Artemether-lumefantrine (AL) and artesunate-amodiaquine have been the first-line recommendations for the treatment of uncomplicated malaria in Mali since 2006. Because of the recently reported delays in parasite clearance after artemisinin combination therapy (ACT) in Southeast Asia and because malaria treatment options are limited, it is imperative to monitor the efficacy of currently utilized ACTs and the prevalence of the single nucleotide polymorphisms associated with resistance to artemisinin and its partner drugs. Because of those concerns, we recently performed a prospective therapeutic efficacy study (TES) to evaluate the efficacy of AL for uncomplicated *P. falciparum* malaria in Dioro, Mali. In this study, 229 patients were enrolled, treated on days 1-3 and followed subsequently on days 2, 3, 7, 14, 21, 28, 35 and 42. Fourteen of these 229 subjects (6%) presented with recurrent parasitemias after day 28. Two of those 14 recurrences (one on day 23, the other on day 42) were classified as recrudescences by microsatellite analysis, yielding a 99% adequate clinical and parasitological response rate. Mutations in the *P. falciparum* K13 (*PfK13*) gene and *Pfmdr-1* gene were examined in all *P. falciparum* positive samples using Sanger sequencing. Analysis of *PfK13* sequence data revealed one sample with a synonymous mutation at codon 496. No other mutations were observed within the kelch 13 propeller domain. Based on analysis of the *Pfmdr-1* gene, there was a high frequency of the N86 and D1246 wildtype alleles: 13% of samples sequenced had the 86Y mutation, one had the 1246Y mutation and 62% had the 184F mutation. One of the two recrudescence samples had the NFD haplotype (codons 86, 184 and 1246), the other had the NYD haplotype. In a setting where the efficacy of AL treatment is high and there was a high frequency of the *Pfmdr-1* N86 allele, which has been associated with lumefantrine resistance, the treatment failure rate was low (1%). Continued monitoring for clinical efficacy and molecular markers associated with treatment failure is essential to provide effective guidance for evidence-based guidelines for malaria treatment.

## BASELINE MOLECULAR DATA BEFORE SCALING-UP OF SEASONAL MALARIA CHEMOPREVENTION IN SEVEN COUNTRIES ACROSS THE SAHEL

**Khalid Beshir**<sup>1</sup>, Sonny Ogoi<sup>2</sup>, Serign Ceesay<sup>3</sup>, Abdoulaye Diallo<sup>4</sup>, Jean Bosco Ouedraogo<sup>5</sup>, Issaka Zongo<sup>5</sup>, Abdoulaye Djimde<sup>6</sup>, Issaka Sagara<sup>6</sup>, Alassane Dicko<sup>6</sup>, Julian Muwanguzi<sup>1</sup>, Corinne Merle<sup>7</sup>, Diego Moroso<sup>8</sup>, Ebenezer Baba<sup>9</sup>, Matt Cairns<sup>1</sup>, Paul Snell<sup>1</sup>, Jean Louis NDiaye<sup>4</sup>, Paul John Milligan<sup>1</sup>, Colin Sutherland<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>JEDIMA, Abuja, Nigeria, <sup>3</sup>MRC Laboratories, Fajara, Gambia, <sup>4</sup>UCAD, Dakar, Senegal, <sup>5</sup>IRSS, Bobo-Dioulasso, Burkina Faso, <sup>6</sup>MRTC, Bamako, Mali, <sup>7</sup>World Health Organization/TDR, Geneva, Switzerland, <sup>8</sup>Malaria Consortium, Kampala, Uganda, <sup>9</sup>Malaria Consortium, Kampala, Uganda

It is essential that national SMC programmes incorporate a drug sensitivity monitoring component, using standardised methods. Through the ACCESS-SMC project, we assessed the prevalence of molecular markers associated with resistance to sulfadoxine-pyrimethamine and amodiaquine, using standardised methods in seven countries, before the scale-up of SMC and, as part of the same project, will assess prevalence again in the same sites, after two years at scale. To measure clinical efficacy, case control studies have also been conducted and blood samples from the cases used for analysis of the prevalence of molecular markers of resistance in relation to time since SMC treatment, to understand factors associated with early breakthrough infection. Baseline surveys were conducted in January and February of 2016, in Burkina Faso, Chad, Gambia, Guinea, Mali, Niger and Nigeria, in areas that had not yet started SMC. Each survey included two age groups, children under 5 years of age, and a group of older children and adults, aged 10 to 30 years, to permit comparison before and after scale up in a group who would not be exposed to SMC drugs, for assessment of the extent of changes in the circulating parasite population. The sample size, 2200 in each age group in each country, provides adequate power to detect important changes in frequencies of the molecular markers between baseline in 2016, when the surveys are repeated in January 2018 and at future intervals. Probability sampling was used to select participants in the community; a short questionnaire was completed to record personal identifiers and the age, date of birth, gender, date of interview, residence location and other details. Finger-prick blood samples were taken onto filter paper and dried. Building on preliminary data presented at ASTMH in 2016, we will present the prevalence of asymptomatic *P. falciparum* carriage and final estimates of the prevalence of mutations at *pfcr*, *pfmdr1*, *pfdhfr* and *pfdhps* known to impact on the efficacy of AQ or SP, and analysis of frequencies of these markers in clinical cases.

## UNDERSTANDING AND OPTIMIZING OPERATIONAL SEASONAL MALARIA CHEMOPREVENTION THROUGH DATA ANALYSIS AND MODELING: THE EXAMPLE OF BURKINA FASO

**André Lin Ouedraogo**<sup>1</sup>, Jaline Gerardin<sup>1</sup>, Pauline Yanogo<sup>2</sup>, Augustin Zongo<sup>3</sup>, Yacouba Savadogo<sup>2</sup>, Philip A. Eckhoff<sup>1</sup>, Edward A. Wenger<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>2</sup>National Malaria Control Program, Ouagadougou, Burkina Faso, <sup>3</sup>Ministry of Health, Ouagadougou, Burkina Faso

In 2015, the seasonal malaria chemoprevention (SMC) campaign in Burkina Faso aimed to significantly reduce the incidence of disease in children below 5 years of age. During the wet season, children were given a full dosage regimen of sulphadoxine-pyrimethamine plus amodiaquine at one-month intervals allowing for up to 4 rounds of treatment per child depending on coverage. At the end of the 2015 campaign, the National Malaria Control Program uncovered widespread heterogeneity in SMC

effectiveness in several intervention areas ranging from 0-50% reduction in clinical incidence compared with previous transmission seasons; these heterogeneities continued into the 2016 campaign, allowing classification of intervention areas into low- or high-performing categories. In contrast, control areas where SMC campaigns were not rolled out showed no reduction in clinical incidence, underscoring the true impact of SMC campaigns in high-performing areas and motivating optimization of SMC in low-performing areas. We combined statistical and modeling frameworks to investigate key determinants of campaign performance. Two cohorts of 500 children each from 10 villages in both low- and high-performing areas were followed up from 2015 throughout 2016, and data was collected on SMC coverage per round as well as malaria incidence per season and village. In a generalized mixed-effect regression analysis, geolocation (accessibility), distance to the nearest health facility, LLIN coverage, and health-seeking behavior were found to be significant predictors of greater reduction in the observed clinical incidence in high-performing areas (50%) as compared to low-performing areas (0-10%) given similar SMC coverage patterns. We simulated SMC campaigns in an agent-based mechanistic model calibrated to local malaria transmission, including suboptimal adherence to dosing regimens and SP/AQ resistance, and find that delivering the first two rounds of SMC treatment results in greater impact on incidence reduction than zero-round or late-round delivery.

## INVESTIGATING THE MUTATIONAL PATHWAYS TO RESISTANCE FOR CLINICALLY-RELEVANT *PLASMODIUM FALCIPARUM* DIHYDROOROTATE DEHYDROGENASE INHIBITORS

**Rebecca E.k. Mandt**<sup>1</sup>, Tomoyo Sakata-Kato<sup>1</sup>, Maria Jose Lafuente-Monasterio<sup>2</sup>, Purva Gupta<sup>3</sup>, Elizabeth Winzeler<sup>3</sup>, Francisco-Javier Gamo<sup>2</sup>, Dyann F. Wirth<sup>1</sup>, Amanda K. Lukens<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Tres Cantos Medicines Development Campus, GlaxoSmithKline, Madrid, Spain, <sup>3</sup>University of California San Diego, San Diego, CA, United States

Widespread drug resistance to frontline antimalarials is an ever-increasing threat. Strategies to prevent the emergence of resistance are urgently needed, particularly for next generation antimalarials progressing through the development pipeline. In developing these strategies, it is critical that we understand the evolutionary pathways to resistance for novel inhibitors. We have begun to characterize the progression of resistance over time with the triazolopyrimidine-based DHODH inhibitor DSM267, a close analog of the clinical candidate, DSM265. Here we present initial results from these studies, showing that progressive *in vitro* selection with DSM267 can result in parasites that are over 200-fold resistant to the compound. We also find that these selected lines are cross-resistant to diverse classes of DHODH inhibitors. Sanger sequencing of the *dhodh* locus revealed that while these highly-resistant parasite lines have mutations in *dhodh*, these mutations do not fully explain the progression of resistance. This work builds on our previous work using an *in vitro* selection approach to identify mutations conferring resistance to distinct *Plasmodium falciparum* dihydroorotate dehydrogenase (PfDHODH) inhibitors. Intriguingly, when screening both wild-type and mutant lines against a panel of inhibitors, we identified examples of compounds with increased activity against DHODH mutants relative to wild-type parental strains. We demonstrated that combinations of "mutant-type" and "wild-type" compounds effectively suppressed the emergence of resistance. We have since completed a follow-up screen of libraries from the Tres Cantos Open Lab Foundation and identified additional compounds with mutant-type or equipotent activities. Cross-resistance profiling of candidate compounds against a panel of DHODH mutants revealed compound combinations active against the full range of resistance mutations identified thus far, providing support for the feasibility of targeting resistance.

**ELUCIDATING THE ROLE OF EIK1 IN NON-GENETIC RESISTANCE TO HALOFUGINONE**

Lola Fagbami<sup>1</sup>, Amy A. Deik<sup>2</sup>, Kritika Singh<sup>3</sup>, Selina E. Bopp<sup>1</sup>, Jonathan D. Herman<sup>1</sup>, Sofia A. Santos<sup>3</sup>, Amanda K. Lukens<sup>2</sup>, Clary B. Clish<sup>2</sup>, Ralph Mazitschek<sup>3</sup>, Dyann F. Wirth<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Broad Institute, Cambridge, MA, United States, <sup>3</sup>Massachusetts General Hospital, Boston, MA, United States

Aminoacyl tRNA synthetases (aaRSs) are attractive targets for chemotherapeutic intervention in malaria. aaRSs are a class of enzymes that catalyze the linkage of a tRNA with its cognate amino acid and are essential for protein translation in all species. They are also highly conserved across protozoan parasites, and thus represent an ideal target for broad-spectrum drug development. Amino acid starvation or inhibition of aaRSs leads to the accumulation of uncharged tRNA, which binds and activates the stress kinase GCN2. Activated GCN2 phosphorylates the regulatory subunit eIF2 $\alpha$  of the ribosome, which blocks general protein translation and subsequently triggers the Amino Acid Response (AAR). We have previously shown that shown that halofuginone (HFG), a potent inhibitor of the cytoplasmic prolyl tRNA synthetase, induces phosphorylation of eIF2 $\alpha$  in *P. falciparum* parasites, which is generally considered as sensitive biomarker of the AAR activation in the context of amino acid starvation. In investigating the antimalarial activity of HFG, we identified an unprecedented mechanism of drug resistance via the upregulation of free intracellular proline. We sought to understand whether the activation of the AAR is required to provide rapid drug tolerance to HFG via upregulation of proline. Here, we present our results elucidating the requirement of eIK1, the *P. falciparum* homolog of GCN2, for the halofuginone-induced resistance phenotype. It has previously been shown that amino acid starvation does not induce the phosphorylation of eIF2 $\alpha$  in eIK1<sup>-/-</sup> blood stage parasites. Using this knockout line, we investigated whether eIK1 activity is essential for induced HFG resistance. We found that HFG-treated wildtype and eIK1 knockout parasites acquired phenotypic resistance in response to drug treatment with a concomitant increase in intraparasitic proline levels. These results suggest that the modulation of proline homeostasis in response to drug treatment is independent of the AAR.

**PHARMACODYNAMIC META-ANALYSIS OF HUMAN PLASMODIUM FALCIPARUM MONOTHERAPY DRUG TRIALS**

Scott Meredith, David J. Sullivan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

A hallmark of uncomplicated and severe malaria is a high microbial load where a 5% parasitemia represents 200 million *Plasmodium* parasites per millil of blood or almost a trillion parasites for the 6 L of adult blood volume. A rapid pharmacodynamics kill rate averts death and theoretically hinders drug resistance. Here we explored the recent 4 decades of published *P. falciparum* monotherapy drug trials on more than 16,000 patients from 330 trials for which we could extract pharmacodynamic data related to parasite reduction or clearance rates. The artemisinin class represented 36%, methanol-quinolines 27%, 4-amino quinolines 20%, antifolates 10% and antibiotics 7% of the useable trials. The ratio of parasites reduced in 48 hours and the time to clear 50% of the initial parasitemia (Parasite Clearance50) were the more robust comparable metrics because either value can be used to reliably predict the other. Other metrics like parasite clearance times (90 or 100%), cure rates, lag times or number reduction have clinical significance and are widely reported but provide little insight into pharmacodynamic kill rates. The critical first 48 hour parasite reduction ratio was upward of 5,100 for artesunate, 1,100 for quinine, 3,700 for chloroquine, 840 for sulfadoxine-pyrimethamine, 100 for atovaquone-proguanil and 2 for clindamycin and

astmh.org

azithromycin. Interestingly, pyronaridine had a 5,700 reduction ratio. The two antibiotics after a three day lag then had a maximum reduction ratio of 5,700 The artemisinins tended to have a smaller lag phase than the quinolines. We plan to compare the monotherapy *P. falciparum* data to drug combination pharmacodynamic data as well to murine malaria.

## 1570

**DETECTION OF PLASMODIA SPP. INFECTION BY MERIDIAN ILLUMIGENE® MALARIA COMPARED TO REFERENCE MICROSCOPY AND REAL-TIME PCR**

Candace Rypien, Barbara Chow, Wilson Chan, Dylan R. Pillai  
University of Calgary, Calgary, AB, Canada

Malaria is one of the leading causes of infectious diseases in returning travelers from the tropics. Diagnosis of malaria is typically performed by Giemsa-stained thick and thin peripheral blood examination. The latter method can be time-consuming, labor-intensive, and require continuous proficiency in a non-endemic area where specimen volumes may be low. Molecular testing has repeatedly demonstrated increased analytical sensitivity. The favored molecular method to date has been polymerase chain reaction (PCR) however this method requires significant capital investment and molecular specialist knowledge. Loop-mediated isothermal amplification (LAMP) is an alternative molecular method which is rapid, sensitive, and requires less capital equipment and technologist training. We conducted a retrospective study comparing a commercial LAMP kit (Meridian illumigene® Malaria) versus reference microscopy on frozen, archived blood specimens (n=139) from returning travelers suspected of having malaria reflecting all human malaria species. The LAMP assay primers are able to detect *Plasmodium falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, and *P. knowlesi*. Discordant results were resolved by using a laboratory developed, ultra-sensitive real-time PCR method. Our results demonstrated that Meridian illumigene® Malaria was 100% sensitive (both M kit and MP kit) and 98.4% (M kit) and 96.7% specific (MP kit) compared to reference microscopy after resolving discrepancies with a validated real-time PCR method and repeat testing for invalid runs. The extraction method followed by run time for the Meridian illumigene® Malaria takes approximately 60 minutes (M kit) with a sample throughput of 10 specimens. No centrifugation is required. The LAMP instrument provided with the Meridian illumigene® Malaria makes an automatic call to the genus level only. Implementation of this assay may be useful in ruling out malaria infection without the need for repeat examination with faster turn-around times and labor cost savings, but does not replace the need for microscopy to confirm positives by speciation and determine parasitemia levels.

## 1571

**MALARIA AND DENGUE INFECTIONS AMONG PATIENTS ATTENDING TERTIARY CARE AND HEALTH CARE CENTERS IN AND AROUND MANGALURU, INDIA: A PROSPECTIVE STUDY**

A. Veena Shetty<sup>1</sup>, Padma Shetty<sup>1</sup>, Adithi Bhandary<sup>1</sup>, Valleesha Chandrashekar<sup>1</sup>, D. Channe Gowda<sup>2</sup>

<sup>1</sup>Kshema, Nitte University, Mangalore, India, <sup>2</sup>Pennsylvania State University College of Medicine, Hershey, PA, United States

Malaria is one of the leading causes of acute febrile illness in India. The prevalence of dengue and malaria infections has not been investigated and very few cases have been reported. To study the association of malaria and dengue among patients with febrile illness. This is a cross-sectional study of patients with febrile illness carried out at a coastal belt of India. The study was conducted after the approval of Institutional Ethics Committee, KSHEMA. This study was carried out in a tertiary care centre and public health centres in and around Mangalore. All blood samples confirmed with either malaria or dengue were included in this study. Malaria and dengue diagnosis was done on the basis of Conventional and molecular methods. Followed by dengue was done by using dengue-specific NS1 antigen kit and real time PCR. The collected information were summarized

by the descriptive Statistics. In our study, 121 samples were confirmed with malaria by conventional and real time PCR reaction. *P. vivax* (*P.v*) was 89%, *P. falciparum* (*P.f*) 0.83% and mixed infection was 10%. 25 were positive for Dengue by NS1 antigen kit method and further confirmed by Dengue real-time polymerase chain reaction (RT-PCR). None of the samples were positive for both malaria and dengue coinfections. To compare the differences in biochemical parameters such as Total bilirubin, SGOT, SGPT and platelet count between Mixed infection and *P.v* independent sample 't' test was used. Since the p value is <0.05 for total bilirubin, there was a difference between mixed infection and infection with *P.v* and it was clinically correlated with the patient outcome. The p value for SGOT/SGPT and platelet count was >0.05, there was no difference between mixed infection and infection with *P.v* Since there was no case of co-infection with dengue and Malaria, association was not performed. In endemic areas for dengue and malaria, jaundice (comorbid patients) and spontaneous bleeding (in malaria patients) should raise the suspicion of co-infection. careful monitoring of the patient is required for reducing the complications which may result in morbidity and mortality of the patients.

## 1572

### PERFORMANCE OF STANDARD AND HIGH SENSITIVITY MALARIA RAPID DIAGNOSTIC TESTS FOR THE DETECTION OF ASYMPTOMATIC PLASMODIUM FALCIPARUM INFECTIONS

**Xavier C. Ding<sup>1</sup>**, Roxanne Rees-Channer<sup>2</sup>, Rushini Perera<sup>2</sup>, Babacar Faye<sup>3</sup>, Dionicia Gamboa<sup>4</sup>, Jennifer Luchavez<sup>5</sup>, Didier Ménard<sup>6</sup>, Kigbafori Silué<sup>7</sup>, Peter L. Chiodini<sup>2</sup>, Iveth J. González<sup>1</sup>

<sup>1</sup>FIND, Geneva, Switzerland, <sup>2</sup>Department of Clinical Parasitology, Hospital for Tropical Diseases, University College London NHS Foundation Trust, London, United Kingdom, <sup>3</sup>Service de Parasitologie, Faculté de Médecine, Université Cheikh Anta Diop, Dakar, Senegal, <sup>4</sup>Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía and Instituto de Medicina Tropical Alexander Von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>5</sup>Research Institute for Tropical Medicine, Muntinlupa City, Philippines, <sup>6</sup>Institut Pasteur in Cambodia, Phnom Penh, Cambodia, <sup>7</sup>Département Environnement et Santé, Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire

In all malaria endemic settings and even more so in areas approaching elimination, asymptomatic malaria infections significantly contribute to the ongoing disease transmission and represent an infectious reservoir that needs to be identified and treated. Most of these asymptomatic infections are characterized by low parasitaemia and represent a diagnostic challenge for classical tests, such as light microscopy or standard rapid diagnostic tests, because of the limited analytical sensitivity of these assays. Improved RDTs with enhanced analytical sensitivity are being developed and could contribute to solve this issue. The aim of this work was to evaluate the performance of RDTs with different analytical sensitivity levels for the detection of *Plasmodium falciparum* asymptomatic infections. A large number of specimens collected from asymptomatic adult volunteers, infected or not by *P. falciparum* as determined by nested PCR, were evaluated with various RDTs based on the detection of the histidine-rich protein 2 (HRP2). The positivity and false positivity rates of the RDTs are reported and analysed taking into account the HRP2 concentrations of the specimens which were measured using a quantitative ELISA method. The use of standard malaria RDTs for active case detection in screen-and-treat campaigns has been shown to be ineffective, largely because of the limited sensitivity of this diagnostic tool. The advent of improved RDTs might overturn this assumption and enable screen-and-treat interventions to be positioned as a suitable complementary strategy in the elimination toolbox. With this study, we provide a first evaluation of the added-value of malaria RDTs with enhanced analytical sensitivity for asymptomatic infections detection and discuss the use of such test for active case detection.

## 1573

### TRACKING HEMOZOIN LEVELS IN SYMPTOMATIC PATIENTS POST TREATMENT USING MAGNETO-OPTICAL DETECTION, MOD

**Brian T. Grimberg<sup>1</sup>**, Emmily Koech<sup>2</sup>, D'Arbra Blankenship<sup>1</sup>, John Vulule<sup>2</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Kenyan Medical Research Institute, Kisumu, Kenya

Hemozoin is a by-product of malaria digestion of haemoglobin. This partially magnetic substance can be used as a biomarker for the presence of malaria in the blood of patients. Still in question is the length of time hemozoin remains detectable in the blood stream post-treatment using modern day drugs and detection methods. The lone previous examination of this question showed that chloroquine treatment eliminated hemozoin from the blood stream by Day 9 on average by microscopy. The current study utilized a novel rapid malaria detection method (Magneto-Optical Detection, MOD) which measures the levels of transmitted light passing through blood samples in the presence and absence of magnetic fields to which the hemozoin particles respond. Patients reporting to Chulaimbo Hospital in western Kenya were monitored before and after their treatment with artemisinin-based drugs by MOD as well as microscopy and RDTs to determine how long after treatment hemozoin and other markers of malaria were detectable. This information helps to define the utility of the new MOD technology by defining the window in which patients can be malaria negative but hemozoin positive.

## 1574

### LIMIT OF DETECTION OF MAGNETO-OPTICAL DETECTION, MOD, ON SAMPLES OF P. VIVAX AND P. FALCIPARUM

**Brian T. Grimberg<sup>1</sup>**, Austin Hise<sup>2</sup>, D'Arbra Blankenship<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Shaker Heights High School, Shaker Heights, OH, United States

Detection of the presence of malaria parasites in patient samples primarily relies upon the use of RDT cards or microscopy-based methods. Microscopy testing time is 30-60 minutes per sample and requires skilled readers. RDT testing time is 15-20 minutes, and sensitivity is lower in some species and variants. There is a need for a malaria diagnostic technique to rapidly and accurately diagnose across all species including those with HRP2 deletions. We have designed an inexpensive, rapid (one minute) malaria detection device called MOD (Magneto-Optical Detection) that indicates the presence of hemozoin, a by-product of parasite digestion of hemoglobin. Polarized light passing through a blood sample is used to diagnose malaria. When the partially magnetic malaria hemozoin is present in a blood sample, it aligns with a magnetic field decreasing the amount of polarized light able to pass through it. In this study, a dilution series of samples of *P. falciparum* and *P. vivax* strains was tested using MOD, RDT, and microscopy using PCR as the gold standard. MOD's limit of detection was shown to be under 10 parasites/uL for both species -- an improvement over microscopy and RDTs. Our long term goal is to translate this MOD technology into a robust, one-minute, \$1 per test device, which can be used in malaria-endemic regions to enable rapid malaria diagnosis at the point-of-care for all species of malaria.

## 1575

### DISTRICT-BASED SUPERVISION AND MENTORSHIP PROGRAM FOR IMPROVING THE QUALITY OF MALARIA RAPID DIAGNOSTIC TESTING IN UGANDA 2014- 2016

**Bosco B. Agaba**<sup>1</sup>, Jimmy Opigo<sup>1</sup>, Ruth Nabwire<sup>1</sup>, Damian Rutazaana<sup>1</sup>, Joselyne Atuhaire<sup>2</sup>, Maureen Amutuhaire<sup>1</sup>, Umaru Sekabira<sup>3</sup>, Ruth Kigozi<sup>4</sup>, Jane Nabakooza<sup>1</sup>, Paul Mbaka<sup>5</sup>, Charles Katureebe<sup>5</sup>, Ann Gasasiira<sup>6</sup>

<sup>1</sup>Department of Disease Control, Malaria Program, Kampala, Uganda, <sup>2</sup>Makerere University School of Public Health, Kampala, Uganda, <sup>3</sup>Infectious Diseases Institute, Kampala, Uganda, <sup>4</sup>Malaria Consortium, Kampala, Uganda, <sup>5</sup>World Health Organization, Kampala, Uganda, <sup>6</sup>African Leaders Malaria Alliance, Kampala, Uganda

Following the World Health Organization recommendation on parasite-based diagnosis for malaria, many endemic countries have scaled-up the use of Rapid Diagnostic Tests (RDTs). While RDTs have increased parasite confirmation, the quality of testing at point of care may be poor. We present findings of the effect of a locally designed supervision and mentorship program on improving the quality of RDT testing at point of care in Uganda. Between 2014 and 2016, we conducted support supervision and mentorship for a total of 4,300 health workers (nurses and laboratory assistants) that were initially trained to perform malaria RDT testing in 21 targeted districts. As the main intervention, each health worker received supervision and mentorship at least twice a year for 3 years. A checklist based on manufacturer's test procedure was used to assess health workers' competency in performing the test at quarterly interval. Re-training was provided where deficiencies in test performance were identified. At each visit the individual health worker's performance was assessed and summarized according to the steps correctly or incorrectly performed. Data was analyzed to determine differences in proportions of health workers that were able to perform the test procedures correctly before and after the intervention. Overall, 4,300 health workers received the initial malaria RDT training. The attrition rate was 18% (774) over the 3-year period of assessment. The proportion of health workers that were able to perform Malaria RDT correctly according to the manufacturer's instructions improved from 68% [CI: 66-79] in 2014 to 94% [CI: 88-96] in 2016,  $p < 0.02$ . Compared to nurses, laboratory assistants were more likely to adhere to the recommended RDT procedure [OR= 3.2, CI: 1.9-4.6]. Regardless of the type of health worker, better improvement was associated with provision of 3 or more supervision and mentorship visits [OR=4.8, CI:3.1-5.4]. Post-training supervision and mentorship improves health workers' competency in Malaria Rapid Diagnostic testing and is vital in maintaining competency levels.

## 1576

### SIMULTANEOUS DETECTION OF FOUR HUMAN MALARIA SPECIES FROM WHOLE BLOOD, GIEMSA STAINED SLIDES AND DRIED BLOOD SPOTS ON FILTER PAPER

**Noel Espina**, Allen Teal, Kimberly Mergen, Susan Madison-Antenucci

Wadsworth Center New York State Department of Health, Albany, NY, United States

Malarial disease is found worldwide with important public health implications. In spite of extensive eradication efforts, there is still a high mortality rate, especially in children. Identification of malarial infections to the species level is most important in endemic regions of Africa, Asia and the Americas. The 'gold standard' in malaria diagnostics is still microscopy but this method is not sensitive at low levels of parasitemia or with mixed infections when one species predominates. Reading slides at very low parasitemia is a challenge even with highly trained and experienced microscopists and leads to false negative results. More sensitive methods are required as cases of low parasitemia occur which allows for continued transmission of the malarial parasite. Blood spots on filter paper have been

used as an alternative to obtaining blood samples from patients and are simpler to obtain, transport and process for diagnostics. We developed a multiplex real-time PCR assay that can identify the most common malarial species that infect humans. The real-time PCR assay is performed on DNA extracted from whole-blood specimens and can simultaneously detect *Plasmodium falciparum*, *P. vivax*, *P. malariae*, *P. ovale curtisi* and *P. ovale wallikeri*. The gene target is the 18S rRNA gene and the limit of detection is 23 gene copies per PCR reaction. The assay identifies mixed infections in patient samples and was shown to be 100% specific when tested against a panel of pathogens that are found in blood. This method is rapid, accurate, inexpensive and very sensitive for detection of *Plasmodium* species in patient samples. In addition to whole blood, the assay can be used with DNA extracted from dried blood scraped off of Giemsa-stained slides. This is especially useful in cases where whole blood samples are difficult to obtain and store, or when only blood smears are available. This assay was also applied on DNA extracted from filter paper using a quick and simple procedure to release malaria DNA from dried blood spots. This method has proven to be a very robust, accurate, cost effective and sensitive method for identification of malaria infections at the species level.

## 1577

### INTRODUCING MALARIA RAPID DIAGNOSTIC TESTS INTO NON-FORMAL PRIVATE SECTOR OUTLETS IN MYANMAR: PRE-POST RESULTS FROM CROSS SECTIONAL STUDIES

**Si Thu Thein**, Hnin Su Su Khin, Manuela Tolmino, Moh Moh Lwin  
*PSI/Myanmar, Yangon, Myanmar*

The Myanmar government is committed to achieving malaria elimination by 2030. To do so, every case must be identified and appropriately treated. 50% of febrile patients in Myanmar seek treatment in the private sector, including at general stores, drug shops and mobile vendors. Non-formal providers are often the only source of care in remote communities where malaria burden is highest. In 2014 only 10% of antimalarial-stocking non-formal outlets stocked malaria rapid diagnostic tests (RDTs). Increasing access to RDTs and promoting rationale treatment have been shown to improve targeting and case management in other settings. Between August 2015 and November 2016 8,728 non-formal providers were trained on a rolling basis and provided RDTs for free. Following training providers received quarterly provider behavior change (PBC) visits. Baseline and endline mystery client surveys were conducted in August 2014 (540 sites) and November 2016 (430 sites) at randomly sampled providers to assess RDT use and medicine prescribing patterns. Mystery clients played the role of a person with fever and were accompanied by the researcher acting as a friend. The researcher completed a questionnaire on leaving the outlet. Data analysis accounted for the survey design. Between 2014 and 2016 the proportion of mystery clients tested by RDT increased from 0.9% to 10.8%. All clients tested negative for malaria. Any use of medical treatment was unchanged over time (67% in 2014, 68% in 2016) but antimalarial treatment practices changed greatly over time. The proportion of clients receiving a quality-assured ACT declined from 17% to 1% and banned oral artemisinin monotherapy use declined from 7.8% to 0.6%. In comparison, antibiotic use remained relatively stable at 21.7% in 2014 and 25.6% in 2016. While training and PBC appears to have influenced prescription practices, the uptake of RDTs has been slower. By better understanding the levers of confidence, incentives and skills in relation to RDT use, programming and PBC activities could be strengthened to accelerate RDT uptake among non-formal outlets to enhance their contribution to the national malaria elimination goal.

### MOLECULAR RE-EXAMINATION OF FALSE-NEGATIVE HISTIDINE-RICH PROTEIN 2 (HRP2)-BASED RAPID DIAGNOSTIC TESTS (RDTs) FOR MALARIA

Trevor A. Thompson<sup>1</sup>, Lansana Sangaré<sup>2</sup>, Youssouf Diarra<sup>2</sup>, Ousmane A. Koita<sup>2</sup>, Donald J. Krogstad<sup>1</sup>

<sup>1</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Faculty of Science, University of the Sciences, Techniques and Technologies, Bamako, Mali

Previous studies in Mali have found high frequencies of false-negative HRP2-based RDTs in subjects with *Plasmodium falciparum* malaria (chills, fever, headache and other symptoms plus a positive thick smear for asexual *P. falciparum* parasites). In addition, the frequencies of false-negative RDT results were higher in the dry season (when parasite densities are low) than in the rainy season (when parasite densities are higher). The first aim of these studies was to add a nested *hrp2* PCR to the HRP2-based RDT to test for both the *hrp2* gene and its protein product; the second was to add real-time PCR for the conserved *P. falciparum* 18S rRNA gene to confirm the validity of the microscopy results and the third was to consider how these results could or should affect current treatment recommendations for symptomatic subjects with negative HRP2-based RDTs. Nested *hrp2* PCR and HRP2-based RDTs: Positive *hrp2* PCRs were more frequent with samples that had positive HRP2-based RDTs; negative *hrp2* PCRs were more frequent with samples that had negative HRP2-based RDTs (30/43 vs. 60/67,  $p < 0.001$ ). Microscopy and real-time PCR for *P. falciparum* 18S rRNA: Positive real-time PCR results for *P. falciparum* 18S rRNA were more frequent among samples with  $\geq 1,000$  asexual parasites per  $\mu\text{l}$  by microscopy than among samples with  $< 1,000$  parasites per  $\mu\text{l}$  (26/31 vs. 13/79,  $p < 0.0001$ ). These results support the treatment of symptomatic subjects with positive HRP2-based RDTs (in whom parasite counts are  $\geq 1,000$  per  $\mu\text{l}$ ). However, they do not resolve the interpretation of negative HRP2-based RDTs in subjects with  $< 1,000$  parasites per  $\mu\text{l}$  because there are more false-negative test results with the nested *hrp2* PCR, the HRP2-based RDT and the real-time PCR for the 18S rRNA gene of *P. falciparum* at parasite densities  $< 1,000$  per  $\mu\text{l}$ .

### A HIGHLY SENSITIVE MULTIPLEXED BEAD-BASED IMMUNOASSAY FOR POTENTIAL MALARIA DIAGNOSTICS

Julie Clor<sup>1</sup>, Mary Otto<sup>2</sup>, John McDonald<sup>2</sup>, Prasanna Jagannathan<sup>3</sup>, Bryan Greenhouse<sup>4</sup>, Abel Kakaru<sup>5</sup>, James Mulry<sup>6</sup>, Beatrice Greco<sup>7</sup>, Kamala Tyagarajan<sup>1</sup>

<sup>1</sup>MilliporeSigma, Hayward, CA, United States, <sup>2</sup>MilliporeSigma, St. Louis, CA, United States, <sup>3</sup>Stanford University, Palo Alto, CA, United States, <sup>4</sup>University of California, San Francisco, CA, United States, <sup>5</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>6</sup>Merck KGaA (EMD Serono Inc.), Coinsins, Switzerland, <sup>7</sup>Merck Global Health Unit, Merck Biopharmaceutical Research and Development, Coinsins, Switzerland

Rapid, accurate and early detection and diagnosis of malaria infection is essential for effective disease management and treatment of the disease. Traditional methods such as rapid diagnostic tests and microscopy often lack the sensitivity and specificity needed for quick disease diagnosis and management; in addition approaches like microscopy often require expert readers to obtain accurate results. Here we present results from novel bead-based immunoassay developed on an affordable miniaturized flow cytometry platform, the Muse® Cell Analyzer. The assay allows for multiplexed, high sensitivity confirmation of malarial antigens (*Plasmodium falciparum* HRP2, *Pf* LDH and *P. Vivax* LDH) and also typing of *Falciparum* and *Vivax* infection from the same sample. In addition the platform can also provide parasitemia/parasitemia density information. Our assays demonstrate high sensitivity detection with pg/mL sensitivity in detection of the 3 key antigens as well as a wide dynamic range of detection. Results will be presented from studies performed with spiked protein standards in blood as well as cultured *P. Falciparum* strains and patient samples. In

a study performed with the Infectious Diseases Research Collaboration, UCSF, and Stanford, frozen whole blood samples were obtained from a cohort of asymptomatic pregnant women from Uganda and samples were first characterized by microscopy to determine presence of *falciparum* infection and degree of parasite density. Samples were next characterized by bead based immunoassay on the Muse® Cell Analyzer and identified as positive and negative for *falciparum* Malaria. The Muse bead-based immunoassay demonstrated great sensitivity in the detection of positive samples and could clearly identify samples with low parasitemia levels. Dilution of samples also enabled determining limit of detection for these assays. The availability of a simple, rapid and highly sensitive test for identification and typing of malaria on an affordable, easy to use platform on which other pathogens can also be identified can greatly amplify the capability for effective and timely malaria diagnostics.

### WHO IS MORE LIKELY TO PERFORM MALARIA RAPID DIAGNOSTIC TESTS IN THE NON-FORMAL SECTOR IN MYANMAR?

Hnin Su Su Khin, Phone Si Hein, Manuela Tolmino, Si Thu Thein, Ashton Strait

Population Services International, Myanmar, Yangon, Myanmar

Non-formal providers are a major source of care for febrile cases in remote communities in Myanmar where malaria burden is highest. However in 2015 malaria rapid diagnostic tests (RDTs) were available in only 13% of antimalarial-stocking non-formal private sector outlets. Subsequently, between August 2015 and June 2016, 5,335 non-formal providers were trained by Population Services International (PSI) to conduct RDTs, treat malaria cases, and report results. The intervention specifically targeted general retail stores (GRS), itinerant drug vendors (IDVs), and drug shops. RDTs were supplied for free. To better understand how these providers can contribute to the national goal of malaria elimination, PSI performed a statistical analysis of the outlet characteristics associated with high RDT testing performance. All outlets trained by June 2016 were included in the analysis, which used routine data on RDT testing rates and supportive supervision visits (SSVs) from July to December 2016. RDT performance was simplified to whether or not an outlet performed at least 5 RDTs per month. Bivariate (Chi square) and multivariate analysis explored the correlation between RDT performance and variables like type of outlet, number of SSVs received, and malaria endemicity of the outlet location. Compared to GRS, IDV are 5 times more likely, and drug shops are 2.3 times more likely, to test at least 5 RDTs per month. Outlets in the highest endemic townships are 1.74 times more likely to test at least 5 RDTs per month compared to those in low risk areas. Outlets that received more than 3 SSVs over 6 months were 13.9 times more likely to test at least 5 RDTs per month than outlets that received fewer. Unsurprisingly, malaria endemicity seems to be a factor in the number of RDTs performed by non-formal providers. The strong positive correlation between SSVs and RDT testing suggests that support and monitoring systems for non-formal providers can improve their performance. The factors underlying different types of providers' RDT performance merit further exploration in order to design a tailored approach for maximum impact and surveillance coverage.

### THE IMPORTANCE OF EXTERNAL QUALITY ASSESSMENT IN FOCUSING IMPLEMENTATION OF QUALITY IMPROVEMENT PROGRAMS ON MALARIA MICROSCOPY IN TANZANIAN MILITARY HEALTH FACILITIES

Saidi Mgata<sup>1</sup>, D. Klarkowski<sup>2</sup>, Lucas Mahikwano<sup>1</sup>, Akili Kalinga<sup>1</sup>, Lucky Temu<sup>1</sup>, Charles Mswanya<sup>3</sup>, Chris Mwanziva<sup>3</sup>, Lalaine Anova<sup>2</sup>, Kofi Wurupa<sup>2</sup>, Dennis Janga<sup>3</sup>, Vesely Brian<sup>2</sup>

<sup>1</sup>Walter Reed Malaria Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD,

United States, <sup>3</sup>Tanzania Peoples Defense Forces, Dar es Salaam, United Republic of Tanzania

Quality malaria microscopy remains the gold standard method for confirmation of malaria parasites in human blood. Innovative strategies to increase access to quality malaria microscopy are now fastened to support case management and research. To ensure quality of malaria microscopy quality control (QC) in selected military health facilities, external quality assessment (EQA) and quality improvement programs (QI) have been collaboratively implemented between Tanzania Peoples Defence Forces (TPDF) and Walter Reed Army Institute of Research (WRAIR). The key objective is to build capacity and readiness of the laboratories under the program to accurately diagnose malaria for patient care and clinical research activities. An assessment is made after all testing sites are provided with high quality equipment, reagents and supplies to perform malaria microscopy. The trend of malaria positivity in the sites is monitored routinely. EQA is conducted quarterly through site evaluations using microscopy check list, randomized slide rechecking and proficiency testing for the technical staffs working in the laboratories. For the purpose of measuring and maintaining competency, at each quarterly supportive supervision cycle every testing staff at the site is given 20 (9 negatives and 11 low density positives) standardized, expert validated blood slides to read as part of EQA. The score of individual technician have been aggregated to provide an average score of a specific site laboratory. We also compared average laboratory performance in EQA and the positivity level at the site and its implications. The results show a relationship between the level of malaria at the site and performance in EQA. The best performing laboratories are also the ones having high malaria positivity rates with few exceptions contributed to lack of training and competency of individual technicians. Additionally, false negative rate was found to be higher among study sites with low malaria whose laboratory EQA performance was also low. The routine exposure to seeing malaria may be advantageous to continued skills.

### THE USE OF FIONET™ TECHNOLOGY IN MALARIA SURVEILLANCE AND EXTERNAL QUALITY CONTROL OF RAPID DIAGNOSTIC TESTS IN MILITARY HEALTH FACILITIES IN TANZANIA

**Christopher Mswanya**<sup>1</sup>, Akili Kalinga<sup>2</sup>, Charles Mwanziva<sup>1</sup>, Lucky Temu<sup>3</sup>, Sarah Chiduo<sup>3</sup>, Lalaine Anova<sup>4</sup>, Lucas Mahikwano<sup>3</sup>, Saidi Mgata<sup>1</sup>, George Amoo<sup>3</sup>, Nora Zwingerman<sup>5</sup>, Ian Fine<sup>5</sup>, Brian Vesely<sup>4</sup>, Eyako Wurapa<sup>4</sup>, Robert Paris<sup>4</sup>, Colin Ohrt<sup>4</sup>, Mark Hickman<sup>4</sup>, Dennis Janga<sup>1</sup>

<sup>1</sup>Tanzania Peoples Defense Force, Dar es Salaam, Tanzania, United Republic of, <sup>2</sup>National Institute for Medical Research, Tukuyu, Tanzania, United Republic of, <sup>3</sup>Walter Reed Project, Dar es Salaam, Tanzania, United Republic of, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>FIO, Toronto, ON, Canada

In Tanzania, an estimated 16-18 million cases of malaria occur each year, resulting in more than 100,000 deaths. Malaria surveillance is useful for gathering data for evaluation of control programs that are ongoing. Although a recent innovation, malaria rapid diagnostic tests (mRDT) have become a viable alternative diagnostic tool for malaria surveillance, however, external quality control (EQC) is a challenge. Walter Reed Army Institute of Research (WRAIR) has partnered with the Tanzanian Peoples Defense Forces (TPDF) to implement a passive malaria surveillance and mRDT EQC strategy using Fionet™ technology. Fionet™ is a digital health system that improves field performance and oversight of mRDT. The system captures RDT images which can be remotely reviewed for EQC, it provides operational quality control measures for the laboratory technician in real-time, it compiles the data and sends data in-real time on a centralized portal that is reviewed by Managers for immediate use. Malaria RDT data and images were monitored regularly at eight military camps. About 82% of 95,247 mRDT records were uploaded over a four year period. Nearly 33% was uploaded in < 1 hour and 80% of all data was

uploaded within 24 hours. Annual average malaria positivity rates (MPR) for all sites increased from 22.9% (2013) to 29.3% (2014) to 37.1% (2015) and then declined to 22.8% (2016). The incorrect interpretation of mRDTs by peripheral healthcare users dropped from an initial 5.5% to 3.7% in the first six months, to 2.5% in the first year and 3.1%, 3.4%, and 2.9% in subsequent years. The preparation problems dropped from 2.5% to 1% after six months and to almost 0% in subsequent years. Fionet™ has improved diagnostic capacity, real-time malaria data tracking and reporting and proved as valuable tool for mRDT EQC.

### CROSS-SECTIONAL ANALYSIS IN YOUNG NON-PREGNANT AND PREGNANT WOMEN IN BURKINA FASO OF ASSOCIATIONS BETWEEN BIOMARKERS OF IRON STATUS AND EFFECT MODIFICATION BY INFLAMMATION AND PLASMODIUM FALCIPARUM INFECTION

**Salou Diallo**<sup>1</sup>, Sabine Gies<sup>2</sup>, Arnaud KI<sup>1</sup>, John G. Pagbelguem<sup>1</sup>, Georges A. Ouedraogo<sup>3</sup>, Halidou Tinto<sup>1</sup>

<sup>1</sup>Clinical Research Unit of Nanoro, Ougadougou, Burkina Faso, <sup>2</sup>Institute of Tropical Medicine, Anvers, Belgium, <sup>3</sup>Université Polytechnique de Bobo Dioulasso, Bobo Dioulasso, Burkina Faso

Iron deficiency is a major cause of anaemia and accurate biomarkers are needed to estimate iron status and its contribution to anaemia. No previous comparative analyses of iron biomarker correlations in non-pregnant and pregnant women or the comparative effect modification by inflammation or malaria. In young non-pregnant and pregnant women living under endemic malaria transmission estimation of iron biomarker correlations, body iron stores, iron deficiency prevalence using single and multiple biomarker definitions, and effect modification by inflammation by C reactive protein and *Plasmodium falciparum* parasitaemia. The data were derived from a randomised controlled trial of periconceptional weekly iron supplementation among young mostly adolescent nulliparous non-pregnant women and primigravidae living within the Nanoro Demographic Surveillance area, Burkina Faso. Data points were at the end assessment survey for non-pregnant women (N=973), and at the first scheduled antenatal visit for nulliparae (N=314). Plasma ferritin, serum transferrin receptor, and C-reactive protein were measured in duplicate by ELISA, zinc protoporphyrin by fluorometry, and haematological indices by automated analyser. *P.falciparum* slide positivity and CRP cut-offs were used to define inflammation categories. At ANC1 69.7% were anemic ( $\leq 11\text{g/dL}$ ), and 53.7% parasitaemic, and at FIN 46.7% were anemic and 41.7% parasitaemic. Anemia prevalence was higher in non-pregnant ( $p < 0.01$ ) and pregnant women ( $p < 0.001$ ) with malaria. Prevalence of iron deficiency (sTfR/Log10ferritin  $> 5.6$ ) did not differ in pregnant or non-pregnant women after adjustment for CRP values ( $< 5$  or  $< 10\ \mu\text{g/ml}$ ), with or without *P.falciparum* parasitemia. High ZPP ( $> 85\ \mu\text{mol/mol}$  heme) was more frequent in non-pregnant or pregnant women (both  $P < 0.01$ ) in the presence of inflammation. In pregnant or non-pregnant women living under endemic malaria transmission the sTfR/log10Ferritin ratio  $> 5.6$  was not significantly affected by inflammation or concurrent malaria infection, and may be the preferred biomarker for estimating iron deficiency prevalence in areas with high infection pressure.

### EVALUATION OF PERFORMANCE OF DEKI READER OF MALARIA RAPID DIAGNOSTIC TEST IN RURAL MILITARY HEALTH FACILITIES IN TANZANIA

**Akili Kalinga**<sup>1</sup>, Reginald Kavishe<sup>2</sup>, Sarah Chiduo<sup>3</sup>, Lucky Temu<sup>3</sup>, Lalaine Anova<sup>4</sup>, Charles Mwanziva<sup>5</sup>, Chris Mswanya<sup>6</sup>, Deus Ishengoma<sup>1</sup>, Lucas Mahikwano<sup>3</sup>, Saidi Mgata<sup>3</sup>, George Amoo<sup>3</sup>, Nora Zwingerman<sup>7</sup>, Santiago Ferro<sup>7</sup>, Geeta Bhat<sup>7</sup>, Ian Fine<sup>7</sup>, Brian Vesely<sup>4</sup>, Eyako Wurapa<sup>4</sup>, Colin Ohrt<sup>4</sup>, Mark Hickman<sup>4</sup>, Robert Paris<sup>4</sup>

<sup>1</sup>NIMR, Tanga, United Republic of Tanzania, <sup>2</sup>KCMUC, Moshu, United Republic of Tanzania, <sup>3</sup>Walter Reed Project, Dar es Salaam, United Republic

of Tanzania, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>Tanzania Peoples Defence Force, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>TPDF, Dar es Salaam, United Republic of Tanzania, <sup>7</sup>FIO, Toronto, ON, Canada

Malaria Rapid diagnostic Tests (mRDTs) are currently advocated and used as adjunct to microscopy in malaria diagnosis. However, at very low parasitaemia (<100p/μl) the test line on mRDT is expected to be weak and consequently affecting visual interpretation of mRDT test results. Fio Corporation's Deki Reader (DR) performs automated interpretation of RDTs, including multiple brands of mRDTs. The accuracy of the DR was compared to visual interpretation by 2 expert laboratory Technicians who were blinded of DR results in two Military facilities in Tanzania. Finger prick blood samples were collected from 1,293 consecutive outpatients with fever and tested for malaria using SD Bioline mRDT and microscopy, which was the gold standard. The parasitemia geometric mean was 3,398 per microliter. The sensitivity of mRDTs interpreted by DR was 94.1% while the sensitivity of manually interpreted mRDTs was 93.5%. The specificity of mRDTs interpreted by DR was 71.8% and that of human was 72.0%. Positive Predictive Value (PPV) of mRDTs by DR and Human was 75.8% and 75.4% respectively. The Negative Predictive Value (NPV) of mRDT by DR was 92.8% and by human was 92.4%. There was no significance difference in sensitivity, specificity, PPV, NPV and accuracy of mRDT interpreted by DR compared to expert human interpretation. The performance of DR in interpreting mRDTs was found to be similar to interpretation by expert laboratory technicians. The application of the DR in remote settings will ensure accurate mRDT diagnostic are available at point-of-care.

Jang<sup>1</sup>, Maria Kahn<sup>1</sup>, Becky Barney<sup>1</sup>, Michael Kalnoky<sup>1</sup>, Smita Das<sup>1</sup>, Roger Peck<sup>1</sup>, Abby Tyler<sup>2</sup>, Chris Lyman<sup>2</sup>, John Rek<sup>3</sup>, Maxwell Murphy<sup>4</sup>, Mallika Imwong<sup>5</sup>, Clare Ling<sup>6</sup>, Stephan Proux<sup>6</sup>, Annette M. Seilie<sup>7</sup>, Sean C. Murphy<sup>8</sup>, Bryan Greenhouse<sup>4</sup>, Francois Nosten<sup>6</sup>, Gonzalo Domingo<sup>1</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>Quansys Biosciences, Logan, UT, United States, <sup>3</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>4</sup>University of California, San Francisco, CA, United States, <sup>5</sup>Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, <sup>6</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, <sup>7</sup>Department of Laboratory Medicine, University of Washington, Seattle, WA, United States, <sup>8</sup>Department of Microbiology, University of Washington, Seattle, WA, United States

Malaria is a vector-borne disease caused by *Plasmodium* parasites that threatens many lives in endemic countries. While there has been an outstanding gain from clinical case management coupled with vector control programs, which has resulted in a significant reduction for malaria burden, low-density and asymptomatic malaria infections represent a serious challenge in malaria elimination. Sensitive detection tests are needed for identifying submicroscopic malaria infection and tracking changes in malaria transmission intensity. Relating parasitemia to antigens commonly used in rapid diagnostic tests for malaria will greatly assist the development of more sensitive tests that capture submicroscopic malaria infections. We developed a multiplex assay to simultaneously detect and quantify antigens from two parasite species, *P. vivax*-specific lactate dehydrogenase (LDH), all *Plasmodium* spp. LDH, and *P. falciparum*-specific histidine-rich protein 2 (HRP2) and the biomarker C-reactive protein (CRP) from human blood specimens. The study on interference between *P. falciparum* and *P. vivax* demonstrated that the detection for each target was not influenced by other *Plasmodium* antigens, indicating the strong robustness of this multiplex assay. Further testing of clinical samples

containing either *P. vivax* or *P. falciparum* showed that differentiating between parasites was concordant with expected results on the basis of the gold standard qRT-PCR method while detecting *Plasmodium* antigen at sub-ng/mL levels. This multiplex platform offers a robust, sensitive, and specific detection tool, through which it is possible to describe the dynamics of infection with *P. vivax* and *P. falciparum* in terms of antigenemia in near-elimination settings where two parasite infections coexist.

## 1586

### COMPARISON OF COMMERCIALY AVAILABLE MOBILE MEDICAL APPLICATIONS (MMAS) FOR INTERPRETING MALARIA RAPID DIAGNOSTIC TEST (RDT) RESULTS

Sumedh Ramachandra<sup>1</sup>, Theodoor Visser<sup>1</sup>, Emilie Pothin<sup>2</sup>, Jan Jacobs<sup>3</sup>, Jane Cunningham<sup>4</sup>, Arnaud Le Menach<sup>1</sup>, Michelle Gatton<sup>5</sup>, Samaly dos Santos Souza<sup>6</sup>, Michael Aidoo<sup>6</sup>

<sup>1</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>3</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>4</sup>World Health Organization, Geneva, Switzerland, <sup>5</sup>Queensland University of Technology, Brisbane, Australia, <sup>6</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

The World Health Organization (WHO) recommends diagnosis by microscopy or malaria rapid diagnostic test (RDT) in all patients with suspected malaria before treatment is administered. Recently, mobile medical applications or MMAs (popularly known as "readers") which have the capability to interpret RDT test results have entered the market. However, limited evidence is available on MMA accuracy. To evaluate MMA accuracy, a laboratory evaluation was conducted by comparing RDT result interpretation by MMAs to those read and interpreted by trained end-users. Five different MMAs were evaluated on six different RDT products from three leading manufacturers using cultured *Plasmodium falciparum* (Pf) samples at dilutions ranging from 20-1000 parasites(p)/μL and negative blood samples. The RDTs were performed in a laboratory by a trained operator who interpreted the RDT results with the human eye. A second operator blinded to the human eye result then used the MMAs to interpret the RDT results, within the RDT manufacturer specified reading time. Sensitivity (Se) and specificity (Sp) were calculated using mixed models. Overall, the human eye had a higher Se than MMAs (89% vs 42-77%). For the Pf test line of Pf-only and combination Pf/Pan-pLDH RDTs, the trained human eye had a significantly higher Se than MMAs (74% vs 47%) at 20 p/μL. However, at 200, 500 and 1000 p/μL, three MMAs had a Se that was comparable to the human eye (97%). For RDTs that detect the *Plasmodium* spp. (Pan-pLDH-only and combination Pf/pan-pLDH RDTs), the human eye had a higher Se than MMAs (79% vs 56%). Sp of the human eye and MMAs was around 99%. Analyses on correlation between RDT band intensity at various sample concentrations and MMA Se will be performed and available for presentation. Overall, the study found that the trained human eye can more accurately interpret RDT results compared to commercially available MMAs. However, MMAs perform as well as the human eye at higher sample concentrations. There is a need for further research to understand the field applicability of MMAs.

## 1587

### CAUSAL CHEMOPROPHYLACTIC ACTIVITY OF PRIMAQUINE - QUINOXALINE HYBRIDS

Alexandra M. Rios Orrego<sup>1</sup>, Ignacio Aldana<sup>2</sup>, Luis Corcuera<sup>2</sup>, Silvia Galiano<sup>3</sup>, Miguel Quiliano<sup>3</sup>, Adriana Pabón Vidal<sup>1</sup>

<sup>1</sup>Universidad de Antioquia, Medellín, Colombia, <sup>2</sup>Department of Organic and Pharmaceutical Chemistry, University of Navarra, Navarra, Spain, <sup>3</sup>Department of Organic and Pharmaceutical Chemistry, University of Navarra, Institute of Tropical Health, University of Navarra, Navarra, Spain

There is an urgent need of new chemotherapeutic agents for malaria treatment due to parasite resistance. The development of new drugs to prevent infection and/or development of liver forms of *Plasmodium*

*spp.* is a research priority. The aim of this study is to evaluate the *in vivo* causal chemoprophylactic effect of primaquine - quinoxaline hybrids in the *Plasmodium yoelii* mouse model. Five primaquine-quinoxaline hybrids were synthesized: QX6, QX7, QX8, QX9 and QX10, their structure was identified and confirmed by spectroscopic methods. The hybrids were administered on days -1, 0, +1 and +2 to Balb/c mice and those were challenged on day 0 with intravenous injection of 5,000 sporozoites of non-lethal strain *P. yoelii* 17XNL to test for causal chemoprophylactic activity. Mice weighing 20±2 g were randomly allotted to five groups and were treated orally with 100 mg/kg of hybrids, diluted in dimethylsulfoxide (DMSO). Tail-blood samples were collected from day 4 to 14 post-inoculation and parasites were quantified using microscopic examination of Giemsa-stained smears and flow cytometry. The group of mice treated with QX6 showed a significant reduction in *Plasmodium yoelii* hepatic forms (inhibition percentage on day 4 of 95.97% with respect to the untreated group) and the parasitemia pre patent period was extended by 24 hours over controls. QX6 was less toxic than the licensed drug primaquine at a dose of 500 mg/ml (acute oral toxicity test), however it was also less active than primaquine (100% inhibition). Different therapeutic schemes and pharmacokinetic parameters should be evaluated in order to continue studies with this primaquine - quinoxaline hybrid. QX6 represents a promising source of new anti-malarial agents.

## 1588

### ACTIVITY OF THE HISTONE DEACETYLASE (HDAC) INHIBITOR AR-42 IN A MURINE MALARIA MODEL

Ming Jang Chua<sup>1</sup>, Darren Do<sup>2</sup>, Prabhakar Bachu<sup>2</sup>, Robert Reid<sup>2</sup>, David Fairlie<sup>2</sup>, Tina Skinner-Adams<sup>1</sup>, **Kathy Andrews<sup>1</sup>**

<sup>1</sup>Griffith University, Nathan, Australia, <sup>2</sup>University of Queensland, St. Lucia, Australia

Histone deacetylase (HDAC) enzymes are involved in the reversible acetylation of histone and non-histone proteins, regulating chromatin structure, gene expression and other important cellular processes. HDACs are validated drug targets for some types of cancer, with some HDAC inhibitors now clinically approved. HDAC inhibitors are also of interest as chemical probes and drug leads for other diseases, including infectious diseases such as malaria. In previous work we have shown that clinical anti-cancer HDAC inhibitors have potent *in vitro* activities against *Plasmodium falciparum* parasites (IC<sub>50</sub> 10-200nM) and cause hyperacetylation of parasite histone proteins. However, these compounds generally have low selectivity for malaria parasites versus human cells and poor *in vivo* efficacy in murine malaria models. Here we show that the next generation hydroxamic acid based HDAC inhibitor AR-42 has low nM *in vitro* activity against *P. falciparum* and greater than 50-fold selectivity for human cells versus *P. falciparum*. *Ex vivo* activity of AR-42 against *P. berghei* and *P. chabaudi* infected mouse erythrocytes was confirmed and *in vivo* efficacy evaluated in a murine model of *P. berghei* infection. Twice-daily oral administration of 25 mg/kg AR-42 attenuated parasitemia in *P. berghei*-infected BALB/c mice, curing 10 of 12 mice. Further studies are currently underway to investigate the potential of analogues of this compound as drug leads for malaria.

## 1589

### GAMETOCYCIDAL AND CURATIVE LIVER AND BLOOD STAGE ANTIMALARIAL ACTIVITY OF CETHROMYCIN

**David J. Sullivan<sup>1</sup>**, Grace Kennedy<sup>1</sup>, Leah Walker<sup>1</sup>, Rachel Evans<sup>1</sup>, Kristin Poti<sup>1</sup>, Nikola Kaludov<sup>2</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Aliquantum Rx, Baltimore, MD, United States

Prophylaxis of malaria in travelers to malaria endemic countries is limited to atovaquone/proguanil, doxycycline, mefloquine and rarely primaquine. We investigated the liver stage activity of cethromycin in the *P. berghei* liver stage model initiated by mosquito bites. Cethromycin was identified by a quantum-based computational approach sifting

through millions of molecules for liver stage malaria activity. Cethromycin is a molecular hybrid of a nonsubstituted quinoline nucleus joined at position 3 to an erythromycin scaffold. Here we demonstrate complete cure of *Plasmodium berghei* infection by single oral dose of 60 mg/kg in mice which is equivalent to the 5 mg/kg human dose of 300 mg a day used in bacterial pneumonia studies. Both quinoline and erythromycin alone at 120 mg/kg for two doses as well as control mice resulted in patent blood stage parasitemia in all mice. Cethromycin at 30 mg/kg was also curative as well as single oral 60 mg/kg given before mosquito infection. Immunofluorescence imaging of cethromycin treated, *in vitro* hepatocyte infected cells shows complete ablation of the apicoplast. Regarding blood stage activity, cethromycin at 60 mg/kg daily for 7 days cured in a high parasitemic *P. berghei* mouse model. While mosquito membrane feeding of *P. falciparum* gametocytes incubated with 20 microM cethromycin demonstrated no decrease in oocyst numbers, oral dosing in mice showed significant decrease in both prevalence and mean number of oocysts suggesting an active metabolite similar to primaquine. Liver pharmacokinetic studies in mice are ongoing. Cethromycin has been evaluated for efficacy against bacterial pneumonia in more than 5,000 patients with good safety profiles. Cethromycin has potential for rapid clinical development for casual malaria prophylaxis and possibly radical cure of dormant liver *P. vivax* or *P. ovale*.

## 1590

### DRUG INTERACTIVITY STUDIES TO DEFINE SYNERGISTIC ANTI-MALARIAL COMBINATORIAL REGIMES FOR EMETINE DIHYDROCHLORIDE

**Muna S. Abubaker**

University of Salford, Salford, United Kingdom

The emergence and spread of artemisinin resistance to *Plasmodium falciparum* in Southeast Asia poses a serious threat to ongoing malaria control efforts. Unless new approaches are deployed rapidly, the health and economic burden related to the disease in tropical countries is certain to worsen. The development of treatments through drug repositioning may offer novel candidates permitting new combinatorial regimes with existing anti-malarials. The approach could present a much needed viable, accelerated route to expand the dwindling antimalarial therapeutic repertoire. Drug repositioning screens previously carried out in our laboratory reported the potent antimalarial efficacy (IC<sub>50</sub> 47nM for *P. falciparum* K1 strain) of the anti-amoebic drug Emetine dihydrochloride hydrate. We present here the preliminary data from a study designed to define the combinatorial therapeutic potential of emetine with a panel of antimalarial drugs, in a bid to minimise non-target effects previously experienced with the use of the drug in amoebiasis. The rational discovery of novel synergistic drug combinations can be accelerated by predictions of combination effects through experimental studies. All combinations were analysed using the optimised CalcuSyn fixed-ratio method validated using the atovaquone-proguanil combination. Following a screen of current antimalarial compounds, our preliminary data identified AN16 as the combinatorial partner drug displaying maximum synergistic interactivity with emetine dihydrochloride. The isobologram plot and the combination index (CI) generated by the CalcuSyn software demonstrated that the interaction between emetine and AN16 is synergistic at IC<sub>50</sub>, 1C75 and IC90 levels. The MTT cytotoxicity results indicated that the emetine-AN16 combination has a better selectivity index in comparison to emetine alone. The results support further *in vivo* investigation of the utility of emetine-AN16 combination as an alternative antimalarial treatment for drug resistance malaria.

## TAFENOQUINE IS NOT NEUROTOXIC FOLLOWING SUPERTHERAPEUTIC DOSING IN RATS

Geoffrey S. Dow<sup>1</sup>, Tracey Brown<sup>2</sup>, Mark Reid<sup>3</sup>, Bryan Smith<sup>1</sup>, Stephen Toovey<sup>3</sup>

<sup>1</sup>60 Degrees Pharmaceuticals LLC, Washington, DC, United States, <sup>2</sup>Clinical Network Services, Brisbane, Australia, <sup>3</sup>Pegasus Research, Bottmingen, Switzerland

Tafenoquine is an 8-aminoquinoline antimalarial being developed for treatment of *Plasmodium vivax* relapse and malaria prophylaxis. The clinical, behavioral, and neurohistopathologic changes induced by different dose levels of tafenoquine were evaluated following single super-therapeutic dose administration in adult rats (doses used were 125, 250 and 500 mg/kg). Toxicokinetic data were generated to allow extrapolation to clinical exposures. At the highest dose, two animals were found dead and animals showed clinical signs of toxicity and reduced body weight 7 to 8 days after dosing. Significant decreases in motor activity were observed on more than one occasion at doses more than 9-fold higher than the clinical exposure. No other statistically significant changes in other functional or neurobehavioral endpoints were noted at any dose. No neurohistopathological changes were noted at any dose. Changes in hematological and clinical pathology endpoints were observed at the lowest dose level tested in a dose range study. Our data show that the principal target organs for tafenoquine-related adverse events in rats are the liver and blood, with sparing of the central nervous system and absence of demonstrable neurotoxicity at exposures achievable in humans.

## PYRAZINE, A NOVEL CLASS OF ORALLY ACTIVE ANTIMALARIAL. MAKING PROGRESS TOWARDS HIGH QUALITY MOLECULES

Maria Isabel Castellote Alvaro

Tres Cantos Medicines Development Campus. Diseases of the Development World. GlaxoSmithKline, Tres Cantos, Spain

Malaria remains one of the most devastating diseases of the developing world, killing 500K people annually. Although several therapies are available for preventing and treating malaria, most antimalarials drugs face decreased efficacy due to the emergence of resistant parasites. Consequently, there is an urgent need to replace those drugs by novel therapies that offer significant advantages over the current standard of care. Over the last years, the malaria community has been successful in identifying a range of novel drugs. As part of this global effort, GSK published TCAMS2 (Tres Cantos Anti-Malarial Set) which comprised 13,533 hits derived from phenotypic screening of 2 million compounds in the corporate collection. Different tools have been used to prioritize this set of compounds in terms of having the best chance of being converted into differentiated antimalarial drugs. As result of this work, a novel chemical series was identified containing a pyrazine scaffold. This series combines a good oral efficacy characterized by a rapid parasite clearance in the *Plasmodium falciparum* mouse model with a low propensity to select resistance. The overall properties of the series constituted a promising profile justifying further development. This communication will describe the progression on this new chemical class from the initial hit to the clinical candidate with emphasis on the different strategies used to address key issues encountered in the lead optimization program. These efforts have culminated in the discovery of a compound combining an excellent *in vivo* potency with a very good developability profile.

## PRIMAQUINE - 1,4-DI-N-OXIDE QUINOXALINE HYBRIDS: POTENTIAL TISSUE SCHIZONTOCIDE ACTIVITY IN MALARIA

Leonardo Bonilla Ramirez<sup>1</sup>, Gustavo Ramirez<sup>2</sup>, Jean François Franetich<sup>3</sup>, Mallaury Bordessoulles<sup>3</sup>, Maurel Tefit<sup>3</sup>, Miguel Quiliano<sup>4</sup>, Luis Corcuera<sup>5</sup>, Ignacio Aldana<sup>4</sup>, Dominique Mazier<sup>3</sup>, Silvia Galiano<sup>4</sup>, Adriana Pabon<sup>2</sup>

<sup>1</sup>Malaria Research Group, Faculty of Medicine, University of Antioquia (UdeA), Sede de Investigación Universitaria (SIU), Medellín, Colombia; <sup>2</sup>Biomedical Sciences Academic Corporation, University of Antioquia, Medellín, Colombia, <sup>3</sup>Malaria Research Group, Faculty of Medicine, University of Antioquia (UdeA), Sede de Investigación Universitaria (SIU), Medellín, Colombia, <sup>4</sup>Sorbonne Universités, UPMC Univ Paris 06, INSERM U1135, CNRS ERL 8255, Centre d'Immunologie et des Maladies Infectieuses (CIMI-Paris), Paris, France, <sup>5</sup>Universidad de Navarra, Institute of Tropical Health (ISTUN), Campus Universitario, Pamplona, Spain; <sup>6</sup>Universidad de Navarra, Facultad de Farmacia y Nutrición, Department of Organic and Pharmaceutical Chemistry, Campus Universitario, Pamplona, Spain, <sup>7</sup>Universidad de Navarra, Facultad de Farmacia y Nutrición, Department of Organic and Pharmaceutical Chemistry, Campus Universitario, Pamplona, Spain

Malaria is one of the world's most important tropical parasitic diseases. Exoerythrocytic stage has been poorly characterized. In the context of malaria elimination, this parasite stage has been postulated as a therapeutic target. Currently, primaquine is the approved treatment for this stage. However, loss of susceptibility to primaquine in around 18% treatments has been reported. For this reason, it is necessary to search for compounds with tissue schizontocide activity. Synthesis of five new primaquine and 1,4-di-N-oxide quinoxaline hybrid compounds (PQ-QdNO) was done. To evaluate the *in vitro* activity, infection of cell lines (HepG2, HepG2-CD81) and primary culture of human's hepatocytes with *P. berghei*, *P. yoelii* and *P. falciparum* sporozoites, respectively, was assayed by immunofluorescence against *Plasmodium* Hsp70 after 2 or 7 days of treatment with PQ-QdNO. Cytotoxicity analyses of hybrids at cell lines and human's hepatocytes was measured by MTT assay. Generation of oxidative stress at Hepa 1-6 cell line was evaluated by flow cytometry using 2',7'-dichlorodihydrofluorescein diacetate. PQ-QdNO compounds showed a median toxic concentration (TC50) >109µM. Compound PQ-QdNO **7** (*P. yoelii* IC50=5.71µM, *P. berghei* IC50= 1.14µM and *P. falciparum* IC50= 4.34µM) was identified as the most active and selective (*P. yoelii* IS= 34, *P. berghei* IS= 136 and *P. falciparum* IS= 45) hybrid compound against hepatic stage of *Plasmodium*. PQ was used as a control (*P. yoelii* IC50=2.13µM, IS=32.7; *P. berghei* IC50= 3.65µM, IS=32.8 and *P. falciparum* IC50= 0,53µM, IS=101.8). Add, PQ-QdNO **7** at IC10 induced oxidative stress levels three folds higher than PQ after 24h post exposition. These preliminary data suggest that PQ-QdNO hybrid compounds can remain as a valid approach to develop new compounds with activity on *Plasmodium* liver stage.

## RESISTANCE SELECTION APPROACH TO IDENTIFY AND VALIDATE TARGETS FOR ANTIMALARIAL DRUG DISCOVERY

Pamela Magistrado<sup>1</sup>, Tomoyo Sakata-Kato<sup>1</sup>, Annie Cowell<sup>2</sup>, Rebecca Mandt<sup>1</sup>, Virginia Franco<sup>3</sup>, Purva Gupta<sup>2</sup>, Sabine Otilie<sup>2</sup>, Amanda K. Lukens<sup>4</sup>, Francisco Javier Gamo<sup>3</sup>, Elizabeth A. Winzeler<sup>5</sup>, Dyann F. Wirth<sup>1</sup>

<sup>1</sup>Harvard Chan School of Public Health, Boston, MA, United States, <sup>2</sup>University of California San Diego, San Diego, CA, United States, <sup>3</sup>GlaxoSmithKline, Tres Cantos, Spain, <sup>4</sup>The Broad Institute, Cambridge, MA, United States, <sup>5</sup>University of California San Diego, San Diego, CA, United States

The emergence and spread of drug resistance to current antimalarial therapies remains a pressing concern, escalating the need for compounds that demonstrate novel modes of action and prevent the development

of drug-resistance. As part of the Malaria Drug Accelerator (MalDA) consortium efforts, we have adopted a chemogenomic approach to identify the targets of the most prominent compounds from chemically diverse libraries. Study compounds were selected based on availability, purity, potency in a multi-drug resistant isolate, and lack of known mechanism of action towards the mitochondrion or folate biosynthesis. To further eliminate overlap with known targets, we performed cross-resistance testing against a panel of drug resistant parasite lines with well-characterized mutations in diverse targets. Here we present studies of two molecules: MMV019721 and MMV084864. *In vitro* resistant lines were generated by single-step selection (MMV019721) and step-wise methodologies (MMV084864) and whole genome sequencing employed to identify genetic variants contributing to the resistance phenotype. In the case of MMV019721 selected lines, variants were identified in a putative acetyl-coA synthetase, representing a potentially novel drug target in the parasite. Studies to validate this target are underway. Selections with MMV084864 resulted in high levels of drug tolerance and a dramatically altered dose-response profile. Whole genome sequencing identified large regions of chromosomal amplifications which also were observed in selections with compounds of diverse chemotypes. These data suggest that these mutations are likely broader resistance mechanisms rather than the drug target. While these results demonstrate that multiple chemical classes are rendered less active by common resistance mechanisms, they also suggest that there are a limited number of pathways in the parasite that contribute to drug-resistance. Drug-development strategies that counteract these common escape mechanisms may therefore become invaluable in extending the usable lifetime of future therapies.

### CHROMOBACTERIUM CSP\_P MEDIATES ITS ANTIMALARIAL ACTIVITY THROUGH SECRETION OF THE HDAC INHIBITOR ROMIDEPSIN

Raul G. Saraiva<sup>1</sup>, Callie Huitt-Roehl<sup>2</sup>, Abhai Tripathi<sup>1</sup>, Jürgen Bosch<sup>1</sup>, Craig Townsend<sup>2</sup>, George Dimopoulos<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States

The limited diversity within the chemical scaffolds of the current clinically available antimalarial drugs, together with the increase of incidence of drug resistance, make it urgent to identify new compounds with novel modes of action that can treat the disease. We have previously shown that a *Chromobacterium* isolate, *Csp\_P*, exerts entomopathogenic activity against both adult and larval stages of malaria and dengue vector mosquitoes, along with *in vivo* and *in vitro* anti-*Plasmodium* and anti-dengue activities. To assess the nature of the *Csp\_P*-produced anti-*Plasmodium* factors, chemical partition was conducted recurring to bioassay-guided fractionation, where different fractions were assayed for activity against asexual stages of *Plasmodium*. It was determined that antimalarial activity was preserved following initial liquid-liquid extraction with *n*-butanol. The isolated compounds were further partitioned by reversed-phase HPLC followed by size-exclusion HPLC. Higher resolution UPLC and ES/MS data were then collected and revealed that the most active fraction contained a depsipeptide (a cyclic peptide ester) notable for an unusual intramolecular disulfide bond, romidepsin. A pure sample of this FDA-approved HDAC inhibitor allowed us to independently verify this finding. Genomic comparisons between *Csp\_P* and multiple species within the *Chromobacterium* genus further indicate a correlation between presence of the gene cluster responsible for romidepsin production and effective antimalarial activity. Taken together, our data indicate that romidepsin mediates the antimalarial activity of *Csp\_P* and further work is underway to evaluate the potential of its development as an antimalarial, both against mosquito and human stages of the disease. Even though there are described side effects for a romidepsin regimen in humans, this molecule shows great promise as a lead compound given the structural novelty and the unique mode of action when compared to the currently used antimalarials.

### DEVELOPING LONG-TERM MALARIAL CHEMOPROPHYLACTIC COMPOUND RELEASING IMPLANTS

Jangwoo Lee<sup>1</sup>, Lisa Xie<sup>1</sup>, Diana Caridha<sup>1</sup>, Qiang Zeng<sup>1</sup>, Norma Roncal<sup>1</sup>, Jing Zhang<sup>1</sup>, Ping Zhang<sup>1</sup>, Hsiuling Lin<sup>1</sup>, Amanda Schenk<sup>1</sup>, Chau Vuong<sup>1</sup>, Brittney Potter<sup>1</sup>, Jason Sousa<sup>1</sup>, Joe McDonough<sup>2</sup>, Qigui Li<sup>1</sup>, Chad Black<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>Southwest Research Institute, San Antonio, TX, United States

Despite the successful development of chemoprophylactic compounds and multi-drug combination therapies, malaria infection remains a crucial health threat to U.S. Soldiers in malaria endemic areas. The successful prevention of malaria infection is highly dependent on compliance with a prescribed chemoprophylaxis regimen. The Experimental Therapeutics (ET) Branch at Walter Reed Army Institute of Research (WRAIR) is the U.S. Army's premier research program for the development of anti-malarial prophylaxis drugs. A current effort of ET, in scientific collaboration with the Southwest Research Institute and Titan Pharmaceuticals, is to develop long-term release implantable anti-malarial drug matrices. These implants provide continuous drug release with a non-fluctuating drug levels over an extended period from two to six months, and could potentially relieve deployed service members from adherence to a daily oral drug dosing schedule. EVA (ethylene-vinyl acetate) implants that contain piperazine, an compound effective against blood stage parasites, was tested in a mouse model with *Plasmodium berghei* to characterize the pharmacokinetics (PK) profile and long-term prophylactic efficacy *in vivo*. The piperazine formulated implant study showed the PK profile exhibited slow drug release for six weeks while maintaining stable plasma levels. Furthermore, the piperazine implants after longer than eight weeks of implantation demonstrated sufficient suppression in early blood stage malaria and complete protection malaria in mice. The development of long-acting prophylactic implants with greater potency and safety is a novel approach, and one that could greatly improve compliance of deployed Soldiers in malaria endemic regions. These preliminary findings with piperazine allow us to pursue a series of long-acting implants that include more regulatorily attractive FDA-approved anti-malarial drugs, atovaquone/proguanil (Malarone®) and doxycycline, for follow-on *in vivo* preclinical studies.

### PROVEBLUE, METHYLENE BLUE, AS AN ANTIMALARIAL DRUG

Bruno Pradines, Mathieu Gendrot, Rémy Amalvict, Joel Mosnier, Nicolas Benoit, Marylin Madamet

Institut de Médecine Tropicale du Service de Santé des Armées, Marseille, France

In 2011, the World Health Organization recommended artesunate as the first-line treatment for severe malaria. In recent years, several studies have reported clinical failures or at least extended parasite clearance times in Asia. There is an urgent need to discover partners for combination with artemisinin derivatives. Proveblue (PVB) (international patent no. PCT/FR/2007/001193), which is a methylene blue preparation that complies with the European Pharmacopoeia and contains limited organic impurities and heavy metals of recognized toxicity, was demonstrated to possess *in vitro* antimalarial activity against *Plasmodium falciparum* strains that were resistant to various other antimalarials and against African isolates. PVB exhibited noticeable *in vitro* high synergistic effects associated with dihydroartemisinin, the active metabolite of artemisinin derivatives. Treatment with 1 to 10 mg/kg of weight of PVB for five days significantly reduced or prevented cerebral malaria in mice. Additionally, the PVB *in vitro* activity was not associated with validated gene polymorphisms involved in antimalarial resistance like *pfcr*, *pfmdr1*, *pfdhfr*, *pf dhps*, *K13*, *plasmepsin 2* or potential genes coding proteins like PfMDR6, PfMDR2,

PfNHE-1, E3 ubiquitin protein ligase or exonuclease. These results confirm the therapeutic potential of Proveblue, which could be integrated into the pipeline of new antimalarial combination therapies.

### NOVEL LIVER STAGE ACTIVE ANTIMALARIALS

**Jane X. Kelly**<sup>1</sup>, Rosie Dodean<sup>1</sup>, Yuexin Li<sup>1</sup>, Christina Nolan<sup>2</sup>, Qigui Li<sup>2</sup>, Richard Sciotti<sup>2</sup>, Raul Olmeda<sup>2</sup>, Thulan Long<sup>2</sup>, Brittney Potter<sup>2</sup>, Jason Sousa<sup>2</sup>, Sean Marcisin<sup>2</sup>, Diana Caridha<sup>2</sup>, Lisa Xie<sup>2</sup>, Chau Vuong<sup>2</sup>, Qiang Zeng<sup>2</sup>, Jing Zhang<sup>2</sup>, Ping Zhang<sup>2</sup>, Kirk Buller<sup>2</sup>, Norma Ronca<sup>2</sup>, Charles Bane<sup>2</sup>, Chad Black<sup>2</sup>, Isaac Forquer<sup>1</sup>, Stephanie Huezos<sup>3</sup>, Stephanie Rasmussen<sup>3</sup>, Roland Cooper<sup>3</sup>, Mike Riscoe<sup>1</sup>, Mara Kreishman-Deitrick<sup>2</sup>

<sup>1</sup>Portland Veterans Affairs Medical Center, Portland, OR, United States,

<sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States,

<sup>3</sup>Dominican University of California, San Rafael, CA, United States

We have previously reported the discovery of a novel antimalarial acridone chemotype that displays efficacy against sporozoite-induced *Plasmodium* infection in addition to efficacy against blood stage parasites. We have been successful in producing extremely potent new lead candidates with pico molar IC50 values against MDR resistant parasites, as well as full protection of liver stage infection at comparable dosage with primaquine. Details of the design, chemistry, structure-activity relationships (SAR), safety, metabolic studies, and mechanism of action will be presented.

## 1599

### NATURAL PRODUCT INSPIRED NOVEL ANTIMALARIALS

**Papireddy Kancharla**<sup>1</sup>, Yuexin Li<sup>2</sup>, Roland Cooper<sup>3</sup>, Jane Kelly<sup>2</sup>, Kevin Reynolds<sup>1</sup>

<sup>1</sup>Portland State University, Portland, OR, United States, <sup>2</sup>Portland Veterans Affairs Medical Center, Portland, OR, United States, <sup>3</sup>Dominican University of California, San Rafael, CA, United States

Natural products have been at the forefront of most approaches to combat many infectious diseases, particularly malaria. Continued discovery of new natural products, their chemical modifications, and synthesis of drugs inspired by natural product have helped to combat the inevitable development of resistance against existing antiparasitic agents. Prodiginines (PGs) and tambjamines (TAs) belong to a family of intriguing pyrrolopyrromethene (PPM) natural products, isolated from bacterial and marine sources. These PPM natural products have a unique structural composition with a wide range of biological properties, including antimalarial activity. Recently, we have developed a series of chemical entities inspired by the PGs and TAs and discovered structures with curative efficacy against *Plasmodium* infection. The mechanisms of action are unknown for these PPM products and the unique structure suggests potential to discover a new drug target to combat malaria parasites. Our data to date on the antimalarial activity of the tambjamines is very exciting and indicate a new structural class of antimalarials that meets the following key criteria: 1) orally efficacious, 2) curative in a single dose, 3) long duration of cover, 4) multistage efficacy with potent activities against liver stage and blood stage parasites, as well as inhibition of gamete formation, 5) fast-acting drug candidate, 6) synthetically accessible with a low-cost of production, 7) active against MDR *Plasmodium falciparum* strains, 8) high potency against clinical isolates, 9) non-genotoxic, 10) unique chemotype as compared to existing antimalarials, and 11) possibly operate by a novel mechanism(s) of action. Continued studies of the lead optimization, multiple stage screening, pharmacology, safety and mode(s) of action studies of the lead tambjamines will permit us to expand a range of novel tambjamines for full preclinical antimalarial studies. The ultimate objective our future work is to develop a novel antimalarial drug to be used in a combination therapy to prevent and treat malaria thus contribute an important tool to help eradicate the disease on a worldwide scale.

## 1600

### OPTIMIZING THE IN VIVO PHARMACODYNAMICS OF THE PLASMODIUM FALCIPARUM APICOPLAST INHIBITORS FOSMIDOMYCIN AND CLINDAMYCIN

**Leah A. Walker**, Vision Bagonza, David J. Sullivan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Reports from Southeast Asia continue to document the decreasing efficacy of artemisinin-based combination therapies, thereby emphasizing the need for novel antimalarials. The antibiotics fosmidomycin and clindamycin are apicoplast inhibitors with relatively short half-lives of approximately 1-2 hours. In clinical trials, this combination has resulted in suboptimal 28-day cure rates. For bacterial infections, fosmidomycin and clindamycin are dosed 4x daily; however, as antimalarials, they are often dosed 2x daily. We have hypothesized that increasing the frequency of daily dosing as well as extending the treatment duration beyond 3 days would improve suboptimal dosing regimens. We have adapted a murine model of malaria, which utilizes a luciferase-reporter *Plasmodium berghei* at high parasitemia, to study the parasite killing *in vivo*. Unlike other drug efficacy assays, which assess cytostatic activity, our assay more accurately mimics high parasitemia infections and cytotoxic drug activity in the field. This model has previously been used to demonstrate the importance of lengthening the artesunate dosing duration to span 3 life cycles in order to make existing artemisinin-based treatments more efficacious. In this study, we have shown the same total dose of fosmidomycin or clindamycin achieves enhanced parasite killing when administered every 6 hours versus when administered in a single dose. For combination therapy, we have shown that noncurative dosing regimens are improved to curative dosing regimens with a lower overall dose. This increased efficacy was achieved by increasing the dosing schedule to 4x daily (vs. 2x) and extending the treatment duration to 4 days (vs. 2 days). Additionally, to support our *in vivo* results, pulse drug studies in *P. falciparum* are currently underway.

## 1601

### IDENTIFYING HEXAHYDROQUINOLINES AS NEW ANTIMALARIALS WITH POTENT BLOOD STAGE AND TRANSMISSION-BLOCKING ACTIVITY

<sup>1</sup>Columbia University, New York, NY, United States, <sup>2</sup>Griffith University, Nathan, Australia, <sup>3</sup>Sanaria, Rockville, MD, United States, <sup>4</sup>University of Cape Town, Cape Town, South Africa, <sup>5</sup>Imperial College, London, United Kingdom, <sup>6</sup>Istituto Superiore di Sanita, Rome, Italy, <sup>7</sup>Universidade de Lisboa, Lisbon, Portugal, <sup>8</sup>University of California San Diego, La Jolla, CA, United States

Novel antimalarial compounds with dual therapeutic and transmission-blocking activity are considered valuable partner drugs for combination therapies, especially in high-burden countries where malaria transmission is high. However, current drugs are either relatively ineffective against the transmissible form of the malaria parasite or risk inducing severe toxicity. Here, we report the identification and characterization of hexahydroquinolines (HHQs) that show low nanomolar potency against both the pathogenic and transmissible intra-erythrocytic forms of the malaria parasite *Plasmodium falciparum*. This activity translates into potent transmission-blocking potential, as shown by *in vitro* male gamete formation assays and reduced oocyst infection and prevalence in *Anopheles* mosquitoes. *In vivo* studies confirmed the potential of HHQs to block transmission of *P. berghei*. Resistance selections and CRISPR-Cas9

based gene editing have identified the ABC transporter PfMDR1 in the action and resistance mechanism of HHQs. Heme fractionation assays suggest a mode of action that inhibits endocytosis of hemoglobin without directly affecting heme metabolism in the digestive vacuole. Furthermore, parasites resistant to HHQs displayed increased susceptibility to several first-line antimalarial drugs, confirming that HHQs have a different mode of action than other antimalarials drugs for which PfMDR1 is known to confer resistance. This work hereby evokes therapeutic strategies that combine opposing selective pressures on this parasite transporter.

## 1602

### MIGRATION AS A DETERMINANT OF MALARIA IN SURINAME: CHALLENGES IN REACHING ELIMINATION

Hedley Cairo, Loretta Hardjopawiro, **Helene Hiwat**  
*Ministry of Health Malaria Program, Paramaribo, Suriname*

Migration is the most important determinant of malaria in Suriname. The populations most at risk are mobile migrant - small scale gold miners (MM). There is a continuous movement of MM within the Guyana Shield in search of gold. This study describes the role of imported malaria in Suriname (2006 - 2015), based on malaria surveillance data. Suriname is reaching elimination. Cases have decreased from 15,967 in 2001 to 373 in 2015 (indigenous and import). As indigenous cases decreased, the proportion of imported cases increased, from 6.8% in 2006 to 79.4% in 2015. The majority of imported malaria in Suriname is related to MM that work French Guiana (territory of France) and buy supplies in Suriname. Imported malaria from other countries is negligible. Between 2006 and 2015 the proportion of French Guianese cases ranged from 6.6% (272 cases) to 73.5% (274 cases) of the total number of cases. The top 3 *foci* producing cases in French Guiana, as observed in Surinamese import data, have been, Sophie, Eau Claire and Tadeu - mining sites -, accounting for 72.2% of the total imported cases from French Guiana. The *Plasmodium falciparum* to non- *P. falciparum* ratio for the French cases was 0.45 for 2015. The results show that Brazilian migrants moving between Suriname and French Guiana account for most cases diagnosed in Suriname, 94 %. Malaria is acquired mostly in the center of the interior of French Guiana and is not the result of border area transmission. While malaria has almost been eliminated from Suriname, there is a continuous risk of re-introduction of malaria as a consequence of cross-border movement and the resulting importation from French Guiana. To sustain the achieved success and to reach elimination in Suriname regional cooperation with the French health services is essential. In addition, it is of eminent importance that France adequately addresses the problem of malaria among the MM on its territory where they have no access to malaria services in small scale mining areas. The Suriname model to deal with malaria among MM - training peers (Malaria Service Deliverers) to provide supervised malaria diagnosis and treatment in remote areas - has been very successful.

## 1603

### FORMATIVE ASSESSMENT TO UNDERSTAND AND TARGET HIGH-RISK POPULATIONS FOR MALARIA INFECTION, CHAMPASAK PROVINCE, LAO PDR

**Emily Dantzer**<sup>1</sup>, Andrew A. Lover<sup>1</sup>, Bouasy Hongvanthong<sup>2</sup>, Keobuphaphone Chindavongsa<sup>2</sup>, Susie Welty<sup>1</sup>, Tania Reza<sup>1</sup>, Vatthana Nanthana<sup>1</sup>, Sophia Hocini<sup>1</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Center for Malariaology, Parasitology and Entomology; Ministry of Health, Vientiane, Lao People's Democratic Republic

In the Greater Mekong Subregion, mobile and migrant populations (MMs) are considered most at risk for malaria due to their occupational environments and limited access to health care. Despite a growing emphasis on targeting MMs, regional data on MMP subpopulations and their unique risk profiles is lacking. A formative assessment set out to identify MMs in Champasak Province, Southern Laos, and characterize

their occupations, seasonality of work, migratory patterns, health-seeking behaviors, and social networks. This study utilized focus group discussions, key informant interviews, retrospective data collection, mapping and observational activities. Sixteen focus groups and 28 in-depth interviews were carried out in four districts including a range of stakeholders: Lao and foreign MMs (forestry, agriculture, industrial projects); provincial, district, facility and community malaria staff; labor, agriculture, and forestry department officials, and owners of venues known to serve MMs (restaurants, karaoke bars). Discussion themes included MMP demographics, occupations, migration patterns, health-seeking practices, social networks, and acceptability of targeted malaria interventions. A recent government decree preventing the sale of timber has led to a large reduction in logging, with subsequent closure of sawmills across Champasak. Most MMs appear to be village-based Lao nationals engaged in seasonally shifting forest and agricultural work. Key livelihood activities include rice cultivation, forest-based hunting and gathering, work on plantations (coffee, rubber), and short-term employment at small-scale factories. MMs reported seeking care at public health facilities, and in general bednet usage appeared to be high. Key findings from this study suggest that Champasak MMs are generally village-based and fairly stationary, suggesting that these populations may be more accessible than previously believed. Any interventions targeting MMs should be tailored to respond to context-specific exposures, behaviors, and access points, which require better defining and understanding of local MMs.

## 1604

### DHIS2 TRACKER DASHBOARD AS A TOOL TO CATALYZE DATA USE IN THE MALARIA ELIMINATION SETTING OF ZIMBABWE

**Joseph Mberikunashe**<sup>1</sup>, Andrew Tangwena<sup>1</sup>, Rangarirai Matavire<sup>2</sup>, Munashe Madinga<sup>3</sup>, Brighton Gumbinga<sup>3</sup>, Deepa Pindolia<sup>4</sup>, Charlotte Dolenz<sup>5</sup>, Busisani Dube<sup>1</sup>

<sup>1</sup>National Malaria Control Programme, Harare, Zimbabwe, <sup>2</sup>IT Nordic, Harare, Zimbabwe, <sup>3</sup>Clinton Health Access Initiative, Harare, Zimbabwe, <sup>4</sup>Clinton Health Access Initiative, Nairobi, Kenya, <sup>5</sup>Clinton Health Access Initiative, Washington, DC, United States

With a goal to eliminate malaria from 9 out of the 20 elimination targeting districts by 2020, Zimbabwe has re-oriented its individual level malaria surveillance system through a phased approach since 2012; first with a transition from paper to electronic data collection using Personal Digital Assistant devices in 2014, then to using an android-based DHIS2 Tracker Capture platform in 2016. To allow for timely decision-making using the high resolution data collected, the National Malaria Control Programme set up a DHIS2-based dashboard to automatically compute key epidemiological indicators. District managers from all elimination districts met to select indicators and design preferred visualizations for the dashboard, based on the review of existing surveillance data and understanding of required decisions. User-specific indicators of interest and preferred visualizations of data, for example in the form of a map versus a chart, informed the design of the dashboard. At routine surveillance trainings in early 2017, selected users had the opportunity to interact with the dashboard. Feedback from the initial reviews of the DHIS2 platform will inform future improvements and related trainings on the dashboard which will continue to be deployed at routine district level meetings. Key lessons from the design process included iterative inclusion of user feedback into dashboard design and provision of additional frequent refresher trainings through opportunistic avenues. Quarterly post-training assessments for detailed dashboard evaluation, which will include follow-up key informant interviews and additional analysis of data inputs, will be carried out to assess the overall impact of dashboard in June 2017.

## THE PERFORMANCE OF G6PD RAPID DIAGNOSTIC TESTS IN CAMBODIA AND IMPLICATIONS FOR PRIMAQUINE THERAPY

Primaquine (PQ) is the only available drug that can provide radical cure of Vivax malaria and thus effectively eliminate the hidden reservoir of *Plasmodium vivax* and reduce the risk of relapse. The national malaria program in Cambodia has recommended that G6PD normal patients be treated with PQ since 2012. However, PQ deployment has been delayed due to unavailability of suitable point-of-care G6PD testing capabilities as well as concerns with potential hemolysis in deficient patients misclassified as G6PD normal. We have evaluated the performance of a fluorescent spot test (FST) and two rapid detection tests (RDTs), CareStart™ and Binax™, in 213 patients with uncomplicated *P. falciparum* or mixed malaria infection in order to assess their performance to detect G6PD enzymatic activities of <10%, <30%, and <60% of the population-adjusted male median, established by spectrophotometry quantitative test (Trinity Biotech, Ireland). The adjusted male median (100% of activity) was 8.28 U/gHb or 8.16 and 8.425, on DO and week 2 following treatment, respectively. At 30% G6PD activity, sensitivity for the FST, CareStart and Binax tests was 100% for male and female volunteers, with a deficient predictive value (DPV) of 96.88% (83.78-99.92%) and a normal predictive value (NPV) of 100 for all three tests performed at the time of acute malaria symptoms (n=29; 14.65% G6PD deficient). At 60% G6PD activity (n=38; 19% G6PD deficient), the sensitivity for FST, CareStart and Binax was 74% (95% CI: 58.83, 86.48), with a DPV of 100% and a NPV of 94.18% (89.83-97.06%). We have shown that G6PD RDTs consistently identified patients with <30% activity in a controlled setting, providing some reassurance that deployment of the RDTs should identify those most at risk for hemolytic effects of primaquine therapy. However, training of local staff in the use and interpretation as well as monitoring for misclassifications or hemolytic events despite testing will be required. Pharmacovigilance measures should be in place to detect future hemolytic risk attending PQ doses for radical cure from possible testing errors.

## IMPACT OF INDOOR RESIDUAL SPRAYING WITH PIRIMIPHOS-METHYL IN THE CONTEXT OF A COMPREHENSIVE MALARIA ELIMINATION STRATEGY IN SOUTHERN PROVINCE ZAMBIA

Adam Bennett<sup>1</sup>, Josh Yukich<sup>2</sup>, Molly Robertson<sup>3</sup>, Busiku Hamainza<sup>4</sup>, Logan Stuck<sup>2</sup>, Francois Rerolle<sup>1</sup>, Travis Porter<sup>2</sup>, Ruben O. Conner<sup>5</sup>, Richard W. Steketee<sup>5</sup>, John M. Miller<sup>6</sup>, **Thomas P. Eisele<sup>2</sup>**

<sup>1</sup>Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>3</sup>PATH, Washington, DC, United States, <sup>4</sup>Zambia National Malaria Elimination Centre, Lusaka, Zambia, <sup>5</sup>PATH-MACEPA, Seattle, WA, United States, <sup>6</sup>PATH-MACEPA, Lusaka, Zambia

Annual rounds of indoor residual spraying with organophosphate insecticide pirimiphos-methyl (IRS-PMCS) were implemented as part of a

comprehensive malaria elimination strategy in Southern Province Zambia from 2014-2016. The impact of mass drug administration (MDA) with dihydroartemisinin-piperazine was also tested as part of the strategy using a community randomized controlled trial in 60 health facility catchment areas during this time. The entire study area received standard of care of long-lasting insecticidal nets (LLINs), IRS-PM CS and improved access to case management over this period. Household LLIN coverage ranged from 73-82% from 2014-2016, but pyrethroid resistance has been documented. Household IRS-PMCS coverage increased from 0% in 2013, 14% in 2014, to 47% in 2016. Child malaria parasite prevalence by RDTs declined across the study area from 31% in 2014 to 4% after 4 MDA rounds in 2016, including in control areas. A spatiotemporal model will be used to assess the dose-response relationship between IRS-PMCS exposure and malaria parasite prevalence and confirmed case incidence between 2011-2017, accounting for LLIN coverage, treatment seeking, mass treatment, community case management, household factors and climate variability. Data from 11 rounds of household-level mass treatment campaigns conducted in the study area since 2011 will be incorporated, including a total of 277,179 households and 1,412,632 individual data points. Interactions between IRS-PMCS and other interventions will also be explored. Results from this study will be critical in understanding the impact of IRS using next-generation chemicals as part of a comprehensive elimination strategy, as well as the role IRS-PMCS played in reducing transmission in areas that did not receive MDA.

