in Bamako, Mali, two patients presented with XDR TB in August 2016 followed by a third patient in March 2017. Diagnostic testing for the first two patients was completed by the Mali WHO Supra national laboratory (ITM/Antwerp), and testing for the third patient was completed by the Mali University Clinical Research Center (UCRC/USTTB, Bamako). Genotypic findings were suggestive of nosocomial transmission from the first patient to both the second and third patients, which resulted in mixed TB infections. Despite receiving a laboratory-confirmed diagnosis of XDR TB, none of the patients have been given the appropriate treatment, Bedaquiline, to-date. This treatment is not readily available in Mali, and the most significant barrier to treatment access is obtaining the drugs from health authorities, including the Malian government, Global Fund, WHO, and TB Union. Without access to adequate treatment, the identification of XDR TB in Mali will result in little advancement against the global spread of XDR TB. In conclusion, the experience from Mali highlights the need for the developing world to not only have access to diagnostics, but also to effective treatments and clinical guidance. Otherwise, preventable XDR TB infections will continue to develop and spread unchecked.

### TUBERCULOSIS RECURRENCE IN POSTPARTUM

**Anastasia Putri<sup>1</sup>**, Risca Marcalene<sup>1</sup>, Irene Purnamawati<sup>1</sup>, Zulkifli Amin<sup>2</sup>, Cleopas Martin Rumende<sup>2</sup>

<sup>1</sup>Department of Internal Medicine, Faculty of Medicine University of Indonesia, Jakarta, Indonesia, <sup>2</sup>Division of Respiriology and Critical Care Internal Medicine, Department of Internal Medicine, Faculty of Medicine University of Indonesia, Jakarta, Indonesia

Active tuberculosis is most common during a woman's reproductive years, the risk in early postpartum women are twice as nonpregnant women. In Jakarta, Indonesia, a 26 year-old woman presented to the Emergency Department with a complaint of worsened dyspnoea 3 days after caesarean section delivery. She was having dyspnoea, coughing with productive white coloured sputum, afebrile with night sweats and weight loss in the past 2 months before delivery. She went to the private hospital, she got cough medicine. She has a history of active TB 6 years ago, and already completed 9 months TB treatment (category-1) with negative acid fast bacilli (AFB) in the end of the course. On examination, she was afebrile, pale but not tachypnic or tachycardic. She was normotensive and the pulse oximetric reading was 96% on room air. Chest auscultation revealed crackles in both lung. Laboratory finding on admission revealed hypochromic microcytic anaemia and neutrophil leucocytosis. Mycobacterium tuberculosis bacillus was detected by sputum AFB staining and positive GeneXpert test without resistance to rifampicin. Chest X-ray on admission showed destroyed of the left lung with pleural effusion, also shows fibrosis with ground glass opacity at the middle lobe of the right lung and fibrosis with calcification at the upper lobe of the right lung. Computed tomographic pulmonary showed atelectasis of the left lung, with retraction of left mediastinal structure, right lung hyperinflation with herniation, fibrosis with ground glass opacity, tree in bud appearance and bronchiectasis. She was initially treated with intravenous ceftriaxone and oral azithromycin for community acquired pneumonia. Anti-tuberculosis treatment under regimen category-2 (rifampicin, isoniazid, pyrazinamide, ethambutol, streptomycin) was started once tuberculosis infection was confirmed together with methylprednisolone (for 3 days). She was discharged after hospitalized for 10 days. The status of TB for the newborn baby are remain unknown. This case reports a challenge to diagnose and treat active TB in postpartum, and show the need of multidisciplinary approaches to deal with it.

### 1252

### DETERMINATION OF MOLECULAR MECHANISMS BEHIND PARASITE EGRESS IN *CRYPTOSPORIDIUM PARVUM* INFECTION

**Samantha Nava**

University of Texas Medical Branch, Galveston, TX, United States

Recent studies have identified *Cryptosporidium* as a major contributor to childhood disease in endemic areas. Complications such as stunting, impairments in cognitive development, and malnutrition are caused by persistent and recurring infections. Persistent infection is contributed by the unique life cycle of the parasite, where asexual replication is continuous until intervention by the host immune response. Current clinical interventions are not ideal where only few have demonstrated anti-Cryptosporidial activity and are often associated with relapses in infection. A vaccine to protect or reduce severity of infection would be ideal to protect young children who are most susceptible to complications associated with disease. Merozoite egress is a crucial event in the life cycle of *Cryptosporidium* before the establishment of a persistent infection in susceptible hosts. By targeting the protein factors that are crucial for parasite egress, we could potentially develop a strain of parasite that would have the ability to infect host cells and reproduce asexually, but not complete the lifecycle. Lifecycle arrest will prevent parasites from exiting the cell. We predict this effect will prolong antigen presentation by intestinal epithelial cells, providing the host immune response time

to develop an immune response. This project proposes to look at these factors in *Cryptosporidium parvum* and analyze their role in infection. We hypothesized that proteins related with motility and proteolysis expressed at 24 hours post-infection must have a key role during *Cryptosporidium* egress. Here we will test the hypothesis that CDPK's, Subtilases, or cGMP's are essential molecules for this process. We predict that if these molecules are involved in this mechanism, then the interruption of its function will result in decreased merozoites released after asexual replication.

### 1253

### VACCINE DEVELOPMENT AGAINST *CRYPTOSPORIDIUM PARVUM* INFECTION USING THE INTERFERON GAMMA RECEPTOR KNOCK-OUT MOUSE MODEL

**Karine Sonzogni-Desautels**, Timothy G. Geary, Momar Ndao  
McGill University, Montreal, QC, Canada

*Cryptosporidium spp.* infection is a major cause of moderate-to-severe diarrhea in children in sub-Saharan Africa and South Asia and is responsible for more than 200,000 deaths yearly in infants in these regions. There is an urgent need to find new treatments and vaccines for this disease. Advantages of the interferon gamma receptor knock-out (IFNgammaR-KO) mouse model were reported by our laboratory when testing oleylphosphocholine, a compound that prevents lethal *C. parvum* infection. This mouse model also facilitates the evaluation of candidate vaccines against *C. parvum* infection *in vivo*, as demonstrated by experiments on the protective effect of a vaccine candidate, the gp45 *C. parvum* surface protein. IgG, IgG1, IgG2c and several cytokines (for example, IFNgamma and IL-5) were measured by ELISA to evaluate immune responses to vaccination. Intestinal parasite burden following challenge was determined by flow cytometry. Recombinant gp45 combined with the TLR9 agonist CpG-B ODN-2006, a TH1-inducer adjuvant, induced a mixed TH1/TH2 immune response represented by high anti-gp45 IgG titers with a high IgG2c/IgG1 ratio. However, gp45 alone elicited a TH2 immune response illustrated by high IgG1 and IL-5 titers and better protected mice (72% reduction in parasite burden). Therefore, a new combination with aluminium hydroxide, a TH2-inducer adjuvant, is being tested in IFNgammaR-KO mice to determine its ability to elicit a protective immune response and to reduce intestinal parasite burden. The IFNgammaR-KO mouse model is valuable for research on *C. parvum* infection because it is particularly susceptible to infection and mimics clinical signs of cryptosporidiosis in infants. Using this model, we demonstrated the potential of a new vaccine to reduce *C. parvum* parasite burden, a step toward the development of new control measures for infants in developing countries.

### 1254

### RESPONSE OF HOST CELLS TO INJECTION WITH EFFECTOR PROTEINS BY *TOXOPLASMA GONDII*

**Suchita Rastogi**

Stanford University, Palo Alto, CA, United States

*Toxoplasma gondii* and its cousin *Plasmodium spp.* are obligate intracellular parasites that pose a global burden on human health. Prior to invasion, both parasites rapidly inject host cells with proteins from a specialized secretory organelle called the rhoptry. Rhoptry protein secretion is necessary for parasite invasion, survival, and virulence; however, the host response to this event is poorly understood, as traditional methods fail to distinguish it from the host response to additional parasite effector secretion events subsequent to invasion. To characterize the host response specifically to rhoptry secretion, we are circumventing traditional approaches by performing transcriptomic analyses of a naturally occurring and reproducible population of host cells that *Toxoplasma* parasites inject with rhoptry proteins, but then subsequently fail to invade ("uninfected-injected" cells as previously described by Koshy et al., PLoS Path. 8(7):

e1002825 (2012)). This work captures a picture of the earliest stage of a host cell's interaction with *Toxoplasma gondii*, and is expected to reveal host targets of the rhopty proteins.

## 1255

### MATHEMATICAL ANALYSIS FOR A MODEL TO CONTROL CHAGAS DISEASE: FIGHTING AN INFECTION WITH AN INFECTION

Jessica R. Conrad

Tulane University, New Orleans, LA, United States

Chagas disease is a vector-borne disease that is endemic across the Americas. We review a single strain infection model for *Trypanosoma cruzi*, the parasite that causes Chagas disease. Then we construct a two strain infection model for *Trypanosoma cruzi* and *T. rangeli* host-vector dynamics. This creates a basis for understanding the dynamics of the competing infections. From here, we can analyze the initial conditions necessary for *T. rangeli* to outcompete *T. cruzi* in a given host-vector population. Recent research has found that infection with the non-pathogenic parasite *T. rangeli* provides protection against infection from the pathogenic parasite *T. cruzi*. No research has yet been done on creating a competition between *T. cruzi* and *T. rangeli* to displace *T. cruzi*, rather than vaccinate or treat animals for the infection. Our two strain model allows us to explore this dynamic. We propose an introduction of *T. rangeli* into host populations endemic with *T. cruzi*. This briefly creates an infection wave of *T. rangeli*, but the single introduction of the *T. rangeli* is insufficient to create a break in the *T. cruzi* infection wave. Multiple introductions of *T. rangeli* under ideal conditions can significantly reduce *T. cruzi* infection, but this effect stops if reintroductions of *T. rangeli* are stopped. Introduction of *T. rangeli* into at risk populations can reduce the invasion rate of *T. cruzi*.

## 1256

### EVALUATION OF THREE COMMERCIAL DIAGNOSTIC TESTS FOR CRYPTOSPORIDIUM INFECTIONS IN HUMANS

Henk Schallig, Daisy de Jong, Nienke Verhaar, Sandra Menting

Academic Medical Centre, Amsterdam, Netherlands

Diarrhea is the second greatest killer of small children worldwide, responsible for 800.000 deaths of under 4-year-olds every year. This is more than AIDS, measles and malaria combined. Even when not fatal, diarrhea often leads to malnutrition, and malnourished children are more prone to develop diarrhea, a vicious cycle difficult to interrupt. Most lethal diarrhea in small children (irrespective of HIV status) is caused by rotavirus, which is soon to be controlled by vaccination programs. This is closely followed by the eukaryote *Cryptosporidium*, which is one of the commonest, and at the same time most poorly understood, water-borne parasites of humans. To aid diagnosis and to support control programmes adequate diagnostic tests should be in place. Several rapid diagnostic tests (RDTs) for cryptosporidiosis are nowadays available and we have evaluated three different brands: RIDA QUICK for *Cryptosporidium/Giardia* Combi (Produced by R-Biopharm, Germany); CRYPTO/GIARDIA DUO-Strip (Produced by Coris BioConcept, Belgium); GIARDIA/CRYPTOSPORIDIUM QUIK CHEK (Produced by TechLab, USA). All three test are based on the lateral flow principle, able to detect both *Cryptosporidium* as well as *Giardia* and are sold as complete test kits. Of each test a single lot was evaluated. Stool samples of children suspected of having a protozoan infection causing diarrhea were used for diagnostic evaluation. Depending on the test used, the incidence of *Cryptosporidium* varied between 9.6% to 18.3%. The incidence of *Giardia* was higher (12.2% to 20%) and in line with previous observations. A small number of children harbored mixed infections: 1.7% to 3.5%. The agreement between the three different tests was determined. The agreement between the Rida test and the Duo-strip test was the best (K-value, as measure to express agreements between diagnostic tests, was 0.721). Also the agreement between Quik Chek test and the Duo -strip test was good, with a k-value of 0.689. The

agreement between the RIDA test and the Quik Chek test was moderate, k-value 0.593. Test performance in terms of sensitivity and specificity will be further assessed by PCR and reported.

## 1257

### THE PREVALENCE AND ASSOCIATION WITH DISEASE OF CRYPTOSPORIDIUM SPECIES AT URBAN AND RURAL SITES IN BANGLADESH

Carol A. Gilchrist<sup>1</sup>, Cecelia Burkey<sup>2</sup>, Emtiaz Ahmed<sup>3</sup>, Shah Nawaz Ahmed<sup>3</sup>, Md. Masud Alam<sup>3</sup>, Tuhinur Arju<sup>3</sup>, Mamun Kabir<sup>3</sup>, Priya Duggal<sup>4</sup>, Poonum Korpe<sup>4</sup>, William A. Petri<sup>2</sup>, Rashidul Haque<sup>3</sup>, Abu S. Faruque<sup>3</sup>

<sup>1</sup>University of Virginia HSC, Charlottesville, VA, United States, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>4</sup>Johns Hopkins University, Baltimore, MD, United States

Three *Cryptosporidium* species are in circulation in Bangladesh: *C. hominis*, *C. parvum* and *C. meleagridis*. A pan-*Cryptosporidium* qPCR assay was run on surveillance and diarrheal samples collected from infants in an urban slum of Dhaka (Mirpur) (n=250), and at a rural location (Mirzapur) (n=258). These children, enrolled at birth into a longitudinal study cohort, were visited at home twice weekly by field staff and brought to the study clinic once a month for a health assessment. Both diarrheal and surveillance samples were collected (Mirpur: 5133 surveillance and 1193 diarrheal; Mirzapur: 5838 surveillance and 263 diarrheal). Positive samples collected at  $\leq 60$  day intervals were considered part of the same infection and designated diarrheal or asymptomatic based on the phenotype at the time of the first positive sample. In Mirpur, 62% of the children were positive for *Cryptosporidium* and multiple infections were common (29% experienced two and 9% three). In Mirzapur, 43% of the children were infected once but only 8% were infected twice. Species specific qPCR assays for *C. parvum*, *C. hominis* and *C. meleagridis* were used to characterize a subset of the samples. *C. hominis* and *C. meleagridis* caused the majority of the infections but the distribution was highly regional. *C. meleagridis* was the major species present at the rural site (98%: 90/92) and was predominant in the surveillance samples (89/90) whereas *C. hominis* was predominant in the urban samples (93%: 118/127) and associated with diarrhea ( $p=0.0002$ ). *Cryptosporidium* diarrhea constituted 6% of year one diarrheal burden and 16% of that in year two. In summary, *C. hominis* but not *C. meleagridis* infection was associated with diarrhea in the first two years of life of infants in Bangladesh.

## 1258

### HISTOPATHOLOGIC DETECTION OF TOXOPLASMA GONDII INFECTION USING A MURINE MODEL UNDER IMMUNOSUPPRESSION

Cristina Montoya<sup>1</sup>, Raul Ynocente<sup>1</sup>, Miguel Mogollon<sup>1</sup>, Christian Huaman<sup>1</sup>, Cusi Ferradas<sup>2</sup>, Noelia Angulo<sup>2</sup>, Alejandro Florentini<sup>2</sup>, Maritza Calderon<sup>2</sup>, Juan Jimenez<sup>1</sup>

<sup>1</sup>UNMSM, Lima, Peru, <sup>2</sup>UPCH, Lima, Peru

Toxoplasmosis, a parasitic disease caused by *Toxoplasma gondii*, is a worldwide distributed zoonoses. One third of the population is believed to be infected with *T. gondii*, but pregnant women and immunosuppressed patients (like HIV infected people) are the most affected. In the intermediate hosts, including humans, the parasite reproduces asexually and cysts are formed in different tissues. The aim of this study was to evaluate the tissue damage caused by the Me49 strain of *T. gondii* in immunosuppressed Swiss mice using histopathology. In order to do this, we used twenty female Swiss mice who were two-months old orally infected with 20 Me49 strain cysts. The animals were divided in four groups (five mice per group): infected and immunosuppressed mice (group A), infected but not immunosuppressed mice (group B), not infected but immunosuppressed mice (group C) and not infected and not immunosuppressed mice (group D). Immunosuppression was done using

Dexamethasone (2 mg/kg). We sacrificed the animals fifteen, thirty and forty-five days' post-immunosuppression. During the necropsy, we took samples of brain, heart, liver, lung, diaphragm, spleen and lymph nodes. The samples were fixated using 10% formol-PBS and processed using the standard histology technique for Hematoxylin and Eosin (H&E) staining. In groups A and B, the brain was the most affected tissue and the parasite was found mostly in the cerebral cortex (gray substance). In the lungs and livers, we observed inflammation. Additionally, the mice of the group A showed higher number of cysts with an average size of 10-23 µm which were surrounded by an inflammatory reaction (neutrophils and plasmatic cells). In group C, we found calcifications in the gray substance of the brain. We present these results as relevant and comparative information to improve the understanding of the histopathologic changes caused by *Toxoplasma gondii* under immunosuppressive conditions in which the murine model simulates what can happen in human patients. We recommend to use immunohistochemistry and molecular tools to improve the detection of the parasite in tissues.

## 1259

### WHAT'S THE COST? PEDIATRIC CRYPTOSPORIDIOSIS IN PERU, BANGLADESH AND KENYA

Robert K. Choy<sup>1</sup>, Ellen R. Rafferty<sup>2</sup>, Janna M. Schurer<sup>3</sup>, Michael B. Arndt<sup>4</sup>, Eugenio L. de Hostos<sup>1</sup>, David A. Shoultz<sup>4</sup>, Marwa Farag<sup>2</sup>

<sup>1</sup>PATH, San Francisco, CA, United States, <sup>2</sup>University of Saskatchewan, Saskatoon, SK, Canada, <sup>3</sup>University of Washington, Seattle, WA, United States, <sup>4</sup>PATH, Seattle, WA, United States

For children under two years of age, infection with *Cryptosporidium* has emerged as a leading cause of diarrhea-related morbidity and mortality in resource-poor regions. Our study quantified direct medical and non-medical costs as well as indirect costs incurred for *Cryptosporidium*-infected children aged 0-23 months in Kenya, and those younger than 12 months in Peru and Bangladesh. Variables factored into the model included age-specific cryptosporidiosis incidence, treatment costs, health care seeking behaviours, travel costs, caregiver productivity losses, mortality costs, and costs associated with growth faltering. Data inputs were extracted from government reports, internationally validated reference tools, peer-reviewed literature, and expert opinion. According to our analysis, medical costs per episode were higher in Kenya (\$27.10 USD) than in Peru (\$9.55) or in Bangladesh (\$2.44); however, the total annual economic burden was highest in Peru (\$28.5M), followed by Kenya (\$24.2M) and Bangladesh (\$5.5M). Indirect costs in each country far outweighed direct costs. This study not only highlights important data gaps impeding more comprehensive economic analyses, but also emphasizes the large economic burden that cryptosporidiosis causes for health systems in high prevalence areas and for caregivers of infected children. There is a critical need to invest in new solutions for *Cryptosporidium* prevention, diagnostics and treatment in order to address the current medical and economic barriers that prevent children from receiving appropriate and timely care in low resource countries.

## 1260

### COMBINATION EFFICACY OF CLOFAZIMINE AGAINST PIROPLASMOSIS

Ikuo Igarashi<sup>1</sup>, Bumduuren Tuvshintulga<sup>1</sup>, Thillaiampalam Sivakumar<sup>1</sup>, Aki Ishiyama<sup>2</sup>, Masato Iwatsuki<sup>2</sup>, Naoaki Yokoyama<sup>1</sup>

<sup>1</sup>Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan, <sup>2</sup>Kitasato University, Tokyo, Japan

In the present study, we evaluated the growth-inhibitory effects of clofazimine, currently used for treating leprosy, against *Babesia bovis*, *B. bigemina*, *B. caballi*, and *Theileria equi* *in vitro* culture, and *B. microti* in mice. The IC50 values of clofazimine against the *in vitro* growth of *B. bovis*, *B. bigemina*, *B. caballi*, and *T. equi* were 4.5, 3, 4.3, and 0.29 µM, respectively. In mice infected with *B. microti*, treatment with oral administration of 20 mg/kg clofazimine resulted in a significant lower

peak parasitemia (5.3%) as compared to a control group (45.9%), which was comparable to subcutaneous administration of 25 mg/kg diminazene aceturate. However, the growth of parasites was observed in mice after blood transfusions from clofazimine-treated mice on day 40 post-infection when parasites were not found in the blood smears. These results suggest that clofazimine has excellent inhibitory effects against *Babesia* and *Theileria* *in vitro* and *in vivo*, but it could not completely eliminate parasites in the host. Therefore, we evaluated the combination treatment with clofazimine and diminazene aceturate against piroplasms both *in vitro* and *in vivo* for the development of a novel chemotherapy with high efficacy and safety against animal piroplasmosis. The clofazimine-diminazene aceturate combination showed to have additive or synergistic effects on *in vitro* growths of *Babesia bovis*, *B. bigemina*, *B. caballi*, and *Theileria equi*. The lower dosages of clofazimine-diminazene aceturate combination showed to have a higher chemotherapeutic efficacy against *B. microti* in mice as compared to clofazimine or diminazene aceturate monotherapy. *B. microti* was not detected in blood, brain, spleen, and heart DNA samples by PCR from combination therapy on day 51 post infection. Furthermore, the parasite did not grow in blood-transfused mice from combination therapy groups. All results suggest that the clofazimine-diminazene aceturate combination chemotherapy will be a better choice to treat animal piroplasmosis instead of diminazene aceturate monochemotherapy.

## 1261

### GENETIC DIVERSITY OF BLASTOCYSTIS SUBTYPES IN PATIENTS WITH CHRONIC URTICARIA

Fabiana M. Paula<sup>1</sup>, Gessica B. Melo<sup>1</sup>, Fernanda M. Malta<sup>1</sup>, Celina W. Maruta<sup>2</sup>, Paulo R. Criado<sup>2</sup>, Vera Lucia P. Castilho<sup>2</sup>, Elenice Mn Gonçalves<sup>2</sup>, Maria Cristina Espirito Santo<sup>1</sup>, Ronaldo Cesar Gryschek<sup>1</sup>

<sup>1</sup>Laboratório de Investigação Médica HCFMUSP, Sao Paulo, Brazil, <sup>2</sup>Hospital das Clínicas da Faculdade de Medicina-USP, Sao Paulo, Brazil

*Blastocystis* sp is a protozoan commonly found in human and animals. Pathogenic and biological aspects of this organism are still unknown but have been related as a possible etiologic agent of gastrointestinal and extraintestinal manifestations such as irritable bowel syndrome, as well as participation in the pathogenesis of chronic urticaria. Several subtypes (1-9) have been described in human samples. However, it remains unclear whether a given subtype may be unrelated to clinical manifestations. Genetic studies could help to establish links between phenotypic properties of the isolates and their subtypes. The aim of the present study was to investigate *Blastocystis* STs in samples from patients with chronic urticaria without definite cause attended at the Hospital das Clínicas of the Faculdade de Medicina da Universidade de São Paulo (HC-FMUSP). Stool samples diagnosed at the Section of Parasitology of the Central Laboratory (HC-FMUSP) were used for DNA isolation. Polymerase chain reaction (PCR) was performed using specific primers targeting the small-subunit rRNA gene of *Blastocystis* sp. DNA sequences were then aligned and compared to other sequences obtained from the GenBank and MLST database. We observed the occurrence of three STs: ST1 (38.5%), ST2 (23%) and ST3 (38.5%). The 18S alleles were retrieved for each subtype where ST2 and 3 showed the highest number of alleles. The present study is one of the few providing ST data from the human population in South-America and which evaluates the possible relationship of subtypes with chronic urticaria. Studies of allelic variation within species provides fundamental insights about the evolution and ecology of organisms. Financial Support FAPESP (2015/18213-6)

## 1262

**ANTISCHISTOSOMAL ACTIVITY OF PYRIDOBENZIMIDAZOLE DERIVATIVES**Godfrey Mayoka<sup>1</sup>, Jennifer Keiser<sup>2</sup>, Kelly Chibale<sup>1</sup><sup>1</sup>University of Cape Town, Cape Town, South Africa, <sup>2</sup>University of Basel and Swiss Tropical and Public Health Institute, Basel, Switzerland

Tropical diseases continue to plague developing countries, hampering economic development in already impoverished regions of the world. Malaria and schistosomiasis, two of the most prevalent parasitic infections, have their transmission exacerbated by geographical factors, poor hygiene and sanitation. Chemotherapy is the backbone of control and treatment of these infections with resistance to current medication posing a threat to the gains made towards eradicating these diseases. Concerted efforts to discover and develop new drugs using both phenotypic whole cell assays and target based approaches are, therefore, warranted. The long development time-lines, high costs and risk of attrition, further compounded by the low projected financial returns discourage research investments in these therapeutic areas. Drug repositioning offers a cheaper and quicker alternative to address this dilemma. In this approach, in which there is usually underlying biochemical or physiological similarities in the therapeutic areas under consideration, a drug or lead compound developed for one disease is used as a template for subsequent medicinal chemistry optimisation to identify a drug for another disease. In this context, based on similarities in the haemoglobin degradation pathway in schistosomes and plasmodia, we evaluated the antischistosomal activity of analogues based on a pyridobenzimidazole hit identified after a whole cell screening assay against human *Plasmodium falciparum*. Several compounds with potent *in vitro* activity, suitable pre-clinical pharmacokinetics and physicochemical properties were identified and prioritised for *in vivo* efficacy evaluation in a murine model of schistosomiasis. Further medicinal chemistry optimisation is ongoing to progress these compounds as prospective antischistosomal leads.

## 1263

**MAGNETIC BEAD-BASED SAMPLE PREPARATION FOR LOW-RESOURCE ENHANCEMENT OF ULTRASENSITIVE LATERAL FLOW ASSAY FOR DETECTION OF SCHISTOSOMA BIOMARKER CAA**Christine F. Markwalter, David W. Wright  
Vanderbilt University, Nashville, TN, United States

Current parasitological methods for *Schistosoma* detection are not sensitive enough to detect low-density infections. Thus, there is a pressing need for highly sensitive and specific schistosomiasis diagnostics to determine prevalence in low-transmission areas and for verification of disease elimination. Recently, GJ van Dam and colleagues developed a urine-based up-converting phosphor lateral flow assay (UCP-LFA) for the *Schistosoma* biomarker circulating anodic antigen (CAA) that was shown to detect CAA for *Schistosoma* burdens as low as one worm pair. However, the UCP-LFA for CAA deviates from conventional point-of-care lateral flow assays because its high sensitivity relies on sample pre-processing that requires laboratory equipment not available in low-resource settings. We have developed a simple-to-use magnetic bead-based sample concentration method and device to enhance the UCP-LFA for CAA by concentrating CAA from larger sample volumes and delivering the enriched CAA to the lateral flow assay. Magnetic beads functionalized with a CAA binding ligand capture the biomarker from large-volume samples. These functionalized beads are deposited onto the UCP-LFA using a stationary magnet within a field-deployable bead-delivery device. A modified running buffer releases the biomarker from the beads, delivering an enriched CAA sample to the test and producing a positive signal at the test line for samples that would otherwise be undetectable.

## 1264

**THE USE OF GEOGRAPHIC INFORMATION SYSTEM AS A TOOL FOR SCHISTOSOMIASIS SURVEILLANCE IN THE PROVINCE OF DAVAO DEL NORTE, PHILIPPINES**Chiqui de Veyra<sup>1</sup>, Vicente Belizario Jr.<sup>1</sup>, John Paul delos Trinos<sup>1</sup>, Berne Silawan<sup>2</sup>, Agapito Hornido<sup>3</sup>, Hansel Amoguis<sup>4</sup>, Dominic Basalo<sup>5</sup>, Cherry Dema-ala<sup>6</sup>, Irenn Mantilla<sup>4</sup>, Rosele Layan<sup>3</sup><sup>1</sup>Neglected Tropical Diseases Study Group, National Institutes of Health, Manila, Philippines, <sup>2</sup>Provincial Planning and Development Office, Davao del Norte, Philippines, <sup>3</sup>Provincial Health Office, Davao del Norte, Philippines, <sup>4</sup>Department of Health Regional Office XI, Davao City, Philippines, <sup>5</sup>Rural Health Unit of Carmen, Davao del Norte, Philippines, <sup>6</sup>Rural Health Unit of Braulio Dujali, Davao del Norte, Philippines

Schistosomiasis (SCH), caused by *Schistosoma japonicum*, remains endemic in the Philippines. Effective SCH control requires describing areas at-risk where control efforts may be focused. This study aimed to demonstrate the utility of geographical information system (GIS) as a tool for SCH surveillance in the province of Davao del Norte, Philippines. Qualitative and quantitative data on SCH determinants were obtained from concerned local government units, partner agencies, and institutions. These were standardized and incorporated in the GIS map. Areas at-risk for SCH were described by overlaying determinants, which include geography and climate, agriculture, poverty, sanitation, presence of intermediate and reservoir hosts, prevalence levels, and mass drug administration coverage rates. The GIS map showed that endemic barangays are located in lowland and flood-prone areas where major rivers and tributaries are found. New Corella has the highest poverty incidence among the reported SCH-endemic areas, as well as the highest number of confirmed snail colonies. Among known endemic localities, Tagum City is the only city in the province which met the poverty incidence target of below 16.6%. Clustering of SCH cases was reported in barangays of the municipalities of Asuncion, New Corella, Tagum City, Kapalong, Braulio Dujali, and Carmen ranging from 0.48% (8 out of 1,655) in Braulio Dujali to 2% (25 out of 1,405) to Asuncion. This study demonstrated the utility of GIS as a tool for SCH surveillance. The use of the GIS map in predicting and assessing risk for SCH may allow prioritization of allocating resources and delivery of services in areas at higher risk for SCH. Likewise, the GIS map may be useful in monitoring and evaluation of the control program through data visualization in space and possibly even time which may help improve program policy and planning for targeted surveillance and effective control. Development of an action plan for SCH prevention and control using data generated by the GIS may guide program policy and planning toward SCH control and prevention in the province and in other endemic areas.

## 1265

**PREVALENCE OF SCHISTOSOMIASIS AROUND THE KAINJI AND JEBBA DAMS**Henry A. Okoro-nwanja<sup>1</sup>, Ogonna N. Nwankwo<sup>2</sup>, Grace I. Nwankwo<sup>3</sup><sup>1</sup>World Health Organization, Ibadan, Nigeria, <sup>2</sup>University of Calabar Teaching Hospital, Calabar, Nigeria, <sup>3</sup>Federal Teaching Hospital Abakaliki, Calabar, Nigeria

Schistosomiasis is one of the commonest neglected tropical diseases worldwide with socio-economic and health impact on infected individuals. Dams though highly desirable for their socio-economic benefits have some unintended consequences on human health and the environment. It often leads to increase in the prevalence of diseases and multiplication of vectors associated with illnesses. Thus Individuals residing close to dams have higher risk schistosomiasis than others. Multi-prong programmatic approaches have been adopted in past years to reduce the impact of this diseases in a region hosting two major dams in Nigeria for which there is a need to continuously monitor and evaluate the impact of the programs to inform more policies and actions to prevent the diseases

hence the need for this study. This study aims to assess the prevalence of schistosomiasis amongst population close to the Kanji dam and Jebba dams of Nigeria. The study was carried out in settlements around the dams in nine LGA located in Kebbi, Kwara and Niger states of Nigeria. A parasitological methods was used to examine the urine sample of 1266 individuals from households recruited through a multi-stage sampling methods. Ethical clearance for the study was obtained from the National Health Research Ethical Committee (NHREC) of the Federal Ministry of Health. Over half (61.8%) of our cases were aged above 17 years with the median age at 24 years(4-94) with cases almost equally divided between males and females. urine microscopy result showed total prevalence of schistosomiasis in communities around the dams was 38.8% with ranges between 8%-60%. The study showed the highest prevalence was in the pre-adolescence age group of 6-10 years(76.5%) followed by the pre-school age group of under-5(71.8%) and declines with ages further away from adolescence. Furthermore, schistosomiasis prevalence is highest among the pupils (63.6%) followed by livestock farmers (41.7%), crop farmers (32.4%) and least amongst civil servants (7.7%). There is a need for continuous surveillance around dams and heightened community wide mass campaign treatment in this areas as the strategy for elimination.

## 1266

### COINFECTION OF SCHISTOSOMIASIS HAEMATOBIMUM AND SEXUALLY TRANSMITTED INFECTIONS IN PREGNANT WOMEN: KISANTU HEALTH ZONE, DEMOCRATIC REPUBLIC OF THE CONGO

**Gisele M. Mvumbi**<sup>1</sup>, Nicole A. Hoff<sup>2</sup>, Kamy Musene<sup>3</sup>, Adva Gadoth<sup>2</sup>, Maxime Masisa<sup>1</sup>, Vivian H. Alfonso<sup>2</sup>, Emile Okitolonda-Wemakoy<sup>1</sup>, Jean-Jacques Muyembe<sup>4</sup>, Pamina Gorbach<sup>2</sup>, Risa Hoffman<sup>5</sup>, Jeffery Klausner<sup>5</sup>, Anne W. Rimoin<sup>2</sup>

<sup>1</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, <sup>3</sup>University of California Los Angeles-DRC Research Program, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Institut National de Recherche Biomedical, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA, United States

*Schistosoma haematobium* (urinary schistosomiasis) infection is a common cause of morbidity among women in schistosomiasis endemic regions. Trematode ova deposition in genital mucosa can lead to inflammatory granulomas, bleeding, pain, and abnormal discharge. Moreover, these lesions are hypothesized to pose a risk for sexually transmitted infection (STI) acquisition and transmission, as they modify the mucosal layer of the genital tract and may alter the local immunologic milieu of infected women. In Kisantu, Democratic Republic of Congo, the overall prevalence of schistosomiasis is 61.8%; however, there is limited information on the prevalence of *S. haematobium* specifically or of STIs in the region. We conducted a cross-sectional study in four clinics providing prenatal and HIV care in Kisantu health zone, DRC from October 2016 to March 2017. A standardized questionnaire was administered to 352 consenting pregnant women, and biological samples (urine and vaginal/ endocervical swabs) were collected and analyzed. *Chlamydia trachomatis* (CT), *Neisseria gonorrhoea* (NG) and *Trichomonas vaginalis* (TV) were then tested for via nucleic acid amplification of vaginal swab samples [Xpert® CT/NG Assay and Xpert® TV Assay (Cepheid, Sunnyvale, CA)], and *S. haematobium* was detected via urine microscopy. The prevalence of *S. haematobium* in the study population was 15.1% (53/352). Among women with schistosomiasis infection, 28.9% were seropositive for HIV, while 18.6% were infected with at least one other STI: two percent of women were found positive for both CT/ *S. haematobium*, 5% were positive for both NG/ *S. haematobium*, and 14% were positive for both TV/ *S. haematobium*. The high prevalence of *S. haematobium* and presence of co-infection with HIV, CT, NG and TV found here among pregnant women is concerning, especially amidst mounting evidence of adverse maternal health and birth outcomes resulting from infection during pregnancy.

Factors related to co-infection should be further explored in order to determine the temporality of co-infective species acquisition, risk factors for co-infection, and consequences of co-infection on pregnancy.

## 1267

### ADDITION OF SNAIL CONTROL TO ACHIEVE DISEASE CONTROL TARGETS SCHISTOSOMIASIS: A COST-EFFECTIVENESS MODELING STUDY

**Nathan C. Lo**<sup>1</sup>, David Gurarie<sup>2</sup>, Nara Yoon<sup>2</sup>, Jean T. Coulibaly<sup>3</sup>, Eran Bendavid<sup>1</sup>, Jason R. Andrews<sup>1</sup>, Charles H. King<sup>2</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Université Félix Houphouët-Boigny, Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Swiss Tropical and Public Health Institute, University of Basel, Abidjan, Côte D'Ivoire

Schistosomiasis affects over 240 million people globally. There is growing interest in adding snail control interventions, but this is not currently emphasized as a global strategy. We aimed to assess the potential cost-effectiveness of various snail control strategies to guide future policymaking for disease control of schistosomiasis. We extended previously published dynamic, age-structured transmission and cost-effectiveness models to simulate mass drug administration (MDA) and snail control interventions against *Schistosoma haematobium*. We calibrated the model to data from low-burden (15% prevalence) and high-burden (48% prevalence) communities in rural Kenya. We simulated a 10-year intervention program with: i) MDA targeting school-aged children and the entire community at 75% coverage (annual and biannual); ii) snail control (annual and biannual); and iii) combined strategies. We estimated direct programmatic costs from literature and expert opinion, and computed the incremental cost-effectiveness ratio (ICER) in 2016 US\$ per disability-adjusted life year (DALY) averted, with a base case comparison of no intervention. We defined strategies as highly cost-effective if the ICER was less than the Kenyan GDP per capita (US\$1,377 US\$/DALY). In the low-burden setting, annual community-wide MDA with annual snail control was optimally cost-effective (ICER: 971 US\$/DALY with 76% of simulations being cost-effective). In the high burden setting, annual community-wide MDA with more frequent biannual snail control was optimally cost-effective (ICER: 486 US\$/DALY with 97% of simulations being cost-effective). In both settings, using the optimally cost-effective strategy reduced total disability by an additional 45% compared to school-based MDA alone over a 10-year period. These findings were sensitive to some programmatic inputs, including the country-specific willingness-to-pay threshold, which should inform generalizability to other settings. These results support inclusion of snail control in the current global guidelines for schistosomiasis.

## 1268

### ARE WE ON OUR WAY TO ACHIEVING THE 2020 GOALS FOR SCHISTOSOMIASIS MORBIDITY CONTROL USING CURRENT WHO GUIDELINES?

**Jaspreet Toor**<sup>1</sup>, James E. Truscott<sup>1</sup>, Ramzi Alsallaq<sup>2</sup>, Marleen Werkman<sup>1</sup>, Hugo C. Turner<sup>1</sup>, David Gurarie<sup>2</sup>, James E. Wright<sup>1</sup>, Sam H. Farrell<sup>1</sup>, Charles H. King<sup>2</sup>, Roy M. Anderson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States

Schistosomiasis remains an endemic parasitic disease affecting millions of people around the world. The World Health Organisation (WHO) has set goals for controlling schistosomiasis morbidity by 2020, along with its elimination as a public health problem in certain regions by 2025. Current WHO guidelines have been established to determine the frequency of treatment for a region depending on its baseline prevalence with a reevaluation done after 5-6 years after which the frequency of treatment may be adapted. Recent mathematical models developed to study the transmission dynamics of schistosomiasis can inform implementation policy

for mass drug administration programmes. Here, we use these models to predict whether the recommended guidelines set by the WHO are on track for reaching their 2020 goals for control of morbidity. In general, we find that the guidelines are sufficient in low to medium prevalence settings, however in high prevalence settings they are likely to fail. It also becomes harder to reach the goals in regions where school-aged children carry most of the infection as here higher levels of treatment are needed. Additionally, we find that although the prevalence of heavy-intensity infections is reduced in some scenarios, the overall prevalence remains high. In cases where the guidelines fail to meet the goals, we suggest alternative strategies, such as an increase in coverage, including the expansion of school-based to community-based treatment, along with an increase in compliance, which could assist in eliminating the morbidity of this disease.

## 1269

### CAA AND CCA DETECTION IN SCHISTOSOMIASIS: ASSURED DIAGNOSTIC TOOLS TO BE EMPLOYED WHEN MOVING FROM CONTROL TO ELIMINATION

**Govert J. van Dam**, Pytsje T. Hoekstra-Mevius, Claudia J. de Dood, Dieuwke Cornelis, Lisette van Lieshout, Paul L. Corstjens  
*LUMC, Leiden, Netherlands*

The renewed interest in mapping, intensified control and elimination of schistosomiasis (World Health Assembly Resolution WHA 65.21) has put the need for highly accurate diagnostic assays high on the agenda. Based on the well-studied schistosome antigen detection (CCA and CAA) ELISA's, a visual, field-friendly point-of-care urine test for CCA and a quantitative, ultra-sensitive reader-assisted assay for CAA have been developed. The CCA test is commercially available and may replace the Kato-Katz for prevalence mapping of community-level *S. mansoni* infections using a single drop of urine and also allows quick evaluation within days of treatment efficacy. The recently developed test for CAA is applicable to serum or urine of all schistosome species at sub-pg levels, which allows finding single worm infections. The assay has been transformed into a robust, dry-reagent test, used in several low-resource settings in Africa. In combination with optimized sampling schedules the CAA could rapidly identify *foci* of low prevalence/intensity of all human schistosome infections. Recent studies using the 2 ml urine format show that in near-elimination settings in China, South-East Asia, Africa and Brazil, prevalence of active schistosome infections by egg microscopy may be underestimated up to 10-fold. Also, decrease of CAA serum and urine levels after treatment has been shown in all effectively treated cases, however complete cure rates are very limited. The CAA strip assay therefore presents itself as a highly accurate diagnostic tool, with a clear value for application in control and elimination settings.

## 1270

### ASSESSING THE IMPACT OF INTENSIFIED TREATMENT STRATEGIES AGAINST UROGENITAL SCHISTOSOMIASIS IN NIGER

**Anna E. Phillips**<sup>1</sup>, Amina Amadou<sup>2</sup>, Amadou Garba<sup>3</sup>

<sup>1</sup>Imperial College, London, United Kingdom, <sup>2</sup>RISEAL Niger, Niamey, Niger, <sup>3</sup>World Health Organization, Geneva, Switzerland

Schistosomiasis is endemic across all of Niger. The National schistosomiasis control program commenced with mass drug administration in 2003 and to date the area has received over a decade of treatments. Both *Schistosoma haematobium* and *S. mansoni* are present, although *S. haematobium* is more common. The highest levels of infection are found along the Niger River Valley, with proximity to irrigation canals a major risk factor. In 2011 the SCORE project commenced in Niger, with a goal of providing an evidence-base and tools for programmatic decisions on how best to gain and sustain control of schistosomiasis, and, ultimately, elimination. The primary objective of the SCORE Niger study was to understand which treatment strategy provided the best reduction in prevalence and intensity of *S. haematobium*. In total 225 villages were

allocated to a four-year treatment strategy that aims to evaluate the impact of twice yearly versus annual treatment versus treatment every two years for urogenital schistosomiasis, both in the context of communitywide treatment (CWT) and school-based treatment (SBT). The villages had been divided into three possible groups with varying treatment combinations:

- Group A: Communities of moderate endemicity (10-24% prevalence) where annual SBT (ssss), biannual SBT (ssssx2), biennial SBT (shsh) and biannual SBT every two years (shshx2).
- Group B: Communities of high prevalence (>25%) where annual SBT (ssss), biannual SBT (ssssx2), biennial SBT (shsh) and biannual SBT every two years (shshx2).
- Group C: Communities of high prevalence were annual CWT (cccc) or biannual CWT (ccccx2). The findings showed that PZQ treatment resulted in an overall reduction in *S. haematobium* infection from Year 1 to Year 5, where the average prevalence went from 15.8% to 9.89%. The absolute difference between prevalence at Year 5 and baseline was greatest in high prevalence villages, with respect to moderate prevalence areas. Furthermore, biannual treatment resulted in a significantly greater reduction in prevalence, with respect to annual treatment, resulting in 9.1% and 1.3% decrease in prevalence respectively.

## 1271

### DYNAMIC OF SCHISTOSOMIASIS PREVALENCE FROM 2011 TO 2016 COHORT STUDY IN KALIFABOUGOU MALI

**Safiadou N. Doumbo**<sup>1</sup>, Kadiatou Sidibé<sup>1</sup>, Abdrahamane Traoré<sup>1</sup>, Jules Sangala<sup>1</sup>, Didier Doumtabe<sup>1</sup>, Aissata Ongoiba<sup>1</sup>, Tran Tuan<sup>2</sup>, Kassoum Kayentao<sup>1</sup>, Peter Crompton<sup>2</sup>, Boubacar Traoré<sup>1</sup>, Ogobara K. Doumbo<sup>1</sup>

<sup>1</sup>Malaria Research and Training Center/ICER/Mali, Bamako, Mali,

<sup>2</sup>Immunogenetic Lab, Rockville, WA, United States

Both Schistosomiasis, *Schistosoma haematobium* and *Schistosoma mansoni* are endemic in Mali. MDA with PZQ is widely applied in Mali since 2005. In Kalifabougou MDA with PZQ have been scaled up since 2010. The goal of this study is to evaluate schistosomiasis's prevalence after PZQ MDA. We have performed a cohort study with repeated cross sectional surveys from 2011 to 2016. Sixty hundred nineteen five (n=695) volunteers aged from 3months to 25 years old living in Kalifabougou village were included. Prevalence's of *Schistosoma haematobium* and *S. mansoni* eggs excretion were measured by urines filtration (*S.h*) and stools Kato Katz technic (*S.m*). During our surveys, all schistosomiasis positive were treated with single dose of Praziquantel. *Student t test*, ANOVA and Chi Square were used to compare means and proportions, with an alpha risk of 0.05. Six hundred seventy six (676) volunteers were included in 2011 and followed until 2016. The prevalence rate of *S.h* varied from 2011, 2013, 2014 with a progressive reduction 10.2%, 5.32%, and 5.25% respectively. However there was an increasing prevalence rate in 2015. This increases of *S.h* prevalence in 2016 was due to the missing campaign of PZQ MDA in 2014. This was corrected in 2015 and *S.h* prevalence was reduce in 2016 at 5.4%. Only one case of *S. mansoni* has been diagnosed in 2011. Children aged from 6 to 10 years old were more infected with *S.h*. In conclusion, MDA – PZQ is an efficient strategy for schistosomiasis control in Kalifabougou. But social science and parasite resistance additional studies are needed to explain the remaining 5% of *S.h* prevalence. These results could help elimination strategies.

### PRELIMINARY OBSERVATIONS ON THE FEASIBILITY OF USING A MAGNETIC PROBE FOR ISOLATION OF SCHISTOSOME EGGS FROM URINE

Renata Russo Frasca Candido<sup>1</sup>, Robert Charles Woodward<sup>1</sup>, Carlos Graeff-Teixeira<sup>2</sup>, Malcolm Kenneth Jones<sup>3</sup>, Timothy Guy St. Pierre<sup>1</sup>

<sup>1</sup>The University of Western Australia, Crawley, Australia, <sup>2</sup>Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil, <sup>3</sup>The University of Queensland, Brisbane, Australia

Genito-urinary schistosomiasis, caused by *S. haematobium*, is diagnosed by identification of eggs in urine samples. The aim of this study was to investigate the feasibility of using a high field gradient magnetic probe to rapidly concentrate and isolate schistosome eggs into 40- $\mu$ L droplets from 100-mL urine samples to enable detection of the eggs using an optical microscope. The probe consists of a device with a needle made from a metal that can be readily magnetized and demagnetized. In the magnetized state the tip of the needle becomes an attractor of any magnetized particles within an approximate 3-mm range. In the demagnetized state, any magnetic particles on the tip are released. To test the feasibility of using such a device for diagnosis of infection, twelve 100-mL urine samples were seeded with either 10, 20, 50, or 100 eggs. Each concentration was prepared in triplicate. Each 100-mL sample of seeded urine was allowed to sediment for 80 minutes in a sedimentation cup. The supernatant from each cup was discarded and 1 mL of urine remaining was transferred to an Eppendorf tube. A 1- $\mu$ L suspension of magnetic particles was added and the tubes were homogenized for 30 mins. Each tube was then stirred with the magnetized probe for 10 seconds. The probe was then withdrawn from the tube with material adhered to the tip. The material was then washed from the tip onto a glass microscope slide with 40- $\mu$ L of water with the probe in the demagnetized state. The droplet was then examined with an optical microscope. Slide examination took 3 to 5 mins during which eggs were counted. Eggs and magnetic particles were observed in all cases (ranging from as low as one egg per slide from the samples seeded with 10 eggs per 100 mL up to as high as 38 eggs per slide for the samples seeded with 100 eggs per 100 mL). In conclusion, the results demonstrate that the methodology has the potential for 100% sensitivity for rapid detection of eggs down to a concentration of 0.1 eggs per mL of urine and suggest further studies with field samples of *S. haematobium* infections are warranted.

### 1273

### SOCIAL DETERMINANTS OF PREVENTIVE CHEMOTHERAPY UPTAKE DURING MASS-DRUG ADMINISTRATION INTERVENTIONS FOR SCHISTOSOMIASIS IN SUB-SAHARAN AFRICA: A SYSTEMATIC REVIEW

Carlos A. Torres-Vitolas, Fiona Fleming, Nadia Ben Meriem, Neerav Dhanani, Elizabeth Hollenberg

*Schistosomiasis Control Initiative, Imperial College London, London, United Kingdom*

Achieving sustained high-uptake of preventive chemotherapy treatment is key for controlling and eliminating schistosomiasis (SCH) in Sub-Saharan Africa. Despite growing investment in mass-drug administration (MDA) interventions, low levels of coverage are often reported in the region. This review aims to identify socioeconomic and cultural determinants affecting at-risk populations' acceptance of, or compliance with, MDA of Praziquantel. The search strategy retrieved qualitative and quantitative studies published between 2002 and March 2017. Bibliographic databases Scopus, PubMed/MEDLINE, EMBASE, PsycINFO, CINAHL and Web of Science were examined. 2294 unique abstracts were identified, 61 underwent full-text screening and 27 were chosen for final review. Most studies came from Uganda (n=12). Quality assessment was conducted to assert strength of evidence. A framework synthesis following an

ecological model of health behavior was adopted to sort emerging themes. At the individual level, results indicate that fear of side effects, having an occupation associated with geographical mobility and limited knowledge of SCH infection dynamics or MDA details limit uptake. At the organizational level, community engagement in the selection of drug distributors (CDDs) and distribution strategies favor acceptance of MDA. Community-level barriers concern misrepresentations of medicine intake, mostly associated with disease-treatment rather than prevention, and of health interventions, considered to have a 'hidden' agenda due to historical distrust toward governments and foreigners. Pre-existence of legitimate community organizations facilitate MDA success. At the policy level, limited resource allocation for health training among CDDs seems to affect local trust whilst lack of material support constrains distributors' reach among distant households and large populations. Results call for widening sensitization campaigns beyond general awareness of SCH and expanding community engagement in MDA schemes. Additional support for frontline workers is needed. Regional bias in review's sources calls for further research.

Kurtis<sup>2</sup>, Hannah Wu<sup>1</sup>, Sunthorn Pond-Tor<sup>2</sup>, Palmera Baltazar<sup>3</sup>, Luz P. Acosta<sup>3</sup>, Remigio M. Olveda<sup>3</sup>, Veronica Tallo<sup>3</sup>, Jennifer F. Friedman<sup>1</sup>

<sup>1</sup>Department of Pediatrics, The Warren Alpert Medical School of Brown University, Providence, RI, United States, <sup>2</sup>Department of Pathology, The Warren Alpert Medical School of Brown University, Providence, RI, United States, <sup>3</sup>Research Institute for Tropical Medicine, Manila, Philippines, Leyte, Philippines

We have previously demonstrated that maternal schistosomiasis is associated with elevated pro-inflammatory cytokines in maternal, placental, and cord blood. In this study, we evaluated the factors associated with shifts in maternal and newborn cytokine profiles, and their association with adverse perinatal outcomes, using samples from a recently completed placebo-controlled trial evaluating praziquantel treatment for schistosomiasis among pregnant women enrolled at 12 – 16 weeks' gestation. Cytokine levels in maternal, placental and cord blood were measured using a bead-based assay (IL-1, 2, 4, 5, 6, 8, 10, 12, and 13, IFN- $\gamma$  and TNF- $\alpha$ ). Cytokines >90th percentile were regarded as elevated. Regression models evaluated the relationships among placental and cord blood cytokines, perinatal outcomes, praziquantel treatment and helminth coinfection. In maternal peripheral blood, IL-6 and IL-8 decreased significantly from 12 to 32 weeks' gestation in both arms, while IL-13 increased only in the praziquantel arm. In addition, the proportion of women with elevated TNF- $\alpha$  at 32 weeks' gestation and placental IL-6 was higher in the praziquantel arm ( $P=0.03$  and  $P=0.04$ , respectively). Hookworm infection was associated with elevated placental IL-4 ( $p=0.023$ ), IL-8 ( $p=0.028$ ) and IFN- $\gamma$  ( $p=0.022$ ). Regarding the association with cytokines and adverse birth outcomes, elevated cord blood IL-2 was associated with the risk of LBW (RR: 2.35; 95% CI: 1.06 – 5.19). The risk of SGA was greater when IL-8 (RR=1.74; 95% CI: 1.11 – 2.72) and IL-13 (RR=1.67; 95% CI: 1.07 – 2.61) in placental blood, and IL-8 (RR=2.37; 95% CI: 1.27 – 4.40) and IL-2 (RR=1.80; 95% CI: 1.01 – 3.21) in cord blood were elevated. Neonatal iron deficiency was associated with elevated cord blood IL-1 (RR=8.77; 95% CI: 1.19 – 64.5). Taken together, these data strengthen the evidence that cytokines in maternal and cord blood may be related to poor intrauterine growth, and helminth coinfections may significantly influence cytokine concentrations. Studies to better define when to treat women for helminth infections that may impact placental and newborn health are needed.

## 1275

**AN EVOLUTION OF PARASITOLOGICAL- AND SEROLOGICAL-BASED METHODS FOR DIAGNOSIS OF INTESTINAL SCHISTOSOMIASIS IN HIGH-LOW ENDEMIC SETTINGS**

Hajri Alshehri<sup>1</sup>, Michelle C. Stanton<sup>1</sup>, Aaron Atuhaire<sup>2</sup>, Moses Arinaitwe<sup>2</sup>, Aida Wamboko<sup>2</sup>, Moses Adriko<sup>2</sup>, Narcis B. Kabatereine<sup>2</sup>, J. Russell Stothard<sup>1</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Vector Control Division, Ministry of Health, Kampala, Uganda

Infection with intestinal schistosomiasis is typically common in children, particularly within regions of sub-Saharan Africa where environmental water contact is high and access to adequate sanitation is poor. Traditional parasitological methods of diagnosis that visualise parasite ova underestimate true prevalence and as control programmes progress, infection egg-tallies may also decline. Consequently, there is a need to develop better methods for detection of schistosomiasis, especially in countries such as Uganda where ongoing school-based control has taken place for over a decade. Against this country-backdrop, we investigate the application of novel diagnostics to shed light on current levels of infection across 5 primary schools within Buliisa District, Lake Albert. We evaluated parasitological- and serological-based methods alongside real-time PCR and focused upon examination of children of school-age (i.e. 5-10 years). PCR-based methods explored the use of Taqman® assays on faecal samples. We assessed the diagnostic congruence between methods and report that intestinal schistosomiasis is still pervasive within this lakeshore environment.

## 1276

**EFFICACY AND SAFETY OF PRAZIQUANTEL IN PRESCHOOL-AGED AFRICAN CHILDREN WITH INTESTINAL OR URINARY SCHISTOSOMIASIS - AN INDIVIDUAL-PATIENT DATA META-ANALYSIS**

Preschool-aged children are recognized as vulnerable group for schistosomiasis, but cannot be treated easily with praziquantel because the drug is registered only for children >4 years-old and can be given routinely only to those >60 cm-tall, in the absence of a paediatric formulation. Moreover, uncertainties persist as to the right dose of praziquantel that is effective and safe in young children, although a recent aggregated-data meta-analysis including 1694 preschool-aged children found no significant difference in efficacy with respect to school-aged children, as reported previously. We conducted an individual-patient data meta-analysis of 4 studies enrolling a total of 1600 children, of whom 899 were preschool-aged (<6 year-olds, mean age 3.8 years) (458 boys, 441 girls); of these, 417 were infected with *S. mansoni* (baseline arithmetic mean

ranging 32-80 eggs/gram of faeces in 4 studies) and 99 with *Schistosoma haematobium* (baseline arithmetic mean 24 and 118 eggs/ml of urine in 2 studies). After praziquantel 40 mg/kg treatment, 352 and 90 respectively had a follow-up visit at which they were found to have arithmetic mean egg reduction rate (ERRam) of 21% (180-d follow-up), 49% (42-d follow-up), 99% (84-d follow-up) and 100% (42-d follow-up) in the four trials of *S. mansoni*, and 93% and 100% in the 2 *S. haematobium* trials. Efficacy of praziquantel 40mg/kg in preschool-aged children varied.

## 1277

**PREVALENCE OF SCHISTOSOMA MANSONI INFECTION AND OTHER PARASITIC DISEASES IN PERIPHERAL AREAS OF BARRA MANSA, RIO DE JANEIRO, BRAZIL**

Espírito-Santo<sup>1</sup>, Pedro Paulo Chieffi<sup>2</sup>, Fabiana Martins de Paula<sup>2</sup>, Vera Lúcia Pagliusi Castilho<sup>2</sup>, Elenice Messias do Nascimento Gonçalves<sup>2</sup>, Magali Orban<sup>2</sup>, João Renato Rebello Pinho<sup>2</sup>, João Renato Rebello Pinho<sup>2</sup>, Expedito José de Albuquerque Luna<sup>2</sup>, Ronaldo Cesar Borges Grysckek<sup>2</sup>

<sup>1</sup>Centro Universitário de Volta Redonda, UniFOA; Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, <sup>2</sup>Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Schistosomiasis mansoni and other intestinal parasites are chronic infections widely spread in the world. Globally, about two billion individuals are infected with parasites and most of them live in resource-poor conditions. Schistosomiasis mansoni continues to be one of the most serious world public health problems and it occurs in 76 countries worldwide. In Brazil, about six million individuals are infected with *Schistosoma mansoni*. The city of Barra Mansa (RJ) is a low transmission area with an estimated prevalence of 1%. The aim of this study was to determine the prevalence of *S. mansoni* infection and other intestinal parasites in five peripheral areas of Barra Mansa/RJ. This was a cross-sectional study conducted from March 2011 to February 2012. The samples were randomly selected from the population. A total of 650 individuals who freely agreed to participate were selected, and we obtained 610 fecal samples. All samples were assayed by using two slides with the Kato-Katz (KK) method using the Helm Test® Kit (Fiocruz) and two slides for Hoffman, Pons & Janer (HH). The slides were analyzed by the Laboratory of Clinical Parasitology of the Central Laboratory Division of the Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Brazil. At the end of the analysis, the results were sent to the Secretary of Health of Barra Mansa, responsible for reporting them and treating the infected individuals. The age of participants ranged from 10 to 91 years, represented by 40.8% males and 59.2% females. The prevalence of parasites found were: *Endolimax nana* 17.4% (n=106); *Blastocystis* spp. 10.8% (n=66); *Entamoeba coli* 4.7% (n=28); *Giardia intestinalis* 1.8% (n=11); *Strongyloides stercoralis* 1.5% (n=9); *Enterobius vermicularis* 0.8% (n=5); *Schistosoma mansoni* 0.8% (n=5); *Ascaris lumbricoides* 0.5% (n=3); *Trichuris trichiura* 5% (n=3); *Taenia* spp. 0.3% (n=2); *Iodamoeba butschlii* 0.2% (n=1). The global prevalence of intestinal parasites was 27.9% (n = 170). The results of this study show the information available to date on these parasites in this population and represent a communication strategy to control these infections.

## 1278

**REVEALING BIOTIC DIVERSITY: HOW DO COMPLEX ENVIRONMENTS OFFER NOVEL WAYS TO CONTROL HUMAN SCHISTOSOMIASIS?**

Martina R. Laidemitt<sup>1</sup>, Martin W. Mutuku<sup>2</sup>, Gerald M. Mkoji<sup>2</sup>, Eric S. Loker<sup>1</sup>

<sup>1</sup>University of New Mexico, Albuquerque, NM, United States, <sup>2</sup>Centre for Biotechnology Research and Development, Kenya Medical Research Institute (KEMRI), Nairobi, Kenya

The growing discipline of disease ecology emphasizes understanding the biotic context in which disease transmission occurs. Such a perspective

is important for understanding transmission of human schistosomiasis in complex tropical aquatic habitats. In western Kenya, *Schistosoma mansoni* is transmitted by *Biomphalaria pfeifferi* in streams and by *B. sudanica* on the shoreline of Lake Victoria. We have undertaken bi-monthly surveys at each habitat where we collect data on abiotic factors, snail densities, and prevalence of larval trematode infections. Our study has revealed that stream transmission sites harbor dynamic populations of 8 different snail species, some of which may compete with *B. pfeifferi* or serve as dead-end hosts for *S. mansoni*. In Lake Victoria shoreline transmission sites, 11 snail species are noted and comprise a different subset of species than found in streams. Habitat use also differs dramatically with respect to vertebrate hosts, with cattle being particularly prominent along streams and with several wild bird species being conspicuous at lakeside habitats. The communities of digenetic trematodes inhabiting stream and lakeshore habitats have also been shown to differ considerably, including the species colonizing *Biomphalaria* snails as first intermediate hosts. In addition to *S. mansoni*, molecular analysis has shown *B. pfeifferi* to harbor 14 additional trematode species, and local prevalence, particularly because of the abundance of cattle-transmitted amphistomes, can rise to 25%, with overall *S. mansoni* prevalence of 4.9%. *Biomphalaria sudanica* transmits 18 species of digenetic trematodes in addition to *S. mansoni*, but the overall prevalence of infection is lower (12%), as is the prevalence of *S. mansoni* (0.4%). We have also established a dominance hierarchy among the trematode species infecting *Biomphalaria* that includes consideration of both predatory interactions and facilitation among the species involved. Further studies will document the extent to which *S. mansoni* transmission may be dampened by the complex webs of competing snails and schistosomes present in typical transmission sites.

## 1279

### EXAMINING THE IMPACT OF THE SCHISTOSOMIASIS CONTROL INITIATIVE ON PRAZIQUANTEL COVERAGE IN SUB-SAHARAN AFRICAN SCHOOLCHILDREN

**Ashley Tseng**, Stephen Lee, Grace O'Brien, Natalie Dang  
McGill University, Montreal, QC, Canada

Schistosomiasis, a two millenia-old neglected tropical disease caused by parasitic worms, is prevalent in marginalized communities without access to safe drinking water and adequate sanitation. *Schistosoma mansoni* and *Schistosoma haematobium* are the two species of blood fluke in Africa. It is estimated that 218 million people required preventive treatment for schistosomiasis in 2015 and 90% of those requiring treatment live in Africa. Praziquantel, an anthelmintic drug, is recommended to treat schistosomiasis infections as it is safe and effective with few adverse effects. Praziquantel coverage consists of distributing the drug to infected parts of the population and putting adequate monitoring in place to assure that the treatment reaches the individuals and is taken properly. In examining the impact of the Schistosomiasis Control Initiative (SCI) on praziquantel delivery and coverage, we seek to analyze the SCI's implementation methods and strategic challenges present in executing control programs in Sub-Saharan Africa. The SCI was established in 2002 with the goal of reducing the global burden of neglected tropical diseases in sub-Saharan Africa by 2030 in accordance with the United Nations Sustainable Development Goals. SCI's role has been to identify country recipients, provide funding to governments for implemented programs, provide advisory support, and conduct monitoring and evaluation on the control programs. Strategic challenges faced by SCI include prioritizing resources, inadequate health care facilities and staff, environmental challenges, public health measures, and sustainability. The SCI predominantly focuses on facilitating vertical mass drug administration, an intervention that historically has had limited benefits in controlling schistosomiasis when used alone. Interrupting transmission through preventative chemotherapy, snail control, improved sanitation and access to safe water, or increased health education are alternative methods to accelerate the elimination of schistosomiasis. We hope this review of SCI's past methods can serve as a pathway to improved control programs in the future.

## 1280

### MOVING FROM CONTROL TO ELIMINATION OF SCHISTOSOMIASIS IN SUB-SAHARAN AFRICA: TIME TO CHANGE AND ADAPT STRATEGIES

**Louis-Albert Tchuem Tchuente**

University of Yaoundé I, Yaoundé, Cameroon

Within the past decade, significant progress has been made on large scale treatments for the control of schistosomiasis. Today, treatment with praziquantel is cost-effective and 'preventive chemotherapy' is the strategy of choice, endorsed by WHO. In sub-Saharan Africa, the landscape is becoming ever more heterogeneous as there are several species of *Schistosoma* that respond in different ways to ongoing preventive chemotherapy. The major focus of preventive chemotherapy is delivery of praziquantel by mass drug administration to those shown to be, or presumed to be, at-risk of infection and disease. In some countries, regional progress may be uneven but in certain locations there are very real prospects to transition from control into interruption of transmission, and ultimately elimination. To manage this transition requires reconsideration of some of the currently deployed diagnostic tools used in surveillance and downward realignment of existing prevalence thresholds to trigger mass treatment. Current strategies were designed primarily for the control of morbidity due to schistosomiasis and were formulated over two decades ago when the availability of praziquantel was limited. Moving from control to elimination of schistosomiasis is a paradigm shift that creates several challenges. The interruption of schistosomiasis transmission requires significant changes in the approach, design and strategies with a focus on reducing transmission and preventing reinfection. This involves several challenges such as implementation of intensified interventions, expansion of treatment coverage, use of alternative strategies, improvement of clean water supply, sanitation and hygiene, health education, reaching hard to reach and vulnerable communities, adapting treatment to transmission dynamics, mapping quality and uncertainties, redefining disease endemicity and focality for eligibility for MDA, monitoring and evaluation, and strengthening of institutional capacities. The presentation will highlight and discuss some of the key challenges and requirements for schistosomiasis elimination in sub-Saharan Africa.

## 1281

### AN IMPACT EVALUATION OF LARGE-SCALE WATER, SANITATION AND DRAINAGE INFRASTRUCTURE IMPROVEMENTS IN LUSAKA, ZAMBIA: PRELIMINARY FINDINGS IN THE DRAINAGE CATCHMENT AREA

**Sydney C. Hubbard**<sup>1</sup>, Manjunath B. Shankar<sup>1</sup>, Bishwa B. Adhikari<sup>1</sup>, Warren Malambo<sup>2</sup>, Sunkyoung Kim<sup>1</sup>, Martin I. Meltzer<sup>1</sup>, Joan M. Brunkard<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Centers for Disease Control and Prevention, Lusaka, Zambia

The Government of Zambia is upgrading and extending water, sanitation, and drainage infrastructure in Lusaka. As part of a planned pre- and post-evaluation of these upgrades and extensions, we conducted a baseline household survey to estimate the impact of the rehabilitation of Lusaka's central drainage on incidence of disease, flooding frequency and duration, household travel time, and employment and expenditure patterns. From January-May 2016, we surveyed 3,142 randomly selected households within 250 meters of the drain. We found that 19% of households had at least one member who had diarrhea (at least three loose stools in a 24 hour period) or respiratory illness [fever and (cough and/or sore throat)] in the 7 day period prior to interview. The incidence of diarrheal illness was 3.0% overall and 7.8% for children <5 years; 6% of individuals with diarrhea reported blood in their stool. Median duration of illness was 3 days (range 1-32). Respiratory illness incidence was 2.4% overall and 7.0% for children <5 years. Median duration of illness was 4 days (range 1-40). Of 1,064 children for whom an under-5 vaccination card was available,

68% were fully vaccinated against rotavirus (had received two doses); 6% had received one dose, and 24% had not been vaccinated. Sixty percent of households reported flooding in the month prior to the interview. Mean duration of flooding was 3.3 days, median 2 days (range 1-31). Median reported travel times were significantly longer during periods with flooding compared to periods without, for both school (15 minutes vs. 25 minutes,  $p < 0.0001$ ) and work (30 minutes vs. 40 minutes,  $p < 0.0001$ ). The majority of households (90%) had at least one adult member employed. Surveyed households spent a mean of \$157 per month on food items. This is similar to the mean of \$161 per month for non-food items (which includes rent). Relatively large proportions of household expenditures on food are indicative of low-income households. Given these baseline measurements, it is anticipated that improvements in drainage in central Lusaka could have a notable effect on the incidence of disease, flooding frequency, household travel time and time use.

## 1282

### WATER TREATMENT FOR THE REMOVAL OF *SCHISTOSOMA CERCARIAE*: A REVIEW AND IDENTIFICATION OF RESEARCH NEEDS

**Laura Braun**, Jack E. Grimes, Michael R. Templeton  
*Imperial College London, London, United Kingdom*

Schistosomiasis control currently focuses on preventive chemotherapy with praziquantel, which is effective, safe and inexpensive. However, this treatment does not prevent subsequent reinfection. As schistosomiasis control targets become more ambitious and move towards elimination, interest is increasing in the potentially complementary roles of water, sanitation and hygiene (WASH) interventions which may disrupt transmission of the parasite, thereby slowing reinfection following treatment. In particular, water treatment for schistosomiasis control seeks to eliminate viable *Schistosoma* cercariae from water. A systematic review was carried out to summarize the existing knowledge on the effectiveness of water treatment for the removal or inactivation of cercariae, by processes including chlorination, filtration and ultraviolet disinfection, as well as water storage. This is the first review of its kind and provides a concise summary of what is known to-date regarding water treatment and cercariae of different *Schistosoma* species. The review also identifies gaps in knowledge and provides crucial and timely guidance for the control and elimination of schistosomiasis, by highlighting the requirements for designing effective, sustainable water infrastructure that minimises re-exposure to cercariae in water.

## 1283

### ENVIRONMENTAL PATHOGEN IDENTIFICATION TO CHARACTERIZE SANITATION LEVELS IN LOW AND MIDDLE INCOME COUNTRIES

**Leon Espira**, Joseph N. Eisenberg  
*University of Michigan, Ann Arbor, MI, United States*

The provision of clean water and access to sanitation is central to the goals set in 2015 by the Sustainable Development Goals (SDGs). The reason for the prominence of water and sanitation in the SDGs is that 2.4 billion people still lack access to basic water and sanitation facilities, placing them at higher risk of diarrheal diseases that remain one of the leading causes of death for children under 5. Current approaches to prevent diarrheal disease and chronic sequelae, however, focus primarily on increasing access to sanitation facilities and less on minimizing transmission of enteric or waterborne pathogens. In light of recent mixed results from randomized control trials evaluating sanitation interventions, it is necessary to take a systems level approach when examining intervention strategies. This systems approach is further necessitated by the fact that enteric pathogens have multiple and often interdependent transmission pathways. An important input of a systems level approach is the accurate measurement of environmental pathogen loads. TaqMan Array Cards provide an efficient means of collecting genomic pathogen identification data from the

environment that is accurate, reliable and allows for the quantification of environmental pathogen concentrations. We present a study plan that used TaqMan Array Cards to characterize the spatio-temporal contamination levels of 40 enteric pathogens in Ethiopian and Mexican communities. We sampled sample both home and shared environments to characterize how sanitation interventions impact pathogen loads in both these environments.

## 1284

### EFFECTS OF A COMBINED WATER QUALITY, SANITATION, HANDWASHING AND NUTRITIONAL INTERVENTION ON TELOMERE LENGTH AMONG YOUNG CHILDREN IN RURAL BANGLADESH

**Audrie Lin**<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>, Andrew N. Mertens<sup>1</sup>, Jue Lin<sup>2</sup>, Jade Benjamin-Chung<sup>1</sup>, Shahjahan Ali<sup>3</sup>, Abul K. Shoab<sup>3</sup>, Md. Ziaur Rahman<sup>3</sup>, Md. Saheen Hossen<sup>3</sup>, Palash Mutsuddi<sup>3</sup>, Syeda L. Kariger<sup>1</sup>, Lia C. Fernald<sup>1</sup>, Alan E. Hubbard<sup>1</sup>, Christine P. Stewart<sup>5</sup>, John M. Colford, Jr.<sup>1</sup>, Stephen P. Luby<sup>6</sup>

<sup>1</sup>University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>4</sup>University of Miami, Miami, FL, United States, <sup>5</sup>University of California Davis, Davis, CA, United States, <sup>6</sup>Stanford University, Stanford, CA, United States

Early life exposures to stress may increase susceptibility to disease later in life. Telomere length (TL) is a prognostic marker of cellular aging and various diseases and could play a causal role in health or disease. Most studies suggest that faster childhood TL attrition is an indication of early life adversity. However, the trajectories of infant TL in low-income settings, the potential effects of childhood interventions on TL, and whether TL is a robust marker to evaluate stress-reducing interventions in children are all unknown. We evaluated whether combined water, sanitation, handwashing, and nutritional interventions improved TL during the first two years of life. We conducted a cluster-randomized trial in rural Bangladesh where geographical clusters of pregnant women were randomized into individual or combined interventions (ClinicalTrials.gov, NCT01590095). This substudy included children in the control and the combined water, sanitation, handwashing, and nutrition arms. Outcomes include TL at 1 and 2 years after intervention and the change in relative TL between years 1 and 2. Analysis was intention-to-treat. We randomized 720 clusters in the control and intervention arms; of these, we measured TL in 662 children at Year 1 (age ~14 months) and 713 children at Year 2 (age ~28 months). TL was normally distributed, and the mean  $\pm$  SD whole blood TL was  $1.43 \pm 0.23$  telomere to single-copy gene ratio (T/S) units at Y1 ( $6729 \pm 549$  base pairs) and  $1.45 \pm 0.24$  T/S units at Y2 ( $6763 \pm 586$  base pairs). We are currently performing the blinded analyses of intervention effects and will unblind after analyses are completed in May 2017. Understanding the critical molecular pathways contributing to TL and its attrition during early life would highlight the potential use of TL as a prognostic marker for future health risks and provide a potential target for future intervention development and evaluation.

## 1285

### ANTIBIOTIC RESISTANT *E. COLI* IN DRINKING WATER SAMPLES FROM RURAL ANDEAN HOUSEHOLDS IN CAJAMARCA, PERU

**Stella M. Hartinger**<sup>1</sup>, Maribel Riveros<sup>1</sup>, Gabriela Salmon-Mulanovich<sup>1</sup>, Hector Verastegui<sup>1</sup>, Nestor Nuño<sup>2</sup>, Guido Bendezu<sup>1</sup>, Theresa J. Ochoa<sup>1</sup>, Daniel Mäusezahl<sup>2</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Antibiotic resistance in pathogenic bacteria is a serious public health issue. The growing threat is a cause for concern and action to prevent the emergence of new resistant strains and the spread of existing ones to humans via the environment. This study was aimed at identifying faecal pathogens in drinking water obtained from rural Andean households from Cajamarca, Peru and measuring the antibiotic resistance profile of *Escherichia coli*. The study was embedded within a community-randomised controlled trial among 102 communities in the northern highlands of the Cajamarca Region, Peru. Generic *Escherichia coli* was isolated from drinking water of 320 households at baseline measurements. The antibiotic resistance pattern was determined against twelve commonly used antibiotics, using the Kirby bauer method. Out of 314 samples collected, 55.4% (n=174) were positive for thermotolerant coliforms. *E. coli* was isolated in 74% of these (n=117), *Klebsiella* spp. in 15.8% (n=25), *Enterobacter* spp. 10.1% (n=16) and *Citrobacter* spp. in 5% (n=8). We isolated multiple thermotolerant bacteria in 14% of the samples. The *E. coli* antibiotic resistance profile showed highest resistance against tetracycline (37.6%), followed by ampicillin (34.2%), sulfatrimethoprim (21.4%), and naladixic acid (13%). The high prevalence of faecal contamination in drinking water highlights the importance of household water treatment methods. Likewise, the high levels of antibiotic resistance found, urges to identify the origins of potential environmental contamination or misuse of antibiotics. Elucidating means for the safe disposal of antibiotic containing waste in this context and promoting such practices is essential.

## 1286

### WATER, SANITATION AND HYGIENE EDUCATION IN SCHOOLS TO PREVENT NEGLECTED TROPICAL DISEASES IN ANGOLA: A PROGRAM REVIEW

**Vasco Carvalho**, Fiona Vincer

*The MENTOR Initiative, Crawley, United Kingdom*

Angola hosts many endemic NTDs that have a detrimental impact on child health, school attendance and quality of life. Concurrently, much of the country suffers from inadequate access to improved water sources and other essential WaSH services. Since 2015 The MENTOR Initiative have been implementing a WaSH education (WASHE) program alongside the government across three provinces in Angola (Huambo, Uige and Zaire). The program aims to increase handwashing practice in school-aged children and incorporate WaSH into the national primary school curriculum - striving for behavior change in schools and empowering the local community. In those three provinces the baseline KAP survey showed that on average, 86% of schools had no handwashing facilities at all and 49% had no access to safe drinking water. Sanitation levels were more promising with 48% of schools with access to basic sanitation, although 31% reported open defecation. The main program activities comprise teacher training and follow up supervisions. The training teaches good WaSH practices and develops a skill-based health education. Supportive supervisions monitor the impact of the training and work with schools to apply its teaching in context. During 2015, 1,082 teachers and directors were trained through the WASHE program - education centered on inclusion, participation and active learning. The attendance rate was excellent and teachers improved their test results by nearly 100% during the training. The program indicators show that, on average, all provinces

improved in all WaSH elements after training, especially in handwashing. Zaire province had the greatest improvement in water and handwashing practices, whilst unfortunately Uige has shown no improvement in sanitation from the baseline. The preliminary program results compare with international WaSH indicators and service ladders, although it is too soon to conduct a full impact assessment.

## 1287

### THE ROLE OF GENDER INEQUITY IN COMMUNITY-LEVEL SOCIAL ORGANIZATION AND REDUCED ENTERIC INFECTION IN RURAL, COASTAL ECUADOR

**Sonia T. Hegde**<sup>1</sup>, James Trostle<sup>2</sup>, Joseph Eisenberg<sup>1</sup>

<sup>1</sup>University of Michigan, Ann Arbor, MI, United States, <sup>2</sup>Trinity College, Hartford, CT, United States

Despite dramatic reductions in childhood mortality in the past decade, diarrhea remains a major cause of preventable childhood deaths worldwide. Well known measures to prevent diarrheal infection include good water, sanitation, and hygiene (WASH) practices. These behavioral practices, however, are influenced by a multitude of factors, including social organization. Women experience a continual tradeoff in daily tasks, particularly in low-resource settings, and play a unique role in influencing community-level social organization. Previous studies conducted on coastal Ecuadorian population have identified that a greater density of social ties between individuals in remote communities may lead to the spread of WASH practices, both individual and collective, and reduced diarrheal disease, however the role of gender was not examined. This study identifies how gender roles at the individual- and community-level are related to social organization in the context of WASH in 18 communities in rural, coastal Ecuador. From August to November 2016, we conducted in-depth interviews with men and women (5 per gender), and 4 focus groups in each community. Focus groups were purposively conducted with community leaders, adult men, adult women, and youth (13-18 years of age). Using a grounded theory approach, the study team transcribed, coded, and discussed interviews for a thematic analysis. We found that women experience a distinct set of stressors, largely, environmental, social, and sexual, and men play a critical role in creating gender equity within communities. Communities with higher agency amongst women, experience high social organization. Furthermore, both men and women identify water insecurity as a primary stress and deterrent to social organization. The intensity of the stressors experienced by women were modified by ethnicity, living environment, and access to a natural water source. This study has the potential to inform context-specific and gender-sensitive interventions.

## 1288

### THE MODERATING EFFECT OF SOCIAL CAPITAL ON WATER AND SANITATION RELATED ADVERSE PREGNANCY OUTCOMES

**Kelly K. Baker**, William T. Story, Cody Hansen, Evans Walsler-Kuntz, Miriam B. Zimmerman

*University of Iowa College of Public Health, Iowa City, IA, United States*

Recent research found that women in rural India who open defecate or who bathe in public surface waters experience higher levels of preterm birth and low birth weight outcomes than women who use a latrine or bathe with an improved water source. Pregnancy outcomes could be caused by the daily physical stress of fetching water or leaving the home to seek a safe, private location to defecate and bathe. Addressing hygiene needs in public places also exposes women to social stressors, which may be more common in communities with high crime or harassment of women, or low social cohesion or social efficacy. This retrospective cohort study examined the effect of social capital on the association between water and sanitation access and pregnancy outcomes in 6,453 women who gave birth to a child between 2004 and 2011 waves of the India Human Development Survey. The prevalence of preterm birth or low

birth weight infancy was 14.2% and 15.0%, respectively. Unadjusted logistic regression analysis found that open defecation (vs private latrine use) was associated with preterm and low birth weight, sharing an in-building latrine was associated with preterm birth, and spending > 2 hours per day fetching water (vs <2 hours) was associated with low birth weight. Improved water access was not associated with either outcome. In fully adjusted models, fatigue and anemia accounted for the observed associations between open defecation and in-building shared latrines with preterm birth, but public latrine use remained negatively associated with preterm birth (Odds Ratio (OR)=0.16; 95% Confidence Interval (CI)=0.08, 0.33). This may be due to skewed levels of wealth among public latrine users. Of social factors, harassment of women was associated with preterm birth (OR=1.70; CI=1.39, 2.07) and low birth weight (OR=1.24; 95% CI=1.02, 1.51). The effect of harassment of women on adverse pregnancy outcomes in Indian women suggests stress-moderated pathways. Anemia and fatigue-mediated sanitation effects on preterm birth could reflect stress or helminth infection pathways. More research on how social factors and water and sanitation access affects pregnancy outcomes is needed.

## 1289

### SOAP ON A ROPE HALL PASS: A RANDOMIZED CONTROLLED TRIAL OF A DISRUPTIVE CUE TO IMPROVE HANDWASHING BEHAVIOR IN NAMWALA DISTRICT, ZAMBIA

**Ilenga Nkhata**<sup>1</sup>, Christina Wakefield<sup>2</sup>, Laurie Markle<sup>1</sup>, Rim Abdullah<sup>3</sup>, David A. Larsen<sup>3</sup>

<sup>1</sup>Akros, Lusaka, Zambia, <sup>2</sup>The Manoff Group, Washington, DC, United States, <sup>3</sup>Syracuse University, Syracuse, NY, United States

The Zambian Ministry of General Education has made strides in improving sanitation across schools, which is known to improve student health, decrease absenteeism and improve learning. Extensive work has been done to reshape policies and guidelines for school water, sanitation and hygiene (WASH). However, access to handwashing facilities and behaviours continue to lag. Several partners in the Zambian WASH sector have used a variety of interventions in schools to improve handwashing, including the provision of handwashing stations. We are conducting a school-randomized trial to evaluate the effectiveness of disruptive cues to improve observed handwashing among primary school-aged children in Zambia. The disruptive cue in this evaluation is a bar of anti-bacterial soap threaded with a piece of rope to be used as a hall pass as students leave the classroom to use pit-latrines. The primary outcome for the evaluation to determine the effectiveness of the trial intervention will be the proportion of school-aged children that wash their hands upon exit from the latrine. This outcome will be measured through latrine-exit observation by an unobtrusive observer at three time points: pre-intervention, 1-month post-intervention, and 3 months' post-intervention for both intervention and control groups. Baseline data collection is scheduled to occur in May, 2017, with the intervention occurring shortly thereafter. Follow-up data collection will occur in June and August 2017, with final analyses conducted by October 2017.

## 1290

### IMPACT OF IMPROVED WATER AND SANITATION PRACTICES ON DIARRHEAL INCIDENCE IN CHILDREN <5 IN A MOUNTAINOUS NORTHEAST PAKISTANI VILLAGE

**Aysha Khan**<sup>1</sup>, Ejaz Hussain<sup>1</sup>, Syed Iqbal Azam<sup>2</sup>, Farah Bader<sup>1</sup>, Lexy Jamison<sup>1</sup>, Sahrish Durrani<sup>1</sup>, Elizabeth Thomas<sup>1</sup>, Julia M. Baker<sup>1</sup>, Saba Wasim<sup>2</sup>, Wasi Shah<sup>1</sup>, Khalil Ahmed<sup>3</sup>, Zeba Rasmussen<sup>1</sup>

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>The Aga Khan University, Karachi, Pakistan, <sup>3</sup>Karakorum International University, Gilgit, Pakistan

From 1989-1996, diarrhea was the second highest cause of childhood mortality in Oshikhandass, Gilgit-Baltistan, where the main water source was untreated glacier melt and toilet facility the traditional pit latrine

(*chukan*). Interventions (water filtration plants, composting pit-latrines, flush-toilets) were introduced from 1996-2002. From 2011-2014, a socioeconomic household (HH) survey (SES) on toilet type and water source and treatment was conducted, and diarrhea incidence re-assessed. Lady Health Workers (LHWs) trained in diarrhea management (WHO-IMCI) did weekly surveillance of children <5 years. LHWs classified diarrheal episodes by severity, gave treatment (ORS, zinc, antibiotics if bloody) or referred, and followed up until recovery. LHWs and social scientists collected SES data on water and sanitation practices. Improved water use meant use of a functional water filtration plant or mineral water and water treatment (boiling, chlorination). Sanitation improvements meant use of flush toilets or new pit latrines. In 1989-96, incidence of diarrhea was 65 episodes/100 child years; in 2011-14, incidence was similar at 68. Diarrheal incidence was lower in households with only new toilets than in those with old toilets (83 vs. 105, Incidence rate ratio 0.8, 95% CI 0.7-.9). Incidence was lower in households using new water sources than in those with old sources (73 vs. 97, incidence rate ratio 0.75, 95% CI 0.66-.86). Treatment of water by boiling or chlorination made no difference to incidence of diarrhea in HH using either old or new water sources. Households that used new toilets had significantly lower diarrheal incidence compared to households with old ones. Households that used new water sources also had significantly lower diarrheal incidence, while treatment of water was not found to have a protective effect. This implies that functional water filtration plants have greater impact on diarrheal incidence than water treatment at home. This study will inform policymakers and NGOs to implement improved community-based water and sanitation practices to include water filtration plants and flush toilets/new pit latrines.

## 1291

### A QUALITATIVE ASSESSMENT OF MOTIVATORS AND BARRIERS TO HANDWASHING BEHAVIORS IN AN EMERGENCY SETTING IN NORTH KIVU, DEMOCRATIC REPUBLIC OF CONGO

**Lauren S. Blum**<sup>1</sup>, Anicet Yemweni<sup>2</sup>, Victoria Trinies<sup>1</sup>, Mimi Kambere<sup>3</sup>, Foyeke Tolani<sup>4</sup>, Marion O'Reilly<sup>4</sup>, Jelena V. Allen<sup>1</sup>, Susan T. Cookson<sup>5</sup>, Thomas Handzel<sup>5</sup>, Pavani K. Ram<sup>6</sup>

<sup>1</sup>Consultant, University at Buffalo, Buffalo, NY, United States, <sup>2</sup>University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>OXFAM, Goma, Democratic Republic of the Congo, <sup>4</sup>OXFAM, Oxford, United Kingdom, <sup>5</sup>Centers for Disease Prevention and Control, Atlanta, GA, United States, <sup>6</sup>University at Buffalo, Buffalo, NY, United States

Diarrhea and acute respiratory infections (ARI) account for about 30% of deaths among children displaced due to humanitarian emergencies. A wealth of evidence supports the positive impact of handwashing promotion for prevention of both diarrhea and ARI. While socially and emotionally driven factors are proven motivators to handwashing in non-emergency situations, little is known about how to improve handwashing behavior in emergency settings. To identify motivators and barriers to handwashing, we conducted a qualitative investigation from June to August 2015 in a camp for internally displaced persons with a population of 6360 in eastern Democratic Republic of Congo. We held key informant interviews with 9 NGO and camp officials, in-depth interviews with 18 mothers of children <5 years, and 4 group discussions with camp residents. Handwashing using either soap or ash was observed to occur after 10% of latrine use events. Messages to promote handwashing were focused on disease transmission and prevention and disseminated regularly since the camp opened. Hardware for communal and home handwashing stations was reported to be old, unavailable or culturally unacceptable. Residents who engaged in day labor outside the camp had limited exposure to hygiene messages and handwashing technology. Mother-respondents identified health and illness prevention as the primary reason for handwashing. Further probing elicited emotionally and socially related motivators, including the desire to maintain a clean appearance and fresh smelling hands, which respondents stated evoked pride and status in the community. Respondents also alluded to social pressure to

follow hygiene practices recommended in the camp. A substantial deficit in handwashing practices with soap highlights the need to improve handwashing promotion strategies. The focus on health-related motivators and failure to use emotive and social drivers for handwashing may have led to missed opportunities of communication approaches shown to be effective in other settings. Findings illuminate that it is essential to develop and maintain culturally relevant handwashing strategies.