## MOVEMENT PATTERNS ASSOCIATED WITH MALARIA RISK DERIVED FROM OUTPATIENT REGISTER BOOKS IN AMHARA REGION, ETHIOPIA

Asnakew Yeshiwondim<sup>1</sup>, Belendia Serda<sup>2</sup>, Caterina Guinovart<sup>3</sup>, Berhane Tesfay<sup>2</sup>, Steffanie Chrtiz<sup>4</sup>, Teklehaimanot G. Kidanemariam<sup>5</sup>, Duncan Earle<sup>6</sup>, Richard W. Steketee<sup>4</sup>, Asefaw Getachew<sup>2</sup>

<sup>1</sup>PATH, Addis Ababa, Ethiopia, <sup>2</sup>PATH MACEPA, Addis Ababa, Ethiopia, <sup>3</sup>PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain, <sup>4</sup>PATH MACEPA, Seattle, WA, United States, <sup>5</sup>Amhara National Regional State Health Bureau, Addis Ababa, Ethiopia, <sup>6</sup>PATH MACEPA, Lusaka, Zambia

The malaria burden in Ethiopia has steadily decreased over the last several decades. As a result, the country aims to achieve subnational malaria elimination in 200 districts by 2020. However, population movement and importation of malaria infections from high- to low-risk areas is a major challenge to achieving zero malaria transmission. We assessed the movement patterns in Amhara Region, Ethiopia, using data from 133 health posts in low-to-moderate transmission areas. In 2014-16, a total of 71,818 outpatients were tested with a rapid diagnostic test (RDT) and travel history in the previous month was recorded. Additional data were extracted from 9,044 RDT-positive cases (with or without travel history) and RDT-negatives with travel history. Among the 8,163 RDT-positive patients, 74% were male and 18% had travel history; 41% of infections were due to *Plasmodium vivax*, 36% were due to *P. falciparum*, and 23% were due to mixed infections. *P. falciparum* (including mixed) infections were more frequent among travelers than non-travelers. The percentage of cases due to *P. vivax*-only decreased with age both in travelers and non-travelers, whereas *P. falciparum* (or mixed) increased with age. The mean age of RDT-positive cases with travel history was significantly higher (25.1 years [SD 10.7]) than those without travel history (20.6 years [SD 14.8]). Among the 2,371 cases with travel history, 84% were males, 80% were 15-44 years old, and 62% were RDT-positive. Patients with travel history had a 6.1 times greater risk of having malaria compared to patients without travel history. Of the travelers, 69% traveled within the Amhara Region, while 31% traveled to other regions such as Tigray (19%), Oromia (6%), Benishangul-Gumuz (5%), and Afar (3%). Nearly all destinations were high-risk areas located in the western lowlands and the Nile valley, and comprised large agricultural farms that attract a high influx

of seasonal laborers. These laborers have a high risk of becoming infected at the farms, and specific strategies are needed to reduce the risk of importing malaria back to their homes in low-transmission areas.

## 1608

### **COST AND EFFECTIVENESS ANALYSIS OF MALARIA CONTROL IN SENEGAL: "THEORETICAL" SINGLE INTERVENTIONS VS. "ACTUAL" PACKAGES OF INTERVENTIONS**

**Sophie Faye**, Altea Cico, Elaine Baruwa

*Abt Associates, Inc., Bethesda, MD, United States*

Malaria prevalence in Senegal varies greatly by district. Senegal's National Malaria Control Program (PNLP) therefore implements control interventions as packages based on prevalence. However, data are only available by single intervention, posing a challenge for the PNLP as it prioritizes packages/interventions during strategic planning for malaria pre-elimination. A broader review of the literature showed that in general, most malaria cost and effectiveness data is based on trials of single interventions. To help address this gap, USAID's Health Finance and Governance (HFG) project worked with the PNLP to design and implement a retrospective study that estimated costs and effectiveness of Senegal's malaria control packages. Cost per DALY (Disability Adjusted Life Years) averted were estimated for the six packages: 1) Scale Up For Impact (or SUFI, which includes bednets, intermittent preventive treatment, rapid diagnostic tests, and artemisinin combination therapies), 2) SUFI + FSAT (focal screen and treat + active surveillance) or MSAT (mass screen and treat + active surveillance), 3) SUFI + interior residual spraying (IRS), 4) SUFI + seasonal malaria chemoprophylaxis (SMC), 5) SUFI + SMC + IRS, and 6) SUFI + SMC + PécadomPlus (active home management). There was wide variation of cost per DALY averted across packages: \$70-\$667. Total and unit costs of single interventions within packages were also estimated. Non-facility-based treatment interventions (\$6-17 per person tested/treated) cost more than facility-based (~\$1). SUFI-only had the lowest unit cost (\$0.54 per person tested/treated), while the SUFI+SMC+IRS package had the highest unit cost (\$4.55 per person). Senegal seems to have effectively distributed packages to target the high burden areas with a wide range of interventions, though greater efficiency gains are still possible. For example, SMC seemed to make IRS more cost effective in the same district (\$274 vs. \$373). This study may assist PNLP and other control programs with the detailed data needed for sustainability planning and domestic resource mobilization needed to eliminate malaria.

## 1609

### **MALARIA PARASITEMIA AND SEROLOGICAL PREVALENCE IN NEAR-ZERO TRANSMISSION SETTINGS IN ETHIOPIA**

**Caterina Guinovart**<sup>1</sup>, Asefaw Getachew<sup>2</sup>, Asnakew Yeshiwondim<sup>3</sup>, Sampa Pal<sup>3</sup>, Belendia Serda<sup>2</sup>, Berhane Tesfay<sup>2</sup>, Adem Agmas<sup>2</sup>, Teklehaimanot G. Kidanemariam<sup>4</sup>, Woyneshet G. Yalew<sup>5</sup>, Duncan Earle<sup>6</sup>, Gonzalo Domingo<sup>3</sup>, Chris Drakeley<sup>7</sup>, Richard W. Steketee<sup>8</sup>

<sup>1</sup>PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain, <sup>2</sup>PATH MACEPA, Addis Ababa, Ethiopia, <sup>3</sup>PATH, Seattle, WA, United States, <sup>4</sup>Amhara National Regional State Health Bureau, Addis Ababa, Ethiopia, <sup>5</sup>Regional Health Research Laboratory Center, Amhara, Addis Ababa, Ethiopia, <sup>6</sup>PATH MACEPA, Lusaka, Zambia, <sup>7</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>8</sup>PATH MACEPA, Seattle, WA, United States

Ethiopia has made enormous progress in the fight against malaria, and is close to elimination in certain regions. Passive incidence of malaria cases is the only metric available in near-zero transmission settings, and other methods to assess potential interruption of transmission at the sub-national level are needed. A study was conducted in Amhara National Regional State in December 2015-February 2016 to estimate prevalence of *Plasmodium* infection by rapid diagnostic test (RDT), microscopy and polymerase chain reaction (PCR), sero-prevalence of anti-AMA-1 and

anti-MSP-1 antibodies, and serological conversion rate. Four health post catchment areas with zero confirmed, locally-acquired malaria cases in the last two years were selected. A community-based cross-sectional study was conducted in the study area in 1,649 randomly selected households, in which all consenting children aged 1-9 years and a subsample of randomly selected individuals aged  $\geq 10$  years old were included. A total of 1,272 individuals were included: 456 aged 1-4 years old, 383 aged 5-9 years old, and 433  $\geq 10$  years old. To assess whether an operationally easier convenience survey could be used instead, a survey in a convenience sample of 404 children 1-4 years old recruited at health facilities and during community health outreach activities in the same areas was also conducted, and prevalence of infection and sero-prevalence results will be compared to the community survey results. In the community survey, there was only one *P. falciparum* infection by both RDT and microscopy. In the convenience sample, no infections were found. Samples are being assayed for PCR and serology, and results will be available by mid-2017. Serological conversion rates will also be estimated for the community survey.

## 1610

### **OPTIMIZING HIGHLY FOCAL MASS DRUG ADMINISTRATION TARGETS FOR MALARIA ELIMINATION ACCELERATION OVER NETWORKED POPULATIONS: THE CASE OF HAITI**

**Milen Nikolov**<sup>1</sup>, Katherine Battle<sup>2</sup>, David L. Smith<sup>3</sup>, Philip A. Eckhoff<sup>1</sup>, Peter Gething<sup>2</sup>, Edward A. Wenger<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>2</sup>University of Oxford, Oxford, United Kingdom, <sup>3</sup>University of Washington, Seattle, WA, United States

With malaria prevalence of ~1%, Haiti is committed to malaria elimination by 2020. The Malaria Zero alliance, planning and implementing elimination activities in the country, has proposed an intervention program with emphasis on strengthening surveillance systems to increase case management (CM) rates throughout the nation; targeted reactive case detection (RCD); and highly focal mass drug administration (fMDA), with only limited vector control interventions. What are the appropriate scale, coverage, and locations of fMDA and targeted RCD deployment in the context of heightened CM to ensure malaria elimination in the country? Is there a requisite passive CM rate that needs to be sustained throughout Haiti? Are these interventions sufficient to achieve elimination sans vector control? We set up a dynamic, spatial, agent-based mathematical model comprising a network of 500m x 500m grid cells spanning the country, capturing multiscale human migration and health-seeking patterns. Heterogeneity in vectorial capacity due to significant small-scale variation in topography leads to high-transmission pockets occasionally seeding short outbreaks in lower-transmission areas. Furthermore, high-transmission pockets are not necessarily proximal to health facilities: a number of treated cases register in health facilities relatively far from infection origins. We caution that reliance on clinical case counts from health facilities alone may lead to inaccurate estimates of transmission pocket locations, rendering highly focal (village scale) MDA and RCD ineffective in the elimination context. Heightened passive CM rates (50%-70%) maintained throughout endemic areas like Grand'Anse have the potential to achieve elimination, but much later than the 2020 target. Including well-connected high-transmission pockets and nearby settlements in fMDA campaigns, in addition to the heightened CM rates, accelerates elimination towards the 2020 target.

## 1611

### **POPULATION GENETIC DIVERSITY OF SAMPLES FROM THE 2012 AND 2015 MALARIA INDICATOR SURVEYS, ZAMBIA**

**Sandra Chishimba**<sup>1</sup>, Mulenga Mwenda<sup>1</sup>, John M. Miller<sup>1</sup>, Hawela Moonga<sup>2</sup>, Rachel Daniels<sup>3</sup>, Roy Mwenechanya<sup>4</sup>, Sarah K. Volkman<sup>3</sup>, David Larsen<sup>4</sup>, Daniel J. Bridges<sup>1</sup>

<sup>1</sup>PATH MACEPA, Lusaka, Zambia, <sup>2</sup>National Malaria Control Centre, Lusaka, Zambia, <sup>3</sup>Department of Immunology and Infectious Diseases, Harvard

School of Public Health, Boston, MA, United States, <sup>4</sup>University of Zambia, School of Veterinary Medicine, Department of Biomedical Sciences, Lusaka, Zambia

To assess progress in malaria burden reduction, biennial malaria indicator surveys (MIS) have been implemented in Zambia since 2006. MIS data show high spatial and temporal heterogeneity in parasite prevalence by rapid diagnostic test, with some areas now approaching elimination, while others display historical resurgence. The variation in transmission intensity may be reflected in the parasite population genetics. As malaria prevalence decreases, the amount of genetic crossing between different parasite strains is expected to decrease. With reduced crossing, population genetic diversity as measured by complexity of infection (COI) should reduce. By selecting samples from both high and low transmission strata across both space and time, this hypothesis can be tested. Parasite DNA was extracted from dried blood spots (DBS) and a 24-point single nucleotide polymorphism barcode was determined by Taqman genotyping. Sample analysis has been completed for 57 and 21 RDT-positive DBS with genotyping results at 15 or more of the SNPs from the 2012 and 2015 MIS, respectively. From 2012, lower burden (10% prevalence by RDT) Southern Province has 36% monogenomic infections vs 10% and 11% in the higher burden provinces of Eastern (51% prevalence by RDT) and Luapula (56% prevalence by RDT) provinces, respectively. Similarly, the average percentage of mixed calls (i.e., those indicating a polygenomic infection with both major and minor alleles present) in Southern at 21% was lower than Eastern and Luapula at 28% and 29%, respectively. Once the remaining samples have been genotyped, COI will be determined using COIL software. Spatial and temporal differences in the COI will be assessed with a chi-square test, comparing complex (multiple genotypes) or simple (single genotype) infections across region (high prevalence compared to low prevalence) and time (2012 compared to 2015). The association between COI and other measures of exposure (e.g., travel, age, sex) will also be investigated using logistic regression, wherein a complex infection is predicted from hypothesized factors. Spatial clustering of the genotype populations will also be assessed.

## 1612

### ADAPTING REACTIVE CASE DETECTION FOR MALARIA IN FOREST WORKERS IN ACEH, INDONESIA

**Adam Bennett**<sup>1</sup>, Farah Coutrier<sup>2</sup>, Jennifer Smith<sup>1</sup>, Jerry Jacobson<sup>1</sup>, Martha Silaen<sup>2</sup>, Chris Cotter<sup>1</sup>, Iska Zarlinda<sup>2</sup>, Cut Maneh<sup>3</sup>, Abdul Fatah<sup>4</sup>, Rintis Noviyanti<sup>2</sup>, Iqbal Elyazar<sup>2</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Eijkman Institute for Molecular Biology, Jakarta, Indonesia, <sup>3</sup>Provincial Health Laboratory, Banda Aceh, Indonesia, <sup>4</sup>Provincial Health Office, Banda Aceh, Indonesia

Reactive case detection (RACD) is conducted by many malaria elimination programs to detect and treat infected individuals living in close proximity to an index case originally presenting to a health facility or community health worker. In settings where risk of malaria infection is primarily due to occupational exposures such as forest work, there may be minimal spatial clustering of infections, which limits the utility of conventional RACD approaches. Recent RACD studies in Aceh, Indonesia found limited clustering of additional infections around the households of index cases, identified forest work as a risk factor for infection among those screened by RACD, and found *Plasmodium knowlesi* to be a common source of infection. Based on these findings, a novel RACD strategy is being tested, whereby an index case that meets pre-determined socio-behavioral risk factors will trigger follow-up testing at forest work sites (i.e. small mines and plantations) and other venues, and amongst socially-networked groups of individuals reporting recent forest travel. Beginning in April 2017, all confirmed malaria cases presenting to health facilities in Aceh Jaya and Aceh Besar districts will be screened for risk factors related to forest work, and a total of at least 1,183 individuals tested as part of this “socio-behavioral RACD” strategy using LAMP and RDTs. A similar number of individuals will be tested by household RACD, and the prevalence of secondary infections found during each activity compared using LAMP

and PCR, in addition to comparisons of geographic and demographic coverage. Spatial and occupational risk factors will be incorporated into the analysis, along with cost data and entomological assessments conducted at high-risk work sites; results of the first six months of data collection will be presented. RACD targeted based upon risk factors such as recent forest work can provide a method for Indonesia's national malaria program to treat the highest-risk populations to help achieve its elimination goals, and has the potential to be adapted to other malaria elimination contexts.

## 1613

### FIRST-YEAR RESULTS FROM THE COMMUNITY-LED RESPONSES FOR ELIMINATION (CORE) TRIAL ASSESSING THE EFFECTIVENESS OF REACTIVE FOCAL DRUG ADMINISTRATION COMPARED TO REACTIVE FOCAL TEST AND TREAT IN REDUCING *PLASMODIUM FALCIPARUM* INFECTION PREVALENCE AND INCIDENCE IN AN ELIMINATION SETTING IN SOUTHERN PROVINCE, ZAMBIA

**Daniel J. Bridges**<sup>1</sup>, John M. Miller<sup>1</sup>, Victor Chalwe<sup>2</sup>, Hawela Moonga<sup>3</sup>, Busiku Hamainza<sup>3</sup>, Richard W. Steketee<sup>4</sup>, Brenda Mambwe<sup>1</sup>, Conceptor Mulube<sup>1</sup>, Sandra Chishimba<sup>1</sup>, Mulenga Mwenda<sup>1</sup>, Kafula Silumbe<sup>1</sup>, Jenala Nyangu<sup>1</sup>, David A. Larsen<sup>5</sup>

<sup>1</sup>PATH MACEPA, Lusaka, Zambia, <sup>2</sup>Zambia Ministry of Health, Mansa, Zambia, <sup>3</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia, <sup>4</sup>PATH MACEPA, Seattle, WA, United States, <sup>5</sup>Syracuse University Department of Public Health, Food Studies and Nutrition, Syracuse, NY, United States

Zambia has seen impressive reductions in malaria transmission, such that the government has set a target of eliminating the disease by 2021. Part of Zambia's success has been the implementation of community-based reactive focal test and treat using rapid diagnostic tests and artemether-lumefantrine. To continue to accelerate toward zero, the use of a more aggressive approach—reactive focal drug administration using longer-acting dihydroartemisinin-piperaquine—is being explored through the Community-led Responses for Elimination (CoRE) community randomized controlled trial. This trial started enrolling in March 2016 and is being implemented in 16 health facility catchment areas in four districts in Southern Province, Zambia—an area of low malaria transmission and high coverage with vector control. Briefly, reactive responses, triggered by a confirmed malaria case at any government health facility, are performed by community health workers (CHWs) within seven days of the index case confirmation date, out to a radius of 140m from the index case household. Drug compliance is monitored over a 3-day visit. As of May 2017, one year's worth of field and laboratory data from the trial will be available, and we will conduct preliminary analyses assessing differences between the two arms of two separate outcomes: 1) PCR positivity during reactions, and 2) health facility trends in case incidence. A subset of the trial population will have dried blood spots (DBS) collected at days 1, 30, and 90 after a reactive response. Samples are analyzed by PET-PCR to determine the sub-patent carriage rate, and reinfection rates will be evaluated in the two study arms. Analyses of the parasite genotypes will be conducted to determine spatial distribution and the association between infection complexity and other risk factors (e.g., age or travel). Finally, the frequency of newly detected infections between the two arms will be examined to look for preliminary evidence of the effect of the different reactive case detection and management approaches.

## 1614

### PROGRAMMATIC MASS DRUG ADMINISTRATION IN SOUTHERN PROVINCE, ZAMBIA: AN EVALUATION OF IMPACT AND POSSIBLE SPILL-OVER EFFECTS USING DHIS2 MALARIA CASE INCIDENCE DATA

Ruben Conner<sup>1</sup>, Mutinta Mudenda<sup>2</sup>, Busiku Hamainza<sup>2</sup>, Hawela Moonga<sup>2</sup>, John M. Miller<sup>3</sup>, Thomas P. Eisele<sup>4</sup>, Adam Bennett<sup>5</sup>, Travis Porter<sup>4</sup>, Kafula Silumbe<sup>3</sup>, Caterina Guinovart<sup>6</sup>, Richard W. Steketee<sup>1</sup>

<sup>1</sup>PATH MACEPA, Seattle, WA, United States, <sup>2</sup>National Malaria Elimination Centre, Lusaka, Zambia, <sup>3</sup>PATH MACEPA, Lusaka, Zambia, <sup>4</sup>Center for Applied Malaria Research and Evaluation, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>5</sup>University of California – San Francisco, San Francisco, CA, United States, <sup>6</sup>PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain

The Zambia National Malaria Elimination Centre began rolling out programmatic mass drug administration (MDA) with dihydroartemisinin-piperazine (DHAP) in combination with high coverage vector control and intensive community-case management and surveillance in late 2016 as part of an updated national malaria elimination strategy. This follows a two-year trial of MDA which demonstrated significant benefit in malaria burden reduction in areas receiving this full package of interventions. We present two related analyses of the programmatic MDA outcomes. The first analysis will examine confirmed case incidence in 50 health facility catchment areas (HFCAs). The first group is 25 HFCAs that received MDA during 2016-2017 but were not previously included in the trial and are at least 25km from previous trial study areas. These 25 catchments are among the highest burden areas within the province with a 2016-2017 malaria season incidence of 61 cases per 1,000 population and were selected for the MDA this year due to their high incidence. The second group is 25 HFCAs selected from neighbouring Western Province using propensity score matching to provide a comparison group. This analysis will use a negative binomial model with a difference-in-difference estimator. The exposure of interest will be the MDA treatment with control variables for environmental factors and concurrent malaria control interventions. The second analysis will assess the possibility of spill-over effects of MDA by comparing changes in malaria incidence among HFCAs that are not receiving MDA (but are geographically contiguous to MDA areas) to more distant catchments. The possibility of a spill-over effect was observed during the trial and this new area of treatment provides a larger geographical area upon which to test the relationship between proximity to treated areas and changes in incidence. This analysis will use a dose-response framework to assess the effect of distance to nearest MDA areas on malaria incidence among a subset of the catchments within Southern Province.

### MONITORING POPULATION AND TRANSMISSION DYNAMICS OF MALARIA VECTORS ALONG LAKE KARIBA OF SOUTHERN ZAMBIA: IMPLICATIONS FOR THE MALARIA CONTROL AND ELIMINATION PROGRAM

Kochelani Saili<sup>1</sup>, Javan Chanda<sup>1</sup>, Mulenga Mwenda<sup>1</sup>, Chadwick Sikaala<sup>2</sup>, Christopher Lungu<sup>1</sup>, Duncan Earle<sup>1</sup>, Adam Bennett<sup>3</sup>, Thomas P. Eisele<sup>4</sup>, Richard W. Steketee<sup>5</sup>, Joseph Keating<sup>4</sup>, John M. Miller<sup>1</sup>

<sup>1</sup>PATH MACEPA, Lusaka, Zambia, <sup>2</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia, <sup>3</sup>Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>5</sup>PATH MACEPA, Seattle, WA, United States

Indoor residual spraying (IRS) and long-lasting insecticidal nets (LLINs) remain the key interventions against malaria vectors in Zambia. However,

the impact of IRS with pirimiphos methyl (PM; brand name Actellic-CS) on malaria vector populations and transmission remains confined to areas targeted for malaria elimination in Southern Zambia. Indoor host-seeking mosquitoes were sampled using CDC light traps and pyrethrum spray catch in 12 study sites where a mass drug administration (MDA) trial using dihydroartemisinin-piperazine was implemented in 2014-2016. Houses in the study areas were also targeted for IRS with PM during the trial. The sporozoite infection rates of malaria vectors were determined by ELISA while sibling species of *An. gambiae* s.l. and *An. funestus* group were identified by PCR. After two rounds of IRS, of all Anopheline species collected, the proportion that were *An. funestus* s.s. mosquitoes was reduced from 95.6% (n=6,302) in 2014 to 12.2% (n=2,334) in 2016, while the average number of *An. funestus* s.s. collected per month per house decreased significantly from 31.63 in 2014 to 3.58 in 2016. In contrast, of all Anopheline species collected, the proportion of *An. arabiensis* increased from 2.4% in 2014 to 81.0% in 2016 and average number per house of *An. arabiensis* increased substantially from 0.79 in 2014 to 14.52 in 2016. The percentage of sampled mosquitoes testing positive for *Plasmodium falciparum* (Pf) sporozoites in *An. funestus* s.s. decreased from 1.75% in 2014 to 0.25% in 2016 while only one positive was detected in populations of *An. arabiensis* in 2014 and no sporozoite positives were found in 2015 or 2016. These data suggest that IRS with PM suppresses the more endophilic *An. funestus* s.s. populations but not the largely exophilic *An. arabiensis* in Southern Zambia. The reduction in *An. funestus* s.s. populations and sporozoite rates further suggests the additive impact of malaria interventions (IRS and MDA) on the malaria parasite reservoir in the study areas. The persistence of *An. arabiensis* could challenge malaria elimination efforts and require additional outdoor vector control interventions.

## 1616

### THE ECONOMIC AND EDUCATIONAL IMPACTS OF A MALARIA ELIMINATION CAMPAIGN IN MOZAMBIQUE

Joe Brew, Laia Cirera, Elisa Sicuri

Barcelona Institute for Global Health, Barcelona, Spain

The elimination of malaria can bring benefits to a society which go well beyond improvements in health. Two areas often cited are education and worker productivity. But these hypothetical benefits have previously only been analyzed retrospectively and at the ecological level, casting doubt on elimination's causal role in societal improvements. The ongoing malaria elimination campaign (MALTEM) in southern Mozambique offers the ideal setting for a retrospective and person-level analysis of the economic and educational effect of malaria elimination. Prospective, observational data collection was carried out on a sample of schoolchildren between 6 and 12 years old, as well as adults working in sugarcane factories from both the malaria elimination intervention area (Magude) as well as a control area (Manhiça). Data were collected for the period one year prior, during, and one year after the initiation of mass drug administration (MDA) in Magude. Difference-in-difference was performed along with regression analysis, allowing for the control of potential confounding factors, such as the demographic, socio-economic, morbidity and mobility status of the population. Preliminary results are expected in June of 2017. The results are still undetermined as the project is currently in progress. However, the results from this study will be crucial to inform policymakers as well as the international community on the magnitude of the economic gains as well as the efficacy of investing resources in moving from a state of controlled malaria to malaria elimination. This research forms part of a more general goal to quantify the economic costs of malaria, and the potential corresponding benefits of its eradication. The data for this project are among the most granular and detailed for any project of similar scope in Sub-Saharan Africa. The findings of this project will inform not only policy-makers's public health decisions, but also those of private industry leaders.

## REACTIVE CASE DETECTION IN A SETTING OF DECLINING TRANSMISSION, SOUTHERN PROVINCE, ZAMBIA

Marie-Reine Rutagwera<sup>1</sup>, Chris Lungu<sup>1</sup>, Busiku Hamainza<sup>2</sup>, Mercy M. Ingwe<sup>2</sup>, John M. Miller<sup>1</sup>

<sup>1</sup>PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, <sup>2</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia

Reactive case detection (RCD) is a malaria surveillance and treatment strategy that has been rolled out in southern Zambia since 2011. RCD is triggered when a patient seeking care at a health facility or by a community health worker is confirmed by a rapid diagnostic test or other laboratory diagnostic test to have malaria (an index case). The investigation tracks index cases back to their corresponding households and neighborhoods, where either all individuals in the immediate area are treated, or all individuals are tested and those who test positive for malaria are treated. The success of this approach rests on the assumption that infections are clustered and that tracking passively detected index cases will find the most infections. We review progress to date with RCD activities and lessons learned for scaling up RCD throughout Zambia.

## REACTIVE CASE DETECTION IN TRANSITION TO PROGRAMMATIC SURVEILLANCE, NORTHERN SENEGAL

As more countries move toward malaria elimination, new strategies need to be implemented in low transmission settings to deal with residual or imported cases before elimination is reached. In northern Senegal, malaria case investigation (CI) and reactive case detection (RCD) are currently being implemented. Case investigation is the characterization of all passively detected malaria cases (sociodemographic characteristics, symptoms, history of travel, use of malaria control tools, etc.), which is followed by RCD to actively search for more infections and/or administer antimalarial treatment at the index case household and neighboring households. The success of this approach rests on the assumption that infections are clustered and that tracking passively detected index cases will find the most infections. However, many questions remain about the effectiveness and operationalization of these strategies and available data from the field should inform policies. Since 2012, Senegal has been implementing CI with RCD in the north, where malaria transmission is the lowest in the country. It initially started in Richard Toll District, where RCD was done using focal test and treat in the index case household and five closest neighboring compounds, changing to focal screen test and treat (only testing with a rapid diagnostic test those with risk factors), and finally to focal drug administration where all eligible individuals in the index case household are treated. Since 2016, RCD has been implemented by the National Malaria Control Program in 10 districts in northern Senegal covering a population of about 1.7 million, with over 90% of passively detected cases investigated. The coverage of the intervention, operational description, and feasibility will be presented. To evaluate whether CI with RCD had an impact on malaria incidence in the intervention areas,

an impact evaluation will be conducted using a quasi-experimental design with a comparison group from areas that have not received the intervention.

## FACTORS ASSOCIATED WITH INTERMITTENT PREVENTIVE TREATMENT OF MALARIA DURING PREGNANCY IN MALI

Souleymane S. Diarra<sup>1</sup>, Drissa Konate<sup>1</sup>, Sory I. Diawara<sup>1</sup>, Mariam Tall<sup>2</sup>, Mahamadou Diakite<sup>1</sup>, Seydou Doumbia<sup>1</sup>

<sup>1</sup>Malaria Research & Training Center, Bamako, Mali, <sup>2</sup>National Program of Malaria Control, Bamako, Mali

Intermittent preventive treatment in pregnancy (IPTp) with three or more doses of sulfadoxine-pyrimethamine (SP) is recommended by WHO to prevent malaria in pregnant women living in high risk areas. According to Mali's 2015 malaria indicator survey the prevalence of malaria was 34.6%. The high risk of malaria among pregnant women and children led government to provide SP free of charge during ANC visits. The government recommends to take three doses least during pregnancy. The proportion of women taking three or more doses of sulfadoxine pyrimethamine to prevent malaria during pregnancy (IPTp 3+) remains low. According to the 2015 Mali MIS, only 37% of women with a live birth in the past two years received IPTp 3+. To investigate factors associated with this low coverage, we carried out a secondary analysis of data from the Mali 2015 Malaria Indicator Survey. A multiple, logistic regression was used to analyze the factors associated with IPTp3+ among the 2382 interviewed women with a live last birth preceding the survey. Factors associated with higher IPTp 3+ after adjustment of potential confounding factors included: the households who had radio as source information (OR=0.71 95% CI [0.53-0.95]), and reside in Segou's region (AOR=0.56 95% CI [0.35; 0.90]). However women aged below 20 years ago was associated in lower IPTp 3+ (AOR=1.43 95% CI [1.03; 1.98]). The place of residence urban or rural, educational level, and wealth index were not associated with IPTp3+. This study identifies that media accessibility and Segou's region residence of women were a factor associated with IPTp3+.

## IMPACT OF STRATIFICATION METHODS USED TO TARGET INDOOR RESIDUAL SPRAYING IN BIKO ISLAND, EQUATORIAL GUINEA

Jackie Cook<sup>1</sup>, Guillermo Garcia<sup>2</sup>, Jordan Smith<sup>2</sup>, Dianna Hergott<sup>2</sup>, Aveika Akum<sup>3</sup>, Immo Kleinschmidt<sup>1</sup>, Wonder P. Phiri<sup>3</sup>, Christopher Schwabe<sup>2</sup>, Julie Niemczura de Carvalho<sup>2</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>3</sup>Medical Care Development International, Malabo, Equatorial Guinea

Targeting of interventions to areas most at risk is common for malaria control programmes, however, the methods used to determine stratification vary and their impact has not been well evaluated. In Bioko Island, Equatorial Guinea, blanket Indoor Residual Spraying (IRS) was policy up until 2014 when an evaluation revealed lower than expected coverage (57%), in part due to high refusal rates. In 2015, the Bioko Island Malaria Control Programme (BIMCP) decided to target communities for IRS utilising data collected from surveys undertaken in 2014. Stratification was based on community-level parasite prevalence, quality of housing, risk of case importation and previous IRS coverage (as a proxy for acceptability in the community). A risk score (R) and a risk-acceptability score (Ra) were derived for each community. In relation to the budget, the top 30% of communities with the highest R and Ra values were selected for IRS- targeting, with over 80% coverage achieved in these areas in 2015. Areas no longer targeted with IRS received a top of bed nets. Results from an island-wide prevalence survey in 2015 prior to spraying were compared to data from the same communities in 2016 to evaluate the impact of the targeted IRS. The data suggests that *P. falciparum* prevalence was significantly reduced in areas that had been targeted in the most

recent spray round. However, areas that were no longer part of the spray campaign maintained similar levels of prevalence between 2015 and 2016 suggesting that current control interventions in these areas are not currently sufficient to further reduce transmission although did prevent any apparent resurgence of transmission. Understanding the impact of stratification is key for future IRS targeting and will help the programme design more efficient strategies for malaria control.

Chan School of Public Health, Boston, MA, United States

African great apes harbor diverse assemblages of malaria parasites, including the progenitors of *Plasmodium falciparum* and *P. vivax*, which adapted to the human population following ancient cross-species transmission events. Vectors of ape parasites exhibit promiscuous biting preferences, presenting a public health imperative to identify human populations at risk of exposure for follow-up assessment of zoonotic potential and molecular barriers to transmission in epidemiologically relevant settings. To elucidate spatiotemporal variation in ape malaria parasitism, we model the ecological niche of ape malaria parasites in wild chimpanzee hosts by analyzing the relationship between environmental variables and fecal parasite rates. Analysis of 878 samples collected longitudinally from a cohort of 54 chimpanzees in western Uganda indicates that high prevalence (31.5%), early age of onset, and seasonality of infection characterize ape malaria epidemiology. These findings are consistent with an elevated magnitude of ongoing transmission within the reservoir, suggesting that humans living on the borders of many equatorial African forests are likely to be exposed to zoonotic parasites. Analysis of 2436 samples collected at 55 sampling sites across equatorial Africa recapitulate these findings and support the hypothesis that mean ambient temperature drives spatiotemporal variation in parasite prevalence. However, chimpanzee parasitism peaked at a lower mean ambient temperature (~24.5°C) than the commonly referenced temperature optimum of *P. falciparum* (~30°C). Forest cover was positively correlated with parasite prevalence, consistent with the finding that forest-dwelling Anopheline species constitute the primary vectors of ape parasites. These results suggest that adaptation of ape parasites to non-forest vectors may be a critical prerequisite for widespread emergence in human populations. We extrapolate these findings across equatorial Africa to generate a hypothetical exposure risk map, offering a tool for the prediction of exposure hotspots that can be mobilized to design zoonotic disease surveillance efforts.

### DIFFERING PATTERNS OF PROTECTIVE ASSOCIATIONS FOR ANTIBODIES TO SURFACE ANTIGENS OF *PLASMODIUM FALCIPARUM*-INFECTED ERYTHROCYTES AND MEROZOITES IN IMMUNITY TO MALARIA IN CHILDREN

**Jo-Anne Chan**<sup>1</sup>, Danielle Stanicic<sup>2</sup>, Michael F. Duffy<sup>3</sup>, Leanne Robinson<sup>1</sup>, Enmoore Lin<sup>4</sup>, James W. Kazura<sup>5</sup>, Christopher L. King<sup>5</sup>, Peter M. Siba<sup>4</sup>, Freya J. Fowkes<sup>1</sup>, Ivo Mueller<sup>6</sup>, James G. Beeson<sup>1</sup>

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>Griffith University, Southport, Australia, <sup>3</sup>University of Melbourne, Melbourne, Australia, <sup>4</sup>Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, <sup>5</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>6</sup>Walter and Eliza Hall Institute, Melbourne, Australia

Acquired antibodies play an important role in immunity to *Plasmodium falciparum* malaria and are typically directed towards surface antigens expressed by blood-stage parasites, such as merozoites and infected erythrocytes (IEs). The importance of specific IE surface antigens as immune targets remains unclear, especially in populations outside Africa, and a lack of tools has hampered the study of individual antigens. We evaluated antibodies and protective associations in two cohorts of older and younger children in Papua New Guinea (PNG). We used genetically-modified *P. falciparum* with reduced PfEMP1 expression to evaluate the importance of IE surface antigens and a *P. falciparum* isolate with a virulent phenotype defined by expression of specific PfEMP1 variants. We found that PfEMP1 was the dominant target of antibodies to the IE surface, with limited reactivity to other antigens. Antibodies were associated with increasing age and active parasitemia, and were higher among children exposed to a higher force-of-infection which was determined using molecular detection and genotyping. Antibodies to IE surface antigens were consistently associated with reduced risk of malaria in both younger and older children's cohorts. However, protective associations for antibodies to merozoite surface antigens was only observed in older children. This suggests that antibodies to IE surface antigens, particularly PfEMP1 variants linked with virulent phenotypes, play an earlier role in acquired immunity to malaria, whereas greater exposure is required to develop protective antibodies to merozoite antigens. These findings have implications for vaccine design, and serosurveillance of malaria transmission and immunity, especially in the current era of declining malaria transmission.

### SEASONAL MALARIA CHEMOPREVENTION IN ANKILILOAKA, MADAGASCAR

**Ramiranirina Brune**, Franchard Thierry, Ratsimbaoa Arsène  
*National Malaria Control Program Madagascar, Antananarivo, Madagascar*

Malaria remains a major public health problem in Madagascar. From 2013 to 2015, an increasing malaria morbidity (6.8% to 12.5%) and malaria mortality (8.4% to 11.9%) was recorded. In 2015, malaria outbreak was mostly observed in South-West of the country, notably in commune of Ankiloaka, district of Toliara II. As a response to this situation, 10,000 long lasting insecticidal nets was distributed especially in this commune. Also, a strengthening of awareness-raising was carried out. Despite this, a resurgence of the number of cases of malaria was observed with 7 times more cases in November 2015 than in September 2015 (234 to 1566). Given this situation, the search of new prevention strategy is necessary to reduce the burden of this disease. The seasonal Malaria Chemo-prevention (SMC) is one of the strategies proposed by WHO to prevent morbidity and mortality related to malaria, particularly in areas where malaria transmission is highly seasonal. Indeed, SMC is able to reduce the incidence of malaria by 82% and severe cases by 77%. SMC was carried from December 2015 to February 2016 in the commune of Ankiloaka. SMC was administered in children 6 months to 14 years old given the dynamics of malaria epidemiology in Madagascar and where

children between 5 and 14 years old are mostly affected by the disease. Also, given that the Amodiaquine is available only as part of ASAQ in Madagascar, Artemisinin Combined Therapy (ACT) was used for 3 days of directly observed treatment. A total of 1686 children was recruited with 13,16% of lost follow up. As a result, we observed a decrease of 72% of malaria prevalence between pre-and post-intervention. A scaling up and an evaluation of cost efficacy of this prevention strategy will be recommended.

## 1624

### THE EFFECT OF HOUSING IMPROVEMENTS ON MALARIA IN AFRICA, 2000-2015

**Lucy S. Tusting<sup>1</sup>**, Donal Bisanzio<sup>1</sup>, Harry Gibson<sup>1</sup>, Jakob Knudsen<sup>2</sup>, Steve W. Lindsay<sup>3</sup>, Peter W. Gething<sup>1</sup>, Samir Bhatt<sup>4</sup>

<sup>1</sup>Oxford Big Data Institute, La Ki Shing Centre for Health Information and Discovery, University of Oxford, Oxford, United Kingdom, <sup>2</sup>The Royal Danish Academy of Fine Arts, Schools of Architecture, Design and Conservation, Copenhagen, Denmark, <sup>3</sup>Department of Biosciences, Durham University, Durham, United Kingdom, <sup>4</sup>Faculty of Medicine, School of Public Health, Imperial College, London, United Kingdom

Improving housing is a promising strategy for sustainable malaria control. As Africa undergoes rapid economic and social change, it is vital to understand continent-wide changes in housing quality and their impact on malaria, to inform effective inter-sectoral malaria strategies. Here we provide the first formal quantification of changes in housing quality across sub-Saharan Africa (SSA) from 2000 to 2015 and of the effect of these changes on malaria endemicity. Data on housing quality were abstracted from 131 unique Demographic and Health and Malaria Indicator Surveys comprising over 1.1 million households, and combined within a Bayesian geostatistical framework to estimate changes in housing quality between 2000 and 2015. These estimates were linked with a large database of malaria prevalence surveys, environmental, sociodemographic, and intervention factors to estimate the effect of housing quality on malaria endemicity in SSA during 2000-2015. We will present data, trends, and maps on changes in house quality across SSA, evaluate the impact on malaria endemicity, and discuss the potential of improved housing as an intervention against malaria in a range of transmission settings across SSA. Alongside the current suite of interventions, improvements in housing quality linked to socioeconomic development may be an important strategy to support long-term and sustainable malaria control, elimination and the prevention of re-emergence.

## 1625

### UNDERSTANDING MIGRANT BEHAVIORS AND MALARIA RISK IN AYEYARWADDY REGION, MYANMAR

**Myat Min Tun<sup>1</sup>**, Sarah Gallalee<sup>2</sup>, Moe Aye<sup>2</sup>, Nan K. Aung<sup>2</sup>, Arnaud LeMenach<sup>2</sup>, Aung Thi<sup>3</sup>, Christopher Lourenço<sup>2</sup>

<sup>1</sup>Vector Borne Disease Control (VBDC) Program, Ayeyarwady Region, Patheingyi, Myanmar, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>Vector Borne Disease Control (VBDC) Program, Yangon, Myanmar

Myanmar reported less than 60,000 malaria cases in 2016, and with the growing threat of artemisinin resistance, is committed to eliminating malaria by 2030. Ayeyarwaddy is the third most populated region in Myanmar and accounts for nearly 10% of total malaria. Mobile and migrant populations (MMPs) in Ayeyarwaddy are considered at greater risk for malaria, but little is known about their malaria knowledge and behavior. A cross-sectional cluster survey was conducted in September 2016 in Ngaputaw township, the area that accounts for 44% of total malaria confirmed cases reported in Ayeyarwaddy. MMPs aged 15 years-old or above were interviewed in 48 village clusters conveniently sampled along the road network. Data were collected about malaria knowledge, prevention measures and access to care through face-to-face interviews conducted by healthcare workers. Among the 230 MMPs interviewed, 70% reported that malaria can be transmitted through a mosquito bite,

and 74% agreed with the statement that there is more risk to contract malaria when working at night. Sleeping under a mosquito net was mentioned as the preferred method for preventing malaria among 90% of the respondents, and 60% reported having at least one net. In relation to case management, 29% of respondents believed they had malaria at least once in the last 6 months, and of those, 95% reported they received a blood test. Additionally, 78% of respondents seeking any type of healthcare sought it in a public facility, and only 1% reported seeking care from village health volunteers (VHVs). MMPs demonstrated relatively good malaria knowledge and prevention practices amongst affected communities. Low utilization of VHVs may be due to the convenient sampling method along the road network. Their role in improving access to malaria diagnosis and treatment among MMPs should be further investigated.

## 1626

### MALARIA DISASTER IN VENEZUELA: TIME FOR ACTIONS

**Leopoldo Villegas**, Maria-Mercedes Villegas, Maria-Victoria Villegas, Maria Guevara

ASOCIS, Tumeremo, Bolivar, Bolivarian Republic of Venezuela

Venezuela was the first nation in the world to be certified by the WHO for eradicating malaria in 70% of its territory in 1961. From 2008 onwards, the number of malaria cases started to increase slowly and, by 2013, progressive malaria epidemics have been affecting the country. The national surveillance system has been reporting confirmed cases weekly since the 1940s, a backbone of the malaria national program. The Ministry of Health (MOH) prohibited the publication of official epidemiological bulletins -including malaria indicators- in late-2014. We reconstructed the national malaria epidemiological data (confirmed cases and deaths) from national sources (weekly reports, key informant interviews, field data and PAHO/WHO). We estimated the number of malaria cases - adjusting for relapses, recrudescences, under-reporting and self-medication- and deaths by 2016. Officially, the MOH reported to PAHO/WHO 136402 and 240631 cases in 2015 and 2016, respectively. However, our findings show 212787 and 437097 cases for the same years. Comparing annual malaria cases between 2000 vs. 2016, there is an increase from 30234 to 240631 cases (officially, 795%) and adjusted cases with an increase of 1446%. Similarly, the number of malaria-related deaths rose from 24 in 2000 to 150 in 2016. Venezuela contributed to nearly half of the malaria cases in the Americas in 2016; it is spreading to its neighbor countries and the national government has not shown effective response to address the situation. Several factors have been contributing to this malaria disaster including a) severe shortages of drugs, insecticides, supplies, etc.; b) massive internal migration to illegal gold mining areas; c) limited financial and logistic support to control activities in the field; d) inadequate prioritization of interventions; and, e) collapse of health services. Effective actions including support with cost-effective interventions are urgently needed by international malaria partners in order to manage the malaria epidemic in Venezuela. An international multisectoral task force is needed to address this regional malaria disaster.

## 1627

### EFFECT OF MALARIA IN THE FIRST TRIMESTER OF PREGNANCY ON FETAL GROWTH: A PRE-CONCEPTIONAL COHORT STUDY IN BENIN

**Valerie Briand<sup>1</sup>**, Manfred Accrombessi<sup>1</sup>, Emmanuel Yovo<sup>2</sup>, Gilles Cottrell<sup>1</sup>, Yves Martin-Prével<sup>3</sup>, Agnès Gartner<sup>3</sup>, Michel Cot<sup>1</sup>, Achille Massougbodji<sup>2</sup>, Nadine Fievet<sup>1</sup>

<sup>1</sup>UMR216, Institut de Recherche pour le Développement (IRD), Université Paris Descartes, Paris, France, <sup>2</sup>Centre d'Etude et de Recherche sur le Paludisme Associé à la Grossesse et à l'Enfance (CERPAGE), Cotonou,

Benin, <sup>3</sup>UMR204, Institut de Recherche pour le Développement (IRD), Université de Montpellier, Montpellier SupAgro, Montpellier, France

In Africa, preventive drug strategies against malaria in pregnancy are recommended from the 2nd trimester, and bed nets are rarely distributed before the 1st antenatal care visit at 4 months of pregnancy. Therefore, women remain insufficiently, or not, protected during the 1st trimester. For the first time, we assessed the consequences of malaria in the first trimester of pregnancy on birth outcomes using a specifically-designed study. From June 2014 to March 2017, South Benin, 1214 women of child bearing age were recruited and followed up monthly until 411 became pregnant. Pregnant women were then followed up from 5-6 weeks of gestation until delivery. Microscopic malarial infections were detected monthly. Five ultrasound scans were performed for the datation of pregnancy and fetal growth assessment. Path analysis was used to assess the direct effect of malaria in the 1st trimester (i.e., not mediated by malaria in the 2nd or 3rd trimester) on small-birthweight-for-gestational age (SGA) according to Schmiegelow's charts. This preliminary analysis was based on the first 180 deliveries. The prevalence of SGA was 11.9%. Malaria in the 1st, 2nd and 3rd trimester of pregnancy accounted for 24.7%, 18.8% and 17.7%, respectively. After adjustment for malaria in the 2nd and 3rd trimester and other potential confounders, we found a marginally significant direct effect of malaria in the 1st trimester on SGA (aORa=2.34 [0.86-6.38]; P=0.10). We did not evidence any effect of malaria in the 2nd or 3rd trimester. Using a multivariate logistic regression model, women with repeated infections in the 1st trimester—and not thereafter—had the highest risk of SGA compared to uninfected women (aORa=6.86 [1.24-38.00], P=0.03). These preliminary results suggest an independent effect of malaria in the 1st trimester on fetal growth, which should be confirmed on the full sample. If confirmed, they may argue in favour of implementing additional preventive measures starting before or during the 1st trimester of pregnancy.

## 1628

### FACTORS ASSOCIATED WITH SUBMICROSCOPIC MALARIA PARASITE CARRIAGE IN SICK CHILDREN AGED 6 - 59 MONTHS OLD IN URBAN AND PERI-URBAN FACILITIES IN BLANTYRE, MALAWI

Atupele Kapito-Tembo<sup>1</sup>, Tapona Msowoya<sup>1</sup>, Andy Bauleni<sup>1</sup>, Emmanuel Mphemo<sup>1</sup>, Mark L. Wilson<sup>2</sup>, Terrie E. Taylor<sup>3</sup>, Don P. Mathanga<sup>1</sup>

<sup>1</sup>University of Malawi College of Medicine - Malaria Alert Centre, Blantyre, Malawi, <sup>2</sup>Department of Epidemiology, School of Public Health University of Michigan, Ann Arbor, MI, United States, <sup>3</sup>College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States

The extent and role of submicroscopic malaria (SM) in *Plasmodium* transmission and clinical disease in urban settings remain unclear. SM contributes to pathogen transmission in sub-Saharan Africa urban settings that experience relatively low incidence, and therefore being able to identify human reservoirs is critical for successful malaria control and elimination. This study assessed factors associated with submicroscopic *Plasmodium* parasite carriage in outpatients presenting to urban and peri-urban facilities in Blantyre, Malawi. Children 6-59 months old attending sick child clinics were enrolled from four urban and two peri-urban facilities from April 2012-October 2015. Children were tested for malaria by both microscopy and real time PCR (rt-PCR). SM was defined as a positive PCR test that was negative by microscopy in any sick child. To evaluate factors associated with SM carriage, we compared all children who had SM in the study to a computer-generated, random sub-sample of children who were *Plasmodium* negative by both microscopy and rt-PCR in the ratio of 1:2. Of the 3,348 children enrolled, 69 (2.1%; 95% CI: 1.6%-2.5%) had SM. Almost all children (98.6%) with SM were not prescribed antimalarial drugs by the attending clinician on the day of clinic visit. There were no statistically significant differences in SM prevalence between urban and peri-urban areas (2.5 vs. 1.8%, p=0.2); between patients with or without history of fever (0.3% vs. 3.9%, p=0.7); between patients whose

temperature was  $\geq 37.5^{\circ}\text{C}$  vs.  $< 37.5^{\circ}\text{C}$  (1.5% vs. 2.4%, p=0.1), nor; between rainy and dry seasons (1.7% vs. 2.4%, p=0.2). In multivariate analyses, residing in an urban site was associated with increased odds of SM, while age (24-59 months) and fever ( $\geq 37.5^{\circ}\text{C}$ ) were associated with decreased odds of SM. Our results show that SM parasite carriage is occurring in sick, under-five children in both urban and peri-urban settings in Malawi. Further studies are needed to investigate the effect of untreated SM parasitemia on illness outcomes in these children, the burden of SM parasite carriage in older age groups and its significance in malaria transmission in urban settings.

## 1629

### DECLINE OF MULTIPLE INFECTIONS OF *PLASMODIUM FALCIPARUM* FROM 2007 TO 2012 AND DIFFERENCE IN MULTIPLE INFECTIONS BETWEEN HUMANS AND MOSQUITOES IN WESTERN KENYA

Ying Liu<sup>1</sup>, Sheila B. Sargent<sup>1</sup>, Benard Abong'oo<sup>2</sup>, Kephass Otieno<sup>2</sup>, John E. Gimnig<sup>1</sup>, Edward D. Walker<sup>3</sup>, Simon Kariuki<sup>2</sup>, Meghna Desai<sup>1</sup>, Ya Ping Shi<sup>1</sup>, Zhiyong Zhou<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, United States

With vector control and efficacious interventions implemented over 15 years, malaria prevalence declined dramatically from approximately 80% in 1996 to 26% in 2008 in an intensely studied rural area in western Kenya, but has stagnated at around 40% since 2009. Our previous studies have reported that overall rates of multiple infection and genetic diversity of *P. falciparum* in human blood did not change from 1996 (baseline) to 2001 and 2007 following intensive malaria control interventions in the same area. An additional follow up study was performed on blood samples collected in a cross-sectional survey in 2012. To explore if the lack of change in the rate of multiple parasite infections in humans was related to vector-parasite interactions, we also genotyped midgut parasites from mosquitoes collected from within the study area in 2012. In total, 258 blood smear-positive samples and 61 oocyst-positive mosquitoes were genotyped employing eight microsatellite markers. The results from blood were compared to our previously reported data in 2007. Differences in rates of multiple infections in humans and mosquitoes were also assessed. Preliminary results show that mean allele counts (MAC) declined from 2.76 (2007) to 1.64 in 2012 (p<0.001), while there was no significant change in the overall proportion of multiple alleles (MA) between 2007 (87.7%) and 2012 (83.3%) in human samples. In addition, overall MAC was significantly higher in human blood (1.64) than in mosquito midguts (1.48) (p<0.001), but no differences were seen in overall MA between human blood and mosquito midgut (p=0.084). For individual *loci*, *adl* and *taa60*, both MAC and MA were significantly higher in human blood compared to mosquito midguts while for *pfpk2* and *p195*, MAC was significantly higher in human blood. No differences in MAC or MA were detected at any other *loci*. The decline in mean allele counts in 2012 may indicate reduced multiple infections within-host. Results from this study also suggest a higher level of multiple infections in humans compared to mosquitoes. Further analysis of genetic diversity and population structure of parasites in the two hosts is needed on these samples.

### AGE-SPECIFIC CHANGES IN THE INCIDENCE OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA: SEASONAL MALARIA CHEMOPREVENTION (SMC) IN AN AREA WITH INTENSE TRANSMISSION: DANGASSA, MALI

**Mahamoudou B. Toure**<sup>1</sup>, Daouda D. Sonogo<sup>1</sup>, Moussa Keita<sup>1</sup>, Ayouba Diarra<sup>1</sup>, Abdoul S. Keita<sup>1</sup>, Drissa D. Konate<sup>1</sup>, Abdrahamane Haidara<sup>1</sup>, Sekou F. Traore<sup>1</sup>, Seydou O. Doumbia<sup>1</sup>, Donald J. Krogstad<sup>2</sup>

<sup>1</sup>University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, <sup>2</sup>Tulane University, New Orleans, LA, United States

The community of Dangassa in Mali has experienced intense malaria transmission during the past 2-3 decades with peak Entomologic Inoculation Rates (EIRs) >10 infectious bites per person per month in October and November and an annual Incidence of uncomplicated malaria that approaches 1.0/person/year for the persons at greatest risk (children 5-14 years of age). Because of interest in the impact of Seasonal Malaria Chemoprevention (SMC) on the incidence of human disease, data from longitudinal cohort-based studies in Dangassa that began in 2012 have been examined to compare the incidence of uncomplicated malaria in 2013-2014 before the implementation of SMC to its incidence during the implementation of SMC in 2015-2016. From 2013-2014 to 2015-2016, the average incidence of uncomplicated malaria in Dangassa rose 9% from 477 to 518 cases of uncomplicated malaria/1,000 persons/year. Across age groups, the only decrease and the lowest increase observed were among children 0-4 and 5-9 years of age. These children were also the only persons in the community who received amodiaquine and sulfadoxine-pyrimethamine 3-4 times during 2015 (children 0-4 years of age) and 2016 (children both 0-4 and 5-9 years of age). Unlike previous reports on SMC, in Dangassa there was no evidence that SMC for children 0-9 years of age provided any benefits to the other (older) members of community. In those groups (persons 10+ years of age), the annual incidence of malaria rose from 2013-2014 (before SMC) to 2015-2016 (during SMC). The average increase in incidence across those age groups was 69% and ranged from 15% in persons 30-39 years of age to 173% in persons 10-14 years of age. These results are consistent with the patient data for this study, which indicate compliance with the amodiaquine + sulfadoxine-pyrimethamine regimen was 85% and with the modest (30%) reduction in disease observed in children 0-4 years of age. They suggest that strategies such as SMC may be less efficacious in areas such as Dangassa where malaria transmission is intense.

### EPIDEMIOLOGICAL TRANSITION OF MALARIA IN GABON: DATA FROM A SENTINEL SITE (MELEN 2010-2016)

**Bertrande Fanny Batchy Ognagosso**, Denise Patricia Mawili-Mboumba, Marielle Karine Bouyou-Akotet

Department of Parasitology-Myology, Libreville, Gabon

Between 2005 and 2008, a decline of malaria prevalence has been observed in Gabon followed by a rebound of the infection rates in 2011. This change in malaria burden related to a slowdown of malaria strategies. Such variation requires a monitoring of malaria prevalence evolution, in order to better define the control strategies. Thus, the aim of the present study was to assess the prevalence of malaria among febrile patients in a sentinel site between 2010 and 2016. Cross-sectional surveys were carried between 2010 and 2016 in a sentinel site for malaria surveillance, located at the Regional Hospital of Estuaire in Gabon. Parasitemia and malaria parasites species were determined. Febrile patients were screened for malaria based on microscopy. Body temperature, history of fever, age, and sex were collected. Any antimalarial drug intake before consultation was also reported. A total of 6,723 febrile patients were enrolled, 58,7% (n=3388) were less than five years. The sex ratio was of 1.08. Overall, 65.4% (n=3821) of the patients used a bed net. Moreover, among patients,

69.9% (n=3744) had a fever that lasted more than 24 hours. History of fever associated to self-medication with anti-malarial drug was found in 50.8% (n=1179) of the study population. The prevalence of malaria was 33.8% (n=2270) essentially at *Plasmodium falciparum* and 33.2% (n=1270) of the patients used bed net was malaria infection. The evolution of malaria prevalence showed 3 phases: the first phase corresponded to the lowest prevalence with 29.4% in 2010 and 27.2% in 2011. The second phase was marked by an increase of malaria between 2012 to 2015 with a peak in 2012 with 40.7% and in 2013 39.6%; 2014 36.3%. During the last phase in 2015 and in 2016 the frequency of malaria infection declined: 32.7% and 33.9% respectively (p<0.01). The present study underlines a variation of malaria prevalence in a sentinel site in Gabon over a period of six years. This data suggest the need of a review of national guidelines of malaria control strategies.

### REGIONAL BURDEN OF MALARIA IN PATIENTS PRESENTING WITH FEBRILE ILLNESS IN KENYAN HOSPITALS

**John N. Waitumbi**<sup>1</sup>, Grace Chebon<sup>2</sup>

<sup>1</sup>KEMRI/WRP Kisumu, Kisumu, Kenya, <sup>2</sup>University of Eldoret, School of Science, Eldoret, Kenya

The prevalence of malaria infection and distribution patterns of *Plasmodium* parasites vary across the country. This can be attributed to varying climatic conditions primarily temperature and rainfall that impact both the rates of sporogonic and mosquito life cycles. This study evaluated the burden of malaria in patients who presented with acute febrile illness at 11 hospitals/clinics in Kenya. A total of 2,522 blood samples were collected and qPCR used for parasite speciation and densities determination. *Plasmodium* parasites were found in 32% (800/2522) of the AFI patients, with the following regional distribution: 38% (397/1038) for hospitals in the Lake Victoria basin, 38% (262/687) for those in Garissa, 28% (29/103) for patients attending Malindi District Hospital and 16% (112/694) for the Kisii District Hospital. In all the surveillance hospitals, about 50% of parasitemias were below the limit of detection by microscopy or RDTs. This number was highest (89%) at the Coast. Unlike in the other surveillance sites, in the Lake Victoria basin, more than 30% of the parasitemias were above pyrogenic threshold (>250,000 parasites/ $\mu$ L). Of the 800 samples with malaria parasites, only 74% (594/800) could be speciated: 73% (434/594) as mono-infections of *P. falciparum*, 7% (42/594) *P. ovale* and 2% (10/594) *P. malariae*. The remaining 18% (108/594) were mixed infections. All the four species of *Plasmodium* were identified at all surveillance sites except *P. malariae* which was not observed in the coastal region. In conclusion, this study identified a huge proportion of individuals with parasitemias below detection limit of microscopy or RDT. In the Lake Victoria basin, over 30% of the parasitemias were above pyrogenic threshold that is associated with increased risk of morbidity and mortality. Efforts are underway to establish why 26% (206/800) of *Plasmodium* positive samples could not be speciated.

### ELUCIDATING THE ROLE OF MOSQUITOES IN DRUG RESISTANT MALARIA EPIDEMIOLOGY

**Hanna Ehrlich**<sup>1</sup>, Martina Wade<sup>1</sup>, Roch Dabire<sup>2</sup>, Benjamin J. Krajacich<sup>3</sup>, Haoues Alout<sup>3</sup>, Brian D. Foy<sup>3</sup>, Sunil Parikh<sup>1</sup>

<sup>1</sup>Yale School of Public Health, New Haven, CT, United States, <sup>2</sup>Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso, <sup>3</sup>Colorado State University, Fort Collins, CO, United States

Molecular surveillance is a critical tool in monitoring drug-resistant malaria, yet little is known about the spread of resistance-mediating polymorphisms through the mosquito vector. In order to gain a more comprehensive understanding of the prevalence and transmission dynamics of drug resistance at the household and village level, this research combines advanced mutation-detection methods with a novel approach: analyzing blood meals in mosquitos that recently fed on humans. Field samples

were obtained over a peak transmission month in eight households in the village of Diarkadougou-East in southwestern Burkina Faso in 2014. Cross-sectional sampling using aspirations of indoor-resting mosquitoes (n=543) was conducted at eleven time points spread over 32 days. Abdominal contents of blood fed mosquitoes were pressed onto 96-well format FTA cards. DNA was extracted and genotyped for clonal diversity using merozoite surface protein-2 (MSP-2), and drug resistance was assessed at 7 parasite polymorphisms in *pfcr1*, *pfmdr1*, *dhps*, and *dhfr*. Thus far, we have analyzed two alleles from the *pfmdr1* gene (N86Y and Y184F) using a ligase detection reaction fluorescence microsphere assay at 4 time points, and MSP-2 genotyping has been conducted using capillary electrophoresis. Notably, over half of collected *Anopheles* blood meals were positive for *Plasmodium falciparum*. Among those samples, there was a high multiplicity of infection (MOI) by MSP-2 genotyping (mean=2.5 strains, range=1-9 per sample) and a high prevalence of resistance-conferring mutations (21% of blood meals contained the 86Y and 73% contained 184F). We plan to examine all time points, and four additional mutations to investigate changes in allele prevalence/frequency over time within a household and within the village. This research will shed light on drug resistance patterns across time and a limited geographic space during peak transmission in a highly endemic region of Burkina Faso.

## 1634

### OVERNIGHT TRAVEL AND THE RISK OF MALARIA: PROSPECTIVE COHORT STUDIES AT 3 SITES IN UGANDA OF VARYING MALARIA TRANSMISSION INTENSITY

**Emmanuel Arinaitwe**<sup>1</sup>, Emmanuel Arinaitwe<sup>2</sup>, Bryan Greenhouse<sup>3</sup>, Moses R. Kanya<sup>4</sup>, Philip J. Rosenthal<sup>3</sup>, Chris Drakeley<sup>2</sup>, Grant Dorsey<sup>3</sup>, Sarah G. Staedke<sup>2</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Department of Medicine, University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda

Although malaria remains highly endemic in most of Uganda, there are areas where transmission is much lower due to urbanization or the implementation of indoor residual spraying of insecticide (IRS). People living in relatively low transmission areas may be at increased risk of malaria following travel. To evaluate associations between overnight travel (a night out of the sub-county of residence) and the incidence of malaria, we conducted cohort studies at 2 sites with relatively low transmission intensity, Walukuba (peri-urban area) and Nagongera (rural area receiving IRS); and 1 site with moderate transmission intensity, Kihhi (rural). All children aged 0.5-10 years and one adult from 100 households per site were enrolled. Data on dates of overnight travel were collected from October 2015 through June 2016. Malaria, defined as fever in the presence of parasites detected by microscopy, was diagnosed using passive surveillance at clinics available full-time to study participants. Any overnight travel was reported in 64 of 273 (23%) study participants in Walukuba, 31 of 313 (10%) in Nagongera, and 22 of 314 (7%) in Kihhi. Considering only participants who reported any overnight travel, we compared the incidence of malaria 1-60 days following overnight travel (recent travel) with that before or >60 days following overnight travel (no recent travel). In Walukuba, recent travel was associated with an almost 5-fold increase in the incidence of malaria (0.80 vs. 0.17 episodes PPY, IRR=4.78, 95% CI 1.70-13.4, p=0.003). In Nagongera, recent travel was associated with an almost 10-fold increase in the incidence of malaria (0.95 vs. 0.10 episodes PPY, IRR=9.85, 95% CI 1.87-51.9, p=0.007). In Kihhi, recent travel was associated with a non-significant 2-fold increase in the incidence of malaria (1.83 vs. 0.79 episodes PPY, IRR=2.05, 95% CI 0.73-5.75, p=0.17). In 2 relatively low transmission areas of Uganda, recent overnight travel was associated with a markedly higher incidence of malaria compared to that in non-travelers. These findings suggest the need for targeted intervention to reduce the risk of malaria during overnight travel.

### LONGITUDINAL SURVEY OF MALARIA BURDEN TO ASSESS THE EFFECTS OF MALARIA CONTROL INTERVENTIONS IN A LOW TRANSMISSION SETTING IN SOUTHERN ZAMBIA

**Mukuma Lubinda**<sup>1</sup>, Ben Katowa<sup>1</sup>, Caison Sing'anga<sup>1</sup>, Japhet Matoba<sup>1</sup>, Jennifer C. Stevenson<sup>2</sup>, Timothy Shields<sup>3</sup>, Clive Shiff<sup>3</sup>, Philip E. Thuma<sup>2</sup>, Bill J. Moss<sup>3</sup>

<sup>1</sup>Macha Research Trust, Choma, Zambia, <sup>2</sup>Johns Hopkins Malaria Research Institute, Baltimore, MD, United States, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Assessment of malaria control interventions is key to guiding future programs to support malaria elimination. Malaria interventions in Southern Province, Zambia, include indoor residual spraying (IRS), insecticide treated net distribution, mass drug administration and a reactive test and treat program. The impact these interventions have had coupled with rainfall on the malaria burden in this area are not well understood. Macha Research Trust in southern Zambia has been using a mobile phone short message service (SMS) surveillance system to transmit weekly malaria cases from 14 rural health centers (RHCs) in the catchment of Macha Mission Hospital, Choma, since 2012. We analyzed this SMS data to assess trends in the burden of malaria and the effect of control efforts across years and health centers. Data showed that malaria transmission in Macha was seasonal with high number of cases after the rainy season (April - July) and low number of cases in the hot dry season (August - October). Inter-annual variation in reported RDT positives was evident, with little change in number of cases in the first year (534 in 2012, test positivity rate (TPR) 7.6% and 517 in 2013, TPR 4.1%), a marked increase in 2014 (957, TPR 8.1%), reductions in 2015 (643, TPR 5.0%), followed by a large spike in 2016 (2318, TPR 12.8%). The high number of cases in both 2016 and 2014 was associated with lower and infrequent rains, hypothesized to support larvae development due to increased and more stable stagnant water. The amount of rainfall received in 2014 was 501 mm and 369 mm in 2016 compared to 750 mm, 640 mm and 578 mm in 2012, 2013 and 2015 respectively. In 2016, three RHCs with catchment areas where IRS was rolled out reported low numbers of malaria cases (52 - 63) compared to (92 - 2318) cases in RHCs without IRS. Malaria transmission in Macha appears to be largely governed by the amount and pattern of rainfall; higher and frequent rainfall of at least four days per week was associated with fewer cases. The Number of malaria cases was lower in RHCs covered by IRS, but further in-depth analysis on this is required. This shows that well timed interventions are key in lessening the malaria burden.

### PREVENTION OF TRANSFUSIONAL MALARIA IN THE STATE OF SAO PAULO BRAZIL

**Silvia M. Di Santi**<sup>1</sup>, Maria Carmen A. Sanchez<sup>1</sup>, Alfredo Mendrone Jr<sup>2</sup>, Giselle F. Lima<sup>1</sup>, Mussya C. Rocha<sup>1</sup>, Maria J. Costa-Nascimento<sup>3</sup>, Mahyumi Fujimori<sup>1</sup>, José E. Levi<sup>1</sup>

<sup>1</sup>São Paulo University, São Paulo, Brazil, <sup>2</sup>Fundação Pro-Sangue Hemocentro de São Paulo, São Paulo, Brazil, <sup>3</sup>Health Secretary Sao Paulo State, São Paulo, Brazil

Malaria is a disease of high morbidity, but the occurrence of asymptomatic carriers with low parasitemias is a challenge for screening of blood donors in endemic and non-endemic areas. This scenario led to the implementation of epidemiological or even laboratory screening in different countries, according to the risk to which they are submitted. In Brazil there is a distinct policy for donating blood in the endemic and non-endemic areas. High-risk donors, coming from endemic areas are rejected for donation for 30 days. From 1-12 months, they are accepted if they test negative for *Plasmodium*. Cases of transfusion malaria in Brazil have been reported in the state of Sao Paulo and the asymptomatic donors were infected in areas considered as non-endemic, where sporadic autochthonous cases are reported. The aim of this study was to evaluate some epidemiological questions that can identify situations of greater

risk of infection, allowing the improvement of the transfusion safety and the screening algorithm, without compromising the bloodstock. Blood samples were collected from 6,324 from candidates that attended Fundação Pró-Sangue/Hemocentro de Sao Paulo. A questionnaire was applied to candidates in order to associate the epidemiological features with laboratorial results. IgG antibodies were surveyed in plasma samples by ELISA using *P. vivax* MSP1-19 recombinant antigen. qPCR *Plasmodium*-genus specific and thick blood smear were carried out. Out of 6,324 donors, 58 (0.9%) were positive for IgG anti-PvMSP1-19. None sample was positive in qPCR or in microscopy. Among the 58 samples positive by serology, 86.2% were from donors with displacements to the Atlantic Forest biome in São Paulo State and/or who live in regions near the Atlantic Forest. Among the 118 candidates living near the Atlantic Forest, 12.7% were positive in ELISA, pointing to the need for using laboratory assays in the screening of donors. The adoption of a questionnaire with specific questions should be applied in areas where the epidemiology of malaria discloses a particular scenario, which do not means less risk for transfusion malaria.

## 1637

### LESSONS FROM TWO DECADES OF MALARIA SURVEILLANCE IN RHODE ISLAND

**Nan Du**<sup>1</sup>, Theresa M. Fiorito<sup>2</sup>, Abby Berns<sup>3</sup>, Ian C. Michelow<sup>2</sup>

<sup>1</sup>Yale-New Haven Hospital, New Haven, CT, United States, <sup>2</sup>Hasbro Children's Hospital, Warren Alpert Medical School at Brown University, Providence, RI, United States, <sup>3</sup>Rhode Island Department of Health, Providence, RI, United States

In the United States, malaria is primarily imported by travelers to endemic areas and immigrants or refugees from those regions. The Centers for Disease Control and Prevention report 1500-2000 cases per year nationally. However, there is a paucity of comprehensive malaria surveillance data at the state level. This study was a retrospective chart review of all patients with a confirmed diagnosis of malaria treated at the two largest academic referral hospitals in Rhode Island from 1997-2015. We identified patients using multiple databases including clinical surveillance software (Theradoc), malaria ICD9/10 discharge codes and cases reported to the RI Department of Health (DOH) and compared trends in annual incidence between these data and RI specific CDC data. There were 192 documented cases of malaria in RI during a 19-year period. None of the available databases was complete with more than 40 patients missing from each one. Of 161 cases with relevant information, 97(51%) were visiting friends or relatives (VFR), 24(13%) were immigrants, 17(9%) were refugees, 18(9%) were business travelers, 10(5%) were tourists, and 6(3%) were related to research/education. 9 individuals had >1 reason for traveling. Most cases were from Sub-Saharan Africa (80%). Appropriate prophylaxis was prescribed in 41 cases (21%) but only 8 patients completed the course. The most common type of malaria was *Plasmodium falciparum* (77%), *P. vivax* (9%), *P. ovale* (3%), *P. malariae* (2%) and 9% were unknown. No mixed infections were reported. 33 (21%) cases required ICU admission. 28(15%) patients had severe manifestations including cerebral malaria (n=18), pulmonary edema (9), and severe anemia (7). No deaths were reported. Almost one-fifth of patients diagnosed with malaria in RI over 2 decades had life-threatening disease requiring intensive care. We identified multiple missed opportunities for malaria prophylaxis, patient education and DOH notification. The public health establishment should address these deficiencies at national and state level to improve malaria prevention and surveillance.

## 1638

### A MALARIA INDICATOR SURVEY IN A MALARIA ELIMINATION AREA OF PHU YEN PROVINCE, COASTAL VIETNAM

**Nicholas J. Martin**<sup>1</sup>, Thuan Huu Vo<sup>2</sup>, Long Tran Khanh<sup>3</sup>, Colin Ohrt<sup>4</sup>, Colin Ohrt<sup>4</sup>, Thang Duc Ngo<sup>5</sup>, Duong Thanh Tran<sup>6</sup>, Sara E. Canavati<sup>7</sup>

<sup>1</sup>Naval Medical Research Center-Asia, Singapore, Singapore, <sup>2</sup>Vysnova Partners Inc., Ha Noi, Vietnam; Faculty of Social Sciences, University of Tampere, Tampere, Finland, Hanoi, Vietnam, <sup>3</sup>Vysnova Partners Inc., Ha Noi, Vietnam; Department of Environmental Health, Ha Noi School of Public Health, Vietnam, Vietnam, <sup>4</sup>Vysnova Partners, Inc., Vietnam, Vietnam, <sup>5</sup>Department of Epidemiology, National Institute of Malariology, Parasitology and Entomology (NIMPE), Vietnam, Vietnam, <sup>6</sup>Department of Epidemiology, National Institute of Malariology, Parasitology and Entomology (NIMPE), Hanoi, Vietnam, <sup>7</sup>Vysnova Partners Inc., Ha Noi, Vietnam; Center for Biomedical Research, Burnet Institute, Melbourne, Australia, Vietnam, Vietnam

Indicators for malaria prevention should reflect the most important interventions for achieving malaria elimination in low endemic areas. We aimed to assess malaria prevention indicators in an elimination setting against Vietnam's malaria elimination strategic targets. We conducted a malaria indicator survey. Census data from 2015 revealed a total of 4668 households among 18 villages in Phu Yen Province. These data were used to select 20% of the households. GPS coordinates were captured where each interview was conducted. Data were collected using a smartphone application (KLL Collect®) and uploaded in real-time into an online database (ONA®). Logistic regression models were used to calculate prevalence odds ratios (PORs) and 95% confidence interval (CI) to assess differences among those who slept in forests and on farms. A total of 4411 people were interviewed, of which 1074 were respondents and 3137 were their members. Among 1074 respondents, 472 slept in forest and 92 slept on a farm, 132 slept both sites, and 378 slept at their villages within last 12 months. Age, gender, literacy, occupation and ethnicity were significantly different among those who slept in forest versus at other sites (p<0.001). Malaria infections were higher among those who reported having slept in the forest (147 [57%]) versus those who slept on a farm (18 [42%]). Ownership and use of all net types among forest-goers was significantly lower than those who reported having slept on a farm or in their village. Huts without walls in the forest were significantly prominent at forest goers' sleeping site (POR=10.3; 95% CI 4.67–22.7). All respondents who slept in a forest requested standby malaria drugs and one-third of them self-treated without blood testing. The proportion of respondents who knew about malaria prevention was 34% (82) without a subjective measure. Data about intervention coverage at the actual transmission site and net preference need to be routinely captured. Targeting preventive interventions where transmission occurs is critical. If malaria elimination is to be achieved, control activities should be scaled up in forest and forest-fringe communities.

1639

### COMMUNITY-BASED SCHEDULED SCREENING AND TREATMENT OF MALARIA DURING PREGNANCY PROVIDES ADDITIONAL PROTECTION AGAINST FEBRILE ILLNESSES DURING THE FIRST YEAR OF LIFE IN A BIRTH COHORT STUDY IN BURKINA FASO

Magloire H. Natama<sup>1</sup>, Eduard Rovira-Vallbona<sup>2</sup>, Hermann Sorgo<sup>1</sup>, Athanase Somé<sup>1</sup>, Maminata Coulibaly-Traoré<sup>1</sup>, Henk Schallig<sup>3</sup>, Umberto D'Alessandro<sup>4</sup>, Luc Kestens<sup>2</sup>, Halidou Tinto<sup>1</sup>, Anna Rosanas-Urgell<sup>2</sup>

<sup>1</sup>Clinical Research Unit of Nanoro, Ouagadougou, Burkina Faso, <sup>2</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>3</sup>Academic Medical Center, Amsterdam, Netherlands, <sup>4</sup>Medical Research Council, Fajara, Gambia

In order to prevent the adverse consequences of malaria in pregnancy (MiP), a community-based scheduled screening and treatment of malaria in combination with intermittent preventive treatment with sulfadoxine-pyrimethamine (CSST+IPTp-SP) has been proposed as potential alternative to the standard IPTp-SP. In this study, we investigated the effect of CSST+IPTp-SP on the risk of malaria and non-malaria fevers (NMFs) during the first year of infant's life. Between June 2014 and October 2016, a birth cohort study (n=734) was conducted in Nanoro, a high seasonal malaria transmission area in Burkina Faso. Clinical malaria episodes were recorded by passive case detection from birth until 12 months of age. In addition, 4 cross-sectional surveys were carried out at 3, 6, 9 and 12 months to detect asymptomatic infections. Multivariate models were used to assess the effect of CSST+IPTp-SP strategy on time to first clinical malaria episode, incidence of malaria episodes, asymptomatic infections and incidence of all NMFs. The overall incidence of clinical malaria was 1.03 episode per child/year whereas incidence of all NMFs was 1.18 episode per child/year. Prevalence of asymptomatic malaria was 17.7% (120/678), 20.1% (127/631), 18.4% (108/587) and 30.9% (200/648) at 3, 6, 9 and 12 months, respectively. Compared to the standard IPTp-SP, the CSST+IPTp-SP strategy significantly increased time from birth to the first clinical malaria episode amongst infants born during malaria low transmission season (HR=0.74, 95% CI= 0.55-0.99, P= 0.047), and reduced the incidence of NMFs in infants born during malaria high transmission season (adjusted IRR= 0.80, 95%CI= 0.65-0.98, P= 0.036). In addition, CSST+IPTp-SP strategy tends to increase chance of having an asymptomatic infection that did not develop into a clinical episode (adjusted RRR= 1.61, 95%CI= 0.93-2.77, P=0.087). Our findings indicate that MiP preventive treatments may provide additional protection against both malaria and NMFs for infants during the first year of life.

1640

### HOST AGE AND PLASMODIUM FALCIPARUM MULTICLONALITY ARE ASSOCIATED WITH GAMETOCYTE PREVALENCE: A 1-YEAR LONGITUDINAL COHORT STUDY

Yaw Adomako-Ankomah<sup>1</sup>, Matthew Chenoweth<sup>1</sup>, Aaron Tocker<sup>1</sup>, Saibou Doumbia<sup>2</sup>, Drissa Konate<sup>2</sup>, Mory Doumbia<sup>2</sup>, Abdoul Keita<sup>2</sup>, Jennifer M. Anderson<sup>1</sup>, Rick M. Fairhurst<sup>1</sup>, Kazutoyo Miura<sup>1</sup>, Mahamadou Diakite<sup>1</sup>, Carole A. Long<sup>1</sup>

<sup>1</sup>National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Malaria Research and Training Centre, Faculty of Medicine, Pharmacy and Odontostomatology, University of Bamako, Bamako, Mali

Since *P. falciparum* (Pf) transmission from humans to mosquitoes relies exclusively on gametocyte infection of mosquitoes, several malaria transmission control strategies aim to disrupt this step of the life cycle. Thus, a better understanding of which individuals constitute the primary gametocyte reservoir within an endemic population, and the temporal dynamics of gametocyte carriage, especially in seasonal transmission settings, will not only support the effective implementation of current transmission control programs but also inform the design of more targeted strategies. From June 2013, we conducted a 1-year longitudinal cohort

study to assess the year-long dynamics of Pf gametocyte carriage in Kenieroba, a village with intense seasonal malaria transmission in Mali. We recruited a cohort of 500 individuals ranging 1-65 years in age, measured gametocyte prevalence every month for 1 year using Pfs25-specific qRT-PCR, and analyzed the effects of host age and multiclonality of Pf infection on gametocyte prevalence for 1 year. During this period, most Pf infections in this population were accompanied by gametocytemia (51-89% of Pf-positive individuals). We observed no effect of seasonality (wet vs. dry) on gametocyte prevalence among Pf carriers, while gametocyte prevalence was significantly affected by age (P = 0.023). Although gametocyte prevalence among >30-year-old Pf carriers appeared relatively lower than in younger age groups, a multiple comparison test detected no statistically significant difference between age groups. Interestingly, we found that Pf infections with gametocytemia had higher multiclonality than Pf infections without gametocytemia. Taken together, our results demonstrate that transmission control programs should target a relatively large section of this population in order to significantly impact transmission. Furthermore, our results indicate that the occurrence of multiple Pf genotypes in an infection, a common feature of Pf infections in high transmission areas, is associated with gametocyte prevalence.

### SCALING IRRIGATION AND MALARIA RISK IN MALAWI

April Frake<sup>1</sup>, Joseph Messina<sup>1</sup>, Edward D. Walker<sup>1</sup>, Leo Zulu<sup>1</sup>, Charles Mangani<sup>2</sup>, Wezi Mkwaila<sup>3</sup>, Grivin Chipula<sup>3</sup>, Terrie E. Taylor<sup>1</sup>, Themba Mzilahowa<sup>2</sup>, Don Mathanga<sup>2</sup>

<sup>1</sup>Michigan State University, East Lansing, MI, United States, <sup>2</sup>University of Malawi, Blantyre, Malawi, <sup>3</sup>Lilongwe University of Agriculture and Natural Resources, Lilongwe, Malawi

Irrigation systems are expanding across Africa to improve food security, particularly given the changing climate and fragility of food security systems. While the expansion of irrigated agriculture has demonstrated a 2-4-fold boost in crop productivity, the agrarian transformation of the landscape for irrigated agriculture is associated with increasing malaria vulnerability for those residing within close proximity to irrigated agricultural schemes. We present a critical examination of the dynamic changes in irrigated agriculture on malaria vulnerability across Malawi. Malawi is a small-holder agrarian society; the government of Malawi established a major program, the Green Belt Initiative (GBI), a long-term program aimed at land use modifications for the development of extensive small and large-scale irrigation. Through the GBI, nearly 1 million hectares of land have been offered to local and international investors for irrigated agriculture. Yet, while Malawians continue to face challenges directly related to food insecurity, the country is simultaneously holoendemic for falciparum malaria. Using the Bwanje Valley Irrigation Scheme as a case study, this work critically examines the impact of spatial structure on malaria risk across scales. Through a combination of time-series remotely sensed land cover data, the proposed GBI sites, and historical malaria prevalence data from the Demographic Health Survey, these spatial relationships offer predictive power for hypothesizing mosquito vulnerability, exposure risk, and malaria transmission driven by irrigated agriculture across Malawi.

### CONFIRMATION OF MALARIA DIAGNOSIS IN AFRICAN COUNTRIES WITH THE HIGHEST BURDEN

José L. Segura<sup>1</sup>, Luis Benavente<sup>2</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States

The increased access to an accurate diagnosis of malaria improves the quality of care, and ensures a rational use of antimalarial medicines. In early 2010, WHO recommended that every suspected malaria case be confirmed by microscopy or a rapid diagnostic test (RDT) prior to treatment. Also since 2010 the World Malaria Report (WMR) 2010

includes the reported number of cases positive for microscopy and/or RDT positive. In order to assess the reported compliance of countries with this policy, we have extracted from the Annex 4H of the WMR 2016 the number of cases, cases confirmed by microscopy and cases confirmed by RDT in 2000, 2005, 2010 and 2015 of those 13 countries which reported 80% of those approximately 129 million malaria cases of 2015 reported by the WHO-Africa Region. Unfortunately, as in previous years, the WMR 16 does not identify the number of cases which were confirmed by both microscopy and RDT; having observed that for these countries and during the years indicated: a) the percentage of cases confirmed by microscopy was never higher than 13%, and b) the sum of cases confirmed by both methods is never higher than the total of cases reported, in this report we will use "confirmed" as the addition of those confirmed for each method. In the countries included in the analysis, the percentage of cases confirmed with respect to the total reported was 1, 9, 16 and 66% in the years 2000, 2005, 2010 and 201, evidencing a remarkable increase in the access to lab confirmation since the WHO policy was set. However inter-annual increases higher than 50% in 2014 and 2015 were observed in six countries which in some cases coincided with a decrease in the total number of cases reported, raising concerns about the inclusion of those cases not confirmed in the country reports. We plan to collect additional information from these countries to assess if changes in the national strategies, availability of resources and projections of the total number of cases, to assess the reliability of the data reported in the WMR.

## 1643

### FIRST TO BED, LAST TO BE BITTEN

**Caroline J. Stephenson**<sup>1</sup>, Matthew E. Rossheim<sup>1</sup>, Cara L. Frankenfeld<sup>1</sup>, Jaques Boncy<sup>2</sup>, Bernard O. Okech<sup>3</sup>, Michael E. von Fricken<sup>1</sup>

<sup>1</sup>George Mason University, Fairfax, VA, United States, <sup>2</sup>Laboratoire National de Santé Publique, Port au Prince, Haiti, <sup>3</sup>University of Florida, Gainesville, FL, United States

The governments of Haiti and the Dominican Republic have a binational agreement to work towards the elimination of malaria on the island of Hispaniola by the year 2020. This study aims to examine individual behaviors, like ITN ownership and time to bed, matched with malaria seroconversion status. In 2013, cross-section survey data ( $n = 377$ ) were collected in community, clinic and school settings from the Ouest and Sud-Est departments of Haiti. Descriptive statistics of survey responses were presented with sample sizes and frequencies. A logistic regression model was constructed to examine associations between bed-time and malaria, as measured by Apical Membrane Antigen (AMA-1) and Merozoite Surface Protein (MSP-1) AMA and MSP antibodies. The majority of survey participants (87%) knew that mosquitoes transmit malaria and owned bed nets (68%). Approximately half of the sample (47.5%) used in-home insecticides. The most common sources of malaria-related education came from clinics, the radio or school. After adjusting for city location, socioeconomic status indicators, age and knowledge of someone with malaria, individuals who indicated going to bed between 18:00-20:00 were 80% less likely to have been exposed to malaria than those who went to bed after 22:00 (OR = 0.20, 95% CI: 0.07-0.52), which is in line with suspected feeding behaviors of *Anopheles albimanus*. The reported frequencies of malaria-related knowledge and behaviors in these departments can be used as a reference point for comparison in future studies or interventions in these departments. This study adds to the limited research on the impact of mosquito biting behavior in Haiti and its link to malaria exposure based on bed time. Future research is needed to investigate vector competence and feeding behavior of *A. albimanus*, to better understand peak biting hours and host seeking preferences.

## 1644

### IMPACT OF MASS NET DISTRIBUTIONS ON MALARIA PREVALENCE, ANEMIA AND INTERVENTION COVERAGE IN ABIA AND PLATEAU STATES, NIGERIA

Elizabeth Heilmann<sup>1</sup>, **Gregory S. Noland**<sup>2</sup>, Adamu Sallau<sup>3</sup>, Joseph Ajiji<sup>4</sup>, Chris Bewa<sup>5</sup>, Abel Eigege<sup>3</sup>, Franklin Orji<sup>6</sup>, Emmanuel Emukah<sup>7</sup>, James Damen<sup>8</sup>, Kenrick Nwodo<sup>3</sup>, Bulus Mancha<sup>3</sup>, Solomon Adelamo<sup>3</sup>, Emily Griswold<sup>2</sup>, Emmanuel Miri<sup>3</sup>, Patricia M. Graves<sup>9</sup>, Frank O. Richards<sup>2</sup>

<sup>1</sup>Emory Rollins School of Public Health, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>The Carter Center, Jos, Nigeria, <sup>4</sup>Plateau State Ministry of Health, Jos, Nigeria, <sup>5</sup>Roll Back Malaria, Jos, Nigeria, <sup>6</sup>Abia State Ministry of Health, Umuahia, Nigeria, <sup>7</sup>The Carter Center, Owerri, Nigeria, <sup>8</sup>University of Jos, Jos, Nigeria, <sup>9</sup>James Cook University, Cairns, Australia

Nigeria accounts for more than 25% of malaria cases globally. As part of the National Plan for malaria elimination, mass distribution of free long-lasting insecticidal nets (LLINs) began in 2009. Abia state, in South East zone, distributed 710,530 nets in 2012; Plateau state, in North Central zone, distributed 1.5 million nets in 2010 and 2.1 million in 2015. Modified malaria indicator surveys were conducted in 2010 (pre-distribution) and September 2015 to assess the impact of mass net distribution on malaria and anemia prevalence. At least 955 households and 4297 individuals per state were sampled in each survey. LLIN ownership increased significantly in both states between 2010 and 2015: the proportion of households owning at least 1 net rose from 10.1% to 58.7% in Abia ( $p < 0.001$ ) and from 35.1% to 85.5% in Plateau ( $p < 0.001$ ). Full net access (1 net/2 persons) also increased in Abia from 1.4% in 2010 to 37.3% in 2015 ( $p < 0.001$ ) and in Plateau from 6.3% to 50.0% ( $p < 0.001$ ). Despite those increases, coverage in both states was less than the national target of 80%. Reported net use the previous night in all individuals increased significantly in Abia from 3.4% to 24.2% ( $p < 0.001$ ) and in Plateau from 14.7% to 65.6% ( $p < 0.001$ ). Net use in children under 5 and pregnant women was 3-4 times higher in 2015 compared to 2010, but failed to reach the 80% goal in either state. Age-adjusted microscopy-diagnosed *Plasmodium* prevalence significantly decreased in Abia from 36.1% (95% CI: 32.3-40.1) in 2010 to 26.4% (95% CI: 20.1-31.5) in 2015. In Plateau, a non-significant increase from 36.6% (95% CI: 31.3-42.3) to 43.4% (95% CI: 39.9-46.9) occurred. Over the same period, anemia in children 10 years and younger also significantly declined in Abia from 74.7% (95% CI: 72.1-81.0) to 58.3% (95% CI: 53.9-62.6), with a non-significant reduction observed in Plateau from 57.1% (95% CI: 50.6-63.4) to 52.5% (95% CI: 44.6-60.2). In summary, significant gains in net coverage and use occurred in both states, with reductions in *Plasmodium* and anemia prevalence observed in Abia, but not Plateau. Additional measures are needed to ensure intervention coverage meets national targets.

## 1645

### GEOGRAPHIC TRENDS IN IDENTITY BY DESCENT BETWEEN MALARIA PARASITE POPULATIONS

**Aimee R. Taylor**<sup>1</sup>, Diego F. Echeverry<sup>2</sup>, Stephen F. Schaffner<sup>3</sup>, Gustavo C. Cerqueira<sup>3</sup>, Standwell C. Nkhoma<sup>4</sup>, Timothy J. Anderson<sup>4</sup>, Kanlaya Sriprawat<sup>5</sup>, Aung Pyae Phyo<sup>5</sup>, François H. Nosten<sup>5</sup>, Daniel E. Neafsey<sup>3</sup>, Caroline O. Buckee<sup>1</sup>

<sup>1</sup>Harvard T. H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>International Center for Medical Research and Training, Cali, Colombia, <sup>3</sup>Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States, <sup>4</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>5</sup>Shoklo Malaria Research Unit, Mae Sot, Thailand

Molecular data are increasingly used to track routes and volumes of disease transmission. However, methods sensitive to recent and local migration events relevant to many disease elimination programs are

lacking for sexually recombining organisms such as the *P. falciparum* malaria parasite. Using data from four clinics on the Thai-Myanmar border, we demonstrated the ability of relatedness based on identity by descent to resolve recent connectivity between proximal *P. falciparum* populations, while traditional metrics ( $F_{ST}$ ) show no such relationship. Here we evaluate this approach using an independent dataset from Colombia. Preliminary results based on data from four states on the Colombian coast, sampled over 8 years, show a decrease of 0.01 in the log odds of relatedness with every kilometer and week between samples, but only when one population is excluded from the analysis. We explored factors influencing the nonconformity of the excluded population, including temporal breadth of sample collection and greater proximity to the international border, and discuss considerations involved in making inferences of population connectivity from empirical genetic data. We believe that this approach has enormous promise for resolving transmission dynamics in natural parasite populations that can be further improved using human behavioral data extracted from travel surveys or mobile phone records.

## 1646

### OPTIMIZING APPROACHES TO GENERATE WHOLE-GENOME SEQUENCE FROM NON-LEUKOCYTE DEPLETED *PLASMODIUM FALCIPARUM* CLINICAL SAMPLES

Zalak Shah<sup>1</sup>, Matthew Adams<sup>1</sup>, Kara Moser<sup>2</sup>, Miriam K. Laufer<sup>1</sup>, Joana C. Silva<sup>2</sup>, Shannon Takala Harrison<sup>1</sup>

<sup>1</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States

With the advancement in high-throughput sequencing technologies, genomics is contributing to progress in understanding the evolution of drug resistance, the dynamics of disease transmission, and the rational design of malaria vaccines. However, obtaining whole genome sequence data from clinical samples is one of the major hurdles in the field of malaria genomics. In order to obtain whole genome sequence data from non-leukocyte depleted blood and dried blood spots, we optimized approaches to generate high-quality, whole genome sequence data from *P. falciparum* clinical samples with low amounts of DNA, including approaches to degrade the host DNA, selectively amplify the parasite genome, and perform whole-genome capture. We used *MspII* to degrade human host DNA, and selective whole-genome amplification to amplify the parasite DNA. Our initial results show that *MspII* is inefficient as it degrades human as well as parasite DNA. We also show that selective whole-genome amplification efficiently amplifies only the parasite DNA in the presence and absence of human DNA contamination. Also, optimizing this approach by diluting and filtering the DNA before amplification greatly enhances the amplification process, suggesting that inhibitors from the extraction could be interfering with the amplification. Indeed, we observed that diluting and filtering the DNA before amplification improves the percent of the parasite genome covered for a range of different parasitemias from 500 parasites/ $\mu$ L to 10,000 parasites/ $\mu$ L, and in non-leukocyte-depleted samples, based on initial results. We are currently exploring the use of whole-genome capture methods to generate sequence data from samples in which the proportion of host DNA makes direct sequencing prohibitively costly. These approaches will help overcome one of the major challenges in the field of *Plasmodium falciparum* genomics and may lessen the need to leukocyte deplete samples in the field.

## 1647

### NEW *PLASMODIUM FALCIPARUM* GENOME ASSEMBLIES FROM DIVERSE ENDEMIC REGIONS ENABLES THE COMPREHENSIVE GENOMIC AND GENETIC CHARACTERIZATION OF CLINICAL ISOLATES

Kara A. Moser<sup>1</sup>, Ankit Dwivedi<sup>1</sup>, Emily M. Stucke<sup>2</sup>, Gurmanna Kalra<sup>1</sup>, Sergey Koren<sup>3</sup>, Adam Phillippy<sup>3</sup>, Mathew Adams<sup>2</sup>, Amed Ouattara<sup>2</sup>, Elliott F. Drabek<sup>1</sup>, Drissa Coulibaly<sup>4</sup>, Ogobara K. Doumbo<sup>4</sup>, Mahamadou A. Thera<sup>4</sup>, Myaing M. Nyunt<sup>2</sup>, Miriam K. Silva<sup>1</sup>

<sup>1</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>National Human Genome Research Institute, Bethesda, MD, United States, <sup>4</sup>Malaria Research and Training Center, University of Science, Techniques and Technologies, Bamako, Mali, <sup>5</sup>Oxford University, Oxford, United Kingdom

The *Plasmodium falciparum* 3D7 genome is the only high quality reference assembly available to the research community to guide genetic and genomic studies. The characterization of other strains is based on the identification of sequence variants relative to 3D7, and both the gene and genome structure of 3D7 are viewed as representative of the species. The lack of other reference assemblies makes it difficult to describe structural variants that occur in natural *P. falciparum* populations, and may result in the underestimation of genetic diversity in highly polymorphic genomic regions obtained through read mapping-based approaches. Similarly, read mapping approaches are also poor at characterizing members of extremely diverse multi-gene families, which are particularly important in immune evasion and malaria clinical outcomes. We have recently generated whole genome sequence data for 23 *P. falciparum* strains from Brazil, Mali, Guinea, Malawi, Myanmar, Laos, and Cambodia using a combination of Pacific Biosciences and Illumina sequencing technologies. We used the Canu assembler to generate assemblies, and then polished with Quiver and Pilon. The Canu assemblies, which consisted on average of 25 contigs each, are much less fragmented than those generated with the HGAP assembler (50 contigs per assembly). These new assemblies will allow a more thorough documentation of genome structural variation among *P. falciparum* strains, and provide new allelic references for genes that have been difficult to assemble with short-read data, such as members of multi-gene families and genes with long repetitive regions. For example, we found that the internal repetitive region in liver stage antigen 1 (LSA-1) is incorrectly collapsed in the 3D7 reference genome. Initial results also show that mapping reads from isolates collected outside of West Africa to an assembly of similar geographic origin results in a more comprehensive characterization of sequence variants than mapping to 3D7, particularly for isolates from South East Asia, exposing the limitations of SNP calling methodologies that rely only on 3D7 for characterization of clinical isolates.

## 1648

### TARGETED DE NOVO ASSEMBLY OF VAR2CSA FROM CLINICAL SAMPLES USING SHORT READ WHOLE GENOME SEQUENCE DATA

Antoine Dara, Mark A. Travassos, Miriam K. Laufer, Christopher V. Plowe, Joana C. Silva

University of Maryland Baltimore, Baltimore, MD, United States

The *Plasmodium falciparum* erythrocyte membrane protein 1 (PfEMP1) family of proteins, which are expressed on the surface of infected erythrocytes, has a central role in malaria pathogenesis. VAR2CSA, a member of this family, is a key ligand that mediates the sequestration of the infected erythrocytes in the placenta, leading to maternal and fetal

complications of malaria during pregnancy. The VAR2CSA protein is an antigen and a leading vaccine candidate for placental malaria. Although it is a desirable vaccine candidate, the major roadblock in the development of VAR2CSA-based vaccines is the genetic variation of the locus encoding this antigen. Despite extensive sequencing efforts, full-length *var2csa* sequence data are very sparse. In this study, we took advantage of a few existing full-length sequences, previously generated by us and others, to serve as a reference database to recruit *var2csa*-like short paired-end reads based on sequence identify. These sequence reads and their mate pairs were then used to target-assemble *var2csa* using the SPAdes assembler. Using this approach we were able to reconstruct 78 full-length *var2csa* exon 1 sequences, encoding the entire extracellular region of the protein, from 130 Illumina whole genome sequence datasets. Analysis of these sequences shows that the protein region containing the receptor-binding site is highly variable, whereas two C-terminal domains, namely DBLepam4 and DBLepam5, were significantly more conserved among geographically distant parasites, highlighting the potential for these domains to be considered in the composition of VAR2CSA-based vaccines. This pipeline is useful for the assembly of *var2csa* using Illumina short read sequence data. The pipeline also has the potential to perform targeted assembly of other *var* genes from clinical isolates, as additional reference alleles for those *loci* are obtained that can be used to recruit reads. The ability to sequence and target-assemble *var2csa* will enable the design of a diversity-covering pregnancy malaria vaccine.

## 1649

### WHOLE GENOME SEQUENCE CAPTURE TO GENERATE HIGH QUALITY GENOMIC DATA FOR *PLASMODIUM VIVAX* FROM CLINICAL ISOLATES

Sonia Agrawal<sup>1</sup>, Fang Huang<sup>1</sup>, Biraj Shrestha<sup>1</sup>, Matthew Adams<sup>1</sup>, Sandra Ott<sup>2</sup>, Lisa Sadzewicz<sup>2</sup>, Hui Liu<sup>3</sup>, David Serre<sup>1</sup>, Shannon Takala-Harrison<sup>1</sup>, Christopher V. Plowe<sup>4</sup>, Myaing M. Nyunt<sup>1</sup>, Joana C. Silva<sup>2</sup>

<sup>1</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Yunnan Institute of Parasitic Diseases, Pu'er, China, <sup>4</sup>Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

*Plasmodium vivax* malaria has been refractory to malaria elimination efforts along the China-Myanmar border. Better understanding of the genomic epidemiology of *P. vivax* could inform these efforts by helping to identify sources and sinks of transmission and distinguish local from imported cases. The usefulness of direct whole genome sequencing (WGS) of clinical isolates is limited by its inability to generate high-quality genome-wide data from infections with low parasite densities and very high content of human DNA. We adapted the Roche-NimbleGen SeqCap EZ whole genome sequence capture method to leukocyte-depleted venous blood samples from 14 patients with RDT-confirmed acute *P. vivax* infection on the China-Myanmar border. Capture probes were designed based on the *P. vivax* Sal I reference genome. The genomic DNA library was sequenced with and without capture, and using Illumina HiSeq and MiSeq platforms, to compare the quality, breadth and depth of genome coverage, and the suitability of the data for genome assembly. Preliminary results show that the whole genome capture method was highly effective in capturing extremely low quantities of parasite DNA from a small amount of total DNA (1.41 µg). Leukocyte depletion eliminated most human DNA, resulting in 89.31% of the pre-capture reads being parasite origin. However, the capture method produced nearly complete enrichment with 98% of parasite DNA post-capture mapping to *P. vivax* reference genome. The breadth of genome coverage was 95%, similar pre- and post-capture, demonstrating that the specificity in this capture approach did not compromise sensitivity. With >99% of *P. vivax* coding regions recovered, this novel whole genome sequence capture application dramatically improves our ability to generate *P. vivax* WGS data from clinical samples, especially if shown to be similarly successful in non-leukocyte depleted

samples. This will empower studies of *P. vivax* genetic diversity, population structure and parasite migration patterns, potentially leading to new tools and approaches for malaria elimination in low transmission and pre-elimination settings.

## 1650

### IMPACT OF THE G6PD DEFICIENCY ON THE PREVALENCE OF MALARIA INFECTION IN SICKLE CELL PATIENTS UNDER 15 YEARS OLD LIVING IN BURKINA FASO

Edith C. Bougouma, Alphonse Ouedraogo, Alfred B. Tiono, Sodiomon B. Sirima

Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso

Sickle Cell Disease SCD and Glucose -6-Phosphate Dehydrogenase (G6PD) confer protection against malaria. Their association would better protect against malaria. In Burkina Faso, the prevalence of these genetic abnormalities varies between 8 and 10%. This study aims to describe malaria morbidity in subjects living with sickle cell and deficit of G6PD. A cross-sectional survey was conducted in children of 6 months to 14 years, at the end of the malaria transmission season to collect malariometric parameters. A review of the medical history of affected children was done to collect sickle cell crisis and the number of blood transfusions during the last 6 months. A total of 120 subjects was enrolled, 12 subjects with G6PD plus SCD and 108 subjects with SCD only. The prevalence of malaria infection was lower in the SCD group (0%) than G6PD plus SCD group (6.5%) ( $p < 0.0001$ ). The prevalence of clinical malaria in subjects presented fever was respectively 91.7% (11/12) in SCD group and 8.3% (1/12) SCD plus G6PD group ( $p < 0.0001$ ). Mean haemoglobin level was 9.61 g/dl (IC95% [9, 33-9, 9]) vs 9,11 g/dl (IC95% [8, 10-9, 25]). The number of subject who had at least one sickle cell crisis during the last 6 months was lower in both groups. Only one subject of the SCD group had blood transfusion during the study period. The burden of malaria seems higher in the groups of subject with SCD compared to the group with SCD and G6PD. The risk of hemolysis associated with these genetic deficiencies necessitates early diagnosis of these genetic factors, for adequate care.

## 1651

### DIFFERENCE IN EXPRESSION AND POLYMORPHISM OF GENE ENCODING FOR THE RECEPTOR FOR ADVANCED GLYCATION ENDPRODUCTS (RAGE) IN FULANI AND DOGON IN MALI

Karim Traore<sup>1</sup>, Mahamadou Ali Thera<sup>1</sup>, Ogobara K. Doumbo<sup>1</sup>, Stephane Picot<sup>2</sup>

<sup>1</sup>Malaria Research and Training Center, Université des Sciences, des Techniques et des Technologies de Bamako, MRTCI/USTTB, Bamako, Mali, <sup>2</sup>Malaria Research Unit, Institut de Chimie et Biochimie Moléculaire et Supramoléculaire, ICBMS-UMR5246, Universities Claude Bernard Lyon 1, Lyon, France

Difference of susceptibility to malaria has been documented by several studies in Fulani and Dogon living in sympatric in malaria endemic area of Mali, with different lifestyles and diet habits. The complex interactions between environment, diet, lifestyle and the modulation of the host's immune responses constitute a research area of great interest in elucidating this phenomenon. The role of the immune system dysfunction induced by nutrients-derived metabolites and the polymorphism of gene encoding for the cellular receptors for AGEs (RAGE) in susceptibility to bacterial infection is already described. But no study has yet explored their role in susceptibility to malaria. This study aimed to investigate the expression and polymorphism of RAGE gene in two sympatric populations with known difference of susceptibility to malaria. We determined by real-time quantitative PCR the expression of RAGE, and the -374 T/A and -429 T/C polymorphisms by fragment length restriction polymorphism (FLRP) in 44 Dogon and 35 Fulani. The blood samples used were collected by cross-sectional survey. RAGE was more expressed in Dogon than Fulani (0.08 vs 0.04),  $P=0.08$ . The -374A polymorphism was more frequent in Fulani

(32%) compared to Dogon (20%). These results showed that the -374A polymorphism was more frequent in naturally resistant Fulani population to malaria while RAGE gene was more expressed in Dogon susceptible to malaria. These differences were not statistically significant. The chronic exposure to dietary advanced glycation endproducts could lead to immune responses impairment and/or polymorphism with implications in malaria susceptibility. But more powerful studies are necessary to better investigate this hypothesis.

## 1652

### CHARACTERIZING *PLASMODIUM FALCIPARUM* GAMETOCYTE GENE EXPRESSION IN A COHORT OF ASYMPTOMATICALLY-INFECTED ADULTS IN WESTERN KENYA

Deborah Stiffler<sup>1</sup>, Carolyne Kifude<sup>2</sup>, Claire Wortmann<sup>1</sup>, David Rockabrand<sup>1</sup>, Priya Venkatesan<sup>1</sup>, John Waitumbi<sup>2</sup>, Shirley Luckhart<sup>3</sup>, Janet Oyieko<sup>2</sup>, V. Ann Stewart<sup>1</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>U.S. Army Medical Research Directorate, USAMRD-Kenya, Kisumu, Kenya, <sup>3</sup>University of Idaho, Moscow, ID, United States

We hypothesize that co-infection with HIV-1 and *Plasmodium falciparum* is associated with an increase in the burden of malaria transmission due to increased gametocyte carriage. Gametocyte carriage in asymptomatic individuals varies over time, and gametocytemia is not routinely quantified during microscopic examination of blood, further complicating attempts to enumerate the prevalence of gametocyte carriage in a given population. To gain a better understanding of gametocyte prevalence, we are developing and validating a multiplex quantitative PCR (qPCR) assay to quantify expression of a panel of genes that are expressed throughout the processes of gametocytogenesis and gametocyte development. Molecular techniques such as qPCR are much more sensitive and specific than microscopy, and a multiplex approach allows simultaneous quantifying of several markers, which reduces the amount of time and volume of sample needed for analysis. As part of the assay validation process, we will quantify gametocyte expression in cultured *P. falciparum* parasites over time to evaluate kinetics. We will also explore the variation in gametocyte production between various lab strains of *P. falciparum*. After the assay has been fully validated, it will be used to quantify gametocyte carriage in a cross-sectional study of HIV-1 and malaria prevalence in asymptomatic persons in Kisumu, Kenya. Specifically, we are looking at the overall prevalence of gametocyte carriage and the relationship between HIV co-infection and gametocytemia. Ultimately, a better understanding of the contributions of HIV to malaria transmission will help focus elimination and eradication strategies to reduce gametocyte burden in populations with disproportionately high transmission potential.

## 1653

### DEVELOPMENT OF TOOLS TO VALIDATE *PLASMODIUM FALCIPARUM* GENOME ASSEMBLIES GENERATED WITH PACBIO DATA

Ankit Dwivedi<sup>1</sup>, Kara A. Moser<sup>1</sup>, Gurmanna Kalra<sup>1</sup>, Christopher V. Plowe<sup>2</sup>, Joana C. Silva<sup>1</sup>

<sup>1</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Malaria is one of the most widespread parasitic diseases in the world. It has been eliminated from major developed countries, but is still highly prevalent in over 100 others, albeit with different transmission intensities. *Plasmodium falciparum* malaria alone is responsible for over 400,000 deaths each year. The *P. falciparum* 3D7 genome is used as the reference for genetic and genomic studies. Studies based on *P. falciparum* whole genome sequence data have revealed important characteristics of the

genome, facilitating drug and vaccine development. All new strains, regardless of geographic origin, are characterized with respect to the 3D7 genome. Varying transmission rates and extent of migration among endemic regions contribute to different levels of genetic diversity within, as well as to genetic differentiation among, parasite populations. Relying on only one reference genome for the genetic characterization of different populations may bias the estimation of strain genetic composition and population diversity, potentially hindering the efforts to identify the genetic basis of drug resistance and the development of vaccines with regional relevance. We recently generated de novo genome assemblies for 23 *P. falciparum* strains from Brazil, Guinea, Mali, Malawi, Myanmar, Laos and Cambodia using long-read PacBio sequence data. In order for these assemblies to serve as the reference, against which strains from the same region are characterized, it is important that their accuracy be validated, to ensure that PacBio sequencing errors have been properly corrected and that no structural errors were introduced during assembly. Initial comparative analyses of genome assemblies from strains originating from West Africa, Brazil and Southeast Asia revealed considerable differences between them and the 3D7 reference genome, in both gene and genome structure. We have developed a pipeline to identify and validate these differences with respect to the 3D7 genome. We use as controls the recently published PacBio-based 3D7 genome assembly, as well as the PacBio assembly we generated for NF54, the parental isolate from which 3D7 was cloned.

### GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM* IN ASYMPTOMATIC AND SYMPTOMATIC CHILDREN IN AN ENDEMIC MALARIA AREA IN BURKINA FASO

Aissatou Diawara<sup>1</sup>, Mame Massar Dieng<sup>1</sup>, Aboubacar S Coulibaly<sup>2</sup>, Amidou Diarra<sup>3</sup>, Vinu Manikandan<sup>1</sup>, Sharon Qiu<sup>1</sup>, Alfred B Tiono<sup>2</sup>, Sirima Sodiomon<sup>2</sup>, Issiaka Soulama<sup>2</sup>, Youssef Idaghdour<sup>1</sup>

<sup>1</sup>New York University Abu Dhabi, Abu Dhabi, United Arab Emirates, <sup>2</sup>Centre National de Recherche et de Formation sur le Paludisme (CNRFP), Ouagadougou, Burkina Faso, <sup>3</sup>New York University Abu Dhabi Centre National de Recherche et de Formation sur le Paludisme (CNRFP), Ouagadougou, Burkina Faso

In areas of high malaria transmission, it is common that infected individuals with *Plasmodium* harbor more than one genetically different parasite. Differences in the multiplicity of infection between asymptomatic and symptomatic individuals infected with *Plasmodium* in the same endemic areas have been reported and multiplicity of infection has been associated with protection against symptomatic malaria. Here, we characterized *Plasmodium falciparum* diversity in a pediatric cohort from Burkina Faso during asymptomatic and symptomatic malaria using Illumina high-throughput sequencing. Hundred fifty children from two malaria-endemic villages of Banfora health district were sampled between May and December over two consecutive years (2015 and 2016). Blood samples were collected before infection as well as during asymptomatic and symptomatic infection and genome-wide host and *P. falciparum* DNA and RNA profiles generated. Bioinformatic analysis of RNASeq data was used to generate a catalogue of genetic variants that are used for strain and clone characterization and population genetic analysis of *P. falciparum* in Burkina Faso. Using this approach, we quantified the diversity of *P. falciparum* within and between individuals during the course of infection and report the results of association tests between host phenotypes and parasite genetic variation.

## 1655

### GENETIC VARIATION IN INTERLEUKIN (IL)-3 AND IL-7 ARE ASSOCIATED WITH ALTERED ERYTHROPOIETIC RESPONSES IN CHILDREN WITH MALARIAL ANEMIA IN SIAYA, KENYA

Lily E. Kisia<sup>1</sup>, Prakasha Kempaiah<sup>2</sup>, Elly O. Munde<sup>1</sup>, Angela O. Achieng<sup>2</sup>, Evans Raballah<sup>1</sup>, John M. Ong'echa<sup>1</sup>, Kiprotich Chelimo<sup>3</sup>, Douglas J. Perkins<sup>2</sup>

<sup>1</sup>University of New Mexico/KEMRI Laboratories, Kisumu, Kenya, <sup>2</sup>University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>3</sup>Department of Biomedical Sciences and Technology, Maseno, Kenya

Severe malarial anemia (SMA, Hb  $\leq$ 5.0 g/dL) is a leading cause of morbidity and mortality in children with malaria. Using genome wide association studies (n=144, age 3-36 months) and transcriptomics (n=72), we have identified several genes associated with SMA, including interleukin (IL)-3 and 7. Expression levels for both genes were non-significantly reduced in children with SMA. Since the role of IL-3 and IL-7 in malarial anemia has not been reported, we selected genetic markers in these genes based on an allelic distribution (>10%), and determined their association with clinical outcomes in children with malarial anemia (n=1,082, age, 3-36 months). IL-3 is important for promoting erythroid development and regulating immunity, while IL-7 is involved in the function of T cells, NK cells and monocytes. The association between SMA and reduced erythropoiesis [reticulocyte production index (RPI), <2.0] were examined for markers in IL-3 (36608A/G, rs 247011; -4651A/G, rs3091336 and -8181A/G, rs246752) and IL-7 (72194C/T, rs 2583759 and -2440 A/G, rs 7007634). Although there were significantly different distributions of the IL-3 GGG haplotype (-4651G, -8181G and 36608G,  $P=0.044$ ) and the IL-7 GT haplotype (-2440G/72194T,  $P=0.030$ ), logistic regression analysis controlling for covariates of anemia, did not reveal any significant associations with SMA for either the genotypes or haplotypes. However, additional analyses revealed that the IL-3 GGG and AGA haplotypes were associated with inefficient erythropoiesis (OR=2.83, 95%CI: 1.46-5.50,  $P=0.002$  and OR=5.36, 95%CI: 1.91-15.01,  $P=0.001$ , respectively), while the IL-7 AC haplotype was protective against inefficient erythropoiesis (OR=0.54, 95%CI: 0.30-0.97,  $P=0.042$ ). Measurement of circulating IL-7 levels showed that IL-7 was significantly lower in children with SMA compared to those with non-SMA ( $P=0.002$ ). IL-3 levels are currently being determined. Taken together, results presented here suggest that the IL-3 and IL-7 variants selected for measurement are associated with altered erythropoiesis, but do not appear to have as strong of impact on susceptibility to SMA.

### TRANSCRIPTIONAL PROFILING AND GENE CO-EXPRESSION NETWORK ANALYSIS IN MALARIA PARASITE IMPROVES UNDERSTANDING OF K13 MECHANISM IN ARTEMISININ RESISTANCE

Kaitlynn Meis<sup>1</sup>, Katrina Button-Simons<sup>1</sup>, Min Zhang<sup>2</sup>, John H. Adams<sup>2</sup>, Michael T. Ferdig<sup>1</sup>

Malaria mortality has decreased substantially over the last 15 years due to widespread use of the key drug for treating malaria, artemisinin, but these gains are threatened by the emergence of resistance in Southeast Asia. If artemisinin resistance in *Plasmodium falciparum* spreads to Africa, as was observed for previous anti-malarial drugs, malaria deaths will increase considerably. A precise understanding of the resistance mechanism is urgently needed to forestall the potential collapse of current control efforts that rely on the efficacy of artemisinin. SNPs in Pf3D7\_1343700 (K13) have been associated with artemisinin resistance, but a detailed molecular understanding of the mechanism of resistance remains elusive. Gene co-expression network analysis can refine the molecular level understandings of complex phenotypes; in malaria parasites, transcriptional profiling of

*pfprt* and *pfmdr* mutants revealed insights about chloroquine resistance. To elucidate K13 function and its role in artemisinin resistance, we transcriptionally profiled seven piggyBac (pB) transposon mutants that clustered with a K13 pB mutant based on highly related chemogenomic signatures. These mutants, along with the isogenic background line, NF54, were profiled for transcripts across the erythrocytic cell cycle every 4 hours. Differentially expressed genes were identified and were further analyzed via gene set enrichment analysis to determine the pathways most affected by each transposon insertion. In addition, gene co-expression networks were constructed and analyzed for all of the pB lines and NF54 to identify alterations in the gene co-expression network. Our results indicate that the combination of transcriptional profiling and network analysis can provide key insights into K13's function and role in artemisinin resistance. Further refinement of these genes and interactions has the potential to point to optimal drug partners that could counteract resistance and restore artemisinin efficacy.

### VARIATION IN THE CD40 PROMOTER IS ASSOCIATED WITH SUSCEPTIBILITY TO PLASMODIUM FALCIPARUM-INDUCED SEVERE MALARIA ANEMIA IN KENYAN CHILDREN

Elly O. Munde<sup>1</sup>, Angela O. Achieng<sup>1</sup>, Lily E. Kisia<sup>2</sup>, Evans O. Raballah<sup>2</sup>, Prakasha Kempaiah<sup>1</sup>, John M. Ong'echa<sup>2</sup>, Collins Ouma<sup>3</sup>, Douglas J. Perkins<sup>4</sup>

<sup>1</sup>University of New Mexico School of Medicine, Albuquerque, NM, United States, <sup>2</sup>University of New Mexico/KEMRI Laboratories, Kisumu, Kenya, <sup>3</sup>Department of Biomedical Sciences and Technology, Maseno, Kenya, <sup>4</sup>University of New Mexico Health Sciences Center, Albuquerque, NM, United States

The etiological basis of pediatric severe malaria anemia (SMA, Hb<5.0g/dL and any density parasitemia) is a multifactorial process. An important element in the pathogenesis of SMA is genetic susceptibility factors in immune response genes. Our global genomic association studies in a subset of children with malarial anemia identified a candidate gene, cluster of differentiation 40 (CD40) that is expressed on both immune and non-immune cells, and has been shown to enhance immunoglobulin G (IgG) class-switching, generation of B-lymphocytes, hyper-mutation, and stimulation of inflammatory responses: processes that may represent signatures of SMA. Based on the important role of CD40 in immunity, we explored genetic polymorphisms in a larger population and determined the association between variation and downstream inflammatory mediators, i.e., IL-12 and IL-17. Three polymorphic variants: [(-1C>T rs1883832, -173C>T rs752118, and -508G>A; rs1800686) were genotyped in children (n=1,118, aged 6-36mos.)] with malaria from Siaya County, western Kenya, a *P. falciparum* holoendemic transmission area. CD40 genotypes were determined using Taqman® allelic discriminations assays and inflammatory mediators were measured using the Hu Cytokine 25-plex Ab Bead Kit. Bivariate regression analysis, controlling for confounders of anemia, revealed that the CCG haplotype (CD40-1C/-173C/-508G) was associated with protection against SMA (OR 0.31, 95%CI 0.14-0.67,  $P=0.003$ ), while the TCG haplotype (CD40-1T/-173C/-508G) was associated with enhanced risk of SMA (OR; 5.24, 95% CI; 3.31-8.82,  $P<0.001$ ). Additional analysis revealed that carriage of TCG haplotype was associated with elevated levels of IL-12 ( $P=0.001$ ) and lower levels of IL-17 ( $P=0.011$ ). These results demonstrate that variation in the CD40 promoter are associated with susceptibility to SMA, and appear to influence levels of circulating IL-12 and IL-17 during *P. falciparum* infection.

Malaria is a complex infectious disease with many genetic and environmental determinants influencing host immune response to infection, the progression of the disease and its severity. To date, surveys of host transcriptional responses were used largely on cross-sectional study designs. Here we investigate several layers of biological variation in both host and parasite including whole genome sequence variation, methylation profiles and transcriptomic data from a pediatric cohort in Burkina Faso. We focus on studying the temporal dynamics of peripheral blood transcription response to *Plasmodium falciparum* infection. We investigate how infection status modulates gene expression of the host and document the nature, magnitude and significance of transcriptional changes taking place during the course of infection. Integrated genotype, gene expression analysis allowed quantification of the contribution of host genotype to response to infection. The study provides a high-resolution picture of temporal transcriptional changes in a highly malaria-endemic region.

## 1659

### GENE CO-EXPRESSION NETWORK ANALYSIS OF MALARIA PARASITE TRANSCRIPTION REFINES POTENTIAL GENE INTERACTION UNDERLYING ARTEMISININ RESISTANCE

**Katrina A. Button-Simons**, Sage Z. Davis, Michael T. Ferdig  
Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States

Malaria infects 212 million people annually and results in 429,000 deaths, primarily in children under age five. Since 2000, significant progress has been made in controlling malaria, with mortality decreasing by 62%. Spread of artemisinin resistance to Africa would have devastating consequences for malaria control. K13 has been identified as a major determinant of artemisinin resistance, however a detailed molecular understanding of K13 function and its role in the resistance mechanism remains to be defined. A clearer understanding of artemisinin resistance could indicate novel partner drugs to prolong artemisinin efficacy. Network analysis can account for gene interactions and refined views of molecular mechanisms underlying complex phenotypes. In a previous study, we used gene co-expression (transcript) networks that distinguish chloroquine resistant and sensitive progeny from a genetic cross to generate a detailed hypothesis of *pfcr* function in chloroquine resistance. Here, we apply network methods to publicly available high resolution transcriptional datasets for parasites from Southeast Asia examine the modular context of K13 and its network neighbors in both resistant and susceptible parasites. We find that K13 'wiring' relationships show differences between artemisinin resistant parasites: in sensitive parasites, the K13 module is enriched for cell cycle progression and homeostasis genes, while in resistant parasites, in addition to homeostasis, K13 expression partners are enriched for protein folding, lipid biosynthesis and metabolism, response to heat, response to stress and response to stimulus. This network analysis relies on network modules to extend our ability to predict the molecular mechanism of artemisinin resistance beyond standard differential expression analysis.

### LEUKOCYTE-ASSOCIATED IMMUNOGLOBULIN LIKE RECEPTORS 1 (LAIR1) AND 2 (LAIR2) EXPRESSION AND POLYMORPHIC VARIATION IN CHILDREN WITH SEVERE MALARIAL ANEMIA FROM WESTERN KENYA

**Angela O. Achieng**<sup>1</sup>, Prakasha Kempaiah<sup>1</sup>, Elly O. Munde<sup>1</sup>, Elizabeth Glenn<sup>1</sup>, Caroline Ndege<sup>1</sup>, Evans Raballah<sup>2</sup>, Qiuying Cheng<sup>1</sup>, Bernard Guyah<sup>3</sup>, Douglas J. Perkins<sup>1</sup>

<sup>1</sup>University of New Mexico School of Medicine, Albuquerque, NM, United States, <sup>2</sup>University of New Mexico/KEMRI Laboratories, Kisumu, Kenya, <sup>3</sup>Department of Biomedical Sciences and Technology, Maseno University, Maseno, Kenya

Severe malarial anemia (SMA) [hemoglobin (Hb) <5.0 g/dL, with any density parasitemia] is a multifactorial complication of malaria and is common in children residing in *Plasmodium falciparum* holoendemic areas. To investigate SMA pathogenesis, we conducted a genome-wide association study (GWAS, n=144, 3-36 months) and whole genome transcriptome profiling in a subset of individuals (n=72) from Western Kenya. These investigations revealed an association between SMA and leukocyte-associated immunoglobulin like receptor (LAIR) genes. Both LAIR1 and LAIR2 are pleiotropic inhibitory receptors important in the prevention of autoimmunity. To validate our initial studies, selected markers in LAIR1 (rs2287827 A/G; rs11084333 A/G, rs6509867 C/A) and LAIR2 (rs6509880 C/T, rs4806767C/T) were measured in our larger cohort (n=1,259; age 3-36 months). Subsequent validation expression assays (TaqMan®) and inflammatory mediator analysis (Hu Cytokine 25-plex Ab Bead Kit) were also performed. Bivariate logistic regression analysis controlling for confounding factors of anemia showed that heterozygous LAIR1 (rs2287827 GA) was associated with protection against SMA (OR=0.657, 95%CI: 0.449-0.962, P=0.031), whereas the mutant LAIR2 (rs4806767 TT) increased susceptibility to SMA (OR=1.89, 95%CI: 0.977-3.66, P=0.059). Associations were also observed between carriage of intragenic and intergenic LAIR haplotypes and SMA: LAIR1 AGC (OR=2.32, 95%CI: 0.99-5.42, P=0.052), LAIR2 CC (OR=1.62, 95%CI: 1.02-2.56, P=0.039), and LAIR1/2 AAAC (OR=0.296, 95%CI: 0.093-0.944, P=0.040). In addition, carriage of LAIR2 CC haplotype was associated with increased RANTES levels (P=0.05), while the LAIR1/2 AAAC haplotype was associated with reduced levels of interleukin (IL)-1β (P=0.034) and IL-8 (P=0.025). TaqMan® LAIR expression analysis confirmed LAIR1 downregulation (-5.0 fold, P=0.017) and LAIR2 upregulation (+2.3 fold, P=0.59) in children with SMA. Findings here demonstrate that genetic variation in LAIR1/2 and altered LAIR gene expression are associated with susceptibility to SMA and immune dysregulation.

### ASSESSING COMPLEXITY OF PLASMODIUM FALCIPARUM INFECTION IN TWO ECOLOGICAL ZONES IN GHANA USING MOLECULAR INVERSION PROBES AND NEXT GENERATION SEQUENCING

**Benedicta Ayiedu Mensah**<sup>1</sup>, Benjamin Abuaku<sup>1</sup>, James Myers-Hansen<sup>1</sup>, Jeffrey Bailey<sup>2</sup>, Ozkan Aydemir<sup>2</sup>, Nicholas Hathaway<sup>2</sup>, Patrick Marsh<sup>2</sup>, Anita Ghansah<sup>1</sup>

<sup>1</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>2</sup>University of Massachusetts Medical School, Worcester, MA, United States

Genetic diversity of the *plasmodium* parasite is the driving factor in the evolution of drug resistance and also affects immune regulation. Complexity of infections (COI) is also important in vaccine efficacy monitoring. Standard methods like PCR and RFLP underestimate the estimation of COI. In order to totally eliminate malaria, it is important to understand the diversity of the parasite in the population and thus a need to develop robust methods to accurately estimate complexity of infection. Children aged between 6 months to 14 years presenting with *Plasmodium falciparum* mono-infection at hospitals in two ecological zones in Ghana

were included in the study. Genetic diversity of a highly polymorphic region of Ama-1 was investigated from dried blood blot samples obtained from 500 children using the molecular inversion probes followed by next-generation sequencing (NGS). Oligonucleotide probes were designed to capture sections of the AMA1 gene and targeted regions amplified using barcoded primers. The amplicons were then sequenced using MiSeq. SeekDeep pipeline was used to analyze the sequence data to estimate haplotypes diversity and frequency. A total of 307 and 190 of samples were analyzed for AMA1 diversity and complexity of infection (COI) respectively. The most variable region of AMA1 had a total of 103 distinct haplotypes. The forest ecological zone had 61 distinct haplotypes while the coastal savanna had 78 haplotypes. The complexity of infection (COI) ranges from 1 to 7 in the forest zone and 1 to 8 in the coastal savanna zone. There was no statistical difference in the mean COI for both sites (COI= 1.56, 1.64 for Begoro and Cape Coast respectively, P value=0.692). The targeted amplicon sequencing using MIP shows higher COI values, which has not been captured before in these sites in Ghana and high number of distinct haplotypes of the vaccine candidate gene AMA1. This method would be beneficial in the search for resistance and monitoring vaccine efficacy.

## 1662

### CAS-9 BASED SEQUENCING ENRICHMENT FOR MALARIA GENOTYPING

**Alison Kuchta**<sup>1</sup>, Emily Crawford<sup>1</sup>, Jenai Quan<sup>1</sup>, Jordan Wilhelm<sup>1</sup>, Maxwell Murphy<sup>1</sup>, Sofonias K. Tessema<sup>1</sup>, Joe Derisi<sup>2</sup>, Bryan Greenhouse<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States,

<sup>2</sup>Chan Zuckerberg Biohub, San Francisco, CA, United States

DNA polymorphisms in *Plasmodium falciparum*, including single nucleotide polymorphisms, microsatellite lengths, and structural variations, can be used to track transmission and drug resistance patterns. Whole genome sequencing produces large amounts of data, most of which does not provide relevant information, whereas targeted genotyping via PCR can be laborious and difficult to multiplex. Here we describe a method for isolation and enrichment of an arbitrary number of genomic regions of interest for Next Generation Sequencing (NGS) based on targeted Cas9 enrichment of multiple regions of interest called FLASH: Finding Low Abundance Sequences by Hybridization. Cas9-based targeting strategies have been successfully used to enhance pathogen detection in patient samples such as cerebral spinal fluid. Here we optimize and apply a related method to selectively enrich for targeted regions of high genetic diversity in *P. falciparum* from dried blood spot samples. This method enables detection of polymorphisms including short range haplotypes and structural variations, allowing for highly multiplexed rapid and reliable sequencing of specific regions of interest. Preliminary results demonstrate significant enrichment of target *P. falciparum* sequences from dried blood spot samples, especially when combined with selective whole genome amplification. Updated results will be presented at the meeting. This method offers the promise of rapid generation acquisition of NGS data from interchangeable sets of target regions from malaria field samples.

## 1663

### ACCURATE ASSEMBLY OF REGIONS OF COMPLEX DIVERSITY IN *PLASMODIUM FALCIPARUM* FROM SHOTGUN GENOME SEQUENCING AND ASSESSMENT OF STRAIN SPECIFIC IMMUNITY--TOWARDS OPTIMAL FORMULATION OF POLYVALENT VACCINES

**Nicholas J. Hathaway**<sup>1</sup>, James Kazura<sup>2</sup>, Ann M. Moormann<sup>1</sup>, John Vulule<sup>3</sup>, Jonathan J. Juliano<sup>1</sup>, Jeffrey A. Bailey<sup>1</sup>

<sup>1</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Kenya Medical Research Institute, Busia, Kenya

A conundrum of malaria vaccine design is that key proteins targeted by the adaptive immune response often display a high level of variation driven by selection for the ability to escape a previous immune response. It can be difficult to determine the extent of variant specific immunity or what key variants to incorporate into polyvalent vaccines. Whole genome sequencing can aid in this but one challenge to standard approaches using reference based mapping is accurately capturing the proper extent of variation. To overcome this, we have developed a novel graph-based program that uses local de novo assembly to infer long haplotypes (300-1800bp) at a region of interest. It accurately assembles highly complex regions of diversity and structural variation including repetitive regions in mixed infections. We used this algorithm to assess available *P. falciparum* whole genome sequence to determine the extent of geographic dispersion of variation within genes focusing on vaccine candidates including Circumsporozoite Surface Antigen (CSP), Apical Membrane Antigen 1 (AMA1), and Pfs48/45. We observe striking patterns of variation within these genes including strong signals of frequency dependent selection. Interestingly, the RTS,S vaccine, based on the African parasite 3D7, represents a CSP haplotype that has minimal similarity to Asian haplotypes, thus underscoring potential challenges for deploying the vaccine worldwide. A second challenge in developing polyvalent vaccines is determining the impact that a singular epitope or epitope combinations imparts to strain specificity. Traditionally this requires laborious immunologic studies to map antibody reactivity to specific variant epitopes. Leveraging targeted high-throughput sequencing, we examined serial infections within large cohorts posited on the fact that strain specific immunity will impart a decreased probability of repeat infection and/or clinical disease. Combined these methods provided improved delineation of vaccine targets and identification of key epitopes within target antigens.

## 1664

### IDENTIFICATION OF PFEMP1 EPITOPES ASSOCIATED WITH SEVERE MALARIA USING A DIVERSITY-COVERING ULTRADENSE PEPTIDE MICROARRAY

When probed with carefully chosen serum samples, an ultra-dense peptide microarray offers the potential to identify epitopes critical for natural protection against malaria. *Plasmodium falciparum* erythrocyte membrane protein-1 (PfEMP1) antigens, which are encoded by 40 to 60 *var* genes per genome, play an important role in parasite sequestration

and host immune evasion and possess extraordinary genetic diversity. Acquired antimalarial immunity is at least partially due to antibodies directed against highly variable antigens like PfEMP1. We designed a pilot PfEMP1 peptide array to identify PfEMP1 epitopes that may underlie this antibody-mediated protection. Ninety-five thousand 16-amino acid (aa) peptides were synthesized *in situ* on an array, spanning the complete *var* repertoires of the reference genome 3D7, the Indochina strain DD2, and an Indian isolate, RAJ116, as well as three PfEMP1s from the Indian isolate IGH-CR14. In total, 151 PfEMP1s were included with 12 aa overlap, with representation of all described PfEMP1 domain cassettes. We probed this array with sera from 20 children aged 1-6 years old and 10 adults from rural Mali. For all PfEMP1 repertoires, adult sera consistently recognized more PfEMP1 peptides than pediatric sera. Peptides from PfEMP1s of Asian origin were just as likely to be recognized by Malian sera as peptides from 3D7 PfEMP1s. Adult sera reacted more intensely than pediatric sera (defined as a ratio of geometric means of the fluorescence intensities of the two groups > 5.0) to less than 10 percent of these serorecognized peptides. For Domain Cassettes 8 and 13, which have previously been associated with severe malaria, we identified a subset of serorecognized peptides. Adult sera reacted more intensely to a small minority of these peptides versus pediatric sera, with most such peptides belonging to Duffy binding-like domains, not the neighboring cysteine-rich interdomain regions. With sera from severe malaria case-control studies, this approach will facilitate further targeting of specific PfEMP1 regions to identify epitopes critical to natural immunity to severe malaria and thus inform vaccine design.

## 1665

### PHAGOCYTTIC EFFICIENCY OF BEADS COATED WITH VARIOUS MALARIAL PFEMP1 DOMAINS BY MONOCYTES/MACROPHAGES DEPENDS ON THE DOMAIN IDENTITY AND/OR BINDING AVIDITY TO MONOCYTE SURFACE RECEPTORS

Jordan B. Merritt<sup>1</sup>, Justin Gullingsrud<sup>2</sup>, Andrew Oleinikov<sup>1</sup>

<sup>1</sup>Florida Atlantic University, Boca Raton, FL, United States, <sup>2</sup>Seattle Biomedical Research Institute, Seattle, WA, United States

Mortalities from *Plasmodium falciparum* infection can be attributed to the ability of infected erythrocytes (IEs) to sequester to endothelium of blood vessels, uninfected erythrocytes, and cells of the immune system. Sequestration leads to blood flow problems, local and systemic immune response, and prolonged malarial infections. Sequestration is mediated by the interaction between specific PfEMP1 domains presented on the surface of IEs and endothelial cell receptors, including CD36 and ICAM-1. The receptors implicated in sequestration of IEs to endothelial cells can also be found on the surface of innate immune cells. However, the consequences of PfEMP1-immune cell receptor interactions are not well understood. Using microscopy and flow cytometry, we have demonstrated that human macrophages isolated from PBMC and THP-1 cell line monocytes phagocytize 5µm polystyrene beads (similar in size to IEs) coated with CD36-binding PfEMP1 CIDR1 domains more efficiently (up to 30%) than beads coated with irrelevant control protein. Moreover, domains with the highest (PF08\_0106) and lowest (PFD1015c) CD36 affinity had the highest and lowest phagocytic efficiency, respectively. Using THP-1 we have confirmed that interaction with CD36 receptor is important for phagocytosis, as pre-incubation of bead-immobilized PF08\_0106-CIDR1 with soluble CD36 reduces phagocytic efficiency. Similarly, in another experiment with bead-immobilized ICAM1-binding domain, we have demonstrated that the phagocytic efficiency was 58%, which was reduced by competition with soluble ICAM1 to 35%. These experiments indicate that PfEMP1 domain sequence identity and/or level of receptor avidity might be an important factor for phagocytic efficiency and will shed light on the mechanisms utilized by innate immune cells for parasite clearance.

## 1666

### MOTHER TO FETAL TRANSFER OF NATURALLY OCCURRING PLASMODIUM FALCIPARUM ANTIBODIES

Edward E. Essuman<sup>1</sup>, Nitin Verma<sup>1</sup>, Isabella A. Quakyi<sup>2</sup>, Julius N. Fobil<sup>2</sup>, Miranda Oakley<sup>1</sup>, Sanjai Kumar<sup>1</sup>

<sup>1</sup>U.S. Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>School of Public Health, UG, Legon, Ghana

Maternal antibodies transferred from mother to child are thought to confer protection against malaria during the early months after birth. We have investigated the effectiveness of the transfer of naturally occurring IgG antibodies against *Plasmodium falciparum* antigens in cord blood from mothers living in an endemic area in the Greater Accra region in Ghana. Paired maternal cord serum samples (n=160; aged 18 years and older) were screened by Enzyme Linked Immunosorbent Assay against pre-erythrocytic *P. falciparum* Circumsporozoite (PfCSP), asexual blood stage Pf Apical Membrane Antigen (PfAMA-1), Pf Merozoite Surface Protein 10 (PfMSP-10), and sexual stage Pfg24, a novel Pf gametocyte antigen recently identified in our laboratory. These antigens were expressed as recombinant proteins in *E. coli*. The magnitude of the mean ± standard deviation of the antibody levels in descending order is as follows: PfAMA-1 (Mother: 1.32±0.76, Infant: 1.17±0.63), PfMSP-10 (Mother: 1.33±0.68, Infant: 1.13±0.63), PfCSP (Mother: 0.71±0.59, Infant: 0.45±0.55) and Pfg24 (Mother: 0.83±0.54, Infant: 0.43±0.40). Importantly, we found a strong correlation in antibody transfer from mother to child (Pearson moment correlation [range]: PfCSP (0.66[0.52 - 0.77]), PfAMA-1 (0.77[0.66 - 0.84]), PfMSP-10 (0.82[0.74 - 0.88]), and Pfg24 (0.73[0.61 - 0.82])). Rapid Detection Test, based on the HRP-2 and LDH combination and performed at the time of birth, showed the absence of parasitemia in the infants. These results establish that in areas of high transmission, at birth, infants possess the same level of antibody-mediated immunity as the mother which may form the basis of immunity against malaria during the first months after birth. IgG isotype analysis is currently being performed on paired maternal cord serum samples to determine whether certain isotypes are preferentially transferred from mother to child.

## 1667

### REDUCED HSP70 AND GLUTAMINE IN PEDIATRIC SEVERE MALARIA ANEMIA: ROLE OF HEMOZOIN IN SUPPRESSING HSP70 AND NF-KB ACTIVATION

Prakasha Kempaiah<sup>1</sup>, Karol Dokladny<sup>1</sup>, Zachary Karim<sup>1</sup>, Evans Raballah<sup>2</sup>, Angela O. Achieng<sup>1</sup>, John M. Ong'echa<sup>2</sup>, Pope L. Moseley<sup>3</sup>, Christophe G. Lambert<sup>1</sup>, Douglas J. Perkins<sup>1</sup>

<sup>1</sup>University of New Mexico School of Medicine, Albuquerque, NM, United States, <sup>2</sup>University of New Mexico/KEMRI Laboratories, Kisumu, Kenya, <sup>3</sup>University of Arkansas for Medical Sciences, Arkansas, AR, United States

Severe malarial anemia [SMA, hemoglobin (Hb) <5.0 g/dL] is a leading cause of global morbidity and mortality among children residing in *Plasmodium falciparum* transmission regions. Our exploration of molecular pathways through genome-wide studies (GWAS) and transcriptomics revealed that SMA is characterized by polymorphic variation in heat shock protein (Hsp) 70 with decreased gene expression. Since the role of host Hsp70 in malaria pathogenesis is unexplored, we investigated Hsp70 and its molecular pathways in children with SMA. Generation of functional pathway networks using significant signatures from GWA and transcriptomics identified the Hsp70/TLR immune pathway as highly significant. Hsp70 is a ubiquitous chaperone that regulates Nuclear Factor-kappa B (NF-κB) signaling and production of pro-inflammatory cytokines known to be important in malaria pathogenesis (e.g., IL-1β, IL-6 and TNF-α). RT-qPCR experiments revealed that leukocytic *HSP70* transcripts were reduced in SMA relative to non-severe malaria, and intraleukocytic *P. falciparum*-derived hemozoin (Pfhz) was associated with lower *HSP70* transcripts. *HSP70* also correlated positively with reticulocyte production and Hb. *In-vitro* studies using PBMCs demonstrated that phagocytosis of hemozoin (Pfhz) causes activation of NF-κB, down-regulation of

Hsp70 expression, and dysregulation in inflammatory mediators known to influence suppression of erythropoiesis. Since glutamine (Gln) can up-regulate Hsp70 and decrease NF- $\kappa$ B activation, circulating Gln was measured in children with malaria. Reduced Gln was associated with an increased risk of developing SMA. In addition, Gln treatment of PBMCs overcame PfHz-induced suppression of HSP70 transcripts/protein, reduced NF- $\kappa$ B activation, and suppressed over-expression of cytokines. Overall findings here demonstrate that SMA is characterized by reduced intraleukocytic HSP70 and circulating Gln, and that PfHz-induced suppression of HSP70 can be reversed by Gln. Thus, Gln supplementation may offer important immunotherapeutic options for future studies in children with SMA.

### CD4 T-CELL EXPRESSION OF IFN- $\gamma$ AND IL-17 IN PEDIATRIC MALARIAL ANEMIA

**Evans Raballah<sup>1</sup>**, Prakasha Kempaiah<sup>2</sup>, Zachary Karim<sup>2</sup>, George O. Orinda<sup>3</sup>, Michael F. Otieno<sup>4</sup>, Douglas J. Perkins<sup>2</sup>, John M. Ong'echa<sup>1</sup>

<sup>1</sup>University of New Mexico/KEMRI Laboratories, Kisumu, Kenya, <sup>2</sup>University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>3</sup>Department of Biochemistry and Biotechnology, Nairobi, Kenya, <sup>4</sup>Department of Medical Laboratory Sciences, Nairobi, Kenya

In *Plasmodium falciparum* holoendemic transmission regions of western Kenya, life-threatening pediatric malaria manifests primarily as severe malarial anemia (SMA, Hb $\leq$ 6.0 g/dL with any density parasitemia). To determine the role that CD4+ T-cell-driven inflammatory responses have in the pathogenesis of SMA, peripheral CD4+ T-cell populations and their intracellular production of pro-inflammatory cytokines (IFN- $\gamma$  and IL-17) were characterized in children aged 12-36 months of age stratified into two groups: non-severe malarial anemia (non-SMA, Hb $\geq$ 6.0 g/dL, n=50) and SMA (n=39). In addition, circulating IFN- $\gamma$  and IL-17 were measured as part of a Cytokine 25-plex Antibody Bead Kit, Human (BioSource™ International). SMA group had higher overall proportions of circulating lymphocytes (P=0.003) and elevated proportions of lymphocytes expressing IFN- $\gamma$  (P=0.014) and comparable IL-17 (P=0.101). In addition, SMA was characterized by decreased memory-like T-cells (CD4+CD45RA-) expressing IL-17 (P=0.009) and lower mean fluorescence intensity in memory-like CD4+ T-cells for both IFN- $\gamma$  (P=0.063) and IL-17 (P=0.006). Circulating concentrations of IFN- $\gamma$  were higher in children with SMA (P=0.009), while IL-17 levels were comparable between the groups (P=0.164). Furthermore, circulating levels of IFN- $\gamma$  were negatively correlated with IL-17 levels in both groups of children (SMA: r=-0.610, P=0.007; and non-SMA: r=-0.516, P=0.001), while production of both cytokines by lymphocytes were positively correlated (SMA: r=0.349, P=0.037; and non-SMA: r=0.475, P=0.001). Taken together, these results suggest that enhanced severity of malarial anemia is associated with higher overall levels of circulating lymphocytes, enhanced intracellular production of IFN- $\gamma$  by peripheral lymphocytes and high circulating IFN- $\gamma$  levels. The observed inverse relationship between the circulating levels of IFN- $\gamma$  and IL-17, with the reduction in levels of memory-like CD4+ T cells expressing IL-17 in SMA group may suggest possible relocation of these cells in the deeper tissues for their pathological effect.

## 1669

### AUTOANTIBODIES IN MALARIA AND SYSTEMIC LUPUS ERYTHEMATOSUS

**Arlene E. Dent<sup>1</sup>**, Huw Davies<sup>2</sup>, Aarti Jain<sup>2</sup>, Philip Felgner<sup>2</sup>, Peter O. Sumba<sup>3</sup>, Susan Malkiel<sup>4</sup>, Betty Diamond<sup>4</sup>, Elena Hsieh<sup>5</sup>, James Kazura<sup>1</sup>

<sup>1</sup>Case University, Cleveland, OH, United States, <sup>2</sup>University of California Irvine, Irvine, CA, United States, <sup>3</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>The Feinstein Institute for Medical Research, Manhasset, NY, United States, <sup>5</sup>University of Colorado, Colorado, CO, United States

It has long been established that people residing in malaria endemic regions have elevated levels of autoantibodies, but lower incidence of autoimmune diseases such as systemic lupus erythematosus (SLE). Autoantibodies in SLE fluctuate with disease activity and directly cause pathology such as lupus nephritis. Malaria induced autoantibodies are speculated to have a role in malaria pathogenesis, but it is unclear if the targets of malaria vs. SLE induced autoantibodies differ. Using a protein microarray platform containing 701 human genes encompassing known targets of autoantibodies, we tested plasma from healthy Kenyan adults (n=34) and children (n=38, ages 1-10years) residing in a malaria endemic area of western Kenya, plasma from US healthy adults (n=16), and plasma from US children with SLE at multiple times in their disease course (n=11 patients). We found that the greatest breadth of antigen recognition was by Kenyan adults followed by Kenyan children and US children with SLE, with US adults having the lowest recognition of human autoantibody targets. The top targets recognized by children with SLE were several SNRPs (small nuclear ribonucleoprotein polypeptides) which are diagnostic for SLE. In Kenyan adults and children, however, the top targets were several myosin light chains, RNA polymerase, insulin-like growth factor binding protein, and a membrane transport protein. Ongoing microarray analysis will compare Kenyan adult vs child targets and Kenyan children vs. US children with SLE. Additionally, preliminary studies indicated that Kenyans have a moderate frequency of B cells specific for human DNA compared to healthy controls (low) and patients with SLE (high). However, DNA-specific B cells may have a differential pattern of distribution in B cell subsets in Kenyans vs patients with SLE. These results show that the autoantibody profiles are different between healthy Kenyans and children with SLE. Further analysis will add to our knowledge of the overlap between malaria and SLE induced autoantibodies and the biological significance of autoantibodies to human malaria pathogenesis.

## 1670

### T FOLLICULAR HELPER CELL SUBSETS AND MEMORY B CELL FUNCTION IN PAPUA NEW GUINEAN CHILDREN WITH SYMPTOMATIC MALARIA AND FEBRILE NON-MALARIA ILLNESS

**Grace E. Weber<sup>1</sup>**, Paula Embury<sup>1</sup>, Rich Fong<sup>1</sup>, Leanne Robinson<sup>2</sup>, Henson Dima<sup>2</sup>, Mary Salib<sup>2</sup>, Daisy Mantila<sup>2</sup>, Thomson Kalaila<sup>2</sup>, Christopher L. King<sup>1</sup>, James Kazura<sup>1</sup>, Arlene Dent<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea

The mechanisms underlying the development of acquired immunity to *Plasmodium falciparum* (Pf) malaria are not fully understood. Repeated exposure to Pf is required before protection from clinical disease develops, implying that B cell memory develops slowly and is incomplete. We examined memory B cell (MBC) recall responses and related T follicular helper cell (Tfh) subset distributions in Papua New Guinean (PNG) children with uncomplicated Pf malaria and compared these data to matching samples obtained at convalescence 9-12 weeks after treatment. MBC recall responses were evaluated by ELISPOT to quantify antibody secreting cells (ASC) following polyclonal stimulation of peripheral blood mononuclear cells. The distribution of MBC subsets and CD3+CD4+CD45RO+CXCR5+ Tfh1, 2 and 17 subsets was estimated by flow cytometry. The number of ASC observed during acute malaria was significantly less than at convalescence (respective average ASCs per 5000 plated cells 56.8 and 121.9, p=0.0018). The frequencies of MBC and quiescent and activated Tfh1, 2 and 17 subsets were similar during acute malaria and at convalescence. However, the proportion of quiescent and activated Tfh2 subsets was expanded compared with malaria naive controls. Ongoing studies are examining the specificity of MBC responses and Tfh subset distributions for Pf infection by comparison to responses of children with non-malaria febrile illness and the mechanisms underlying differences of MBC responses and cognate Tfh cell subsets.

### QUEST FOR IMMUNE CORRELATES OF PROTECTION USING A STREAMLINED ANALYSIS APPROACH

Elizabeth H. Duncan<sup>1</sup>, Tanmaya Atre<sup>1</sup>, Kevin Beck<sup>2</sup>, Sheetij Dutta<sup>1</sup>, Michele Spring<sup>3</sup>, **Elke S. Bergmann-Leitner**<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute, Silver Spring, MD, United States, <sup>2</sup>Miltenyi Biotec, San Diego, CA, United States, <sup>3</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

The lack of known Immune correlates of protection has been a major hurdle for the development of effective vaccines. To generate insights into protective immune mechanisms, novel readout methods and advanced technologies are urgently needed for the in-depth immunoprofiling of responses induced by protective vaccines. The work presented here applies a two-step approach to samples from a previously reported AMA-1 based vaccine that had shown promising clinical responses. The first step of the process established a broad cytokine profile of antigen-specific responses in *ex vivo* stimulated PBMCs using a multiplex testing platform (Mesoscale). These results are the basis for the design of the subsequent flow cytometric analysis; whereby, the antigen-specific cells are characterized in detail. The targets of the flow-based analyses are rare cell subpopulations. The low precursor frequency of key immune cell populations has slowed progress in this research area. To overcome this obstacle, we are enriching antigen-specific, activated cells using an automated system for magnetic bead separation and analyzing these cells based on their lineage, activation and differentiation state. Here, we report on changes in the functional subsets of AMA-1 specific follicular helper T cells. By combining state-of-the art technologies, we continue to generate unprecedented insights into vaccine-induced protective immune mechanisms studying viral and parasitic vaccines. Computational integration of the immunoprofiling, characterization of antigen-specific cells, serology, and clinical outcome after a controlled human malaria infection will be reported in an effort to identify immune correlates of protection.

### MULTI-OMIC ANALYSIS OF SEVERITY OF INFECTION IN MACACA MULATTA INFECTED WITH PLASMODIUM CYNOMOLGI

Juan B. Gutierrez<sup>1</sup>, Yi H. Yan<sup>1</sup>, Elizabeth D. Trippe<sup>1</sup>, Diego M. Moncada<sup>2</sup>, Mary R. Galinski<sup>3</sup>, Alberto Moreno<sup>3</sup>, Jessica C. Kissinger<sup>1</sup>, Rabindra Tirouvanziam<sup>3</sup>, MaHPIC Consortium<sup>4</sup>

<sup>1</sup>University of Georgia, Athens, GA, United States, <sup>2</sup>Universidad del Quindío, Armenia, Colombia, <sup>3</sup>Emory University, Atlanta, GA, United States, <sup>4</sup>Atlanta, GA, United States

Severe anemia accounts for a large portion of the complications associated with malaria. This phenomenon is multifactorial, and the mechanisms that cause it remain elusive. A multi-omic approach comprised of immunology, transcriptomics, metabolomics, lipidomics, and proteomics was used to study five *M. mulatta* infected with *P. cynomolgi*. This experiment resulted in one death, two severe infections, and two mild infections. Particularly, we discovered that TLR3 and RIG-I pathways in macrophages and dendritic cells, conventionally linked to host antiviral responses, are upregulated in severe malaria. These pathways cross-talk, and their interaction had not been clearly implicated before in severe malaria. Associated with the activation of these pathways are changes in the effector response proteins IL1 $\beta$ , AP1, MX1, MX2, OAS1-3, and PML. Our analysis provides novel insight into the molecular and cellular basis for the development of severe malaria. This project has been funded in whole or in part with Federal funds from the National Institute of Allergy and Infectious Diseases; National Institutes of Health, Department of Health and Human Services [Contract No. HHSN272201200031C] and the National Center for Research Resources [ORIP/OD P51OD011132].

### EFFECT OF MALARIA ON CXCL10 AND ANGIPOYETIN-2 IN PATIENTS FROM A COLOMBIAN ENDEMIC AREA

**Maria F. Yasnot**, Gladys Gonzales, William Hoyos  
*Universidad de Cordoba, Monteria, Colombia*

Malaria is a widespread disease in the world. Data provided by WHO estimate that about 3.8 million people are at risk of contracting it. Colombia has many regions with geographical and climatic conditions that favor the proliferation of the vector and for that reason it increases the transmission of the Plasmodium, generating a serious public health problem. Córdoba is a state affected by this disease in much of its territory, reporting a large number of annual cases. Malaria is a complex disease with many genetic and environmental determinants that influence the response to infection, progression and severity of the disease. The inflammatory response generated by the infection induces the release of cytokines that lead to tissue damage and favor the activation of macrophages in order to eliminate circulating parasites. The association between complicated non-cerebral malaria, cytokine levels and angiogenic factors such as CXCL10 and ANG-2 has been poorly studied. The aim of this study is to evaluate the effect of CXCL10 and ANG-2 in patients infected with malaria. Plasma levels of the CXCL10 and ANG-2 molecules were determined by ELISA techniques. Confirmation of the Plasmodium species was performed by PCR. The 86.4% of patients hospitalized with some type of complication were infected with *P. vivax*. The levels of CXCL10 and ANG-2 were higher in the group of hospitalized patients with some type of complication compared to the group of patients with uncomplicated malaria ( $p < 0.0001$ ). There was no significant correlation between hemoglobin levels and parasitemia versus concentrations of the molecules studied. The results suggest that these molecules are potential biomarkers predictors of complicated malaria.

### THE MOST EFFECTIVE FUNCTIONAL RESPONSES AGAINST PLASMODIUM FALCIPARUM MEROZOITE INVASION LIGANDS ARE MEDIATED BY IGG3 SUBCLASS ANTIBODIES

**Vashti Irani**<sup>1</sup>, Peck Szee Tan<sup>2</sup>, Andrew J. Guy<sup>1</sup>, Dean W. Andrew<sup>1</sup>, Gaoqian Feng<sup>1</sup>, Linda Reiling<sup>1</sup>, Kathirvel Alagesan<sup>3</sup>, Daniel Kolarich<sup>3</sup>, Bruce D. Wines<sup>1</sup>, Mirielle H. Lahoud<sup>2</sup>, James G. Beeson<sup>1</sup>, Paul A. Ramsland<sup>1</sup>, Jack S. Richards<sup>1</sup>

<sup>1</sup>Burnet Institute, Melbourne, Australia, <sup>2</sup>Monash University, Melbourne, Australia, <sup>3</sup>Max Planck Institute of Colloids and Interfaces, Potsdam, Germany

Naturally-acquired antibodies are important for protection from symptomatic malaria. Some antibodies target merozoites and inhibit erythrocyte invasion. Field studies suggest that these antibody responses are typically skewed to IgG1 or IgG3 subclasses, and that IgG3 responses often have a stronger association with protection. However, it is unclear how their different properties impact protective immunity, and therefore which IgG subclass is required for the most effective vaccine response. We hypothesised that the different effector responses of these IgG subclasses would impact functional immunity. To assess this, we made IgG subclass-switch antibodies and compared them using *in vitro* functional assays. We focused on merozoite antigens EBA-175, Rh5 and AMA-1, as they are important invasion ligands and leading vaccine candidates. For each antigen, existing monoclonal antibodies (mAbs) that target known neutralising epitopes were selected, and used to express IgG subclass-switch mAbs; these are mAbs engineered with the same variable region, i.e. same epitope target, but different human IgG subclass backbones. Characterisation confirmed their expected size, subclass, similar N-glycosylation patterns and ability to bind their respective recombinant and native proteins. Unexpectedly, IgG3 variants showed significantly greater inhibition of merozoite invasion compared to other IgG subclasses. IgG3 variants were most effective at C1q fixation and subsequent deposition of the membrane attack complex. IgG3 also demonstrated

strongest interactions with Fcγ receptors (FcγRIIa and FcγRIIIa). These results indicate the key role of IgG3 in mediating functional immunity and support findings from field studies that show strong associations between IgG3 responses and protection. It is likely that the superior Fab flexibility of IgG3 enables more effective antigen binding leading to enhanced neutralisation and formation of IgG complexes for complement and Fcγ receptor interactions. These findings provide a strong rationale to explore the development and efficacy of vaccines that induce strong IgG3 responses.

## 1675

### MALARIA IN PREGNANCY: IMPLICATIONS OF MICROSCOPIC AND SUB-MICROSCOPIC INFECTION ON CORD BLOOD CYTOKINE RESPONSES

Ronald Ottichilo<sup>1</sup>, Ruth Nyakundi<sup>2</sup>, Francis Mutuku<sup>3</sup>, Indu Malhotra<sup>3</sup>, Desiree LaBeaud<sup>4</sup>, Charles King<sup>3</sup>

<sup>1</sup>Maseno University, Kisumu, Kenya, <sup>2</sup>University of Copenhagen, Copenhagen, Denmark, <sup>3</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>4</sup>Stanford, California, CA, United States

Children exposed *in utero* to maternal malaria are immunologically less responsive to malarial antigens and are more susceptible to malaria. This study examined the relationship between timing of exposure to both heavy (microscopic) and light (sub-microscopic) malaria infection on fetal immunity at birth. 500 pregnant women residing in a malaria endemic area in Kenya were recruited at various stages of pregnancy and followed to delivery. Mothers received the standard 2 dose malarial prophylaxis and those found positive by blood smear were treated. Maternal malaria infection was defined as either heavy (detectable by both blood smear and PCR) or light (sub-microscopic, only detectable by PCR). Newborns' cord blood lymphocytes (CBL) were examined for malaria antigen-specific cytokine responses. Newborns were categorized by timing of maternal infection i) malaria pos. at ANC and neg. at delivery (ANC+/DEL-) (n=169 for heavy infection, n=205 for light infection); ii) malaria pos. at delivery (DEL+) (n=19 heavy infection, n=39 light infection); and iii) malaria neg. at ANC and delivery (ANC-, DEL-) (n=312 heavy infection, n=257 light infection). Newborns from ANC+/DEL- mothers showed higher stimulation index, with significance noted in heavy infection p=0.0001. Newborns from ANC+/DEL- mothers showed elevated levels of Th-1 cytokines than those from DEL+ with significance in IFN-γ and IL-2 at heavy infection (0.792 pg/ml, 0.443 pg/ml, 0.379 pg/ml p<0.0001 and 0.223 pg/ml, 0.074 pg/ml, pg/ml 0.114, p= 0.047 respectively). Newborns from DEL+ mothers had significantly elevated IL-10 levels when compared to newborns from ANC-/DEL- (0.340 pg/ml, 0.456 pg/ml, 0.201 p=0.013). These preliminary results indicate that heavy infections have a significant influence on the immune response at birth. The high cellular response to malarial antigens in CBL from neonates of mothers with heavy infection in ANC may be due to early detection and treatment. Further analysis is needed to determine the implications of treatment of antenatal malaria on neonatal immunity

## 1676

### DEFORESTATION AND LAND COVER CHANGES: DRIVERS OF DISAPPEARING MALARIA IN NORTHERN LAO PDR?

Francois Rerolle<sup>1</sup>, Andrew A. Lover<sup>1</sup>, Emily Dantzer<sup>1</sup>, Sophia Hocini<sup>1</sup>, Hugh Sturrock<sup>1</sup>, Alemayehu Midekisa<sup>1</sup>, Bouasy Hongvanthong<sup>2</sup>, Keobuphaphone Chindavongsa<sup>2</sup>, Susie Welty<sup>1</sup>, Tania Reza<sup>1</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Center for Malariology, Parasitology and Entomology; Ministry of Health, Vientiane, Lao People's Democratic Republic

Between 2001 and 2011, Lao People's Democratic Republic (PDR) made substantial progress in reducing the burden of malaria, as the number of reported cases fell by 83%. In spite of a large-scale resurgence in southern Lao PDR in 2012-2015, the northern half of the country has successfully

maintained these gains. Exposure to *Anopheles* mosquitoes while working in the forest is considered a primary risk factor for malaria infection in much of Southeast Asia. This study aims to assess the environmental drivers of falling malaria transmission in northern Lao PDR, specifically considering land cover and forest changes. Landsat 7 Enhanced Thematic Mapper Plus (ETM+) data were obtained from the Google Earth Engine data library and 5 spectral bands were used as predictors of land cover. We collected training data (7210 points classified in 7 land cover classes) using manual digitization and photo interpretation techniques from high-resolution satellite imageries. A random forest algorithm was used to generate annual land cover maps from 2008 to 2016 (30m resolution). Malaria prevalence was determined using a cross-sectional survey of 1,500 households across 100 villages in 4 districts in northern Lao PDR in September-October 2016. Out of a total of 5,082 persons enrolled, 39 infections were detected by PCR, with substantial village-level clustering. The land cover layers will be used to assess forest change and included in a geostatistical model along with other climatic and environmental layers, intervention coverage, and epidemiologic risk factors to assess the relationship between recent forest change and observed malaria infection prevalence. Health facility confirmed case incidence collected from the surveillance system and serology results will also be incorporated into an historical assessment of land cover change and malaria infection. Finally, predictive risk maps will be produced to assist in targeting remaining *foci* of transmission as Lao PDR pursues subnational elimination.

## 1677

### HOW INCREASING ACCESS TO CASE MANAGEMENT COULD BE SUFFICIENT TO ACHIEVE AND MAINTAIN MALARIA ELIMINATION

Emilie Pothin<sup>1</sup>, Arnaud Le Menach<sup>2</sup>, Theodoor Visser<sup>2</sup>, Justin M. Cohen<sup>2</sup>

<sup>1</sup>Clinton Health Access Initiative - Swiss TPH, Basel, Switzerland, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States

Malaria elimination efforts typically focus on intervention campaigns to reduce transmission through vector control interventions such as indoor residual spraying and clear the parasite reservoir through drug-based interventions such as mass drug administration. Yet routine, passive treatment of malaria infected individuals also plays an important role in reducing the reservoir of infections and thus diminishing onwards transmission. Evidence from several settings suggests that expanding timely, curative treatment for malaria may result in marked, sustained reductions in malaria transmission, but this effect is likely context-specific given heterogeneity in transmission risk, treatment accessibility, and human behavior. To evaluate the potential for strengthened case management to contribute to elimination goals, a mathematical model was constructed that takes into account level of malaria transmission, current access to treatment, the mobility of individuals, and the impact of vector control interventions. Using gridded data on population distributions and treatment-seeking behavior across Southern Africa, we evaluated the fraction of incident infections that could feasibly be cured by increasing case management access points (e.g., via community health workers) and strengthening testing and treatment practices at existing access points (including both public and private facilities and outlets). The impact on transmission of strengthening case management up to this feasible level across the region was then evaluated using the mathematical model. Results indicate that in Southern Africa, improving passive case management to effectively treat 60% of the malaria infections (currently around 45%) would result in interrupting transmission within 95% of the region's population currently residing within endemic areas. Given that strong case management can also result in the strong surveillance that will be critical for the sustainability of malaria elimination, achievement of the highest possible coverage of effective case management should be a priority for all malaria elimination programs.

1678

### MODELLING THE DYNAMICS OF *PLASMODIUM FALCIPARUM* HISTIDINE-RICH PROTEIN 2 IN HUMAN BLOOD STAGE CHALLENGE STUDIES

Louise Marquart<sup>1</sup>, Lachlan Webb<sup>1</sup>, Michael Kalnoky<sup>2</sup>, Smita Das<sup>2</sup>, Gonzalo Domingo<sup>2</sup>, James McCarthy<sup>1</sup>, Michelle Gatton<sup>3</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>PATH, Seattle, WA, United States, <sup>3</sup>Queensland University of Technology, Brisbane, Australia

Sensitive detection of malaria cases in a community is important for effective malaria control and elimination. Rapid diagnostic tests (RDTs) based on *Plasmodium falciparum* histidine-rich protein 2 (PfHRP2) are important public health tools. Although PfHRP2 persists in the circulation following successful treatment, the kinetics of PfHRP2 antigenaemia during infections are not well understood. This current study builds on an earlier model (Marquart et al 2012) using rich sampling of PfHRP2 and parasitemia data collected from 16 participants infected with *P. falciparum* in an induced blood stage challenge model. Participants were infected with approximately 1,800 *P. falciparum* (3D7 strain) asexual parasites, and received curative antimalarial treatment seven days after inoculation. Parasitemia and concentration of PfHRP2 were measured every 12 hours between days 4 and 11, using a 18s rDNA qPCR assay and a Quansys ELISA respectively. The updated kinetic model incorporated revised estimates of PfHRP2 half-life, the 40 hour asexual life-cycle of the 3D7 strain and individualised estimates of blood volume based on participant body weight. The half-life for PfHRP2 in the 3D7 strain was estimated assuming a first-order elimination model using individual PfHRP2 concentration-time curves from administration of treatment up to 4 days post-treatment. Calibration of the model with pre-treatment data predicted the amount of PfHRP2 produced per parasite lifecycle as a median of 31 fg (IQR: 20 - 39fg). Sensitivity analyses on key parameters were used to determine an optimal model of PfHRP2 kinetics in a human blood stage challenge model. This provides an opportunity to understand the performance characteristics of malaria RDTs detecting this antigen in low level infections.

1679

### NOVEL MODELING APPROACHES TO IMPROVE SPATIAL PREDICTIONS OF MALARIA PREVALENCE

Denis Valle, Punam Amratia, Justin Millar, Kok Ben Toh, Pedro Albuquerque

University of Florida, Gainesville, FL, United States

Accurate spatial prediction of malaria prevalence is important to help improve targeting of malaria prevention and control interventions, potentially leading to substantial cost-savings, as well as to assess the effectiveness of past interventions in reducing malaria risk. Current modeling approaches to create these spatial predictions have relied extensively on Bayesian geospatial models. Besides coherently representing uncertainty in predictions, these models leverage Gaussian Processes to generate better spatial predictions than simpler Generalized Linear Models. Here we explore novel classes of models including generalized Gaussian Processes and Bayesian Generalized Kernel Mixed Models (BGKMM). The advantage of these models is that they can represent nonlinear relationship and higher-order interaction terms, similar to Support Vector Machines, while still adequately representing the uncertainty in spatial predictions. We compare the out-of-sample predictive performance of these models to that of standard Bayesian geospatial models using the 2014 Demographic and Health Survey (DHS) from Ghana. Finally, we also explore how these modeling approaches can incorporate data from earlier surveys (i.e., 2011 Multiple Indicator Cluster Survey (MICS)) to generate improved spatial predictions. Our results are likely to be useful in generating better malaria prevalence maps, which can ultimately lead to more cost-effective spatially-targeted malaria prevention and control interventions.

### ASSESSING THE IMPACT OF IMPERFECT ADHERENCE TO ARTEMETHER-LUMEFANTRINE ON MALARIA TREATMENT OUTCOMES USING WITHIN-HOST MODELLING

Joseph D. Challenger<sup>1</sup>, Katia Bruxvoort<sup>2</sup>, Azra C. Ghani<sup>1</sup>, Lucy C. Okell<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Artemether-lumefantrine (AL) is the most widely recommended and prescribed treatment for uncomplicated falciparum malaria worldwide. Clinical trials have clearly demonstrated its safety and efficacy. However, its performance in routine healthcare settings, where adherence to treatment may be suboptimal, is more difficult to assess. There are very few studies that record both detailed information on patients' adherence to AL and their treatment outcomes. Therefore, it is difficult to quantify the impact of imperfect adherence on the efficacy of treatment. In this work we develop a within-host modelling framework to explore the link between patient adherence to AL and the efficacy of treatment. We incorporate parasite dynamics, human immune responses, and pharmacokinetic-pharmacodynamic modelling. We use this model to estimate the role imperfect adherence plays in treatment failure. To obtain examples of real-life adherence behaviour we use individual-level data on pills taken and their timings in 482 malaria patients in Tanzania in 2012 as an input to our within-host model. The failure rate we estimate from our model using the Tanzanian adherence data for dose timings is higher (9%) than predicted for an equivalent cohort for which adherence was optimal (4%). The percentage of pills taken explains much of the variation in treatment outcomes found in the model simulations. Imperfect adherence was predicted to cause greatest increase in failure rates in young children, highlighting the importance of communications with caregivers. The addition of gametocyte production to the model enables us to assess the contribution of imperfect adherence to onward transmission of the parasite.

1681

### MODELING THE EFFECTS OF TRANSMISSION AND HOST POPULATION STRUCTURE ON MALARIA POPULATION GENETICS

Wesley Wong<sup>1</sup>, Edward Wenger<sup>2</sup>, Daniel Hartl<sup>1</sup>, Dyann Wirth<sup>1</sup>

<sup>1</sup>Harvard University, Boston, MA, United States, <sup>2</sup>Institute for Disease Modeling, Bellevue, MA, United States

Renewed interest in malaria eradication has emphasized the need to accurately monitor changes in malaria transmission. Population studies have recently identified genomic signals associated with differences in transmission intensity. Genetic epidemiology models provide a framework for predicting how these signals react to changes in transmission, but the models typically lack host population structure and assume that infected individuals are equally likely to transmit to any other member of the population. Although epidemiological models indicate that host population structure and transmission heterogeneity can affect the spread of epidemics, little is known about how they can affect parasite population genomics or the magnitude of these effects. We simulated malaria epidemics on networks representing highly clustered populations or populations containing super-spreaders at different transmission intensities. We focused on how differences in host population structure affect the frequency and genetic composition of simulated polygenomic (multi-strain) infections. These results will improve our understanding of how both transmission intensity and host population structure can influence parasite population genomics and potentially impact the efficacy of eradication campaigns.

## 1682

### TO SCREEN OR NOT TO SCREEN: AN INTERACTIVE TOOL THAT INTEGRATES COSTS AND SPATIAL HETEROGENEITY TO DETERMINE WHEN MASS-SCREEN-AND-TREAT IS AN EFFECTIVE MALARIA CONTROL STRATEGY

Justin J. Millar, Kok Ben Toh, Denis R. Valle  
University of Florida, Gainesville, FL, United States

Resource management is critical to designing effective malaria interventions. The wide availability of rapid diagnostic testing has made pre-screening a viable method for reducing the waste and costs associated with mass drug administration. However, there has been mixed results regarding the effectiveness of mass-screen-and-treat (MSAT) interventions as a means of reducing morbidity and/or interrupting transmission. Two factors that influence intervention efficacy are (1) spatial heterogeneity of disease prevalence and diagnostic performance, and (2) cost of screenings and treatment. We propose a framework for interactively evaluating the cost effectiveness of presumptive treatment versus MSAT interventions. First, we modeled region-specific disease prevalence and diagnostic performances. With the model results, an interactive web application was created using R Shiny, which can incorporate relevant factors (e.g. urban/rural, age, fever history), allows the user to input cost of treatment, screening, and misdiagnoses, and compares the cost efficiency of these interventions in each region of a country. We present an example using DHS data from seven West African countries (Burkina Faso, Cote d'Ivoire, Ghana, Guinea, Mali, Nigeria, and Togo). We believe that this framework can be easily adapted for many contexts and is a useful tool for decision makers to design data-driven, cost-effective interventions.

## 1683

### MODELING THE GLOBAL BURDEN OF PREGNANCY-ASSOCIATED MALARIA DEATHS

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>University of Chicago Pritzker School of Medicine, Chicago, IL, United States, <sup>3</sup>Emory University School of Medicine and Emory University Rollins School of Public Health, Atlanta, GA, United States, <sup>4</sup>Harvard Medical School, Boston, MA, United States, <sup>5</sup>University of Illinois at Urbana-Champaign College of Veterinary Medicine and the University of Illinois at Chicago School of Public Health, Chicago, IL, United States

Approximately 125 million pregnancies occur annually in areas with malaria transmission. Malaria is an important cause of pregnancy-associated death in endemic areas. While Guyatt and Snow proposed in 2001 that 10,000 annual maternal deaths in sub-Saharan Africa could be explained by malarial anemia, no contemporary estimates exist. We conducted a systematic review to determine the proportion of pregnancy-associated deaths attributable to malaria and used the data to model the global burden. We conducted a systematic literature search on March 22, 2017 to identify observational studies on causes of maternal death, including the proportion of maternal deaths due to malaria, in malaria endemic areas. Two reviewers independently extracted data to create a primary dataset. A secondary dataset consisting of key predictors (antenatal attendance, delivery at a facility and with a skilled birth attendant, ITN, IRS, and IPTp3 coverage, Pf prevalence rate, and adult HIV prevalence) from malaria endemic countries was compiled. A predictive model was constructed using the primary dataset and applied to the secondary dataset to calculate the estimated number of pregnancy-associated malaria deaths worldwide. Monte Carlo simulation (10,000 simulations) was used to generate a 95% confidence interval (CI). Our search identified 11,870 records; after title review, 1665 abstracts were reviewed. Data from 71 articles from 25 countries with at least 1 year of data collection was included. On average, 7.9 (95% CI: 6.1-10.4) of maternal deaths were due to malaria. On preliminary estimate, this

translates to 30,404 (95% CI 1,615-230,458) annual maternal deaths associated with malaria infection, about 7% of malaria deaths in 2015. Despite improvements in coverage of malaria preventive interventions, maternal mortality due to malaria remains high. Furthermore, the total burden of malaria is likely underestimated, as our model does not account for maternal deaths related to severe anemia resulting from malaria infection. Continued interventions to minimize the effects of malaria in pregnancy are critical to achieve Sustainable Development Goal 3.1.

## 1684

### A NOVEL HUMANIZED PSEUDO-LIVER MOUSE MODEL FOR DISCOVERY OF ANTIMALARIAL DRUGS

Kristina S. Wickham<sup>1</sup>, Siobhan Flaherty<sup>2</sup>, Sara Viera-Morilla<sup>3</sup>, Maria José Lafuente-Monasterio<sup>3</sup>, Gregory A. Reichard<sup>1</sup>, Rosemary Rochford<sup>2</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>University of Colorado Denver, Denver, CO, United States, <sup>3</sup>GlaxoSmithKline, Tres Cantos, Madrid, Spain

Of the *Plasmodium* species that infect humans, *Plasmodium vivax* has the largest geographical distribution and together with *Plasmodium falciparum*, contribute significantly to the burden of malaria associated morbidity and mortality worldwide. There are few preclinical animal models available to address the unique challenges of investigating the exoerythrocytic phase of *P. vivax* infection. This impedes our capability to develop effective antimalarial drugs that target the liver stage as well as the hypnozoite forms responsible for relapsing malaria. A biologically relevant, cost-effective, readily manipulable and adaptable animal model is needed to test new drugs for treatment and chemoprophylaxis, which is a key component in an era of malaria eradication as a global health agenda. To address this inadequacy, we have developed a humanized mouse model with a "pseudo-liver" that can host human *Plasmodium* infection. NOD/SCID IL2Rg<sup>-/-</sup> (NSG) mice at 6-8 weeks old were injected with 1x10<sup>7</sup> HC-04 cells subcutaneously (s.c.) and tumor growth was monitored by caliper measurement. Tumors approximately 1 cm in size were observed by 14 days post-injection. Mice received direct intratumoral (i.t.) or i.v. injections of 5-7 x 10<sup>5</sup> *P. falciparum* sporozoites. Packed human red blood cells were injected i.p. At 6-7 dpi, tumors were removed and evaluated for *P. falciparum* infection. Thick and thin blood smears were evaluated to confirm erythrocytic infection. Results show that hepatocyte cell lines engrafted s.c. in the flank of NSG immunodeficient mice developed into well vascularized tumors or "pseudo-livers" with liver-like characteristics. Following injection of *P. falciparum* sporozoites either i.t. or i.v., *P. falciparum* was detected in the pseudo-liver at 6 days post infection. In mice engrafted with human RBC, we also observed development of ring stage parasites in Giemsa stained blood smears. Validation of this model is currently ongoing. The NSG pseudo-liver model could provide a relatively low cost, reproducible, standardized liver stage malaria drug discovery tool to test antimalarial drugs in the context of human *Plasmodium* infection.

## 1685

### IMPACT OF HUMAN MIGRATION PATTERNS ON MALARIA ELIMINATION FEASIBILITY IN THE GREATER MEKONG SUBREGION

Amelia Bertozzi-Villa<sup>1</sup>, Nicholas P. Day<sup>2</sup>, Jordi Landier<sup>3</sup>, Philip A. Eckhoff<sup>1</sup>, Edward A. Wenger<sup>1</sup>, Jaline Gerardin<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>2</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>3</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mae Sot, Thailand

Myanmar has the highest burden of malaria in the Greater Mekong Subregion, with 152,000 cases in 2014, and has pledged to eliminate falciparum malaria by 2025. Achieving this goal is particularly urgent given increasing levels of ACT resistance, especially along border regions with Thailand. Challenges to elimination in the area include high prevalence of

submicroscopic infection that makes detection of the infectious reservoir difficult, poorly understood patterns of human movement on both short and long time scales, and disparate access to health care for different ethnic and socioeconomic groups. We use a stochastic simulation-based model to test elimination feasibility under a number of scenarios for a high-burden region along the Thai-Myanmar border, accounting for submicroscopic infections, ACT resistance, and subpopulations systematically unable to access care. A village-level simulation of Karen state in Myanmar was calibrated to longitudinal data collected by the Malaria Elimination Task Force. Using this model framework, we tested the efficacy of different intervention combinations, including scaled-up case management, increased usage of insecticide-treated nets, and implementation of mass drug administration for high-prevalence villages. These intervention packages were considered under a combination of migration types, including short-term ambulatory migration, short-term road-based migration, medium-term migration to and from the forest, seasonal migration for farm or factory work, and long-term displacement due to internal conflicts, to quantify the impact of different migration patterns on success of elimination programs. We find that mass drug campaigns in particular lose impact in scenarios where index cases are primarily acquired in the forest or other areas far from where the campaign is implemented, and both case management and vector control also vary in effectiveness under different migration and accessibility patterns. Better data about true migration patterns in Karen and elsewhere is essential for planning effective elimination campaigns.

## 1686

### MAPPING MALARIA METRICS USING SURVEILLANCE DATA ACROSS HETEROGENEOUS LANDSCAPES

**Katherine E. Battle**<sup>1</sup>, Ewan Cameron<sup>1</sup>, Su Kang<sup>1</sup>, Daniel J. Weiss<sup>1</sup>, Samir Bhatt<sup>1</sup>, Arnaud Le Menach<sup>2</sup>, Justin Cohen<sup>2</sup>, Peter W. Gething<sup>1</sup>

<sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States

As malaria endemic countries move towards elimination, the control strategies shift from mass intervention campaigns to targeted measures that aim at more focal and heterogeneous transmission landscapes. Routine or responsive surveillance are deployed to describe these settings, but the strength of surveillance systems vary both among and within countries. Understanding the accuracy of the surveillance and malaria situation between sentinel sites can be challenging. Newly developed spatial modelling techniques, along with remotely sensed high resolution environmental and socio-demographic variables, can be used to translate case data observed at varying surveillance resolutions to fine-scale malaria incidence maps. This includes down-scaling the most widely available surveillance data source, case counts reported at the administrative-level, to illustrate sub-unit heterogeneity. Case counts from health facilities are increasingly obtainable and can also inform pixel-level maps while also accounting for aspects that may contribute to under-reporting such as accessibility to health facilities and care-seeking behaviours. Finally, cases followed up from facility and geospatially to the household level increase the resolution of the predictions through point-process models. Bespoke modelling frameworks developed for countries based on the type of data available can produce pixel-level maps that support countries in developing informed and sustainable elimination strategies in a wide range of settings.

## 1686A

### PHARMACOKINETIC AND PHARMACODYNAMIC MODELING FOR THE PREDICTION OF THE MOSQUITOCIDAL EFFECT DURATION OF HIGH-DOSE IVERMECTIN (THE IVERMAL PK/PD MODEL)

**Menno R. Smit**<sup>1</sup>, Eric O. Ochomo<sup>2</sup>, David Waterhouse<sup>1</sup>, Titus K. Kwambai<sup>3</sup>, Bernard O. Abong'or<sup>2</sup>, Teun Bousema<sup>4</sup>, Nabie M. Bayoh<sup>5</sup>, John E. Gimnig<sup>5</sup>, Aaron M. Samuels<sup>5</sup>, Meghna R. Desai<sup>5</sup>, Penelope A. Phillips-Howard<sup>1</sup>, Simon K. Kariuki<sup>2</sup>, Duolao Wang<sup>1</sup>, Feiko O. ter Kuile<sup>1</sup>, Steve A. Ward<sup>1</sup>, Ghaith Aljayoussi<sup>1</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Kenya Medical Research Institute (KEMRI), Kisumu, Kenya, <sup>3</sup>Kenya Ministry of Health, Kisumu, Kenya, <sup>4</sup>Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, <sup>5</sup>U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

It was recently shown that the mosquitocidal effect on *Anopheles gambiae* s.s. populations feeding on malaria patients treated with high-dose ivermectin lasts for at least 28 days after the start of ivermectin administration when co-administered with 3 days of dihydroartemisinin-piperazine (DP). The current pharmacokinetic and pharmacodynamic analysis aimed to determine whether a drug interaction or an unidentified ivermectin metabolite could be contributing to the prolonged mosquitocidal effect of ivermectin. In the main trial, 141 adults with uncomplicated malaria were randomly assigned to receive ivermectin 0, 300, or 600 mcg/kg/day for 3 days. During 28 days of follow-up, 1,393 venous plasma samples were collected. Paired mosquito incidence rates for death (IDR) during 14-days post-feeding were available for 850 time points. Following liquid-liquid extraction, ivermectin concentrations were measured using liquid chromatography-mass spectrometry (LC-MS). Pmetrics@ 1.5.0 was used for the population modelling of both PK and PD data. Ivermectin concentrations were above the lower limit of quantification (LLOQ: 5 ng/mL) for 534 time points, of which 246 had paired IDR's. The population pharmacokinetics of ivermectin were best described by a two-compartment oral absorption model. Based on the PK/PD model there was a consistent association between (1) predicted and observed ivermectin concentrations and (2) predicted ivermectin concentrations and observed mosquitocidal effect throughout the entire duration of the study (28 days). The half maximal effective concentration (EC50) for incidence rate of death by day 14 was 17.1 ng/mL (IQR 15.1, 19.1). Predicted median concentrations remained mosquitocidal for at least 28 days. The PK/PD model accurately predicted mosquitocidal activity for the entire duration of the study (28 days) without the need to invoke unidentified variables such as an active metabolite. (ClinicalTrials.gov: NCT02511353)

## 1687

### RESULTS FROM A FORMATIVE EVALUATION OF THE MALARIA IN PREGNANCY CASE MANAGEMENT JOB AID IN NIGERIA

**Bright Orji**, Enobong Ndekhedehe, Elana Fiekowsky, Patricia Gomez, Aimee Dickerson, Reena Sethi, Bibian Udeh, Kristin Vibbert, Robert Sellke

Jhpiego, Baltimore, MD, United States

Annually, nearly 7 million pregnant women in Nigeria are at risk of malaria in pregnancy (MIP). Although antenatal care is the platform for the prevention and treatment of MIP, malaria is also treated at outpatient departments. It is known that women of reproductive age (WRA) are often treated for malaria without assessing pregnancy status, although artemisinin combination therapies are contraindicated in the first trimester of pregnancy, and many pregnant women do not receive the recommended low cost interventions. In order to increase access to these MIP interventions, the President's Malaria Initiative supported the Maternal and Child Survival Program and partners to develop a two-page job aid for

case management of uncomplicated malaria among WRA. In collaboration with the Nigeria Malaria Elimination Program, the job aid was evaluated in Ebonyi State, a high malaria burden area, to determine providers' perceptions of its clarity, acceptability, and utility. A half-day workshop on use of the job aid was provided to 35 health workers (nurses - 20%; nurse-midwives - 20%; community health extension workers - 48%; and medical doctors - 12%) already trained on MIP case management, selected from 15 facilities where WRA seek care. After 3 months of use, a one-page questionnaire was administered to 34 health workers. One-hundred percent stated that the job aid helped them to do the following: identify pregnant women among the WCBA presenting with fever; use rapid diagnostic tests to diagnose malaria; and treat uncomplicated MIP. Sixty-eight percent used the job aid to provide correct treatment for severe malaria and 88% used it while providing services all or most of the time. The results indicated that after a half-day orientation on use of the job aid, health workers were able to use it to help them identify women who may be pregnant and provide appropriate treatment for uncomplicated MIP. They are also able to explain its use to colleagues. It is suggested that a poster-size version could be printed and disseminated to appropriate cadres of health workers in clinics where WRA seek care for fever, as it is anticipated that providers could benefit from its use.

## 1688

### CAREGIVER RESPONSES TO CHILDREN WITH UNCOMPLICATED AND SEVERE MALARIA: CHOICES AND DELAYED CARE SEEKING

Arthur Mpimbaza<sup>1</sup>, Anne Katahoire<sup>1</sup>, Philip J. Rosenthal<sup>2</sup>, Charles Karamagi<sup>3</sup>, Grace Ndeezi<sup>3</sup>

<sup>1</sup>Child Health and Development Centre, Makerere University, College of Health Sciences, Kampala, Uganda, <sup>2</sup>Department of Medicine, University of California San Francisco, California, CA, United States, <sup>3</sup>Department of Paediatrics and Child Health, Makerere University, College of Health Sciences, Kampala, Uganda

Delayed care seeking contributes to progression from uncomplicated to severe malaria. The impact of caregivers' choices on time to seek appropriate care has not been reported. We present results on choices of care and their determinants, and the impact of choices on time to seek care among caregivers of children with uncomplicated and severe malaria in rural Uganda. We used a case control study to enroll 325 children with severe malaria (cases) and 325 children with uncomplicated malaria (controls) in Jinja, Uganda. Caregivers' responses to their children's illnesses, including choice of action and time to seeking care were documented. Conditional logistic regression and Cox regression were used to determine risk factors for choices of care and delay in care seeking, respectively. Staying at home (72.9%) and seeking care at a drug shop (22.3%) were the most common initial responses to illness. Staying home was more common among controls compared to cases (82.7% vs. 63.0%; 95%CI 12.9, 26.2), in contrast with seeking care at drug shops, which was more common among cases than controls (32.3% vs. 12.3%; 95%CI 13.7, 26.2). Delayed care seeking (OR 4.21; 95%CI 1.52, 11.6) and longer distance to the nearest public health facility (OR 1.39; 95%CI 1.08, 1.79) were predictors of seeking care at drug shops. Over time, caregivers of cases were less likely to seek care compared to controls, with differences peaking in the first 48 hours (35.0% vs. 60.0%; HR 0.29, 95%CI 0.20, 0.43). Upon adjusting for known determinants of delayed care seeking, caregivers of cases whose initial response was staying at home (HR 0.29, 95%CI 0.17, 0.49) or who sought care at a drug shop (HR 0.37, 95%CI 0.19, 0.74) were more likely to delay care compared to caregivers of controls who stayed at home. Staying at home and seeking care at a drug shop were associated with delay in seeking care among caregivers of cases. Longer distance to a public health facility predicted seeking care at drug shops and delay. The impact of drug shops on time to seek appropriate treatment for children with malaria and influences of behavioral factors that impact caregiver response to illness need further study.

## 1689

### DEALING WITH G6PD DEFICIENCY ON THE WAY TO MALARIA ELIMINATION IN MYANMAR

Tin M. Hlaing, Zaw M. Htet, Ko K. Win, Win M. Aye, Tin M. Mya, Thein Zaw

Defence Services Medical Research Centre, Nay Pyi Taw, Myanmar

Glucose-6-phosphate dehydrogenase (G6PD) is the enzyme important in red blood cells required for pentose phosphate pathway. Its deficiency is the most common human enzyme condition which Myanmar people are no exception. Myanmar is striving for malaria elimination by 2030 although having long history of malaria. Being part of malaria treatment, the use of Primaquine (PQ) can cause haemolysis in G6PD deficient patients. It is prescribed to control transmission in falciparum malaria while it is used to eradicate liver stage in vivax malaria. This is encountered in malaria endemic country like Myanmar where there is no established system of recording individual G6PD status as well as national survey data. Such limited information makes healthcare providers overcautious to use PQ. To overcome setbacks in use of PQ by healthcare personnel, few studies were conducted to demonstrate the G6PD status in Myanmar. One of the studies in 2001 showed that 4.5% of 1079 samples were severely deficient whereas deficiency by races revealed 5.5% in Bamar, 3.2% in local Chinese, 3.4% in local Indians, 3.3% in Mon, 5.1% in Shan and 6.7% in Kayin. Another study in Chin race in 2009, showed G6PD deficiency of 2.9% and severe deficiency of 0.5%. In 2014, a study on 916 people in living in Yangon showed 6.6% of G6PD deficiency. Those studies were conducted in civilian population but malaria posed greater threats on the armed forces and police whose nature of work is at high stake to contract malaria. Filling the gap of G6PD status data in armed forces and police, two studies were carried out by DSMRC. In 2015, 567 military personnel were tested for G6PD enzyme activity. There were 12.4% of active servicemen found to have low enzyme activity reflecting enzyme deficiency and severe enzyme deficiency was 1.2%. In January of 2017, 129 samples of blood were collected from police force to determine the G6PD enzyme activity. There were only 14 police personnel found to have moderate enzyme deficiency but there was no severe enzyme deficiency. Further studies to establish national figures firmly supporting the use of PQ are anticipated.

## 1690

### AWARENESS AND USE OF MALARIA CONTROL STRATEGIES IN KANO AND ZAMFARA STATES, NIGERIA - 2016

Olufemi O. Ajumobi, Adefisoye Adewole, Usaini Bala, Amina Umar, Ndadilnasiya Waziri, Saheed Gidado, Iren Isaac, Gideon Ugbenyo, Edwin Simple

African Field Epidemiology Network, Nigeria Country Office, Asokoro Abuja, Nigeria

The Nigeria Malaria Frontline Project is a collaboration among the National Malaria Elimination Programme, State governments, United States Centers for Disease Control and President's Malaria Initiative, the National Stop Transmission of Polio Program, the Nigeria Field Epidemiology and Laboratory Training Program and other partners. Prior to its implementation in Kano and Zamfara states, we conducted a baseline household survey to assess awareness and use of malaria control intervention strategies. We surveyed women in reproductive age in Kano and Zamfara states, Nigeria from July to August 2016 using World Health Organization recommended cluster sampling method. We interviewed 551 women: 249 in 207 households (HHs) in Kano and 302 in 210HHs in Zamfara using standardized Malaria Indicator Survey questionnaire. We collected data on awareness and use of malaria control strategies. Of 551 women interviewed, 520 (94.4%) women were aware of malaria; 150 (63.6%) in Kano and 179 (63.0%) in Zamfara knew children were at risk. Of the 518 (99.6%) who responded to questions on ways to avoid malaria, 483 (93.2%) knew how to avoid malaria in pregnancy, sleeping inside net being the most mentioned (80.5% in Kano, 90.7% in Zamfara).

Awareness of use of artemisinin-based combination therapy (ACT) for malaria treatment was 14.8% in Zamfara and 28.8% in Kano. Radio was the main source of information on malaria prevention (77.6% in Kano, 76.6% in Zamfara). Ownership of long lasting insecticidal nets (LLINs) was 62.9% in Kano and 62.3% in Zamfara. Use of LLINs was 68.0% in Kano and 67.9% in Zamfara, with use being 70.8% in Kano and 81.8% in Zamfara among pregnant women. Heat / claustrophobia (Kano: 13.9%, Zamfara: 12.1%) and difficulty experienced during net hanging (Kano: 2.8%, Zamfara: 6.1%) were identified reasons for not using nets. The HH revealed high awareness of malaria prevention strategies, low awareness of use of ACT, high LLIN ownership and use among reproductive age women in Kano and Zamfara states Nigeria. Increased sensitization on ACT use and deployment of LLIN hanging initiatives are recommended.

## 1691

### FACTORS LIMITING THE EFFECTIVENESS OF STANDARDIZED MALARIA CONTROL STRATEGIES IN FORESTED HIGHLANDS OF VIETNAM: A QUALITATIVE STUDY

**Thuan T. Nguyen<sup>1</sup>**, Xa Xuan Nguyen<sup>2</sup>, Duong Thanh Tran<sup>2</sup>, Dung Anh Khac Vu<sup>2</sup>, Ky Van Pham<sup>3</sup>, Annette Erhart<sup>4</sup>, Koen Grietens Peeters<sup>5</sup>

<sup>1</sup>Institute of Tropical Medicine in Antwerpen and National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, <sup>2</sup>National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, <sup>3</sup>Provincial Center of Malariology, Parasitology and Entomology, Ninh Thuan, Vietnam, <sup>4</sup>Institute of Tropical Medicine in Antwerpen and the Medical Research Council in the Gambia, Antwerpen, Belgium, <sup>5</sup>Medical Anthropology Unit, Institute of Tropical Medicine, Antwerpen, Belgium

Despite radical improvements in malaria control in Vietnam in the past decades, malaria persists among impoverished ethnic minorities in south-central Vietnam where the same strategies that lead to its reduction and elimination elsewhere in the country have been applied. An ethnographic study to assess socio-cultural and health systems factors limiting the effectiveness of malaria preventive measures among the Ra-glai ethnic minority was conducted in nine villages in Ninh Thuan province in south-central Vietnam. Qualitative data were collected through in-depth interviews, informal conversations and participation observation. Retroductive data analysis was concurrent to data collection and carried out using Nvivo 11. A combination of factors contributed to limiting effective malaria control in this minority setting. Firstly, the constant contact with the forest and slash-and-burn subsistence agriculture exposed the Ra-glai to the main early biting and outdoor-resting sylvatic vector *An. dirus*, limiting the effectiveness of bed nets and indoor residual spraying. Secondly, health messages on malaria prevention were not adapted to a context characterized by the Ra-glai culture, a different language, illiteracy and different living conditions than the majority society, making part of the messages irrelevant to the local situation. Thirdly, the doctor-patient hierarchy consisting of limited communications between health professionals and patients due to language barriers and the perspectives on minority patients further enhanced the difficulties during the health encounter. Waiting times and geographic distance in the context of high work burden during the malaria transmission season limited the use of the public health system. Private health practitioners and local shamans bridged this gap by providing services perceived as effective, friendly and accessible. This study provides the insights into barriers to the current malaria control strategies and the need to further assess how to improve interventions in minority settings, with different ecological and socio-cultural characteristics than the majority society.