## 1292

### EVALUATION OF COMMUNITY-DERIVED ECOLOGICAL SANITATION TECHNOLOGY IN THE PERUVIAN AMAZON

Jessica Rothstein, Krista Liguori, Steven J. Chow, Margaret Kosek, Peter J. Winch

Johns Hopkins University, Baltimore, MD, United States

Ecological sanitation (EcoSan) offers a promising alternative to pit latrines in low-resource settings that lack options for the safe disposal of human waste. EcoSan manages waste by reducing human exposure to infectious pathogens while recycling valuable nutrients back into the environment as fertilizer. The overall goal of this longitudinal study is to assess the effectiveness of a community-based compost toilet system in the Peruvian Amazon implemented by a local non-governmental organization, *Instituto de Formación de Adolescentes y Niños Trabajadores* (INFANT). This system utilizes a small network of toilets located in community centers to collect human waste mixed with sawdust in sturdy bags, which are subsequently transported to a centralized, protected storage structure to facilitate pathogen attenuation. To reduce pathogens, bags are stored statically for 6 months and then transferred to an actively-mixed compost heap with waste vegetation for 6 additional months. Our specific aims are: 1) to survey pathogen reduction of waste collected from toilets already deployed in the field over the six-month static storage period, and 2) to model the static bags using controlled experimental conditions to determine the factors affecting pathogen reduction. To achieve these aims, we have taken monthly samples from field bags (n=5) from INFANT's compost toilets, as well as from model bags (n=10) that were created using defined amounts of inputs of stool, sawdust, and urine. Pathogen reduction was estimated using most probable number analysis of indicator organisms, total coliform and *E. coli*. At each sampling event, temperature, weight, pH, and field observations were also measured. Preliminary results indicate that the six-month static storage period resulted in pathogen reduction through a combination of desiccation and anti-microbial action of the sawdust amendment. Data from the controlled study component suggest that modifying the compost toilet design to utilize a urine diversion system may improve compost potential and reduce environmental contamination via leachate.

## 1293

### KNOWLEDGE, ATTITUDES AND PRACTICES (KAP) RELATED TO DIARRHEA IN A RURAL CARIBBEAN POPULATION WITH POOR WATER, SANITATION AND HYGIENE CONDITIONS

Maria S. Ruiz-Diaz, Gustavo J. Mora-Garcia, Doris E. Gomez-Camargo

Universidad de Cartagena, Cartagena de Indias, Colombia

Water, sanitation and hygiene (WaSH) conditions are closely linked with the presence of several infectious diseases that increase the mortality rates and health expenditures globally. Each year about 842,000 diarrhea deaths were estimated to be caused by poor WaSH conditions. Rural areas are more vulnerable to acquire these types of diseases, thus the assessment of the knowledge, attitudes and practices (KAP) represent an important point to cope it. In this sense, it was carried out a study in Barú village, a rural Colombian Caribbean community where WaSH indicators and KAP regarding diarrhea were evaluated. A total 124 dwellings were included. This community showed poor WaSH conditions: none dwelling presented water supply, instead this was obtained through adapted tanker ship (inadequate for human consumption). The community also have not

sewage system. Most of household used septic tank system 71.2% (n=89), the other 28.8% (n=35) use alternatives as throwing sewage into open field. About KAP, 73.4% (n=91) of respondents reported at least one episode during the previous year; "children" were reported as the family members who suffers episodes most frequently (36.3%, n=45), followed by "mother" (23.4%, n=29), and "father" (21.8%, n=27), the remaining 18.5% (n=23) corresponded to "grandfather/mother", "other adults" or "other children". Concerning, knowledge about causes of diarrhea, food poisoning was identified as the most frequent suspected etiology (25%, n=31), followed by unsafe water (16.1%, n=20), only 9.7% (n=12) of answer corresponded to intestinal parasite infections. 17.7% (n=22) of subjects mentioned unknowing the cause, and the remaining 25.8% (n=32) reported other diverse causes. Hydration was the most frequently treatment reported (43.6%, n=96). 20.9% (n=46) of families commonly employ antibiotics as the main treatment against the disease. WaSH conditions represent an important point in the improvement of health conditions in vulnerable populations. This community present not only poor WaSH conditions but also have high risk of present diarrhea cases due to insufficient knowledge about the disease.

## 1294

### A NON-KELCH13 MOLECULAR MARKER OF ARTEMISININ RESISTANCE IDENTIFIED BY IN VITRO SELECTION OF RECENTLY-ADAPTED WEST AFRICAN *PLASMODIUM FALCIPARUM* ISOLATES

Allison R. Demas<sup>1</sup>, Wesley Wong<sup>1</sup>, Angela Early<sup>2</sup>, Seth Redmond<sup>2</sup>, Selina Bopp<sup>1</sup>, Daniel E. Neafsey<sup>2</sup>, Sarah K. Volkman<sup>1</sup>, Daniel L. Hartl<sup>3</sup>, Dyann F. Wirth<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>The Broad Institute, Cambridge, MA, United States, <sup>3</sup>Harvard University, Cambridge, MA, United States

Drug resistance is one of the most pervasive challenges for malaria control, and the recent emergence and spread of artemisinin resistance in Southeast Asia is cause for serious concern. Identifying the genetic determinants of artemisinin resistance in *Plasmodium falciparum* is crucial for understanding this phenomenon and tracking the spread of resistant parasites. In 2011, prior to publication of the kelch13 resistance marker by Ariey and colleagues, we began *in vitro* selection experiments to identify the genetic determinants of artemisinin resistance. Here we present the characterization of three independently generated artemisinin-resistant parasite lines, selected on a background of recently culture-adapted Senegalese isolates. Using intermittent and step-wise *in vitro* selection methods, we pulsed the selections with steadily increasing concentrations of dihydro-artemisinin (DHA) for four years. Selected lines Pikine A, Pikine B, and Thies A all show a significant increase in their 0-3hour Ring Stage Survival Assay (RSA) survival percentage (6%, 7.9%, and 9.6%, respectively) as compared to their sensitive parents (0-3hRSA < 1%). These same lines show no change in their EC50 response to DHA, artemisinin, or other antimalarials in a 72-hour dose-response assay. Propeller domain kelch13 mutations were not found in the selected lines, suggesting a non-kelch13 mechanism of resistance. Whole genome sequencing identified mutations in Pf coronin (PF3D7\_1251200) that were associated with artemisinin resistance in all three selected lines. Functional evaluation using CRISPR-Cas9 gene editing will confirm the role of these candidate mutations in conferring artemisinin resistance *in vitro*. This study identifies additional molecular markers of artemisinin resistance, increases our understanding of how this resistance is acquired, and will provide insights into the molecular mechanism of artemisinin resistance in *P. falciparum*.

## 1295

### PHENOTYPIC CHANGES AND DRUG SENSITIVITY ASSOCIATED WITH AN *ATG18* MUTATION IN *PLASMODIUM FALCIPARUM*

Kimberly F. Breglio<sup>1</sup>, Richard T. Eastman<sup>1</sup>, David Roberts<sup>2</sup>, Anna Katharina Simon<sup>2</sup>, Craig J. Thomas<sup>1</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>University of Oxford, Oxford, United Kingdom

Delayed parasite clearance half-life for *Plasmodium falciparum* parasites treated with artemisinin derivatives was first reported in 2007 in Southeast Asia. This artemisinin resistance has been partly attributed to single nucleotide polymorphisms (SNPs) in the *KELCH* gene; however, these mutations occur on a genetic background of mutations in other genes. SNPs in autophagy related gene 18 (*ATG18*) that are associated with artemisinin delayed parasite clearance half-life have been found independently in Cambodia (T38I) and along the China/Myanmar border (T38N). Given that the Atg18 protein binds to PI3P in other organisms and that PI3P is thought to be involved in artemisinin resistance, we decided to investigate the contribution of a SNP in *ATG18*. Using CRISPR-Cas9 editing, we added the T38I SNP to a Dd2 laboratory line with a *KELCH* mutation (R539T). We intend to compare phenotypic changes in the *ATG18* T38I line vs. *ATG18* WT line. Further, we will determine the relative sensitivity of these lines to artemisinin derivatives using the ring survival assay as well as their sensitivity against an FDA drug library using IC50 assays.

## 1296

### MULTIPLEX COMPETITIVE GROWTH ASSAYS FOR MEASURING THE BIOLOGICAL IMPACT OF FITNESS IN DRUG-RESISTANT *PLASMODIUM FALCIPARUM*

Manuela Carrasquilla, Oliver Billker, Julian Rayner, Marcus Lee  
Wellcome Trust Sanger Institute, Cambridge, United Kingdom

The repeated emergence of drug resistance in *Plasmodium falciparum* underscores the importance of understanding the genetic architecture of current resistance pathways, as well as any associated fitness costs. Parasite fitness is likely to play a key role in driving the epidemiology of drug resistance, but it is infrequently studied in a laboratory setting. Competitive head-to-head assays comparing fitness between strains are typically laborious and limited in throughput, and suffer from issues when comparing growth between strains growing in different wells or flasks. We present a high-throughput method to profile fitness of multiple parasite lines in parallel in a single flask using barcode sequencing. CRISPR-Cas9 genome editing was used to insert a unique barcode into multiple parasite lines of different genetic backgrounds that possess well-described sensitivities to several standard antimalarials. These barcoded lines were then mixed together and grown in a single culture, with relative growth rates in the presence and absence of drug accurately quantified by next-generation sequencing of the barcodes. We are now using this method to study the effects of parasite background on fitness in artemisinin resistant strains isolated from Southeast Asia, using genome editing on these parasites to examine the importance of specific alleles of candidate genes. Overall, we describe a new approach that combines CRISPR-Cas9 editing and next-generation sequencing to address the biological impact of fitness in multiplex competitive growth assays.

## 1297

### A MALARIA GENETIC CROSS GENERATED IN A HUMANIZED MOUSE INDICATE MULTI-GENE CONTROL OF RESISTANCES TO ARTEMISININ AND PIPERAQUINE

Sage Z. Davis<sup>1</sup>, Lisa Checkley<sup>1</sup>, Richard S. Pinapati<sup>1</sup>, Ashley Vaughan<sup>2</sup>, Matthew Fishbaugher<sup>2</sup>, Nelly Camargo<sup>2</sup>, Marina McDew-White<sup>3</sup>, Shalini Nair<sup>3</sup>, François H. Nosten<sup>4</sup>, Stefan Kappe<sup>2</sup>, Ian Cheeseman<sup>3</sup>, Timothy JC Anderson<sup>3</sup>, Michael T. Ferdig<sup>1</sup>

<sup>1</sup>Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, South Bend, IN, United States, <sup>2</sup>Center for Infectious Disease Research, Seattle, WA, United States, <sup>3</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>4</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mahidol, Mahidol, Thailand

Repeated emergence of drug resistant parasites in response to antimalarial drugs has rendered many drugs less effective, including chloroquine and mefloquine. Artemisinin (ART) and its derivatives are the last line of defense against multi-drug resistant malaria. The slow clearance rate of parasites in response to treatment with ART and its derivatives is of grave concern. Resistance to partner drugs of ART, such as piperazine, is also emerging, raising concerns for the future of ART combination therapies (ACTs). To preserve the efficacy of ACTs there is an urgent need to determine the genetic causes of resistance and understand the mechanism by which resistance has developed. Quantitative genetics techniques, such as quantitative trait loci (QTL) mapping in *Plasmodium falciparum* experimental genetic crosses, have been successful in defining resistance mechanisms but past genetic crosses are not relevant for these recently emerged resistances. We analyzed 33 progeny from a recently developed genetic cross between an ART resistant clone with no mutations in the coding regions of K13 (PF3D7\_1343700), the putative resistance gene, and an ART sensitive clone that was generated in a humanized mouse model. Proof of concept QTL mapping using chloroquine phenotype data produces a strong peak on chromosome 7 coinciding with the *pfcr* locus, validating our genetic mapping approach. Dihydroartemisinin, the active metabolite of ART derivatives, was analyzed for both IC50 results and the ring stage survival assay (RSA). QTL mapping of RSA data identifies a suggestive statistical peak on chromosome 14, not linked to the well-known chromosome 13 locus carrying K13. Piperazine and mefloquine, both drugs used in ACTs were also mapped using IC50 data resulting in peaks on a locus containing plasmepsins II (PF3D7\_1408000) and III (PF3D7\_1408100). Interestingly, we find no evidence for copy number changes in these plasmepsins between the two parents. This work highlights biological and evolutionary implications of previously unidentified loci responsible for ART and piperazine resistance.

## 1298

### ISOLATION OF PIPERAQUINE RESISTANT RODENT MALARIA PARASITE FROM MUTATOR MALARIA

Makoto Hirai, Mie Ikeda, Shin-Ichiro Tachibana, Toshihiro Mita  
Juntendo University, Bunkyo-ku, Japan

While antimalarial drugs have been employed in prevention and treatment of malaria, emergence of drug resistant parasites remains a major issue for the achievement of malaria elimination. Defining the molecular mechanisms of drug resistance is crucial for designing new drug and prevention of emergence and spread of drug resistant parasites. However, molecular dissection of parasite drug resistance is hindered by scarcity of available genetic tools for Plasmodia. We developed a transgenic *P. berghei* parasite, malaria mutator, which shows over 80 times higher mutation rate than wild type parasite because of an artificially lack of proof reading activity of DNA polymerase. It is anticipated that the malaria mutator produces many mutants with various traits including drug resistance and thus their analysis would widen our knowledge for the mechanisms of parasite drug resistance. Here we provide a proof of concept by showing that resistant parasite to piperazine (PQ), one of the partner drugs

for artemisinin-based combination therapies, was quickly isolated from malaria mutator. Whole-genome sequence analysis revealed several SNPs shared among PQ-resistant parasite clones, which included a novel type of mutation in *Pbcrt* gene. An introduction of this mutation into the *Pbcrt* gene by CRISPR/CAS9 technology conferred PQ resistance to a susceptible parasite. We will discuss PbcRT-mediated PQ resistance and provide our view for malaria mutator as a novel research tool of drug resistance.

## 1299

### CURRENT STATE OF MALARONE RESISTANCE IN CAMBODIA AND ITS IMPLICATIONS ON THE TREATMENT OF *PLASMODIUM FALCIPARUM* IN SOUTHEAST ASIA

**Mariusz Wojnarski**<sup>1</sup>, Panita Gosi<sup>1</sup>, Andreea Waltmann<sup>2</sup>, Jessica Lin<sup>2</sup>, Catherine Berjohn<sup>3</sup>, Michele Spring<sup>1</sup>, Suwanna Chaorattanakawee<sup>1</sup>, Nonlawat Boonyalai<sup>1</sup>, Pattaraporn Vanachayangkul<sup>1</sup>, Dustin Harrison<sup>3</sup>, Somethy Sok<sup>4</sup>, Mali Ittiverakul<sup>1</sup>, Nillawan Buathong<sup>1</sup>, Soklyda Chann<sup>5</sup>, Worachet Kuntawunginn<sup>1</sup>, Vireak Heang<sup>3</sup>, Nareth Kong<sup>6</sup>, Bolin Chum<sup>3</sup>, Agus Ratchmat<sup>3</sup>, Andrew Vaughn<sup>3</sup>, Satharath Prom<sup>4</sup>, Dysoley Lek<sup>6</sup>, Philip Smith<sup>1</sup>, Mark Fukuda<sup>1</sup>, David Saunders<sup>1</sup>, Chanthap Lon<sup>1</sup>

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Division of Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, <sup>3</sup>Naval Medical Research Unit-2, Phnom Penh, Cambodia, <sup>4</sup>Ministry of National Defense, Department of Health, Phnom Penh, Cambodia, <sup>5</sup>Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, <sup>6</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Atovaquone-proguanil (AP) is an attractive treatment option for malaria in Southeast Asia as it is generally well-tolerated and effective against *Plasmodium falciparum* resistant strains. However, there are concerns over emergence of atovaquone resistance during therapy. We have analyzed atovaquone and cycloguanil markers of resistance in parasite isolates from 205 patients with uncomplicated *P. falciparum* or mixed *P.falciparum/P. vivax* malaria infections who participated in a therapeutic efficacy study of AP with or without oral artesunate (AS) at two sites in Cambodia. At enrollment, all 205 samples samples (157 from Anlong Veng and 48 from the Kratie site) evaluated at the *Pf* cytochrome b (*cytb*) Y268 locus by Sanger sequencing were wild type. Of 14 *P.falciparum* recrudescences, only one carried the Y268C mutation from volunteer at the Anlong Veng site, treated with AP without AS, whose parasite clearance time was 64 hours and recrudescence parasitemia on day 36 days following treatment. Amplicon deep sequencing targeting *cytb* confirmed the presence of the Y268C mutation in 99.6% of the sequence reads at recrudescence, but did not detect the mutation pre-treatment or 24 hours into treatment, even at a minor allele frequency down to 0.25% (33,267 and 6,047 reads at D0 and D1). This suggests de novo development of atovaquone resistance through treatment rather than expansion of a pre-existing parasite subpopulation. All isolates from the Anlong Veng and Kratie sites had normal atovaquone IC50 but with significant elevation of the cycloquanyl IC50 (2,987 nM, 95% CI = 2415 – 3559) in the 44 isolates tested to date, consistent with high prevalence of DHFR mutations which may have contributed to treatment failures. There was no efficacy benefit from adding AS and nearly all isolates carried K13 mutations. Analysis of pharmacokinetics data and its contribution to treatment failures will also be presented. Deployment of AP under triple combination therapy may be a more viable option against MDR parasites, but clinical efficacy studies are needed to identify safe and effective drug combinations without cross resistance between partner drugs.

## 1300

### TRANSCRIPTIONAL RESPONSE OF *PLASMODIUM VIVAX* PARASITES TO CHLOROQUINE IN VIVO

**Adam Kim**<sup>1</sup>, Jean Popovici<sup>2</sup>, Didier Menard<sup>2</sup>, David Serre<sup>1</sup>

<sup>1</sup>University of Maryland, Baltimore, MD, United States, <sup>2</sup>Institut Pasteur in Cambodia, Phnom Penh, Cambodia

Resistance to antimalarial drugs is challenging the effort to eradicate malaria worldwide. This issue is particularly problematic for *Plasmodium vivax*; since this parasite cannot be cultured *in vitro*, the mechanisms of resistance remain largely unknown. Here, we used RNA-seq to characterize the transcriptional changes in *P. vivax* parasites from Cambodian vivax malaria patients following chloroquine (CQ) treatment. Using stranded RNA-seq, we generated 3-29 million paired-end reads mapped to the *P. vivax* genome (10-43% of the total reads) before treatment. Eight hours after CQ treatment, the proportion of reads mapping to the *P. vivax* genome was dramatically reduced in all patients, with an average reduction of 71.0%, 95% CI [65.8-76.2]. Using paired analyses, we identified 570 genes that were significantly differentially expressed post CQ treatment (FDR<0.01). Heat-shock proteins and genes associated with gametocytes were induced after CQ treatment, while vir genes, tryptophan-rich antigens, and RNA-binding proteins were downregulated. PvCRT (chloroquine resistance transporter), which has been implicated in CQ resistance, showed decreased expression following treatment (q-value=0.004). Additionally, we observed variable extent of retention of the 9th intron of PvCRT: the parasites that retained this intron were more susceptible to CQ than parasites with complete splicing (though all infections were successfully cleared after 72 hours). Our study shows that rigorous gene expression profiles can be generated directly from vivax malaria patients without short-term culture or other processing. Our findings highlight the diversity and complexity of parasite gene expression and provide a unique perspective on the molecular response of the parasite to antimalarials *in vivo*. By investigating changes in gene expression, splice isoforms, and noncoding RNAs, we will better understand how this parasite responds to antimalarial drugs and potentially develops resistance.

### ESTIMATING HEALTH IMPACT OF RAPID DIAGNOSTIC TESTS FOR MALARIA

**Elina Pradhan**, Jessica Cohen, Joshua Salomon

Harvard T.H. Chan School of Public Health, Boston, MA, United States

Scaling up access to diagnostic testing is a cornerstone of malaria control policy. Rapid Diagnostic Tests (RDTs) for malaria have a potential of providing universal access to highly specific malaria diagnostic services. The potential health impact of RDTs for malaria however, is determined by a multitude of factors including disease epidemiology, natural history, care-seeking patterns and patient and provider adherence to the test results. We construct a decision model that explicitly parameterizes these epidemiological and behavioral factors to estimate the impact and effectiveness of scaling up RDTs, and perform global sensitivity analysis to evaluate the relative importance of these factors in modulating RDT impact and effectiveness in malaria endemic countries. We find that compliance to disease diagnosis, uptake of RDTs by providers and patients during scale up, co-incidence of malaria and bacterial pneumonia, and the overall effectiveness of Artemisinin Combination Therapies (the first line treatment for malaria) are the most important factors influencing the impact and effectiveness of RDTs on under-five malaria and pneumonia burden in 24 malaria endemic Sub-Saharan African countries. Further, we find that scaling up RDTs in public and private health facilities in malaria endemic countries with moderate RDT uptake and compliance to test results and medication could increase appropriate treatment of malaria and pneumonia by 20 million cases, which would avert 56,000 under-five deaths, or 1.5 million DALYs annually.

## 1302

### EVIDENCE OF CHANGING CASE MANAGEMENT BEHAVIORS FOLLOWING AN INTERVENTION TO INTRODUCE MALARIA RAPID DIAGNOSTIC TESTS TO PRIVATE PHARMACIES IN KINSHASA

Marcel Lama<sup>1</sup>, Willy Onema<sup>1</sup>, Robi Okara<sup>2</sup>, Katie MacDonald<sup>1</sup>, Nikki Charman<sup>2</sup>, Stephen Poyer<sup>2</sup>

<sup>1</sup>Population Services International/ASF, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Population Services International, Nairobi, Kenya

DRC DFID Abstract ASTMH 2017 Fever case management in Kinshasa centres on the private sector, where 70% of childhood fevers seek care. While diagnostic testing is available in clinics, RDT services have not historically been provided in private pharmacies or drug shops. As drug shops had 81% antimalarial market share in 2015 this leaves a critical gap in testing access. A policy change in November 2015 permitted RDTs to be used in pharmacies with qualified pharmacists nationwide, expanding possible testing channels. We conducted pre- (Oct 2015) and post- (Dec 2016) exit interview and post-only mystery client surveys to evaluate an intervention training pharmacists and supplying free RDTs after the policy change. Eligible exit interview clients were adults seeking treatment for fever for themselves or on behalf of someone else. We captured information on previous sources of care, diagnostic services and medicines received or prescribed during the current visit. Brand names were recorded from packaging when available. In 2016, confirmed RDT-negative mystery clients with no reported fever in the past four weeks were additionally recruited to assess provider adherence to algorithms for test-negative patients. Clients bought all medicines prescribed and data were captured shortly after exiting the pharmacy. 421 clients from 44 pharmacies were interviewed in 2105, and 398 from 83 sites in 2016. Reported mRDT testing increased from 0% in 2015 to 32% in 2016. In 2015 under presumptive treatment, 41% of clients received any antimalarial and 7% received an ACT. In 2016, 79% of positive clients received an ACT; presumptive antimalarial use was stable (38%). 127 mystery client visits were conducted at 64 pharmacies in 2016. 98% clients were tested for malaria. 32% of clients were told they were given a positive diagnosis and all mystery clients receiving a negative diagnosis went on to be prescribed an antimalarial. These data suggest mRDTs have been keenly adopted by pharmacists. However, prescribing practices for presumptive treatment appear slower to change and there is more work to be done to adhere to negative test results and ensure correct treatment.

## 1303

### IMPACT OF A MALARIA RAPID DIAGNOSTIC TEST DETECTING PLASMODIUM FALCIPARUM-SPECIFIC HISTIDINE-RICH PROTEIN-2 (RDT-PfHRP2) ON THE MANAGEMENT OF FEBRILE CHILDREN UNDER-5 YEARS OF AGE IN A HIGH SEASONAL MALARIA TRANSMISSION AREA

Francois Kiemde<sup>1</sup>, Petra Mens<sup>2</sup>, Achille Bonko<sup>1</sup>, Marc Tahita<sup>1</sup>, Palpiguine Lompo<sup>1</sup>, Halidou Tinto<sup>1</sup>, Michael Boele van Hensbroek<sup>2</sup>, Henk Schallig<sup>2</sup>

<sup>1</sup>Institut de Recherche en Science de la Sante-Unité de Recherche Clinique de Nanoro, Nanoro, Burkina Faso, <sup>2</sup>Academic Medical Centre, Amsterdam, Netherlands

The WHO recommends to screen febrile patients by microscopy or malaria rapid diagnostic test such as *Plasmodium falciparum* histidine-rich protein-2 (RDT-PfHRP2) before start of treatment. But antigen persistence after successful antimalarial treatment can affect the performance of this RDT and may result in missing true cause of fever in a malaria endemic area. The aim of our study was to determine the impact of RDT-PfHRP2 on the management of other causes of fever in children under-5 years of age. A prospective etiology study was conducted in 2015 among febrile children under 5 years (axillary temperature  $\geq 37.5^{\circ}\text{C}$ ) in the Nanoro Health District (Burkina Faso). In order to assess the impact of RDT-PfHRP2 testing

on the management of febrile children, the malaria RDT was performed at health facility levels and the matching blood smear was independently assessed by microscopy at the laboratory of the Clinical Research Unit of Nanoro. Additional blood, urine and stool samples were collected to perform bacterial and viral testing in the laboratory. In total 683 blood samples were analyzed with microscopy and RDT-PfHRP2. *Plasmodium falciparum* malaria was diagnosed in 49.78% cases by microscopy compared to 69.55% by RDT-PfHRP2. The RDT-PfHRP2 reported 29.68% (141/475) false positive and 1.76% (6/340) of false negative cases. The RDT-PfHRP2 had a high sensitivity (98.2%) and NPV (97.1%), but a low specificity (58.9%) and PPV (70.3%). Almost 50% of alternative cause of fever were diagnosed by laboratory testing in the RDT false positive malaria group. The corrected accuracy of the RDT by removing all alternative cause of fever diagnosed and children with 2 weeks' malaria treatment antecedent did not affect the sensitivity (98.2%) and NPV (96.4%) but improve the specificity (63.0%) and the PPV (77.22%) of RDT-PfHRP2. The use of a malaria RDT-PfHRP2 in a malaria endemic area may cause misdiagnosis of the actual cause of fever due to false positive test results. The development of practical diagnostic tool to screen for other causes of fever in malaria endemic areas is required to save lives and to improve the performance of the RDT.

## 1304

### ASSESSING THE FIELD SENSITIVITY OF MALARIA ANTIGEN DETECTION TESTS USING AN ULTRA-SENSITIVE BEAD-BASED ASSAY

Mateusz Plucinski<sup>1</sup>, Eric Rogier<sup>1</sup>, Pedro R. Dimbu<sup>2</sup>, Filomeno Fortes<sup>2</sup>, Eric S. Halsey<sup>1</sup>, Michael Aidoo<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention Malaria Branch, Atlanta, GA, United States, <sup>2</sup>National Malaria Control Program, Luanda, Angola

The large-scale introduction of antigen detection tests has revolutionized malaria diagnosis in malaria-endemic countries, allowing for the change in policy to universal confirmation of suspected malaria cases. In 2015, over 70% of malaria testing in sub-Saharan Africa was done using rapid diagnostic tests (RDTs), most of which detect the presence of the *Plasmodium falciparum* histidine rich protein 2 (HRP2). Several RDT manufacturers are developing highly sensitive RDTs (hsRDTs), which promise a limit of detection (LOD) orders of magnitude lower than conventional RDTs. However, it is not known how sensitive current RDTs are in field circumstances, as there is no single standard HRP2 limit of detection (LOD) for malaria RDT product testing. The HRP2 concentration in samples from patients attending outpatient clinics in one high- and one low-transmission province in Angola was measured quantitatively using a recently-developed ultrasensitive bead-based assay, capable of detecting HRP2 concentration at low picogram levels. Samples were analyzed from patients presenting with and without febrile illness. The number of patients with HRP2 concentration above the LOD for a conventional RDT was compared to the number of patients HRP2-positive by the ultrasensitive assay. The distribution of HRP2 concentrations was bimodal in both provinces in both afebrile and febrile patients. Conventional RDTs detected 81% of all HRP2-positive febrile patients and 52-77% of HRP2-positive afebrile patients. The added utility of an hsRDT would be greater in afebrile patients, where an hsRDT with a LOD of 200pg/mL would detect an additional 40-50% of HRP2-positive persons compared to a conventional RDT with a LOD of 1000pg/mL. In febrile patients, the hsRDT would detect an additional 10-20% of cases. The added utility of a hypothetical hsRDT in outpatients did not vary by transmission setting. Conventional RDTs already capture over 80% of symptomatic HRP2-positive individuals, regardless of underlying transmission intensity. The LOD of an hsRDT would need to approach 200 pg/mL to provide a substantial benefit over conventional RDTs in this setting.

### PREVALENCE AND OUTCOMES OF *PLASMODIUM FALCIPARUM* INFECTIONS DETECTED ONLY BY ULTRA-SENSITIVE PCR IN SCHOOL CHILDREN IN SOUTHERN MALAWI

Anna Opoku-Agyeman<sup>1</sup>, Gillian Mbambo<sup>2</sup>, Sudhanshu Joshi<sup>2</sup>, Matthew Adams<sup>2</sup>, Jenna E. Coalson<sup>3</sup>, Mark L. Wilson<sup>3</sup>, Terrie E. Taylor<sup>4</sup>, Don P. Mathanga<sup>2</sup>, Miriam K. Laufer<sup>2</sup>, Lauren M. Cohee<sup>2</sup>

<sup>1</sup>University of Maryland Baltimore County, Baltimore, MD, United States, <sup>2</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Department of Epidemiology, University of Michigan School of Public Health, Ann Arbor, MI, United States, <sup>4</sup>Department of Osteopathic Medical Specialties, College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, <sup>5</sup>Malaria Alert Center, University of Malawi College of Medicine, Blantyre, Malawi

New ultra-sensitive PCR (us-PCR) techniques can detect *Plasmodium falciparum* infections below the limit of detection (LOD) of traditional molecular methods. In areas where elimination is considered, identifying these infections is important because low density infections are common and may help perpetuate transmission. However, the utility of these more labor-intensive methods is not clear in higher transmission settings. We tested specimens from a primary school-based study to evaluate the impact of using us-PCR to estimate infection prevalence in a high transmission setting. Students were interviewed about symptoms and treatment, axillary temperature was measured, and samples were collected for microscopy, PCR, rapid diagnostic test (RDT) and hemoglobin at baseline and after 1, 2 and 6 weeks. Our standard real time PCR detected *Pf*LDH with a LOD ~2.6 parasites/ $\mu$ l and our us-PCR, targeting *Pf*18S ribosomal DNA and RNA, had a LOD of ~0.02 parasites/ $\mu$ l. We used logistic regression adjusting for school and sample weighting to compare outcomes between students who at baseline had infections detected only by us-PCR and uninfected students. Infection prevalence was estimated as 39% using traditional PCR vs. 49% using us-PCR. The proportion of infections detected only by us-PCR was inversely correlated with prevalence by traditional PCR, i.e. the highest proportions of us-PCR infections were in the lowest prevalence schools. Infections detected only by us-PCR were not associated with fever, treatment or anemia at the time of the evaluation, or in the subsequent six weeks. However, students with us-PCR-detectable infections at baseline were more likely to have infections detected by RDT, microscopy, and traditional PCR during follow-up than were students with no infection detected at baseline. Thus, using us-PCR did not substantially alter our understanding of the epidemiology of infection in this population. Infections that are below the LOD of standard PCR would likely be detected by subsequent sampling. Our results do not suggest a need for ultra-sensitive techniques to detect infection in high-burden settings.

### SENSITIVITY COMPARISONS AMONG MOLECULAR DIAGNOSTIC TOOLS FOR MALARIA DIAGNOSIS REQUIRED FOR MALARIA ELIMINATION IN MADAGASCAR

Stéphanie Ramboarina<sup>1</sup>, Fidiarivelo Rabearifeno<sup>2</sup>, Fanomezansoa Ralinoro<sup>1</sup>, Lovanirina Andrianjafy<sup>1</sup>, Melinda Zikursh<sup>3</sup>, Brunette Razanadrazina<sup>1</sup>, Thierry Franchard<sup>1</sup>, Sedera Mioramalala<sup>1</sup>, Peter A. Zimmerman<sup>3</sup>, Arsene Ratsimbasa<sup>1</sup>

<sup>1</sup>National Malaria Control Program, Androhibe, Antananarivo, Madagascar, <sup>2</sup>Faculty of Sciences, University of Ankatso, Antananarivo, Madagascar, <sup>3</sup>Case Western Reserve University, Cleveland, OH, United States

Sensitive and accurate diagnosis is required for malaria elimination. Facing the limits of detection of microscopy and RDT, PCR assays have been developed showing a variable level of sensitivity depending on the methodology and targeted gene. The 18S RNA gene (18S) PCR

assay remains the standard for malaria diagnosis. However, the 18S PCR is time-consuming and labour intensive making its usage difficult for high-volume sample processing. Our aim here was to design the most sensitive PCR diagnostic assay for use at the Madagascar NMCP by targeting the cytochrome b (cytb) gene that presents 40 to 100 copies more than 18S. For this we compared the cytb approach with two PCR methods: the Snounou-18S nested PCR and the 18S-based LDR-FDA multiplex assay. 200 samples were processed from Ankililoaka commune in southwest Madagascar collected in April 2016 after seasonal malaria chemoprevention. 18S and cytb PCR assays were performed in the NMCP laboratory; blinded assessment of this comparison was performed by LDR-FDA at Case Western Reserve University. Results showed that 18S PCR detected a prevalence of 18.5% while cytb PCR detected a prevalence of 23% with 5 *P. falciparum* (Pf) and 2 *P. vivax* (Pv) concordant samples. 6 samples were Pv positive with 18S PCR while 22 were diagnosed as Pv by cytb PCR. No mixed infections were detected by 18S PCR while 4 were detected by cytb PCR. Cytb PCR showed a full concordance with Pf positive microscopic samples whereas 18S PCR detected only 25% of them. Among 133 samples negative by RDT and microscopy, 18S and cytb PCR assays detected *Plasmodium* in 24 and 32 samples, respectively, indicative of submicroscopic infections. In contrast to other published studies the cytb PCR assay achieved better sensitivity than the 18S assay. Results of the LDR-FDA diagnosis of these 200 samples allow an independent evaluation of both the cytb and 18S PCR assays. Implementation of sensitive PCR assays is crucial for epidemiology studies and accurate surveillance for supporting the elaboration of appropriate strategies towards malaria elimination in Madagascar.

### REAL-TIME DETECTION OF DEFECTIVE MRDTS IN THE FIELD: THE APPLICATION OF A SURVEILLANCE-RESPONSE SYSTEM FOR POST-MARKET SURVEILLANCE OF DIAGNOSTICS

Santiago Ferro<sup>1</sup>, Patrick Adah<sup>2</sup>, Orode Doherty<sup>2</sup>, Kayla Seadon<sup>1</sup>, Ernest Yeung<sup>1</sup>, Nora Zwingerman<sup>3</sup>

<sup>1</sup>Fio Corporation, Toronto, ON, Canada, <sup>2</sup>Africare, Lagos, Nigeria, <sup>3</sup>University of Toronto, Toronto, ON, Canada

It is estimated that >350 million malaria RDTs were used in 2015 and utilization continues to increase. Malaria RDTs are primarily procured by NGOs, aid agencies and governments to implement the WHO recommendation for treatment of parasite confirmed cases. Selection of RDTs have been guided by FIND's RDT lab evaluations. However, RDTs are primarily used in remote areas where information about the RDT quality and performance is limited, and no system for post-marketing surveillance exists. Fionet (Fio Corp, Toronto) has been designed to strengthen quality control both directly at the user interface in facilities and remotely through a web-based portal. Fionet includes a mobile device that performs automated interpretation of RDTs, captures a high-resolution image of RDTs and collects patient data. Information is summarized in portal reports that can be monitored in real-time. Quality features of the system include immediate feedback to the user on processing errors, and portal reports on cumulative errors stratified by facility, user, type of error and time. In June 2016, a deployment of Fionet begun in 30 health facilities located in two states of Nigeria. Within two weeks, an abnormal frequency (~11%) of malaria RDTs with no control line detected was apparent. The RDT manufacturing defect was observed across multiple facilities and remained constant over subsequent months - during which >2500 malaria RDTs were processed. Notification from the portal prompted personnel to conduct site visits and confirm the RDTs came from multiple lot numbers, had not expired, and had been properly stored and processed. The manufacturer issue has been confirmed in subsequent laboratory testing. The system ensured that decision-makers, those procuring RDTs, were aware of a quality control issue occurring in remote health facilities. Subsequently, Fionet has detected this defect in two additional deployments, located in Kenya and Nigeria, with all three

deployments sourcing malaria RDTs from the same manufacturer. Post-market surveillance is crucial to ensure the quality and effectiveness of malaria RDTs in the field.

### DRIED BLOOD SPOTS ALLOW FOR EFFICIENT, LARGESCALE SURVEYS OF HEPATITIS C VIREMIA

**Jonathan B. Parr**<sup>1</sup>, Evans Lodge<sup>1</sup>, Vera Holzmayer<sup>2</sup>, Jacques Pepin<sup>3</sup>, Eric H. Frost<sup>3</sup>, Michael W. Fried<sup>1</sup>, David R. McGivern<sup>1</sup>, Stanley M. Lemon<sup>1</sup>, Corinna Keeler<sup>1</sup>, Michael Emch<sup>1</sup>, Kashamuka Mwandagali<sup>1</sup>, Antoinette Tshetu<sup>4</sup>, Franck Fwamba<sup>5</sup>, Jeremie Muwonga<sup>5</sup>, Steven R. Meshnick<sup>1</sup>, Gavin Cloherty<sup>2</sup>

<sup>1</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>2</sup>Abbott Laboratories, Abbott Park, IL, United States, <sup>3</sup>University of Sherbrooke, Sherbrooke, QC, Canada, <sup>4</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>Programme National de Lutte contre le SIDA et les IST, Kinshasa, Democratic Republic of the Congo

Efficient viral load testing is needed for hepatitis C (HCV) surveillance and diagnosis. HCV viral load testing using dried blood spots (DBS), made with a single drop of finger-prick, whole blood on filter paper, is a promising alternative to traditional serum- or plasma-based approaches. We adapted the *m2000* instrument (Abbott Molecular, Des Plaines, IL) for high-throughput HCV viremia testing using dried blood spots with simple specimen processing and applied these methods to estimate the national burden of infection in the Democratic Republic of Congo (DRC). We tested DBS collected during the 2013-2014 DRC Demographic and Health Survey (DHS), including 1,309 adults  $\geq 40$  years of age. HCV-positive samples underwent targeted sequencing, genotyping, and phylogenetic analyses. This high-throughput screening approach reliably identified HCV RNA extracted from DBS prepared using whole blood, with a 95% limit of detection of 1196 IU/mL (95% CI 866-2,280 IU/mL) for individual 6mm punches and 494 IU/mL (95% CI 372-1,228 IU/mL) for larger 12mm punches. Fifteen infections were identified among samples from the DRC DHS; the weighted country-wide prevalence of HCV viremia was 0.9% (95% CI 0.3-1.6%) among adults  $\geq 40$  years of age and 0.7% (95% CI 0.6-0.8%) among HIV-positive subjects. All successfully genotyped cases were due to genotype 4 infection. In conclusion, DBS-based HCV testing represents a useful tool for the diagnosis and surveillance of HCV viremia. 100,000-200,000 adults  $\geq 40$  years of age in the DRC may have active infection and be eligible for treatment.

## 1309

### A NOVEL ROLE OF SCHLAFEN4 IN WEST NILE VIRUS REPLICATION AND PATHOGENESIS

**Francine Azouz**, Keeton Krause, Lauren Ching, Vivek Nerurkar, Mukesh Kumar

University of Hawaii at Manoa, Honolulu, HI, United States

West Nile virus (WNV) is a neurotropic flavivirus that has emerged globally as a significant cause of viral encephalitis in humans. No effective therapies exist for treating individuals with WNV infection, and pathogenesis of WNV encephalitis (WNVE) is not completely understood. Addressing the fundamental questions regarding host proteins recruited by the WNV to establish infection in the primary target cells is an integrated and indispensable part of the effort towards development of effective therapeutics. Schlafen4 (SLFN4) is a poorly characterized but important member of the Schlafen family that includes several mouse and human genes. Role of SLFN4 in virus infections is yet to be determined. Herein, we demonstrate that WNV infection induces a dramatic up-regulation of SLFN4 in mouse brain, as well as in mouse primary cells, including mouse embryonic fibroblasts (MEFs), macrophages, dendritic cells, astrocytes, and neurons. Similarly, we found that WNV infection of human brain cells induced up-regulation of human orthologs of mouse SLFN4, namely SLFN12 and SLFN12L. Furthermore, knocking down of SLFN4 in MEFs resulted in significant decrease of WNV infectivity titers, suggesting that

SLFN4 is required for WNV replication. Additionally, mRNA and protein expression of WNV-induced interferons, chemokines, and cytokines were significantly decreased in SLFN4-knockdown MEFs. We next used SLFN4-deficient mice and an established murine model of WNVE to determine the role of SLFN4 in WNV disease pathogenesis. After subcutaneous inoculation with 100 plaque forming units WNV, SLFN4-deficient mice exhibited significantly higher survival percentage than wild-type mice. Increased survival in SLFN4-deficient mice was associated with significantly reduced viral burden in circulating blood compared to wild-type mice. Collectively our data for the first time indicate the novel role of SLFN4 in WNV replication and pathogenesis.

## 1310

### A CROSS-SECTIONAL STUDY OF NEUROCOGNITIVE OUTCOMES POST-WEST NILE VIRUS INFECTION

**Shannon E. Ronca**<sup>1</sup>, Melissa N. Garcia<sup>1</sup>, Sushmita Datta<sup>2</sup>, Koushik Govindarajan<sup>2</sup>, Ponnada Narayana<sup>2</sup>, Lucrecia Salazar<sup>2</sup>, Steven P. Woods<sup>3</sup>, Rodrigo Hasbun<sup>2</sup>, Kristy O. Murray<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>UTHealth, Houston, TX, United States, <sup>3</sup>The University of Houston, Houston, TX, United States

With West Nile virus (WNV) now endemic throughout North America, with upwards of 3 million cases, it is critical to document the long-term clinical outcomes. Among a large cohort of WNV patients in Houston, Texas, we found up to 40% of those who presented with clinical disease continued to experience WNV-related morbidity up to 8 years post-infection. This percentage was up to 70% for those who initially presented with encephalitis. There is a need to understand the long-term neurological outcomes resultant of WNV infection. From 2002-2012, a total of 262 patients were enrolled as research participants in this longitudinal cohort. Of the 262 potential participants, 117 took part in neurologic and neurocognitive evaluations, with 30 of those patients receiving MRIs to evaluate cortical thinning and regional atrophy. Correlations of clinical syndrome with neurologic and neurocognitive dysfunctions were evaluated, as well as correlations of neurocognitive outcomes with MRI results. Across the entire cohort, almost half (49%; 57/117) of patients had some type of abnormal neurological exam finding, with most abnormalities being unilateral in nature. The most common abnormalities included decreased strength (26%; 30/117), abnormal reflexes (14%; 16/117), and tremors (10%; 12/117). We observed a 22% overall rate of impairment on the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS), with the domains of immediate (31%) and delayed memory (25%) being the most frequently impaired. WNV patients showed significant thinning as compared to controls in both the left and right hemispheres, primarily in the frontal and limbic lobes. Significant regional atrophy was identified in the cerebellum, brain stem, thalamus, putamen, and globus pallidus. This study provides valuable new information regarding the neurologic neurocognitive changes resultant of WNV infection and how those changes relate to cortical thinning and regional atrophy.

## 1311

### EVOLUTION OF STRUCTURAL VARIATION IN THE UNTRANSLATED REGIONS OF THE WEST NILE VIRUS GENOME

**Stacey L. Scroggs**<sup>1</sup>, Johnny A. Sena<sup>2</sup>, Anitha Sundararajan<sup>2</sup>, Faye D. Schilkey<sup>2</sup>, Gregory D. Ebel<sup>3</sup>, Kathryn A. Hanley<sup>1</sup>

<sup>1</sup>New Mexico State University, Las Cruces, NM, United States, <sup>2</sup>National Center for Genome Resources, Santa Fe, NM, United States, <sup>3</sup>Colorado State University, Fort Collins, CO, United States

The RNA genome of West Nile virus (WNV) is flanked by 5' and 3' untranslated regions (UTRs), that fold into structures required for replication. These structures appear to be highly conserved across WNV isolates, however analysis to date has relied on consensus sequences,

which may miss variation within the viral quasispecies. To analyze structural dynamics in WNV quasispecies, we passaged WNV99 in triplicate in 3 bird species (crow, robin, house sparrow), sampling at each passage (N=45), and subjected these populations to next-generation sequencing. Ten reads from each UTR that carried at least 1 mutation from the consensus sequence were sampled at random from each population and the impact of each mutation on structure was analyzed using Mfold. We hypothesized that: (i) mutations in double-stranded (DS) regions would be more likely to cause structure change compared to mutations in single-stranded (SS) regions, (ii) mutations would be more common in SS than DS regions, (iii) mutations producing major structural changes would be less common than those producing minor changes, and (iv) mutations producing major structural changes would be most common in robins and least common in crows, which sustain the lowest and highest viremia, respectively. Over the course of passaging, quasispecies diversity did not increase or decrease for all bird-passaged WNVs. In general, mutations in DS regions were more likely to result in structure change than mutations in SS regions. Contra hypothesis (ii), mutations were more frequent in DS than SS regions of the 3' UTR, while the distribution was not different from the expected in the 5' UTR. The frequency of mutations that produced major, minor, or no structure change was similar in both UTRs. The frequency of major structure change was not related to viremia. The 5' UTR consensus sequences for passage 5 were conserved for all three bird-passaged viruses when compared to the WNV NY99. However, the robin-passaged 3' UTR consensus sequence at passage 5, contained several substitutions that result in minimal structure change.

## 1312

### THE IMPACT OF INTRODUCTION OF JAPANESE ENCEPHALITIS VACCINE IN INDIA - THE SUCCESS STORY

Pradeep Haldar<sup>1</sup>, Shalini Khare<sup>2</sup>, Padmalochan Biswal<sup>2</sup>

<sup>1</sup>Government of India, New Delhi, India, <sup>2</sup>PATH, New Delhi, India

In 2005, a massive Japanese encephalitis (JE) outbreak occurred in many districts of Uttar Pradesh and Bihar, claiming the lives of more than 1,500 children. Based on requests from many states, the Government of India (GoI) decided to initiate JE vaccination campaigns in the endemic districts to protect vulnerable children from future disease outbreaks. The strategy was a one-time mass JE vaccination campaign with a single dose of live attenuated SA 14 14-2 JE vaccine for children between 1-15 years. This was to be followed by integration of JE vaccine into routine immunization in the campaign districts for the new cohort aged 16-24 months. Viewing PATH's expertise in the field of JE vaccination, the GoI requested PATH to provide technical support in planning and implementation of the JE vaccination campaigns in all the JE-endemic states of India. Hundred and four districts of 11 states were selected for JE vaccination campaigns in a span of 5 years in a phased manner. The Government of India also made efforts for strengthening the acute encephalitis syndrome (AES)/JE surveillance system and established 121 sentinel sites. Capacity of health personnel was built in all the states for lab testing and improving the surveillance system. This has contributed to more states/districts reporting AES/JE cases thereby increasing the number of endemic states to 22 and districts to 216. From 2006 to 2016, through the successful JE vaccination program, around 148 million children have been immunized and there has been a significant decline in JE positivity rate from 58% to 11.4%. Following JE vaccination in the pediatric population, an age shift has been observed amongst children above 15 and adults. This led to the decision by the Government of India to introduce JE vaccination for the age group of 16- 65 years in selected JE endemic districts. Based on evidence, the government is expanding JE vaccination to new areas. This presentation will showcase the success story and the lessons learned through JE vaccination.

## 1313

### IMPAIRING THE INFECTION PROCESS OF YELLOW FEVER VIRUS IN *Aedes aegypti* BY MANIPULATING THE MOLECULAR HINGE REGION OF THE ENVELOPE PROTEIN

Yan-Jang S. Huang<sup>1</sup>, John T. Nuckols<sup>2</sup>, Amy C. Lyons<sup>1</sup>, So Lee Park<sup>1</sup>, Alan D. Barrett<sup>3</sup>, Stephen Higgs<sup>1</sup>, Dana L. Vanlandingham<sup>1</sup>

<sup>1</sup>Kansas State University, Manhattan, KS, United States, <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>3</sup>University of Texas Medical Branch, Galveston, TX, United States

The re-emergence of yellow fever virus in Africa and Latin America since 2015 has created a significant human public health threat to tropical regions worldwide. The shortage of the live-attenuated 17D vaccine limits disease control capabilities in response to outbreaks of yellow fever and highlights the importance of global vaccine stockpiles. Whilst it is well-accepted that genetic mutations in the 17D vaccine strains are responsible for the loss of viscerotropism in humans and reduced efficiency in infection and dissemination in *Aedes aegypti*, the attenuation mechanisms caused by genetic mutations remains unknown. Without such knowledge, the rationale-based design of efficacious vaccine candidates against YFV and other related flaviviruses cannot be achieved. In this study, the attenuation of YFV in *Ae. aegypti* caused by the vaccine-associated G52R mutation, located in the molecular hinge region between the domain I and domain II of the envelope (E) protein, was evaluated. *Per os* challenge of *Ae. aegypti* was performed to determine the phenotypic difference between the wildtype and mutant viruses. The results demonstrate the contribution of the G52R mutation to the attenuation of YFV and the functional importance of the molecular hinge region of YFV E protein for the infection process in *Ae. aegypti*.

### A PAN-VIRAL CAPTURE SEQUENCING APPROACH TO ELUCIDATE THE VIROME OF ACUTE FEVER AND ENHANCE VIRAL SURVEILLANCE IN WEST AFRICA

Katherine J. Siddle<sup>1</sup>, Hayden Metsky<sup>2</sup>, Simon Ye<sup>2</sup>, Mouhamad Sy<sup>3</sup>, Patrick Brehio<sup>4</sup>, Adrienne Gladden-Young<sup>4</sup>, James Qu<sup>4</sup>, Christopher Tomkins-Tinch<sup>4</sup>, Daniel Park<sup>4</sup>, Christian Happi<sup>5</sup>, Daouda Ndiaye<sup>3</sup>, Christian B. Matranga<sup>4</sup>, Pardis C. Sabeti<sup>1</sup>

<sup>1</sup>Harvard University, Cambridge, MA, United States, <sup>2</sup>Massachusetts Institute of Technology, Cambridge, MA, United States, <sup>3</sup>Universite Cheikh Anta Diop, Dakar, Senegal, <sup>4</sup>The Broad Institute, Cambridge, MA, United States, <sup>5</sup>Redeemer's University, Osun State, Nigeria

Recent public health emergencies, such as those caused by Ebola and Zika viruses, have highlighted vulnerabilities in public health systems and the need to greatly expand our ability to rapidly identify and stop these threats. The 2013-16 Ebola outbreak expanded in part because many regions lacked local diagnostic capacity to rapidly detect and respond to the virus. Despite the burden of infectious disease in sub-Saharan Africa, little is known about the spectrum of viral infections responsible for disease in many regions. Recent advances in next generation sequencing (NGS) have the potential to transform viral detection and discovery by enabling unbiased pathogen detection in clinical samples. However, the low titer of virus and high human background present in many clinical samples greatly reduces the efficiency and increases the cost of this approach, posing a major challenge for the application of these technologies locally for surveillance and diagnostics. Hybrid capture techniques can address these challenges by enriching for viral nucleic acids, though this conventionally requires a priori knowledge of the viral targets. To address this, we designed and validated a pan-viral hybrid capture panel containing > 300 viral taxa known to infect humans. We show that this approach significantly improves virus detection and genome assembly in both mock and clinical samples from a panel of viruses, including viral co-infections and genetically diverse strains. We next used this pan-viral capture approach to identify viruses present in a cohort

of serum samples collected from individuals with an acute fever from Senegal. This work is the first genome sequencing-based viral surveillance effort in Senegal and demonstrates the utility of our pan-viral hybrid capture approach for this application. We will discuss the metagenomic findings from our studies.

### WUCHERERIA BANCROFTI INFECTION IS LINKED TO SYSTEMIC ACTIVATION OF CD4 AND CD8 T CELLS

Inge Kroidl<sup>1</sup>, Mkunde Chachage<sup>2</sup>, Jonathan Mnkai<sup>2</sup>, Jaco J. Verweij<sup>3</sup>, Myrna Berninghoff<sup>1</sup>, Lucas Maganga<sup>2</sup>, Leonard Maboko<sup>2</sup>, Petra Clowes<sup>2</sup>, Michael Hoelscher<sup>1</sup>, Elmar Saathoff<sup>1</sup>, Christof Geldmacher<sup>1</sup>

<sup>1</sup>Medical Center of the University of Munich (LMU), Munich, Germany, <sup>2</sup>National Institute for Medical Research Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, <sup>3</sup>Laboratory for Medical Microbiology and Immunology, Elisabeth Twesteden Hospital, Tilburg, Netherlands

Susceptibility to HIV has been linked to CD4+ T cell activation in cohorts of seronegative individuals with high HIV-exposure. Our group recently described an increase of HIV transmission in individuals infected with *Wuchereria bancrofti*, the causative agent for lymphatic filariasis (LF). However, the underlying reason for this phenomenon needs further investigation. Previous studies revealed an increase in HLADR/CD38 positive CD4 cells for soil transmitted helminths (STH), especially *T. trichiura* (TT) infection, but this has not yet been evaluated for *W. bancrofti*. Methods: Two-hundred and fifty HIV negative participants above 18 years of age from the Worm HIV Interaction study (WHIS) were grouped on the basis of their helminth infection status, according to Trop Bio ELISA (LF), Kato Katz and stool based RT-PCR. FACS analysis of the peripheral blood was used to measure T cell activation markers (HLA-DR, CD38), differentiation markers (CD45, CD27) regulatory markers (FoxP3, CD25) and HIV co-receptor (CCR5) expression. Results: Five groups of different helminth infection status were defined and compared: Forty-six individuals were free of helminths, 20 were infected with LF, 27 with TT and 146 participants with other STH. We noticed a significantly higher percentage of HLA-DR positive cells among CD4+ T cells in patients with LF (11.1%) and TT (10.1%) infection compared to helminth free individuals (8.0%) or participants infected with other STH (8.1%) (LF versus helminth free;  $p=0.001$  after adjustment for age and sex). Furthermore, the percentage of CCR5 expressing regulatory CD4 T cells was significantly higher in LF infected, compared to helminth free individuals (61.2% versus 53.2%,  $p=0.041$ ) or other helminths (61.2% versus 55.2%,  $p=0.049$ ). Interpretation: A higher level of CCR5 positive CD4 T regulatory cells in addition increased immune activation as demonstrated by HLADR/CD38 cells was found in LF positive individuals when compared to participants infected with other helminths. This could explain the increased susceptibility to HIV infection of *W. bancrofti* infected individuals.

## 1316

### MODULATION OF HUMAN INNATE LYMPHOID CELL FUNCTION BY IL-10 AND TGF-BETA

Sandra Bonne-Annee, Thomas Nutman

National Institute of Allergy and Infectious Diseases National Institutes of Health, Bethesda, MD, United States

Chronic human filarial infection is associated with an immune-modulatory state mediated largely by IL-10 (and to a lesser extent TGF- $\beta$ ), cytokines that alter antigen-specific effector T cell responses. These filarial infections are also associated with an expansion of innate lymphoid cell (ILC) subsets that mirror in many ways the CD4+ helper cell (Th) subsets: ILC1s (IFN- $\gamma$ ), ILC2s (IL-5 and IL-13) and ILC3s (IL-17A or IL-22). Human ILC subsets can easily be detected in the circulation accounting for only 0.21% (range 0.023-3.58%) of lymphocytes under homeostatic conditions. Despite the low frequency of ILCs in circulation, *ex vivo* experiments have demonstrated that these ILCs release extremely large per cell quantities

of cytokines following activation and, if left unchecked, these ILC-derived cytokines can have deleterious effects on the host. To explore the interface between ILC expansion and the regulation of ILC activation ILC subsets were isolated from the peripheral blood of healthy donors by flow cytometry-based sorting and activated in the presence or absence of IL-10. ILCs stimulated in the presence of IL-10 had a marked reduction (range from 2-3.6 fold) in cytokine production when compared to ILCs activated without IL-10. Similar cytokine regulation was seen with TGF- $\beta$ . To explore the mechanisms underlying the inhibition of ILC cytokine production, we examined the expression of IL-10R on ILC subsets and found that ~20-45% of each subset expressed IL-10R and did so at the same per cell intensity (GeoMFI=839) as did human monocytes, known to express IL-10R. Studies are currently underway to explore the downstream effects of IL-10R engagement on ILCs and to identify additional mechanisms that regulate ILC cytokine production, including the role of the related cytokines IL-19 and IL-24 known also to regulate T cell responses in filarial infections.

## 1317

### BIOMARKERS OF ACTIVE INFECTION WITH ONCHOCERCA VOLVULUS

Sasisekhar Bennuru<sup>1</sup>, Georgiette Oduro-Boateng<sup>1</sup>, Papa M. Drame<sup>1</sup>, David Abraham<sup>2</sup>, Sara Lustigman<sup>3</sup>, Thomas B. Nutman<sup>1</sup>

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Thomas Jefferson University, Philadelphia, PA, United States, <sup>3</sup>New York Blood Center, New York, NY, United States

Onchocerciasis (river blindness) is a neglected tropical disease that has been targeted for control and elimination through mass drug administration (MDA) of ivermectin that ultimately interrupts transmission. As efforts shift from control to disease elimination, better tools are needed to identify the presence of viable *Onchocerca volvulus* (*Ov*) parasites that can be used in surveillance and eventually for certification of elimination. To identify potential biomarkers that could be used in an immunologically-based rapid diagnostic assay, we utilized the stage-specific transcriptomes and proteomes of *Ov* and shortlisted 30 candidates as potential biomarkers based on *Ov* specificity and over representative (or unique) expression in the adult female stage. From these 30, we were able to develop immunoassays to quantify 2 of the most promising biomarkers OVOC8995 and OVOC12838. Antisera against peptides derived from OVOC8995 and OVOC12838 were raised in rabbits and then the IgG from each were affinity purified using specific peptide affinity columns. We then developed immunoassays that can reliably detect OVOC8995 and OVOC12838 in human serum with lower detection limits of 1ng/ml and 0.1ng/ml respectively. Using sera from microfilariae (mf)-positive *Ov*-infected individuals and sera from uninfected healthy controls or from those with other non-*Ov* filarial infections (e.g. *W. bancrofti* and *L. loa*) as comparators, we were able to detect OVOC12838 and OVOC8995 in *Ov*-infected samples only with very minimal to no reactivity in the various control sera. Given the high degree of *Ov*-specificity shown by OVOC12838 and OVOC8995 and the sensitivity of the assay to detect sub-nanogram levels of circulating antigen in *Ov*-infected individuals provides a promising platform to detect low-level infections during surveillance. Ongoing analyses with larger cohorts comprising of samples across geographical regions and pre- and post-treatment sera samples are currently underway for the validation of these two assays.

### AN INVESTIGATION OF *ONCHOCERCA VOLVULUS* GEOGRAPHIC POPULATION-SPECIFIC SECRETED MIRNA PROFILES

Carmelle T. Norice-Tra<sup>1</sup>, Ian Misner<sup>1</sup>, Rahul Tyagi<sup>2</sup>, Makedonka Mitreva<sup>2</sup>, Thomas B. Nutman<sup>1</sup>

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Washington University School of Medicine, St. Louis, MO, United States

Studies of geographic differences in *Onchocerca volvulus* (Ov) biology and pathogenesis may facilitate eradication efforts. It has recently been shown that Ov secretes microRNA (miRNA) into the host circulation and that Ov from differing geographic locations secrete different miRNA species. In the present study, we investigated the diversity of circulating Ov microRNAs in pools of 12 sera each from microfilariae-positive patients with onchocerciasis from the Americas, West Africa, Central Africa and East Africa and from Ov-uninfected individuals. RNA was extracted from these pools and single-end 50 base-pair sequencing reads were obtained using an Illumina HiSeq Rapid approach. These reads were then mapped to the Ov genome, the human genome, and the Nematoda miRNA sequences in miRBase v21, revealing 116 putative Ov-specific miRNA species that had not been previously identified. Alignments of the RNA-Seq reads showed that single nucleotide polymorphisms (SNPs) were present in a subset of the miRNAs identified. Comparative analysis of RNA-Seq data from the four regions studied also suggested geographic variation in the miRNA species secreted. Thus, we have found novel secreted Ov miRNAs with considerable diversity in their sequences and geospatial presentation. Taken together, these findings support a model for Ov population diversity reflecting geographic origin.

### DEVELOPMENT OF AN ANTIGEN-CAPTURE IMMUNOASSAY FOR THE DIAGNOSIS OF ACTIVE *LOA LOA* INFECTION

Papa M. Drame<sup>1</sup>, Marco Biamonte<sup>2</sup>, Thomas B. Nutman<sup>1</sup>

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Drugs and Diagnostics for Tropical Diseases, San Diego, CA, United States

Antigen-capture immunoassays are needed for the diagnosis of loiasis. We recently developed assays to quantify two microfilaria (mf) specific antigens whose quantity in sera reflects *Loa loa* mf counts. However, having an immunoassay that could detect all actively infected patients with loiasis, irrespective of their mf load, is of additional importance. To this end, we developed a capture (sandwich) ELISA assay to quantify *L. loa* SXP1 (LI-SXP1), an 148 amino-acid antigen protein expressed in all stages the *L. loa* parasite. Using purified polyclonal anti-LI-SXP1 IgG as a capture antibody, we were able to show that LI-SXP-1 antigen can be detected in both mf positive (n=28) and amicrofilaremic (n=20) *L. loa*-infected patients, but not in *L. loa*-uninfected (n=22) sera. Because of the significant conservation of sequence of the SXP1 protein across the various filariae, there was some level of antigen cross-reactivity in sera from mf positive patients with *Wuchereria bancrofti* and *Onchocerca volvulus* although the quantities measured were markedly lower than what was seen in *L. loa* infection. We next generated monoclonal antibodies to *L. loa*-SXP1 and found that 2 of these, when used as capture antibodies, significantly improved both the sensitivity and specificity of the capture ELISA assay. We are now assessing the alterations in LI-SXP1 levels following definitive treatment of *L. loa* with diethylcarbamazine. Taken together, circulating LI-SXP1 protein may be a very promising biomarker that can be exploited in a point-of-care immunoassay for the diagnosis of active *L. loa* infections.

### COMPARISON OF PCR-METHODS FOR *ONCHOCERCA VOLVULUS* DETECTION IN SKIN BIOPSIES FROM THE TSHOPO PROVINCE, DRC

Jessica Prince-Guerra<sup>1</sup>, Vitaliano A. Cama<sup>2</sup>, Nana Wilson<sup>2</sup>, Josias Likwela<sup>3</sup>, Nestor Ndakala<sup>4</sup>, J. Muzinga Muzinga<sup>4</sup>, Nicholas Ayebazibwe<sup>5</sup>, Yassa Ndjakani<sup>6</sup>, Naomi Awaca<sup>3</sup>, D. Mumba<sup>7</sup>, Antoinette Tshetu<sup>8</sup>, Paul Cantey<sup>2</sup>

<sup>1</sup>ASM/Centers for Disease Control and Prevention Fellowship Program, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Programme National de la Lutte contre l'Onchocercose, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>FELTP, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>AFENET, Kampala, Uganda, <sup>6</sup>CDC-DRC, Kinshasa, Democratic Republic of the Congo, <sup>7</sup>Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo, <sup>8</sup>Ecole de Sante Publique, Kinshasa, Democratic Republic of the Congo

Current WHO criteria for stopping mass drug administration (MDA) for onchocerciasis allows skin snip PCR to rule out infection if less than 10 children have positive OV-16 serology results. Negative skin snip PCR results allow the OV-16 serology results to be considered false positives. PCR methods need to be optimized for this use. We compared the performance of two PCR methods for *O. volvulus* detection, a real-time PCR targeting the O150 repeat region (qPCR) and the O150-PCR ELISA (PCR-E), in 471 residual skin snip biopsy samples. Limits of detection (LOD) were compared using dilutions of qDNA of adult *O. volvulus*. PCR+E results were considered positive if the optical density (OD) > 0.1 and repeat testing was positive. Receiver Operator Characteristics (ROC) analysis was used to evaluate the performance of PCR-E. The LODs for qPCR and PCR-E were 20 fg and 5pg, respectively. qPCR detected a significantly higher number of positive skin snips (224/471 or 47.5%) than PCR-E (127/471 or 27%) ( $p < 0.0003$ ). A total of 161/471 (34.2%) samples were initially positive by PCR-E. However, 34/471 (7.2%) were negative upon repeat testing, and 24 of those 34 (70.6%) were qPCR+. Compared to qPCR, PCR-E had a sensitivity and specificity of 56.7% and 100%, respectively. ROC analysis for PCR-E showed the optimal threshold at OD=0.055, with a sensitivity of 83% and specificity of 90.7%. Because PCR-E missed 43.3% of qPCR+ samples, the qPCR assay may be more appropriate for evaluating the snips of OV-16+ children. As qPCR may not be feasible in all settings and detection of *O. volvulus* DNA in snips is used to make decisions about stopping MDA, improving the performance of other PCR methods as an alternative is critical. Adjusting the PCR-E OD cut-off could improve sensitivity but at a cost to specificity. The LOD of the conventional PCR method using qPCR primers was 20 fg - comparable to qPCR, thus incorporating this PCR method into the PCR-E might increase test sensitivity. All these options should be considered and further validated when defining the appropriate PCR assay to detect *Onchocerca* DNA in skin snips.

### IDENTIFYING "WINDOWS OF OPPORTUNITY" FOR THE DETECTION OF PARASITE MATERIAL IN THE EXCRETA/FECES OF VECTOR AND NON-VECTOR MOSQUITOES

Nils Pilotte<sup>1</sup>, Darren Cook<sup>2</sup>, Lisa J. Reimer<sup>2</sup>, Steven A. Williams<sup>1</sup>

<sup>1</sup>Smith College, Northampton, MA, United States, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Previous experiments have demonstrated that the DNA of various human parasites, including *Brugia malayi*, can be detected in the excreta/feces (E/F) of both vector and non-vector mosquito species. Such detection has the potential to enable alternative E/F-based molecular xenomonitoring approaches, allowing for the improved throughput of testing in low prevalence settings. However, if field-based utilization of this novel approach to testing is to occur, clear definition of the E/F-based windows of parasite detection must be defined for each mosquito species of

interest. As factors such as vector competency, and metabolic differences impact the timing of the deposition of parasite material into the E/F, identification of such time periods will be critical for proper study designs, and will shape critical decision making processes regarding target species, and trapping methodologies. Accordingly, utilizing both real-time PCR and digital PCR techniques, we have identified the corresponding detection windows for a series of vector and non-vector mosquito species. This testing has enabled us to determine the time frame during which the deposition of parasite DNA occurs, with vectors demonstrating a narrow window of detection in comparison to non-vector species. Similarly, the post-blood meal time point at which parasite DNA becomes most readily and easily detectable has also been identified for each species tested. We believe that this information provides a critical step forward in elucidating a field-applicable methodology for E/F collection and testing.

## 1322

### IMPACT OF TWO ANNUAL CYCLES OF MASS DRUG ADMINISTRATION ON TEMPORAL TRENDS OF CLINICAL MALARIA

**Julia Mwesigwa**<sup>1</sup>, Jane Achan<sup>1</sup>, Archibald Worwui<sup>1</sup>, Jean-Pierre Van geertruyden<sup>2</sup>, Umberto D'Alessandro<sup>1</sup>

<sup>1</sup>Medical Research Council Unit The Gambia, Banjul, Gambia, <sup>2</sup>University of Antwerp, Antwerp, Belgium

Though a substantial decline in malaria burden has been observed in The Gambia, areas of on-going transmission still persist in the country. We evaluated the impact of Mass Drug Administration (MDA) on clinical malaria. Residents of twelve villages across The Gambia were enrolled into a prospective cohort were followed up from June 2013 to December 2015. Two rounds of MDA with dihydroartemisinin-piperazine (DHAPQ) were conducted at the start of the transmission seasons (TS) in June 2014 and May 2015. Follow-up surveys were conducted monthly for 6 months in each TS where finger prick samples were collected for haemoglobin estimation and *P. falciparum* detection. Clinical malaria was detected by passive case detection during the TS. DHAPQ coverage was 80.9% (3784/4678) in 2014 and 84.3% (4394/5210) in 2015. In 2014 during the first 21 days post MDA, prevalence of clinical malaria was 0.2%, (5/2500) compared to the prevalence at the end of the previous TS in December 2013; 1.75%, (58/3301). *P.falciparum* individuals at the end of the 2013 TS who took DHAPQ had a higher odds OR=1.94 (95% CI: 1.4 - 2.8) of clinical malaria subsequently in the 2014 TS between August to December. The prevalence of clinical malaria two months post MDA was 0.14%, (5/3549). Following the second annual round in 2015, no case of clinical malaria was detected in the first 21 days post MDA. Only 3 cases (0.1%, 3/2999) were detected two months post MDA, compared to the prevalence in December 2014; 0.4% (12/3135) at the end of the TS. The incidence rate of malaria in 2014 was 0.07 episodes (95% CI: 0.07-0.08) PPY (per person per year at risk) compared to 0.4 episodes PPY (95% CI 0.38-0.39) in 2013. Individuals had a lower risk of developing clinical disease in 2014 compared to 2013, an incidence rate ratio (IRR) = 0.8 (95% CI: 0.68-0.83). In 2015 the incidence rate of clinical malaria was 0.5 episodes PPY (95% CI 0.46-0.52). The risk of developing clinical malaria was higher in 2015 compared to 2013; IRR=1.3 (95% CI: 1.2-1.4). A second annual cycle of DHAPQ is protective from malaria within the first 21 days however, single annual MDA with DHAPQ is not sufficient to interrupt transmission of clinical malaria.

## 1323

### SPEEDING UP MALARIA ELIMINATION; A CLUSTER RANDOMIZED CONTROLLED TRIAL OF MASS DRUG ADMINISTRATION IN SOUTHEAST MYANMAR, AN AREA WITH ARTEMISININ RESISTANCE

**James Heaton**<sup>1</sup>, Alistair McLean<sup>2</sup>, Myo Maung Maung Swe<sup>1</sup>, Kyaw Soe<sup>1</sup>, Chanida Indrasuta<sup>2</sup>, Zay Soe Khant<sup>2</sup>, Mallika Imwong<sup>3</sup>, Elizabeth Ashley<sup>1</sup>, Arjen Dondorp<sup>3</sup>, Nicholas White<sup>3</sup>, Frank Smithuis<sup>1</sup>

<sup>1</sup>Myanmar Oxford Clinical Research Unit, Yangon, Myanmar, <sup>2</sup>Medical Action Myanmar, Yangon, Myanmar, <sup>3</sup>Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Artemisinin resistant malaria is present throughout Southeast Asia. It has been followed by partner drug resistance in some areas, where artemisinin based combination therapy is now failing. With no new drugs on the horizon elimination of artemisinin resistant *P. falciparum* may be the only way to prevent further spread. Mass drug administration (MDA) has successfully eliminated malaria in some areas in the past. We conducted a paired cluster-randomised controlled trial to determine the effectiveness of 3 rounds of MDA of dihydroartemisinin-piperazine plus a single low dose primaquine in addition to routine malaria control activities as part of a pilot project to speed up malaria elimination. The study assessed the feasibility, acceptability, safety and its effect on malaria. Malaria prevalence was assessed using ultrasensitive PCR before and 3, 5, 10 and 15 months after MDA. Sixteen clusters (population 8721) were enrolled, paired and randomised. MDA coverage was 90% (4164/4622). It was well tolerated with few (151), mostly mild, adverse events reported. *P. falciparum* prevalence dropped from 14.2% at baseline to 1.4% ( $p < 0.001$ ) 3 months post MDA in the intervention group, while it dropped from 15.6% at baseline to 10.4% in control villages in the same period. Over time the difference in malaria prevalence between MDA and control clusters diminished, possibly as a result of migration and re-introduction of new infections from neighbouring villages where MDA was not provided. Kelch 13 mutations associated with artemisinin resistance comprised 57% (54/94) of samples at baseline and 54% (7/13) at month 3 post MDA. MDA can be considered safe and effective to reduce *P. falciparum* prevalence in low transmission areas with artemisinin resistance.

## 1324

### REACTIVE CASE DETECTION WITH TARGETED MASS DRUG ADMINISTRATION: INTERRUPTING MALARIA TRANSMISSION AND ACHIEVING ELIMINATION BEYOND INTERVENTION AREAS IN NORTHWESTERN PERU

**Antonio M. Quispe**<sup>1</sup>, Fernando A. Quintana<sup>2</sup>, Edwar Pozo<sup>3</sup>, Margaret N. Kosek<sup>4</sup>, Eduardo Gotuzzo<sup>5</sup>

<sup>1</sup>Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Dirección Regional de Salud, Tumbes, Peru, <sup>3</sup>Dirección Regional de Salud, Piura, Peru, <sup>4</sup>Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>5</sup>Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

Reactive case detection (RCD) with targeted mass drug administration (tMDA) was previously found to be an effective strategy to support malaria elimination initiatives in Tumbes Peru, a region with a predominance of vivax malaria. We assessed the effect of RCD/tMDA on malaria incidence in intervention areas of Tumbes and the surrounding region of Piura. A pilot malaria elimination program based on RCD/tMDA was rolled out in the two most highly malaria-endemic districts (nine reporting units) in Tumbes from 2009-2010 and then scaled up to 11 additional districts (34 reporting units) from 2011-2014. Non-intervention areas in Piura were evaluated from 2011-2016. Malaria cases were passively detected, and followed-up within 24 hours together with household contacts (excluding elders, pregnant women, and chronically-ill subjects). The primary study endpoint

was a temporospatial reduction in weekly parasite incidence (WPI = total malaria cases per week/ 1,000 inhabitants) across all reporting units, analyzed by proximity to the intervention area's reporting unit. During the study period (2009-2014) we analyzed a total of 9102 autochthonous malaria cases. During the pilot program we estimated a mean reduction in WPI across Tumbes intervention areas of 99% (97–100) and 85% (77–94) at 12 and 24 months (m), respectively; and non-intervention areas of 34% (27–40) and 86% (76–93) at 12m and 24m, respectively. During the same period, we estimated a mean reduction in WPI at the near, mid and far range Piura districts of 63%, -73%, and -420% at 12m, and 91%, -126% and 91% at 24m, respectively. After scale up, we found a negative association between the mean WPI reduction and proximity to intervention area across the Piura districts, at both 24m ( $p=0.04$ ) and 48m ( $p<0.01$ ). During years 2015 and 2016, neither area in Tumbes nor in Piura has reported any autochthonous malaria cases. The RCD/tMDA strategy has shown to effectively interrupt malaria transmission in the Piura region and may support malaria elimination initiatives in other settings with a high predominance of vivax malaria.

## 1325

### REACTIVE CASE DETECTION FOR MALARIA IN AMHARA NATIONAL REGIONAL STATE, ETHIOPIA: DESCRIPTIVE AND IMPACT EVALUATION ANALYSIS

**Asefaw Getachew**<sup>1</sup>, Asnakew Yeshiwondim<sup>1</sup>, Pooja Bansil<sup>2</sup>, Belendia Serda<sup>1</sup>, Berhane Tesfay<sup>1</sup>, Adem Agmas<sup>1</sup>, Melkamu T. Zeleke<sup>1</sup>, Girma S. Guesses<sup>1</sup>, Asmamaw L. Ayenew<sup>1</sup>, Worku M. Workie<sup>1</sup>, Teklehaimanot G. Kidanemariam<sup>3</sup>, Duncan Earle<sup>4</sup>, Caterina Guinovart<sup>5</sup>, Richard W. Steketee<sup>2</sup>

<sup>1</sup>PATH MACEPA, Addis Ababa, Ethiopia, <sup>2</sup>PATH MACEPA, Seattle, WA, United States, <sup>3</sup>Amhara National Regional State Health Bureau, Addis Ababa, Ethiopia, <sup>4</sup>PATH MACEPA, Lusaka, Zambia, <sup>5</sup>PATH MACEPA/ ISGlobal collaboration, Barcelona, Spain

Case investigation (CI) of malaria cases and reactive case detection (RCD) of malaria infections are strategies that can contribute to malaria elimination in low-transmission settings. In Amhara region, Ethiopia, CI with RCD was conducted in 37 villages during the malaria transmission seasons in 2015-2016. *P. falciparum* or mixed malaria cases diagnosed at the health posts were considered index cases and were investigated (regarding socioeconomic characteristics, travel history, etc.). RCD with focal test and treat (FTAT) was conducted in the index case household and the ten closest neighboring households within a 100 meter radius. During the FTAT, all individuals in the targeted households were tested with a rapid diagnostic test (RDT) and all positives were treated with an antimalarial drug. Preliminary results from April 2015 to August 2016 indicate that there were 179 index cases, of which 47% were investigated. Of these, 58% were male and only 23% were children younger than ten years of age. During the FTAT, 548 households were visited, of which 96% were investigated. Of the 2,372 individuals in those households, 85% were tested, of which 1.7% were positive (56% *P. falciparum*, 18% *P. vivax*, 26% mixed). Risk factors for RDT-positivity included travel history, reported or measured fever, sleeping under a bednet, and recent antimalarial treatment. There were different transmission patterns, with several villages having very few cases, some villages having mostly imported cases, and others having mostly local cases. To evaluate whether CI with RCD had an impact on malaria incidence in the intervention villages, a quasi-experimental design with a comparison group of villages from the same regions—matched by pre-intervention incidence and altitude—will be used. A difference-in-differences analysis using negative binomial regression will be conducted. Final descriptive and impact evaluation results will be presented.

## 1326

### EVALUATING THE EFFICIENCY OF REACTIVE CASE DETECTION TO ACHIEVE MALARIA ELIMINATION IN RURAL SOUTHERN ZAMBIA USING FOLLOW-UP HOUSEHOLD VISITS AND PARASITE GENOTYPING

**Kelly M. Searle**<sup>1</sup>, Julia Pringle<sup>1</sup>, Harry Hamapumbu<sup>2</sup>, Michael Musonda<sup>2</sup>, Ben Katowa<sup>2</sup>, Tamaki Kobayashi<sup>1</sup>, Jennifer C. Stevenson<sup>2</sup>, Douglas E. Norris<sup>1</sup>, Philip E. Thuma<sup>2</sup>, William J. Moss<sup>1</sup>

Targeted interventions to identify and treat the asymptomatic reservoir have been implemented in areas approaching malaria elimination. Reactive case detection is currently conducted in Southern Province, Zambia to enhance surveillance and clear the asymptomatic reservoir. After an index case is confirmed with malaria by a rapid diagnostic test (RDT), household members and neighbors residing within 140-meters are tested with an RDT and treated with ACT if positive. The efficiency of this strategy to detect and treat *P. falciparum* infections was evaluated in the catchment area of Macha Hospital in Southern Province. A subset of index cases was evaluated by a study team who administered a questionnaire, performed an RDT, and collected a blood sample on filter paper for detection of *P. falciparum* DNA by qPCR. As part of the study, the screening radius was extended to 250-meters and follow-up visits were performed 30 and 90 days after the initial visit. From March 2016-January 2017, 139 households with 935 residents participated. Parasite prevalence and transitions between RDT and qPCR positivity were compared between residents of index and neighboring households over the follow-up. Parasite genetic relatedness between persistent infections within individuals and new infections within households were analyzed using a *P. falciparum* 24 SNP molecular barcode. Overall, parasite prevalence was higher in index households (1.4% by RDT, 6.9% by qPCR) compared to neighboring households (0.7% by RDT, 2.7% by qPCR). Parasite prevalence by RDT and qPCR decreased over follow-up visits but *P. falciparum* infection persisted and was not eliminated in study households. Persistent infections were detected by qPCR among those negative by RDT. Identical molecular barcodes were detected among persistent infections within individuals and among newly identified infections within households. The efficiency of reactive case detection in this setting is limited by the low sensitivity of the RDT and continued focal transmission after the intervention. Focal drug administration in the index household may be a more efficient strategy to achieve elimination.

### ACHIEVING INTERRUPTION OF LOCALLY TRANSMITTED PLASMODIUM FALCIPARUM MALARIA CASES THROUGH PILOTING A BASIC ESSENTIAL PACKAGE OF ACTIVITIES FOR MALARIA ELIMINATION IN THE CONTEXT OF ARTEMISININ RESISTANCE, 2015-2017

**Soy Ty Kheang**<sup>1</sup>, Say Chy<sup>1</sup>, Sokomar Nguon<sup>1</sup>, Kong Meng Seak<sup>1</sup>, John Hustedt<sup>1</sup>, Sam An Sen<sup>1</sup>, Linna Khorn<sup>1</sup>, Sovann Ek<sup>1</sup>, Bunthy Om<sup>2</sup>, Pisal Heng<sup>2</sup>, Sovannaroth Siv<sup>2</sup>, Rekol Huy<sup>2</sup>, Rida Slot<sup>3</sup>

<sup>1</sup>University Research Co., LLC, Chevy Chase, MD, United States, <sup>2</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>3</sup>President's Malaria Initiative, U.S. Agency for International Development, Phnom Penh, Cambodia

The Cambodian/Thai border area has long been an area of concern for malaria control efforts due to the emergence and spread of chloroquine-resistant and more recently artemisinin-resistant *Plasmodium falciparum* malaria parasites. This recent spread led international health organizations to suggest a move from containment to elimination strategies. Subsequently, the Cambodia Strategic Plan for Malaria Elimination 2011-2025 was developed, which calls for elimination of *P. falciparum* by 2020 and all malaria species by 2025. A basic essential package of activities for

malaria elimination was developed following the 1-3-7 model developed in China (notification within 24 hours, investigation within 3 days, and response within 7 days). The package used rural health facilities and community health workers to form response teams for conducting active surveillance in their catchment areas. Simultaneously, management capacity at district and central levels was strengthened. The model was implemented in 3 administrative districts in Battambang Province from July 2015 to January 2017. Results show an increase in notification, investigation, and response of reported cases from 52%, 20%, and 36%, respectively, to 100% in all categories by May 2016. Response activities included health education to 2,492 people, 242 insecticide treated nets distributed, and 1,377 individuals screened through reactive case detection (RACD). RACD identified no cases among index and surrounding households, however 2.53% of co-travelers were infected. There was a reduction in the average monthly *falciparum* incidence from 0.089 (SD=0.055) during July 2015 - April 2016 to 0.017 (SD=0.012) during May 2016 - January 2017. Additionally, the percentage of locally transmitted cases during the same periods above dropped from 10.3% to 0%, with no locally acquired cases reported since March 2016. The data illustrates the potential of the model to increase the quality of programmatic activities and reduce malaria incidence. The model will be reevaluated and revised as necessary in April 2017 after which implementation will continue in the study site.

### A MULTI-COUNTRY INITIATIVE TO ACCELERATE ELIMINATION BY REDUCING CROSS-BORDER IMPORTATION OF MALARIA

**Immo Kleinschmidt**<sup>1</sup>, Bongani Dlamini<sup>2</sup>, Nyasha Mwendera<sup>2</sup>, Phelele Fakudze<sup>2</sup>, Kudzai Makomva<sup>2</sup>, Simon Kunene<sup>3</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine/Elimination 8, London, United Kingdom, <sup>2</sup>Elimination 8, Windhoek, Namibia, <sup>3</sup>Swaziland Ministry of Health, Mbabane, Swaziland

The importation of pathogens, including malaria, through population movement has long been recognised as a contributor to the transmission of infectious diseases and an obstacle to disease elimination. The Elimination Eight (E8) is a multi-country Southern African regional initiative to coordinate the elimination of malaria in four frontline countries (Botswana, Namibia, South Africa and Swaziland) by 2020, and pave the way for elimination in four second line countries (Angola, Mozambique, Zambia and Zimbabwe) by 2030. The frontline four countries have reduced malaria incidence to pre-elimination levels; their highest burden areas are generally adjacent to borders with second line countries. The region is experiencing a steady rise in both regular (formal) and irregular (informal) migration and travel. The persistence of malaria transmission in the pre-elimination countries is partially caused by ongoing importation of infections from across the borders, where malaria transmission is higher, and access to health services is limited. As they reduce malaria incidence, E8 countries therefore remain vulnerable and receptive to malaria outbreaks triggered by imported cases from their neighbors. To counter this risk, E8 countries, working through their National Malaria Control Programs, have established a mix of approximately 40 static and mobile border health facilities on 5 key international borders between high and low transmission districts of E8 countries. The goal of these health posts is to improve access to malaria testing and treatment services, among mobile and migrant populations and underserved resident communities in border districts. All health posts provide core diagnosis and treatment of malaria, whilst static facilities additionally provide a basic package of primary health care services. An evaluation study will be carried out to assess the impact of these border posts on mobile and resident populations. This presentation will describe the E8 border health post project and its evaluation.

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, United States, <sup>3</sup>Department of Oncological Sciences, Tisch Cancer Institute and the Immunology Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States, <sup>4</sup>Division of Infectious Diseases, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, <sup>5</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>6</sup>Health Center Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua, <sup>7</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Zika virus (ZIKV) is an emerging, mosquito-borne flavivirus that is responsible for the recent pandemic in the Americas. ZIKV usually causes a mild febrile illness; however, it has been linked with Guillain Barré Syndrome in adults and congenital birth defects, including microcephaly, when infection occurs during pregnancy. However, much remains to be defined regarding the human immune response to ZIKV infection. In this study, we collected blood in PAXgene solution and plasma at acute (days 1-3 and days 4-6 post-onset of symptoms) and convalescent (day 14-16) time-points and peripheral blood mononuclear cells (PBMCs) at day 4-6 and convalescence from symptomatic ZIKV-infected pediatric cases in a 13-year ongoing cohort study in Managua, Nicaragua, who presented to the study health center. Patients were documented to be either previously exposed to DENV (n=45) or DENV-naïve (n=45). Comprehensive innate immune responses were investigated by CyTOF, Luminex cytokine assays, and RNA-seq. Initial CyTOF analysis revealed significant differences between acute and convalescence in the cytokine and chemokine profile, and differences in frequencies and phenotype of specific circulating leukocytes subsets, including significantly elevated expression of CD169 on monocytes in convalescent samples. Luminex results revealed that levels of CCL2, CCL5 and CXCL10 are significantly higher in DENV-immune patients compared to DENV-naïve individuals on days 4-6 of infection. Type I and II interferon levels were significantly higher on days 1-3 of infection compared to other time-points along with several other interleukins and chemokines. We also performed RNA-seq analysis during the acute (days 1-3) and convalescent phase of ZIKV infection to identify differences in gene expression at the transcriptomic level. These data are being analyzed and integrated into our network modeling and key driver analysis. This study will provide the most comprehensive immune profiling and network analysis of the human response to ZIKV infection to date, will illuminate the effect of prior DENV infection, and will help inform future diagnostics and drug therapies.

### LABORATORY IDENTIFICATION OF PERSISTENT ZIKA VIRAL RNA IN SEMEN OF A U.S. COHORT

**Nisha Duggal**, Paul Mead, Alison Hinckley, Sarah Hook, Erin McDonald, Mark Delorey, Heidi Becksted, Michael Anishchenko, Ryan Max, Amy Schwartz, Aaron Brault

Centers for Disease Control and Prevention, Fort Collins, CO, United States

Zika virus (ZIKV; *Flavivirus*) is an emerging mosquito-borne virus that is capable of sexual transmission. ZIKV infection during pregnancy can cause congenital disease. In order to assess the risk of sexual transmission, the duration and frequency of ZIKV shedding in semen was evaluated through

a prospective study of men in the U.S. with symptomatic, laboratory-confirmed ZIKV infection. 225 men were enrolled in the study, and home-collected semen and urine were provided every 2 weeks for up to 6 months after symptom onset. Samples were tested for ZIKV RNA by real-time RT-PCR, and a subset of samples were tested by plaque assay for infectious virus. In the first 30 days post-onset of disease, 56% of men tested (23 out of 41) had at least one sample with detectable ZIKV RNA in semen, and 7% (3 out of 41) had at least one sample with detectable infectious ZIKV in semen. By 65 days post-onset of disease, the proportion of semen samples with detectable ZIKV RNA had declined 2-fold, and by 211 days, 99% of men had undetectable ZIKV RNA levels in their semen. To date, the latest day post-onset of disease with detectable ZIKV RNA was 256 days. The latest day post-onset of disease with detectable infectious virus was 25 days, and the lowest RNA level corresponding to detectable infectious virus was 7.3 log<sub>10</sub> RNA copies/mL semen. Semen from vasectomized men (n=30) also were positive for ZIKV RNA but at significantly lower levels. The study results suggest that ZIKV RNA shedding in semen is common and long-lasting, even in vasectomized men. However, the implications for sexual transmission remain somewhat unclear, as infectious virus was not detected from any tested samples that contained less than 7.0 log<sub>10</sub> RNA copies/mL semen. Further studies to determine the cell populations in the male urogenital tract that are persistently infected and to identify immune correlates of persistent ZIKV RNA shedding will provide additional insights into the sexual transmission risk potential from ZIKV infected men.