## 1692

### MALARIA CASE MANAGEMENT AND PREVENTIVE PRACTICES IN KANO AND ZAMFARA STATES, NIGERIA: HEALTHCARE WORKERS PERSPECTIVE, 2016

**Adefisoye O. Adewole**, Olufemi Ajumobi, Amina Umar, Usain Bala, Edwin Simple, Gideon Ugbenyo, Ieren Isaac, Saheed Gidado, NdadiInasiya Waziri

*African Field Epidemiology Network, Abuja, Nigeria*

Preventive practices, prompt and effective case management of uncomplicated malaria is critical to malaria control. These involve accurate clinical assessment, laboratory confirmation by malaria rapid diagnostic test (RDT) or microscopy prior to treatment with an effective antimalarial. We conducted a study to assess the malaria case management and preventive practices of healthcare workers in Kano and Zamfara states, Nigeria. A health facility based cross sectional study was conducted in 23 primary health centers [PHCs] and 29 General Hospitals [GHs] in Kano State and Zamfara 23 PHCs and 16 GHs in Zamfara State states from July - August 2016. Two health care workers were purposively selected from each PHC and GH. We defined intermittent preventive treatment of malaria in pregnancy (IPTp-SP) as the administration of a dose of three white tablets of sulphadoxine-pyrimethamine (SP) to a pregnant woman. Data was collected electronically using open data kit to obtain knowledge on case management and prevention practices. Data was entered, cleaned and analyzed using Statistical Package for Social Sciences version 20 software and Microsoft Excel. Frequencies, means, and proportions was done. Overall, 145 and 75 HCWs were interviewed in Kano and Zamfara States respectively. One hundred and twenty-three (56%) from PHCs and 97 (44%) from GHs in both states. Majority (85.0%) of respondents in both states correctly defined IPTp-SP and 83.6% knew SP as the medicine of choice. One hundred and sixty-six (75.5%) respondents knew malaria is caused by *Plasmodium spp.* while 195 (89.5%) identified artemether-lumefantrine as a first line treatment. About 92.2% of health workers in both states adhered to the national guideline to confirm malaria diagnosis using RDT and nearly 38.6% used microscopy. Healthcare workers were knowledgeable on IPTp, cause of malaria and practice the test and treat strategy for the management of uncomplicated malaria. There is need to sustain adherence to the national guidelines on malaria diagnosis and treatment among healthcare workers in both states.

## 1693

### EVOLVING GOVERNANCE OPTIONS TO ENHANCE EQUITABLE DATA SHARING

**Aileen Sheehy**, Anne Whitehouse, Philippe J. Guerin, Laura Merson

*Infectious Diseases Data Observatory, Oxford, United Kingdom*

The WorldWide Antimalarial Resistance Network (WWARN) was established with the aim of generating new evidence to optimise antimalarial treatment through meta-analysis of individual patient data. Its success is driven by the collaboration with the research community in the analysis of research questions of relevance to their patients. Despite the perceived benefits and the success of such models, the recent obligation of mandatory sharing of clinical data from a number of funders and publishers has triggered concerns for researchers and research participants alike. Notably, the benefits of increasing access to data may be not be equally shared by patients or researchers in resource limited countries. To address these potential inequities, WWARN now offers two models for data access - the original model used by WWARN to date whereby data held within the WWARN Data Platform can only be accessed with the permission of the data contributor, and now a governed access model whereby decisions on data access can be delegated by the data contributor to the newly established independent Data Access Committee. Led by TDR, the Special Programme for Research and Training in Tropical Diseases, the Committee assesses requests for data access to ensure that they are ethically and scientifically sound, before releasing the data to

researchers who agree to a framework which protects the rights of both researchers and patients. These data access models enable researchers to maximise the use of existing data to further improve public health while ensuring that data generators receive due credit for their contribution to the research output and the identities of participants are protected. These models aim to increase cross collaboration between those who generate the data and those who request to use it for secondary analysis.

## 1694

### SCALING UP SEASONAL MALARIA CHEMOPREVENTION IN MALI: IMPLEMENTATION CHALLENGES AND LESSONS LEARNED

**Beh Kamate**<sup>1</sup>, Eric A. Swedberg<sup>2</sup>, Drissa Outtara<sup>1</sup>, Diakalia Kone<sup>3</sup>, Jules Mihigo<sup>4</sup>

<sup>1</sup>Save the Children, Bamako, Mali, <sup>2</sup>Save the Children, Fairfield, CT, United States, <sup>3</sup>National Malaria Control Program, Bamako, Mali, <sup>4</sup>U.S. Agency for International Development/U.S. President's Malaria Initiative, Bamako, Mali

Seasonal malaria chemoprevention (SMC), the administration of complete therapeutic courses of antimalarial to all children 3 - 59 months old during the malaria transmission season, is a strategy recommended by WHO in areas of highly seasonal transmission. Despite the challenges of organizing the delivery of SMC, which requires monthly contacts with health workers to receive antimalarial drugs, National Malaria Control Programs (NMCP) have been quick to adopt this new strategy, including Mali, which extended SMC to the entire country (65 districts) in 2016. In 2016, USAID/PMI supported the NMCP campaign in 12 districts in two regions of Mali reaching a total average of 573,040 children 3-59 months old over four rounds of therapeutic courses. We analyzed the SMC programmatic data together with malaria case reporting from the Malian health management information system to evaluate the impact of the SMC campaign on malaria morbidity. The average coverage rate in the Kayes and Sikasso regions respectively were 98% and 92%. In 2016, Mali also extended SMC to children 5 - 10 years old in 3 districts. The three districts reported a 27.7% seasonal reduction in confirmed malaria cases in 5-10 year olds: 2764 cases in 2015 to 1992 cases in 2016. The malaria cases reported decreased from 32.4% in 2015 to 24.9% in 2016, and the malaria mortality rate decreased from 0.42% in 2015 to 0 cases in 2016. These results were achieved through clear planning, strong coordination of partners, multi-channel social and behavior change communications, close supervision and rigorous monitoring. These strategies have been effective in addressing the challenges in the Malian context, which include difficult logistics during the rainy season, high opportunity costs to families who are busy with agricultural work, the adverse effects of the drug treatment in some children, and the limited capacity of some volunteer distributors. SMC has contributed to: (1) a reduction in reported malaria cases; and (2) a reduction of the workload in health centers and a reduction in anti-malarial required during the peak malaria season.

## 1695

### RESULTS OF AN EVALUATION OF THE TOOLKIT TO IMPROVE EARLY AND SUSTAINED INTERMITTENT PREVENTIVE TREATMENT IN PREGNANCY (IPTP) UPTAKE IN MOZAMBIQUE AND MADAGASCAR

**Lalanirina Ravony**<sup>1</sup>, Elana Fiekowsky<sup>2</sup>, Lisa Noguchi<sup>2</sup>, Patricia P. Gomez<sup>2</sup>, Jean Pierre Rakotovo<sup>1</sup>, Eliane Razafimandimby<sup>1</sup>, Armando Tiago<sup>3</sup>, Kathryn Smock<sup>3</sup>, Arsene Ratsimbarisoa<sup>4</sup>, Kristen Vibbert<sup>2</sup>, Robert Sellke<sup>2</sup>

<sup>1</sup>Maternal and Child Health Survival Program/Jhpiego, Antananarivo, Madagascar, <sup>2</sup>Maternal and Child Survival Program/Jhpiego, Baltimore, MD, United States, <sup>3</sup>Maternal and Child Health Survival Program/Jhpiego,

Maputo, Mozambique, <sup>4</sup>Madagascar National Malaria Control Program, Antananarivo, Madagascar

Malaria in pregnancy (MIP) is a leading cause of maternal and newborn morbidity and mortality; however uptake of intermittent preventive treatment in pregnancy with sulfadoxine-pyrimethamine (IPTp-SP), an effective prevention tool, remains alarmingly low across sub-Saharan Africa, including Mozambique and Madagascar. The WHO 2012 policy recommendations to prevent MIP include early enrollment into antenatal care (ANC), accurate estimation of gestational age (GA) and administration of IPTp-SP during ANC visits beginning early in the second trimester, spaced at least one month apart. Preventing MIP remains a challenge in settings with inconsistent application of these recommendations and inadequate provider training in estimating GA. To improve adherence to these recommendations, a toolkit was designed which includes a job aid with an algorithm to guide providers during ANC visits to determine IPTp-SP eligibility. Twenty-four providers from 24 facilities in Madagascar and 29 providers from seven facilities in Mozambique were trained on use of the job aid and interviewed three months later about their experience. Individual providers were interviewed using a questionnaire to assess the clarity and utility to the job aid, and their opinions of the practicality of the orientation. Interviewers also gathered information on years of experience and clinical certification. All providers reported that the job aid reminded them to estimate GA and measure fundal height, which is particularly helpful since few women remember the date of their last menstrual period (LMP). Health workers also reported that the job helped them encourage the use of long-lasting insecticide treated nets, and reminded them of the proper timing to start IPTp-SP. We conclude that the toolkit is useful to prompt providers to calculate GA and offer IPTp as early as possible in the second trimester. Future potential directions include revision of all Toolkit components to reflect input from this evaluation, including development of a wall poster version to enhance readability, and inclusion of a pregnancy wheel to facilitate calculation of GA and estimated date of delivery.

### MONITORING SEASONAL MALARIA CHEMOPREVENTION CAMPAIGNS: LESSONS LEARNED FROM COVERAGE SURVEYS IN 7 COUNTRIES

**Abdoulaye Diallo**<sup>1</sup>, Kovana Loua<sup>2</sup>, Issaka Sagara<sup>3</sup>, Alassane Dicko<sup>3</sup>, Issaka Zongo<sup>4</sup>, Jean Bosco Ouedraogo<sup>5</sup>, H. Kessely<sup>6</sup>, Daugla Doumagoum<sup>6</sup>, Serign Ceessay<sup>7</sup>, Jean Louis NDiaye<sup>1</sup>, Matt Coldiron<sup>8</sup>, Diego Moroso<sup>9</sup>, Ibrahim Laminou<sup>10</sup>, Ebenezer Baba<sup>9</sup>, Eric Hubbard<sup>11</sup>, Lanto Razafindralanto<sup>12</sup>, Paul Snell<sup>13</sup>, Susana Scott<sup>13</sup>, Sham Lal<sup>13</sup>, Matt Cairns<sup>13</sup>, Paul John Milligan<sup>13</sup>

<sup>1</sup>Universite Cheikh Anta Diop, Dakar, Senegal, <sup>2</sup>UGANC, Conakry, Guinea, <sup>3</sup>MRTC, Bamako, Mali, <sup>4</sup>IRSS, Bobo-Dioulasso, Burkina Faso, <sup>5</sup>IRSS, Bobo-Dioulasso, Burkina Faso, <sup>6</sup>CSSI, NDjamena, Chad, <sup>7</sup>MRC Laboratories, Fajara, Gambia, <sup>8</sup>EpiCentre, Niamey, Niger, <sup>9</sup>Malaria Consortium, Kampala, Uganda, <sup>10</sup>CERMES, Niamey, Niger, <sup>11</sup>CRS, Bamako, Mali, <sup>12</sup>CRS, Dakar, Senegal, <sup>13</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Household surveys are the primary method for assessing intervention coverage. They provide key information to support donor investment and to allow programme managers to improve the effectiveness of delivery. SMC (Seasonal Malaria Chemoprevention) programmes aim to ensure that children receive preventive treatments once a month during the malaria season, if the monthly campaigns are well timed four treatments can provide protection throughout the high risk period. Programme managers therefore need simple, reliable monitoring tools which allow assessment of coverage of SMC campaigns. We monitored coverage in 7 countries during the 2015 and 2016 transmission seasons, and based on this experience compiled key lessons learned for the assessment of SMC coverage as part of routine monitoring of national malaria control programmes. Receipt of SMC treatment was assessed from dates recorded on the child's SMC distribution card and from caregiver recall. Assessment

of validity, by comparing with administration registers which recorded the treatments administered to each child, showed excellent agreement with respect to the distribution of the number of treatments received among those reached by the programme. Overall, in 2015, 88% of children in targeted areas were reached by the programme, 74% of children received at least three monthly treatments and 56% received 4 treatments, and in 2016, 92% were reached, 71% received at least three treatments and 54% received four, in most countries the first years of full-scale implementation. SMC indicators should be included in national malaria indicator surveys but in countries with sub-national implementation of SMC, additional sampling in SMC areas may be required to yield sufficient precision for SMC coverage. This should be supplemented by assessment of the quality of SMC delivery, and adherence to the treatment regimen, through interviews with caregiver and community health workers during and immediately after SMC monthly campaigns.

## 1697

### IMPROVING INTERMITTENT PREVENTIVE TREATMENT FOR PREGNANT WOMEN (IPTP) COVERAGE IN 5 DISTRICTS IN CHAD (DOBA, BEBEDJIA, BODO AND BEBOTO) AND KRIBI DISTRICT IN CAMEROON

**Kodjo Morgah**, Naibei Mbaibardoum

*Jhpiego, N'Djamena, Chad*

Malaria is the leading cause of morbidity and mortality in Cameroon and Chad, where an estimated 500,000 and 1.5 million cases occur every year, respectively. In Cameroon, 55% of hospitalizations and 241 deaths among pregnant women reported in 2010 were due to malaria. In Chad, malaria accounted for 30% of hospital admissions and 41% of deaths among pregnant women in 2013. To improve uptake of intermittent preventive treatment for pregnant women (IPTp) for malaria in 5 districts in Chad and the Kribi district of Cameroon, Jhpiego adopted strategies targeting the 4 levels of the health system in each country: updating national policies and guidelines, building capacity of providers, building community health workers' (CHWs) capacity, and engaging in behavior change communication. Nationally, Jhpiego provided technical guidance to the Ministries of Health to develop tools including: training and malaria in pregnancy (MIP) reference manuals for providers and CHWs, guidelines on IPTp, and key supervision and data collection tools. At the regional/district levels, 38 supervisors were trained, and they conducted 248 supervisory visits in both countries, reaching 137 health facilities. At the facility level, 234 providers were trained in malaria prevention and management, MIP, data collection and commodity management. At the community level, 146 CHWs in both countries were trained to raise awareness on malaria prevention and control. In Chad, CHWs referred 6424 pregnant women for antenatal care/IPTp and 11679 pregnant women for malaria treatment in 2014 and 2015. Health facility and CHW data collection tools were revised and monthly validation of district data was implemented to improve data reliability, completeness, and readiness. As a result of Jhpiego's activities in Kribi, IPTp rates increased from the start of the project in 2012 to 2015: from 70% to 83% (IPTp1), 61% to 80% (IPTp2), and 12.7% to 28.1% (IPTp3). Similarly, from 2012 to 2015 in Chad, IPTp1 rates increased from 40% to 83% and from 30% to 50% for IPTp2. These gains are a result of training paired with coaching and supervision activities of trained providers and targeted facilities.

## 1698

### COSTS OF CONTINUOUS ITN DISTRIBUTION CHANNELS: A MULTI-COUNTRY CASE SERIES

**Sara Scates**<sup>1</sup>, Timothy Finn<sup>1</sup>, Angela Acosta<sup>2</sup>, Waziri Nyoni<sup>2</sup>, Mwinyi Khamis<sup>3</sup>, Renata Mandike<sup>4</sup>, Ally Mohamed<sup>4</sup>, Karen Kramer<sup>5</sup>, George Greer<sup>6</sup>, Naomi Kaspar<sup>6</sup>, Emmanuel Flagbey<sup>2</sup>, Prince Owusu<sup>2</sup>, Mavis Osafo<sup>2</sup>, Alex Brown<sup>7</sup>, Mamadou Sangare<sup>7</sup>, Melanie Joiner<sup>7</sup>, Jules Mihigo<sup>8</sup>, Diakalia Koné<sup>9</sup>, Hannah Koenker<sup>2</sup>, Joshua Yukich<sup>1</sup>

<sup>1</sup>Tulane University School of Public Health and Tropical Medicine, Department of Tropical Medicine and Center for Applied Malaria Research and Evaluation, New Orleans, LA, United States, <sup>2</sup>VectorWorks Project, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, <sup>3</sup>Zanzibar National Malaria Elimination Program, Zanzibar, United Republic of Tanzania, <sup>4</sup>Tanzania National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>6</sup>U.S. Agency for International Development/ President's Malaria Initiative Tanzania, Dar es Salaam, United Republic of Tanzania, <sup>7</sup>Population Services International Mali, Bamako, Mali, <sup>8</sup>U.S. Agency for International Development/President's Malaria Initiative Mali, Bamako, Mali, <sup>9</sup>Mali National Malaria Control Program, Bamako, Mali

Sustained universal coverage with ITNs is essential to malaria control. While mass campaigns deliver nets in a single time-limited operation, continuous distribution systems (CD) use existing infrastructure such as clinics, schools, religious leaders and community-based workers to deliver nets continuously over time. WHO recommends the use of continuous distribution channels for maintaining universal coverage of insecticide treated nets (ITNs), but little is known about the cost or cost-effectiveness of this approach relative to others. The cost of ITN distribution was estimated in four settings including five distribution modalities: Zanzibar (community), Ghana (schools, ANC/EPI), Tanzania (schools, ANC/EPI), Mali (urban mass campaign, rural mass campaign, and ANC). The study utilized the provider perspective and estimated both economic and financial costs. Costs were collected retrospectively from financial and operational records and through stakeholder interviews at the national and regional level. A survey instrument was utilized to collect resource use and expenditure information at the subnational and distribution point levels. Preliminary results show a range of financial costs for LLIN distribution from 0.78 - 3.34 USD per LLIN incurred to international donors. Most of the ITN distributions studied (campaign and continuous) had similar donor costs ranging from 0.78 to 1.46 USD, with the Tanzania 2015 school distribution was an outlier, likely because donors covered costs that might have been contributed by the country in other settings. Continuous distribution systems involved higher contributions from countries compared to campaigns, suggesting greater buy-in or potential for health system strengthening with continuous distribution. Malaria transmission models will be used to estimate the epidemiological benefits of maintaining high coverage of ITNs between mass campaigns. These results will be combined with the estimated costs to produce estimates of the epidemiological effects, cost-effectiveness and net health benefit of continuous distribution.

## 1699

### IMPROVED METHOD FOR PURIFICATION OF *PLASMODIUM FALCIPARUM* LATE STAGE TROPHOZOITES AND SCHIZONTS FROM *IN VITRO* CULTURES USING MAGNETIC SELECTION

**Sebastien Dechavanne**<sup>1</sup>, Celia Dechavanne<sup>1</sup>, Benoit Gamain<sup>2</sup>, Christopher L. King<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Institut National de Transfusion Sanguine, Paris, France

*In vitro* culture of *Plasmodium falciparum* has provided important insights for parasite biology and pathogenesis as well as studies of drug resistance and targets of host immunity. Cultures are commonly maintained

asynchronized at low parasitemia. However, certain experiments require high parasitemia and/or highly synchronized parasites that can be difficult to achieve with current methods. Enrichment and synchronization of parasite-infected red blood cells (irbc) are currently based on density, osmotic fragility of irbcs or on magnetic properties of hemozoin, a disposal product from the digestion of hemoglobin by the parasite containing iron. The magnetic purification is less stressful to parasites compared to other methods because they are maintained in physiological buffer. The culture is loaded into a column containing small iron beads and placed in a magnet. Late stage irbcs that contain large amounts of hemozoin are preferentially retained on the column and subsequently eluted from the column by removing the magnet. Current protocols add physiological buffers to the column to elute irbcs by gravity, however many late stage irbcs that contain more hemozoin can be retained on the column. By eluting parasites using a syringe to increase negative pressure to the column, the quantity and purity of mature stage parasites, especially late stage schizonts, are routinely increased by 2 fold or more. Parasite growth and survival was not compromised by this method in culture. Other modifications such as changes in hematocrit, buffers and number of elutions per column were tested to further optimize the late stage irbcs purification and will be described. Obtaining larger quantities of late mature stages can be valuable in many different fields of malaria research.

## 1700

### IMPROVING MALARIA CASE MANAGEMENT AND SURVEILLANCE THROUGH A COMMUNITY-BASED PILOT IN PANAMA

**Carmela M. Jackman Smith<sup>1</sup>**, Luis De Urriola<sup>1</sup>, Lizbeth Cerezo<sup>1</sup>, Fernando Vizcaino<sup>1</sup>, Carlos Victoria<sup>1</sup>, David Cortes<sup>1</sup>, Christina Bradley<sup>2</sup>, Darlene Bhavnani<sup>2</sup>, Sebastian Salvador<sup>2</sup>, Theodoor Visser<sup>2</sup>, Itza Barahona de Mosca<sup>1</sup>

<sup>1</sup>Ministerio de Salud de Panama, Panama, Panama, <sup>2</sup>Clinton Health Access Initiative, Panama, Panama

Panama aims to eliminate malaria by 2020. In 2016, 61% (496/811) of reported cases in Panama were detected in the Guna comarcas, indigenously populated areas requiring culturally appropriate case management and surveillance strategies. The comarca Guna Yala, located along the northeast coast of Panama is comprised of 49 communities, many of which are accessible only by boat. Due to the remote location of these communities, diagnosis, treatment, and reporting are often delayed. Time between symptom onset and diagnosis via microscopy may be up to 30 days. In an effort to strengthen case management and surveillance in Guna Yala, the Ministry of Health of Panama (MINSa), Guna authorities, and Clinton Health Access Initiative, launched a 12-month pilot program in October 2016. Community health workers (CHWs) were recruited and trained to perform malaria rapid diagnostic tests (RDTs), treat positive cases, report RDT results, and prepare blood smears for microscopy confirmation. CHWs were trained according to MINSa guidelines specific to malaria case management in remote areas. In October 2016, 44 CHWs from 42 communities in Guna Yala were trained and equipped. In the first three months of the pilot, CHWs tested 203 febrile patients using RDTs; 48 (24%) were both RDT and microscopy positive. An additional 10 cases were detected during microscopy confirmation. Cases found by CHWs represented 41% (58/143) of those reported in Guna Yala during this period. In January 2017, a supervision visit was made to CHWs. Of the 44 trained CHWs, 80% (35) were still active and 32 were evaluated on their malaria knowledge, diagnostic and treatment practices, and stock management. Almost all CHWs visited (29/32) performed RDTs appropriately, but only two-thirds (21/32) accurately interpreted RDT results. When presented with case scenarios, nearly two-thirds of CHWs (20/32) demonstrated that they would administer the correct treatment. In response, 30 CHWs were provided with additional training and a dosing wheel. Through community participation, this pilot program has helped to strengthen passive surveillance and to provide timely treatment to malaria cases.

## 1701

### ANTIMALARIAL PRESCRIPTION PRACTICES AT 21 PUBLIC OUTPATIENT FACILITIES LOCATED IN REGIONS OF VARYING MALARIA ENDEMICITY IN UGANDA

**James A. Kapisi<sup>1</sup>**, Asadu Sserwanga<sup>1</sup>, Ruth Kigozi<sup>1</sup>, Jimmy Opigo<sup>2</sup>, Adoke Yeka<sup>3</sup>, Moses R. Kanya<sup>4</sup>, Arthur Mpimbaza<sup>5</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>National Malaria Control Programme, Ministry of Health, Kampala, Uganda, <sup>3</sup>Makerere University School of Public Health, College of Health Sciences, Kampala, Uganda, <sup>4</sup>Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, <sup>5</sup>Child Health and Development Centre, Makerere University, Kampala, Uganda

In Uganda antimalarials are often prescribed when malaria is unlikely, a problem that is becoming critical following the adaptation of effective but expensive ACTs as the first and second line treatment for uncomplicated malaria. We present data on antimalarial prescription practices among outpatients seen at Malaria Reference Centers (MRCs) who had malaria test results. The Uganda Malaria Surveillance Program (UMSP) collects individual level data from 21 MRCs located in different regions of the country including the Northern region (Acholi sub-region (8); Lango sub-region (7)), South-west (2), West Nile (1), Eastern (1), East central (1) and Central (1). At each site data including medicines prescribed are captured in standard outpatient registers. The data are then entered into an electronic data base, and submitted to a core facility at weekly and monthly intervals for analysis and report generation. Between Jan 2015 and March 2017, a total of 1,651,950 patients were seen at all the MRCs; Acholi sub-region (669,050), Lango sub-region (549, 705) and other regions (433,195). Most (87.2%) patients had a malaria test performed, of which 70.3% were confirmed by Rapid Diagnostic Testing (RDT). Proportion of patients with a positive test was 71.3% in Acholi sub-region, 51.9% in Lango sub-region and 38.9% in the other regions. Of children with a negative blood smear, 11,888 (12.4%) in Acholi sub-region, 12113 (11.8%) in Lango sub-region and 6232 (5.9%) in other regions were prescribed an antimalarial. Artemether-lumefantrine was the most commonly prescribed antimalarial among children with positive (92.3%) and negative (91.2%) malaria test results. Among patients with a negative malaria test result, patients with a negative RDT (OR 1.2, 95%CI 1.17, 1.24, p<0.001) were more likely to be prescribed antimalarials compared to those with negative microscopy result. Prescription of antimalarials to patients with negative malaria test results is common at MRCs. With no clear benefit of this practice, there is an need to understand reasons why clinicians continue to prescribe antimalarials even when test results are negative.

## 1702

### CONTRIBUTION OF THE IMPROVING MALARIA CARE (IMC) PROJECT TO IMPROVING MALARIA CASE MANAGEMENT IN BURKINA FASO: STRENGTHENING THE CAPACITY OF HEALTH CARE PROVIDERS

**Thierry D. Ouedraogo**, Ousmane Badolo, Mathurin Dodo, Moumouni Bonkougou

*Jhpiego/Improving Malaria Care (IMC) Project, Ouagadougou, Burkina Faso*

Malaria kills mostly children under five and pregnant women in Burkina Faso, and is the leading reason for medical consultation and hospitalization. Improving case management is a real challenge in reducing morbidity and mortality. The goal of the National Malaria Control Program (NMCP) was to reduce the morbidity by 75% by end of 2000 and malaria mortality to close to zero by the end of 2015. The United States Agency for International Development-supported Improving Malaria Care (IMC) project aims to reduce malaria morbidity and mortality. This includes strengthening the capacity of health providers to deliver high quality management- diagnosis and treatment, of malaria cases. Between 2014 and 2016 IMC and the NMCP revised malaria guidelines, oriented 163

national trainers, trained 1,819 providers at all levels and organized supportive supervision of these staff. As a result correct diagnostic testing of malaria cases increased from 62% to 82%. The proportion of people with uncomplicated malaria who received artemisinin combination therapy (ACT) increased from 85% to 94%. Strengthening of the data management system facilitated this information to be collected. Training these providers based on national guidelines and reinforcing their learning through supervision has enabled the NMCP to have a pool of health providers capable of treating the most vulnerable population and helping to reduce malaria mortality level in Burkina Faso. This training is accompanied by the implementation of formative supervision. Continued supervision and quality data management positions the NMCP to reach and document its goals.

## 1703

### PLASMODIUM RIBOSOMES DO NOT STALL ON POLYA TRACKS

Slavica Pavlovic Djuranovic

Washington University School of Medicine, St. Louis, MO, United States

We have recently described a gene regulatory mechanism that is based on coding polyadenylate - poly(A) tracks that stall and frameshift translation apparatus in multiple model organisms. The levels of mRNAs of genes with A-rich motifs are regulated by the programmed mRNA decay through a combination of no-go (NGD) and nonsense-mediated (NMD) decay. Analysis of eukaryotic genomes coding sequence indicates a potential pool of polyA track regulated genes that range from 2% in most of the species, including human, to 60% in *Plasmodium falciparum*. The extreme AT richness (80%) of *P. falciparum* genome, an unusually high number (>2000 copies) and length of polyA tracks (111As in a row) indicates possible differences in the translational machinery and mRNA surveillance mechanisms compared to the other organisms. Here we show that *P. falciparum*, in contrary to the other tested organisms, can efficiently translate mRNAs with polyA tracks without notable effects on mRNA and protein stability. Biochemical and ribosome profiling analyses of endogenous genes and reporter sequences with engineered polyA motifs indicate that polyA tracks don't induce ribosomal stalling and/or frameshifting in *P. falciparum*. Biochemical analysis of the same reporter sequences in *T. thermophila*, a eukaryotic organism with 75% AT-rich genome, indicates the *Plasmodium* genus as a specific group of organisms with these capabilities. Further, we have dissected components of *P. falciparum* translational machinery and mRNA surveillance pathways. We find that in comparison to human cells, an absence of classical NGD pathway as well as specific features of *Plasmodium* ribosomes play a role in polyA track translation. Our analysis of RACK1 protein in human cells indicates a role for this protein in both NGD and non-stop decay (NSD) mechanisms. The lack of ribosome-associated *P. falciparum* RACK1 protein compared to the other eukaryotes suggests alternate mechanisms for targeting NSD and NGD substrates in malaria parasites.

## 1704

### MAPPING THE POLICY AND PROGRAMMATIC DECISION-MAKING LANDSCAPE FOR MALARIA CONTROL INTERVENTIONS: A CASE STUDY FOR MALI AND ZAMBIA

Kenzie Tynuv<sup>1</sup>, Christelle Gogue<sup>1</sup>, Joseph Wagman<sup>1</sup>, Jeff Bernson<sup>1</sup>, Naomi Printz<sup>2</sup>, Marlize Coleman<sup>3</sup>, Molly Robertson<sup>1</sup>  
<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>John Snow, Inc., Rosslyn, VA, United States, <sup>3</sup>IVCC, Liverpool, United Kingdom

Global efforts to fight malaria have proven successful in recent years, yet the financial resources required to sustain progress and further reduce the malaria burden remain limited. To best optimize available funding, countries and programs have to make evidence-based decisions when choosing if and how to implement malaria control interventions, including new vector control tools. However, the translation of evidence into policy and practice is a complex process unique to each country that must

be understood to better support evidence utilization. This study aims to describe the malaria control decision-making landscape in Mali and Zambia and provide an assessment of the facilitators and barriers that affect evidence generation and utilization. We employed a case-study methodology involving a comprehensive document review that was used to inform the development of a semi-structured interview guide for each stakeholder group and country program. Snowball and purposive sampling methods were used to identify relevant stakeholders, and semi-structured interviews were conducted with consenting participants. Questionnaires were distributed to informants not able to attend in-person interviews. Interview transcripts and questionnaires were then coded to conduct thematic analyses. The results presented provide details on the roles of stakeholders involved in the decision-making process, the platforms used for collaboration and strategy discussions, the variables and evidence considered when making decisions, the methods used to prioritize and allocate resources, the influence shifting entomological and epidemiological patterns have on decision making, and the challenges encountered in the decision-making process. This study provides a contextual understanding of how malaria policy and programmatic decisions are made in Mali and Zambia and the role of evidence use in each country. Understanding these complex landscapes is an important step in promoting collaboration between researchers and policy and program officials to maximize the utilization of evidence when making decisions about malaria control interventions.

## 1705

### CONTRIBUTION OF THE STANDARDS-BASED MANAGEMENT AND RECOGNITION (SBM-R) APPROACH TO FIGHTING MALARIA IN BURKINA FASO

Moumouni Bonkougou, Ousmane Badolo, Thierry Ouedraogo  
*Jhpiego/Improving Malaria Care (IMC) Project, Ouagadougou, Burkina Faso*

In 2015, Burkina Faso recorded 8,286,463 malaria cases, including 450,024 severe cases with 5379 deaths. The main reasons for these death are: Inadequate application of national malaria diagnosis and treatment guidelines, delays in seeking health care and poor quality of case management. The Standards-Based Management and Recognition (SBM-R) approach is used to improve quality of care using performance standards based on national guidelines. SBM-R includes the following steps: set performance standards; implement the standards; monitor progress and recognize as well as celebrate achievements. Areas covered by the approach are: services organization, case management at both health center and community, Intermittent Preventive Treatment in Pregnancy (IPTp), promotion of Long Lasting Insecticide treated Nets (LLIN) use and infection prevention and control. Since June 2016, 26 health facilities in three regions have been implementing SBMR. Therefore, 105 health workers have been trained. Performance progress was measured through 5 evaluations including baseline. Baseline has shown the highest score was 47% (Kounda) while the lowest was 9% (Niangoloko). The main issues observed were: lack of program activities, management tools, handwashing facilities, LLINs and misuse of Rapid Diagnosis Tests. Their cause was determined and an improvement plan was developed by each site. The second, third and final evaluations revealed a change in performance scores for all sites. The external evaluation showed 17 out of 26 health facilities with a score higher than 60%; among them 10 with a score above 80% (Bougoula, 94%). At the same time, IPTp 3 increased from 34.48% in 2014 to 78.38% in 2016 and no malaria death has been registered since October 2015. For the site under 80% the key reasons were: staff turnover, commodities stock-out and lack of infrastructure. The process continues with recognition of health facilities and supporting others (those at less than 80%) to reach the desired performance level. The SBM-R approach appears to be a great tool for improving quality and performance of health facilities.

## 1706

**THE KENYAN MALARIA MARKET AFTER AMFM**

**Anne M. Musuva**<sup>1</sup>, Dennis Mwambi<sup>1</sup>, Julius Njogu<sup>2</sup>, Kate O'Connell<sup>2</sup>

<sup>1</sup>*Population Services Kenya, Nairobi, Kenya*, <sup>2</sup>*ACT Watch, Population Services International, Washington, DC, United States*

In Kenya, the Affordable Medicines Facility for malaria medicines (AMFm) pilot project was implemented in 2010-2013. The objective was to scale up quality assured ACTs (QAACT) by bringing down the price through factory gate subsidies, and flush out antimalarial monotherapies. The MOH recommends test before treatment of positive cases with ACTs across all malaria epidemiological zones and the administration of Sulphadoxine Pyrimethamine (SP) is restricted to endemic areas for malaria prophylaxis in pregnancy. ACTWatch survey is a multi-country research project implemented by PSI with the goal of monitoring key antimalarial market indicators at national level. Between 2010-2016, four rounds of descriptive cross-sectional surveys were conducted with representative sample of locations. In each sampled location, a census of all public and private outlets with potential to sell or distribute antimalarials or provide malaria blood testing was conducted. Data were analysed using Stata. Availability of quality assured ACTs (QAACTs) among public facilities increased from 88% in 2010 to 95% in 2016. In 2016, among public facilities, SP availability was 70% in endemic areas, and not available in other zones. In the anti-malarial stocking private sector, availability of QAACTs rose from 20% in 2010 to 46% in 2016. Availability of non-QAACTs in private facilities increased to 52% in 2016 and SP availability was common (76%). The private sector dominated the antimalarial market share at 70%, most commonly by pharmacies. SP was commonly distributed in the private sector. Availability of malaria testing was high in the public sector at 88%, but low in the private sector- 20%. There is a high readiness for the management of malaria in Kenya, particularly in the public sector. The high market share and low testing in the private sector indicates widespread presumptive treatment. The wide availability of SP in non-endemic areas in the private sector indicates that it is unlikely that it is being used for IPTp. The MOH and regulatory bodies should engage the private sector to decrease the use of non-QAACTs and ensure SP is not used for malaria treatment.

## 1707

**"IT'S BEEN USED FOR A LONG TIME": EXPLORING PRIVATE PROVIDERS' PREFERENCE FOR CONTINUED USE OF ORAL ARTEMISININ-BASED MONOTHERAPY IN MYANMAR**

**Manuela Tolmino**, Hnin Su Su Khin, Si Thu Thein, Ashton Strait, D. Par Kyaw

*Population Services International, Myanmar, Yangon, Myanmar*

Continued use of oral artemisinin-based monotherapy (oAMT) is widely considered to be one of the main factors in the development and spread of resistance to artemisinin and its derivatives. Importation and registration of oAMT was banned in Myanmar in 2011. Since 2012 a program has been underway to crowd-out oAMT from the private sector with subsidized, quality assured ACT (QAACT). Outlet survey data show oAMT availability decreased from 67% in 2012 to 20% in 2016 and market share from 44.3% to 10.6%. Despite these impressive gains, oAMT use persists. We conducted a qualitative study at 24 private sector outlets in May 2016 to better understand provider motivation to stock and sell oAMT. Providers were purposively sampled for inclusion from townships with the highest oAMT availability reported in the 2015 outlet survey. In-depth interviews were conducted at the provider's outlet or a location of their choosing in local languages, and were recorded. Discussions covered providers' historical and current malaria treatment practices, reasons for stocking/selling oAMT and business decision-making, among other topics. Transcripts were coded, and codes were compiled to generate emerging themes. Providers perceived oAMT as being an effective medicine with few side effects and a quick action, requiring few tablets (compared to

QAACTs). Providers were either motivated by continued demand from clients or reluctance to change a familiar approach to malaria treatment. Providers reported a higher profit margin with oAMT, compared with price-controlled ACTs. Most respondents described oAMT as a replacement drug for older antimalarials but none were motivated to switch from oAMT to ACT. Few providers were aware of the ban on monotherapy. Findings from this study can inform the revision of provider communication messages to better address the reasons why providers continue to stock oAMT. Future efforts should also focus on strengthening consumer behaviour change communication to address patient demand for oAMT. In addition, increased government enforcement of the oAMT regulations could help counter the profit incentive driving the sale of some oAMTs.

## 1708

**RESULTS FROM A BASELINE SURVEY TO EVALUATE DIFFERENT INDOOR RESIDUAL SPRAY IMPLEMENTATION STRATEGIES FOR MALARIA CONTROL**

**Derek Pollard**<sup>1</sup>, Anna Winters<sup>1</sup>, Busiku Hamainza<sup>2</sup>, David Larsen<sup>3</sup>

<sup>1</sup>*Akros, Lusaka, Zambia*, <sup>2</sup>*National Malaria Elimination Center, Government of Zambia, Lusaka, Zambia*, <sup>3</sup>*Syracuse University, Syracuse, NY, United States*

Indoor residual spray is an important intervention for the control of malaria vectors. Most national malaria control programs do not have large IRS operations due to the costs involved, and those that do are rarely able to protect more than 30% of the population at any risk of malaria transmission. To implement IRS therefore begs the question, if we cannot spray all the houses at risk how should we prioritize which houses we spray? IRS works through a type of herd protection, wherein a blood-seeking mosquito may feed on an individual in a house protected by IRS but dies while resting on the sprayed wall following the bloodmeal. Therefore at the local spatial scale, we know that IRS needs to be applied in a high concentration. Unfortunately, information is scarce on the threshold needed for herd protection, but the WHO sets an 85% coverage target as the standard for successful IRS implementation at local spatial scales. Yet, at larger spatial scales it remains unknown whether concentrating limited resources in one area (at the expense of others) is better than spreading limited resources across the entire area (while still maintaining high concentration at local spatial scales). We are currently conducting a trial of different IRS implementation strategies at the district level. Three strategies will be compared: 1) concentrating all available IRS resources in a single district, 2) spraying highest risk communities in 2 districts with risk defined as proximity of a community to health centers with the highest incidence of malaria, and 3) spraying highest risk communities in 2 districts with risk defined as communities with the highest likelihood of having *Anopheles funestus* populations. The three outcomes of *Plasmodium falciparum* infection, counts and densities of *Anopheles* mosquitos, and health facility incidence will be analyzed using a difference-in-differences approach to assess the effectiveness of each strategy. Herein we will present the study design and results from the baseline cross-sectional survey.

## 1709

**USING SMS TO REPORT STOCK-OUTS OF ANTI-MALARIA MEDICINE AND BED NETS IN GUINEA**

**Rajeev Colaco**<sup>1</sup>, Rebecca M. Flueckiger<sup>1</sup>, Molly Chen<sup>2</sup>

<sup>1</sup>*RTI International, Washington, DC, United States*, <sup>2</sup>*RTI International, Durham, NC, United States*

The millennium development target 6c1 calls for the halt and reverse of malaria incidence by 2015. The global malaria mortality rate reduced by 58% between 2000 and 2015. It is estimated that 6.2 million deaths from malaria were averted, the majority of which are children under five years old in Sub-Saharan Africa. While great strides have been made in malaria control, in 2015 over 212 million new cases were reported worldwide, 90% of which were from the WHO Africa Region<sup>3</sup>. In 2015 Guinea

reported an estimated 4.6 million cases and 9,900 deaths. The global technical strategy for malaria 2016-2030, which targets a 90% reduction of malaria incidence and mortality globally by 2030 was approved by the world health assembly in May 2015. The first step to better provide services to those at risk of malaria in Guinea is an efficient and effective reporting system. RTI International is conducting a formative evaluation that aims to determine if weekly SMS reporting is more beneficial than monthly paper based reporting through evaluating report quality, reporting cost and frequency of antimalaria medication and bed net stock-out and the secondary aims of the evaluation are to determine the perception of a SMS reporting system. As a result of analyzing the StopPalu's intervention outcomes, RTI International proposed to integrate technology to accelerate the development outcomes of the project. The integration of technology into a project intervention is a new area that is being explored across USAID and other donor-funded projects as the rapid spread of mobile technologies to developing countries continues. The findings of this evaluation can serve as a base for similar project interventions.

## 1710

### SEASONAL MALARIA CHEMOPREVENTION SCALING UP AND ITS IMPACT ASSESSMENT IN MALI

**Issaka Sagara**<sup>1</sup>, **Hamma Maiga**<sup>1</sup>, **Mahamadou Kaya**<sup>1</sup>, **Seydou Traore**<sup>1</sup>, **Alassane Dembele**<sup>1</sup>, **Sanga Goro**<sup>1</sup>, **Moussa Traore**<sup>1</sup>, **Paul Snell**<sup>2</sup>, **Diakalia Kone**<sup>1</sup>, **Patrice Coulibaly**<sup>3</sup>, **Eric Hubbard**<sup>3</sup>, **Ogobara Doumbo**<sup>1</sup>, **Matthew Cairns**<sup>2</sup>, **Paul Milligan**<sup>2</sup>, **Alassane Dicko**<sup>1</sup>

<sup>1</sup>University of Bamako, Bamako, Mali, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Catholic Relief Services (CRS), Bamako, Mali

Seasonal Malaria Chemoprevention (SMC) was recommended in March 2012 by World Health Organization for sahelian countries as control strategy. Mali was one of the first countries to introduce SMC and reaching nationwide coverage in 2016. From 2014, the ACCESS-SMC project funded by UNITAID has supported the scale up and monitoring and evaluation (ME) of SMC in seven sahelian countries including Mali. As part of the ME the coverage of the intervention using cross-sectional surveys and its impact on malaria burden were assessed. Children aged from 3 to 59 months years old received rounds of SMC with Sulfadoxine-pyrimethamine plus Amodiaquine at monthly interval during rainy season up to four months. SMC drugs were given at fix point in village or area. Rapid diagnostic test for malaria was performed in case of fever during the drug distribution campaign and malaria cases was treated on site during the campaigns. Cross-sectional survey was undertaken in 2015 and 2016 in December to assess coverage in 50 clusters (villages or quarters of urban areas) randomly selected with probability proportional to size in 5 districts. In each cluster about 20 children aged between 4 months and 7 years were surveyed. Impact of SMC on malaria burden was assessed using data routine malaria data from 2013 to 2016 from health centers. In addition, routine individual malaria data from health center registers are being collected using tablets PC. Coverage of SMC defined as proportion of children who received the four rounds of SMC was 43% in 2015 and 53% in 2016. The coverage rate was relatively lower (42%) in children from parents considered themselves poor than in children of non poor parents (58%). Preliminary analysis indicated that SMC was associated with a reduction of 49% of malaria cases. Additional results on the impact of SMC using data from sentinel sites being collected from health center registers will be available and presented.

## 1711

### SCALING-UP OF SEASONAL MALARIA CHEMOPREVENTION IN SOKOTO AND ZAMFARA STATES, NIGERIA: MONITORING DELIVERY AND IMPACT

**Musa A. Kana**<sup>1</sup>, **Matthew Cairns**<sup>2</sup>, **Sham Lal**<sup>2</sup>, **Ahmad Luqman**<sup>3</sup>, **Ibrahim Maikore**<sup>4</sup>, **Paul Snell**<sup>2</sup>, **Harriet Kivumbi**<sup>5</sup>, **Ebenezer Baba**<sup>5</sup>, **Diego Moroso**<sup>5</sup>, **Paul Milligan**<sup>2</sup>

<sup>1</sup>Department of Community Medicine, Kaduna State University, Kaduna, Nigeria, <sup>2</sup>MRC Tropical Epidemiology Group, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>ACCESS-SMC Project, Malaria Consortium, Abuja, Nigeria, <sup>4</sup>Monitoring and Evaluation Branch, National Malaria Elimination Programme, Abuja, Nigeria, <sup>5</sup>Malaria Consortium, Abuja, Nigeria

Following pilot schemes in Katsina and Jigawa, SMC was introduced in Zamfara and Sokoto states in 2015 and 2016 through the ACCESS-SMC project, an area, which includes 37 Local Government Areas (LGAs) and 1.8 million children (2016 estimate). SMC was introduced in 17 LGAs in 2015 and all 37 LGAs in 2016. A sentinel surveillance system was established to monitor impact of SMC on malaria by collecting routine data on malaria cases before and after SMC scale-up from 24 health facilities, including details of cases of all ages, tested or treated for malaria. At first visit to each facility, retrospective data from 2013-2015 was collected. Subsequently, selected facilities were visited every 3 months to assemble data from the registers. Community-based surveys were conducted at the end of 2015 and 2016 transmission seasons to assess coverage and quality of SMC delivery. Each year, 60 settlements were selected with probability proportional to size, and compact segment sampling used to select survey households. Children up to 7 years of age were included in the survey in order to be able to assess SMC coverage in the target age group (at least 3 months old at the time of SMC administration, and who were less than 5 years at the first cycle), and to determine whether older children were being treated. Receipt of SMC was determined from SMC record cards held by caregivers for each child, and from caregiver recall. In 2015, 84% of eligible children received SMC at least once, 77% received at least three SMC treatments and 54% were protected for four months. In 2016, delivery was expanded to cover all 37 LGAs, but delays in registration of dispersible tablets led to a shortage of drugs at the start of the campaign so that not all areas could be reached at cycle 1. 81% of children received SMC at least once, 46% at least three times, and 21% received four treatments. SMC is part of Nigeria's strategic plan for malaria control for 2014-2020 with nine states eligible to receive SMC, representing 12 million children under 5 years of age. Careful supervision of delivery will be required to maximize the impact of this intervention.

## 1712

### A FATAL CASE OF IMPORTED MALARIA IN MONGOLIA

**Michael E. von Fricken**<sup>1</sup>, **Leslie Valenzuela**<sup>1</sup>, **Bekh-Ochir Baigalmaa**<sup>2</sup>, **Ganbold Dalantai**<sup>2</sup>, **Nymadorj Tsogbadrakh**<sup>2</sup>, **Paul M. Lantos**<sup>3</sup>

<sup>1</sup>George Mason University, Department of Global and Community Health, Fairfax, VA, United States, <sup>2</sup>National Center for Zoonotic Diseases, Ulaanbaatar, Mongolia, <sup>3</sup>Duke University School of Medicine, Division of Pediatric Infectious Diseases, Durham, NC, United States

On day nine from onset of symptoms, Mongolia reported its first ever malaria case fatality. A 31-year-old Mongolian engineer who was infected with *Plasmodium falciparum* while working in the Democratic Republic of the Congo died of severe malaria shortly after his return to Mongolia. He initially presented at Darkhan-Uul provincial hospital on day five from onset of first symptoms, with malaria like symptoms. He was later hospitalized on day six, when his condition failed to improve. On day 6, the patient tested positive for malaria by microscopy (32% parasitemia). The results were confirmed using a Pf/Pan specific malaria rapid diagnostic test (RDT) and PCR on day seven. Treatment for malaria was initiated

on the evening of day seven. After entering into a coma on the 8th day, the patient died of complications due to malaria the following day, day 9th. Increased international travel and expanded efforts for global development in Africa have led to a rise in imported cases of malaria into non-endemic developing countries like Mongolia. This report focuses on the tenth imported case of malaria in Mongolia since 2005, with more cases expected in the future. This fatal case illustrates the need for readily available RDTs and treatment for suspected cases of imported malaria in Mongolia.

### AUTOMATION TRIPLES THROUGHPUT OF PFSMZ MALARIA VACCINE EXTRACTION FROM MOSQUITOES WITH 20-FOLD REDUCTION IN TRAINING TIME

Sumana Chakravarty<sup>1</sup>, Amanda Canezin<sup>2</sup>, Mariah Schrum<sup>2</sup>, Michelle Laskowski<sup>3</sup>, Yunuscan Sevimli<sup>2</sup>, Gregory Chirikjian<sup>4</sup>, Russell H. Taylor<sup>2</sup>, Stephen L. Hoffman<sup>1</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Laboratory for Computational Sensing and Robotics, Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>Leidos Life Sciences, Frederick, MD, United States, <sup>4</sup>Department of Mechanical Engineering, Johns Hopkins University, Baltimore, MD, United States

The global death toll from Malaria is estimated to be upwards of 600,000 people each year, with more than 1,000 children succumbing every day. *Plasmodium falciparum* (Pf) Sporozoite (SPZ)-based vaccines are the only intervention in humans, proven to induce robust, high-level (>90%) and long-lasting (at least 14 months) protective efficacy against malaria, forming the basis of Sanaria's unique technology platform of aseptic, purified, cryopreserved live *Plasmodium falciparum* Sporozoites (PFSMZ). PFSMZ Vaccine contains live PFSMZ attenuated by radiation, PFSMZ-GA1 is attenuated genetically, and infectious parasites in PFSMZ-CVac are arrested at the blood stage by drugs like chloroquine. Driven by stellar clinical safety and efficacy results, and backed by an uncommon consortium of international investigators from >35 research groups in 18 countries, Sanaria plans to receive approval for a Biologics License Application (BLA) by the beginning of 2019 for travelers and by 2020 for all age groups and for mass vaccination programs, and has received Fast Track Designation in 2016 from the FDA for PFSMZ Vaccine, in recognition of its progress. In keeping with scaling-up manufacturing operations, our goal was to automate a key step of isolating SPZ from the salivary glands of mosquitoes based on amalgamating and integrating various biological, physical, chemical and engineering principles. Significant technological advancements included the first-ever development of prototypes for batch-processing mosquitoes in two steps of decapitation and gland extrusion and collection, resulting in at least a 3-fold higher throughput with reduced operator fatigue, a 15-20 fold reduction in operator training time, and significantly improved product purity. Further increase in efficiency is expected through leveraging alternative task-distribution methods that have already been implemented for manual dissection. Data from rigorous workflow analysis and the steps involved in transitioning the semi-automated mosquito microdissection system from laboratory to cGMP-compliant prototypes will be presented.

## 1714

### USING ANTIBODIES TO SIMULATE THE CO-ADMINISTRATION OF TRANSMISSION-BLOCKING AND PRE-ERYTHROCYTIC VACCINES ACCELERATES MALARIA ELIMINATION IN MICE

Ellie Sherrard-Smith<sup>1</sup>, Katarzyna A. Sala<sup>1</sup>, Michael Betancourt<sup>2</sup>, Leanna M. Upton<sup>1</sup>, Fiona Angrisano<sup>1</sup>, Meribeth J. Morin<sup>3</sup>, Azra C. Ghani<sup>1</sup>, Thomas S. Churcher<sup>1</sup>, Andrew M. Blagborough<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Columbia University, New York, United Kingdom, <sup>3</sup>PATH Malaria Vaccine Initiative, Washington, DC, United States

Vaccines that reduce human-to-mosquito and mosquito-to-human transmission have the potential to accelerate malaria elimination and can help to achieve eventual eradication. Currently, the lead candidates for transmission-blocking vaccines (TBVs, which restrict parasite development in the mosquito) are in the early stages of development, while pre-erythrocytic vaccines (PEVs, which inhibit hepatocyte invasion) have been shown to be partially effective against clinical malaria in a Phase 3 trial. We explored the benefit that co-administering TBVs and PEVs could have by administering antibodies to a murine population. These antibodies would be upregulated in hosts as a consequence of using vaccines. Multigenerational assays, passaging *Plasmodium berghei* between murine and *Anopheles stephensi* mosquito populations, were conducted simulating different doses of TBV, (these doses were titrated to reduce the percentage of oocyst-infected mosquitoes by 50%, 65% or 85%), or PEV (titrated to reduce the percentage of infected mice by 47.2%). These vaccines target different life-stages of the parasite life cycle and were found to enhance the efficacy of the PEV by 70% when used in combination compared to the expected efficacy were the two vaccines acting independently. This synergism is produced by reductions in parasite density caused by the partially-effective interventions. Using a rodent multigenerational system, we demonstrate that simulating the co-administration of a TBV with a PEV has the potential to accelerate elimination.

## 1715

### CONTROLLED *PLASMODIUM VIVAX* BLOOD STAGE REPEATED INFECTION INDUCES PROTECTION AGAINST HETEROLOGOUS CHALLENGE IN THE NON-HUMAN PRIMATE MODEL

Nicanor III Obaldia<sup>1</sup>, Marlon Nunez<sup>2</sup>, Manoj Duraisingh<sup>3</sup>, Matthias Marti<sup>4</sup>

<sup>1</sup>Instituto Conmemorativo Gorgas, Panama and Harvard | T.H. Chan School of Public Health, Boston, MA, Panama, Panama, <sup>2</sup>Instituto Conmemorativo Gorgas, Panama, Panama, <sup>3</sup>Harvard | T.H. Chan School of Public Health, Boston, MA, United States, <sup>4</sup>Institute of Infection Immunity and Inflammation, College of Medical Veterinary and Life Sciences, University of Glasgow, Glasgow, Scotland, United Kingdom

Malaria is caused by parasites of the genus *Plasmodium* that are transmitted to humans by the bites of *Anopheles* mosquitoes. After the elimination of *Plasmodium falciparum* it is predicted that *Plasmodium vivax* will remain a major cause of morbidity and mortality outside of Africa, stressing the importance of developing a vaccine against *P. vivax* malaria. The blood stage antigens AMA1 and MSP142 have individually been shown to induce partially protective immune responses in *Aotus* monkeys. Current studies to develop a *P. vivax* vaccine are focused on inducing stronger antibody responses in combination with already robust T cell responses. At present there is no benchmark to assess the level of protection (cellular or humoral) needed to achieve sterile protection against a heterologous *P. vivax* blood stage challenge in both *Aotus* and humans. We have previously demonstrated successful induction of sterile protection in *Aotus* monkeys by repeated blood stage infection with homologous and heterologous *P. falciparum* strains. Here we present a model to induce sterile protection against *P. vivax* by repeated blood stage

infections and challenge with homologous (Sal-1) or heterologous (AMRU-1) strains. Blood samples were collected across the experiment to measure parasite and host parameters, including correlates of protection against blood stage antigens such as AMA1, MSP142 and DBP. This study will provide a benchmark for testing the efficacy of candidate blood stage *P. vivax* malaria vaccines in the non-human primate model.

## 1716

### HUMAN TO MOSQUITO TRANSMISSION OF SUB-MICROSCOPIC *PLASMODIUM FALCIPARUM* GAMETOCYTE DENSITIES DURING CONTROLLED HUMAN MALARIA INFECTION AND QUANTIFICATION OF MALE AND FEMALE GAMETOCYTES

**Katharine A. Collins**<sup>1</sup>, Hayley Mitchell<sup>1</sup>, Matthew Adams<sup>1</sup>, Melanie Rampton<sup>1</sup>, Gregory J. Robinson<sup>1</sup>, Claire Wang<sup>2</sup>, Teun Bousema<sup>3</sup>, Robert Sauerwein<sup>3</sup>, Stephan Chalou<sup>4</sup>, Jörg J. Möhrle<sup>4</sup>, James S. McCarthy<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>QPID Pty Ltd, Brisbane, Australia, <sup>3</sup>Radboud University Medical Centre, Nijmegen, Netherlands, <sup>4</sup>Medicines for Malaria Venture, Geneva, Switzerland

The controlled human malaria infection (CHMI) model has been used successfully to assess efficacy of drugs and vaccines targeting the pre-erythrocytic and blood stages of malaria infection. However, existing models have yet to be used to assess the ability of interventions to interrupt transmission of malaria from humans to mosquitoes. Such a model would be an invaluable tool for selecting the most promising transmission blocking interventions (TBIs) for further evaluation. Here we report the reproducible induction of gametocytes in CHMI participants and the transmission of these gametocytes to *Anopheles* mosquitoes. We used the induced blood stage malaria (IBSM) model with *P. falciparum*-infected red blood cells to initiate blood stage infection in malaria-naïve volunteers (n=17). Volunteers were then treated with piperazine (480mg) to clear asexual parasitemia and allow development of gametocytes. Utilizing RT-qPCR with sex specific mRNA markers we were able to detect and quantify sub-microscopic levels of male and female gametocytes circulating in all 17 volunteers. Following gametocyte detection, transmission studies were performed on a subset of volunteers using direct skin feeds and membrane feeding assays. Successful transmission of gametocytes to laboratory reared *An. stephensi* mosquitoes was achieved from 73% of participants (8/11), and transmission success was related to gametocyte density. Prevalence of infection was up to 16.7%, and quantitative analysis of specific biomarkers was undertaken to further evaluate factors that may contribute to transmission efficiency, including male:female gametocyte sex ratios and gametocyte commitment. This is the first step in the development of a valuable new tool that may accelerate the discovery and prioritization of the most promising TBIs. These studies also provide a novel insight into the dynamics of sexual stage malaria parasite development and transmissibility in a controlled infection setting. This work may therefore contribute to the current understanding of natural malaria transmission, a critical consideration of malaria elimination and eradication agendas.

## 1717

### IMMUNOGENICITY OF THE RTS,S/AS01E VACCINE IN AFRICAN CHILDREN: EFFECT OF AGE, MALARIA TRANSMISSION INTENSITY AND ASSOCIATION WITH PROTECTIVE EFFICACY

Campo<sup>4</sup>, Alfons Jiménez<sup>2</sup>, Marta Vidal<sup>2</sup>, Hector Sanz<sup>2</sup>, Ruth Aguilar<sup>5</sup>, Nuria Diez<sup>2</sup>, Nana Williams<sup>5</sup>, Ben Gyan<sup>6</sup>, Clarissa Valim<sup>7</sup>, Sheetij Dutta<sup>8</sup>, Carlota Dobaño<sup>2</sup>

<sup>1</sup>Centro de investigação de Saúde de Manhica, Vila da Manhica, Mozambique, <sup>2</sup>ISGlobal, Barcelona Center Int. Health Res. (CRESIB),

Hospital Clinic - Universitat de Barcelona, Barcelona, Spain, <sup>3</sup>Kintampo Health Research Centre (KHRC), Kintampo, Ghana, <sup>4</sup>Antigen Discovery, Irvine, CA, United States, <sup>5</sup>ISGlobal, Barcelona Center Int. Health Res. (CRESIB), Hospital Clinic - Universitat de Barcelona, Vila da Manhica, Spain, <sup>6</sup>Noguchi Memorial Institute for Medical Research (NMIMR), Accra, Ghana, <sup>7</sup>Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>8</sup>Walter Reed Army Institute of Research, Washington, DC, United States

RTS,S/AS01E is the most advanced malaria vaccine candidate in the clinical pipeline. The vaccine efficacy is moderate, lower in infants (6-12 weeks) than children (5-17 months), and of limited duration. Furthermore, little is known about its mode of action, epitope specificity, the quality of antibodies elicited, including Ig subclass patterns, and how they are affected by age and malaria endemicity. We have applied an in-house multiplex bead-based antibody assay to assess the immunogenicity of RTS,S malaria vaccine in children and infants participating in the Phase 3 African trial. We performed a case control study analyzing IgG subclasses 1-4 and IgM elicited by RTS,S in participants from Kintampo (high-medium malaria endemicity, n=80) and Manhica (low malaria endemicity, N=125). Additionally, the effect of age and malaria intensity transmission were determined, and associations with malaria protection were explored. A total of 393 samples at baseline and month 3 (peak response) in RTS,S vaccinees and comparators were analyzed against 3 CSP antigen constructs: the CSP full length, the NANP central repeat, and the C-terminal, and HBsAg by Luminex. The RTS,S vaccine induced high antibody responses to CSP full length, NANP and C-terminal one month after 3 vaccinations for all Ig isotypes and subclasses (p-value < 0.001). We found higher IgG and subclass antibody levels in children than in infants (p-value < 0.01), except for IgM and IgG2. Baseline levels of anti-CSP IgG and IgG subclasses were higher in Kintampo (p-value < 0.001) but no differences between sites were found for IgM levels. Furthermore, the vaccine induced higher levels of anti-CSPs IgM at month 3 in Manhica than in Kintampo, whereas no differences at peak response on antibody levels were found for IgG. Finally, we will report data on the association between anti-CSP antibody levels at month 3 and occurrence of clinical malaria cases in an exploratory single-marker analysis in this set of volunteers. A better characterization of the mode of action of RTS,S will greatly facilitate the development of more efficacious and long-lasting vaccines for malaria eradication.

## 1718

### IMMUNE CORRELATES OF PROTECTION AFTER VACCINATION WITH RTS,S-AS01E: ROLE OF ANTI-CSP ANTIBODY AVIDITY

**Hermann Sorgho**<sup>1</sup>, David Dosoo<sup>2</sup>, Maximilian Mpina<sup>3</sup>, Hector Sanz<sup>4</sup>, Itziar Ubillos<sup>4</sup>, Ruth Aguilar<sup>4</sup>, Gemma Moncunill<sup>4</sup>, Aintzane Ayestaran<sup>4</sup>, Nana Williams<sup>4</sup>, Nuria Diez<sup>4</sup>, Franck Lemiale<sup>5</sup>, Merribeth Morin<sup>5</sup>, Tom Ford<sup>6</sup>, Ben Gyan<sup>7</sup>, Claudia Daubenberger<sup>8</sup>, Clarissa Valim<sup>9</sup>, Carlota Dobaño<sup>4</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Santé (IRSS), Nanoro, Burkina Faso, <sup>2</sup>Kintampo Health Research Centre (KHRC), Kintampo, Ghana, <sup>3</sup>Ifakara Health Institute (IHI), Bagamoyo, United Republic of Tanzania, <sup>4</sup>Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, <sup>5</sup>PATH - Malaria Vaccine Initiative (MVI), Washington, DC, United States, <sup>6</sup>Human Immunology Laboratory (IAVI-HIL), London, United Kingdom, <sup>7</sup>Noguchi Memorial Institute for Medical Research (NMIMR), Accra, Ghana, <sup>8</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>9</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States

The completion of the RTS,S phase 3 trial and its planned pilot implementation in endemic countries constitute landmark events in the history of malaria vaccine development. The results generated during this unprecedented trial have also shown the compelling need to better understand the mechanisms underlying the protection induced by RTS,S/AS01E but also to describe the factors influencing the immune response induced by the vaccine during the early stages following the vaccination. To this perspective we have analyzed the IgG antibody avidity to the circumsporozoite protein repeat (NANP) and C-terminal regions of CSP in plasma/serum of participants in the phase 3 trial at baseline (M0) and at 1

month (M3) after the third dose of RTS,S. The samples were obtained from volunteers enrolled in the African multicenter RTS,S phase 3 trial. In total, 500 children aged between 5 to 17 months and 309 infants aged between 6 to 12 weeks at the time of first dose of RTS,S/AS01E inhabiting Nanoro (Burkina Faso), Kintampo (Ghana) and Bagamoyo (Tanzania) participated our study. We found that RTS,S vaccination resulted in a highly significant increase in IgG responses not only to NANP but also to the C-terminal CSP antigens at M3. We will present the comparison of the magnitude and avidity of response between the three sites of different malaria transmission intensity and between the two age cohorts. Furthermore, we will show data on the importance of the differences in CSP IgG avidity at M3 between protected and non-protected RTS,S vaccinated children after one year follow up. Data from this study provides valuable information on the fine specificity of the vaccine and the quality of the antibodies induced and their importance towards protection against malaria.

## 1719

### A CONTROLLED HUMAN MALARIA INFECTION MODEL COMPARING LOW-DOSE PIPERAQUINE AND SULFADOXINE-PYRIMETHAMINE TO INDUCE INFECTIOUS MALE AND FEMALE *P. FALCIPARUM* GAMETOCYTES

**Isaie J. Reuling<sup>1</sup>**, Lianne van de Schans<sup>1</sup>, Luc E. Coffeng<sup>2</sup>, Kjerstin Lanke<sup>1</sup>, Geert-Jan van Gemert<sup>1</sup>, Wouter Graumans<sup>1</sup>, Karina Teelen<sup>1</sup>, Rianne Siebelink-Stoter<sup>1</sup>, Marga van de Vegte-Bolmer<sup>1</sup>, Quirijn de Mast<sup>1</sup>, Andre J. van der Ven<sup>1</sup>, Karen Ivinson<sup>3</sup>, Cornelius C. Hermsen<sup>1</sup>, Sake J. de Vlas<sup>2</sup>, John Bradley<sup>4</sup>, Katharine E. Collins<sup>5</sup>, Christian F. Ockenhouse<sup>3</sup>, James S. McCarthy<sup>5</sup>, Robert W. Sauerwein<sup>1</sup>, Teun Bousema<sup>1</sup>

<sup>1</sup>Radboud University Medical Center, Nijmegen, Netherlands, <sup>2</sup>Erasmus University Medical Center, Rotterdam, Netherlands, <sup>3</sup>PATH, Malaria Vaccine Initiative, Washington, DC, United States, <sup>4</sup>MRC Tropical Epidemiology Group, London, United Kingdom, <sup>5</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia

The renewed focus on malaria elimination has increased the priority of research towards development of transmission blocking interventions (TBI) such as vaccines targeting the sexual, sporogonic, or mosquito stages of the parasite, and gametocytocidal drugs. Whilst there is broad consensus that TBI can play a significant role in malaria elimination initiatives, an effective model for the early clinical evaluation of TBI is currently unavailable. Here, we present a model to induce gametocyte carriage in participants by four different drug regimens to attenuate asexual parasitaemia without affecting developing or circulating gametocytes: low-dose piperazine (LD-PIP) followed by curative piperazine (PIP); LD-PIP followed by curative sulfadoxine-pyrimethamine (SP); low-dose sulfadoxine-pyrimethamine (LD-SP) followed by PIP; and LD-SP followed by SP. Four participants were enrolled per arm. All participants (16/16) developed mature gametocytes. Male (by novel PF3D7\_14699000 qRT-PCR) and female gametocytes (Pfs25 qRT-PCR) were observed 10-12 days after the first appearance of asexual parasites, supporting the hypothesis of gametocyte commitment during the first wave of asexual parasites. Gametocyte densities and the area under the curve of gametocytaemia versus time were highest in the LD-PIP/SP arm ( $p=0.04$ ). We demonstrated that the peak and total gametocyte burden are associated with the preceding asexual parasite biomass. Upon release in the circulation, male gametocytes had a mean circulation time of 2.68 days (95% CI 1.46 – 3.91) compared to 5.12 days (95% CI 4.10 – 6.14) for female gametocytes. The estimated female/male sex ratio of gametocytes in our study participants was 2.1 (SD=1.3). Exploratory mosquito feeding assays confirmed the viability of these gametocytes by demonstrating successful mosquito infections in a small subset of participants. In this study we present promising data for a critical unmet need by making available a more biologically relevant assay to address gametocyte biology and dynamics, and potential to evaluate TBI against *falciparum* malaria during early clinical development.

RTS,S/AS01E is the most advanced malaria vaccine candidate in clinical development, having undergone a phase 3 trial for licensure. Many gaps in knowledge remain as to how and why vaccine efficacy is affected by age and malaria endemicity, and what is the impact of RTS,S vaccination on naturally acquired immunity. In this study, we assessed antibody responses to a large panel of *Plasmodium falciparum* antigens and their association with RTS,S/AS01E vaccination and protection from clinical malaria, as well as the effect of age and malaria endemicity. We performed an exploratory case control study including 80 children (5-17 months) and infants (6-12 weeks) from Kintampo (high-medium malaria endemicity) and 117 from Manhica (low malaria endemicity). Samples were analyzed at baseline and month 3 (peak vaccine response) in RTS,S vaccines and comparators. We applied an in-house multiplex assay to measure IgG, IgG subclasses 1-4 and IgM levels to 34 blood-stage, 3 pre-erythrocytic and 4 RTS,S-specific antigens. We will report the effect of RTS,S vaccination in naturally acquired antibody responses to diverse antigens in both sites and age cohorts, taking into account endemicity and maternal antibodies. We will also report preliminary data of the association between levels and breadth of antibody isotypes/subclasses and future clinical malaria over a one year follow up. Finally, this study will allow to down-select and prioritize immunological variables, before conducting a larger longitudinal immune correlates study in multiple trial sites. A systems biology approach will be adopted to integrate the data and identify signatures associated with vaccination and protective immunity. Identifying the immune correlates of protection against malaria in the context of the large phase 3 trial gives unprecedented potential to obtain valuable information useful for the development of more efficacious and long-lasting vaccines for malaria eradication.

Controlled human malaria infection (CHMI) using aseptic, purified, cryopreserved, infectious *Plasmodium falciparum* strain NF54 sporozoites (Sanaria® PfSPZ Challenge) is being used to investigate novel malaria drugs, vaccines, and innate and naturally acquired immunity. Standardized use of 3,200 PfSPZ administered by direct venous inoculation (DVI) enables comparison of outcomes across sites and trials. Conduct of CHMI in African populations ensures that results are generated in the individuals most in need of novel interventions against malaria. During the past 4 years we have conducted CHMI in 94 Tanzanian adults with self-reported minimal recent malaria. Monitoring of asexual blood stage parasitemia during CHMI was done by thick blood smear (TBS) microscopy and DNA based qPCR assays. In 3 of 36 non-vaccinated control volunteers, qPCR but not microscopy positivity thresholds were reached within the pre-defined 28 days of follow-up. Parasite genotyping based on MSP1, MSP2 and microsatellite size polymorphisms confirmed that all parasites detected during CHMI were NF54. On average, volunteers were treated for malaria 5.5 days after parasites were detected in blood by qPCR. Thus, there were ~2 cycles of asexual parasite growth between detection and treatment. Post CHMI blood samples were collected daily enabling calculation of parasite multiplication rates (PMR). We will present data on the PMR in Tanzanians and compare these with the PMR from malaria naïve volunteers. A group of five placebo control volunteers in the BSPZV2 trial underwent two consecutive homologous CHMIs ~6 months apart. During the first CHMI, 5 of 5 volunteers has positive TBSs by microscopy during the 28 day follow up. However, during the second CHMI, 4 out of 5 volunteers remained negative by TBSs, but were identified as malaria positive by qPCR. We conclude that CHMI in malaria pre-exposed volunteers leads to a significant boost of acquired asexual erythrocytic stage immunity as indicated by a highly reduced PMR. CHMI studies in Tanzanian volunteers provide a unique tool to identify immune effector mechanisms under highly controlled conditions.

Effective malaria vaccines capable of preventing disease in a wide range of populations living in regions with vastly different transmission rates and with a multitude of genetically diverse *Plasmodium* species/strains are needed. Multi-antigen vaccines provide a unique opportunity to address this need in a manner that permits inclusion of critical cross stage and cross-species/strain epitopes into a single vaccine candidate. Therefore, we took advantage of the recent advances regarding in silico epitope prediction and analysis tools to identify class I and class II epitopes across a range of malaria antigens including both well-known and lesser known targets. Predictive binding analysis was used to identify sets of epitopes that provide broad HLA coverage. Sequence conservation analyses were performed to identify epitopes conserved across malaria parasite strains or to include additional sequences to fill gaps in cross-strain coverage. In addition, sequence similarity to the human proteome regarding the potential for cross-reactive epitopes, which may induce regulatory T cell responses, was also analyzed. Of interest is that several well-studied malaria vaccine candidates, such as TRAP, CSP, and EBA-175 score low regarding overall levels of class I and class II T cell epitope content, whereas, more novel proteins, such as Rh5 and SPECT-2, score higher in these areas. Further several of the proteins analyzed show regulatory T cell flags that overlap regions containing T cell epitope clusters. To identify critical B cell epitopes, we employed bacteriophage display to bio-pan for mimotopes of antibodies with strong neutralizing activity against conserved protein regions. The resulting VLP-based mimotopes are evaluated for their ability to elicit a parasite neutralizing humoral response. Further, different strategies for displaying these critical epitopes on a VLP platform capable of incorporating multiple insertions are employed to reverse engineer a vaccine. These data along with strategies for epitope selection and testing will be presented.

A Phase 2 vaccine trial of *Plasmodium falciparum* apical membrane antigen 1 (AMA1), FMP2.1/AS02A failed to demonstrate clinical efficacy against the primary study endpoint, but did show significant strain specific efficacy with parasites expressing AMA1 homologous to the vaccine strain with respect to key polymorphic amino acid residues. Sieve analyses of this strain-specific efficacy pinpointed polymorphisms in a hypervariable region of the AMA1 cluster 1 loop (c1L). Earlier molecular epidemiological and *in vitro* antibody-binding studies also pointed to c1L as a key determinant of immunity to AMA1. To determine the underlying strain- and epitope-specific antibody responses in vaccinated children that these molecular and *in vitro* analyses predicted, we used a high-density peptide microarray to measure the difference in seroreactivity to AMA1 peptides in sera from

Malian children who had received the AMA1 vaccine or a control rabies vaccine. Post-immunization sera from AMA1-vaccinated children had 6-fold greater mean seroreactivity to peptides spanning c1L matching the vaccine strain, compared to the seroreactivity to heterologous c1L peptides. To identify the precise amino acids responsible for this allele-specific efficacy, we tested sera against a collection of peptides containing substitutions of every possible amino acid or a deletion at each c1L position. None of the substitutions were associated with differences in seroreactivity in pre-vaccinated sera. However, in post-vaccination sera, perturbation of the vaccine-homologous glutamic acid residue at position 197, whether by substitution or deletion, significantly reduced seroreactivity. These results establish an immunologic basis for the earlier molecular epidemiological evidence that a single amino acid at position 197 in the AMA1 c1L is the primary determinant of strain-specific efficacy of the AMA1 vaccine. This result suggests that strain-transcending efficacy can potentially be achieved using multiple AMA1 antigens that vary at this single amino acid position despite polymorphisms at other positions in a multivalent next-generation malaria vaccine.

## 1724

### IMPACT OF PROTEIN TARGETING ON IMMUNOGENICITY OF Pfs25 ENCODED BY DNA VACCINE PLASMIDS

**Robert J. Hart**, Yi Cao, Geetha Bansal, Nirbhay Kumar

*Department of Tropical Medicine, School of Public Health and Tropical Medicine, Vector-Borne Infectious Disease Research Center, Tulane University, New Orleans, LA, United States*

Pfs25 is a leading candidate for the development of *Plasmodium falciparum* transmission blocking vaccines (TBV). Many different vaccine delivery platforms are currently being evaluated to develop an effective vaccine and considerable progress has been made with Pfs25 based DNA vaccines, evaluated in mice and nonhuman primates. Subsequent studies have also shown improved immunogenicity of codon optimized Pfs25 DNA plasmid delivered by intramuscular electroporation. In an effort to further optimize immunogenicity of DNA vaccines we evaluated the impact of protein targeting. We designed plasmids that would allow immunogenicity differences among encoded proteins destined for (1) secretion, (2) endosomal targeting, and (3) retention in the cytoplasm. Female Balb/c mice (5-6 weeks old) were immunized (intramuscular) with three doses, at one month apart, by *in vivo* electroporation with a final Pfs25/alum protein boost. Immune response parameters analyzed included Pfs25-specific antibodies and T cell responses. Studies revealed significant differences between targeted and non-targeted encoded Pfs25 and further emphasize evaluating similar approaches for any future DNA vaccine.

### IMMUNIZATION WITH MULTIPLE ALLELES OF *PLASMODIUM FALCIPARUM* FULL LENGTH VAR2CSA DNA CONSTRUCTS TO GENERATE A PLACENTAL MALARIA VACCINE SHOWING BROAD HETEROLOGOUS PROTECTION

**Shaji Daniel**<sup>1</sup>, Justin Doritchamou<sup>1</sup>, Pascal Bigey<sup>2</sup>, Nicaise Tuikue-Ndam<sup>3</sup>, Holly Torano<sup>1</sup>, Charles Anderson<sup>1</sup>, Lynn Lambert<sup>1</sup>, Michal Fried<sup>1</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Unité de Technologies Chimiques et Biologiques pour la Santé, CNRS UMR8258 – Inserm U1022 – Université Paris Descartes, Chimie ParisTech, Paris, France, <sup>3</sup>Institut de Recherche pour le Développement, MERIT UMR216, COMUE Sorbonne Paris Cité, Université Paris Descartes, Faculté de Pharmacie, Paris, France

Placental malaria (PM) is caused by adhesion of *Plasmodium falciparum* (Pf) infected erythrocytes (IE) to the placental receptor chondroitin sulfate A (CSA), mediated by the *P. falciparum* erythrocyte membrane protein 1 (PfEMP1) family member called VAR2CSA. Over successive pregnancies, women acquire antibodies against VAR2CSA as they acquire clinical

resistance to malaria. VAR2CSA is a 350kDa, multi-domain protein: many different domain combinations of the protein used as immunogens have failed to generate broadly neutralizing activity against diverse CSA-binding isolates. Recent studies have shown that the full length extracellular domain of the protein has a 100,000-fold higher affinity for CSA compared to any individual domain. Moreover, the extracellular domain has also been shown to be structurally more compact compared to individual domains and antibodies raised against the full length (FL) extracellular protein could completely block homologous IE binding to CSA indicating that the full-length protein could serve as a better vaccine. In preliminary studies with FL VAR2CSA from PfNF54 and PfFCR3 we found that FL VAR2CSA DNA vaccine constructs delivered by electroporation induced neutralizing activity against diverse field isolates. To extend these findings, we have prepared codon-optimized glycosylated versions of six different Pf VAR2CSA alleles: NF54, M1010, Brazil 7G8, HB3, FCR3 and Malayan Camp, and cloned them into the mammalian expression vector VRC8400 such that the proteins will be expressed on the cell surface. A rat immunization study using these constructs either individually or as a blend of six alleles has been initiated. We will report the ability of these individual constructs to show anti adhesion activity against multiple Pf isolates as well as the ability of antibodies generated against the blend of six different Pf VAR2CSA alleles to show broad anti adhesion activity.

<sup>1</sup>Center for Infectious Disease Research, Seattle, WA, United States, <sup>2</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>3</sup>Swiss TPH, Basel, Switzerland and Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>4</sup>Sanaria, Inc., Rockville, MD, United States, <sup>5</sup>U.S. Military Malaria Vaccine Program, Naval Medical Research Center, Silver Spring, MD, United States

Immunization with radiation attenuated *P. falciparum* sporozoites provides protection from infection by non-attenuated parasites. We performed RNAseq transcriptional analysis on blood samples from subjects who were immunized with purified, cryopreserved radiation attenuated sporozoites and had protection was determined by controlled human malaria infection (CHMI) challenge. We determined responses in two vaccine trials that differed by prior malaria exposure and modes of immunization and CHMI and responses of non-immunized subjects to infection. We employed statistical methods that take into account uncontrolled variations within individual volunteers and differences between trials and performed multiple comparisons to determine host gene expression responses at various time points after vaccination and/or parasite challenge. We also compared responses between protected and non-protected people after vaccination and parasite challenge. Numerous changes in mRNA expression levels occurred following immunization and CHMI. Similar kinetics of gene expression responses to vaccination and CHMI were observed including between trials. For example: genes associated with neutrophils and erythrocyte development were significantly up-regulated 7 days after the 2nd vaccination. In addition, genes associated with myeloid lineage, coagulation cascade and metabolism had similar responses to CHMI. Furthermore, genes associated with neutrophils and erythrocyte development had similar kinetics in response to vaccination and to CHMI of non-immunized subjects. Analysis of genes for interferon responses, erythrocyte development, and hematopoietic precursors showed a trend for higher expression in protected compared to non-protected subjects after CHMI. In contrast, B-cell-related genes were more highly expressed in non-protected subjects. These changes in the blood likely reflect a combination of changes in immune cell gene expression, proliferation, apoptosis and cell trafficking and provide insights into immunological processes that are associated with infection and protection.

1727

### A NOVEL BLOOD-STAGE VACCINE CANDIDATE MEDIATES PROTECTION AGAINST FALCIPARUM MALARIA IN MICE AND CHILDREN

Ian C. Michelow<sup>1</sup>, Shu-Whei Tsai<sup>1</sup>, Sara Nelson<sup>1</sup>, Sangshin Park<sup>1</sup>, Dipak K. Raj<sup>1</sup>, Christian P. Nixon<sup>1</sup>, Christina E. Nixon<sup>1</sup>, Sunthorn Pond-Tor<sup>1</sup>, Jennifer F. Friedman<sup>1</sup>, Michal Fried<sup>2</sup>, Patrick E. Duffy<sup>2</sup>, Jonathan D. Kurtis<sup>1</sup>

<sup>1</sup>Brown University, Providence, RI, United States, <sup>2</sup>National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

There is an urgent need to develop new, highly effective malaria vaccines. We previously screened a *P. falciparum* blood-stage cDNA lambda phage library and identified a novel protein (PF3D7\_1134300) that is uniquely recognized by antibodies from a group of malaria-resistant Tanzanian children who controlled parasite density during infection but not by those from a group of susceptible children whose non-immunological risk factors were carefully balanced. The objectives of this study were to 1) confirm our findings in a large human cohort, 2) immunolocalize the protein, 3) test the hypothesis that this protein induces growth-limiting antibodies and 4) assess protection against parasite challenge in a murine model. After adjusting for repeated measures and potential confounders using generalized estimating equations, we confirmed that high levels of monospecific human antibodies (upper 5th percentile) from an actively monitored longitudinal cohort of 450 Tanzanian children 2 to 3.5 years of age (1020 observations), were associated with an almost 50% reduction in parasite densities on blood smears (124 vs 68 parasites/200 WBC;  $p=0.04$ ). We showed by means of immunolocalization studies that the native protein is expressed in trophozoite- and schizont-stage parasites. It is trafficked via Maurer's clefts to the RBC membrane inner leaflet despite lacking a recognizable export signal, thereby constituting a novel PEXEL-negative exported protein (PNEP). In antibody-mediated growth inhibition and schizont arrest assays, we showed that murine purified anti-PF3D71134300 IgG decreased parasite replication and egress from RBCs in a dose-dependent fashion by up to 75% compared to pre-immune controls. We then immunized mice with an adjuvanted *P. berghei* ANKA ortholog of PF3D7\_1134300 or adjuvant alone and found that actively immunized mice challenged with 1x10<sup>4</sup> *P. berghei* ANKA had significantly longer median survival ( $p=0.014$ ). These data support development of PF3D7\_1134300 as a viable vaccine candidate, and present a unique opportunity to elucidate poorly understood mechanisms of protein export and immune protection.

1728

### CORRELATION BETWEEN PLASMODIUM FALCIPARUM NF54 STRAIN OOCYSTS AND SPOROZOITES COUNTS IN ANOPHELES STEPHENSI MOSQUITOES

Abraham G. Eappen, Tao Li, Sumana Chakravarty, Thomas Pike, Ming Li, Peter F. Billingsley, B. Kim Lee Sim, Stephen L. Hoffman  
Sanaria Inc., Rockville, MD, United States

Sanaria® PfSPZ Vaccine and PfSPZ-CVac (chemoattenuated PfSPZ vaccine) are highly protective vaccines composed of aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ) that are currently being evaluated in clinical trials in the U.S., Europe, and Africa. The immunogens, PfSPZ, are manufactured using *Anopheles stephensi* mosquitoes as bioreactors. We have systematically collected data on numbers of oocysts and sporozoites in mosquitoes fed the same blood meal of Pf strain NF54 gametocytes to characterize parasite developmental kinetics, and determine how accurately we can predict salivary gland sporozoite numbers from oocyst counts. For this analysis we are using mosquitoes that had a range of a mean of 43 to 165 oocysts/mosquito and a mean of 32,000 to 185,037 PfSPZ/mosquito. Conversion rates from

oocysts to salivary gland PfSPZ varied from 990-2905 PfSPZ/oocyst. We will present the results of analyses to establish how accurately oocyst counts can be used to predict numbers of PfSPZ per mosquito.

1729

### IMPROVED DISPLAY OF THE MALARIA TRANSMISSION BLOCKING PFS25 ANTIGEN ON A SECOND-GENERATION PLANT-PRODUCED VLP

Robert Mark Jones, Steve Tottey, Jessica Chichester, Konstantin Musiychuk, Stephen Streatfield, Vidadi Yusibov  
Fraunhofer Center for Molecular Biotechnology, Newark, DE, United States

The Pfs25-VLP produced in plants using transient expression technology is a fusion of the *Plasmodium falciparum* Pfs25 protein to the alfalfa mosaic virus coat protein antigen display molecule. This Pfs25-VLP has previously been shown in animal studies to be highly effective at preventing the transmission of malaria, and was tested through a Phase 1 clinical trial, where it showed no adverse reactivity. The effectiveness of this VLP molecule was hampered, however, by in *planta* cleavage events within the coat protein display molecule, resulting in considerable loss of the Pfs25 antigen from the VLP. Through N-terminal sequence analysis and molecular engineering, a second generation Pfs25-VLP molecule has been developed, reducing the loss of the Pfs25 antigen. This second-generation molecule has more Pfs25 antigens displayed per VLP than the original Pfs25-VLP and has equivalent or better malaria transmission blocking activity in animal models. At the same time, the Pfs25-VLP purification method was simplified to a two step all chromatography purification approach, resulting in improved Pfs25-VLP purity and yield.

1730

### EFFECTIVENESS OF COMMUNITY-BASED LARVICIDING PROGRAM ON MALARIA VECTOR ABUNDANCE ON BIKO ISLAND, EQUATORIAL GUINEA

Godwin Fuseini<sup>1</sup>, Wonder Philip Phiri<sup>1</sup>, Jose Antonio Esono Mba Nlang<sup>1</sup>, Prudencio Bibang Engono Efiri<sup>1</sup>, Aveika Akum<sup>1</sup>, Jordan Smith<sup>1</sup>, J. Luis Segura<sup>1</sup>, Megan Perry<sup>2</sup>, Guillermo Garcia<sup>2</sup>, Julie Niemczura de Carvalho<sup>2</sup>, Christopher Schwabe<sup>2</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea,

<sup>2</sup>Medical Care Development International, Silver Spring, MD, United States

Recommended as a supplement to the core vector control interventions of IRS and ITNs, several African countries are introducing larval source management (LSM) into their malaria control programs. Vectors resistance to insecticides and the change in the biting behavior of the vectors to more of outdoor biting have renewed the interest in LSM. However, the operational delivery strategy that will realize the full potential of LSM in reducing malaria transmission in sub Saharan Africa is still not clear. The Bioko Island Malaria Control Project (BIMCP) in Equatorial Guinea introduced a pilot larviciding program using community volunteers to assess the sustainability and the impact on malaria vector densities on Bioko Island. After community engagement in each community, community members were identified and recruited as volunteers with the help of the community leaders. The community-based larviciding program was introduced in 2015 in 13 communities where community volunteers were willing to participate. In phase I of the program in 2015, the volunteers were fully supported by the BIMCP. The community volunteers were trained and assisted in identifying, monitoring, and treating all potential breeding sites, including those that they had missed to treat. However, during phase II of the program in 2016, the community volunteers took ownership of conducting all larviciding activities while the BIMCP monitored and evaluated the program. Though there was no significant difference in the average number of breeding sites monitored in the two phases (N=1,033 in phase I and N=970 in phase II), the treatment coverage was lower in phase II than in phase I by about 25%. This was also reflected in the total amount of larvicide consumed in phase I (5,585.8kg) as compared to phase II (2,936.9kg). The average human

biting rate of the vector also doubled from an average of three bites per person per night in phase I to six bites per person per night in phase II. A community-based larviciding program in Bioko Island can significantly reduce the vectors abundance on the Island only through strong operational and managerial expert support.

## 1731

### FACTORS ASSOCIATED WITH THE UPTAKE OF AT LEAST TWO DOSES OF SULFADOXINE/PYRIMETHAMINE FOR THE PREVENTION OF MALARIA IN PREGNANT WOMEN, BENIN, 2015

Bella Hounkpe-Dos Santos<sup>1</sup>, Abou Bakary Pio<sup>1</sup>, Filemon Tokponnon<sup>1</sup>, **Jean Fortuné Dagnon**<sup>2</sup>, Mariam Oke<sup>1</sup>, Alexis Yemalin Tchevoede<sup>1</sup>, Clarisse Assogba<sup>1</sup>, Boniface Denakpo<sup>1</sup>, Michelle Kouletio<sup>2</sup>, Virgile Capo-Chichi<sup>3</sup>

<sup>1</sup>National Malaria Control Program (NMCP), Cotonou, Benin, <sup>2</sup>United States President's Malaria Initiative/U.S. Agency for International Development-Benin, Cotonou, Benin, <sup>3</sup>LEADD Consulting, Cotonou, Benin

In Benin, an estimated 29% of pregnant women receive at least two doses of sulfadoxine/pyrimethamine (SP) as a prophylaxis against malaria in pregnancy (2015 Benin Malaria Indicator Survey). This is well below the national target of 80%. To determine factors associated with SP uptake during pregnancy, we sampled responses from 3,555 women aged 15-49 in the 2015 Benin MIS database. We used a logistic regression model ( $\alpha = 0.05$ ) and 10 variables related to women's demographics and access to health care to describe the factors associated with successful and unsuccessful uptake of two or more doses of SP. A correlation matrix was created to identify associations between variables. Variables with a positive effect on the uptake of at least two doses of SP were: High socioeconomic status ( $p = 0.010$ ); early use of antenatal care (ANC) services during the first trimester of pregnancy ( $p = 0.000$ ); a live birth preceding the most recent delivery ( $p = 0.038$ ), and; southern (higher coverage) vs. northern (lower coverage) geographic region of origin ( $p = 0.000$ ). Factors that did not influence the use of at least two doses of SP were: Education level, ANC visit during the third trimester of pregnancy, and; urban vs. rural residence. To increase SP uptake among pregnant women, behavior change communication interventions should be reinforced, especially among women with low socioeconomic status and primigravidae in geographic areas with low coverage. Emphasis should be placed on early ANC visits during the first trimester of pregnancy.

## 1732

### TRACKING LONG LASTING INSECTICIDAL NET (LLIN) PHYSICAL INTEGRITY AND BIOEFFICACY 2 YEARS AFTER A MASS CAMPAIGN IN BENIN

Filemon Tokponnon<sup>1</sup>, Idelphonse Ahogni<sup>2</sup>, Alexis Yemalin Tchevoede<sup>1</sup>, Adicatou-Lai Adeothy<sup>1</sup>, Mariam Oke<sup>1</sup>, **Jean Fortuné Dagnon**<sup>3</sup>, Virgile Gnanguenon<sup>1</sup>, Michelle Kouletio<sup>3</sup>, Hector Fassinou<sup>1</sup>, Desiré Missikpode<sup>1</sup>, Bella Hounkpe-Dos Santos<sup>1</sup>, Raymond Beach<sup>4</sup>, Martin Akogbeto<sup>2</sup>

<sup>1</sup>National Malaria Control Program (NMCP), Cotonou, Benin, <sup>2</sup>Centre de Recherche Entomologique (CREC), Cotonou, Benin, <sup>3</sup>United States President's Malaria Initiative/U.S. Agency for International Development-Benin, Cotonou, Benin, <sup>4</sup>United States President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

Benin's National Malaria Control Program (NMCP) distributed three types of long-lasting insecticide-treated nets (LLINs) during a mass campaign in 2014: PermaNet 2.0®, DuraNet®, and DawaPlus 2.0®. Based on the manufacturers' claims and WHO recommendations, the NMCP assumed that each population of nets would meet accepted norms of fabric integrity and bio-efficacy during a three-year distribution cycle. To validate this assumption, we monitored standard LLIN durability indicators for bio-efficacy and physical integrity during a 2-year period following distribution.

We selected one LLIN in each of the 300 enrolled households in each of the 3 health districts. In each district, a total of 300 LLINs from rural ( $n=150$ ) and urban ( $n=150$ ) settings were randomly selected and tracked. Physical integrity was assessed using methods recommended by the World Health Organization (WHO). Bio-efficacy was monitored using the WHO cone test method. After 2 years, only 46% (416/900) of HHs were opened to the surveyors who were able to assess only 31% (283/900) of the LLINs on track. This high rate of nets lost-during the follow up could be explained by the lost or the replacement of the LLINs in the enrolled households. Out of the 283 LLINs found, we observed that 87% (248/283) had some physical damage after two years and cannot be used. Both rural and urban areas showed similar rates of net loss associated with fabric integrity: rural 91% (131/144) and urban 84% (117/139) ( $p>0.05$ ). The range of proportionate hole index (PHI) values in rural versus urban areas, (754-870) and (663-929) respectively, were similar. None of the 3 types of LLINs distributed by the NMCP in 2014 were in 'good shape', defined as a PHI < 64, after 24 months. The bio-efficacy of PermaNet 2.0® and DuraNet® after 2 years was 80% mosquito mortality for each net type, was somewhat better than DawaPlus 2.0®, which showed 69% mosquito mortality. In summary, after two years, each population of LLINs showed loss of fabric integrity at greater than expected levels. Such results argue for the strengthening of behavior change communication efforts aimed at improving net care behaviors among LLINs recipients.

## 1733

### CURRENT PRACTICES IN URBAN INSECTICIDE-TREATED NET DISTRIBUTION ACROSS SUB-SAHARAN AFRICA

Sean C. Blaufuss

Johns Hopkins Center for Communication Programs, Baltimore, MD, United States

Universal coverage campaigns are the primary distribution channel for insecticide-treated nets (ITN) across malaria endemic countries. Campaigns distribute ITNs to diverse populations across socioeconomic and urban/rural gradients. Urban settings present distribution challenges as a byproduct of unique social patterns and population diversity that is rarely found in rural zones. Gated communities, urban slums, population density, security issues, and busy social movement patterns represent some of these challenges. Using the 2013 report *Experiences in Long Lasting Insecticidal Net (LLIN) Urban Distribution Campaigns* as a baseline to measure progress, the VectorWorks Project conducted interviews with consultants, implementing partners, and national malaria control program staff from eleven countries where urban distribution or its planning occurred in 2016. The results indicate that the vast majority of countries are registering urban households during evenings and weekends to accommodate urban social movement patterns and have increased the number of distribution points to manage urban density. Despite this progress, many aspects of urban distribution require attention. The lack of standardization in determining which municipalities are operationally "urban" needs to be addressed. Key recommendations include the need to employ technology to aid in supervision and harmonization; potentially limiting or ceasing ITN distribution in high socioeconomic areas that are difficult to register; and creating an urban distribution task force during the planning phase in more urbanized countries. The ramifications of not developing comprehensive urban-specific strategies can include reduced ITN coverage and the need for expensive duplicate activities to make up for poor initial registration or distribution. Best practices and opportunities for improvement will be discussed, with a look toward creating a set of recommendations for future ITN distribution in urban settings.

**LESSONS LEARNED AROUND IMPROVED IRS PLANNING AND MONITORING IN SOUTHERN AFRICA**

**Tara Seethaler**<sup>1</sup>, Katelyn Woolheater<sup>1</sup>, Deepa Pindolia<sup>1</sup>, Inessa Ba<sup>1</sup>, Charlotte Dolenz<sup>1</sup>, Brad Didier<sup>1</sup>, Ayokunle Abogan<sup>1</sup>, Manik Saini<sup>1</sup>, Nontoko Mngadi<sup>1</sup>, Munashe Madinga<sup>1</sup>, Brighton Gambia<sup>1</sup>, Davies Ntebela<sup>2</sup>, Hans Angula<sup>3</sup>, litula litula<sup>3</sup>, Wilson Chauke<sup>4</sup>, Tjantlili Mosweunyane<sup>2</sup>, Joseph Mberikunashe<sup>4</sup>, Petrina Uusiku<sup>3</sup>, Anne-Marie Nitschke<sup>3</sup>

<sup>1</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>2</sup>National Malaria Programme, Gaborone, Botswana, <sup>3</sup>National Vector-Borne Diseases Control Programme, Windhoek, Namibia, <sup>4</sup>National Malaria Control Programme, Harare, Zimbabwe

Indoor Residual Spraying (IRS) is a critical but resource-intensive intervention of malaria elimination programs. Using Geographical Information System (GIS) technologies, electronic data collection and dashboard visualizations, malaria programs in Botswana, Namibia, and Zimbabwe have improved IRS operational planning, implementation, and during- and post-season data analysis. In the planning phase, household enumeration, surveillance, and malaria risk data were used to determine operationally feasible and priority target clusters to spray. This information was shared with IRS teams using simple tables and easy-to-read maps. Pre-implementation household enumeration data and geo-locations collected during IRS campaigns provided the programs with timely data for estimating process and impact indicators. Post-implementation, government programs across these countries documented lessons learned and stakeholders provided feedback on the new process, technical challenges, and on timeliness, completeness, and utility of resulting data. Several thematic lessons emerged across the countries: 1) timely initiation of planning is essential to uptake and comfort with new data collection and dashboard tools; 2) selection of target clusters is an iterative process, so quick-to-update mapping and analysis tools are required; 3) considering map literacy, maps should include context-specific information such as key landmarks and have easy-to-read legends and scales; 4) readable screens, long battery life, and extra battery packs are important attributes of hardware; 5) data collection tools should mirror existing paper-based forms; and 6) technical guidance and assistance via a qualified consultancy on enumeration, data management, and overall process flow are necessary for at least one season to improve familiarity with new tools. Lessons learned in these countries including technical and operational issues show the utility of incorporating spatial and other analytical software into IRS planning and monitoring, while highlighting areas for improvement in future spray seasons and in other countries implementing IRS.

## 1735

**NET MIGRATION OR NON-USE? BED NET OWNERSHIP FOLLOWING MASS DISTRIBUTION CAMPAIGNS ON BIKO ISLAND, EQUATORIAL GUINEA**

**Jordan M. Smith**<sup>1</sup>, Jose Osa Osa Nfumu<sup>1</sup>, Liberato Motobe Vaz<sup>1</sup>, Wonder Philip Phiri<sup>1</sup>, Dianna E.B. Hergott<sup>2</sup>, Julie Niemczura de Carvalho<sup>2</sup>, Guillermo Garcia<sup>2</sup>, Christopher Schwabe<sup>2</sup>, Jackie Cook<sup>3</sup>, Immo Kleinschmidt<sup>3</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The objective of this study was to describe the patterns of use and explore factors related to attrition following two long-lasting insecticide treated net (LLIN) distribution campaigns. A large discrepancy was measured between the numbers of LLINs that households received during mass distribution versus the numbers reported and observed in the same households at three intervals. In 2015, the National Malaria Control Program (NMCP) led a mass distribution campaign on Bioko Island. At least one new LLIN for every two people was delivered to 88.2% of households, and the numbers of LLINs physically hung were recorded. One

year later, before a campaign to hang LLINs in 3,510 high-risk households, the NMCP recorded the number of LLINs households reported owning. During an indoor residual spraying (IRS) campaign, 78% of the high-risk households were revisited, and the number of LLINs observed was compared to the number hung during previous distributions. Before the top-up campaign, the number of LLINs households reported owning fell 55.6% from the number that had been hung during mass distribution. During the targeted IRS campaign that occurred on average 30 days after top-up, the number of LLINs observed by sprayers decreased 40.5% from the number hung during the top-up campaign. Approximately 58 days after top-up, the annual malaria indicator survey visited 267 of the high-risk households. Only 58.6% of respondents reported sleeping under a bed net the night before. Among respondents who reported no longer owning a bed net, 21.3% reported transferring a net to others. The average number of LLINs observed decreased from the number previously distributed by -1.63 among households that reported not travelling off the Island in the previous 8 weeks and by -2.33 among households that did. Despite achieving target LLIN coverage on Bioko Island, attrition rates pose a threat to one of the principal vector control strategies established by the NMCP. Work should be undertaken to address the lack of vector control interventions on the mainland of Equatorial Guinea, where it is believed many LLINs are being transferred to populations at high risk of malaria infection.

## 1736

**SUSTAINING HIGH NET OWNERSHIP THROUGH CONTINUOUS COMMUNITY DISTRIBUTION**

**Dennis O. Mwambi**<sup>1</sup>, Ann Musuva<sup>1</sup>, Esendi Hilda<sup>1</sup>, Omar Ahmedin<sup>2</sup>

<sup>1</sup>Population Services Kenya, Nairobi, Kenya, <sup>2</sup>National Malaria Control Program, Kenya, Nairobi, Kenya

The main malaria vector control strategies in Kenya are Long Lasting Insecticidal Nets, Indoor Residual Spraying and Integrated Vector Management. LLINs are distributed through mass campaigns every three years, routinely through ANC/EPI clinics, social marketing and commercial. Sustaining this high net coverage attained after mass net is a challenge and hence, the continuous community net distribution was piloted. The pilot strategy included a mechanism where trained community health volunteers visit households, verify net need and issue a coupon to HH head to redeem the net at the nearest distribution point for free. In addition, the CHVs integrated interpersonal communication to address barriers to net use. The pilot was implemented between August 2014 and May 2015 within Samia Sub-county Busia county in Kenya. Using a community-based cluster randomized control trial; the study site was divided into 29 clusters (sub-locations) and randomized to Intervention (received intervention), and a Control group. Using a design effect of 2, a 95% confidence interval with an 80% power, and the estimated prevalence of 59.6% of universal coverage the sample size was calculated at 875 per arm. A pretested household questionnaire was administered at baseline and end line. Data were analyzed using Stata. A significant proportion of respondents in the intervention group had more than one LLIN (Baseline; 76.9 % versus Endline; 93.9%) as compared to the control (Baseline; 75.8 % versus Endline; 78.1%). The majority of respondents in the intervention area attained universal coverage (Baseline; 50.4% versus Endline; 78.7%) as compared to the control (Baseline; 49.7% versus Endline; 44.6%). More household members significantly slept under an LLIN the previous night in the intervention group (Baseline; 91.4% at versus Endline; 96.4%) compared to the control (Baseline; 87.9% versus Endline; 85.8). In conclusion, continuous community net distribution is a feasible approach to sustaining high net ownership, universal coverage and use at household level. However, there is need to invest in community health systems and volunteers.

### USING THE ANTENATAL CARE QUALITY IMPROVEMENT TOOL AND TARGETED TRAINING TO STRENGTHEN ANC SERVICES INCLUDING MIP IN KAGERA AND MARA REGIONS, TANZANIA

Jasmine Chadewa<sup>1</sup>, Dunstan Bishanga<sup>1</sup>, Elaine Roman<sup>2</sup>, Godlisten Martin<sup>1</sup>, Kristen Vibbert<sup>2</sup>, Lauren Borsa<sup>2</sup>, Agrey Mbilinyi<sup>1</sup>, Jérémie Zoungrana<sup>1</sup>, Hussein Kidanto<sup>3</sup>

<sup>1</sup>Jhpiego Corporation, Dar es Salaam, United Republic of Tanzania,

<sup>2</sup>Jhpiego Corporation, Baltimore, MD, United States, <sup>3</sup>Tanzania Ministry of Health, Dar es Salaam, United Republic of Tanzania

Malaria in Pregnancy (MiP) is a major, preventable cause of maternal morbidity and poor birth outcomes. In collaborations with partners, Tanzania's National Malaria Control Program (NMCP) and the Reproductive and Child Health Unit has been working to promote the World Health Organization's three-pronged approach to address the burden of MiP.

A malaria training for 180 supervisors and 360 ANC providers from 221 health facilities was conducted in the Kagera and Mara regions. Updates included an orientation on MiP as well as malaria case management, screening, data management and ITN promotion.

Prior to the training, facility baseline assessments were conducted using the Ministry of Health, Community Development, Gender, Elderly and Children (MOHCDGEC) antenatal care quality improvement (ANC QI) tool to identify gaps in knowledge and skills of health providers to better target trainings to improving the quality of ANC services. A second assessment took place six months post training. Both assessments included hospital, health facility and dispensary levels and included observation, interviews, record reviews and skills assessments. Results demonstrated that over 90% of the facilities scored below 30% across all categories in the overall baseline assessment with a high score of 35 %, while the 2nd assessment showed a large improvement with 40% of the facilities scoring below 30% and a high score of 70%.

The ANC QI tool is effective in determining the impact of ANC health provider's knowledge and skills to target training to improve ANC service quality.

### NET USE AND PREFERENCE AMONG INDIVIDUALS SLEEPING IN FORESTS OR FARMS IN MALARIA MULTI-DRUG RESISTANT AREAS

Thang Duc Ngo<sup>1</sup>, Thuan Huu Vo<sup>2</sup>, Sara E. Canavati<sup>3</sup>, Long Khanh Tran<sup>4</sup>, Colin Ohrt<sup>5</sup>, Duong Thanh Tran<sup>1</sup>, Nicholas J. Martin<sup>6</sup>

<sup>1</sup>National Institute of Malariology, Parasitology and Entomology (NIMPE), Ha Noi, Vietnam, <sup>2</sup>Vysnova Partners Inc.; Faculty of Social Sciences, University of Tampere, Tampere, Finland, Ha Noi, Vietnam, <sup>3</sup>Vysnova Partners Inc.; Center for Biomedical Research, Burnet Institute, Melbourne, Australia, Ha Noi, Vietnam, <sup>4</sup>Vysnova Partners Inc.; Department of Environmental Health, Ha Noi School of Public Health, Ha Noi, Vietnam, <sup>5</sup>Vysnova Partners, Inc., Ha Noi, Vietnam, <sup>6</sup>Naval Medical Research Center-Asia, Singapore, Singapore

Strengthening vector control measures among mobile and migrant populations (MMPs) is crucial to malaria elimination, particularly in multi-drug resistant areas. We aimed to assess mosquito net use and preference among those who slept in a forest or farm in a priority area of Vietnam. Census data from 2015 revealed a total of 4668 households in 18 villages in northwest Phu Yen Province, Vietnam. These data were used to select 20% of the households and survey identified residents who sleep in forests or farms on their mosquito net preferences. Data were collected using a smartphone application (KLL Collect®) and uploaded into an online database (ONA®). Logistic regression were used to calculate prevalence odds ratios (PORs) and 95% confidence interval

(CI) to assess differences among those who slept in forests and farms. Of 301 respondents, 258 slept in forests and 43 on farms. Most respondents preferred to bring hammock nets (277, 92%) rather than bed nets (74, 25%) to their sleeping sites. They preferred to bring thick hammock nets with zippers (52%) as opposed to 'hard' long lasting insecticidal nets (LLINs). Most respondents regularly used hammock nets with a separate flip over (RAI hammock net) in forests (18 [67%]) compared to those on farms (4 [36%]). Respondents sleeping in forests were more likely to want hammock nets only rather than carry both bed nets and hammock nets (adjusted POR=4.63; 95% CI 2.33-9.21) compared to the 43 respondents slept on farms. Respondents sleeping in the forest preferred the RAI hammock net (POR=20.0; 95% CI 2.20-181.55), but were less likely to receive a RAI hammock net (adjusted POR=0.34; 95% CI 0.15-0.75). We recommend scaling up the distribution of LLINs or hammock-nets to 100% coverage in high-risk population areas. Interventions could include distributing forest-packages to forest goers including insecticide treated hammock nets, repellent and information on the benefits of protective clothing, nets and repellents; as well as engaging the private sector to establish malaria focal points within workplaces associated with malaria risk. Additional implementation research is needed to the uptake of net use by MMPs.

### OBSERVATIONAL EVIDENCE OF A COMPLIMENTARY EFFECT OF COMBINING NEXT GENERATION INDOOR RESIDUAL SPRAYING AND SEASONAL MALARIA CHEMOPREVENTION IN THE SÉGOU REGION OF MALI, 2014

Joseph Wagman<sup>1</sup>, Christelle Gogue<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Jules Mihigo<sup>2</sup>, Diadier Diallo<sup>3</sup>, Elie Bankineza<sup>4</sup>, Mamadou Bah<sup>4</sup>, Andrew Saibu<sup>5</sup>, Jason Richardson<sup>6</sup>, Diakalia Kone<sup>7</sup>, Seydou Fomba<sup>7</sup>, Laurence Slutsker<sup>1</sup>, Molly Robertson<sup>1</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>U.S. President's Malaria Initiative, Bamako, Mali, <sup>3</sup>MEASURE Evaluation, Bamako, Mali, <sup>4</sup>Abt Associates, Bamako, Mali, <sup>5</sup>Abt Associates, Accra, Ghana, <sup>6</sup>IVCC, Washington, DC, United States, <sup>7</sup>Programme National de Lutte contre le Paludisme, Bamako, Mali

By 2014, concerns about pyrethroid resistance in the Ségou Region of Mali had prompted a shift in indoor residual spraying (IRS) products to a micro-encapsulated formulation of the organophosphate insecticide pirimiphos-methyl. Also in 2014, Ségou was in the midst of expanding a pilot program to provide seasonal malaria chemoprevention (SMC) to children aged 3 to 59 months in select districts. The timing of these decisions presented an opportunity to analyze the impact of both interventions, deployed individually and in combination, using quality-assured passive surveillance data. District-level analysis of 2014 monthly malaria incidence (total rapid diagnostic test-confirmed cases/total district population) showed that compared to contiguous non-intervention districts in Ségou: SMC by itself in San corresponded to 306 fewer cases/10,000 person-months; IRS by itself in Barouéli corresponded to 492 fewer cases/10,000 person-months; and combined implementation of both IRS and SMC in Bla corresponded to 661 fewer cases/10,000 person-months. Further analysis of epidemiologic curves, by plotting the reduced incidence observed in intervention districts as a percentage of the background incidence observed in non-intervention districts, is useful for describing the magnitude and timing of an intervention's impact. This analysis suggests that the SMC only intervention had a more moderate (24% fewer cases in the first month) but longer duration (6 months) effect while the IRS only intervention had a rapid, comparatively large impact (50% fewer cases in the first month) of shorter duration (4 months); the impact of the combined intervention was both rapid (68% fewer cases in the first month) and of a longer duration (6 months). Though observational studies should always be interpreted with caution, these results suggest a possible combinatorial effect of implementing both IRS and SMC in central Mali. This work also supports the utility of quality-assured and validated

routine surveillance data in rapidly assessing the impact of malaria control interventions in operational settings to empower evidence-based decision making.

### MALARIA VECTOR DENSITY AND PROXIMITY OF HUMAN RESIDENCE TO AN IRRIGATED AGRO-ECOSYSTEM IN MALAWI

Wezi Mkwaila<sup>1</sup>, Edward D. Walker<sup>2</sup>, Charles Mangani<sup>3</sup>, Leo Zulu<sup>2</sup>, Terrie E. Taylor<sup>2</sup>, Don Mathanga<sup>3</sup>, Themba Mzilahowa<sup>3</sup>

<sup>1</sup>Lilongwe University of Agriculture and Natural Resources, East Lansing, MI, United States, <sup>2</sup>Michigan State University, East Lansing, MI, United States, <sup>3</sup>University of Malawi, Blantyre, Malawi

Although malaria control interventions have led to a decline in transmission intensity, the disease continues to be a major public health problem in Malawi. Proximity of vector breeding sites to human residences affects malaria risk. Irrigation plays an increasingly important role in Malawi to improve food security and the rural economy. However, land transformation for irrigated agriculture could increase malaria vulnerability for those residing in proximity to irrigation schemes by creating more *Anopheles* breeding habitat, thereby increasing local transmission. Therefore, we aimed to determine the effect of irrigated agriculture on variation in *Anopheles* mosquito density in 14 villages around the Bwanje Valley rice irrigation scheme in eastern Dedza District. Two sampling efforts were conducted at the end of the rainy seasons of April 2016 and 2017 involving 338 households per year. A total of 6700 mosquitoes were collected from 344 households sampled by indoor CDC light trap without dry ice and played in sleeping rooms. Mosquitoes were identified morphologically and by PCR methods to species. Of the malaria vectors, *Anopheles arabiensis* (68%) was the dominant mosquito in collections and *Anopheles funestus* was second most common (10%), whilst *Culex* sp represented 18% and *Mansonia* sp represented 2% of total collections, respectively. An average of 19 mosquitoes per household were collected (5-56 range) per trap-night and six villages had counts above the average. All were close to the scheme. The malaria transmitting species were most abundant in six of the fourteen villages and in these villages. *An. funestus* was relatively more abundant in four villages only. Villages most proximal to the scheme had the highest *Anopheles* abundance compared to those those further away. Vector density declined as an exponential function of distance of house from the irrigation scheme.

## 1741

### MONITORING THE PROTECTIVE EFFICACY OF SEASONAL MALARIA CHEMOPREVENTION USING CASE-CONTROL STUDIES: METHODOLOGY AND RESULTS FROM 5 COUNTRIES

Matthew Cairns<sup>1</sup>, Serign Ceesay<sup>2</sup>, Issaka Zongo<sup>3</sup>, Issaka Sagara<sup>4</sup>, H. Kessely<sup>5</sup>, Sonny Ogboi<sup>6</sup>, Tony Eloike<sup>6</sup>, Ebenezer Baba<sup>7</sup>, Abdoulaye Diallo<sup>8</sup>, Jean Louis NDiaye<sup>8</sup>, Paul Snell<sup>1</sup>, Corinne Merle<sup>9</sup>, Paul John Milligan<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>MRC Laboratories, Fajara, Gambia, <sup>3</sup>IRSS, Bobo-Dioulasso, Burkina Faso, <sup>4</sup>MRTC, Bamako, Mali, <sup>5</sup>CSSI, NDjamena, Chad, <sup>6</sup>JEDIMA, Abuja, Nigeria, <sup>7</sup>Malaria Consortium, Kampala, Uganda, <sup>8</sup>UCAD, Dakar, Senegal, <sup>9</sup>World Health Organization/ITDR, Geneva, Switzerland

During the 2015 and 2016 rainy season, we conducted case-control studies in countries implementing SMC to estimate the protective efficacy of SMC against malaria, and to explore the duration of protection, and any changes in efficacy over time. Malaria cases in children below five years of age were recruited at health facilities, with caregivers then interviewed at home to document prior receipt of SMC and potential confounders, including age, socio-economic status and use of insecticide-treated nets. Recruitment of cases was stratified over the entire transmission season to

allow estimation of efficacy in different time periods. Two controls were selected from households in the same community at the same time that each case was recruited, and the same information collected. The sample size of approximately 250 cases and 500 controls per country. All data collection was carried out using tablet-PCs, allowing geo-location of cases and controls. These studies illustrate several important practical issues in the use of case-control studies to estimate SMC efficacy, and intervention efficacy more generally. These include measurement of exposure (the date of receipt of SMC and adherence to the regimen) and potentially confounding factors, which require a home visit to assess carefully; the definition of cases (in terms of parasitology and clinical symptoms) and the selection of controls; the recruitment strategy over time; and choice of reference group. Case control studies are vulnerable to bias, but a useful feature of SMC is that efficacy since efficacy is known to be very low more than 6 weeks after treatment, this permits a check of validity. Results from 2015 indicate protective efficacy of SMC over 80% in the first month after treatment, and preliminary analysis of data from 2016 indicate a similar picture of high SMC efficacy. By linking estimates of efficacy from these studies to results from large-scale surveys of molecular markers of drug resistance conducted nearby under the ACCESS-SMC project, we will suggest how these two approaches can be combined for ongoing monitoring of SMC efficacy in the future.

## 1742

### SEASONAL BIONOMICS OF MALARIA VECTORS IN KILWA AND KASHOBWE, HAUT-KATANGA PROVINCE, DEMOCRATIC REPUBLIC OF CONGO

Tamaki Kobayashi<sup>1</sup>, Thierry Bobanga<sup>2</sup>, Solange Umesumbu<sup>3</sup>, Christine M. Jones<sup>1</sup>, Jennifer C. Stevenson<sup>1</sup>, William J. Moss<sup>1</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Université Protestante au Congo, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Programme National de Lutte contre le Paludisme, Kinshasa, Democratic Republic of the Congo

The goal of the Southern and Central Africa International Centers of Excellence for Malaria Research is to address critical research questions on barriers to malaria control and elimination in Zambia, Zimbabwe and the Democratic Republic of Congo (DRC). Of importance for regional malaria control is movement of parasites and vectors across international borders. In this study, baseline data are presented on malaria vectors in the southern Haut-Katanga Province, DRC, which shares a border with Luapula Province, northern Zambia along Lake Mweru and the Luapula River. Two cross-sectional surveys were conducted in Kilwa and Kashobwe in Haut-Katanga Province in February (rainy season) and July 2016 (dry season). Kilwa is located near Lake Mweru and Kashobwe is located near the Luapula River, providing abundant vector breeding sites throughout the year. Six villages were selected at each site. Mosquitoes were collected using CDC light traps and pyrethroid spray catches. Species identifications of female *Anopheles* mosquitoes were determined morphologically and confirmed by PCR. Sources of blood meals were identified by PCR. In total, 479 female anophelines were caught and analyzed (189 in February and 290 in July 2016). The majority of mosquitoes caught in the rainy season were *An. gambiae* s.s., whereas the majority of mosquitoes caught in the dry season were *An. funestus* s.s. Blood meal PCR revealed that the captured mosquitoes were highly anthropophilic. In Kilwa and Kashobwe, malaria vectors are abundant throughout the year; however, *An. gambiae* dominates during the rainy season whereas *An. funestus* dominates during the dry season. This bionomic pattern for the anopheline malaria vectors is very similar to that observed in a few sites along Lake Mweru in Luapula Province, in Zambia. Further cross sectional studies are necessary to expand the findings and better delineate the foraging and resting behaviors of these mosquitoes such that they may be better exploited for malaria control.

### OUTDOOR MALARIA TRANSMISSION IN DANGASSA, A COMMUNITY WHERE MALARIA CONTROL IS FAILING DESPITE THE USE OF LONG-LASTING INSECTICIDAL NETS (LLINS)

Moussa Keita<sup>1</sup>, Mamadou B. Coulibaly<sup>1</sup>, Nafomon Sogoba<sup>1</sup>, Sidy Doumbia<sup>1</sup>, Ibrahim Sissoko<sup>1</sup>, Seydou O. Doumbia<sup>1</sup>, Sekou F. Traore<sup>1</sup>, Donald J. Krogstad<sup>2</sup>

<sup>1</sup>University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, <sup>2</sup>Tulane University, New Orleans, LA, United States

Long-lasting insecticide-treated bed nets (LLINs) and indoor residual spraying (IRS) are key elements of malaria vector control in Mali. Both these strategies target endophilic and endophagic mosquitoes, and therefore may select for changes in the trophic behavior of *Anopheles gambiae s.l.*, such as outdoor feeding. The purpose of these studies was to assess the level of transmission occurring outdoors in a rural Malian setting where conventional malaria control strategies have failed to reduce the either intensity of transmission or the incidence of human disease. Human landing catches were performed indoors and outdoors from 2012 to 2016 in the village of Dangassa. A total of 2463 female *Anopheles gambiae s.l.* were collected: 1225 indoors and 1238 outdoors. The human biting rates were similar indoors and outdoors (132.5 and 134.0 bites per person per night indoors and outdoors) from 2012 to 2013 before universal coverage with LLINs. Likewise, before universal coverage with LLINs, Entomologic Inoculation Rates (EIRs) were similar indoors and outdoors (69.0 and 67.6 infective bites per person per month, respectively). Similar results were again observed for biting rates three years after the introduction of universal coverage with LLINs. At that time, human biting rates were 71.7 and 72.3 bites per person per night indoors and outdoors, respectively. However, three years after the introduction of universal coverage with LLINs, the outdoor EIR rose while the indoor EIR remained stable (indoor and outdoor EIRs of 56.0 and 92.3 infective bites per person per month, respectively). Based on changes in the EIR (an increase in the outdoor EIR), these results may explain in part the failure of conventional malaria control strategies in communities such as Dangassa. If confirmed, these results suggest that the exclusively indoor focus of most malaria control strategies such as LLINs and IRS may be a serious limiting factor in the current global effort to improve malaria control. They suggest that additional strategies which reduce outdoor biting and transmission will be needed to achieve better malaria control in communities with intense transmission.

### ANALYSES OF THE IMPACT OF SHIFTING IRS OPERATIONS ON MALARIA TRANSMISSION RATES IN THE NORTHERN, UPPER EAST AND UPPER WEST REGIONS OF GHANA: 2014-2015

Christelle Gogue<sup>1</sup>, Joseph Wagman<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Jason Richardson<sup>2</sup>, Andrew Saibu<sup>3</sup>, Yemane Yihdego<sup>3</sup>, Sylvester Coleman<sup>3</sup>, Constance Bart-Plange<sup>4</sup>, Wahjib Mohamed<sup>4</sup>, Anthony Ofose<sup>5</sup>, Richard Steketee<sup>1</sup>, Molly Robertson<sup>1</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>IVCC, Washington, DC, United States, <sup>3</sup>Abt Associates, Accra, Ghana, <sup>4</sup>National Malaria Control Program, Accra, Ghana, <sup>5</sup>Ghana Health Services, Accra, Ghana

The indoor residual spraying (IRS) of insecticides has contributed substantially to the recent successes enjoyed by many malaria control programs, and IRS is positioned to remain one of the central components of the global malaria control strategy moving forward. Nonetheless, insecticide resistance concerns in Ghana prompted a switch from pyrethroids to a microencapsulated formulation of the organophosphate insecticide pirimiphos-methyl beginning in 2012. These changes in active ingredient, as well as other logistical considerations, contributed to some shifts in IRS operations and changes in the IRS status of several districts in the north of Ghana between 2013 and 2015. These changes allow

for observational study to better describe the public health impact of IRS with a next generation product, with a particular focus on the impact of (1) shifting active ingredients and (2) introducing IRS into previously unsprayed districts in the Northern, Upper East, and Upper West Regions of Ghana. Routine epidemiological data from the national District Health Information Management System II allow for the calculation of monthly malaria Rapid Diagnostic Test (RDT)-positive incidence rates at the health facility level across the three districts of northernmost Ghana. Changes in incidence rates observed at health facilities experiencing a change in IRS status from one year to the next are compared to changes in incidence observed at health facilities where IRS implementation status does not change, providing an estimate of intervention impact standardized for seasonal changes in baseline transmission. Particular attention is given to the impact of: suspension of IRS in Upper East Region in 2015 and Upper West Region in 2014; introduction and reintroduction of IRS into five districts of Upper West Region in 2015; in Northern region, suspension of IRS in Savelugu-Nanton district in 2015 and reintroduction of IRS in Kumbungu district in 2015. Analyses will also include results from routine entomological surveillance conducted by the President's Malaria Initiative (PMI)/Africa Indoor Residual Spraying (AIRS) project.

### COVERING HOUSE EAVE GAPS AND CEILINGS WITH INSECTICIDE TREATED NETS MAY REDUCE THE RISK OF PLASMODIUM INFECTION AMONG CHILDREN IN SIAYA SUB-COUNTY, KENYA

Mariko Yamaguchi<sup>1</sup>, George O. Sonye<sup>2</sup>, Beatrice Awuor<sup>2</sup>, Noriko Tamari<sup>3</sup>, Noboru Minakawa<sup>4</sup>

<sup>1</sup>United Nations Children's Fund (UNICEF) Cambodia County Office, Phnom Penh, Cambodia, <sup>2</sup>ASK Project, Mbita, Kenya, <sup>3</sup>School of Tropical Medicine and Global Health, Nagasaki University, Nagasaki, Japan, <sup>4</sup>Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan

Long-lasting insecticidal nets have been widely used for reducing malaria cases. A persisting challenge is how to protect children who do not adhere to net use. This study examined whether covering house eave gaps and ceilings with a fabric made of insecticide treated nets (ceiling nets) reduces the risk of *Plasmodium* infection among children in a village in Siaya Sub-County, Kenya. Ceiling nets were installed in half of the houses that were randomly selected. Two to three months after the installation, indoor resting anophelines were sampled from the houses with ceiling nets and those without the nets. Then, nearly all children aged between 0 and 17 in the village were tested for *Plasmodium* infection and hemoglobin concentration. Within one month after the test, ceiling nets were installed in the remaining houses. Monthly hospital records of malaria cases were compared before and after the intervention for the village and an adjacent village. The number of indoor resting anophelines was significantly fewer in the houses with ceiling nets compared with those without the nets ( $P < 0.001$ ,  $n = 40$ ). The Giemsa stained slide-positive prevalence for children with and without ceiling nets was 42.5% and 50.0%, respectively. The difference was not statistically significant (adjusted odd ratio: 0.61, CI: 0.22-1.60,  $P = 0.319$ ,  $n = 102$ ). On the other hand, the mean hemoglobin concentration of children with ceiling nets was 12.55 (sd=1.27) g/dL, and that of children without the nets was 11.50 (sd=2.04) g/dL. The difference was statistically significant ( $P = 0.029$ ,  $n = 102$ ). The proportion of the number of malaria cases to non-malaria cases for the village was significantly lower after the intervention ( $P < 0.001$ ,  $n = 36$ ) while the difference was not significant for the adjacent village ( $P = 0.328$ ,  $n = 36$ ). As the children were tested for infection two to three months after the intervention, the duration might not have been long enough to evaluate the effects with Giemsa staining. These results suggest that covering house eave gaps and ceilings with insecticide treated nets may reduce the risk of *Plasmodium* infection among children.

**HPLC-FLUORESCENCE METHOD FOR DETECTION OF IVERMECTIN IN MOSQUITO BLOOD MEALS**

Chilinh Nguyen, Brian D. Foy

Colorado State University, Fort Collins, CO, United States

Ivermectin (IVM) is an endectocidal drug that can be lethal to many biting arthropod vectors, including mosquitoes. We have been developing IVM mass drug administrations (MDA) as a tool for integrated malaria control due to its effect on *Anopheles* mosquitoes when they bite IVM-treated people, and as a control method for West Nile virus transmission due to its effect on *Culex tarsalis* when they bite birds given IVM-treated feed. While IVM has been shown to be toxic to these species, IVM detection and quantification in mosquito blood meals has not been published. This is important as IVM pharmacokinetics is studied using venous-drawn serum or plasma samples, however, given the highly lipophilic nature of IVM, mosquitoes may be ingesting a different amount of IVM from subdermal capillaries as they are often in close proximity to subdermal fat deposits. *An. gambiae* were fed serial dilutions of IVM in artificial blood meals at concentrations of 50, 25, 12.5, 6.25, 3.125, and 1.56 ng/ml and frozen at 0 hr and 12 hr post blood meal. IVM was detected at the lowest blood meal concentration of 1.56 ng/ml at both time points in individual blood fed *An. gambiae* using HPLC-fluorescence methods. This represents a potential ability to detect IVM in *Anopheles* caught resting in houses after blood feeding on treated humans the previous night, and IVM serum concentrations that can be found in humans at least a week following MDA on onchocerciasis control. Our method was also able to detect IVM in individual *Cx. tarsalis* given an artificial blood meal of 25 ng/ml and held for either 0 hr or 20 hr post-blood feed. Future experiments will include determining the limits of quantification and analyzing *in vivo* IVM blood meals of *Cx. tarsalis* from birds and *An. gambiae* from humans. This method could be used to determine IVM coverage within mosquito populations following IVM application to hosts, and could provide a critical link in understanding mosquito mortality dynamics in relation to IVM pharmacokinetics in humans and birds. This could contribute to a better understanding of the use of IVM for integrated vector control.

## 1747

**A MURINE MODEL OF DIARRHEA AND GROWTH IMPAIRMENT WITH *SHIGELLA FLEXNERI* INFECTION AND THE ROLE OF ZINC DEFICIENCY**Pedro Henrique Q. Medeiros<sup>1</sup>, Solanka E. Ledwaba<sup>1</sup>, David T. Bolick<sup>1</sup>, Reinaldo B. Oriá<sup>1</sup>, Aldo A. Lima<sup>2</sup>, Richard L. Guerrant<sup>1</sup><sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>Federal University of Ceara, Fortaleza, Brazil

*Shigella* is a highly infectious enteric pathogen often associated with bloody diarrhea worldwide. However, the lack of a robust murine model impairs study of *Shigella* pathobiology and the pursuit of vaccines. This study aimed to establish a murine model of *S. flexneri* infection. C57BL/6 mice received either standard chow (nourished controls, n=8) or zinc-deficient (n=8) diets for two weeks, as zinc deficiency has been implicated in worse diarrheal illness in children. Prior to *S. flexneri* infection, a broad-spectrum antibiotic cocktail was given in the drinking water for three days. Then mice were infected with *S. flexneri* 2457T strain (10<sup>9</sup> CFU/mouse) by gavage and followed daily for measures of weights and stool collection. Stools were used to quantify intestinal inflammation biomarkers (myeloperoxidase-MPO and lipocalin-LCN) using ELISA assays. In addition, bacterial DNA was extracted from stools for *S. flexneri* detection by qPCR (*ipaH* gene). *S. flexneri*-infected mice showed diarrhea and significant weight loss on days 2 and 3 post-infection, recovering subsequently. Nourished mice showed significantly higher *S. flexneri* stool shedding on day 1, whereas zinc-deficient mice showed higher stool shedding on day 5 and thereafter. Both infected groups had robust stool shedding until day 15, when nourished mice stopped shedding. Zinc-deficient mice continued to shed at least until day 33 post-challenge. Increased levels

of fecal MPO and LCN were found in the nourished infected mice on day 2. Increased levels of fecal LCN were found in the zinc-deficient infected mice on days 23, 25 and 27. IL-10 and TNF- $\alpha$  levels from cecal contents were significantly increased in the zinc-deficient infected mice on day 15. This study describes a novel murine model of shigellosis leading to growth impairment, diarrhea, heavy stool shedding and intestinal inflammation. Our findings also show that zinc deficient mice challenged by *S. flexneri* infection showed more prolonged colonization and inflammation.

## 1748

**PLASMA IGA RESPONSES AGAINST THREE *SALMONELLA* TYPHI ANTIGENS IDENTIFY PATIENTS WITH TYPHOID FEVER WITH EXCELLENT SENSITIVITY AND SPECIFICITY IN DHAKA, BANGLADESH**Richelle C. Charles<sup>1</sup>, Farhana Khanam<sup>2</sup>, Jason R. Andrews<sup>3</sup>, Motaher Hossain<sup>4</sup>, Meagan Kelly<sup>1</sup>, Stephen B. Calderwood<sup>1</sup>, Taufiqur Rahman Bhuiyan<sup>2</sup>, Firdausi Qadri<sup>2</sup>, Edward T. Ryan<sup>1</sup><sup>1</sup>Massachusetts General Hospital, Boston, MA, United States,<sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>4</sup>Stanford University School of Medicine, Dhaka, Bangladesh

There is a need for a reliable and simple diagnostic assay for typhoid fever. Currently, available commercial serologic assays using plasma and serum for typhoid fever have sensitivities and specificities of 50-75% and 70-90%, respectively. We have used a number of high throughput immuno-screening technologies and have identified immuno-reactive *S. Typhi* antigens that appear promising for inclusion in a new assay. Our data also suggest that assessing IgA responses in plasma can accurately identify patients with acute typhoid fever, even in highly typhoid-endemic areas. We therefore assessed IgA responses in plasma drawn on patients presenting with a febrile illness in Dhaka Bangladesh (day 0; n=28) who subsequently were determined to have *S. Typhi* bacteremia. We compared these responses to those detected in febrile (confirmed non-typhoid; n=15) and healthy endemic zone controls in Dhaka (n=20). We assessed IgA responses against HlyE, LPS, and MP (membrane preparation) via standard ELISA. We compared results to those obtained by using two commercially available tests: Tubex and Typhidot, as well as to a recently developed Typhoid/Paratyphoid test (TPTest). Of the 28 bacteremic individuals, 28 (100%) were positive by HlyE/MP IgA, HlyE/LPS/MP IgA, and TPTest; whereas 27 (96%), 21 (75%) and 18 (64%) patients were positive by HlyE/LPS IgA, Tubex and Typhidot, respectively. In healthy endemic zone and other febrile controls, the HlyE/MP IgA, HlyE/LPS IgA, HlyE/LPS/MP IgA, TPTest, Tubex and Typhidot were negative in 97%, 94%, 94%, 97%, 89% and 80%, respectively. Conclusion: Assessment of acute phase plasma IgA responses by ELISA for HlyE/MP (+/-LPS) gave a sensitivity of 100% and specificity of >95% in this small study and warrants further evaluation.

## 1749

**PREVALENCE OF CHILDHOOD DIARRHEAL ILLNESSES IN A PERUVIAN AMAZON RIVER BASIN COMMUNITY**Sanika Gadkari<sup>1</sup>, Marian Poley<sup>1</sup>, Ricardo Abedie<sup>2</sup>, Rosa Burga<sup>2</sup>, Melita Pizango<sup>2</sup>, Claudio Rocha<sup>2</sup>, David Craft<sup>1</sup><sup>1</sup>Pennsylvania State College of Medicine, Hershey, PA, United States, <sup>2</sup>Naval Medical Research Unit-6, Lima, Peru

Diarrheal disease continues to be a leading cause of childhood morbidity and mortality in resource-poor settings lacking water sanitation infrastructure. This longitudinal study focuses on the prevalence of enteric bacterial pathogens and parasites in stool samples from children under the age of 5 in the underserved community of Belén, Perú. Under an internationally approved IRB, consent was obtained from the mother or primary caregiver of each child under the age of 5. Households were excluded from the study if there was no adult over 18 present or child under 5 in the home. One hundred surveys were conducted and 87 stool samples were collected from children under the age of 5 from Jul - Aug

2016. Each survey was conducted in Spanish by translators. Stool samples were processed and cultured for bacterial pathogens, and processed and examined by microscopy for the presence of parasites, using standardized clinical microbiology procedures. Stool samples were further analyzed using QUIK CHEK (TechLab, Blacksburg, VA) test kits for the rapid detection of shiga toxin producing *E. coli* (STEC), Giardia, Cryptosporidia and *Entamoeba histolytica*. 16.9% of samples yielded at least one enteric bacterial pathogen and 60.9% of samples yielded at least one enteric parasitic pathogen. The most prevalent parasites were *Giardia lamblia* (37.9%), *Entamoeba coli* (14.9%), and *Ascaris lumbricoides* (10.3%). The most prevalent bacterial pathogens were *Aeromonas* spp. and *Salmonella* spp. (4.6% each), and *Shigella* spp. (3.4%). There is no evidence of STEC or *E. histolytica* in this population. Although clinical data was not collected to determine disease incidence, the presence of enteric parasites (60.9%) and enteric bacteria (16.9%) in the microbial flora of the stool is concerning for the potential for diarrheal disease. High parasite burden is consistent with previously presented data in which parasite burden was inversely proportional to chlorinated drinking water and enteric bacterial burden. Future studies are planned to include interventions such as a public health infection prevention seminar (charla) in the surveyed community.

## 1750

### MONITORING AND EVALUATION IN A MULTI-COUNTRY SURVEILLANCE SYSTEM: SEVERE TYPHOID IN AFRICA PROGRAM

**Ondari D. Mogeni**<sup>1</sup>, Ligia Maria Cruz Espinoza<sup>1</sup>, Isaac Osei<sup>2</sup>, Raphaël Rakotozandrindrainy<sup>3</sup>, Ellis Owusu-Dabo<sup>2</sup>, Se Eun Park<sup>1</sup>, Florian Marks<sup>1</sup>

<sup>1</sup>International Vaccine Institute, Seoul, Republic of Korea, <sup>2</sup>Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, <sup>3</sup>University of Antananarivo, Antananarivo, Madagascar

The Severe Typhoid in Africa (SETA) is a standardized, multi-country, surveillance network with the purpose of estimating the burden and severity of invasive salmonellosis. Monitoring and evaluation (M&E) of the surveillance network/system is important for data quality and comparability across sites; however, there is limited evidence on the best approaches to implement adequate M&E for multi-country, standardized surveillance studies. We present the process to develop the M&E plan for SETA and the lessons learnt during the pilot testing of the plan. Different steps were undertaken to develop the SETA M&E plan. First, the key elements and data flow through the surveillance system were ascertained and described. Second, the core activities and minimum standards required for the project to meet its main deliverables were identified. Third, using the two pieces of information mentioned above, a compilation of monthly monitoring data, indicators, targets associated with indicators and thresholds for actions were developed. Fourth, systematic field monitoring assessment visits were scheduled, and tools to report information on a monthly basis and during the monitoring visits were drafted. Lastly, pilot testing of the M&E strategies and documents took place at two of the 6 SETA countries. During the field visits, the core activities and minimum standards listed were observed and documented. Two main lessons were learnt. First, each site organized the logistics to implement the study standard procedures differently. This resulted in a variety of approaches that needed to be registered and documented. Second, not all study procedures could be observed. This was due to absence of patients at the recruitment healthcare facilities at the time of the visit, and follow-up visits scheduled outside of the time period of the visit. The logistics and organization to implement the study standard procedures may vary across SETA sites. A M&E plan than can leverage on the unique strategies or approaches of each site to implement the surveillance system will help to ensure data quality, comparability, and good performance across sites.

## 1751

### LONGITUDINAL ASSESSMENT OF ANTIBIOTIC RESISTANCE IN *E. COLI* ISOLATED FROM THE MAL-ED BIRTH COHORT STUDY IN RURAL TANZANIA

**Molly Erin Fleece**<sup>1</sup>, Rosemary Nshama<sup>2</sup>, Thomas Walongo<sup>2</sup>, Jean Gratz<sup>1</sup>, James Platts-Mills<sup>1</sup>, Esto Mduma<sup>2</sup>, Eric Houpt<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>Haydom Global Health Institute, Haydom, United Republic of Tanzania

Antimicrobial resistance is a serious global public health threat. Drug-resistant gram negative bacteria (GNB), such as *Escherichia coli*, are of particular concern. Despite the increasing prevalence of drug-resistant GNB in low resource countries, there is a lack of data concerning risk factors for acquisition. We aimed to characterize the prevalence, phenotypes, and risk factors for acquisition of drug-resistant *E. coli* from stool collected in the Etiology, Risk Factors, and Interactions of Enteric Infections and Malnutrition and the Consequences for Child Health and Development (MAL-ED) birth cohort study in rural Tanzania. 262 children were enrolled in the MAL-ED Tanzania site. We randomly selected 100 children who had *E. coli* isolates or stools archived every 6 months until 60 months, totaling 928 specimens. Susceptibility testing of 18 antibiotics was performed by disk diffusion. CLSI interpretive criteria were used for determination of resistance. Azithromycin was tested by E-test (MIC, µg/mL). From 270 *E. coli* specimens tested, resistance was identified in some samples for all drugs except ertapenem (100% susceptible). The highest rate of resistance was for ceftazolin (89%) followed by ampicillin (84%) and cotrimoxazole (81%). 18% of specimens had an azithromycin MIC  $\geq 32$  µg/mL. Four (1.5%) met criteria for ESBL based on combination disk testing with cefotaxime/cefotaxime-clavulanate and ceftazidime/ceftazidime-clavulanate. In conclusion, ESBL *E. coli* carriage appears to be rare in this community. Use of, and resistance to, ampicillin is common. After finishing all testing, we will analyze the longitudinal surveillance data of MAL-ED for potential risk factors of drug-resistant *E. coli* acquisition, including antibiotic use, hospitalizations, sociodemographic determinants, and diarrheal illnesses.

## 1752

### ETIOLOGY-SPECIFIC DIARRHEA BY QPCR AND LINEAR GROWTH DEFICITS IN BANGLADESHI INFANTS

**Amanda E. Schnee**<sup>1</sup>, Mami Taniuchi<sup>1</sup>, Md Jashim Uddin<sup>1</sup>, Elizabeth Rogawski<sup>1</sup>, Rashidul Haque<sup>2</sup>, Jie Liu<sup>1</sup>, Beth Kirkpatrick<sup>3</sup>, Eric Houpt<sup>1</sup>, William A. Petri Jr.<sup>1</sup>, James Platts-Mills<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>University of Vermont, Burlington, VT, United States

Childhood diarrhea has been identified as a risk factor for linear growth shortfalls. This association has been inconsistent, and the relationship between diarrhea attributable to specific pathogens and growth has not been comprehensively evaluated. In this study, we sought to characterize the etiology of diarrhea, as well as determine the relationship between pathogen-attributable diarrhea with linear growth and systemic inflammation by analyzing data collected during the Performance of Rotavirus and Oral Polio Vaccines in Developing Countries (PROVIDE) study. In this study, children were enrolled from birth to age 7 days and were followed via in-home surveillance for diarrhea. Diarrheal stools were collected, and subsequently tested with Taqman Array Cards (TAC) for causal pathogens. To account for asymptomatic carriage, we attributed pathogens as the etiology of diarrhea by calculating attributable fractions using odds ratios derived from the Global Enteric Multicenter Study. To assess growth impact, we fit a multivariable linear regression model with an outcome of length-for-age Z score (LAZ) at 12 months and used generalized estimating equations to assess potential delays in noticeable growth outcomes as well as resultant systemic inflammation. Of 700 enrolled children, 603 were included in the analysis. *Campylobacter jejuni*/*coli* was the primary bacterial etiology of diarrhea. Diarrheal episodes

independent of etiology did not have an impact on growth at 52 weeks. When analyzed by pathogen, both *Cryptosporidium* and *C. jejuni/coli* decreased LAZ (-0.26,  $p=0.05$  and -0.17,  $p=0.03$ , respectively), although *C. jejuni/coli* had a larger effect in the first 6 months of life (-0.52 decrease in LAZ per additional AE,  $p = 0.009$ ). Both *C. jejuni/coli* and *Shigella/EIEC* were associated with heightened inflammation (0.169 increase in log CRP,  $p=0.06$  and 0.183 increase in log CRP,  $p=0.04$ , respectively). *C. jejuni/coli* was the most common bacterial etiology of diarrhea in this cohort. Pathogen-specific diarrhea is associated with decreased linear growth at 52 weeks, as well as heightened systemic inflammation.

## 1753

### FOAM DRY STABILIZATION OF TYORASS, THE RECOMBINANT TY21A-SHIGELLOSIS VACCINE

Victoria Laney<sup>1</sup>, Henry Huang<sup>1</sup>, Yun Wu<sup>2</sup>, Jonathan Jackson<sup>2</sup>, Minglin Li<sup>2</sup>, Lixin Gao<sup>2</sup>, Rui Xu<sup>2</sup>, Sumana Chakravarty<sup>1</sup>, B. Kim Lee Sim<sup>2</sup>, Stephen L. Hoffman<sup>1</sup>, Eric R. James<sup>1</sup>

<sup>1</sup>Sanaria, Rockville, MD, United States, <sup>2</sup>Protein Potential, Rockville, MD, United States

The usual method for thermostabilizing live attenuated viral and bacterial vaccines is lyophilization. However, this involves initial freezing, which is damaging, and product stability is frequently less than optimal with bacterial products. Here we investigated the use of foam drying to thermostabilize an orally-administered *Salmonella* Typhi Ty21a-vectored vaccine expressing both the *Shigella sonnei* protective antigen and its acid resistance genes. TyOraSs was grown in supplemented CY medium to early stationary phase, harvested, resuspended in CY medium and mixed 1:1 with a 2x foam dry protective additive (FPA) cocktail. FPA ingredients evaluated included trehalose, sucrose, gelatin (porcine and piscine), agar, methionine, serine, glycerol, DMSO and potassium phosphate, at a range of pH values. Samples were aliquoted into 50 mL Schott vials, foam dried using a VirTis lyophilizer; varying the vacuum, number of vacuum steps and shelf temperature(s). Stoppering was performed after argon purging. Optimization of FPA, pH and lyophilizer program will be reported. Water content was determined using the Karl Fischer method. Foam dried vaccine was stored at 4 oC, ambient and 37 oC for accelerated stability testing. Samples were removed and assayed for viable counts by reconstituting to the original pre-foam dried volume, serially diluted and quantitated by colony enumeration on TSA plates. Residual water contents in the samples ranged from 2-6% at t=0. Our FPA formulation demonstrated the lowest post-process loss of 53% when trehalose, fish gelatin and glycerol were included; in comparison, experimental foam dried vaccines produced by others gave an average process loss of 70%. Work is continuing with agar-based FPA cocktails which have initially shown post-process viability of 36%. Long term stability for a similar strain, Ty21a-PA, at ambient and 4 oC at 20 months was 47% and 100%, respectively, compared to t=0 viability, which we hope to replicate in TyOraSs. Immunogenicity studies of foam dried TyOraSs in mice are ongoing. These results provide a basis for future development of large scale physically stable formulations of TyOraSs.

## 1754

### SALMONELLA ENTERICA SEROVARS ISOLATED FROM STOOLS OF CHILDREN ENROLLED IN THE GLOBAL ENTERIC MULTICENTER STUDY

I. N. Kasumba<sup>1</sup>, S. Sen<sup>1</sup>, N. Sayed<sup>1</sup>, J. Permala-Booth<sup>1</sup>, B. Tamboura<sup>2</sup>, J.B. Ochieng<sup>3</sup>, M. Antonio<sup>4</sup>, I. Mandomando<sup>5</sup>, D. Saha<sup>4</sup>, Q. Bassat<sup>5</sup>, P.I. Alonso<sup>5</sup>, R. Omoro<sup>3</sup>, M.J. Hossain<sup>6</sup>, S. Sow<sup>2</sup>, J.O. Oundo<sup>3</sup>, R.F. Breiman<sup>3</sup>, J.P. Nataro<sup>1</sup>, K.L. Kotloff<sup>1</sup>, M.M. Levine<sup>1</sup>, S.M. Tennant<sup>1</sup>

<sup>1</sup>University of Maryland, Baltimore, Baltimore, MD, United States, <sup>2</sup>Centre pour le Developpement des Vaccins, Bamako, Mali, Bamako, Mali, <sup>3</sup>Kenya Medical Research Institute/Centers for Disease Control and Prevention, Kenya, Kisumu, Kenya, <sup>4</sup>Medical Research Council Unit, Fajara, Fajara,

Gambia, <sup>5</sup>Centro de Investigacao em Saude da Manhica, Maputo, Mozambique, <sup>6</sup>Medical Research Council Unit, Fajara, Fajara, Gambia

The Global Enteric Multicenter Study (GEMS) determined the etiological agents of moderate-to-severe diarrhea (MSD) in children under the age of five years in four countries in Africa and three countries in Asia. *Salmonella* was not strongly associated with MSD. However, non-typhoidal *Salmonella* (NTS) infections are an important cause of septicemia in infants in Africa. Here, we present the NTS serovars isolated during GEMS from Africa. *Salmonella* spp. identified in Kenya, Mali, the Gambia and Mozambique were shipped to the Center for Vaccine Development in Baltimore for complete identification of serovars using antisera and biochemical tests. We tested 181 African *Salmonella* isolates, of which 101 were from cases and 80 were from controls. Multiplex PCR was employed to confirm agglutination results and to determine *Salmonella* Typhimurium sequence types. We also tested sensitivity to selected antibiotics by the Kirby Bauer disk diffusion method. Of the 181 *Salmonella* enterica strains, 138, 35, 2 and 6 were from Kenya, the Gambia, Mali and Mozambique, respectively. 38.7% were *S. Typhimurium*, 9.4% were *S. Virchow*, 6.6% were *S. Newport*, 6.6% were *S. Enteritidis*, 5.5% were *S. Heidelberg*, 3.9% were *S. Paratyphi B Java*, 1.7 % were *S. Hissar*, 1.1% were *S. Wingrove*, *S. Aberdeen*, or *S. Bovismorbificans*, 0.6% were *S. Muenster*, *Ssilla*, *Larochelle*, *Eastbourne* or *S. Muenchen*, 8.3% were other *Salmonella* serovars and 13.3% were non-typable. Antibiotic resistance of *S. Typhimurium* was 96% for ampicillin and trimethoprim-sulfamethoxazole (SXT) and 79% and < 1 percentage for chloramphenicol and gentamicin, respectively. 88.2% of tested *S. Typhimurium* strains were ST313. The most common *Salmonella* serovar that was isolated in GEMS was *S. Typhimurium*, followed by *S. Virchow* and *S. Newport*. Although *S. Typhimurium* ST313 has been associated with invasive disease in sub-Saharan Africa, we determined that it was isolated from the stools of children in this region too.

## 1755

### PREVALENCE AND ANTIBIOTIC RESISTANCE OF ENTEROPATHOGENS BACTERIAL ISOLATED FROM FECAL SAMPLES AT A HOSPITAL OF THE PERUVIAN AMAZON

Rosa Burga<sup>1</sup>, Ricardo Abadie<sup>1</sup>, Norma Wong<sup>2</sup>, James Regeimbal<sup>3</sup>, Claudio Rocha<sup>3</sup>, Andrea McCoy<sup>3</sup>

<sup>1</sup>Naval Medical Research Unit-6, Iquitos, Peru, <sup>2</sup>Apoyo Iquitos Hospital "Cesar Garayar Garcia", Iquitos, Peru, <sup>3</sup>Naval Medical Research Unit-6, Lima, Peru

Diarrheal disease is the major cause of death in children under 5 in developing countries, and is a significant threat to public health. Acute gastroenteritis also remains a very important cause of morbidity in adults, and morbidity and mortality in children in Latin America. Antimicrobial resistance among enteric pathogens has also been increasing over the last decade in Latin America due to the indiscriminate use of antibiotics without prescription. Poor infection control standards and few antibiotic stewardship programs have resulted in many hospitals continuing to use ineffective antibiotics for the treatment of resistant enteric infections. In the present study, 174 samples of diarrhea were collected from August 2015 to March 2017. These samples were processed by standard laboratory culture techniques for bacterial pathogen identification and antibiotic susceptibility was determined by disk diffusion on all isolates. Of these samples, 16% (29/174) were positive for enteropathogenic bacteria. A total of 31 bacteria were isolated (27 samples with only one pathogen and 2 samples with two pathogens each). *Shigella* sp. and *Salmonella* sp. were the pathogens most common with 11 and 10 isolates, respectively, comprising 67% (21/31) of the enteric bacterial isolates, followed by 5 *Plesiomonas shigelloides* (16%), 2 isolates of *Aeromonas* spp. (6%), and one isolate of *Campylobacter* spp., *Vibrio cholera* Non-O1, and *Yersinia enterocolitica* each. Of the *Shigella* isolates, 90% were resistant to trimethoprim/sulfamethoxazole and tetracycline, followed by 81% resistant to chloramphenicol and ampicillin, and finally 9% were resistant to azithromycin. Of all the tested *Salmonella* spp, 70% were resistant to

nalidixic acid, 50% to ampicillin and tetracycline, 40% to chloramphenicol, 30% to trimethoprim/sulfamethoxazole, and 90% of the *Salmonella* spp showed intermediate resistance to ciprofloxacin. Because of growing resistance in the two most common enteric bacterial pathogens, *Shigella* and *Salmonella*, new strategies for the treatment of diarrheal diseases in Peru should be adjusted to control the emerging antimicrobial resistance.

## 1756

### COST-EFFECTIVENESS OF INTERVENTIONS TO PREVENT DIARRHEA: INTRODUCING A MICROSIMULATION MODEL FOR CHILDREN UNDER FIVE IN EVERY COUNTRY FROM 2005 TO 2015

**John Everett Mumford**, Abraham D. Flaxman, Alec W. Deason, Ibrahim Adib Abdel-Messih, Tom Shonka, Jonathan Brown, Marcia Weaver, Ali H. Mokdad

*IHME, Seattle, WA, United States*

Diarrhea is one of the leading causes of morbidity and mortality among children under five. The global under five diarrhea mortality rate declined by 39% between 2005 and 2015, but the burden remains immense. Policymakers need to be informed as to which interventions better reduce the burden of diarrhea. We developed a cost-effectiveness analysis microsimulation (CEAM) model using an individual-based discrete-time Markov model. CEAM has three sections: a general, modular framework for running agent-oriented microsimulations, a repository of applications specific to public health, and a repository of data ingestion code that pulls, transforms, and preprocesses data from the Global Burden of Disease (GBD). We leveraged data from GBD to estimate the health burden due to specific diarrhea-causing pathogens (e.g. rotavirus) as well as the effect of treatments that target specific pathogens (e.g. rotavirus vaccines). We have decided to compare two vaccines - RotaTeq and BRV-PV - that reduce the burden of diarrhea due to rotavirus as an example. We will generate estimates of deaths, YLLs, DALYs, and costs of supplying the rotavirus vaccines using a population of 20,000 simulants in Kenya. We will compare RotaTeq and BRV-PV in terms of cost-effectiveness. Our simulation will provide a tool to facilitate comparisons between interventions and guide policymakers, governments, and funding organizations to make informed, evidence-based decisions for prioritizing investments in diarrheal disease interventions. Our work will allow for a better allocation of limited resources to reduce the burden of diarrhea.

## 1757

### GENOMIC AND PHENOTYPIC CHARACTERIZATION OF TYPHOID VACCINE STRAIN TY21A REVEALS INSIGHTS IMPACTING FUTURE VACCINE DEVELOPMENT AND OPTIMIZATION

**Yun Wu**<sup>1</sup>, Tint T. Wai<sup>1</sup>, Jonathan M. Jackson<sup>1</sup>, Stephen L. Hoffman<sup>2</sup>, B. Kim Lee Sim<sup>1</sup>

<sup>1</sup>Protein Potential LLC, Rockville, MD, United States, <sup>2</sup>Sanaria Inc., Rockville, MD, United States

The live, oral, attenuated *Salmonella* Typhi vaccine Ty21a is one of only two licensed typhoid vaccines. Ty21a was developed in the 1970s by chemical mutagenesis of the virulent strain Ty2. Ty21a triggers long-lasting immunity and has been safely administered to > 200 million recipients, a safety record that is unrivaled by any live attenuated bacterial vaccines or vaccine candidates produced by modern, gene-specific attenuation. Nevertheless, bystander mutations that reduce overall fitness of the bacterium without contributing to safety can reduce vaccine efficacy. We use Ty21a as a platform technology for multivalent vaccines and such information are of utmost interest. The total genome sequence of both Ty2 and Ty21a are available in NCBI GenBank. However, these assemblies harbor ambiguous nucleotides and errors, particularly in the assembly of Ty21a. Therefore, we carried out *de novo* assembly of Ty2 and Ty21a genomes using next- and third-generation sequencing and compared the assembled sequences

to the reference genomes by variant analyses. Our preliminary results showed that a long-range translocation due to rDNA recombination occurred in Ty21a but was not accounted for previously. There were at least 41 and 119 previously misannotated nucleotides in Ty2 and Ty21a reference genomes, respectively. Of the 689 previously identified SNPs between Ty2 and Ty21a, only 522 were identified in our analysis and 1 more SNP was identified. Additionally, we detected the signature mutation of Ty21a, C444Δ in the *galE* gene that was inadvertently missed in the Ty21a reference genome. We are currently verifying our findings by PCR-sequencing of independent sources of Ty2 and Ty21a. Furthermore, SNP mutations that might contribute to overall fitness and survival of the bacterium are being characterized by genetic complementation tests. Such a detailed characterization will provide insights in future optimization of the Ty21a vaccine platform as a vector for development of multivalent vaccines. Furthermore, our findings will also benefit the development of novel live attenuated bacterial vaccine platforms.

### ETIOLOGY AND SEVERITY OF DIARRHEAL DISEASE IN INFANTS IN BRAZIL SEMIARID REGION: A CROSS-SECTIONAL CASE-CONTROL STUDY

**Aldo A. Lima**<sup>1</sup>, Domingos B. Oliveira<sup>1</sup>, Josiane S. Quetz<sup>1</sup>, Alexandre H. Binda<sup>1</sup>, Mara M. Prata<sup>1</sup>, Ila F. Lima<sup>1</sup>, Alberto M. Soares<sup>1</sup>, José Q. Filho<sup>1</sup>, Noélia L. Lima<sup>1</sup>, Noélia L. Lima<sup>1</sup>, Pedro H. Medeiros<sup>1</sup>, Ana K. Santos<sup>1</sup>, Herlice N. Veras<sup>1</sup>, Raffaella N. Gondim<sup>1</sup>, Rafaela Pankov<sup>1</sup>, Mariana D. Bona<sup>1</sup>, Francisco A. Rodrigues<sup>1</sup>, Eric R. Houpt<sup>2</sup>, Richard L. Guerrant<sup>2</sup>

<sup>1</sup>Federal University of Ceara, Fortaleza, Brazil, <sup>2</sup>University of Virginia, Charlottesville, VA, United States

We designed this study to identify the etiology and severity of diarrheal disease in children in the low-income Brazil semiarid region. The study is a cross-sectional, age-matched case-control of diarrhea in children aged 2-36 months residing in six cities from Brazil semiarid region. We recruited children with diarrhea seeking care at health centers along with selected age-matched community control children. We obtained informed consent from their parents, clinical and epidemiological data, and a fecal sample to identify enteropathogens using Luminex System. We enrolled 1200 children, 600 children with diarrhea and 600 children without diarrhea. By bivariate analysis the enteric pathogens associated significantly with diarrhea were: *Norovirus* GII (OR 5.14, 95% CI 2.13, 12.46), *Adenovirus* (OR 3.84, 95% CI 1.42, 10.36), typical enteropathogen *Escherichia coli* (tEPEC) (OR 3.16, 95% CI 1.33, 7.49), enterotoxigenic *E. coli* (ETEC LT-ST producing toxins) (OR 2.61, 95% CI 1.01, 6.77) *Rotavirus* (OR 1.93, 95% CI 1.22, 3.06), enterohemorrhagic *E. coli* (EHEC) (OR 1.76, 95% CI 1.15, 2.68), enteroaggregative *E. coli* (EAEC) (OR 1.42, 95% CI 1.13, 1.79) and *Giardia* (OR 1.41, 95% CI 1.07, 1.87). By logistic regression, the best predictors of diarrhea were in descending order: *Norovirus*, *Adenovirus*, *Rotavirus*, *Giardia* and EAEC. Severity diarrhea scores were significantly associated with *Norovirus* and EAEC ( $p < 0.034$ ). Five enteric pathogens (*Norovirus*, *Adenovirus*, *Rotavirus*, *Giardia* and EAEC) are associated with diarrhea in children in the low-income Brazil semiarid region.

## 1759

### HUMAN CHALLENGE MODEL REFINEMENT FOR B7A, AN ENTEROTOXIGENIC *ESCHERICHIA COLI* (ETEC) CHALLENGE STRAIN THAT EXPRESSES CS6

**Kawsar R. Talaat**<sup>1</sup>, Christopher Duplessis<sup>2</sup>, A. Louis Bourgeois<sup>1</sup>, Chad Porter<sup>2</sup>, Milton Maciel, Jr.<sup>2</sup>, Ramiro Gutierrez<sup>2</sup>, Brittany Adjoodani<sup>1</sup>, Barbara DeNearing<sup>1</sup>, Brittany Feijoo<sup>1</sup>, Subhra Chakraborty<sup>1</sup>, Jessica Brubaker<sup>1</sup>, Stefanie Trop<sup>2</sup>, Kayla Jaep<sup>1</sup>, Mark Riddle<sup>2</sup>, Sabrina Joseph<sup>2</sup>, Michael G. Prouty<sup>2</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Naval Medical Research Center, Silver Spring, MD, United States

Enterotoxigenic *Escherichia coli* (ETEC) is a major cause of diarrhea in children under the age of 2. The primary objective of this randomized, open label phase 1 trial was to refine the ETEC strain B7A (CS6, LT, ST positive strain) challenge model: to determine the safety of B7A and to identify a dose and fasting regimen that reproducibly induced moderate-severe diarrhea in at least 70% of naïve subjects. Twenty-eight subjects were randomized to one of 4 study groups for Cohort 1 with either an overnight (108 or 109 cfu) or ninety minute (109 or 1010 cfu) fast. Of the subjects receiving B7A doses of 108 cfu with an overnight fast or 109 cfu following a 90-minute fast, 3/7 met the primary endpoint of moderate to severe diarrhea. The groups receiving B7A at a 1010 cfu dose with a 90-minute fast and 109 cfu dose following overnight fast had a higher attack rate with 5/7 experiencing moderate to severe diarrhea. To assess the reproducibility of the attack rate of the target regimen and to determine homologous protection against rechallenge, 11 subjects who met the moderate-severe diarrhea endpoint in cohort 1 were re-admitted along with 19 naïve subjects; all subjects received 109 cfu of B7A following an overnight fast. The proportion of naïve subjects with moderate-severe diarrhea was lower than observed in the initial cohort with only 11/19 (58%) meeting the primary endpoint. Additionally, the incidence of moderate-severe diarrhea in previously challenged subjects was not significantly different than in naïve subjects 5/11 (46%). Antibody responses to CS6 were modest as measured by ELISA or ALS across all dosing groups. LPS was the most immunogenic antigen measured. In this study, we attempted to identify an optimal dosing and fasting regimen that maximizes attack rate while minimizing the inoculum necessary to achieve a high and reproducible attack rate. We found that increasing the fasting time was not sufficient to allow for a decrease in the inoculum dose while maintaining a consistent attack rate, but it caused more symptoms in the volunteers. In addition, there was a lack of protection upon rechallenge with the 109 cfu with an overnight fast dosing regimen.

### CORRELATING THE PREVALENCE OF *VIBRIO CHOLERAE* AND *SHIGELLA* SPP. IN HIV-SERO POSITIVE PEDIATRIC PATIENTS WITH THEIR CD4 T-CELLS COUNT ATTENDING THE ART REFERENCE LABORATORY IN CENTRAL HOSPITAL OF NEPAL: FIRST CASE STUDY FROM THE COUNTRY

**Binod Rayamajhee**<sup>1</sup>, Sarita Manandhar<sup>2</sup>, Shardulendra Prasad Sherchan<sup>3</sup>, Samendra Sherchan<sup>4</sup>, Samendra Sherchan<sup>4</sup>, Jyoti Acharya<sup>5</sup>

<sup>1</sup>Kathmandu Research Institute for Biological Sciences, National College (Tribhuvan University), Khusibu, Kathmandu, Nepal, <sup>2</sup>Tri-Chandra Multiple College (Tribhuvan University), Ghantaghar, Kathmandu, Nepal, <sup>3</sup>Department of Microbiology, Immunology, and Parasitology, Louisiana State University Health Sciences Center, New Orleans, LA, United States, <sup>4</sup>School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States, <sup>5</sup>National Public Health Laboratory, Ministry of Health Government of Nepal, Teku, Kathmandu, Nepal

The diarrheal disease in children living with HIV/AIDS (CLWHA) being an indicator of lack of social development continues to be a major public health problem in Nepal. Opportunistic infection (OI) diarrhoea affects

nearly 90% of CLWHA in underdeveloped countries like Nepal. The cardinal aim of this research was to correlate the level of CD4 T-cells with the prevalence of *Vibrio cholerae* and *Shigella* spp. among the CLWHA. Right antibiotics treatment can reduce the volume of diarrhoea and reduce the disease burden. Diarrhoeal stool samples of HIV sero-positive paediatric (below 16 years) patient's visiting the antiretroviral therapy (ART) reference laboratory of Sukraraj Tropical and Infectious Disease Hospital (STIDH) in Kathmandu were collected and analysed following microbiological procedures recommended by the Clinical Laboratory Standards Institute. Serological confirmation and serotyping of *Shigella* and *V. cholerae* isolates were done using specific antisera from Denka Seiken Co., Tokyo, Japan. CD4 T-cell counting was done using computerized Partec flow-cytometer. Among 337 stool samples analysed, 59 samples were found to be positive for enteric bacterial pathogens, of which 33 were *V. cholerae* (9.8%) and 26 were *Shigella* spp. (7.7%), the total prevalence being 17.6%. The identified enteropathogens showed that *V. cholerae* was found to be the highest with 9.8%, followed by *Shigella flexneri*, *Shigella sonnei*, *S. dysenteriae*, and *S. boydii*. All isolated *V. cholerae* strains belonged to the serogroup O1 and serovar Ogawa and of biotype El Tor. There was high rate of culture positivity (63.7%) among the children patients having low level of CD4 count. All the *Vibrio* isolates were resistant to nalidixic acid and cotrimoxazole while 91.7% were sensitive to ciprofloxacin. *Shigella* isolates were mostly susceptible to cefotaxime (80.9%) while ciprofloxacin (19%) was the least effective drug. Among the isolated *Shigella* spp. 61% were multiple drug resistant (MDR) while 56% of *V. cholerae* were MDR. HIV positive paediatric patients are in high risk of OIs like diarrhoea hence treatment of diarrhoea on time is becoming crucial.

## 1761

### VILLAGE-LEVEL MEDICATION LOGBOOK AUDIT FOLLOWING A TRACHOMA MASS DRUG ADMINISTRATION CAMPAIGN IN AMHARA REGION, ETHIOPIA IN 2016

**Alex M. Jordan**<sup>1</sup>, Tigist Astale<sup>2</sup>, Eshetu Sata<sup>2</sup>, Mulat Zerihun<sup>2</sup>, Andrew Nute<sup>1</sup>, Aisha E.P. Stewart<sup>1</sup>, Demelash Gessesse<sup>2</sup>, Gedefaw Ayenew<sup>2</sup>, Berhanu Melak<sup>2</sup>, Melsew Chanyalew<sup>3</sup>, Zerihun Tadesse<sup>2</sup>, E. Kelly Callahan<sup>1</sup>, Scott D. Nash<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Addis Ababa, Ethiopia, <sup>3</sup>The Amhara Regional Health Bureau, Bahir Dar, Ethiopia

Trachoma programs throughout the Amhara National Regional State of Ethiopia use village-level medication logbooks to track distribution of azithromycin during mass drug administration (MDA) for trachoma. However, audits of the quality of this approach have not been commonly reported. This survey assessed MDA coverage as recorded in logbooks for a random selection of households in a representative sample of villages in the Amhara region. Following a post-MDA cluster-randomized coverage survey in Amhara, data collectors visited health posts for each cluster (village) to assess presence of logbooks and household pages for participating households from each cluster. When located, drug dosage information for each household member was recorded. Overall, logbooks were located for 296 clusters (93%). From these clusters, family pages were located for 3,495 households (72.7%) and contained data for 18,547 individuals. Treatment coverage as recorded in family pages for all ages was 76.3% for Amhara region, and ranged from 64.9% in South Gondar zone to 89.7% in East Gojjam zone. Recorded treatment coverage among children ages 1-9 years was 81% regionally, and was higher than the all-ages coverage in all zones, ranging from 74.3% in North Wollo to 93.5% in East Gojjam zone. Recorded treatment coverage differed widely across surveyed districts within each zone, with coverage as high as 97.7% and as low as 13%. Recorded treatment coverage for Amhara was close to the World Health Organization's recommended threshold of 80%, and suggests that the MDA campaign in this region reached a high percentage of eligible residents. Reasons for missing household pages, and reasons for low recorded coverage in certain areas should be investigated. Further analyses to compare self-reported coverage from the post-MDA coverage survey to recorded coverage from medication logbooks at the individual level is ongoing. The results of this audit demonstrate that the quality of

medication record keeping as well as the recorded MDA coverage varies within a mature MDA program. Lessons learned from this audit should help regions scaling up MDA programs throughout Ethiopia.

### ONE ROUND OF TARGETED SUB-DISTRICT TREATMENT IN THE DISTRICT OF OUSSOUBIDIAGNA, MALI ACHIEVED THE CRITERIA OF STOPPING TRACHOMA MASS DRUG ADMINISTRATION

Lamine Traoré<sup>1</sup>, Modibo Keita<sup>2</sup>, Benoit Dembélé<sup>2</sup>, Mamadou Dembélé<sup>1</sup>, Boubacar Guindo<sup>2</sup>, Dramane Traoré<sup>2</sup>, Oumar Bouré<sup>1</sup>, Famolo Coulibaly<sup>1</sup>, Daouda Coulibaly<sup>1</sup>, Seydou Goita<sup>2</sup>, Abdoul Karim Sidibé<sup>1</sup>, Steven David Reid<sup>3</sup>, Amy R. Veinoglou<sup>3</sup>, Marily Knieriemen<sup>2</sup>, Yaobi Zhang<sup>4</sup>

<sup>1</sup>Ministère de la Santé et de l'Hygiène Publique, Bamako, Mali, <sup>2</sup>Helen Keller International, Bamako, Mali, <sup>3</sup>Helen Keller International, New York, NY, United States, <sup>4</sup>Helen Keller International, Dakar, Senegal

Oussoubidiagna health district (HD) in Mali was originally part of Bafoulabé HD that was found to be endemic for trachoma in 1997, with a baseline active trachoma prevalence of 42.5% (range: 37.5-47.2%) in children aged under 10 years. Three rounds of annual mass drug administration (MDA) with azithromycin and 1% tetracycline eye ointment was conducted in 2003-2005, and MDA was stopped in 2006 following an impact assessment showing prevalence of trachomatous inflammation follicular (TF) had dropped to 1.2%. However, a surveillance survey in 2009 showed a recrudescence of trachoma in Bafoulabé (TF: 15%), and three further rounds of MDA were conducted in 2010-2012. A sub-district level impact assessment was conducted in the HD in 2013 per WHO recommendations. The results indicated that one out of five sub-districts in Bafoulabé had a TF prevalence of 5.58% (3.68-8.37%) in children aged 1-9 years and should receive one more round of MDA per the WHO guidelines. In 2014, Bafoulabé was split into two HDs: Bafoulabé and Oussoubidiagna. The Oussoubidiagna HD inherited the sub-district requiring MDA. In February 2016, the national program conducted MDA targeting the sub-district only (9 of the 20 health areas), achieving a programmatic coverage of 88.1%. A district-level assessment using a cross-sectional, randomized, two-degree cluster survey of 20 clusters was conducted in Oussoubidiagna in January 2017, one year after the MDA to assess the TF prevalence in children aged 1-9 years. The clusters in the treated sub-district accounted for 40% (8/20) of the total clusters surveyed. The WHO simplified grading system was used to identify TF cases. A total of 1,116 children aged 1-9 years were examined with a male-to-female ratio of 1.27. No cases of TF were detected (0/1116), resulting in a TF prevalence of 0%. These data indicate that implementing MDA at the sub-district level, rather than the district level enabled the country programme to reach the TF elimination threshold (<5%) in Oussoubidiagna while saving resources. Surveillance is needed to avoid further recrudescence.

## 1763

### PROGRESS TOWARDS ACHIEVING TRACHOMA ELIMINATION: RESULTS FROM 6 LOCALITY-LEVEL IMPACT SURVEYS IN SUDAN

Angelia Sanders<sup>1</sup>, Zeinab Abdalla<sup>2</sup>, Balgesa Elshafie<sup>3</sup>, Mazin Elsanosi<sup>2</sup>, Nabil Mikhail<sup>2</sup>, E. Kelly Callahan<sup>1</sup>, Scott D. Nash<sup>1</sup>

<sup>1</sup>The Carter Center, Decatur, GA, United States, <sup>2</sup>The Carter Center, Khartoum, Sudan, <sup>3</sup>Sudan Federal Ministry of Health, Khartoum, Sudan

In 2016 and 2017 The Carter Center supported the Sudan Federal Ministry of Health to conduct trachoma impact surveys to evaluate the success of program interventions and determine if additional rounds of mass drug administration (MDA) with azithromycin were needed. For each locality-level survey, a multi-stage cluster-random sampling method was used whereby clusters (villages) were selected using probability proportional

to population size in the first stage, and households selected randomly from a village household register and segmentation method in the second stage. Households within a cluster were selected with equal probability and all present household members examined using the WHO simplified trachoma grading scheme. A total of 14,741 individuals in 3,692 households were surveyed across six localities spanning five states (Red Sea, Gedarif, Sinnar, Blue Nile and South Kordofan). The prevalence of trachomatous inflammation follicular (TF) in children age 1-9 years ranged from 0.4%, (95% Confidence Interval (CI): 0.0, 0.8) in El Fashaga locality, Gedarif to 8.3%, (95% CI: 0.6, 15.9) in El Quraisha locality, Gedarif. In those 15 years and older, trachomatous trichiasis (TT) ranged between 0.1% (95% CI: 0.1, 0.3) in Abu Jebaiha locality, South Kordofan to 2.5% (95% CI: 0.8, 4.2) in Gaissan locality, Blue Nile. The prevalence of water and sanitation indicators were moderate with an average of 78% of children age 1-9 years having a clean face and household latrine coverage ranging from 13.2% to 86.5%. The prevalence of TF among children ages 1-9 years was less than 5% in five out of six localities which allows the government to stop MDA in these 5 localities. The sixth locality, Al Quraisha, will require one more round of MDA before another impact survey. The prevalence of TT in those 15 years and older was above the WHO thresholds of 0.2% in five out of six localities, demonstrating the need for continued surgical interventions to avoid blindness. Results from these impact surveys show that the program is on-track to reaching its target of elimination of trachoma as a public health problem by 2020.

## 1764

### RELIABILITY OF THE ABBOTT REALTIME ASSAY FOR THE QUANTIFICATION OF CHLAMYDIA TRACHOMATIS IN CONJUNCTIVAL SAMPLES FROM A TRACHOMA-ENDEMIC AREA OF ETHIOPIA

Kieran S. O'Brien<sup>1</sup>, Jeanne Moncada<sup>1</sup>, Julius Schachter<sup>1</sup>, Paul M. Emerson<sup>2</sup>, Scott D. Nash<sup>2</sup>, Zerihun Tadesse<sup>3</sup>, Zhaoxia Zhou<sup>1</sup>, Charles E. McCulloch<sup>1</sup>, Thomas M. Lietman<sup>1</sup>, Jeremy D. Keenan<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>The Carter Center, Addis Ababa, Ethiopia

The World Health Organization recommends monitoring trachoma programs by assessing trachomatous inflammation-follicular in children aged 1-9 years (TF1-9). Unfortunately, TF1-9 correlates poorly with infection, particularly after mass antibiotics. Commercial Nucleic Acid Amplification Tests can be used to estimate the prevalence of ocular infection with *Chlamydia trachomatis* in a community, and have become standard in research. Home-brew tests using real-time PCR are even used to quantify load of infection in individuals and burden in communities. The Abbott RealTime assay allows for quantification of load of infection, as opposed to earlier qualitative tests. To assess the reliability of Abbott RealTime for detection of *C. trachomatis* on the m2000 platform, conjunctival samples were taken from 69 children aged 0-9 years from 6 communities in the Amhara region in Ethiopia. Three swabs were taken from each child: 2 per right eye and 1 per left eye. Calibration curves were calculated using known concentrations of *C. trachomatis*. Four aliquots were run for each child: 2 from 1 right eye swab, 1 from the other right eye swab, and 1 from the left eye swab. A linear mixed effects model with child, eye, and swab included as random effects was used to evaluate intra-class correlation coefficients (ICC) for the following comparisons: 2 aliquots from the same swab, 2 swabs from the right eye, and 1 right and 1 left eye swab from the same child. Twenty-one children (30.4%) had at least 1 positive swab. The range of elementary bodies detected was 0-28,390 (median=0, IQR=0, 0). The ICC for 2 runs of the same swab was 0.97, indicating that results from duplicate aliquots are essentially the same. The ICC for the 2 right eye swabs was 0.88, suggesting some variation in sample collection. Specifically, 3 children (0.04%) had 1 positive and 1 negative swab from the right eye. The ICC for right and left eye swabs was 0.71, consistent with the belief that some children have

unilateral infection. Overall, the majority of variance was due to between-child variability in all comparisons, indicating that the Abbott RealTime assay provides highly concordant chlamydial loads.

## 1765

### PROVIDING TRACHOMATOUS TRICHIASIS SURGICAL SERVICES IN RURAL TANZANIA

**Alistidia S. Wenfurebe**<sup>1</sup>, Jeremiah Ngondi<sup>2</sup>, Joseph Sambali<sup>3</sup>, Edward Kirumbi<sup>4</sup>, Upendo Mwingira<sup>4</sup>, Jennifer Harding<sup>3</sup>, Riziki Ponsiano<sup>5</sup>

<sup>1</sup>National Institute of Medical Research, Dar es salaam, United Republic of Tanzania, <sup>2</sup>RTI International, Dar es salaam, United Republic of Tanzania, <sup>3</sup>Hellen Keller International, Dar es salaam, United Republic of Tanzania, <sup>4</sup>Neglected Tropical Diseases Control Program, Dar es salaam, United Republic of Tanzania, <sup>5</sup>Sightsavers, Dar es salaam, United Republic of Tanzania

The World Health Organization (WHO) targets global elimination of trachoma as a public health problem by the 2020 through the SAFE (surgery, antibiotics, facial cleanliness, environmental change) strategy. Since inception of SAFE in 1999, Tanzania implements trichiasis surgical services in rural areas based on WHO guidelines with the aim of achieving GET 2020 goals. According to WHO elimination of trachomatous trichiasis (TT) is considered when the prevalence of trichiasis cases un-known to the health system is <1/1000 in the whole population (i.e. <0.2/1000 in people aged 15 years and above). In Tanzania TT surgical services are provided through camps and static units. Trained case finders search for TT cases around their community and report back the number of cases identified to the nearest health facility. Case finding is followed by social mobilization around the endemic community and visit by a TT surgeon to review the cases identified and plan for TT surgery camp. During social mobilization information on the date and location of TT camp are given to each community so that all identified TT cases can visit for TT surgical services. Based on the latest survey data, there are an estimates 53,426 TT un-operated TT cases. Account for elimination target of 1/1000 population, there were an estimated 28,478 TT cases requiring surgery for TT before intervention. Over the 2012 to 2016 implementation period, a total of 10,739 TT cases received surgery. The number of people that still need trichiasis surgery to reach elimination of TT are estimated to be 17,739. Implementing TT surgical services in rural areas has been a challenge especially in pastoralist areas which are nomadic in nature. This challenge has been addressed by using cultural leaders to advocate for the services provided and in other areas to use them as advocates and champions of TT surgical services. With concerted effort, Tanzania is on track to reach the TT elimination goal by 2020.

## 1766

### CONFIRMING TRACHOMATOUS TRICHIASIS PREVALENCE: PILOT TT-ONLY SURVEY IN TOUBORO HEALTH DISTRICT IN NORTH CAMEROON

**Emilienne Epee**<sup>1</sup>, Assumpta Bella<sup>1</sup>, Julie Akame<sup>2</sup>, Yannick Nkoumou<sup>2</sup>, Emily Gower<sup>3</sup>, Henri C. MOUNGUI<sup>2</sup>

<sup>1</sup>Ministry of Public Health, Yaounde, Cameroon, <sup>2</sup>Helen Keller International, Yaounde, Cameroon, <sup>3</sup>University of North Carolina/Helen Keller International, Chapel Hill, NC, United States

Through baseline mapping of trachoma following World Health Organization (WHO) recommended methodology, 47 health districts (HDs) in North, Far North and Adamaoua regions of Cameroon were found endemic for trachoma, with rates of active trachoma >10% for 16HDs, between 5-9.9% for 4HDs, and <5% for 27 HDs. Following the WHO SAFE strategy - Surgery, Antibiotics, Face washing and Environment improvement -, the ministry of public health implemented mass drug administration in the 20 HDs with active trachoma of at least 5%. 31 of the 47 HDs (66%), including 4HDs in Adamaoua, 8HDs in North and 19HDs in Far North regions, were identified as having trachomatous

trichiasis (TT) as a public health problem, with TT >0.1%. The Ministry started implementing TT surgery in the North and Far North Regions with these baseline data. Recently, trachoma experts have suggested that TT-only surveys may be needed in some regions where it is unclear whether TT is a public health problem, given that baseline mapping surveys might not have been statistically powered to provide a precise estimate of TT. WHO suggested pilot-testing TT-only surveys (TT-only), and Cameroon was selected for the pilot testing. Data from the baseline mapping showed Touboro HD in North region had active trachoma of <5% and TT of 0.23%. The teams used the WHO trachoma grading system to examine 5,378 people and entered the data into the Tropical Data collection system using smartphones. TT prevalence was 1.73% (95% CI: 1.37-2.19%) in 15 years olds and above and 1.26% (95% CI: 0.10-0.16%) in all ages. The TT prevalence from the TT-only survey is over 5 times higher than the rate found with the baseline mapping carried out in 2011. Moreover, the TT-only survey suggests a backlog of 2,497 TT cases while the Ultimate Intervention Goal is 198. Further investigations are needed to understand why the rates of TT from the two methods do not align.

## 1767

### TRACHOMA ENDGAME IN TANZANIA: TEMPORAL-SPATIAL ANALYSIS OF CLUSTERING OF TRACHOMATOUS INFLAMMATION FOLLICULAR (TF) IN DISTRICTS WITH PERSISTENT TF FOLLOWING MASS DRUG ADMINISTRATION WITH AZITHROMYCIN

**George Kabona**<sup>1</sup>, Upendo Mwingira<sup>2</sup>, Edward Kirumbi<sup>2</sup>, Andreas Nshala<sup>2</sup>, Boniphace Idindili<sup>3</sup>, Delali Bonuedi<sup>4</sup>, Aryc Mosher<sup>5</sup>, Lisa Rotondo<sup>4</sup>, Jeremiah Ngondi<sup>6</sup>

<sup>1</sup>Iringa Regional Referral Hospital, Iringa, United Republic of Tanzania, <sup>2</sup>National NTD Secretariat, MoHCDGEC, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>RTI International, Washington, DC, United States, <sup>5</sup>U.S. Agency for International Development, Washington, DC, United States, <sup>6</sup>RTI International, Dar es Salaam, United Republic of Tanzania

Tanzania began implementation of SAFE strategy in 1999 and has made tremendous progress towards trachoma elimination with 40 of 55 endemic districts having stopped mass drug administration (MDA). Impact surveys have shown that some districts continue to have TF prevalence of 5-9.9% thus warranting further MDA. We defined TF as persistent when a district continued to have TF ≥5% at two consecutive impact surveys. We investigated temporal-spatial distribution of TF prevalence in districts with persistent TF. Data were reviewed for 6 districts with TF=5.0-9.9% after the first impact surveys. Data from impact surveys were summarized to provide cluster level TF prevalence in children 1-9 years. Distribution of cluster TF prevalence were assessed for each impact survey using box plots. Household coordinates were averaged to provide a single set of coordinates for each cluster. Cluster level data were plotted on a map using QGIS to investigate temporal spatial clustering. Of 6 districts that had a second impact survey, TF prevalence was <5% in 2; 5-9.9% in 3; and ≥10 in 1. In one district TF has remained between 5-9.9% for three impact surveys. Distributions of cluster level prevalence showed that in districts where TF was <5% at the second impact survey, TF prevalence declined across all clusters. However, where TF was persistent the distribution of cluster prevalence remained the same or had a wider distribution at subsequent survey. In districts with persistent TF, the findings suggest that clusters with highest prevalence of children with TF were located in the same areas across the different survey periods. In 3 districts, trachoma was widespread throughout the district while in the fourth trachoma was clustered in specific areas. Based on these findings, it appears that districts with TF>5% at the first impact survey have high possibility of continued TF>5% and potentially an increase in TF prevalence at the subsequent impact surveys, even after a single round of MDA. Further studies are needed to investigate ocular chlamydial infection and associations of persistent TF with chlamydia infection, antibiotic coverage and other potential risk factors.

## THE CHANGING FACE OF TRACHOMA CONTROL IN TANZANIA: RESULTS FROM THE 2016 TRACHOMA IMPACT SURVEYS

Edward Kirumbi<sup>1</sup>, Jeremiah Ngondi<sup>2</sup>, Mathias Kamugisha<sup>1</sup>, Alistidia Simon<sup>1</sup>, Andreas Nshala<sup>3</sup>, Upendo Mwingira<sup>1</sup>

<sup>1</sup>Tanzania NTD Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania

The World Health Organization (WHO) recommends evaluation of the surgery, antibiotic therapy, facial cleanliness and environmental change (SAFE) strategy after three to five years of implementation. In Tanzania, a total of 95 districts were surveyed for baseline trachoma prevalence between 2004 and 2014, and total of 59 districts were identified as endemic for trachoma. In 2016, 16 districts were eligible for trachoma impact surveys (TIS). Between July and September 2016, the Tanzania NTD Control Program (TZNTDCP) investigated: 1) the prevalence of trachomatous inflammation-follicular (TF) in children aged 1-9 years; 2) prevalence of trachomatous trichiasis (TT) in people aged 15 years and above; and 3) estimated TT backlog. A two stage cluster random survey design was used to select sample, with clusters (villages) selected in the first stage, and households selected using systematic random sampling in the second stage. In sampled households, children aged 1-9 years were examined for TF and persons aged 15 years and above were examined for TT using the WHO standard simplified grading system. Of the districts surveyed, 9 had reached the WHO threshold for stopping mass drug administration (MDA) of TF prevalence of <5%. A total of 5 districts had TF prevalence of 5-9.9% thus MDA was needed for one more annual round before another impact survey could be undertaken. Two districts had TF of > 10% thus another 5 round of annual MDA were warranted. Prevalence of TT by district ranged from 0.00% to 0.94%. TT backlog was estimated to be 67,000 across the 16 districts. Survey findings over the years suggest that, the ultimate intervention goal for TF of <5% has been attained in 48 surveyed districts therefore MDA with Zithromax should be stopped and surveillance surveys undertaken after 2 years. However, in several districts TT still remains a public health problem and therefore trichiasis surgery is required to clear the TT backlog. Concurrently, F&E (WASH) implementation need to be accelerated in all districts in order to sustain the gains so far achieved in trachoma elimination efforts in the country.

## IMPROVING TRACHOMA MASS DRUG ADMINISTRATION UPTAKE AMONG NOMADIC AND PASTORALIST COMMUNITIES OF RURAL TANZANIA

Alistidia Simon<sup>1</sup>, Upendo Mwingira<sup>1</sup>, Jeremiah Ngondi<sup>2</sup>, Juliana John<sup>3</sup>, Boniphace Idindili<sup>3</sup>, Said Makora<sup>1</sup>

<sup>1</sup>Tanzania NTD Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania

According to baseline surveys conducted between 2004 and 2014, 59 districts in Tanzania are endemic for trachoma. Following baseline surveys, implementation of the SAFE (surgery, antibiotics, facial cleanliness and environmental change) strategy was initiated in a phased approach. The Tanzania NTD Control Program (TZNTDCP) has carried out mass drug administration (MDA) with azithromycin in endemic districts since 2011; reaching all endemic districts by 2015. MDA epidemiological coverage across trachoma endemic districts nationwide has ranged from 43% to 95%. Uptake in nomadic and pastoralist communities has been particularly challenging because community members do not fully participate in MDAs, leading to poor coverage rates. In January 2017, the program developed a behavior change communication (BCC) strategy for nomadic and pastoralist communities. The BCC strategy aims to improve

the understanding of the MDA approach and to encourage participation in NTD control activities. The strategy will be piloted in 3 districts of Arusha region (Ngorongoro, Monduli and Longido). A two-phased approach will be implemented before and during MDA. Phase 1 will focus on primary school children and women attending health facilities, in addition to key opinion leaders such as cultural leaders, local government authorities and community health workers. Phase 2 will target areas with severe cases of trachoma, while a more general campaign will cover the rest of the campaign area. A number of BCC approaches will be employed including football leagues in specific districts, creation of primary school hygiene and sanitation clubs, health facility campaigns for women during antenatal visits, open-market day events, an SMS campaign using geo-location of mobile phones, and mainstream media campaigns (radio, TV and newspapers). Output and outcome indicators will be used to monitor and evaluate the process. The campaign is expected to raise awareness of NTD interventions, improve MDA coverage, and increased uptake of TT surgery. Results of the BCC strategy's effect on MDA coverage will be determined after the next MDA (scheduled for July/August 2017).

## FOLLOW-UP OF TRICHIASIS PATIENTS OPERATED DURING AN EVALUATION OF THE SURGICAL SIMULATION DEVICE HEAD START

Chano Hamiden<sup>1</sup>, Mahamane Abdou<sup>1</sup>, Hadiara Adamou<sup>2</sup>, Stephanie L. Palmer<sup>3</sup>, Kadri Boubacar<sup>3</sup>, Tchouloum Toudja<sup>2</sup>, Josette Vignon<sup>2</sup>, Thierno Faye<sup>2</sup>, Abdou Amza<sup>1</sup>

<sup>1</sup>Programme National de Santé Oculaire, Ministère de la Santé Niger, Niamey, Niger, <sup>2</sup>Helen Keller International, Niamey, Niger, <sup>3</sup>Helen Keller International, New York, NY, United States

From September 2015-January 2016, a study was carried out in Niger's Maradi region to determine whether the HEAD START surgical simulation device helps improve experienced trichiasis (TT) surgeons' operating skills. As part of this research, study participants operated on 2-4 TT patients, for a total of 61 patients. Patients should be followed up post-surgery to determine whether further care is required and for National Trachoma Programs to monitor program quality. In addition, as HEAD START has been introduced to improve surgical quality, patient follow-up is necessary to determine whether this tool is successful. A follow-up of patients operated on during the HEAD START study took place in January 2017. Only villages where  $\geq 2$  patients had been operated were visited, yielding a list of 50 patients. An examination of the patients' eyelids was conducted by the HEAD START master trainers and a questionnaire administered to each patient. Thirty-five patients were followed up; 15 were absent at the time of the study team's passage. Post-surgical guidelines had been followed: dressings were removed 1 day post-surgery and sutures removed 7 days following the surgery in all patients. Three patients complained of watery eyes and 8 patients had post-operative TT; of these, 7 had both eyelids operated during the study. Since the follow-up took place between 12-16 months after their surgery, we cannot conclude that the post-operative trichiasis is due to the surgery; it may be due to further disease progression. This may be evidenced by the fact that 7/8 of the post-operative TT cases had TT in both eyes, indicative of more severe TT. However, this follow-up provided an opportunity to refer these patients for further services. We also cannot conclude whether the HEAD START training improved patient outcomes, as we had no data on patients operated by these surgeons prior to the training. To determine whether HEAD START can improve patient outcomes, we recommend collecting data on patients operated by surgeons who are to undergo HEAD START training prior to the training and ensure patient follow-up 3-6 months following their surgeries.

1771

## FACTORS ASSOCIATED WITH MORTALITY AMONG PATIENTS WHO ABSCONDED FROM JINJA CHILDREN'S HOSPITAL

Asadu Sserwanga<sup>1</sup>, Peter Waiswa<sup>2</sup>, Arthur Mpimbaza<sup>3</sup>, Adoke Yeka<sup>2</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Makerere University School of Public Health, Kampala, Uganda, <sup>3</sup>Child Health and Development Centre Makerere University, Kampala, Uganda

Patients admitted to hospital may abscond before discharge or completing treatment, predisposing them to poor health outcomes and increased likelihood of mortality. We determined factors associated with mortality among patients who absconded from Jinja Children hospital in eastern Uganda. We reviewed case records of children who absconded from Jinja Children's hospital from 2012 to 2013 and managed to trace 313 patients in the surrounding community. Caretakers of children who absconded from hospital were interviewed. About 14 % (44/313) of the children that absconded from hospital had died by the time of the survey. Mortality was significantly lower among patients who consulted a pediatrician before abscondment compared to those who did not (OR 0.1, 95% CI 0.17-0.59). Mortality was not associated with social demographic characteristics of the patient and caretaker. Mortality was high among patients who abscond from hospital and lack of review previous review of the patients by the specialist's increases mortality among those who absconded. Further studies are needed to examine factors associated with abscondment and review of patients by specialised health workers should be strengthened at facilities.

1772

## COMMUNITY SENSITIZATION AND DECISION-MAKING FOR TRIAL PARTICIPATION: A MIXED-METHODS STUDY FROM THE GAMBIA

Susan Dierickx<sup>1</sup>, Sarah O'Neill<sup>2</sup>, Charlotte Gryseels<sup>2</sup>, Edna A. Immaculate<sup>3</sup>, Melanie Bannister-Tyrell<sup>2</sup>, Joseph Okebe<sup>3</sup>, Julia Mwesigwa<sup>3</sup>, Fatou Jaiteh<sup>3</sup>, René Gerrets<sup>4</sup>, Raffaella Ravinetto<sup>2</sup>, Umberto D'Alessandro<sup>3</sup>, Koen Peeters Grietens<sup>2</sup>

<sup>1</sup>Vrije Universiteit Brussel, Brussel, Belgium, <sup>2</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>3</sup>Medical Research Council Unit Gambia, Fajara, Gambia, <sup>4</sup>Amsterdam Institute of Social Science Research, Amsterdam, Netherlands

Ensuring individual free and informed decision-making for research participation is challenging. It is thought that preliminarily informing communities through 'community sensitization' procedures may improve individual decision-making. This study set out to assess the relevance of community sensitization for individual decision-making in research participation in rural Gambia. This anthropological mixed-methods study triangulated qualitative methods and quantitative survey methods in the context of an observational study and a clinical trial on malaria carried out by the Medical Research Council Unit in rural Gambia. Although 38.7% of adult community members were present during sensitization sessions, 91.1% of the respondents were inclined to participate in the trial when surveyed after the sensitization and prior to the informed consent process. This difference can be explained by the informal transmission of information within the community after the community sensitization, the expectations such as the benefits of participation based on previous research experiences, and the positive reputation of the research institute. Commonly mentioned barriers to participation were blood sampling and the potential disapproval of the household head. Community sensitization is effective in providing first-hand, reliable information to communities as the information is cascaded to those who could not attend the sessions. However, further research is needed to assess how the informal spread of information further shapes people's expectations, how the process engages with existing social relations and hierarchies (e.g. local political power structures; permissions of heads of households) and how this influences or changes individual consent.

## IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON HOSPITAL ADMISSIONS AND MORTALITY IN CHILDREN UNDER 5 YEARS IN OUELESSEBOUGOU, MALI

Djibrilla Issiaka<sup>1</sup>, Jean Gaudart<sup>2</sup>, Amadou Barry<sup>1</sup>, Tiangoua Traore<sup>1</sup>, Boubacar Diarra<sup>3</sup>, Diakalia Kone<sup>4</sup>, Issaka Sagara<sup>1</sup>, Patrick Duffy<sup>5</sup>, Michal Fried<sup>5</sup>, Alassane Dicko<sup>1</sup>

<sup>1</sup>Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Bamako, Bamako, Mali, <sup>2</sup>Aix Marseille University, INSERM, IRD, SESSTIM UMR912, Faculty of Medicine, Marseille, France, <sup>3</sup>Centre de Santé de Référence de Ouelessebouougou, Mali, Ouelessebouougou, Mali, <sup>4</sup>Programme National de Lutte contre le Paludisme, Bamako, Mali, <sup>5</sup>National Institutes of Health/National Institute of Allergy and Infectious Diseases, Washington, DC, United States

Over the past 15 years, overall mortality rates in African children under five have been reduced by 57% due to expanded health interventions including control of malaria, a major killer in sub-Saharan Africa. Seasonal malaria chemoprevention (SMC) has been recommended for malaria prevention in areas of high seasonal malaria transmission since 2012, and is now in large-scale implementation in most Sahelian countries including Mali. To assess the impact of SMC on hospitalizations, we conducted surveys in December 2016 to assess and compare the rate of hospital admissions and deaths in children under 5 years of age from two health sub-districts of Ouelessebouougou receiving SMC and two health sub-districts where SMC had not yet been implemented during the malaria transmission season. Information on hospital admissions and deaths in children under 5 years of age in 2015 were collected by interview. A total of 7867 children (4637 from the intervention areas and 3230 from the nonintervention area) were surveyed. Preliminary analysis indicated a mortality rate per 1,000 children of 3.0 in the SMC intervention area compared to 8.01 in the non SMC area (age and gender adjusted mortality rate ratio (MRR) = 0.39, 95% CI: 0.19- 0.78, p = 0.008). Incidence rate of hospital admission per year per 1,000 children was 23 in the SMC intervention area compared to 34 in the non SMC area (age and gender adjusted incidence rate ratio (IRR) = 0.69, 95% CI: 0.52- 0.91, p = 0.009). SMC implementation was associated with a substantial reduction in all-cause mortality and hospital admission in children under 5 years of age in Ouelessebouougou, Mali.

## DEVELOPMENT OF AN ANTISENSE RNA (ASRNA) STRATEGY FOR GENE SILENCING IN *LEPTOSPIRA* SPP.

Luis Guilherme Fernandes<sup>1</sup>, Ana Lúcia Nascimento<sup>1</sup>, Mathieu Picaudeau<sup>2</sup>

<sup>1</sup>Instituto Butantan, São Paulo, Brazil, <sup>2</sup>Institute Pasteur, Paris, France

The genus *Leptospira* encompasses both pathogenic and saprophytic species. Pathogenic *Leptospira* are the etiological agents of leptospirosis, while saprophytic bacteria are environment free-living organisms. The mechanisms responsible for leptospirosis pathogenesis are yet poorly understood, mainly due the lack of genetic tools available for the pathogen. Antisense control in bacteria is now recognized as an efficient and specific mechanism for gene regulation. This control occurs at many levels, including premature transcription termination and direct or indirect blocking of translation. In order to expand the possibilities of genetic tools for *Leptospira* gene silencing, we evaluated the effect of expressed asRNA upon gene expression; we selected the  $\beta$ -galactosidase gene in order to assess the enzyme activity in the saprophyte strain. Four different constructs were employed, encompassing two different promoters (leptospiiral *lipL32* and borrelial *flgB*) controlling the transcription of the asRNA containing or not a paired-termini (PT) secondary structure. The antisense sequence was designed to be complementary to the 5' UTR region of the  $\beta$ -galactosidase mRNA. The constructs were ligated into the pMaOri vector, replicative in *Leptospira* and recombinant plasmids were used to transform *L. biflexa*. The expression of the asRNA in the leptospiral

strains was validated by Northern Blotting and  $\beta$ -galactosidase activity was assessed by chromogenic substrate assay. Northern blotting analysis showed that all constructs were able to successfully express the asRNA and the inclusion of the PT rendered higher stability of the transcripts. *L. biflexa* cells containing asRNA1 and asRNA2 (*lipL32* promoter with and without secondary structure, respectively) presented less enzymatic activity. The results demonstrate the feasibility and applicability of the antisense RNA molecules as a tool for gene silencing in *Leptospira*. This strategy will help elucidating the function of different genes and consequently shed light to the basic aspects of biology and pathogenesis of *Leptospira*.

### DIFFERENCES IN SYMPTOMATOLOGY OF CHILDHOOD DENGUE, CHIKUNGUNYA AND MALARIA INFECTION IN KENYA

David M. Vu<sup>1</sup>, Elysse N. Grossi-Soyster<sup>1</sup>, Amy R. Krystosik<sup>1</sup>, Cornelius Kiptoo<sup>2</sup>, Charles H. King<sup>3</sup>, John Vulule<sup>2</sup>, Dunstan Mukoko<sup>4</sup>, Bryson A. Ndenga<sup>2</sup>, Francis M. Mutuku<sup>5</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>4</sup>Ministry of Public Health and Sanitation, Nairobi, Kenya, <sup>5</sup>Technical University of Mombasa, Mombasa, Kenya

Diagnosis of dengue (DENV) and chikungunya (CHIKV) occurs infrequently during the evaluation of childhood febrile illness in Kenya, leaving the burdens of arboviral infections in Kenyan children largely unknown. To investigate, we enrolled children (age 1- to 17-years) in an ongoing study (2014-2018) who presented with fever to one of four study sites in western and coastal Kenya. Malaria was diagnosed by peripheral blood smear examination, and DENV and CHIKV infections were diagnosed by RT-PCR of acute blood samples, or IgG seroconversion between the acute and convalescent samples. To date, we have enrolled 3835 subjects. 33.4% had malaria parasitemia. 6.2% (83/1346) of samples tested thus far by PCR were positive for DENV RNA. An additional 7 DENV infections were identified based on IgG seroconversion. None of the samples tested by CHIKV PCR were positive, however 0.8% (14/1738) individuals seroconverted for CHIKV IgG. Vomiting and aches and pains were reported by half of the subjects, regardless of infectious etiology. Rashes, edema, and eye complaints occurred rarely and did not differ by pathogen. However a higher proportion of CHIKV-infected subjects reported abdominal pain (43%) than did subjects with either DENV infection (15%) or malaria (26%,  $p=0.025$ ,  $\chi^2$ ). Unexpectedly, bleeding symptoms were reported by 7% of CHIKV-infected subjects, compared with 0.01% and 0.0056% of DENV- or malaria-infected subjects, respectively ( $p=0.011$ ,  $\chi^2$ ). Our findings suggest some differences in patterns of clinical symptomatology of DENV or CHIKV infection in children, which may aid clinicians in establishing alternative diagnoses to malaria when evaluating febrile illness. In our cohort, 86% of CHIKV- and 58% of DENV-infected subjects were treated with antimalarial medications despite available malaria test results. Given the overtreatment of malaria in sub-Saharan Africa, prioritizing development of arbovirus clinical diagnostic aids, in the form of accessible rapid diagnostic tests or clinical disease pattern recognition algorithms, is an important strategy for combating the growing problem of antimalarial and antibiotic overuse.

## 1776

### IMPROVING EFFICIENCY AND PATIENT EDUCATION IN THE DARTMOUTH TRAVEL CLINIC

Jessie Leyse, Elizabeth Talbot

Dartmouth Hitchcock Medical Center, Lebanon, NH, United States

The number of US citizens traveling internationally increased from 59 million to 74 million from 2011-2015. Many of these travelers stay healthy by visiting specialized travel clinics before their trips. The Dartmouth

Travel Clinic sees ~1400 patients annually. Surveys regarding areas for improvement were sent to 90 patients over a 3-month period. Based on 28 responses as well as provider input, we identified better efficiency and patient education as target areas for improvement. Toward this aim, we developed a questionnaire requesting information about travel plans and medical and vaccination history that was mailed or emailed to patients when their appointment was scheduled. Providers received the completed forms prior to the appointment in order to improve encounter efficiency and personalization. We also developed four internet-based interactive decision tools for frequently-discussed vaccinations so patients could understand key elements of vaccination recommendations prior to their appointment. We re-surveyed 49 patients after implementation of these interventions to assess their impact. After implementation of the pre-appointment questionnaire, the number of patients who provided their vaccination history prior to their appointment increased (~half to 72%), and 74% of patients reported that the pre-appointment questionnaire helped their provider address their specific needs. Comparing before and after questionnaire implementation, providers were able to decrease the amount of time spent acquiring history from 10 to 8 minutes. Patient satisfaction scores increased from 78% prior to quality improvement efforts to 100% after. Data analysis of online vaccine decision tools is underway. By collecting patient data before appointments, providers were able to make appointments more efficient and personalized. This resulted in high patient satisfaction scores while still ensuring that patients had access to quality, evidence-based information. Our study demonstrates the possible benefits and future uses for technology and patient-centered care in travel medicine.

## 1777

### SNAKEBITES IN A RESOURCE POOR AREA ALONG THE SOUTHERN KENYAN COAST: SPATIAL RESULTS AND VICTIM PROFILES

Peter S. Larson<sup>1</sup>, Noriko Tamari<sup>2</sup>, Morris Ndemwa<sup>1</sup>

<sup>1</sup>Nagasaki University Kenya Research Station, Nairobi, Kenya, <sup>2</sup>Nagasaki University, Nagasaki, Japan

Snakebites are a serious and often overlooked health problem in developing countries. Victims are principally children from poor households, and bites can result in lifelong debilitation and even death. In 2009, the World Health Organization approved snakebites as a neglected tropical disease (NTD). Nagasaki University, in cooperation with the Kenya Medical Research Institute (NITM-KEMRI), surveys more than 100,000 people in two areas of Kenya on a thrice yearly basis as part of a Health and Demographic Surveillance System (HDSS). Field workers visit households individually and track household population change, pregnancies, deaths and major health events. GPS locations of all households are contained within the database, allowing for detailed spatial analyses. A brief set of questions on past incidence of snakebites was included in a routine round of the HDSS. A follow up survey was conducted of households which reported that someone in the household had been bitten in the past year. Of 8,756 household included, 453 (5.17%) households reported that at least one household member had been bitten in the past year. The mean age of victims was ~31 years of age. Bites occurred mainly on the feet (55%) and occurred near the home (35%). Black (47%) and green mambas (29%) were the most common species of snake. Only half of all victims reported to a hospital after injury. Reporting to a local herbal practitioner was associated with a decreased odds of going to a clinic (OR(.20 (.13,.31)) and that persons who received treatment from a traditional healer were much more likely to have permanent injury than those who did not (OR 9.67 (2.92, 31.99)). Spatial analyses indicated that bites were highly concentrated in a low lying wet region of Kwale indicating that while death (3.8%) and debilitation (8.6%) were uncommon over all, certain populations were at high risk. Future work should include researcher strategies to improve uptake of formal treatment for snakebites to prevent serious injury in resource poor environments.

1778

### VALIDATION OF A CLINICAL CASE DEFINITION OF ACUTE MESOAMERICAN NEPHROPATHY USING A LARGE RETROSPECTIVE COHORT IN NICARAGUA

Hannah Worrall<sup>1</sup>, Rebecca S. Fischer<sup>1</sup>, Melissa N. Garcia<sup>1</sup>, Linda L. Garcia<sup>1</sup>, Lauren Middleton<sup>2</sup>, Sreedhar Mandayam<sup>1</sup>, Kristy O. Murray<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Mercer University School of Medicine, Macon, GA, United States

Mesoamerican nephropathy (MeN), a tropical medicine mystery of Central America, affects mostly young agricultural workers who lack traditional risk factors for kidney disease. Although previously known as a chronic kidney disease (CKD), we recently reported that an early stage of acute kidney injury with systemic inflammation can precede CKD and proposed a clinical case definition of acute MeN. Our goals with this analysis were to (1) describe the initial, acute clinical presentation in a large cohort of historic MeN CKD cases and (2) validate the acute clinical case definition in that population. We conducted a retrospective study at a large sugar estate in Nicaragua, a locale disproportionately affected by MeN. We abstracted clinical, demographic, and medical history data from records at the estate's private hospital, which implemented surveillance for MeN CKD in the late 1990's. We documented events associated with the first elevated serum creatinine recorded in the medical record for each patient. Data were available on 746 cases, diagnosed at various stages of CKD: 18% Stage 1, 40% Stage 2, 30% Stage 3, and 12% Stage 4-5. Patients were male (98%) and young (median age 33 years). The mean acute serum creatinine level was  $2.0 \pm 1.3$  mg/dL. Symptoms included back pain (23%), fever (19%), and urinary signs (15%); 17% were asymptomatic. Prior diabetes (2%) and hypertension (8%) were rare. Neutrophilia (53%), leukocytosis (33%), lymphopenia (25%), anemia (68%), and hyperuricemia (51%) were noted. Urine analysis revealed shedding of leukocytes (99%), leukocyte casts (18%), and bacteria (19%). This evidence confirms a systemic inflammatory response in most patients during acute MeN and documents a high frequency of asymptomatic acute MeN. Sensitivity and specificity analyses for the proposed case definition and alternatives are discussed in the context of detecting MeN that later progress to advanced disease. We discuss challenges to using historical data to validate the clinical case definition, propose an alternative definition, and suggest an additional validation study as a planned prospective clinical investigation.

1779

### IMS, CRP AND PROCALCITONIN TO DIFFERENTIATE CAUSES OF ACUTE INFECTIONS IN INDONESIA

Andre van der Ven<sup>1</sup>, Susantina Prodjosoejo<sup>2</sup>, Bacti Alisjahbana<sup>2</sup>, Quirijn de Mast<sup>1</sup>

<sup>1</sup>Radboud University Medical Center, Nijmegen, Netherlands, <sup>2</sup>Padjadjaran University and Hasan Sadikin Hospital, Bandung, Indonesia

Early differentiation between different causes of acute febrile illness is important to rationalize antimicrobial prescription. Clinical examination or early microbiological confirmation often fails to differentiate these causes. A point of care screening tool that differentiates viral and bacterial infections is therefore urgently needed. Febrile infectious diseases induce a systemic inflammatory immune response that is often accompanied by changes in circulating blood cells in quantity, composition, function and morphology. This acute systemic inflammatory immune response is different in viral and bacterial infections, which is reflected by distinctive changes in the number, functionality state and morphological changes in the various blood cell subsets. Whereas classical hemocytometry mainly detected changes in the number of cells, e.g. lymphocytosis in viral and neutrophilia in bacterial infections, the newest generation of Sysmex analyzers is also capable of measuring phenotypic changes e.g. functionality state in these circulating cells in real time. Applying these innovative techniques allows a specific characterization of the respective

type of immune response and as such allow a better differentiation between the various causes of infection. Diagnostic algorithms (Infection Manager System: IMS) have been developed using various combinations of cell subsets. A prospective study was carried out in Indonesia to investigate the potential of this approach to differentiate between acute infectious diseases common in tropical regions and compare results with C-reactive protein (CRP) and Procalcitonin (PCT). Out of 466 evaluable patients, a total number of 71 adult patients with proven bacterial infections and 90 with proven arboviral infections (mainly dengue) were enrolled. All cases were flagged as infections. Sensitivity and specificity of IMS to diagnose bacterial or arboviral infection was >95%, outperforming CRP or PCT. Similar results were obtained combining proven and probable cases (n=271). We conclude that IMS may be a valuable and cheap tool to rationalize antimicrobial prescription.

1780

### SCHISTOSOMA HAEMATOBIIUM EGG EXCRETION IN URINE DOES NOT INCREASE AFTER EXERCISE: IMPLICATIONS FOR DIAGNOSTIC TESTING

Jean T. Coulibaly<sup>1</sup>, Jason R. Andrews<sup>2</sup>, Nathan C. Lo<sup>2</sup>, Eliézer K. N'Goran<sup>1</sup>, Jürg Utzinger<sup>3</sup>, Jennifer Keiser<sup>3</sup>, Isaac I. Bogoch<sup>4</sup>

<sup>1</sup>Unité de Formation et de Recherche Biosciences, Université Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire, <sup>2</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>3</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>4</sup>Infectious Diseases, Toronto General Hospital, Toronto, ON, Canada

A common practice in many African settings is to have children exercise or jump vigorously shortly before providing a mid-day urine specimen for *Schistosoma haematobium* diagnosis to help increase diagnostic sensitivity. However, the evidence driving this procedure is sparse. We assessed the effect of prior exercise on *S. haematobium* diagnosis in 329 pre-school and school-aged children from five villages in the district of Adzopé, south Côte d'Ivoire. Children provided two urine specimens on consecutive days, collected between 10:00 and 12:00 hours. From each specimen, 10 ml were processed by filtration and evaluated under a microscope by experienced laboratory technicians adhering to WHO guidelines. Children did not jump or exercise on the first day of urine collection. On the second day, children older than 4 years were asked to do 20 jumping jacks prior to providing a urine sample with the exercise performed under the supervision of parents or teachers and our field team. Children under the age of 4 years were gently 'bounced' in a jumping motion 20 times by their parent or guardian. 257 children between ages 1 and 15 years (mean 6.8 years; 39% female) provided urine samples on consecutive days and were included in the analysis. After completion of the study, all study participants received praziquantel (single 40 mg/kg oral dose) at no cost as per national protocols. On the day without exercise, 66/257 (25.7%) urine samples were positive for *S. haematobium*, and on the day with exercise, 59/257 (23.0%) urine samples were positive (McNemar's p-value: 0.31). Among those with eggs present in urine, there were no differences in egg counts between the two days (p=0.62). Age and gender based sub-analyses with revealed no significant differences in egg counts for exercise versus non-exercise days. We conclude that exercise prior to providing a urine specimen for *S. haematobium* diagnosis does not increase the number of eggs excreted.

1781

### POTENTIALLY SERIOUS DRUG INTERACTIONS RESULTING FROM THE PRE-TRAVEL HEALTH ENCOUNTER

Daniel T. Leung<sup>1</sup>, Nadine Sbaih<sup>1</sup>, Brian Buss<sup>1</sup>, Russell J. Benefield<sup>1</sup>, Dheeraj Goyal<sup>1</sup>, Sowmya R. Rao<sup>2</sup>, Edward T. Ryan<sup>3</sup>, Regina C. LaRocque<sup>3</sup>

<sup>1</sup>Division of Infectious Diseases, University of Utah, Salt Lake City, UT, United States, <sup>2</sup>MGH Biostatistics Center, Boston, MA, United States,

<sup>3</sup>Travelers' Advice and Immunization Center, Massachusetts General Hospital, Boston, MA, United States

Medications prescribed during the pre-travel encounter may have interactions with travelers' existing prescriptions. We evaluated travelers seen for pre-travel health encounters at 21 Global TravEpiNet (GTEN) sites from January 2009 to December 2015. Infectious disease pharmacists identified pre-existing medications with potential for serious drug-drug interactions (based on severity, frequency, quality of published reports) associated with six commonly prescribed travel medications: acetazolamide, ciprofloxacin, azithromycin, atovaquone-proguanil, doxycycline, and chloroquine. We characterized the demographics, medical conditions and travel plans of all travelers with serious drug interactions. We evaluated 73,794 travelers seen at GTEN sites. Of these travelers, 2530 (3%) had a potentially serious drug interaction between an existing prescription and a medication prescribed at the pre-travel health encounter. The most common existing prescription medications associated with a potentially serious drug interaction were selective serotonin reuptake inhibitors (SSRIs) such as citalopram (n=428), escitalopram (n=312) and fluoxetine (n=416), the HMG-CoA reductase inhibitor simvastatin (n=1013), and warfarin (n=281). The median age of travelers with potential drug interactions was 55 years. Fifty-six percent of travelers with potential interactions were female, 42% traveled for >=14 days, 68% traveled for leisure, 74% traveled to a country of low/medium human development, and about half had 3 or more medical conditions. In univariate comparisons, travelers with potential drug interactions were more likely to be older, travel for a shorter duration, travel for leisure or service work, and have a pre-existing medical condition. In conclusion, potentially serious drug interactions may occur between existing prescriptions and medications prescribed during the pre-travel health encounter. Travel practitioners should consider the possibility of serious drug interactions, particularly in older travelers and those taking SSRIs and simvastatin.

### IN VITRO ANTIFUNGAL ACTIVITY OF *CRYPTOLEPIS SANGUINOLENTA* ON CLINICAL *CANDIDA* ISOLATES FROM GHANA

Gloria Adjapong<sup>1</sup>, Mark A. Appenteng<sup>1</sup>, Sylvester Kaminta<sup>1</sup>, Jerry Aseidu-Larbi<sup>2</sup>, Augustine A. Ocloo<sup>2</sup>, Olga Quarsie<sup>2</sup>, Doris Kumadoh<sup>3</sup>, Ashley Garrill<sup>4</sup>, Felix C. Mills-Robertson<sup>5</sup>

<sup>1</sup>Department of Microbiology, Centre for Plant Medicine Research (CPMR), Mampong-Akwapim, Ghana, <sup>2</sup>Department of Pharmacology, Centre for Plant Medicine Research (CPMR), Mampong-Akwapim, Ghana, <sup>3</sup>Department of Pharmaceutics, Centre for Plant Medicine Research (CPMR), Mampong-Akwapim, Ghana, <sup>4</sup>School of Biological Sciences, University of Canterbury, Canterbury, New Zealand, <sup>5</sup>Department of Biochemistry and Biotechnology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

*Cryptolepis sanguinolenta* (Linn.) Schltr. (Periplocaceae), is a plant widely used in indigenous traditional medicine for its anti-malarial properties. In Ghana, it has been used as an anti-malarial agent for over 100 years and has recently undergone a clinical study. In this study, the antifungal activity *C. sanguinolenta* was investigated using *Candida* species isolated from female patients presenting with candidal vaginitis from Korle-Bu Teaching Hospital (KBTH), Centre for Plant Medicine Research (CPMR) and Tetteh-Quarshie Memorial Hospitals (TQMH), all in Ghana. Aqueous and 70% ethanol extracts of roots, stems and leaves of *C. sanguinolenta* were evaluated using a modified agar well diffusion assay. Minimum inhibitory concentrations (MICs) and Minimum fungicidal concentrations (MFC) were also determined using standard microbiological methods. Results from the study, showed that the aqueous and ethanol extracts of the leaves, stems and roots of *C. sanguinolenta* have significant antifungal activities against clinical and standard *Candida* isolates with the root extract showing the highest antifungal activity. Average diameter zones of inhibition (DZI) for the aqueous and ethanol extracts ranged respectively from 8.00 ±

0.50 to 30.00 ± 0.10 mm and 8.00 ± 0.10 to 31.00 ± 1.50 mm for the leaves, stems and roots. Minimum inhibitory concentrations (MICs) of the ethanol extracts of the stems and the roots both ranged from 0.15625 to 1.25 mg/mL while the minimum fungicidal concentrations (MFC) ranged from 0.15625 to 1.25 mg/mL for both the ethanol stem and root extracts. Encapsulated *C. sanguinolenta* powder (250 and 500 mg), which contained 25 and 50 mg of the 70% ethanol extracts from the roots both yielded fungicidal activity ranging from 9.00 ± 0.10 to 31.00 ± 0.50 and 8.00 ± 0.10 to 31.00 ± 0.50 respectively. Thus, in addition to the anti-malarial activity, *C. sanguinolenta* has anti-fungal activity. The results obtained may provide valuable information for further detailed studies of the active compounds, necessary for the development of new antifungal drugs in the future.

## 1783

### INCIDENCE AND RISK FACTORS FOR PERIPARTUM FEVER IN PUERTO RICO, OCTOBER 2016 - MARCH 2017

Nicole M. Perez-Rodriguez, Veronica M. Frasqueri-Quintana, Getzabeth E. Bosques-Gomez, Angel L. Perez-Caro, Xiomara Torres-Figueroa, Luzeida Vargas-Lassalle, Luisa I. Alvarado-Domenech

Ponce Health Sciences University, Ponce, Puerto Rico

Peripartum fever, defined as a temperature ≥ 38°C prior to, during, and immediately after delivery, is not uncommon. It has been linked to complications such as early labor, operative deliveries, and may be the consequence of infection with etiologic agents of acute febrile illness (AFI) such as dengue and chikungunya. In some cases peripartum fever can result in neonatal infection, which in turn is associated with increased risk of admission of the neonate to the Intensive Care Unit, low Apgar scores, and sepsis. The reported prevalence of peripartum fever varies widely by region, and has not been reported in Puerto Rico. The aim of the study is to describe the prevalence and outcomes of peripartum fever among women identified by the Sentinel Enhanced Dengue Surveillance System (SEDSS), a facility-based epidemiologic platform established in a tertiary care hospital in southern Puerto Rico. Women reporting fever of ≤7 day's duration before and during active labor from October 2016 to March 2017 were enrolled. Data regarding history of fever ≤7 days prior to delivery was collected in the Delivery Room. Relative and absolute frequencies were calculated for categorical variables, and central tendency and dispersion measures were calculated for quantitative variables. Out of 598 deliveries, a total of 11 women presenting with fever during the peripartum period were enrolled in the study, among whom median age was 27 years (19–36). Preliminary results indicate that the prevalence of peripartum fever is approximately 1.84%. Most cases (36%) occurred in December. Among eight participants with peripartum fever for which medical records have been reviewed, seven (87.5%) had a vaginal delivery and four (50.0%) were positive for Group B *Streptococcus*. Further analysis is being conducted to describe the maternal and neonatal outcomes through medical chart review, and enrollment is expected to continue through at least October 2017. Identifying the causes of fever during the peripartum period could enable targeted interventions in pregnant woman and their infants, and thereby assist in avoiding unnecessary procedures or lengthy medical stays.

## 1784

### ENDOTOXIN LEVELS AT THE MATERNAL-FETAL INTERFACE AND THE ASSOCIATION WITH INTRAUTERINE GROWTH

Emily A. McDonald<sup>1</sup>, Hannah W. Wu<sup>1</sup>, Remigio M. Olveda<sup>2</sup>, Luz P. Acosta<sup>2</sup>, Veronica Tallo<sup>2</sup>, Palmera I. Baltazar<sup>2</sup>, Jonathan D. Kurtis<sup>1</sup>, Jennifer F. Friedman<sup>1</sup>

<sup>1</sup>Rhode Island Hospital, Providence, RI, United States, <sup>2</sup>Research Institute of Tropical Medicine, Manila, Philippines

Low- and middle-income countries (LMICs) carry a high burden of parasitic diseases that are associated with impaired gut integrity. Children in many

of these countries also experience a high rate of poor intrauterine growth. We hypothesized that factors culminating in microbial translocation (i.e. schistosoma and/or hookworm infection, alcohol consumption) during pregnancy may negatively impact fetal growth by changing the microbial load of the placenta. The placental microbiome is suggested to reflect colonization, in part, via hematogenous spread, and has been linked to poor pregnancy outcomes such as preterm birth. We examined the association between specific risk factors for impaired gut integrity and endotoxin, a key component of the cell wall of gram-negative bacteria, in blood collected from the maternal-fetal interface (MFI) and the umbilical cord at delivery. In addition, we examined the relationship between endotoxin levels and poor intrauterine growth. We utilized samples collected from a recently completed trial, in which women with schistosomiasis were randomized to praziquantel treatment or placebo at 12-16 weeks gestation. None of the risk factors examined had an impact on the endotoxin levels at the MFI, although there were trends for higher endotoxin at the MFI in women who received praziquantel ( $P = 0.08$ ) and those who reported heavy drinking ( $>3$  drinks/week;  $P = 0.06$ ) during pregnancy. Maternal alcohol consumption increased the amount of endotoxin found in cord blood (1.8-fold higher,  $P = 0.01$ ) and cord blood endotoxin levels were associated with higher levels of free amino acids in fetal circulation ( $P < 0.01$ ). In keeping with these data, infants born small for gestational age (SGA) also had higher levels of endotoxin at the MFI ( $P = 0.03$ ). Our findings suggest that maternal alcohol consumption may contribute to gut microbial translocation, increasing levels of endotoxin at the MFI and cord blood. These alterations in the microbial abundance at the MFI and in fetal circulation may contribute to the poor growth *in utero* associated with pre-natal alcohol exposure.

### GUILLAIN-BARRÉ SYNDROME IN PATIENTS WITH ZIKA: CLINICAL SERIES WITH LABORATORY CONFIRMATION IN THE STATE OF YUCATAN

**Claudio H. Pech-Cervantes<sup>1</sup>**, Emily G. Lara-Romero<sup>1</sup>, Emy G. Haas-Solis<sup>1</sup>, Juan-Pablo Guillermo-Durán<sup>1</sup>, Salvador Gomez-Carro<sup>2</sup>, Nina Mendez-Dominguez<sup>1</sup>

<sup>1</sup>Universidad Marista de Merida, Merida, Yucatan, Mexico, <sup>2</sup>O'Horan General Hospital, Merida, Yucatan, Mexico

In 2016, over 1700 cases of Zika were confirmed nationwide in Mexico. By the end of the the first half of 2016, autochthonous cases of Zika virus were confirmed in the State of Yucatan. Aedes-borne viral diseases are common in Yucatan, in 2015 a Chikungunya outbreak took place and increased the burden of Aedes-borne diseases in addition to the previous burden. Flaccid palsy (FP) and Guillain-Barre syndrome (GBS) increased their occurrence during 2016, particularly in people under 15 years of age. FP increase its incidence three times between 2015 and 2016 for the same periods. The etiology of GBS and FP in most cases was neither studied nor suspected, Mexican epidemiologic surveillance system is focused exclusively in their relationship with poliomyelitis in young people. In this abstract we present an analysis of the incidence trends in FP among <15 years people and Guillain-Barré syndrome, with emphasis in the specific number of cases that occurred simultaneously with the Zika outbreak in Mexico and in Yucatan, while we analyze a clinical series recorded at a public general hospital. Four patients positive for Zika infection began with clinical traits that suggested GBS 7 days after diagnosis, approximately. Electromyography tests were performed, finding damage compatible with GBS. However, they had different varieties of GBS, two of them had acute inflammatory demyelinating polyneuropathy (AIDP) which is the most common of the GBS subtypes and two of them, acute motor axonal neuropathy (AMAN), this difference was established with the findings in electromyography. Those with AIDP variety, had a favorable outcome after treatment and discharge was achieved. The other two patients with AMAN subtype had a very different evolution. One was a 6 years old male who didn't achieve full recovery even after IVI therapy, and the other was a 15 y/o female who died despite rapid treatment. Zika virus as etiologic agent should have been tested. All patients had had previous positive IgG

test for Dengue, and that could have enhanced the clinical traits or even caused the GBS, this theory corresponds with Halstead's enhancement theory.

## 1786

### MALARIA TRANSMISSION AS MEASURED BY DIRECT SKIN FEEDING OVER A TWO-YEAR PERIOD IN MALI AS AN EFFICACY ENDPOINT FOR A TRANSMISSION BLOCKING VACCINE

**Daman Sylla<sup>1</sup>**, Adama Sacko<sup>1</sup>, Jen C. Hume<sup>2</sup>, Abdoulaye Keita<sup>1</sup>, Boubacar Coulibaly<sup>1</sup>, Daouda Ouologuem<sup>1</sup>, Lakamy Sylla<sup>1</sup>, Chata Doumbia<sup>1</sup>, Issa Traore<sup>1</sup>, Sidiki Kamissoko<sup>1</sup>, Youssef Siniba<sup>1</sup>, Mahamadou H. Assadou<sup>1</sup>, Issaka Sagara<sup>1</sup>, Sara A. Healy<sup>2</sup>, Ogobara Doumbo<sup>1</sup>, Sekou F. Traore<sup>1</sup>, Patrick E. Duffy<sup>2</sup>, Mamadou B. Coulibaly<sup>1</sup>

<sup>1</sup>MRTC, University of Science, Techniques and Technologies, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Malaria transmission from human to mosquito is a complex process depending on a number of human and mosquito factors including the density and maturation of gametocytes present in the capillaries, innate mosquito susceptibility to malaria infection and host immunity. Transmission blocking vaccines work by mounting a host immune response that prevents malaria infection developing in a mosquito despite taking a potentially infectious bloodmeal and direct skin feeding (DSF) assays are an ideal way to measure vaccine efficacy in a more natural manner than assays such as the standard membrane feeding assay. Here we will present data from a transmission blocking vaccine trial conducted in Bancoumana, Mali, where DSFs were conducted twice weekly for a six-week period in two subsequent years (post vaccination 3 and post vaccination 4). In total 175 individuals underwent DSFs with a total of 3,849 feeding assays conducted. 88 infected feeds were observed (2.3%) where at least one oocyst was observed seven days post DSF. We will discuss the transmission dynamics across the two years including parasite and gametocyte carriage rates amongst participants with different DSF outcomes, mosquito feeding and survival rates including a change in feeding methodology implemented in the second year and compare between vaccinated and control individuals.

## 1787

### CYTOKINES PROFILES IN PATIENTS WITH HANSEN'S DISEASE AND PARASITIC CO-INFECTIONS IN HYPERENDEMIC AREA OF BRASIL: IMPLICATIONS FOR TRANSMISSION

**Lorena B. Oliveira<sup>1</sup>**, Rosemary Ker e Lima<sup>2</sup>, Laura de Mondesert<sup>3</sup>, Rodrigo Paiva<sup>4</sup>, Jessica Stephens<sup>3</sup>, Jose Ferreira<sup>5</sup>, Maria Aparecida Grossi<sup>6</sup>, Jessica Fairley<sup>3</sup>, Lucia Fraga<sup>7</sup>

<sup>1</sup>Universidade Vale do Rio Doce, Programa Multicêntrico de Bioquímica e Biologia Molecular PMBqBMIUFJ/GV, Governador Valadares, Brazil, <sup>2</sup>Universidade Vale do Rio Doce, Governador Valadares, Brazil, <sup>3</sup>Emory University, Georgia, GA, United States, <sup>4</sup>Universidade Federal de Juiz de Fora campus GV, Governador Valadares, Brazil, <sup>5</sup>FASEH, Belo Horizonte, Brazil, <sup>6</sup>Secretaria Estadual de Saúde/BH/MG, Belo Horizonte, Brazil, <sup>7</sup>Universidade Federal de Juiz de Fora/GV, Programa Multicêntrico de Bioquímica e Biologia Molecular, Governador Valadares, Brazil

While cases of Hansen's disease have decreased over the last 20 years, there is still a steady number of new cases diagnosed each year. Mycobacterium leprae infection has been shown to increase cells producing Th2 cytokines (IL-4/IL-10) in multibacillary (MB) infection. The overall aim of this project is to better delineate the role of parasitic co-infections as well as select micronutrient deficiencies in the transmission and immunologic response of leprosy. Cases of leprosy and controls were enrolled in the rural areas outside GV, MG, Brazil. Structured and pre-

coded questionnaires were applied for demographic and socioeconomic data. PBMC were obtained from cases of leprosy and healthy controls selected for the study. The levels of cytokines in the supernatant of PBMC cultures were determined by CBA Th1/Th2/Th17 Human - BD. Stool was examined for ova and parasites. Preliminary results show a higher production of IL-10 (mean: 252.4 pg/mL specific to ML) by MB patients compared to healthy individuals (mean: 45.3 pg/mL specific to ML). On the other hand, a decreased production of IFN- $\gamma$  was noted by MB patients (mean: 8.0 pg/mL specific to ML) in comparison with healthy individuals (mean: 15.0 pg/mL specific to ML). *S. mansoni* infection has been found in several cases and controls but ova and parasite exams not currently available for all participants. In the sense that the cytokine IL-10 modulates IFN- $\gamma$  levels, our preliminary results confirm that there is a trend of MB patients to display a profile of modulatory response given by an increase of IL-10 and consequently a reduction of IFN- $\gamma$ . Comparison of cases with parasitic co-infections and those with micronutrient deficiencies will further delineate differences in cytokine profiles among cases and controls and increase our understanding of the immune response associated with co-infection. These analyses can help determine whether actors such as co-infections and micronutrients may influence the immune response and propensity for MB disease, and thus lead to ongoing transmission of *M. leprae*. ## 1788

### ALTERED FETAL IMMUNE RESPONSES BY PRENATAL EXPOSURE TO MATERNAL CO-INFECTIONS

Ruth K. Nyakundi<sup>1</sup>, Ronald Ottichilo<sup>2</sup>, Francis Mutuku<sup>2</sup>, Thomas Kariuki<sup>3</sup>, Desiree LaBeaud<sup>4</sup>, Charles H. King<sup>5</sup>, Indu Malhotra<sup>5</sup>

<sup>1</sup>Institute of Primate Research, Nairobi, Kenya, <sup>2</sup>Division of Vector Borne and Neglected Tropical Diseases, Ministry of Public Health and Sanitation, Nairobi, Kenya, <sup>3</sup>The Alliance for Accelerating Excellence in Science in Africa, The African Academy of Sciences, Nairobi, Kenya, <sup>4</sup>Stanford School of Medicine, Stanford, CA, United States, <sup>5</sup>Case Western Reserve University, Centre for Global Health and Diseases, Cleveland, OH, United States

In developing countries, parasitic infections are prevalent during pregnancy and approximately 40% percent of these women present with multiple infections. Co-infections are known to alter disease outcome and may affect vaccine and drug efficacy. Since prenatal maternal infections are known to influence fetal immunity, we investigated whether helminth co-infections will have an impact on the neonates' immune response. 331 Kenyan women were tested for the presence of *Schistosoma haematobium* (Sh, n=65), malaria (n=79), filariasis (n=23), Sh co-infection with filariasis (Sh-f, n=31), malaria (Sh-m, n=54) and malaria+filariasis (Sh-fm, n=52) and were compared to non-infected (n=27). Neonates' cord blood lymphocyte responses to Sh worm (SWAP) and egg antigens (SEA) were analyzed for production of IL-2, IL-5, IL-6, IL-10, IL-12, IL-13, IFN- $\gamma$ , TNF- $\alpha$  and GM-CSF. Analysis was done using unpaired t test with Welch's correction. Results showed: i) higher IL-5 to SEA in the Sh and Sh-m groups compared to non-infected (0.012, 0.002) and Sh-f (0.026, 0.023), ii) higher IL-13 to SEA in the Sh (0.006) and Sh-m (0.033) compared to non-infected, iii) higher IL-10 to SWAP and SEA in the Sh (0.023, 0.009) and Sh-m groups (0.015, 0.016) compared to non-infected, iv) lower IFN- $\gamma$  to SEA (0.032, 0.040) and TNF- $\alpha$  to SWAP (0.026, 0.035) in Sh-f compared to non-infected and Sh-m groups, v) higher TNF- $\alpha$  to SEA in the Sh-m group compared to non-infected (0.012), Sh (0.012), Sh-f (0.010) and Sh-mf (0.013) and vi) higher IL-6 to SWAP (0.037) and GM-CSF (0.012) to SEA in the Sh-m group compared to non-infected group. These results indicate that co-infections induce a shift in fetal immune priming with a predominant pro-inflammatory response in the schistosome and malaria co-infection group compared to schistosome only infected. On the other hand, schistosome and filariasis co-infections induce immune suppression on both Th1 and Th2 cytokines. We conclude that maternal co-infections (and type) modifies fetal immune priming. This shift in immune response may influence the child's ability to respond to infections and vaccination later in life.

## 1789

### DOUBLE JEOPARDY: RECURRENT CASE OF DENGUE FEVER

Benjamin Chou, Silvio Goris, Javeria Shakil

Flushing Hospital Medical Center, Flushing, NY, United States

Case Discussion: 55 year old male with a past medical history DM2, BPH and HLD presented from home with generalized body aches and fevers for one week duration. Associated with headache, nausea, diarrhea, fevers along with joint pains and a diffuse itchy rash across the chest and abdomen. Patient also complained of dysuria without discharge. He denied abdominal pain, chest pain, shortness of breath or cough. He had recent travel to Dominican Republic one week ago but denied any sick contacts. His vitals were significant for low blood pressure of 101/63, tachycardia of 106 and a temperature of 101.8F. On physical, he had a diffuse maculopapular rash on the chest and abdomen without petechiae. Laboratory studies showed anemia and mild hyponatremia. His urinalysis, chest x-ray and EKG were also normal. Supportive care was initiated with intravenous fluids and pain control. ID was consulted, bacteria, viral and febrile infections workup was started. Patient developed a fever, antibiotics were started empirically for bacterial infection. Subsequently, he developed thrombocytopenia with elevated LFTs and AKI. He also developed retro-orbital pain, scleral icterus and abdominal pain. Patient had a similar episode 2 years prior and was diagnosed with dengue fever. His symptoms as well as elevated LFTs and thrombocytopenia resolved. Typhoid, HIV, Hepatitis C, Influenza, Zika, Yellow fever and Chikungunya were ruled out. Patient was discharged with positive antibodies to Dengue IgM/IgG. Conclusion: Dengue fever is a non-contagious vector-borne illness, transmitted by *Aedes aegypti* mosquito. There are 4 different serotypes of dengue fever, recovery from one serotype results in lifelong immunity. However, recurrent infections of dengue fever is usually more severe with different serotypes as it can cause massive internal bleeding. In a patient presenting with fevers, myalgia and joint pains checking for bacterial and viral infections are important. Dengue should always be on top of the list if patient has traveled to an endemic area. Even if patient has had dengue before as recurrent dengue though rare, can happen as in the case we presented.

## 1790

### TRAVEL-RELATED BEHAVIORS OF ADOLESCENTS ON SHORT-TERM INTERNATIONAL SERVICE MISSIONS

Hemantha Walaliyadda<sup>1</sup>, Benjamin Tasevac<sup>1</sup>, Michael Graves<sup>1</sup>, Peter Hale<sup>1</sup>, In K. Park<sup>1</sup>, Nora Sooklaris<sup>1</sup>, L. Scott Benson<sup>1</sup>, Justin Powell<sup>2</sup>, Jakrapun Pupaibool<sup>1</sup>, Daniel T. Leung<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases, University of Utah, Salt Lake City, UT, United States, <sup>2</sup>Youthlinc, Salt Lake City, UT, United States

There is an increasing number of adolescents participating in short-term international service missions. Despite this fact, little is known about travel-related behaviors and health risks associated with this age group. We administered an anonymous web-based survey to groups of mixed-age travelers following their short-term international missions in seven countries. All participants attended the same pre-travel educational lecture and participated in similar service activities during their trips. We compared the self-reported travel-related behaviors between adolescent ( $\leq 20$  years old, n=82) and older ( $\geq 21$  years old, n=60) participants. We did not detect any differences between age groups for health-related behaviors such as malaria prophylaxis compliance, hand-cleaning practices, or insect precautions taken. We found that adolescent participants were more likely to report insect bites (P=0.04), experience jetlag (P<0.0001), and sustain injuries (P=0.001) during their trips. We did not find any differences in rates of fever, diarrhea, or animal contact. In conclusion, in a group of travelers that received the same pre-travel health education, younger (adolescent) travelers reported similar rates of compliance with preventive behaviors but these did not protect them from travel-related adverse outcomes such as insect bites, jetlag, and injuries. Our findings suggest

the need to customize pre-travel education for adolescent travelers. Our study is ongoing and we expect to present analysis of a larger number of subjects at the meeting.

## 1791

### IRON, INFLAMMATION AND ERYTHROPOIESIS: ANALYSIS OF FACTORS CONTRIBUTING TO SEVERE ANEMIA IN UGANDAN CHILDREN WITH SICKLE CELL ANEMIA

**Aubri S. Carman**<sup>1</sup>, Andrea L. Conroy<sup>1</sup>, Robert O. Opoka<sup>2</sup>, Adam Lane<sup>3</sup>, Russell E. Ware<sup>3</sup>, Sarah E. Cusick<sup>4</sup>, Chandy C. John<sup>1</sup>

<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN, United States, <sup>2</sup>Makerere University, Kampala, Uganda, <sup>3</sup>Cincinnati Childrens Hospital Medical Center, Cincinnati, OH, United States, <sup>4</sup>The University of Minnesota, Minneapolis, MN, United States

African children have a high prevalence of sickle cell anemia (SCA), causing significant morbidity and early mortality. The prevalence of iron deficiency (ID) and the degree to which it contributes to anemia in children with SCA is unknown. The severity of anemia in children with SCA has been previously associated with increases in morbidity and mortality, emphasizing the importance of understanding the various etiologies of severe anemia, including concurrent ID, in this population. Novel use Of Hydroxyurea in an African Region with Malaria (NOHARM) is a Phase III randomized double-blinded placebo-controlled trial of hydroxyurea in children with SCA in Kampala, Uganda. Using plasma from 205 participants collected at enrollment (mean age 27.2 months; 53.7% male), we measured 5 biomarkers of iron status or inflammation by ELISA: ferritin, soluble transferrin receptor (sTfR), C-reactive protein (CRP), hepcidin, and erythropoietin (EPO), in addition to erythrocyte parameters including hemoglobin (Hb), mean corpuscular volume (MCV), and absolute reticulocyte count (ARC). ID was defined as ferritin <12 µg/L or ferritin <30 µg/L if CRP ≥10 mg/L. Median (IQR) values for ferritin, 170.8 µg/L (86.2-329.8), and CRP, 6.6 mg/L (2.5-15.6), were high, collectively reflecting high iron stores in the face of mild inflammation. Low median (IQR) hepcidin, 7.7 mg/L (1.2-20.9), along with high median (IQR) sTfR, 7.2 mg/L (5.4-9.0), is consistent with ongoing gut absorption to support active erythropoiesis. ID prevalence based on ferritin was low (n=7, 3.4%). A larger MCV (OR=1.05, p=0.18), increased EPO (OR=1.2, p=0.003), and increased CRP (OR=1.02, p=0.02) were significantly associated with severe anemia (Hb<7.0 g/dL). Our data reflect a complex picture of iron handling and erythropoiesis in young African children with SCA and demonstrate that inflammation and chronic hemolysis contribute to severe anemia in this population.

## 1792

### THE DEMOGRAPHY, CLINICAL CHARACTERISTICS AND DIAGNOSES OF ACUTE FEBRILE ILLNESS REQUIRING HOSPITALIZATION IN INDONESIA

**Herman Kosasih**<sup>1</sup>, M. H. Gasem<sup>2</sup>, Emiliana Tjitra<sup>3</sup>, Bacht Alisjahbana<sup>4</sup>, Dewi Lokida<sup>5</sup>, Mansyur Arief<sup>6</sup>, Sophia Siddiqui<sup>7</sup>, Muhammad Karyana<sup>3</sup>

<sup>1</sup>INA-RESPOND, Jakarta, Indonesia, <sup>2</sup>Kariadi Hospital, Semarang, Indonesia, <sup>3</sup>NIHRD, Jakarta, Indonesia, <sup>4</sup>Hasan Sadikin Hospital, Bandung, Indonesia, <sup>5</sup>Tangerang Hospital, Banten, Indonesia, <sup>6</sup>Wahidin Sudirohusodo Hospital, Makassar, Indonesia, <sup>7</sup>U.S. National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Fever is a common cause of hospitalization, particularly in developing countries. Identifying the etiologies of fever influences case management and the success of patient outcomes. Unfortunately, the limited diagnostic capabilities of developing countries leads to both undiagnosed and misdiagnosed illness, resulting in prolonged hospitalization, severe complications, and death. To understand Indonesia's capacity to manage patients presenting with fever, an observational study of acute febrile illness requiring hospitalization was conducted at 8 top-referral hospitals across the country from 2013 to 2016. This study followed subjects as they

received both standard-of-care diagnostic testing and advanced, study-specific diagnostic testing. Demographic and clinical data were collected at enrollment, and blood samples were collected at each study visit for testing. From 5,213 screened patients, 1,486 were enrolled and monitored during enrollment, once during the 14-28 days following enrollment, and at 3 months after enrollment. Based on clinical manifestations, study physicians categorized patient infections as systemic (61.1%), respiratory (19.7%), digestive (8.3%), genitourinary (4.7%), skin/soft-tissue (2.4%), and central nervous system (1.8%). Standard-of-care, molecular, and serological testing identified pathogens in 66% of cases, the majority being dengue virus (44.5%), *Salmonella spp.* (11.7%), *Leptospira spp.* (4.6%), influenza A&B (4.2%), and chikungunya virus (3.3%). Surprisingly, *Rickettsia spp.* were detected in 103 (10.7%) cases, all of which were clinically misdiagnosed. Co-infections were detected in 2.7% of identified cases, and patient mortality was 6.0% overall, mostly in subjects with underlying conditions. Discordance between lab results and clinical diagnoses were found in 325 (33.7%) cases, including cases of rickettsiosis (103), dengue (36) chikungunya (33), HHV-6 (33), leptospirosis (25), and typhoid (15). These findings inform national approaches to the diagnosis and treatment of acute febrile illness and highlight the need for greater diagnostic testing capacity.

## 1793

### WAIT, IS THIS AN ID BOARD QUESTION? CHRONIC HEPATITIS IN A BROADLY EXPOSED LIVER TRANSPLANT PATIENT

**Megan McKenna**, Vagish Hemmige

Baylor College of Medicine, Houston, TX, United States

A 32-year-old male with a history of hepatocellular carcinoma, glycogen storage disease, cirrhosis, and successful orthotic liver transplant 11 years ago (on mycophenolate, tacrolimus, and prednisone) was admitted for two weeks of fever and worsening transaminitis. Alanine aminotransferase and aspartate aminotransferase were elevated for the previous six months (173 and 241 U/L, respectively) despite adherence to immuno-suppressive medication. These values continued to up-trend to a maximum of 380 U/L on the day of admission. Previous biopsies did not reveal any evidence of organ rejection, but he was restarted on prednisone (20mg daily) four months ago. The patient reported no significant travel or arthropod bites, however, he had multiple animal exposures within the last few months. He worked as a butcher with occasional blood exposure, he previously worked in the seafood department, handling raw seafood, and at home, he is exposed to a rabbit, dogs, and several parakeets. On arrival to the hospital, the patient was febrile (103.3F), with a white blood cell count and platelet level somewhat decreased from baseline (3,300 and 138,000, respectively). Blood cultures, urinalysis, and chest x-ray were non-diagnostic. A liver biopsy revealed the presence of granulomas with intracellular yeast-like, budding fungal elements, consistent with histoplasmosis. Urine Histoplasmosis antigen also resulted positive (15.7 ng/ml). The patient was started on Ambisome and then transitioned to Itraconazole. He defervesced and had improvement of transaminitis. *Histoplasma capsulatum* is the most common endemic mycoses in the United States and a frequent opportunistic infection among the immuno-compromised. Granulomatous hepatitis has been associated as a cause of fevers of unknown origin in up to 13% of cases and has a broad etiology, including endemic fungal infections, Q fever, tularemia, tuberculosis, viruses, and leptospirosis, among others. Given the patient's exposures to parakeets, as well as increasing steroid dosage, this immune-compromised patient was placed at even higher risk for *Histoplasma* infection and disease progression.

## HOT OR NOT? MANAGEMENT OF UNCLASSIFIED FEVER IN CHILDREN IN SUB-SAHARAN AFRICA

**Karin Källander**<sup>1</sup>, Tobias Alfvén<sup>2</sup>, Ayalkibet Abebe<sup>3</sup>, Abreham Hailemariam<sup>3</sup>, Dawit Getachew<sup>3</sup>, Max Petzold<sup>4</sup>, Laura C. Steinhardt<sup>5</sup>, Julie R. Gutman<sup>5</sup>

<sup>1</sup>Malaria Consortium, London, United Kingdom, <sup>2</sup>Dept Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, <sup>3</sup>Malaria Consortium, Addis Ababa, Ethiopia, <sup>4</sup>Health Metrics, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, <sup>5</sup>Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

The World Health Organisation's (WHO) integrated Community Case Management (iCCM) strategy states that febrile children seen by community health workers (CHW) without a diagnosable cause of illness and without danger signs are advised to return to the CHW for a follow-up visit on day 3, regardless of symptom resolution. Yet, fever is common in children in sub-Saharan Africa and generally resolves by itself. The day 3 follow-up visit might therefore be unnecessary and there is limited evidence of whether caregivers of children complete their follow-up assessment visit promptly. The outcome of the febrile children from whom treatment was withheld is also unknown. The safety of a conditional three-day reassessment visit only in cases where symptoms did not resolve, was compared with a universal follow-up visit at day 3 for all children. A two-arm cluster-randomised controlled non-inferiority trial was conducted in Southwest Ethiopia with 25 health facility clusters. All 282 CHWs (in Ethiopia, Health Extension Workers - HEWs) in these clusters enrolled children 2-59 months with fever and no malaria, no pneumonia, no diarrhoea or danger signs. Caregivers of children received advice to come back on day 3 (control), or to only come back on day 3 if fever persisted (intervention), according to cluster assignment. The primary outcome was treatment failure by day 7. We did a per-protocol analysis with a non-inferiority margin of 4% for treatment failure rate using generalised linear models with binomial distribution and identity link using robust variance estimator, treating cluster as a random effect. From Dec 1, 2015, to Nov 30, 2016, 4626 children were enrolled. Of these, 1953 (87.7%) children in the universal follow-up group and 1993 (84.1%) children in the conditional follow-up group had a day 7 ( $\pm 1$  day) follow-up visit. The conditional follow-up advice was non-inferior to the universal follow-up advice in terms of treatment failure (-3.81% [95% CI  $-\infty$  to 0.65%]). There were no deaths recorded by day 28. Conditional follow-up of children with non-severe unclassified fever in a low malaria setting in Ethiopia was concluded to be safe in children 2-59 months.

## IMPACT OF FIVE YEARS OF CDTI ON ENTOMOLOGICAL TRANSMISSION INDICATORS OF ONCHOCERCIASIS BY SIMULIUM DAMNOSUM S.L. IN THE CASCADES REGION OF BURKINA FASO

**Lassane Koala**<sup>1</sup>, Achille Nikiema<sup>1</sup>, Rock K. Dabire<sup>1</sup>, Soungalo Traore<sup>1</sup>, Adrien M. Belem<sup>2</sup>, François Drabo<sup>3</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Santé (IRSS)/Direction Regionale de l'Ouest, Bobo Dioulasso, Burkina Faso, <sup>2</sup>Université Polytechnique de Bobo (UPB), Bobo Dioulasso, Burkina Faso, <sup>3</sup>Coordination nationale de lutte contre les maladies tropicales et négligées au Burkina Faso, Bobo Dioulasso, Burkina Faso

**Abstract :** Onchocerciasis or river blindness is a dermal filariasis due to the development in human subcutaneous tissue of a nematode called *Onchocerca volvulus*. This parasite is transmitted to humans through the bites of blackflies of the genus *Simulium*. Mass ivermectin administration to populations of endemic areas is the strategy recommended by WHO in the elimination of onchocerciasis. Since 2011, this strategy has been applied in the form of Community-directed treatment with ivermectin (CDTI) to the Cascades Region of Burkina Faso following a resurgence

of the disease in the aforesaid region. Evidence of the interruption of onchocerciasis transmission through CDTI campaigns has been demonstrated in the past. In this study, we evaluated the impact of 5 years of CDTI treatments on parasite loads and infestation rates of *Simulium damnosum s.l.* in order to evaluate the first phase of elimination of onchocerciasis in Burkina Faso. For this purpose, we collected blackflies in the breeding sites near the four villages which had the highest prevalences of the disease during the recrudescence. We carried out the first collection of blackflies at the beginning of CDTI treatments and a second collection after 5 successive years of annual treatments. Flies were dissected and any larvae found were identified molecularly. The infective larvae of 2012 have been identified and the identification of the 2016 infective larvae is ongoing. Finally, infective rates of flies and the annual potential of transmission for each village will be calculated at the completion of the molecular analysis. Comparison of the entomological indicators of onchocerciasis transmission from 2012 to 2016 will allow us to better understand the dynamics of the infectivity of blackflies as a function of CDTI treatments.

## ONCHOCERCIASIS IN CAMEROON: A SYSTEMATIC REVIEW OF HISTORY AND IMPACT OF CONTROL INTERVENTIONS

**André Domche**, Hugues Clotaire Nana Djeunga, Guy Roger Kamga, Joseph Kamgno

Centre for Research on Filariasis and other Tropical Diseases (CRFILMT), Yaoundé, Cameroon

Onchocerciasis or river blindness remains a major public health problem, especially in Africa where more than 99% of infected population reside. This parasitic disease is responsible of severe skin disease with unsightly lesions and intense itching, the main complication being severe eye disease that can lead to blindness. Also, the huge burden of river blindness has a great impact on socio-economic development of infected population. Many control methods had been implemented to tackle river blindness and great successes had been achieved, so that the paradigm has shifted from control to complete elimination. However, high discrepancies have been observed in prevalence and intensities of the disease, and different scenarios to explain this persistence of infection have been evoked. The mandate of the African Programme for Onchocerciasis Control (APOC) ended in 2015 and endemic countries need to move toward elimination by themselves. In Cameroon, an elimination committee is being putting in place and data on the situation of onchocerciasis are highly needed. In this context, the present study aimed at systematically review available data on prevalence of onchocerciasis and different control interventions in order to provide pertinent information that will be useful to defeat onchocerciasis in Cameroon. To this end, all published and unpublished data were gathered from different sources, and inspected for inclusion in the study. Environmental (climate, season, vegetation ...), and socio-demographic factors have also been collected. A countrywide map was generated to provide the dynamics of river blindness prevalence according to MDA status, as well as environmental and socio-demographic factors to guide the decision of the Cameroon elimination committee.

## LYMPHATIC FILARIASIS IN MAINLAND SOUTHEAST ASIA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF PREVALENCE AND DISEASE BURDEN

**Benjamin F. Dickson**, Patricia M. Graves, William J. McBride  
James Cook University, Cairns, Australia

Accurate prevalence data is essential for the elimination of lymphatic filariasis as a public health problem. Despite bearing one of the highest burdens of disease globally, there remains limited reliable information on the current epidemiology of filariasis in mainland South-East Asia. We conducted a systematic review and meta-analysis of available literature to assess the current prevalence of infection and morbidity in the region.

56 journal articles and reports containing original prevalence data were identified including over 512 010 participants. Data were summarised using percentage prevalence estimates and a subset compared using a random effects meta-analysis by country and year. Pooled estimates for microfilaraemia, immunochromatographic card positivity and combined morbidity were 2.64%, 4.48% and 1.34% respectively. Taking into account pooled country estimates, grey literature and the quality of available data, we conclude that North-East India, Lao PDR and Myanmar demonstrate ongoing evidence LF transmission that will require multiple further rounds of MDA. Bangladesh, Malaysia, Thailand and Vietnam appear close to eliminated LF, whilst Cambodia has already achieved elimination status. We estimated that the burden of morbidity is likely high in Bangladesh and Northeast India, moderate in Cambodia, Myanmar and Thailand and low in Vietnam. There was insufficient evidence to accurately estimate the disease burden in Lao PDR or Malaysia. The results of this study will assist policy makers to advocate and budget for future control programs, and highlights the significant need for further filariasis prevalence studies in the region.

## 1798

### LYMPHATIC FILARIASIS SERO PREVALENCE IN MOMBASA COUNTY

Stephen Mwatha

*Neglected Tropical Medicine, Nairobi, Kenya*

**Background:** Lymphatic Filariasis (LF) is a neglected tropical disease targeted for elimination in Kenya. In Kenya's coastal region, LF affects about 3.5 million people. We aimed to determine the sero-prevalence and distribution of LF in Mombasa County. **Methods:** This was a cross-sectional survey involving multistage sampling in which one village was randomly selected from each of the six sub-counties. In each village, a minimum of 300 individuals were randomly selected from 233 randomly selected households (HHs). Persons aged  $\geq 3$  years, a resident of the county between January and December 2016 was included in the study. Persons on anti-filarial chemotherapy were excluded. We collected blood samples from participants and collected demographic information using questionnaires. We used Filarial test strip (sensitivity = 98% and specificity = 99%) for detecting circulating LF antigens in blood. We analyzed data using Microsoft Excel and Epi-Info, calculated proportions for and used chi-square ( $\chi^2$ ) to compare sero-prevalence with demographic characteristics. **Results:** A total of 1,826 individuals from 233 HHs were sampled. The overall sero-prevalence was 1.1% (95% CI: 0.7-1.7). There were 14 (6%) HHs with at-least a positive case. The sero-prevalence in males was 1.4% [(1/1772); (95% CI: 0.8-2.5)] compared to females 0.9% [(9/1056); (95% CI: 0.4-1.6)]; [ $\chi^2 = 0.87$ ; p-value=0.352]. The mean age of the sero-positive individuals was  $17.4 \pm 9.8$  years compared to sero-negative which was  $21.8 \pm 15.6$  years (t Stat=1.28; p-value=0.201). All positive cases were from Jomvu sub-county where 14 (35%) of 40 HHs had at-least one positive case. Clustering was seen in 4 (29%) of 14 HHs; 2 HHs had 3 cases each while 2 HHs had 2 cases each. **Conclusion:** Sero-prevalence estimates show presence of LF in Jomvu Sub-County. We recommend intensification of anti-filarial chemotherapy in Jomvu. The findings provide baseline information for future epidemiologic investigations and response to LF in Mombasa County.

Implementation of ivermectin-based community treatment for onchocerciasis or lymphatic filariasis elimination has been delayed in Central Africa because of the severe adverse events (SAEs), including death, in people with high levels of circulating *Loa loa* microfilariae (mf). Between August and October 2015, *L. loa* microfilaremia was measured in 16,205 individuals living in an area of central Cameroon that is also co-endemic for onchocerciasis. This testing was performed as part of a "Test and (not) Treat" (TNT) with ivermectin strategy for onchocerciasis elimination based on excluding from ivermectin treatment those with  $>20,000$  mf/ml deemed at-risk for SAEs. Among those tested in 2015, 342 (2.1%) did not receive ivermectin because of an excessive *L. loa* density, whereas 15,469 persons were safely treated with ivermectin. A second TNT campaign is currently being conducted 18 months after the first TNT campaign in the same population. Interim results based on the  $>9000$  individuals that have already been tested so far show that none of the individuals treated with ivermectin in 2015 (those with  $<20,000$ /ml) have *L. loa* mf levels that would preclude safe ivermectin treatment in 2017. Interestingly, mf densities of 21 individuals that were unable to receive ivermectin in 2015 had mf levels that had decreased below the 'at-risk' threshold and were therefore treated with ivermectin in 2017. Finally, mf densities of 24 individuals that could not receive ivermectin in 2015 were still above the threshold in 2017. Results for the entire district of  $>16,000$  people will be available in May, 2017. These interim results suggest that, in onchocerciasis/loiasis co-endemic areas, pretreatment testing for *L. loa* microfilaremia is necessary only before the very first treatment with ivermectin and that ivermectin can be safely administered to all individuals treated within the previous 18 months.

African onchocerciasis control and elimination programmes rely predominantly on annual mass drug administration of ivermectin. Phase II and III clinical trials have indicated that moxidectin, a registered veterinary anthelmintic, is a more efficacious treatment. Both drugs, given as a single oral dose, suppress skin microfilarial (mf) loads, but ivermectin does this for a shorter period and with greater variation among individual responses than moxidectin. The influence of the duration of mf suppression and the distribution of individual pharmacodynamic (PD) responses on the projected impact of community-directed treatment with ivermectin (CDTI)

or moxidectin (CDTM) has not been investigated. Using phase II and III clinical trial data, and our individual-based analogue of the EPIONCHO transmission model (EPIONCHO-IBM), we capture inter-individual PD variation for standard dose ivermectin and ascending (2mg (n=45), 4mg (n=44), 8mg (n=1,016)) doses of moxidectin. We model interventions based on annual and biannual CDTI and CDTM, comparing how long it takes to eliminate onchocerciasis under these different strategies with and without variation in PD responses. Annual CDTM is similar to biannual CDTI (in the absence of PD variation) but biannual CDTM always eliminates onchocerciasis more rapidly. Persistent infection and transmission with multiple treatment rounds of CDTI may be due to inter-individual and inter-treatment round variability in PD responses. Inter-individual variation in responses is substantially lower for moxidectin, and with biannual CDTM there would be minimal opportunity for inter-treatment transmission to vectors, which contributes to its potential for accelerating elimination. The cost-effectiveness implications of the various strategies modelled will be discussed.

### ARE WE ON THE RIGHT TRACK? STOPPING CRITERIA FOR ENDING SOIL-TRANSMITTED HELMINTHS RANDOMIZED CLINICAL TRIALS

**Marleen Werkman**<sup>1</sup>, James E. Truscott<sup>1</sup>, James E. Wright<sup>1</sup>, Jaspreet Toor<sup>1</sup>, Kristjana H. Asbjornsdottir<sup>2</sup>, Sam H. Farrell<sup>1</sup>, Judd L. Walson<sup>2</sup>, Roy M. Anderson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>University of Washington, Seattle, WA, United States

Throughout the last decade, the World Health Organisation's (WHO) efforts with regards to soil-transmitted helminths (STH) have been focused on morbidity control in children. However, there now exists a shift towards elimination beyond 2020. Models indicate that with a high coverage level and good compliance, elimination may be achievable with mass-drug administration (MDA) alone; however, this has not been verified. Trials to investigate the possibility of elimination are ongoing (e.g. the TUMIKIA and DeWorm3 studies). Achieving high coverage levels may be difficult in areas with high migration or low compliance in the study population. If target coverage is not achieved or prevalence is not coming down, it may be better to stop an ongoing trial and to investigate the reasons. In this work, we investigate the stopping criteria which would be necessary to make this decision. We adopt a stochastic simulation model to simulate the DeWorm3 randomized trial. In short, this trial compares two arms, including a control arm (treating school-aged children with MDA once a year) and an intervention arm (biannual treatment of the whole community with MDA). The DeWorm3 trial lasts for three years and the sites are closely monitored for the following two years. At the end of year five, a cross-sectional survey is performed to investigate if the prevalence thresholds for interruption of transmission (<2%) have been achieved. As the whole process is costly, it may be more efficient to stop the trial when interruption of transmission can be ruled out, to determine why it was not achieved in order to inform future trials. In this study, we investigate if stopping criteria can be defined *in situ* where interruption of transmission is unlikely, resulting in higher prevalence levels than expected during the study period. This may occur when high coverage levels needed to reach this goal are not achieved or when immigration results in re-infection of the study-site. We investigate different time points and the effects of varying prevalence thresholds that can determine the stopping criteria.

## 1802

### ASSESSMENT OF TWO DENSITOMETRIC READERS TO MEASURE RESULTS OF FILARIASIS TEST STRIPS IN THE DEMOCRATIC REPUBLIC OF CONGO

**Cédric B. Chesnais**<sup>1</sup>, Sébastien D. Pion<sup>1</sup>, Naomi-Pitchouna Awaca-Uvon<sup>2</sup>, Jean-Paul Tambwe<sup>2</sup>, Michel Boussinesq<sup>1</sup>, Donald C. Cooper<sup>3</sup>, Katherine Gass<sup>4</sup>

<sup>1</sup>IRD UMI 233-INSERM U1175-Montpellier University, Montpellier, France, <sup>2</sup>National Onchocerciasis Control Programme, Ministry of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>President, Mobile Assay LLC, Boulder, CO, United States, <sup>4</sup>Neglected Tropical Disease Support Center, Task Force for Global Health, Decatur, GA, United States

The Alere Filariasis Test Strip (FTS) is a point-of-care diagnostic tool that detects *Wuchereria bancrofti* circulating filarial antigen (CFA) in blood. The Global Program to Eliminate Lymphatic Filariasis (GPELF) employs the FTS for mapping filariasis-endemic areas and assessing the success of elimination efforts. Recently, we demonstrated that the quantitative reading of FTS results (qFTS) using a densitometric reader (FD5, Konica-Minolta) provides additional information because the intensity of the test-line is correlated with CFA titers. In June 2016, we conducted a study in the Kwilu Province (DRC) to compare the performance of the FD5 reader with a new an Android-based ratiometric image analysis software application (mReader) operating on a low-cost Amazon Fire (2015 Tablet), which is more adapted for the field than the FD5. We tested 586 individuals and assessed the results by visual reading (vFTS), qFTS, and reading with mReader (mFTS). 152 (25.9%) individuals were positive by vFTS. Both qFTS and mFTS results were correlated with the vFTS scores (Spearman's coefficients 0.72 and 0.72 respectively, for all the subjects, and 0.82 and 0.78 respectively for only the positive vFTS), and were correlated between themselves ( $p = 0.55$  and  $0.78$  respectively, for total population and positive vFTS). The quantitative ROC analysis showed that the areas under the curves (AUC) were similar for qFTS ratios and mFTS values (96.5 and 96.4, respectively;  $P = 0.880$ ). Following the sensitivity analysis, we defined cut-offs of 0.46 and 16.5 for the qFTS and mFTS, respectively. For the qualitative performances, AUC were 92.3 and 91.2 for qFTS and mFTS, respectively ( $P = 0.396$ ). In conclusion, the new tablet-based ratiometric image analysis application tool, mReader has similar performance to qFTS, and we hypothesize that results are similarly correlated with CFA titers. Although minor problems with misclassification remain, our preliminary testing demonstrates that it is possible to extract a quantitative indicator from the FTS. Such an indicator could provide the GPELF with greater information on which to base stopping MDA and surveillance decisions.

### EMPIRIC TESTING OF A MODEL TO IDENTIFY DISTRICTS ELIGIBLE FOR SAFE IVERMECTIN-BASED MASS TREATMENTS FOLLOWING INTEGRATED MAPPING FOR ONCHOCERCIASIS, LYMPHATIC FILARIASIS AND LOIASIS

**Joseph Kamgno**<sup>1</sup>, Hugues Nana-Djeunga<sup>2</sup>, Jules Tchatchueng-Mbouqua<sup>2</sup>, Guy-Roger Njitchouang<sup>2</sup>, Divine B Agbor-Arrey<sup>2</sup>, Aurel Tankeu-Tiakouang<sup>1</sup>, André Domche<sup>2</sup>, Kisito T Ogoussan<sup>3</sup>, Maria P Rebollo<sup>4</sup>

<sup>1</sup>Centre for Research on Filariasis and Other Tropical Diseases and Faculty of Medicine and Biomedical Sciences University of Yaounde I, Yaounde, Cameroon, <sup>2</sup>Centre for Research on Filariasis and Other Tropical Diseases, Yaounde, Cameroon, <sup>3</sup>NTDs Support Center, Task Force for Global Health, Atlanta, USA, Decatur, GA, United States, <sup>4</sup>Expanded Special Project for Elimination of NTDs, World Health Organization-AFRO, Brazzaville, Republic of the Congo

Onchocerciasis (Oncho) and lymphatic filariasis (LF) are among neglected tropical diseases (NTDs) targeted for elimination by preventive chemotherapy (PC-NTD). As a consequence of post-ivermectin (IVM) SAEs

occurring in individuals harboring very high *Loa* microfilarial (mf) densities, this drug is not recommended in areas hypo-endemic for *Oncho* or endemic for LF, that are co-endemic for loiasis. However, to achieve global elimination of *Oncho* and LF, PCs are also needed in areas where loiasis is endemic, regardless the infection rate of the targeted filarial disease. Recent MDA campaign using the Test and Not Treat strategy in Cameroon has demonstrated that *Loa* mf load of 20,000 mf/ml is a safe threshold for MDA. From existing data, we hypothesized using a mathematical model that IVM-based PC can be safely implemented in community with probability to have < 1% of *Loa* mf load >20 000mf/mL is above 95%. To test this model and define a cost effective and accurate method to map IVM-naïve health districts (HD) for *Oncho*, LF and loiasis, and therefore identify HD eligible for safe IVM-based MDA, two community-based cross sectional surveys were carried out in the Garoua Boulai HD (Cameroon) where no IVM MDA was ever performed. (1) a cluster survey using the probability proportionate to estimated size strategy, and (2) a systematic random survey in communities that pass mathematical model predictions. To do this, finger-prick blood samples were collected for loiasis (LoaScope), *Oncho* (IgG4 antibody to human Ov16 antigen) and LF (filaria test strip, FTS). The prevalence of loiasis was 8.0% (95% CI: 7.2 - 9.0), with high heterogeneity between clusters (Min: 0.0%; Max: 43.5%). *Oncho* was found to be hypo-endemic (Ov16 prevalence: 4.9%; 95% CI: 4.2 - 5.7), and LF infection rate was quite low (prevalence: 0.4%; 95% CI: 0.2 - 0.7). The likelihood to find >1% of individuals harboring *Loa* mf densities > 20,000 mf/mL in a cluster seems to be positively associated with the prevalence of loiasis. Systematic sampling allow to validate data from cluster survey, both for loiasis prevalence and percentage of individuals harboring more than 20,000 mf/mL.

## 1804

### STOPPING IVERMECTIN DISTRIBUTION IN ONCHOCERCIASIS AND LYMPHATIC FILARIASIS CO-ENDEMIC FOCI. WHAT IS THE WAY FORWARD?

**Andreas Nshala**<sup>1</sup>, Maria Chikawe<sup>2</sup>, Cecilia Cecilia Uisso<sup>2</sup>, Oscar Kaitaba<sup>1</sup>, Sarah Craciunoiu<sup>3</sup>, Kathryn Crowley<sup>4</sup>, Delali Bonuedi<sup>4</sup>, Darin Evans<sup>5</sup>, William Kisoka<sup>6</sup>, Mathias Kamugisha<sup>6</sup>, Upendo Mwingira<sup>2</sup>

<sup>1</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Tanzania NTD Control Program, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>IMA World Health, Washington, DC, United States, <sup>4</sup>RTI International, Washington, DC, United States, <sup>5</sup>U.S. Agency for International Development, Washington, DC, United States, <sup>6</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

In Tanzania, in communities where onchocerciasis (OV) is co-endemic with lymphatic filariasis (LF), treatment programs have been achieving high mass drug administration (MDA) coverage rates and reduction of infection levels. Tukuyu is one of the co-endemic foci, where over 800,000 inhabitants, spread across four districts, have received 15 rounds of annual ivermectin and albendazole treatments. In 2015, all districts achieved the criteria for stopping LF MDA, but OV transmission status was not known so treatment has continued. At mapping/baseline, clinical manifestations included skin lesions and nodule prevalence was up to 70%. After initiation of MDA four focus-wide assessments of human onchocerciasis infection have been conducted. First, an APOC phase 1a epidemiological assessment conducted in 2012 after 12 effective treatment rounds, in 10 villages, indicated 0% (n=1861) microfilaridemia among the general population. Second, an APOC phase 1b epidemiological assessment in 2013 in 20 villages indicated again microfilaridemia level of 0% (n=3146) in the general. An entomology assessment was not done at the time. Third, an independent assessment (n=948) in 2015, carried out skin exam, skin snips for microfilaria count (≥5 years-old only) and skin snip PCR, and blood draw for the rapid OV16 antibody test (RDT). OV16 ELISA and daytime blood smears reported overall prevalence 0.9% among children 0-10 years of age and 5.5% overall on OV16 RDT. Finally, in December 2016, an epidemiological evaluation using OV16 RDT and OV16 ELISA among children below 10 years of age, (mean age 7.5 years), reported

1 child positive for OV16 antibodies 0.03% (n=3198). An entomological study was also conducted in 2015 where O-150 PCR was carried in in 8000+ *simulium spp* flies collected from all active breeding sites across the focus area. The PCR results reported zero infected black flies. It would appear to that the Tukuyu focus has interrupted onchocerciasis transmission. However, since the Tanzania program aims at elimination, in line with the new WHO guidelines, (despite zero infective vectors and one positive child) has transmission really been interrupted?

## 1805

### RESPONSES OF *ONCHOCERCA VOLVULUS* AFTER THE INTRODUCTION OF BIENNIAL TREATMENT WITH IVERMECTIN IN GHANA

**Kwadwo K. Frempong**<sup>1</sup>, Martin Walker<sup>2</sup>, Robert A. Cheke<sup>3</sup>, Edward Jenner Tetevi<sup>4</sup>, Ernest Tawiah Gyan<sup>4</sup>, Ebenezer O. Owusu<sup>5</sup>, Michael D. Wilson<sup>1</sup>, Daniel A. Boakye<sup>1</sup>, Mark J. Taylor<sup>6</sup>, Nana Kwadwo Biritwum<sup>7</sup>, Mike Osei-Atweneboana<sup>4</sup>, Maria Gloria Basanez<sup>2</sup>

<sup>1</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>2</sup>Department of Infectious Disease Epidemiology, School of Public Health, Imperial College London, London, United Kingdom, <sup>3</sup>Natural Resources Institute, University of Greenwich, Medway, United Kingdom, <sup>4</sup>Council for Scientific and Industrial Research, Water Research Institute, Accra, Ghana, <sup>5</sup>Department of Animal Biology and Conservation Science, University of Ghana, Legon, Accra, Ghana, <sup>6</sup>Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>7</sup>Neglected Tropical Diseases Programme, Ghana Health Services, Accra, Ghana

Despite many years of onchocerciasis control in Ghana, the disease remains persistent in pockets of endemic areas. Due to reports of sub-optimal responses in parasite population, treatment strategy was changed from annual to biennial in 2010. This study assessed the impact of the first three years of biennial strategy on the microfilarial loads in hosts' skin and the embryostatic effect on the adult female worm. A community-wide skin snipping was performed on 956 consenting adults aged ≥20 years from 10 sentinel communities. A cohort of 217 participants who were microfilaria (mf) positive and/or had palpable nodules at baseline were followed up over the first two rounds of biennial treatment to estimate the rates of microfilarial repopulation. Nodules were performed on consenting participants and adult worms were isolated using the collagenase technique. Embryogram analyses were performed on intact female worms and classified into three response groups (good, intermediate and poor). The baseline mf prevalence was 22.7% (1-45%). The biennial treatment substantially reduced infection intensity in most communities, although infections were detected in all communities even after 4 or 5 rounds of treatment. The 6-month repopulation rates were generally higher than 10% in all the communities. Three communities previously identified as sub-optimal to ivermectin were observed to have statistically significantly high microfilarial repopulation rates. A total of 225 nodules were excised from 106 participants with an average of 1.4 female worms and 0.7 male worms per nodule. Twenty eight percent of the adult female worms isolated were observed with normal intra-uterine mf whiles 72% were observed with either degenerated or no stretched mf three months after treatment. In all 10 communities, there were female worms observed with normal intra-uterine mf three months after treatment. Constant monitoring of parasite response to ivermectin treatment is necessary to ascertain any resistance developing in parasite population. A study is ongoing to identify any genetic changes that may be associated with these response phenotypes.

## 1806

**ALL FOR ONE, ONE FOR ALL: ACROSS BORDER LYMPHATIC FILARIASIS TRANSMISSION CAN COMPROMISE NATIONAL ELIMINATION PROGRAMS IN SOME SETTINGS**Joaquin M. Prada<sup>1</sup>, Lisa J. Reimer<sup>2</sup>, Deirdre Hollingsworth<sup>1</sup><sup>1</sup>University of Warwick, Coventry, United Kingdom, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Lymphatic filariasis (LF) is one of the neglected tropical diseases (NTD) with ambitious global targets for elimination as a public health problem. Most LF elimination programs involve multiple rounds of mass drug administration (MDA) and a post campaign evaluation at some defined sentinel sites. Since progress in each country occurs independently, we explored the across border transmission between neighbouring countries where one of them is further in their elimination program. However, the extent and rate of spatial spread of LF transmission across a landscape of variable suitability for LF is poorly understood. Using a well-described mathematical model of transmission publicly available, we investigated under what circumstances can foreign countries reduce or compromise, at least locally, elimination of LF in some regions, which could give rise to hotspots of transmission. This work helps better understand border effects and illustrates that combined efforts for LF elimination could potentially be more effective.

## 1807

**LESSONS LEARNED FROM IMPLEMENTING LYMPHATIC FILARIASIS TRANSMISSION ASSESSMENT SURVEYS IN THE FIRE BELT OF NORTH DEPARTMENT IN HAITI**Carl Renand Fayette<sup>1</sup>, Franck Monestime<sup>1</sup>, Alain Javel<sup>1</sup>, Luula Mariano<sup>1</sup>, Ellen Knowles<sup>2</sup>, Sarah Craciunoiu<sup>2</sup>, Cudjoe Bennett<sup>2</sup>, Abdel Direny<sup>3</sup>, Jean-Frantz Lemoine<sup>4</sup><sup>1</sup>IMA World Health, Port Au Prince, Haiti, <sup>2</sup>IMA World Health, Washington, DC, United States, <sup>3</sup>RTI International, Washington, DC, United States, <sup>4</sup>Ministry of Public Health and Population, Port Au Prince, Haiti

To achieve global goals to eliminate lymphatic filariasis (LF) by 2020, the Haiti NTD Control Program follows WHO's recommendations to implement 5 rounds of annual mass drug administration (MDA) of diethylcarbamazine (DEC) and albendazole among at risk populations to halt LF transmission. MDA is followed by a transmission assessment survey (TAS) to determine if the commune has met the criteria for stopping MDA (<2% antigenemia). Efforts to halt transmission have been successful in two-thirds of the country. However, prevalence remains high in five contiguous communes in the North department (Quartier Morin, Milot, Acul-du-Nord, Limonade, and Plaine du Nord) that had prevalence between 28-45% at baseline. By 2014, they received five rounds of MDA before conducting pre-TAS through use of immunochromatographic card test (ICT). Three communes failed: a total sample size of 1,513 were tested across Quartier Morin, Milot and Acul-du-Nord, of which prevalence was 4.2%, 3.35%, and 2.35% respectively. The communes were subsequently given two additional rounds of MDA before another pre-TAS was conducted in 2016 using a different test: filariasis test strip (FTS). The three communes failed again with an increase in positive cases at 9.2%, 11%, and 2.35%, respectively. The remaining two communes barely passed, so were recommended to implement TAS using FTS in 2016, which subsequently failed. A pattern within the five communes has emerged: the *ceinture de feu filarirose*, or LF Fire Belt appears to fail or succeed together. Sustained high prevalence, despite high MDA coverage, may require alternative strategies. A study in Quartier Morin is using a triple drug combination (adding ivermectin) to test the safety and acceptability of the drug combination and its effects on LF prevalence. If successful, it represents a new approach that could be used in communes with high baseline prevalence. Additional combined interventions, such as intensified

vector control, increased communication, door-to-door strategies during MDA and advocacy with local leaders should also be applied across all 5 communes, instead of individual ones, in order to stop transmission.

## 1808

**THE ROAD MAP TO LF ELIMINATION IN TANZANIA - THE CHALLENGING END GAME**Upendo Mwingira<sup>1</sup>, Andreas Nshala<sup>2</sup>, Maria Chikawe<sup>1</sup>, Lousie Kelly Hope<sup>3</sup>, Charles Mackenzie<sup>4</sup>, Sarah Craciunoiu<sup>5</sup>, Delali Bonuedi<sup>6</sup>, Mwele Malecela<sup>7</sup><sup>1</sup>Tanzania NTD Control Program; National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Tanzania NTD Control Program; IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>4</sup>Michigan State University, East Lansing, MI, United States, <sup>5</sup>IMA World Health, Washington, DC, United States, <sup>6</sup>RTI International, Washington, DC, United States, <sup>7</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

Lymphatic filariasis (LF), caused by *Wuchereria bancrofti*, is a leading cause of morbidity in Tanzania. The Tanzania NTD Control Program (TZNTDCP) has a target to eliminate LF by 2020. When treatment started, the entire country was considered endemic. Elimination efforts by the TZNTDCP have largely targeted interruption of transmission through mass drug administration (MDA) and alleviation of morbidity for those already affected. Since 2001, ivermectin and albendazole have been distributed in affected communities as funding has allowed, with increasing geographical coverage reaching all endemic communities by 2015. In 2016, 41 million treatments were distributed to 20.6 million people at an epidemiological coverage rate of 74% (where the minimum coverage rate is 65%). Recently, programmatic and independent disease monitoring have recorded reduction in prevalence levels of LF. The reduction has resulted in scaling down of MDA as more and more communities now live in transmission free zones. Re-mapping assessments in 2015 in 65 districts, indicated prevalence levels of below 1% circulating filarial antigen thus not warranting MDA. This brought the LF endemic district count down to 121 (out of 186). In 2017, via transmission assessment surveys (TAS), 74 districts recorded circulating filarial antigen levels below 1% among children 6-7 years age, thus meeting the criteria for stopping LF MDA. It is the remaining 47 districts which are still conducting MDA that pose a challenge in reaching elimination targets. Most of these districts are along the Indian Ocean coast where the vector is abundant and mapping/baseline circulating filarial antigen (CFA) levels ranged from 7.5% to 74%. Routine disease monitoring in these districts has indicated declining trends of CFA levels, but not to a level where MDA can be stopped. For instance in Mafia district, LF prevalence levels have decreased from 49% at mapping/baseline to 4% after 11 treatment rounds. Additional treatment rounds as well as alternative strategies might be required to achieve the 2020 elimination targets in Tanzania.

## 1809

**EPIDEMIOLOGY OF FILARIASIS IN ZAIRE PROVINCE, ANGOLA**Célio C. Njinga<sup>1</sup>, Filipa Vaz<sup>1</sup>, Rossely C. Paulo<sup>2</sup>, Pedro Van Dunem<sup>3</sup>, Miguel Brito<sup>4</sup><sup>1</sup>CISA, Luanda, Angola, <sup>2</sup>Liverpool School of Tropical Medicine/CISA, Luanda and Liverpool, Angola, <sup>3</sup>National Coordinator at Public Health Department, Luanda, Angola, <sup>4</sup>Lisbon School of Health Technology, Lisbon, Portugal

Filariasis are known to be endemic in Angola and contributes to outpatient morbidity and mortality of the country with over 12 million people at risk of infection. As so, little is known about the geographical distribution and co-endemicity of three filarial parasites such as *Onchocerca volvulus*, *Wuchereria bancrofti*, and *Loa loa*. Hence, it is important to understand the distribution in co-endemic areas with multiple species of Filariasis with the assess of the prevalence of lymphatic filariasis (LF), onchocerciasis

and loiasis. The 6 municipalities of Zaire were surveyed and 7 communes were selected based on the geographical location-river proximity and swampy areas of plantation or forest. The random sampled respondents were interviewed using the Rapid assessment procedure (RAPLOA) for *Loa loa* and the Rapid Epidemiological Mapping of onchocerciasis (REMO) surveys to assess LF clinical signs (hydrocele and/or Lymphedema). A total of 157 respondents took part in the survey. The nested Polymerase Chain Reaction (PCR), followed by electrophoresis and visualization with staining with ethidium bromide was performed to detect *Loa loa* infection. For *Wuchereria bancrofti* (LF), Real-Time PCR with specific Taqman probes, Dried Blood Spot (DBS) samples was used. In addition, for each subject an onchocerciasis rapid test and dried blood spot (DBS) was performed between 8 a.m. - 3 p.m. The results of molecular testing were combined with conventional epidemiological approaches to determine the spatial-temporal distribution of loiasis and population-level risk factors for reported diseases. Moreover, the nested PCR assay showed 0% prevalence for loiasis. Still, the prevalence for LF is also found to be 0%, according to the Real-Time PCR. Conversely, with the rapid tests for onchocerciasis infection, it was found that males have higher prevalence (6.3%) compared to females (3.8%). The molecular biology did not find co-endemicity but it provided insights for the importance for innovative approaches and alternative strategies for filarial infections required for the elimination targets established by the World Health Organization.

## 1810

### THERAPEUTIC POTENTIAL OF *WITHANIA SOMNIFERA* IN FILARIAL INDUCED SECONDARY LYMPHEDEMA

Anand Setty Balakrishnan<sup>1</sup>, Ramaswamy Kalyanasundaram<sup>2</sup>, Abel Arul Nathan<sup>1</sup>

<sup>1</sup>Madurai Kamaraj University, Madurai, India, <sup>2</sup>University of Illinois Rockford, Rockford, IL, United States

Lymphatic filariasis is a major parasitic disease caused by nematodes *Brugia malayi* and *Wuchereria bancrofti*. Our present study aimed at evaluating the bacterial killing, free radical scavenging and cytokine inhibiting potential of thymol derived from *Trachyspermum ammi*. Thymol shows a clear zone of inhibition against *Bacillus cereus* and *Staphylococcus epidermidis* associated with filarial lymphedema. Further, thymol scavenges the DPPH and Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) free radicals at a dose dependent manner, indicating its inherent anti-oxidant property. In-vitro lymphangiogenic activity of thymol was evaluated by 2D matrigel and Nitric Oxide (NO) production in human endothelial cells in response to TNF- $\alpha$  (10ng/ml). These studies showed that thymol favours the formation of the tubular network and interestingly the NO production is elevated with increasing concentrations of thymol. Bacterial Infection Assay and Viable cell count analysis were carried out to evaluate the internalization of bacteria into the host cells and the viability of host cells after infection respectively. RT-PCR analysis and Confocal Imaging studies are under progress.

## 1811

### BARRIERS TO CONTROL AND ELIMINATE LYMPHATIC FILARIASIS IN ZANZIBAR: TACKLING THE REALITY OF THE MASS DRUG ADMINISTRATION PROGRAM

Vanessa Laveglia<sup>1</sup>, Fatma Mohd<sup>2</sup>, Khalfan Mohammed<sup>2</sup>, Saleh Juma<sup>2</sup>, Hayley E. Mableson<sup>1</sup>, Hannah Betts<sup>1</sup>, Louise A. Kelly-Hope<sup>1</sup>

<sup>1</sup>Centre for Neglected Tropical Diseases, Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Ministry of Health and Social Welfare, Zanzibar, United Republic of Tanzania

In 2001, Zanzibar started the mass drug administration (MDA) programme as part of Global Programme to Eliminate Lymphatic Filariasis (LF). The programme stopped MDA in 2006 after showing a significant reduction in prevalence, however, in 2012 the Transmission Assessment Survey

(TAS) highlighted areas of ongoing transmission. This resulted in a further two MDA rounds, which recorded low coverage rates in some areas that geographically overlapped with areas of ongoing transmission. The island of Unguja had low transmission/high MDA coverage, whereas Pemba Island had high transmission/low MDA coverage. This study aimed to identify the barriers in achieving LF elimination by comparing the contrasting areas between islands; specifically, i) health care workers' knowledge, attitudes, practices and challenges during MDA, ii) community members' perceptions of LF and MDA participation. Cross-sectional surveys, interviews and focus group discussions (FGD) were conducted. The community drug distributor (CDD) surveys indicated that participants in Pemba were less satisfied with the training and MDA campaigns. CDDs returning to partially empty households was significantly less frequent in Pemba ( $p=0.053$ ), and was correlated to the number of years working on MDA campaigns. The FGD highlighted inadequate training and poor salaries as challenges for CDDs. Community member surveys found that reasons for non-compliance included lack of information and poor awareness. Community members also reported that direct observation of drug intake was significantly lower in Pemba ( $p=0.004$ ), which correlated with what the CDDs reported ( $p=0.001$ ). Factors related to low coverage and low compliance geographically coincided in northern Pemba where evidence of ongoing transmission was found during TAS. In order for the LF programme to move forward and achieve elimination, selected problem areas need to be provided with specific CDD training on MDA 'best practice', increasing motivation and monitoring drug consumption, together with improved community awareness of the disease and benefits of the medication.

## 1812

### COMPARISON OF THE *IN VITRO* SUSCEPTIBILITY TO EMODEPSIDE OF MICROFILARIAE, THIRD STAGE LARVAE AND ADULT WORMS OF RELATED FILARIAL NEMATODES

Daniel Kulke<sup>1</sup>, Simon Townson<sup>2</sup>, Dominique Bloemker<sup>3</sup>, Stefan Frohberger<sup>3</sup>, Sabine Specht<sup>3</sup>, Ivan Scandale<sup>4</sup>, Martin Glenschek-Sieberth<sup>5</sup>, Achim Harder<sup>6</sup>, Achim Hoerauf<sup>3</sup>, Marc P. Hübner<sup>3</sup>

<sup>1</sup>Bayer Animal Health, Monheim, Germany, <sup>2</sup>Northwick Park Institute for Medical Research, London, United Kingdom, <sup>3</sup>University Hospital of Bonn, Bonn, Germany, <sup>4</sup>Drugs for Neglected Diseases initiative, Geneva, Switzerland, <sup>5</sup>Bayer AG, Wuppertal, Germany, <sup>6</sup>WE Biology, Heinrich-Heine-Universität, Düsseldorf, Germany

Current efforts to eliminate onchocerciasis are hampered by the lack of a drug that can be used for mass drug administration and either has macrofilaricidal efficacy or leads to a permanent sterilization of female adult worms. Emodepside has been shown to have a broad spectrum efficacy against gastrointestinal nematodes and is approved for use in veterinary dewormers for cats and dogs. Emodepside is under evaluation as an adulticide treatment of human onchocerciasis by a joint collaboration with academia, DNDi and Bayer. Therefore, the *in vitro* potency of emodepside against a range of filarial life-cycle stages and filarial species was compared. In general, emodepside was capable of reducing the motility of adult filariae, third-stage larvae and/or microfilariae of *Onchocerca gutturosa*, *Onchocerca lienalis*, *Brugia pahangi*, *Litomosoides sigmodontis*, *Dirofilaria immitis*, and *Acanthocheilonema viteae* in a concentration-dependent manner. Emodepside had a broad *in vitro* activity against the microfilarial stage of related filarial species, although differences in the susceptibility were detected (*A. viteae* > *D. immitis* > *L. sigmodontis* > *O. lienalis*). Similarly, infectious L3 larvae of *D. immitis* had an increased emodepside susceptibility compared to *L. sigmodontis*. With regard to adult worms, emodepside failed to completely inhibit motility of *B. pahangi* adults at concentrations up to 12.5  $\mu$ M, whereas *L. sigmodontis* adult female worms and *O. gutturosa* adult male worms were completely paralyzed by low to sub  $\mu$ M emodepside concentrations. Those results demonstrate that emodepside has a broad range of activity against the microfilarial, L3 and adult worm stage of related filarial species. Based on these findings, emodepside is validated as promising candidate for treatment of human onchocerciasis.

## INVESTIGATION INTO THE EFFECT OF HOST MIGRATION ON THE TRANSMISSION OF *ONCHOCERCA VOLVULUS* USING A PATCH MODEL

Karen McCulloch<sup>1</sup>, James McCaw<sup>2</sup>, Jodie McVernon<sup>3</sup>, Shannon M. Hedtke<sup>4</sup>, Martin Walker<sup>5</sup>, Philip Milton<sup>6</sup>, Maria-Gloria Basáñez<sup>6</sup>, Warwick Grant<sup>4</sup>

<sup>1</sup>La Trobe University and University of Melbourne, Melbourne, Australia, <sup>2</sup>School of Mathematics and Statistics, University of Melbourne, Melbourne, Australia, <sup>3</sup>The Peter Doherty Institute for Infection and Immunity, University of Melbourne and Royal Melbourne Hospital, Melbourne, Australia, <sup>4</sup>Department of Animal, Plant and Soil Sciences, AgriBio, La Trobe University, Bundoora, Australia, <sup>5</sup>Royal Veterinary College and London Centre for Neglected Tropical Disease Research, Hatfield, United Kingdom, <sup>6</sup>Imperial College London and London Centre for Neglected Tropical Disease Research, London, United Kingdom

Despite the elimination of onchocerciasis in some regions, infection remains endemic in many African countries despite decades of concerted control efforts such as large-scale mass drug administration (MDA) of ivermectin. Furthermore, there is documented evidence of *Onchocerca volvulus* recrudescence in populations of Burkina Faso; ongoing transmission in Senegalese foci in which the infection was deemed to have been eliminated, and rapid reappearance of skin microfilariae following ivermectin treatment in Ghana. Resurgence could be due to (and difficult to distinguish from): i) premature cessation of control efforts (affected by the duration and/or coverage of MDA) particularly in areas with high vector biting rates; ii) re-introduction of infection from neighbouring foci (via vectors or infected persons), or iii) possible emergence of sub-optimal ivermectin responses. Two mathematical models for onchocerciasis transmission and control (EPIONCHO and ONCHOSIM) have been used extensively to evaluate the feasibility of eliminating onchocerciasis under a variety of scenarios, but both models consider transmission within single, isolated populations. It is however clear from geostatistical modelling that infection prevalence (and intensity) is unevenly distributed and that transmission should be considered as a spatial mosaic of infection "patches". By extending the population-based version of EPIONCHO into a spatial model framework, we investigate the effect of parasite migration (via vectors or humans) on *O. volvulus* transmission between neighbouring patches or regions. Results from different scenarios will be discussed based on varying the coupling strength (rate of migration) between two regions with different levels of endemicity (hypo-, meso-, or hyperendemic). Our work provides further insight into the underlying driving factors that may contribute to the sustained transmission of *O. volvulus* in areas where ivermectin MDA has been unsuccessful, particularly regarding decisions on cessation of treatment where elimination may have been achieved on one "patch" but persists in a neighbouring "patch".

## FOLLOWING 11 ROUNDS OF IVERMECTIN DISTRIBUTION, HOW CLOSE IS INTERRUPTION OF ONCHOCERCIASIS TRANSMISSION IN THE TUNDURU FOCUS IN TANZANIA?