#### STAGING EARLY AND LATE EVENTS IN ACUTE ZIKA VIRUS INFECTION USING RNA+ PUERTO RICAN AND CONTINENTAL U.S. BLOOD DONORS

**Graham Simmons**<sup>1</sup>, Mars Stone<sup>1</sup>, Kai Lu<sup>1</sup>, Sonia Bakkour<sup>1</sup>, Phillip C. Williamson<sup>2</sup>, Donald J. Brambilla<sup>3</sup>, Michael P. Busch<sup>1</sup>, for the NHLBI Recipient Epidemiology and Donor Evaluation Study-III (REDS-III)<sup>4</sup>

<sup>1</sup>Blood Systems Research Institute, San Francisco, CA, United States,

<sup>2</sup>Creative Testing Solutions, Tempe, AZ, United States, <sup>3</sup>RTI International, Rockville, MD, United States, <sup>4</sup>NHLBI, Rockville, MD, United States

Due to the risk of blood transfusion-transmission, nucleic acid amplification testing (NAT) of the blood supply for Zika virus (ZIKV) RNA was implemented during 2016 in the U.S. and its territories. At the peak of the epidemic in Puerto Rico (PR) over 1.5% of blood donors were detected as infected by ZIKV NAT, with ~350 total infected donations interdicted. Fifty-one ZIKV+ donors identified in 2016 from both PR and the continental US were enrolled into longitudinal follow-up studies. Using the index donation and follow-ups we were able to classify eight distinct stages of acute infection based on plasma viral load (VL), anti-ZIKV IgM seroconversion and the persistent viral RNA in blood compartments. These stages begin with IgM seronegative donors with VLs below or above 300 IU/ml (stages I and II, respectively), progress to IgM seropositive stages with VLs >300 (stage III) and VLs <300 with either repeat testing reactive or non-reactive ID-NAT results (stages IV and V, respectively). Follow-up samples could be classified into a further stage with negative NAT on plasma, but with detectable persistent viral RNA in packed red blood cell (pRBC) preparations (stage VI). Finally, RNA non-reactive eclipse and convalescent stages book-end the six stages with detectable viral RNA. Early in the epidemic most of the index donations were stage I and II donors. All of the stage I and II donors seroconverted to IgM+ within 5-24 days of index donation. The duration of ZIKV IgM seroreactivity ranged from 40 to over 185 days. Overall, approximately 50% of plasma RNA+ donors fell into the IgM seropositive stages (III-V) at index, with a higher percentage of tail-end stage IV and V infections observed towards the end of the epidemic. Many of the stage IV and V donors rapidly progressed to stage VI with non-detectable plasma viremia, but persistent viral RNA in the pRBC compartment. Further studies are required to demonstrate the risk to blood safety that donations from individuals in stage VI would

represent. Using the data collected in this study we will approximate the duration of the various stages and the length of the window for transmissibility.

While progress has been made in characterizing humoral immunity to Zika virus (ZIKV) in humans, little is known regarding the corresponding T cell responses to ZIKV. Here we investigate the kinetics and viral epitopes targeted by T cells responding to ZIKV and address the critical question of whether pre-existing dengue virus (DENV) T cell immunity modulates these responses. We find that memory T cell responses elicited by prior infection with DENV recognize ZIKV-derived peptides. This cross-reactivity is explained by the sequence similarity of the two viruses, as the ZIKV peptides recognized by DENV-elicited memory T cells are identical or highly conserved in DENV and ZIKV. We further show that DENV exposure prior to ZIKV infection influences the timing and magnitude of the T cell response. ZIKV-reactive T cells in the acute phase of infection are detected earlier and in greater magnitude in DENV-immune patients. Conversely, the frequency of ZIKV-reactive T cells continues to rise in the convalescent phase in DENV-naïve donors, but declines in DENV pre-exposed donors, compatible with more efficient control of ZIKV replication and/or clearance of ZIKV antigen. Finally, we discovered that ZIKV structural proteins (E, prM and C) are major targets of both the CD4 and CD8 T cell responses, whereas DENV T cell epitopes are found primarily in nonstructural proteins - thus highlighting a fundamental difference between the immunodominant antigens targeted by human T cell responses against DENV and ZIKV viruses.

**INDEX CLUSTER STUDY OF ZIKA VIRUS INFECTION IN MANAGUA, NICARAGUA**

**Raquel Burger-Calderon**<sup>1</sup>, Karla González<sup>2</sup>, Nery Sanchez<sup>3</sup>, José Victor Zambrana<sup>3</sup>, Sergio Ojeda<sup>3</sup>, Cristhiam Cerpas<sup>2</sup>, Harold Suazo Laguna<sup>3</sup>, Fausto Bustos<sup>1</sup>, Josefina Coloma<sup>1</sup>, Guillermina Kuan<sup>4</sup>, Angel Balmaseda<sup>2</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>2</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, <sup>3</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>4</sup>Health Center Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Zika virus (ZIKV) recently caused major epidemics in the Americas and is linked to congenital neurological birth defects and Guillain-Barré Syndrome. A pilot Zika index cluster study was conducted from August 31 to October 21 of 2016 in Managua, Nicaragua, towards the end of the initial ZIKV epidemic and during government vector control activities targeting Zika-positive households. Real-time RT-PCR (rRT-PCR)-confirmed symptomatic Zika cases from the study Health Center were selected as index cases (n=33), and contacts (household members) were enrolled during a home visit the next day (n=109). Enrollment and 4 follow-up visits (days 3-4, 6-7, 9-10, and 21) included blood, urine and saliva collection, along with clinical, demographic, socio-economic status (SES) and risk factor questionnaires. Samples were analyzed by the ZCD rRT-PCR assay, which detects Zika, dengue, and chikungunya viruses; only ZIKV was detected during the study period. ZIKV serological responses were assessed by a highly ZIKV-specific in-house ZIKV IgM capture ELISA (IgM) and a standardized in-house ZIKV Inhibition ELISA (IE), using enrollment and day-21 serum samples. An entomological household survey was performed on day 10. At enrollment, 11 (31%) contacts were ZIKV-positive (4 by rRT-PCR and 7 by rRT-PCR and IgM), and 3 showed IgM seroconversion and 2 a ≥4-fold rise in IE titer during the study. In addition, 23 (21%) were positive by IgM, indicating a recent ZIKV infection. Analysis of clinical information enabled estimation of the symptomatic to asymptomatic (S:A) ratio of 5:11 (1:2.2.) among the contacts. Of the 11 asymptomatic ZIKV-positive contacts, 6 were rRT-PCR-positive and 5 were positive by serology. Entomological analysis revealed no rRT-PCR ZIKV-positive *Aedes aegypti* mosquitoes. Initial evaluation of ZIKV viral load kinetics indicated that ZIKV is detectable up to visit 3 (days 6-7) in saliva and up to visit 4 (day 9-10) in urine. SES and household data is being analyzed to identify potential protective and risk factors for ZIKV infection. Overall, these data inform the development of public health decisions that target prevention of ZIKV transmission.

## 1334

**PREVALENCE AND INCIDENCE OF ZIKA VIRUS INFECTION AMONG HOUSEHOLD CONTACTS OF ZIKA PATIENTS, PUERTO RICO, 2016-2017**

**Eli Rosenberg**<sup>1</sup>, Katherine Doyle<sup>2</sup>, Jorge L. Munoz-Jordan<sup>3</sup>, Liore Klein<sup>4</sup>, Laura Adams<sup>3</sup>, Matthew Lozier<sup>3</sup>, Tyler M. Sharp<sup>3</sup>, Gabriela Paz-Bailey<sup>2</sup>

<sup>1</sup>Emory University Rollins School of Public Health, Atlanta, GA, United States, <sup>2</sup>Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States, <sup>4</sup>Caduceus Healthcare, San Juan, PR, United States

Little is known about prevalence or incidence of Zika virus (ZIKV) infection among household contacts of infected patients or risk factors for infection, including sexual practices. The Zika virus Persistence (ZiPer) study is an ongoing cohort study in Puerto Rico, begun in May 2016. After presenting to care, index patients with ZIKV RNA in blood or urine and their household contacts were offered study participation, including a survey and diagnostic testing for: a) ZIKV RNA in serum, urine, saliva,

vaginal fluid, and semen; and b) anti-ZIKV IgM antibody in serum. ZIKV RNA- and IgM-negative contacts were offered additional testing at a 4-month follow-up visit. We assessed ZIKV prevalence (RNA or IgM) in contacts, and factors correlated with prevalence with bivariate prevalence ratios (PR), 95% confidence intervals (CI). Associations with sexual contact were assessed by evaluating reported sex with the index patient, and a social-network method that evaluated all pairwise household relationships using a matched odds ratio (mOR). Incidence among retested contacts was measured with rates per 100 person-days (PD) and 95% CI. Among 352 household contacts of 167 index patients, prevalence of ZIKV infection was 35% (CI: 30-40%). Age, sex, and other demographics were not associated with prevalent infection. Sexual contacts of index cases did not have significantly higher prevalence than non-sexual ones (PR=1.25, 95%CI: 0.89-1.76), and the network approach found no association (mOR=1.01). Household factors associated with infection included reporting ever leaving windows open (PR=2.33, CI: 1.33-4.06) and not having window screens (PR=1.59, CI: 1.20-2.10). Among 118 ZIKV-negative members retested, 10 (8%) had incident infections (rate: 0.11/100PD, CI: 0.05-0.19). One-third of household members of Zika patients had prevalent infection, and nearly one-in-ten became infected within four months. For this population there was insufficient evidence to implicate sexual transmission as a major mode of ZIKV transmission. In regions with ongoing ZIKV transmission, personal and household measures to prevent ZIKV infection should be sustained.

## 1335

**VIRAL LOAD DOES NOT SUPPORT ADE HYPOTHESIS IN DENGUE-PRIMED ZIKA-INFECTED PATIENTS**

Ana Terzian<sup>1</sup>, Alessandra Schanoski<sup>1</sup>, Manlio Mota<sup>1</sup>, Rafael Silva<sup>1</sup>, Cassia Estofolete<sup>1</sup>, Tatiana Colombo<sup>1</sup>, Kathryn A. Hanley<sup>2</sup>, Nikos Vasilakis<sup>3</sup>, Jorge Kalil<sup>4</sup>, **Maurício L. Nogueira**<sup>1</sup>

<sup>1</sup>Faculdade de Medicina de Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil, <sup>2</sup>New Mexico State University, Las Cruces, NM, United States, <sup>3</sup>University of Texas Medical Branch, Galveston, TX, United States, <sup>4</sup>Universidade de Sao Paulo, Sao Paulo, Brazil

Most studies on the pathogenesis of severe dengue disease focus on the process of antibody-dependent enhancement (ADE) as a primary risk factor. With the circulation of ZIKV in DENV-endemic areas, many people infected by ZIKV were likely exposed to DENV. Currently, the influence of such exposure on Zika disease outcomes remains unknown, despite several *in vitro* data suggests that ADE may play a role in Zika pathogenesis. We investigated whether patients previously exposed to dengue exhibited higher viremia when exposed to a subsequent, heterologous dengue or Zika infection than those patients not previously exposed to dengue. We measured viral loads and cytokines profile during patients' acute infections. Neither dengue nor Zika viremia was higher in patients with prior DENV infection. Of the ten cytokines measured, only one significant difference was detected: levels of IL-1β were lower in dengue-infected patients that had experienced a previous dengue infection than patients infected with dengue for the first time. Taken together this data shows no signs of ADE were observed *in vivo* in patients with acute ZIKV infection who had prior exposure to DENV.

## 1336

**HOST BLOODMEAL REMNANT ANALYSIS DEMONSTRATES THE VARIABLE CONTRIBUTION OF WHITE FOOTED MICE TO ENZOOTIC TRANSMISSION OF LYME DISEASE SPIROCHETES**

**Heidi Goethert**, Sam Telford

Tufts University School of Veterinary Medicine, N. Grafton, MA, United States

The public health burden of Lyme disease continues to increase. Modes of intervention include those that target the putative main reservoir mouse, *Peromyscus leucopus*, but such interventions are not consistently effective in reducing the entomological inoculation rate. One explanation

for varying results is that in some sites, mice may not be the sole source of infected ticks. The incrimination of reservoirs for the agent of Lyme disease has been largely based on indirect measures, such as relative tick burdens and infectivity of diverse hosts. Bloodmeal analysis of host-seeking ticks would directly and definitively incriminate the reservoir as it does for mosquito-borne infections. To date, bloodmeal remnant analysis of ticks (particularly nymphs) has been limited because assays lack sensitivity; typically only about half of the samples yield results. We developed a sensitive real-time PCR assay targeting host-specific retrotransposons that yields a signal in over 98% of the ticks tested. Retrotransposons are genetic elements that can integrate themselves into and typically are present as thousands of copies per genome. In addition, they have coevolved with diverse mammalian families making it possible to design host-specific PCR primers. We designed primers to identify the most likely hosts for subadult deer ticks in New England: white-footed mouse, meadow vole, cottontail rabbit, squirrel/chipmunk, skunk/raccoon, deer and shrew. Host-seeking nymphal deer ticks from Martha's Vineyard were individually homogenized and analyzed for evidence of infection by *Borrelia burgdorferi*; host bloodmeal remnants were determined for those that were infected. Host DNA was detected in 98% of the ticks tested. During 2016, *P. leucopus* had served as the source of infection for 64% [95% CI 51-76] of the infected ticks and rabbits 22% [12-35]. During 2015, only 43% [29- 57] of the infected ticks had fed as larvae on *P. leucopus*; rabbits and shrews each fed 22% [12-36]. We conclude that although *P. leucopus* serves as a major source of *B. burgdorferi* for larval deer ticks, other animals significantly contribute to maintaining enzootic transmission.

### 1337

#### COMPARISON OF AN ULTRA-SENSITIVE PCR-BASED ASSAY TO TWO-TIER SEROLOGY IN THE DIAGNOSIS OF EARLY LYME DISEASE

John N. Aucott<sup>1</sup>, Alison W. Rebman<sup>1</sup>, Steven E. Schutzer<sup>2</sup>, Ting Yang<sup>1</sup>, Michael R. Mosel<sup>3</sup>, Mark J. Soloski<sup>1</sup>, Mark W. Eshoo<sup>3</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>Rutgers New Jersey Medical School, Newark, NJ, United States, <sup>3</sup>Ibis Biosciences, Inc., Carlsbad, CA, United States

Lyme disease is a tick-borne infection caused by the bacteria *Borrelia burgdorferi*. Current diagnostic testing relies on a two-tier ELISA and western blot serology performed during acute and convalescent phases. Limitations of serology include both insensitivity for early and non-specificity for later infection. The purpose of this study is to compare performance of an assay for direct detection of *B. burgdorferi* in skin and whole blood to two-tier serology among a sample of patients diagnosed with early Lyme disease. Thirty-nine patients from Maryland with physician-documented erythema migrans rash were enrolled. A 2mm skin biopsy sample and 20ml of whole blood were obtained and tested using an ultra-sensitive, nucleic acid-based PCR assay employing isothermal amplification and multiple PCR primers. Acute and convalescent serologies were measured by a large commercial laboratory and interpreted by CDC criteria. Group comparisons were determined by chi-square or Fisher's exact tests for categorical and Wilcoxon Rank Sum test for continuous variables. At time of diagnosis, thirty participants (76.9%) were skin PCR positive (S+) for *B. burgdorferi*, 10/39 (25.6%) were blood positive (B+), and 5/39 (12.8%) were serology positive. Nine participants (23.1%) were skin biopsy and blood PCR negative (S-/B-), and all 9 were also serology negative. No participants were (S-/ B+). There was a statistically significant difference in the proportion serology positive at the time of diagnosis between the S+/B+ and the S+/B- groups (40% vs. 5%, respectively,  $p=0.03$ ), and a statistically significant difference in median number of new-onset symptoms reported at the time of diagnosis between the three groups (S+/B+: 10, S+/B-: 5, S-/B-: 2,  $p=0.002$ ). Skin biopsy PCR is a more sensitive diagnostic test for early Lyme disease than whole blood PCR or two-tier antibody testing. We did not find PCR or serologic evidence of infection with *B. burgdorferi* among a subgroup of patients

with physician-diagnosed erythema migrans. At time of initial diagnosis, a higher proportion of those with evidence of bacterial blood stream dissemination had a positive serologic test.

#### GENOMIC SURVEILLANCE AND DIAGNOSIS OF TICK-BORNE DISEASE *BABESIA MICROTI*

Mary Lynn Baniecki Baniecki<sup>1</sup>, Jade Moon<sup>2</sup>, Kian Sani<sup>3</sup>, Jacob E. Jacob<sup>1</sup>, Lisa Freimark<sup>1</sup>, Pardis C. Sabeti<sup>1</sup>

<sup>1</sup>The Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States, <sup>2</sup>Harvard University, Cambridge, MA, United States, <sup>3</sup>Harvard University, Cambridge, MA, United States

*Babesia microti* is tick-borne disease that is an emerging threat to public health due to increasing prevalence and expanding geographic range. Despite ongoing research, the care of patients with tick-borne disease is frustrated by the limited number of diagnostic assays and surveillance tools. Leveraging the genetic diversity, we identified through our whole genome sequence (WGS) analyses of *B. microti*, we have developed a rapid lineage-specific qPCR-based diagnostic and single nucleotide polymorphism (SNP)-based high resolution melting (HRM) surveillance tool for *B. microti*. These tools were built on our experience in developing diagnostics for hemorrhagic fever viruses and *Plasmodium vivax* malaria. Our *B. microti* qPCR assay is robust and targets a conserved region within the mitochondrial gene cytochrome oxidase B and is highly sensitive, with a detection limit of 2pg of parasitic gDNA. In addition to detection, constant surveillance of hotspots of Babesiosis is imperative to diagnosis and to predict the spread of the pathogen. Using our WGS data we developed a SNP-based barcode using HRM. We identified candidate SNPs for our barcode by performing SNP calling using available sequence data (with quality scores of > 30) on 26 parasite strains from 4 geographic locations and identified 775 informative SNPs. Screening this set of informative SNPs, we developed a 40-SNP barcode consisting of 20 mitochondrial SNPs and 20 nuclear SNPs that capture high degrees of population diversity and differentiate geographically distinct populations. We used our HRM assay to identify *B. microti* infections in a pilot study of 50 clinical specimens with high reproducibility and sensitivity and to identify the geographic origin of a given strain. By implementing field-deployable genotyping tools, the HRM platform can be expanded to include new variants identified by WGS analysis such as drug resistance. Most importantly, this approach provides a technology that is easily transferred to researchers as many real-time PCR instruments are coupled with HRM analysis software, creating a rapid genotyping technique where analysis can be completed in 1.5 hours.

### 1339

#### NOVEL IMMUNO-DOMINANT *BABESIA MICROTI* ANTIGENS THAT INDUCE PROTECTIVE IMMUNITY AGAINST PARASITE CHALLENGE IN MICE

Nitin K. Verma<sup>1</sup>, Edward E. Essuman<sup>1</sup>, Hong Zheng<sup>1</sup>, Ankit Puri<sup>1</sup>, Peter J. Krause<sup>2</sup>, Sanjai Kumar<sup>1</sup>

<sup>1</sup>CBER/Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>Yale School of Public Health and Yale School of Medicine, New Haven, CT, United States

Human babesiosis caused by *Babesia microti* is a major public health concern in the United States and is found in temperate regions throughout the world. While the disease is generally mild to moderate in children and young adults, it is more severe or even fatal in newborn infants, the elderly and immunocompromised individuals such as those with cancer, HIV, asplenia, and those who acquire the infection through blood transfusion. Additionally, asymptomatic persistent infection presents a serious risk to blood safety. A vaccine targeted against high risk populations could reduce disease severity and mortality in vaccinated individuals. Using a genomics approach, we have identified a battery of novel immunodominant antigens that are reactive against plasma/sera from *B. microti*-infected individuals.

We have chosen the nine highest ranking immunodominant antigens for vaccine efficacy studies using multiple rounds of immunoselection. BALB/c mice were immunized three times with these recombinant protein antigens formulated in Complete/Incomplete Freund's adjuvant while control group mice were given only adjuvant. Both groups were infected with *B. microti* parasites through syringe inoculation. We noted a significant reduction in parasite burden after vaccination with 3 of the 9 candidate antigens - BmSERA (Serine Repeat Antigen), BmMCFRP (Maltese-cross form related protein) and Bm3 (function unknown). The geometric mean of maximum percent parasitemia (95% CIs) was significantly reduced in the BmSERA, BmMCFRP and Bm3 immunized groups (0.3%, 1.5% and 1.6%, respectively) compared with the control group (2.9%). Furthermore, a significant delay in peak parasitemia was observed in the vaccinated versus control mice with the mean peak parasitemia (95% CIs) at 18.8, 18.4 and 17.5 days for the BmSERA, BmMCFRP and Bm3 immunized group, respectively, compared to 15.6 days for the control mice. Studies to determine the vaccination induced antibody and cellular immune mechanisms of protection are in progress.

### 1340

#### SCRUB TYPHUS NO LONGER RESTRICTED TO THE TSUTSUGAMUSHI TRIANGLE

**Allen L. Richards**

*Naval Medical Research Center, Silver Spring, MD, United States*

Scrub typhus, a vector-borne disease, has for many years been considered endemic to a region bordering central and eastern Asia, northern Australia and the Western Pacific. This no longer is true as cases of scrub typhus have been found in the Chile and United Arab Emirates. In addition, others have reported scrub typhus-like cases from Africa and orientia DNA from rodents of Europe and Africa. Moreover, serological evidence of orientia infection have been reported from Africa. Recent work in South America, including studies in Peru and Chile corroborate the findings that scrub typhus should no longer be restricted to the Tsutsugamushi Triangle.

### 1341

#### A SYSTEMIC FUNCTIONAL ANALYSIS OF THE PHOSPHOINOSITIDE METABOLIC PATHWAY IN *PLASMODIUM FALCIPARUM*

**Angana Mukherjee**, Dominic Gagnon, Zeinab Ebrahimzadeh, Dave Richard

*Centre for Infectious Diseases and Immunology, Laval University, Quebec, QC, Canada*

Phosphoinositides (PIPs) are critical components of cellular membranes in eukaryotes, playing massive roles in signal transduction, cell motility, cytoskeletal reorganisation, DNA synthesis, cell cycle, adhesion, membrane transport, permeability and intracellular trafficking. Collectively, seven isoforms of PIPs, the protein effectors that bind them and enzymes that generate or modify them compose a remarkably complex protein-lipid signalling network. Despite their crucial role in eukaryotes little is known about PIP metabolism and functions in the malaria parasite *Plasmodium falciparum* where the PIP profile is much complex than in uninfected RBCs. Here, in this study we performed a comprehensive knock out screen, by employing the recently reported Selection-Linked Integration (SLI) method to select for targeted gene disruptions (TGD), wherein we attempted to disrupt the complement of the PIP metabolic pathway including PIP kinases, phosphatases, putative PIP effectors and PIP transfer proteins, a total of ~30 targets to identify the genes that are essential for asexual proliferation in *P. falciparum*. Integration of the SLI-TGD vector at the correct genomic locus was monitored by PCR products across the 5' and 3' integration junctions and the quantitative absence of the original WT locus. Our study shows that >50% of the genes in the PIP metabolic pathway could not be disrupted and are likely to be essential for the maintenance of parasite viability, which correlated well with the sparse essentiality data from homologs in *P. berghei* or *T. gondii*. This lack of

redundancy points not only to the vital role of a number of individual kinases/effectors/phosphatases but also to a potentially abundant source of anti-malarial targets. We will describe asexual growth, susceptibility to antimalarials and gametocytogenesis in the knock outs generated. Additionally, we have also employed the recently reported strategy of knock sideways to localize native proteins by fusing with GFP and functionally analyzing the essential PIP kinases at the protein levels by mislocalizing the native proteins.

### 1342

#### CAPTURING DIFFERENTIAL PROTEIN TURNOVER DYNAMICS IN ARTEMISININ RESISTANT *PLASMODIUM FALCIPARUM* USING PULSE-SILAC

**Tuo Yang**, Simon Cobbold, Stanley C. Xie, Leann Tilley

*The University of Melbourne, Melbourne, Australia*

Malaria caused an estimated 438,000 deaths in 2015. Although the first-line antimalarial - artemisinins (ARTs) - have contributed to decreased mortality rates, ART resistance is a major threat. Several lines of evidence indicate that artemisinin resistance is mediated, at least in part, by altered protein turnover dynamics. To investigate how ART-resistant parasites are capable of overcoming artemisinin-induced toxicity we developed a pulse-SILAC (stable isotope labeling amino acid in cell culture) approach that is capable of quantifying the rates of protein synthesis, degradation and turnover across the proteome. We observe that following ART exposure, both sensitive and resistant lines have impaired protein turnover that affects all detectable proteins. However, ART-resistant lines begin recovering protein synthesis after 12 hours post drug exposure with increased turnover of proteins associated with protein folding, translation and response to oxidative stress. This difference in parasite recovery at 12-18 hours post-artemisinin treatment was independently validated with a firefly luciferase reporter assay. Here we present how this novel triplex pulse-SILAC approach can provide insight into investigating protein turnover dynamics across the intra-erythrocytic developmental cycle for artemisinin-resistant parasites. These findings indicate that long-lasting endoperoxides should overcome artemisinin resistance and we present our evidence for the enhanced efficacy against ART-resistant parasites of OZ439, an endoperoxide with enhanced pharmacokinetics.

### 1343

#### USING SINGLE-CELL TRANSCRIPTOMICS TO ELUCIDATE SEXUAL COMMITMENT AND DIFFERENTIATION IN *PLASMODIUM FALCIPARUM*

**Katelyn A. Walzer**, Liane Y. Emerson, Danielle Kubicki, David L. Corcoran, Jen-Tsan Ashley Chi

*Duke University, Durham, NC, United States*

Sexual reproduction is an obligate step in the *Plasmodium falciparum* life cycle, with mature gametocytes being the only form of the parasite capable of human-to-mosquito transmission. During the red blood cell stage of human infection, less than five percent of *P. falciparum* parasites commit to a sexual fate and become gametocytes. This occurs in a 3:1 ratio of females to males that mature through five distinct gametocyte stages over 10-12 days before being transmitted to the mosquito. Previous studies utilizing *Plasmodium berghei* indicate that male and female gene expression is highly distinct. But in *P. falciparum*, although over 300 genes are predicted to be gametocyte-specific, only a few genes have been postulated to be male or female specific. Since these markers are expressed at late stages and their gender-specific expression is debated, separating male and female populations remains technically challenging. Most importantly, there is a large amount of heterogeneity in the parasite population, especially at early gametocyte stages. To overcome these challenges, we have developed an unbiased single-cell approach to determine which transcripts are temporally expressed in males versus females. Using microfluidic technology, we have isolated over 300 single parasites at synchronized asexual and sexual stages to

compare the expression of 90 conserved gametocyte-specific genes. These analyses have identified gender-specific gene expression for mid-to-late stage gametocytes, including two male-specific candidate genes. These validated male-specific genes are being knocked out using CRISPR-Cas9 technology and will be tested for their functional roles in male gametocyte development and gamete exflagellation.

### 1344

#### CHARACTERIZING THE POTENTIAL BIAS WITHIN GENOMIC TOOLS FOR INFERRING CHANGES IN *PLASMODIUM FALCIPARUM* TRANSMISSION INTENSITIES

**Oliver J. Watson**, Robert Verity, Lucy Okell, Azra Ghani

*MRC Centre for Outbreak Analysis and Modelling, Imperial College London, London, United Kingdom*

Substantial progress has been made globally to control malaria, however there is a growing need for innovative new tools to ensure continued progress. In response, a number of genomic studies have been conducted detailing the potential for utilising measures of *Plasmodium falciparum* genetic diversity to infer changes in transmission intensity and the role of intervention policies. This work has revealed that the complexity of infection (COI), genetic relatedness and degree of clonality could be used as metrics with which to guide programmatic surveillance efforts. These studies, however, have noted a need to better understand both the interacting role of super-infection and cotransmission upon genetic epidemiological models and the impact of transmission heterogeneity within the population. Here we present a mathematical transmission model to identify potential bias that may be introduced by these processes upon the predictive accuracy of these genomic tools. Using an individual-based model of both human and mosquito dynamics, we incorporate a parasite genetic barcode model that identifies parasites based on 24 unlinked SNPs. Our modelling predicts firstly that heterogeneity within the human population can lead to bias in estimates of the mean population COI, with preferentially sampling clinical cases and young children leading to potential underestimates of transmission declines as a result of interventions. As a result we identify optimal sampling schemes that ensure sufficient representation of the genetic diversity of the parasite population for accurate inferences of transmission intensity. Additionally we characterise the impact of increased rates of cotransmission, and through sensitivity analysis identify transmission settings in which the role of cotransmission leads to overestimation of transmission intensity based upon genetic diversity inference. Through highlighting where potential bias exists, we further show support for how genomic tools could be deployed effectively to provide real-time inference upon the effectiveness of intervention programmes.

### 1345

#### THE CONSEQUENCES OF CENSORING NEW INFECTIONS WHEN DERIVING ANTIMALARIAL EFFICACY AGAINST UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA

**Prabin Dahal**, on behalf of the WWARN Methods Study Group

*WorldWide Antimalarial Resistance Network, Oxford, Oxford, United Kingdom*

The primary endpoint in efficacy trials of uncomplicated *P. falciparum* is polymerase chain reaction adjusted failure defined as the reappearance of the same parasite which caused the initial infection (recrudescence). Competing risk event (CE) of a new infection can be observed during the follow-up. These are censored in Kaplan Meier (K-M) analysis, the currently recommended statistical method for deriving failure. In the presence of CE, K-M is known to result in an overestimate of cumulative failure compared to Cumulative Incidence Function (CIF). The overall aim of this work is to quantify the bias due to the use of K-M in estimating cumulative failure in studies with artemisinin combination therapies (ACTs) in uncomplicated *P. falciparum*. Cumulative failure for recrudescence were derived using:

1 minus K-M estimate where competing events were censored, and CIF which accounts for competing event by still maintaining them in the risk set. The discrepancy between the two estimates was expressed as absolute and relative difference. The impact of study duration, proportion of recrudescences and new infections on the difference was investigated. Data on 31379 patients treated with ACTs from 87 trials (1996-2014) in Africa, Asia and S.America were available. There were 682 (2.2%) recrudescences and 3,738 (11.9%) new infections as classified by study investigators. A total of 85% (199/233) of treatment arms reported at least one new infection. On absolute scale, the overestimation using K-M was small with a median of 0 [range: 0- 0.06]. The median relative overestimation was: 2.4% [range: 0- 67.1%] and this increased with study duration: 0.6% on day28, 4.7% on day42, and 9.3% on day63. The relative overestimation was correlated with the proportion of new infections which becomes greater with longer follow-up (correlation 0.67 [95% CI 0.61-0.73]). Censoring new infections in the K-M analysis led to a marginal overestimation of cumulative failure of recrudescence which increased with study duration. The CIF approach is ideally suited to derive cumulative failure estimate when the observed proportion of new infection is high.

### 1346

#### SINGLE CELL GENOMICS OF MALARIA INFECTIONS

Simon G. Trevino<sup>1</sup>, Standwell Nkhoma<sup>2</sup>, Shalini Nair<sup>1</sup>, Timothy Anderson<sup>1</sup>, Karla Moncada<sup>3</sup>, Benjamin Daniel<sup>3</sup>, **Ian H. Cheeseman<sup>1</sup>**

<sup>1</sup>Texas Biomedical Research Institute, San Antonio, TX, United States,

<sup>2</sup>Malawi-Wellcome-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, <sup>3</sup>UTHSCSA, San Antonio, TX, United States

Single-cell genomics can provide a means to determine the genetic structure of complex communities of unicellular organisms. Genetic analysis of infections with malaria parasites are complicated by multiple parasite lineages. These cannot be unambiguously determined from bulk resequencing efforts, severely restricting the effectiveness of association studies, and of our understanding of gene flow through parasite populations. To better understand parasite ecology at the level of individual cells, we have developed a method to capture single-cell haplotypes. Our optimized approach uses fluorescence assisted flow cytometry to capture singly-infected red blood cells, followed by whole genome amplification and next generation sequencing. By focusing our single cell method on replicating parasites we improve the overall success rate of amplification reactions (from 65% to 95%) and routinely generate near complete capture of the 23Mb parasite genome (mean genome coverage 90%). We use this approach to sequence hundreds of single genomes from an area of intense malaria transmission in Chikhwawa, Malawi. This data allows us to build a fine scale picture of the population structure of malaria parasites, both within and between infections.

#### VARYING IMPACT OF MALARIA INTERVENTIONS AT DISTRICT LEVEL - IMPLICATIONS OF A MATHEMATICAL MODEL FOR STRATEGIC PLANNING

**Manuela Runge<sup>1</sup>**, Emilie Pothin<sup>1</sup>, Renata Mandike<sup>2</sup>, Ally Mohamed<sup>3</sup>, Susan Rumisha<sup>3</sup>, Fabrizio Molteni<sup>1</sup>, Tom Smith<sup>1</sup>, Christian Lengeler<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute; University of Basel, Basel, Switzerland, <sup>2</sup>Ministry of Health, Community Development, Gender, Elderly and Children, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

National Malaria Control Programs (NMCPs) are tasked with identifying the most efficient intervention packages and their optimal deployment strategies. Mathematical models can provide guidance in this process by predicting the impact of potential intervention packages in different settings. Tanzania is currently re-defining the national malaria strategic

plan and goals for 2020 which should be tailored to local variations in the impacts of different interventions. We calibrated a population-based dynamic differential model at sub-regional level to provide support for the update of the 2017-2020 national strategic plan for Tanzania. Estimates of prevalence and intervention coverage were obtained from various country-wide datasets including malaria indicator surveys, Insecticidal Treated Nets (ITN) distribution data and predictions from the Malaria Atlas Project (MAP). Models were fitted to prevalence data while estimating the baseline level of transmission as well as the relative ratio between indoors and outdoors biting mosquitoes. The impacts of a selection of potential interventions were simulated per district, projecting the prevalence in 2020 and the average number of cases averted between 2017 and 2020. In low transmission and urban areas, ITNs are expected to have limited impact on the transmission intensity compared to Indoor Residual Spraying (IRS). Irrespective of other interventions, in high transmission settings, ITNs are indispensable and ITN coverage must be at least maintained to avoid rebound of both transmission and burden. At moderate transmission intensity both IRS with a high coverage and the maintenance of the current ITN coverage are expected to lower the transmission. The greatest impact was predicted when these were combined with increasing case management coverage. The modelling results suggest that depending on the local setting, the most appropriate interventions will vary, and the most effective strategy therefore involves sub-national stratification. The integration of this modelling framework into the NMCP strategic planning should ensure that an appropriate strategy will be implemented.

### 1348

#### POTENTIAL FOR ZIKA VIRUS TRANSMISSION FROM MATERNAL CIRCULATION TO FETAL BLOOD STREAM BY A PARAPLACENTAL ROUTE ACROSS AMNIOCHORIONIC MEMBRANE AND FETAL SKIN

**Matthew Pettitt<sup>1</sup>**, Takako Tabata<sup>1</sup>, Daniela Michlmayr<sup>2</sup>, Henry Puerta-Guardo<sup>2</sup>, Eva Harris<sup>2</sup>, Lenore Pereira<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>University of California Berkeley, Berkeley, CA, United States

Zika virus (ZIKV) infection in pregnancy leads to fetal infection and a syndrome of severe birth defects. We previously reported that American and prototype African ZIKV strains infect human cytotrophoblasts and other placental cells, consistent with transmission across placenta, but also that amniotic epithelial cells (AmEpCs) lining the amniochorionic membrane are highly susceptible (Tabata, et al. *Cell Host & Microbe*, 2016). By mid-gestation, amniochorionic membrane abuts parietal decidua opposite the placenta. We therefore hypothesized two routes of transmission - one placental, from basal decidua and the intervillous blood space, and one paraplacental, from parietal decidua across the amniochorionic membrane. Here we explore paraplacental transmission by examining AmEpC infection and modeling transmission to fetal skin. We show that American and prototype strains infect mitotic AmEpCs and that cytokines and interferon are produced, which could modulate infection in the tissue environment. We also show that mid-gestation fetal skin explants (3 donors of 14-17 weeks) are susceptible to infection by the American strain and produce infectious progeny. Infected cell types identified by immunofluorescence and flow cytometry include keratinocytes and CD14+ monocytes. Paraplacental transmission could therefore proceed from maternal blood vessels in parietal decidua to susceptible cell types, including cytotrophoblasts invading parietal decidua, trophoblast progenitor cells in the chorion, and mitotic AmEpCs. Cytokine and interferon responses by AmEpCs could suppress infection while enabling persistent infection. Transmission to fetal circulation could occur through infected CD14+ immune cells associated with fetal vessels in skin. Alternatively, infection of amniotic epithelium could be secondary to fetal infection but nonetheless increase fetal exposure by prolonging or amplifying virus production. Our results suggest that fetal infection might be reduced by therapies that target infection of amniotic epithelium and dissemination to fetal skin.

### 1349

#### RAPID DEVELOPMENT OF A REPLICATING VIRAL RNA VACCINE FOR ZIKA VIRUS

**Jesse Erasmus**, Amit P. Khandhar, Brian Granger, Jacob Archer, Christopher Fox, Steven G. Reed, Rhea Coler, Dan Stinchcomb, Neal Van Hoven

*Infectious Disease Research Institute, Seattle, WA, United States*

Due to the immediate and on-going public health threat posed by Zika virus (ZIKV), there is an urgent need for a safe and effective vaccine. In addition, platform technologies that facilitate rapid responses to emerging diseases are needed to address future infectious disease epidemics in a timely manner. Nucleic acid-based vaccine platforms have the potential to revolutionize the vaccine industry due to reduced cost, less complexity of manufacturing, and the potential for rapid vaccine design in response to new disease targets. Plasmid DNA vaccines are showing promise in the clinic. However, antigen expression requires delivery to host cell nuclei for RNA transcription and regulatory agencies have expressed safety concerns over potential for genomic integration events. RNA-encoded vaccines alleviate this concern, only requiring cytoplasmic delivery. However, this approach has historically suffered from other hurdles, including relatively low RNA stability, difficult delivery, and insufficient expression levels due to immune detection and host-translation shut-off. We have developed an RNA based vaccine platform, which is comprised of novel delivery formulations to enhance stability and cellular uptake and subsequent expression of RNA-encoded antigens, and an alphavirus-based replicating viral RNA (rvRNA). The rvRNA effectively subverts the host innate immune response through virus-specific mechanisms and amplifies an mRNA encoding the vaccine antigen for robust expression and immunogenicity. We applied this platform technology towards the development of a ZIKV vaccine. In an immunocompetent murine model of ZIKV infection, we demonstrated high-titer neutralizing antibodies following a single intramuscular or intradermal dose of our formulated rvRNA encoding the ZIKV structural protein genes. Seroconversion is observed as early as 14 days after vaccination with 100-fold dose sparing compared to unformulated RNA. The rapid and robust immunogenicity observed warrants further development of this technology in the application of vaccines for emerging infectious diseases.

### 1350

#### DIFFERENCES IN PREVALENCE OF SYMPTOMATIC ZIKA VIRUS INFECTION BY AGE AND SEX

**Matthew J. Lozier<sup>1</sup>**, Rachel Burke<sup>2</sup>, Juan Lopez<sup>3</sup>, Veronica Acevedo<sup>1</sup>, Manuel Amador<sup>1</sup>, Jennifer S. Read<sup>1</sup>, Amanda Jara<sup>4</sup>, Stephen H. Waterman<sup>1</sup>, Roberto Barrera<sup>1</sup>, Jorge Muñoz-Jordan<sup>1</sup>, Brenda Garcia-Rivera<sup>5</sup>, Tyler M. Sharp<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, San Juan, Puerto Rico,

<sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>3</sup>Florida State University, Tallahassee, FL, United States, <sup>4</sup>University of Georgia, Athens, GA, United States, <sup>5</sup>Puerto Rico Department of Health, San Juan, Puerto Rico

During the Zika virus (ZIKV) outbreak in Puerto Rico in 2016, non-pregnant women aged 20-39 years were disproportionately identified with ZIKV disease. We used household-based cluster investigations to determine if this disparity was attributable to age- or sex-dependent differences in the rate of ZIKV infection or reported symptoms. We offered participation to residents of households within a 100-meter radius of the residences of a convenience sample of 19 laboratory-positive ZIKV disease cases. Participation included answering a questionnaire and testing for: a) ZIKV RNA in serum and urine; and b) anti-ZIKV IgM antibody in serum. Participants were defined as ZIKV-positive if either assay was positive. We used general estimating equations with a binomial distribution and assumed an exchangeable correlation matrix to model associations among individual and household characteristics and binary outcomes of ZIKV infection and symptomatic ZIKV infection (defined by reported

rash or arthralgia in the previous six months based on a sensitivity analysis). Among 367 study participants, 114 (31.1%) were laboratory-positive for ZIKV infection; 17 for ZIKV RNA, 87 for ZIKV IgM, and 10 for both. Age, sex, income, and education were not associated with ZIKV infection. However, ZIKV infection was significantly more common among participants who: reported a household member ill in previous three months (adjusted odds ratio [aOR] = 2.6; 95% confidence interval [CI] = 1.3, 5.2); and, lived in a cluster with a greater number of vacant houses (aOR for 1-unit increase = 1.2; 95% CI = 1.0, 1.3). Prevalence of symptomatic infection attributable to ZIKV was 30%. Female sex (aOR = 5.7; 95% CI = 2.0, 15.9), age <40 years (aOR = 10.4; 95% CI = 3.0, 36.2), and asthma (aOR = 3.4; 95% CI = 1.1, 10.7) were independently associated with symptomatic ZIKV infection. While neither female sex nor age were associated with an increased risk of ZIKV infection, both were associated with symptomatic ZIKV infection. Further investigation to identify a potential mechanism of age- and sex-dependent differences in reporting symptomatic ZIKV infection is warranted.

## 1351

### INCIDENCE OF ZIKA VIRUS INFECTION AND EFFECT OF PRE-EXISTING DENGUE VIRUS EXPOSURE ON ZIKA VIRUS INFECTION AND DISEASE IN A PEDIATRIC COHORT IN NICARAGUA

Angel Balmaseda<sup>1</sup>, Damaris Collado<sup>2</sup>, Juan Carlos Mercado<sup>1</sup>, José Víctor Zambrana<sup>2</sup>, Sergio Ojeda<sup>2</sup>, Nery Sanchez<sup>2</sup>, Douglas Elizondo<sup>2</sup>, Josefina Coloma<sup>3</sup>, Lionel Gresh<sup>2</sup>, Leah Katzelnick<sup>3</sup>, Raquel Burger-Calderon<sup>3</sup>, Aubree Gordon<sup>4</sup>, Guillermina Kuan<sup>5</sup>, **Eva Harris<sup>3</sup>**

<sup>1</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>4</sup>Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, <sup>5</sup>Health Center Sócrates Flores Vivas, Ministry of Health, Berkeley, CA, United States

Zika virus (ZIKV) was introduced into Brazil in 2015 and spread rapidly across the Americas. In Nicaragua, the first case was reported in January 2016, followed by an explosive epidemic in July-August of 2016. We developed sensitive and specific serological assays that enable detection of anti-ZIKV antibodies to determine the incidence of ZIKV infection in a prospective, community-based pediatric cohort study of dengue and Zika in Managua, Nicaragua. This study, ongoing since 2004, follows ~3,500 children aged 2-14 in a low- to middle-income area of Managua, the capital. Suspected Zika, chikungunya, and/or dengue cases and undifferentiated febrile illnesses are screened by realtime RT-PCR (rRT-PCR) for infection with all three arboviruses. Blood, saliva and urine samples are collected from suspected cases during the acute phase and at convalescence (2-3 weeks post-symptom onset). Additionally, annual blood samples are collected from all healthy subjects every March/April. A total of 314 Zika cases and only 4 dengue cases were confirmed by rRT-PCR in the cohort from January to October of 2016. To determine the incidence rate of ZIKV infection, we are analyzing 2016 and 2017 annual serum samples side-by-side using a highly sensitive and specific ZIKV NS1 blockade-of-binding ELISA as well as a ZIKV Inhibition ELISA to detect a ≥4-fold rise in antibody titer in paired samples. These data enable calculation of the Symptomatic to Inapparent (S:I) ZIKV infection ratio. We are also determining the effect of prior DENV exposure on ZIKV infection and disease incidence, S:I ratio, and disease severity by analyzing: 1) documented prior DENV exposure in the cohort, 2) number of DENV infections, 3) pre-existing cross-reactive anti-ZIKV antibody titers, and 4) pre-existing cross-reactive anti-DENV antibody titers. These measurements will enable estimation of the force of infection and Ro of ZIKV as well as evaluation of potential immune correlates of protection against and risk of ZIKV infection and disease.

## 1352

### ANALYZING THE IMMUNE RESPONSE TO ZIKA VIRUS USING REPORTER VIRUS PARTICLES, ANTI-ZIKV ANTIBODIES AND EPIOTOPE MAPPING

**Chuck Whitbeck<sup>1</sup>**, Anu Thomas<sup>1</sup>, Aubrey Bryan<sup>1</sup>, Lewis J. Stafford<sup>1</sup>, Ross Chambers<sup>1</sup>, Gopal Sapparapu<sup>2</sup>, James E. Crowe Jr<sup>2</sup>, Edgar Davidson<sup>1</sup>, Benjamin J. Doranz<sup>1</sup>

<sup>1</sup>Integral Molecular, Inc., Philadelphia, PA, United States, <sup>2</sup>Vanderbilt University, Nashville, TN, United States

We have analyzed the human immune response to Zika virus (ZIKV) using a number of novel tools. (1) Pseudoinfectious ZIKV reporter virus particles (RVPs) provide one round of infectivity in permissive cells, with a luminescent or fluorescent readout for infectivity. RVPs have been used to identify patient sera and individual monoclonal antibodies (MAbs) that neutralize ZIKV, and provide a rapid and reliable alternative to PRNT-based assays. We have also used RVPs to characterize MAb binding, including highly conformational MAbs that do not recognize ZIKV envelope protein expressed in cells. RVPs maintain the native antigenicity of wild-type virions allowing characterization of MAb binding by ELISA or biosensor. (2) Anti-ZIKV MAbs were isolated following immunization with DNA and sub-viral particles, and phage library panning with RVPs. We isolated 48 MAbs that bound specifically to conformational epitopes on prM/E from ZIKV, but not DENV, including a MAb that potently neutralized ZIKV RVPs (IC50 45 ng/ml). The MAbs are being used as critical reagents for ZIKV-specific immunodetection, diagnostic applications, and ZIKV neutralization studies. (3) An Ala-scan mutation library of ZIKV prM/E is being used to epitope map the immune response to ZIKV. We used Shotgun Mutagenesis technology to create a comprehensive ZIKV prM/E library of 672 single mutations arrayed in 384 well plates and expressed in human cells. We quantified immunoreactivity by high-throughput flow cytometry, enabling us to epitope map anti-ZIKV MAbs for a published study that included a highly neutralizing MAb, isolated from a Brazilian patient, that was protective in animal models of ZIKV fetal disease. The epitope location of this MAb suggested that it binds across adjacent protein E dimers, preventing rearrangements necessary for infectivity. We have also screened each individual prM/E variant for ZIKV particle budding and infectivity by applying the RVP system to the mutation library to produce ZIKV virions. This identified mutations that increased ZIKV RVP budding, which may be applicable to the design and production of anti-ZIKV vaccines.

### ZIKA VIRUS CLINICAL ISOLATES REPLICATE IN HUMAN PROSTATE CELLS AND ORGANOID

**Jennifer L. Spencer**, Anismrita Lahon, Linda L. Tran, Ravi P. Arya, Megan B. Vogt, David R. Rowley, Jason T. Kimata, Rebecca R. Rico-Hesse

Baylor College of Medicine, Houston, TX, United States

Zika virus (ZIKV) is an ssRNA Flavivirus, traditionally known to cause Zika fever but recently linked to Guillain-Barré Syndrome in adults and microcephaly in newborns. While ZIKV is mainly transmitted by *Aedes* species mosquitoes, numerous cases of sexual transmission have been reported during the current outbreak. Little is known about which host cell types or entry factors aid in mediating this sexual transmission. While ZIKV RNA has been detected in the semen of infected males as well as in the urine, saliva and plasma of their partners following sexual contact, ZIKV urogenital tract tropism remains poorly understood. Infected males have also reported symptoms including prostatitis and hematospermia, which indicate that the prostate may be involved in infection as a reservoir for viral replication. We are currently investigating ZIKV cell tropism in prostate cells using contemporary ZIKV clinical isolates from persons infected in Central and South America. To investigate whether ZIKV infects the prostate, we infected human prostate cells and organoid co-cultures with low passage ZIKV isolates. The prostate organoids are composed of both stromal mesenchymal stem cells and epithelial cells

to better recapitulate *in vivo* conditions. Using qRT-PCR to detect viral RNA and immunohistochemistry to detect active ZIKV replication, we determined that ZIKV infects and replicates in the organoids. Infectious virus was also cultured from infected organoids using limiting dilution assays. These results suggest low-level viral persistence can occur within the prostate over extended time periods and might ultimately explain the presence of ZIKV in semen. Virus produced by infected prostate cells may be introduced into the seminal fluids secreted with sperm cells during ejaculation. Currently, we are using flow cytometry to determine which of the known flavivirus attachment factors are expressed in the organoids. Assessing ZIKV urogenital tract tropism and elucidating host cell attachment factors are imperative to better understand the mechanism of ZIKV pathogenesis and sexual transmission.

#### REPLICATION OF ZIKA VIRUS AND CYTOMEGALOVIRUS IN FIRST-TRIMESTER HUMAN PLACENTAS SHOWS DIVERGENT PATTERNS OF INFECTION AND PATHOGENESIS THAT COULD AFFECT TRANSMISSION

Lenore Pereira<sup>1</sup>, Takako Tabata<sup>1</sup>, Matthew Petitt<sup>1</sup>, Henry Puerta-Guardo<sup>2</sup>, Daniela Michlmayr<sup>2</sup>, Eva Harris<sup>2</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>University of California Berkeley, Berkeley, CA, United States

Zika virus (ZIKV), a *Flavivirus* responsible for the recent American epidemic, causes Congenital Zika Syndrome, a spectrum of severe malformations in the fetus/infant including microcephaly rarely seen with other neurotropic viruses. The exception is human cytomegalovirus (HCMV), a *Herpesvirus*, the leading viral cause of congenital infection and birth defects in the U.S. How these viruses are transmitted from disparate infectious sources - mosquitoes and toddlers, respectively - to maternal circulation and how they disseminate to the fetus *in utero* is poorly understood. We reported that ZIKV replicates in primary cells isolated from human placentas and amniochorionic (fetal) membranes and in explants of first-trimester placentas and infectious progeny are produced (Tabata, *et al.* Cell Host & Microbe, 2016). Here we compared ZIKV and HCMV infection in anchoring villus explants, a functional model of the developing human placenta. Patterns of ZIKV infection revealed that the American Nicaraguan and prototype African ZIKV strains replicate in cytotrophoblasts and Hofbauer cells (fetal macrophages) and release infectious virus. Consistently reproducible infection was observed in proliferating cytotrophoblasts in cell columns and Hofbauer cells near villous cores. Among 355 villus explants dissected from 6 placentas 8 to 11 weeks in gestational age, productive ZIKV infection was consistently observed in proliferating cytotrophoblasts in cell columns and branching villi (23%), invasive cytotrophoblasts (46%) and Hofbauer cells (22%). In contrast, HCMV failed to infect Hofbauer cells and only pathogenic clinical strains replicated efficiently in villus explants but nonetheless failed to release infectious progeny. Our results suggest that ZIKV and HCMV reach the developing placenta by hematogenous dissemination in the intervillous blood space, but patterns of infection and pathogenesis differ suggesting that the mechanisms of transmission could also diverge *in utero*.

### 1355

#### PROTECTIVE EFFECTIVENESS OF SEASONAL MALARIA CHEMOPREVENTION IN NIGER: A PROSPECTIVE CASE-CONTROL STUDY

Matthew E. Coldiron<sup>1</sup>, Bachir Assao<sup>2</sup>, Alena Koscalova<sup>3</sup>, Michel Quere<sup>3</sup>, Céline Langendorf<sup>1</sup>, Rebecca F. Grais<sup>1</sup>

<sup>1</sup>Epicentre, Paris, France, <sup>2</sup>Epicentre, Maradi, Niger, <sup>3</sup>Médecins Sans Frontières, Geneva, Switzerland

Seasonal malaria chemoprevention (SMC) is recommended in the Sahel: monthly courses of sulfadoxine-pyrimethamine and amodiaquine (SPAQ) are given to children aged 3-59 months during the high transmission

season. Despite high SMC program coverage, malaria continues to overwhelm health structures in Magaria District of Niger, so we aimed to estimate the protective effectiveness of SMC (PESMC) in field conditions. We conducted a prospective case-control study, stratified by SMC distribution method (directly-observed vs. non-directly observed first doses). Cases of clinical malaria (fever+positive pLDH RDT) were enrolled. Three age-matched healthy controls were enrolled in the case's village of origin on the same day. Caregivers were asked about receipt of SMC, access to care, demographics, diet and socio-economic status. Thick and thin smears were prepared and blood was collected to measure plasma levels of amodiaquine. We estimated that 590 cases and 1770 controls would provide 90% power to describe PESMC of 50% with 5% precision. Conditional logistic regression was used to compare cases and controls; PESMC was calculated as (1-OR)x100%. 577 cases and 1700 controls were enrolled between 1 Aug and 2 Dec 2016. Among children with a card proving receipt of SMC, PESMC against clinical malaria was 85.1% [95%CI: 78.7-89.6]. When children without a program card but whose parents reported receipt of SMC are also considered, PESMC was 50.2% [27.6-65.7]. PESMC was significantly higher in the first-dose DOT zone than in the first-dose non-DOT zone: with card 96.8% [93.1-98.5] vs 59.1% [34.5-74.4],  $p < 0.001$ , and with card or verbal report 88.6% [77.7-94.2] vs 20.5% [-30.5-51.5],  $p < 0.001$ . Similar trends were seen for PESMC against microscopy-confirmed malaria and asymptomatic parasitemia. Among children with cards proving receipt, overall point estimates of PESMC were above 70% for 4 weeks after each SMC distribution. In conclusion, important differences in PESMC were seen with different distribution strategies. Analysis of plasma amodiaquine levels is ongoing and will provide important information about adherence to treatment.

### 1356

#### COMMUNITY-LED IMPLEMENTATION OF INTEGRATED MALARIA CONTROL IN SOUTHERN MALAWI

Robert S. McCann<sup>1</sup>, Henk van den Berg<sup>1</sup>, Michèle van Vugt<sup>2</sup>, Dianne J. Terlouw<sup>3</sup>, Kamija S. Phiri<sup>4</sup>, Peter J. Diggle<sup>5</sup>, Themba Mzilahowa<sup>4</sup>, Lucinda Manda-Taylor<sup>4</sup>, Steve Gowelo<sup>4</sup>, Monicah Mburu<sup>1</sup>, Alinune N. Kabaghe<sup>2</sup>, Michael G. Chipeta<sup>5</sup>, Tumaini Malenga<sup>4</sup>, Willem Takken<sup>1</sup>

Netherlands, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>4</sup>College of Medicine, University of Malawi, Blantyre, Malawi,

<sup>5</sup>Lancaster University, Lancaster, United Kingdom

Sub-optimal coverage of malaria interventions limits the potential for achieving malaria elimination. Additionally, bed nets and indoor residual spraying are not universally sufficient for elimination, especially in areas with outdoor transmission or insecticide resistance. Community engagement strategies may increase the use of interventions by populations at risk through increased acceptability and understanding. Integrating additional vector control interventions with current strategies could lead to further reductions in transmission. We have established a multi-disciplinary project with an emphasis on community engagement and locally-appropriate integrated vector management to address these challenges in a rural community of 25,000 people in southern Malawi. Community engagement has been facilitated by training community volunteers as health animators and supporting the organisation of village-level committees in collaboration with a non-governmental organisation working in the community. Larval source management (LSM) and structural house improvements (HI) are implemented as additional vector control interventions. We are measuring the effectiveness of LSM and HI using a randomised block, 2x2 factorial, cluster-randomised trial design from 2016 to 2018. Household-level cross-sectional surveys are conducted on a rolling, 2-monthly basis to measure parasitological and entomological outcomes over three years, beginning with one baseline year. The effectiveness of the community engagement is being assessed through participant observations, focus group discussions, in depth interviews, and standardized surveys. In the baseline year, the prevalence of parasitemia in

children aged 6-59 months varied seasonally, ranging from 5% to 65%. In the same year, malaria vector mosquito densities ranged from 0.0 to 0.5 *Anopheles* females per house per night. In this presentation, we will discuss lessons learned regarding community engagement and adaptation of LSM and HI to the local ecological and social setting.

### 1357

#### INSECTICIDAL WALL LINING FOR MALARIA CONTROL IN LIBERIA: RESULTS FROM A CLUSTER RANDOMIZED CONTROL TRIAL

David J. Giesbrecht<sup>1</sup>, Julie Pontarollo<sup>2</sup>, Jonas Ecke<sup>3</sup>, Sajid Kamal<sup>2</sup>, Vincent Koko<sup>4</sup>, Levi Hinneh<sup>4</sup>, Oliver Pratt<sup>4</sup>, Richard Allan<sup>2</sup>

<sup>1</sup>University of Manitoba, Winnipeg, MB, Canada, <sup>2</sup>The MENTOR Initiative, Crawley, United Kingdom, <sup>3</sup>Purdue University, West Lafayette, IN, United States, <sup>4</sup>National Malaria Control Program Liberia, Monrovia, Liberia

Control of malaria vectors in Liberia depends on pyrethroid-impregnated long-lasting insecticidal nets (LLINs). Despite regular mass distribution, LLIN usage is patchy, and pyrethroid resistance in the key vectors may further reduce their efficacy. Durable, insecticidal wall liners (DL) which create a long-lasting insecticidal surface on walls are a promising new vector control method. The current study is a cluster-randomized control trial of a prototype wall liner impregnated with Fenpyroximate and Avermectin. In 20 clusters, rooms of consenting homeowners received DL in addition to existing LLINs. In 20 control clusters, homeowners used only LLINs. Community-based teams were trained to install DL using locally-available fasteners and nailing strips. *Plasmodium falciparum* prevalence in children 2-59 months was measured by rapid diagnostic tests before DL installation and again 12 months later. DL retention was measured 12 months after installation. A qualitative study of recipient and installer perceptions was conducted during installation and again after 18 months. Malaria prevalence in intervention clusters after 12 months was 34.6% compared to 40.1% in control clusters ( $p=0.052$ ), despite reduced LLIN usage where DL was installed. Wall lining was installed in 69% of rooms surveyed 12 months after installation. Homeowners without the lining cited absence at the time of installation (35%) or the room being under construction (33%) as the most common reasons for not installing DL. Perceptions of the community-based installation process were frequently positive, though additional non-cash incentives were requested. Recipients of DL cited aesthetic improvements to their rooms and perceived reduction in nuisance mosquitoes. These results show that community-based teams can successfully deliver DL. Despite lower LLIN usage after DL installation, we measured a small reduction in malaria prevalence after 12 months. Together, these results suggest that DL is a scalable intervention for control of pyrethroid-resistant vectors in locations where high LLIN usage is difficult to achieve.

#### IMPACT OF INDOOR RESIDUAL SPRAYING WITH ACTELIC 300CS IN MALI ON KEY ENTOMOLOGICAL INDICATORS OF MALARIA TRANSMISSION

Arthur Sovi<sup>1</sup>, Chitan Keita<sup>1</sup>, Abdourhamane Dicko<sup>2</sup>, Dereje Dengela<sup>3</sup>, Elie Bankineza<sup>1</sup>, Jules Mihigo<sup>4</sup>, Kristen George<sup>5</sup>, Laura Norris<sup>5</sup>, Raymond Beach<sup>6</sup>, Richard M. Oxborough<sup>7</sup>

<sup>1</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, Bamako, Mali, <sup>2</sup>National Malaria Control Program, Bamako, Mali, <sup>3</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, Washington, DC, United States, <sup>4</sup>U.S. Centers for Disease Control and Prevention, Bamako, Mali, <sup>5</sup>U.S. President's Malaria Initiative, US Agency for International Development, Washington, DC, United States, <sup>6</sup>Entomology Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>7</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, London, United Kingdom

According to the 2015 malaria indicator survey, 93% of households in Mali owned an ITN, while 71% of children under five years old and 78%

of pregnant women used an ITN the previous night. PMI supported IRS at the start of the short seasonal rains in July in three districts in 2016; namely Barouéli, Koulikoro, and Fana using an organophosphate, Actellic 300CS. Overall 228,672 structures were sprayed, with 788,922 persons protected. Entomological monitoring was conducted in six villages, (3 sprayed and 3 adjacent unsprayed), between July and December. Monthly pyrethrum spray catches (PSC) were conducted in 20 houses per site to determine indoor resting densities. Monthly human landing catches (HLC) were conducted in 8 houses per village to determine biting rates, time of biting, species composition and entomological inoculation rate (EIR). The residual activity of Actellic 300CS was assessed with WHO cone bioassay using susceptible, insectary reared *An. gambiae* in 19 houses. The residual efficacy of IRS with Actellic 300CS in Mali was two months according to WHO criteria of mortality >80%, although mortality was >60% after 5 months. Molecular analysis indicated *An. coluzzii* as the most common species (71.6%) followed by *An. gambiae* (17.3%). Biting rates were particularly high in August and September both indoors and outdoors with a peak in biting late at night between 22:00 and 4:00am. Therefore, people who frequently use LLINs should be more protected. The three IRS areas had lower indoor resting densities of *An. gambiae* s.l. for 2 months compared to unsprayed areas. Similarly, the human biting rate was lower in sprayed areas, with a mean of 6.1 bites p/person/night, compared with 11.9 in unsprayed sites. The combined effect of lower biting rates and similar sporozoite rates (2.1% IRS districts, 2.9% unsprayed areas) meant the EIR was 84.5% lower in sprayed sites compared to unsprayed sites over five months. However, the EIR in IRS areas was still high with a mean of 7.0 infectious bites per person over 5 months. In areas with intense seasonal malaria transmission, additional prevention and control tools may be needed beyond LLINs and IRS.

### 1359

#### EVALUATION OF THE RESIDUAL EFFECTIVENESS OF FLUDORA FUSION WP-SB, A FORMULATED COMBINATION OF CLOTHIANIDIN AND DELTAMETHRIN, FOR THE CONTROL OF PYRETHROID-RESISTANCE MALARIA VECTORS ON BIKO ISLAND, EQUATORIAL GUINEA

Godwin Fuseini<sup>1</sup>, Wonder Philip Phiri<sup>1</sup>, Liberato Motobe Vaz<sup>1</sup>, Raul Nguema<sup>1</sup>, Abrahan Mathias<sup>1</sup>, Jordan Smith<sup>1</sup>, J. Luis Segura<sup>1</sup>, Justin McBeath<sup>2</sup>, Frederic Schmitt<sup>2</sup>, Julie Niemczura de Carvalho<sup>3</sup>, Guillermo Garcia<sup>3</sup>, Christopher Schwabe<sup>3</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Bayer AG, Monheim, Germany, <sup>3</sup>Medical Care Development International, Silver Spring, MD, United States

Insecticide resistance to malaria vectors has been identified in some 60 malaria endemic countries. This has posed a global health challenge in the fight against malaria. Pyrethroid-resistance is the most commonly reported. Unfortunately, pyrethroids are not only relatively safe and less expensive, but also the only class of insecticides currently recommended for use in insecticide-treated mosquito nets. The global decline of indoor residual spraying coverage in recent times has been attributed to pyrethroid-resistance. The quest for safer insecticides with different modes of action against malaria vectors is a priority. As part of its vector control monitoring strategies, the Bioko Island Malaria Control Project (BIMCP) in Equatorial Guinea conducted routine insecticide resistance tests using the WHO's standard susceptibility tests from 2013 to 2016. During the same period, the frequency of the target-site knockdown resistance (*kdr*) in the local vector population was also determined using polymerase chain reaction based *kdr* genotyping. Biochemical analysis for metabolic resistance was also conducted in 2015. Fludora Fusion was evaluated for 9 months on Bioko Island from 2016 to 2017, using the WHO's standard test procedure for determining residual effectiveness of insecticides on sprayed surfaces. The product is a formulated combination of clothianidin and deltamethrin (a pyrethroid). In 2016, the percentage mortality of the vectors to 0.05% deltamethrin was as low as 38%. The frequency of the West African form of knockdown resistance (*kdr-w*) in the vector population was as high as 80%, and metabolic resistance analysis indicated high upregulated

cytochrome P450s. However, the residual effectiveness of Fludora Fusion recorded mortalities above 80% after 72 hours for 8 months. Although both target-site knockdown resistance and metabolic resistance to pyrethroids were implicated in the local malaria vector population, Fludora Fusion was effective under field conditions in controlling the resistant vectors for a period of 8 months on wooden surfaces on Bioko Island.

#### THE IMPACT OF INDOOR RESIDUAL SPRAYING (IRS) WITH PIRIMIPHOS-METHYL ON ENTOMOLOGICAL INDICES IN A MALARIA HYPERENDEMIC REGION OF WESTERN KENYA

**Bernard Abong'o**<sup>1</sup>, Diana Omoke<sup>1</sup>, Eric Ochomo<sup>2</sup>, Nabie Bayoh<sup>3</sup>, Kiambu Njangi<sup>4</sup>, Solomon Karuki<sup>4</sup>, Waqo Ejersa<sup>4</sup>, Robert Perry<sup>5</sup>, Laura Norris<sup>6</sup>, Brad Longman<sup>1</sup>, John Gimnig<sup>7</sup>, Richard Oxborough<sup>8</sup>

<sup>1</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, Kisumu, Kenya, <sup>2</sup>Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, <sup>3</sup>U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Nairobi, Kenya, <sup>4</sup>National Malaria Control Programme, Nairobi, Kenya, <sup>5</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Nairobi, Kenya, <sup>6</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States, <sup>7</sup>U.S. Centers for Disease Control and Prevention, Division of Parasitic Diseases, Atlanta, GA, United States, <sup>8</sup>U.S. Agency for International Development PMI AIRS Project, Abt Associates, London, United Kingdom

The Lake Victoria region of western Kenya remains one of the most important sources of malaria transmission nationally. IRS was last conducted in western Kenya with deltamethrin in 2012. Spraying was interrupted due to pyrethroid resistance and a lack of registered alternative insecticides. IRS with pirimiphos-methyl was reintroduced in Migori County in March 2017 with 212,049 structures sprayed. Fifteen months of baseline vector surveillance was conducted between December 2015 through February 2017 in 12 sentinel villages (6 designated for IRS and 6 unsprayed). Post-IRS surveillance will continue through September 2017. Monthly collections were performed by pyrethrum spray catch (PSC), indoor CDC light traps (CDC-LT) and window exit traps. During baseline a total of 135 houses were sampled by PSC, 170 by CDC-LT, and 70 exit traps in each sentinel village. Malaria vector species comprised of 85% *An. funestus* s.s., 13% *An. arabiensis* and 1% *An. gambiae* s.s. *An. funestus* was the dominant vector throughout, with two peaks of indoor resting density and biting rates associated with high rainfall between December to February and May to July. *An. funestus* biting began before 18:00 indoors and outdoors but peaked between 4:00 am and 6:00 am, with indoor biting continuing until 7:00 am. A total of 5,073 samples were analyzed for sporozoite ELISA with a 3.28% overall sporozoite rate for *An. funestus*. Both adult collected *An. funestus* and larval collected *An. arabiensis* were fully susceptible to pirimiphos-methyl and bendiocarb but strongly resistant to deltamethrin and permethrin. Both East (L1014S) and West (L1014F) *kdr* mutation was absent in *An. funestus* and occurred in *An. arabiensis* at low frequencies of <1%. The majority of *An. funestus* caught in exit traps were unfed or gravid with a greater proportion of blood-feds and half-gravids resting indoors. IRS with pirimiphos-methyl is expected to have a major impact against pyrethroid resistant, indoor resting *An. funestus* that currently dominate. Analysis of the effectiveness of pirimiphos-methyl IRS on entomological indicators of malaria transmission up to six months after spraying will be presented.

#### DIFFERENTIAL IMPACTS OF INDOOR RESIDUAL SPRAYING ON THE CHARACTERISTICS OF MALARIA INFECTIONS IN A HIGH TRANSMISSION SETTING IN UGANDA

**Joaniter I. Nankabirwa**<sup>1</sup>, John Rek<sup>2</sup>, Emmanuel Arinaitwe<sup>2</sup>, Patience Nayebare<sup>2</sup>, Shereen Katrak<sup>3</sup>, Sarah Staedke<sup>4</sup>, Moses Kanya<sup>1</sup>, Philip Rosenthal<sup>3</sup>, Isabel-Barraquer Rodriguez<sup>3</sup>, Bryan Greenhouse<sup>3</sup>, Grant Dorsey<sup>3</sup>

<sup>1</sup>Makarere University Kampala, Kampala, Uganda, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Significant progress in malaria control has been realized over the last decade. However, progress in Uganda has been slow, and gains have been fragile. In Tororo, indoor residual spraying of insecticides (IRS) has been associated with a dramatic decline in the incidence of symptomatic malaria, but the impact of IRS on the prevalence of microscopic and sub-microscopic parasitemia has not been reported. Between August 2011 and May 2016, we followed a cohort of 364 children aged 0.5 - 10 years and 105 adults living in 117 households in Tororo. IRS with bendiocarb was initiated in December 2014 and has been conducted every 6 months thereafter. Routine blood smears were performed at least every three months; 7139 samples from children, 1713 samples from adults) were tested for microscopic parasitemia, and *P. falciparum*-specific loop-mediated isothermal amplification (LAMP) was performed on all smear negative samples to test for sub-microscopic parasitemia. Following the implementation of IRS, the incidence of malaria decreased from 3.25 to 0.63 episodes/person/year ( $p < 0.001$ ), the prevalence of microscopic parasitemia decreased from 32.1% to 17.3% in children (prevalence ratio (PR) = 0.60, 95% CI 0.56-0.66,  $p < 0.001$ ) but there was no significant change in adults (6.1% vs. 6.4%, PR=1.04, 95% CI 0.75-1.43,  $p=0.82$ ). The prevalence of any parasitemia (microscopic + sub-microscopic) decreased following implementation of IRS in both children (67.5% to 32.4%, PR=0.42, 95% CI 0.39-0.45,  $p < 0.001$ ) and adults (52.2% to 26.1%, PR=0.43, 95% CI 0.36-0.52,  $p < 0.001$ ). Our results suggest that, although IRS was associated with significant reductions in the incidence of malaria and prevalence of parasitemia, a substantial proportion of the population remained parasitemic, providing a continued reservoir for malaria transmission.

### 1362

#### POPULATION GENOMICS IN *PLASMODIUM VIVAX*: LEVELS OF GENETIC DIVERSITY IN AMERICA

**Thais Crippa de Oliveira**<sup>1</sup>, Priscila Thihara Rodrigues<sup>1</sup>, Maria José Menezes<sup>1</sup>, Raquel Muller Gonçalves-Lopes<sup>1</sup>, Melissa Silva Bastos<sup>1</sup>, Nathália Ferreira Lima<sup>1</sup>, Susana Barbosa<sup>1</sup>, Alexandra Lehmkuhl Gerber<sup>2</sup>, Guilherme Loss Moraes<sup>3</sup>, Luisa Berná<sup>4</sup>, Jody Phelan<sup>5</sup>, Carlos Robello<sup>4</sup>, Ana Tereza Ribeiro Vasconcelos<sup>2</sup>, João Marcelo Alves<sup>1</sup>, Marcelo Urbano Ferreira<sup>1</sup>

<sup>1</sup>University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>National Laboratory of Scientific Computation, Petrópolis, Brazil, <sup>3</sup>National Laboratory of Scientific Computation, Petrópolis, Brazil, <sup>4</sup>Pasteur Institute of Montevideo, Montevideo, Uruguay, <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The Americas were the last continent to be colonized by humans carrying malaria parasites. Not unexpectedly, *Plasmodium falciparum* from the New World shows very little genetic diversity and meiotic recombination, compared with its African counterparts, and is clearly subdivided into local, highly divergent populations. However, limited available data have revealed an extensive genetic diversity in American populations of another major human malaria parasite, *P. vivax*. We characterize 9 genome sequences from a population from northwestern Brazil and compare these new data with published sequences from recently sampled clinical isolates from Brazil (n=11), Peru (n=23), Colombia (n=31), and

Mexico (n=19) to further explore genome-wide variation and divergence patterns in New World populations of *P. vivax*. The following main features of New World populations were revealed: (a) These parasites are as diverse (nucleotide diversity  $\pi$  between  $5.2 \times 10^{-4}$  and  $6.2 \times 10^{-4}$ ) as *P. falciparum* populations from sub-Saharan Africa and *P. vivax* populations from Southeast Asia (malaria transmission is substantially more intense); (b) they display several nonsynonymous nucleotide substitutions (some of them previously undescribed) in genes known or suspected to be involved in antimalarial drug resistance, such as *dhfr*, *dhps*, *mdr1*, and *mp1*, but not in the *crt-o* gene; and (c) *P. vivax* populations in the Americas are much less geographically substructured than local *P. falciparum* populations, with relatively little between-population genome-wide divergence.

### 1363

#### FINE-SCALE POPULATION GENETICS OF *PLASMODIUM FALCIPARUM* IN NORTHERN NAMIBIA

Sofonias Tessema<sup>1</sup>, Maxwell Murphy<sup>1</sup>, Anna-Rosa Mupiri<sup>2</sup>, Jennifer L. Smith<sup>3</sup>, Anna Chen<sup>1</sup>, Jordan Wilhelm<sup>1</sup>, Michelle S. Hsiang<sup>1</sup>, Hugh J. Sturrock<sup>3</sup>, Davis Mumbengegwi<sup>2</sup>, Bryan Greenhouse<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Multidisciplinary Research Center, University of Namibia, Windhoek, Namibia, <sup>3</sup>Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States

Namibia has a national goal to eliminate malaria by 2020, however pockets of transmission and risks of importation still remain in Northern regions bordering Angola and Zambia. Molecular epidemiology can reveal important insights regarding contemporary and historical transmission and assess the impact of sustained control and elimination efforts. A total of 1696 samples from symptomatic malaria cases collected in 2016 from 23 clinics in 3 districts of the Kavango East region (Rundu (n=611), Nyangana (n=382), Andara (n=430)) and 6 clinics from the Zambezi region (n=273) were genotyped using 26 neutral microsatellite markers. 551 (32.5%) of the samples had monoclonal infections, of which 511 were unique haplotypes. Most infections in Kavango region contained multiple parasite genotypes (71%) with mean multiplicity of infection (MOI) of 2.4, high within-host diversity (mean Fws=0.7) and high genetic diversity (mean HE = 0.74), reflecting high rates of transmission and superinfection present during the regional outbreak which occurred at that time. Fine-scale temporal and spatial variation was observed in MOI consistent with the history of transmission intensity within this region. In contrast, Zambezi region had significantly lower polyclonal infection (49%), MOI (1.7), higher mean FWS score (0.86) and lower genetic diversity (0.69),  $p < 0.001$  vs. Kavango for all. In all districts, low but significant linkage disequilibrium (ISA: 0.01 - 0.04,  $p < 0.001$ ) and genetic differentiation between districts (Gst: 0.02-0.06,  $p < 0.001$ ) were observed. Genetic differentiation was strongly correlated with the distance between the districts ( $\rho = 0.95$ ,  $p = 0.003$ ), reflecting some population fragmentation due to isolation by distance along with spread of parasites between the districts via vector or human travel. The findings of this study suggest targeted elimination of malaria in one region would be difficult to achieve without a similar effort throughout Northern Namibia. Integrated analyses of genetic and human mobility data can give insight to accurately estimate routes of parasite importation and transmission dynamics in space and time.

Over the last decade, multiple independent emergences of artemisinin-resistant parasite strains have occurred in SE Asia. More recently the emergence and spread of parasites resistant to partner drugs in artemisinin combination therapies presents a challenge to the goal of elimination in the Greater Mekong Subregion. What are the characteristics of transmission networks in Cambodia that are responsible for the emergence and spread of ACT-resistant strains? Using a dynamical malaria model that tracks full parasite genomes, we have simulated a range of transmission topologies characteristic of malaria exposure in small forest-going populations. We relate the time series of genetic signatures observed in clinical samples — e.g. region of origin, drug-resistant markers, relatedness of parasite strains within and among infections — to infer the local intensity of transmission and connectivity between regions. We find that small effective populations, frequent founder effects, focal risk, long-range migration, and drug-usage patterns significantly affect the rate of selecting resistance in our simulations. Finally, we demonstrate the value of timely genetic surveillance to inform future treatment strategies in a world of widespread ACT failure.

### 1365

#### COMPARATIVE LONGITUDINAL POPULATION GENOMIC SURVEYS OF *PLASMODIUM FALCIPARUM* MALARIA PARASITES IN FRENCH GUIANA AND THAILAND

Gustavo C. Cerqueira<sup>1</sup>, Stephane Pelleau<sup>2</sup>, Alexandre Melnikov<sup>1</sup>, Steven F. Schaffner<sup>1</sup>, Béatrice Volney<sup>2</sup>, Ian H. Cheeseman<sup>3</sup>, Yassamine Lazrek<sup>2</sup>, Félix Djossou<sup>4</sup>, Marina McDew-White<sup>3</sup>, Shalini Nair<sup>3</sup>, Aung P. Phy<sup>5</sup>, Elizabeth A. Ashley<sup>5</sup>, Timothy J. Anderson<sup>3</sup>, Eric Legrand<sup>2</sup>, François Nosten<sup>5</sup>, Bruce Birren<sup>1</sup>, Lise Musset<sup>2</sup>, Daniel Neafsey<sup>1</sup>

<sup>1</sup>Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States, <sup>2</sup>Institute Pasteur de la Guyane, Cayenne, French Guiana, <sup>3</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>4</sup>Tropical Disease Unit, Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana, <sup>5</sup>Shoklo Malaria Research Unit, Mahidol University, Mae Sot, Thailand

Drug-induced selection pressures combined with changing epidemiological patterns can create strong signals in population genomic datasets, especially when the selected variants are new mutations and when they only originate once. Conventional tests for selection on contemporaneous sample collections are less powered to detect selection on pre-existing variants, or selection that acts on particular combinations of variants in different parts of the genome. Longitudinal population genomic surveys can complement these deficiencies and reveal the pattern and process of resistance evolution. Artemisinin combination therapies (ACTs) are exerting selective pressure on *P. falciparum* in northern South America, a region where *de novo* resistance to previous antimalarial drugs has repeatedly emerged in the past. We sequenced the genomes of a longitudinal collection of 243 *Plasmodium falciparum* parasite samples from French Guiana spanning 17 years to identify mutations that have changed in frequency due to natural selection or genetic drift. We identified and annotated single nucleotide polymorphisms (SNPs) from Illumina sequencing data and evaluated the functional enrichment and classes of SNP alleles that increased or decreased in frequency over time. We also intersected these results with a previous study we performed of

longitudinal population genomic variation in *P. falciparum* in Thailand, an epicenter of ACT resistance. In both locations we find evidence of changing allele frequencies in genes belonging to pathways previously implicated in artemisinin resistance (phosphatidylinositol phosphate regulation, proteasome/ubiquitination), as well as pathways that may represent an evolutionary response to drug pressure that does not explicitly confer drug resistance. We discuss the potential for this approach to detect early signs of ongoing adaptation and the implications of these findings for the mechanism of artemisinin resistance.

### DUAL RNA SEQUENCING IDENTIFIES NOVEL HOST BIOMARKERS OF *PLASMODIUM* HEPATIC INFECTION

**Gregory M. LaMonte**, Pamela Orjuela-Sanchez, Lawrence Wang, Justine Swann, Shangzhong Li, Bing Yu Zou, Annie Cowell, Nathan Lewis, Elizabeth Winzeler

University of California San Diego, La Jolla, CA, United States

While efforts to ultimately eradicate malaria expand, the liver-stage of *Plasmodium* has gained in importance. As the first major step in the human cycle of infection, the liver-stage of *Plasmodium* infection represents the critical window for prophylactic intervention. The parasite burden in hepatic development is also substantially lower than in later human stages and therefore represents a critical developmental bottleneck in the parasite lifecycle. Several recent studies, using newly developed genetic tools, have identified host cell factors and receptors, such as EphA2, which play a critical role in parasite exoerythrocytic development. In order to expand our understanding of liver-stage parasite biology, we report the findings of a dual RNA sequencing study to identify new host-parasite interactions via patterns of genetic dysregulation during hepatic infection. GFP-expressing *Plasmodium berghei* sporozoites were used to infect huh-7.5.1 liver cells, sorted via flow cytometry and combined host and parasite RNA was then extracted, sequenced and analyzed. We identified 3,142 host and 3,788 parasite genes with differential expression patterns during the *Plasmodium* exoerythrocytic lifecycle. These differentially expressed genes were validated through a variety of procedures, including comparison with a separate dual RNA-seq dataset from an independent human hepatocyte cell line (HC04), qPCR in multiple human cell lines as well as primary human hepatocytes and immunofluorescence in both *P. berghei* and *P. vivax*. Of all the differentially expressed genes identified, the most prominent was the host-factor *mucin13* (*muc13*). We observe that *muc13* is highly upregulated during late-stage parasite development in both *P. berghei* and *P. vivax*. In addition, genetic alteration of *muc13*, via either shRNA knockdown or CRISPR/Cas9 knockout, indicates that altered *muc13* levels affect parasite development. We believe *muc13* represents a novel host biomarker of parasite infection, the characterization of which will increase our understanding of both parasite detection and hepatic development and advancing malaria eradication efforts.

### *PLASMODIUM VIVAX* WHOLE GENOME SEQUENCING TO ASSESS GENETIC RELATEDNESS OF POLYCLONAL RELAPSES IN CAMBODIA

**Nicholas F. Brazeau**<sup>1</sup>, Chanthap Lon<sup>2</sup>, Pavitra Rao<sup>3</sup>, Christian Parobek<sup>4</sup>, Sujata Balasubramanian<sup>5</sup>, Mark M. Fukada<sup>6</sup>, Mariusz Wojnarski<sup>6</sup>, Philip Smith<sup>6</sup>, Michele Spring<sup>6</sup>, Jonathan J. Juliano<sup>5</sup>, Jane M. Carlton<sup>3</sup>, David L. Saunders<sup>6</sup>, Jessica T. Lin<sup>5</sup>

<sup>1</sup>Department of Epidemiology, University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC, United States, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, <sup>3</sup>Center for Genomics and Systems Biology, Department of Biology, New York, NY, United States, <sup>4</sup>University of North Carolina School of Medicine, Chapel Hill, NC, United States, <sup>5</sup>Division of Infectious Diseases, University of North

Carolina School of Medicine, Chapel Hill, NC, United States, <sup>6</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

We previously performed targeted deep sequencing of *pvmsp1* in a Cambodian cohort, including 22 persons who developed 29 *Plasmodium vivax* recurrences in the absence of primaquine treatment. We found frequent multiclonal infection and recurrences with homologous strains suggestive of relapse. We are now pursuing whole genome sequencing of these relapses. For 10 isolates from 3 patients who each suffered multiple relapses containing homologous strains, *P. vivax* DNA was enriched by hybrid capture, sheared, then sequenced on an Illumina HiSeq2000. Reads were aligned to the Sal-1 reference genome and variants called using the GATK pipeline. Coverage  $\geq 5x$  was achieved across half the genome in 8/10 relapse isolates. We assessed genetic complexity and relatedness of the isolates in the context of 70 previously sequenced *vivax* genomes from the same region in northwestern Cambodia. The high complexity of infection found by deep sequencing was recapitulated on a genome-wide scale. 102,835 biallelic SNPs with 5x coverage across 80% of the 80 samples were used for an estimate of clonality based on the FWS statistic. All 10 relapse isolates were identified as polyclonal, with a median FWS of 0.60 (range 0.16-0.90). The FWS for each isolate decreased with successive episodes in 2/3 persons. Principal coordinates analysis of the 10 relapse genomes showed clustering by patient, indicating greater genetic relatedness among episodes within than between individuals. This genetic relatedness was recapitulated by STRUCTURE, which assigned isolates to three distinct "populations" corresponding to the three patients. Identity by descent analyses, with a framework to handle multiclonal infections, indicated a high degree of haplotype sharing among relapse samples within persons, consistent with our previous findings. All ten relapse samples aligned to the *pvmsp* VK210 clade. These analyses suggest that waves of reactivated hypnozoites within individuals are polyclonal and genetically related, with implications for distinguishing relapses from re-infections. Ongoing efforts are using whole genome amplification to sequence more relapses from the cohort.

## 1368

### ASSOCIATION BETWEEN DIFFERENT POLYMORPHISMS OF MTMR3 AND C1QTNF6 ON CHROMOSOME 22 AND SEVERE MALARIAL ANEMIA IN CHILDREN FROM WESTERN KENYA

**Niraj Ganjawala**<sup>1</sup>, Angela O. Achieng<sup>1</sup>, Evans Raballah<sup>2</sup>, Qiuying Cheng<sup>1</sup>, Douglas J. Perkins<sup>1</sup>, Prakasha Kempaiah<sup>1</sup>

<sup>1</sup>University of New Mexico School of Medicine, Albuquerque, NM, United States, <sup>2</sup>University of New Mexico/KEMRI Laboratories, Kisumu, Kenya

Severe malarial anemia [SMA, hemoglobin (hb)  $<5.0g/dL$ ] is the primary clinical manifestation of *Plasmodium falciparum* malaria in children ( $<5$  years). We used genome wide association studies and transcriptomics, to discover candidate genes associated with SMA. The selection strategy utilized polarized extremes of children ( $n=144$ ) with malaria stratified into low Hb (avg. Hb=4.1) and high Hb (avg. Hb=10.8) categories. For validation in the larger population ( $n=1,236$ ; age 3-36 mos.), we selected genetic variants based on an allelic distribution ( $>10\%$ ) for two genes: Myotubularin related protein 3 (MTMR3: -1207A/G, rs9614122 and 38935A/G, rs41158) and Complement C1q Tumor Necrosis Factor related protein 6 (C1QTNF6: -46 C/T, rs1001810 and 139 C/A, rs31015763). MTMR3 binds to phosphoinositide lipids and hydrolyze phosphatidylinositol phosphate, variation in MTMR3 is linked to lupus nephritis. C1QTNF6 increases phosphorylation of protein kinase B (PKB, AKT) and regulates proliferation, survival and angiogenesis. Global genomics revealed an increase in MTMR3 (2.65 fold,  $P=0.017$ ) and C1QTNF6 transcripts (1.30 fold,  $P<0.001$ ) in SMA. There was also copy number variation (CNV) gain for both genes. Logistic regression analysis controlling for confounding factors revealed that GG (38935) at MTMR3 was associated with susceptibility to SMA (OR=1.65; 95% CI: 1.10-2.46;  $P=0.015$ ). None of the MTMR3 haplotypes were associated with SMA. CT (-46) at C1QTNF6 was associated with susceptibility to SMA (OR=3.59; 95% CI: 2.07-6.22;  $P<0.001$ ). Haplotypic analyses showed that carriage of

CA (-46 C/139A) was associated with protection against SMA (OR=0.69; 95% CI: 0.46-1.03;  $P=0.068$ ), whereas TC (-46T/139C) was associated with susceptibility to SMA (OR=4.14; 95% CI: 1.25-13.67;  $P=0.020$ ). In addition, analysis of inefficient erythropoiesis [reticulocyte production index (RPI) <2.0] showed that C1QTNF6 CC139 genotype was protective against inefficient erythropoiesis (OR=0.49, 95%CI: 0.26-0.90,  $P=0.022$ ). These results demonstrate that variation in MTMR3 and C1QTNF6 alters transcription, susceptibility to SMA and erythropoiesis.