Oscar Kaitaba<sup>1</sup>, Andreas Nshala<sup>2</sup>, Maria Chikawe<sup>1</sup>, Cecilia Uisso<sup>1</sup>, Boniphace Idindili<sup>2</sup>, Sarah Craciunoiu<sup>3</sup>, Delali Bonuedi<sup>4</sup>, Kathryn Crowley<sup>4</sup>, Darin Evans<sup>5</sup>, William Kisoka<sup>6</sup>, Mathias Kamugisha<sup>6</sup>, Upendo Mwingira<sup>1</sup>

<sup>1</sup>Tanzania NTD Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>IMA World Health, Washington, DC, United States, <sup>4</sup>RTI International, Washington, DC, United States, <sup>5</sup>U.S. Agency for International Development, Washington, DC, United States, <sup>6</sup>National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

In Tanzania, over 6 million people are at risk of infection with onchocerciasis (OV), a parasitic filarial infection caused by *Onchocerca*

*volvulus*. The disease is spread by black flies, in poor rural communities, that breed in fast flowing rivers and streams. Control efforts, focusing on annual ivermectin preventive chemotherapy started in the 1990s. The Tunduru OV transmission focus, comprised of 1 district with 330,942 people, has received 11 rounds of ivermectin plus albendazole treatment due to co-endemicity with lymphatic filariasis (LF). In 2015, LF transmission was declared interrupted but ivermectin treatments for OV continued with sufficient coverage. A cross-sectional assessment of the prevalence of antibodies to OV16 protein of *Onchocerca volvulus* was conducted in December 2016 using OV16 RDT. The Tanzania Neglected Tropical Disease Control Program (TZNTDCP) purposively sampled 10 villages representative of the hypo-, meso- and hyperendemic transmission zones. In each of the selected villages, systematic sampling was used to select households where all consenting residents, over 5 years were tested for antibodies to the OV16 protein using the OV16 rapid diagnostic tests. A total of 2,732 individuals were tested (560 below 10 years of age) and only 11 (0.4%) had positive results. All positive individuals were above 15 years old. Reactivity rates increased with age. At 50 years and over, OV16 antibody prevalence was at 1.53% (95CI 0.6-2.53). Results from this assessment provide a clear signal that new transmission could have been halted. These findings are in line with the results from the APOC phase 1a epidemiological evaluation carried out in 2013 after seven rounds of treatment that indicated 0% *Onchocerca volvulus* microfilaridemia in the general population aged 5 years and above. With no phase 1b or entomological study done in the past, this rapid assessment provided useful insight. A full epidemiological and entomological evaluation is now warranted to evaluate interruption of transmission in line with WHO guidelines.

## DEMONSTRATED CAPACITY BUILDING OF LOCAL SURGEONS TO PERFORM HYDROCELECTOMY IN REMOTE HOSPITALS IN TANZANIA

Maria Chikawe<sup>1</sup>, Larry Akoko<sup>2</sup>, Ally Mwangi<sup>2</sup>, Naomi Makota<sup>3</sup>, Boniphace Idindili<sup>4</sup>, Andreas Nshala<sup>4</sup>, Upendo Mwingira<sup>1</sup>

<sup>1</sup>Tanzania NTD Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Muhimbili University Of Health And Allied Sciences, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Statoil, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania

In Tanzania, lymphatic filariasis (LF) affects millions of people leading to a high burden among men of LF associated hydrocele; a fluid-filled enlargement of the tunica vaginalis sac around the testes. The economic, physical, and psychosocial impact of hydrocele can be devastating not only for the individual, but also for the family and community. In the Lindi and Mtwara regions alone, hydrocele backlog was estimated at 6000 men awaiting hydrocele surgery in 2014. Some hospitals perform routine hydrocelectomy but for only a few patients compared to the backlog. Typically surgeons use sac eversion technique under spinal or general anesthesia which requires lengthy hospital stays. In 2014, the Tanzania NTD Control Program (TZNTDCP) with support from partner NGOs and international donors introduced a safer technique and built capacity of local surgical teams. In 2015 and 2016, the TZNTDCP carried out surgeries in 3 districts in Mtwara and Lindi regions including patients who had hydrocele with no signs of scrotal skin involvement, no need for scrotoplasty, and an absence of medical comorbidities that could affect surgery. Two consultant surgeons trained 16 district level surgeons to perform the surgeries. All surgeries were done under local anesthesia; only in few cases was ketamine added for hernioraphy. The technique included: median raphe incision; draining of hydrocele fluid; its volume, and report on color; report on state of testes, sac and epididymis; partial excision and hemostatic vicryl 2/0 sutures; layered closure of hemiscrota; and subcuticular skin closure using catgut 3/0. Scrotal support was applied and patients had one night stay post operation with follow up after two weeks. A total of 1641 patients received surgery (age range 10 – 99 years). In only 1.9% of the patients, the hydrocele fluid color contained

necrotic tissue, blood, or pus. In conclusion, the new technique of partial sac excision under local anesthesia was easily adapted by local surgical teams through pre-camp training, demonstration, direct observation and consistent support and mentorship.

## 1816

### MULTIPLE PATHS TOWARDS LOSS OF DRUG SENSITIVITY: WHOLE-GENOME SEQUENCING OF *ONCHOCERCA VOLVULUS* INDICATES GENES UNDER SELECTION ARE DEPENDENT ON TRANSMISSION ZONE

Shannon M. Hedtke<sup>1</sup>, Stephen R. Doyle<sup>2</sup>, Samuel Armoo<sup>3</sup>, Mike Y. Osei-Atweneboana<sup>3</sup>, Annette C. Kuesel<sup>4</sup>, Warwick N. Grant<sup>1</sup>

<sup>1</sup>La Trobe University, Bundoora, Australia, <sup>2</sup>Wellcome Trust Sanger Institute, Cambridge, United Kingdom, <sup>3</sup>Council for Scientific and Industrial Research, Accra, Ghana, <sup>4</sup>UNICEF/UNDP/World Bank/World Health Organization Special Programme for Research and Training in Tropical Diseases, World Health Organization, Geneva, Switzerland

Onchocerciasis is a disease caused by the filarial nematode *Onchocerca volvulus*, targeted for elimination in many of the 31 African countries in which it is endemic. The drug deployed for mass treatment and elimination is ivermectin, which kills microfilariae and suppresses adult female fertility. In several African communities, a sub-optimal response to ivermectin has been observed. Our goal is to identify genetic markers associated with variation in drug response which control programmes could use to monitor presence and change in frequency of sub-optimal responders. We have scored female worms from Ghana for variation in drug response based on uterine embryograms. Whole-genome sequencing identified windows that are genetically differentiated between good and poor responders to ivermectin. Ivermectin response in *O. volvulus* involves multiple genes, with contributions from changes in both protein sequence and expression likely. However, the genetic variants that are associated with variation in drug response differ among populations, highlighting the importance of defining transmission boundaries when determining the possible effects of any genetic association. We discuss strategies for using these markers to screen African communities for *O. volvulus* with sub-optimal response to ivermectin and define transmission zones.

## 1817

### COMPARISON OF WET MOUNT MICROSCOPY, MINI-FLOTAC AND PCR FOR THE DIAGNOSIS OF *ASCARIS LUMBRICOIDES*

Frank P. Mockenhaupt<sup>1</sup>, Kira Fraundorfer<sup>2</sup>, Jean Claude Mugisha<sup>3</sup>, Prabhanjan P. Gai<sup>1</sup>, Kevin C. Siff<sup>1</sup>, Dominik Geus<sup>1</sup>, Felix Habarugira<sup>3</sup>, Claude Bayingana<sup>3</sup>, Jules Ndoli<sup>3</sup>, Augustin Sendegeya<sup>3</sup>, Jürgen Krücken<sup>2</sup>, Jean Bosco Gahutu<sup>3</sup>, Georg von Samson-Himmelstjerna<sup>2</sup>

<sup>1</sup>Charité-Universitätsmedizin Berlin, Berlin, Germany, <sup>2</sup>Freie Universität Berlin, Berlin, Germany, <sup>3</sup>University Teaching Hospital of Butare, University of Rwanda, Butare, Rwanda

Single wet mount microscopy of stool samples is the usual tool for the diagnosis of soil-transmitted helminths in many resource-limited areas. However, sensitivity is imperfect. Mini-FLOTAC is a rather novel, low-cost method, which does not require extensive equipment, and PCR assays presumably show highest sensitivity. The clinical significance of additional infections detected by these more advanced techniques is, however, not well established. In an area of predominant *Ascaris lumbricoides* infection in southern highland Rwanda, stool samples from 845 schoolchildren were examined for this helminth in a blinded fashion by wet mount microscopy, mini-FLOTAC, and PCR. The prevalence of *A. lumbricoides* infection detected by wet mount microscopy, mini-FLOTAC and PCR was 25%, 32%, and 37%, respectively. Agreement was moderate for wet mount microscopy and mini-FLOTAC or PCR, and good for mini-FLOTAC and PCR. Setting *A. lumbricoides* detected by any of the three methods as reference, the sensitivities (and 95% confidence intervals) of wet mount microscopy, mini-FLOTAC, and PCR were 56.4% (51.3-61.4), 71.9% (67.1-76.3), and

81.9% (77.6-85.6), respectively. *A. lumbricoides* infections diagnosed by mini-FLOTAC but not by wet mount microscopy showed clear associations with clinical manifestation whereas this was hardly the case for infections detected by PCR exclusively. Wet mount microscopy missed almost half of the *A. lumbricoides* infections actually present. Mini-FLOTAC showed superior sensitivity including otherwise missed, clinically relevant infections while PCR had highest sensitivity. These findings argue for the extended use of mini-FLOTAC in patient management in endemic regions and for the application of PCR in assessing actual prevalence and epidemiology.

## 1818

### INSIGHTS FROM MATHEMATICAL MODELS OF SOIL TRANSMITTED HELMINTH (STH) TRANSMISSION INTO POLICY FOR THEIR CONTROL AND ELIMINATION BY MASS DRUG ADMINISTRATION (MDA)

Sam Farrell<sup>1</sup>, Luc Coffeng<sup>2</sup>, James Truscott<sup>1</sup>, Sake de Vlas<sup>2</sup>, Roy Anderson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Erasmus Medical Center, Rotterdam, Netherlands

The soil transmitted helminths (STH) include three important gut nematode parasites; the round worm *Ascaris lumbricoides*, the hookworms (*Ancylostoma duodenale* and *Necator americanus*) and the whip worm *Trichuris trichiura*. There is a requirement for well-validated policy recommendations on strategies for control and elimination of these diseases. We discuss the contributions modelling work can make in this area and set these findings in the context of prior modelling work. Examining current treatment strategies based on prevalence monitoring, we evaluate the likely impact of WHO recommendations on communities in a range of transmission settings across the three diseases. Following this up we propose new guidelines improving the chances of achieving target outcomes particularly on medium and heavy infection burdens and with a view toward elimination where appropriate, and demonstrate the impact of the guideline recommendations.

## 1819

### EFFICACY OF ANTHELMINTHIC DRUGS AND DRUG COMBINATIONS AGAINST SOIL-TRANSMITTED HELMINTHS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Naomi Clarke<sup>1</sup>, Suhail A. Doi<sup>2</sup>, Kinley Wangdi<sup>1</sup>, Yingxi Chen<sup>1</sup>, Archie C. Clements<sup>1</sup>, Susana Vaz Nery<sup>1</sup>

<sup>1</sup>Australian National University, Canberra, Australia, <sup>2</sup>Qatar University, Doha, Qatar

The mainstay of soil-transmitted helminth (STH) control is regular distribution of benzimidazole anthelmintics through mass drug administration campaigns, which have seen a dramatic global scale-up in the past five years. Benzimidazoles, particularly albendazole, have high efficacy against *Ascaris lumbricoides* and hookworm; however, efficacy against *Trichuris trichiura* is poor and control of this parasite remains a significant challenge. Given the commitment of the WHO and endemic countries implementing deworming programs and of pharmaceutical companies donating drugs, it is important to reflect on whether we are currently using the most adequate drug regimen. Previous meta-analyses of anthelmintic efficacy have been limited to placebo-controlled studies and a small number of standard anthelmintic drugs. In order to allow examination of a broader evidence space, we conducted a network meta-analysis to compare the efficacy of a wide variety of both standard and novel anthelmintic drugs. Studies reporting efficacy of individual drugs or drug combinations against STH were systematically identified. Analysis involved comparing available drug efficacy data to standard treatment (single-dose albendazole), using an automated generalized pairwise modeling framework for network meta-analysis to generate mixed treatment effects against a common comparator. Preliminary results from the analysis of 102 included studies showed that for *A. lumbricoides* and

hookworm, single-dose albendazole was equally or more efficacious than other drugs and drug combinations. However, for *T. trichiura*, several drug combinations - albendazole plus ivermectin, mebendazole plus ivermectin, and albendazole plus oxfantel pamoate - were significantly more efficacious than single-dose albendazole. These results suggest that combining benzimidazole drugs with other anthelmintics is a promising strategy that may represent a feasible alternative in areas where *T. trichiura* is prevalent. Use of drug combinations may also decrease the likelihood of emerging drug resistance, although economic implications must also be considered.

## 1820

### SEASONAL INFLUENCERS FOR ASCARIS TRANSMISSION: WHAT COULD THEY MEAN FOR PUBLIC HEALTH PROGRAMS AND THE 2020 GOALS?

Emma L. Davis, Deirdre Hollingsworth

University of Warwick, Coventry, United Kingdom

*Ascaris* eggs are exposed to the environment during maturation, leaving them at the mercy of the seasons. There is clear empirical evidence that temperature can influence egg development, but rainfall and moisture availability are also important contributing factors to parasite survival and transmission. Previous studies suggest that in temperate climates there will be sufficient moisture in the feces and surrounding soil, but settings with extremely high temperatures and low rainfall will see retarded development and viability. Rainfall is also associated with greater sequestration of eggs through the soil and studies have shown that soil samples during rainy seasons often produce the highest yield of viable ova. Settings with extreme fluctuations in rainfall or temperature will hence exhibit strong seasonal transmission patterns that may be partially masked by the longevity of *Ascaris* infections. With the 2020 goals, laid out in the World Health Organization neglected tropical disease roadmap, calling for a scale up in control and hundreds of millions of doses donated, there is a need to maximise their impact by assessing potential obstacles and limitations of current programs. Incorporating rainfall into a previous model that used temperature to predict optimal timing of mass drug administration (MDA) for temperate climates allows for a more generalizable template for a wide range of settings. This is then used to demonstrate how seasonally timed MDA could increase the probability of meeting WHO targets in Africa and make comparisons between best and worst case scenarios. Bi-annual MDA instead of annual MDA results in a less marked seasonal effect, with a higher chance of elimination, but timing of treatment can still impact the predicted outcome and could be important for onward surveillance as well as elimination.

## 1821

### INTESTINAL POLYPARASITISM IN PAMPA DEL INDI, CHACO PROVINCE, ARGENTINA

Maria V. Periago<sup>1</sup>, Cintia Delgado<sup>1</sup>, Sergio Wasilewsky<sup>1</sup>, Marta Cabrera<sup>2</sup>

<sup>1</sup>Fundación Mundo Sano, Buenos Aires, Argentina, <sup>2</sup>Instituto Nacional de Enfermedades Infecciosas, Administración Nacional de Laboratorios e Institutos de Salud "Dr. Carlos G. Malbrán", Buenos Aires, Argentina

The prevalence on intestinal parasites in Argentina is largely unknown and available data is from a restricted number of research studies that have been conducted in different localities depending on the interest of each research team or according to institutional affiliation. Few data from the Province of Chaco has been publicly available and therefore this study was conducted in the locality of Pampa del Indio, Department of General San Martín where Mundo Sano has a regional office and a long standing collaboration with the local hospital. Since there is no record of prevalence for either STHs or other intestinal parasites in this area, the aim of this study was to determine the prevalence of intestinal parasites in a community from a peri-urban neighborhood of Pampa del Indio. Parque Industrial is composed of 22 blocks and at least five houses from each block were randomly selected for participation, a total of 109 houses

were visited and 528 containers distributed for the collection of stool samples. A total of 315 samples (59.7% participation) were received for coprological analysis through sedimentation and flotation techniques. Houses were georeferenced and a questionnaire with socioeconomic and housing characteristics was filled out. Age of participants ranged from 1 to 76 years old (mean = 19) and 57.1% of them were female. Many of the individuals, concretely 11.1% were polyparasitized and 25.4% were infected with parasites of waterborne transmission. The most prevalent parasite was *Giardia lamblia* (12.7%) and the only STH found was *Strongyloides stercoralis* with a prevalence of 2.5%.

Human strongyloidiasis has assumed great importance in public health, in the context of neglected diseases of Brazil and worldwide. It is known that the rodent species, *Strongyloides venezuelensis*, has been used for the development of molecular and serological diagnostic methods of human strongyloidiasis. The present study aims to identify the differential proteome found in the membrane fraction from filariform larvae (L3) and adult female of *S. venezuelensis*. Larvae L3 were obtained from charcoal culture of feces of experimentally infected *Rattus norvegicus* and adult females recovered from the infected intestines. Firstly, a Tris HCl soluble supernatant were prepared after homogenization of the larvae and female parasites. Membrane fractions from both stages were obtained by centrifugation of the recovered homogenates. After digestion with trypsin, the recovered peptides from both fractions were analyzed by mass spectrometry using an Ultimate 3000 UHPLC in line with a Q Exactive mass spectrometer. Protein identification was performed using the Proteome Discoverer platform using the *Strongyloides ratti* database as a reference proteome. The differential proteomic analysis revealed the majority of proteins upregulated in the female involved in biogenesis of ribosomes, translation machinery, protein phosphorylation and transport across membranes. In contrast, in the L3 larvae stage, proteins related to motor activity and ATP binding were among the most upregulated molecules. Our preliminary data revealed a membrane proteome associated to a high metabolic state in the female whilst the major processes operating in the active migrating larvae are intimately associated to muscle activity. We believe this differential membrane proteome of *S. venezuelensis* can contribute to the elucidation of proteins involved in the parasite-host relationship and direct new studies aimed at the identification of diagnostic targets. Financial Support: FAPESP (2016/06185-0)

## 1823

### DIAGNOSIS OF *ASCARIS LUMBRICOIDES* INFECTIONS IN ETHIOPIAN CHILDREN AND ADULTS BY THREE COPROLOGICAL TECHNIQUES AND TWO NOVEL SEROLOGICAL TESTS

Daniel Dana<sup>1</sup>, Johnny Vlaminc<sup>2</sup>, Mio Ayana<sup>1</sup>, Zeleke Mekonnen<sup>1</sup>, Peter Geldhof<sup>2</sup>, Bruno Levecke<sup>2</sup>

<sup>1</sup>Jimma University, Jimma, Ethiopia, <sup>2</sup>Ghent University, Merelbeke, Belgium

The nematode parasite *Ascaris lumbricoides* is estimated to infect over 800 million people and is considered to be an important neglected tropical disease pathogen. Ascariasis has a substantial impact on public health with routine diagnosis still relying on the detection of eggs in stool. This technique has important limitations in terms of both application and interpretation. Recently, two different ELISA tests were developed in our lab to measure exposure to *Ascaris* infection. In this study, we aim to compare established coprological techniques with these novel serological tests for the detection of *Ascaris* infection and exposure. Stool and serum samples were collected from 600 children and 600 adults from Jimma town in the Western part of Ethiopia. In addition, dried blood spots (DBS) were also collected from 95 individuals. Parasite eggs in each of the stool samples were detected by Kato-Katz, McMaster and Mini-FLOTAC. The collected sera and DBS samples were evaluated for anti-*Ascaris* IgG4 antibody levels using two serological tests. The first ELISA detects antibodies against purified adult *A. suum* haemoglobin (AsHb), while the second detects antibodies directed against an extract of the lung stage larvae of *A. suum* (As-Lung-L3). When the results of all three coprological techniques were combined, a total of 35.2% of children had *Ascaris* eggs in their stool. The highest percentage of infected children were detected by Kato-Katz (31.5%) followed by the Mini-FLOTAC (26.3%) and McMaster (23.7%) technique. Using serology, 24.3% of the children were seropositive on the AsHb ELISA whereas double the amount (48.3%) were positive on the As-Lung-L3 ELISA. No correlations were found between eggs per gram and antibody response. Currently, collection of samples from the adult population and evaluation of DBS samples is still ongoing. All data is expected by this summer and will also be presented in detail. Serology using the As-Lung-L3 ELISA was able to detect a much higher percentage of individuals exposed to ascariasis than when traditional coprology is used. Serology could be a useful tool during certain stages of control programs.

Spring, MD, United States, <sup>9</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Helminth infections can negatively impact vaccination outcomes. Additionally, infants born to mothers that are helminth-infected during pregnancy show reduced vaccine take and responsiveness. Data on prevalence of soil-transmitted helminth infections (STH) in Equatorial Guinea in all age groups are limited. We are currently conducting a randomized, double-blind placebo controlled trial to evaluate the safety, tolerability, and immunogenicity of a whole sporozoite PfSPZ candidate vaccine (PfSPZ Vaccine) in 135 healthy Equatoguineans within an age range of 6 months to 65 years. Since ongoing STH infection was an exclusion criteria for trial participation, stool samples were collected from more than 250 potential volunteers during screening. Stool samples were analyzed using the Kato-Katz technique to identify type of helminth infection and to quantify parasite burden. STH-positive individuals were treated with oral mebendazole and repeat stool samples were analyzed to assess treatment success. We will report on the prevalence of *Ascaris lumbricoides* and *Trichuris trichiura* in our volunteers stratified by age groups and the potential impact of recent STH infection on PfSPZ Vaccine immunogenicity.

### DETECTION OF SOIL TRANSMITTED HELMINTH DNA IN STOOL SAMPLES DRIED ON FILTER PAPER

Kerstin Fischer<sup>1</sup>, Lincoln Gankpala<sup>2</sup>, Kurt C. Curtis<sup>1</sup>, Peter U. Fischer<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>Liberian Institute for Biomedical Research, Charlesville, Liberia

In order to facilitate integrated assessment of helminth control and elimination programs better methods of the detection of soil transmitted helminthes (STH) are needed. To improve sample preservation and archiving of stool samples for PCR detection of STH we selected 103 STH positive stool samples collected in rural Liberia. Duplicate Kato Katz smears were performed on fresh samples and equal aliquots were preserved in RNA later (-20C) and dried on FTA cards (room temperature, RT). Kato Katz detected 31 hookworm, 95 *Ascaris*, and 30 *Trichuris* positive samples. qPCR revealed more positive samples for RNA later and FTA card preserved samples: 34 and 56 for *Necator*, 97 and 99 for *Ascaris* and 30 and 45 for *Trichuris*. To examine whether storage duration of FTA cards affects the results of DNA extraction and qPCR, we compared qPCR results from another set of 69 samples that was extracted and tested directly after collection in 2014 and another aliquot was extracted and tested 36 months later. Similar results were obtained for both time points for *Necator* (46 vs 49), for *Ascaris* (22 vs 21), for *Trichuris* (15 vs 15) and for *S. mansoni* (39 vs 43). The average Ct value for positive samples was also very similar at both time times. Our results confirmed other studies that show that qPCR is more sensitive than the traditional Kato Katz smear for the detection of for STH infection. Furthermore, the results show that the preservation of dried stool samples on FTA cards provides suitable templates for qPCR analysis and samples can be stored at RT for at least 36 months without significant degradation of target DNA. The novel storage protocol for stool samples may facilitate assessment of STH by qPCR during integrated assessment of helminth infections.

### TESTING FOR STH ELIMINATION: MODELLING THE IMPACT OF DIFFERENT DIAGNOSTICS TOOLS

James Truscott, Marleen Werkman, James Wright, Roy Anderson  
Imperial College London, London, United Kingdom

Technological advances and falling costs are making new diagnostic tools available for field use, offering improved sensitivity and specificity. For the soil-transmitted helminth diseases, this includes the use of PCR and qPCR techniques for egg detection in stool samples. Although new techniques offer greater accuracy at low disease prevalence levels, it is important to understand how they correspond statistically to the host's worm burden. Additionally, most monitoring and evaluation (and the WHO treatment guidelines based on them) are currently expressed in terms of prevalences and intensities as measured by the Kato-Katz egg counting method. A means of conversion between old and new diagnostic measures are necessary to ensure consistency and continuity. We attempt to answer these questions using a dataset comprising matching sets of Kato-Katz readings, qPCR readings and worm expulsions for each individual. We fit models of egg production and qPCR reading per female worm. These allow us to compare the sensitivity and specificity of the two tests as prevalence measures against each other. We examine the relationship between light, medium and heavy infection categories under the two diagnostic approaches. We show how using qPCR rather than Kato-Katz affects the measured prevalence in a population as it approaches elimination and the thresholds used to detect it.

### COMPARISON OF KATO-KATZ, MINI-FLOTAC AND MULTI-PARALLEL REAL-TIME POLYMERASE CHAIN REACTION TECHNIQUES FOR DETECTION OF SOIL-TRANSMITTED HELMINTHS IN FEIRA DE SANTANA, BRAZIL

Ryan H. Avery<sup>1</sup>, Simone S. Oliveira<sup>2</sup>, Aristeu V. da Silva<sup>2</sup>, Rojelio A. Mejia<sup>3</sup>, Marta M. Silva<sup>4</sup>, Rebecca C. Christofferson<sup>1</sup>, Laura Rinaldi<sup>5</sup>, John B. Malone<sup>1</sup>

<sup>1</sup>Louisiana State University, Baton Rouge, LA, United States, <sup>2</sup>State University of Feira de Santana, Feira de Santana, Brazil, <sup>3</sup>Baylor College of Medicine, Houston, TX, United States, <sup>4</sup>Federal University of Bahia, Salvador, Brazil, <sup>5</sup>University of Naples Federico II, Naples, Italy

Soil-transmitted helminth (STH) infections, primarily caused by the roundworm *Ascaris lumbricoides*, the hookworm species *Necator americanus* and *Ancylostoma duodenale*, and the whipworm *Trichuris trichiura*, affect over 1 billion people, with billions more at risk, especially in warm, moist climates. Current STH control efforts in Brazil are conducted using passive surveillance and incidental case finding, such as by the Schistosomiasis Control Program, which is limited to schistosomiasis endemic areas, leaving STH infection prevalence under-notified. Diagnostic testing for the STH relies mainly on the World Health Organization (WHO) recommended Kato-Katz thick smear method, a quantitative technique that has been shown to lack sensitivity. Other economical, feasible, and higher-accuracy diagnostic methods are needed to detect and combat STH, especially in areas of low endemicity. In the city of Feira de Santana, Brazil, we collected human stool samples and analyzed them using the WHO recommended Kato-Katz thick smear method, as well as with two more recently developed diagnostic methods, the mini-FLOTAC method and a multi-parallel quantitative polymerase chain reaction (qPCR) method. The mini-FLOTAC method allows for quick analysis of fresh or preserved feces with minimal equipment needed. The qPCR method allows for detection and quantification of parasites with a high degree of specificity and sensitivity, and is optimized to allow for inexpensive analysis of each sample. All three diagnostic methods are being analyzed and compared for both parasite detection and quantification. Analysis of the qPCR samples is currently underway, and all comparative analyses will be complete by the conference. Both the mini-FLOTAC and qPCR methods offer feasible, higher-accuracy diagnostic alternatives to the standard Kato-Katz method, and will be useful in enabling a shift away from the current STH morbidity control approach and towards an elimination approach.

### NA-GST-1/ALHYDROGEL HOOKWORM VACCINE CO-ADMINISTERED WITH CPG 10104 IMPROVES IMMUNOGENICITY IN HEALTHY, HOOKWORM NAIVE ADULTS

David Diemert<sup>1</sup>, Maria Zumer<sup>1</sup>, Doreen Campbell<sup>1</sup>, Catherine Hatch<sup>1</sup>, Shannon Grahek<sup>1</sup>, Jill Brelford<sup>1</sup>, Anna Yakovleva<sup>1</sup>, Guangzhao Li<sup>1</sup>, Jin Peng<sup>1</sup>, Maria Elena Bottazzi<sup>2</sup>, Peter Hotez<sup>2</sup>, Jeffery Bethony<sup>1</sup>

<sup>1</sup>George Washington University, Washington, DC, United States, <sup>2</sup>Baylor College of Medicine, Houston, TX, United States

*Necator americanus* glutathione S-transferase-1 (Na-GST-1) is a 24-kDa protein produced by adult hookworms that is thought to play a role in detoxifying heme and other breakdown products of the hookworm blood digestion pathway. Recombinant Na-GST-1 was expressed in *Pichia pastoris* and formulated on Alhydrogel. A series of Phase 1 trials have been conducted in the USA, Brazil, and Gabon of Na-GST-1/Alhydrogel in combination with an aqueous formulation of glucopyranosyl lipid A, a synthetic Toll-like receptor (TLR)-4 agonist. In these studies, the vaccine was safe, well tolerated and induced anti-Na-GST-1 IgG antibodies; however, induced IgG did not significantly inhibit native GST enzymatic activity. To improve immunogenicity, Na-GST-1/Alhydrogel was tested

with or without the point-of-injection addition of CPG 10104, a synthetic oligodeoxynucleotide and TLR-9 agonist, in a Phase 1 trial in Washington, DC. Hookworm-naïve healthy adults (n=24) were vaccinated with 30 or 100 µg Na-GST-1 coadministered with 500 µg CPG 10104 (n=8 per dose), or 100 µg Na-GST-1/Alhydrogel (n=8). Subjects received 3 intramuscular injections at 2-month intervals. Common adverse events included mild to moderate injection site pain and tenderness, headache, and nausea. No significant differences were observed in adverse events between dose groups or formulations, although arthralgia and myalgia were more common in those receiving CPG 10104. Anti-Na-GST-1 IgG antibody levels as measured by indirect ELISA were detected in all subjects, with a peak 2 weeks after the 3rd vaccination. Geometric mean antibody levels at this time point were higher in the two groups that received CPG 10104 compared to the non-CPG group, although differences were not statistically significant: 49.4 Arbitrary Units (AU) for 100 µg Na-GST-1/Alhydrogel, 300.7 AU for 30 Na-GST-1/Alhydrogel/CPG (p=0.08 for comparison to non-CPG group), and 389.5 AU for Na-GST-1/Alhydrogel/CPG (p=0.067). Addition of CPG 10104 to Na-GST-1/Alhydrogel improves IgG responses but does not compromise safety. Further clinical testing of this vaccine formulation in endemic areas is justified.

1829

### EXPLORING CHAGAS DISEASE ECO-EPIDEMIOLOGY IN CENTRAL PANAMA

Erin Allmann Updyke, Brian F. Allan

University of Illinois Urbana Champaign, Urbana, IL, United States

Chagas disease, a neglected tropical disease affecting millions of people throughout the world, is transmitted by multiple species of triatomine “kissing bug” (Hemiptera: Reduviidae). In Panama, species that transmit the disease are sylvatic (ie: wild-living), and the risk factors that govern human transmission are not well characterized. This study investigates the factors potentially contributing to Chagas disease exposure risk across a human land-use gradient in central Panama. Epidemiological surveys and sixteen months of in-home kissing bug collection were performed in nine communities across three urban to rural land-use gradients. Household surveys explored social and behavioral factors, such as living conditions, education level, socioeconomic status, and knowledge of both kissing bugs and Chagas disease. Reported presence of domestic and wild animals around the home was positively correlated with having seen kissing bugs around the home and with greater average kissing bug capture during the study. Entomological surveys captured five common species of kissing bug across the gradients, with a greater diversity of kissing bug species in more rural areas. Significantly more kissing bugs were captured on average in semi-urban and rural areas as compared to urban areas, and houses that kept chickens captured significantly more kissing bugs than houses without chickens. Preliminary testing has indicated presence of *Trypanosoma cruzi* in kissing bugs; further tests will reveal if infection prevalence differs across the land use gradient. Better understanding of these risk factors is integral to successful control efforts.

Institute of Allergy and Infectious Diseases, National Institute of Health, Bethesda, MD, United States

Visceral leishmaniasis (VL) is the most fatal form of leishmaniasis caused by protozoan parasite *Leishmania donovani* complex and transmitted between people by the bites of blood sucking vector sand fly *Phlebotomus argentipes*. An important factor influencing the transmission dynamics of disease is the unknown contribution of human host with different parasitemia to infected sand fly population. The aim of present study is to investigate the infectiousness profile of VL patients by xenodiagnosis during repeat exposure of colony reared sand flies. Direct xenodiagnosis was performed on 25 active VL patients using 10 male and 30 female pathogen free colonies of *P. argentipes* sand flies. After 60 hrs of post blood meal, fed sand flies were dissected and infections of sand flies were evaluated by microscopy. Repeat xenodiagnosis was performed at same site after 24hrs to investigate the effect of biting response on parasite transmission. We found varying sand fly feeding response (3-94%, Mean: 57.2%) with VL patients, and transmission of *L. donovani* to *P. argentipes* female sand flies was low (Mean: 30% of fed sand flies). No significant effects on transmission of parasites were seen during repeated xenodiagnosis. In conclusion, the study shows first time on human that VL patients harbored parasites in sufficient numbers to promote infections in vector sand flies.

### A LEISHMANIA SKIN TEST SURVEY OF CUTANEOUS LEISHMANIASIS IN THE HUMAN POPULATION OF DIEMA DISTRICT, WESTERN MALI

Bourama Traoré<sup>1</sup>, Oliveira Fabiano<sup>2</sup>, Ousmane Faye<sup>3</sup>, Cheick A. Coulibaly<sup>1</sup>, Adama Dicko<sup>3</sup>, Ibrahim M. Sissoko<sup>1</sup>, Sibiry Samake<sup>1</sup>, Nafomon Sogoba<sup>1</sup>, Pierre Traoré<sup>1</sup>, Sekou F. Traoré<sup>1</sup>, Jennifer M. Anderson<sup>2</sup>, Somita Keita<sup>3</sup>, Jesus G. Valenzuela<sup>1</sup>, Shaden Kamhawi<sup>2</sup>, Seydou Doumbia<sup>1</sup>

<sup>1</sup>International Center of Excellence in Research (ICER-MALI), Bamako, Mali, <sup>2</sup>Vector Molecular Biology Unit, Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>3</sup>Centre National d'Appui à la lutte contre la Maladie (CNAM), Bamako, Mali

Cutaneous leishmaniasis (CL) has been reported as an endemic disease in the western region of Kayes, Mali. The aim of this study was to determine the prevalence and annual incidence rates of *Leishmania major* exposure by leishmanin skin test (LST) in 3 villages on the District of Diema (Nafadji, Guemou, Debo Massassi), Kayes region. LST was performed among 2466 subjects aged 2 to 18 years old residents of the study villages. Of those, 2020 negative LST subjects were followed up and re-tested one year later for the development of CL to estimate the annual incidence of *Leishmania* infection. The prevalence of LST positive individuals was 18.73% and 18.53% in Nafadji and Debo Massassi, respectively and lower in Guemou (8.51%). The prevalence increased by age varying from 5.37%, to 19.69% and 39.20% among 2 to 6 years old, 7 to 12 years and 13 to 18 years respectively. Moreover, we observed a higher annual incidence of *Leishmania* infection with 23% in Nafadji, 26.22% in Guemou and 23.45% in Debo Massassi, respectively. This high incidence of LST reflects a stable high endemicity of *Leishmania* transmission in the district Diema.

1832

### BIOGEOGRAPHY OF *TRYPANOSOMA CRUZI* IN AREQUIPA, PERU

Alexander Berry, Michael Z. Levy, Dustin Brisson  
University of Pennsylvania, Philadelphia, PA, United States

Chagas disease is caused by the zoonotic protozoan parasite *Trypanosoma cruzi*. *T. cruzi* is endemic in 21 countries throughout the Americas, and has migrated to countries around the globe. Despite causing more than 12,000 deaths annually, and despite 65 million people currently at

risk of infection, the epidemiological patterns of *T. cruzi* remain poorly understood. *T. cruzi* and its insect vector thrive in urban environments and have spread rapidly across urban landscapes throughout South America. In an increasingly urban world, it is important to understand how disease systems that thrive in urban environments migrate through them. Determining migration patterns and the processes that affect migration of such populations in urban environments requires evaluation at fine spatial and temporal scales (<1km and annual). Population genetic and coalescent approaches are powerful tools to assess population patterns and processes, but their power scales with the genetic variation per sample analyzed. We therefore sequenced and assembled complete genomes of ~150 *T. cruzi* isolates collected in Arequipa, Peru. Arequipa, the second largest city in Peru, is a rapidly urbanizing city that is experiencing an epidemic of *T. cruzi*. We used Bayesian methods to reconstruct the phylogenetic history and to determine migration patterns and colonization history of *T. cruzi* within the urban environment of Arequipa. The migratory patterns of *T. cruzi* suggest a single introduction into Arequipa followed by multiple "micro-epidemics" in which rare long-distance migration events seed local epidemics that are limited to neighboring city blocks. Between-district migration is beyond the migratory capabilities of the insect vector, suggesting that human migration and the trading of small domestic mammals are responsible for long-range migration, while within-district migration is facilitated by the vector.

### 1833

#### **TRYPANOSOMA CRUZI ECOLOGY AT FACILITIES HOUSING NATURALLY INFECTED NON-HUMAN PRIMATES IN TEXAS, USA**

Carolyn L. Hodo<sup>1</sup>, Elise C. Birkner<sup>1</sup>, Gregory K. Wilkerson<sup>2</sup>, Stanton B. Gray<sup>2</sup>, Rachel Curtis-Robles<sup>1</sup>, Mark Cottingham<sup>3</sup>, Geraldine Fleurie<sup>3</sup>, Sarah A. Hamer<sup>1</sup>

<sup>1</sup>Texas A&M University, College Station, TX, United States, <sup>2</sup>MD Anderson Michale E. Keeling Center for Comparative Medicine and Research, Bastrop, TX, United States, <sup>3</sup>SNBL-USA, Alice, TX, United States

*Trypanosoma cruzi*, agent of Chagas disease, is a vector-borne protozoan parasite that infects a wide range of mammalian hosts throughout the Americas. Spillover from wildlife in sylvatic cycles results in local transmission to humans, domestic dogs, and non-human primates (NHPs) in the southern US. This region, particularly Texas, is home to many biomedical research facilities housing NHPs with outdoor access. Locally-acquired *T. cruzi* infection has been reported in these animals since the 1970s, with negative impacts on the use of infected animals in research and breeding programs. *T. cruzi* transmission at NHP facilities is poorly characterized, specifically the infectiousness of seropositive NHPs to vectors or other NHPs; the importance of local wildlife reservoirs; and the presence, infection status, and feeding behavior of local triatomine vectors. We investigated *T. cruzi* infection in NHPs, vectors, and wildlife at NHP facilities in Texas. We hypothesized that robust sylvatic transmission cycles would exist in proximity to NHP housing, characterized by highly infected wildlife and triatomines. Further, we expected variation in infection prevalence, infectiousness, and *T. cruzi* strain type among wildlife species and NHPs, with relevance to reservoir status. *T. cruzi* was detected via PCR in the blood of 33/45 (73.3%) seropositive rhesus macaques (*Macaca mulatta*) and 23/34 (67.6%) seropositive cynomolgus macaques (*Macaca fascicularis*) with intermittent or low level parasitemia in many animals. Strain types TcI and TcIV were detected in NHPs in nearly even proportion ( $p=0.94$ ), with 4 mixed TcI+TcIV infections. While none of 182 rodents were infected, 8/10 wild mesomammals were PCR positive in heart and blood. Infected opossums harbored only TcI whereas raccoons harbored TcIV. Of 78 triatomines collected at NHP facilities, 45% were infected: 62% with TcI, 24% with TcIV and 14% with mixed TcI+TcIV infection. Blood meal analysis of some bugs ( $n=11$ ) shows they fed on diverse species, including human, dog, raccoon, deer, and gecko. These ecological data will be used to define parasite transmission pathways and targets for intervention.

### 1834

#### **ANTIMONY SENSITIVITY OF LEISHMANIA BRAZILIENSIS PROMASTIGOTES VARIES ACCORDING TO THE FORM OF LEISHMANIASIS THEY DERIVE**

Silvana C. Silva<sup>1</sup>, Luiz Henrique Guimarães<sup>2</sup>, Juliana A. Silva<sup>1</sup>, Viviane Magalhães<sup>1</sup>, Lilian Medina<sup>1</sup>, Adriano Queiroz<sup>1</sup>, Paulo Roberto L. Machado<sup>1</sup>, Albert Schriefer<sup>1</sup>

<sup>1</sup>Hospital Universitário Prof. Edgard Santos, Salvador, Brazil, <sup>2</sup>Universidade Federal do Sul da Bahia, Teixeira de Freitas, Brazil

Antimony is the first line drug for treating American tegumentary leishmaniasis (ATL) in Brazil. In this country, *Leishmania braziliensis* causes at least three distinct forms of disease: localized cutaneous (CL), mucosal (ML) and disseminated leishmaniasis (DL). All forms can be found in Corte de Pedra, Northeast Brazil. ML and DL respond poorly to antimony, in contrast to CL. The *L. braziliensis* population causing ATL in Corte de Pedra is complex, with strains of the parasite associating with form of leishmaniasis. We tested the hypotheses that antimony refractoriness is associated with *L. braziliensis* genotypes, and that parasites from ML and DL present greater *in vitro* resistance to antimony than *L. braziliensis* from CL. Comparison of geographic coordinates of living sites between antimony responders and non-responders by Cusick and Edward's test showed that refractoriness and responsiveness to the drug were similarly wide spread in the region ( $p>0.05$ ). Parasites were then genotyped by sequencing a locus starting at position 425,451 on chromosome 28, which is polymorphic among *L. braziliensis* of Corte de Pedra. Haplotype CC- in CHR28/425451 was associated with risk of treatment failure among CL patients (Fisher's exact test,  $p=0.03$ , odds ratio=4.65). This haplotype could not be found among parasites from ML or DL. Finally, sensitivity to antimony was evaluated exposing *L. braziliensis* promastigotes to increasing concentrations of meglumine antimoniate *in vitro*. Parasites from ML and DL were more resistant to antimony at doses of 2 mg/100  $\mu$ L and beyond than those isolated from CL (Fisher's exact test,  $p=0.02$  and  $p=0.004$ , respectively). The intrinsically lower susceptibility of *L. braziliensis* from ML and DL to antimony parallels what is observed for patients' responsiveness in the field. This finding reinforces that ML and DL patients would benefit from initiating treatment with drugs currently considered as second line, like amphotericin B.

### 1835

#### **LYMPHATIC FILARIASIS MASS DRUG ADMINISTRATION COVERAGE, COASTAL REGION, KENYA, 2015 AND 2016**

Cecilia N. Wandera

Ministry of Health, Nairobi, Kenya

Lymphatic Filariasis (LF) is one of the diseases targeted for elimination. It has affected over 120 million in the world and about 3.5 million people in Kenya. We aimed to compare the reporting rates and coverage of LF in 6 counties within the coastal region. This was a programmatic operation where mass drug administration (MDA) of albendazole (ALB) and diethyl carbamazine (DEC) was distributed in 5 and 6 counties in 2015 and 2016 respectively in the endemic coastal region of Kenya. A register of all residents living in the area was developed just before the MDA by community health volunteers (CHV). The registered data was used to estimate the number of tablets needed by each of them. The CHVs distributed the tablets in houses they had registered. The target population were aged two years and above but excluded pregnant women. However, coverage denominator was the total population in the target counties and sub counties. Data was collected and aggregated using registers and tally sheets then analyzed using Microsoft Excel and Epi-Info. A population of 2,447,764 was targeted in 2015 and 3,486,730 in 2016. County reporting rates were above 93% in both years. County coverage ranged from 49% in Lamu to 99% (Taita Taveta) and 57% (Mombasa) to 76% in 2015 and 2016 respectively. Of the 16 sub counties dewormed in 2016, 11 (68%) recorded 100% reporting rate with 8 (50%) recording coverage above 65% in 2015. In 2016, 20 (87%) out of the 23 sub counties dewormed

recorded reporting rate of 100% while 13 (57%) recorded coverage above 65%. In conclusion, there was a general improvement in the proportion of counties and sub counties recording 100% reporting rate as well as those recording coverage above 65%.

## 1836

### ECO-BIO-SOCIAL DETERMINANTS OF HUMAN INFECTION WITH *TRYPANOSOMA CRUZI* IN RURAL COMMUNITIES IN THE ARGENTINE CHACO

**Maria P. Fernandez<sup>1</sup>**, Maria S. Gaspe<sup>1</sup>, Paula Sartor<sup>2</sup>, Ricardo E. Gürtler<sup>1</sup>

<sup>1</sup>Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Técnicas. Instituto de Ecología, Genética y Evolución de Buenos Aires (IEGEB), Facultad de Ciencias Exactas y Naturales, Buenos Aires, Argentina, <sup>2</sup>Programa Provincial de Chagas, Resistencia, Chaco, Argentina

Neglected tropical diseases (NTDs) are complex systems composed of multiple biological, ecological, socio-economic, and cultural factors acting at different scales in variable environments. The multivariate association between these factors and human infection with *Trypanosoma cruzi*, the causative agent of Chagas disease, has rarely been studied. Here we assessed the spatial patterns of human and vector (*Triatoma infestans*) infection with *T. cruzi* and identified the eco-bio-social determinants of human infection in a well-defined rural area of Pampa del Indio, northern Argentina, 10 years after the last community-wide insecticide spraying campaign. Most residents were indigenous (90%) and a creole minority. A cross-sectional serosurvey aiming at full coverage was conducted over 2012-2015 using two ELISA tests (Wiener). The seroprevalence of *T. cruzi* infection was 25.3% (n=1929, ≥8 months old), increased with age, and was nearly twofold higher among indigenous people (26%) than creoles (15%). The risk of human infection increased 60% with each additional *T. cruzi*-infected vector collected by timed-manual searches in human sleeping quarters; 40% with each infected household resident, and also increased with increasing household social vulnerability (a multidimensional index of poverty), and decreased with domestic host availability (humans, cats, dogs and chickens). We found a significant negative interaction between household social vulnerability and the relative abundance of infected *T. infestans*, indicating that residents from vulnerable households were exposed to a greater risk of infection at low vector abundance than less vulnerable residents. Although local *T. cruzi* transmission occurs at a household level, spatial analysis identified local hot-spots of human and vector infection. Integration of these results into a disease risk map revealed high-risk areas that would benefit from targeted vector surveillance and control combined with etiologic treatment. This approach is useful to develop cost-effective strategies oriented to reduce the burden of Chagas disease and other NTDs in the affected areas.

## 1837

### SEROLOGICAL EVIDENCE OF *TRYPANOSOMA CRUZI* INFECTION AMONG BLOOD DONORS IN MARICOPA COUNTY, ARIZONA, 2007-2016

**Norman Beatty<sup>1</sup>**, Craig Levy<sup>2</sup>

<sup>1</sup>University of Arizona College of Medicine, Department of Medicine, Division of Infectious Diseases, Tucson, AZ, United States, <sup>2</sup>Maricopa County Public Health Department, Office of Epidemiology, Communicable Disease Unit, Phoenix, AZ, United States

In the United States (US) the voluntary testing of blood donors for antibodies to *Trypanosoma cruzi* was initiated in January 2007. Since April 2010 the US Food and Drug Administration has approved several tests to allow blood, tissue, and organ donors to be screened for serological evidence of *T. cruzi* infection. Since 2007 Maricopa County Department of Public Health (MCDPH) in Phoenix, Arizona, USA has been notified of any blood donor with antibodies to *T. cruzi*. We analyzed retrospective data on all blood donors reported to MCDPH who were positive for serological

evidence of *T. cruzi* infection. Demographic information, travel history, *Triatoma* species (kissing bug) exposure and bite history, and symptoms of Chagas disease were collected when available. From 2007 to 2016 there were 31 blood donors reported to MCDPH with serologic evidence of *T. cruzi* infection. Of these, 58% were male, 83.8% were of Hispanic ethnicity; ages ranged from 17-69 (median 36) years, with 16% (5/31) ≤18 years. United blood services reported 28 donors and the American Red Cross reported 3 donors. Twenty-nine donors (93.5%) were reactive using the *T. cruzi* enzyme immunoassay (EIA) and confirmed with either *T. cruzi* radioimmunoprecipitation analysis (27/29) or ABOIT<sup>®</sup> ESA Chagas (2/29). Two donor results were reactive using the *T. cruzi* screening EIA but were not confirmed. Seventeen donors (55%) were unable to be contacted for follow-up or questioning. Among the 14 (45%) donors interviewed, all reported travel outside of the US, 13 (93%) were either born or spent > 2 weeks in Mexico, and 1 donor vacationed in Argentina. Only 1 donor remembered kissing bug exposure and bites; 3 (21%) donors reported symptoms consistent with chronic Chagas disease. Arizona blood donor screening for *T. cruzi* infection initiated in 2007 has led to the identification of more than 30 cases of probable Chagas disease in Maricopa County. Although all cases available for interview reported travel to a Chagas endemic area, this screening program provides a surveillance mechanism to identify new cases and endemic spread of Chagas disease in Maricopa County and Arizona.

## 1838

### CHAGAS DISEASE. A SYSTEMATIC REVIEW OF CASE REPORTS THROUGH THE LAST 50 YEARS

**Diego Abelardo Alvarez Hernandez<sup>1</sup>**, Maria Jose Diaz Huizar<sup>1</sup>, Jorge Alberto Ascencio Aragon<sup>1</sup>, Yolanda Hernandez Ponce<sup>1</sup>, Alexia S. Rivera<sup>1</sup>, Alberto Manuel Gonzalez Chavez<sup>2</sup>, Ana Maria Fernandez Presas<sup>3</sup>

<sup>1</sup>Universidad Anahuac Mexico Norte, Mexico State, Mexico, <sup>2</sup>Hospital Español de Mexico, Mexico City, Mexico, <sup>3</sup>Universidad Nacional Autonoma de Mexico, Mexico City, Mexico

Chagas disease is a parasitic disease caused by *Trypanosoma cruzi*, a protozoan which is transmitted to humans primarily vector-borne. The clinical spectrum of the disease is widely broad. During the acute phase patients present unspecific manifestations and during the chronic phase they may develop life-threatening complications. Chagas disease is frequently underdiagnosed and untreated, increasing morbimortality of those who suffer from it. The objective of our review was to describe demographics, mechanisms of transmission, clinical manifestations, diagnosis and treatment of the disease. A systematic review was conducted following the "Preferred Reporting Items for Systematic Reviews and Meta-Analyses" guideline. PubMed database was searched using the search terms "*Chagas disease*" or "*American trypanosomiasis*" and limited to case reports published without time frame in English or Spanish. Full text articles were assessed for relevance and data extraction was performed as an iterative process. During initial search, 227 items were obtained. Until now, 134 items have been included, describing 149 patients with Chagas disease from which 54% were females. Human Immunodeficiency Virus was the most common associated comorbidity observed. Non vector-borne transmission was reported in 38 cases (25%) and vector-borne transmission in 10 cases (7%). The route of transmission was unknown in 101 cases (68%). Fever, asthenia and headache were the most common initial clinical manifestations during the acute phase; and dyspnea, chest pain and tachycardia during the chronic phase. For diagnosis, Polymerase Chain Reaction, Enzyme-linked Immunosorbent Assay and Indirect Immunofluorescence were used in 51 cases (34%). Benznidazole was the treatment of choice in 73 cases (48%), Nifurtimox in 16 cases (11%) and Itraconazole in 1 case (1%). Mortality rate was of 22%. The conducted systematic review provides valuable information about Chagas disease reported cases that have been published in the literature. It demonstrates how its trends and behaviors have been changing through the last 50 years and enriches previous published data.

## TRYPANOSOMA CRUZI INFECTION AND CARDIAC OUTCOMES IN GOVERNMENT WORKING DOGS ACROSS THE UNITED STATES

Alyssa Meyers<sup>1</sup>, Marvin Meinders<sup>2</sup>, Sarah Hamer<sup>1</sup>

<sup>1</sup>Department of Veterinary Integrative Biosciences, Texas A&M University, College Station, TX, United States, <sup>2</sup>Office of Health Affairs, Department of Homeland Security, Washington, DC, United States

Infection with the protozoan parasite *Trypanosoma cruzi* can cause Chagas disease in humans and animals, and in some ecological settings canines may be sentinels of human disease risk. Chagas is increasingly recognized in the southern US, where triatomine vectors transmit the parasite among diverse wildlife and domestic dogs in sylvatic transmission cycles. The Department of Homeland Security trains thousands of working dogs to provide detection and security functions across the country. We hypothesized that *T. cruzi* infection would be greatest in dogs that work in the southern states- coinciding with established sylvatic cycles- but that dogs in northern states may also be exposed owing to required training in the south. In 2015-16, we sampled working dogs from the US-Mexico border in Texas and New Mexico, and expanded our study in 2017 to include dogs across the country. Additionally, we opportunistically collected kissing bugs from canine environments. While cross-country collections are ongoing, the working dogs in Texas and New Mexico showed significant variation in seroprevalence across management areas 18.3-26.7% (n=528; P=0.02-0.04) compared to 11.6% seroprevalence in young dogs at a training center based on immunochromatographic tests and indirect fluorescent antibody testing. Using multiplex rt-PCR of the spliced leader intergenic region (SL-IR) to determine parasite discrete typing unit (DTU), we found three dogs (0.6%) had parasite DNA in the blood, including TcI and TcI/TcIV mix. Nine of 20 (45%) *T. gerstaeckeri* and *T. rubida* from the canine environments were infected with TcI and TcIV; insects analyzed for bloodmeals (n=11) fed primarily on canine (54.5%) but also human and wildlife. Ongoing clinical assessments of infected dogs include the use of 24-hour Holter monitors for electrocardiogram assessment of the heart, and abnormalities in electrical activity of the heart will be analyzed in relation to parasite DTU. Epidemiological and clinical assessment of *T. cruzi*-infection in these high value working dogs will provide a basis for quantifying the economic impact of the disease and implementing control measures.

## 1840

### VISCERAL LEISHMANIASIS IN SYRIA: A SILENT KILLER UNCOVERED

Alice L. Cowley, Jonathan Hollins, Richard Allan

The MENTOR Initiative, Crawley, United Kingdom

Historically, Syria is listed as one of the top six countries in the world for cutaneous leishmaniasis, but is not a country that has been associated with visceral leishmaniasis. Between 2004 and 2008 the World Health Organization recorded a national average of just 14 cases of visceral leishmaniasis per annum, rising to 36 cases in 2014. Across MENTOR's areas of activity in the north of Syria alone, notably in Idlib, MENTOR had 88 confirmed cases reported between 2014 and 2016 - a large escalation compared to nationwide pre-war figures. In May 2016 MENTOR conducted an RDT survey in the two villages of Betya and Tellemar, Salqin, Idlib. An awareness campaign coupled with the support of local authorities produced a turnout of 90%, with 4,226 people tested. MENTOR disclosed a high prevalence of visceral leishmaniasis infection, with 8 people in the two villages testing positive (a rate of 19/10,000 population, compared to WHO's national estimate of 0.02/10,000). This survey has exposed the possibility of a hidden lethal epidemic. MENTOR has raised awareness among health workers about the existence of the disease and provided them with the easy-to-use RDT. Since the survey there has been a further increase in the diagnosis of visceral leishmaniasis in local MENTOR supported health facilities, as health workers now include the disease as

a differential diagnosis for symptoms such as fevers of unknown origin, anemia, lethargy and organ involvement. This suggests that many deaths in this area previously attributed to organ or heart failure may have actually been caused by visceral leishmaniasis. The survey is an important first step towards a new understanding of visceral leishmaniasis epidemiology and control in Syria, which could ultimately save many lives. More research remains to be done but the data accumulated so far indicates that there is, at least locally, a high rate of undetected infection which could be more widespread across the country. It is imperative that efforts are now made to capitalize on the momentum gained by the first survey, and MENTOR intends to implement further surveys in 2017 to verify this apparent silent epidemic.

## 1841

### HEALTH SECURITY DURING ERA OF CONFLICT AND FORCED DISPLACEMENT: LEISHMANIASIS AS A CASE STUDY

Amina Olabi<sup>1</sup>, Mohamad Haj Omar Albathish<sup>2</sup>, Rabab Almalki<sup>3</sup>, Karina Mondragon-Shem<sup>4</sup>, Peter Hotez<sup>5</sup>, Alvaro Acosta-Serrano<sup>4</sup>, Waleed S. Al Salem<sup>6</sup>

<sup>1</sup>Liverpool University, Liverpool, United Kingdom, <sup>2</sup>Syria Relief Network, Southern Turkey, Turkey, <sup>3</sup>Warwick Law School, Coventry, United Kingdom, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States, <sup>6</sup>Saudi Ministry of Health, Riyadh, Saudi Arabia

The Syrian conflict reports the worst forced displacement after the Second World War as a consequence of the increasing violence and escalations by the Government of Syria and their allies. Approximately, nine million people have been displaced internally as well as five million who have been recorded as refugees in neighbouring countries. Health infrastructure suffered immensely from the increased attacks on health facilities- three quarters of health service facilities have been destroyed. Over the course of 2016, 101 attacks on hospitals and health care centres across Syria have been recorded, with 14 healthcare workers killed and 40 injured. Moreover, a severe collapse in public services has been reported affecting rubbish accumulations and water supplies. Since 2013, terrorist networks have gained a foothold within the fragile states of Syria and Iraq. Consequently, the terrorist group ISIL ruled Deir ez-Zor, Al-Raqqa and Al-Hasakah in Syria as well as Ninewa, Anbar, Salah ad-Din and Kirkuk in Iraq. Leishmaniasis outbreaks have been reported throughout the period of the conflict, with an unprecedented increase as the proxy-war unfolds. The intervention of the international community affected disease dynamics in areas such as Al-Hasakah Syrian governorate which is situated on the Iraqi-Syrian border. Human movement driven by attacks on civilian populations, absence of immunity to leishmaniasis and poor access to the health services were all found to play a key role in the current outbreak.

## 1842

### VISCERAL LEISHMANIASIS IN THE URBAN AREA OF TWO MUNICIPALITIES OF SAO PAULO STATE, BRAZIL: A KEY TO UNDERSTAND THE ROLE OF THE STREET LEVEL BUREAUCRATS

Lourdes A. D'Andrea, Elivelton S. Fonseca, Raul B. Guimarães  
São Paulo State University, Presidente Prudente, Brazil

The street level bureaucracy can be a key to understand how some diseases spread in urban areas and how to block it in some contexts, because it means the way the workers represent the public health programs they work for. In Brazil, the surveillance and control program for Visceral Leishmaniasis (SCPVLeish) is structured at the national level, accompanied at the state level by different protocols. However, it is on the local scale, in the municipalities, that actions are triggered in the territory. This study presents itself as an excellent opportunity to test the hypothesis that the street level bureaucracy can promote a better understanding of the intra-urban actions for VLeish. The objective was to analyze, from

the point of view of the set of actions of the Program, how the frontline intervention can influence the spatial distribution of human and canine VLeish cases in two endemic municipalities: Dracena and Tupi Paulista. We performed statistical descriptive and geospatial analysis of serum samples collected in the field. The patterns of practice, routines and simplifications of the local-based SCPVLeish personnel were also evaluated, in order to compare their behavior with stipulations of SCPVLeish. There were 145 cases of human VLeish, with 5 deaths in the city of Dracena and in Tupi Paulista, 36 cases of human VLeish with 3 deaths. From 2006 to 2015, a total of 27,586 canine serum samples from Dracena were analyzed, identifying prevalence of 26.3% (7,268), accounting 58.5% (4,489) of euthanasia and 4.9% (373) with refusal. In the same period in Tupi Paulista, a total of 8,317 serum samples were analyzed for canine VLeish, identifying prevalence of 22.1% (1,877), accounting 80.6% (1,757) of euthanasia and a refusal of 13.5% (310). The Municipality of Dracena can be considered in intense transmission and Tupi Paulista in moderate transmission. The spatial distribution of canine VLeish presented in the urban area of Dracena and Tupi Paulista allowed us to infer on the occurrence of the increase of the number of human cases. Hot spots of VLeish have to intensify SCPVLeish practices, in continuous work and specialized team.

### 1843

#### EPIDEMIOLOGY OF *TRYPANOSOMA CRUZI* IN URBAN DWELLING OPOSSUM (*DIDELPHIS VIRGINIANA*) AND FERAL CAT (*FELIS CATUS*) POPULATIONS OF THE RIO GRANDE VALLEY, TEXAS

Italo B. Zecca, Lisa Auckland, Sarah Hamer

Texas A&M University, College Station, TX, United States

*Trypanosoma cruzi* is a zoonotic protozoan parasite known to infect a wide range of mammals but minimal information is known about the infection of urban dwelling animals in the United States. In the Rio Grande Valley of TX, our ongoing epidemiological investigations have documented anti *T. cruzi*-antibodies in 1.8% of people and >21% of their pet dogs. We hypothesized that urban wild and feral animals from the region serve as infectious reservoirs that may serve as a bridge between sylvatic and domestic transmission cycles. In early 2017, samples were collected from urban dwelling opossums (*Didelphis virginiana*) and feral cats (*Felis catus*) of Hidalgo Co., TX, an area with documented human and canine Chagas disease and from where we regularly collect infected triatomine vectors. After euthanasia (performed by animal control for reasons unrelated to our study), whole blood and cardiac tissue were collected from feral cats and wild opossums. Additionally, anal gland secretions were collected from opossums because previous research has documented *T. cruzi* epimastigotes in possum reservoirs with uncertain ecological and epidemiological relevance. Through serological testing of 120 cats using two immunochromatographic tests and indirect fluorescent antibody testing, 14.2% individuals on at least two independent antibody detection platforms. All cardiac tissue, whole blood, and anal gland samples were subjected to qPCR for parasite detection and discrete typing unit (DTU) determination. None of the seropositive or negative cats tested positive for parasite DNA. In contrast, of 56 opossums sampled, parasite DNA was found in matched whole blood and cardiac tissue of two (3.6%) individuals, and in 6 (10.7%) anal gland secretions, including the one with positive heart and blood. The three typed anal secretion samples were all TcI- the DTU previously associated with human disease in the US. Ongoing histopathology evaluation of cardiac tissue will identify if cardiac pathology is associated with infection. Given the high abundance of feral cats and opossums in urban foci, it is likely these species serve as wild reservoirs around urban dwellings.

### 1844

#### PILOTING WORKSTATIONS TO IMPROVE HYGIENE PRACTICES AMONG POULTRY WORKERS DURING POULTRY PROCESSING IN A LIVE BIRD MARKET IN BANGLADESH

Nadia A. Rimi<sup>1</sup>, Md. H. Fahad<sup>1</sup>, Syed M. Mortaza<sup>1</sup>, Abdullah A. Mahmud<sup>1</sup>, Md. A. Islam<sup>1</sup>, Md. Z. Hassan<sup>1</sup>, Rebeca Sultana<sup>1</sup>, Katharine Sturm-Ramirez<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

In Bangladesh, influenza A/H5N1 has become endemic in poultry and there are 8 human infections reported since 2008. Live bird markets have been implicated as a source of H5N1 and identified as lacking infrastructure required to maintain biosecurity. To reduce risk of environmental contamination and improve handwashing practices, we designed and piloted portable workstations (including a worktop and handwashing facility) in 13 shops in a live bird market in June 2015 and explored their functionality, acceptability and feasibility. We recommended the workers to use the worktop to process birds and wash hands with soapy water after processing each batch of birds. During June-November 2015, we conducted 4 hours of structured observation in 6 shops at each of 3 time points (before intervention, and at 2 weeks and 2 months after intervention) and 8 in-depth interviews to collect users' feedback. On average, we observed 45 batches of birds processed by 2 persons per batch in each 4 hours. Before intervention, we observed 90 handwashing opportunities; handwashing with soap was not observed. Handwashing with soapy water increased to 21% (22/104) at 2 weeks after intervention but then decreased to 2% (1/67) at 2 months after intervention. In all shops, workers used water and soapy water to clean utensils and the worktop to process birds after intervention. Rinsing hands with clean water increased after intervention: 12% (12/104) at 2 weeks and 24% (16/67) at 2 months, whereas rinsing hands with blood-mixed water was observed before intervention. Major barriers identified were difficulty to manage increased water cost by individual shops and inability to frequently wash hands during busy hours. As motivation, workers mentioned that customers preferred shops with workstation and that workers did not have to leave the shop to go to the public toilets for handwashing anymore. The workstations were acceptable, functional, and improved handwashing practices and the use of clean water. However, handwashing decreased over time. A complete solution at the shop level has feasibility concerns; hence a market level slaughtering arrangement may be more appropriate.

### 1845

#### DOG OWNERS' ATTITUDE, A RISK FACTOR FOR HUMAN RABIES IN NIGERIA

Christianah I. Odita, Ishaya S. Tekki, Gyang D. Moses, Okoh K. Egwu, Stella E. Idachaba, Israel J. Barde, Isioma V. Ifende, Olabisi A. Makanju, James S. Ahmed, Yakubu G. Dashe, Chika I. Nwosuh, Philip A. Okewole

National Veterinary Research Institute Vom Plateau State Nigeria, Jos, Nigeria

Rabies is an endemic zoonotic disease in Nigeria occurring in dogs, other domestic animals and sometimes man. Elimination of rabies in humans is dependent on effective control in dogs. Diagnostic records of the National Veterinary Research Institute Vom, Nigeria, 2011- 2016 showed 686 rabies positive of 1,226 canine case samples submitted for laboratory investigation. Of the positive cases, 635 involved human exposures. We conducted a field investigation and interviewed 743 dog owners in November 2016 using structured questionnaires and random selection of dog owners to ascertain factors responsible for the high incidences of rabid dog bites, and to assess dog owners' knowledge, attitude and practice towards rabies and dog vaccination in Jos South administrative area of Plateau State (LAT: 9.728; LONG: 8.794); which had the highest number of reported cases. Associations between demographic variables

and knowledge, attitude or practice scores were also assessed using Chi squared analysis. Of the population interviewed, 698 (94%) had knowledge of rabies and 622 (89%) of them know about anti-rabies vaccine. Among those who know about anti-rabies vaccine, 396 (63.7%) know about yearly vaccination while 385 (61.9%) claimed to vaccinate their dogs. From the group that claimed to vaccinate dogs, only 116 (30%) had evidence of vaccination history. Knowledge of yearly anti-rabies vaccination, length of dog keeping and dog management systems were found to be significantly associated with dog vaccination. Independent Population attributable risks associated with non-vaccination of dogs were ignorance (22.4%), carelessness (9.7%) and financial constraints (0.09%). Illiteracy and wrong perception about rabies and dog vaccination are factors that could impact global human deaths due to rabies of which Africa and Asia are known to contribute significantly. Considering that 627 (84.4%) of the survey group did not vaccinate dogs, awareness campaign on rabies, enforcement of responsible dog ownership, and government intervention by mass vaccination of dogs are essential for the control of rabies and to reduce risk of infection in humans in Nigeria.

## 1846

### MARINE MAMMAL STRANDINGS IN PERUVIAN COAST: AN ELEVEN YEARS STUDY

**Adrian Vasquez-Mejía**, Guillermo Salvatierra R., Andrés G. Lescano

*Universidad Peruana Cayetano Heredia, Lima, Peru*

Marine mammals are considered to be excellent sentinels of environmental health and monitoring reflects the state of the ecosystem in which they inhabit. The presence of marine mammal's stranding are a reflection of the ecosystem situation and an alert of human being, connecting interdependently animal, human and environmental health as a one health. The aim of the study was to describe and analyze the epidemiological characteristics as well as the annual trends of stranding events reported along the Peruvian coast between 2006-2016. The variables analyzed were the number of beached specimens, type of beached specimen, type of stranding and localization where the stranding took place. Stranding reports were found through the Google search engine through algorithms in English and Spanish; and the review of official documents available on the IMARPE (Peruvian Institute of the Sea) website. A total of 22 reported stranding events were found, of which 14 were single individuals and 8 mass events. There were 1746 animals that included Odontocetes (77.3%), Pinnipeds (22.3%) and Mysticetes (0.4%). The largest number of strandings occurred on the north coast of Peru, with a total of beached animals ( $n = 1739$ ) and stranding events ( $n = 15$ ). Observing the seasonality of these events, the greatest number of animals has been reported in the summer months, with a total of beached animals ( $n = 1737$ ) and stranding events ( $n = 13$ ). All mass stranding events were reported in summer and on the north coast. All the years included in the study presented at least one stranding event, except for 2007 and 2016. Reports with the largest number of beached animals occurred in 2009 ( $n = 266$ ), 2012 ( $n = 965$ ), 2013 ( $n = 98$ ) and 2014 ( $n = 410$ ). The data obtained from the mentioned websites were consistent with the data of the IMARPE reports, for each stranding event. Understanding the patterns of temporality of the occurrence of these events will be useful to establish future conservation and prevention strategies. This work is an important step in future research to monitor and associate the consequences of climate change on marine ecosystems and human populations.

## 1847

### RESEARCH ON ZOOONOTIC AND NEGLECTED DISEASES IN CHAD: CASE OF TUBERCULOSIS, RIFT VALLEY FEVER, BRUCELLOSIS AND Q FEVER

**Ngandolo Bongo Nare B. Nare**

*Institut de Recherche en Elevage pour le Developpement (IRED), N'Djamena, Chad*

In 2012, Cross-sectional studies were conducted by staffs from Chadian Animal and Public health systems in order to point out the importance of TB and RVF, Brucellosis, Q fever. From 478 TB suspected patients, sputum samples were collected on Cethyl pyridinium (5%) and sent to IRED for bacteriological and molecular diagnostic. Seventy seven were identified as Acid Fast Bacilli (AFB) infection cases, from which, 71 were from genus mycobacteria: 42 *M. tuberculosis*, 1 *M. bovis*, 1 *M. avium* and 30 non tuberculosis mycobacteria. Ten suspected cases were due to other mycobacteria. From 332 carcasses suspected as TB cases, 236 were identified as AFB infection cases within which only 66 were characterized as belonging to the genus Mycobacterium: one case of infection was due to *M. tuberculosis*, 44 to *M. bovis*, and 11 to Non Tuberculosis Mycobacteria. From 924 sera collected in Lake Chad region, ELISA test showed that RVF apparent prevalence of 32.9% (29.9 - 35.9) at 95% CI was identified among ruminants. The prevalence by species was 37.8% (34.2%-41.3%) in cattle, 18.8% (12.3%-25.3%) in sheep and 10.8% (3%-18.5%) in goats. For a total number of 561 cattle, 7.8 % (5.6 - 10.1) of Q fever and 11.9% (9.3 - 14.6) of Brucellosis cases were detected. Our main findings were the isolation of *Mycobacterium bovis* from human and *Mybacterium tuberculosis* from animal. A co-infection *M. bovis* - *M. avium* in human was identified highlighting the importance of the zoonotic aspect of mycobacterial diseases in Chad. Importance of other mycobacteria as causes of lung infections in human and animal have to be more investigated. Suspicions of RVF, Q fever and Brucellosis from domestic animal are at risk for human population in Lake Chad region.

## 1848

### EMERGING INFECTIOUS DISEASES PREDICTION: A STUDY ON IxODES SCAPULARIS-BORNE PATHOGENS

**Tam Tran**, Dustin Brisson

*University of Pennsylvania, Philadelphia, PA, United States*

Vector-borne diseases (VBDs) are the most common types of emerging infectious diseases and constitute major threats to public health. Understanding the interplay between the environment, vectors, pathogens, and humans that expedite pathogen population growth or range expansions remains a challenge. The rapid increase in availability of ecological information has led to "big data" opportunities and challenges in disease surveillance. The goal of this study is to build geospatial models to predict disease risk by accounting for the interaction of human characteristics and ecological factors, using multiple analytical frameworks. We have previously identified some of the environmental features that have influenced population dynamics on *I. scapularis*, but not on the pathogens specifically, using conventional regression methods. In this study, we focus on pathogens transmitted by the black-legged tick, *Ixodes scapularis*, including human granulocytic anaplasmosis (HGA), babesiosis, and Lyme disease. We are investigating the entomological, environmental, and human demographic factors that determine tick-borne disease risk using multiple regression, stochastic search variable selection (SSVS), and boosted regression trees (BRTs) analysis. Using SSVS, a big-data Bayesian analytic approach, allows us to identify that factors that influence the population dynamics of tick-borne pathogens due to its high precision and statistical power. SSVS addresses many of the limitations of multiple regression methods to identify variables of both practical and statistical significance. Preliminary coarse-scale analyses suggest that human incidence rates of each pathogen are linked to both age and gender. BRTs are highly effective for pathogen prevalence and disease predictions in addition to the identification of important environmental factors. We will

present these results as well as a comparison of the predictive power of these models at the ASTMH meeting in November 2017. Our preliminary studies demonstrate that these models effectively forecast disease risk over time and space with greater accuracy than conventional methods.

### CATTLE-ASSOCIATED RISK FACTORS FOR HUMAN TUBERCULOSIS IN RURAL LIVESTOCK KEEPING COMMUNITIES, UGANDA

Julianne Meisner<sup>1</sup>, Kellie Curtis<sup>2</sup>, Thomas W. Graham<sup>2</sup>, Michael Apamaku<sup>2</sup>, Lisa E. Manhart<sup>1</sup>, Gerard Cangelosi<sup>1</sup>, Peter R. Rabinowitz<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>Veterinarians Without Borders, Davis, CA, United States

Tuberculosis (TB) is a leading infectious cause of human death worldwide. TB can also infect cattle, resulting in productivity losses, trade barriers, and zoonotic transmission via milk, meat, or direct contact. While the majority of TB cases are non-zoonotic, an unknown proportion are acquired from cattle; in Africa, this proportion is estimated to be 0.4% to 10%. We conducted a cross-sectional study in rural communities in southeastern and northwestern Uganda between 2014 and 2016 to evaluate the association between tuberculosis skin test (TST) positivity in humans and cattle-associated risk factors. Human and cattle skin testing was performed in communities followed by a survey of household practices. TST data are available on 493 humans, 250 men and 243 women; 184 individuals in total—111 men and 73 women—tested positive. Separate log binomial models were fit to estimate relative risks (RR) for herd TST positivity stratified on gender and for raw milk consumption, using generalized estimating equations. Having at least one TST positive bovid in the household's herd was significantly associated with decreased risk of TB among men (RR 0.61, 95% CI 0.47, 0.79) but was not significantly associated with TB among women (RR 1.26, 95% CI 0.80, 1.97), contrary to the hypothesized higher risk among men, the primary caretakers of cattle. This apparent protective effect may be the result of residual confounding by socioeconomic status: wealthier individuals may be less likely to be TB positive, but more likely to have TST positive herds by virtue of larger herd sizes, ability to purchase new and possibly infected stock, and propensity to keep more TB-susceptible European breeds. No significant effect was found for raw milk consumption, and adjustment for confounders or pathways mediated by non-zoonotic TB exposure did not change effect estimates. The importance of cattle-associated risk factors for human TB burden may be setting-specific, as suggested by the lack of consensus reached by prior research. In settings where bovine TB prevalence is low, such as Uganda, cattle-associated zoonotic transmission may be rare.

### ANTIMICROBIAL RESISTANCE TRANSMISSION ASSOCIATED WITH SMALL-SCALE FOOD-ANIMAL PRODUCTION IN PERI-URBAN COMMUNITIES OF QUITO, ECUADOR

Jay Paul Graham

Public Health Institute, Oakland, CA, United States

Small-scale food animal production is widely practiced around the globe, yet it is often overlooked in terms of the public health risks. Evidence suggests that small-scale food animal producers regularly employ the use of antimicrobials to improve the survival and growth of their animals, and that this practice leads to the development of antimicrobial resistance (AMR) that can potentially spread to humans. We conducted an analysis of AMR among *E. coli* isolates present in fecal samples from young children (n=64) and domestic animals (n=174) living in the same neighborhood. In this analysis, we selected one dominant *E. coli* isolate from each fecal sample to assess AMR transmission. Thirty-five children (56%) and 46 domestic animals (26%) carried MDR *E. coli* (defined as resistance to  $\geq 3$  classes of antimicrobials). Three children and 5 food-animals carried *E.*

*coli* that were resistant to more than 9 of the 12 antibiotics tested using CLSI guidelines. In the relatively small set of *E. coli* isolates analyzed, we found evidence that animal and human *E. coli* isolates are recently linked clones that have changed slightly in resistance phenotype. Three isolates (one from a child and two from animals) were resistant to eight of the same drugs, but among those only two animal isolates shared the same sequence type, suggesting that horizontal gene transfer could be driving AMR gene movement. These same three isolates were resistant to cefotaxime, a third-generation cephalosporin. This study elucidates the mechanisms of AMR transmission (i.e. clonal spread versus horizontal gene transfer) and provides an understanding of the driving factors for use of antimicrobials in small-scale food-animal production. This research will have important implications in low- and middle-income countries where small-scale food animal production is often promoted to reduce poverty and food insecurity.

## 1851

### "LET'S GET THIS TICKING TIME BOMB!"

Patricia Pow-Brown, Candice Sant, Karla C. Georges

The University of The West Indies, Mt. Hope, Trinidad and Tobago

Tick borne diseases cause high morbidity and mortality in dogs in the Caribbean. *Rhipicephalus sanguineus*, is known to be a main vector for *Ehrlichia canis*, *Babesia canis* and may also be implicated in the transmission of *Bartonella henselae*, *B. vinsonii berkhoffii* and *B. clarridgeiae*. These organisms cause a myriad of non-specific clinical signs in dogs and humans including pyrexia, anorexia, joint pain and swelling. Bartonellosis is an emerging and potentially hidden epidemic affecting dogs and humans and is considered especially important as opportunistic pathogens. It is also associated with cardiac arrhythmias and endocarditis in dogs. *Borrelia burgdorferi*, the vector for Lyme Disease is transmitted by *Ixodes scapularis*. Erythema Migrans-like Illness have been documented in Caribbean islanders however to date there has been no comprehensive study to detect these agents in both dogs and humans. We suspect that cases of dogs which were unsuccessfully treated for Ehrlichiosis or Babesiosis, were possibly undiagnosed Bartonellosis and that veterinarians, owners and animal handlers have been exposed to tick borne diseases. This study aims to detect the presence of *E. canis*, *A. phagocytophilum*, *Babesia spp.*, *B.v.berkhoffii*, *B. burgdorferi* in dogs and humans. High risk groups in Trinidad and Tobago, Barbados, St Maarten and Jamaica will be sampled for TBD, in addition all dogs with endocarditis will be investigated for tick borne illnesses. In human cases, a questionnaire will be administered and a blood sample taken to test for these organisms. We suspect that these organisms will be definitively diagnosed in humans and dogs in the Caribbean Islands.

## 1852

### THE ROLE OF ANTHROPOGENIC LAND-USE CHANGE IN DRIVING DISEASE EMERGENCE IN HIGHLY-COUPLED VECTOR-HOST SYSTEMS: ZONOTIC CUTANEOUS LEISHMANIASIS AS A CASE SYSTEM

Gideon Wasserberg<sup>1</sup>, Clifford Smyth<sup>1</sup>, Ido Tsurim<sup>2</sup>

<sup>1</sup>University of North Carolina at Greensboro, Greensboro, NC, United States, <sup>2</sup>Achva Academic College, Gedera, Israel

The role of the reservoir host is often neglected when studying vector-borne zoonoses. The classical Ross-MacDonald model predicts positive effect of vector density on disease spread rate but inverse relationship with respect to host density. This model, originally developed in the context of Malaria, assumes that with the exception of obtaining a blood-meal, vector's and host's life-cycles are largely independent of one another. However, in systems where the host either constitutes or provides a habitat for the vector (hereafter "coupled vector-host systems") more complex relationship are expected. In this talk, we present the results of an individual-based simulation model that evaluates the effect of the vector's host-dependence on epizootiological patterns within the host

population. We demonstrated that, in contrast to the predictions of the Ross-MacDonald model, in coupled systems hump-shaped or positive association between host abundance and infection prevalence could occur. This mechanism suggests that anthropogenic land-use change affecting reservoir host density could drive disease emergence in competent ("source") or sub-competent ("sink") reservoir host systems. Empirical evidences from Zoonotic Cutaneous Leishmaniasis in Israel support this prediction: Infection occurrence in the fat sand rat (*Psammomys obesus*) was found to be positively correlated with its density. Epidemic emergence in the new sub-competent host system of *Meriones tristrami* is also suggested to be associated with such a density-dependent effect. Therefore, in vector-host systems characterized by high degree of coupling host-culling becomes a viable control option. But even more exciting, in this kind of system, systemic control becomes a particularly promising control alternative. We report results of a systemic control in a lab study with *P. obesus* and in the field in Israel with *M. tristrami*.

## 1853

### MATHEMATICAL MODELLING OF DOG RABIES TRANSMISSION IN AN AFRICAN CITY

Mirjam Laager<sup>1</sup>, Celine Mbilo<sup>1</sup>, Monique Léchenne<sup>1</sup>, Kemdongarti Naissengar<sup>2</sup>, Assandi Oussiguéré<sup>2</sup>, Rolande Mindekem<sup>3</sup>, Jakob Zinsstag<sup>1</sup>, **Nakul Chitnis<sup>1</sup>**

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Institut de Recherche en Elevage pour le Développement, N'Djamena, Chad, <sup>3</sup>Centre de Support en Santé Internationale, N'Djamena, Chad

Rabies is a viral disease that affects the central nervous system of humans and other mammals. The disease is transmitted by bite and is fatal after the onset of symptoms. Rabies is endemic in many countries, where the domestic dog is the primary vector, and causes approximately 59,000 human deaths worldwide annually. Two mass vaccination campaigns of dogs were conducted in N'Djamena, Chad, in 2012 and 2013, reaching a vaccination coverage of more than 70% in both years. The campaigns interrupted transmission for several months, but recently there has been a resurgence in cases, earlier than suggested by previous homogeneous models of rabies transmission. We developed new population-based and individual-based models to explore possible causes for this resurgence and to simulate the effects of different interventions on dog rabies transmission. We calibrated model parameters to four years of geolocated weekly incidence data of dog rabies and subsequent human exposure. For the individual based models, we used additional data on dog movement and contact patterns from GPS collars. We analysed the models to derive threshold conditions of vaccination coverage and importation of latent dogs, and conducted simulations to assess the long term effects of different vaccination scenarios. Our analysis suggests that underreporting of rabies cases is unlikely to lead to the early resurgence seen in N'Djamena. Incorporating heterogeneity showed that the reproductive ratio was underestimated in the previous homogeneous models, but our simulation results suggest that while spatial heterogeneity and the decrease of the vaccination coverage due to population turnover seemed to facilitate the fast re-establishment of rabies in N'Djamena, the main cause for the recent cases was the importation of latent dogs. Therefore, to sustain elimination of rabies after the vaccination campaigns, reintroduction of rabid dogs from the surroundings of the city would need to be prevented through alternative strategies, such as the vaccination of surrounding areas.

## 1854

### NEEDS ASSESSMENT AND ALTERNATIVE STRATEGIES TO ACHIEVE THE ELIMINATION OF DOG-MEDIATED HUMAN RABIES DEATHS BY 2030 BASED ON DOG VACCINATION

Ryan M. Wallace, **Eduardo A. Undurraga**, Jesse D. Blanton, Julie Cleaton, Richard Franka

*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Every year, rabies kills about 60,000 people globally; most (~99%) originate in domestic dogs. The WHO and collaborating agencies have set the goal of eliminating dog-mediated human rabies deaths globally by 2030. This goal could be achieved by providing massive post-exposure prophylaxis, with ever increasing costs; through mass dog rabies vaccination, requiring a sustained effort and long-term planning; or by a combination of both strategies. Drawing from multiple datasets and using a country-level analysis, we estimated the years and resources required to achieve global dog rabies elimination based on four factors: country development status, dog vaccination costs, availability of dog rabies vaccine, and estimated number of vaccinators. Following WHO, we assumed that vaccinating 70% of the dog population for 7 consecutive years would eliminate dog rabies. Using 2015 dog vaccination rates, we estimated a cumulative global shortage of ~7.5 billion doses to eliminate dog rabies in endemic countries. We estimated a vaccination cost of \$6,300 million to eliminate dog rabies in all endemic countries, or a \$3,900 million gap, compared to current spending. The estimated vaccination workforce may suffice to eliminate dog rabies, only if all public health veterinarians in endemic countries dedicated 3 months to dog rabies vaccination annually. We discuss implications of plausible technology improvements, including population management, vaccine price, and increases in dog-vaccinating capabilities. We suggest pragmatic and feasible options toward dog rabies elimination by 2030, while identifying several benefits and drawbacks of specific approaches. In addition to providing global estimates, we created a user-friendly tool to assist countries in their long-term planning efforts. The tool allows users to estimate the required resources to achieve rabies elimination using country-specific input values. Comparable, systematic, quantitative estimates are important to inform the discussion about global and regional strategic planning and resource mobilization towards the goal of dog rabies virus elimination.

## 1855

### THE COST-EFFECTIVENESS OF A NOVEL INTEGRATED BITE CASE MANAGEMENT PROGRAM FOR THE CONTROL OF DOG-MEDIATED HUMAN RABIES, WEST DEPARTMENT, HAITI, 2014-2015

**Eduardo A. Undurraga<sup>1</sup>**, Martin I. Meltzer<sup>1</sup>, Cuc H. Tran<sup>1</sup>, Charisma Y. Atkins<sup>1</sup>, Melissa D. Etheart<sup>1</sup>, Max F. Millien<sup>2</sup>, Paul Adrien<sup>3</sup>, Ryan M. Wallace<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Ministère de l'Agriculture, des Ressources Naturelles et du Développement Rural, Port-au-Prince, Haiti, <sup>3</sup>Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti

Haiti has the highest burden of rabies in the Western hemisphere, with 130 estimated annual deaths. As in many developing countries, most human and dog rabies cases are not recognized and are not reported to health authorities, thus limiting rabies awareness, funding, and prevention efforts. We present the cost-effectiveness evaluation of an integrated bite case management program combining community bite investigations and passive animal rabies surveillance, using a governmental perspective. In collaboration with the CDC, the Haitian government initiated in 2013 the Haiti Animal Rabies Surveillance Program (HARSP), a form of integrated bite case management combining community bite investigations and passive animal rabies investigations to provide tailored rabies risk assessments for persons potentially exposed to the rabies virus. The

Haiti Animal Rabies Surveillance Program (HARSP) was first implemented in three communes of the West Department, Haiti. Our evaluation encompassed all individuals exposed to rabies in the study area (n=2,289) in 2014-2015. Costs (2014 US dollars) included diagnostic laboratory development, training of surveillance officers, operational costs, and post-exposure prophylaxis (PEP). We used estimated deaths averted and years of life gained (YLG) from prevented rabies as health outcomes. Our results suggest that HARSP had higher overall costs (range: \$39,568-\$80,290) than the no-bite-case-management (NBCM) scenario (\$15,988-\$26,976), partly from an increased number receiving PEP. But HARSP had better health outcomes than NBCM, with estimated 11 additional annual averted deaths in 2014 and 9 in 2015, and 654 additional YLG in 2014 and 535 in 2015. Overall, HARSP was more cost-effective (US\$ per death-averted) than NBCM (2014, HARSP: \$2,891-\$4,735, NBCM: \$5,980-\$8,453; 2015, HARSP: \$3,534-\$7,171, NBCM: \$7,298-\$12,284). HARSP offers an effective human-rabies prevention solution for countries transitioning from reactive to preventive strategies (i.e., comprehensive dog vaccination).

## 1856

### ONE HEALTH APPROACH TO COST-EFFECTIVE RABIES CONTROL IN INDIA

**Meagan C. Fitzpatrick<sup>1</sup>**, Hiral A. Shah<sup>2</sup>, Alyssa M. Bilinski<sup>3</sup>, Manish Kakkar<sup>4</sup>, Andrew D. Clark<sup>5</sup>, Jeffrey P. Townsend<sup>6</sup>, Syed S. Abbas<sup>4</sup>, Alison P. Galvani<sup>6</sup>

<sup>1</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Imperial College, London, United Kingdom, <sup>3</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>4</sup>Public Health Foundation of India, New Delhi, India, <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>6</sup>Yale School of Public Health, New Haven, CT, United States

Over 20,000 rabies deaths occur annually in India, representing one-third of global human rabies. The Indian state of Tamil Nadu has pioneered a "One Health" committee to address the challenge of rabies in dogs and humans. Currently, rabies control in Tamil Nadu involves post-exposure vaccination of humans following dog bites, while potential supplemental approaches include canine vaccination and sterilization. We developed a data-driven rabies transmission model, fit to human rabies autopsy data and human rabies surveillance data from Tamil Nadu. Integrating local estimates for canine demography and costs, we predicted the impact of canine vaccination and sterilization on human health outcomes and evaluated cost-effectiveness according to WHO criteria for India, which correspond to thresholds of \$1582 and \$4746 per DALY for very cost-effective and cost-effective strategies, respectively. We found that highly feasible supplemental strategies focused on stray dogs, vaccinating as few as 7% of dogs annually, could very cost-effectively reduce human rabies deaths by 70% within five years, and a modest expansion to vaccinating 13% of stray dogs could cost-effectively reduce human rabies by almost 90%. Through integration over parameter uncertainty, we find that for a cost-effectiveness threshold above \$1400 per DALY, canine interventions is at least 95% likely to be optimal. If owners are willing to bring dogs to central-point campaigns at double the rate that campaign teams can capture strays, expanded annual targets become cost-effective. This case study of cost-effective canine interventions in Tamil Nadu may have applicability to other settings in India and beyond.

## 1857

### THE CONTROL OF ZONOTIC VISCERAL LEISHMANIASIS IN EUROPE

**Epke Le Rutte<sup>1</sup>**, Roosmarijn van Straten<sup>2</sup>, Paul A. Overgaauw<sup>2</sup>

<sup>1</sup>Erasmus MC, Rotterdam, Netherlands, <sup>2</sup>Faculty of Veterinary Medicine, Utrecht University, Netherlands

Zoonotic visceral leishmaniasis (ZVL) is a tropical infection transmitted by female sandflies that may infect dogs, humans, and wildlife. In the last decade the disease prevalence has increased fivefold in several parts

of southern Europe, where currently an estimated 2.5 million dogs are infected. The main drivers of transmission are the increase in sandfly distribution due to climate change and the traveling and migration of dogs. Many international organisations have created guidelines, providing protocols describing intervention strategies to control the spread of this tropical infection into Europe. In this study, we research whether these guidelines are being implemented in the field to control the further spread of ZVL. We conducted a survey consisting of 24 questions that we distributed via many online platforms and through multiple mailing lists to reach practicing veterinarians in Spain and France. The questions tested their 1) awareness of the spread and public health risks of ZVL in Europe, 2) awareness of the international guidelines, 3) type of protocol used when suspecting and confirming a ZVL case, and 4) their reporting of confirmed cases. 889 veterinarians participated in the survey of which 616 were Spanish (64%) or French (36%). Even though 60% of them were aware of the current increase of ZVL in Europe, 70% were not aware of any guidelines. However, most of their preventive and treatment actions were in line with the intervention strategies as advised in the guidelines' protocols, apart from the fact that only 12% of veterinarians would report a confirmed case, including notifying colleagues within the same practice. In conclusion, we suggest that an easy online international network is founded where both veterinarians as well as general practitioners report confirmed cases of ZVL. This will be crucial for monitoring, control and preventing the further spread of this tropical zoonotic infection into Europe at the regional, national and international level.

## 1858

### HOUSEHOLD PARTICIPATION IN PIG AND HUMAN INTERVENTIONS FOR CONTROL OF *TAENIA SOLIUM* AND LIKELIHOOD OF CONTINUED TRANSMISSION A YEAR LATER IN NORTHERN PERU

**Lauralee J. Fernandez<sup>1</sup>**, Michelle Beam<sup>1</sup>, Ruth Atto<sup>2</sup>, Roberto Camizan<sup>2</sup>, Angela Spencer<sup>1</sup>, Brian Garvey<sup>1</sup>, Ian Pray<sup>1</sup>, Ricardo Gamboa<sup>2</sup>, Percy Vilchez<sup>2</sup>, Claudio Muro<sup>2</sup>, Sandra Olaya<sup>2</sup>, Luz Maria Moyano<sup>3</sup>, Hector H. Garcia<sup>4</sup>, Seth E. O'Neal<sup>1</sup>, For the Cysticercosis Working Group in Peru<sup>4</sup>

<sup>1</sup>Oregon Health & Science University, Portland, OR, United States,

<sup>2</sup>Center for Global Health Tumbes, Universidad Peruana, Tumbes,

Peru, <sup>3</sup>Epidemiology Unit, Hospital Regional JAMO II-2, Tumbes, Peru,

<sup>4</sup>Cysticercosis Unit, Instituto Nacional de Ciencias Neurológicas, Lima, Peru

*Taenia solium* is one of the leading causes of adult onset epilepsy in the world. Mass screening and treatment interventions in humans and pigs are core components of strategies to control this zoonosis, but participation is rarely if ever complete. Few studies have explored whether participation influences future risk of parasite transmission at the household level. In this analysis, we take advantage of the sequential inclusion of 4 communities in two studies to evaluate the relationship of household participation in control interventions and risk of continued *T. solium* transmission 16 months later measured by seropositivity in pigs using LLGP EITB. Mass screening for taeniasis and purchase of seropositive pigs was conducted in August 2015 in 4 communities to end an education-based intervention, and in December 2016 all pigs in these communities were serotested using EITB as part of the baseline for a new intervention. Household data from the two studies were matched resulting in a total of 99 households that raised pigs in 2016. We evaluated the effect of prior participation in 2015 on household pig seropositivity in 2016 expressed as an odds ratio. Although results were not statistically significant, point estimates suggest that those with incomplete participation in mass screening for taeniasis were more likely to have a seropositive pig (OR=1.79[.76, 4.19]). The magnitude of this association was greater in those with incomplete participation in mass screening who also retained a seropositive pig (OR=2.33[.47, 11.46]). These results suggest that there may be a decreased risk of exposure for households participating fully in intervention, and that full household participation should be encouraged. This preliminary finding warrants future studies that are sufficiently powered to describe this possible risk.

### REEMERGENCE OF CANINE RABIES IN COMPLEX URBAN ENVIRONMENTS: LESSONS FROM AN OUTBREAK IN AREQUIPA, PERU

Ricardo Castillo-Neyra<sup>1</sup>, Valerie Paz-Soldan<sup>2</sup>, Alison Buttenheim<sup>3</sup>, Hannelore MacDonald<sup>4</sup>, Andrew Johnson<sup>4</sup>, Cesar Naquira<sup>5</sup>, Michael Z. Levy<sup>1</sup>

<sup>1</sup>Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States, <sup>2</sup>School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States, <sup>3</sup>School of Nursing, Family and Community Health, University of Pennsylvania, Philadelphia, PA, United States, <sup>4</sup>Department of Biology, University of Pennsylvania, Philadelphia, PA, United States, <sup>5</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

The city of Arequipa, Peru is in the midst of an urban rabies epidemic that was identified in March 2015. This is a rare case worldwide of reintroduction of canine rabies into an area that had previously been declared free of transmission. Continued transmission in dog populations puts the one million inhabitants of the city at risk of infection. During the last two years we have conducted dog GPS-tracking and community-based studies to understand the ecological and social drivers of the reemergence and persistence of the rabies virus. We found that the urban layout dictates the presence of rabid dogs: cases are detected closer to some urban structures—dry water channels—than expected by chance (mean distance = 335m;  $p=0.027$ ). Also, movement of free-ranging dogs is highly heterogeneous, temporally and spatially, suggesting that the ring containment practiced by health authorities might not be effective. Mass dog rabies vaccination campaigns have been conducted but do not reach the appropriate coverage. We coupled a qualitative study and a quantitative survey on more than 5,400 houses to determine factors associated with vaccination coverage. The survey obtained demographic variables of dog owners, household level variables (e.g. age of the house), dog care practices within the house, and knowledge about the vaccination campaign. All houses were georeferenced. Importantly, our spatial analysis shows significant pockets of unvaccinated dogs threatening to maintain transmission of the virus and these pockets aggregate significantly the further the campaign is located. Distance to the vaccination campaign reduces greatly the odds of dogs being vaccinated (OR = 0.71 for every 100m;  $p<0.001$ ), after controlling for other variables. In addition, the level of urbanization and the city layout also influence people's preferences on the location of the vaccination campaign. The reemergence of rabies in Arequipa is the result of complex urban socio-ecological drivers that call for the implementation of a One Health approach to halt rabies virus transmission.