### 1369

#### HIV-EXPOSED BUT UNINFECTED INFANTS ARE AT INCREASED RISK FOR NEONATAL GBS DISEASE: SYSTEMATIC REVIEW AND META-ANALYSIS

Piet Cools<sup>1</sup>, Janneke H. van de Wijgert<sup>2</sup>, Vicky Jespers<sup>3</sup>, Tania Crucitte<sup>3</sup>, Eduard Sanders<sup>4</sup>, Hans Verstraelen<sup>5</sup>, Mario Vaneechoutte<sup>1</sup>

<sup>1</sup>Ghent University, Ghent, Belgium, <sup>2</sup>Liverpool University, Liverpool, United Kingdom, <sup>3</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>4</sup>Oxford University, Oxford, United Kingdom, <sup>5</sup>Ghent University Hospital, Ghent, Belgium

One million children die each year because of neonatal disease, *Streptococcus agalactiae* (group B *Streptococcus*, GBS) is the leading cause worldwide. Since 2010, evidence for an association between neonates born to HIV-infected mothers and GBS neonatal disease has been accumulating. We sought to assess to which extent HIV exposure of neonates is associated with GBS neonatal disease. We also assessed to which extent HIV infection in women is associated with maternal rectovaginal GBS carriage, the single most important risk factor for GBS neonatal disease. We searched MEDLINE, Embase, and Web of Science for studies assessing the association between neonatal GBS disease and HIV-status of the mother and studies that assessed the association between rectovaginal GBS colonization and HIV status in adult women, published up to 1 November 2015. We used the Newcastle-Ottawa Scale to assess quality of the studies and heterogeneity was assessed using the  $I^2$  statistic. A priori planned subanalyses were performed for the early-onset and the late-onset form of neonatal GBS disease separately. A total of 546 unduplicated citations were identified, 19 studies met the inclusion criteria. HIV-exposed neonates were more than twice as likely to have neonatal GBS disease compared to unexposed neonates (OR, 2.39;  $p=0.005$ ). HIV-exposed neonates were not at increased risk for early-onset neonatal disease (OR, 1.31;  $p=0.240$ ), but were 4.43 times more likely to have late-onset neonatal GBS disease (95% CI,  $p=0.001$ ). We built and will present a conceptual framework explaining these (discrepant) findings. There was no significant association between HIV infection status and rectovaginal GBS carriage (OR 1.09;  $p=0.55$ ), but these studies suffered from major limitations. Public health interventions preventing neonatal GBS disease are urgently needed for the increasing group of HIV-exposed neonates. Our conceptual framework identifies opportunities, such as different (breast) feeding strategies, for the clinical practice and global health policy to prevent disease. Well-designed studies should clarify the relation between HIV-status and GBS carriage.

Cleveland, OH, United States, <sup>4</sup>University of Colorado School of Medicine, Denver, CO, United States

Approximately 1.5 million adults in Kenya are infected with HIV. Due to increased access to antiretroviral therapy and mother to child transmission interventions, the number of babies infected with HIV via vertical transmission is low resulting in a growing population: HIV exposed but uninfected (HEU) infants. While HEU infants are healthier than HIV positive infants, studies suggest that HEU infants/children experience increased morbidity, mortality, and hospitalizations compared to HIV unexposed uninfected (HUU) infants. We hypothesized that *in utero* exposure to HIV and/or HIV associated chronically activated maternal immune environment affects fetal immune development leading to immune dysfunction. We examined (1) the magnitude and duration of pro-inflammatory biomarkers in HEU vs. HUU infants using MagPix analysis, (2) the prevalence of *Plasmodium falciparum* malaria infection by PCR, (3) the prevalence and magnitude of antibodies against four vaccine antigens and fourteen different pre-erythrocytic and blood stage malaria antigens from birth to two years, and (4) the frequency and character of clinical events experienced by HEU vs. HUU infants. There were no significant differences in the levels of twelve different pro-inflammatory biomarkers in plasma of HEU vs. HUU infants at seven time points between birth (cord blood) and one year. Remaining analyses of laboratory studies are currently ongoing. Additionally, analyses of clinical events found that HUU infants experienced a greater number of sick visits as well as a greater number of severe disease diagnoses (severe malaria, severe pneumonia, gastroenteritis with severe dehydration) and hospital admissions compared to HEU infants. Possible explanations for these preliminary findings may include the prophylactic Bactrim given monthly up to 18 months, more frequent clinic visits, and more frequently replaced mosquito nets in the HEU infant cohort compared to the HUU cohort. Ongoing analyses will hopefully provide more complete information regarding the outcomes of HEU infants and help inform future recommendations and decisions concerning their care.

### 1371

#### USE OF BED NETS A SURROGATE MARKER FOR RISK BEHAVIOR TOWARDS HIV

Inge Kroidl<sup>1</sup>, Petra Clowes<sup>2</sup>, Lucas Maganga<sup>2</sup>, Leonard Maboko<sup>2</sup>, Upendo Mwingira<sup>3</sup>, Michael Hoelscher<sup>1</sup>, Elmar Saathoff<sup>1</sup>

<sup>1</sup>Medical Center of the University of Munich (LMU), Munich, Germany, <sup>2</sup>National Institute for Medical Research Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, <sup>3</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

Despite huge global efforts, the incidence of HIV infection did not substantially decrease over the last years. Therefore, HIV prevention efforts need to more effectively identify and target individual risk groups. Information on bed net ownership and bed net use was collected during a population based cohort study in Southwest Tanzania, which investigated the occurrence of HIV, malaria and lymphatic filariasis (LF). A total of 2,189 participants from the Kyela District were included in the study in 2007, with 82% confirming the possession of a bed net. The prevalence of falciparum malaria was 7.1% in households without bed nets and, 4.1% in households with bed nets (RR 0.56, 95% CI 0.35 to 0.89,  $p=0.015$ ) and the prevalence of LF was 35.3% versus 23.6% (RR 0.76; 95% CI 0.64 to 0.91,  $p=0.003$ ) in the two groups respectively. HIV prevalence among the adult population was 21.0% in households without bed nets, but only 16.7% if a bed net was owned (RR 0.78; 95% CI 0.53 to 1.16,  $p=0.225$ ). For 1,360 individuals above the age of 14 years and during 3,819 person years (PY) of observation, 45 new HIV infections were observed. Adjusted for age, gender and socio economic status we found a significant association of bed net ownership and HIV incidence, with 2.82 new HIV infections/100 PY among those without bed net, compared to 0.97/100 PY among those with bed nets (RR 2.66; 95% CI 1.33 to 5.30,  $p=0.006$ ). When analyzing behavioral factors, we found significant differences in bed net ownership between different groups. Condom users were 5% (RR = 1.05, 95% CI 1.02 to 1.08,  $p=0.003$ ), circumcised individuals were 9%

(RR = 1.09 95%CI 1.05 to 1.14,  $p < 0.001$ ) more likely to own a bed net than non-users. Persons with more than one sex partners owned bed nets 8% less likely (RR 0.92 (0.87 to 0.97,  $p = 0.001$ ) with two sex partners and 16% less likely (RR = 0.84, 95% CI 0.77 to 0.92,  $p < 0.001$ ) with three sex partners. Religion or gender had no association with bed net ownership. Bed net ownership was associated with both, significantly lower HIV incidence and lowered behavioral HIV risk profile. These findings might be useful to identify persons at risk for HIV.

## 1372

### DEMOGRAPHIC AND CONTEXTUAL FACTORS ASSOCIATED WITH HIV MORTALITY IN AN AFRICAN COHORT IN EAST AFRICA AND NIGERIA

**Hannah Kibuuka<sup>1</sup>**, Francis Kiweewa<sup>1</sup>, Ezra Musingye<sup>1</sup>, Jonah Maswai<sup>2</sup>, John Owouth<sup>3</sup>, Lucas Maganga<sup>4</sup>, Senate Amusu<sup>5</sup>, Michael Semwogerere<sup>1</sup>, Christina Polyak<sup>6</sup>, Julie Ake<sup>6</sup>

<sup>1</sup>Makerere University Walter Reed Project, Kampala, Uganda, <sup>2</sup>Walter Reed Project, Kericho, Kenya, <sup>3</sup>Walter Reed Project HIV Program, Kisumu West Districts, Kisumu, Kenya, <sup>4</sup>Mbeya Medical Research Program, Mbeya, United Republic of Tanzania, <sup>5</sup>U.S. Military HIV Research Program, Abuja, Nigeria, <sup>6</sup>U.S. Military HIV Research Program, Bethesda, MD, United States

Several studies have documented clinical factors as predictors of mortality among HIV. However, the contribution of contextual factors is not well documented. The African HIV cohort provides an opportunity to examine the potential influence of some of these. The African HIV Cohort Study prospectively enrolls adults at 11 PEPFAR-supported facilities in Uganda, Kenya, Tanzania and Nigeria. Data was collected on a variety of individual social factors at enrolment into the cohort and every 6 months thereafter. Mortality data from Jan 2013 to Feb 2017 was analyzed. Data from participants that had completed only a single visit was excluded unless status change data was available. Person time, mortality rates and site adjusted Cox proportional hazards models were fitted to evaluate the social and contextual factors associated with mortality. Data from 2172 HIV infected participants was used for analysis. Median age was 41 years (IQR: 34-48) and the majority were females (58.7%) and non-Catholic Christians (67.5%). During a median follow up period of 1.6 years (3796.07 PY), a total of 57 deaths were observed translating into a mortality rate of 15.02/1000 PY (95%CI: 11.58-19.47). Adjusted for site; age, gender, marital status, education and employment status did not predict mortality. Hazard for death was twice for Catholic Christian compared to non-Catholic Christian, HR 2.01(95%CI: 1.51-3.50,  $p = 0.014$ ). Hazard for death increased if a sibling or any immediate family member had been diagnosed with HIV, HR 5.6 (95%CI: 2.01-15.65,  $p = 0.001$ ) and HR 3.67(95%CI: 1.45-9.27,  $p = 0.006$ ) respectively, participant experienced domestic violence, HR4.9 (95%CI: 1.18-20.39,  $p = 0.029$ ), or homelessness/displacement, HR 7.62 (95%CI: 2.35-24.68,  $p = 0.001$ ) or use of traditional remedies for HIV/ other ailments, HR 3.66(95%CI: 1.75-7.68,  $p = 0.001$ ). Factors not associated with mortality included: distance from or time taken to get to health facility, travel costs, having a treatment supporter, alcohol consumption or cigarette smoking. Understanding contextual factors beyond achieving the goal of antiretroviral therapy is important in reducing HIV mortality.

## 1373

### RATE OF VIREMIA AND ITS PREDICTORS AMONG ADULT HIV INFECTED PATIENTS IN THE AFRICAN HIV COHORT

**Francis Kiweewa<sup>1</sup>**, Ezra Musingye<sup>1</sup>, Hannah Kibuuka<sup>1</sup>, Babajide Keshinro<sup>2</sup>, Trevor A. Crowell<sup>3</sup>, Trevor A. Crowell<sup>3</sup>, Trevor A. Crowell<sup>3</sup>, Jonah Maswai Maswai<sup>4</sup>, John Owouth<sup>5</sup>, Lucas Maganga Maganga<sup>6</sup>, Julie Ake Ake<sup>3</sup>, Christina Polyak<sup>3</sup>

<sup>1</sup>Makerere University Walter Reed Project (MUWRP), Kampala, Uganda, <sup>2</sup>Walter Reed Program-Nigeria, Abuja, Nigeria, <sup>3</sup>U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>4</sup>KEMRI/Walter Reed Project, Kericho, Kenya, <sup>5</sup>Walter Reed

Program, Kisumu, Kenya, <sup>6</sup>Walter Reed Program-Tanzania, Mbeya, United Republic of Tanzania

Progress towards the UNAIDS 90-90-90 target requires regular monitoring of HIV treatment outcomes. We evaluated the rate of viremia and its associated factors in HIV infected participants in the African Cohort Study. The African Cohort Study prospectively enrolls adults at PEPFAR-supported facilities in Uganda, Kenya, Tanzania, and Nigeria. HIV management history and laboratory assessments are obtained at entry and every 6 months. Participants on antiretroviral therapy (ART) for >6 months were evaluated for viremia (HIV RNA >50 copies/ml) and change in CD4 count. A modified-Poisson generalized linear model was used to evaluate factors associated with viremia at the participant's most recent visit. As of June 2016, 1712 HIV-infected adults were eligible for this analysis across five recruitment locations: Kayunga, Uganda (16.4%); South Rift Valley, Kenya (39.4%); Kisumu, Kenya (17.0%); Mbeya, Tanzania (16.1%); Abuja and Lagos, Nigeria (11.0%). Viremia was observed in 315 participants (18.4%, 95% CI: 16.6% -20.2%); viral load >1,000 copies/ml in 171 individuals (10.0%, 95% CI: 8.6%-11.4%). Compared to Uganda, the risk of viremia at the most recent visit was statistically similar for the Kenyan sites, but was 2.56 and 3.42 fold higher for the Tanzanian and Nigerian sites respectively. In the multi-variable analysis, factors directly associated with viremia included any prior viremia (RR:1.54, 95% CI:1.01-2.37,  $p = 0.049$ ), viremia at the second most recent visit (RR:1.91, 95% CI: 1.24-2.92,  $p = 0.003$ ), being on second line ART (RR:1.49, 95% CI: 1.05-2.11,  $p = 0.027$ ) and having recently missed  $\geq 2$  days of ART by self-report (RR=1.90, 95% CI: 1.33-2.70). Increasing CD4 count at the most recent visit was inversely associated with viremia (RR: 0.51, 95% CI: 0.40-0.66,  $p < 0.001$ ). Results show that viremia in patients on ART in the African setting is common. CD4 count, past viremia, and ART adherence levels are predictors that should be closely monitored and can inform clinical practice. The association of second line therapy with viremia highlights the at-risk nature of this group and suggests a requirement for intensive monitoring and management.

## 1374

### CRYPTOCOCCAL ANTIGENEMIA IN HIV-INFECTED ADULTS IN THE AFRICAN COHORT STUDY

**Valentine Sing'oei<sup>1</sup>**, John Owuoth<sup>1</sup>, Kavitha Ganesan<sup>2</sup>, Ben Andagalu<sup>1</sup>, Senate Amusu<sup>3</sup>, Emmanuel Bahemana<sup>4</sup>, Francis Kiweewa<sup>5</sup>, Jonah Maswai<sup>6</sup>, Julie Ake<sup>2</sup>, Allahna Esber<sup>2</sup>, Trevor A. Crowell<sup>2</sup>, Christina Polyak<sup>2</sup>

<sup>1</sup>Kenya Medical Research Institute/Walter Reed Project, Kisumu, Kenya, <sup>2</sup>U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>3</sup>Walter Reed Program, Abuja, Nigeria, <sup>4</sup>Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, <sup>5</sup>Makerere University-Walter Reed Project, Kampala, Uganda, <sup>6</sup>Kenya Medical Research Institute/Walter Reed Project, Kericho, Kenya

In many low resource settings, patients with advanced immunosuppression continue to present late to antiretroviral therapy (ART) treatment programs with opportunistic infections. Cryptococcal meningitis is a co-infection associated with high risk of mortality before and after ART is started. The World Health Organization recommends routine Cryptococcus antigen(CrAg) screen in ART-Naïve adults followed by pre-emptive antifungal therapy if CrAg is positive for patients with a CD4 count less than 100 cells/mm<sup>3</sup>. The African Cohort Study(AFRICOS) prospectively enrolls HIV infected and HIV uninfected adults at 11 PEPFAR-supported facilities in Uganda, Kenya, Tanzania, and Nigeria. Serum CrAg was measured using latex agglutination(LA) at enrollment in HIV infected participants with CD4<200cells/ul irrespective of ART status. CrAg prevalence was estimated and assessed for associations with age, sex, CD4+ count, ART status and viral load using Student's t-test, chi2 test and a regression model as appropriate. From January 21, 2013 to March 1, 2017, 3,085 participants were enrolled in AFRICOS and 494 participants were eligible for CrAg screening, 97 had missing CrAg status. The seroprevalence of CrAg among the remaining 397 was 0.04%. The mean age for the CrAg positives was 42.0(SD11.2) compared to 39.2(SD9.9)

for the CrAg negatives. The proportion of males who were CrAg positive was 53.3%(8/15) versus 47.9%(183/397) who were CrAg negative. Sixty percent (9/15) of the CrAg positives were ART naive as opposed to 51.1%(195/382) who were negative. The mean CD4 count was 51 cells/mm<sup>3</sup> (SD50) for the CrAg positives while that of the negatives was 108 cells/mm<sup>3</sup> (SD 60). The mean log of viral load was 11.9copies/ml(SD2.1) for the CrAg positives versus 10.1(SD3.4) for the negatives. In the logistic regression model, CD4 count had a statistically significant influence on CrAg serostatus (P value=0.001) while viral load had borderline statistical significance (P value = 0.05). Age, gender and ART status had P values > 0.05. CrAg prevalence is low but CrAg screening is still warranted for all patients with CD4<200cells/ml irrespective of their ART status .

## 1375

### UNFAVORABLE TUBERCULOSIS OUTCOME ASSOCIATED WITH HIV, DRUG RESISTANCE, AND PREVIOUS TREATMENT IN INDONESIA

**Dona Arlinda**, Retna Mustika Indah, Aris Yulianto, Agus Dwi Harso, Armaji Kamaludi Syarif, Muhammad Karyana

*Indonesia National Institute of Health Research and Development, Jakarta, Indonesia*

Indonesia is a country with double burden of tuberculosis (TB) and HIV. The objective of this study is to determine factors associated with unfavourable TB treatment outcomes. A hospital-based TB Registry recorded data from 15 years old patients and older who were diagnosed with TB (ICD-10 code A15-A19). We analysed data collected from 1 January 2014 to 12 January 2016 in seven referral hospitals in Java and Bali Island. Data was analysed with SPSS ver. 22 and logistic regression was used to assess determinants of TB treatment outcomes. 2,051 TB patients were recorded. 1180 subjects (57.5%) were male and the median age was 38 years (IQR 27-50 years). 452 subjects (22.0%) had previous history of TB treatment. 1447 subjects (70.6%) had pulmonary TB, 580 subjects (28.3%) had extra pulmonary TB, 24 subjects (1.2%) had pulmonary and extra pulmonary TB. 216 subjects were HIV positive (10.5%) and 296 subjects had DM (14.4%). 248 subjects (12.1%) were resistant to at least one anti-TB drug by either X-pert or drug susceptibility test. Treatment outcome was unknown for 135 subjects (6.6%) and was unavailable for 1137 subjects (55.4%) who were still on treatment. Among 779 subjects with outcome, 358 (46.0%) were treatment success, 248 (31.8%) transferred out, 112 (14.4%) defaulted, 46 (5.9%) died, and 15 (1.9%) failed. After controlling for other factors, mortality was associated with resistance (P=0.000; aOR 53.1; 95% CI 9.7-290.0) and HIV (P=0.016; aOR 9.3; 95% CI 1.5-57.8), while unsuccessful TB treatment outcome was associated with resistance (P=0.001; aOR 8.2; 95% CI 2.4-28.2) and previous TB treatment (P=0.000; aOR 4.7; 95% CI 2.0-11.1). Engaging TB patients with their treatment remains a challenge in Indonesia, especially those with coinfections, comorbidities, and drug resistance. More effort should be made to identify drug resistant TB and HIV, as well as maintaining compliance to TB treatment.

## 1376

### SEROPREVALENCE OF CHIKUNGUNYA IN VIETNAM - EVIDENCE OF PAST BUT NOT PRESENT TRANSMISSION

**Quan Minh Tran**, Vy Ha Nguyen, Phuong Thi Huynh, Thanh Thi Nguyen, Maciej F. Boni, Hannah Clapham

*Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam*

Arboviral infections have been a serious concern in tropical countries due to high-levels of transmission and complex transmission dynamics. Currently in Vietnam, there is a focus on dengue and Zika virus. As the global interest in chikungunya virus (CHIKV) is rising [1] an estimated 1.3 billion people are living in areas of potential transmission [2], the information about the CHIKV activity in Vietnam remains tenuous. Previously there have been only brief mentions of chikungunya cases in a few papers, mainly without solid evidence and data [2-5]. Furthermore,

those references were only about CHIKV in Vietnam a half decade ago, and there is little to no information about the current situation. The fact there have been recent outbreaks in the neighboring countries - Cambodia and Laos [6, 7] - leads us to pay more attention to chikungunya transmission in Vietnam. We performed a systematic review of CHIKV in Vietnam until present. We also conducted a seroprevalence survey using the chikungunya ELISA IgG test on serum samples from An Giang province (n = 91) and Ho Chi Minh city (n = 91) from 2015. The findings give us a certain evidence of past CHIKV activity: 25/182 seropositive (13.2%) overall samples, 9/91 seropositive (9.9%) with the age-adjusted value 10.44% in An Giang province, and 15/91 seropositive (16.5%), with the age-adjusted value 12.79% in Ho Chi Minh City. However, the age-stratified seroprevalence suggests that the last endemic ended about 30 years ago, and that there may be no current transmission activity in these places. The R0 for the past epidemics were calculated as R0 =1.12 and R0 =1.15 in An Giang and Ho Chi Minh City respectively. In conclusion, we find evidence of CHIKV outbreaks in the past, but little evidence of recent transmission. This is remarkable considering that the vectors of CHIKV have a high environmental suitability to Vietnam and are the same as dengue, which is known to have high transmission in Vietnam. Therefore, the possibility of future chikungunya transmissions remains, especially as we have shown here, when the proportion of the population that is susceptible is high.

## 1377

### CHARACTERIZATION OF SINDBIS VIRUS CIRCULATING IN KENYAN ECOSYSTEMS

**Faith Sigei**<sup>1</sup>, Fredrick Nindo<sup>2</sup>, Silvanos Mukunzi<sup>3</sup>, Zipporah Ng'ang'a<sup>1</sup>, Rosemary Sang<sup>3</sup>

<sup>1</sup>*Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya,*

<sup>2</sup>*University of Cape Town, Cape Town, South Africa,* <sup>3</sup>*Kenya Medical Research Institute, Nairobi, Kenya*

Sindbis virus (SINV) is one of the most widespread mosquito-borne viruses, with human outbreaks known to occur in Northern Europe and parts of Africa. Presently, little is known about Sindbis virus strains circulating in Kenya. We analyzed five SINV strains isolated in Kenya from mosquitoes trapped from diverse species and geographic locations between 2007 and 2013 to gain insight into their phenotypic and evolutionary aspects. In-vitro growth kinetic assays were determined by virus titration in Vero cells. Phylogenetic relationships and evolutionary inferences were performed using maximum likelihood and Bayesian statistical inference approaches. Genetic and adaptive molecular analyses were carried out targeting the virus envelope glycoproteins (E1, E2) and non-structural protein (nsP4) genes. In-vitro growth assays showed that one Kenyan SINV isolate had highest replication efficiency in culture. Phylogenetic analysis revealed that all the Kenyan SINV isolates belonged to genotype 1, clustering with strains originating mostly from northern Europe and other African countries. Alignment of protein sequences of the E1, E2 and nsP4 genes revealed a significant proportion of conserved sites among the Kenyan and foreign SINV strains. Evolutionary analysis predicted that the earliest introduction of SINV in Kenya may have occurred around the shores of Lake Naivasha 400 years ago. Evolutionary rate of SINV was estimated to be 6.89X10<sup>-5</sup> substitutions/site/year (95% highest posterior probability (HPD); 2.47X10<sup>-5</sup>-1.15X10<sup>-4</sup>). Natural selection analyses indicated that SINV E1, E2 and nsP4 protein encoding genes were predominantly evolving under negative selection. From 2007 to 2013, our results indicate that circulating SINV strains in Kenya were largely genetically similar to those detected in other African countries and northern Europe where human outbreaks have been reported. There is need to assess the public health impacts of SINV in Kenya and further surveillance is needed to establish the molecular diversity among SINV strains in the African region.

## 1378

**PREVALENCE OF CHRONIC JOINT PAIN FOLLOWING CHIKUNGUNYA INFECTION FROM A COLUMBIAN COHORT**

**Priyanka Kamalopathy**<sup>1</sup>, Liliana Encinales<sup>2</sup>, Karen Martins<sup>3</sup>, Patrick Reid<sup>4</sup>, Nelly Pacheco<sup>2</sup>, Shamila Pacheco<sup>2</sup>, Eyda Bravo<sup>2</sup>, Marianda Navarno<sup>2</sup>, Carlos Encinales<sup>2</sup>, Alexandra Porras<sup>2</sup>, Alejandro Rico<sup>2</sup>, Richard Amdur<sup>1</sup>, Gary Firestein<sup>5</sup>, Gary Simon<sup>1</sup>, Jeff Bethony<sup>1</sup>, Aileen Chang<sup>1</sup>

<sup>1</sup>George Washington, Washington, DC, United States, <sup>2</sup>Allied Research Society, Barranquilla, Colombia, <sup>3</sup>U.S. Army Medical Research Institute for Infectious Disease, Washington, DC, United States, <sup>4</sup>University of Nebraska, Lincoln, NE, United States, <sup>5</sup>University of California, San Diego, CA, United States

Chikungunya (CHIK) fever is a viral illness spread by mosquitos that presents with fever, headache, muscle pain, rash and joint pain. Outbreaks have previously been restricted to Africa, Asia, and Europe, causing chronic arthritis lasting months to years in these areas. In 2013, CHIK virus was found for the first time in the Americas and has now infected over 800,000 people. The objective of this study was to determine the prevalence of chronic arthritis after CHIK infection in a Latin American cohort and define the clinical characteristics associated with chronic arthritis symptoms. 485 Colombian patients with serologically confirmed CHIK were included in the study. Patients received a baseline and a 20-month follow-up symptom questionnaire. Comparisons of the reported symptoms were analyzed using chi-square or the Kruskal-Wallis. The baseline characteristics of the patients include mean age 49±16 years, 80% female, 94% Mestizo ethnicity, and 78% with high school or less education. Common comorbidities seen in the study sample were hypertension, diabetes, lung disease and depression. 25% of the patients reported current joint pain at 20-month follow-up. The patients with persistent joint pain in weeks had increased duration of initial joint pain (45.3±39.5) compared to the no persistent joint pain group (10.5±25.1) with  $p < 0.0001$ . Of the 79 patients that missed work, 49 patients had persistent joint pain ( $p < 0.001$ ). Of the 46 patients that had symptoms impact their capacity to continue normal activity, 33 had chronic joint pain ( $p < 0.001$ ). Patients with persistent joint pain had increased disease activity of swollen joint count (0.5±1.0) and tender joint count (2.9±2.3) compared to the no persistent joint pain groups (0.06±0.3, 0.2±0.8, respectively) with  $p < 0.0001$ . CHIK caused significant debilitating chronic arthritis in 25% of the patients at 20-months post infection. The baseline cytokine profile of cases of CHIK arthritis in comparison to age and gender matched controls without persistent arthritis will be evaluated to further understand the development CHIK arthritis and the biomarkers that may predict persistent arthritis.

## 1379

**CHIKUNGUNYA - A RE-EMERGED TROPICAL DISEASE - DEVELOPMENT OF A NEW VACCINE**

**Nina Wressnigg**, Urban Lundberg, Andrea Fritzer, Romana Hochreiter, Andreas Meinke

Valneva Austria GmbH, Vienna, Austria

Chikungunya virus (CHIKV) is a mosquito-borne virus resulting in many patients in chronic and incapacitating arthralgia affecting all gender and age groups. Coinciding with an adaptation enabling unusually efficient transmission by *Aedes albopictus* mosquitoes, the virus re-emerged in 2004 and rapidly spread over Africa, Asia, the Americas and locally also in Europe since then. Hence, CHIKV is regarded as one of the most-likely re-emerged viruses to spread globally and morbidity due to this virus is considered a serious threat to global public health raising an urgent demand for efficient prophylaxis. However, at present there is no treatment or vaccine available. Facing the unmet medical need for a prophylactic intervention we initiated a program to develop a vaccine candidate (VLA1553) against CHIKV infections. Valneva's live-attenuated CHIKV vaccine candidate is based on the La Reunion strain

of the East Central South African genotype, is produced in Vero cells and is characterized by a 60 amino acid deletion in its nsP3 viral replicase complex gene leading to attenuation of the virus *in vivo*. The safety, immunogenicity as well as protective efficacy of the vaccine candidate was evaluated in mice and non-human primates. We demonstrate that our vaccine candidate is highly attenuated in animal models and causes no clinical manifestations typically associated with wt CHIKV infections in addition to strongly reduced viremia and cytokine levels. Moreover, VLA1553 is highly immunogenic, induces a strong and long-lasting neutralizing antibody response in animal models and protects against a high dose wt CHIKV challenge. Due to its safe and immunogenic potential we will enter into a blinded, randomized phase 1 first-in-human clinical study investigating the safety and immunogenicity of three dose levels administered intramuscularly in a CHIKV-naïve population as a single-shot immunization designed to elicit long-term immunological memory.

## 1380

**LOW FIDELITY ARBOVIRUS VACCINE STABILITY**

**Tiffany F. Kautz**, Kamil Khanipov, Mathilde Guerbois, Yuriy Fofanov, Scott C. Weaver, Naomi L. Forrester

University of Texas Medical Branch, Galveston, TX, United States

While live-attenuated vaccines (LAVs) against RNA viruses are inexpensive and immunogenic, there is a risk of reversion or pseudoreversion due to the high error rate during RNA virus replication. There has been interest in increasing the safety of these LAVs by altering virus polymerase fidelity, which lowers virus virulence while theoretically increasing vaccine stability. We have created a low fidelity version (LF) of TC-83, a LAV for the arbovirus Venezuelan equine encephalitis virus. Mice vaccinated with LF TC-83 exhibit no morbidity post-vaccination, and result in complete protection post-challenge, as well as higher neutralizing antibody titers than the parental TC-83. To determine how decreasing fidelity affects the stability of the LF genotype and phenotype in a transmission cycle, TC-83 and LF TC-83 were passaged *in vitro* and *in vivo*. This is crucial to examine, because mice vaccinated with LF TC-83 produce viremias identical to wild-type vaccines, suggesting no difference in the probability of transmission to the mosquito vector. To examine how mutations accumulate and virulence changes during growth in a permissive host environment, TC-83 and LF TC-83 were passaged 10 times intracranially in infant mice. After passaging, virulence was assayed by subcutaneous injection into infant mice. Both TC-83 and LF TC-83 gained virulence during passaging. However, passaged LF TC-83 remained significantly less virulent than TC-83, which increased time to death from 10 to 5 days post-infection. Sequencing revealed no reversion of attenuating mutations in either virus, suggesting the appearance of pseudoreversions. To determine stability in a transmission cycle TC-83 and LF TC-83 were also passaged serially or alternating between two hosts *in vitro* using mosquito and mammalian cells. After 6 passages, TC-83 accumulated a greater number of SNPs than LF TC-83, but there were no reversions of the attenuating mutations for either virus. This all suggests that LF LAVs are still able to propagate through a transmission cycle, but are less likely to fully revert than wild-type LAVs making them a potential strategy for attenuating vaccines.

## 1381

**DENGUE AND CHIKUNGUNYA HUMAN TRANSMISSION IN WESTERN AND COASTAL KENYA: GEOGRAPHIC, CLIMACTIC, VECTORIAL AND SOCIODEMOGRAPHIC RISK FACTORS FOR EXPOSURE AND DISEASE**

**A. Desiree LaBeaud**<sup>1</sup>, Bryson A. Ndenga<sup>2</sup>, Elyse N. Grossi-Soyster<sup>1</sup>, David M. Vu<sup>1</sup>, Amy R. Krystosik<sup>1</sup>, Harun Njenga Ngugi<sup>3</sup>, Assaf Anyamba<sup>4</sup>, Richard Damoah<sup>5</sup>, Cornelius Kiptoo<sup>2</sup>, John Vulule<sup>2</sup>, Dunstan Mukoko<sup>6</sup>, Uriel Kitron<sup>7</sup>, Charles H. King<sup>8</sup>, Francis M. Mutuku<sup>9</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Kenya Medical Research Institute, Kisian, Kenya, <sup>3</sup>University of Nairobi/Chuka University, Nairobi/

Chuka, Kenya, <sup>4</sup>Universities Space Research Association and NASA Goddard Space Flight Center, Greenbelt, MD, United States, <sup>5</sup>Morgan State University and NASA Goddard Space Flight Center, Greenbelt, MD, United States, <sup>6</sup>Ministry of Health, Nairobi, Kenya, <sup>7</sup>Emory University, Atlanta, GA, United States, <sup>8</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>9</sup>Technical University of Mombasa, Mombasa, Kenya

Recent dengue (DENV) and chikungunya (CHIKV) outbreaks have occurred in Kenya; however, the extent of their transmission and their public health impact have gone unmeasured. In order to understand the burden of exposure and resultant disease, and the continuum of risk created by climate, vector abundance, and human infection, both active and passive human surveillance, linked to vector and weather data, are needed. Two cohorts of children (Jan 2014- present) were enrolled at four Kenyan study sites (rural west, rural coast, urban west, urban coast): a healthy child cohort followed every six months to document asymptomatic CHIKV and/or DENV infections via IgG ELISA testing, and an acutely febrile child cohort followed to convalescence to document symptomatic disease via PCR and IgG ELISA testing. Questionnaire data were collected to describe demography, socioeconomic status (SES), and household environment. All life stages of *Aedes* spp. vectors were collected monthly in each site and immatures were reared to adulthood for species identification. Weather variables were collected both locally using HOBO loggers and remotely by satellite. Overall prevalence was 4.2-5.9% for DENV and 3.7-5.5% for CHIKV. For acutely ill participants, 0.7% (13/1844) seroconverted for CHIKV and 5.4% (97/1790) for DENV. CHIKV was more common in the west (4.9% vs. 1.7%). DENV was more common in rural sites (5.4% vs 3.6%). Among healthy cohorts (500 children per site), 11 seroconverted for CHIKV (0.6%) and 3 for DENV (0.1%). Seroconversion for CHIKV or DENV was associated with age, SES, mosquito exposure and avoidance behaviors, and hygiene and wealth indices. Infections were spatially clustered in all sites, indicating important ecological risks. Increased vector abundance and human transmission were noted during dry seasons, likely due to unsafe water storage. These data demonstrate ongoing transmission of DENV and CHIKV across diverse regions in Kenya and undocumented disease burden. Spatial and temporal heterogeneities in transmission patterns point to the potential of social and vector interventions to reduce risk of human DENV and CHIKV infection in Kenya.

### 1382

#### UTILIZING CERVIDS AS SENTINELS FOR EVALUATION OF EASTERN EQUINE ENCEPHALITIS EMERGENCE IN MAINE

Joan L. Kenney<sup>1</sup>, Charles Lubelczyk<sup>2</sup>, Susan P. Elias<sup>2</sup>, Margret Welch<sup>2</sup>, Robert P. Smith<sup>2</sup>, Sara Robinson<sup>3</sup>, John-Paul Mutebi<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Fort Collins, CO, United States, <sup>2</sup>Maine Medical Center Research Institute, Scarborough, ME, United States, <sup>3</sup>Maine Centers for Disease Control, Augusta, ME, United States

Despite a long history of eastern equine encephalitis virus (EEEV) detection in northeastern states such as Massachusetts, New York, Connecticut, and Rhode Island, EEEV has only recently been detected in the most north eastern states. Specifically, in Maine, the virus was first detected in migratory birds in 2001. Following individual veterinary cases reported from 2005-2008, an epizootic occurred 2009 that expanded the spatial extent of virus activity from two counties (York and Cumberland) to include three additional counties (Kennebec, Waldo, and Penobscot) in central Maine. In order to determine the distribution of EEEV in Maine, a collaboration among the CDC, Maine CDC, and Maine Medical Center Research Institute initiated an investigation into the geographic range of EEEV antibody seroprevalence using white-tailed deer (*Odocoileus virginianus*) and moose (*Alces americana*) as sentinels. Samples were collected from statewide tagging stations throughout the firearm season from 2009-2014. Collected serum samples were tested by plaque reduction neutralization assay (PRNT) for EEEV seropositivity. Initial findings from 2009-2011, which were previously reported, indicated a widespread prevalence of EEEV antibodies with positive samples identified from 10 out of 16 counties. Our supplemental findings from 2012 - 2014 indicate the

presence of EEEV in all 16 Maine counties. Combined cervid seropositivity rates were 6.7% (41/609), 8.9% (69/771), and 10.7% (51/473) for 2012, 2013, and 2014, respectively. Herein we report the additional findings from samples collected from 2012 -2014 and discuss the state of EEEV in Maine.

### 1383

#### EPITOPE EXPOSURE ON THE OUTER FACE OF THE CHIKUNGUNYA VIRUS ENVELOPE DETERMINES ANTIBODY NEUTRALIZING EFFICACY

Rachel H. Fong<sup>1</sup>, Soma R. Banik<sup>1</sup>, Jin Jing<sup>2</sup>, Graham Simmons<sup>2</sup>, Benjamin J. Doranz<sup>1</sup>

<sup>1</sup>Integral Molecular, Inc., Philadelphia, PA, United States, <sup>2</sup>Blood Systems Research Institute, San Francisco, CA, United States

Chikungunya virus (CHIKV) is a re-emerging alphavirus that infects millions of people and causes a debilitating arthritic disease for which no specific treatment is available. Like many alphaviruses, the structural targets on CHIKV that elicit a protective humoral immune response in humans are poorly defined. We have used phage display against virus-like particles (VLPs) to isolate seven human monoclonal antibodies (MAbs) against the CHIKV envelope glycoproteins E2 and E1. One MAb, IM-CKV063, was highly neutralizing (50% inhibitory concentration, 7.4 ng/ml), demonstrated high-affinity binding (320 pM), and was capable of therapeutic and prophylactic protection in multiple animal models up to 24 h post-exposure. Epitope mapping using a comprehensive shotgun mutagenesis library of 910 E2/E1 alanine-scan mutants demonstrated that IM-CKV063 binds to an inter-subunit conformational epitope on domain A, a functionally important region of E2. Subsequent publications have expanded on this using cryo-EM analysis, and by demonstrating that IM-CKV063 blocks both virus entry and virus release steps. MAbs against the highly conserved fusion loop have not previously been reported but were also isolated in our studies. The fusion loop MAbs were broadly cross-reactive against diverse alphaviruses but were non-neutralizing. Fusion loop MAb reactivity was affected by temperature and reactivity conditions, suggesting that the fusion loop is hidden in infectious virions. Visualization of the binding sites of 15 different MAbs on the structure of E2/E1 revealed that all epitopes are located at the membrane-distal region of the E2/E1 spike. Interestingly, epitopes on the exposed topmost and outer surfaces of the E2/E1 trimer structure were neutralizing, whereas epitopes facing the interior of the trimer were not, providing a rationale for vaccine design and therapeutic MAb development using the intact CHIKV E2/E1 trimer.

### 1384

#### EL NIÑO AND DENGUE PREDICTION IN ECUADOR

Rachel Lowe<sup>1</sup>, Anna M. Stewart-Ibarra<sup>2</sup>, Desislava Petrova<sup>3</sup>, Markel García-Díez<sup>4</sup>, Mercy J. Borbor-Cordova<sup>5</sup>, Raul Mejía<sup>6</sup>, Mary Regato<sup>7</sup>, Xavier Rodó<sup>3</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>SUNY Upstate Medical University, Syracuse, NY, United States, <sup>3</sup>Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, <sup>4</sup>Predictia Intelligent Data Solutions, Santander, Spain, <sup>5</sup>Escuela Superior Politécnica del Litoral (ESPOL), Guayaquil, Ecuador, <sup>6</sup>National Institute of Meteorology and Hydrology (INAMHI), Guayaquil, Ecuador, <sup>7</sup>National Institute of Public Health Research (INSPI), Guayaquil, Ecuador

El Niño and its impact on local meteorological conditions potentially influences interannual variability in dengue fever transmission in southern coastal Ecuador. El Oro province is a key dengue surveillance site, due the high burden of dengue fever, co-circulation of all four dengue serotypes, proximity to an international border and major port, and the recent introduction of chikungunya and Zika viruses. In this study, we used climate forecasts to predict the evolution of the 2016 dengue season in the city of Machala, following one of the strongest El Niño events on record. We incorporated precipitation, temperature and Oceanic Niño

Index forecasts in a Bayesian hierarchical mixed model to predict dengue incidence. The model was initiated on 1 January 2016, producing monthly dengue forecasts until October 2016. We accounted for misreporting due to the introduction of chikungunya virus in 2015, by using active surveillance data to correct reported dengue case data. We then evaluated the forecast retrospectively with available epidemiological information. The predictions correctly forecast an early peak in dengue incidence in March 2016, with a 91% chance of exceeding the mean dengue incidence for the previous five years. Accounting for the proportion of chikungunya infections that had been incorrectly recorded as dengue cases in 2015 improved the prediction of the magnitude of dengue incidence in 2016. The main advantage of this dengue prediction framework is the use of long-lead seasonal climate and El Niño forecasts, which permits a prediction to be made at the start of the year for the entire dengue season. Combining active surveillance data with routine dengue reports improved not only model fit and performance, but also the accuracy of benchmark estimates based on historic seasonal averages. This study advances the state-of-the-art of climate services for the health, by demonstrating the potential value of incorporating climate information in the public health decision-making process in Ecuador.

### 1385

#### EFFICACY OF A DENGUE PURIFIED INACTIVATED VACCINE CANDIDATE IN MACAQUES REVEALS INSIGHTS ON ACCURATE CHARACTERIZATION OF POST-CHALLENGE VIRAL REPLICATION AND ON CORRELATES OF PROTECTION

Maria Beatriz Borges<sup>1</sup>, Renata Carvalho-Pereira<sup>1</sup>, Renato Marchevsky<sup>1</sup>, Ygara S. Mendes<sup>1</sup>, Luiz Gustavo Mendes<sup>1</sup>, Leonardo Diniz-Mendes<sup>1</sup>, Marcos Freire<sup>1</sup>, Akira Homma<sup>1</sup>, Edith Lepine<sup>2</sup>, David Vaughn<sup>3</sup>, Clarisse Lorin<sup>2</sup>, Marie-Pierre Malice<sup>2</sup>, Elena Caride<sup>1</sup>, Lucile Warter<sup>2</sup>

<sup>1</sup>Fiocruz, Rio De Janeiro, Brazil, <sup>2</sup>GlaxoSmithKline Vaccines, Rixensart, Belgium, <sup>3</sup>GlaxoSmithKline Vaccines, Rockville, MD, United States

The need for improved dengue vaccine candidates remains since the only licensed vaccine shows variable efficacy depending on dengue virus (DENV) serotype and age. We previously reported that different formulations of adjuvanted dengue purified inactivated vaccine (DPIV) developed by the Walter Reed Army Institute of Research were immunogenic and efficacious against DENV replication in macaques. A GSK DPIV candidate, adjuvanted with either aluminum hydroxide or AS03 and based on attenuated viral strains, has now been tested in macaques. While all tested formulations induced neutralizing antibody responses against the four DENV serotypes, only partial efficacy at preventing replication of DENV1 and DENV2 challenge strains was observed. Post-challenge viral replication was monitored by measuring viremia and RNAemia using both freshly collected and frozen/thawed sera samples. We observed that freeze/thaw had moderate or no impact on viremia quantification in sera derived from naïve macaques at the time of the challenge (control animals), whereas, in DPIV-vaccinated macaques, the viremia was markedly reduced when measured using frozen/thawed sera compared to freshly collected sera. In contrast, RNAemia quantification was not impacted by freeze/thaw irrespective of the DENV immune status of the animals at the time of the challenge, and RNAemia profiles were highly similar to viremia profiles when this was determined using freshly collected sera. These results suggest that measuring DENV viremia using frozen/thawed samples may bias the results and lead to a possible over-estimation of vaccine efficacy. While viremia on frozen/thawed samples has been largely used in the past decades, RNAemia might be a preferred alternative to viremia quantification to accurately assess DENV replication. Finally, a statistically significant negative correlation was detected between the pre-challenge DENV-neutralizing antibody titers and post-challenge RNAemia levels, further supporting the role of neutralizing antibody responses in controlling DENV infection.

### 1386

#### DENGUE VIRUS SEROPREVALENCE IN MEXICO

Irma Y Amayo Larios<sup>1</sup>, Mario Rosas-Rusell<sup>2</sup>, Elsa Sarti<sup>3</sup>, Laura Tirado-Gomez<sup>2</sup>, Esteban Puentes<sup>3</sup>, Liliana Castro-Porras<sup>2</sup>, Victoria Castro-Borbonio<sup>2</sup>, Gustavo Olaiz<sup>2</sup>, José Ramos Castañeda<sup>1</sup>

<sup>1</sup>Instituto Nacional de Salud Pública, Cuernavaca, Mexico, <sup>2</sup>Universidad Nacional Autónoma de México, Ciudad de México, Mexico, <sup>3</sup>Sanofi Pasteur, Ciudad de México, Mexico

Dengue is the most important arboviral disease in the world. From an epidemiological perspective, several indicators have been used to determine the level of endemicity in different areas. Seroprevalence has been proposed as a marker of endemicity, but seroprevalence studies are scarce at community level and have been concentrated in geographic areas where dengue transmission is intense. We conducted a cross-sectional study with a stratified cluster random sampling design to measure the level of seroprevalence of antibodies to dengue virus (DENV) in México. The target population was school children from 6-17 years old from 22 of 32 states in Mexico. These 22 states were clustered in 4 regions: Pacific, South-Central, South-East and Low endemicity region. The Primary Unit Samples were schools randomly selected among those located in communities under 1,800 meters above sea level and with more than 10,000 inhabitants. A total of 2,548 subjects provided blood samples after informed consent signature to detect IgG antibodies in the serum through indirect ELISA test (Panbio E-DEN 01G). The overall seroprevalence of antibodies against dengue was 33.5% (CI95% 27.5-40.1). The highest regional seroprevalence was found in the South East, reaching 70.9% (CI95% 60.3-79.7), followed by South Central (44.5%; CI95% 33.0-56.5) and Pacific (38.8%; CI95% 25.3-54.4). Seroprevalence was significantly higher in older than younger children in South East region: 62.1% (CI95% 46.9-75.2) in children 6-8 years; 71.3% (CI95% 59.3-80.9) among those of 9-12 and 82.6% (CI95% 73.8-88.9) in 13-17 years-old. However, this pattern was not consistent in all regions. We did not find differences related to gender. According to the results, DENV seroprevalence in Mexico is heterogeneous not only at country level but even at regional and state level. Besides, as known, seroprevalence is linked to long term exposure and do not adequately reflects recent pattern of transmission, therefore we conclude to avoid the utilization of only one epidemiological indicator to define endemic regions.

### 1387

#### DEVELOPING AND OPERATIONALIZING NATIONAL-LEVEL EARLY WARNING AND RESPONSE SYSTEMS (EWARS) FOR DENGUE AND OTHER Aedes-BORNE ARBOVIRAL DISEASES

Piero Olliaro<sup>1</sup>, Axel Kroeger<sup>2</sup>, Yesim Tozan<sup>3</sup>, Joacim Rocklöv<sup>4</sup>

<sup>1</sup>Special Programme for Research and Training in Tropical Diseases, Geneva, Switzerland, <sup>2</sup>Center for Medicine and Society, University of Freiburg, Freiburg, Germany, <sup>3</sup>New York University College of Global Public Health, New York, NY, United States, <sup>4</sup>Epidemiology and Global Health Unit, Department of Public Health and Clinical Medicine and Umeå Centre for Global Health Research, Umeå University, Umeå, Sweden

Dengue and other *Aedes*-borne arboviral diseases are a growing global health threat. Country ability to identify an impending outbreak and deploy an early response is key to reducing the health, societal and economic burden of these diseases. However, outbreak alerts are not currently used to trigger early response. Developing, testing and adopting early warning and response systems (EWARS) will help countries mount effective outbreak response systems. To provide countries with a toolset for accurate temporal and geospatial prediction of outbreaks, WHO/TDR and its partners developed a model contingency plan for dengue surveillance, outbreak prediction/detection and response, supported by an operational guide - a computer-assisted programme to facilitate the practical use of the early warning tool at district level. These tools are being further developed towards including *Aedes*-borne diseases at-large through consultations with stakeholders and partners. A WHO/TDR

expert consultation examined the current opportunities and challenges of developing and operationalizing national-level, early warning and response systems (EWARS). It discussed experiences drawn from field-testing of the EWARS operational guide and the research needs to improve and evaluate this tool by country health systems. This presentation will summarize the recommendations emerged from this meeting and the future studies needed. Well-functioning EWARS can, in principle, improve population health by translating early signals into a set of explicit and geographically-targeted response measures, and direct the mobilization of appropriate resources in a timely fashion at the appropriate scale (i.e. local, regional, national). EWARS developed for dengue should be refined and adapted to country needs; they should also be further developed for other Aedes-borne arboviruses. Both generic and disease-specific EWARS are required for Aedes-borne arboviruses.

### PATTERNS OF CELLULAR IMMUNITY AFTER INFECTION WITH A HUMAN CHALLENGE STRAIN

Alba Grifoni<sup>1</sup>, Michael Angelo<sup>1</sup>, Bjoern Peters<sup>1</sup>, Aruna D. de Silva<sup>2</sup>, Sean A. Diehl<sup>3</sup>, Jason Botten<sup>3</sup>, Johnathan Boyson<sup>3</sup>, Beth D. Kirkpatrick<sup>3</sup>, Stephen S. Whitehead<sup>4</sup>, Anna P. Durbin<sup>5</sup>, Alessandro Sette<sup>1</sup>, Daniela Weiskopf<sup>1</sup>

<sup>1</sup>La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, <sup>2</sup>Genetech Research Institute, Sri Lanka, Sri Lanka, <sup>3</sup>University of Vermont, College of Medicine and Vaccine Testing Center, Burlington, VT, United States, <sup>4</sup>National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, <sup>5</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States

A deletion variant of the DENV2 Tonga/74 strain lacking 30 nucleotides from its 3' untranslated region has previously been established for use in a controlled DENV human challenge model. To evaluate if this model is appropriate to derive correlates of protection for DENV vaccines based on cellular immunity, we wanted to compare how the cellular immune response to this challenge strain compares to the response induced by natural infection. To achieve this, we predicted HLA class I and class II restricted peptides from rDEN2Δ30 and used them, in an IFN-γ ELISPOT assay, to interrogate CD8+ and CD4+ T cell responses in healthy volunteers infected with rDEN2Δ30. At the level of CD8 responses, vigorous *ex vivo* responses were detected in approximately 80% of donors. These responses were similar in terms of magnitude and numbers of epitopes recognized to previously reported responses observed in PBMC from donors from DENV hyper-endemic regions. The similarity extended to the immunodominance hierarchy of the DENV nonstructural proteins NS3, NS5, and NS1 being dominant in both donor cohorts. At the CD4 level, responses were less vigorous compared to natural DENV infection, and were more focused on nonstructural proteins. The epitopes recognized following rDEN2Δ30 infection and natural infection were largely overlapping for both CD8 (100%) and CD4 (85%) responses. Finally, rDEN2Δ30 induced stronger CD8 responses compared to other more attenuated DENV isolates.

### OPTIMIZATION OF THE PLAQUE REDUCTION NEUTRALIZATION TEST ON 96-WELL PLATES FOR DIVERSE DENGUE VIRUS 1-4 STRAINS

Ana Coello Escoto<sup>1</sup>, Leah Katzelnick<sup>1</sup>, Christian Chavez<sup>1</sup>, Henrik Salje<sup>2</sup>, Derek Smith<sup>3</sup>, Richard Jarman<sup>4</sup>, Derek Cummings<sup>1</sup>, Stephen Whitehead<sup>5</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>University of Cambridge, Cambridge, United Kingdom, <sup>4</sup>Walter Reed

Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>National Institutes of Health, Bethesda, MD, United States

The plaque reduction neutralization test (PRNT, also called the immunofocus reduction neutralization test, FRNT) is the most accepted approach for quantifying neutralizing-antibody responses to dengue virus (DENV) infection. While it is customary to perform this assay on 6- or 24-well plates to make plaque counting easier, we have adapted and optimized the PRNT for 96-well plates, which enables researchers to test more serum samples at a time and use less serum volume. We tested various assay parameters, including virus-serum incubation time, cell growth conditions, and plaque staining. By adjusting the experimental conditions of the assay, we obtained maximal neutralization titers, uniformity of plaque size and count, and consistency in staining intensity across all four DENV serotypes. To maximize PRNT50, we assessed multiple virus-incubation times of the serum mix (30, 60, 90, and 120min). We found that by 90min the PRNT50 doubled from the 30min titer for DENV-positive antisera, without increasing PRNT50 titers in DENV-negative antisera, indicating no false positives. To obtain a confluent monolayer of viable C6/36 cells, we adjusted the volume of resuspended cells (100μl or 200μl) used to prepare the 96-well plates, the incubator humidity (80% or 90%), and the number of days between plating cells and starting the neutralization assay (1-5 days). We observed significantly fewer plaques in wells at the edge of the plate as compared to the centers of each plate under conditions of low humidity, low volume, and more days until starting the neutralization assay; direct investigation of the cells revealed edge wells had fewer cells. Finally, to standardize the immunostaining process across DENV serotypes, we tested different concentrations of 2H2 1° (0.25-0.5μg/ml) and peroxidase conjugated 2° (0.25-0.33μg/ml) antibodies and found that some DENV strains could not be reliably stained with lower mAb concentrations. Together, our analyses of factors that influence PRNTs in 96-well plates reveal assay conditions that reliably produce high quality wells of plaques, reduce edge effects, and generate a cost efficient neutralization assay.

## 1390

### FLAVIVIRUS SEROPREVALENCE IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Alexandra C. Willcox<sup>1</sup>, Matthew Collins<sup>1</sup>, Ross Boyce<sup>1</sup>, Antoinette Tshetu<sup>2</sup>, Aravinda de Silva<sup>1</sup>, Steven R. Meshnick<sup>1</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Flaviviruses such as Zika virus and dengue virus are known to be widespread in the Americas, but little is known about their current prevalence in African countries. Interestingly, recent reports indicate that Zika may have circulated unrecognized for years in certain parts of Africa and Southeast Asia, illustrating two key points: 1) Emerging pathogens with epidemic potential may be present in human populations prior to abrupt expansion, providing a window of opportunity for detection and prevention; and 2) infections causing nonspecific, acute febrile illness may be misdiagnosed, leading to suboptimal clinical management of patients and resource allocation. To address these gaps, we tested for antibodies to Zika virus, dengue virus and yellow fever virus in children under 5 from the Democratic Republic of the Congo using 978 dried blood spots collected during the 2013 Demographic and Health Survey. Sera was eluted from blood spots and stored at -80°C prior to screening with an IgG antigen capture ELISA. Preliminary results indicate a general flavivirus seroprevalence of approximately 3%, with many samples containing antibodies that react to antigens from multiple viruses, suggesting possible cross-reactivity or multiple exposures. Neutralization assays will clarify specific exposures. To complement this retrospective analysis, a prospective study is underway to estimate prevalence of flavivirus infection among patients presenting with febrile illness in Uganda. Results will support the development of better approaches for prevention, diagnostics and treatment of flavivirus infections in Africa.

## 1391

**SPACE-TIME INTERACTION OF DENGUE CASES IN AN AGENT-BASED MODEL**

Jeon-Young Kang, Jared Aldstadt

*University at Buffalo, Amherst, NY, United States*

Dengue is a common mosquito-borne disease in tropical and subtropical regions. For a better understanding of the dynamic nature of dengue transmission, many studies have been conducted to find ecological and environmental factors that are associated with dengue virus (DENV) transmission. Due to limited range of mosquito movement, dengue cases are spatially and temporally clustered. This focality and space-time interaction have been examined through the analysis of reported cases with spatial statistics. Ecological analyses are most often based on the aggregated populations in enumeration units (e.g., census tract). Additionally, agent-based models (ABMs) have been employed by integrating domain knowledge of dengue to address research questions through simulations. For simulation-based research, validation is an important process that determines whether or not a model has sufficient accuracy to address research questions. Nonetheless, it is often neglected due to difficulties in obtaining data suitable for comparison with model outputs. To mitigate uncertainty about model specification, sensitivity analysis (SA) is often employed. SA helps researchers to understand model robustness or sensitivity of model outcomes to parameters of the model. In addition, pattern-oriented modelling (POM) has been emphasized for the purposes of designing, testing, and evaluating simulation models. Here, we employ a pattern oriented framework that uses both population level infection rates and local spatial pattern of infections to calibrate the model. The parameters with respect to mosquito population density, mosquito behavior, DENV introduction rates, and DENV transmission that reproduce realistic local clustering of dengue virus infection are often outside the range of previous models. Our spatial-statistics-based framework may be used for validation of individual-level simulation models of other infectious diseases and dynamic processes with observed space-time pattern data.

## 1392

**IMMUNOGENICITY OF THE CYD TETRAVALENT DENGUE VACCINE (CYD-TDV) USING A COMPRESSED SCHEDULE: RANDOMIZED PHASE II STUDY IN U.S. ADULTS**Judith Kirstein<sup>1</sup>, William Douglas<sup>2</sup>, Manoj Thakur<sup>3</sup>, Mark Boaz<sup>3</sup>, Thomas Papa<sup>4</sup>, Anna Skipetrova<sup>4</sup>, Eric Plennevaux<sup>4</sup>*<sup>1</sup>Advanced Clinical Research, West Jordan, UT, United States, <sup>2</sup>Benchmark Research, Sacramento, CA, United States, <sup>3</sup>Sanofi Pasteur, Swiftwater, PA, United States, <sup>4</sup>Sanofi Pasteur, Lyon, France*

The live attenuated tetravalent dengue vaccine (CYD-TDV) has been approved for use in endemic areas using a 3-dose schedule at 0, 6 and 12 months. An effective shorter schedule would have important implications for both travelers to endemic areas as well as public health programs in dengue endemic countries. We compared immune responses of 2 schedules of CYD-TDV in a non-endemic population. We also evaluated the impact of yellow fever (YF) co-administration. This phase II, open-label, multicentre study (NCT01488890) enrolled 390 healthy 18-45-year-olds in the USA with no prior dengue exposure. Participants were randomized (4:4:4:1) to 4 groups stratified by prior YF vaccination: Group 1, CYD-TDV standard 0-6-12 months schedule; Group 2, CYD-TDV compressed 0-2-6 months schedule; Group 3, CYD-TDV compressed schedule with YF co-administered (dose 1); Group 4, YF vaccination only. Neutralizing antibody (Ab) geometric mean titers (GMTs) and percentages of seropositive subjects (Ab titers  $\geq 10$  [1/dil]) were measured against each dengue serotype using a 50% plaque reduction neutralization test. On D28 after the 3rd CYD-TDV dose, there were no marked differences in GMTs or seropositivity rates between Groups 1 and 2. In each group respectively, 73.4% and 82.4% were dengue seropositive for  $\geq 3$  serotypes, with 50.0% and 42.6% seropositive against all 4 serotypes. There was no difference

between subjects who were flavivirus seropositive and seronegative at baseline with either schedule. At 6 months after the 3rd dose of CYD-TDV, in Groups 1 and 2, GMTs and dengue seropositivity decreased compared with D28 post-dose 3 for all serotypes, with the exception of a small increase in GMT for serotype 4 in Group 1. Dengue seropositivity remained above 70% for serotypes 2, 3 and 4 in Groups 1 and 2. Co-administration with YF did not affect Ab responses against dengue or impact vaccine safety after completion of the compressed schedule, compared to dengue or YF vaccination alone. Based on 6-month data post-dose 3, CYD-TDV given in a compressed schedule in a non-endemic setting can elicit similar Ab responses to the licensed CYD-TDV schedule.

## 1393

**SPATIOTEMPORAL EPIDEMIOLOGY OF DENGUE IN MYANMAR 2012-2016**Win Zaw<sup>1</sup>, Zaw Lin<sup>2</sup>, July Ko Ko<sup>1</sup>, Neriza M. Pantanilla<sup>3</sup>, Steeve Ebener<sup>3</sup>, Richard J. Maude<sup>1</sup>*<sup>1</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>Vector Borne Disease Control, Department of Public Health, Ministry of Health, Nay Pyi Taw, Myanmar, <sup>3</sup>AeHIN GIS Lab, Manila, Philippines*

Dengue is a major public health burden in Myanmar. The National Strategic Plan for Dengue Prevention and Control aims by 2020 to reduce dengue morbidity by 25% and mortality by 50%; and by 2025 to reduce morbidity by 50% and mortality by 90% based on 2015 data. To support efforts to reach these goals it is important to have a detailed picture of the epidemiology of dengue in the country with which to plan control efforts. Health facility-level data on numbers of dengue cases from 2012 to 2016 were obtained from the Vector Borne Disease Control Unit, Department of Public Health, Myanmar. A detailed analysis of routine dengue haemorrhagic fever (DHF) incidence data over space and time was conducted to examine the spatial and temporal epidemiology of DHF. Detailed maps of incidence were prepared and trends in numbers of cases analysed and related to climate. DHF was found to be widespread across the country. The temporal pattern of dengue cases and fatalities was episodic with annual outbreaks and no clear longitudinal trend. There were around 40,000 reported cases and over 100 deaths in 2013 and 2015 with much lower numbers in 2012 and 2014 and 10,771 cases and 58 deaths in 2016. Case fatality rate was around 0.5% throughout. The peak season of dengue cases was from May to August in the wet season but in 2014 peak dengue season continued until November. In most years, the majority of cases were in urban areas whereas in 2015 rural areas reported more cases (>25000 compared to >15000 cases). To meet the national goals will require concerted control efforts across much of the country engaging populations in both urban and rural areas.

## 1394

**SPATIOTEMPORAL EPIDEMIOLOGY OF DENGUE IN THAILAND 2010-2016**Nattwut Ekapirat<sup>1</sup>, Darin Areechokchai<sup>2</sup>, Nipon Chinanonwait<sup>2</sup>, Steeve Ebener<sup>3</sup>, Richard J. Maude<sup>1</sup>*<sup>1</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>Bureau of Vector Borne Disease, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, <sup>3</sup>AeHIN GIS Lab, Manila, Philippines*

Dengue virus infection is a major cause of major public health problems in many tropical countries including Thailand. In Thailand, dengue is widespread, particularly in urban areas, and numbers of cases peak during each rainy season between June and September. Dengue incidence varies greatly over space and time each year and it is essential to have a highly effective surveillance system to identify risk areas and detect spread of the infection for targeting of control measures to limit the size of outbreaks. By working in partnership with the Ministry of Public Health (MOPH), detailed routine surveillance data from whole of Thailand from 2010 to 2016 were analyzed and mapped at subdistrict level to identify the highest risk areas and determine trends in case numbers over time.

These incidence data were combined with detailed information from the Thai government on climate, population distribution and health service provision to produce maps of dengue risk and healthcare care with which to help guide service provision and control activities. In Thailand, dengue is highly seasonal with peaks in the wet season each year and predominance in urban areas particularly Chiang Mai and Bangkok. Numbers vary greatly year to year with large outbreaks in some years, including over 140,000 cases in 2015. This had fallen to 38,466 confirmed cases reported in 2016. The majority infected were aged 10 to 34 years (56%). Data analysis is ongoing including producing detailed annual maps of incidence and risk and time series analyses to help inform planning of disease control activities.

## 1395

### INTEGRATED IMMUNOGENICITY ANALYSIS OF A TETRAVALENT DENGUE VACCINE (CYD-TDV) UP TO 4 YEARS AFTER VACCINATION

**Claire Vigne<sup>1</sup>**, Martin Dupuy<sup>1</sup>, Aline Richetin-Guilluy<sup>1</sup>, Bruno Guy<sup>1</sup>, Nicholas Jackson<sup>2</sup>, Matthew Bonaparte<sup>3</sup>, Branda Hu<sup>3</sup>, Melanie Saville<sup>4</sup>, Danaya Chansinghaku<sup>5</sup>, Fernando Noriega<sup>3</sup>, Eric Plennevaux<sup>2</sup>

<sup>1</sup>Sanofi Pasteur, Marcy l'Etoile, France, <sup>2</sup>Sanofi Pasteur, Lyon, France, <sup>3</sup>Sanofi Pasteur, Swiftwater, PA, United States, <sup>4</sup>The Janssen Pharmaceutical Companies of Johnson & Johnson, The Hague area, Netherlands, <sup>5</sup>Sanofi Pasteur, Bangkok, Thailand

The efficacy of the tetravalent dengue vaccine CYD-TDV against all 4 dengue serotypes was demonstrated in 2 large pivotal phase III studies (pooled efficacy rates of 60.3% against virologically-confirmed dengue) conducting to WHO recommendation and licensure in several endemic countries for the prevention of dengue in individuals aged  $\geq 9$  years. An integrated summary of the immunogenicity of CYD-TDV was conducted in 5,780 participants aged  $\geq 9$  months to identify the parameters driving the neutralizing humoral immune response and to evaluate persistence over time. The immunogenicity profile of a 3-dose schedule of CYD-TDV (3 doses administered 6 months apart) was established across 16 phase II and III trials undertaken in endemic and non-endemic countries. Neutralizing antibody titres (Nab) in sera were determined at centralized laboratories using the 50% plaque reduction neutralization test (PRNT50) at baseline, 28 days post-dose 3 (PD3), and annually thereafter for up to 4 years PD3 in some studies. CYD-TDV elicits Nab responses against all dengue serotypes; geometric mean titres (GMTs) increased from baseline to PD3 regardless of baseline dengue status, region and age. A trend towards lower GMTs against serotype 1 compared to other serotypes was observed. Age, baseline dengue seropositivity - usually increasing with age - and region influenced GMTs: i) GMTs were usually higher in adults and adolescents compared to younger participants in endemic regions; ii) baseline dengue seropositive participants in general achieved higher PD3 GMTs for all serotypes than those who were seronegative regardless of the region; iii) participants in endemic countries achieved higher level of Nab than in non-endemic countries. Differences by age and region of endemicity persist above baseline levels in endemic countries. No effect of gender or prior exposure to other flaviviruses was observed. In the two pivotal studies, GMTs decreased initially during the first 2 years PD3 but appear to stabilize or slightly increase again in the third year which is consistent with other persistence studies conducted up to 5 years PD3.

## 1396

### SOCIO-ECOLOGICAL FACTORS AND PREVENTIVE ACTIONS ASSOCIATED WITH DENGUE INFECTIONS AT THE HOUSEHOLD-LEVEL IDENTIFIED IN A PROSPECTIVE DENGUE SURVEILLANCE STUDY IN MACHALA, ECUADOR

**Aileen Kenneson<sup>1</sup>**, Efrain Beltran-Ayala<sup>2</sup>, Mercy Borbor-Cordova<sup>3</sup>, Mark Polhemus<sup>1</sup>, Sadie Ryan<sup>4</sup>, Timothy Endy<sup>1</sup>, Anna Stewart Ibarra<sup>1</sup>

<sup>1</sup>SUNY Upstate Medical University, Syracuse, NY, United States, <sup>2</sup>Universidad Tecnica de Machala, Machala, Ecuador, <sup>3</sup>Escuela Superior Politecnica del Litoral, Guayaquil, Ecuador, <sup>4</sup>University of Florida, Gainesville, FL, United States

In Ecuador, dengue fever and other febrile diseases transmitted by the *Aedes aegypti* mosquito are among the greatest public health concerns in urban coastal communities. Community- and household-level vector control is the principal means of controlling disease outbreaks. The purpose of this study was to assess the impact of dengue prevention knowledge, attitudes, and practices (KAPs), as well as socio-ecological factors, on the presence or absence of acute or recent dengue infections in the household. As part of dengue surveillance in Machala, Ecuador, we invited individuals with an acute dengue illness to participate, along with other members of the household and members of four neighboring households. We conducted diagnostic testing for dengue on all study participants, and we surveyed heads of households (HOHs) regarding KAPs. We compared KAPs and socio-ecological factors between households with (n=139) versus without (n=80) acute or recent dengue infections, using both bivariate and multivariate models. In bivariate analyses (but not multivariate modeling), the presence of dengue infections was positively associated with HOHs who were male, employed, and of younger age than households without recent or acute dengue infections ( $p < 0.05$ ). Dengue infection was not associated with knowledge or attitude, or with reported barriers to prevention activities. Dengue infections were associated with application of chemicals to standing water, and less use of indoor fumigation. Households with dengue infections were more likely to have a patio with more than 50% shade or to have adjacent abandoned property, and were less likely to have piped water inside of the house or have their trash picked up daily ( $p < 0.05$ ). We also present the results of multivariate modeling. Specific effective actions that can be considered to decrease the risk of dengue infections in the household include reduction of shade on the property, fumigating inside the home, and use of mosquito nets. Community-level interventions include clean-up of abandoned properties, daily trash pick-up, and reliable piped water inside houses.

## 1397

### DESIALYLATION OF PLATELETS CORRELATES WITH THROMBOCYTOPENIA IN ACUTE DENGUE

Silvita Fitri Riswari<sup>1</sup>, Rahajeng N. Tunjungputri<sup>2</sup>, Vesla Kullaya<sup>3</sup>, Fadel M. Gharishah<sup>2</sup>, Gloria Sheila<sup>2</sup>, Erlieza Roosdhaniana<sup>4</sup>, Philip de Groot<sup>5</sup>, Bacht Alisjahbana<sup>1</sup>, Dirk Lefeber<sup>5</sup>, Muhammad Hussein Gasem<sup>2</sup>, Andre J. van der Ven<sup>5</sup>, **Quirijn de Mast<sup>5</sup>**

<sup>1</sup>Faculty of Medicine, Universitas Padjadjaran, Bandung, Indonesia, <sup>2</sup>Center for Tropical and Infectious Diseases (CENTRID), Diponegoro University-Dr. Kariadi Hospital, Semarang, Indonesia, <sup>3</sup>Kilimanjaro Clinical Research Institute, Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, <sup>4</sup>Kartini Hospital, Jepara, Indonesia, <sup>5</sup>Radboud University Medical Center, Nijmegen, Netherlands

Thrombocytopenia and platelet dysfunction are common in dengue and associated with complications such as bleeding and plasma leakage. The etiology of dengue-associated thrombocytopenia is multifactorial and includes increased platelet clearance. Two mechanisms that mediate platelet clearance are increased binding of the coagulation protein von Willebrand factor (VWF) to the platelet membrane and removal of sialic

acid (desialylation) from the platelet membrane. Using flow cytometry-based assays, we first showed in an observational study in Bandung, Indonesia, that circulating platelets of adult patients with acute dengue had bound more VWF to their membrane, which correlated inversely with platelet count ( $R = -0.65$ ;  $P < 0.001$ ). Next, we showed in a consecutive observational study in dengue patients in Jepara, Indonesia, that sialic acid was removed from the platelet membrane, which was also related to the severity of thrombocytopenia. Sialic acid on the platelet membrane is neuraminidase-labile, but dengue virus has no known neuraminidase activity, and plasma neuraminidase activity of patients was not increased. In a series of *ex vivo* laboratory experiments, we were able to demonstrate that the binding of VWF to platelets, by the addition of the VWF-activating protein ristocetin, leads to removal of sialic acid from platelets by translocation of platelet neuraminidase to the platelet surface. This VWF-induced removal of sialic acid from the platelet membrane could be prevented by the neuraminidase inhibitor oseltamivir. In summary, our findings suggest that the excessive binding of VWF to the membrane of platelets in acute dengue results in platelet neuraminidase-mediated removal of sialic acid. This process is likely to contribute to the dengue-induced thrombocytopenia and may be inhibited by oseltamivir.

### 1398

#### LEVERAGING STUDIES IN RETURNED U.S. TRAVELERS TO COMBAT EMERGING INFECTIOUS DISEASES

**Guei-Jiun A. Liou**, Matthew Collins, Aravinda de Silva  
*University of North Carolina Chapel Hill, Chapel Hill, NC, United States*

Emerging infectious diseases affect the the health, economic productivity, and quality of life of billions throughout the world. Dengue, one of the most important arboviral infection, causes 400 million infections annually, resulting in 20,000 deaths. Emerging pathogens such as Ebola in 2014 and Zika in 2015 continue to present new challenges to the public health community. Thorough understanding of human immunity is key for developing vaccines and rapid diagnostic tests; however, challenges exist for high quality immunological studies in the resource-limited areas where these infections often occur. An attractive alternative approach is to study returned travelers exposed to tropical infections as we have done for over a decade for dengue and more recently for Zika. We recruit adult US travelers with confirmed infection or suspicion for exposure to arboviruses by word of mouth and targeted advertising campaigns among our university community and academic medical center. A short questionnaire is administered, 10 - 100 mL of peripheral blood are drawn, and plasma and PBMC are isolated and stored. As of April, 2017, we have enrolled 264 participants representing geographic regions of the US, Caribbean, Central America, South America, India, Sri Lanka, Europe, and Southeast Asia. To characterize the plasma, we screen via dengue or Zika IgG capture ELISA. Neutralization assays are run on the ELISA positive plasma to define the likely infecting flavivirus with greater specificity. This study has proved to be a valuable resource for various applications. We initially sought to determine the molecular determinants by which neutralizing antibodies interact with the four serotypes of dengue virus, finding that quaternary epitopes are targeted, and these are highly specific to the infecting serotype. We have recently used this tool to demonstrate that Zika type-specific antibodies are elicited in humans regardless of dengue exposure. Assessment of binding by Zika type-specific antibodies is a primary benchmark for our strategy to identify and develop recombinant antigens that may distinguish flavivirus infections in simple serologic assays.

#### MOSQUITO-DELIVERY OF DENGUE VIRUS IN RHESUS MACAQUES DELAYED ONSET AND INCREASED PEAK VIREMIA COMPARED TO SUBCUTANEOUS INOCULATION

**Michael K. McCracken**<sup>1</sup>, Gregory D. Gromowski<sup>1</sup>, Lindsey S. Garver<sup>1</sup>, Brad A. Goupil<sup>2</sup>, Heather Friberg<sup>1</sup>, Jeffrey R. Carrier<sup>1</sup>, Christopher N. Mores<sup>2</sup>, David Vaughn<sup>3</sup>, Edith Lepine<sup>3</sup>, Clarisse Lorin<sup>4</sup>, Marie-Pierre Malice<sup>4</sup>, Stephen J. Thomas<sup>1</sup>, Richard G. Jarman<sup>1</sup>, J. Robert Putnak<sup>1</sup>, Lucile Warter<sup>4</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>Louisiana State University, Baton Rouge, LA, United States, <sup>3</sup>GlaxoSmithKline Vaccines, Rockville, MD, United States, <sup>4</sup>GlaxoSmithKline Vaccines, Rixensart, Belgium

Dengue virus (DENV) is transmitted by infectious mosquitoes via saliva containing antigenic proteins, with anti-hemostatic and immunomodulatory activities shown to promote arboviral infection in mouse models. In the present study, we examined the effect of varying routes of exposure in addition to mosquito factors on DENV infection in rhesus macaques in an effort to improve the DENV NHP challenge model. Prior to infection and assuming that pre-exposure to mosquito saliva impacts the host response to saliva components in the context of an infectious mosquito bite, all NHPs were sensitized to *Aedes aegypti* saliva by three weekly uninfected mosquito feedings. Four weeks later NHPs were then exposed to DENV-1 via subcutaneous (SC) inoculation of virus only, intradermal inoculation (ID) of virus only, ID inoculation of virus combined with salivary gland extract (SGE), or infectious mosquito feeding (IMF). NHPs were then followed for clinical signs, RNAemia, viremia, serum cytokines, hematology, clinical chemistries, and inoculation site histopathology. Although there were no overt signs of disease, the IMF group showed delayed onset of viremia of 2 days and up to 4-fold higher geometric mean peak viral loads compared to the SC group pre-specified as the control group. All groups demonstrated seroconversion with the highest neutralizing antibody titers against DENV-1 and high cross-reactive titers to DENV-2 and, to a lesser degree, DENV-3. A trend for lower cytokine levels in the ID+SGE and IMF groups compared to SC and ID groups was observed. More than one year after primary DENV-1 infection, NHPs in the SC and IMF groups were re-exposed by the same method to either DENV-1 (homologous challenge) or DENV-2 (heterologous challenge) to characterize viral replication patterns and host responses after a secondary infection. Analysis of the secondary infection is ongoing. Altogether, our current results showed that a more natural exposure method utilizing saliva-sensitized animals and infectious mosquitoes resulted in viral replication closer to what occurs in human, when compared with SC inoculation.

### 1400

#### ESTIMATING THE UNDERREPORTING OF DENGUE CASES, ARARAQUARA, BRAZIL, 2015

**Expedito J. Luna**<sup>1</sup>, Gerusa M. Figueiredo<sup>1</sup>, Sergio R. Campos<sup>1</sup>, Jose E. Levi<sup>1</sup>, Walter M. Figueiredo<sup>2</sup>, Angela A. Costa<sup>2</sup>, Alvina C. Felix<sup>1</sup>, Nathalia S. Souza<sup>1</sup>, Maria R. Cardoso<sup>1</sup>, Claudio S. Pannuti<sup>1</sup>

<sup>1</sup>Universidade de Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Universidade de Sao Paulo, Araraquara, Brazil

Brazil is the country that reports the largest number of dengue cases in the world. Despite that, estimates on underreporting are also high. To estimate underreporting of dengue we have used the incidence data obtained from an ongoing cohort study and the cases reported to the Brazilian National Disease Reporting System (SINAN). A cohort study to assess the incidence of dengue among children and adolescents, from 2 to 16 years of age, in a previously recognized as a low endemic setting has started in August, 2014. A random sample of children and adolescents was selected from the population of Araraquara, a city in Central São Paulo State. Home visits were made to the families of selected children, to present the study and invite them to participate. The one who agreed

to participate signed an Informed Consent Form. An interview on socio-demographic characteristics was carried out and blood samples from the selected children were drawn for dengue baseline serology. Dengue IgG antibodies were tested by enzyme-linked immunosorbent assay (ELISA). Families are being contacted weekly for fever surveillance. Fever cases are submitted to dengue diagnosis tests (IgM, IgG, NS1 and PCR). The baseline seroprevalence of dengue IgG antibodies among the cohort participants was 15.3%. SINAN is the official web-based system for mandatory reporting diseases, run by the Brazilian Ministry of Health. City health departments are responsible for the implementation of the surveillance system. In the 2015 dengue epidemic season the cumulative incidence of symptomatic laboratory confirmed dengue among the cohort's participants was 8.3% (290/3.514). 8,408 confirmed autochthonous dengue cases were reported to SINAN in Araraquara in 2015, an incidence of 3.7%. The ratio of cohort/surveillance incidence was 2.2. It is smaller than previously reported for other settings in the country. The performance of local disease reporting services is probably related to the observed differences in underreporting estimates.

### A PURIFIED INACTIVATED VIRION-BASED DENGUE VACCINE INDUCES NEUTRALIZING ANTIBODIES THAT TARGET QUATERNARY EPITOPES AND PROTECT FROM CHALLENGE IN RHESUS MACAQUES

**Laura White**<sup>1</sup>, Melissa Mattocks<sup>1</sup>, Wahala Wahala<sup>2</sup>, Mark Stoops<sup>1</sup>, Idia Rodriguez<sup>3</sup>, Melween Martinez<sup>3</sup>, Petraleigh Maldonado<sup>3</sup>, Teresa Santiago<sup>3</sup>, Aravinda de Silva<sup>1</sup>, Carlos Sariol<sup>3</sup>, Robert Johnston<sup>4</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Eli Lilly & Company, Greenfield, IN, United States, <sup>3</sup>University of Puerto Rico, San Juan, PR, United States, <sup>4</sup>Global Vaccines Inc., Research Triangle Park, NC, United States

Dengue viruses (DENV1-4) are considered the most important emerging, human arboviruses with worldwide distribution in the tropics. Although there are live attenuated virus vaccine candidates in advanced clinical trials, and one has been approved to use in several countries, there is an urgent need to accelerate the development of second-generation vaccine strategies with less interference among the vaccine components while inducing antibodies (Abs) to relevant epitopes present on the whole virion. We tested a dengue vaccine based on a purified, inactivated virion (iDV) mixed with a novel alphavirus adjuvant (GVI3000), which consist of disarmed viruses that derive their activity from the replication of a truncated alphavirus RNA and *in vivo* mimic the earliest stages of a viral infection. The antigenic integrity of purified dengue virus antigens after inactivation by different protocols was determined using a panel of mouse and human monoclonal antibodies (MAbs) by ELISA. We confirmed the preservation of conformational epitopes in different domains of E protein, including recently characterized serotype specific, strongly neutralizing human MAbs that map to epitopes only preserved in the quaternary structure of the virion. Two doses of a tetravalent iDV mixture formulated with the GVI3000 adjuvant were administered to rhesus macaques six weeks apart. Neutralizing Abs to all 4 serotypes were induced and maintained in 15/16 animals for 18 weeks. The quality of the Abs induced after 2 immunizations and before challenge was determined by performing blockade of MAb binding assays and by depleting heterotypic Abs from immune serum samples, to estimate the contribution of serotype cross-reactive and type-specific Abs to neutralization. We found that iDV+GVI3000 immune sera blocked the binding of human MAb 1F4 to DENV1, and of human MAb 5J7 to DENV3. These type-specific MAbs bind to quaternary epitopes only present in virions and map to the ED/II hinge region in the respective serotype. These results suggest that inactivated DENV+GVI3000 induces Abs qualitatively similar to those found after natural infection.

## 1402

### POTENTIAL IMPACT OF DENGUE VACCINATION STRATEGIES WITH SEROTESTING IN VARIOUS ENDEMIC SETTINGS

Laurent Coudeville<sup>1</sup>, Nicolas Baurin<sup>2</sup>

<sup>1</sup>Sanofi Pasteur, Lyon, France, <sup>2</sup>sanofipasteur, LYON, France

Dengue is a fast-spreading vector borne viral disease currently posing a risk for half of the world's population. CYD-TDV is currently licensed in 16 countries and was recommended in 2016 by the WHO for use in settings with high burden and in age groups with high level of seroprevalence. Phase III trials have shown that the efficacy of the vaccine varied based on prior dengue exposure. Although serotesting is neither available nor recommended, this difference triggered questions around the potential value of limiting vaccination to those with prior dengue exposure. This was investigated using an existing dynamic transmission model and we considered various levels of dengue transmission intensity (corresponding to a level of seropositivity at age 9 ranging from 10 to 90%). Using this model, we explored, both at the population and individual levels, how CYD-TDV vaccination would impact the population living in these settings, depending on whether serotesting is implemented or not to select people eligible for vaccination. We also assessed how this impact would be modified according to the performance of the test in terms of sensitivity and specificity. Our analysis indicates that serotesting generally leads to a reduced vaccination impact at the population level when compared to the same strategy without serotesting. In terms of efficiency (measured by the number of vaccinations and tests to be performed to prevent a dengue case), the value of serotesting is critically dependent on the level of transmission intensity: it is limited in high transmission settings but increased as the level of transmission intensity decreases. Performance was also found to be a critical factor: a lower sensitivity and specificity has always a negative impact in terms of efficiency. Our analysis did not address the feasibility aspects of using serotesting in large vaccination programs that are expected to raise significant challenges. In conclusion, our analysis highlights that the value of serotesting prior to dengue vaccination is critically dependent on the level of transmission of the setting for which vaccination is considered and on the performance of the test used.

## 1403

### A METHODOLOGICAL FRAMEWORK FOR ECONOMIC EVALUATION OF OPERATIONAL RESPONSE TO VECTOR-BORNE DISEASE FORECASTS

**Maquins Odhiambo Sewe**<sup>1</sup>, Yesim Tozan<sup>2</sup>, Clas Ahlm<sup>3</sup>, Joacim Rocklöv<sup>4</sup>

<sup>1</sup>Epidemiology and Global Health Unit, Department of Public Health and Clinical Medicine and Umeå Centre for Global Health Research, Umeå University, Umeå, Sweden, <sup>2</sup>New York University College of Global Public Health, New York, NY, United States, <sup>3</sup>Umeå University, Department of Clinical Microbiology, Infectious Diseases, Umeå, Sweden, <sup>4</sup>Umeå University, Department of Public Health and Clinical Medicine, Epidemiology and Global Health and Umeå Centre for Global Health Research, Umeå, Sweden

Prediction information from infectious disease forecasting models are rarely used in response planning due to several factors, among which the most important is the inherent uncertainty associated with predicted disease events at different lead times. Incorporating prediction uncertainty in economic evaluations of early warning systems can be very informative for decision making among policy makers. In this study, we propose a methodological framework to assess the economic value of responding to early warnings of abnormal disease events. Using a probabilistic approach, we estimate the costs and the benefits of response at various lead times. We consider two scenarios where an early warning system provides (1) threshold based outbreak alerts or (2) actual disease forecasts. Adopting a health care provider perspective, the framework considers the costs of disease on the health system, the costs of response strategies

and the cost of running information management systems to arrive at total costs. Total benefits are measured as averted disease burden as a function of the effectiveness of response strategies at different lead times and are quantified as costs averted. We estimate the economic value as a net benefit which is calculated as total costs minus total benefits. We produce a probability density function for the net benefit using Monte Carlo simulations to factor in the uncertainty with predictions and the effectiveness of response strategies at each lead time and present the probability of a positive net benefit, which is a general signal to policy makers that the proposed response strategy is economically feasible. The proposed framework makes it explicit the trade-offs between forecast accuracy, response effectiveness, and costs in responding to infectious disease threats as a function of lead time and should guide sustainable integration of early warning systems into public health systems.

## 1404

### MODELLING THE REQUIREMENTS FOR SUCCESSFUL REACTIVE CASE DETECTION FOR DENGUE IN SINGAPORE

**Oliver J. Brady**, Adam Kucharski, Sebastian Funk, Stephane Hue, John Edmunds, Martin Hibberd

*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Following a period of successful suppression of dengue in the 1980s and 1990s, Singapore has more recently experienced a resurgence triggered by repeated introductions from neighbouring endemic countries. While Singapore, arguably has a world leading dengue surveillance and control programme, the challenges of increased population density and an aetiology where dengue infected individuals are infectious before becoming symptomatic (and thus detectable) questions whether long term reactive case detection is a feasible strategy in this setting. Here we use geospatial data from 32,000 reported dengue cases 2013-2016 to characterise the spatial patterns of dengue spread using a mathematical model. This model was then used to test a range of hypothetical response and containment strategies with the ultimate goal of cessation of the outbreak. This revealed the increase in response time, control effectiveness or surveillance sensitivity that would be required to prevent future dengue outbreaks in Singapore. These findings and methods can be used by public health policymakers to design better strategies against emerging infectious diseases. These findings give insight into how to prioritise resources on activities that are most likely to stop an outbreak from spreading and can be reapplied to other vector-borne diseases such as chikungunya and Zika at a time when they are spreading globally.

## 1405

### DEVELOPMENT OF ENVELOPE-MODIFIED TETRAVALENT DENGUE VIRUS-LIKE PARTICLE VACCINE: IMPLICATION FOR FLAVIVIRUS VACCINE DESIGN

**Akane Urakami**<sup>1</sup>, Mya M. Ngwe Tun<sup>2</sup>, Meng Ling Moi<sup>2</sup>, Atsuko Sakurai<sup>1</sup>, Momoko Ishikawa<sup>1</sup>, Sachiko Kuno<sup>1</sup>, Ryuji Ueno<sup>1</sup>, Kouichi Morita<sup>2</sup>, Wataru Akahata<sup>1</sup>

<sup>1</sup>VLP Therapeutics, Gaithersburg, MD, United States, <sup>2</sup>Department of Virology, Institute of Tropical Medicine, Leading Graduate School Program, Nagasaki University, Nagasaki, Japan

The major challenge in dengue vaccine development has been the existence of antigenically distinct, but closely related four serotypes of dengue virus (DENV1-4). An ideal dengue vaccine should induce neutralizing antibody (NAbs) responses against all four serotypes simultaneously in a short period of time. Here we developed a novel tetravalent dengue vaccine utilizing virus-like particle (VLP) technology. VLPs are self-assembled particles consisted of viral structural proteins, which mimic the conformation of authentic native virus without viral genome. VLP vaccines offer several advantages in terms of safety and high immunogenicity. It has been reported that flavivirus VLPs including DENV VLP can be produced by co-expressing two viral proteins, pre-membrane and envelope (E). However, VLP yields were generally poor. Based on our previous finding in

alphavirus VLP development, we hypothesized that modification of the E conformation may increase the DENV VLP yield. We designed new DENV E by introducing mutations in the amino acids which may impact the conformational change of E. Among a total of 41 mutants, we found that a single amino acid change (F108A) in the fusion loop region increased the DENV1 VLP expression by 15-fold. By introducing F108A mutation and replacing the domain III of DENV2-4 E with the corresponding region of DENV1 E, we successfully created DENV2, 3, and 4 VLPs at a high yield. Tetravalent vaccination of DENV VLPs elicited high titer of NABs against all four serotypes. Geometric mean 50% focus reduction neutralization titers for DENV1-4 were 800-8,000. Antibody-dependent enhancement, which is considered to be the major mechanism underlying severe dengue, was not observed against any serotype. Notably, F108, the amino acid which we found to be critical for high-yield VLP production, is conserved among all flaviviruses. We also found that F108A mutation increased Zika virus VLP yield significantly. Our finding will not only facilitate vaccine development against DENV, but also against other structurally similar flaviviruses such as Zika or West Nile virus.

## 1406

### METABOLIC BIOSIGNATURES OF INFECTION: HOW DENGUE, CHIKUNGUNYA AND ZIKA VIRUSES DIFFERENTIALLY PERTURB HOST METABOLIC HOMEOSTASES

**Rushika Perera**<sup>1</sup>, Rebekah C. Gullberg<sup>1</sup>, Barbara G. Andre<sup>1</sup>, Kimberly Anderson<sup>1</sup>, Lionel Gresh<sup>2</sup>, Raquel Burger-Calderon<sup>3</sup>, Amber Hopf-Jannasch<sup>4</sup>, Angel Balmaseda<sup>5</sup>, Barry Beaty<sup>1</sup>, Eva Harris<sup>3</sup>, Carol D. Blair<sup>1</sup>

<sup>1</sup>Department of Microbiology, Immunology and Pathology, Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, CA, United States, <sup>4</sup>Metabolite Profiling Facility, Bindley Bioscience Center, Purdue University, West Lafayette, IN, United States, <sup>5</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua

Arboviruses such as dengue (DENV), chikungunya (CHIKV) and Zika (ZIKV) viruses place over three billion people at risk for infection. We have demonstrated that metabolic signatures in acute-phase clinical specimens have the potential to function as prognostic biomarkers of disease etiology, pathology and severity and could play a critical role in improving triage and clinical management of these viral diseases at an early stage. Specifically, we had previously reported that using a versatile metabolomics platform, we identified small molecule biomarkers (SMBs) that differentiate DENV, CHIKV and ZIKV infections from other febrile illnesses in acute-phase serum. These SMBs were also capable of predicting dengue disease severity. These studies used both reverse phase ultra-high performance liquid chromatography-mass spectrometry (RP-UPLC-MS) and hydrophilic interaction liquid chromatography (HILIC) LC-MS to characterize the serum metabolome of 535 patients from Nicaragua. These patients experienced different grades of dengue severity or infection with CHIKV or ZIKV and included cases with subsequently diagnosed dengue fever, dengue hemorrhagic fever, dengue shock syndrome, and confirmed chikungunya and Zika infections. We have now further identified biochemical pathways in which these SMBs have a role, and which may provide better insight into the metabolic signatures that are unique to infection with each of these viruses. We have validated and confirmed particular biochemical classes of metabolites and unique SMB bio-signatures that were previously identified as specific for dengue disease severity classifications and distinct from infections with CHIKV and ZIKV. Our SMB panel and pathway analyses have the potential to improve therapeutic options and early disease diagnoses and treatments to combat these devastating arboviral diseases.

### PRIOR YEAR'S TRANSMISSION INTENSITY INFORMS CURRENT RISK OF DENGUE VIRUS INFECTION IN THAI VILLAGES

**Kathryn B. Anderson**<sup>1</sup>, Darunee Buddhari<sup>2</sup>, Louis R. Macareo<sup>2</sup>, Alden L. Weg<sup>2</sup>, Damon H. Ellison<sup>2</sup>, Stephen J. Thomas<sup>3</sup>, Ananda Nisalak<sup>2</sup>, Richard G. Jarman<sup>4</sup>, In-Kyu Yoon<sup>5</sup>, Jared Aldstadt<sup>6</sup>, Daniel H. Libraty<sup>7</sup>, Robert V. Gibbons<sup>8</sup>, Alan L. Rothman<sup>9</sup>, Timothy P. Endy<sup>3</sup>

<sup>1</sup>University of Minnesota, Minneapolis, MN, United States, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>3</sup>SUNY-Upstate Medical University, Syracuse, NY, United States, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>International Vaccine Institute, Seoul, Republic of Korea, <sup>6</sup>SUNY-Buffalo University, Buffalo, NY, United States, <sup>7</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>8</sup>United States Army Institute of Surgical Research, San Antonio, TX, United States, <sup>9</sup>University of Rhode Island, Providence, RI, United States

Dengue virus (DENV) infection generates broadly cross-reactive antibodies which may modulate the subsequent risk of infection and illness. For individuals, a transient period of cross-protection has been reported following infection. For populations, this transient, cross-protective, herd immunity following epidemics could manifest as oscillations in incidence in susceptible individuals. To study this, we used data derived from a longitudinal cohort study of DENV infection in schoolchildren in Kamphaeng Phet, Thailand, from 1998-2002. Active fever surveillance during epidemic periods and hemagglutination inhibition (HAI) testing of routine specimens identified dengue illnesses and seroconversions. Individuals with any DENV HAI titers  $\geq 320$  during the pre-season blood draw, reflecting possible recent exposure, were excluded from analysis. Hot spot analysis was performed using GPS coordinates for the child's home. Mixed effects logistic regression estimated the risk of DENV infection based upon the prior year's incidence rate for that child's village, controlling for age, mean age of the enrolled children in the village, and with random effects for individual and village. A total of 9579 person-years and 1216 dengue infections were eligible for analysis. Several communities demonstrated oscillations in transmission intensity, with significantly higher transmission years (hot spots) followed by significantly lower transmission years (cold spots), while others demonstrated more stable, mid-level transmission continuously across the five-year period. In regression analysis, the prior year's incidence in a village was significantly negatively correlated with current risk of infection for an individual; a 20% increase in prior incidence was associated with a 25% reduction in current risk. These findings indicate that the risk of DENV infection in Thai villages is associated with the intensity of prior epidemics and potentially driven by shifts in the degree of cross-protective herd immunity. These findings are limited by challenges in defining 'susceptibility' and 'herd immunity' and merit further investigation.

### TWO WAYS OR ONE: THE RELATIONSHIP OF ENDEMIC AND SYLVATIC DENGUE VIRUS

**Lambodhar Damodaran**, Adriano de Bernardi Schneider, Daniel Janies

University of North Carolina at Charlotte, Charlotte, NC, United States

Endemic viral lineages are believed to emerge from sylvatic lineages (hosted by wild non-human vectors). In arbovirus evolution, published work supports this hypothesis with a low amount of sequence data. In order to test this hypothesis we examined whether endemic strains evolved independently of sylvatic strains by examining the polarity of changes between endemic to sylvatic states based on a phylogenetic analysis. Using an original dataset published by Wang et al, 2001, which included 86 Dengue nucleotide sequences of the gene for the E protein of varying serotypes (Dengue 1-4) and epidemiological type (sylvatic vs endemic),

we expanded the dataset by adding 103 sequences with corresponding metadata of the gene for the E protein from NCBI's Genbank. We performed multiple sequence alignments with MAFFT under default parameters. A phylogenetic tree search under the maximum likelihood criterion for 100 replicates of RAxML was performed. The tree with the best likelihood score was visualized and sylvatic/endemic shifts were reconstructed in MESQUITE. The number of shifts between sylvatic and endemic strains was recorded and compared to the phylogeny constructed from the original dataset. By determining these patterns, targeted host control methods to mitigate the spread of these pathogens can be implemented for the different dengue serotypes and other flaviviruses with similar host biology.

### THE FIRST COMMUNITY-BASED INTERVENTION TO PREVENT DENGUE FEVER IN BURKINA FASO: AN IMPACT EVALUATION STUDY

**Samiratou Ouédraogo**<sup>1</sup>, Tarik Benmarhnia<sup>2</sup>, Emmanuel Bonnet<sup>3</sup>, Ahmed Sié Barro<sup>4</sup>, Yamba Kafando<sup>4</sup>, Paul André Somé<sup>4</sup>, Diane Saré<sup>1</sup>, Florence Fournet<sup>3</sup>, Valéry Ridde<sup>1</sup>

<sup>1</sup>University of Montreal Public Health Research Institute, Montréal, QC, Canada, <sup>2</sup>University of California, San Diego, CA, United States, <sup>3</sup>The French Research Institute for Development, Paris, France, <sup>4</sup>NGO AGIR, Ouagadougou, Burkina Faso

Dengue Fever (DF) has emerged as the most abundant vector-borne viral infection. Since 2013, DF outbreaks have been consistently reported during raining season in Burkina Faso (July-October). This study aims to evaluate the effectiveness of a community-based intervention implemented in August 2016 to prevent DF in a neighborhood of Ouagadougou, the capital city of Burkina Faso. The intervention was conducted in an area of the city (secteur 22) located at 1km around a public health care center. It had 3 components: i) support the community mobilisation and engagement; ii) develop trainings for the community leaders; iii) improve household knowledge's, attitude and practices (KAP) related to DF prevention. The intervention area has been compared with a control area (Juvenat) with the same socioeconomic characteristics, sanitation habits and 250 households have been randomly selected in both area for the study. The data collected before (October 2015) and after the intervention (October 2016) included 3 outcomes: i) the household respondents' KAP related to DF prevention; ii) the density of Aedes (DF vector) larvae and nymph in human-generated containers; iii) 2 household members (1 child and 1 adult) blood sample to test their exposure to Aedes bites (saliva) using blotting paper. We calculated a propensity score (PS) using each household characteristics and matched households from the intervention area with those from the control area using a stratification on the PS. Multilevel models with fixed effects were used to assess the effect of the intervention on the 3 outcomes. The households who received the intervention increased their knowledges on DF, the disease symptom, the number of mosquito nets and where less likely to assimilate DF to malaria; the Risk Ratio (RR) and 95% CI where respectively 1.13 (1.01-1.27); 1.44 (1.22-1.69); 1.30 (1.23-1.37); 0.7(0.58-0.84). The intervention reduced people exposure to DF vector bites but we did not find any impact on the density of vector larvae nor nymph in the households' domestic environment. Rigorous and well planned community-based interventions are feasible and can be effective to prevent DF.

### DETECTION OF DENGUE AND WEST NILE ANTIBODIES IN HUMANS IN CIUDAD JUAREZ, MEXICO

**Pedro Palermo**<sup>1</sup>, Antonio de la Mora<sup>2</sup>, Douglas Watts<sup>1</sup>

<sup>1</sup>University of Texas at El Paso, El Paso, TX, United States, <sup>2</sup>Universidad Autonoma de Ciudad Juarez, Ciudad Juarez, Mexico

Arboviruses are considered one of the most prevalent sources of disease in subtropical and tropical areas. Currently, there is some evidence of dengue

and West Nile viruses' transmission in U.S.-Mexican border communities. A serosurveillance study for dengue (DENV) and West Nile (WNV) viruses was performed in a human cohort in Ciudad Juarez, Mexico. Two blood samples were collected in June and November 2015 and tested for DENV or WNV IgG antibodies by ELISA (Enzyme-linked immunosorbent assay) and the specificity was confirmed by neutralization assays. The baseline seroprevalence rate was 12.8% (10/78) for DENV and 3.8% (3/78) for WNV, and the specific seroconversion rate for DENV (DENV-1 and/or DENV-2 serotypes) and WNV occurred in 8.2% (4/49) and 2% (1/49) respectively of those individuals with no antibodies in the first sample. With the seroconversion data, the overall seroprevalence was 19.7% (12/61) for DENV and 6.6% (4/61) for WNV, thus suggesting local transmission of DENV and WNV in Ciudad Juarez. Future epidemiological studies could help to understand the dynamic of these viruses in this U.S.-Mexican border city.

### THE DYNAMICS OF DENGUE VIRUS INFECTION IN INDONESIA: OBSERVATIONS FROM A NATIONAL, MULTICENTER STUDY OF ACUTE FEBRILE ILLNESS AMONG HOSPITALIZED PATIENTS

**Pratiwi Sudarmono**<sup>1</sup>, Usman Hadi<sup>2</sup>, MH Gasem<sup>3</sup>, Ketut Tuti Parwati<sup>4</sup>, Ida Laksono<sup>5</sup>, Muhammad Karyana<sup>6</sup>, Abu Tholib<sup>5</sup>, Herman Kosasih<sup>7</sup>, Sophia Siddiqi<sup>8</sup>

<sup>1</sup>Faculty of Medicine, Indonesia University, Jakarta, Indonesia, <sup>2</sup>Soetomo Hospital, Surabaya, Indonesia, <sup>3</sup>Kariadi Hospital, Semarang, Indonesia, <sup>4</sup>Sanglah Hospital, Denpasar, Indonesia, <sup>5</sup>Sardjito Hospital, Yogyakarta, Indonesia, <sup>6</sup>NIHRD, Jakarta, Indonesia, <sup>7</sup>INA-RESPOND, Jakarta, Indonesia, <sup>8</sup>U.S. National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Recent estimates indicate that 3.9 billion people are at risk of dengue virus infection. In Southeast Asia, Indonesia shoulders the greatest burden of disease, with over 50,000 cases per year and a case fatality rate of 0.8%. Though the signs and symptoms of dengue fever are generally well-defined, the reduced diagnostic capacities of developing countries such as Indonesia can result in the misdiagnosis of cases. From 2013-2016, an observational study of patients hospitalized with an acute febrile illness was conducted at 8 top-referral hospitals across Indonesia to better understand the etiologies and diagnoses of infections. 1,486 patients enrolled in the study and provided acute and convalescent blood specimens for standard-of-care and study-specific diagnostic testing. Prior to hospitalization, 1212 (81.6%) subjects showed evidence of previous dengue virus infection by IgG ELISA. Acute dengue fever was confirmed in 428 (28.8%) subjects, 351 cases being secondary infections, making dengue virus the most common etiological agent in the study. Across study sites, the proportion of dengue fever cases ranged from 21.2% to 51.2%. A higher proportion of cases was observed in children, 226/623 (36.3%), compared to adults, 202/863 (23.4%). Using RT-PCR and sequencing, dengue virus serotypes were identified in 351/428 (82.0%) acute cases, the prevalence being 22.5% for DENV-1, 23.4% for DENV-2, 48.7% for DENV-3, and 5.4% for DENV-4. Clinically, the 428 lab-confirmed infections were initially diagnosed as dengue fever (141), dengue hemorrhagic fever grade 1 (176), grade 2 (55), grade 3 (3), grade 4 (5), typhoid fever (20), general viral infection (4), urinary tract infection (3), undifferentiated (6), and other illness (15). Dengue virus infection was not lab-confirmed in 71 subjects clinically diagnosed with dengue fever, suggesting an over-diagnosis of the illness in our study. One subject with confirmed DENV-3 infection died. The results of this study further strengthen our understanding of dengue fever in Indonesia and highlight the need for an accurate rapid diagnostic test to improve clinical case management.

## 1412

### ARTHROPOD EXOSOMES MEDIATE DENGUE INFECTION THROUGH A NOVEL EXOSOMAL MARKER

**Hameeda Sultana**

*Old Dominion University, Norfolk, VA, United States*

The transmission strategies used by flaviviruses to exit arthropods and infect human host were envisioned as best approaches to develop transmission-blocking vaccines against vector molecules or determinants that facilitates pathogen transmission. Research in our laboratory has shown that mosquito-borne flaviviruses such as dengue and Zika viruses uses arthropod exosomes for transmission to human and other vertebrate cells. We have found that dengue and ZIKA viral RNA and proteins are transmitted from vector to the vertebrate host through exosomes. The exosomes containing dengue or ZIKA viral RNA and proteins were viable, secured and highly virulent in all tests such as re-infection kinetics, trans-migration assays and viral plaque formations suggesting arthropod exosomes as favorable modes of transmission. Our data also showed that arthropod derived exosomes facilitate infection of human cells that eventually produce exosomes loaded with viral RNA and proteins. We have identified a novel tetraspanin domain containing protein from mosquitoes that is involved in dengue viral RNA and protein transmission. Also, our studies highlight a direct interaction of the arthropod tetraspanin exosomal marker with dengue Envelope protein. Silencing of this novel arthropod exosomal marker, or treatments of antibody against this molecule or exosome release inhibitor (GW4869) lead to significantly reduced loads of viral RNA and E-protein in exosomes and in total cell lysates. Taking together, arthropod exosomes serve as secured vesicles for transmission of mosquito-borne flaviviral RNA and proteins that evade the human or vertebrate cells and blocking of novel arthropod exosomal marker blocks transmission.

## 1413

### A COMPARISON OF FOUR SEROLOGICAL METHODS AND TWO RT-PCR ASSAYS FOR DIAGNOSIS AND SURVEILLANCE OF ZIKA

Angel Balmaseda<sup>1</sup>, José Victor Zambrana<sup>2</sup>, Damaris Collado<sup>2</sup>, Karla González<sup>1</sup>, Nadezna Garcia<sup>1</sup>, Saira Saborio<sup>1</sup>, Cristhiam Cerpas<sup>1</sup>, Andrea Nuñez<sup>1</sup>, Douglas Elizondo<sup>2</sup>, Jesse J. Waggoner<sup>3</sup>, Davide Corti<sup>4</sup>, Raquel Burger-Calderon<sup>5</sup>, Guillermina Kuan<sup>6</sup>, **Eva Harris**<sup>5</sup>

<sup>1</sup>Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Department of Medicine, Division of Infectious Diseases, Emory University, Atlanta, GA, United States, <sup>4</sup>Humabs BioMed SA, Bellinzona, Switzerland, <sup>5</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, <sup>6</sup>Health Center Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Zika virus (ZIKV) is a mosquito-borne flavivirus responsible for recent explosive epidemics in the Americas, and infection during pregnancy is linked to congenital birth defects. Diagnosis and surveillance of Zika have been challenging due to similar clinical manifestations and extensive antibody cross-reactivity with endemic flaviviruses, such as dengue virus (DENV). Here, we evaluated four serological and two real-time RT-PCR methods in paired acute (day 2-4) and convalescent (day 14-16) samples from our 13-year on-going Pediatric Dengue Cohort Study in Nicaragua, to which Zika was added in January 2016. 264 paired samples were tested from 110 Zika cases confirmed by rRT-PCR - 44 with documented history of previous DENV infection (DENV-immune) and 66 DENV-naïve; 79 RT-PCR-confirmed dengue cases; and 75 non-Zika, non-dengue other febrile illnesses. Two IgM capture ELISAs were evaluated: a standardized in-house assay (CNDR MAC-ELISA) and the NIAID-BE1 MAC-ELISA, based on CDC's initial ZIKV MAC-ELISA test. In preliminary analysis, the sensitivity and specificity of the CNDR MAC-ELISA was 96.3% (95%CI 90.8-99.0) and 90.8% (85.1-94.9), respectively, while the NIAID-BE1 MAC-ELISA had a

specificity of 87.9% (80.1-93.4) and sensitivity of 85.5% (78.9-90.7). The CNDR MAC-ELISA displayed equal sensitivity in DENV-naïve and DENV-immune Zika cases, whereas the NIAID-BEI MAC-ELISA demonstrated lower sensitivity in DENV-immune cases. An Inhibition ELISA method for detecting total Zika antibody was standardized, resulting in a sensitivity and specificity of 67.3% (57.5-76) and 62% (54.4-70.4), respectively. The NS1 blockade-of-binding (BOB) ELISA that measures anti-ZIKV NS1 antibodies was also evaluated, yielding 86.2% (77.1-91.3) and 92.8% (87.5-96.4) sensitivity and specificity, respectively. Finally, two rRT-PCR methods that detect ZIKV, DENV, and chikungunya virus were compared: the ZCD and the Triplex assays. The high sensitivity and specificity of the CNDR MAC-ELISA and the BOB ELISA implicate these assays as solutions to the urgent need for serological diagnostic and surveillance tools for countries affected by Zika.

## 1414

### DIFFERENTIATING ZIKA AND DENGUE VIRUS INFECTIONS WITH A LINEAR PEPTIDE ARRAY

Emma L. Mohr<sup>1</sup>, John C. Tan<sup>2</sup>, Adam Bailey<sup>1</sup>, Adam Ericson<sup>1</sup>, Connor R. Buechler<sup>1</sup>, Dawn M. Dudley<sup>1</sup>, Christina M. Newman<sup>1</sup>, Mariel S. Mohns<sup>1</sup>, Meghan E. Breitbart<sup>1</sup>, Laurel M. Stewart<sup>1</sup>, Sarah J. Barilovits<sup>2</sup>, Jigar Patel<sup>2</sup>, David H. O'Connor<sup>1</sup>

<sup>1</sup>University of Wisconsin Madison, Madison, WI, United States, <sup>2</sup>Roche Sequencing Solutions, Madison, WI, United States

Identifying women at risk of congenital Zika virus (ZIKV) infection is complicated by the lack of sensitive, specific, and scalable diagnostic tools. Conventional serologic assays, which are necessary to identify at-risk pregnancies in women who have already cleared viremia, cannot distinguish between ZIKV and closely related, co-endemic flaviviruses such as Dengue virus (DENV). In order to develop ZIKV-specific serologic assays, ZIKV-specific epitopes that do not cross react with DENV-specific epitopes must be identified. We utilized rhesus macaque serum from pre-ZIKV challenge and post-ZIKV challenge timepoints to identify linear B cell epitopes unique to ZIKV. We designed a high density peptide array containing peptides representing a library of multiple Flavivirus polyproteins and measured the reactivity of pre-ZIKV challenge and post-ZIKV challenge rhesus macaque sera to the peptides. We identified two linear epitopes in the ZIKV envelope glycoprotein region that demonstrate reactivity with post-ZIKV challenge sera in three macaques challenged with Asian lineage ZIKV. The pre-ZIKV challenge sera from these animals did not react with these linear peptides. Importantly, this ZIKV-immune sera did not cross react with the corresponding peptides in the envelope glycoprotein of DENV serotypes 1, 2, 3 or 4. Studies evaluating the peptide array with DENV immune sera and the development of enzyme-linked immunosorbent assays with these peptides are underway. These unique linear epitopes may be utilized to develop sensitive and specific diagnostic serologic assays for ZIKV infection.

## 1415

### ASSESSMENT OF SEXUAL TRANSMISSION POTENTIAL OF SPONDWENI SEROGROUP VIRUSES

Erin M. McDonald, Nisha K. Duggal, Aaron C. Brault

Centers for Disease Control and Prevention, Fort Collins, CO, United States

Spondweni virus (SPONV) and Zika virus (ZIKV) are mosquito-borne flaviviruses that are classified in the Spondweni serogroup. Although primarily transmitted by mosquitoes, human-to-human sexual transmission of ZIKV has been documented with the Asian genotype during the ongoing outbreak in the Americas and an African ZIKV genotype was implicated with the first reported case of ZIKV sexual transmission. In order to assess the potential for sexual transmission of SPONV, the most closely related virus to ZIKV, and to assess the efficiency of sexual transmission by Asian and African genotype ZIKVs, testicular tropism and the presence of virus in seminal fluids was assessed in inoculated interferon alpha/beta and gamma receptor deficient mice (AG129). Male mice were inoculated

subcutaneously (s.c.) with SPONV (South Africa, 1955), ZIKV-PRVABC59 (Asian-Puerto Rico, 2015), ZIKV-P6-740 (Asian-Malaysia, 1966), or ZIKV-DakAr 41524 (African-Senegal, 1984) viruses. To determine the potential for sexual transmission, seminal fluids were collected from the uteri of mated female CD1 mice and the presence of infectious virus in these ejaculates determined by plaque assay. Only 3-8% of ejaculates from SPONV-inoculated males were positive for infectious virus, despite titers in the testes that were comparable to those of PRVABC59 (mean 7-7.2 log<sub>10</sub> PFU/g tissue). In contrast, virus was detected in 83% of the ejaculates from PRVABC59-inoculated mice. Significantly fewer (25%) ejaculates from P6-740-inoculated mice had detectable infectious virus. Due to the rapid mortality of the s.c inoculated males with the DakAr strain, the potential for sexual transmission could not be assessed in this model. Overall, infection with the PRVABC59 strain resulted in a significantly higher sexual transmission potential in this mouse model compared to the other two ZIKV strains or SPONV. Application of this model for future single-cell analysis using flow cytometry will delineate host cell populations that harbor virus and grant viral access to, and persistence in, immune privileged sites protected by the testes-blood barrier.

## 1416

### LONG TERM ASYMPTOMATIC DETECTION OF VIRAL RNA IN URINE AND SALIVA FOLLOWING ACUTE ZIKA INFECTION IN NICARAGUA 2016 - 2017

Yaoska Reyes<sup>1</sup>, Natalie Bowman<sup>2</sup>, Edwing Centeno<sup>1</sup>, Matthew Collins<sup>2</sup>, Sylvia Becker-Dreps<sup>2</sup>, Aravinda de Silva<sup>2</sup>, Filemon Bucardo<sup>1</sup>

<sup>1</sup>National Autonomous University of Leon, Nicaragua, Leon, Nicaragua, <sup>2</sup>School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Case studies of travelers returned from Zika-endemic areas have documented likely sexual transmission of Zika virus (ZIKV), and a longitudinal study in Puerto Rico described persistently positive PCR for ZIKV in different body fluids with rare recovery of infectious virus from semen or serum. To further define the timing of risk for non-vector-borne transmission, we monitored the presence of ZIKV RNA in blood, saliva, urine, and vaginal fluid or semen following acute infection in León, Nicaragua. To date, we have enrolled 12 cases and obtained specimens at 7, 14, 21, 28, 60, and 90 days post symptom onset. The mean age of the cases was 21 years of age (range 10 - 54 years), 50% were female with 4 of them being of reproductive age, 1 was pregnant (32 weeks at enrollment). In total, 108 of 238 (45%) specimens tested ZIKV-positive by real time PCR. The frequency of ZIKV detection by specimen type was as follows: 51 (70%) of 73 urine, 39 (50%) of 78 saliva, 11 (14%) of 79 whole blood and 7 (88%) of 8 vaginal fluid. Of note, 6 (50%) of 12 cases showed ongoing asymptomatic shedding of ZIKV RNA in saliva and urine through 90 days. In general, ZIKV was more consistently detected in urine at later time points than in other fluids. ZIKV RNA was intermittently detected in whole blood, out to 90 days in one case, indicating that a single negative result does not rule out future shedding and potential ongoing risk for transmission. Three of the 4 women of reproductive age shed the virus in vaginal fluids for 21, 28 and 90 days, respectively. This study extends previous knowledge about asymptomatic shedding of ZIKV and highlights the potential risk for asymptomatic ZIKV transmission via fluids from genitourinary organs or by blood transfusion.

## 1417

### A NOVEL MOLECULAR ASSAY FOR THE DETECTION OF ZIKA RNA IN WHOLE BLOOD AND URINE SAMPLES

Nikolay Sergeev

Theranos, Palo Alto, CA, United States

The recent ZIKA virus (ZIKV) outbreak in the Americas has been shown to cause a spectrum of neurologic complications including microcephaly. Greater access to testing is needed to improve clinical outcomes and aid

epidemiological surveillance in these impacted regions. We developed a novel molecular assay that includes reverse-transcription PCR (RT-PCR) pre-amplification followed by isothermal amplification/detection steps. The assay was used for the detection of ZIKV RNA in whole blood and urine specimens. The assay incorporated MS2 bacteriophage as an internal positive control for all sample preparation, RNA extraction, amplification and detection steps. Magnetic bead-based RNA extraction was used on the raw samples. Following the multiplexed RT-PCR pre-amplification step, the amplified products were split into two separate wells for isothermal amplification and detection of ZIKV and MS2, respectively. The isothermal amplification method utilized nested primer pairs enabling both amplification and detection. These primer pairs contained pairwise complementary 5' ends that resulted in amplicons containing 5' overhangs. During the isothermal amplification, these overhangs facilitated the generation of concatemers, which are detected with a dsDNA-specific fluorescent dye. Limits of detection (LoD) of 400 RNA copies/mL for whole blood and 200 copies/mL for urine were achieved for the ZIKV PRVABC59 strain. The assay detected multiple ZIKV strains including the recent Puerto Rican PRVABC59 strain and two African strains DakArdD 41662 and MR766. No cross-reactivity with eight closely related viruses and pathogens that produce ZIKA-like symptoms at clinically relevant concentrations was observed. A high load (>106 copies/mL) of the same pathogens did not inhibit detection of ZIKV present at 2xLoD. The ZIKV assay showed reliable results with small-volume (75uL-100uL) whole blood and urine specimens. This assay is currently being integrated onto an automated sample-to-answer diagnostic platform which will increase the access to ZIKV testing at point of care settings.

## 1418

### POTENT AND BROADLY NEUTRALIZING DOMAIN II ANTIBODIES INDUCED DURING ACUTE ZIKA VIRUS INFECTION OF A PREVIOUSLY DENGUE-EXPOSED INDIVIDUAL

**Anushka T. Ramjag<sup>1</sup>**, Alusha Mamchak<sup>2</sup>, Kai Lu<sup>3</sup>, Ngan Nguyen<sup>2</sup>, Edgar Davidson<sup>4</sup>, Benjamin J. Doranz<sup>4</sup>, Guy Cavet<sup>2</sup>, Christine V. Carrington<sup>1</sup>, Graham Simmons<sup>3</sup>

<sup>1</sup>University of the West Indies, St. Augustine Campus, Trinidad and Tobago, <sup>2</sup>Atreca Inc., Redwood City, CA, United States, <sup>3</sup>Blood Systems Research Institute, San Francisco, CA, United States, <sup>4</sup>Integral Molecular, Philadelphia, PA, United States

Zika virus (ZIKV) is a mosquito-borne flavivirus associated with fetal microcephaly and serious neurological complications. To date, the majority of ZIKV infections have occurred in endemic regions for the related dengue virus (DENV). A number of anti-DENV antibodies have been demonstrated to cross-react with ZIKV, both in terms of neutralizing antibodies (NAbs) and antibody dependent enhancement (ADE). In DENV-naïve individuals neutralizing responses are generally ZIKV-specific, while in DENV-experienced individuals ZIKV infection leads to potent anamnestic anti-DENV responses. It is unknown what constitutes these responses, in particular whether it consists of broad NAbs or a mix of more specific NAbs. Characterization of plasmablasts using Immune Repertoire Capture technology (IRC™) was performed on PBMCs from an individual with acute ZIKV infection and previous exposure to DENV. A large plasmablast expansion was observed. Analysis of heavy- and light-chain (VD)J sequence usage revealed evolution of clonal families of antibodies in response to infection. Two distinct lineages emerged representing 70% of total Ig sequences. 18 mAbs representing the two major lineages, together with five smaller families, were screened for neutralization and ADE between DENV and ZIKV. All but two of the smaller lineages were neutralizing, including potent mAbs with ZIKV NT50's <0.01 µg/ml. No highly type-specific mAbs were observed, rather a diverse pattern of neutralization, even within an individual lineage. Among 5 mAbs representing one major lineage, some were most potent against DENV1, others against DENV4, and others against ZIKV, with ratios of D1/ZIKV titers varying from 0.1 - 8. Shotgun mutagenesis epitope mapping demonstrated epitopes for two of these broadly neutralizing mAb lineages lay within domain II of E, close to

the fusion loop. Overall, this work suggests that NAb responses to ZIKV in flavivirus-experienced individuals are extensively shaped by previous DENV exposure. We will continue to study longitudinal samples in DENV-naïve and experienced individuals in order to determine the extent of diversification and selection

## 1419

### HUMAN PRIMARY CELL IMMUNE RESPONSES TO FLAVIVIRUSES ARE MODULATED BY BOTH THE VIRAL SPECIES AND THE AGE OF THE DONOR

**Kara Jensen**, Jesica Swanstrom, Jessica Plante, Ralph Baric  
University of North Carolina Chapel Hill, Chapel Hill, NC, United States

The emerging Zika virus epidemic across the Americas has resulted in many public health challenges, particularly because of its ability to cause severe congenital defects and Guillain-Barre Syndrome. Circulating in regions endemic to Dengue infections, Zika is also transmitted by infected *Aedes* mosquitoes, leading to plausible exposure to both viruses. In an *in vitro* model of primary monocytes enriched from either human adult peripheral blood or cord blood, we infected cells with DENV or ZIKV in the presence or absence of monoclonal antibodies that permit infection via Fc receptor-mediated entry. Cells and supernatants were collected longitudinally to evaluate the kinetics of the immunological responses to DENV and ZIKV infection. While little-to-no infection occurred without antibody treatment, we observed distinct age correlates of infection, with cells of fetal origin demonstrating greater susceptibility to infection in the presence of antibody. Further, immune responses to ZIKV were far less robust compared to DENV, with the fetal responses even further attenuated compared to adult cells. The low, or even absent, primary cell immune response to ZIKV mirrors the mild nature of clinical symptoms following ZIKV infection. Specific understanding of the immune parameters involved in response to Fc receptor-mediated ZIKV entry and how the virus is modulating the innate host response to infection will provide valuable direction for the development of vaccines and therapeutics, specifically for the fetal population that is at such risk for adverse effects following ZIKV infection.

## 1420

### ZIKA VIRUS INFECTION IN HUMAN SERTOLI CELLS INDUCES ROBUST ANTIVIRAL DEFENSE RESPONSE AND COMPROMISES BLOOD-TESTES BARRIER INTEGRITY

**Saguna Verma<sup>1</sup>**, David N. Siemann<sup>1</sup>, Daniel P. Strange<sup>1</sup>, Pei-Yong Shi<sup>2</sup>

<sup>1</sup>University of Hawaii, Honolulu, HI, United States, <sup>2</sup>University of Texas Medical Branch, Galveston, TX, United States

Recent outbreaks of Zika virus (ZIKV), a neglected mosquito-borne flavivirus, have identified sexual transmission as a new route of disease spread, not reported for other flaviviruses. Confirmed reports of ZIKV in human seminal fluid for months after the clearance of viremia suggest the ability of ZIKV to establish persistent infection in the seminiferous tubules, an immune privileged site in the testis protected by the blood-testis barrier, also called the Sertoli cell barrier (SCB). However, cellular targets of ZIKV in human testis and mechanisms by which the virus enters seminiferous tubules remain unclear. We demonstrate that primary human SCs were highly susceptible to ZIKV as compared to the closely related dengue virus and induced expression of IFN-α, key cytokines and cell-adhesion molecules (VCAM-1 and ICAM-1). Further, using an *in vitro* SCB model, we show ZIKV was released on the adluminal side of the SCB model with higher efficiency than the blood-brain barrier. ZIKV-infected SCs exhibited enhanced adhesion of leukocytes that correlated with decrease in the SCB integrity. ZIKV infection did not affect the expression of tight and adherens junction proteins such as ZO-1, claudin and JAM-A, however exposure of SCs with inflammatory mediators derived from ZIKV-infected macrophages led to the degradation of ZO-1 protein that correlated with increased SCB permeability. Taken together, our data suggest that infection of SCs

may be one of the crucial steps by which ZIKV gains access to the site of spermatozoa development and identify SCs as a therapeutic target to clear testicular infections. The SCB model opens up opportunities to assess interactions of SCs with other testicular cells and test the ability of anti-ZIKV drugs to cross the barrier.

## 1421

### SEARCHING FOR ZIKA VIRUS IN INDIA

**Govindakarnavar Arunkumar<sup>1</sup>**, S. Robin<sup>1</sup>, Sushama Aswathyraj<sup>1</sup>, Giselle D'Souza<sup>1</sup>, Sasidharan Pillai Sabeena<sup>1</sup>, Devadiga Santhosh<sup>1</sup>, Abdulmajeed Jazeel<sup>1</sup>, Jayaram Anup<sup>1</sup>, Suresh Prabhu<sup>1</sup>, Revti Bhaskar<sup>1</sup>, Anjali Aithal<sup>1</sup>, Hindol Maity<sup>1</sup>, Anitha Jagadesh<sup>1</sup>, Nittur Sudheesh<sup>1</sup>, Mala Chhabra<sup>2</sup>, Pradeep Khasnobis<sup>2</sup>, Srinivas Venkatesh<sup>2</sup>, Jagdish Prasad<sup>3</sup>, Kayla F. Laserson<sup>4</sup>

<sup>1</sup>Manipal University, UDUPI, Karnataka, India, <sup>2</sup>National Centre for Disease Control, Ministry of Health and Family Welfare, Govt of India, Delhi, India, <sup>3</sup>Directorate General of Health Services, Ministry of Health and Family Welfare, Govt of India, New Delhi, India, <sup>4</sup>U.S. Centers for Disease Control and Prevention, India Office, New Delhi, India

In 1952, Zika neutralizing antibodies were reported from patients in India. As of early 2015 Zika outbreaks have been reported from >65 countries. With ever increasing international travel and the presence of both the mosquito vector and susceptible individuals, India is at high risk for Zika reintroduction and transmission. Manipal University Center for Virus Research (MCVR) conducts Zika virus surveillance in India, and reports to the state and national levels weekly. In 2014, MCVR, as part of Global Health Security (GHS), established prospective hospital-based surveillance for acute febrile illness (AFI) in India. This platform now comprises 29 sentinel hospitals across 10 Indian states. All specimens are sent to MCVR via cold chain (maintained at 2-80 C) daily. Beginning in 2016, all samples are screened for Zika virus. Archived samples collected and stored before January 2016 have also been tested for Zika. Uniplex rRT-PCR testing is performed on serum and urine of all cases and a subset of 2000 samples were tested by Triplex RT-PCR Assay. Sera were also tested for dengue by IgM ELISA / NS1Ag / PCR and for Chikungunya by IgM ELISA / PCR. We tested 17,050 AFI cases and all were negative for Zika [Karnataka (0/4538), Kerala (0/1788), Goa (0/1789), Assam (0/2020), Gujarat (0/573), Maharashtra (0/792), Jharkhand (0/793), Tripura (0/1032), Tamil Nadu (0/2778), and Odisha (0/947)]. Patients ranged between 1 to 65 years (median 26 years); 53% were males. 887/17,050 (5%) serum samples were dengue-positive and 162/17,050 (1%) were Chikungunya-positive. Although India is endemic for dengue and chikungunya, has a history of Zika presence, and the vector and ecological conditions are conducive for Zika transmission, our comprehensive surveillance has found no evidence of Zika virus activity in the country. This extensive AFI surveillance network, and the larger GHS platform, will be essential for early detection of Zika introduction and other emerging pathogens in India.

## 1422

### PROLONGED RNA SHEDDING OF ZIKA VIRUS (ZIKV) AND CHIKUNGUNYA VIRUS (CHIKV) DURING ZIKV AND CHIK CO-INFECTION IN DIFFERENT COMPARTMENTS

**Marta G. Cavalcanti**, Mauro J. Cabral-Castro, Eduardo Scarlatelli Pimenta, Larissa S. Santana, Jorge L. Gonçalves, José Mauro Peralta

*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*

Virus detection in body fluids may persist for several weeks or months in ZIKV mono-infections (ZIKVMono). Prolonged RNA shedding in some compartments have implications for non-vector-transmission, diagnosis and probably, pathogenesis. In areas of arbovirus co-transmission, the occurrence of co-infections is not uncommon, but virus dynamics in ZIKV and CHIKV in co-infection (Coinf) is poorly established. The aim of the present study is to determine the duration of ZIKV and CHIKV RNA shedding in different body fluids of ZIKV/CHIKV co-infected

individuals. ZIKV and CHIKV serum, urine, tissue-sample, synovial (SF) and cerebrospinal fluid (CSF) sample collection were obtained from 49 individuals attending a tertiary-care hospital (HUCFF/UFRJ, Rio de Janeiro, Brazil). RT-PCR for detection of ZIKV and CHIKV RNA was performed, and reactive samples underwent viral isolation. In serum, the medians (MD) for the time of the last detection of ZIKV RNA in ZIKVMono were 4.5 days (95% confidence intervals [CI] 2 - 9) and 95th percentiles (95th %iles), 54 days. In Coinf, the median was 25 days (95% CI: 7-41) and 95th %iles, 284 days. In urine, MD was 9 days (95% CI: 4 - 30) and, 95th %iles, 31 day, in ZIKVMono, while in Coinf, MD= 30.5 days (95% CI: 10 - 46) and 95th %iles, 259.9 days. Prolonged viremia and viruria in ZIKVMono and Coinf groups differed significantly ( $p < 0.05$ ). MDs were 13 days (95% CI: 5 - 32) and 14.5 days (95% CI: 6 - 59) in serum from CHIKV mono infection (CHIKVMono) and Coinf, respectively. In mono and coinfection, the latest detection of CHIKV RNA was 120 days. Duration of CHIKV detection in the urine of CHIK Mono and Coinf were similar (MD=8.5 days (95% CI: 0 - 32) vs. 9 (95% CI: 0 - 14) and maximum of 120 days in both groups. ZIKV RNA shedding in SF was detected at 4 days post onset (dpo) in ZIKV Mono and 61dpo, in Coinf. Also, CHIKV RNA was detectable at 120dpo and 76 dpo in CHIKV Mono and Coinf, respectively. Maximum time of detection in CSF was 34 dpo. Prolonged times of ZIKV RNA clearance in different compartments occur during ZIKV/CHIKV co-infections. In contrast, duration of CHIKV RNA shedding remains the same in mono and co-infections.

## 1423

### LACK OF EVIDENCE OF ANTECEDENT ZIKA VIRUS INFECTION IN GUILLAIN-BARRE SYNDROME PATIENTS HOSPITALIZED IN A REFERRAL HOSPITAL IN SOUTH INDIA, 2014 - 2016

**Vasanthapuram Ravi<sup>1</sup>**, Monojit Debnath<sup>1</sup>, Madhu Nagappa<sup>1</sup>, Arun B. Taly<sup>1</sup>, Anita Desai<sup>1</sup>, Reeta S. Mani<sup>1</sup>, Vijayalakshmi Reddy<sup>1</sup>, Rakhi Sharma<sup>1</sup>, Sampada Sudershan<sup>1</sup>, Rahul Wahatule<sup>1</sup>, Sundaravadivel Pandarisamy<sup>1</sup>, Debprasad Dutta<sup>1</sup>, Shafeeq Shahul Hameed<sup>1</sup>, Anoop Velayudhan<sup>2</sup>, Kayla Laserson<sup>2</sup>, Padmini Srikantiah<sup>2</sup>

<sup>1</sup>National Institute of Mental Health and Neuro Sciences, Bengaluru, India, <sup>2</sup>U.S. Centers for Disease Control and Prevention, New Delhi, India

Zika virus (ZIKV) infection has been associated with increased incidence of Guillain-Barré syndrome (GBS). In the context of global travel and the presence of both the mosquito vector and susceptible individuals, India is at risk for ZIKV transmission. We conducted a retrospective evaluation for ZIKV infection among patients admitted with GBS to the National Institute of Mental Health And Neuro Sciences (NIMHANS) hospital, a large referral neurological tertiary care center in south India. A case was defined as a patient admitted to NIMHANS from June 2014 to December 2016 with GBS, defined according to National Institute of Neurological Disorders and Stroke criteria. All GBS patients received standard neurological exam; serum and cerebrospinal fluid was obtained. Stored serum specimens were tested for ZIKV RNA, dengue RNA and chikungunya RNA (CHIKV) using the CDC Triplex real time polymerase chain reaction assay (RT-PCR). Of 222 GBS cases, the mean age was 36 years (range 2 - 76 years) and 151 (68%) were male; 98 (44%) of cases occurred during the monsoon season. The mean duration between onset of illness to hospitalization was 8 days (range 1 - 30 days). Of 222 patients, 202 (91%) had upper limb weakness, 39 (18%) had impaired joint position sense, and 20 (9%) had difficulty breathing. The mean Hughes disability scale score during hospitalization was  $3.6 \pm 0.8$ . Of 222 patients, 70 (32%) reported symptoms of an antecedent illness [fever (35, 50%), diarrhea (22, 31%), respiratory symptoms (10, 14%)] before neurological symptom onset. All tested serum specimens were negative for ZIKV and CHIKV; one sample was positive for dengue. Although India is endemic for dengue and CHIKV, and ecological conditions are conducive to possible Zika transmission, our retrospective analysis of hospitalized GBS patients found no evidence of antecedent ZIKV infection. Evaluation of sera collected late in the course of illness may have limited the sensitivity of RT-PCR testing. Continued

prospective evaluation for ZIKV among GBS patients, which includes testing of both serum and urine collected during acute illness, is warranted to support early detection of ZIKV in India.

## 1424

### SCREENING OF RECOMBINANT ZIKA VIRUS PROTEINS AS ANTIGENS TO DEVELOP AN ELISA FOR THE SERODIAGNOSIS OF ZIKA VIRUS INFECTION

**Sharada Sivaraman**, Ran Hu, Netra Joshi, Samantha Zamora  
*Theranos Inc., Palo Alto, CA, United States*

The severe clinical sequelae following Zika virus (ZIKV) infection warrants development of a sensitive diagnostic assay. Due to shorter duration of ZIKV viremia in infected patients, a serological assay plays an essential role in Zika diagnosis. Unfortunately, clinical interpretation of the current antibody detection assays for ZIKV is challenging due to significant level of cross-reactivity observed among ZIKV patient antibodies with other flaviviruses. With a goal of developing an IgM ELISA with high sensitivity and minimal cross reactivity, we extensively screened ZIKV viral proteins (NS1, NS5, Envelope, and VLP) to be used as antigens to bind ZIKV antibodies. We sought to minimize cross reactivity by incorporating a cocktail of flaviviral antigens as competitors in the ZIKV specific detection conjugate. Assay performance was evaluated for positive percent agreement (PPA) using panels of serial bleeds collected from 50 symptomatic subjects from a ZIKV endemic region that tested positive for Zika RNA, and for negative percent agreement (NPA) with a separate set of 50 donors that exhibited febrile symptoms. Samples from patients positive for IgM against Dengue, West Nile and Chikungunya viruses as well as IgM positive samples from eight other viruses including specimens confirmed positive for Malaria infection were also examined. The Inbios ZIKV Detect™ IgM capture ELISA was used as the comparator method. Among the antigens and combinations tested the highest specificity was observed with the Antigen format 1 with 100% NPA and 3% cross reactivity primarily against malarial infection and CHIKUN samples. No cross reactivity was detected against DENV and WNV positive IgM samples for this format. The relatively lower PPA (89%) obtained with this antigen format was maximized to 96% by replacing antigen format 1 with another antigen combination. Antigen format 2, however, showed relatively lower specificity due to the cross reactivity to some other viruses in the flavivirus family. Our results indicate that with careful selection of ZIKV antigens it is possible to attenuate cross reactivity and maintain good sensitivity for the Zika IgM assay.

## 1425

### PUBLIC HEALTH AT THE FOREFRONT: BUILDING LOCAL HEALTH DEPARTMENT CAPACITY TO IMPROVE ZIKA PREGNANCY AND BIRTH DEFECTS SURVEILLANCE AND REFERRAL TO SERVICE IN UNITED STATES (US)

**Tina Mendelson**

*Deloitte, Arlington, VA, United States*

Local health departments are on the front lines meeting the needs of pregnant women and children affected by Zika across the US communities. Through partnerships with national clinical and community organizations and state and local health departments, the US Centers for Disease Control and Prevention (CDC) has increased the capacity of local health departments to conduct Zika pregnancy and birth defects surveillance by providing field support and tools and resources. Representatives from CDC, local health departments, and maternal and child health care organizations will interactively describe their challenges, solutions and lessons learned in working to improve Zika surveillance and referral to service for affected pregnant women and children. We will select several local health department representatives that received CDC field support to share their stories at the session to illustrate how local partners, clinicians, state, federal, vector, and community organizations came together in

focusing on building communities response to fight the Zika outbreak. The session will describe approaches, tools, and resources local health departments, ranging from data collection, to public health education and clinical outreach. The participants will end the session by discussing how lessons learned and models of targeted local capacity development can be scaled to a national level during the Zika outbreak and future infectious disease emergencies.

## 1426

### PREVALENCE OF PREVIOUS AND RECENT INFECTIONS BY ZIKA VIRUS, DENGUE VIRUS AND CHIKUNGUNYA VIRUS IN PREGNANT WOMEN AND SURVEILLANCE FOR CONGENITAL ZIKA INFECTIONS IN SALVADOR, BRAZIL

Joao V. Oliveira<sup>1</sup>, Lorena Pessoa<sup>1</sup>, Claudio Magalhães<sup>1</sup>, Jessica G. Lima<sup>1</sup>, Daniel A. Carvalho<sup>1</sup>, Tereza C. Xavier<sup>2</sup>, Rosana Pellegrini<sup>2</sup>, Gloryane Bessa<sup>2</sup>, Eduardo M. Figueiredo<sup>2</sup>, Juan I. Calgano<sup>2</sup>, Fernando Romero<sup>2</sup>, Daiana dos Santos<sup>1</sup>, Aline Oliveira<sup>1</sup>, Paloma Silva<sup>1</sup>, Marta Giovanetti<sup>1</sup>, Jaqueline Goes<sup>1</sup>, Breno Lima<sup>1</sup>, Marcia W. Carneiro<sup>1</sup>, Alan Duarte<sup>3</sup>, Fernanda W. Lima<sup>3</sup>, Luiz C. Alcantara<sup>1</sup>, **Isadora C. de Siqueira<sup>1</sup>**

<sup>1</sup>Instituto Gonçalo Moniz-Fiocruz, Salvador, Brazil, <sup>2</sup>Secretaria de Saude do Estado da Bahia, Salvador, Brazil, <sup>3</sup>Faculdade de Farmacia- UFBA, Salvador, Brazil

An unprecedented outbreak of Zika virus (ZIKV) happened in Brazil in 2015. Approximately 18,372 cases were notified in Salvador, Bahia, northeastern Brazil. Since February 2016, we started an active hospital surveillance for congenital Zika virus infection and a cross-sectional study in a reference maternity hospital to evaluate the prevalence of previous and recent infections by ZIKV, Dengue virus and Chikungunya virus in pregnant women as well as the prevalence of congenital infections by ZIKV in newborns. Until now, we enrolled 224 women and 223 newborns. The mean age of women was 25 years and 146 (61%) reported an exanthematous illness during pregnancy. The majority of cases occurred between February and April 2016. Most babies were born in a vaginal delivery (60%), with gestational age of 37.4 weeks. 53% of the newborns were male. 48 (21.5%) of the newborns were reported as microcephaly, of these, 16 (33%) were admitted in a neonatal intensive care unit and 4 (8.3%) died. 133 women were tested by ELISA IgG for Zika, Dengue and Chikungunya by the time of the delivery. The majority of them (94%) were Dengue IgG positive, 94 (71%) Zika IgG positive and 39 (28,6%) Chikungunya IgG positive. The Zika IgM ELISA in samples from mothers and newborns are in progress. ZIKV RT-PCR was done in 114 newborns samples (umbilical cord blood and urine), with 17 (15%) positive results, of these 5 were from microcephalic babies but 12 were normocephalic babies. The RT-PCR positivity was 19.2% in microcephalic newborns and 13.6% in normocephalic newborns. Thus, we suggest that microcephaly should be considered the severe form of congenital Zika infection and that less severe presentations of this congenital infection should be evaluate. We intend to further characterize the clinical manifestations associated with congenital ZIKV infection in a prospective follow-up study of these babies with congenital infections by ZIKV (with and without microcephaly) to describe clinical manifestations, complications and natural history of the disease.

## 1427

### GROWTH OUTCOMES OF NEWBORNS BORN TO WOMEN BORN TO WOMEN WITH POSITIVE ZIKA SCREENS DURING PREGNANCY, HIMA SAN PABLO BAYAMÓN CASE SERIES

**Maribel Campos<sup>1</sup>**, Yolymar Poventud<sup>2</sup>, José Nieves<sup>3</sup>, Javier Noriega<sup>3</sup>, Rey Hernandez<sup>4</sup>, Alexandra Benitez<sup>4</sup>, Lizzie Ramos<sup>3</sup>, Wanda Cubero<sup>4</sup>, Josefina Romaguera<sup>3</sup>, Vivek Nerurkar<sup>5</sup>

<sup>1</sup>HIMA San Pablo Bayamón, Puerto Rico Clinical and Translational Research Consortium, San Juan, PR, United States, <sup>2</sup>University of Puerto Rico, Medical Sciences Campus, San Juan, PR, United States, <sup>3</sup>Puerto Rico

Clinical and Translational Research Consortium, San Juan, PR, United States, <sup>4</sup>University of Puerto Rico, Rio Piedras Campus, San Juan, PR, United States, <sup>5</sup>University of Hawaii, Manoa, HI, United States

Since the Zika Virus epidemic outbreak in the Americas in 2015, several studies have confirmed a causal link between infection during pregnancy and a range of congenital anomalies. In response to the global public health emergency, mandatory active surveillance during pregnancy was established in Puerto Rico. Both symptomatic and asymptomatic exposures in pregnancy are documented. There is a growing body of evidence supporting that the risk of intrauterine Zika infection related to central nervous system development persist throughout pregnancy. However, we have identified a gap in the evidence regarding disproportionate growth parameters and sex discrepancies in the susceptibility to adverse outcomes. A consecutive case series was established through examination of hospital registry of live births from August 2016 through March 2017. Sample selection was based on exposure to maternal Zika infection during pregnancy following the Puerto Rico Department of Health reporting criteria. Growth measures including head circumference (HC, cm), Length (cm) and weight (kg) extracted from the hospital registry was evaluated using the World Health Organization's Nutritional Survey platform to determine the sex adjusted Z scores. The criteria for microcephalus as defined by the Department of Health was defined by a HC Z score < -3. Sex specific prevalence was also evaluated. We identified 82 infants (56.1% female) with history of maternal Zika exposure as confirmed by laboratory testing. The prevalence of premature birth was 8.5%, and the mean Z score for HC was  $-0.29 \pm 1.34$ , Length  $-0.22 \pm 1.56$ , and weight  $-0.35 \pm 1.17$ . The prevalence of microcephalus for the entire series was 3.7%, while the sex specific prevalence for females was 6.7%. This reports adds to the evidence confirming the central nervous system effects of intrauterine Zika exposure. A sex disparity for microcephaly was observed, which requires further study.

## 1428

### BREAST MILK AND ZIKA VIRUS INFECTION IN PREGNANCY, THAILAND 2016 - 2017

Rome Buathong<sup>1</sup>, Supaporn Wacharapluesadee<sup>2</sup>, Chanida Ruchiseesarod<sup>3</sup>, Yutthana Joyjinda<sup>2</sup>, Nuchanart Sae-Liang<sup>3</sup>, Hataya Kanjanasombut<sup>1</sup>, Orathai Suwanchairob<sup>1</sup>, Potjaman Siriarayapon<sup>1</sup>, Thiravat Hemachudha<sup>4</sup>

<sup>1</sup>Bureau of Epidemiology, Ministry of Public Health, Nonthaburi, Thailand, <sup>2</sup>The Emerging Infectious Disease Center, The Thai Red Cross Society, Bangkok, Thailand, <sup>3</sup>The Emerging Infectious Disease Center, The Thai Red Cross Society, Nonthaburi, Thailand, <sup>4</sup>Emerging Infectious Disease, The Thai Red Cross and Chulalongkorn University, Bangkok, Thailand

Zika virus (ZIKV) infection in pregnancy causes a serious birth defect of fetus and newborn. Further more, the newborn may be at risk of infection by ZIKV-contaminated in breast milk. We evaluated the ZIKV presenting in the breast milk among postpartum mothers who infected in different gestational age (GA) with aimed to describe the incidence and characteristic of pregnancy. The national guideline for ZIKV testing in breast milk was established since February 2016. The criteria for testing by real-time RT-PCR in the breast milk (volume 7-10 mL) was any postpartum woman who had history of 1) prolong ZIKV viremia duration > 1 month or 2) ZIKV infection before delivery < 1 month or 3) ZIKV infection in postpartum. Molecular sequencing was used for confirmation the virus. Newborns were required to test ZIKV-PCR in their blood and urine including IgM within 3 days after delivery. Total 27 postpartum women were met criteria for breast milk testing. Number of case in category 1, 2 and 3 was 16, 10 and 1 respectively. Six cases (22%) were positive ZIKV-PCR in breast milk. Molecular sequencing revealed Asian lineage. Among 6 positive-postpartum women were aged range from 16 to 32 years old (median 26.5) and 4 of them (67%) were symptomatic. All of them were infected during 36 - 39 weeks of GA (60%,  $p = 0.04$ ). The duration from detection till delivery was 1 - 2 weeks. The 6 babies's birth weight was 2,770 - 3,640 grams (median 3,110) with normal head size (range 32 - 34 centimeters). Six newborns were negative ZIKV-PCR and IgM. So far,

none of them was reported abnormality and still be follow up for at least 2 years. The 6 babies were temporally suspended breast feeding till test negative in breast milk. In conclusion, the risk of ZIKV presenting in the breast milk is clearly demonstrated in pregnant who infected in very late third trimester and was regardless of clinical presentation. The prolong viremia in first and second trimester was not positive in the milk might due to milk production starting in perinatal period. We strongly advice to test the ZIKV in breast milk among postpartum who was ZIKV infection in third trimester particularly above 36 weeks of GA.

## 1429

### FUNCTIONAL DIFFERENCES AND HOST ANTIVIRAL RESPONSES TO NICARAGUAN ZIKA VIRUS AND PROTOTYPE STRAINS REVEALED IN FIRST-TRIMESTER VILLUS EXPLANTS

Takako Tabata<sup>1</sup>, Matthew Petitt<sup>1</sup>, Henry Puerta-Guardo<sup>2</sup>, Daniela Michlmayr<sup>2</sup>, Eva Harris<sup>2</sup>, Lenore Pereira<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>University of California Berkeley, Berkeley, CA, United States

Zika virus (ZIKV), a member of the *Flavivirus* family, is responsible for the recent Zika pandemic in the Americas. Women infected during pregnancy have prolonged viremia and increased risk of infecting their babies, which can result in devastating birth defects designated Congenital Zika Syndrome. Why the American ZIKV strains disseminate to the human placenta during gestation is unknown. We reported that both American and prototype African ZIKV infect numerous primary cells from human placentas and fetal membranes, and viral envelope (E) and nonstructural protein 3 (NS3) are expressed and infectious progeny produced (Tabata, *et al.* Cell Host & Microbe, 2016). Here, we studied ZIKV replication in a functional model of first-trimester, anchoring villus explants and compared Nicaraguan (Nica1, Nica 2) strains with a highly-passaged, prototype Ugandan strain (MR766). Infection was observed in *foci* of mitotic cytotrophoblasts (CTBs) proximal to villus cores in columns of proliferating cells and invasive CTBs and in Hofbauer cells nearby and new villus sprouts. CTBs in Nica ZIKV-infected villi migrated from distal cell columns, invaded extracellular matrix and formed anchoring villi. In contrast, migration of prototype-infected CTBs was limited, higher titers of progeny were made, and fragmentation occurred, suggesting cell death. Given that ZIKV infection varied among placentas, we considered host cell factors might suppress infection. Accordingly, we discovered uninfected villi secrete cytokines that contribute to a precipitous reduction of ZIKV titers. Robust production of IFN- $\beta$  in explants infected in the presence of conditioned medium from uninfected explants was observed, and NS3 protein was reduced in CTBs. Our results identified mitotic CTBs and Hofbauer cells as primary targets of infection in anchoring villi and detected production of cytokines, including IFN- $\beta$ , that naturally reduce ZIKV replication. Our results suggest CTBs and Hofbauer cells could sustain persistent infection under conditions that limit antiviral responses, and that early treatment might reduce the viral load and transplacental transmission.

## 1430

### POTENT ACTIVITY OF THE BROAD SPECTRUM INHIBITOR FAVIPRAVIR ON IN VITRO USUTU VIRUS REPLICATION AND IN A MOUSE INFECTION MODEL

Nidya A. Segura Guerrero<sup>1</sup>, Sapna Sharma<sup>2</sup>, Suzanne J. Kaptein<sup>2</sup>, Johan Neyts<sup>2</sup>

<sup>1</sup>KU Leuven, Universidad Pedagógica y Tecnológica de Colombia, Leuven, Belgium, <sup>2</sup>KU Leuven, Leuven, Belgium

Usutu virus (USUV) is an emerging flavivirus in Europe, and member of the Japanese encephalitis serocomplex. Furthermore, *Culex pipiens* is the main vector of the virus. However, *Aedes albopictus* can be involved as well. This virus mainly affects birds, however, it has also been found in rodents, bats and horses. In addition, a few cases of human infection have also been reported, showing that USUV has the capacity of adapt to new

hosts. Currently, there are no antiviral drugs available for the treatment or prevention of USUV infections. Favipiravir, also known as T-705, is a broad-spectrum antiviral agent of RNA viruses. This molecule has been approved in Japan for treatment of influenza virus infections. We report here for the first time on the selective antiviral activity of favipiravir on USUV replication in tissue culture with an EC50 of  $90 \pm 26.1 \mu\text{M}$ . Moreover, we established a panel of *in vitro* assays to allow the identification of USUV inhibitors and demonstrate that favipiravir efficiently inhibits viral replication. Infection of AG129 mice (which lack alpha/beta IFN and gamma IFN receptor genes) with USUV showed disease symptoms after 2 days of infection. Besides, high levels of viral RNA were detected in the serum, spleen and brain, of USUV-infected mice. Additionally, first proof-of-concept of the anti-USUV effect of favipiravir is demonstrated *in vivo*. In the AG129 mice oral administration of favipiravir (300 mg/kg/day) reduced viremia and it delays the time to disease progression, which also validates this small animal model to assess the *in vivo* efficacy of novel USUV inhibitors.

## 1431

### SERODIAGNOSIS OF FLAVIVIRUS INFECTIONS AMONG THE BAKA PYGMY POPULATIONS IN CAMEROON USING AN IN-HOUSE MAC-ELISA

Maurice Demanou<sup>1</sup>, Isabelle Jala<sup>1</sup>, Nora Ntsiba<sup>2</sup>, Magalie Mazelier<sup>1</sup>, Richard Njouom<sup>1</sup>, Edouard Betsem<sup>3</sup>, Antoine Gessain<sup>4</sup>

<sup>1</sup>Centre Pasteur Cameroon, Yaounde, Cameroon, <sup>2</sup>UFR Pharmacie Université Paris XI, Châtenay-Malabry, France, <sup>3</sup>Faculté de médecine et des Sciences Biomédicales, Université de Yaoundé, Yaounde, Cameroon, <sup>4</sup>Unité d'Epidémiologie et Physiopathologie des Virus Oncogènes, Institut Pasteur, Paris, France

Although there are several types of life cycles, many arboviruses have basically a sylvatic cycle. Pygmies are known to be the first inhabitants of the forest. In Cameroon, little is known about arboviruses prevalence among these populations. Since 2004, Centre Pasteur of Cameroon (CPC) is the reference center for the yellow fever case-based surveillance. In 2013, CPC launched the first sentinel surveillance project of arboviruses. All these monitoring activities however do not involve the Pygmy populations, who seldom visit hospitals and whose lifestyle increases the risk of exposure to arboviruses. The aim of this study was to assess the endemicity of yellow fever virus (YFV), dengue virus (DENV) and West Nile virus (WNV) in the Baka Pygmy population of Cameroon. A cross-sectional study was carried out in different pygmy camps in Cameroon between 2005 and 2010. Serum samples from volunteers were collected and processed. A total of 242 samples obtained from the Baka pygmies were included in this study. These sera were tested for the detection of Immunoglobulin M antibodies (IgM) to three most common *Flaviviruses* such as YFV, DENV and WNV; using in-house M Antibody Capture Enzyme Link ImmunoSorbent Assay (MAC-ELISA) technique adapted from CDC (Center for Disease Control and Prevention, Atlanta, USA) and World Health Organization (WHO) protocols. Antigens used were either produced by the CPC arbovirus laboratory (DENV and WNV antigens) or provided by WHO (YFV antigens). Of the 242 serum samples tested, 9 (4%) were IgM positive for *Flavivirus* antibodies, synonym of recent or ongoing arbovirus infections. IgM ELISA was positive in 8 (3.3%) and 1 (0.4%) samples respectively for YFV and WNV. One sample was IgM positive for both YFV and DENV suggesting *Flavivirus*-induced antibody cross-reactivity. *Flaviviruses* are prevalent in pygmy camps in Cameroon and remind us to pay attention to these populations when implementing public health activities. Therefore, further clinical and virological surveillance of arbovirus infections among Pygmies should be considered, and could lead to their isolation and characterization.

## 1432

### MODELING THE SPREAD OF MOSQUITO-BORNE DISEASE IN THE NORTHERN GREAT PLAINS OF THE U.S

Hiroko Mori, Motomu Ibaraki, Franklin W. Schwartz

The Ohio State University, Columbus, OH, United States

Despite advances in the control of infectious diseases, mosquito-borne diseases still pose an enormous threat to humans around the globe. The virus has complex transmission dynamics, which will require efficacious tools for disease mitigation. Not surprisingly, statistical models have become powerful tools that are particularly helpful in understanding factors contributing to increase the incidence. However, recent work is often limited by the simple assumption that WNV cases increase with increasing mosquito numbers, which ignores the fact that outbreaks can take place even when mosquito abundance is low. Our research focus here is the West Nile Virus (WNV), which has been endemic in the U.S for past 15 years. The study objective is to design statistical approaches capable of identifying and determining the relative importance of factors controlling the prevalence of WNV in humans across the Northern Great Plains. Our modeling is unique in its focus on both mosquito numbers and human disease cases independently. In effect, we developed two statistical models - one tracking mosquito abundance and the other simulating numbers of human disease cases. Our findings demonstrated that incorporating water body information improved the simulation of mosquito abundances. River flooding, driven by weather hundreds of miles away, turned out to be more important than variability in the area of lakes due to rainfall. Moreover, we found transmission rate and mosquito numbers to be the key controlling factors for human disease cases. The model showed that disease cases were not abundant when the transmission rate was low, even if mosquito numbers were relatively high. This was the first study to show the importance of individually assessing the dynamics of mosquito abundances and disease cases. This work provides statistically rigorous tools for prediction of WNV risk. The findings and conceptual framework of this statistical approach could potentially be applied to prediction analysis of other mosquito-borne diseases.

Flavivirus infection is the leading cause of death due to mosquito-borne viruses worldwide. Clinical development efforts for this virus family include promising vaccine candidates for dengue virus (DENV), Zika virus (ZIKV), West Nile Virus (WNV), tick-borne encephalitis (TBE), and yellow fever (YF, 2nd generation). We have previously described the preclinical development of an adjuvanted subunit vaccine for WNV that is capable of generating complete and durable protection after a single immunization. The protection observed with our vaccine required a formulated TLR-agonist adjuvant. In order to better understand the mechanism of adjuvant enhanced protection, we have examined the effect of adjuvant formulation on antibody diversity following immunization in preclinical models. Using a novel, deep sequencing-based methodology, we find that protective adjuvant formulations induce a more diverse antibody response characterized by expanded V-gene usage and increased sequence diversity. In addition, we have examined the role of the bioactive adjuvant components and find that TLR agonists in combination with saponin molecules result in the highest antibody diversity following immunization.

We have subsequently extended these findings to similar vaccines for ZIKV, suggesting that induction of a diverse antibody response may generally correlate with preclinical protection. In addition, these studies identify adjuvant formulations which may generally enhance antibody diversity when combined with flaviviral antigens.

## 1434

### USE OF QUANTITATIVE REAL-TIME POLYMERASE CHAIN REACTION TO IDENTIFY NOROVIRUS DIARRHEA IN INDIAN CHILDREN IN THE FIRST 3 YEARS OF LIFE: A REANALYSIS OF A BIRTH COHORT STUDY

Sidhartha Giri<sup>1</sup>, Maheshwari K<sup>2</sup>, Ben Lopman<sup>3</sup>, Jan Vinje<sup>4</sup>, Gagandeep Kang<sup>2</sup>

<sup>1</sup>Wellcome Trust Research Laboratory, Department of Gastrointestinal Sciences, <sup>2</sup>Christian Medical College, Vellore, Vellore, India, <sup>3</sup>Emory University, Atlanta, GA, United States, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Noroviruses are an important cause of acute gastroenteritis in children. However, limited data is available on norovirus diarrhea in community settings in Asia. In our study, norovirus gastroenteritis was evaluated in 1856 diarrheal episodes in a birth cohort of 373 children followed up to the age of 3 years in a semi-urban slum in Vellore, India, from 2002 to 2006. We used quantitative multiplex real-time PCR (qPCR) to detect norovirus GI and GII in 1711 (92.2%, 1711/1856) available stool samples from the 1856 diarrheal episodes and compared it with previous results where conventional PCR had been used to test all the 1856 diarrheal samples for GI and GII. A Ct value cut-off of 35 for GI and 37 for GII was used for the qPCR assay. qPCR detected noroviruses in 334 episodes (19.5%, 334/1711), of which 60 episodes (3.5%, 60/1711) were norovirus GI, 269 (15.7%) norovirus GII, while 5 (0.3%) were mixed infections with both norovirus GI and GII. In comparison, conventional PCR was able to detect noroviruses in 207 (11.2%, 207/1856) episodes, of which 49 (2.6%) were norovirus GI, 150 (8.1%) norovirus GII, and 8 (0.4%) were mixed infections with both norovirus GI and GII. The use of qPCR improved the detection of noroviruses in diarrheal samples from 11.2% (conventional PCR) to 19.5% and indicated a high burden of diarrheal disease associated with this pathogen in developing countries.

## 1435

### POPULATION STRUCTURE AND TRANSMISSION DYNAMICS OF NOROVIRUS IN A PERUVIAN BIRTH COHORT

Simon Pollett<sup>1</sup>, John-Sebastian Eden<sup>2</sup>, Sarah B. Ballard<sup>3</sup>, Robert Gilman<sup>3</sup>, Mayuko Saito<sup>4</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>University of Sydney, Sydney, Australia, <sup>3</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>4</sup>Tohoku University, Sendai, Japan

The population structure and transmission dynamics of norovirus (NoV) epidemics in tropical regions like Peru remains unclear. Redressing this knowledge gap has relevance for NoV vaccine design and public health response. We therefore undertook a fine-scale phylogenetic analysis leveraging molecular data collected as part of NoV surveillance birth cohort in a Lima shanty-town. RT-PCR NoV positive fecal specimens were collected longitudinally from 291 symptomatic and asymptomatic immunocompetent infants and children in Las Pampas de San Juan de Miraflores, Lima Peru over 2007-2011 and then sequenced targeting the 5' 330 nt region of the capsid gene VP1. GI (n = 84) and GII (n = 458) sequences were aligned with background data from public databases. Maximum likelihood phylogenies were inferred using RAXML with nucleotide substitution models selected by JModelTest2. The age structure of NoV epidemics was estimated by performing an equality-of-medians test of ages from well-supported transmission clusters, and within-host persistence times of NoV strains were determined. The majority of known GI and GII genotypes were detected in the birth cohort, with co-circulation of up to 25 variants per year, including within-genotype variants and

a novel divergent lineage. There was evidence of multi-year subtype persistence within the cohort. Within-host strain persistence times was as high as 47 days (median 12 days, IQR 7-28 days). There was weak evidence that NoV transmissions occurred between participants of similar ages ( $p = 0.09$ ), and national and continental spatial structure was noted across Peru and other Latin American countries. In conclusion, the ecology of NoV in a Peruvian birth cohort is characterized by broad diversity, including a possible novel genotype. NoV epidemics may have a fine-scale age structure suggestive of an age-dependent host susceptibility to particular NoV subtypes. The upper range of gut NoV strain shedding time is high and further supports the concept of a pediatric enteric "virome".

## 1436

### PRELIMINARY REPORT OF A STUDY ON EFFECTIVENESS, SAFETY AND ACCEPTABILITY OF CERVICAL CANCER SCREENING USING VISUAL INSPECTION WITH ACETIC ACID AND COLD COAGULATION BASED SINGLE VISIT APPROACH IN YAT SAUK TOWNSHIP IN SHAN STATE, MYANMAR

Mya Thida<sup>1</sup>, Khin May Thin<sup>2</sup>, Kyi Thar Htun<sup>1</sup>, Myint Oo<sup>3</sup>, Min Min Thant<sup>3</sup>, Thin Thin Aye<sup>3</sup>, Thant Sandar<sup>3</sup>, Kyi Kyi Mar<sup>4</sup>, Zay Yar Moe<sup>5</sup>, Lin Bo<sup>6</sup>, Ohnmar Ohnmar<sup>7</sup>, Farshid Meidany<sup>7</sup>

<sup>1</sup>University of Medicine 1, Yangon, Myanmar, <sup>2</sup>University of Medicine 2, Yangon, Myanmar, <sup>3</sup>Women and Children Hospital, Taungyi, Myanmar, <sup>4</sup>Yat Sauk Township Hospital, Yat Sauk, Myanmar, <sup>5</sup>Indaw Station Hospital, Yat Sauk, Myanmar, <sup>6</sup>State Public Health Department, Taungyi, Myanmar, <sup>7</sup>Medical Care Development International, Silver Spring, MD, United States

Cervical cancer is the second most frequent woman cancer in Myanmar and screen coverage was lower than one percent in Myanmar (WHO, 2014). Cryotherapy for treatment of pre-malignant lesion has been found not feasible for women in rural area. Being a preventable cancer, the organized screening program using simple, practical and cost effective technology is necessary to improve coverage. The aim of this study is to evaluate the effectiveness, safety and acceptability of visual inspection with acetic acid (VIA) and cold coagulation (CC) based single-visit approach in cervical cancer prevention (CCP). A descriptive community-based action research was conducted from June 2016 to March 2017. Well-trained central CCP mobile team from Women and Children Hospital, Taungyi and medical officers from Yat Sauk township, visited to Yat Sauk Township, Shan State fortnightly during the weekends and mass screening was conducted using VIA and CC based single-visit approach. During 9 visits, 1867 married women of 30-49 years aged group were screened and screen coverage was 2.66%. Test was positive in 48 women and screen-positive rate was 2.57%. All VIA positive women were eligible to CC and all agreed to have treatment on the same visit after proper counseling and treatment rate was 100%. On one-month follow up visit, watery vaginal discharge for 2 to 3 weeks was the only symptom reported by all except two women. One needed antibiotics for infection and another one needed reassurance for symptom of burning sensation at SPA. On one-year follow up visit, VIA will be repeated to check persistence after CC and will assess women's satisfaction on CCS program. CC is a safe alternative way of treatment for VIA positive women of CCS program for areas where cryotherapy is not feasible because of difficulty to have medical grade carbon-dioxide. We need to wait one year follow up visit to assess the effectiveness of CC. During screening visits, VIA training was given to 42 local basic health staff to sustain CCS.

## 1437

**AN OUTBREAK OF FEBRILE SYNDROMES IN THE NORTH OF PERU: EMERGING AND REEMERGING ARBOVIRUSES**

**Juana Mercedes del Valle-Mendoza**<sup>1</sup>, Miguel Angel Aguilar-Luis<sup>1</sup>, Carlos Palomares-Reyes<sup>1</sup>, Fernando Vásquez-Achaya<sup>1</sup>, Jorge Bazán Mayra<sup>2</sup>, Víctor Zavaleta-Gavidea<sup>2</sup>, Daniel Cornejo-Pacherres<sup>2</sup>, Wilmer Silva-Caso<sup>1</sup>, Pablo Weigl<sup>1</sup>

<sup>1</sup>Universidad Peruana de Ciencias Aplicadas, Lima, Peru, <sup>2</sup>DIRESA-Cajamarca, Cajamarca, Peru

Arboviruses are one of the most common causes of acute febrile illness and an emerging health problem in South America. In Peru, the number of Dengue cases have double in the last year; however, less than 50% of acute febrile illness are laboratory confirmed leading to an underdiagnoses of other important arboviruses. This study was undertaken to assess the prevalence of Dengue (DENV), Oropuche (OROV), Chikungunya (CHIKV) and Zika ZIKV in patients with acute febrile illness from Cajamarca, Peru. Samples were obtained from patients with acute febrile illness during an outbreak of febrile syndromes in the North of Peru in November 2016.

A total of 95 specimens were collected and assessed for the presence of DENV, OROV, CHIKV, and ZIKV via RT-PCR. DENV virus RNA was detected in 29.47% (28/95) was the most prevalent arboviruses, CHIKV 3.16% (3/95), ZIKV 6.32% (6/95) and OROV with 0% cases. Among all patients, the most common symptoms accompanying DENV positives were: fever 82.15% (23/28), headache 35.1% (10/28), retrocular pain 21.43% (6/28), myalgias 17.86% (5/28) and arthralgias 14.29% (4/28). In the case of ZIKV the most common symptoms is fever 83.33% (5/6) and headache 33% (2/6) cases. For CHXV the most common symptoms is fever, headache and arthralgias with 66.67% (2/3) for each case. DENV-3 was the most predominant in 14.29% (4/28); DENV-2 was found only 2 sample and 7.14% (2/28). No DENV-1 or DENV-4 serotypes were observed. Twenty-two cases 78.57% (22/28) couldn't be characterized for any serotype. In conclusion, DENV are the most common arboviruses in Cajamarca. However, there is a need to characterize the unidentified serotypes, in order to determine if there is a new variant or a new serotype circulating. To enhance arbovirus surveillance is crucial to understand the role of these pathogens in Peru. PCR represents a reliable test for arboviral surveillance and should be considered as the preferred method for laboratory confirmation in Peru.

## 1438

**SEROPREVALENCE OF EBOLA VIRUS AMONG HEALTH CARE WORKERS IN YAMBUKU HEALTH ZONE, DEMOCRATIC REPUBLIC OF CONGO**

**Nicole A. Hoff**<sup>1</sup>, Patrick Mukadi<sup>2</sup>, Daniel Mukadi<sup>2</sup>, Reena H. Doshi<sup>1</sup>, Joseph Wasiswa<sup>3</sup>, Vivian H<sup>1</sup>, Russell Williams<sup>2</sup>, Rachel Mutombe<sup>2</sup>, Alexis Mwanza<sup>2</sup>, Beniot Kebela-Ilunga<sup>4</sup>, Emile Okitolonda-Wemakoy<sup>5</sup>, Jean-Jacques Muyembe-Tamfum<sup>2</sup>, Anne W. Rimoin<sup>1</sup>

<sup>1</sup>University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, <sup>2</sup>Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>University of Kinshasa/FELTP, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Direction de lutte contre la maladie-Ministère de la santé Publique, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>Kinshasa School of Public Health, University of Kinshasa, Kinshasa, Democratic Republic of the Congo

Ebola virus disease (EVD) is caused by a zoonotic filovirus infection that can be highly lethal in humans. Since the first outbreak in Yambuku in 1976, a total of seven confirmed EVD outbreaks have occurred in the Democratic Republic of Congo (DRC). Health care workers (HCW) are at particularly high risk of EVD infection given the high titers of virus in bodily fluids and lack of compliance with universal precautions to prevent exposure either due to lack of knowledge, training or equipment. We conducted a study in Yambuku, to determine the prevalence of Ebola antibodies in HCWs. Field collection occurred in April 2016. Interviews and blood specimens

were collected from all consenting individuals. Serum samples from 250 HCWs based in 8 health facilities in Yambuku health zone were screened for Ebola virus zaire (EBOV) GP Ig using Human Anti-Zaire Ebola Virus Glycoprotein (GP) IgG ELISA Assay kits (Alpha diagnostic International, Inc.) in Kinshasa, DRC. Among 250 health care workers, 36% (n=90) were seropositive for EBOV GP IgG. Notably, 30.8% (n=41) of subjects born before the 1976 outbreak were seropositive, while among those born after 1977, 43.3% (n=49) were seropositive. Also, we found that HCWs with direct contact with patients were 34.4% (n=113) seropositive, indirect contact, 39.1% (n=18), and limited contact 43.8% (n=7). Our findings suggest that despite the absence of a reported outbreak since 1976, many HCWs are still potentially exposed to EBOV in Yambuku. Additionally, the general population may also be continually be exposed to EBOV. Further research is needed to determine if virus is still circulating in the area and could pose a risk for an outbreak.

## 1439

**SEROPREVALENCE OF POLIOVIRUS ANTIBODIES SURVEY IN MALI, GUINEA AND CÔTE D'IVOIRE**

**Guindo Umar**<sup>1</sup>, Abdoul Habib Beavogui<sup>2</sup>, Daniel Kouadio Ekra<sup>3</sup>, Mahamadou Diakite<sup>1</sup>, Susan Orsega<sup>4</sup>, Sophia Siddiqui<sup>5</sup>, Mach Ondrej<sup>6</sup>, Seydou Doumbia<sup>1</sup>

<sup>1</sup>University of Sciences, Techniques and Technology, Bamako, Mali, <sup>2</sup>Centre de Formation et de Recherche en Santé Rurale de Maferinyah, Conakry, Guinea, <sup>3</sup>Institut National d'Hygiène, Abidjan, Côte D'Ivoire, <sup>4</sup>Collaborative Clinical Research Branch, Division of Clinical Research, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, <sup>5</sup>Collaborative Clinical Research Branch, Division of Clinical Research, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, <sup>6</sup>Centers for Disease Control and Prevention, Atlanta, AL, United States

Since the launch of Global Polio Eradication Initiative in 1988, great strides have been made towards the goal of polio eradication. The latest Wild Poliovirus was detected in West Africa in 2011, however, acute Flaccid Paralysis surveillance in West Africa has not been consistent. There is concern that population immunity to polioviruses may be low, especially in the Ebola affected countries; the potential population immunity gap favors spread of wild poliovirus if imported from endemic zones and favors emergence and transmission of vaccine derived polioviruses. Worldwide Polio program needs to understand underlying population immunity estimates to guide future programmatic actions. We conducted a cross sectional study to quantify the level of serological protection against poliovirus serotypes 1,2 and 3 in children aged 6-11 months and 36-48 months. From June 2016 to January 2017, 1059 subjects were enrolled in Mali, Guinea and Côte d'Ivoire based on the list obtained from the census data at each site and each age group. 526 children were in the age group 6-11 months and 533 in the 36-48 months. The neutralization assay was performed at the CDC laboratory (Atlanta) to determine the seropositivity for antibodies defined as reciprocal titer greater or equal to 8. The three West African Countries achieved high population immunity against PV1 and PV3 however PV2 seroprevalence was low in the young age group in Côte d'Ivoire and Guinea. Children born after the tOPV to bOPV switch has lower seroprevalence for PV2 than those born before the switch. Age, Country, vaccination history and nutritional status were predictive of seronegativity. Acute malnutrition was observed in 13% of children in Côte d'Ivoire, 15% in Mali and 45% in Guinea, chronic malnutrition was observed in 15% of children in Guinea, 19% in Côte d'Ivoire and 24% in Mali. In conclusion, there continues to be a high degree of immunity to PV1 and PV3 strains in the population. Decreased immunity to PV2 could have implications for disease and vaccine.

### SEROLOGICAL SURVEY TO MONITOR POPULATION IMMUNITY TO MEASLES AND RUBELLA VIRUSES AFTER A NATIONAL MEASLES-RUBELLA VACCINATION CAMPAIGN IN ZAMBIA

Andrea Carcelen<sup>1</sup>, Simon Mutembo<sup>2</sup>, Jane Wanyiri<sup>1</sup>, Philip E. Thuma<sup>3</sup>, William J. Moss<sup>1</sup>, Kelly Searle<sup>1</sup>, Hellen Matakala<sup>3</sup>, Kyla Hayford<sup>1</sup>

<sup>1</sup>International Vaccine Access Center, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Zambia Ministry of Health, Choma, Zambia, <sup>3</sup>Macha Research Trust, Macha, Zambia

Household surveys are routinely conducted after vaccination campaigns to estimate coverage; however, they remain an indirect measure of population immunity. Serological surveys directly measure population immunity and can be used to identify pockets of susceptibility and inform targeted vaccination strategies. In September 2016, Zambia conducted a national measles-rubella vaccination campaign for children 9 months to 14 years of age. Following the campaign, the Ministry of Health conducted a nationwide post-campaign evaluation survey (PCES) to assess vaccination coverage. We nested a serological survey within the PCES in Southern Province to estimate population immunity to measles and rubella viruses and evaluate the feasibility of nesting a serosurvey within a household survey. The four serological survey teams consisted of two field coordinators, four supervisors and 16 data collectors and were paired with a PCES team in the field. The serosurvey team administered a brief questionnaire and obtained dried blood spots by fingerprick from all members in a household selected for the PCES. Fifteen of the 26 clusters selected for the PCES were included in the serosurvey and 148 households were enrolled. Of the 978 residents of enrolled households, 801 were home at the time of the survey and 698 (89.5%) agreed to participate. Of these, 419 (60%) were <15 years old and eligible for the campaign. The median age of participants was 11 years [IQR 6-26] and 47% were male. Three percent of participants refused blood collection, resulting in DBS specimens from 679 participants. The DBS are being tested for anti-measles and anti-rubella virus IgG by enzyme immunoassay and seroprevalence results will be presented. This study demonstrated that fingerprick blood samples for serology can be collected during household surveys, although operational challenges were encountered. Social mobilization activities may have reduced the refusal rate to lower than anticipated. These findings will inform future studies and programs that aim to integrate serology into household surveys to assess age-specific population immunity.

### MAPPING ANTIBODY EPITOPES ON THE EBOLA VIRUS ENVELOPE PROTEIN BY SHOTGUN MUTAGENESIS

J. Tabb Sullivan<sup>1</sup>, Aubrey Bryan<sup>1</sup>, Edgar Davidson<sup>1</sup>, Andrew Flyak<sup>2</sup>, Katie Howell<sup>3</sup>, M. Javad Aman<sup>3</sup>, James E. Crowe Jr.<sup>2</sup>, Benjamin J. Doranz<sup>1</sup>

<sup>1</sup>Integral Molecular, Inc., Philadelphia, PA, United States, <sup>2</sup>Vanderbilt University, Nashville, TN, United States, <sup>3</sup>Integrated BioTherapeutics, Inc., Rockville, MD, United States

To characterize the detailed immune response to Ebola virus (EBOV), we have mapped the epitopes for over 100 monoclonal antibodies (MAbs) that target the EBOV surface glycoprotein, GP. We used Shotgun Mutagenesis to create two comprehensive alanine scan libraries arrayed in 384 well plates, one comprising 641 single Ala mutations in full-length EBOV GP, and a second library for GP lacking the mucin-like domain. GP variants were expressed in human cells and assayed for reactivity with MAbs, using high-throughput flow cytometry to identify GP residues required for the binding of each MAb. As described in recent publications, a broad variety of MAbs have been mapped, including the ZMapp therapeutic MAb cocktail; MAbs from human survivors, including 6 MAbs

from a human survivor of Bundibugyo ebolavirus infection; a MAb, cross-reactive with other ebolavirus species, which binds to the GP head region and blocks the interaction of GP with its endosomal receptor Niemann-Pick C1; and MAbs whose synergistic combination transformed a non-neutralizing MAb into a potent neutralizer. The epitope maps obtained for these different types of MAbs have expanded our understanding of how the immune system recognizes EBOV GP, and correlating MAb epitopes with their neutralizing capabilities is being used to develop anti-EBOV therapeutics and vaccines. This includes identifying mutations that increase the exposure of neutralizing epitopes, which can impact the design of future anti-ebolavirus vaccine strategies. For insights into the requirements for EBOV infectivity we also performed infectivity assays with the full EBOV GP mutation library using a lentivirus pseudotype system. To identify uncharacterized EBOV cellular receptors we similarly assayed wild-type GP infectivity in non-permissive cells expressing our membrane proteome array (MPA) of over 4,500 unique human membrane proteins individually expressed in eukaryotic cells. This has identified a number of candidate membrane proteins that enable EBOV infectivity.

### HOUSEHOLD LEVEL MEASLES VACCINATION COVERAGE AND ASSOCIATED HISTORY OF MEASLES DISEASE AMONG CHILDREN 9-59 MONTHS IN THE DEMOCRATIC REPUBLIC OF CONGO

Hayley Ashbaugh<sup>1</sup>, Robert Weiss<sup>1</sup>, Adva Gadoth<sup>1</sup>, Reena H. Doshi<sup>1</sup>, Patrick Mukadi<sup>2</sup>, Nicole A. Hoff<sup>1</sup>, Jean-Jacque Muyembe<sup>3</sup>, Emile Okitolonda<sup>4</sup>, Anne W. Rimoin<sup>1</sup>

<sup>1</sup>University of California Los Angeles, Los Angeles, CA, United States, <sup>2</sup>National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Kinasha School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Global suboptimal measles vaccination coverage ensures that measles remains an important public health concern. The Democratic Republic of Congo (DRC) demonstrates heterogeneous measles vaccination coverage, and quantifying the risk of measles for children within households at varying vaccination coverage levels is necessary to evaluate the overall effects of immunization programs. We assessed measles disease history among children participating in the 2013-2014 DRC Demographic and Health Survey (DHS). Our study sample consisted of 6,597 children aged 9-59 months whose mothers were selected for household interview. Measles vaccination status was obtained either via maternal report or vaccination card. A hierarchical Bayesian model was used to examine effects at the household, cluster, and provincial levels. An index child was selected from each household, and households were categorized by number of siblings vaccinated (excluding the index child) out of total number of siblings, forming three main categories: no vaccination coverage, heterogeneous coverage, and full (100%) coverage for measles vaccination). In households with completely unvaccinated siblings, 13% of unvaccinated and 10% of vaccinated index children reported measles. In households with a mixture of vaccinated and unvaccinated siblings, 12% of unvaccinated and 6% of vaccinated index children reported measles. In households with fully vaccinated siblings, 8% of unvaccinated and 10% of vaccinated index children reported measles. Further adjusted analyses were completed to quantify measles risk to vaccinated and unvaccinated children within households, and sensitivity analysis limited to vaccination report via dated card was performed. This study demonstrates the importance of quantifying the impact of household vaccination coverage among vaccinated and unvaccinated children 9-59 months in DRC and suggests the need for further research to aid strategic vaccination program policy development.

## 1443

**FORECASTING AND ASSESSMENT OF AUTOCHTHONOUS YELLOW FEVER OUTBREAK IN BRAZIL**Dhananjai M. Rao<sup>1</sup>, Carmen Asburn<sup>2</sup>, Paul D. Stamper<sup>2</sup><sup>1</sup>Miami University, Oxford, OH, United States, <sup>2</sup>MRI Global, Gaithersburg, MD, United States

As of March 2017, two states of Espírito Santo (ES) and Minas Gerais (MG) in Brazil have accounted for over 561 confirmed and 416 suspected cases of Yellow Fever (YF). The number and rate of cases is growing at an alarming rate, particularly when compared to prior outbreaks. With the vaccine stockpile depleted from the mid-2016 Angola outbreak in West Africa, forecasting epidemic progression is necessary to enable judicious use of vaccines to contain the outbreak. Accordingly, we propose the use of a novel computational epidemiology system called EpiRadar for forecasting and analysis of YF progression to inform health policy to contain the outbreak. EpiRadar was used to conduct analysis of the YF outbreak using a detailed temporospatial epidemic model of ES and MG states, involving: humans and three jungle mosquito species (*H. Janthinomys*, *H. Leucocephala*, and *S. Chloropterus*). Machine-learning methods based on a genetic algorithm have been used to calibrate parameters to fit the model to current outbreak in ES and MG. The calibration also accounts for ~55% of infections being asymptomatic and ~33% have mild or subclinical symptoms (estimates from past outbreaks) -- that is ~88% of infected individuals typically do not seek medical help and thus are not included in outbreak reports. Leave one out cross validation has been used to ensure that the model is not overfitted. Stochastic simulations into the future have been used to generate forecasts. Calibration data indicates that 45% ( $\pm 5\%$ ) of the population is immune due to prior outbreaks or vaccinations. Our forecasts show that, if current trends continue, then by July we predict the reported severe cases to grow to 4000 to 6000 cases, with 6000 to 10,000 infective individuals in ES and MG area alone. Generalized Sensitivity Analysis (GSA) shows that mosquito population plays a greater role than bite rate suggesting that controlling mosquito population is important. Analysis on policy and comparisons of our model predictions to incoming data is ongoing. Additionally, the influence of non-human primates to the force-of-infection is underway.

## 1444

**IDENTIFICATION OF CONSERVED MOTIFS IN VIRUSES BELONGING TO GUAMA SEROGROUP (ORTHOBUNYAVIRUS, BUNYAVIRIDAE)**Valéria L. Carvalho, Márcio R. Nunes, Daniele B. Medeiros, Sandro P. Silva, Clayton P. Lima, Jedson F. Cardoso, João L. Vianez Júnior, Davi T. Inada, Sueli G. Rodrigues, Pedro F. Vasconcelos  
*Evandro Chagas Institute, Belém, Brazil*

The Guama serogroup belongs to the *Orthobunyavirus* genus, *Bunyaviridae* family, composed of tripartite, single-stranded, and negative-sense RNA genomes, namely, large (L), medium (M), and small (S) genomes. The Guama serogroup includes viruses isolated in the Brazilian Amazon such as *Guama virus* (GMAV), *Catu virus* (CATUV), *Bimiti virus* (BIMV), *Mirim virus*, *Moju virus* (MOJUV) *Ananindeua virus* (ANUV), *Timboteua virus*, as well as others. This study aimed to identify orthobunyavirus conserved motifs in the aminoacidic sequences of the GMAV, CATUV, BIMV, ANUV and MOJUV. These viruses were sequenced, and we got complete sequences of the S-RNA (GMAV, CATUV, BIMV, ANUV, MOJUV), M-RNA and L-RNA (GMAV, BIMV, MOJUV) segment of them. We recognized in the viruses of the Guama serogroup the six conserved motifs in the gene N described by Saeed *et al.* (2001) and a seventh motif group specific (positions 212 to 237). Conserved residues observed in orthobunyaviruses related to packaging of the ribonucleoprotein were identified in the GMAV, CATUV, BIMV, ANUV and MOJUV alignment (positions P129, G135, I/L162, I235); there was a change in the residue Y158/I. Residues conserved associated to the

RNA synthesis were detected in the Guama serogroup viruses: positions F22, F148, L164, F180, L181, K183, Y189, W197, W217, F229 with the change of residue Y176F, and the residues R45, R99 and K55 related to binding with RNA were found in these viruses. In the NSm protein (GMAV, BIMV, MOJUV) was observed the motif GDFTNxCNSC (position 423 to 432; x: K→F) found in the Bunyamwera and California groups. The cleavage site between NSm/Gc correspond to the residue A475. A transmembrane region with potential to anchor the membrane in the Gc protein was identified (1.411 to 1.431 aa.). The cleavage sites to the trypsin were predicted: LRPI (MOJUV), THAV (BIMV) and SYVL (GMAV). The fusion peptide in the glycoprotein Gc was identified: GMAV (1062 to 1078), BIMV (1065 to 1081), MOJUV (1064 to 1080). In the gene L of GMAV, BIMV, MOJUV, we detected four conserved regions (I, II, III, IV) described to others orthobunyaviruses, including the motifs Pré-A, A, B, C, D, E in the region III.

## 1445

**ANALYTICAL PERFORMANCE OF THE FILMARRAY® GLOBAL FEVER PANEL**Jared R. Helm<sup>1</sup>, Corike Toxopeus<sup>1</sup>, Natalie Batty<sup>1</sup>, Olivia Davidson<sup>1</sup>, Brandon Marble<sup>1</sup>, Bryan T. Gnade<sup>2</sup>, Stefan Fernandez<sup>2</sup>, Cynthia Phillips<sup>1</sup><sup>1</sup>BioFire Defense, Salt Lake City, UT, United States, <sup>2</sup>U.S. Army Medical Materiel Development Activity, Fort Detrick, MD, United States

Acute Febrile Illness (AFI) can be caused by a large number of pathogens that include bacteria, viruses and parasites. BioFire Defense is developing the Global Fever (GF) Panel to be used on the FilmArray System in collaboration with the Department of Defense and NIAIDb. The FilmArray is an *in vitro* diagnostic test platform that combines nucleic acid purification and nested multiplex PCR for the simultaneous identification of many infectious agents in under an hour using a closed, sample-to-answer system. The FilmArray GF Panel detects and identifies nucleic acid from Chikungunya virus, CCHF virus, dengue virus (serotypes 1-4), Ebolavirus, Lassa virus, Marburgvirus, West Nile virus, Yellow fever virus, Zika virus, *Bacillus anthracis*, *Francisella tularensis*, *Leptospira* spp., *Salmonella enterica* serovar Typhi and Paratyphi A, *Yersinia pestis*, *Leishmania donovani* complex, and *Plasmodium* spp. in venous blood specimens from individuals with signs and/or symptoms of AFI or recent AFI and with known or suspected exposure to target pathogens. Estimated LoD studies demonstrate clinically relevant detection levels and exclusivity testing shows high specificity. For example, LoD levels for the following organisms: dengue virus (serotypes 1-4) at 7-150 copies/mL, Marburgvirus at 2-10 copies/mL, Zika virus at 2 copies/mL, *Leishmania* at 22 parasites/mL, *Plasmodium* at 180 parasites/mL, *Bacillus anthracis* at 3 CFU/mL, and *Yersinia pestis* at 3 CFU/mL. Off-panel exclusivity studies assessing specificity with closely related organisms or organisms that may be found in whole blood show no significant cross-reactivity. A multiplex FilmArray panel could aid in rapid and actionable AFI diagnosis. (a. MCS-JPEO and USAMMDA Contract No. W911QY-13-D-0080, under the NGDS program b. NIAID Contract No. HHSN27220160002C, "Advanced Development of Multiplex Diagnostic Platforms for Infectious Diseases (Global Fever Panel)")

## 1446

**DETECTION OF MLB ASTROVIRUS IN A PEDIATRIC HOSPITAL AT LIMA-PERÚ**Macarena Vittet<sup>1</sup>, Giuliana Oyola<sup>1</sup>, Gerardo Sanchez<sup>1</sup>, Mayra Ochoa<sup>1</sup>, Fabiola Colquechagua-Aliaga<sup>2</sup>, Dante Figueroa-Quintanilla<sup>2</sup>, Holger Mayta<sup>1</sup>, Mayuko Saito<sup>3</sup>, Sarah-Blythe Ballard<sup>4</sup>, Robert Gilman<sup>4</sup><sup>1</sup>Infectious Diseases Research Laboratory, Department of Cellular and Molecular Sciences, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Unidad de Rehidratación Oral, Instituto Nacional de Salud del Niño, Lima, Peru, <sup>3</sup>Tohoku University Graduate School of Medicine, Sendai, Japan,

<sup>4</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States

Human Astroviruses (HastV) are one of the major viral agents of acute gastroenteritis in young children, recently, a new genogroup has been reported as MLB. This new genogroup has been found in stool samples from patients with diarrhea. However, there is a lack of understanding if this genogroup is related to acute gastroenteritis or other diseases. We evaluated the burden of HastV associated to diarrhea. We collected stool samples from a case-control study from the hospital "Instituto Nacional de Salud del Niño" in Lima, Perú, samples were collected from October 2013 to May 2016. Cases were children with gastroenteritis symptoms who met the WHO definitions. Controls were children without gastroenteritis symptoms at the time of enrollment or in the past 30 days. Classic HastV detection was performed by RT-q PCR, all positives samples were amplified by conventional PCR and send for sequencing. MLB Astrovirus detection was performed by RT-PCR with consensus primers targeting a partial region from RdRp gene. All positive samples were amplified with another PCR with specific primers for MLB and amplification products were send for sequencing. A total of 1117 samples from diarrhea cases and 482 from controls were analyzed. Prevalence of classic HastV among cases was 5.81% (65/1117) and 2.07% (10/482) among controls (OR=2.92). HastV was detected mostly in children aged 12-24 months. The most common genotype was HastV1. Severity analysis was performed using Vesikari score. Preliminary data on MLB detection involved a total of 399 samples (133 diarrhea and 266 non- diarrhea). A prevalence of 1.72% was found (3/174).

## 1447

### MIDGUT MICROBIOTA COMPOSITION FROM FIELD COLLECTED AND EMERGED MOSQUITOES *ANOPHELES ALBIMANUS* FROM COLOMBIA

Yadira Galeano-Castañeda<sup>1</sup>, Paula A. Urrea<sup>1</sup>, Priscila Bascuñán-García<sup>1</sup>, Juan David Sánchez-Rodríguez<sup>1</sup>, Nicola Segata<sup>2</sup>, Francesco Beghini<sup>2</sup>, David Serre<sup>3</sup>, **Margarita M. Correa<sup>1</sup>**

<sup>1</sup>Grupo de Microbiología Molecular. Escuela de Microbiología de la Universidad de Antioquia, Medellín, Colombia, <sup>2</sup>Laboratory of Computational Metagenomics. University of Trento, Trento, Italy, <sup>3</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States

Recent work has revealed an important role of specific mosquito midgut microbiota in reducing *Plasmodium* parasite development, and those bacteria constitute valuable candidates for a biocontrol approach. Mosquitoes acquire their microbiota from the environment and transfer it trans-stage; however, little is known about the factors influencing the bacterial community composition of Neotropical *Anopheles* mosquitoes. Therefore, this study characterized the midgut microbiota of the Colombian main malaria vector *An. albimanus*. Mosquitoes analyzed were field adults and emerged from larvae collected in a locality of the Colombian Pacific Coast. Their midgut microbiota was analyzed by 16S rRNA gene Illumina Mi-Seq. At the genus level, higher bacterial richness was detected in mosquitoes from the field compared to emerged mosquitoes. *Bacillus* spp. predominated in field collected mosquitoes and *Acinetobacter* spp. in emerged mosquitoes. An increased abundance of bacterial genera detected in field collected mosquitoes suggests that bacterial communities are more influenced by the mosquito environment than by the breeding sites where their larvae develop. This result provides the basis for the design of new and effective vector interventions to control malaria transmission.

## 1448

### SPATIAL TOOLS FOR OPTIMIZING TSETSE CONTROL IN GAMBIAN SLEEPING SICKNESS FOCI

**Michelle C. Stanton**, Johan Esterhuizen, Ana Krause, Steve J. Torr

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Human African trypanosomiasis (HAT), commonly known as sleeping sickness, is a neglected tropical disease affecting populations in sub-Saharan Africa, with Gambian HAT (gHAT) being the most common form of the disease. Whilst control of gHAT is predominantly achieved through case detection, tsetse control using small insecticide treated targets ('tiny targets') has also been shown to reduce transmission risk in gHAT foci in Uganda, Guinea, Chad, and Côte d'Ivoire. At present, tiny targets are being deployed along rivers located within high transmission risk areas. Once deployed, the progress of the intervention is monitored using a network of tsetse traps to assess the abundance of tsetse in and around the area over time. As the tiny target programme continues to geographically scale up, it is becoming increasingly challenging to manage these monitoring activities. The goal of this project was therefore to develop and implement spatial tools for optimising this process. The aims of the project were two-fold: (1) to analyse the current costs (both financial and time) of the current monitoring programme in north west Uganda, and establish a method of determining optimal monitoring sites, and (2) to develop an electronic system for collecting, collating and visualising monitoring data. To address (1), remotely sensed, and field data were collected for the study area, and used to undertake a land cover classification analysis. These data, in addition to information on the costs associated with travelling between monitoring sites, were used to undertake a cost-distance analysis and subsequently produce an accessibility map. This map was then combined with information on the spatial distribution of tsetse to derive a monitoring site selection strategy. To address (2), an electronic system was developed which involved both a smartphone app for collecting daily monitoring data, and a web browser which displayed a map of the resulting data in real-time. This electronic system was trialled in Uganda in June 2017, and a series of interviews were conducted with both the trap monitors and the control programme supervisor to assess its utility and scalability.

## 1449

### DEVELOPMENT OF MOLECULAR METHODS FOR THE DETECTION AND QUANTIFICATION OF PHLEBOTOMINE SAND FLY LARVAL DNA IN SOIL

**Ioannis A. Giantsis<sup>1</sup>**, Marie Claude Bon<sup>2</sup>, Alexandra Chaskopoulou<sup>1</sup>

<sup>1</sup>European Biological Control Laboratory, U.S.D.A. ARS, Thessaloniki, Greece, <sup>2</sup>European Biological Control Laboratory, U.S.D.A. ARS, Montferrier-sur-Lez, France

Sand flies (Diptera: Psychodidae: Phlebotominae) are a group of haematophagous insects of great medical concern. They are known vectors of several parasites including *Leishmania* protozoans, which are responsible for 20,000-40,000 human deaths per year globally. The ecology, geographical distribution and vectorial competence of Phlebotomine sand flies has been the subject of significant research during the last decades, resulting in the description of more than 900 different species including proven or suspected vectors. Currently, available sand fly control techniques are focused to a significant extent on controlling adult stages, due to the wide knowledge gap regarding the ecology of sand fly larvae. Better understanding of larval ecology will result in designing more efficient and targeted control strategies against major *Leishmania* vectors. The majority of previous studies investigating sand fly breeding sites were based on emergence trapping techniques of adult sand flies with limited information in relation to abiotic and organic matter parameters of the soil or the preferred depth for breeding. Here we developed a novel real-time PCR technique aiming to detect, identify and quantify sand

fly DNA directly from soil. The method was optimized under laboratory conditions for the identification of two major leishmaniasis vectors of the Mediterranean region, *Phlebotomus tobbi* and *P. papatasi*. Since the majority of DNA extraction kits from soil samples focus on bacterial DNA, 3 different protocols were tested in order to design the most appropriate one for targeting sand fly DNA. The developed method is appropriate for detecting sand fly DNA from different layers of soil avoiding the need for mechanical recovery of larvae or trapping emerging adults. This new approach can be used to build on our currently available knowledge on larval ecology by adding accurate information on the breeding site preferences of sand flies.

## 1450

### ENTOMOLOGICAL STUDY ON A RECENT MALARIA OUTBREAK IN ANKILILOAKA, A SEMI-ARID AREA IN THE SOUTHWESTERN REGION OF MADAGASCAR

**Jacquelin Randriamihaja**, Alice Zilera Suzanantsoa, Raharimanga Rakotoson, Teddy Michael Andriantsolofomboahangy, Memy Malala Heriniaina Andriamizely, Jocelyn Ratovonjato, Arsène Ratsimbaoa

*National Malaria Control Program, Antananarivo, Madagascar*

The southwestern region of the Island is characterized by a sub arid climate. However, since December 2015, Ankiloaka which parts of the region is subjected to a multiple recrudescence of human malaria. A basic entomological data collection was carried out in March and April 2016 in two villages of Ankiloaka to study the malaria vector species composition, their behaviors, their density and their infectivity. Study of mosquito larvae breeding sites was conducted according to the WHO method. Adult mosquito sampling was performed using human landing catches, indoor pyrethrum spray catches and mouth aspirator for outdoor mosquitoes. Collected mosquitoes were morphologically identified. The standard PCR method was used to identify the sibling species of the complex *An. gambiae*. Overall, 153 *Anopheles* larvae breeding sites were found in Ankiloaka: rice fields (67%) were the most abundant and permanent breeding site identified. Seven *Anopheles* species were found. All *An.gambiae* s.l. was identified as *An. arabiensis*. Three malaria vector species: *Anopheles funestus*, *An. arabiensis*, *An. mascarensis* were found. The relative density of *An. funestus* was very high. Overall, 270 *Anopheles* vectors were collected. In the first village, *An. funestus*, *An. arabiensis*, *An. mascarensis* represent respectively 70.31%, 26.56%, 3.12%. In the second village, they represent respectively 83.78%, 15.31% and 0.9%. *An. funestus* is the most abundant vector; its aggressive density indoor was high and the aggressive density outdoors of *An. arabiensis* was important. The basic entomological data collected during this study revealed that permanent irrigated rice fields were the main mosquito breeding sites in Ankiloaka. They may maintain the high density of malaria vectors in Ankiloaka area. *An. funestus* and *An. arabiensis* were the main malaria parasite vectors in Ankiloaka, and possibly implicated to the malaria outbreak occurring there in 2015. All data collected during the study were essential for the malaria vector control in the southwestern region of Madagascar and used as baseline for the next entomological survey.

## 1451

### GENERATING LAB-REARED MOSQUITOES WITH FIELD-RELEVANT MICROBIOMES

**Justine Alexander**, Brittany Dodson, Jason Rasgon

*The Pennsylvania State University, State College, PA, United States*

The microbiome of mosquitoes has been demonstrated to affect many important biological phenotypes such as development, fitness, and vector competence for numerous pathogens. Studies with mosquitoes invariably do not control for microbiome effects, and the relevance of laboratory-acquired microbiomes to mosquito biological parameters in the field is unclear. This study was undertaken to determine if mosquitoes could be

reared in the laboratory with field-relevant microbiomes. *Culex territans* and *Anopheles punctipennis* larvae were harvested from multiple sites in Central Pennsylvania and raised in one of three conditions: standard lab conditions, natural pond water supplemented with sterile nutrients, or natural pond water with no supplementation. Pupae/emerging adults were collected from the same sites. Microbiomes were characterized via MiSeq sequencing of the V4 region of the 16S rRNA gene. Results from this study will guide efforts to recreate naturalistic mosquito microbiomes in the lab for experimental studies, as well as helping to understand factors influencing mosquito microbiome composition in the field.

## 1452

### EVALUATING GRAVID AEDES TRAPS AND PROKOPACK ASPIRATORS FOR AEDES ALBOPICTUS SURVEILLANCE IN TWO NEIGHBORHOODS OF ATLANTA, GEORGIA

**Rebekah Blakney**, Jessica Stephens, Uriel Kitron, Gonzalo Vazquez Prokopec

*Emory University, Atlanta, GA, United States*

The invasive, container-dwelling mosquito species *Aedes albopictus* spread rapidly from its introduction to Texas in 1985 and is now well established in most of the Southeast, South Central, and Mid-Atlantic United States. Accurate surveillance for *Ae. Albopictus* is important for monitoring the potential introduction of arboviruses. Although several methods are available, they vary in their cost, personnel involvement and requirement of specialized equipment. The Biogents Sentinel trap is commonly used for passive adult *Aedes spp.* collections, however its reliance on electricity and chemical lures as well as cost limit their widespread adoption. The Gravid Aedes Trap has emerged as a low-cost option for passive *Ae. spp.* sampling that does not require batteries or chemical attractants, but its use in the United States has been limited. We conducted surveillance for *Ae. Albopictus* in two neighborhoods in Atlanta, Georgia, one with low *Ae. Albopictus* abundance (Grant Park) and one with high *Ae. Albopictus* (Shallowford), with a matched-pair design comparing GATs with aspiration of adult mosquitoes resting outdoors. The backyards of 55 houses (26 in Grant Park, 29 in Shallowford) were aspirated for 10 minutes using a Prokopack and one GAT placed for 4 days from mid-August to mid-September 2016. A total of 191 adult mosquitoes including 122 female *Ae. Albopictus* were collected by GATs and 163 adult mosquitoes including 54 female *Ae. Albopictus* by aspiration. The percentage of infested houses detected by a GAT was 82% for Grant Park and 85% for Shallowford, while the percentage of infested houses detected by a Prokopack was 45% for Grant Park and 50% for Shallowford. The odds of detecting female *Ae. Albopictus* in Shallowford was 3.25 times higher with a GAT than a Prokopack, but the odds of detection with a GAT vs Prokopack did not differ significantly in Grant Park. Our study demonstrates successful collection of *Ae. Albopictus* using GATs compared to Prokopack aspirators for neighborhood-level surveillance and has implications for future *Ae. Albopictus* surveillance in the United States.

## 1453

### ASSESSMENT OF POTENTIAL SAND FLY VECTORS IN LEISHMANIASIS AND BARTONELLOSIS ENDEMIC AREAS IN THE ECUADORIAN SIDE OF THE ECUADOR-PERU BORDER

Andres Carrazzo<sup>1</sup>, Victor Zorrilla<sup>2</sup>, Hector Olalla<sup>3</sup>, Leonardo Fárez-Noblecilla<sup>4</sup>, Liz Espada<sup>2</sup>, Marisa Lozano<sup>2</sup>, Craig A. Stoops<sup>2</sup>, **Gissella Vasquez<sup>2</sup>**, Renato León<sup>1</sup>

<sup>1</sup>Laboratorio de Entomología Médica and Medicina Tropical LEMMT, Universidad San Francisco de Quito, Quito, Ecuador, <sup>2</sup>U.S. Naval Medical Research Unit-6, Callao, Peru, <sup>3</sup>Ministry of Health, District 19D03, Zamora Chinchipe, Ecuador, <sup>4</sup>Ministry of Health, Entomology Laboratory, 07D02 Machala-Salud, El Oro, Ecuador

Phlebotomine sand flies (Diptera: Psychodidae) are vectors of leishmaniasis in coastal, Andean and Amazonian regions of South America. These species also are vectors of human bartonellosis or Carrion's disease in

Ecuador and Peru. Leishmaniasis and human bartonellosis are known to be endemic along the Ecuador-Peru border with hundreds of cases of both diseases reported every year in northern Peru, whereas there have been few leishmaniasis cases and no bartonellosis cases reported from the Ecuadorian side in the last few years. Moreover, information on sand flies transmitting these pathogens in this region is lacking. This study aimed to characterize the sand fly fauna and identify potential leishmaniasis and bartonellosis vectors in two provinces of Ecuador close to the Peruvian border: El Oro (southwestern Pacific coast) and Zamora-Chinchipec (southeastern Amazonian region). Sand flies were collected in November and December 2016 using standard CDC light traps, Mosquito Magnet trap and Protected Human Bait. A total of 221 specimens belonging to different *Lutzomyia* species were identified: 107 (48%) from El Oro and 114 (52%) from Zamora-Chinchipec. Standard CDC light traps collected the highest number of sand flies in El Oro (83%), whereas Protected Human Bait was the most effective in Zamora-Chinchipec (78%). In El Oro, the species collected were *Lutzomyia trapidoi* (33%), *Lu. gomezi* (30%), *Lu. (Pressatia) spp.* (23%), *Lu. abonnenci* (5%), *Lu. hartmanni* (2%), *Lu. amazonensis* (2%), *Lu. aragaoi* (1%), *Lu. undulata* (1%), *Lu. shannoni* (1%), *Lu. serrana* (1%), and *Lu. barretoii majuscula* (1%). In Zamora-Chinchipec, only three species were recorded: *Lu. robusta* (95%), *Lu. maranonensis* (4%), and *Lu. castanea* (1%). *Lutzomyia trapidoi* and *Lu. gomezi* are highly anthropophilic and thus considered potential vectors in El Oro, whereas *Lu. robusta* and *Lu. maranonensis* are likely to play a role in pathogen transmission in Zamora-Chinchipec. Assessment of *Leishmania* spp. and *Bartonella* spp. infection rates in captured sand flies will further define the role of these species as potential vectors in this region.

## 1454

### THE RURAL-URBAN GRADIENT OF HOUSE INFESTATION WITH *TRITOMA INFESTANS* IN AN ENDEMIC MUNICIPALITY OF THE ARGENTINE CHACO REGION

**María Sol Gaspe**, María del Pilar Fernandez, Marta V. Cardinal, Gustavo F. Enriquez, Lucía I. Rodríguez-Planes, Natalia P. Macchiaverna, Ricardo E. Gürtler

*Universidad de Buenos Aires, Consejo Nacional de Investigaciones Científicas y Técnicas, Instituto de Ecología, Genética y Evolución de Buenos Aires (IEGEB), Facultad de Ciencias Exactas y Naturales, Ciudad Autónoma de Buenos Aires, Argentina*

The Gran Chaco ecoregion is one of the main hotspots of neglected tropical diseases in the Americas, including Chagas disease. The occurrence of the major vector *Triatoma infestans* has historically been linked to poor rural housing, but (peri)urban infestations have been increasingly reported over recent decades. We conducted a cross-sectional survey of house infestation with *T. infestans* in all rural, periurban and urban sections of Avia Terai, an endemic municipality in the Argentine Chaco, as part of a 3-year intervention program combining insecticide spraying with educational aspects and community mobilization. The district had been sprayed with pyrethroid insecticides by Chagas vector control technicians 2-5 years before our survey. The baseline prevalence of house infestation decreased along a rural-to-urban gradient ranging from 43% (among 275 rural houses inspected), 16% (367 periurban houses) to 14% (402 urban houses), as determined by manual searches with a dislodging aerosol conducted over October 2015-March 2016. Bug colonies were found in nearly all infested houses. Most infestations occurred in peridomestic structures housing chickens and other domestic animals. Domestic infestations displayed a similar rural-to-urban gradient from 9%, 4% to 2%. Urban foci were spread through the town, and periurban infestations largely differed among neighborhoods (range, 0-59%). The village-specific prevalence rates of house infestation recorded in rural areas before control interventions (2011-2013) and in 2015 were similar. These results attest the fast recovery of triatomine populations after traditional insecticide spraying campaigns that did not include sustained vector surveillance and control afterwards. The large indices of

house infestation found in periurban and urban habitats of traditionally endemic regions reveal the need of revising current vector control practices in affected areas of the Gran Chaco.

## 1455

### CHALLENGES IN MEASURING AND ANALYZING VECTOR CONTROL INTERVENTIONS: INDICATORS, BASELINES AND DEFINITIONS

**Molly Robertson**<sup>1</sup>, Christelle Gogue<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Joseph Wagman<sup>1</sup>, Keith Mangam<sup>2</sup>, David Larsen<sup>3</sup>, Francisco Saute<sup>4</sup>, Baltazar Candrinho<sup>5</sup>, John Miller<sup>1</sup>, Richard Steketee<sup>1</sup>, Jeff Bernson<sup>1</sup>  
*<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>Abt Associates, Bethesda, MD, United States, <sup>3</sup>Syracuse University, Syracuse, NY, United States, <sup>4</sup>Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, <sup>5</sup>Programa Nacional do Controlo da Malaria, Maputo, Mozambique*

Implementation of Indoor residual spraying (IRS) for vector control is undergoing significant shifts as insecticide resistance has emerged for some insecticides and other insecticides are coming onto the marketplace, driving a need for rotation and layering of products. In addition, insecticide treated bednets (ITNs) and other vector control tools are similarly undergoing transformations that could add complexity to malaria impact evaluations. At the same time, advances in satellite technology, rapid reporting, and routine surveillance system have allowed for more comprehensive assessment of the impact of these tools and their combinations in near real time. However, the ability to cross-analyze vector control interventions across different countries, implementing partners, and implementation strategies is hampered by a multiplicity of measurement methods and indicator definitions. As new vector control tools are implemented, and current tools are expanded, the need for robust and translatable definitions, indicators and enumeration strategies becomes ever more necessary. This paper focuses first on the challenges of definitions for standard indicators such as coverage, populations at risk, and populations protected. It shows how a small change in definition can impact the interpretation and analysis of the effectiveness of vector control programs. This paper also addresses how differences in definitions for baselines, including coverage and targeting metrics, affect the interpretation of impact. Finally, examples of enumeration strategies, to accurately define households/structures and populations at risk are presented. Standardization is especially important for programs that seek to understand cost-effectiveness of vector control interventions across various countries and epidemiological settings without reliance on costly trials. A unified, or translatable, set of definitions, indicators, and enumeration methodologies is critical at this stage to adequately assess the impact of vector control tools and their combinations in real settings as part of a robust monitoring and evaluation system.

## 1456

### ENVIRONMENTAL RISK FACTORS OF TUNGIASIS IN HAITI: A NEGLECTED DISEASE

**Elisha R. Musih**, Leslie Valenzuela, Heather S. Davies, Michael von Fricken

*George Mason University, Fairfax, VA, United States*

Tungiasis, a skin disease caused by the penetration of sand fleas (jiggers), is a neglected tropical disease endemic to impoverished regions of the Americas, especially Haiti. Unfortunately, there has been little surveillance for this condition, despite prevalence rates as high as 30% in a cross-sectional study of four distinct geographical locations in Haiti. Complicating the matter further, Haiti has lost 97% of its forests since 1987 creating an environment that is hospitable to sand flea infestation, which may increase the risk of tungiasis. Other studies have identified environmental risk factors for tungiasis including elevation above 2000 meters, sandy soil (which can result from deforestation), and poverty. This study aims to identify potential high risk regions of tungiasis transmission based on environmental factors, including remote sensing data focusing

on normalized vegetation difference index (NDVI), elevation, and population density. Through spatial analysis of these variables, we hope to identify high risk regions that can guide future surveillance efforts investigating the burden of tungiasis in Haiti.

## 1457

### THE STEROID HORMONE 20-HYDROXYECDYSONE (20E) TRANSCRIPTIONALLY REGULATES THE MIDGUT OF *ANOPHELES GAMBIAE* AND *Aedes Aegypti* TO PROMOTE BACTERIAL EXPANSION

Sarah Sneed, Michael Povelones

University of Pennsylvania, Philadelphia, PA, United States

*Anopheles gambiae* and *Aedes aegypti* mosquitoes serve as important vectors for human pathogens. As the first major tissue barrier bloodmeal-acquired pathogens encounter in the mosquito, understanding the different signals that regulate cells of the midgut epithelium during a bloodmeal is critical for identifying novel mechanisms that may be important during infection. We found that injection of 20-hydroxyecdysone (20E), a steroid hormone that is essential for vitellogenesis, induces expansion of commensal bacteria in the absence of a bloodmeal in both *An. gambiae* and *Ae. aegypti* as measured by colony-forming-units and 16S qPCR. Bacterial commensals have been shown to be important in shaping midgut epithelial responses to both *Plasmodium* and Dengue virus (DENV) infections. During a bloodmeal, the commensal population undergoes dramatic quantitative and population level changes. A bloodmeal results in an overall increase in the number of commensals, with the peak of expansion occurring between 18 and 30hr post-bloodmeal (PBM) and corresponding to a loss in community diversity. While the dramatic increase in nutrients from a bloodmeal enables robust bacterial proliferation, we hypothesize that the expansion also requires a tolerating signal from the midgut epithelium. On average, the commensal expansion post-20E injection is 60% of the expansion post-bloodfeeding. In addition to quantification, we characterized the microbial communities expanding in the midgut after 20E injection and bloodfeeding. To elucidate the molecular mechanism responsible for commensal expansion we performed RNA-Seq in both of these mosquitoes to identify early(5hr)- and late(18hr)- midgut-specific transcriptional targets of 20E and comparative analysis of differences between the two species is ongoing. We hypothesize that a subset of targets found in both mosquitoes are directly responsible for a tolerating signal that allows the bacteria to expand post-bloodmeal and may simultaneously increase susceptibility of the midgut epithelium to pathogen infection.

## 1458

### RETENTION OF DUPLICATED LIGHT AND VISUAL RECEPTORS IN MOSQUITO LINEAGES BY POSITIVE SELECTION AND DIFFERENTIAL EXPRESSION

Gloria I. Giraldo-Calderón<sup>1</sup>, Michael J. Zanis<sup>2</sup>, Catherine A. Hill<sup>3</sup>

<sup>1</sup>Purdue University (present address: University of Notre Dame), Notre Dame, IN, United States, <sup>2</sup>Purdue University (present address: Seattle University), Seattle, WA, United States, <sup>3</sup>Purdue University, West Lafayette, IN, United States

Opsins are light sensitive receptors associated with visual processes. Insects typically possess opsins that are stimulated by ultraviolet, short and long wavelength (LW) radiation. Six putative LW-sensitive opsins predicted in the yellow fever mosquito, *Aedes aegypti* and malaria mosquito, *Anopheles gambiae*, and eight in the southern house mosquito, *Culex quinquefasciatus*, suggest gene expansion in the Family Culicidae (mosquitoes) relative to other insects. Here we report the first detailed molecular and evolutionary analyses of LW opsins in three mosquito vectors, with a goal to understanding the molecular basis of opsin-mediated visual processes that could be exploited for mosquito control. The transmembrane domains of the mosquito LW opsins share between

60 to 100% amino acid identity. Time of divergence estimates suggest that the mosquito LW opsins originated from 18 or 19 duplication events between 166.9/197.5 to 1.07/0.94 million years ago (MY) and that these likely occurred following the predicted divergence of the lineages Anophelinae and Culicinae 145–226 MY. Fitmodel analyses identified nine amino acid residues in the LW opsins that may be under positive selection. Of these, eight amino acids occur in the N and C termini and are shared among all three species, and one residue in TMIII was unique to culicine species. Alignment of 5' non-coding regions revealed potential Conserved Non-coding Sequences (CNS) and transcription factor binding sites (TFBS) in seven pairs of LW opsin paralogs. Our analyses suggest opsin gene duplication and residues possibly associated with spectral tuning of LW-sensitive photoreceptors. We explore two mechanisms – positive selection and differential expression mediated by regulatory units in CNS – that may have contributed to the retention of LW opsin genes in Culicinae and Anophelinae. We discuss the evolution of mosquito LW opsins in the context of major Earth events and possible adaptation of mosquitoes to LW-dominated photo environments, and implications for mosquito control strategies based on disrupting vision-mediated behaviors.

## 1459

### THE MIDGUT ESCAPE BARRIER FOR CHIKUNGUNYA VIRUS IN *Aedes Aegypti* IS ASSOCIATED WITH PROTEINASE ACTIVITY

Shengzhang Dong, Asher Kantor, Jingyi Lin, Alexander W. Franz

University of Missouri, Columbia, MO, United States

Chikungunya virus (*Togaviridae*; *Alphavirus*; CHIKV) is an emerging mosquito-borne virus, which is transmitted to humans by *Aedes aegypti* and *Ae. albopictus*. Following oral acquisition from a vertebrate host, the virus containing bloodmeal is deposited in the midgut lumen. Virus enters the epithelial cells and replicates in them before disseminating from the midgut to secondary tissues including the salivary glands. Once the latter are infected the virus is transmitted to another vertebrate host. The viral exit mechanism from the mosquito midgut, the midgut escape barrier (MEB), is poorly understood although it is an important determinant of vector competence. We hypothesize that bloodmeal intake leading to midgut tissue expansion causes structural changes in the midgut surrounding basal lamina (BL). These structural changes, which are caused by enzymatic processes involving proteinases, make the BL permissive for virions to pass through. Collagen IV, an essential component of the BL, was less abundant in midguts of females at 12-36 h post-bloodmeal. This correlated with a high collagenase activity in midguts and high virus dissemination rates. To reveal candidate genes involved in the process, we conducted a comparative transcriptomic analysis of midgut samples from mosquitoes, which had received a saline meal (SM) or a protein meal (PM) containing CHIKV as substitutes for a CHIKV containing bloodmeal. Twenty three genes encoding trypsin, metalloproteinases, and serine-type endopeptidases were significantly upregulated in midguts of mosquitoes at day 1 following SM or PM ingestion. Two of the genes were *Ae. aegypti* late trypsin (*AeLT*) and serine collagenase 1 precursor (*AeSP1*), the former of which showed strong metalloproteinase activity *in vitro*. Similarly, matrix metalloproteinases (MMPs) *AeMMP1* and *AeMMP2* showed strong metalloproteinase activity *in vitro*, which was inhibited by the *Ae. aegypti* tissue inhibitor of metalloproteinases (*AeTIMP*). Our results support the conclusion that BL degradation due to proteinase activity during meal digestion may be the mechanism behind CHIKV dissemination from the midgut in *Ae. aegypti*.

## 1460

**DETERMINING THE EXPRESSION PROFILE OF SPERMATOGENESIS GENE HOMOLOGUES THROUGHOUT ALL DEVELOPMENTAL STAGES OF ANOPHELES ALBIMANUS, MAIN MALARIA VECTOR IN CENTRAL AMERICA**

Andrea Ramos, Mabel Taracena, Claudia Paiz, Pamela Flores, Pamela Pennington

*Universidad del Valle de Guatemala, Guatemala, Guatemala*

Central America is currently working towards malaria elimination. Despite the mass distribution of insecticide treated nets, malaria persists in focalized areas of Guatemala. This has important social and economic consequences for the elimination target, and sustainable and specific methods for mosquito control will be required to reach the regional malaria elimination target. The sterile male technique was successful in the 1970's at controlling *Anopheles albimanus*, the main vector in the region. We propose that sterile males may be produced by silencing genes vital for spermatogenesis. A loss of function of *boule (bol)* and zero population growth (*zpg*) genes in mosquitos generates sterile adults. In the present study, we quantified *bol* and *zpg* expression profiles by real time PCR, to determinate in which life stage of *An. albimanus* these genes will have a higher expression. For that, we extracted RNA from all life stages, using a standardized amount of 30mg of tissue per pool. We generated cDNA from larval, pupal and adult stages, with females and males analyzed separately. Finally, we measured mRNA expression levels for each stage by qPCR. The results showed that *bol* and *zpg* have high expression rates in male adult stages, with three- and 30- fold the initial gene expression observed in first instar larvae, respectively. Interestingly, we also detected expression of both genes in female adults, which could suggest that these genes have other functions on females. According to these results, we propose that continuously feeding dsRNA to larvae for silencing these genes when they begin to be expressed, at first instar larvae, would have a high impact on adult male fertility. If that is the case, using dsRNA to silence one of these genes could lead to adult sterile males that could be used as a complementary strategy for malaria elimination.

## 1461

**IDENTIFICATION OF METABOLIC CHOKE POINTS FOR CONTROLLING DENGUE VIRUS TYPE 2 INFECTION IN THE MIDGUT OF AEADES AEGYPTI MOSQUITOES**

Nunya Chotiwan<sup>1</sup>, Barbara G. Andre<sup>1</sup>, Irma Sanchez-Vargas<sup>1</sup>, Jeffrey M. Grabowski<sup>2</sup>, Amber Hopf-Jannasch<sup>2</sup>, Erik Gough<sup>2</sup>, Ernesto Nakayasu<sup>2</sup>, Carol D. Blair<sup>1</sup>, Catherine A. Hill<sup>2</sup>, Richard J. Kuhn<sup>2</sup>, Rushika Perera<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Purdue University, West Lafayette, IN, United States

Dengue viruses (DENV) are mosquito-borne viruses that cause almost 400 million infections and 10,000 deaths in humans annually. The biochemical environment within both human and mosquito hosts is known to play a critical role in determining the outcome of virus infection. Previous studies have found alterations in lipid profiles and rearrangement of the membrane architecture of host cells to support viral genome replication, protein translation and particle assembly during DENV type 2 infections. In this study, we adopted an untargeted metabolomics approach to explore temporal alterations of the lipid environment in the midgut of *Aedes aegypti* mosquitoes during DENV infection. Using high-resolution liquid chromatography-mass spectrometry, we observed a shift of several lipid classes during the time course of infection. Phosphoglycerolipids, major components of cellular membranes, temporally increased coincident with viral replication dynamics. The abundance of certain bioactive sphingolipids was also elevated early post infection. To identify the role of these lipids in defining the outcome of virus infection, we knocked down the expression or inhibited the function of key enzymes in select pathways using double stranded RNA and chemical inhibitors. We observed a reduction of DENV

replication and particle production in both mosquito cells and the midgut of *Aedes* mosquitoes. Specifically, inhibition of *de novo* fatty acyl-CoA synthesis, key intermediates of lipid metabolic pathways, and enzymes along the *de novo* sphingolipid and sphingosine synthesis pathways were detrimental to the virus. Similar effects were also observed in human cells upon DENV infection indicating a conserved requirement of these host resources during the viral life cycle. In summary, we have carried out the first study interrogating the biochemical environment required for DENV replication in the mosquito and identified the role of sphingolipids in the complex interaction of virus and host. Our data suggested that these metabolic control points could be targeted for intervention of virus transmission by the mosquito vector.

## 1462

**THE STRUCTURE AND FUNCTION OF ALBICIN: A NEW WORLD ANOPHELINE MOSQUITO SALIVARY PROTEIN THAT INHIBITS OF THE ALTERNATIVE PATHWAY OF THE HUMAN COMPLEMENT**

Ethan Strayer, John Andersen

*Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States*

Albicin is a 13.4 kDa member of the SG7 protein family expressed in the salivary glands of the central American malaria vector *Anopheles albimanus*. Albicin inhibits the human alternative complement pathway, by stabilizing the C3 convertase (C3bBb). More specifically, the inhibitor-bound convertase is unable to cleave C3, which in turn prevents the amplification of the complement response. Here we present the crystal structure of albicin along with analysis of the physical properties of its complex with C3bBb. Using site-directed mutagenesis in conjunction with surface plasmon resonance and size exclusion chromatography, we identify key residues, which stabilize the albicin bound convertase complex. The composition and thermodynamic properties of the bound complex were examined using analytical ultracentrifugation. While the structural homolog of albicin, expressed in the salivary glands of *Anopheles darlingi*, also inhibits the C3 convertase, the related SG7 proteins in *Anopheles gambiae* and *Anopheles stephensi* do not exhibit anti-complement activity. A better understanding of structure of albicin and its complex with C3bBb may facilitate the identification of the function of other SG7 protein family members.

## 1463

**STEROID HORMONE SIGNALING IN ANOPHELES GAMBIAE MOSQUITOES AFFECTS THE SPOROGONIC CYCLE OF PLASMODIUM FALCIPARUM PARASITES**

Kristine Werling, Maurice Itoe, Douglas Paton, Flaminia Catteruccia

*Harvard T.H. Chan School of Public Health, Boston, MA, United States*

After an infectious blood meal, oogenesis in *Anopheles gambiae* females is spatially and temporally linked with *Plasmodium falciparum* development. Oogenesis is initiated following blood feeding by a peak of the insect steroid hormone 20-hydroxyecdysone (20E). This 20E signal induces vast transcriptional and metabolic responses in multiple female tissues to promote blood meal digestion and the incorporation of nutrients into developing eggs. While these dramatic 20E-regulated changes occur, *Plasmodium falciparum* parasites also attempt to establish infection in the mosquito. Here we reveal an unexpected interplay between the pathways regulated by 20E and parasite development in *An. gambiae*. We show that impairing 20E signaling via depletion of the 20E nuclear hormone receptor, Ecdysone Receptor (EcR), differentially affects female reproductive processes and multiple stages of *P. falciparum* development. Females impaired in 20E signaling develop significantly fewer eggs, a phenotype at least partially mediated by the reduced expression of known 20E-induced yolk protein precursors. These EcR-depleted females also

harbor fewer *P. falciparum* oocysts. Strikingly, however, in EcR-silenced females, *P. falciparum* parasites develop faster and become infectious sooner, consistently producing more salivary glands sporozoites at earlier time points after an infectious blood meal. The mechanisms driving these contrasting effects on parasite development are still being determined, nonetheless this first demonstration that 20E signaling impacts the rate of *P. falciparum* development has marked implications for our understanding of the molecular mechanisms critical for disease transmission. Overall, these data demonstrate that steroid hormone signaling plays a complex and previously unappreciated role in regulating the sporogonic cycle of *Plasmodium* parasites.

## 1464

### MULTIPLE TISSUE MICRORNA TRANSCRIPTOME-WIDE ANALYSIS IN THE MALARIA VECTOR, *ANOPHELES GAMBIAE* S.S.

William Bart Bryant, Bradley J. Olson, Kristin Michel  
Kansas State University, Manhattan, KS, United States

A key component of regulating gene expression is a small class of RNA molecules termed microRNAs (miRNAs). Most miRNAs are differentially expressed in tissues, while a small number are solely expressed in specific tissues. Recent studies illustrate the significance of miRNAs in regulating blood feeding and immunity in mosquitoes. As a first step towards our goal to identify miRNAs that regulate tissue-specific functions, twelve small RNA libraries consisting of four different tissue types with three biological replicates were constructed and analyzed. Tissues analyzed were midgut, fat body, ovaries, and remaining tissues, the latter group includes the head and thorax of the mosquito. Small RNA libraries were prepped using Illumina TruSeq Small RNA Prep Kit. Library size selection was done by Pippin Prep to ensure proper selection of miRNAs. Small RNA libraries were sequenced by TruSeq Sequence-By Synthesis v3 chemistry. Raw reads were analyzed by CLC genomics software. Our preliminary analysis found approximately 75% of reads for the fat body libraries matched current known miRNAs. However, other tissue libraries found a higher percentage of non-annotated reads. Preliminary analysis found multiple instances of miRNAs enriched in specific tissues. *miR-1174*, *miR-1175*, and *miR-12* were enriched in the midgut. *miR-92b* and *miR-989* were enriched in ovaries. *miR-957*, *miR-133*, and *miR-210* were enriched in our 'remaining tissue'. Our data agrees with previous results of tissue-specific miRNA expression. Further validation by real time PCR expression analysis agreed with our small RNA library analysis. Lastly, we tested the effects of blood feeding on the expression levels of candidate miRNAs with interesting results. Overall, understanding expression patterns of miRNAs in multiple tissues demonstrates their complexity and starts the groundwork for determining their relevance in disease transmission in the malaria vector, *Anopheles gambiae*. Lastly, defining candidate tissue-specific miRNAs is of importance as these miRNAs likely play key roles in maintaining tissue complexity.

## 1465

### GENOMIC AND PHYSIOLOGIC CHARACTERIZATION OF *SERRATIA MARCESCENS* ISOLATED FROM THE GUT OF *ANOPHELES STEPHENSI*

Shicheng Chen, Edward D. Walker  
Michigan State University, East Lansing, MI, United States

Bacteria of the genus *Serratia* are common commensals in the *Anopheles* mosquito midgut, and show great potential to repress *Plasmodium* development. However, the molecular mechanisms involved in interactions between commensal *Serratia* and mosquito hosts as well as other associated symbionts remain largely unknown. Our study demonstrated that *Serratia marcescens* strain ano1 and the bacterium *Elizabethkingia anophelis* isolated from *Anopheles stephensi* stably persisted in larval and adult mosquitoes (98.5% infection rate) while *Serratia fonticola* isolated from *Aedes* had significantly lower infection rate (32.5%) in *Anopheles*,

supporting the hypothesis that *S. marcescens* is a stable commensal in *A. stephensi* gut. Nevertheless, *S. marcescens* caused up to 67% death rates in larval or adult mosquito within 4 days when inoculated into mosquito hemolymph, indicating that *S. marcescens* is also an opportunistic pathogen in *Anopheles stephensi* when it bypasses the gut. To explore these phenotypic and genetic attributes, we sequenced and annotated genomes from two *A. stephensi*-associated *S. marcescens* and compared them to those forming symbiotic relationships to other mosquitoes, insects, nematodes and plants. *S. marcescens* ano1 and ano2 were quite distinct from *Serratia* sp. previously isolated from *Anopheles gambiae*. *S. marcescens* ano1 was resistant to numerous antibiotics, and showed high survival in the mosquito gut niche. It produced alpha-hemolysin(s), possibly contributing to lysis of ingested erythrocytes. *S. marcescens* ano1 and ano2 had predicted virulence factors that are possibly involved in attacking parasites and/or could cause opportunistic infection for mosquito hosts. *S. marcescens* ano1 and ano2 possessed multiple mechanisms for antagonism against other microorganisms, including the production of bacteriocins and multi-antibiotic resistant determinants. Genes contributing to potential anti-malaria activity including serralysins, hemolysins and chitinases only found in some *Serratia* species.

## 1466

### A HETERODIMER OF AALRIM1 AND AAAPL1 IS REQUIRED FOR *AEDES AEGYPTI* IMMUNE REACTIONS TARGETING DIVERSE PATHOGENS

Letitia K. Thompson, Sarah D. Sneed, Greg L. Sousa, Elizabeth Edgerton, Michael Povelones  
University of Pennsylvania, Philadelphia, PA, United States

*Aedes aegypti* is responsible for transmission of several arboviruses as well as filarial nematodes and *Plasmodium* parasites. For transmission to occur, pathogens must overcome the mosquito immune system. Therefore, we are interested dissecting molecular immune mechanisms required for limiting infection with the goal of developing novel strategies to block disease transmission. We have taken a comparative approach to analyze *Ae. aegypti* complement components given that this pathway provides robust protection against infection by diverse pathogens in *Anopheles gambiae*. We found that, like their orthologs in *An. gambiae*, two Leucine-Rich Repeat Immune Proteins, AaLRIM1 and AaAPL1, circulate in the hemolymph of *Ae. aegypti* in a disulfide-linked complex. RNAi silencing of either AaLRIM1 or AaAPL1 abrogates the complex. These genes, as well as several other putative *Ae. aegypti* complement components, are upregulated following bacterial challenge, infection by a filarial nematode, and activation of the REL1 signaling pathway. Furthermore, silencing AaLRIM1 or AaAPL1 renders mosquitoes highly susceptible to bacterial infection. We are currently addressing the role the AaLRIM1/AaAPL1 complex plays in complement activation, what immune effector functions it triggers, how the *Ae. aegypti* complement pathway is regulated, and whether it functions to limit arboviral infection.

## 1467

### FABULOUS SIGNALING: THE IMPACT OF THE TOLL PATHWAY ON MOSQUITO-PATHOGEN INTERACTIONS

Kristin Michel, Victoria L. Rhodes  
Kansas State University, Manhattan, KS, United States

The Toll pathway is a central regulator of immunity in insects and controls innate immune reactions that limit a wide range of infections. Manual annotation and phylogenetic analysis of the entire Toll-like receptor (TLR) gene repertoire in 20 sequenced mosquito species reveal expansions of the TOLL1 and TOLL5 clade, hypothesized to contain the immune-functioning TLRs in mosquitoes. Our data indicate that this gene family has a larger gene repertoire than previously described with clade-specific expansions within distinct anopheline lineages. To probe this pathway, we utilized a fungal infection model using the entomopathogen, *Beauveria bassiana*. We show dose-dependent modulation of *B. bassiana* within

the malaria vector, *Anopheles gambiae*. The cuticle of 2-4 day old females was exposed by direct contact to an oil suspension of spores [ $1.24 \times 10^9$  spores/mL] applied to filter paper substrate. Infection with *B. bassiana* decreased median survival of *An. gambiae* by  $10 \pm 1.5$  days compared to controls (Unpaired t-test,  $P=0.003$ ). Quantification of fungal genome equivalents by qPCR revealed logarithmic growth over six days, culminating in a conidial genome count of  $2.3 \times 10^5 \pm 0.6 \times 10^5$  at six days post infection, coinciding with an incidence of high mortality. The course of infection is modulated by the Toll pathway; knockdown of the downstream transcription factor *REL1* and the pathway inhibitor *Cactus* by RNAi show decreased and increased survivorship to fungal infection, respectively. Importantly, these knockdown phenotypes were strongly influenced by dose, with highest fitness gains (using survival as proxy) observed in low dose infections. Together with published data, your findings confirm *B. bassiana* as a natural infection model to probe the role of the Toll pathway in mosquito humoral immunity. Importantly, these data suggest that increased Toll pathway signaling may provide a resistance mechanism to *B. bassiana* infections dependent on dose and coverage if used as a mosquito bioinsecticide. Partial funding provided by the National Institutes of Health through R01-AI095842.

## 1468

### PYRETHROIDS MAINTAIN REPELLENT EFFECT ON Aedes Aegypti MOSQUITOS WITH KNOWN RESISTANCE

Natalie M. Bowman<sup>1</sup>, Kristen Akialis<sup>1</sup>, Grayson Cave<sup>2</sup>, Charles Apperson<sup>2</sup>, Steven R. Meshnick<sup>1</sup>

<sup>1</sup>University of North Carolina Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>North Carolina State University, Raleigh, NC, United States

Pyrethroid-treated clothing is commonly worn for protection against mosquitoes; pyrethroids are both insecticides and repellents. Pyrethroid resistance has become increasingly common in *Aedes aegypti*, the vector of dengue, Zika, and other arboviruses. Specific mutations to the voltage-gated sodium channel lead to knockdown resistance (kdr), but it is not clear whether they are associated with alterations in repellency. We measured mutations in kdr in *Aedes aegypti* from New Orleans, LA (pyrethroid-sensitive) and San Juan, PR (resistant) and measured both lethality and repellency for clothing impregnated with pyrethroids using arm-in-cage tests. PCR and Sanger sequencing were used to detect mutations at loci known to be associated with pyrethroid resistance (1016 and 1534). 7/19 New Orleans mosquitos and 10/13 San Juan mosquitos had 1016 kdr mutations (OR 5.71; 95%CI 0.95, 41.23); 9/19 New Orleans mosquitos and 6/9 San Juan mosquitos had 1534 kdr mutations (OR 2.22; 95%CI 0.33, 17.45). Arm-in-cage trials of 100 sensitive or resistant *Aedes aegypti* females were performed for 10 minutes to bare arm or an arm clothed in military camouflage impregnated with deltamethrin, permethrin, or etofenprox. Trials were repeated 4-5 times on different days. Number of landings, number of blood meals, and immediate and 24-hour mortality were recorded. Mortality was extremely low in all trials. Compared to bare arm, mosquitos demonstrated a 16%-65% reduction in landings on pyrethroid-treated cloth. Etofenprox had less repellent activity than deltamethrin and permethrin. Resistant (San Juan) mosquitos showed a greater reduction in landings on etofenprox and permethrin than wild-type mosquitos. Our data show that kdr mutations are associated with pyrethroid resistance but are likely not the only contributors. Pyrethroids appear to maintain repellent effect against resistant mosquitos. This suggests that even in places where pyrethroid resistance is widespread, these insecticides still have a role for use as repellents on clothing.

## 1469

### IMPLICATIONS OF REDUCED SUSCEPTIBILITY TO INSECTICIDES IN MALARIA VECTORS IN AN AREA WITH HIGH ITN COVERAGE

Lucy Abel<sup>1</sup>, Rebecca Nanjala Wafula<sup>2</sup>, Daniel Evans<sup>2</sup>, Steve M. Taylor<sup>2</sup>, Wendy Prudhomme O'Meara<sup>2</sup>, Andrew A. Obala<sup>3</sup>

<sup>1</sup>Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, <sup>2</sup>Duke University, Durham, NC, United States, <sup>3</sup>Moi University College of Health Sciences, Eldoret, Kenya

In sub-Saharan Africa, insecticide treated net (ITN) coverage has greatly improved in the last 10 years. Despite this, Bungoma East Sub County in Western Kenya has recorded little reduction in malaria prevalence. Biological factors in the mosquito vectors, especially shift in biting times and increased tolerance towards the insecticides used in malaria control may contribute to persistent malaria burden. The present study was designed to determine the susceptibility status of malaria vectors and ITN coverage related to ability of vectors to obtain a blood meal in Bungoma East sub-county. Larvae were sampled from breeding sites in 4 villages and transferred to an insectary. Mosquito larvae were raised in their own breeding water and fed with yeast. 3-5 day-old adult female anopheles were then exposed to 0.05% deltamethrin and 0.75% permethrin according to the standard WHO test procedure. In addition, WHO cone assays were conducted on pieces cut from new Olyset long-lasting ITN. In order to assess the ITN usage and coverage, households around the sampled villages were asked about bednet ownership. In addition, the study enrolled 9 households and measured ITN use longitudinally. Indoor resting adult mosquitoes were collected from these homes, sorted by genus, and graded according to abdominal status. The 1-hr knocked-down rate varied considerably between the 4 villages, from 50-90% for permethrin and 60-90% for deltamethrin. 24-hour mortality in all villages was less than 90% threshold set by the WHO. Permethrin mortality was lowest in K village (66%) and highest in M village (88%), whereas deltamethrin mortality was lowest in L (36%) and highest in J (88%). We observed very low mortality in WHO cone assays (0-16.7%). The longitudinal study showed that 100% of sleeping spaces had an ITN and daily individual usage exceeded 97% over 10 weeks. Despite this, almost 50% of the total female mosquitoes collected indoors were blood fed or half gravid. When compared to the low levels of insecticide susceptibility, particularly in the cone assays, we cannot rule out an effect of resistance on vector feeding in our study area.

## 1470

### INVESTIGATING ENDECTOCIDE USE IN LIVESTOCK AS A TOOL TO HELP ELIMINATE RESIDUAL MALARIA IN CENTRAL AMERICA

Jefferson A. Vaughan, Staci M. Dreyer, Kelsey J. Morin  
University of North Dakota, Grand Forks, ND, United States

In Central America, malaria has been reduced using indoor insecticide spraying and insecticide-treated bed nets. But these tactics may not eradicate malaria because they rely on certain behavioral traits of the *Anopheles* vector - e.g., entering houses at night to feed and rest. Much of the malaria transmission in Central America occurs outdoors by *Anopheles* species that are as likely to feed on non-humans as humans (=zoophagic). To address this issue, additional tactics need to target these behaviors. Livestock management may hold the key. Our project examines the potential of endectocides to help reduce zoophagic *Anopheles* populations and eliminate residual transmission of malaria in Central America. Endectocides are chemicals widely used in the livestock industry to control intestinal nematodes and ticks. The most widely-used endectocide, ivermectin, has been shown to reduce the survival and fecundity of several *Anopheles* species when ingested in a bloodmeal. Ivermectin is increasingly important for vector control in Africa. We compared the dose-responses to ivermectin between

the Central American vector, *A. (Nyssorynchus) albimanus*, and the Asian vector, *A. (Cellia) stephensi*. Toxicity of ingested ivermectin in *A. albimanus* (oral IC-50=1,349 mg/ml) was significantly less than in *A. stephensi* (oral IC-50=11 mg/ml) and far exceeded the normal range of ivermectin plasma concentration typically found in treated cattle (20-50 ng/ml). Ivermectin was 10x more toxic when injected into the thorax of *A. albimanus* (parenteral IC-50=100 ng/ml), but was still less toxic than when injected into *A. stephensi* (parenteral IC-50=16 ng/ml). This suggests that ivermectin is not readily absorbed across the gut in *A. albimanus*, and that the molecular targets of ivermectin (i.e., glutamate-gated chloride channels) in *A. albimanus* are more resistant to the effects of ivermectin than are those in *A. stephensi*. Another related endectocide, abamectin, proved much more toxic to *A. albimanus* (oral IC-50=107 ng/ml) than ivermectin. Thus, abamectin may be a better choice of endectocide to reduce zoophagic vector populations in Central America.

## 1471

### INSECTICIDE RESISTANCE IN JAMAICAN *Aedes aegypti*

Sheena Francis<sup>1</sup>, Karla Saavedra-Rodriguez<sup>2</sup>, Rushika Perera<sup>2</sup>, Mark Paine<sup>3</sup>, William Black IV<sup>2</sup>, Rupika Delgoda<sup>1</sup>

<sup>1</sup>Natural Products Institute, University of the West Indies, Kingston, Jamaica, <sup>2</sup>Arthropod-borne and Infectious Diseases Laboratory, Department of Microbiology, Immunology and Pathology, Fort Collins, CO, United States, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

For the past thirty years, Jamaica has been using the insecticide malathion in its mosquito control programme in an effort to minimize the spread of dengue. Recently, the introduction of the Zika and chikungunya viruses prompted the switch from malathion to a permethrin-based insecticide. Resistance to insecticide has been identified as an impediment to successful vector control programs world-wide, as such we undertook to investigate the status of resistance in the most populous parish of Jamaica. We report for the first time, metabolic and target site to permethrin- and malathion-resistance in *Aedes aegypti* from St. Andrew, Jamaica. The Center for Disease Control bioassay revealed that Jamaican *Ae. aegypti* collected from five sites in the parish of St. Andrew were resistant to permethrin (15 µg/bottle). 100 - 92% of the mosquitoes survived up to 120 minutes of contact. Surprisingly, contact with malathion (50 µg/bottle) revealed 57 - 87% survival after 15 minutes, which decreased to 5 - 16% after 30 minutes. The standard susceptible New Orleans (NO) strain exhibited 0% survival within 15 minutes contact with either permethrin or malathion. The activities of enzymes, the mixed function oxidases and *p*-nitro phenyl-acetate esterases, commonly over-expressed in insecticide resistant mosquitoes, were significantly greater in most Jamaican populations in comparison to the NO strain, however, the activities of glutathione-S-transferase, acetylcholinesterase,  $\alpha$ -esterase and  $\beta$ -esterase were relatively equal to- or lower than that of the control strain. Mutations in the voltage dependent sodium channel gene, which are usually observed in permethrin resistant *Aedes*, revealed that phenylalanine to cysteine substitution (Cys1534) was fixed in all Jamaican *Ae. aegypti* populations, while the valine to isoleucine mutation (Ile1016) was 56% heterozygotes and 33% homozygotes. The results show that *Aedes aegypti* from St. Andrew Jamaica are resistant to permethrin with variations in the mode of mechanism, and possibly developing resistance to malathion. Such findings will be useful for developing an effective vector control program in Jamaica.

## 1472

### OUTCOMES OF A SURVEY OF AGRICULTURAL INSECTICIDE USE PRACTICES IN A MALARIA ENDEMIC SETTING IN RURAL COTE D'IVOIRE

Justin Mcbeath<sup>1</sup>, Sarah de Souza<sup>2</sup>

<sup>1</sup>Bayer, Monheim am Rhein, Germany, <sup>2</sup>Bayer, Abidjan, Côte D'Ivoire

At a time when insecticide resistance threatens the gains made in the fight against malaria and facing a limited array of available vector control tools; the introduction of new insecticide modes of action is crucially important. Certain repurposed agricultural compounds are already under evaluation within the WHOPES-PQ evaluation scheme for use in IRS and LLINs and thus there is some promise of respite on the selection pressure to existing chemistry. However there is also much debate about the role agricultural insecticide usage plays in the selection of resistance in malaria vectors and as these new repurposed agricultural compounds are being developed it is important to understand the environment into which they will be introduced - most notably the degree to which those families of compounds are already used in agriculture in malaria endemic areas and what propensity that might convey to any reduced susceptibility in a given mosquito population. Neonicotinoids are one such family of repurposed agricultural insecticides which are being developed for IRS application; neonicotinoids are also one of the most widely used insecticide classes in agriculture. There is little sharing of knowledge between the agricultural sector and the public health sector in terms of insecticide usage in many (most) malaria endemic countries. Previous studies have collated circumstantial data around insecticide usage based on either the brands stocked within distribution outlets or on registrations of insecticides in countries. This does not take into account actual practice. This paper reports on results of surveys carried out with farmers involved in production of the main crops of cocoa, cotton, vegetables and rice in 11 districts in Cote D'Ivoire. It addresses some of the challenges of previous studies by engaging direct surveys with farmers - reflecting actual usage patterns. It reveals that neonicotinoids are used quite commonly in certain cropping systems. The implications of these results, in terms of next steps and considerations for introduction of repurposed agricultural compounds, is discussed.

### ANOPHELES GAMBIAE S.L. INSECTICIDE RESISTANCE OF IN KINSHASA, IDJWI ISLAND (SUD KIVU), LUBUMBASHI (HAUT KATANGA) AND KWILU-NGONGO SUGARCANE PLANTATIONS (KONGO CENTRAL) IN DEMOCRATIC REPUBLIC OF THE CONGO

Thierry L. Bobanga<sup>1</sup>, Solange Umesumbu<sup>2</sup>, Mitterrand Moyo<sup>1</sup>, Patrick Mamona<sup>1</sup>, Cedric Vulu<sup>1</sup>, Jean Louis Bahizire<sup>3</sup>

<sup>1</sup>University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>National Malaria Control program, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Centre de Recherche de Lwiro, Lwiro, Democratic Republic of the Congo

Malaria is a major public health problem with serious consequences for the economy of a post-conflict country. Long lasting impregnated nets (LLINs) is the principal vector control intervention in Democratic Republic of Congo (DRC). For almost 5 years, million nets were distributed. However, knowledge of insecticide resistance level in *Anopheles gambiae s.l.*, the main malaria vector, is limited. Insecticide resistance is recorded throughout the world in many malaria vectors populations such as *Anopheles gambiae*. As current control methods against malaria currently depend on LLINs and vector resistance The study objective was to characterize insecticide resistance in five sites. Wild *Anopheles gambiae s.l.* mosquitoes were collected, reared to adults and tested with different insecticides for their susceptibility using the WHO standard protocol under optimum conditions Insecticides tested included pyrethroids (0.05% deltamethrin and 0.75% permethrin), organochlorines (4%

DDT) and carbamates (0.1% bendiocarb). In addition the susceptibility of populations of *An.gambiae* from deltamethrin and permethrin resistance sites were tested with after pre exposure with PBO during 1 hour to assess the involvement of P450 metabolic mechanisms. Resistance or suspected resistance was observed in all visited sites specifically on pyrethroids (permethrin and deltamethrin). This resistance was very high in Kwilu-Ngongo (31% - 51%) and Kimpese (33,7% - 53,%) a sugarcane plantation region. Carbamate remains susceptible in all sites tested. Resistance to DDT was observed in all sites (11,5-33%) Synergists (PBO) were able to restore efficacy of deltamethrin or permethrin in different sites that suggest metabolic mechanisms (P450s) are partially or fully involved in the observed resistance. In conclusion, further analysis should be done on *Anopheles* of different sites to obtain more information. Insecticide resistance is an emerging problem in DRC. The susceptibility of malaria vectors to insecticide must be considered in the choice of vector control tools such as LLIN or IRS.

## 1474

### METHANOL KILLS *ANOPHELES COLUZZII* MOSQUITOES DURING IN VITRO FEEDING EXPERIMENTS

**Fatoumata I. Ballo**, Aminatou Kone, Ali Kodio, Sekou Koumare, Diagassan Doumbia, Souleymane Dama, Dinkorma Ouologuem, Bakary Fofana, Mamadou Tekete, Adama Dao, Mamadou B. Coulibaly, Ogobara K. Doumbo, Abdoulaye Djimde

*University of Science and Technologies of Bamako, Bamako, Mali*

Our previous experiments suggested that sulfadoxine fed to laboratory reared *Anopheles stephensi* mosquitoes during standard membrane feeding assays had a significant lethal effect of these malaria vectors. In the present study we attempted to replicate these experiments with field *Anopheles coluzzii* mosquitoes in Mali. Sulfadoxine was dissolved in methanol. The final tested concentrations of sulfadoxine were equivalent to *in vivo* plasma concentration reached on days 1, 3, 7 and 14 after a single oral dose of sulfadoxine-pyrimethamine. Five hundred anopheles, were fed through an artificial membrane with a solution containing the respective concentrations of sulfadoxine dissolved in methanol. As Control No1 five hundred mosquitoes were fed on blood without neither sulfadoxine nor methanol. As control No2, five hundred mosquitoes were fed on blood without sulfadoxine but containing methanol. Cumulative mosquitoes' mortality was assessed by 72h after the feeding experiments. Seventy-two hours after feeding with day 1 (65.9 ug/ml), day 3 (54.9 ug/ml), day 7 (30.4ug/ml) and day14 (12.8ug/ml) concentrations of sulfadoxine the observed mosquitoes' mortality compared to the control No1 (blood without methanol) were 70.5% vs. 2.1% ( $p < 10^{-3}$ ); 14.7% vs. 3.4% ( $p < 10^{-3}$ ); 5.3% vs. 5.7% ( $p > 0.05$ ), and 3.6 vs. 2.5% ( $p > 0.05$ ). However, when compared with the control No2 (blood with methanol), observed mosquitoes' mortality with day 1 and day 3 concentrations of sulfadoxine were 34.4% versus 39.4% ( $p > 0.05$ ) and 12.7% vs. 13.8%, ( $p > 0.05$ ), respectively. This study indicates that mosquitoes' mortality was due to a toxic effect of the methanol used to dissolve sulfadoxine rather than to an effect by the antimalarial drug itself. We show that methanol kills *Anopheles coluzzii* mosquitoes.

### INSECTICIDE RESISTANCE AND MECHANISMS IN *AEDES* ARBOVIRAL VECTORS: A WORLDWIDE SYNTHESIS

**David Weetman**<sup>1</sup>, Catherine Moyes<sup>2</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom,

<sup>2</sup>University of Oxford, Oxford, United Kingdom

*Aedes aegypti* and *Ae. albopictus* are major vectors of multiple important arboviruses and control using insecticides is a critical component of disease management and prevention. As part of a WHO-TDR commission to the Worldwide Insecticide resistance Network, we review all accessible datasets to investigate the geographical distribution of *Aedes* insecticide resistance and underlying mechanisms. Resistance to all four main classes

of neurotoxic insecticide has been detected in the Americas, Africa and Asia. Interacting target site mutations are especially important in *Ae. aegypti* and show evidence of geographical patterning, whilst major resistance-linked detoxification gene overexpression appears more widespread in both species. Resistance-linked metabolic genes are highlighted from the meta-analysis to prioritise candidates for functional assessment and diagnostic development, key steps in understanding their relative impact on phenotypes relative to target site mutations. Estimating insecticide resistance in unsampled locations is currently hampered by a lack of standardisation and diagnostic doses, but could be greatly assisted by calibration and predictive application of existing DNA diagnostics for resistance. Widespread resistance calls for the careful use of existing formulations and implementation of insecticides with alternate modes of action, as part of well-planned resistance management programmes.

### EXON-ENRICHED LIBRARIES OF DELTAMETHRIN RESISTANT *AEDES AEGYPTI* REVEAL STRONG POSITIVE SELECTION AT THE VOLTAGE GATED SODIUM CHANNEL

**Karla L. Saavedra-Rodriguez**<sup>1</sup>, Corey L. Campbell<sup>1</sup>, Audrey Lenhart<sup>2</sup>, Saul Lozano Fuentes<sup>3</sup>, Julian Garcia Rejon<sup>4</sup>, Patricia Penilla<sup>5</sup>, William C. Black IV<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Centers for Disease Control and Prevention, Fort Collins, CO, United States, <sup>4</sup>Universidad Autonoma de Yucatan, Merida, Mexico, <sup>5</sup>Centro Regional de Investigaciones en Salud Publica, Tapachula, Mexico

Resurgence of pyrethroid resistance in *Aedes aegypti* mosquito populations threatens our ability to control several arbovirus diseases, including dengue, Zika and chikungunya. Mechanisms of pyrethroid resistance involve knockdown resistance (kdr) and increased metabolism by multifunction oxidases. Two kdr-associated mutations at the pyrethroid target site, the voltage gated sodium channel gene (*vgsc*) rapidly increased across mosquito populations in Mexico as a result of continuous permethrin applications from 1999 to 2010. Currently, alternative pyrethroids are used in mosquito control campaigns, including deltamethrin (pyrethroid type 2). In this study, we identified replacement coding polymorphisms associated with deltamethrin resistance in *Ae. aegypti*, using an exome-targeting sequencing approach. Mosquito females from Yucatan México were exposed to 3 µg deltamethrin in a bottle bioassay during one hour. DNA from alive and dead mosquitoes was pooled to build duplicate high throughput sequencing (HTS) libraries. A total of 7,392 replacement substitution SNPs were significantly different between the resistant and susceptible mosquitoes. We identified a cluster of SNPs with high allelic differentiation in chromosome 3. The Phe1,534Cys, Val1,016Ile and two novel replacements at *vgsc* were strongly associated with deltamethrin resistance. A cluster of replacement SNPs near *vgsc*, corresponding to genes coding for a phosphatase, RNA binding, trypsins and metalloproteinases were identified in this region. An analysis of heterozygosity in the resistant relative to the susceptible mosquitoes suggests that nearby gene-replacements have swept by positive selection of *vgsc* resistant haplotypes.

## 1477

### NOOTKATONE: A NATURALLY OCCURRING, NEXT-GENERATION PEST MANAGEMENT STRATEGY

**Kim Greenbaum**

*Evolva Inc., Larkspur, CA, United States*

Thanks in large part to the global outbreak of Zika virus, gaps in pest management are once again drawing attention from consumers and Public Health experts alike. Many of these concerns are once again focused upon growing insecticide resistance, community compliance, gaps in public engagement and education, and environmental impacts. For years, the most ubiquitous and cost-effective pest management

strategies have been built around legacy repel-and-kill products for biting pests. One of the key challenges to this construct is that the all-natural pest control agents that consumers and the media view most favourably, produce limited results, while the petrochemical-based synthetic agents that these same constituencies often mistrust, produce tangible results, albeit at the expense of target-vector resistance. The naturally-occurring sesquiterpene nootkatone carves a path between these two legacy constructs. This familiar, pleasant-smelling citrus fragrance can be extracted in minute quantities from the skin of grapefruit or from the bark of the Alaska Yellow Cedar tree (*also known as the Nootka cypress*). The challenge is that an estimated 400,000 grapefruits are needed to produce a single kilogram of nootkatone; and extraction from tree bark is equally unsustainable and economically problematic. The Swiss-American company Evolva has demonstrated that nootkatone can be produced on an industrial scale from biotechnology and yeast fermentation, using essentially the same production platform used to brew beer or make wine. Working closely with the CDC and others, Evolva has been compiling data for EPA registration (and other geographies) that also demonstrates the broad spectrum activity of nootkatone against a range of biting pests (including resistant vectors) such as the mosquitoes that transmit diseases like Zika, chikungunya, and Dengue fever, and the black-legged tick that transmits Lyme disease.

## 1478

### IMPACT OF HOLE SIZE AND LOCATION AND INTERACTION WITH INSECTICIDE CONCENTRATION ON THE PERSONAL AND COMMUNITY PROTECTION PROVIDED BY BEDNETS AGAINST PYRETHROID SUSCEPTIBLE, AND RESISTANT *ANOPHELES GAMBIAE* AND *ARABIENSIS*

Sarah J. Moore<sup>1</sup>, Dennis J. Massue<sup>2</sup>, Olivier J. Briët<sup>2</sup>

<sup>1</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>2</sup>Ifakara Health Institute, Ifakara, United Republic of Tanzania

Data on mosquito net durability in the field in terms of physical integrity (holes) and insecticide content is only useful if we can understand how this affects the ability of these nets to protect against transmission of vector borne diseases. In an experiment in Tanzania, nets were treated with a series of concentrations of the insecticide deltamethrin (0, 5, 15, 25 and 55mg/m<sup>2</sup>) and deliberately torn, either in the top or side panels, over a range of total hole surface area (0-5800cm<sup>2</sup>) to reflect the range of net integrity and insecticidal content observed in a nationwide longitudinal study in Tanzania. Whole nets in each category were tested in an ambient chamber to measure the protective efficacy to people resting underneath them overnight with released *Anopheles gambiae* s.s. susceptible to pyrethroids, low resistant (80% mortality with deltamethrin in standard WHO susceptibility tests) and high resistant (20% mortality) *An. arabiensis*. The relative importance of hole size, hole location, and insecticidal content of nets for mosquito entry in resistant and susceptible mosquitoes is presented, as well as the impact on personal and community protection through the use of a mathematical malaria transmission model. Early data demonstrate a linear relationship between pyrethroid resistance and feeding success as well as mortality, and also a strong preference for entry through holes in the roof of the nets. We present a modified method for measuring the quality of nets in the field by teams performing routine surveys.

## 1479

### DIFFERENTIAL TRANSCRIPTOMIC RESPONSES ASSOCIATED WITH DENV EIP IN *Aedes aegypti*

Cassandra Koh<sup>1</sup>, Scott L. Allen<sup>2</sup>, Rosemarie I. Herbert<sup>1</sup>, Elizabeth A. McGraw<sup>1</sup>, Stephen F. Chenoweth<sup>2</sup>

<sup>1</sup>Monash University, Clayton, Vic, Australia, <sup>2</sup>The University of Queensland, Brisbane, Australia

The extrinsic incubation period (EIP) is an important determinant of vectorial capacity. In *Aedes aegypti* mosquitoes, the EIP of dengue virus has been shown to be heritable. EIP is also genetically correlated with decreased lifespan, suggesting negative fitness consequences are associated with rapid body infection. This suggests that evolutionary pressures may limit the persistence of mosquitoes with short EIP in a population. To investigate whether EIP trait can be altered by selective breeding, we created 38 families with a half-sib breeding design, phenotyped them for EIP and selected the extremes for interbreeding. We found that despite selection for short EIP lengths, the trait shifted toward longer EIP lengths within just one generation. Selection for long EIP led to no change in phenotype. To understand the mechanisms driving the evolutionary pressures around EIP, we then performed transcriptome sequencing on mosquitoes characterised for their EIP phenotypes (6, 8, 10, or 12 days post-infection) and studied their transcriptomic responses to dengue infection. Functional clustering analysis performed on mosquitoes with the extreme EIPs of 6 and 12 DPI revealed very distinct biological processes. Mosquitoes with short EIP exhibited higher rates of transcription for a range of genes encoding structural components of the ribosome. Given viral dependence on host ribosomal machinery, these changes may enhance the rate of viral replication and spread. The evidence of reduced fitness for short EIP mosquitoes may potentially be explained by the extra costs associated with their enhanced protein synthesis activities. The profile of long EIP mosquitoes featured an increase in protein degradation, a process shown to be associated with flaviviral replication in mammalian cells. Our results suggest multiple physiological responses of mosquitoes to virus that may determine the balance between viral success and host fitness. The specific genes identified may underpin mosquito transmission of virus and hence warrant further functional study.

## 1480

### TARGETED DELIVERY OF CRISPR/CAS9 INTO THE ADULT MOSQUITO GERMLINE

Duverney Chaverra-Rodriguez, Vanessa M. Macias, Grant L. Hughes, Yasutsugu Suzuki, David R. Peterson, Sujit Pujhari, Jason L. Rasgon

Pennsylvania State University, State College, PA, United States

Cas9-mediated gene editing is a powerful technique for addressing research questions in arthropods of medical importance. There is a critical need to develop methods for Cas9 delivery that are simple, accessible for many researchers, and generally compatible for a large variety of arthropod species. Here, we propose to deliver Cas9 into the mosquito germline via hemolymph injections into adult females. We generated a peptide ligand (P2C) with highly specific tropism for the female mosquito germline. When fused to Cas9, the fusion protein is internalized into oocytes after injection into the hemolymph of *Ae. aegypti* and *An. stephensi* mosquitoes during oocyte development. The optimization of Cas9 delivery via maternal injections will benefit researchers who wish to perform genome editing in mosquitoes and other disease vectors.

## GENETIC ANALYSIS OF MOSQUITO ITCH

Hillery C. Metz

Princeton University, Princeton, NJ, United States

The mosquito, *Aedes aegypti*, can spread devastating viruses when it injects saliva into human skin while blood-feeding. Mosquito saliva is a pharmacopeia of biologically active molecules that not only facilitate the spread of disease, but also affect skin physiology and induce swelling and itching. Yet few individual salivary molecules have a known function. Here, we take advantage of natural variation between two subspecies (or forms) of *Aedes aegypti* to understand the role of mosquito saliva in generating itch in humans. The forest form feeds mainly on non-human animals, while the recently-evolved domestic subspecies is anthropophilic and specializes in biting humans. Interestingly, we recently discovered that domestic mosquito bites are judged by humans to be less itchy and painful than forest bites in side-by-side comparisons. Additionally, humans are slower to detect a biting domestic mosquito. We hypothesize that milder bites are an adaptation that helps domestic mosquitoes avoid detection when they blood-feed on human hosts. These natural differences in bite severity are striking and present a unique opportunity to capitalize on evolutionary divergence to uncover the molecular basis of mosquito itch. Because reactions to mosquito bites are known to have an immunologic component, the causal agents in mosquito saliva may act on the human immune system, thus having implications for the spread of disease. We are taking a transcriptomic and proteomic approach to search for the molecular basis of differences in saliva between these two mosquitoes. Additionally, we are using QTL mapping to identify mosquito *loci* that mediate human itch. Our results promise to shed light on how mosquitoes have evolved to overcome host defenses and may provide new information helpful in fighting mosquito-borne illness.

## STRUCTURAL VARIANT DETECTION BY READ-CLOUD SEQUENCING IN THE ZIKA VECTOR *Aedes aegypti*

Seth N. Redmond<sup>1</sup>, Maria V. Sharakhova<sup>2</sup>, Igor V. Sharakhov<sup>2</sup>, Zhijian Tu<sup>2</sup>, Carolyn S. McBride<sup>3</sup>, Jeffrey R. Powell<sup>4</sup>, Bruce Birren<sup>1</sup>, Daniel E. Neafsey<sup>1</sup>

<sup>1</sup>Broad Institute, Cambridge, MA, United States, <sup>2</sup>Virginia Tech, Blacksburg, VA, United States, <sup>3</sup>Princeton University, Princeton, NJ, United States, <sup>4</sup>Yale University, New Haven, CT, United States

The recent re-emergence of Zika virus has focused attention on the arbovirus vector *Aedes aegypti*, a mosquito which is also the transmits dengue virus, yellow fever and chikungunya. Yet compared to the better-studied *Anopheles* mosquitoes that transmit malaria, population genetics studies in *Aedes aegypti* have been hampered by a lack of genome-scale resources. A large and repetitive genome, high diversity, and potentially extensive structural variation combine to hamper genomic analyses, and until this year had prevented even the full assembly of the genome. Structural variants themselves have proven to be key features for studying dipteran population structure. Across the full range of the order, large chromosomal inversions exist both as clearly identifiable markers distinguishing sub-populations, as well as potential sites of divergence that could underlie speciation or local adaptation. Although the intractable genome of *Aedes* has prevented any such survey being carried out in the past, characterising structural variation will be an important asset for mapping insecticide resistance markers, examining population structure, or identifying suitable targets for gene-drive systems, among other approaches. Building on the work performed by the *Aedes* Genome Working Group, we have performed the first large-scale investigation of structural variation in *Aedes aegypti*. Using linked-read (10X) technology and a variety of algorithmic approaches we have identified segregating inversions in a world-wide sample set along with a large number of duplications and deletions. By studying SVs within mosquito colonies

sampled from across the globe, this work will provide the foundation to subsequent studies of *Aedes* population structure and the potential for disease transmission by this vector.

## WHOLE GENOME SEQUENCING OF THE ANOPHELES FUNESTUS SUBGROUP REVEALS ANCIENT INTROGRESSION

Scott T. Small<sup>1</sup>, Neil F. Lobo<sup>1</sup>, Chadwick Sikaala<sup>2</sup>, Lizette L. Koekemoer<sup>3</sup>, Nora J. Besansky<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>National Malaria Control Program, Zambia, Zambia, <sup>3</sup>University of Witwatersrand, Johannesburg, South Africa

*Anopheles funestus* is one of the four most important and widespread vectors of human malaria in tropical Africa, but unlike *An. gambiae*, it remains understudied. Whole genome sequencing of *An. gambiae* sibling species yielded important insights into genomic changes that contribute to making it a major malaria vector. A similar approach applied to the *Funestus* Subgroup, including sequencing both vector and non-vector species, would likely provide further insights into anopheline biology and malaria epidemiology. The current state of genomic data on *An. funestus* consists of a single reference genome. There is no genomic information on other *Funestus* Subgroup members, and no whole genome data from wild-caught species necessary to characterize genetic diversity. The *Funestus* Subgroup consists of six recognized species: *An. funestus*, *An. funestus-like*, *An. parensis*, *An. vaneedeni*, *An. aruni*, *An. longipalpus* C. and *An. confusus*. The potential contribution of these species to malaria transmission is uncertain as only *An. funestus* has been implicated as a major malaria vector. The first step to understanding species diversity is to reconstruct the evolutionary relationship between species using phylogenetics. A phylogenomic approach leverages information from the entire genome, but requires genomic data on all subgroup members. To this end, we assembled 20 *de novo* genomes by implementing a novel pipeline for assembling highly heterozygous genomes. Our preliminary results demonstrate a high discordance among the mitochondrial and nuclear genomes. We hypothesize that historical introgression among the *Funestus* Subgroup has led to reciprocal mitochondrial capture events. Future analysis is continuing to uncover the extent of the introgression between Subgroup species and reconstruct a likely species topology. The continued study of anopheline species groups that contain both vector and non-vector members will allow us to better characterize malaria vectors at a genomic level and therefore more effectively identify and eliminate potential vectors from malaria endemic areas.

## SPATIO-TEMPORAL GENETIC STRUCTURE OF ANOPHELES GAMBIAE IN THE NORTHWESTERN LAKE VICTORIA BASIN, UGANDA: IMPLICATIONS FOR GENETIC CONTROL TRIALS IN MALARIA ENDEMIC REGIONS

Martin Lukindu<sup>1</sup>, Christina M. Bergey<sup>1</sup>, Rachel M. Wiltshire<sup>1</sup>, Jonathan K. Kayondo<sup>2</sup>, Nora J. Besansky<sup>1</sup>

<sup>1</sup>Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Department of Entomology, Uganda Virus Research Institute (UVRI), Entebbe, Uganda

It is anticipated that genetic control approaches will complement existing malaria vector management approaches in the near future. However, before outright deployment of such tools, prior field tests in isolated sites in endemic areas are recommended. We assessed the level of spatial and temporal genetic differentiation between island and mainland *Anopheles gambiae* populations in the Northwestern Lake Victoria basin (LVB) in Uganda, using whole genome sequences (WGS) of samples collected in 2015 and the ND5 region of the mitochondrial DNA (mtDNA) for these and samples from 2002 and 2012. Most pairwise *F*<sub>ST</sub> values between mainland and island *An. gambiae* populations were low but significant (Average *F*<sub>ST</sub>=0.07 and 0.02 for mtDNA and WGS respectively) while

most mainland-mainland pairwise FST values were much lower and not significant (FST=0.007 and 0 for mtDNA and WGS respectively). Temporal variation in genetic structure was not significant over the three sampling periods. The differentiation observed on this and other island *An. gambiae* contrasts with shallow structure seen across the continent in the species, reflective of the species' recent history of population expansion, extremely large population sizes, and remarkably high genetic diversity. These conditions depress FST values even between mainland samples separated by 7,000 km, but our study and previous work in the LVB suggests that under-appreciated structure may exist on lacustrine islands. A combination of a water barrier presented by L. Victoria and/or other local adaptive factors (see also Bergey et al., abstract) could account for the observed genetic substructure in the LVB making these islands suitable sites for future genetic control trials against malaria.

NB: \* Both ML and CMB contributed equally

### WHY INDELS MATTER: INSERTION-DELETION VARIANTS IN THE ANOPHELES GAMBIAE COMPLEX

**R. Rebecca Love**<sup>1</sup>, Alistair Miles<sup>2</sup>, Nick Harding<sup>2</sup>, Chris Clarkson<sup>3</sup>, Dominic Kwiatkowski<sup>3</sup>, The Anopheles gambiae 1000 Genomes Project<sup>4</sup>, Nora J. Besansky<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>University of Oxford, Oxford, United Kingdom, <sup>3</sup>Wellcome Trust Sanger Institute, Hinxton, United Kingdom, <sup>4</sup>Consortium, Multiple, United Kingdom

Analysis of single nucleotide polymorphisms (SNPs) within vector genomes is now common, but longer insertion-deletion variants (indels) are often ignored. While indels may present more analytical challenges than SNPs, they also have the potential to cause greater disruption to the genome. Research in other species, including humans and *Plasmodium*, has shown that indels are common and important sources of variation. To extend this research to malaria vectors, we used data from phase 1 of the *Anopheles gambiae* 1000 Genomes Project to identify a set of indels segregating within the parents and progeny of a cross between *An. coluzzii* and *An. gambiae*. Exploiting the nature of the cross, we filtered these indels by removing any variants that displayed violations of expected Mendelian segregation. Further quality filtering produced a set of high-confidence indels found in coding regions; as expected, these indels were strongly enriched for length changes in multiples of three. Using field-caught specimens of *An. gambiae*, we confirmed that the vast majority of indels in this high-confidence set also segregate in the wild. The high-confidence coding-region indels overlapped 2,285 genes. Functional enrichment analysis of these genes showed enrichment of genes involved in transcriptional regulation, as well as of genes whose protein product includes a coiled coil motif. Interestingly, a number of the genes overlapped by high-confidence indels are known or believed to have a role in reproduction, including AGAP009002, which interacts with the receptor of 20-hydroxyecdysone; AGAP009368, a component of the mating plug; and AGAP005194, which interacts with the mating plug.

### STRUCTURE OF SELECTED VARIATION IN ANOPHELES GAMBIAE ON LAKE VICTORIA ISLANDS AND IMPLICATIONS FOR GENETIC CONTROL FIELD TRIALS

**Christina M. Bergey**<sup>1</sup>, Martin Lukindu<sup>1</sup>, Rachel M. Wiltshire<sup>1</sup>, Jonathan Kayondo<sup>2</sup>, Nora J. Besansky<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Uganda Virus Research Institute (UVRI), Entebbe, Uganda

Geographically isolated islands have been proposed as sites for initial transgenic mosquito release to test the dynamics of the spread of beneficial introduced transgenes while limiting their movement beyond the study population. However, antecedent studies of population structure and connectivity of potential release sites are necessary to evaluate the success of such field trials, as well as to quantify the risk of escapee

transgenic insects carrying constructs designed to propagate across mosquito populations and country borders. A limited number of such field assessments has been conducted on lacustrine and oceanic islands. In the present study, we sequence the full genomes of 116 *Anopheles gambiae* mosquitoes living near and on islands in Lake Victoria to analyze signatures of selection and explore how beneficial alleles have moved through geographically semi-isolated populations and variable genetic backgrounds. Despite the geographic isolation (see also Lukindu *et al.* abstract), we find that alleles having undergone recent selective sweeps have colonized the islands to different extents, with the migration of the carriers likely aided by human transport. We hypothesize that the islands' differing environments, in both natural and anthropogenic dimensions, may have influenced the timing and intensity of such sweeps. These regions with signatures of selection include *loci* with known roles in insecticide resistance as well as a locus involved in sensory processing, retinal degeneration A. The dynamics of these beneficial alleles can serve as a model for those of a transgenic construct, allowing us to assess the islands' suitability as a potential site for field trials of genetically modified mosquitoes.

### INVESTIGATING THE EFFECTS OF LATITUDE AND TEMPERATURE ON THE LIFE HISTORY TRAITS OF THE MAJOR LATIN AMERICAN MALARIA VECTOR, ANOPHELES DARLINGI

**Virginia M. Chu**<sup>1</sup>, Maria Anice Sallum<sup>2</sup>, Jan E. Conn<sup>3</sup>

<sup>1</sup>SUNY Albany, Albany, NY, United States, <sup>2</sup>Universidade de Sao Paulo, Sao Paulo, Brazil, <sup>3</sup>Wadsworth Center, Albany, NY, United States

Brazil has the second largest burden of malaria in Latin America, with most cases occurring in the Amazonia biome. The primary vector in Brazil is the widespread species *Anopheles darlingi*. Both a conservative and an extreme ecological niche model have predicted an expansion of *An. darlingi* and *Plasmodium falciparum* distribution into southern Brazil by the year 2070. It is unclear whether this invasion will arise from local adaptation of southern populations or from an invasion of northern populations. Laboratory experiments at three fixed temperatures were conducted on *An. darlingi* populations distributed along a latitudinal gradient to test for the presence of a plastic response using a suite of life history traits. Variation in life history traits can have a substantial impact on vectorial capacity. Adult female mosquitoes were collected from replicated localities spanning three latitudes and three biomes in Brazil (Amazonia, Cerrado, Mata Atlântica). Eggs from individual females were reared at 20, 24 and 28°C. Six life history traits were analyzed: larval growth rate, preadult developmental time (hatch to emergence), starved adult life span, adult size, daily survival, and sex ratio. Across all sites in response to temperature, the fastest larval growth rate, fastest preadult development, and the shortest adult life span of both sexes occurred at 28°C. At 24°C all populations had the same survival probability. Mosquitoes from the Mata Atlântica (most southern) biome developed slowest of the three biomes tested at 20 and 28°C. Sex ratio was not affected by biome, latitude or temperature. Despite having the most rapid development, the smallest body size and shortest life span, *An. darlingi* from Amazonia (lowest latitude) had the highest survival to adulthood across all temperatures, likely contributing to its role in malaria transmission. Models of climate change and vector-borne disease distribution must utilize data from multiple populations to increase their accuracy.

### DISTRIBUTION, INFECTION STATUS AND BLOOD-FEEDING BEHAVIOR OF ANOPHELES SPP. MOSQUITOES IN SOUTHERN MALAWI

**Andrew Pike**<sup>1</sup>, Chifundo Kadangwe<sup>2</sup>, Jenna E. Coalson<sup>3</sup>, Lauren M. Cohee<sup>1</sup>, Andy Bauleni<sup>2</sup>, Clarissa Valim<sup>2</sup>, Terrie E. Taylor<sup>4</sup>, Don P. Mathanga<sup>2</sup>, Atupele Kapito-Tembo<sup>2</sup>, Mark L. Wilson<sup>3</sup>, Edward Walker<sup>5</sup>, Miriam K. Laufer<sup>1</sup>, Themba Mzilahowa<sup>4</sup>

<sup>1</sup>University of Maryland, Baltimore, Baltimore, MD, United States, <sup>2</sup>Malaria Alert Center, Blantyre, Malawi, <sup>3</sup>University of Michigan, Ann Arbor, MI, United States, <sup>4</sup>Blantyre Malaria Project, Blantyre, Malawi, <sup>5</sup>Michigan State University, East Lansing, MI, United States

Despite multiple nationwide campaigns that distributed long lasting insecticide treated bed nets, malaria infection and disease remain a large problem in Malawi. Although malaria transmission occurs year-round, Malawi experiences elevated transmission during the rainy season, typically from November to April. Transmission is highest in rural and humid lowland areas. We collected and analyzed entomological data in relation to human infection at the end of five rainy seasons (2012-2016) and three dry seasons (2013-2015) from cross-sectional studies in southern Malawi. Adult mosquitoes were captured indoors by aspiration during all surveys and by CDC light trap during the last three surveys. The number, species and sex of mosquitoes was determined by visual identification and species was confirmed by PCR. The blood-feeding status was also determined visually, and the blood-meal source was determined for blood-fed mosquitoes by PCR. Finally, presence or absence of sporozoites in the mosquito salivary glands was determined by ELISA. 4,047 mosquitoes were collected, nearly all of which were identified as *Anopheles funestus* s.s. or *An. arabiensis*. More mosquitoes were captured during the rainy than the dry season, and *An. arabiensis* was more common during the dry season while *An. funestus* constituted a greater proportion of collected mosquitoes during the rainy season. Both species fed extensively on humans, with an overall human biting index of 0.96 and the remaining meals coming from cattle or goats. However, overall sporozoite infection levels were low, at 1.4% as measured by CSP ELISA. These patterns are similar to those seen in neighboring countries such as Zambia. Despite the low level of sporozoite infections, the large preference for human biting and the presence of *An. arabiensis* during the dry season allows malaria transmission to continue at these sites.

### ABILITY OF COMMERCIALY AVAILABLE HUMAN RAPID DIAGNOSTIC TESTS (RDTs) TO DETECT DENGUE AND MALARIA IN ARTHROPOD VECTORS

**Kathryne D. Walker**<sup>1</sup>, Tobin Rowland<sup>1</sup>, Emily McDermott<sup>1</sup>, Ying Jin-Clark<sup>1</sup>, Ratawan Ubalee<sup>2</sup>, Amnart Kayha<sup>2</sup>, Waranya Buadok<sup>2</sup>, Vichit Phunkitchar<sup>2</sup>, Jorge Lopez<sup>1</sup>, Silas Davidson<sup>2</sup>, Lindsey Garver<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Malaria and dengue are the two most significant worldwide infectious disease threats; both have global endemicity, cause morbidity and mortality, and are transmitted by mosquito vectors. The primary infection countermeasure against these vector-borne diseases is bite protection including bednets, insect repellent, and permethrin-treated uniforms although user compliance can compromise efficacy. Such bite protection efforts can be strengthened and prioritized if disease agents are detected in the local circulating vectors, verifying an immediate risk. Multiple rapid diagnostic tests (RDTs) are commercially available for detection of malaria parasites (*Plasmodium falciparum* and *Plasmodium vivax*) or dengue virus (DENV) in human blood samples; some of these detect antigens that are also expressed by mosquito-stage parasites and viruses. We hypothesized that clinical RDTs exploiting those antigens would be capable of detecting infection in mosquitoes. To test this, we seeded single infected mosquitoes

in pools of 24 uninfected mosquitoes, mechanically homogenized them in buffer, and applied the homogenate to the RDTs in lieu of a blood sample and three independent analysts read each test. Three DENV RDTs were capable of detecting in-vector virus, with one achieving 100% detection. We downselected this RDT for further assessment of cross-reactivity with other arboviruses and limit of detection. Of three malaria RDTs tested thus far, none detect in-vector *Plasmodium*. In sum, this indicates at surveillance of at least one vector-borne disease can be achieved both in vector collections and in the clinic using the same RDT.

### SOCIOECONOMIC AND LIFESTYLE DRIVERS OF Aedes Aegypti Abundance Across Diverse Urban Landscapes in Los Angeles, California: A Cross-Sectional Study

**Marisa A. Donnelly**<sup>1</sup>, Susanne Kluh<sup>2</sup>, Christopher M. Barker<sup>1</sup>

<sup>1</sup>University of California Davis, Davis, CA, United States, <sup>2</sup>Greater Los Angeles County Vector Control District, Santa Fe Springs, CA, United States

Since the start of the current widespread Zika virus outbreak originating in South America and as of April 2017, 4,886 travel-associated infections and 222 locally-acquired infections have been reported in the continental United States, including > 500 cases of travel-associated infections in California, which is the 3rd highest number among U.S. states. Due to the recent increase in the number of Zika virus-infected travelers returning to areas of the U.S. with the primary Zika virus vector, *Aedes aegypti*, there is an urgent need to understand the genesis of local chains of transmission. Low dengue incidence in the U.S. has been attributed in previous studies to lifestyle factors such as improved housing quality and air-conditioning usage that may limit humans' exposure to *Aedes aegypti* biting. Biting is a function of *Ae. aegypti* abundance and availability of bloodmeal hosts, and in this study, we consider whether socio-economic status and lifestyle factors explain differences in *Ae. aegypti* distribution and abundance in two contrasting neighborhoods in Los Angeles, California. We conducted surveys in randomly selected households and compared relative abundance of *Ae. aegypti* indoors vs. outdoors to determine whether total abundance and endophily can be explained by socio-economic variables that could be mapped at broader scales to guide surveillance and control efforts.

### ROAD-SIDE CATCH BASINS AS SENTINELS FOR WEST NILE VIRUS INFECTED Culex spp. Mosquitoes

**Joseph R. McMillan**<sup>1</sup>, Rebekah Blakney<sup>1</sup>, Andrea Lund<sup>2</sup>, Daniel Mead<sup>3</sup>, Sarah Coker<sup>3</sup>, Donal Bisanzio<sup>4</sup>, William Koval<sup>1</sup>, Uriel Kitron<sup>1</sup>, Gonzalo Vazquez-Prokopec<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Stanford University, Stanford, CA, United States, <sup>3</sup>University of Georgia, Athens, GA, United States, <sup>4</sup>Oxford University, Oxford, United Kingdom

CDC-gravid traps are a standard vector surveillance tool for West Nile virus (WNV) detection in the United States because they can capture a substantial number of gravid (i.e. previously blood fed) mosquitoes. However, the testing of a large number of specimens can be a financial and personnel burden for vector control districts, and trap placement may be limited by the availability of public spaces and permissions from land owners, which can influence the design of virus surveillance programs. In an effort to devise a more targeted and accessible approach to the surveillance of urban arboviruses transmitted by *Culex spp.*, we compared morphological identification success and WNV detection of paired gravid traps and targeted Prokopack aspiration collections inside road-side catch basins in 4 neighborhoods in the City of Atlanta (Georgia, USA) from 2014 to 2016. For each method, all collected mosquitoes were morphologically identified, and specimens were pooled (up to 25 individuals) by species, date, location, and trap type. Pools were tested for WNV through virus isolation, Vec-Tests, and RT-PCR. A total of 8,262 mosquitoes were

collected from weekly aspiration in 47 catch-basins and 55,709 were collected in 775 trap-nights. On average, 69.7% of *Culex spp.* collected from catch basins were successfully identified to species compared to 48.8% from gravid traps. Weekly WNV minimum infection rates (MIR, number infected per 1,000 individuals) ranged from 6.1 to 143.6 for catch basin collections and from 1.3 and 28.9 for gravid trap collections. Though the percentage of positive pools was higher for gravid traps (2.2%) than catch basins (1.2%), weekly MIRs were significantly higher for catch basins than for gravid collections (Wilcoxon Test,  $W=417$ ,  $p<0.01$ ). Total costs of testing mosquitoes in the parks was reduced by 63% when aspirating in catch basins (\$44,000 to \$15,000). Thus, aspirating catch basins may be a cost-effective approach for vector and virus surveillance as the lower number of collected mosquitoes translates into fewer pools that need to be tested without lowering the rate of WNV detection.

## 1493

### DESIGN OF STRATEGIES FOR SURVEILLANCE AND EFFICIENT MANAGEMENT OF *Aedes aegypti*

Manuel O. Espinosa, Marcelo C. Abril

Fundación Mundo Sano, Caba, Argentina

The goal of entomological surveillance is to generate necessary information for the organization of vector control actions in order to prevent, predict and ameliorate the consequences of an epidemiological outbreak, as well as to evaluate the implemented control measures. Due to epidemiological dynamism, characteristic of diseases like dengue, chikungunya and zika, all of them transmitted by *Aedes aegypti* mosquitoes, monitoring of populations of this vector must be performed in a continuous manner, in order to obtain timely information about its distribution, abundance, and local characteristics that modulate its life cycle. Since 2002, Mundo Sano Foundation, implements surveillance and monitoring strategies of *Ae. aegypti* populations in localities affected by seasonal outbreaks of dengue. These strategies are planned and implemented in a continuous manner, generating information on the temporal population dynamic of the vector and its breeding sites, weekly gonadotrophic activity and recognition of persistent infestation areas, as well as the main urban and sociocultural determinants that influence the abundance of the mosquito. All this information permits the detection of associations with environmental variables obtained with remote sensors that can then be modelled due to the availability of temporally consistent data. The management of data is performed through the use of an online platform in a way that the information obtained from larval sampling is digitalized *in situ* and analyzed remotely within 24 hours, constituting an important operational tool that allows the manager to count with precise and timely information for quick decision making and guidance of control actions. In this poster, the main results of the activities developed in an uninterrupted manner during seven years of implementation of the "Program of Surveillance and Control for *Aedes aegypti*" in Tartagal City are presented as well as the impact these actions had on the vector and the incidence of the diseases it transmits.

## 1494

### BIONOMICS OF *Aedes aegypti* IMMEDIATELY PRECEDING THE 2016 DENGUE OUTBREAK IN OUAGADOUGOU, BURKINA FASO

Athanase Badolo<sup>1</sup>, Aboubacar Sombie<sup>1</sup>, Felix Yameogo<sup>1</sup>, Dimitri Wangrawa<sup>1</sup>, Wamdaogo M. Guelbego<sup>2</sup>, Hiroataka Kanuka<sup>3</sup>, Antoine Sanon<sup>1</sup>, N'Falè Sagnon<sup>2</sup>, David Weetman<sup>4</sup>, Philip J. McCall<sup>4</sup>

Ouagadougou, Burkina Faso, <sup>3</sup>Department of Tropical Medicine, The

Jikei School of Medicine, Tokyo, Japan, <sup>4</sup>Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The dengue outbreak in Ouagadougou in late 2016 resulted in 2,600 cases and 21 deaths. As elsewhere, an evidence-based vector control response would have enabled a rapid and more effective impact. We report on a three-month surveillance study of *Aedes spp.* and other mosquito populations in three localities (urban, periurban and rural) in and around Ouagadougou, prior to and overlapping the outbreak. Together with characterisation of insecticide resistance profiles, the data provide an essential contemporary evidence base, fundamental to development of a locally-specific vector control strategy. *Aedes aegypti* and other mosquitoes were collected indoors and outdoors using vacuum aspirators and all potential breeding sites were sampled for immature stages. All *Ae. aegypti* were assessed morphologically to investigate their subspecies status (*i.e.* whether *Ae. a. formosus* or *Ae. a. aegypti*). To assess susceptibility to commonly-used insecticides, standard WHO bioassay tests were performed on larvae and adults. Blood meal origins were identified by PCR and the mechanisms underlying resistance to insecticides investigated using qPCR. *Ae. aegypti* exhibited more outdoor than indoor biting and, although mixed human-animal blood meals were detected, showed a strong preference for human hosts. An increasing gradient of *Ae. aegypti* density was recorded from urban to rural localities, which was also seen in the variation in abundance and diversity of productive breeding sites. Larval stages displayed susceptibility to organophosphates but adults showed high levels of resistance to pyrethroid insecticides, a difference that was at least partly explained by metabolic resistance mechanisms. The results provide much-needed data on *Ae. aegypti* bionomics in Ouagadougou to enable targeting of efforts to prevent or to mount a vector control response to outbreaks of dengue, or other arboviruses transmitted by the same vector, in Burkina Faso.

## 1495

### IMPACTS OF VECTORS ABUNDANCE AND WEATHER ON RISK OF DENGUE AND CHIKUNGUNYA INCIDENCE ACROSS KENYA

Amy R. Krystosik<sup>1</sup>, Cornelius Kiptoo<sup>2</sup>, Elysse Grossi-Soyster<sup>1</sup>, Njenga Ngugi<sup>3</sup>, Peter Siema<sup>4</sup>, Peter Aswani<sup>2</sup>, Joel Mbakaya<sup>2</sup>, Dunstan Mukoko<sup>5</sup>, John Vulule<sup>2</sup>, Uriel Kitron<sup>6</sup>, Charles H. Chuka University, Nairobi/Chuka, Kenya, <sup>4</sup>Ministry of Health, Msambweni,

Kenya, <sup>5</sup>Ministry of Health, Nairobi, Kenya, <sup>6</sup>Emory University, Atlanta, GA,

United States, <sup>7</sup>Case Western Reserve University, Cleveland, OH, United

States, <sup>8</sup>Technical University of Mombasa, Mombasa, Kenya

Dengue (DENV) and chikungunya (CHIKV) viruses are arboviruses of increasing global concern that are transmitted by *Aedes spp.* mosquitoes. Attributing human disease incidence to *Aedes* abundance is rarely possible. We investigated how climate and vector abundance affect risk of DENV and CHIKV seroconversion among healthy and febrile child cohorts in Kenya. Children aged 1-17 were enrolled in an ongoing study beginning in January 2014 at four Kenyan study sites (rural west, rural coast, urban west, urban coast). Surveillance was both active, with children tested every six months to document asymptomatic CHIKV and/or DENV infections via IgG ELISA testing, and passive at local hospitals to capture symptomatic disease via PCR and IgG ELISA testing. Questionnaire data were collected to describe demography, socioeconomic status, and household environment. *Aedes spp.* vectors at all life stages were collected monthly in each site, and immatures were reared to adulthood for identification. Weather variables were collected locally at each site using HOBO loggers. DENV incidence (104/2131) increased with abundance of immature *Aedes spp.* outdoors ( $p<0.001$ ), primarily due to ovitrap sampling, and mature *Aedes spp.* indoors ( $p<0.001$ ), primarily due to prokopack sampling. Incidence also increased during rainfall anomalies ( $p<0.001$ ), but decreased with average temperature, relative humidity, and dew point.

CHIKV seroconversion (28/4983) risk increased with age ( $p < 0.05$ ) and was higher in females ( $p < 0.05$ ) but not linked to climate or vector variables, likely due to low case numbers. We hypothesize that incidence is also related to the built environment such as house construction, population density, urbanity, and land use. This study provides an important link between vector abundance and disease incidence due to robust sampling among humans and vectors over a prolonged period at the local level. Comprehensive data collection systems that include human, vector, and climate inputs can provide important guidance on predictors of human risk.

## 1496

### PILOT PROJECT OF AN ENTOMOLOGICAL AND MOLECULAR SENTINEL SURVEILLANCE SYSTEM BASED IN THE ENTOMOLOGIST CITIZEN IN PUERTO RICO

Juan C. Orengo<sup>1</sup>, Luisa Morales<sup>1</sup>, Yamileth Ortiz<sup>2</sup>, Clara Isaza<sup>1</sup>, Mauricio Cabrera<sup>3</sup>, Yashira Sanchez<sup>1</sup>, Mayra Roubert<sup>1</sup>, Jose J. Orengo<sup>3</sup>, Robert Rodriguez<sup>1</sup>, Javier Orengo<sup>4</sup>, Jania Garcia<sup>1</sup>, Carla Reyes<sup>5</sup>, Gabriel Baez<sup>3</sup>, Nathalie Ayala<sup>3</sup>, Bryan Rodriguez<sup>3</sup>, Griselle Morales<sup>1</sup>, Alexia Orengo<sup>5</sup>, Orlando Geli<sup>6</sup>, Fernando Rosado<sup>7</sup>, Vivian Green<sup>1</sup>

<sup>1</sup>Ponce Health Sciences University, Ponce, PR, United States, <sup>2</sup>Instituto Nacional de Salud, Bogota, Colombia, <sup>3</sup>University of Puerto Rico, Mayaguez, PR, United States, <sup>4</sup>Universidad Castilla La Mancha, Albacete, Spain, <sup>5</sup>Dickinson College, Carlisle, PA, United States, <sup>6</sup>University of Puerto Rico, Ponce, PR, United States, <sup>7</sup>Pontificia Universidad Catolica de Puerto Rico, Ponce, PR, United States

40,000 cases (rate 1,172 x 100,000) of arboviral disease were reported in Puerto Rico in 2016. The vectors *Aedes aegypti* and *Aedes albopictus* are endemic and reported in Puerto Rico respectively. Among other actions, the Technical Advisory Group on Public Health Entomology of the Panamerican Health Organization/WHO recommends "strengthen and enhance" the entomological surveillance and to adapt the "integrated vector management of Dengue model to both Chikungunya and Zika disease prevention and control" including the community. At present Puerto Rico has not an entomological-molecular surveillance system aimed at the prevention and control of the arboviral diseases. This study was undertaken to assess the feasibility of an entomological-molecular surveillance system based on the Entomologist Citizen in Puerto Rico. Entomologist Citizen (EC) is a "person of the community, who has no experience or advanced knowledge in entomology and is trained in the basic skills and knowledge of entomology aimed to be active part of a vector sentinel surveillance system". Fourteen EC in sixteen zones of Puerto Rico collected information about: mosquitos, bites, larvae and pupae and other variables. We calculated: mean, SD, absolute and relative frequency, ANOVA, female/male ratio, classification of mosquitoes and RT PCR analysis are being performed to assess the presence in the mosquito of arbovirus (dengue, chikungunya, zika). In 87.5% of the zones under study (ZUS) were observed mosquitoes (*Aedes spp.* (72%)) and in 53% of the ZUS were reported bites. Regarding the quantity of mosquitos observed a  $p < 0.05$  was found between ZUS, the same result was found to the quantity of bites reported. The male:female ratio was 0.31. The classification of collected mosquitoes confirmed the observations made by EC. A potential (real world evidence) mosquito insecticide resistance was reported by an EC in one ZUS. We still processing the RT PCR analysis. In conclusion, 1) the project is feasible; 2) sentinel surveillance based in EC bring information about arboviral diseases risk; 3) The community increased its vector control and prevention empowerment.

## 1497

### INTEGRATING METEOROLOGICAL DATA IN A NEW MODEL OF ENTOMOLOGICAL-MOLECULAR SENTINEL SURVEILLANCE SYSTEM IN PUERTO RICO

Robert Rodriguez-Gonzalez<sup>1</sup>, Grisel Morales<sup>1</sup>, Paola Luciano<sup>2</sup>, Fernando Rosado<sup>3</sup>, Natalie Ayala<sup>4</sup>, Luisa Morales<sup>1</sup>, Clara Isaza<sup>1</sup>, Vivian Green<sup>1</sup>, Mauricio Cabrera<sup>4</sup>, Mayra Roubert<sup>1</sup>, Yashira Sanchez<sup>1</sup>, Jose J. Orengo<sup>4</sup>, Javier Orengo<sup>5</sup>, Juan C. Orengo<sup>1</sup>

<sup>1</sup>Ponce Health Sciences University, Ponce, Puerto Rico, <sup>2</sup>University of Puerto Rico, Ponce, Puerto Rico, <sup>3</sup>Pontifical Catholic University, Ponce, Puerto Rico, <sup>4</sup>University of Puerto Rico, Mayagüez, Puerto Rico, <sup>5</sup>Universidad Castilla la Mancha, Albacete, Spain

The increase in temperature, precipitation and humidity are factors that positively influence the incidence of vector-borne diseases. In Puerto Rico the arboviral disease is endemic (dengue, chikungunya (cases reported from 2014) and zika (cases reported since 2015)) and the vector is the *Aedes aegypti* (in 2006 was reported the presence of *Aedes albopictus*). The climate change, trade and developmental model can increase the risk of transmission of vector borne diseases. This study of meteorological variables correlated to the distribution of mosquitoes as vectors will allow to identify vulnerable areas that requires interventions to prevent future outbreaks of emerging vector borne diseases impacting the health disparities that suppose these diseases. This study was undertaken: 1) to evaluate the distributions of mosquitos by cluster and identifying whether meteorological variables such as mean temperature, precipitation and evaporation are associated with these distributions. This study use the same methodology of the *Arbovirus Project* (Entomologist-Citizen Sentinel Surveillance System ECSSS). To this study seven areas across Puerto Rico were studied. The meteorological data is from NOAA. Latitude and longitude for mosquito was identified in ArcGIS and meteorological variables were correlate to each cluster. The mosquitoes caught were classified, a spatial analysis was done and the statistical analysis was: mean, SD, ANOVA, absolute and relative frequency. Arecibo and Yauco notified the major quantity of mosquitoes observed with a  $p < 0.05$  when comparing with the others areas. The mean of temperature in Arecibo was 64.70F (zone of development zero is 570F), and this factor can be the reason of notify just one bite/day while Yauco (74.90F) notified 4 bites/day. Analysis of the other areas still in process and currently a RT-PCR analysis to evaluate arbovirus in mosquito is in process. In conclusion, 1) the climate characteristics and the data from the ECSSS can be a proxy of transmission risk in real time; 2) establish the *hot spot* of risk can improve both prevention and control actions.

## 1498

### OUTDOOR BARRIER COLLECTION IN NCHELANGE DISTRICT, ZAMBIA

Christine M. Jones<sup>1</sup>, Jennifer C. Stevenson<sup>1</sup>, James Lupiya<sup>2</sup>, David Mbewe<sup>2</sup>, Mbanga Muleba<sup>2</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Disease Research Center, Ndola, Zambia

Nchelenge District of northern Zambia experiences high levels of malaria transmission despite decades of control, including artemisinin combination therapies, insecticide treated nets, and indoor residual spraying. This district is under study by the Southern African International Centers for Excellence in Malaria Research (ICEMR) as part of an effort to understand the mechanisms underlying such persistently high transmission. Among the major challenges faced in the global drive to eradicate malaria is the existence of vectors exhibiting behaviors that allow avoidance of indoor-directed vector control. In Nchelenge the only vector control measures deployed are ITNs and IRS, and so one possible contributor to transmission in this district may be non-canonical outdoor foraging or resting behaviors exhibited by the known vectors, *An. funestus s.s.* and *An. gambiae s.s.*, as well as previously unrecognized and potential vectors in the region. In order to study outdoor foraging vectors, we trialed barrier screens to

sample mosquitoes mid-flight. We characterized mosquitoes from four hourly barrier collections conducted on each of two trap nights from 8 households. Time series showed that vectors are potentially present outdoors from 8PM until 6AM, with an overall peak of vector numbers seen around 1AM. This is a range of vector presence that includes times when household residents are outdoors and unprotected by either bed nets or residual spray programs. The overall proportion of *An. gambiae* to *An. funestus* was 1:1, in contrast to the roughly 1:2 composition seen in indoor collections conducted during the same time period. Species composition was skewed more heavily toward *An. gambiae* at collections taken close to nearby Lake Mweru than for those taken at inland locations. The overall vector infection rate was ~2%, lower than had been previously observed from indoor collections.

## 1499

### CLIMATE CHANGE MAY DECLINE PREVALENCES OF DISEASE VECTORS IN ECUADOR

**Daniel Romero-Alvarez**<sup>1</sup>, Manuel A. Lepe-Lopez<sup>2</sup>, Renato León<sup>3</sup>, Mercy J. Borbor-Cordova<sup>4</sup>, Luis E. Escobar<sup>5</sup>

<sup>1</sup>Hospital General Enrique Garcés, Unidad de Epidemiología, Quito, Ecuador, <sup>2</sup>Facultad de Medicina Veterinaria y Zootecnia, Universidad de San Carlos de Guatemala, Guatemala City, Guatemala, <sup>3</sup>Laboratorio de Entomología Médica and Medicina Tropical, Universidad San Francisco de Quito, Quito, Ecuador, <sup>4</sup>Faculty of Marine Sciences, Biology, Oceanic Sciences and Natural Resources, Escuela Superior Politécnica del Litoral, Guayaquil, Ecuador, <sup>5</sup>Minnesota Aquatic Invasive Species Research Center, Department of Fisheries, Wildlife and Conservation Biology, University of Minnesota, St. Paul, MN, United States

Vector-borne diseases are of global concern with >50% of the world's population at risk, and health consequences that include mortality and disabilities. In Ecuador, vector-borne diseases are a growing public health drawback owing to high prevalences of diverse vectors species across the country carrying new emerging pathogens such as chikungunya and zika viruses, and re-emergent epidemic threats such as yellow fever. Other diseases such as dengue and leishmaniasis pose important ongoing burdens to the Ecuadorian population; moreover although malaria and Chagas disease have been reduced in past years, a raise in cases have been identified more recently. To incorporate environmental features of Ecuador on the potential distributions of vectors for arboviruses, malaria, leishmaniasis, and Chagas disease, we used worldwide reports of 14 vector species coupled with climate information to calibrate ecological niche models (ENMs). Models were used to forecast present-day and future-climate distributions of such disease vectors. ENMs were developed using a logistic-regression like algorithm with species-specific configurations selected via an information theory metrics. We found a strong signal of shrink in the distribution of several vectors (e.g., *Aedes aegypti*) under future climates, and identified new areas of distribution for some species, suggesting a plausible shift to Andean regions (e.g., *Anopheles darlingi*). From shrink and shift of vector ranges, we identified reductions of people potentially exposed to vectors, which will resemble an uncommon scenario for climate change offering a likely benefit in terms of people expose to vector-borne diseases. Our findings may be provocative, but also may encourage a reconsideration of climate change as main concern for these diseases and, instead, may help prioritize prevention strategies at landscape level in the short term, including improvements in health disparity and mitigations of the rapid land cover change as drivers of epidemics.

## 1500

### MIDGUT BACTERIA EXERT IMMUNE PRIMING WITH A CERTAIN LEVEL OF SPECIFICITY IN *ANOPHELES GAMBIAE*

**Jiannong Xu**, Aditi Kulkarni, Wanqin Yu, Jainder Chhilar

New Mexico State University, Las Cruces, NM, United States

Mosquito immune repertoire has been built upon encounter with various mosquito associated microbes throughout evolution. The interactions with midgut symbiotic microbial residents contribute to the evolution of mosquito immune system. In this study, we tested that immune priming effects of gut bacterial residents *Cedecea* sp. Ag1 and *Serratia fonticola* S1. Oral ingested bacteria can prime mosquito immunity by providing protection against a homocoel infection by bacterial injection. Intriguingly, the protection shows a pattern of specificity. *Cedecea* primed mosquitoes were resistant to *Cedecea* infection with a survival of 92.2% vs 62.5% in unprimed control mosquitoes (P<0.01). However, *Cedecea* primed mosquitoes were less resistant to *Serratia* infection with a survival of 56.8% (P<0.01). Similarly, the *Serratia* primed mosquitoes showed a survival of 76.6% upon *Serratia* infection higher than the survival of 45.4% upon *Enterobacter* infection (P<0.05). Both bacteria are Gram negative and have smooth type of lipopolysaccharide (LPS) with O antigen. The O antigens of the two bacteria show different banding patterns on a PAGE gel. *waaL* gene encodes an O antigen ligase that ligates O antigen to the LPS core. The *waaL* mutant of *Cedecea*, which lacks O antigen, showed a reduced priming effect against *Cedecea* challenge. Furthermore, the *waaL* mutant was less effective than wildtype in priming mosquitoes against rodent malaria *Plasmodium berghei*. The data indicate that midgut bacteria exert immune priming with a certain level of specificity, and O antigen may be involved in immunogenicity.

## 1501

### CLIMATE SERVICES FOR HEALTH: SUPPLEMENTING LOCAL AND REGIONAL DENGUE EARLY WARNING SYSTEMS IN THE SOUTH EAST ASIA WITH OCEAN NINO INDEX IMPROVES OUTBREAK PREDICTIONS

**Mikkel B. Quam**<sup>1</sup>, Prasad Liyanage<sup>1</sup>, Mahesh Appannan<sup>2</sup>, Aditya L. Ramadona<sup>1</sup>, Tran K. Long<sup>3</sup>, Abqariyah Yahya<sup>2</sup>, Nasrin Aghamohammadi<sup>2</sup>, Joacim Rocklöv<sup>1</sup>, Rafdzah A. Zaki<sup>2</sup>, Yien Ling Hii<sup>1</sup>

<sup>1</sup>Umeå University, Umeå, Sweden, <sup>2</sup>University of Malaya, Kuala Lumpur, Malaysia, <sup>3</sup>Hanoi University of Public Health, Hanoi, Vietnam

Dengue, Chikungunya, Zika, and Yellow Fever are of serious public health concern in many regions of the world, and may threaten populations in Southeast Asia. Climate services can inform actionable, data-driven decisions to protect public health in a myriad of manners, which may include augmenting the early warning of vector-borne disease outbreaks. Some climate signals may be more predictable and have longer lead-time than meteorological and surveillance only methods, which may detect outbreaks only after they are already underway. Posing an exacerbated threat to human health, corresponding to greater variability and intensity of infectious disease outbreaks, climate change may further complicate the existing public health problems associated with *Aedes* vectors in communities of Southeast Asia. Our study aimed to examine the utility of spatial and time-series analysis including specific Oceanic Nino Indices (ONI) in five countries at the local level, to determine stable associations needed for reliable disease early warnings systems based on combinations of climate signals, meteorological observations and disease surveillance. In this analysis, for best regional comparison, we used notifications of dengue in the public health surveillance system, however, some methods and conclusions may be conserved for other warnings of *Aedes*-borne arboviruses. Analysis from Malaysia, Singapore, Indonesia, Sri Lanka, and Vietnam during 2009 through 2015 yielded largely converging findings especially during larger dengue outbreak years corresponding to trends in ONI. Year to year epidemiological analysis revealed seasonality, trend,

and cycle in many study areas were persistent throughout the datasets, indicating strong potential for climate and meteorological services to be mainstreamed used in dengue early warnings systems utilized by public health planners working both in vector control and clinical management of arboviruses. Having early reliable disease predictions, public health practitioners may better plan, budget and coordinate efforts to prevent large scale dengue epidemics.

## 1502

### HEALTH SEEKING BEHAVIOR AMONG UNDER-2 CHILDREN IN VELLORE HEALTH UNIT DISTRICT

**Rajan Srinivasan**, Karthikeyan Ramanujam, Venkata Raghava Mohan, Gagandeep Kang

*Christian Medical College, Vellore, Vellore, India*

Health Seeking Behaviour (HSB) of children in India is influenced by multiple factors. Governments constantly try to innovate and incentivize services to make them accessible and acceptable to target populations. A survey among parents/ care-givers of 3123 (2403- urban, 720- rural) under-2 children was done in Vellore health unit district to understand utilization of antenatal and immunization services; place of birth, illness in preceding 4-weeks, health center visited and health centres preferred for hypothetical future mild/ severe illness. A majority (2552, 81.7%) had used government antenatal services while 2623 (84%) had utilized government immunization services. Of the 2192 (70%) who recalled illness in the preceding 4-week recall 2120 (96.7%) sought care. The commonest health center visited was private (1733, 81.7%) while 378 (18%) visited government centers, both urban and rural population had preferred private health care during prior illness (87%, 69% respectively). For hypothetical future mild illnesses, 2342 (75%) preferred private health care while 624 (20%) preferred government health services. For hypothetical severe illnesses, 2498 (80%) preferred private health care with the rest choosing government services. Private health care was the most preferred health care irrespective of urban rural divide. While most preferred government centers for antenatal and immunization services, they preferred private health care for curative services. Among private health care seekers, majority preferred to consult a specific physician for most illnesses. Among those preferring government health services most 353 (56.7%) visited the medical officer at the closest primary health center with very few (<5%) preferring the nurse run health sub-center while the rest preferred the government hospitals. Centers preferred by more than 10% of respondents identified 17 for mild and 8 for serious illness. Incentivized schemes have shown an increase in institutional antenatal and immunization services, more innovation in required to increase acceptability of curative services offered by public health institutions.

## 1503

### QUALITY AND INTEGRATED SERVICE DELIVERY: A CROSS-SECTIONAL STUDY OF THE EFFECTS OF MALARIA AND ANTENATAL SERVICE QUALITY ON MALARIA INTERVENTION USE IN SUB-SAHARAN AFRICA

**Elizabeth H. Lee**<sup>1</sup>, James Mancuso<sup>2</sup>, Tracey Koehlmoos<sup>3</sup>, V. Ann Stewart<sup>3</sup>, Jason W. Bennett<sup>4</sup>, Cara H. Olsen<sup>3</sup>

<sup>1</sup>*The Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States*, <sup>2</sup>*United States Army Medical Research Directorate-Kenya, Nairobi, Kenya*, <sup>3</sup>*The Uniformed Services University of the Health Sciences, Bethesda, MD, United States*, <sup>4</sup>*Walter Reed Army Institute of Research, Silver Spring, MD, United States*

Service integration remains an underexplored area of study for systems strengthening and improved health outcomes. In the field of malaria service delivery, a pertinent gap in knowledge exists with respect to the role of quality of integrated malaria and antenatal services. This knowledge deficit warrants attention, given persistent gaps in national coverage and use targets for malaria interventions in pregnancy and childhood in sub-Saharan Africa. Using regionally-linked, cross-sectional facility and

household data from the Demographic and Health Surveys, we aimed to determine whether quality of integrated malaria with antenatal services in Kenya, Namibia, Senegal, and Tanzania predicted malaria intervention use during pregnancy and in children under-five. We assessed quality of these services using a novel combination of quality frameworks to select suitable indicators, and modeled the relationships of interest using pooled and country-stratified multilevel mixed effects modified Poisson models for three outcomes: insecticide-treated bed net use in currently pregnant women or children under-five, and receipt of two or more doses of intermittent preventive treatment in last pregnancy. We found modest, positive associations between malaria in pregnancy quality and study outcomes across pooled models and for most countries, with evidence of heterogeneity in strength of associations and relevant confounding factors. On average and using our indicator set, there was significant room for improvement in the quality of malaria in pregnancy services. Study findings indicate quality improvement of maternal health services delivering well-accepted interventions like malaria prophylaxis and bed nets is necessary to address gaps in national coverage and use targets for pregnancy and childhood. Consensus on a set of malaria in pregnancy service quality indicators and best practices for measuring integration of these services with antenatal care are needed.

## 1504

### TWITTER REACTIONS TO GLOBAL HEALTH NEWS RELATED TO FIVE DIFFERENT COUNTRIES: A CASE STUDY OF #POLIO

Braydon J. Schaible<sup>1</sup>, Cassandra R. Snook<sup>1</sup>, Jingjing Yin<sup>1</sup>, Ashley M. Jackson<sup>1</sup>, Jennifer O. Ahweyevu<sup>1</sup>, Muhling Chong<sup>1</sup>, Zion Tsz Ho Tse<sup>2</sup>, Hai Liang<sup>3</sup>, King-Wa Fu<sup>4</sup>, **Isaac Chun-Hai Fung**<sup>1</sup>

<sup>1</sup>*Georgia Southern University, Statesboro, GA, United States*, <sup>2</sup>*The University of Georgia, Athens, GA, United States*, <sup>3</sup>*The Chinese University of Hong Kong, Hong Kong, Hong Kong*, <sup>4</sup>*The University of Hong Kong, Hong Kong, Hong Kong*

Social media has become a vital tool for global health communication, given the penetration of the internet and mobile phones across the world. In addition to disseminating health information, public health professionals also monitor traditional media and social media to assess the communication environment. Prior research showed that outbreak-related social media contents were largely driven by traditional media reports. However, we hypothesized that different types of news contents could trigger different levels of reaction on social media. In this study, we retrospectively examined a 40% random sample of Twitter data containing the hashtag #polio from January 2014 to April 2015 (N=79333), from which we extracted five sub-corpora each with a co-occurring hashtag #India, #Iraq, #Nigeria, #Pakistan, and #Syria respectively. We also retrieved 104 polio-related traditional news stories from 2 newspapers, 2 television news stations, and 2 radio news stations within the same time frame. We assessed the relationship between polio-related news from traditional news sources and the Twitter content. We hypothesized that polio-specific Twitter conversations differed by the location of interest and they were reactions to traditional media news articles. Descriptive analyses and unsupervised machine learning were conducted on the 5 Twitter sub-corpora to elucidate their underlying topics. Traditional media articles were grouped according to the country of interest and were categorized into the following topics: celebrations or achievements; violence or crises; political actions; vaccinations or other programs/aid; new cases or spreading of polio; and miscellaneous. Strong Twitter reactions were observed following a few news stories published by traditional media but not the others. Our evidences suggest a nuanced relationship between outbreak-related traditional media stories and Twitter contents. Evidence from our study helps inform media monitoring and communication surveillance during global public health crises, such as infectious disease outbreaks, as well as reactions to health promotion campaigns.

## 1505

### A QUALITATIVE STUDY OF THE ACCEPTABILITY OF WEEKLY IRON SUPPLEMENTATION PRIOR TO THE FIRST PREGNANCY IN BURKINA FASO

Adelaide Compaore<sup>1</sup>, Sabine Gies<sup>2</sup>, Bernard Brabin<sup>3</sup>, Halidou Tinto<sup>1</sup>, Loretta Brabin<sup>4</sup>

<sup>1</sup>Clinical Research Unit of Nanoro/Institute for Research in Health Sciences (IRSS), Ouagadougou, Burkina Faso, <sup>2</sup>Medical Mission Institute, Würzburg, Germany, <sup>3</sup>Liverpool School of Tropical Medicine and Institute of Infection and Global Health, Liverpool, United Kingdom, <sup>4</sup>Institute of Cancer Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom

Reducing anaemia in women of reproductive age is a global priority as iron deficiency anaemia (IDA) is a leading cause of years lived with disability. To reduce IDA iron supplementation for menstruating women is recommended. This includes adolescent girls as adolescence may be the optimal time to build iron stores in readiness for pregnancy. The success of such interventions largely depends on their feasibility and acceptability to adolescents and their communities. This study explored the acceptability of weekly iron supplementation given preconceptionally for up to 18 months to non-pregnant adolescents (mean age 16 years) enrolled in a randomised controlled trial. Before and during the trial systematic information on the role of iron in health was provided. In-depth interviews were conducted with young women, selected according to their level of adherence in either trial arm (iron and folic acid versus folic acid alone) by field workers who had provided directly observed capsule intake. Tape recorded transcripts were translated from Mooré into French and analyzed thematically. 38 interviews were conducted with young women, some of whom had become pregnant during follow-up. At the outset, the research focus on adolescents suggested to communities that supplements were contraceptives and this led to drop out by some, but not other, interviewees. Adolescents expected curative and health benefits from the supplements which, when not experienced, engendered negative views. Commitment to the intervention was affected by mobility. Some were students who returned to homes outside the study area during holidays. Unplanned pregnancy and domestic assistance to relatives living elsewhere affected the mobility patterns of other interviewees. Despite health education, iron supplementation was not seen as a high priority by communities nor did the benefits persuade adolescents themselves of its importance.

## 1506

### STRENGTHENING NURSING AND MIDWIFERY TRAINING THROUGH IMPLEMENTATION OF CONTINUOUS QUALITY IMPROVEMENT PROCESS: THE TANZANIA EXPERIENCE

Annamagreth Mukwenda<sup>1</sup>, John George<sup>1</sup>, Mary Rose Giatas<sup>1</sup>, Gustav Moyo<sup>2</sup>, Justine Ngenda<sup>3</sup>

<sup>1</sup>Jhpiego, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Ministry of Health Community Development Gender Elderly and Children, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Mwanza Zonal Health Resource Center, Dar es Salaam, United Republic of Tanzania

Tanzania is one of the countries with critical shortage of human resource for health. The coverage of skilled birth attendants is about 50%, which connote suboptimal quality of care contributing to poor neonatal and maternal outcomes. Training and deploying adequate numbers of competent health workers is one of the objectives of the Tanzania National Health Policy. The government of Tanzania and partners like Jhpiego led Maternal and Child Health Survival Program, are working to improve the training environment hence competent graduates. In support of quality trainings; Jhpiego in collaboration with the Ministry of Health are implementing the Continuous Quality Improvement (CQI) process which encourages health training institutions to improve quality teaching and learning by focusing on Classroom and Practical Instructions,

Clinical instruction and practice, Institutional Infrastructure, Learning and Teaching Materials and Institutional Governance and Administration. A baseline assessment was done using the CQI guide in 10 training institutions to assess the quality of training and educational process, output and outcomes for the provision of quality nursing and midwifery care. Results indicated substandard outcomes with scores less than 50% at most schools. All 10 schools were oriented on CQI process including its implementation. Quarterly assessment by a team comprised of institutions' quality improvement teams, Ministry of Health and Jhpiego were done and gaps identified addressed through supportive supervision and mentorship. Training institutions are progressively improving their training capabilities. The teaching learning environment has improved substantially with an average score 95% during external verification from 45% baseline score. After eighteen months of program implementation, three schools have been recognized for their outstanding performance and were presented with trophies and certificates as a motivation. This translates into increased number of skilled health care workers from rural nursing schools with required competency to avert maternal and neonatal deaths.

## 1507

### COMMUNITY HEALTH VOLUNTEERS PROVIDE ESSENTIAL PRIMARY HEALTH CARE SERVICES IN MADAGASCAR

John Yanulis<sup>1</sup>, Herivololona Rabemanantsoa<sup>1</sup>, Mamy Tiana Andrianarilala<sup>1</sup>, Aishling Thurrow<sup>2</sup>, Elke Konings<sup>2</sup>

<sup>1</sup>U.S. Agency for International Development Mikolo, Antananarivo, Madagascar, <sup>2</sup>Management Sciences for Health, Medford, MA, United States

Community Health Volunteers (CHVs) are the pillar of Madagascar's health system, as they meet the health needs of underserved and vulnerable populations who live more than 5km from a formal health facility. CHVs provide information, education, and services for family planning, maternal and newborn health care, and child health services, including the prevention, diagnosis, and treatment of malaria. The USAID Mikolo project assists and supports CHVs to provide services and promote health in their communities in 8 regions. Overall, CHVs expand access to crucial health services beyond the reach of the formal health system and thus help improve maternal and child health outcomes. Routine service data reported by CHVs were compared to routine service statistics reported by basic health centers between 2014 and 2016. The data were recorded and reported through the health information system and obtained by USAID Mikolo. Data were entered into an electronic database and analyzed in MS Excel. Between 2014 and 2016, the number of CHVs supported by USAID Mikolo rose from 4,489 in 375 communes to 6,694 in 506 communes. The number and proportion of children under the age of five years who were treated for malaria by CHVs and health centers, respectively, increased from 2014 (93,257) to 2016 (130,841). The same is true for children treated for diarrhea—increasing from 66,043 cases in 2014 to 101,969 cases in 2016. The number of referrals made for long-acting and permanent methods (LAPM) of FP rose from 4,009 in 2014 to 5,993 in 2016. The number of pregnant women referred to the nearest health facility by CHVs for and receiving ANC increased from 10,071 in 2014 to 30,728 in 2016. Finally, the number of newborns referred by CHVs for and obtaining emergency care increased from 2,032 in 2014 to 3,138 in 2016. The data also shows an important increase in the proportions of clients reached by CHVs relative to health centers over time. Ultimately, the evidence demonstrates that CHVs play a critical role in the provision of FP; reproductive, maternal, newborn, and child health; and referral services, stimulating both access to and use of services in Madagascar.

### PSYCHOLOGICAL DISTRESS AND ZIKA, DENGUE, AND CHIKUNGUNYA INFECTIONS FOLLOWING 2016 EARTHQUAKE IN COASTAL ECUADOR

**Avriell R. Diaz**<sup>1</sup>, Anna Stewart<sup>2</sup>, Anita Hargrave<sup>3</sup>, Aileen Kenneson-Adams<sup>2</sup>, Juan Pablo Molina<sup>4</sup>, Angelica Gonzales<sup>4</sup>, Moory Romero<sup>2</sup>, David Madden<sup>2</sup>, Reese Garcia<sup>5</sup>, Elizabeth Domachowske<sup>2</sup>

<sup>1</sup>Columbia University, New York, NY, United States, <sup>2</sup>State University of New York Upstate Medical University, Syracuse, NY, United States, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>Ministerio de Salud Pública, San Vicente, Ecuador, <sup>5</sup>University of Colorado, Denver, CO, United States

Stress from catastrophic events can decrease people's capacity to mount an effective immune response to infectious pathogens. In April 2016, a 7.8 magnitude earthquake struck coastal Ecuador, which resulted in significant mortality and morbidity, damages to housing structures and piped water infrastructure, and psychological trauma. This event occurred in an area with a historically high burden of dengue fever and coincided with the first outbreak of Zika fever. This cross-sectional analysis aims to describe the co-occurrence of psychological distress from the 2016 earthquake and viral transmission of Zika, Dengue and Chikungunya, and to determine whether greater distress was associated with a higher average number of self-reported disease. In July 2016, heads of household from four communities were interviewed in face-to-face surveys over a seven-day period in Bahía de Caráquez, Ecuador (n = 573 people) as part of a post-disaster evaluation by the Ministry of Health. Survey questions included demographics, psychological symptoms, physical damages caused by the earthquake, healthcare-seeking behavior, and self-reported symptoms of Zika fever, Dengue fever and Chikungunya. Results showed the prevalence of reported viral symptoms was 23% across the entire study population, and over 50% survey participants reported symptoms of psychological distress. Bivariate analyses showed the average number of psychological distress symptoms was higher among people with arbovirus symptomatology than among people without those symptoms (1.48 vs. 0.95; p=0.003). This is observed in the communities of Junco (1.96 vs. 1.12; p=0.003) and Bella Vista (1.25 vs. 0.70; p=0.003), among women (1.68 vs. 1.00; p=0.002) and in participants 19-39 years old (1.34 vs. 0.69; p = 0.03). In conclusion, we documented a high burden of psychological stress, and positive associations with self-reported arboviral infections. The results of this study highlight the need for integrated health responses following natural disasters that include mental health professionals and infectious disease physicians.

### AN EXAMINATION OF THE BARRIERS AND ENABLERS TO HEALTH AND WELLBEING IN THE COMMUNITIES ALONG THE INTER-OCEANIC HIGHWAY IN MADRE DE DIOS, PERU

**Amy R. Riley-Powell**<sup>1</sup>, Nehal S. Naik<sup>2</sup>, Kelly Jensen<sup>1</sup>, Gabriela Salmón-Mulanovich<sup>3</sup>, Gwenyth O. Lee<sup>1</sup>, Stella M. Hartinger-Peña<sup>3</sup>, Valerie A. Paz-Soldan<sup>1</sup>

<sup>1</sup>Tulane University, New Orleans, LA, United States, <sup>2</sup>Virginia Commonwealth University, Richmond, VA, United States, <sup>3</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

The interoceanic highway in Madre de Dios, Peru, paved in 2006, has driven dramatic change in the Peruvian Amazon basin with increases in movement of people and goods and decreases in biodiversity, flora, and fauna. The impacts of the interoceanic highway on the health and wellbeing of people living nearby, however, has been less characterized. Our study examines threats, barriers, and enablers to health and wellbeing in these communities, using a modified socio-ecological model, which stratifies the threats, barriers and enablers at the individual, community, and societal levels. The mixed methods include a survey (N= 522), key

informant interviews (N=34) and 12 focus group discussions (N= 83 individuals). At the individual level, we find that enablers to improved health and well-being are improved access to health services, food, and economic opportunities. Sixty-six percent of survey participants list poor personal health as the greatest threat to their well-being, and the most common barrier is decreased access to natural resources. At the community level, the key enabler is improved cultural exchange and the key barrier is poor access to water and sewage facilities. Enablers at the societal level are access to health insurance (68% of survey respondents have basic insurance) and the presence of health campaigns, including a local campaign to eliminate mosquito breeding areas following a positive dengue case. The key barrier to health and well-being is the limited quality and availability of health services. These findings reveal dynamic and rapidly changing communities, which would benefit from improved sewage and potable water services. Furthermore, focusing on improving health care access, service, infrastructure, is necessary to respond to changes in this region. Health education messages need to address the decrease in natural resources (bush meat, fishing, and forest products) in order to mitigate the impact of environmental changes on health and well-being.

### MANAGEMENT OF THE QUALITY OF TRICHIASIS SURGERY SERVICES IN A COMMUNITY SETTING IN CAMEROON: IMPLEMENTING A QUALITY ASSURANCE APPROACH

**Souleymanou Yaya**<sup>1</sup>, Assumpta Bella<sup>1</sup>, Michel Paradis<sup>2</sup>, Julie Akame<sup>2</sup>, Yannick Nkoumou<sup>2</sup>, Henri MOUNGUI<sup>2</sup>, Awa Dieng<sup>3</sup>, Sabrina La Torre<sup>3</sup>, Emily Gower<sup>4</sup>, Amir Bedri<sup>5</sup>

<sup>1</sup>Ministry of Public Health, Yaounde, Cameroon, <sup>2</sup>Helen Keller International, Yaounde, Cameroon, <sup>3</sup>Helen Keller International, Dakar, Senegal, <sup>4</sup>University of North Carolina/Helen Keller International, Chapel Hill, NC, United States, <sup>5</sup>Helen Keller International, Washington, DC, United States

Several quality approaches exist for patient care, such as total quality management, the Plan-Do-Check-Act (PDCA) or Deming wheel approach, and the business process reengineering. To ensure the delivery of high quality trachomatous trichiasis (TT) surgery services at the community level, in collaboration with the Ministry of Health Helen Keller International (HKI) has implemented the PDCA approach in Cameroon, through its USAID-funded MMDP Project. Plan: The Project evaluated the capacity of the health care system from the outset to provide an idea of the resources (physical, human, infrastructural) available for TT surgery. Do: A training of master trainers of surgeons followed by a training / certification of surgeons was undertaken through the use of the Trachomatous Trichiasis surgery manual (WHO 2015, 2nd edition) and the HEADSTART surgical simulator. Attention was paid on the selection process of the master trainers and surgeons based on their profile and experience. For field practice, the surgeons each operated on 15 eyes under the observation of the master trainer. The Project designed a trichiasis surgery calculator to estimate the quantities of consumables required and helped train a dedicated health team responsible for waste management and equipment sterilization. Check: At the end of each campaign, an evaluation meeting was conducted with the surgeons, district and region level managers, program managers and partners. A post-operative follow-up evaluation activity was conducted 3 to 6 months after each surgical campaign. Results were analyzed and discussed with the surgeons and program managers to identify areas for improvement. The average per surgeon surgical failure rate was estimated to be between 20-60%. Act: Based on these findings, a recommendation was made to provide supportive supervision and a training of surgeon supervisors was developed and conducted including the use of HEADSTART. A refresher training of surgeons was also recommended before the next surgery campaign. The PDCA approach has proven to be very useful and adaptable to improve the quality of community TT surgery services as part of the MMDP Project.

## 1511

### PRE-TRANSMISSION ASSESSMENT SURVEY OF LYMPHATIC FILARIASIS IN THREE HEALTH DISTRICTS IN INSECURITY ZONE IN NIGER

Adamou B. Salissou<sup>1</sup>, Mariama Mossi<sup>1</sup>, Maimouna Lamine<sup>1</sup>, Youssouf Yaye<sup>2</sup>, Yaobi Zhang<sup>3</sup>

<sup>1</sup>National Onchocerciasis and Lymphatic Filariasis Program, Ministry of Health, Niamey, Niger, <sup>2</sup>Helen Keller International, Niamey, Niger, <sup>3</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal

Lymphatic filariasis (LF) is endemic in 31 health districts (HDs) across all regions of Niger. Annual mass drug administration (MDA) with ivermectin and albendazole for LF elimination began in 2007 and progressively reached full national geographical MDA coverage in 2014. Diffa region, where a state of emergency was put in place due to the insecurity caused by Boko Haram, started MDA in 2010 in all three HDs (Diffa, N'Guigmin and Mainé Soroa) regardless of the insecurity, and completed 5 rounds of MDA by 2015. The national program conducted the pre-transmission assessment survey (pre-TAS) in these HDs in January 2016. One sentinel site (SS) and one spot check site (SC) from each HD was surveyed by nocturnal microfilaria examination: Asaga and Gueskerou for Diffa HD, Kablewa and Bilabrine for N'Guigmi HD, and Boudoum and Djanguiri for Mainé Soroa HD. Night blood samples were collected between 11pm to 4am from each site and thick blood smear was prepared and examined for the presence of microfilariae. The survey teams moved house to house to perform blood sampling. The number of persons examined was 303 in Asaga, 304 in Gueskerou, 305 in Kablewa, 317 in Bilabrine, 304 in Boudoum, and 301 in Djanguiri. The prevalence of microfilariaemia was 0% in all 4 sites in Diffa and N'Guigmin HDs, while it was 0.33% in Boudoum and 0.66% in Djanguiri in Mainé Soroa HD. The results showed that these HDs in Diffa region qualified for conducting transmission assessment survey to assess whether MDA can be stopped. The survey was conducted in the context of a nocturnal curfew due to insecurity. The movement of people was prohibited from 8pm to 6am. Special authorization and assistance was obtained from the military services for securing the zone of the survey. These villages are less than 5 kilometers from the Boko Haram carpet lines in the green meadows of the rice paddies. 20% of the households awakened refused to open their doors for lack of confidence. 5% of people climbed their walls to escape when the teams passed. However, the national program successfully conducted the pre-TAS, a step forward in achieving the LF elimination objective in challenging situation in Niger.

## 1512

### THE MOST IMPORTANT ELEMENTS OF INFORMED CONSENT PROCESS AS RATED BY NEW AND EXPERIENCED RESEARCHERS: AN ONLINE SURVEY

Jaranit Kaewkungwal, Pornpimon Adams

Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Informed consent process is a requirement when conducting human research. The researchers have to respect basic ethical principles of autonomy while balancing risks and benefits of study procedures. The objective of this study was to explore the opinions of researchers about the importance of ethical elements of informed consent process. An anonymous online questionnaire was sent to biomedical and health researchers in various academic and research institutes in Thailand on March 2017. Based on the importance level identified with a 5-point Likert rating scale, the ratings per item were analyzed. The ratings differed among 61 researchers, classified by years of experiences as: 22 with 1-5 years, 18 with 6-10 years and 21 with >11 years. For ethical considerations in informed consent process, the ratings for "most important" among the 3 groups of researchers with different experiences included: comprehension of information (82%,44%,72%), communication of risks and risk minimization (77%,67%,76%); decisional authority for consent

to research (82%,61%,62%); communication and power inequities (67%,24%,57%); timing for making decision (64%,17%,43%); request for maintaining specimen for future use (59%,44%,43%); and process in approaching research participants (64%,44%,65%). The consent form was rated differently as "most important" by the three groups for language (73%,50%,75%); form length (64%,33%,62%); completeness of the information given in relation to the protocol (73%,67%,71%); provision of alternatives and different choices (77%,61%,71%); having contact person regarding deviation/violation (82%,35%,87%), and handling of documentation (82%,28%,76%). The study results showed different weights of the elements given by the researchers. Interestingly, more new researchers with experiences 1-5 years tended to give most importance ratings for all elements compared to those working 6-10 years. This suggests gaps in their perceptions of informed consent process. The communication of these findings would help plan supports for researchers who may need to understand the importance of informed consent requirement.

## 1513

### DEVELOPMENT OF MULTIPLEX TAQMAN ARRAY CARDS FOR THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) PROGRAM

Maureen H. Diaz<sup>1</sup>, Jessica L. Waller<sup>1</sup>, Mary J. Theodore<sup>1</sup>, Alvaro J. Benitez<sup>1</sup>, Bernard J. Wolff<sup>1</sup>, Dianna M. Blau<sup>1</sup>, Pratima Raghunathan<sup>1</sup>, Robert F. Breiman<sup>2</sup>, Jeffrey P. Koplan<sup>2</sup>, Jonas M. Winchell<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Emory Global Health Institute, Atlanta, GA, United States

Every year, approximately 5.9 million children under the age of five die; two-thirds of these deaths are due to infectious causes. The Child Health and Mortality Prevention Surveillance (CHAMPS) program, supported by a Bill & Melinda Gates Foundation award to Emory Global Health Institute, aims to increase understanding of why children die, including identifying the specific pathogens contributing to child mortality. CHAMPS is focused on strengthening public health capacity in developing countries in Sub-Saharan Africa and South Asia. Laboratory data includes pathology analysis of tissue specimens obtained from minimally invasive tissue sampling (MITS) and molecular testing of tissue and non-tissue specimens collected post-mortem. Five unique multiplex TaqMan Array Card (TAC) configurations were developed for the molecular detection of pathogens from various specimen types: Respiratory (nasopharyngeal/oropharyngeal swabs and lung tissue), Enteric (stool and rectal swabs), Blood/CSF Tier 1 and 2 (whole blood and cerebrospinal fluid (CSF)), and Neonatal (whole blood and CSF specimens from neonates and stillbirths). Over 100 assays were developed, modified, and/or optimized for detection of bacterial, viral, fungal, and parasitic agents. Each assay underwent comprehensive evaluation, including determination of analytical sensitivity and specificity. Application of multiplexing to TAC increased the number of potential individual test results from 48 to as many as 144 per specimen while also allowing for multiple replicates to maximize detection in clinical specimens that may contain very low amounts of targeted nucleic acid. When possible, previously characterized clinical specimens were used to evaluate assay performance. Optimization of oligonucleotide sequences and modifications and multiplex assay combinations based on preliminary findings from CHAMPS sites is ongoing. Adaptation of innovative pathogen detection methods is planned to evolve over the duration of CHAMPS surveillance to increase sensitivity and specificity in assigning infectious causes of child death.

## 1514

### STRENGTHENING IMPLEMENTATION OF ROUTINE IMMUNIZATION PROGRAMS: PERSPECTIVES OF PRIMARY HEALTHCARE FACILITY MANAGERS IN WESTERN KENYA

Moshood Omotayo<sup>1</sup>, Rose Chesoli<sup>2</sup>, Roseanne Schuster<sup>3</sup>

<sup>1</sup>State University of New York at Buffalo, Buffalo, NY, United States,

<sup>2</sup>University of Nairobi, Nairobi, Kenya, <sup>3</sup>Arizona State University, Tempe, AZ, United States

Vaccine-preventable diseases, including diarrhea and pneumonia, cause a high burden globally. Despite development of several strategies to increase vaccine coverage, current coverage is not optimal in many developing countries. Routine immunization programs rely on primary healthcare systems and primary healthcare facility managers (PHFM) constitute a critical link in the impact pathway of immunization programs in developing countries. Yet, few studies elucidate their perspectives on intervention targets for improving vaccine delivery in primary healthcare facilities. We explored perspectives of PHFMs on how human resource factors might influence delivery of immunization programs. We conducted in-depth interviews with 14 purposively selected key informants in Kakamega County, Kenya. Interviews were transcribed, coded and explored for salient themes. Emergent themes from the interviews were used to guide questionnaire development for a cross sectional survey with 94 PHFMs. Descriptive analyses of survey data were carried out. Most PHFMs were female (72%) and registered nurses (77%). Most frequently reported consequences of high workload were reduced accuracy of vaccination records (47%) and poor client counseling (47%). Hiring more clinical staff was identified as an effective remedy to high workload (69%). Few respondents (20%) felt highly motivated to ensure full immunization coverage in their communities. Increasing frequency of immunization-relevant supervisory visits and acting on the feedback received during those visits were most frequently perceived as important measures to improve effectiveness of immunization programs. PHFMs can provide insight into contextually relevant intervention targets to improve immunization programs. Besides increasing clinical staff, acting on feedback garnered from more frequent immunization-relevant supervision visits was perceived as a measure to increase effectiveness of immunization programs. Future studies should compare impact of developing coverage interventions based on PHFM perspectives to current intervention development approaches.

## 1515

### CLIENT SATISFACTION WITH COMMUNITY CASE MANAGEMENT OF UNCOMPLICATED MALARIA IN BUNGOMA COUNTY, KENYA

Chrisanthus L. Okutoyi, Jared Oule, Mable Jerop

*Amref Health Africa in Kenya, Nairobi, Kenya*

Owing to the burden of malaria in Kenya, community case management of Malaria (CCMM) has been adopted to overcome barriers to prompt access to Malaria treatment as recommended by World Health Organisation. This initiative is part of the contributions to achieving malaria eradication. Community members' feedback is essential in evaluating the process as implemented by Amref Health Africa. This study therefore sought to evaluate the extent to which clients were satisfied with Community Case Management of Malaria. A cross-sectional study was conducted whereby a client satisfaction tool was administered to 381 clients offered CCMM services at household level. All suspected malaria tested by Community Health Volunteers (CHVs) were asked to consent to participate in the assessment. The inclusion criteria included individual or child must have been sick or presented with a new health problem or does not require urgent referral. Parameters used to measure satisfaction were availability of CHVs, convenience of getting CCMM service and promptness to respond to a call by CHVs. Data was analysed using descriptive statistics. Average age of the respondents was 40

years, 81% were female and majority of respondents practised farming (61%). Majority (93%, 94% and 91%) of the clients were satisfied with availability (obtainability/readiness), convenience (suitability/ease) and promptness (timeliness/punctuality) to respond to a call by CHVs. They further felt that the time taken to conduct the test, explanations given on treatment and friendliness during CCMM was good (94%, 90%, and 95% respectively). Most (98%) of the clients considered CHVs a regular source of basic healthcare on Malaria. Health education received was highly perceived to be helpful (93%). The community was satisfied with CCMM due to accessibility to diagnosis and treatment of uncomplicated malaria in relation to convenience, promptness and additional health education services received.

## 1516

### EFFECTS OF DEWORMING ON MATERNAL AND CHILD HEALTH: A LITERATURE REVIEW AND META-ANALYSIS FOR THE LIVES SAVED TOOL

Winter M. Thayer, Adrienne Clermont, Neff Walker

*Johns Hopkins University, Baltimore, MD, United States*

Soil-transmitted helminth infections affect an estimated 1.3 billion people worldwide. The World Health Organization recommends mass drug administration as the primary method of control for soil-transmitted helminth due to the expense of helminth diagnosis and low cost of deworming drugs. In 2014, over 400 million preschool-aged and school-aged children were targeted for deworming globally. The Lives Saved Tool is a software package that uses a linear deterministic mathematical model to estimate the effect of scaling up interventions on maternal and child health outcomes. This review and meta-analysis investigates the scope of available evidence for benefits of deworming treatments to assess the advisability of including deworming in the Lives Saved Tool. We searched for studies in PubMed, the Cochrane Library, Google Scholar, and published reviews. We included studies that reported pre/post data in children younger than five years, or pregnant women for outcomes related to mortality and growth. Studies that did not include a non-antihelminthic comparison group, or did not report post-intervention outcomes were excluded. We categorized articles by treated population, experimental versus observational studies, mass drug administration versus treatment, multiple versus single dose, length of follow up, and reported outcomes. Disagreements exist about the appropriate effect estimates to include in deworming meta-analyses. To address this, we conducted sensitivity analyses regarding the impact of different combinations of effect estimates. We identified 27 trials that investigated children younger than five years and 11 that investigated pregnant women. We conducted meta-analyses of relevant outcomes in children younger than five years. Our analyses suggest that deworming does not show consistent benefits at the population level for indicators of mortality, anemia, or growth in children younger than five or women of reproductive age. Although benefits of deworming may exist, we do not recommend including the effect of deworming in the Lives Saved Tool.

## 1517

### AN INNOVATION IN PRIMARY HEALTH CARE: A STEP TOWARDS UNIVERSAL HEALTH COVERAGE

Sarah Kedenge, Boniface Oyugi, Caroline Gitonga, Albert Orwa, Caroline Kyalo, Karthik Subbaraman, Eddine Sarroukh

*Philips, Nairobi, Kenya*

A UN resolution passed in 2012, endorsed universal health coverage as a pillar for sustainable development and global security. The World Health Organization's Alma Ata declaration in 1978, identified primary health care as key in delivering equitable health for all. Decades of research have also shown that investments to strengthen primary health care (PHC) are vital in achieving universal health coverage, lower inequality in access to services and improve health of populations. Philips through collaboration with local government has set up the Community Life Centre (CLC)

intervention as a PHC solution, intended for low-resource settings, which aims to address some of the challenges confronting health and health systems in developing markets. The CLC is an integrated primary health care solution aimed at providing sustainable improvement in health and well-being for entire communities across the health care continuum. The CLC Project started in 2014 as a community hub offering primary health care with the main aim of improving access to services, improving quality and efficiency of primary health services in low resource settings and enhancing connected care to the community and referrals to higher facilities. Through a co-creation approach between the county, local community and Philips, the first CLC was developed and deployed in Githurai, Kiambu County, Kenya. The intervention was deployed through a modular approach that saw improvements in infrastructure, staff capacity building, innovations in energy solutions, monitoring and evaluation and community outreach. Since deployment, utilization of services in outpatient department has increased by 30%; child welfare clinic by 250% and antenatal services by over 600%. In addition, increased involvement of community health workers has seen improvement of community-referrals and early identification of diseases, including non-communicable diseases. Based on the learnings from Githurai, other CLCs are in the process of development and implementation in Kenya, DRC and Zimbabwe.

## 1518

### IMPROVING QUALITY OF CARE AND PERCEIVED CLIENT SATISFACTION WITH PERFORMANCE-BASED FINANCING IN LESOTHO

**Ntoetse Mofoka**<sup>1</sup>, Ismael A. Sued<sup>2</sup>, Kimberly McLeod<sup>2</sup>, Clarisse Uzamukunda<sup>3</sup>, Martijn Vink<sup>3</sup>, Farshid Meidany<sup>2</sup>

<sup>1</sup>Ministry of Health, Maseru, Lesotho, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>3</sup>HealthNet TPO, Amsterdam, Netherlands

The Lesotho Ministry of Health initiated a World Bank funded Maternal and Newborn Health Performance-Based Financing (PBF) project in 2014, later re-structured as Health Sector Performance Enhancement Project. The project is operational in 6 of the 10 districts of Lesotho and aims to improve both the quantity of services in Health Centers (HC) and the quality of care in HC and District Hospitals (DH). The project incentivizes health workers by providing individual monetary incentives and promotes operational autonomy of their Health Facilities (HF) by making direct performance-based payments. The project's impact on quantity of services (measured through 14 indicators) has shown mixed results, although certain indicators have clearly improved; for instance, the percentage of pregnant women delivering in PBF participating HF rose from 53% to 74% between December 2009 and December 2016. Moreover, one of the highlights of the project has been an increase in the quality of care provided by the HF. This is measured by quarterly assessments using specifically designed quality checklists, an innovative approach to trace patients and conducting quarterly satisfaction surveys in the communities. The methodology also includes analysis of reports from exchange workshops and field visits to assess the motivation of health workers. Overall, HF are able to improve quality of care by implementing PBF concepts such as: contracting-in with relevant government authorities, improving record keeping and reporting, developing quarterly business plans to strategies on which indicators to improve, involving the community in decision making while rewarding client satisfaction. In addition, the staff motivation methods resulted in improved team work and workers motivation. In the coming two years of project implementation, we aim to develop a clearer understanding as to what extent the increase individual incentives and increased autonomy of the facilities has positively impacted on the quality of care and the perceived client satisfaction.

## 1519

### AVAILABILITY OF TREATMENTS IN MANAGING DIARRHEA, PNEUMONIA IN CHILDREN IN KENYA

**Nancy Njoki**<sup>1</sup>, Ann Musuva<sup>1</sup>, Julius Ngigi<sup>2</sup>

<sup>1</sup>Population Services Kenya, Nairobi, Kenya, <sup>2</sup>Population Services International, Nairobi, Kenya

Kenya has made significant progress in reducing child mortality over the last decade. Child mortality declined from 74 to 52 deaths per 1000 live births between 2009 and 2014. Among children under 5 (CU5), major causes of death are diarrhea (21%), pneumonia (16%) and malaria (11%). The Kenya policy on management of diarrhea in CU5 recommends the use of zinc and oral rehydration salts (ORS) for the treatment of diarrhea. Studies show that when ORS is given to a sick child with diarrhea it can reduce mortality by up to 93% and Zinc is effective in the reduction of mortality by diarrhea of up to 23%. The 2014 KDHS survey shows that only 8% of children with diarrhea were treated with both ORS and zinc with 66% of CU5 having acute respiratory infections. A National outlet survey was carried out in June-August, 2016 among 84 clusters targeting public and private sector. Representative samples of locations was selected in each research domain using one-stage cluster sampling. 84 census locations were selected where a sample of 2,272 outlets completed interview amongst eligible outlets. In the findings, availability of any ORS in public health facilities dropped from 80.1% (2014) to 76 % (2016) and in private health facilities from 7% to 4%. A similar downward trend on availability of ORS and Zinc packaged differently across the sectors was observed. ORS and zinc stock was found in 70% of public health facilities in 2016 and stocked by 80% of registered pharmacies. Availability of QA ACT, ORS, zinc, and Amoxicillin DT was quite low or non-existent across all public- and private-sector outlets in 2016. However the availability of any antibiotic in Public sector was 92.8% and 6.8% private sector. Proven interventions exist to mitigate deaths caused by diarrhea and pneumonia including antibiotics for pneumonia and ORS/Zn for diarrhea. In conclusion, there is need for commodity and allocation of adequate resources, political will and focused action for ending preventable childhood deaths. For new interventions like Amoxyl DT, public private partnerships need to be embraced towards growing a market for adequate product market traction.

## 1520

### SPATIAL ASSOCIATIONS OF LEPROSY AND SCHISTOSOMIASIS AND POTENTIAL EFFECTS OF THE CO-ENDEMIC HELMINTH ON THE TRANSMISSION OF LEPROSY IN THE MICROREGION OF GOVERNADOR VALADARES, BRAZIL

**Jessica L. Stephens**<sup>1</sup>, Jose A. Ferreira<sup>2</sup>, Lucia Alves de Oliveira Fraga<sup>3</sup>, Julie Clennon<sup>1</sup>, Uriel Kitron<sup>1</sup>, Jessica K. Fairley<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Faculdade da Saúde e Ecologia Humana, Vespasiano, Brazil, <sup>3</sup>Universidade Federal Juiz de Fora - Campus Governador Valadares, Governador Valadares, Brazil

Brazil has the second highest prevalence of leprosy (Hansen's Disease, HD), but factors contributing to transmission remain unclear. Pilot data suggest a potential spatial association between HD and schistosomiasis in Brazil. Studies have also shown a predisposition to the more infectious multibacillary leprosy (MB) in those co-infected with helminths. An ecological study using public health surveillance and census data was conducted to investigate whether the occurrence of HD-and specifically MB disease-is related to the presence of schistosomiasis in the community in 41 municipalities of the state of Minas Gerais, Brazil, 2011 to 2015. Multivariate logistic regression analysis and spatial cluster analyses using geographic information systems (GIS) were performed. The average annual incidence was high for HD at 35.3 per 100,000. *Schistosoma mansoni* average annual incidence was 26 per 100,000. Bivariate local indicator of spatial autocorrelation (LISA) analysis identified 15 high-high clusters

of HD and schistosomiasis and 11 of MB and schistosomiasis. However, there was no overlap between significant most likely clusters of HD or MB disease with schistosomiasis in Kulldorff's spatial scan. In census level multivariate analysis, the risk of MB presence was over 1.5 time greater in tracts with reported schistosomiasis than in tracts without it reported, adjusted for population density, household density, and household income (aOR=1.66, 95% CI 1.01, 2.71). This study provides a novel means to study HD transmission using GIS to analyze co-occurrence of schistosomiasis which may affect HD transmission in an area with clusters of hyperendemic HD. LISA clusters provide a depiction of areas of high risk for co-occurrence. Furthermore, census tract multivariate analysis show association of schistosomiasis with MB disease warrant more detailed analysis through co-infection studies. These findings not only suggest that helminth infections can influence HD transmission, they can guide integrated control programs in co-endemic areas to decrease the burden of these infections.

## 1521

### EVALUATING THE EFFECTIVENESS OF A VILLAGE GOVERNANCE MODEL FOR IMPROVING NEGLECTED TROPICAL DISEASE (NTD) AND WATER, SANITATION AND HYGIENE (WASH) RELATED OUTCOMES IN PWANI REGION, TANZANIA

**Rose E. Donohue<sup>1</sup>**, Kijakazi O. Mashoto<sup>2</sup>, Shirin Madon<sup>3</sup>, Mwele N. Malecela<sup>2</sup>, Edwin Michael<sup>1</sup>

<sup>1</sup>University of Notre Dame, South Bend, IN, United States, <sup>2</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>London School of Economics and Political Science, London, United Kingdom

While the importance of improved Water, Sanitation, and Hygiene (WASH) for Neglected Tropical Disease (NTD) control is well-established, the WASH and NTD sectors currently operate independently. Additionally, the governance of NTD control programs has been largely top-down in nature, with relatively little focus at the village-level. We created and implemented a governance structure, called the Enhanced Development Governance (EDG) model, that facilitates multi-sectoral coordination at the village level in an attempt to improve performance, reach, and outcomes of both the NTD and WASH sectors. In this study, we quantitatively evaluate whether the EDG model was associated with improved health and WASH-related outcomes. We conducted a case-control study in Tanzania whereby the six-month intervention was implemented in four villages of Rufiji district while four villages in Mkuranga district served as the control. Questionnaire surveys were conducted among schoolchildren and parents before and after the intervention to assess disease and WASH-related outcomes. To analyze the effect of the EDG model on the change in outcomes between the intervention and control districts, we utilized logistic generalized estimating equations regression models. Our results show that the intervention was associated with a significantly larger reduction in schistosomiasis prevalence compared to the control district (ROR = 0.67, 95% CI= 0.48 – 0.93). Incidence of diarrheal diseases was reduced in both districts, resulting in an insignificant intervention effect. Several key WASH indicators experienced significantly greater improvements in the intervention district, including reported handwashing and soap utilization. We conclude that the intervention was associated with several favorable health and WASH-related outcomes; however, additional research is needed to understand the exact mechanism by which these changes occurred and the reasons for outcome changes in control villages. These results suggest that the EDG model has the potential to improve both NTD and WASH-related outcomes, warranting further study.

## 1522

### EVALUATION OF SURGICAL INSTRUMENT DISINFECTION SYSTEMS AT THE EMERGENCY DEPARTMENT OF HIGHER LEVEL HOSPITALS IN SANTO DOMINGO, DOMINICAN REPUBLIC

**Maria A. Pimentel Herrera<sup>1</sup>**, Laura G. Conde Vásquez<sup>1</sup>, Robert Paulino-Ramirez<sup>2</sup>, Angiolina A. Camilo Reynoso<sup>1</sup>

<sup>1</sup>School of Medicine, Universidad Iberoamericana, Santo Domingo, Dominican Republic, <sup>2</sup>Instituto de Medicina Tropical and Salud Global, Universidad Iberoamericana, Santo Domingo, Dominican Republic

The evaluation of the surgical instrument disinfection processes is a key element for the elimination of any microbial form and to avoid nosocomial infections. The aims of this study was to evaluate the application of home-based methods of sterilization across five hospitals that offer attention at the emergency department for wounds and other injuries. An observational, descriptive, cross-sectional study was performed before and after disinfection of reusable devices at the emergency department of higher level hospitals in Santo Domingo, the capital city of Dominican Republic. A total of sixty samples were collected. Sterile transport sampling swabs were used to be cultured, and isolation of any microorganisms. The process was also described per each hospital. Three types of disinfection and sterilization were identified: a) hot air oven, b) 3% glutaraldehyde submersion, in hospital A and B respectively, and c) autoclave in C, D, and E, all after mechanical disinfection. Direct observational evaluation showed that 6 out of 36 (16.7%) sterilized instruments showed residues, and in 17 (47.2%) it was impossible to determine the presence of residues because of rust, while 7 out of 60 (11.7%) instruments showed bacterial growth, all of them before disinfection procedures. In 3 (42.9%) of them moderate colonies (3+) *Staphylococcus* spp were isolated; 2 (28.6%) *Staphylococcus* spp with low growth (1+); in one swab collected was isolated (14.3%) *Streptococcus* spp with abundant growth (4+) and 1 (14.3%) *E. coli* in abundant growth (4+). Although there is no standard guidelines of disinfection in use in the Dominican Republic; during the period of the study, pathogens were isolated. There is a lack of evidence-based interventions to reduce nosocomial transmission of bacteria, and this will impacted the flora of co-infections, leading to multiresistant strains, and other complications. It is recommended the creation of a standardized system of sterilization across the country, and enforcement in the application of International regulations for these departments.

## 1523

### OPTIMIZATION OF EXTRACTION PROCEDURES FOR DIVERSE CLINICAL SPECIMEN TYPES AND GLOBAL IMPLEMENTATION OF MULTIPLEX TAQMAN ARRAY CARDS FOR THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) PROGRAM

**Jessica L. Waller<sup>1</sup>**, Maureen H. Diaz<sup>1</sup>, Mary J. Theodore<sup>1</sup>, Alvaro J. Benitez<sup>1</sup>, Bernard J. Wolff<sup>1</sup>, Dianna M. Blau<sup>1</sup>, Pratima Raghunathan<sup>1</sup>, Robert F. Breiman<sup>2</sup>, Jeffrey P. Koplan<sup>2</sup>, Jonas M. Winchell<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Emory Global Health Institute, Atlanta, GA, United States

The Child Health and Mortality Prevention Surveillance (CHAMPS) Program, funded by the Bill and Melinda Gates Foundation, provides the opportunity to build local laboratory capacity and promote global health partnerships in Sub-Saharan Africa and South Asia in order to track preventable causes of mortality among children under five years of age. Global laboratory capacity building is impacted by numerous technical and logistical challenges, particularly in low-income settings. We have expanded laboratory capacity at five CHAMPS sites to identify common infectious causes of childhood deaths by implementing methods to detect diverse pathogens in multiple specimen types. We optimized and standardized specimen processing and testing protocols and transferred

the TaqMan Array Card (TAC), a multiple-pathogen detection system, to each site. We conducted field trainings at four global sites, instructing over 17 laboratorians. Specifically, we developed a more efficient method for simultaneous inactivation and lysis of parasitic, bacterial, viral, and fungal organisms in respiratory swab specimens, whole blood, cerebrospinal fluid, stool, and lung tissue for the capture of total nucleic acid. Various mechanical disruption methods were evaluated to replace expensive lysis enzymes for extracting relatively small amounts of pathogen nucleic acid from specimen types with abundant human nucleic acid (e.g. whole blood), from difficult to lyse microorganisms (e.g. gram-positive bacteria, fungi, and parasites), and from specimen types requiring extensive homogenization (e.g. lung tissue and stool). We adjusted the extraction protocol for use with various automated platforms in order to standardize procedures across field sites with different equipment and reagent resources. Together, optimizing technical aspects and conducting hands-on field site trainings for CHAMPS specimen processing has strengthened laboratory capacity. This capacity-building, along with newly forged scientific collaborations, will promote sharing of high-quality data and the ability to improve and adapt molecular detection methods in the future.

## 1524

### PROJECT TYCHO 2.0: A NEW OPEN ACCESS, GLOBAL DATA INFRASTRUCTURE FOR INFECTIOUS DISEASES TO IMPROVE RESEARCH CAPACITY AND INNOVATION THROUGH NORTH-SOUTH PARTNERSHIPS

**Willem G. Van Panhuis**

*University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States*

Project Tycho 2.0 is a new iteration of the open access Project Tycho database that was released in 2013 and now includes case counts of dengue fever for 100 countries between 1955 and 2010 at subnational and subannual resolution, obtained from the World Health Organization and country health agencies. This expansion has made Project Tycho 2.0 a new, global-scale, infrastructure for infectious disease data. In addition to new dengue data, the database now includes case counts for 45 additional notifiable conditions in the US, resulting from an extensive standardization process: we classified all diseases according to the Systematized Nomenclature of Medicine -- Clinical Terms (SNOMED-CT) and the International Classification of Diseases (ICD) version 10; we linked each disease with its causative pathogens and their NCBI Taxonomy ID numbers; we also standardized location names according to existing ISO and Global Administrative Boundary (GADM) definitions. This standardization makes Project Tycho data interoperable with other datasets and improves the reusability of these data. The impact of open access to infectious disease data is illustrated by our 3,000+ registered users, 16 peer-reviewed papers, and 235 media articles that used or mentioned Project Tycho data. We added the collection of global dengue data through partnerships between research institutes in the US and low- and middle-income countries in Asia and Latin America that involved joint research and infrastructure development. Project Tycho 2.0 data can be accessed through an online user interface, an application programming interface, an R-package, and a Github repository, to maximize the discoverability and reuse of this new data resource for global health research and innovation.

## 1525

### INVESTIGATING THE SATISFACTION OF REPUBLIC OF BENIN MINISTRY OF HEALTH FIELD STAFF PAID THROUGH THE MOBILE MONEY PLATFORM

**Alexandre Assogba**

*RTI International, Cotonou, Benin*

Benin's MoH started receiving support from the USAID funded project, ENVISION, for NTD programs in 2013. Back then, at completion of

activities, all involved MoH field staff received per diem payments through a local Credit Union, FECECAM. Due to the delay in receiving supporting documentation for payments, in 2014 the country started using another platform to pay per diems: Mobile Money (MM). MM sends money using a cellular phone subscribed to the MTN network. The objective of this study was to determine if MM is a viable and satisfactory method of payment for NTD programs. A questionnaire was designed and administered to 852 MoH field staff in different districts. Data was collected between February and March 2017. About 78% of participants reported being satisfied with the MM platform. Most of participants found the money recovery process through MM easy (90.3%), fast (82.3%), and safe (88.8%). Satisfaction varied according to education level and title. Participants who completed vocational training or university reported being more satisfied with the MM platform (respectively 94% and 86%) than those who completed high school or primary school only (73% and 80% respectively,  $p < 0.0001$ ). Issues frequently experienced with MM were: delays in reception of per diem (31%) and difficulty of withdrawing money due to technical problems such as poor MTN network coverage, slow or unstable internet connection- (13%). Besides the technical problems, the most frequently reported causes of complication during money retrieval (59%) were cash unavailability or slow service in some MM service delivery points. About 12% also reported non reception of per diem as a cause of complication for money retrieval. Despite the problems reported, almost all the participants (91%) judged that MM was the best way to pay because of its ease of use, the security it offers and other advantages in terms of services. MM proved to be a very good platform to transfer per diem payment. The availability of complete attendance lists and improved network coverage and internet quality would likely lead to an increase in payments received on time and therefore in user satisfaction.

## 1526

### SUPPORTIVE SUPERVISION FOR MALARIA CASE MANAGEMENT IN ZAMBIA - THE EFFECTS OF FOCUSED CAPACITY BUILDING ON INDICATORS OF DIAGNOSTIC AND CLINICAL PERFORMANCE

**Matt Worgees<sup>1</sup>**, Nicole Whitehurst<sup>1</sup>, Timothy Nzangwa<sup>1</sup>, Chris Petrucci<sup>1</sup>, Sean Fennell<sup>1</sup>, Hawela Moonga<sup>2</sup>, Luis Benavente<sup>1</sup>

<sup>1</sup>*Medical Care Development International, Silver Spring, MD, United States,*

<sup>2</sup>*National Malaria Control Centre, Zambia Ministry of Health, Lusaka, Zambia*

Zambia was the first country in Africa to introduce the use of Artemether Lumefantrine as a first-line ACT and subsequently called for parasite-based diagnosis in order to curb over-prescription of ACTs due to clinical misdiagnosis of malaria. From 2008-2012 the Zambia NMCC, with support from the international community, implemented an external quality assurance (EQA) scheme to support malaria case management across a spectrum of health facilities performing laboratory-based malaria diagnostics. Supportive supervisory assessments, coupled with focused on-the-job training, were conducted on a quarterly basis to measure changes in health facility staff performance over time and to collect diagnostic and clinical data. A total of 88 health facilities (36 health centers and 52 provincial/district hospitals) with 4 repeated supervisory assessments were included in this analysis. Bivariate analysis (McNemar's test) shows significant differences from assessment 1 to assessment 4 for stock-outs of microscopy reagents/consumables (35 vs 7,  $p < 0.0000$ ) and instituting internal quality assurance measures such as use of microscopy positive controls (3 vs 17,  $p < 0.0026$ ), conducting parasite counting (6 vs 19,  $p < 0.0146$ ), and converting from the plus system to an alternative counting methodology (e.g. parasites/ $\mu$ l) (2 vs 20,  $p < 0.0001$ ). Improvements to malaria diagnostic and clinical performance (i.e. RDT use (mean(diff)=15.89%,  $p < 0.0000$ ), blood slide preparation (mean(diff)=12.90%,  $p < 0.0001$ ), blood slide staining and reading (mean(diff)=13.48%,  $p < 0.0000$ ), febrile case management (mean(diff)=8.38%,  $p < 0.0006$ ) and prescriber adherence to diagnostic test results (mean(diff)=7.18%,  $p < 0.028$ ) were also found to be significantly different from assessment 1 to assessment 4 via paired t-tests.

The EQA scheme provided periodic, cross-sectional representations of clinical and laboratory staff performance. Supportive supervision with focused capacity building can lead to improved malaria diagnostic skills and strengthened febrile case management practices leading to more appropriate treatment with ACTs.

## 1527

### TREATING MALNUTRITION IN THE COMMUNITY: A FEASIBILITY STUDY OF LOW-LITERACY COMMUNITY HEALTH WORKERS TREATING SEVERE ACUTE MALNUTRITION USING SIMPLIFIED TOOLS AND PROTOCOL IN SOUTH SUDAN

Naoko Kozuki<sup>1</sup>, Elburg Van Boetzel<sup>2</sup>, Casie Tesfai<sup>3</sup>, Annie Zhou<sup>3</sup>

<sup>1</sup>International Rescue Committee, Washington, DC, United States,

<sup>2</sup>International Rescue Committee, Panthou, South Sudan, <sup>3</sup>International Rescue Committee, New York, NY, United States

UNICEF estimates that 270,000 children in South Sudan are currently suffering from severe acute malnutrition (SAM). Coverage surveys in Northern Bahr el Ghazal State found that roughly 60% of severely malnourished children were not enrolled in treatment programs. Long distance, rough terrain, and high opportunity costs deter caregivers from accessing essential treatment. The International Rescue Committee (IRC) assessed through a two-part process the feasibility of community-based treatment for uncomplicated SAM cases, provided by community health workers (CHW). First, innovative tools for low-literacy CHWs were developed through an iterative, human-centered design process. More than 50 CHWs and 30 nutrition staff participated in five field tests in Mali, Chad, and South Sudan. Participants practiced using prototypes of the tools, gave feedback, and revisions were further tested until a toolkit was finalized. In the second stage, the IRC evaluated in Aweil South County the CHWs' performance in treating SAM children using the finalized toolkit and the outcomes of children treated. 57 CHWs, all with no formal education, were trained and tested at an outpatient clinic and their performance scored against a checklist of critical actions. After six days of training, CHW performance score was an average 93.4% and ranged from 67.5% to 100%. 52 of the 57 CHWs (91.2%) passed at an a priori determined standard of 80%, and 28 of 57 CHWs (49.1%) had perfect scores. As of April 2017, 44 of the highest scoring CHWs were recruited to treat uncomplicated cases of SAM in their communities. Their on-the-job performance scores and the treatment outcomes of the children enrolled in the study (expected sample size of 320 children) will be available in September 2017. Current outpatient treatment programs for SAM can be taxing on families, based on distance to the clinic and weekly frequency of visits. A successful community-based treatment program can alleviate the burden of SAM worldwide.

## 1528

### DRUG COVERAGE AND FACTORS ASSOCIATED WITH MDA IN PAPUA NEW GUINEA

Krufinta Bun, Catherine Stein, Darcy Freedman, Peter Zimmerman, Daniel Tisch

Case Western Reserve University, Cleveland, OH, United States

Papua New Guinea (PNG) bears one of the highest burdens of Lymphatic Filariasis (LF) in the South Pacific region and experiences extensive logistical barriers to implementing repeated, high-coverage Mass Drug Administration (MDA) against LF. High drug coverage during MDA is considered a key predictor of successful LF elimination. This study investigates factors that influence population coverage in East and West Sepik provinces currently implementing MDA to improve LF elimination programs. Seven villages currently implementing MDA were randomly selected with a WHO-based cluster-survey protocol to assess MDA coverage in households. A key respondent per household answered questions relating to knowledge of lymphatic filariasis, reasons for participation and perception of the MDA program. Households were

divided into 3 groups for analysis: (i) Households who received MDA only (ii) Households who did not receive MDA (iii) Households with incomplete MDA participation. There were 506 households within the 7 villages with a total population 2271 people. Six of the 7 villages had population coverage > 70- 95%. Only one village coverage fell below the programmatic minimum of 65% (57% reported coverage). The factors that were significantly associated with having all eligible members per household receiving MDA across all villages were; Being informed by health workers (OR= 3.2, p=0.0009); Concern about acquiring LF (OR= 2.5, p=0.002); and distribution site close to homes (OR=2.1, p=0.010). The factor that decreased the probability of all eligible members to receive MDA per household was; (i) High number of people per household (OR= 0.8, p<0.0001). Some individual villages had unique factors associated with all eligible members receiving MDA per household including knowledge of LF prevention (OR= 13.6, p=0.003). The results indicate that concerns about acquiring LF and close MDA distribution site were positive factors in all 7 villages. There variation in significant factors unique to individual villages highlights the importance of delivering MDA information tailored to specific communities.

## 1529

### EVALUATION OF THE IMPACT OF THE 2014-2015 EBOLA OUTBREAK ON ACUTE FLACCID PARALYSIS SURVEILLANCE IN LIBERIA

Grace Umutesi Wa Mana<sup>1</sup>, Troy D. Moon<sup>1</sup>, Mary Alleman<sup>2</sup>, Jeevan Makam<sup>2</sup>, Charlotte B. Cherry<sup>1</sup>, Fabien Diomande<sup>2</sup>, Roland N.o. Tuopileyi, II<sup>3</sup>, Adolphus Clark<sup>4</sup>, Wambai Zakari<sup>3</sup>, Allen S. Craig<sup>2</sup>

<sup>1</sup>Vanderbilt Institute for Global Health, Nashville, TN, United States,

<sup>2</sup>Centers for Diseases Control and Prevention-Global Immunization

Division, Atlanta, GA, United States, <sup>3</sup>World Health Organization,

Monrovia, Liberia, <sup>4</sup>Ministry of Health, Monrovia, Liberia

The Global Polio Eradication Initiative (GPEI) was launched in 1988 with a goal to eradicate poliomyelitis worldwide. Since its inception, the number of WPV cases dropped from 350,000 in 1988 to 37 in 2016. Acute flaccid paralysis (AFP) surveillance is the GPEI tool used for detecting poliovirus circulation. In 2014, the Ebola outbreak infected over 28,000 people in Guinea, Liberia and Sierra Leone. The outbreak disproportionately affected health workers who were 21-32 times more likely to be infected than the general population. This resulted in an overall reduction in the health workforce of 8% in Liberia, 7% in Sierra Leone, and 1% in Guinea. In order to quantify the effects that the outbreak had on AFP surveillance activities in Liberia, we assessed the performance of AFP surveillance before (2012-2013) and during the Ebola outbreak (2014-2015). AFP surveillance data obtained from the Expanded Program on Immunization (EPI) were analyzed to calculate five World Health Organization (WHO) AFP surveillance performance indicators: the non-polio AFP rate, notification, investigation, stool collection, and stool adequacy. Logistic and Poisson regressions were run to detect associations between changes in surveillance indicators and the Ebola time periods (before and during the outbreak). ArcGIS (Version 10.3.1) was used to visualize the overlap between number of Ebola cases reported in each county and corresponding NP AFP rates. During the Ebola outbreak, the overall national NP AFP rate dropped from 2.7 to 1.1 (RR: 0.41; 95% CI: 0.24, 0.69; P=0.001). The NPAFP rate dropped below the WHO recommended target in 10 out of 15 counties during the Ebola outbreak period. Among these 10 counties, 8 of them had high number of Ebola cases detected. Lofa County did not report any AFP cases in 2014 and 2015, while Bong, Grand Cape Mount, Margibi and Rivercess counties did not report any AFP cases in 2015. The other 4 surveillance indicators, except NPAFP rate, met the WHO target with some exceptions in counties that had high numbers of Ebola cases. These findings highlight the association in time between a decline in sensitivity of AFP surveillance and the Ebola outbreak.

## 1530

### USE OF AN UNMODIFIED OFFICE SCANNER FOR DIGITALIZATION OF CHEST X-RAY FILMS FROM TUBERCULOSIS PATIENTS

German Comina<sup>1</sup>, Gustavo Hernandez<sup>1</sup>, Gwentyth Lee<sup>1</sup>, Nehal Naik<sup>2</sup>, Eduardo Ticona<sup>3</sup>, Oscar Gayoso<sup>4</sup>, Mirko Zimic<sup>5</sup>, Robert H. Gilman<sup>6</sup>, Valerie A. Paz-Soldan<sup>1</sup>, Richard Oberhelman<sup>1</sup>

<sup>1</sup>Department of Global Community Health and Behavioral Sciences, Tulane University, New Orleans, LA, United States, <sup>2</sup>Virginia Commonwealth University, Richmond, VA, United States, <sup>3</sup>Facultad de Medicina, Universidad Nacional Mayor de San Marcos, and Servicio de Enfermedades Infecciosas y Tropicales, Hospital Nacional Dos de Mayo, Lima, Peru, <sup>4</sup>Servicio de Neumología, Hospital Nacional Cayetano Heredia, Lima, Peru, <sup>5</sup>Laboratorio de Investigación en Enfermedades Infecciosas, Laboratorio de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>Global Disease Epidemiology and Control Program, Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

When managing tuberculosis (TB) patients in sites where clinical records are maintained physically, the digitalization of the archived chest x-rays films provides major benefits in both efficiency and accessibility. There are several ways to digitalize chest x-rays films: using commercial medical x-ray film scanners, photo-camera or smartphone cameras coupled with light sources and special software. In all instances transmitted light is used to create the image. The reliability of radiologist's interpretations of the x-ray depends on the quality of the scanned image. In this study, we propose a method that uses an unmodified office scanner with no special software and no adhoc-light-source to obtain useful digital images from chest x-rays films from TB patients. In this method the x-ray film is placed on the scanning area of a scanner (Epson XP-100 multifunction printer + scanner), then a paper sheet (A4, white paper bond 70gr) is placed on top of the film, and the x-ray film is scanned maintaining the scanner cover open during the process. It was found that this process provides enough illuminance of 360lx on the scanning surface (measured using a digital lux meter CEM DT-1309) to obtain useful quality scans. We obtained that illuminance, simply locating the scanner on a desk under the office spotlight or close to a window during the day. We tested this procedure scanning three x-ray films with different qualities based on human perception (good, medium and medium-low contrast). The scanned digital images had different average Contrast to Noise Ratio (CNR=55.5, 33.6, 30.3). A radiologist evaluated and filled a report of 45 items (number of cavities, consolidations, etc.) for each film, and digital image (JPEG format). Cavitation items were matched perfectly for the middle and high CNR, and failed detecting one cavity in the low quality image. With this image was possible to match 90.2% of the items and with the images with highest CNC=55.5 and CNC= 33.6 was possible to match 95.6% and 97.8% respectively.

## 1531

### STIGMA AMONG BATEY RESIDENTS IN THE DOMINICAN REPUBLIC: IMPLICATIONS FOR MALARIA ELIMINATION

Hunter Keys<sup>1</sup>, Gregory Noland<sup>2</sup>, Madsen Beau De Rochars<sup>3</sup>, Stephen Blount<sup>2</sup>, Thomas H. Taylor<sup>4</sup>, Manuel Gonzales<sup>5</sup>

<sup>1</sup>University of Amsterdam, Amsterdam, Netherlands, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>University of Florida, Gainesville, FL, United States, <sup>4</sup>Taylor Engineering, Atlanta, GA, United States, <sup>5</sup>Centro Nacional para el Control de Enfermedades Tropicales, Santo Domingo, Dominican Republic

Malaria elimination efforts often require engagement with groups that may already experience stigma, such as the rural poor or migrants. Consequently, elimination programs can inadvertently worsen stigma if they feed into narratives of blame. To avoid adverse social impacts and strengthen community engagement, a first step is to assess how stigma is already felt and interpreted. The island of Hispaniola, shared by Haiti

and the Dominican Republic (DR), is the last malaria-endemic island in the Caribbean. In the DR, malaria outbreaks occur along the Haitian border and in *bateyes*, agricultural areas historically reliant on migrant labor from Haiti. A legacy of stigma against migrants and their descendants exists in the DR. The goals of this study were to: 1) measure stigma among *batey* residents; 2) determine which stigmatizing experiences were most relevant across social groups; and 3) compare explanations for stigma. In 2016, a stratified cluster survey was conducted in *bateyes* across the DR. The sample population (n=780) contained three distinct social groups: Haitian-born persons (33.1%), persons of Haitian descent (29.4%), and those without Haitian descent (37.5%). Mean total stigma score was 17.3 out of maximum 55 (range 0-55). Highest scores were noted among Haitian-born persons, followed by those of Haitian-descent, and lastly by those without Haitian-descent. Factor analysis within each group revealed two main components: 1) feeling treated with less courtesy and respect, and 2) feeling humiliated. While these experiences were common to all participants, their explanations differed. Skin color or origin were more readily endorsed as reasons for stigma among persons born in Haiti or of Haitian-descent, whereas poverty or lack of education were cited by those without Haitian descent. For all groups, disease-related stigma was less important. In this setting, stigma is common but interpreted differently. To build trust and maximize engagement, elimination programs should recognize these underlying stigma processes and avoid reinforcing them.

## 1532

### FEASIBILITY OF IMPLEMENTING POINT-OF-CARE ULTRASOUND IN A MSF HOSPITAL-TEACHING LUNG ULTRASOUND TO CLINICAL OFFICERS IN SOUTH SUDAN

Aditya Nadimpalli<sup>1</sup>, Carrie Teicher<sup>1</sup>, Jim Tsung<sup>2</sup>, Ramon Sanchez<sup>3</sup>, Sachita Shah<sup>4</sup>, Evgenia Zelikova<sup>5</sup>, Lisa Umphrey<sup>6</sup>, Northan Hurtado<sup>1</sup>, Alan Gonzalez<sup>1</sup>

<sup>1</sup>Doctors Without Borders, New York, NY, United States, <sup>2</sup>Ichan School of Medicine at Mt. Sinai, New York, NY, United States, <sup>3</sup>University of Michigan School of Medicine, Ann Arbor, MI, United States, <sup>4</sup>University of Washington School of Medicine, Seattle, WA, United States, <sup>5</sup>Doctors Without Borders, Juba, South Sudan, <sup>6</sup>Doctors Without Borders, Sydney, Australia

Medecins Sans Frontieres has been operating a pediatric inpatient service in Aweil State Hospital, Northern Bahr al-Ghazal state in South Sudan for more than 8 years. This includes 150 inpatient beds, which expand to over 300 beds during peaks of malnutrition and malaria. This is a low-resource area, with the only x-ray services 15 minutes by car. There are over 900 admissions annually for Lower Respiratory Tract Infections (LRTIs). But the current MSF/WHO protocol is quite broad and includes disease processes that mimic LRTIs, frequently necessitating further diagnostic testing. Bedside Lung US is a novel tool available to clinicians to aid diagnosis. As Clinical Officers (COs) are responsible for the primary evaluation of most patients, we evaluated the ability to teach COs a lung algorithm at an acceptable level. We trained 6 COs to perform a protocolized Lung Ultrasound. Subsequently, each CO submitted 3 sets of 20 Lung US exams. Expert reviewers evaluated both the image acquisition and image analysis. A CO would be deemed successful if he reached 90% positive scores in any of the three sets of 20 exams. We used the Philips Lumify US machine, a tablet based portable portable ultrasound. The training was a protocol-based with an algorithm of various internationally standard Lung US findings, including A-lines, B-lines, sub-pleural consolidations, consolidations and effusions to conclude an overall impression according to the following list: Normal Lungs; Bronchiolitis or Viral Pneumonia; Consolidation/Pneumonia (Possibly Bacterial); Pulmonary Interstitial Disease; Pleural Effusion; Pneumothorax. We did not alter patient management based on the CO ultrasounds. The study is ongoing. Each CO has finished his 60 exams and the Experts are reviewing the images – expected completion is mid-May 2017. POCUS is becoming an essential diagnostic tool in resource-poor settings. This study is intended to show that with proper tools, training and protocols, Clinical Officers can

safely and effectively perform a key POCUS application. If successful, this study will set a model for future trainings of clinicians in resource-limited settings.

## 1533

### EVD OUTBREAK PREPAREDNESS OF LABORATORY AND HEALTHCARE WORKERS IN SIERRA LEONE

Victor Matt-Lebby<sup>1</sup>, Jane S. Alam<sup>2</sup>, Jeanette Coffin<sup>2</sup>, Steve Krcha<sup>2</sup>, Doris Harding<sup>1</sup>, **Paul D. Stamper<sup>2</sup>**, Isatta M. Wurie<sup>3</sup>

<sup>1</sup>Ministry of Health and Sanitation, Freetown, Sierra Leone, <sup>2</sup>MRIGlobal, Gaithersburg, MD, United States, <sup>3</sup>Association of Public Health Laboratories, Freetown, Sierra Leone

The 2014 West African Ebola outbreak was unparalleled with over 14,000 cases of Ebola Virus Disease (EVD) in Sierra Leone resulting in approximately 4000 deaths before waning in 2016. According to WHO estimates, healthcare workers (HCWs), including laboratory staff, were more than 20 times more likely to become infected with EVD than the general adult population in Sierra Leone. Tabletop Exercise (TTX) events have been employed as a means of discussing and evaluating emergency scenarios, and in the past proved valuable and effective in gathering HCW information, particularly useful identifying preparation needed for future EVD events. In accordance with the National Laboratory Strategic Plan, key stakeholders including the Sierra Leone National Public Health Rapid Response Team (NPHRRT) and healthcare workers associated with the EVD response were invited. The informal TTX event was held on September 17, 2016 to facilitate candid discussions on the EVD diagnostic laboratories in Sierra Leone between 40 stakeholders as part the national EVD response (Laboratory staff, Ministry of Health and Sanitation (MOHS) Ebola Virus Disease (EVD) staff, National Rapid Response Team (NRRT), and the World Health Organization (WHO)). HCWs described their understanding of current national outbreak response capabilities in relation to themselves, MOHS, and other EVD diagnostic laboratories. At the TTX event, 75% (n=30) completed a preparedness survey which compared and contrasted laboratory capabilities with solutions addressing functional gaps in training and EVD diagnostics workflow within the EVD response system. TTX participants recognized gaps and challenges to better support EVD diagnostics efforts in the future. In addition to an acknowledgement of the local concerns and challenges to EVD diagnostics in Sierra Leone, the exercise also provided a better understanding of what the local experts consider important shortfalls in their system, thereby allowing for formal preparedness recommendations of appropriate solutions to long-term and sustainable EVD laboratory functionality.

## 1534

### ASSESSMENT OF HYDROCELECTOMY SURGICAL CAPACITY IN SUB-SAHARAN AFRICA USING THE WHO SITUATIONAL ANALYSIS TOOL

**Clementine Laetitia Soraya Koa Affana<sup>1</sup>**, Yihan Lin<sup>2</sup>, Neema Kaseje<sup>3</sup>, Walter Johnson<sup>4</sup>

<sup>1</sup>All Saints University School of Medicine, Roseau, Dominica, <sup>2</sup>Paul Farmer Global Surgery Fellow, Harvard Program in Global Surgery and Social Change, Boston, MA, United States, <sup>3</sup>Boston Children's Hospital and Harvard Medical School Program in Global Surgery and Social Change, Boston, MA, United States, <sup>4</sup>World Health Organization, Geneva, Switzerland

Diagnosis of hydroceles is closely linked to lymphatic filariasis in endemic areas. Managing morbidity and disability from hydroceles is halted by poor access to essential surgical care in sub-Saharan Africa, resulting in significant psychosocial sequelae. Our aims were to evaluate hydrocelectomy capacity in sub-Saharan Africa using the WHO SAT by comparing facilities that provide hydrocelectomy to those that do not; and determine factors associated with increased hydrocelectomy delivery. Using a retrospective analysis of the WHO SAT administered between 2010 and 2013, facilities were organized by whether or not they perform

hydrocelectomy, and each group was compared to determine differences in workforce, infrastructure, and reasons for referrals if the procedure was not provided. Significance was determined using student t tests. Data was collected from 365 facilities from 25 countries in sub Saharan Africa. 231 facilities performed the procedure, the majority were district hospitals (37%) and mission hospitals (20%). 134 facilities did not perform the procedure, 75% of them were health centers and 25% district and general hospitals. Reasons for referrals were lack of equipment (16.42%), lack of skills (25.37%) lack of both (35.82%), undisclosed (22.39%). Comparing facility types, those performing hydrocelectomy had more qualified surgeons (means 4.63 vs 0.45, p<0.01) and non physician providers (means 6.62 vs 0.74, p<0.01); more qualified anesthetists (means 0.92 vs 0.08, p<0.01) and non physician providers (means 5.06 vs 0.41, p< 0.01), and more functioning operating rooms (means 2.9 vs 0.9, p< 0.01). Facilities performing hydrocelectomy had significantly more providers and functioning operating rooms. Lack of skills and equipment were the most common causes of referrals to other facilities. Efforts to improve surgical care and hydrocelectomy provision should include building a surgical workforce, including mid-level providers and improving infrastructure, including equipment and supplies.

## 1535

### THE ROLE OF PARTICIPANT TRACKERS IN THE PREVAIL EBOLA VACCINES TRIAL IN LIBERIA

**Joseph B. Cooper**, Bartholomew Wilson, Julia Endee, Julia Lysander, Khalifa Bility, Jestina Doe Anderson, Laurie Cooper, Hassan Kiawu, Patrick Falley, Elizabeth Higgs

*Partnership for Research on Ebola Virus in Liberia, Monrovia, Liberia*

A quality clinical research has the potential to mitigate mortality and accelerate the end of outbreaks as well as contribute to the prevention of future outbreaks. The West African Ebola outbreak began in December 2013 in Guinea and went on to cause over 28,000 cases and claim over 11,000 lives. Conducting quality research in the setting of an infectious disease outbreak requires systematic process in the setting of dynamic outbreak challenges. The Liberia-US Joint Clinical Research Program (PREVAIL) was established in October 2014 to accelerate the development of Ebola vaccines and therapeutics. With the Liberian scientists identified Social Mobilization and Community Engagement (SMC) as one of those key processes necessary for a more successful conduct of a clinical research program, the PREVAIL team worked with outbreak response structures in both community and the Incident Management System (IMS) to establish a unique robust community support for a clinical research. Working with the District Community Ebola Task Force and community leaders, provided a smooth way forward in establishing a social and cultural valued SMC for the research. Having Communicators, Mobilizers and Trackers for a comprehensive message dissemination and follow-up on participants regularly, led to the study achieving a 98% follow-up retention rate.

The 2013-2016 Ebola virus disease (EVD) outbreak in West Africa was associated with unprecedented challenges in the provision of care to EVD patients, including lack of pre-existing isolation and treatment facilities, patients' reluctance to present for medical care due to fear of a high risk of mortality in treatment units, lack of effective Ebola virus-specific therapy and limitations in provision of supportive medical care. Case fatality rates (CFR) in West Africa were initially greater than 70% but over time decreased with increasing clinical and health system experience that included improvements in supportive care. To inform optimal care in a future EVD outbreak, we employed the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology to develop evidence-informed guidelines for the delivery of supportive care to patients admitted to Ebola treatment units.

### GEOHEALTH: A GEOSPATIAL SURVEILLANCE AND RESPONSE SYSTEM RESOURCE FOR VECTOR-BORNE DISEASE IN THE AMERICAS

John B. Malone<sup>1</sup>, Rebecca Christofferson<sup>1</sup>, Jeffrey C. Luvall<sup>2</sup>, Jennifer C. McCarroll<sup>1</sup>, Laura Rinaldi<sup>3</sup>

<sup>1</sup>Louisiana State University, Baton Rouge, LA, United States, <sup>2</sup>NASA Marshall Space Flight Center, Huntsville, AL, United States, <sup>3</sup>University of Naples Federico II, Naples, Italy

Implementation of a geospatial surveillance and response system data resource for vector borne disease in the Americas (GeoHealth) is proposed using geographic information systems and ecological niche modeling, available global databases on climate-hydrology and NASA earth observing satellite data systems to characterize the environmental suitability and potential for spread of endemic and epizootic vector borne diseases. The initial focus is on developing prototype geospatial models for visceral leishmaniasis, an expanding endemic disease in Latin America, and geospatial models for Dengue and other *Aedes aegypti* borne arboviruses (Zika, Chikungunya), emerging arboviruses with potential for epizootic spread from Latin America and the Caribbean and establishment in North America. Use of geospatial surveillance and response system open-source data bases and models will be made available through the International Society for Geospatial Health-GnosisGIS, with training courses, to other investigators interested in mapping and modeling other vector borne diseases in the western hemisphere. GeoHealth is designed to be part of the NASA public health societal benefit area and the Global Earth Observation System of Systems (GEOSS) architecture and voluntary open source data sharing concept of the Group on Earth Observations (GEO).

### A NEW APPROACH FOR PROVIDER PERFORMANCE IMPROVEMENT WITH CLINICAL AND QUALITY ASSURANCE COMPONENTS IN MORAMANGA, MADAGASCAR

Norohaingo Andrianaivo, Eliane Razafimandimby, Jean Pierre Rakotovoao, Marc Eric Rajaonarison Razakariasy, Lalanirina Ravony Jhpiego, Antananarivo, Madagascar

Malaria is endemic in 90% of Madagascar. However, the entire population is considered to be at risk for the disease, with pregnant women particularly vulnerable. Madagascar adopted the IPT in pregnancy policy in 2004. The Malaria Indicator Survey in 2016 in Madagascar showed only 10% of Malagasy pregnant women receiving three doses of SP (IPT3). MCSP previously conducted health provider training in antenatal care in workshop style, with usually one provider per facility attending each training. To increase the number of providers offering standardized service according to the new WHO recommendations for IPTp, in 2016 MCSP Madagascar began implementing a new low dose/high frequency training approach, with routine supportive supervision. On-site training and supportive supervision provide the opportunity for the trainer and providers to discuss the barriers to delivery of IPTp-SP. Additionally, with the addition of a new IPTp indicator in the facility dashboard, the trainer/supervisor can monitor the indicator, and discuss plan of action with providers as needed. To date, in Moramanga District, 16 providers in six facilities have benefited from this performance improvement approach. The qualitative and quantitative study of provider performance and results from January 2017 to May 2017 shows Adequate action plans were implemented to prevent SP stock out and to commit community health workers. The increase of antenatal care utilization rate in these facilities. The IPT uptake increased. This intervention is expected to show that IPT uptake and other maternal and newborn outcomes are improving in Madagascar.

### A PVDBP MONOCLONAL ANTIBODY RECOGNIZES A CONSERVED EPITOPE IN *PLASMODIUM FALCIPARUM* AND *P. CHABAUDI* ANTIGENS

Catherine J. Mitran<sup>1</sup>, Shanna Banman<sup>1</sup>, Sedami Gnidehou<sup>2</sup>, Brian Taylor<sup>1</sup>, Aja M. Rieger<sup>1</sup>, Francis Ntumngia<sup>3</sup>, John H. Adams<sup>3</sup>, Michael F. Good<sup>4</sup>, Stephanie K. Yanow<sup>1</sup>

<sup>1</sup>University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Campus Saint-Jean, University of Alberta, Edmonton, AB, Canada, <sup>3</sup>University of South Florida, Tampa, FL, United States, <sup>4</sup>Institute for Glycomics, Griffith University, Gold Coast, Australia

The *Plasmodium falciparum* parasite has evolved numerous adaptations to survive in its human host. A key adaptation is the cytoadherence of infected erythrocytes (IE) to host tissues, allowing the parasite to escape detection by the immune system and resulting in the significant pathologies associated with malaria. In pregnancy, *P. falciparum* expresses the protein VAR2CSA on the surface of IEs, which allows the parasite to adhere to chondroitin sulfate A (CSA) expressed on the surface of the placenta. In Africa, where *P. falciparum* is holoendemic, antibodies to VAR2CSA are acquired through successive exposure to *P. falciparum* in pregnancy and are able to protect the mother and child by blocking parasite adhesion to CSA. Recently, we discovered a novel mechanism for protection against malaria in pregnancy through exposure to a surface protein from *P. vivax* that is structurally related to VAR2CSA. We found that a monoclonal antibody (mAb) against the *P. vivax* protein, PvDBP, recognized VAR2CSA through shared DBL domains. Here, using live and fixed CS2 IEs, we show that there is partial overlap between the recognition sites of a polyclonal antibody against VAR2CSA and the PvDBP mAb. In addition, prior incubation of IE with the VAR2CSA antibody did not block recognition by the PvDBP mAb, suggesting there are epitopes, possibly cryptic, that are exclusively recognized by the mAb. We further show that cross-recognition extends beyond VAR2CSA. As

demonstrated by flow cytometry, the PvDBP mAb recognized a significant proportion of unselected 3D7 IEs. Lastly, using ELISA and western blot methods, we found that the mAb recognized a recombinant protein from the murine malaria parasite *P. chabaudi*, which we identified based on sequence homology with PvDBP. These results suggest that there is a highly conserved epitope in proteins expressed by several species in the *Plasmodium* genus, which could offer important insight into malaria immunity and for vaccine development.

## 1540

### PITTING-RELATED PERSISTENCE OF *PLASMODIUM FALCIPARUM* HRP2 IN PERIPHERAL BLOOD PREDICTS POST-ARTESUNATE DELAYED HEMOLYSIS IN SEVERE MALARIA

**Alioune Ndour**<sup>1</sup>, Sébastien Larréché<sup>2</sup>, Oussama Mouri<sup>3</sup>, Nicolas Argy<sup>3</sup>, Frédéric Gay<sup>3</sup>, Camille Roussel<sup>1</sup>, Stéphane Jauréguiberry<sup>3</sup>, Claire Périllaud<sup>3</sup>, Dominique Langui<sup>4</sup>, Sylvestre Biligui<sup>3</sup>, Nathalie Chartrel<sup>3</sup>, Audrey Mérens<sup>2</sup>, Eric Kendjo<sup>3</sup>, Arjen Dondorp<sup>5</sup>, Martin Danis<sup>3</sup>, Sandrine Houzé<sup>3</sup>, Serge Bonnefoy<sup>6</sup>, Thellier Marc<sup>3</sup>, Charlie Woodrow<sup>5</sup>, Pierre Buffet<sup>1</sup>

<sup>1</sup>Paris Descartes University, Inserm U1134, Paris, France, <sup>2</sup>Hôpital d'instruction des armées Bégin, Paris, France, <sup>3</sup>APHP, Centre National du Paludisme, Paris, France, <sup>4</sup>Université Pierre et Marie Curie, Paris, France, <sup>5</sup>Mahidol University, Bangkok, Thailand, <sup>6</sup>Institut Pasteur, Paris, France

Post-artesunate delayed hemolysis (PADH) occurs in 7-25% of patients treated with artemisinin derivatives and 60% of them requiring blood transfusion in severe imported malaria. This adverse event do not compromise the use of artemisinins because it remains the most effective drug against malaria. However, its evaluation is becoming an important public health problem. In severe malaria patients treated with intravenous artesunate, we reported that PADH is related to the lifesaving effect of artemisinins: The dead parasites are expelled from the host red cells by the spleen. These pitted red cells that previously contained a parasite persist in circulation and retain the parasite protein HRP2 as an imprint. Dipstick-based titration of HRP2 predicts frequent, potentially severe hemolysis induced by artemisinins. This recent finding was initially confirmed retrospectively in more than 100 patients with severe malaria in France where the highest number of imported malaria is annually recorded. Through an observational and prospective analysis in the severe malaria program surveillance, we propose a field use of this HRP2-based RDT method for the prediction of PADH. The standardization of this method with the widely available HRP2-based RDTs would help to predict this potentially severe adverse event, several days before it occurs and would significantly improve healthcare in patients treated with artemisinin derivatives.

## 1541

### *PLASMODIUM FALCIPARUM* ERYTHROCYTE MEMBRANE PROTEIN 1 (PFEMP1) VARIANT EXPRESSION PROFILES IN KENYAN CHILDREN WITH SEVERE MALARIAL ANEMIA FROM WESTERN KENYA

**Elizabeth M. Glenn**<sup>1</sup>, Angela O. Achieng<sup>1</sup>, Qiuying Cheng<sup>1</sup>, Prakasha Kempaiah<sup>1</sup>, Ananias Escalante<sup>2</sup>, Douglas J. Perkins<sup>1</sup>

<sup>1</sup>University of New Mexico School of Medicine, Albuquerque, NM, United States, <sup>2</sup>Institute for Genomics and Evolutionary Medicine, Temple University, Philadelphia, PA, United States

Annually millions of individuals are infected with *Plasmodium falciparum*, the majority of whom reside in sub-Saharan Africa. *P. falciparum* infection in children under 5 years of age in holoendemic regions, such as western Kenya, can cause severe malarial anemia (SMA, hemoglobin [Hb] ≤ 5.0 g/dL). Although the complex host-parasite interactions that culminate in SMA are largely undefined, previous investigations suggest that variant expression of *P. falciparum* erythrocyte membrane protein 1 (PFEMP1) may influence malarial disease outcomes. PFEMP1 is expressed on the surface of

infected erythrocytes, and is important for parasite immune evasion, and erythrocyte adhesion to the microvasculature. We determined if expression levels of five PFEMP1 domains previously associated with disease outcomes, were associated with the development of SMA in Kenyan children. *P. falciparum* RNA was extracted from erythrocytes collected on their first hospital visit prior to antimalarial treatment. Domain-specific primer and probe sets were used to quantify DBLα and CIDRα subdomains (and serylRNA as an endogenous control) with the qRT-PCR ΔΔC<sub>t</sub> method. Samples were selected from a cohort (n=1,218, aged 3-36 months) and stratified into discrete 'polarized' groups of non-SMA (Hb≥5.0 g/dL, Avg: Hb, 9.98 g/dL; n=18) and SMA (Hb<5.0 g/dL, Avg: Hb, 3.78 g/dL; n=18, cases), excluding children with co-morbidities. These studies revealed that expression levels for the CIDRα1.1 domain was ~3-fold lower in the SMA group (P=0.050). Although differences in expression levels between the groups were not significant for the DBLα0, DBLα1, DBLα2/ α1.1/2/4/7, and DBLβ1.2 domains (P=0.59, P=0.73, and P=0.81, respectively), interesting patterns emerged. As expected based on previous results, DBLα0 was used as an internal control and did not differ between the groups (P=0.956). Studies are currently ongoing in a larger sample size to validate these initial findings and determine the impact of variation in the PFEMP1 on the cross-sectional and longitudinal development of SMA.

### SEVERE DEFICIENCIES OF AMINO ACID PRECURSORS FOR L-ARGININE DE NOVO BIOSYNTHESIS IN PEDIATRIC *FALCIPARUM* MALARIA: IMPLICATIONS FOR NITRIC OXIDE INSUFFICIENCY

**Matthew P. Rubach**<sup>1</sup>, Jackson Mukemba<sup>2</sup>, Salvatore Florence<sup>2</sup>, Nicholas M. Anstey<sup>3</sup>, Tsin W. Yeo<sup>3</sup>, Esther D. Mwaikambo<sup>2</sup>, J. Brice Weinberg<sup>1</sup>, Donald L. Granger<sup>4</sup>

<sup>1</sup>Duke University and Veterans Affairs Medical Centers, Durham, NC, United States, <sup>2</sup>Hubert Kairuki Memorial University, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Menzies School for Health Research, Darwin, Australia, <sup>4</sup>University of Utah and Veterans Affairs Medical Centers, Salt Lake City, UT, United States

Work by us and others has previously demonstrated nitric oxide (NO) insufficiency and low plasma levels of the NO synthase substrate L-arginine in severe falciparum malaria. Arginine is derived from several sources—diet, protein catabolism, and *de novo* synthesis primarily in the small intestine and kidney through the glutamine → glutamate → ornithine → citrulline → arginine pathway. Here we assessed this biosynthetic pathway in Tanzanian healthy children (HC, n=109), and in Tanzanian children with falciparum malaria [mild (uncomplicated) malaria (UM, n=61) and cerebral malaria (CM, n=45)]. All children were 6 months to 6 years of age. HC subjects had no malaria parasites and were without fever or signs of illness. Detailed criteria for categorizing HC, UM, and CM subjects were as we have noted before (J Exp Med 184:557-567, 1996). Plasma amino acids were quantified by ion-exchange chromatography with detection using spectrophotometry after reaction with ninhydrin. Wilcoxon rank-sum was used to determine statistical significance. Compared to HC children, measurements of each amino acid in the pathway was significantly lower in the UM and CM patients. Glutamine measurements (μM) were as follows (median [interquartile range]): 457 [400-508] in HC, 300 [256-365] in UM, and 257 [195-320] in SM (p<0.02 for all pairwise comparisons). Glutamate measurements showed a similar pattern: 73 [58-105] in HC, 42 [29-60] in UM, and 28 [17-65] in SM (p<0.04 for all pairwise comparisons). Ornithine, citrulline and arginine levels were decreased in children with malaria (all pairwise comparisons of HC vs. UM and HC vs. CM p<0.001; UM vs. CM p>0.05). Relative to pediatric normal reference range for glutamine with a lower limit of 410 μM, glutamine was markedly decreased in children with malaria. These findings suggest that low precursor amino acids, most notably glutamine, contribute to low arginine and NO insufficiency in severe malaria. The underlying mechanism(s) of glutamine deficiency in malaria warrants further study. Adjunctive therapy to replenish glutamine levels may improve NO bioavailability in severe malaria, and improve outcomes.

## 1543

**DIFFERING RECEPTOR EXPRESSION IN BRAIN MICROVESSELS DERIVED FROM WHITE AND GRAY MATTER: IMPLICATIONS FOR CEREBRAL MALARIA**Midrelle Nandjou<sup>1</sup>, Bianca Galasso<sup>2</sup>, Monique Stins<sup>1</sup><sup>1</sup>Johns Hopkins University/School of Public Health, Baltimore, MD, United States, <sup>2</sup>Johns Hopkins University/Krieger School of Arts and Sciences, Baltimore, MD, United States

Cerebral malaria (CM) is a severe complication of malaria with mortality rates of up to 30%. It affects mostly children in sub-Saharan Africa where it causes neurological impairment. CM occurs when *Plasmodium falciparum*-infected red blood cells (Pf-IRBC) sequester into the brain microvasculature via binding of *Plasmodium falciparum*-encoded erythrocyte membrane protein-1 to intercellular adhesion molecule-1 and endothelial protein C receptor (EPCR) on the surface of brain endothelial cells. The pathogenesis of CM is still not well understood and its comprehension will be helpful in the development of appropriate neurological interventions. Sequestration of Pf-IRBC in CM is observed in both the white matter (WM) and gray matter (GM) of the brain although both regions have distinct cellular environments. Importantly, the pathology of CM in the WM is predominantly hemorrhagic, whereas this is not observed in the GM. In this study, we hypothesized that the difference in CM pathology observed in the GM versus WM of the brain is due to differences in the protein receptors expression profile of their respective vasculature. We isolated microvessels from different brain areas, including corpus callosum, deep white matter, frontal cortex white matter, and frontal cortex gray matter. These microvessels were then stained for CD31 (endothelial marker), GLUT-1 (glucose transporter type 1), EPCR and AP (alkaline phosphatase). The expression of GLUT-1, CD31, EPCR, and AP in these areas was also quantified by western blot. Overall, microvessels from different areas of the brain differed in their expression of EPCR, GLUT-1 and AP. This difference might indicate that specific vessels in various brain areas will be more susceptible to sequestration of Pf-IRBC in CM and may explain the observed differential pathologies of the GM vs WM in CM patients. Knowing that the brain microvasculature differs in the expression of some receptors/transporters will lead to a better understanding of CM pathology and may have implications for other neurological diseases involving vessel pathologies, such as multiple sclerosis and stroke.

## 1544

**BIOENERGETIC ANALYSIS REVEALS OXPHOS ACTIVITY IN THE LATE STAGE GAMETOCYTES**

Tomoyo Kato, Dyann F. Wirth

Harvard T.H.Chan School of Public Health, Boston, MA, United States

*Plasmodium falciparum* has a complicated life cycle consisting of multiple developmental stages in both the human host as well as the mosquito vector. During these developmental and host changes, the parasites are exposed to dramatic environmental shifts. Previous reports have indicated that blood stage parasites in the human host rely on glycolysis as their primary energy source, while mosquito stages fully depend on mitochondrial respiration, or oxidative phosphorylation (OXPHOS). These observations suggest that malaria parasites achieve a huge metabolic shift from human to mosquito life-cycle stages, but raise the question of when this shift occurs. Previously, we developed a robust bioenergetic assay for asexual blood stage parasites utilizing an Extracellular Flux Analyzer. It enables simultaneous investigation of mitochondrial respiration and glycolysis in a physiologically relevant microenvironment with readouts of an oxygen consumption rate (OCR) and extracellular acidification rate (ECAR). With this assay system, we have discovered strong glycolytic activity, inefficient OXPHOS, and a glucose-regulated metabolic shift in asexual blood stage parasites. In this study, we applied our assay system to tightly synchronized gametocytes to evaluate OXPHOS and glycolysis activities in each stage of gametocytogenesis. We found a strong increase of basal OCR over the course of gametocyte maturation. In addition, we

observed that oligomycin A decreased OCR in day 5 gametocytes but not in earlier stage gametocytes and asexual stage parasites. The values of oligomycin A-sensitive OCR increased and became maximal around day 12 (stage IV), suggesting that late stage gametocytes actively conduct OXPHOS. Altogether our observation reveals the bioenergetically active nature of late stage gametocytes and the significant increase of OXPHOS activity that occurs during gametocyte maturation. This additional OXPHOS activity is presumably required for successful transmission to mosquitoes where the parasite is dependent upon OXPHOS, suggesting a promising target for transmission blocking therapeutics.

## 1545

**THE PLASMODIUM FALCIPARUM 130 KDA MAURER'S CLEFT PROTEIN IS A RESIDENT MAURER'S LEFT PROTEIN PERIPHERALLY ASSOCIATED WITH THE MEMBRANES OF THE CLEFTS**Raghavendra Yadavalli<sup>1</sup>, John W. Peterson<sup>2</sup>, Judith A. Drazba<sup>2</sup>, Tobili Yvonne Sam-Yellowe<sup>1</sup><sup>1</sup>Cleveland State University, Cleveland, OH, United States, <sup>2</sup>The Cleveland Clinic, Cleveland, OH, United States

Maurer's clefts (MCs) are membranous structures formed immediately after *Plasmodium falciparum* merozoite invasion into the erythrocyte host. The virulence marker PfEMP-1 is trafficked through the MCs to the surface of the IE in the asexual blood stage. In this study, we investigated a soluble 130 kDa MC protein. Previously, Immunoelectron microscopy localized the 130 kDa protein underneath knobs and associated with the MC in the asexual blood stage. The protein colocalized with known resident MC proteins suggesting it is a resident protein of the clefts. The stage specific expression and pattern of association of the 130 kDa protein with the MC membrane is not known. In addition, the gene encoding the 130 kDa protein has not been identified. In the present study, we performed biochemical experiments to analyze the topology, solubility and trafficking of the protein from the parasite to the erythrocyte cytoplasm using brefeldin A (BFA). Protease digested bands of the 130kDa protein were also subjected to LC-MS/MS analysis followed by data base searches using Mascot and Sequest to identify the gene encoding the 130 kDa protein. Peptides corresponding predominantly to the high molecular weight rhoptry protein 2 (RhopH2; PF3D7\_0929400) were obtained. Additional peptide matches were obtained with Falcilysin (PF3D7\_1360800). The solubilization and permeabilization studies show that the 130 kDa protein is synthesized and trafficked into the erythrocyte cytoplasm as a peripheral membrane protein insensitive to BFA, and that it associates peripherally to the MCs. Immunofluorescence (IFA) microscopy shows the 130 kDa protein is a resident MC protein due to its colocalization with the MC protein REX-1. Our results also show that the 130 kDa protein is associated with the infected erythrocyte membrane. IFA colocalization of monoclonal antibodies specific to the 130 kDa MC protein with Rhop-3 specific antibodies showed independent distribution of both proteins within the infected erythrocyte suggesting that the 130 kDa protein is not localized to the rhoptries and is not a member of the high molecular weight rhoptry protein complex.

## 1546

**ROLE OF PKA SIGNALING IN ARTEMISININ INDUCED DORMANCY IN RING STAGE PLASMODIUM FALCIPARUM**

Garima Chopra, J. Kathleen Moch, Norman C. Waters

Walter Reed Army Institute of Research, Silver Spring, MD, United States

The cell cycle control mechanisms remain largely unexplored in *Plasmodium falciparum*, but the progression through the developmental stages of erythrocytic life cycle of the parasite seems to involve an intricate interplay between the parasite's changing environment and its cellular regulation. Artemisinin induced dormancy, is a stress response that allows parasites to sustain the cytotoxic effects of the drug. Artemisinin induces dormancy in the ring stage parasite, during which the parasite is under

temporal growth arrest and resumes growth between 9 to 12 days after drug treatment. This quiescent state seems analogous to a G1 cell cycle arrest and provides a plausible explanation to recrudescence reported in field, following artemisinin monotherapy. There is an increasing evidence of involvement of cAMP signaling in the regulation of stress response pathways like gametogenesis in parasites. In this study, we investigated the implication of cAMP signaling in dormancy induction. Dormancy was induced in transgenic parasites overexpressing the regulatory subunit of PKA and their recovery rates were compared to the control strain. We observed that the percentage of surviving parasites on day 8 (after the drug treatment) for PfPKA-R overexpressing strain was 1.7 times of the control strain, resulting in faster recovery from dormancy. This phenotype was reversed by treatment of cultures with PDE inhibitor IBMX that prevents the degradation of cAMP. We conclude that, downregulation of PKA pathway might be aiding parasites' entry into dormant phase, analogous to yeast, this would allow higher percentage of parasites to evade the drug pressure. On the contrary, the constitutively active PKA pathway in IBMX treated cultures might be interfering parasites' ability to enter dormancy, thereby making them more susceptible to the drug pressure. To further investigate the role of PKA pathway in dormancy, our future focus is to test the PKA kinase activity, cAMP modulation and transcription levels of key players of PKA pathway in dormancy by RT-qPCR.

## 1547

### RESISTANCE TO A NONCOVALENT SELECTIVE PROTEASOME INHIBITOR IN *PLASMODIUM FALCIPARUM*

Joeseeph E. Visone, Alexis Dziedziech, Bjorn Kafsack, Gang Lin, **Laura Kirkman**

Weill Cornell Medical College, New York, NY, United States

The proteasome is a multi-subunit complex (26S) with a regulatory cap (19S) and a catalytic core (20S). Proteasome inhibition leads to the accumulation of unfolded or oxidatively modified proteins in the intracellular environment causing endoplasmic reticulum overload and stress and eventually cell death. Proteasome inhibitors, currently used as anti-neoplastics, have also been identified as novel and potentially potent anti-protozoal agents. We have been working with a compound that selectively targets the *Plasmodium falciparum* proteasome over the human constitutive and immune proteasomes, PKS21004. To further assess this compound and the role of the proteasome in the parasite lifecycle we set out to generate parasites that are resistant to our malaria specific inhibitor. Parasites were grown *in vitro* under continued and escalating drug pressure. Regrowth was only found in one of our test flasks. Two clonal lines were isolated and used in further studies. Repeat drug assays revealed a stable 130 fold change in EC50 to PKS21004 compared to the parental line. There was no change in EC50s to other antimalarials surveyed. Phenotypic studies revealed a potential fitness cost associated with resistance with slower growth of the resistant parasite line compared to controls. Resistant parasites were subjected to whole genome sequencing revealing a mutation in PF3D7\_0518300, the Beta 6 subunit of the proteasome core (20S). This mutation is associated with an A117D amino acid change. The identification of a mutation associated with PKS21004 resistance away from the Beta 5 active site is consistent with the noncompetitive mode of action previously identified for this compound. When compared with other eukaryotic Beta 6 sequences this alanine was found to be highly conserved suggesting a conserved function within this primarily structural, non-catalytic 20S subunit. Further studies should reveal more about the impact of this mutation on proteasome function and parasite growth.

## 1548

### 3D BRAIN MICROVESSEL MODEL FOR THE STUDY OF CEREBRAL MALARIA PATHOGENESIS

**Maria Bernabeu**<sup>1</sup>, Celina Gunnarsson<sup>2</sup>, Ryan Nagao<sup>2</sup>, Ying Zheng<sup>2</sup>, Joseph Smith<sup>1</sup>

<sup>1</sup>Center for Infectious Disease Research, Seattle, WA, United States,

<sup>2</sup>Department of Bioengineering, University of Washington, Seattle, WA, United States

Cerebral malaria is the most life-threatening disease complication, and still carries 15-20% mortality rates. *Plasmodium falciparum* sequestration in the brain microvasculature is considered the main pathogenic event leading to brain damage, but the lack of a suitable animal model has hampered research on cerebral malaria. Taking advantage of the recent advances in the generation of 3D microvascular platforms, we have developed an engineered 3D human brain microvessel model to study cerebral malaria pathogenesis. Primary human brain endothelial cells grow in the three dimensional collagen matrix and establish complex tight junctions, as revealed by transmission electron microscopy and ZO-1 staining. The geometry of the 3D microvessels generates a shear stress gradient within the device, and reproduces the complex microfluidics of the brain vasculature. Clonally variant *P. falciparum* lines present a distinctive binding behavior to endothelial cells that is both shear-stress and endothelial activation status dependent. While ICAM-1 binders present a strong binding in regions of medium shear stress, EPCR binders adhere maximally in regions of low shear stress. In addition, activation of the endothelial cells causes a significant increase in the cytoadhesion of ICAM-1-binding strains, while other parasite variants present similar or weaker binding to activated endothelium. Our findings with 3D human brain microvessels reveal considerable heterogeneity in parasite interaction with resting and activated endothelium and establish a novel *in vitro* model for cerebral malaria.

## 1549

### THE TOXIC TABLET: ACCIDENTAL ANTI-MALARIAL POISONINGS IN FAMILIES OF FRENCH AND U.S. VIETNAM VETERANS

**David Adams**<sup>1</sup>, Femi Taiwo<sup>1</sup>, Valerie Adams<sup>2</sup>, Joseph Miller<sup>2</sup>

<sup>1</sup>Point University, Savannah, GA, United States, <sup>2</sup>Armstrong State University, Savannah, GA, United States

The control and prevention of malaria among French and American troops were key military objectives in colonial and post-colonial Indochina. Among the most common anti-malarials included atabrine, chloroquine, and primaquine. "Malaria discipline" provided an effective way to minimize malaria among the ranks. Its rationale was simple: If malaria cases remained in the rear, then they were of little combat-use. In American units, medics weekly distributed anti-malarials to their members, watching closely to ensure that troops had swallowed the medication. Among U.S. troops who soon would rotate state-side after completion of their 365-day tour, a simple urine test was used to ensure compliance with the weekly chloroquine regimen. Medical personnel employed the Edeson-Wilson Test to detect the presence or absence of chloroquine (the most commonly used drug among American troops) metabolites. A *negative* chloroquine test suggested that an individual had not complied with the weekly chloroquine regimen, thus disobeying a standing order that dated from 1965. A *negative* chloroquine assay could delay their return stateside indefinitely. Most troops passed the chloroquine test. As they departed for home, positive results in hand, they received a six-week supply of chloroquine to continue as directed once stateside. (Their signatures also affirmed that they were under orders to continue the medication until finished.) Soon, however, reports began to appear in the lay and professional press about accidental chloroquine poisonings—many fatal and among children—in the homes of returned veterans. (A similar phenomenon had occurred in 1950s families of French troops who had served in colonial Indochina.) The scenario (in a pre-childproof medicine-

bottle era) had become all too common: A returned vet would carelessly leave an unsecured bottle of chloroquine tablets on a kitchen table or counter. A family member--not least a small child--then might accidentally ingest them. This presentation will examine the rash of chloroquine poisonings among the children or newly-returned French and American vets veterans from the late 1950s to the mid-1970s.

## 1550

### HUMANIZED MOUSE MODELS TO BOOST ANTIMALARIAL DRUG DISCOVERY

**Maria J. Lafuente**, Sara Viera, Delfina Segura, David Calvo, Lorena Cortes, Carmen Cuevas, Helena Garuti, Vanesa Gomez, Noemi Magan, Alba Pablos, Francisco Javier Gamo

*Tres Cantos Medicines Development Campus. Diseases of the Developing World. GlaxoSmithKline, Severo Ochoa 2, 28760 Tres Cantos, Spain*

Malaria is caused by the erythrocytic stages of protozoa of the genus *Plasmodium* and is transmitted by infected female *Anopheles* mosquitoes. To counter this disease, animal models of malaria are essential tools particularly for drug discovery. Understanding and determining efficacy parameters using preclinical models is critical to estimate effective human doses and allow an effective progression of candidate antimalarials. The generation of SCID mice has allowed successful engraftment with human red blood cells (hRBCs). SCID mice have enabled the generation of *in vivo* *P. falciparum* blood-stage infections that can be used to improve rational drug discovery efforts. Some of the potential uses of this model are: i) Build PK/PD relationships of preclinical candidates: assessment of *in vivo* parasite clearance with simultaneously PK sampling allows determining *in vivo* critical drug concentrations producing efficacy. *In vivo* clearance and time to recrudescence can be used to determine MPC and MIC. These parameters can be used to inform clinical trials and select the most appropriated human doses. ii) Monitor *in vivo* parasite rate reduction (PRR) profiles: *ex vivo* culturing of parasites after drug treatment and determination of viable counts (*ex vivo* PRR) allows to determine killing kinetics in an *in vivo* setting and can be used to assist modeling of curative doses. iii) Selection on *in vivo* resistant mutants: to gain pre-clinical understanding of resistance issues for new chemical entities (NCE's). Propensity to select resistance in an *in vivo* environment and effects of resistance on efficacy parameters can be used to anticipate and try to prevent clinical failure. iv) Translational model for transmission blocking potential: *Anopheles stephensi* mosquitoes can directly fed on SCID mice engrafted with *P. falciparum* gametocytes and develop oocysts. This direct feeding assay can be exploited to develop an *in vivo* transmission blocking assay with translational meaning. All these uses place humanized mouse models at the forefront of antimalarial drug research as a state-of-the-art tool to boost the discovery of novel antimalarial drugs.

## 1551

### A NATIONAL MOLECULAR SURVEILLANCE PROGRAM FOR THE DETECTION OF *PLASMODIUM FALCIPARUM* MARKERS OF RESISTANCE TO ANTIMALARIAL MEDICATIONS IN HAITI

**Karen E. Hamre**<sup>1</sup>, Pierre Baby<sup>2</sup>, Ruth Namuyinga<sup>1</sup>, Eric Rogier<sup>1</sup>, Venkatachalam Udhayakumar<sup>1</sup>, Jacques Boncy<sup>2</sup>, Jean Frantz Lemoine<sup>2</sup>, Michelle A. Chang<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti

Chloroquine (CQ) and sulfadoxine-pyrimethamine (SP) remain the 1st and 2nd line treatments for uncomplicated malaria in Haiti. Few studies have reported the presence of molecular markers for resistance in *Pf* parasites, and *in vivo* therapeutic efficacy studies (TES) have been limited. Recognizing the history of antimalarial (AM) resistance worldwide, and the challenges of implementing TES in low-endemic areas, the Ministry of Health established a surveillance program to detect molecular markers of AM resistance in Haiti. Sentinel sites were selected in each of Haiti's 10 administrative departments, and an 11th site in Grand'Anse, the

department with the highest number of reported cases. Factors for site selection included the number of malaria cases identified, observed skills of laboratory technicians conducting rapid diagnostic tests (RDTs), stock/storage conditions of RDTs, accuracy of data reporting to the national surveillance system, and motivation to participate. Sentinel site staff administered the RDTs, obtained consent, collected filter paper blood samples, and completed the surveillance forms. Associated costs included the time and supplies for the project manager, supplies for collecting blood spots, transportation, and molecular sequencing. Filter paper samples were stored on site at room temperature and retrieved quarterly for storage at the national public health laboratory. Samples from 919 RDT positive patients were collected from Mar-Dec 2016. Of these, 381 (41.5%) patients reported having taken medication since the onset of their illness prior to diagnosis; 43 (4.7%) reported taking an AM. Six patients (0.01%) reported sleeping away from home for at least 1 night in the month before diagnosis; 1 was outside of their home department. Among the 668 samples successfully sequenced for *Pfcr* to date, no markers of CQ resistance (C72S, M74I, N75E, K76T) were detected; SP analysis pending. Establishing a molecular surveillance program proved practical and feasible in a resource-limited setting, and will provide the evidence needed to make informed treatment policy decisions at the national level moving forward.

## 1552

### RANDOMIZED CLINICAL TRIAL: EFFICACY OF ARTEMISININ COMBINATION THERAPIES FOR UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN SELINGUE, MALI, 2016

Krogstad<sup>8</sup>, Eric S. Halsey S. Halsey<sup>9</sup>, Venkatachalam Udhayakumar<sup>2</sup>, Naomi Lucchi<sup>2</sup>, Erin Eckert<sup>10</sup>, Ousmane Koita<sup>1</sup>

<sup>1</sup>USTTB, Bamako, Mali, <sup>2</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Atlanta Research and Education Foundation, Atlanta, GA, United States, <sup>4</sup>Referral Health Center of Sélingué, Ministry of Health and Public Hygiene, Bamako, Mali, <sup>5</sup>National Malaria Control Program, Ministry of Health and Public Hygiene, Bamako, Mali, <sup>6</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development Office, Bamako, Mali, <sup>7</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>8</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>9</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, U.S. President's Malaria Initiative, Atlanta, GA, United States, <sup>10</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development Office, Washington, DC, United States

In 2016, a therapeutic efficacy study using artemether-lumefantrine (AL) and artesunate-amodiaquine (AS-AQ) for treatment of uncomplicated *Plasmodium falciparum* malaria was conducted as a randomized clinical trial in Sélingué, Mali. Four hundred and eighty patients were enrolled in this study, with 240 patients enrolled in each treatment arm (AL and ASAQ). Of the 387 completing the study at 28 days (93 of those enrolled were lost to follow-up), 3 (all of whom had received AL) were recrudescence late treatment failures (days 14, 14, and 25) using microsatellite markers. For the 309 day 0 samples successfully sequenced for the *k13* gene, only one possessed a non-synonymous mutation. This mutation was A578S, which is not associated with artemisinin resistance. For the 309 day 0 samples successfully sequenced for the *Pfmdr1* gene, 68 (27.1%) possessed a non-synonymous mutation: 6 with N86Y, 61 with Y184F, and 1 with D1246Y. For the recrudescence patients, all 3 had the NFD haplotype in the day 0 samples. In the recrudescence samples, 2 of these had the NFD and one had the NYD haplotype. In summary, we observed no *k13* mutations associated with artemisinin resistance and high efficacy of AL and ASAQ treatment in Sélingué, Mali. Continued monitoring

for molecular markers of resistance to artemisinin-based combination therapies is critical in supporting therapeutic efficacy studies and providing timely evidence-based malaria treatment policies.

## 1553

### COMPARATIVE EFFICACY OF ARTEMETHER-LUMEFANTRINE AND DIHYDROARTEMISININ-PIPERAQUINE FOR TREATMENT OF UNCOMPLICATED MALARIA IN CHILDREN IN UGANDA

Adoke Yeka<sup>1</sup>, Erika Wallender<sup>2</sup>, Ronald Mulebeke<sup>1</sup>, Melissa Conrad<sup>2</sup>, Philip Rosenthal<sup>2</sup>

<sup>1</sup>Makerere University, Kampala, Uganda, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States

*Plasmodium falciparum* resistance to artemisinin derivatives and artemisinin partner drugs is emerging in Southeast Asia. In Uganda, artemether-lumefantrine (AL) is the first-line therapy and dihydroartemisinin-piperaquine (DP) the second line therapy for the treatment of uncomplicated malaria. Recent changes in treatment practices and evidence of shifting drug sensitivities prompted a reassessment of the relative efficacies of these regimens. This study was a randomized, single blinded, longitudinal phase IV clinical trial. A total of 600 children aged 6-59 months was randomized to receive treatment for uncomplicated malaria with AL or DP (100 per treatment arm in Arua, Mbale, and Gulu, Uganda), and followed for 42 days. The primary outcome was the risk of treatment failure unadjusted and adjusted by genotyping to distinguish recrudescence and new infection at day 42. Parasite clearance was evaluated by blood smears every 6 hours. Recruitment and follow-up have been completed at all sites and genotyping of recurrent infections to distinguish recrudescence from new infection and to characterize *Plasmodium falciparum* resistance-mediating polymorphisms is ongoing. Of 600 children enrolled, 587 (98%) completed follow-up. Preliminary results showed no early treatment failures. Time to fever clearance and parasite clearance were similar in the two treatment groups. The uncorrected 42-day risk of treatment failure was significantly higher for children treated with AL than for those treated with DP at Arua (42.0% vs 15.0 %;  $p < 0.005$ ), Mbale (38.0% vs 23.0 %;  $p < 0.005$ ) and Gulu (72.0% vs 37.0 %;  $p < 0.005$ ). Overall, fever clearance and parasite clearance were similar in the two treatment groups, but DP resulted in fewer recurrent infections. Studies to assess comparative adjusted treatment efficacy, safety, and prevalence of drug resistance-associated *P. falciparum* genetic polymorphisms are ongoing.

## 1554

### ASSESSMENT OF EFFICACY OF ARTESUNATE AMODIAQUINE IN DISTRICT OF IFANADIANA MADAGASCAR

Raobela Oméga<sup>1</sup>, Ralinoro Fanomezantsoa<sup>1</sup>, Rakotomanga Tovonahary<sup>1</sup>, Marolahy Michel<sup>1</sup>, Rasoarilalao Noéline<sup>1</sup>, Razanadrazanina Brunette<sup>1</sup>, Miarimbola Raharizo<sup>2</sup>, Ratsimbaso Arsène<sup>3</sup>

<sup>1</sup>National Malaria Control Program, Antananarivo, Madagascar, <sup>2</sup>Faculty of Medicine, Antananarivo, Madagascar, <sup>3</sup>National Malaria Control Program, Faculty of Medicine, Antananarivo, Madagascar

Since 2012, a study to monitor the therapeutic efficacy of Artemisinin Combined Therapy (ACT) recommended as first line treatment for the uncomplicated *falciparum* malaria has been conducted by National Malaria Control Program (NMCP) Madagascar. The aim is to improve the orientation of treatment policy. This was a cohort study that was conducted from March to June 2016 in Tsaratanana village, district of Ifanadiana, an endemic area of Malaria. The criteria of inclusion (WHO 2009) was all outpatients between six months to fifteen years old who consulted at the health facilities for fever  $\geq 37.5^\circ\text{C}$  or history of fever  $< 24$  hours, diagnosed for uncomplicated malaria to *Plasmodium falciparum* and parasitemia between 1 000 - 200 000 p/μl. The criteria of assessment were the rates of parasitological and clinical failure in day 3, day 7, 14, 21 and 28 of follow up by microscopy then after adjusted by PCR. The

risks of these failures were analyzed by the Kaplan Meier. The clearance of fever and parasites, as well as the incidence of side effects was analyzed during follow up. Also hemoglobin rate was calculated in day 0 and day 28. A total of 450 patients were tested for malaria and RDT positivity rate was 44.2%. For 67 patients recruited, 65 (97%) patients were followed up until day 28. Two patients was voluntary withdrawn from the study. 58 (89.2%) of patients presented fever at day 0 and none from day 3. The median parasitemia was 32 796 p/μl [Min 1 591; Max 185 103]. The clearance of parasites by microscopy was 0% from Day 3, but by PCR was 55.4 % in day 3, then 98.5% in day 7 and 0% from day 14. The improvement of anemia in day 0 compared to day 28 was observed (76.9% vs 38.5%). No side effects were noted. The results of the follow-up demonstrated the efficacy and safety of the use of as ACT (ASAQ) in Madagascar. Regular monitoring of safety and therapeutic efficacy is useful to observe the failure rate of recommended national policy treatment for *Plasmodium falciparum*.

### SINGLE DOSE SUPERIOR PHARMACODYNAMICS OF PYRONARIDINE COMPARED TO ARTESUNATE, CHLOROQUINE AND AMODIAQUINE IN A HIGH DENSITY MURINE MALARIA-LUCIFERASE MODEL

Winter Okoth, David Sullivan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The majority of previous preclinical malaria drug studies have relied on drug inhibition of low parasites numbers numerically compared to untreated controls both *in vitro* and *in vivo*. In contrast, human malaria drug studies measure the decline or killing of high parasite densities near 100 million per mL. Here we compared the *in vivo* single dose pharmacodynamic properties of artesunate and 4-aminoquinolines-pyronaridine, chloroquine, and amodiaquine, in a *Plasmodium berghei*ANKA-GFP-Luciferase-based murine malaria blood stage model. In this study, pyronaridine exhibited dose-independent killing, achieving parasite reduction near 5-6 log drop at 48 hours post dosing with complete cure at 10 mg/kg compared to artesunate, which exhibited a 48 hour dose-dependent killing with a 2 log drop at the noncurative high dose of 250 mg/kg. Chloroquine (noncurative) and amodiaquine (partially curative) have nearly the same initial dose-independent killing with a lag phase of no parasite reduction between 6 and 24 hours post dosing, but a 2.5 log reduction at 48 hours. In drug treated, washed infected blood transfer experiments to a naïve mouse, chloroquine and amodiaquine showed less viable parasites at the 24 hour compared to 8 hour transfer measured by a prolonged return to measured parasitemia, despite a similar log reduction, in contrast to the correlation of parasite log reduction to viable parasites with artesunate and pyronaridine. Artesunate in combination with pyronaridine exhibited a slightly weak antagonistic effect, while the combination with chloroquine or amodiaquine, showed an additive effect. Single oral dose pyronaridine was much more potent *in vivo* than artesunate, chloroquine and amodiaquine.

### OPPORTUNISTIC PHARMACOKINETIC DETERMINATIONS OF LUMEFANTRINE FROM DRIED BLOOD SPOTS BY LC-MS/MS FOR PHARMACOKINETIC-PHARMACODYNAMIC MODELING OF MALARIA

Matthew M. Ippolito<sup>1</sup>, Liusheng Huang<sup>2</sup>, Mwiche Siame<sup>3</sup>, William J. Moss<sup>4</sup>, Theresa A. Shapiro<sup>1</sup>, Philip E. Thuma<sup>5</sup>, Francesca T. Aweeka<sup>2</sup>

<sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD, United States, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Ministry of Health, Lusaka, Zambia, <sup>4</sup>Johns Hopkins Bloomberg

School of Public Health, Baltimore, MD, United States, <sup>5</sup>Macha Research Trust, Macha, Zambia

Study of the clinical effects of combination therapy for malaria is aided by measuring infected persons' exposure to individual partner drugs. Existing methods for measuring lumefantrine (LF) from dried blood spots (DBS) rely on pretreatment of paper with tartaric acid to facilitate drug elution. Untreated DBS may offer some utility when pretreatment was not done but pharmacokinetic-pharmacodynamic (PKPD) analyses are retrospectively considered. We assessed various methods for LF quantitation from untreated DBS using different combinations of solvents and mixers. LC-MS/MS methods were adapted from an existing protocol for plasma. Clinical application was assessed by exploratory PKPD analyses using post-treatment day 7 PK samples, parasite clearance times estimated from serial blood smears, and recurrence of malaria following treatment in a drug efficacy trial of artemether-lumefantrine for children with uncomplicated falciparum malaria. Optimal recovery was achieved by extraction from 3 mm punches of DBS (0.5-1 cm dia) with 5% formic acid in acetone, vortex mixing, sonication, and centrifugation. The lower limit of quantitation was 100 ng/ml. The median day 7 concentration among study participants (n=71) was 145 ng/ml (IQR: 120-233 ng/ml). There were no associations between drug concentration and location of the punch (center or periphery), weight of the punch, or storage duration (range: 16-24 mo). Controlling for participant age, gender, and parasite burden, each log increase in LF day 7 concentration corresponded to a decrease of 3.3 hrs in mean parasite clearance time (95% CI: 0.3-6.3 hrs, P=0.03). A nested case-control study of time-matched participants (n=18) with and without recurrent malaria showed mean post-treatment day 7 concentrations of 174 ng/ml and 223 ng/ml, respectively, but the difference was not significant (P=0.48). A method for LF determinations from post-treatment day 7 collections of DBS on untreated filter paper stored up to 24 months yielded results comparable to those previously reported. Clinical application was tentatively demonstrated in an exploratory PKPD analysis of parasite clearance.

## 1557

### INVESTIGATING THE PRESENCE OF MUTATIONS IN THE *PFKELCH13* GENE IN CHILDREN FROM UGANDA AFRICA WITH SEVERE MALARIA AND ASYMPTOMATIC PARASITEMIA

Adnan Gopinadhan<sup>1</sup>, Robert Opoka<sup>2</sup>, Andrea Conroy<sup>1</sup>, Lindsey Turnbull<sup>1</sup>, Dibadyuti Datta<sup>1</sup>, Chandy John<sup>1</sup>

<sup>1</sup>Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States, <sup>2</sup>Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda

Artemisinin resistance was first observed in Southeast Asia (SEA) and could pose a threat to malaria treatment all over the world. Recently mutations in the propeller region of *Pfkelch13* gene have been used as a genetic marker for resistance observed in SEA. We investigated the presence of mutations in the *Pfkelch* gene in children in Kampala, Uganda with severe malaria (SM) treated with intravenous quinine, or with asymptomatic *P.falciparum* infection (AP) treated with artemether-lumefantrine. We sequenced the *Pfkelch* gene (2178bp) in 176 children with SM and 49 children with AP infection. In children with SM and AP we identified 106 (60.8%) and 27 (55.1%) parasites with mutations upstream of the *Pfkelch13* propeller region. The two most prevalent mutations were 142NN (26.1% in SM, 32.6% in AP) and K189T (16.5% in SM, 12.2% in AP). In SM, only a single infection had a mutation in the propeller region (A578S), while in AP, mutations in the propeller region included A578S (n=1) and S522C (n=1). In children with SM, parasites with 142NN insertion compared to 3D7 *Pfkelch13* parasites had lower parasite density (median [IQR], 20780 parasites/ $\mu$ l [2000-63570] vs 57100 parasites/ $\mu$ l [12300-224600], p=0.006) and lower parasite biomass (*Pf*HRP2, ng/ml, median [IQR]; 295 [113-3142] vs. 3251 [281-6612] p=0.02). Children with SM who either had 142NN or K189T mutation cleared parasites after quinine treatment faster than those with the 3D7 *Pfkelch13* genotype

astmh.org

(median, interquartile range, in hours; 142NN: 24, [24-48]; K189T: 24, [24-48]; 3D7: 48, [24-72]), P<0.001 for both mutations compared to 3D7). In this cohort mutations upstream of the *Pfkelch13* propeller region were common. The *Pfkelch13* 142NN insertion in children with severe malaria was associated with decreased parasite density, decreased parasite biomass and more rapid parasite clearance with quinine. Future studies will assess the presence of *Pfcr*t and *Pfmdr* mutations in this cohort, and how these relate to the *Pfkelch13* mutations and to parasite clearance.

## 1558

### CONTINUED ABSENCE OF *PF CRT* GENE MUTATIONS WITHIN THE HAITIAN *PLASMODIUM FALCIPARUM* POPULATION

Eric Rogier<sup>1</sup>, Curtis Huber<sup>1</sup>, Camelia Herman<sup>1</sup>, Stella Chenet<sup>2</sup>, Baby Pierre<sup>3</sup>, Ruth Namuyinga<sup>1</sup>, Kimberly Mace<sup>1</sup>, Ito Journal<sup>4</sup>, Sarah Volkman<sup>2</sup>, Jacques Boncy<sup>4</sup>, Ventkatachalam Udhayakumar<sup>1</sup>, Jean F. Lemoine<sup>3</sup>, Michelle Chang<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States,

<sup>3</sup>Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti,

<sup>4</sup>Laboratoire National de Santé Publique, Port-au-Prince, Haiti

Previous reports have shown little indication that the island nation of Haiti harbors *Plasmodium falciparum* parasites bearing genetic resistance markers to chloroquine-based therapies. This has provided cautious optimism for the national control program and partner organizations seeking to accomplish malaria elimination in the near future, as having this chemotherapy tool still available remains an asset. However, as resistance mutations to *Pfcr*t are nearly fixed in South America and other regions of the world, surveillance efforts are needed to monitor this parasite population continually for potential emergence or importation of chloroquine resistant alleles. Recently, a national drug surveillance strategy was developed for *P. falciparum* in Haiti, including 11 health facility sentinel sites strategically selected to monitor for changes in drug resistant alleles. Throughout the course of 2016, 706 persons who tested positive for *P. falciparum* malaria by histidine-rich protein 2 (HRP2) rapid diagnostic test (RDT) were enrolled from seven health facilities throughout Haiti to attempt *Pfcr*t gene sequencing and identification of any functional mutations. Of these 706 RDT positive persons, 693 (98.2%) were found to contain *P. falciparum* DNA, and the *Pfcr*t gene was successfully sequenced in 668 (94.9%). All 668 isolates were found to be the wild-type CVMNK genotype with no putative chloroquine resistance markers (C72S, M74I, N75E, or K76T) detected. These data represent the largest recent screening of the Haitian *P. falciparum* population for functional *Pfcr*t mutations, and provide further evidence of the unique genetic signature of the Haitian parasite population in the Western hemisphere. Continued absence of chloroquine resistant *Pfcr*t alleles in this population is consistent with the current policy to use chloroquine as the primary drug for treatment of uncomplicated malaria in Haiti.

<sup>2</sup>Jilin University, Changchun, China. <sup>2</sup>College of Veterinary Medicine, Jilin University, Changchun, Jilin, China.

Artemisinin-based combination therapies (ACTs) are the first-line drugs for treatment of malaria parasites, *Plasmodium falciparum*. Unfortunately, clinical resistance to artemisinin and its derivatives has emerged in Southeast Asia. The clinical manifestation of artemisinin resistance as delayed parasite clearance is mediated by mutations in the kelch-domain protein PfK13. To identify whether additional resistance mechanisms are involved, we selected dihydroartemisinin (DHA) resistance in the P.

falciparum Dd2 strain using a step-wise procedure with continuous DHA exposure. The resistant clones grew stably in culture medium with 50 nM of DHA. In addition, they had significant increases in IC50 to most of commonly used antimalarial drugs in an in vitro assay. Further, ring-stage survival assay and mature-stage survival assay revealed DHA resistance occurred at both of ring and trophozoites stage. The resistant parasites showed prolonged ring stage. Using whole-genome sequencing, we showed that the parasites showed increased copy number in several drug resistance genes. RNA-seq analysis was conducted to determine transcriptomic changes associated with the acquisition of DHA resistance. This study identified phenotypic and genotypic changes in vitro selected DHA-resistant *P. falciparum* and provides important information for monitoring artemisinin resistance under field settings.

## 1560

### EVALUATION OF THE USE OF PARENTERAL ARTESUNATE BY CARE PROVIDERS FOR THE MANAGEMENT OF SEVERE CASES OF MALARIA IN SENEGAL

**Alioune Badara Gueye**

*National Malaria Control Program, Dakar, Senegal*

Since 2014 Senegal has adopted the use of parenteral artesunate as a first-line treatment in the management of severe malaria cases, in accordance with WHO recommendations. To operationalize this guideline, the Senegal NMCP in collaboration with partners, conducted an assessment of the use of this drug by care providers, prior to scaling up at the national level. Seven hospitals, including four pediatric structures, were selected in the regions of Dakar, Kolda, Tambacounda, Kaolack and Touba for this purpose. Between October 2015 and February 2016, we conducted a prospective, observational, open and multicenter study. We enrolled 508 patients who were admitted for severe malaria with diagnostic confirmation by RDT or microscopy and all of whom received parenteral artesunate upon hospitalization. Follow-up continued for 28 days after hospitalization (day 0) and assessment criteria were clinical, biological and parasitological, including time to clearance of fever and parasitemia, correction of anemia and occurrence of adverse reactions. Of the 508 patients, 394 (77%) were under 15 years of age, 468 (92%) recovered fully between day 1 and day 3, with a mean temperature drop from 38.7 °C to 37.1 °C, a mean parasitic density drop from 9737 to 413p/μL; The mean hemoglobin concentration increased from 8.06/dl on day 0 to 10.58/dl on day 28. The average length of hospitalization was 3.14 days and no major adverse events were recorded during the follow-up period. These results confirm the efficacy and good tolerance of injectable Artesunate in the treatment of severe cases of malaria and highlighted the ease of use, as reported by the care providers. This ease of use will be a critical characteristic to support scale up at the national level in all health centers and hospitals.

### PREDICTING OPTIMAL DIHYDROARTEMISININ-PIPERAQUINE DOSING TO PREVENT MALARIA DURING PREGNANCY FOR UGANDAN WOMEN RECEIVING ANTIRETROVIRAL THERAPY

**Erika Wallender**<sup>1</sup>, Prasanna Jagannathan<sup>2</sup>, Paul Natureeba<sup>3</sup>, Abel Kakura<sup>3</sup>, Mary Muhindo<sup>3</sup>, Miriam Nakalembe<sup>4</sup>, Philip Rosenthal<sup>1</sup>, Diane Havlir<sup>1</sup>, Moses Kanya<sup>4</sup>, Francesca Aweeka<sup>1</sup>, Grant Dorsey<sup>1</sup>, Rada Savic<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Stanford University, Stanford, CA, United States, <sup>3</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>4</sup>Makerere University, Kampala, Uganda

A recent randomized trial in Tororo, Uganda compared 3 doses of dihydroartemisinin-piperazine (DP) given once a month plus daily trimethoprim-sulfamethoxazole (TS) to daily TS alone for malaria chemoprevention during pregnancy among HIV-infected women receiving efavirenz based antiretroviral therapy. Intensive pharmacokinetic (PK)

evaluation of piperazine (PQ) showed that pregnancy plus efavirenz use reduced PQ exposure by 62% compared to HIV-uninfected non-pregnant controls. The primary outcome of placental malaria was too low to allow for an assessment of comparative efficacy due to the implementation of indoor residual spraying of insecticide. The aim of this analysis was to use population PK data from the trial to determine the DP dose and frequency needed for HIV-infected women receiving efavirenz to achieve protective PQ trough concentrations. 82 women contributed PQ troughs at 28 days, and 35 contributed longitudinal PK data. Nonlinear mixed effects modeling was used. Target protective PQ trough concentrations based on prior studies were 5.5 ng/mL (95% protection for HIV-negative pregnant women), 13.9 ng/mL (99% protection for pregnant women), and 20 ng/mL (99% protection for Thai adults). Simulations of different DP dosing schemes (3 dose regimen monthly, 1 dose weekly, 2 doses weekly, and 3 doses every 2 weeks) were modeled for 1,000 individuals. Modeled population clearance of PQ was 5196 L/day (relative standard error 6%), with between subject variability of 30% (RSE 12%). Only 2% of women maintained a concentration >5.5 ng/mL for >95% of the time with monthly DP (none reached higher PQ trough targets). With 1 dose weekly DP, 30% of women achieved a PQ concentration >5.5 ng/mL for 80% of the time and 52% were above the PQ target 50% of the time. 2 doses weekly provided the highest coverage (80% of women had a PQ concentration >5.5 ng/mL for 80% of the time; 97% were above the PQ target 50% of the time). Due to rapid PQ clearance, intermittent preventive treatment during pregnancy with monthly DP may not effectively protect pregnant women receiving efavirenz against malaria. Alternative dosing strategies should be evaluated.

## 1562

### IMPACT OF DIFFERENT MALARIA CHEMOPREVENTION REGIMENS FOR PREGNANT UGANDAN WOMEN ON *PLASMODIUM FALCIPARUM* DRUG RESISTANCE-MEDIATING POLYMORPHISMS

**Melissa D. Conrad**<sup>1</sup>, Daniel Mota<sup>1</sup>, Stephen Tukwasibwe<sup>2</sup>, Jennifer Legac<sup>1</sup>, Patrick Tumwebaze<sup>2</sup>, Meghan Whalen<sup>1</sup>, Abel Kakuru<sup>2</sup>, Patience Nayebare<sup>2</sup>, Erika Wallender<sup>1</sup>, Diane V. Havlir<sup>1</sup>, Prasanna Jagannathan<sup>3</sup>, Moses Kanya<sup>4</sup>, Grant Dorsey<sup>1</sup>, Philip J. Rosenthal<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>3</sup>Stanford University, Palo Alto, CA, United States, <sup>4</sup>Makerere University College of Health Sciences, Kampala, Uganda

In a recent randomized controlled trial of intermittent preventive therapy in pregnancy among 300 women in Tororo, Uganda, dihydroartemisinin-piperazine given every 4 weeks (DP4w) or every 8 weeks (DP8w) was superior to sulfadoxine-pyrimethamine every 8 weeks (SP8w). We now report how the different regimens impacted on *Plasmodium falciparum* genetic polymorphisms associated with sensitivity to antimalarial drugs. Blood samples collected monthly from asymptomatic women were tested for *P. falciparum* using a highly sensitive loop mediated isothermal amplification (LAMP) assay. 374 samples positive by LAMP and 33 episodes of symptomatic malaria (diagnosed by blood smear) were genotyped for polymorphisms in genes encoding putative drug transporters (*pfcr1* and *pfmdr1*) and folate enzymes (*pfdfhr* and *pfhdps*). 219 samples were isolated before chemoprevention was initiated; after initiation 122 samples were from the SP8w arm, 37 the DP8w arm, and 29 the DP4w arm. Considering transporter genes, treatment with DP was associated with reduced prevalence ratios (PRs) for wild type alleles at *pfmdr1* N86Y, *pfmdr1* Y184F, and *pfcr1* K76T compared to samples collected before treatment was initiated (PRs: 0.45 95% CI:[0.32-0.63], p<0.001; 0.17 [0.06-0.46], p<0.001; and, 0.47 [0.24-0.94], p=0.03, respectively) or to samples from the SP8w arm (PRs: 0.49 [0.34-0.70], p<0.001; 0.15 [0.06-0.41], p<0.001; and, 0.50 [0.25 – 1.01], p=0.054, respectively). Treatment with DP4w was associated with a reduced prevalence of wild type *pfmdr1* N86Y compared to DP8w (PR: 0.28 [0.11-0.72], p=0.009). Increased prevalences were detected for wild type *pfmdr1* D1246Y in the DP arms

compared to the SP arm (PR: 1.20 [1.06-1.36],  $p=0.004$ ). Considering folate enzyme genes, treatment with SP was associated with increased prevalences for mutant alleles at *pfdhfr* I51N and *pfdhps* K540E compared to the DP arms (PRs: 1.26 [1.10-1.45],  $p=0.001$ ; and, 1.29 [1.07-1.55],  $p=0.009$ , respectively). These findings suggest that IPTp with SP or DP selects parasite genotypes associated with decreased sensitivity to these regimens.

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>U.S. Naval Medical Research Unit-6, Lima, Peru, <sup>3</sup>U.S. Army Medical Research Unit, Nairobi, Kenya, <sup>4</sup>Armed Forces Health Surveillance Branch, Silver Spring, MD, United States, <sup>5</sup>Peruvian National Institute of Health-INS, Lima, Peru, <sup>6</sup>Cesar Garayar Hospital, Peruvian Ministry of Health, Lima, Peru, <sup>7</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>8</sup>U.S. Army Medical Materiel Development Activity, Fort Detrick, MD, United States, <sup>9</sup>Global Scientific Solutions for Health, Baltimore, MD, United States, <sup>10</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>11</sup>Walter Reed National Military Medical Center, Bethesda, MD, United States

Artemisinin-resistant (ART-R) *Plasmodium falciparum* poses a significant threat to global malaria elimination efforts. To examine the extent of ART-R across three continents, we conducted a prospective clinical study in Iquitos, Peru (P), Kisumu, Kenya (K), and Sangklaburi, Thailand (T) in patients treated with standard doses of artesunate (AS), followed by mefloquine (MQ) at 72 hours. The primary endpoint was comparison of microscopically determined parasite clearance half-life (PC1/2) for the 72-hour period of unopposed AS. Secondary endpoints included clinical outcome and determination of Kelch propeller gene (K13) ART-R mutations. *P. falciparum* patients aged 5-65 years were enrolled with 1000-200,000 p/μl and received directly observed AS (4 mg/kg) at 0, 24, and 48h, followed by 15 mg/kg MQ at 72 h, and 10 mg/kg MQ at 84-96 h. Microscopy was performed every 4h for the first 12h after first AS dose and every 6h until 72h or two consecutive negative smears. K13 mutations were correlated with subjects with PC1/2 ≥ 5h. In K, P, and T, respectively, 59, 45, and 47 subjects were evaluable for determination of PC1/2. In P and K all K13 genotypes were wild type (WT), thereby excluding ART-R. In T, however, 34 subjects (72%) were WT and 13 (28%) harbored K13 mutations (MT) including G449A (n=1), N537I (6), P553L (1), R561H (3), and C580Y (2). The median PC1/2 of the WT-K13-T group (3.27h [IQR 2.62, 4.20]) was longer than the P (1.91h [IQR 1.71, 2.23],  $p<.0001$ ) and K (2.35h [IQR: 1.78, 2.68],  $p<.0001$ ) sites. The T K13MT group was longer (5.50h [IQR 4.94, 6.20]) than the T K13 WT group ( $p=.015$ ) and included five subjects with PC1/2 ≥ 5h; four of these (9% of total evaluable) had WHO "resistance confirmed" mutations (R561H and C580Y). All subjects achieved 42-day cure. To our knowledge, this study is the first to assess ART-R by comparing PC1/2s in Africa, Southeast Asia and South America. In T, the finding that 9% of subjects satisfy WHO criteria establishes this area as ART-R "endemic". K13 MT ART-R appears to be confined to the T site, but PC1/2s in T WT infections are still longer than in K or P, underscoring the need to identify potential alternative mechanisms of ART-R.