### ANTIMYCOBACTERIAL EFFECT OF VARYING CONCENTRATIONS OF E559: A NATURAL PLANT PRODUCT IN NIGERIA

Wisdom O. Iyanda-Joel, Emeka E. Iweala, Shalom N. Chinedu  
Covenant University, Ota, Nigeria

The global tuberculosis (TB) report for 2016 revealed that Nigeria is listed among the high burden countries (HBCs) for TB, HIV/TB and MDR-TB (multidrug-resistant TB). In a bid to proffer an in-house solution with global relevance, the current study was carried out to explore the potential of a plant extract, E559 at varied concentrations against local and standard strains of *Mycobacterium tuberculosis* (MTB). The golden standard procedure for drug susceptibility testing on Löwenstein Jensen (LJ) media using the proportion method was employed in a Biosafety Level-3 facility for antimycobacterial screening. Phytochemical screening was also carried out. Phase I extract concentrations was between 1 and 250 µg/ml while that of phase II was > 1000 µg/ml. The extracts were prepared with the LJ media and subsequently inoculated with 10-3 and 10-5 suspensions of both local (MTB-584) and standard (H37Rv) strains

of *Mycobacterium tuberculosis*. Rifampicin served as the standard drug for positive control while inoculated media was taken as negative control. The inoculated LJ media and control slants were incubated at 37°C and observed every seven days for six weeks. The antimycobacterial screening result showed that both local and standard strains displayed resistance (> 200 colonies) to the extracts at Phase I concentrations (between 1 and 250 µg/ml) evidenced by the ample growth with typical creamy non-pigmented morphology on all the LJ media prepared with extracts. However, there was no single growth (zero colony: 0%) up to six weeks on all the LJ media prepared with > 1000 µg/ml of E559; compared to the substantial growth observed on the negative control (150 and 500 colonies respectively for MTB-584 and H37Rv: 100%). Alkaloids, phenols, steroids, tannins and terpenoids were present in the extract. It can therefore be inferred that elevated crude concentrations of E559 possibly possess strong antimycobacterial activity which can give rise to pure lead bioactive compounds against MTB while activity is minimal at minute concentrations.

### EVALUATION OF A LOW-COST AIR SAMPLING SYSTEM FOR THE DETECTION OF MYCOBACTERIUM TUBERCULOSIS IN COUGHING PATIENTS

Nehal S. Naik<sup>1</sup>, Gwenyth O. Lee<sup>2</sup>, German Comina<sup>2</sup>, Gustavo Hernandez<sup>2</sup>, Carlton Evans<sup>3</sup>, Sumona Datta<sup>3</sup>, Eduardo Ticona<sup>4</sup>, Eric Ramos<sup>5</sup>, Jorge Coronel<sup>5</sup>, Robert Gilman<sup>6</sup>, Valerie A. Paz-Soldan<sup>2</sup>, Richard Oberhelman<sup>2</sup>

<sup>1</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>2</sup>Tulane University, New Orleans, LA, United States, <sup>3</sup>Imperial College, London, United Kingdom, <sup>4</sup>Hospital Nacional Dos de Mayo, Lima, Peru, <sup>5</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>Johns Hopkins University, Baltimore, MD, United States

*Mycobacterium tuberculosis* (TB) aerosol droplets pose significant occupational risks, particularly to healthcare workers in low and middle-income countries. Improvement of airborne TB detection could have broad impacts on global TB control. Our study evaluated an air sampling system to assess active TB aerosols from coughing patients with active pulmonary TB. We enrolled subjects with 2+ or 3+ auramine sputum smear in Lima, Peru, and collected paired sputum samples and cough frequency data. Air-sampling was performed over a 15 minute period of maximally induced cough via a portable 2L/minute vacuum pump onto a PTFE filter with 0.3µm pores. Samples were taken on day 0 and 14 of treatment and at 1m distance from the patient's face in an airborne infection isolation room. In parallel, we performed serial dilutions of 1 McFarland TB and fungal contaminant suspension overlaid on filter material, to define the thresholds of detection of TB on this medium. The filters were subsequently tested with GeneXpert PCR, culture using Middlebrook 7H9 broth, culture with a trisodium phosphate decontamination, and culture with NaOH decontamination. Cultures were assessed up to 8 weeks or until positivity. Our final cohort included 7 patients, of which 5 were 3+ auramine smear and 1 was multi-drug resistant. Clinical samples revealed no positive GeneXpert PCR nor positive culture. A validation lab study revealed threshold of detection of the filters by GeneXpert was 1 in 10 colonies of TB, while by culture was 1 in 100 colonies of TB, suggesting our clinical samples were below this threshold of detection. Growth of TB on filters notably decreased over time, compared to control, suggesting PTFE filters were inhibitory to growth. Decontamination of was also less effective on filters. Our study supports existing hypothesis that PCR can be used to determine TB microbial load from air filters. Assessment of active infectious TB requires culture, which remains difficult due to issues of fungal contamination and poor TB growth on PTFE filters. Future studies will assess broader options for low-cost aerosol filters to assess patient infectivity and occupational risk.

## 1862

**CO-INFECTION AS A RISK FACTOR FOR DISEASE SEVERITY AMONG PATIENTS WITH ADENOVIRUS INFECTION**

**Olga D. Lorenzi-Pena**<sup>1</sup>, Xiomara Torres-Figueroa<sup>2</sup>, Jennifer S. Read<sup>1</sup>, Brenda C. Torres-Velasquez<sup>1</sup>, Carlos Garcia-Gubern<sup>2</sup>, Luisa Alvarado<sup>2</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Dengue Branch, San Juan, PR, United States, <sup>2</sup>Saint Luke's Episcopal Hospital-Ponce Health Sciences University Consortium, Ponce, PR, United States

Adenovirus (AdV) infection results in a broad range of clinical manifestations, with illness severity ranging from asymptomatic/mildly symptomatic to severe/life-threatening. AdV-infected individuals with co-infections (AdV-CO) may have more severe illness, but relevant data are limited. To analyze co-infection as a risk factor for more severe AdV infection, we analyzed data from an acute febrile illness surveillance system in southern Puerto Rico which enrolled patients presenting with fever for <7 days. Naso/oropharyngeal samples were tested for AdV and up to 12 other respiratory viruses. Serum samples were tested for dengue, chikungunya, and Zika viruses. This analysis included all subjects enrolled between May 2012 and May 2016 in whom AdV was detected by PCR in naso/oropharyngeal secretions. Of 497 patients with AdV infection, 92% were <18 years old and 48% were male. In total, 43 (9%) patients had AdV-CO, most of whom (75%) were <14 years of age. All co-infections were viral: influenza A (n=10; 33%), respiratory syncytial virus (n=8; 26%), dengue (n=7; 16%), chikungunya (n=6; 14%), human metapneumovirus (n=3; 10%), parainfluenza-3 (n=3; 10%), human coronavirus HKU1 (n=2; 7%), influenza B (n=2, 7%), and parainfluenza-1 (n=2, 7%). The proportion of patients with rhinorrhea, chills, conjunctivitis, nausea and anorexia did not differ significantly between the two groups ( $\geq 0.08$ ), but a higher proportion of AdV-CO participants (83% vs. 63%) reported cough ( $p=0.007$ ). Patients with AdV and AdV-CO did not differ significantly according to proportion hospitalized [115 (25%) versus 9 (21%), respectively ( $p=0.52$ )] or duration of hospitalization (3.7 days versus 4.3 days, respectively ( $p=0.56$ )). In summary, with the exception of cough occurring more frequently in AdV-CO patients, AdV and AdV-CO patients had similar clinical manifestations. Similarly, AdV and AdV-CO patients did not differ significantly in terms of the proportion hospitalized and the duration of hospitalization. Additional analyses are underway to further evaluate co-infections as well as other potential risk factors for severe AdV infection.

## 1863

**MEASUREMENT OF POA EFFLUX PUMPS RATE IN MYCOBACTERIUM SMEGMATIS STRAINS OBTAINED BY GENE KNOCKOUT**

**Ricardo Antiparra**, Marco Santos, Katherine Vallejos, Fabiana Málaga, Rodolfo Huerta, Patricia Sheen, Mirko Zimic

Universidad Peruana Cayetano Heredia, Lima, Peru

Pyrazinamide (PZA) is a first-line drug used in the treatment of tuberculosis. Inside the cytosol, the bacterial nicotinamidase (PZAse) transforms the PZA into pyrazinoic acid, POA is expelled from the bacteria by an uncharacterized efflux-pump to the external environment causing cytoplasm acidification and lethal disruption of the membrane transport. We evaluated 9 potential candidate genes to encode POA efflux pump in *Mycobacterium tuberculosis*, based on a bioinformatic study. For this purpose, we knocked-out homologous genes in *M. smegmatis*, which has a highly active POA efflux pump. Knockout of these genes were done using a two-step strategy using p2NIL/pGOAL vectors. POA efflux rate were estimated by measuring extracellular POA after incubation with PZA (3 repetitions were performed). Finally, mutant of *Mycobacterium smegmatis* strains were analyzed for its PZA level of resistance by minimum inhibitory concentration (MIC). Knockout of the POA efflux pump decreased the rate of pumping pyrazinoic acid outside the *M. smegmatis* below its normal value only in genes MSMEG 3815 (Gene Rv1634 in MTB)

astmh.org

and MSMEG 0410 (Gene Rv 1183 in MTB). Rates were 1023.82; 1162.40 and 2307.805 nmol POA/mg protein/min for MSMEG 3815, MSMEG 0410 and Wild Type *M. smegmatis* strain, respectively. These rate differences were statistically significant. *M. smegmatis* mutant strains with altered POA efflux rate below its normal value (MSMEG 3815 and MSMEG 0410) did not show changes for its PZA level of resistance. We obtain viable mutant strains with deletion of individual POA efflux pump genes from the chromosome of *M. smegmatis* with changes in their POA efflux rate below its normal value (MSMEG 3815 and MSMEG 0410).

## 1864

**CARETAKERS PERSPECTIVES OF PEDIATRIC TUBERCULOSIS AND IMPLICATIONS FOR CARE SEEKING BEHAVIORS IN SOUTHERN MOZAMBIQUE**

**Yolanda Mause**, Khatia Munguambe, Carolina Mindu, Orvalho Augusto, Jose Munoz, Rui Anselmo, Kisito Gondo, Jahit Sacarlal, Alberto Garcia Bateriro, Elisa Lopez-Varela, Pedro Alonso  
Manhica Health Research Center, Vila da Manhica, Mozambique

Tuberculosis remains an important public health problem, especially in poorly resourced settings. Lack of knowledge and awareness of the disease compromises prompt diagnosis and treatment compliance. To gain insights regarding caretakers knowledge of the aetiology and prevention of paediatric TB, to describe their care seeking behaviours and to assess the acceptability of diagnostic procedures. This study was carried out in Manhica and Macia district in Mozambique using qualitative methods. The qualitative data were collected through an interview guide. All underwent the same semi-structured interviews, the results of which were analysed and compared using content analysis. 11 were caretakers of children diagnosed with TB at the health facility, 11 of children for whom TB was discarded at the health facility and 13 of children with TB compatible symptoms identified in the community. The first 2 groups took part in a TB incidence study, while the third group did not. All underwent the same semistructured interviews, the results of which were analysed and compared using content analysis. Even when confronted with signs suggestive of TB, most caretakers never suspected it or misinterpreted the signs, even among TB positive caretakers and those with TB contacts. There was limited knowledge of TB, The transgression of social norms was often presented as an explanation for TB. The use of traditional care for prevention is widespread, but it varied for treatment purposes. TB diagnostic procedures were considered painful but were unanimously tolerated. Caretakers have low knowledge of TB, seldom suspect paediatric TB, which is often confounded by other illnesses. Moreover, the causes of TB are also mixed with traditional concepts. Health seeking is complex and alternates between conventional and traditional health care providers. TB diagnostic procedures were accepted and tolerated by caretakers regardless of the transitory feelings of fear they elicited. Misconceptions of paediatric TB, associated complex care seeking itineraries and negative feelings of the diagnostic procedures may result in delays, and lost to follow up.

## 1865

**EFFECTIVENESS OF PCV-10 VACCINE AGAINST VACCINE TYPE IPD IN PAKISTAN: IMPACT ASSESSMENT AFTER INTRODUCTION OF PCV-10 IN ROUTINE IMMUNIZATION PROGRAM**

**Asad Ali**, Atif Riaz, Syed Mohiuddin, Tahir Yousafzai, Sara Husain, Furqan Kabir, Anita K. Zaidi

Aga Khan University, Karachi, Pakistan

Pakistan is the first country in South Asia to introduce Pneumococcal Conjugate Vaccine (PCV) in its National Expanded Program on immunization (EPI). Impact assessment of this program is essential for its continuity and to guide other countries in the region regarding introduction of PCV in their EPI programmes. The primary objective of

this study is to assess PCV-10 effectiveness on invasive pneumococcal disease (IPD) due to vaccine serotypes of pneumococcus. A matched case-control study is enrolling children eligible to receive PCV-10 vaccine who present with meningitis and/or radiologically-confirmed pneumonia at 15 hospitals serving low and middle income population in Sindh province of Pakistan. In order to detect IPD proportion of these cases, *lytA* gene is tested by PCR in blood (for radiologically proven pneumonia) and CSF (for purulent meningitis). The proportion of IPD due to vaccine type serotypes is determined through serial multiplex PCR. Five controls are enrolled for each case of vaccine type IPD, matched by age, catchment and season. Enrollment started in July 2013. Of the required sample size of 28 vaccine type IPD cases, 24 cases have been enrolled so far. This includes 17 cases of meningitis and 7 cases of pneumonia. 134 controls have been enrolled for these cases. Estimated PCV-10 vaccine effectiveness (VE) against vaccine type IPD was 70.1% with at least one dose of vaccine and 77.0% for at least two doses of vaccine. The study points towards high effectiveness of PCV-10 vaccine against vaccine type IPD in children in Pakistan.

## 1866

### IMPACT OF PNEUMOCOCCAL CONJUGATE VACCINE (PCV-10) ON PNEUMOCOCCAL NASOPHARYNGEAL CARRIAGE IN CHILDREN IN PAKISTAN: RESULTS OF SERIAL SURVEYS PRE AND POST INTRODUCTION OF VACCINE IN ROUTINE IMMUNIZATION PROGRAM

**Imran Nisar**, Atif Riaz, Furqan Kabir, Fyezah Jehan, Asad Ali  
*Aga Khan University, Karachi, Pakistan*

Pakistan introduced PCV-10 vaccine in EPI programme in April 2013 in Sindh province. We hypothesized that with increase in coverage of PCV-10; there will be decrease in nasopharyngeal carriage of pneumococcal serotypes which are included in PCV-10. Aim of the study was to determine if there is serial decline in carriage among children of age less than five years, after introduction of PCV-10 in routine immunization programme. Yearly cross sectional surveys were planned over the past five years, one before and four after the introduction of PCV-10 in EPI programme. Nasopharyngeal swabs were obtained from representative randomly sampled healthy children in one urban and one rural district of Sindh. Swabs were collected in STGG media and Pneumococci were identified through routine microbiology. Serotypes were identified through real-time sequential multiplex PCR using Centre of Disease Control (CDC) scheme. Each year 220 children of age 3-12 months were enrolled from one rural and one urban district. In rural district, PCV-10 serotypes reduced from 34% in first round to 16% in fourth round among children of age 3-12 months. While in urban district, it remained stable from 30% in first round to 35% in fourth round. Most common PCV-10 serotypes in rural district included 23F, 14, 9V and in urban included 6B, 19F and 23F. While there has been significant reduction in nasopharyngeal carriage of PCV-10 serotypes in rural district, there has been no significant change in urban district after introduction of vaccine. Data from subsequent round may provide better understanding about impact of PCV-10 on nasopharyngeal carriage of serotypes.

## 1867

### FOOD SECURITY AND DIETARY INTAKE OF TUBERCULOSIS PATIENTS IN LIMA, PERU

**Gwenyth Lee**<sup>1</sup>, Valerie Paz-Soldan<sup>1</sup>, Andrea Gomez<sup>2</sup>, Katerine Villaizan<sup>3</sup>, Amy R. Riley-Powell<sup>1</sup>, Carla Tarazona<sup>4</sup>, Ramya Ambikapathi<sup>5</sup>, Katherine Ortiz<sup>1</sup>, German Comina<sup>1</sup>, Gustavo Hernandez<sup>1</sup>, Nehal Naik<sup>6</sup>, Richard Oberhelman<sup>1</sup>, Cesar Ugarte-Gil<sup>3</sup>

<sup>1</sup>Tulane University, New Orleans, LA, United States, <sup>2</sup>Tulane University/Universidad Autónoma Metropolitana, Mexico City, Mexico, <sup>3</sup>Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>Asociación Benéfica PRISMA, Lima, Peru, <sup>5</sup>the Harvard T.H. Chan School of Public Health, Boston, MA,

*United States, <sup>6</sup>Virginia Commonwealth University, Richmond, VA, United States*

Food insecurity and malnutrition are risk factors for contracting tuberculosis (TB), and for failing to complete treatment. In Lima, Peru, TB is often perceived by the community as a nutritional disease. It has been reported that people are more likely to seek screening for tuberculosis because of weight loss than because of cough, and contracting TB is often attributed to poor dietary habits. However, relatively few studies have investigated how these beliefs impact patients' dietary preferences during treatment. To characterize the dietary preferences of recently diagnosed TB patients, we conducted a mixed-methods pilot study in the east of Lima. Structured questionnaires were administered to 45 patients to characterize food security and socio-economic status at baseline and after one and two months of treatment. At one month, twenty-four hour dietary recalls were administered to determine average daily intake of macro and micro-nutrients. Qualitative key informant interviews were also conducted with a subgroup of 9 participants. An equal proportion of patients were overweight, as were underweight, at baseline (14%). Potential micro-nutrient deficiencies, estimated based on the percent of patients eating below estimated average requirements, were common. Qualitative results suggest that patients made active efforts to improve their diets during treatment, were receptive to nutritional information received through their participation in the national TB program, and actively sought out additional nutritional information from other sources. However, misinformation and increased spending on un-evidenced "nutritional" products was also common. Recall data suggested that patients ate an average of approximately 1000 calories/day in excess to what was needed to maintain their current weight, and that most of these additional calories came from carbohydrates. Our results suggest that TB patients in Lima have both positive dietary preferences, that should be reinforced, but are also at risk of misinformation. Dietary guidelines should promote strategies to improve dietary quality through low-cost and locally available foods.

## 1868

### ANTIMICROBIAL RESISTANCE PATTERNS OF COLONIZING STREPTOCOCCUS PNEUMONIAE AMONG YOUNG CHILD-MOTHER PAIRS IN THE RURAL HIGHLANDS OF THE PERUVIAN ANDES

Leigh M. Howard<sup>1</sup>, Kathryn M. Edwards<sup>1</sup>, Marie R. Griffin<sup>1</sup>, Ana I. Gil<sup>2</sup>, Erik Mercado<sup>3</sup>, Theresa J. Ochoa<sup>3</sup>, Gina Minaya<sup>2</sup>, **Claudio F. Lanata**<sup>2</sup>, Carlos G. Grijalva<sup>1</sup>

<sup>1</sup>Vanderbilt University Medical Center, Nashville, TN, United States, <sup>2</sup>Instituto de Investigación Nutricional, Lima, Peru, <sup>3</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

Pneumococcus is a cause of pneumonia among children and adults, despite the use of pneumococcal conjugate vaccines (PCVs). We saw a high prevalence of nasopharyngeal colonization with pneumococcus resistant to multiple antibiotic classes (including tetracyclines) among children in rural Peru, prior to PCV use. We sought to confirm whether this resistance pattern persisted in the post-PCV era. We enrolled subjects from the same households that participated in our previous study, which currently had children <3 years of age in the province of San Marcos - Cajamarca, in rural Peruvian Andes. Nasopharyngeal samples were collected from children, mothers, cows, guinea pigs, and dogs, when available. Samples were cultured for pneumococcus and disk susceptibility testing was performed for several antibiotic classes. Drinking water and milk samples were tested for the presence of beta-lactam and tetracycline residues using the IDEXX Snap-Duo Beta-Tetra testing kit (Westbrook, ME, USA). 47 households were enrolled, encompassing 50 children and 47 mothers. The median (interquartile range) age of children was 1.2 years (0.6-2.2), and the median number of household members was 5 (4-6). Among children, 16/50 (32%) had received an antibiotic course in the prior 6 months, while 7/47 mothers (15%) reported recent antibiotic exposure. Pneumococcus was detected in culture from 31/50 (62%) children, 9/47 (19%) mothers, and 1/31 (3%) guinea pigs. Pneumococci

were not detected in any dogs or cows. Resistance to several classes of antibiotics was common among both children and adults. No beta-lactam or tetracycline residues were detected among drinking water (n=41) or milk (n=7) samples. In conclusion, pneumococcal colonization was common among young children, less prevalent among adults, and minimal among animals. The prevalence of resistance to trimethoprim-sulfamethoxazole, oxacillin, macrolides, and tetracycline was high among children and adults. Additional studies are needed to determine if antimicrobial-resistant pneumococci in this rural area occurs because of local prescribing practices or unintentional environmental exposures.

## 1869

### THERAPEUTIC DRUG LEVELS OF FIRST-LINE TUBERCULOSIS MEDICATIONS AMONG CHILDREN FROM RURAL TANZANIA

Museveni Justine<sup>1</sup>, Anita Yeconia<sup>1</sup>, Nicodemu Ingi<sup>1</sup>, Domitila Augustino<sup>1</sup>, Jean Gratz<sup>2</sup>, Estomih Mduma<sup>1</sup>, Sayoki Mfinanga<sup>3</sup>, Charles Peloquin<sup>4</sup>, Scott Heysell<sup>2</sup>, Eric Houpt<sup>2</sup>, **Tania A. Thomas**<sup>2</sup>

<sup>1</sup>Haydom Lutheran Hospital, Haydom, United Republic of Tanzania, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>National Institute of Medical Research, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>University of Florida, Gainesville, FL, United States

Although newer pediatric dosing recommendations for tuberculosis (TB) have been issued by the World Health Organization (WHO), the number of pharmacokinetic studies in children is limited. Understanding plasma drug concentrations is important to minimize toxicity and maximize successful outcomes. We evaluated plasma drug levels of Rifampin (RIF), Isoniazid (INH), Pyrazinamide (PZA) and Ethambutol (EMB) among children undergoing TB treatment in Haydom, Tanzania. Two months after starting TB therapy, phlebotomy was performed two hours after a witnessed medication administration to estimate peak drug concentrations (C<sub>2h</sub>). Plasma drug concentrations were measured using validated high performance liquid chromatography or liquid chromatography-mass spectrometry methods. Risk factors for low drug levels were analyzed. Between January 2014 and January 2016, 52 children were enrolled (median age 5.3 years, range 0.75-14), including 8 (16%) who were younger than 2 years. All were HIV negative and 24 (46%) were female. Moderate/severe malnutrition affected 40 (77%) participants; persistent diarrhea was reported by 7 (14%) participants. Pulmonary involvement was found in 34 (66%) children; 20 (39%) had microbiologically-confirmed TB. Mean drug concentrations to all TB drugs were significantly below target ranges (RIF: 1.68 mcg/mL, target range 8-24 mcg/mL; INH: 2.03 mcg/mL, target range 3-6 mcg/mL; PZA 19.22 mcg/mL, target range: 20-50 mcg/mL; EMB 1.03 mcg/mL, target range: 2-6 mcg/mL). Children receiving the newer WHO dosing recommendations had higher drug levels for RIF, PZA and EMB, but not for INH; however overall, very few (16%) achieved levels within the target range. Multivariate regression analysis identified malnutrition as a significant risk factor for low RIF and INH levels. In this cohort, estimated peak two-hour drug concentrations of TB medications fell below the target values. The prevalence of malnutrition in this setting may be contributing to suboptimal drug exposure. Maximizing the weight-based doses according to the revised WHO guidelines holds promise for improving drug levels.

## 1870

### DRUG RESISTANT TUBERCULOSIS

**Stellah G. Mpagama**<sup>1</sup>, Peter Mbelele<sup>1</sup>, Anna Chongolo<sup>1</sup>, Isaack Lekule<sup>1</sup>, Johnson Lyimo<sup>2</sup>, Scott Heysell<sup>3</sup>

<sup>1</sup>Kibong'oto Infectious Diseases Hospital, Moshi, United Republic of Tanzania, <sup>2</sup>National TB and Leprosy Programme, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Division of Infectious Diseases and International Health, University of Virginia, Charlottesville, VA, United States

Multidrug-resistant tuberculosis (MDR-TB) control is adversely impacted by delay in diagnosis and treatment. This study was undertaken to identify operational factors contributing to ongoing delay from MDR-TB diagnosis

with molecular methods to treatment initiation. Mixed qualitative and quantitative approaches were utilized within randomly sampled districts from high burden regions during the fourth quarter of 2016. District TB and Leprosy Coordinators (DTLCs), and District AIDS Coordinators (DACs) were interviewed, along with all laboratories within the selected districts where molecular diagnostics tests for MDR-TB were performed. Furthermore, the 2015 registers for retreatment TB cases were audited as these patients were targeted for molecular diagnostic testing within the Tanzania National TB and Leprosy program (NTP). Twenty-eight TB Districts from 5 Regions provided 53 clinicians' interviews; 27 (51%) DTLCs and 26(49%) DACs. DTLCs and DACs with intermediate and no knowledge on the clinical application of XpertMTB/RIF was 5(19%) and 11(42%) [p=0.02] while GenotypeMTBDRplus was 19(70%) and 25(96%) [p=0.04] respectively. Of the 399 retreatment TB cases, only 160 (40%) had specimens collected for drug-susceptibility testing (molecular or phenotypic methods), and of those specimens only 120 (75%) had results communicated back to the clinic. Additionally, 11 (100%) of the laboratories surveyed only 4-module XpertMTB/RIF equipment was available, while 5 (45%) and 6 (55%) were maintained by the government and private donors respectively. As a consequence, the median number of specimens received for XpertMTB/RIF was 12 (Min/Max 10 - 30) per day but the median number processed was only 12 (IQR 6 - 24) per day. Reported challenges for molecular diagnostics maintenance included equipment out of service for a median duration of 2 months (IQR; 1 - 4) and periodic stock-out of cartridges found in 9 (82%) of laboratories. In Conclusion, innovative programmatic interventions are required before the full potential of molecular diagnostics for MDR-TB can be realized in Tanzania.

## 1871

### MYCOBACTERIUM TUBERCULOSIS PREVALENCE IN A MILITARY POPULATION

**John Mark Velasco**<sup>1</sup>, Noel Gaurano<sup>2</sup>, Paula Corazon Diones<sup>1</sup>, Ma. Theresa Valderama<sup>1</sup>, Kathyleen Nogrado<sup>1</sup>, Ma. Theresa Alera<sup>1</sup>, Domingo Jr Chua<sup>2</sup>, Damon Ellison<sup>1</sup>, Alden Weg<sup>1</sup>, Louis Macareo<sup>1</sup>, Brett Swierczewski<sup>1</sup>

<sup>1</sup>U.S. Army Medical Directorate-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>VLGH, AFPMC, Manila, Philippines

About one third of the world population is estimated to be infected with *Mycobacterium tuberculosis* (TB) and this proportion is expected to be higher in countries with a high TB burden. The Philippines is considered as both high TB burden (incidence  $\approx$  324,000 with 14,000 deaths) and high MDR-TB ( $\approx$ 17,000 cases) burden country (WHO Global tuberculosis report 2016). In military populations, TB has been historically responsible for causing considerable burden of disease due to unique factors such as working and living in confined environments and deployment to areas with high TB rates. Though TB has been extensively addressed in the Philippines civilian population, the burden of disease among military personnel has not yet been characterized. In 2015, the Armed Forces of the Philippines Medical Center (AFPMC), Manila was designated as a TB Xpert testing facility with the capability to detect TB and rifampicin (RIF) resistance or multi-drug resistant TB (MDR-TB) via real-time reverse transcriptase polymerase chain reaction. From July 2015 to March 2017, patients seen at AFPMC underwent testing for *M. tuberculosis* using a combination of direct sputum smear microscopy (DSSM) and real-time RT-PCR: 40/278 (14%) were TB positive by real-time RT-PCR and RIF resistance (MDR-TB) was detected in 8/40 (20%). Age range of the TB positive cases was 1 to 72 years and male to female ratio was 3:1. While there were more confirmed TB and MDR-TB cases in the civilian vs the military population, the proportion of TB positive cases was higher in the active duty military [OR 1.54] versus the civilian population. This initial report describes TB prevalence among active duty military personnel in a high TB and MDR-TB burden setting and indicates that this communicable disease poses a substantial force health protection threat.

## 1872

**MAPPING LOWER RESPIRATORY INFECTIONS IN SPACE AND TIME IN AFRICA**

**Robert C. Reiner**, Nick Graetz, Scott Swartz, Puja C. Rao, Jonathan Mosser, Aniruddha Deshpande, Aaron Osgood-Zimmerman, Roy Burstein, Chris Troeger, Simon Hay

*University of Washington, Seattle, WA, United States*

Lower respiratory infections (LRI) are some of the leading causes of death in the world, particularly in lower and middle income countries. Much of the burden of LRIs are felt in Africa, where they were responsible for more than 790,000 deaths and more than 70,000,000 infections in 2015. Moreover, LRIs were the 2nd leading cause of death and disability-adjusted life-years (DALYs) in Africa across all age groups as well as for children under the age of 5. Despite a growing population in Africa, mortality and morbidity associated with LRIs have decreased in the last 25 years. However, these changes vary significantly across both regions and countries. Assessing progress and identifying locations most in need of further interventions requires an accurate understanding of spatial variation at the scales on which public policy acts. Past efforts have focused on estimating burden either for a single country at a fine spatial resolution, or continent-wide at very coarse spatial resolution (country by country). Here we present the first effort to model yearly all-cause LRI prevalence and mortality at a 5km<sup>2</sup> resolution across all of Africa. Our model-based geo-statistical approach captures significant spatiotemporal variation in prevalence and mortality. Further, it exposes substantial heterogeneity in both of these metrics of burden, as well as spatial inequality in gains made against them through time. Finally, this Bayesian approach also propagates uncertainty through the model to expose not only locations with high or low burden, but also understudied locations whose burden may or may not be considerable but require further investigation. These results will guide targeted interventions within or between countries and regions as well as assess the effectiveness of current strategies.

## 1873

**DOES THE ABSENCE OF HYBRIDIZATION WITH THE WILD-TYPE PROBE IN THE GENOTYPE MTBDRPLUS ASSAY MEAN THE MYCOBACTERIUM TUBERCULOSIS ISOLATE IS RIFAMPICIN RESISTANT?**

**Ngu N. Abanda**

*University of Hawaii at Manoa, Honolulu, HI, United States*

Effective management of drug-resistant TB including Rifampicin-resistant TB (RR-TB) relies on accurate and rapid diagnosis. In 2008, WHO endorsed the Genotype MTBDRplus assay for the rapid diagnosis of drug-resistant TB including RR-TB. This assay detects resistance to RIF by identifying mutations in the *rpoB* gene of *Mycobacterium tuberculosis* (Mtb) from codons 507 to 534. Mutations that enable Mtb to be resistant to RIF are located within this region. However, not every mutation in this region is associated with resistance to RIF. A recommendation in interpreting the Genotype MTBDRplus assumes that the detection of any mutation in this region based solely on the absence of hybridization to an assay probe should be considered as resistant. Some of the mutations in *rpoB* gene region could be silent mutations or missense mutations with unclear association with resistance to RIF. Here, we screened 275 Mtb isolates from naïve and previously treated Cameroonian TB patients with the Genotype MTBDRplus assay and identified 6% of Mtb isolates classified as resistant to RIF based on this recommendation. Sequencing of these Mtb isolates revealed that impaired hybridization to the assay probes was due to the presence 'disputed' RIF mutations (511Pro, 513Pro, 516Tyr, 526Arg, 526Leu, 526Asn, 531Trp, and 533Pro). These mutations are called 'disputed' because not all Mtb isolates bearing them have a RIF-resistant phenotype. As such, using the recommend interpretation for the Genotype MTBDRplus assay will lead to the over-diagnosis of very

few RIF resistant cases. Considering these few cases have been reported to result in adverse treatment outcome, they should be reviewed and treated as 'true' Rifampicin resistant cases. Thus, the recommendation of the Genotype MTBDRplus assay to assume resistance based solely on the absence of hybridization to wildtype probe allows the identification of clinically significant Rifampicin-resistant Mtb isolates.

## 1874

**AFFINITY NANOCAGES ENABLE DETECTION OF MYCOBACTERIUM TUBERCULOSIS LAM AND PROTEIN ANTIGENS IN THE URINE OF HIV NEGATIVE PULMONARY TB PATIENTS**

**Alessandra Luchini**<sup>1</sup>, Luisa Paris<sup>1</sup>, Ruben Magni<sup>1</sup>, Jorge Coronel<sup>2</sup>, Daniela Kirwan<sup>3</sup>, Hannah Steinberg<sup>4</sup>, Emanuel Petricoin<sup>1</sup>, Roberto Nisini<sup>5</sup>, Lance Liotta<sup>1</sup>

<sup>1</sup>George Mason University, Manassas, VA, United States, <sup>2</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>St. George's Hospital, London, United Kingdom, <sup>4</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>5</sup>Istituto Superiore di Sanita', Rome, Italy

A non invasive urine test for pulmonary TB patients who are not co-infected with HIV (85% of 9.6 million with active TB) is critically needed for worldwide surveillance, and treatment management. We have created a novel multifunctional nanoparticle buoyant cage that contains a new class high affinity copper dye which binds carbohydrate and glycoprotein TB antigens with an affinity hundreds of times higher than existing antibodies or lectins. We used this technology in one step, in solution, to affinity capture, concentrate, and displace from interfering biomolecules, TB antigens present in patient's urine. Past attempts failed to reliably detect the mycobacterial glycan antigen lipoarabinomannan (LAM), or ESAT6, well characterized TB antigens, in the urine of HIV negative pulmonary TB infected patients' urine. Our technology can increase the analytical sensitivity of downstream analytical techniques greater than 100 fold, and reduce the background, with a yield close to 100 percent to achieve a new class of urinary TB immunoassay. Our technology was applied to study pretreatment urine from hospitalized Peruvian patients, all negative for HIV, with microbiologically-confirmed, culture positive, active pulmonary TB. LAM was quantitatively measured in the urine via immunoblot with a sensitivity >95% and a specificity >80% (p<0.00001, N=101) in a concentration range of 14 to 2000 picograms per mL, as compared to non-TB, healthy and diseased, age matched controls (ROC AUC = 0.95, 95% CI: 0.9005-0.9957). Moreover, urinary LAM was significantly (p<0.05) elevated in patients with a higher mycobacterial burden, or a higher diseases severity (cachexia, cough rate). Finally, we used our nanotechnology and mass spectrometry to identify unique peptides specific for *Mycobacterium* proteins in the urine of a subset of patients harboring active pulmonary TB. Our technology, coupled to immunoassay or mass spectrometry analysis, has broad implications for pulmonary TB screening, transmission control, and treatment management for HIV negative patients.

## 1875

**QUALITATIVE AND QUANTITATIVE ANALYSIS OF CRYPTOSPORIDIUM PARVUM GROWTH IN POLARIZED INTESTINAL EPITHELIAL CELLS**

**Robert E. Molestina**, Biniam Hagos, Timothy T. Stedman

*ATCC, Manassas, VA, United States*

*Cryptosporidium parvum* is an obligate intracellular parasite that can cause life-threatening diarrhea among children and immunocompromised adults. Optimal *in vitro* models of long-term *C. parvum* growth remain to be developed, constituting an obstacle to the study of host-parasite interactions and standardization of *in vitro* drug screening assays. The present study evaluated the growth of *C. parvum* in polarized human intestinal epithelial cell lines as a physiologically-relevant model of the

intestinal lumen. Human colorectal adenocarcinoma Hct-8 cells and small intestinal epithelial FHs 74 cells were grown on polycarbonate membrane supports. Cell cultures were inoculated with *C. parvum* Iowa and infection was assessed qualitatively and quantitatively by immunofluorescence microscopy assay (IFA) and qRT-PCR, respectively. IFA experiments showed that trophozoite and meront I stages of *C. parvum* were predominant between 24 h and 72 h of infection in both cell lines. The larger meront II stages were more evident at 72 h in Hct-8 compared to FHs 74 cells. This difference was also apparent at 7 and 10 days of infection. Quantitative analysis of parasite growth by qRT-PCR showed peak levels of *C. parvum* 18S rRNA expression between 48-72 h in both cell lines and progressive decreases after 7-10 days of infection. Of note, different expression patterns between the cell lines were observed among genes coding for oocyst wall proteins, sporozoite surface antigens, metabolic proteins, and proteins with roles in sexual replication. In summary, we have established a framework to monitor the growth of *C. parvum* in different polarized cell lines in a qualitative and quantitative manner. Polarized FHs 74 cells offer a better model to visualize the intracellular stages of *C. parvum* and to study the asexual life cycle of the parasite. Optimization of *in vitro* models that better resemble the *in vivo* state as closely as possible should provide improved tools to study the pathogenesis and drug susceptibility properties of *C. parvum*.

## 1876

### COMPARATIVE TRANSCRIPTOMICS ANALYSIS OF ZOOTIC PROTOZOAN PARASITE, *BABESIA MICROTI* FROM MOUSE MODEL

Shen-Bo Chen<sup>1</sup>, Hai-Mo Shen<sup>1</sup>, Jun-Hu Chen<sup>1</sup>, Wei Hu<sup>2</sup>

<sup>1</sup>National Institute of Parasitic Diseases, Chinese Center for Disease Control and Prevention, Shanghai, China, <sup>2</sup>School of Life Sciences, Fudan University, Shanghai, China

We have sequenced the transcriptome of the emerging human pathogen *Babesia microti* from mouse model and compared it with that of other protozoa. Our sequencing generated 731,487 reads with an average read length of 416 bp and GC content of 39%. The transcriptome was constructed using Newbler 2.6. Our de novo assembly yielded a database with 6,573 contigs (N50 of 1,317 bp) and 18,530 singlets, and generated 11,893 unigenes with CD-hit. In those unigenes, approximately 30% of them could be annotated to public database (swiss-prot and NR), and 1,683 unigenes were confirmed as orthology with *Babesia bovis*. Parasite ligands and proteases play a role in the merozoite invasion process, the moving junction complex protein apical membrane antigen 1 and its receptor, the rhoptry neck protein 2 (AMA1-RON2), a key factor of merozoite invasion mechanism was identified for *B. microti*. Furthermore, a new group of invasion related proteins containing the conserved TSP-1 motif has been identified from *B. microti*, namely merozoite specific thrombospondin-related anonymous protein (MTRAP) and thrombospondin related apical merozoite protein (TRAMP). However, the family of *Plasmodium falciparum* erythrocyte binding antigens (PfEBAs) and reticulocyte binding-like homologous proteins (PfRHs) as important invasion related proteins haven't been identified in *B. microti*, as well as SUB1, a member of subtilisin-like serine protease and serine-rich antigens (SERAs). Knowledge gained from these comparisons can shed light on the development of diagnosis methods, improved vaccines and new chemotherapy targets and provide a better understanding of the underlying biology and evolution.

## 1877

### WHOLE GENOME DNA SEQUENCE CAPTURE APPROACH REVEALS TREMENDOUS GENETIC DIVERSITY IN INTRACELLULAR PATHOGEN *THEILERIA PARVA*

Nicholas C. Palmateer<sup>1</sup>, Kyle Tretina<sup>1</sup>, Roger Pelle<sup>2</sup>, Elias Awino<sup>2</sup>, Hanzel T. Gotia<sup>1</sup>, Vish Nene<sup>2</sup>, Claudia A. Daubenberger<sup>3</sup>, Richard P. Bishop<sup>2</sup>, Joana C. Silva<sup>1</sup>

<sup>1</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>International Livestock Research Institute, Nairobi, Kenya, <sup>3</sup>Swiss Tropical and Public Health Institute and University of Basel, Basel, Switzerland

*Theileria parva* is a tick-transmitted apicomplexan parasite that causes East Coast fever (ECF), an acute fatal disease of cattle in sub-Saharan Africa. A vaccine for this disease currently exists, which is effective against cattle-transmissible strains but less effective against those originating from the African Cape buffalo, the natural reservoir of *T. parva*. Knowledge of genetic variation in both cattle- and buffalo-derived *T. parva* strains is critical for the design of next-generation vaccines against the parasite. The biology of *T. parva* has so far proven a powerful obstacle to the acquisition of DNA in sufficient quantity and quality for whole genome sequencing. DNA extracted early in the infection cycle is heavily contaminated with host DNA and parasite DNA from late-stage infections cannot be obtained sustainably on a large scale. We have adapted a DNA sequence capture approach to select *T. parva* from a mix of parasite and bovine DNA obtained from *T. parva*-infected bovine lymphocytes. In order to gain access to variable genomic regions that cannot be characterized through read mapping approaches, we assembled the captured reads *de novo* and analyzed the assemblies for completeness, including the presence of highly variable genes. From starting material of <1%-4% parasite DNA in a mixed sample from host and parasite, >98% of sequence reads post-capture mapped to the parasite genome, reflecting the method's high specificity. *De novo* assemblies generated from these data correspond to >97% of the reference genome, with all but two protein-coding genes present. This approach is successful even when applied to highly divergent *T. parva* isolates from buffalo, for which we present the first publicly available assembly. The ability to characterize genome-wide polymorphism based on *de novo* genome assemblies, an approach with higher resolution than read-mapping approaches, allows us to identify regions of greater diversity in the *T. parva* genome. We are able to identify the most divergent genes across isolates, the significance of their genomic location and use these results to inform the potential function of hypothetical proteins.

## 1878

### BLASTOCYSTIS AS A MARKER OF FECAL-ORAL OR WATER CONTAMINATION IS ASSOCIATED WITH AN INCREASED RISK FOR GASTROINTESTINAL PARASITIC INFECTION

Kevin Naceanceno<sup>1</sup>, Gabriela Matamoros<sup>2</sup>, Maria Elena Botazzi<sup>1</sup>, Ana Sanchez<sup>3</sup>, Rojelio Mejia<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>National University of Honduras, Tegucigalpa, Honduras, <sup>3</sup>Brock University, St. Catharines, ON, Canada

Polyparasitism is widespread in developing communities and may persist even after antiparasitic drug therapy. Risk factors for persistent infection may be attributed to resistance or reinfection. For proper intervention, the predominant risk factors must be determined. *Blastocystis* spp. are common intestinal protists whose role as human pathogens is disputed. To investigate whether the presence of *Blastocystis* is associated with gastrointestinal (GI) parasite infection in a rural location in Honduras regularly treated with Albendazole, stool samples from 99 children (mean age = 6.1 yrs) were analyzed using multi-parallel quantitative real-time PCR (qPCR) for *Ascaris lumbricoides*, *Ancylostoma duodenale*, *Necator americanus*, *Trichuris trichiura*, *Strongyloides stercoralis*, *Cryptosporidium*, *Entamoeba histolytica*, *Giardia lamblia*, and *Blastocystis*. Overall, 71.6%

of children tested positive for *Blastocystis*, 11.1% *Ascaris*, 2.0% *Necator*, 1.0% *Strongyloides*, 46.5% *Trichuris*, and 41.4% *Giardia*. Study participants infected with *Blastocystis* were more likely to be infected by one or more other GI parasites compared to participants not infected with *Blastocystis* (relative risk 1.946, 1.24 to 3.40; odds ratio 4.384, 1.62 to 10.4; sensitivity 83.1%, specificity 47.0%;  $p = 0.002$ ). Helminth infection was correlated to *Blastocystis* infection ( $p < 0.001$ ) while protozoan infection was not ( $p = 0.248$ ). Interestingly, our studies revealed a strong correlation ( $p = 0.0002$ ) between *Blastocystis* positive participants and *Trichuris* positive participants. Our data suggests that *Blastocystis* is a useful indicator of GI parasite exposure rates. Because *Blastocystis* is reported to be transmitted by both fecal-oral contamination and cyst-infected water sources, further studies will investigate the transmission modes and subtypes of *Blastocystis* and connections to the transmission of helminth infections.

## 1879

### SINGLE MOLECULE, REAL-TIME SEQUENCING OF PCR PRODUCTS REVEALS *THEILERIA* PARASITE SPECIES AND ANTIGEN DIVERSITY

Kyle Tretina<sup>1</sup>, Jamal Badoui<sup>1</sup>, Nicholas C. Palmateer<sup>1</sup>, Richard P. Bishop<sup>2</sup>, Joana C. Silva<sup>1</sup>

<sup>1</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>International Livestock Research Institute, Nairobi, Kenya

Infection of cattle with the apicomplexan parasite *Theileria parva* causes an acute and often deadly disease that imposes a significant economic burden on several countries in sub-Saharan Africa. Host CD8+ cytotoxic T cells are believed to play an important role in protection, which can be achieved by immunization via an infection-and-treatment method. However, this immunity is often strain-specific, and antigenic variation can play an important role in the effectiveness of the immunization regimen. Therefore, an understanding of the diversity of *Theileria* species that infect cattle in endemic regions, and the diversity of their antigens, is important for improving vaccine design and implementation. Here, we report a new molecular assay to characterize *Theileria* infections in cattle and buffalo, which will identify both multiple species as well as multiple strains of a single species. This assay is based on the PCR amplification of three *Theileria loci*, followed by deep sequencing of the amplicons, multiplexed across *loci* and samples with a Pacific Biosciences (PacBio) sequencing platform. One amplicon represents partial sequence of the 18S ribosomal DNA gene while the other two produce full length sequences of two highly variable *Theileria* antigens, Tp2 and Tp9, known to be recognized by CD8+ T cells activated in response to *T. parva* infection. Consequently, this assay also allows the investigation of genetic diversity in two critical parasite antigens. The assay was used in 23 cattle biopsies from a farm in Naivasha, Kenya, where cattle and buffalo co-mingle. Using bioinformatics approaches, we were able to uncover new, potentially biologically relevant, sequence variation in known parasite antigens and reveal patterns of co-infection with *T. parva* and a recently discovered parasite, *Theileria* sp. (buffalo). We propose that this approach could be used as an economical epidemiological tool to study the etiology of *Theileria* infection of bovinds in sub-Saharan Africa, as well as parasite antigenic diversity.

## 1880

### EVIDENCE OF RNA EDITING IN *BABESIA MICROTI*

Olukemi O. Ifeonu, Ankit Dwivedi, Joana C. Silva  
University of Maryland School of Medicine, Baltimore, MD, United States

RNA editing is a molecular process by which isolated alterations can be made to specific nucleotide sequences within an RNA molecule after it has been transcribed by RNA polymerase, but before it is translated into protein. These changes may in turn lead to amino acid sequence differences in the resulting polypeptide relative to what is encoded in the DNA, with potential consequences to parasite metabolism. *Babesia microti* is the primary cause of human babesiosis, an emerging infectious

disease in the United States. In order to better understand the genetic and genomic diversity among *B. microti* isolates and thus improve diagnosis, treatment and prevention, we recently generated genomic and immunological data for seven *B. microti* strains. In addition, we generated strand-specific RNA-seq data for six of these isolates. Preliminary results from short read alignment of both genomic DNA (gDNA) and RNA-seq data of the same strain against the reference R1 genome suggest the presence of several unambiguous single nucleotide polymorphisms (SNPs) differences between the two data types generated from the same strain. These differences were confirmed by manual inspection of the read alignments. We are currently using systematic bioinformatics approaches to characterize, for each strain, the differences observed in the gDNA and RNA-seq data, including the nucleotides involved, directionality and genomic context of such changes. We are also investigating whether these differences are similar among strains, and whether this editing, if true, has potential public health implications.

## 1881

### KILLING OF *CRYPTOSPORIDIUM* SPOOROZITES BY LACTOFERRIN

Jose L. Paredes<sup>1</sup>, Hayley Sparks<sup>2</sup>, A. Clinton White, Jr.<sup>2</sup>, Theresa J. Ochoa<sup>1</sup>, Alejandro Castellanos-González<sup>2</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Infectious Disease Division, Department of Internal Medicine, University of Texas Medical Branch, Galveston, TX, United States

*Cryptosporidium* species are major causes of diarrhea morbidity and mortality in children from resource-limited countries specially children below 24 months of age. A large number of therapeutic agents have been evaluated for their anticryptosporidial activity, but only nitazoxanide has been approved by the FDA. Lactoferrin is a multifunctional glycoprotein present in breast milk with bacteriostatic, antimicrobial and anti-inflammatory activity. We conducted a study to determine the effect of lactoferrin during *Cryptosporidium* infection and on its sporozoites. An experimental study was conducted. We tested the effect of physiological concentrations of lactoferrin (0, 1, 2.5, 5, and 10 mg/mL) on *Cryptosporidium parvum* oocysts determined by the excystation rates via microscopy. The effect on sporozoite infectivity was evaluated by exposing excystated sporozoites to physiological concentrations of lactoferrin and the infection was evaluated in the infection model using HCT-8 cells and a RT-PCR. We observed that biological concentrations of lactoferrin did not affect excystation and had no effect on intracellular stages of the parasite. However sporozoites treated with  $\geq 5$  mg/mL lactoferrin (for 2 hours during the time of infection) resulted in significantly reduced numbers of parasites present after 24 hours of infection and parasites treated with 10 mg/mL lactoferrin didn't show fluorescence during microscopic analysis indicating that all parasites were killed after treatment, opposite to untreated parasites. Since the sporozoites are important during the infection process, then our data point to the potential of lactoferrin as a novel therapeutic agent for cryptosporidiosis and that continuous presence of breast milk in an infant's diet may decrease or inhibit *Cryptosporidium* infection. Further clinical studies are needed to confirm these findings in cases of cryptosporidiosis in children and other at-risk patients. If successful, lactoferrin may be a much-needed treatment option for cryptosporidiosis.

## 1882

### REAL-TIME PCR STRATEGY FOR DETECTION OF *TOXOPLASMA GONDII* FROM PERIPHERAL BLOOD CLOT

Cusi Ferradas<sup>1</sup>, Renzo Gutierrez-Loli<sup>1</sup>, Andrea Diestra<sup>1</sup>, Aliko Traianou<sup>1</sup>, Holger Mayta<sup>1</sup>, Maritza Calderon<sup>1</sup>, Jaeson S. Calla-Choque<sup>2</sup>, Robert H. Gilman<sup>3</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>School of Medicine, University of California, San Diego, CA, United States, <sup>3</sup>Department of

*International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States*

Toxoplasmosis is a zoonotic disease caused by *Toxoplasma gondii*, an obligate intracellular coccidian parasite that infects humans as well as virtually all warm-blooded organisms. In most cases toxoplasmosis is asymptomatic; however, it can cause serious and life-threatening conditions in immunocompromised subjects. Diagnosis of toxoplasmosis includes serological tests and clinical and radiological response to treatment. However, a serological approach has low detection power since reactivation of the infection is not always followed by changes in antibody production, and correlation with other assays is needed for accurate diagnosis. For this reason, direct demonstration of the presence of the parasite in body fluids would mean a breakthrough for the diagnosis of this disease. The quantitative polymerase chain reaction (qPCR), directed to B1 and REP529 multicopy genes, has shown variable sensitivity which might be affected by the amount of parasite DNA present in different blood sample specimens. There is no consensus on which one yields the best performance. In this study we developed a qPCR method for accurate quantification of *T. gondii* loads using clot samples along with an adequate DNA extraction protocol. Additionally, we compared the sensitivity of the clot-based qPCR reaction with two other common types of blood specimens: whole blood in EDTA and guanidine EDTA blood (GEB). Before DNA extraction, clot specimens were transferred with a lysing matrix tube followed of an agitation cycle in a tissue homogenizer machine to ensure the clot disaggregation. The clot standard curve detected the lowest parasite load when compared to the ones from whole blood and GEB. The detection limit for clot samples was ten parasites with B1 as the target and one parasite using REP529. The high sensitivity of clot qPCR suggests widespread use of this specimen as a powerful tool for toxoplasmosis diagnosis. The future direction is to validate this technique using different blood samples from patients with neurological symptoms compatible with a *Toxoplasma gondii* infection.

## 1883

### URBANORUM SPP. EMERGING MICROORGANISM IN FECAL SAMPLES OF CHILDREN AT THE NATIONAL INSTITUTE OF CHILD HEALTH, AND OF ANIMALS: PIG AND CATTLE FROM LIMA, PERU FROM JANUARY TO MARCH, 2017

Enfermedades Neoplásicas, Lima, Peru, <sup>5</sup>Frigorífico La Colonial Sac, Lima,

Peru, <sup>6</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

*Urbanorum* spp. is described as "protozoan" emerging in Colombia, Ecuador, Venezuela and Mexico, and there is a first reported case in Peru in 2016; it is described as a protozoan similar to amoebae, with a round shaped form, 80-100µm of size, that releases "pseudopodia" and has been found in parasitic exams of adult and child patients, with a prevalence from 0-16%. The objective of this work is to investigate *Urbanorum* spp. in faecal samples obtained from children aged 0-16 years. A total of 305 samples from routine parasitological diagnostic in the National Institute of Child Health's Microbiology Service were processed and additional exams for *Urbanorum* spp. were realized at the Daniel A. Carrión Institute of Tropical Medicine of the National University of San Marcos, Lima, Peru, between January and March, 2017. Samples were processed with saline serum and Lugol, as well as other stains such as Ziehl Neelsen, Methylene Blue, Malachite Green, Safranin and Giemsa. *Urbanorum* spp. was found in 50 of the 305 (16.4%) samples from faecal samples of children. *Urbanorum* spp. was also studied in 200 faecal colon samples from pigs and recently slaughtered cattle from the Frigorífico La Colonial Sac, Lima, Peru, showing no presence of *Urbanorum* spp. Conclusion: *Urbanorum* spp. has been found in 16.4% of faecal samples of children and none in

the faecal samples of animals; it is necessary to perform microbiological studies including molecular biology, clinical epidemiology, pathogenesis, treatment and control of this emerging microorganism.

## 1884

### EVALUATION OF THE IMMUNOSUPPRESSIVE EFFECT OF DEXAMETHASONE IN SWISS MICE INFECTED WITH TOXOPLASMA GONDII ME49 STRAIN

Juan Jimenez<sup>1</sup>, Raul Ynocente<sup>1</sup>, Christian Huaman<sup>1</sup>, Noelia Angulo<sup>2</sup>, Alejandro Florentini<sup>2</sup>, Maritza Calderon<sup>2</sup>

<sup>1</sup>UNMSM, Lima, Peru, <sup>2</sup>UPCH, Lima, Peru

*Toxoplasma gondii* is a protozoan that can cause disease, especially in immunocompromised patients. The main form of dissemination of the parasite is by blood. In this study we evaluated leukocyte levels and the variation of their populations during experimental infection with *T. gondii* under immunosuppression. Three groups of mice were studied: group A: infected and immunosuppressed (n = 15), group B: uninfected and immunosuppressed (n = 10), group C: uninfected, non-immunosuppressed (n = 5). Group A were orally infected with 10 to 20 cysts of the Me49 strain, mice were immunosuppressed after 60 days of infection. The immunosuppression was intraperitoneally with 100 mg / kg of dexamethasone. We collected peripheral blood from the mouse tail at the beginning and end of the experiment at 0, 7, 21, 50 and 80 days post infection and 30 days after immunosuppression. Leukocyte quantification was performed using Turk method. The proportions of leukocytes were evaluate in a blood smear stained with Giemsa. The total leukocyte count showed : Group A, 17,220 cells / mm<sup>3</sup>, group B of 19,400 cells / mm<sup>3</sup> and group C 19,983 cells / mm<sup>3</sup>. After immunosuppression, group A: 3,166 cells / mm<sup>3</sup>, group B: 12,865 cells / mm<sup>3</sup> and group C: 27,350 cells / mm<sup>3</sup>. The percentage of leukocytes and neutrophils for mice in group A and B before immunosuppression was 90% and 25%, respectively. This percentages for these groups changed markedly after 60 days of immunosuppression: for group A it was 40% and 80% of lymphocytes (L) and neutrophils (N), respectively. For group B, it was 60% and 70%, of L and N, respectively. For the control group this percentage was 90% of L and 20% of N. In normal Swiss mice lymphocytes predominate more than neutrophils. Experimentally mice infected with *T. gondii* and subsequently treated with dexamethasone show a low lymphocyte population and increased neutrophils. The conclusion was the immunosuppression method was successful, confirmed by the cell count and the presence of a large number of cysts in the brains in group A. We suggest to develop this type of methodology in order to get biological samples for the diagnosis and to give better treatment of this parasitosis.

## 1885

### IMPACT OF IMPLEMENTING A STATE CERTIFIED IMPROVED COOKSTOVE ON CONCENTRATION LEVELS OF PARTICULATE MATTER (PM) AND CARBON MONOXIDE (CO) IN RURAL ANDEAN HOUSEHOLD IN PERU

Patricia Mallma<sup>1</sup>, Stella M. Hartinger<sup>1</sup>, Cesar Carcamo<sup>1</sup>, Hector Verastegui<sup>1</sup>, Nestor Nuño<sup>2</sup>, Daniel Mäusezahl<sup>2</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Worldwide, rural populations are exposed to numerous contaminants inside their homes by cooking or heating using traditional stoves or open fires burning biomass fuels (wood, coal, dung). Peru is among the six Latin American countries with the highest percentage of biomass fuel use. In this study we determined if a state-certified improved cookstoves reduce household air pollution levels in rural high-altitude homes of San Marcos, Cajamarca. This evaluation was embedded within a community-randomised controlled trial with two integrated health intervention packages (IHIP), a) the environmental health intervention comprised improved cookstoves (ICS), kitchen sinks and hygiene education (IHIP) and

b) the before-mentioned IHIP plus an early child development intervention (ECD). We determined 24hr indoor air concentration levels of CO and PM<sub>2.5</sub> in 33 kitchen environments, before and after (3-months after installment) the OPTIMA-improved stoves had been installed. Geometric means were calculated to describe PM and CO concentrations within households, due to the biased distribution to the right. To evaluate the impact of the intervention, the data were fitted to a mixed effects model; previously the data of PM and CO concentrations were transformed through a natural logarithm function. The geometric mean at baseline for PM levels was 46.60 µg/m<sup>3</sup>. After installing the OPTIMA-improved stove we observe a statistically significant (p-value <0.01) reduction (30.85 µg/m<sup>3</sup>) Regarding the CO levels, the geometric mean was also reduced when compared to baseline, (1.32 ppm for baseline to 1.19 ppm after installation). The difference is statistically significant (p-value <0.01). The OPTIMA-improved stove three months after installation shows a significant reduction in PM and CO.

## 1886

### IMPACT OF HOUSEHOLD WATER SOURCE ON SCHOOL ABSENCE AMONG CHILDREN LIVING OUTSIDE OF PORT-AU-PRINCE, HAITI

Suyane Viana de O. Mesquita<sup>1</sup>, Julia Painter<sup>1</sup>, Marie Y. Remy<sup>2</sup>, Robert Nicolas<sup>2</sup>, Michael E. von Fricken<sup>1</sup>

<sup>1</sup>George Mason University, Department of Global and Community Health, Fairfax, VA, United States, <sup>2</sup>African Methodist Episcopal Church - Service and Development Agency Inc., Washington, DC, United States

As one of the poorest populations in the world, 56% of Haitians live in urban areas, less than 70% have access to improved drinking water sources and less than 30% have improved sanitation facilities. Although vaccination coverage has been increasing, less than 50% of children under the age of one year receive all recommended vaccines. Acute respiratory disease was the major cause of death (20%) among under-5 children in 2013. Respiratory diseases also affect older children and can impact school absence. Understanding the impact of household water source on children's health and its relationship with school absence is critical to design and enhance future interventions to improve health among Haitian families. Data were collected through surveys between June and July, 2016 from 39 different schools located outside Port-au-Prince region in Haiti. In total, 387 mothers described their socioeconomic status, educational level, children's health status, access to healthcare, among other characteristics. Chi-square tests, using SPSS (version 24), demonstrated associations. Mothers had a mean age of 36.9 years (SD 9.65) and 41.8% reported having no educational level, while only 14.1% completed secondary school. Only 18.6% of participants reported not having a source of income, compared to 81.4% employed. Father/partner contributed to household income in 84% of answers, resulting in a monthly income ranging between \$30.00-74.96 dollars for 45% of surveyed participants. Findings indicated more than 94% of participants had no water, electricity or latrine in the household; chi-square tests also indicated an association between illness-related school absences and water source. Cough/cold and/or fever accounted for more than 17% of cases. However, other built environmental factors, like access to latrines, were not significantly associated with illness related school absences. This study provides unique insight to the household dynamics of Haitian families and demonstrates the need for further qualitative investigations examining behavioral risk factors associated with respiratory disease spreading.

## 1887

### INFLUENCE OF ENVIRONMENTAL CONDITIONS ON NUTRITIONAL STATUS AMONG SCHOOL-AGE CHILDREN IN HAITI

Michael E. von Fricken<sup>1</sup>, Chike Achudume<sup>1</sup>, Suyane Viana de O. Mesquita<sup>1</sup>, Marie Y. Remy<sup>2</sup>, Robert Nicolas<sup>2</sup>, Ivan Ng<sup>1</sup>

<sup>1</sup>George Mason University, Department of Global and Community Health, Fairfax, VA, United States, <sup>2</sup>African Methodist Episcopal Church - Service and Development Agency Inc., Washington, DC, United States

Understanding the influence of living conditions on indicators of malnutrition among Haitians school-children, is vital for guiding future interventions. This study investigates the potential influence of built environment on nutritional status, as measured by body mass index (BMI). Haitians aged 3-20 years were surveyed from 41 schools across Archaie Commune of Haiti, from June to July 2016. Data recorded includes age, sex, height, weight, BMI, and environmental factors including housing material, access to latrine, waste collection, and drinking water source. Logistic regression and Chi-square were performed to determine the association between malnutrition data and built environmental factors. A total of 4,964 schoolchildren were included in this study, of which 52% (2,584) were male and 48% (2,380) were female, of which 68.5% of the population had a low BMI (<18.5 BMI). Malnutrition was significantly associated with housing materials-roofing (OR: 1.37 [95% CI: 1.07-1.76]), flooring (OR: 1.91 [95% CI: 1.08-1.31]), and waste collection (OR: 0.67 [95% CI: 0.59-0.76]). Built environmental conditions like roofing, flooring, and waste collection are likely proxies for socio-economic status, however this survey was implemented in an impoverished rural mountain region. These findings add to the body of literature on malnutrition in Haiti, while investigating the associations between household environmental conditions and malnutrition measurements. Furthermore, this research suggests a potential link between household environmental conditions and nutritional outcomes among Haitians, which could potentially be used to identify at risk population.

## 1888

### THE INFLUENCE OF SANITATION ON CHILDHOOD DIARRHEA IN 2016 AND ITS IMPLICATIONS ON INTEGRATED COMMUNITY CASE MANAGEMENT OF ENDEMIC CHILDHOOD DISEASES IN ABIA STATE, NIGERIA

Ugo U. Enebeli

Federal University of Technology, Owerri, Nigeria

Every second, a child in Nigeria dies as a result of poor sanitation. Childhood diarrhoeal disease is of public health significance in under fives being the second leading cause of death as well as the leading cause of malnutrition in this age bracket. Consequently Abia State of Nigeria has maintained high prevalence of diarrhoea and frequent outbreaks despite government- and non-government oriented interventions. This is a cross-sectional study carried out in Abia State from January 2016 to December 2016 among 403 caregivers with children under five in 27 randomly selected (multistage randomization) communities. Data were collected using a well structured interviewer-administered questionnaire. Ethical Approval was obtained from Abia State University Teaching Hospital Aba, and informed consents were obtained from all caregivers of children assessed. Data analysis was done with Statistical Package for Social Sciences version 22 (International Business Machine, New York). The results showed major gaps in sanitation as 79.4% of households do not treat their drinking water; 55.8% of respondents do not have private toilet facility; 15.4% practise open defecation; 75.7% of young children's faeces are not dropped into a toilet facility; 51.6% did not have hand washing device; and only 50.4% of respondents have ever received any health information about water hygiene. The prevalence of diarrhoea (over the previous 6 months) was high at 44.7%. Inferential analysis showed that many components of sanitation statistically significantly predicted

the prevalence of diarrhoea among children 0 to 59 months,  $f(18, 384) = 5.496$ ,  $p = 0.000$ ,  $R = 0.453$ . This study thus elucidates that sanitation statistically significantly predicted prevalence of diarrhoea among children, and the inadequate health education on sanitation compounds the problem. Thus, we recommend that sanitation components be integrated into efforts aimed at curbing endemic childhood diarrhoea, in order to guarantee their success and for greater impact on the scourge of childhood diarrhoea.

## 1889

### ENVIRONMENTAL IMPACT ON HELMINTH AND PROTOZOA INTESTINAL INFECTIONS IN URBAN SLUMS VERSUS RURAL COLOMBIA

Alejandro Restrepo<sup>1</sup>, Patricia E. Bryan<sup>1</sup>, Marcela Romero<sup>2</sup>, Giovanni Torres<sup>2</sup>, Wilber Gómez<sup>2</sup>, Marcos Restrepo<sup>2</sup>, Rojelio Mejía<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Instituto Colombiano de Medicina Tropical, Medellín, Colombia

Intestinal parasites are globally widespread infectious agents disproportionately affecting children in resource-deprived areas. Environmental surroundings influence exposure to these parasites between different community settings (urban, rural). Stool samples from 132 children in an urban slum ( $n = 72$ , mean age = 2.5 yrs), and rural ( $n = 72$ , mean age = 2 yrs) areas were analyzed using multi-parallel quantitative real-time PCR (qPCR) for *Ascaris lumbricoides*, *Ancylostoma duodenale*, *Necator americanus*, *Trichuris trichiura*, *Strongyloides stercoralis*, *Blastocystis* spp, *Cryptosporidium* spp, *Entamoeba histolytica*, and *Giardia lamblia*. Prevalence for positive samples was 19%, 50% *Ascaris* ( $p = 0.002$ ); 0%, 2% *Strongyloides*; 6%, 46% *Trichuris* ( $p = 0.0001$ ); 86%, 76% *Blastocystis*; 19%, 0% *Cryptosporidium*; 0%, 20% *Entamoeba*; 63%, 68% *Giardia* for urban and rural respectively. Higher *Giardia* cyst per gram (CPG) of stool (calculate from qPCR standard curves) correlated to living in urban slums versus rural areas (4719 versus 702 CPG,  $p = 0.008$ ). *Blastocystis* DNA burden was higher in urban pre-school children (2 to 4 yrs) compared to infants (0 to 1 yrs) and school age (5 to 8 yrs) (3.4 versus 0.04, 0.025 fg/μl respectively,  $p = 0.020$ ). *Blastocystis* was associated with having any helminth infection in both urban and rural settings ( $p = 0.0491$ ). Helminth burden was correlated to qPCR derived eggs per gram (EPG) with higher *Trichuris* burden found in rural areas compared to urban slum (9953 versus 325 EPG,  $p = 0.0023$ ). Children infected with polyparasitism (2 or more parasites) correlated to living in rural areas compared to urban (59%, 19%,  $p = 0.001$ ). Our data shows the differences in infections between an urban slum and rural areas for intestinal parasites. Rural areas had significantly higher helminth infections likely due to soil exposure. Urban slum areas had surprisingly higher protozoa burdens, potentially due to crowding and sharing contaminated water. This study will guide public health initiatives on mass drug administration and water, sanitation projects.

### HOUSEHOLD CONTAMINATION OF BABY BOTTLES USED FOR FORMULA FEEDING IN PERI-URBAN LIMA, PERU

Jessica Rothstein<sup>1</sup>, Alejandra Llican Mendoza<sup>2</sup>, Lilia Cabrera<sup>3</sup>, Maritza Calderon<sup>2</sup>, Robert Gilman<sup>1</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Asociación Benéfica PRISMA, Lima, Peru

Feeding of infant formula or cow's milk using contaminated bottles may be an important transmission pathway of pathogens leading to enteric infections during the first two years of a child's life. This research aims to (1) estimate the levels of fecal contamination of baby bottles and (2) assess the behavioral determinants of such contamination in a peri-urban district outside of Lima, Peru. Samples are taken from bottles that are either in use or classified by the caregiver as "ready to use" at the sampling event. Caregivers' hands are also sampled to allow for the comparison

of bottle contamination with another widely recognized source of disease transmission within the home. Bottles and hands are sampled aseptically in the participant's home by rinsing with 50 mL of sterile water for 60 seconds. Samples are processed using membrane filtration and cultured for outgrowth of indicator organisms, total coliform and *E. coli*. A structured questionnaire is administered to the caregiver at each sampling event in order to evaluate practices associated with bottle use and hygiene. Variables to be derived from the questionnaire data include bottle characteristics (material, size, age of bottle, number of bottles in home), bottle preparation (time elapsed since bottle prepared, if bottle is stored in refrigerator when not in use), and bottle cleaning (use of detergent, sponge, or brush during washing, frequency of bottle cleaning and/or boiling). Preliminary results of bottle sampling and testing to date have demonstrated that 43.8% (21/48) of bottles are contaminated with *E. coli*. Of these, 42.9% (9/21) have concentrations of more than  $1 \times 10^2$  bacteria/mL of sample. Fecal contamination is more common and found in higher quantities in bottles as compared to caregivers' hands. Future analyses of the bacteriological and questionnaire data will help to identify factors associated with higher levels of contamination, and will shed light on practices that might be appropriate targets for a behavior change campaign.

## 1891

### A SCALABLE HOSPITAL-BASED HANDWASHING WITH SOAP AND WATER TREATMENT INTERVENTION FOR HOUSEHOLD MEMBERS OF DIARRHEA PATIENTS IN BANGLADESH (CHOBI7 TRIAL): INTERVENTION DEVELOPMENT AND USERS' EXPERIENCES

Elizabeth D. Thomas<sup>1</sup>, M. Tasdik Hasan<sup>2</sup>, Fatema Zohura<sup>2</sup>, Md Sohel Rana<sup>1</sup>, Tahmina Parvin<sup>2</sup>, Md Khobair Hossain<sup>2</sup>, Maynul Hasan<sup>2</sup>, Khaled Hasan<sup>1</sup>, Shirajum Monira<sup>2</sup>, Mahamud-ur Rashid<sup>2</sup>, Sazzadul Islam Bhuyian<sup>2</sup>, Peter J. Winch<sup>1</sup>, Elli Leontsini<sup>1</sup>, Jamie Perin<sup>1</sup>, Alain Labrique<sup>1</sup>, Kelsey Zeller<sup>1</sup>, Farzana Begum<sup>2</sup>, Alana Teman<sup>1</sup>, Vanessa Burrowes<sup>1</sup>, Fosiul A. <sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Diarrhea is a leading cause of child death and a major contributor to morbidity globally. Household contacts of diarrhea patients are at a much higher risk of diarrheal disease than the general population during the one-week period after the patient presents in a health facility. This higher risk is likely due to shared contaminated environmental sources, such as household drinking water, and secondary transmission from poor hygiene practices in the home. The Cholera-Hospital-Based Intervention for 7 days (CHoBI7) is a one-week water treatment and handwashing with soap intervention, targeting diarrhea patients and their household contacts in Dhaka, Bangladesh. The intervention package, delivered at the patient's bedside, includes a pictorial module on diarrhea transmission, a handwashing station, soapy water bottle, sealed drinking water vessel, and chlorine tablets for water treatment. In collaboration with the Bangladesh Ministry of Health and Family Welfare, we conducted formative research to develop a scalable approach for integration of CHoBI7 into services provided to diarrhea patients in government and private health facilities in Bangladesh. Formative research included a total of 52 in-depth interviews with diarrhea patients and their household contacts, health facility staff, and government officials; hospital and household structured observations; and a pilot study of the developed CHoBI7 intervention. Interviews were also conducted with pilot household beneficiaries to explore experiences with each component of the intervention package, including 1) use and perceptions of chlorinated drinking water, 2) benefits and challenges of handwashing and water storage hardware, and 3) communication of key program messages among household members. Findings from interviews and observations, and feedback from pilot study participants, allowed us to identify key challenges for program implementation and

develop strategies to overcome these potential barriers to successful implementation. We are currently conducting a randomized controlled trial of our scalable approaches for delivery of the CHoB17 intervention.

## 1892

### VARIABILITY IN STRENGTH OF ASSOCIATION WITH DIARRHEA OF PATHOGENIC *E. COLI* ALONG AN URBAN-RURAL GRADIENT IN ECUADOR

**Karen Levy**<sup>1</sup>, Shanon Smith<sup>1</sup>, William Cevallos<sup>2</sup>, Loreno Montero<sup>3</sup>, Maritza Paez<sup>3</sup>, Estefania Ortega<sup>3</sup>, Xavier Sanchez<sup>2</sup>, Edison Puebla<sup>2</sup>, Pablo Endara<sup>3</sup>, Gabriel Trueba<sup>3</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Universidad Central del Ecuador, Quito, Ecuador, <sup>3</sup>Universidad San Francisco de Quito, Quito, Ecuador

Pathogenic *E. coli* is a major cause of diarrhea in developing countries, yet it is often isolated from controls without diarrhea. Understanding why some infections are symptomatic and some are asymptomatic is a major outstanding question. We report on the results of a case-control study of diarrhea along a rural-urban gradient in Ecuador. We sampled ~100 subjects with diarrhea and ~100 age-matched controls at each of four sites: a large clinic in Quito, Ecuador's capital, a hospital in the capital of Esmeraldas Province, a hospital in the town of Borbón, and clinics in outlying rural communities. The urban-rural gradient also represents a gradient of access to clean and safe water. We identified pathogenic *E. coli* from fecal samples of study subjects through PCR and carried out whole genome sequencing on these isolates. In the two urban sites, diffuse adherent *E. coli* (DAEC) was the dominant *E. coli* pathotype, whereas in the more rural sites atypical enteropathogenic *E. coli* (EPEC) was the most prevalent pathotype. Infection with DAEC was associated with diarrhea symptoms in the urban sites [Quito: OR=2.8 (95% CI: 1.11, 7.06); Esmeraldas: OR=2.5 (95% CI: 1.19, 5.24)] but not in the rural sites. DAEC isolates causing diarrhea were found to be dispersed along the phylogenetic tree, suggesting that the diarrhea cases represent multiple lineages of DAEC rather than a large outbreak of a clonal genotype. Reported travel in the past year to Guayaquil, another major urban center, was associated with increased risk of DAEC infection, further suggesting that DAEC is associated with urban areas. Travel in the past year both into and out of Quito was a predictor for pathogenic *E. coli* infection. We found differential distribution of *E. coli* pathotypes in urban versus rural areas, and in urban areas *E. coli* pathotypes had stronger associations with diarrheal illness. This study highlights the potential for within-country "travelers' diarrhea" in a developing country context, and provides insights into countrywide transmission of pathogens. This information can help guide decisions on where to focus intervention strategies between urban versus rural regions.

## 1893

### DETERMINANTS OF DIARRHEAL DISEASE IN CHILDREN UNDER FIVE YEARS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

**Andrea Smith**, Janna Wisniewskie, Paul Lusamba, Paul Hutchinson, Joshua Yukich, Paul R. Hotchkiss

Tulane University, New Orleans, LA, United States

Two alternative approaches to community-led total sanitation (CLTS) are being carried out in the Democratic Republic of the Congo (DRC) as part of a health systems strengthening project (ASSP). This study examines data from a cross-sectional household survey conducted from April to May 2014 designed to capture information on factors related to water, sanitation, and hygiene (WASH) in the context of ASSP. A two stage – cluster sampling design was employed to select households from project supported health zones in three areas: 1) Tshopo and Maniema, 2) Kasai, Kasai Central, and Kasai-Oriental and 3) Nord Ubangi and Sud Ubangi, as well as matched clusters from non-project (control) areas. The survey measured two-week diarrheal disease prevalence among children under

five years of age as reported by the primary caregiver. Determinants of diarrheal disease were evaluated using bivariate and random effects logistic regression analysis. The analysis was limited to households with under-five children. 4,362 under-five children were identified in 2,223 households, however, only 3,942 observations were included in the final model due to missing values. The prevalence of diarrhea among provinces ranged from 8.92% to 16.56%. In multivariate analysis, significant risk factors for under-five diarrheal disease included primary maternal education [ORadj: 1.53, 95% CI (1.17, 2.00), p = 0.002], sharing a toilet facility with another family [ORadj: 1.63, 95% CI (1.27, 2.10), p < 0.001] and the presence of flies around the toilet facility [ORadj: 1.50 95% CI (1.09, 2.09) p = 0.014]. Understanding the determinants of diarrhea in children is crucial to the successful development and implementation of targeted WASH interventions. Although there is substantial evidence in the literature linking poor WASH to diarrheal disease in children under five, there is almost no evidence from the DRC that explores this association. The results of this analysis will help contextualize the outcomes of the CLTS approaches and comparing the effectiveness of these interventions will be critical in guiding the scale up of future WASH interventions in the DRC.

## 1894

### ASSOCIATION OF WATER SUPPLY WITH BRETEAU INDEX IN TWO RURAL CARIBBEAN POPULATION

**Maria S. Ruiz-Diaz**, Gustavo J. Mora-Garcia, Doris E. Gomez-Camargo

Universidad de Cartagena, Cartagena de Indias, Colombia

Vectorborne diseases represent an important problem that affect several regions worldwide. Features such as poor infrastructure, climatic conditions and water scarcity constitute some of the risk factors that increase this issue. Populations on tropical regions often exhibit features that worsen these conditions and consequently increase the presence of vectors. In this case, it was carried out a study in two rural populations of the coast Caribbean Coast, whose main difference is that one of them (Ararca) has a water supply system, while the other (Barú) lacks it. This particular difference allowed us to observe the influence that water supply system has in the increase of vector that transmit these diseases. It was examined 200 dwellings, and a total of 2012 containers between the two communities. Container index was higher in Barú (31.5%) than in Ararca (22.5) (p = 0.0002). Equally Breteau index, which was of 4.2 and 1.3 in Barú and Ararca respectively (p = 1.12x10<sup>-11</sup>). Aedes index was superior in Ararca (70.2%) than Barú (68.1%), but in these cases was not significant difference (p = 0.86). Due to the absence of water service supply, the Barú community has the necessity to acquire water through other ways which entails the storage of the resource for long periods, and this situation increases the container and Breteau index. Although these two indices were highest in Barú than in Ararca, did not happen the same with the Aedes index. This is due perhaps that Ararca also presents other risk factors that make it vulnerable (e.g. absence of sanitation facilities). Although also this information indicates that having a water supply system is not sufficient for improving some parameters as the Aedes index.

## 1895

### ASSESSMENT OF ABATTOIRS AND MARKETS SANITATION IN THE FEDERAL CAPITAL TERRITORY (ABUJA) AND ENUGU STATE, NIGERIA

**Agwu N. Amadi**<sup>1</sup>, D. O. Abonyi<sup>2</sup>, B. Njoku<sup>1</sup>, C. O. Amadi<sup>1</sup>, U. Enebeli<sup>1</sup>

<sup>1</sup>Department of Public Health, Federal University of Technology, Owerri, Imo State, Nigeria, <sup>2</sup>Department of Environmental Health Science, College of Medicine and Health Sciences, Abia State University, Uturu, Abia State, Nigeria

This study was done between June 2015 and November, 2016 on the assessment of abattoirs and markets sanitation in the Federal Capital Territory (Abuja) and Enugu state. The objective was to assess sanitary

conditions of the selected Markets and Abattoirs and to identify basic sanitary facilities present, and assess adequacy; determine levels of sanitation awareness and assess personal hygiene practices among workers in FCT and Enugu state. A cross sectional study design was employed. One thousand structured questionnaires were administered to the randomly selected traders, butchers, market and abattoir workers. Data collected were analyzed using descriptive and inferential statistics. Result showed that 969 (97.7%) respondents have heard about market and abattoir sanitation and hygiene. 60% of the respondents were not aware of Hazard Analysis and Critical Control Points (HACCP) principle in food and meat hygiene. 73.39% of respondents showed knowledge of waste management in markets and abattoirs. 675 (68%) of the respondents confirmed the non-availability of sanitary facilities in their market and abattoirs, vs 272 (27%) who affirmed availability of sanitary facilities. 45 (4.5%) had no idea, when compared with the statutory requirements for such premises. Traders, market and abattoir workers do not effectively use the toilet facilities. Refuse management and water supply facilities were inadequate in all study locations. We recommend investment during the developmental phase of market and abattoirs, enforcement of sanitary best practices and the deployment of Environmental Health Officers for risk assessment of markets and abattoirs.

## 1896

### EVERYBODY POOPS: SOCIAL AND CULTURAL NORMS AS PROXY MEASUREMENTS OF INDIVIDUAL-LEVEL DEFECATION PRACTICES

**Velma Lopez<sup>1</sup>**, Veronica Berrocal<sup>1</sup>, Pavani Ram<sup>2</sup>, Joseph Eisenberg<sup>1</sup>  
<sup>1</sup>University of Michigan, Ann Arbor, MI, United States, <sup>2</sup>University of Buffalo, Buffalo, NY, United States

There is growing evidence that latrine access does equate to uptake of latrines. To better implement sanitation interventions, it is necessary to first understand individual-level latrine use behavior. Using an ethnography that described defecation practices among individuals living in rural communities in coastal Ecuador and incorporating survey questions asked in other parts of the world, we designed a survey instrument to capture attitudes, norms, and beliefs related to latrine use and open defecation. We interviewed 89 adults with this tool. We applied Adaptive Elastic Nets (ENET) and Supervised Principal Component Analysis (SPCA) to reduce the data to a set of variables that predicted latrine use, as measured by self-report. The SPCA model reduced the dataset to 10 questions of importance, whereas Adaptive ENET identified 15 questions as having an association with reported latrine use. Demographic variables were not selected by either analytical approach and seven questions were selected by both models as having an association with the outcome. These models do not present statistically different results (chi-squared = 2.78, 1 degree of freedom, p-value = 0.10). Using machine learning techniques, we identified a list of social and cultural norms that predict individual-level latrine use. Indicators of cultural and social norms provide insight into behavior, and may also be subject to less misclassification than self-report of a sensitive behavior. These variables can be used in future work as a proxy measurement of latrine use, which would provide the WASH sector with a more robust variable for program evaluation than simply household access to a latrine.

## 1897

### COMPARATIVE PREVALENCE OF *PLASMODIUM FALCIPARUM* RESISTANCE-ASSOCIATED GENETIC POLYMORPHISMS IN PARASITES INFECTING HUMANS AND MOSQUITOES IN UGANDA

**Melissa D. Conrad<sup>1</sup>**, Daniel Mota<sup>1</sup>, Alex Musiime<sup>2</sup>, Maxwell Kilama<sup>2</sup>, John Rek<sup>2</sup>, Moses Kamy<sup>3</sup>, Grant Dorsey<sup>1</sup>, Philip J. Rosenthal<sup>1</sup>

<sup>1</sup>University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>3</sup>Makerere University College of Health Sciences, Kampala, Uganda

Controlling malaria in high transmission areas, such as much of sub-Saharan Africa, will require concerted efforts to slow the spread of drug resistance and to develop strategies to impede transmission. Understanding the fitness costs associated with drug resistance, particularly within the context of transmission, can help guide policy decisions to accomplish these goals. Fitness constraints might lead to decreased transmission of drug-resistant strains. To determine if *Plasmodium falciparum* resistance-mediating polymorphisms impact on development at different parasite stages, we compared the genotypes of parasites infecting humans and mosquitoes from households in Tororo, Uganda. We genotyped 154 *P. falciparum* infected mosquitoes and 446 human samples at 14 polymorphic *loci* in genes encoding putative transporters (*pfprt* and *pfmdr1*) and folate pathway enzymes (*pfdhfr* and *dhrs*) using ligase detection reaction-fluorescent microsphere assays. Human and mosquito samples were from the same or nearby households within 40 days of each other. Of the 446 human samples that yielded data for our analysis, 122 were from the same household from which mosquitoes were collected and 324 were from a different household within 4 km (median distance 803 meters) of mosquito collection; matched human and mosquito samples were collected with 40 days of each other. Prevalences of key polymorphisms were similar between human and *Anopheles gambiae* s.l. infections, but pure mutant alleles were less common in human infections at the *pfmdr1* 86 (3% human vs. 19% mosquito,  $p < 0.001$ ) and *pfdhfr* 164 (0% in humans vs. 5% in mosquitoes,  $p = 0.001$ ) *loci*, and more common in human infections at *pfdhfr* 51 (99% humans vs. 93% mosquito,  $p = 0.003$ ). Mixed genotypes were more common in human infections, potentially explaining differences in allele prevalences. Overall, our results suggest modest directional selection resulting from varied fitness costs during the *P. falciparum* life cycle. Better appreciation of the fitness implications of different drug resistance mediating mutations can inform optimal malaria treatment and prevention strategies.

## 1898

### MOLECULAR SURVEILLANCE OF *PLASMODIUM FALCIPARUM* ANTIMALARIAL RESISTANCE IN SENTINEL SITES FROM MOZAMBIQUE

**Himanshu Gupta<sup>1</sup>**, Eusebio Macete<sup>2</sup>, Augusto Nahbomba<sup>2</sup>, Helder Buló<sup>2</sup>, Crizolgo Salvador<sup>3</sup>, Marian Warsame<sup>4</sup>, Eva Carvalho<sup>5</sup>, Didier Ménard<sup>6</sup>, Pascal Ringwald<sup>4</sup>, Quique Bassat<sup>7</sup>, Sonia Enosse<sup>3</sup>, Alfredo Mayor<sup>8</sup>

<sup>1</sup>Barcelona Institute for Global Health, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain, <sup>2</sup>Cento de Investigaçao em Saude da Manhiça (CISM), Manhiça, Mozambique, <sup>3</sup>Instituto Nacional de Saude (INS), Ministerio da Saude, Maputo, Mozambique, <sup>4</sup>World Health Organization, Global Malaria Programme, Geneva, Switzerland, <sup>5</sup>World Health Organization, Maputo, Mozambique, <sup>6</sup>Malaria Molecular Epidemiology Unit, Institut Pasteur du Cambodge, Phnom Penh, Cambodia, <sup>7</sup>Barcelona Institute for Global Health, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain; Cento de Investigaçao em Saude da Manhiça (CISM), Mozambique; ICREA, Barcelona, Spain, <sup>8</sup>Barcelona Institute for Global

Health, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain; Centro de Investigação em Saúde da Manhica (CISM), Manhica, Mozambique

The use of antimalarial drugs is one of the fundamental steps towards malaria control and elimination. The success of antimalarial treatment can be affected by drug resistant *Plasmodium falciparum* (Pf) populations, warranting the need to incorporate adequate molecular surveillance of known parasite factors associated with drug resistance for the early detection of resistant parasites. Pf positive dried blood spots from individuals (N=352) in four sentinel sites (Montepuez, Dondo, Moatize and Chokwe) from Mozambique were investigated for the presence of *k13* (dihydroartemisinin), *pfmdr1* (chloroquine), *pfcr1* (chloroquine, amodiaquine, artemether-lumefantrine) and *pfdhps* (sulfadoxine-pyrimethamine) polymorphisms using Sanger sequencing and restriction fragment length polymorphism. Plasmepsin (*pfpm*) 2 (piperazine) and *pfmdr1* (mefloquine and lumefantrine) copy numbers (CNs) were assessed by qPCR. The polymorphism analyses of *k13*, *pfmdr1*, *pfcr1* and *pfdhps* genes were successful in 98.3% to 100% isolates. Novel polymorphisms in *k13* (Leu619Leu, Phe656Ile, Val666Val and Gly690Gly) and *pfmdr1* (L1030L, D1061D, D1127D, S1137S, L1174L, D1179D, N1189N, T1192A, F1194S and Y1197N) were observed in the present study. The prevalence of *pfmdr1* 86Y and 184F mutant alleles was 3.1% and 46.7% respectively. The *pfcr1* mutant alleles (74I, 75E and 76T) were only present in Chokwe isolates (9.2%). The prevalence of *pfdhps* gene 436F, 437A and 540E mutant alleles were 9.3%, 26.7% and 82.2% respectively. Frequencies of *pfdhps* polymorphisms were significantly different between four sites. The prevalence of isolates with multiple copies (CN>1.5) of *pfpm2* and *pfmdr1* genes were 4/351 (1.1%) and 5/351 (1.4%) respectively. Markers of resistance to dihydroartemisinin were not found in the studied Pf isolates. At present the prevalence of Pf isolates with multiple copies of *pfpm2* gene is low. However, with adequate piperazine drug pressure resistant isolates may spread in Mozambique. This study also supports previous evidence for the return of chloroquine sensitive Pf isolates in Mozambique based on the low prevalence of *pfcr1* markers of resistance.

## 1899

### PATTERN OF K13 POLYMORPHISMS AMONG PLASMODIUM FALCIPARUM ISOLATES FROM BORDER AREAS IN THE MEKONG SUBREGION

Chaiyaporn Chaisatit<sup>1</sup>, Piyaporn Sai-ngam<sup>1</sup>, Kirakarn Kirativanich<sup>1</sup>, Thay Kheang Heng<sup>1</sup>, Worachet Kuntawunginn<sup>1</sup>, Jariyanart Gaywee<sup>1</sup>, David Saunders<sup>2</sup>, Chanthap Lon<sup>1</sup>, Krisada Jongsakul<sup>1</sup>, Michele Spring<sup>1</sup>, Mariusz Wojnarski<sup>1</sup>, Philip Smith<sup>1</sup>, Mark Fukuda<sup>1</sup>, Panita Gosi<sup>1</sup>

<sup>1</sup>Armed Forces Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>U.S. Army Medical Materiel Development Activity, Fort Detrick, MD, United States

Emergence of artemisinin resistance of *Plasmodium falciparum* in Southeast Asia and the possibility of further geographical spread pose a serious threat to global elimination efforts, emphasizing the need to conduct surveillance of resistant strains. Mutations in the propeller domain of K13 gene of *P. falciparum* have been shown to correlate with delayed parasite clearance times and enhanced survival and are a prerequisite to meet the WHO definition of artemisinin resistance. In this study, we determined the prevalence of K13 polymorphisms by Sanger sequencing in samples collected from Western Cambodia, Eastern Thailand (along the Thai-Cambodian border), and along the Thailand-Myanmar border. From a total of 351 samples from Western Cambodia, the C580Y mutation was present in a majority of isolates (327; 93.16%) followed by R539T mutation (16; 4.56%) and wild type (8; 2.28%). Not surprisingly, this pattern was similar to that found in Thailand near the Cambodian border with C580Y mutation (74%, 49/66) also present in most of the isolates followed by R539T mutation (24.24%, 16/66) and R539I (1.52%, 1/66). In contrast, along the Thailand-Myanmar border, wild type was most common (72.92%, 35/48) followed by N537I (12.5%, 6/48), R561H (6.25%, 3/48), C580Y (4.17%, 2/48), G449A (2.08%, 1/48), and

P553L (2.08%, 1.48). Our study suggests a bimodal population of K13 polymorphisms that should be continuously monitored, especially in border areas in Thailand, where overlap of K13 resistant strains may accelerate fixation of delayed parasite clearance phenotypes and clinically significant artemisinin resistance. To identify minor K13 allelic variants circulating in individual patients that may not be picked up by Sanger sequencing alone, we are also performing amplicon deep sequencing on an Illumina MiSeq platform. These results, plus the prevalence of other molecular resistance markers such as *plasmepsin*, *pfmdr1* and *pfcr1* will be presented. Taken together, we hope to be able to identify major and minor resistance variant frequencies and develop a more accurate picture regarding the distribution of infection haplotypes in border regions.

## 1900

### IMPACT OF DIHYDROARTEMISININ-PIPERAZINE FOR INTERMITTENT PREVENTIVE TREATMENT OF MALARIA DURING PREGNANCY ON MALARIA INCIDENCE IN EARLY CHILDHOOD

Abel Kakuru<sup>1</sup>, Jaffer Okiring<sup>1</sup>, Mary K. Muhindo<sup>1</sup>, Paul Natureeba<sup>1</sup>, Patricia Awori<sup>1</sup>, Miriam Nakalembe<sup>2</sup>, Bishop Opira<sup>1</sup>, Peter Olwoch<sup>1</sup>, John Ategeka<sup>1</sup>, Patience Nayebare<sup>1</sup>, Tamara D. Clark<sup>3</sup>, Margret E. Feeney<sup>3</sup>, Edwin D. Charlebois<sup>3</sup>, Theodore Ruel<sup>3</sup>, Diane V. Havlir<sup>3</sup>, Moses R. Kamya<sup>2</sup>, Grant Dorsey<sup>3</sup>, Prasanna Jagannathan<sup>4</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Makerere University College of Health Sciences, Kampala, Uganda, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>Stanford University, Stanford, CA, United States

Intermittent preventive treatment of malaria in pregnancy (IPTp) with dihydroartemisinin piperazine (DP) is an effective and promising strategy in settings with widespread resistance to sulfadoxine-pyrimethamine (SP), but its impact on the risk of malaria during early childhood is unknown. We evaluated the impact of IPTp-DP on malaria incidence in early childhood in a birth cohort of children born to HIV-uninfected pregnant women living in Tororo, Uganda, who took part in a double blinded randomized controlled trial (NCT02163447). Pregnant women were enrolled at 12-20 weeks gestation and randomized to either SP given every 8 weeks or DP every 8 weeks or DP every 4 weeks. Children born to these mothers were given chemoprevention with DP every 12 weeks starting at 8 weeks of age, and followed from birth to 2 years of age. Women and children received all their medical care at a study clinic open 7 days a week. Incident episodes of malaria were defined as all treatments for malaria (fever and presence of malaria parasites by blood smear (BS)) not preceded by another treatment in the prior 14 days. Parasite prevalence (assessed by BS and loop mediated isothermal amplification (LAMP), and prevalence of anemia (hemoglobin <10g/dL), were assessed monthly and every 4 months respectively. The primary outcome was incidence of malaria from birth to 2 years of age; secondary outcomes included parasite prevalence and prevalence of anemia. The primary exposure was maternal IPTp randomization assignment. Through March 31, 2017, there were 192 live births, and 146 children have reached 2 years of age. During 355.2 person years of follow-up, there were 113 incident malaria episodes (overall malaria incidence of 0.32 episodes per person year). Overall prevalence of malaria parasites during monthly assessments by BS and LAMP was 50/4566 (1.1%) and 113/3652 (3.0%), respectively. Prevalence of anemia (hemoglobin <10 g/dL) was 155/1201 (3.0%). The last child will reach 2 years of age on May 18, 2017. Final unblinded results by maternal randomization will be presented at the time of the conference.

## 1901

### EFFICACY OF ARTEMISININ-BASED AND QUININE-BASED TREATMENTS FOR UNCOMPLICATED FALCIPARUM MALARIA IN PREGNANCY IN ASIA: A SYSTEMATIC REVIEW AND INDIVIDUAL PATIENT DATA META-ANALYSIS

Makoto Saito<sup>1</sup>, Rashid Mansoor<sup>1</sup>, Mary E. Tyrosvoutis<sup>2</sup>, Kalynn E. Kennon<sup>1</sup>, Kasia Stepniewska<sup>1</sup>, Georgina S. Humphreys<sup>1</sup>, Mupawjay Pimanpanarak<sup>2</sup>, Moo Kho Paw<sup>2</sup>, François H. Nosten<sup>2</sup>, Philippe J. Guérin<sup>1</sup>, Rose McGready<sup>2</sup>

<sup>1</sup>WorldWide Antimalarial Resistance Network, Oxford, United Kingdom, <sup>2</sup>Shoklo Malaria Research Unit, Mae Sot, Thailand

Pregnant women are more vulnerable to falciparum malaria and even asymptomatic infection can affect both mother and fetus. In non-African settings, early diagnosis and prompt treatment with effective drugs is the strategy recommended by WHO. However, the evidence to support current recommendations is sparse, as pregnant women have been systematically excluded from standard drug efficacy trials. In addition, there is no agreed standard method to assess antimalarial efficacy in pregnancy. We aim to summarise the current evidence of antimalarial efficacy in pregnancy and explore a standard methodology of assessment. We conducted a systematic review of antimalarial efficacy studies against uncomplicated falciparum malaria in pregnancy in Asia. Individual patient data (IPD) were sought and IPD meta-analysis was conducted using a random effects model to explore the clinical determinants associated with recrudescence failures. We identified 20 relevant studies, including two unpublished randomised control trials. Ten published studies used polymerase chain reaction (PCR) for differentiating recrudescence from reinfection, and all were conducted on the Thailand-Myanmar border. From all ten published studies with documented PCR, IPD of 1,466 malaria episodes from 1,396 women were analysed, of which 634 (43%) and 832 (57%) episodes were treated with quinine-based treatment (QBT) and artemisinin-based treatment (ABT) respectively. A total of 259 episodes occurred during the first trimester, 47 (18%) of them with ABT. Patients were followed up every 1–2 weeks until delivery (or for 42–63 days, whichever came later). PCR-adjusted adequate clinical and parasitological responses (ACPR) proportion of ABT were generally >90%, and this proportion decreased with longer follow-up duration. Risk of treatment failure was higher in patients treated with QBT compared to ABT. PCR-corrected ACPR of each ABT and QBT, and risk factors associated with treatment failure will be presented. This review highlighted a substantial methodological heterogeneity in clinical practices in MIP, calling for an urgent need to adopt a standardised methodology.

## 1902

### RELATIONSHIP BETWEEN LUMEFANTRINE PHARMACOKINETICS AND THE SELECTION OF DRUG RESISTANCE MUTATIONS FOLLOWING ARTEMETHER-LUMEFANTRINE IN HIV-UNINFECTED AND HIV-INFECTED CHILDREN ON ANTIRETROVIRAL THERAPY

Joyce Ou<sup>1</sup>, Richard Kajubi<sup>2</sup>, Martina Wade<sup>3</sup>, Liusheng Huang<sup>4</sup>, Moses Were<sup>2</sup>, Norah Mwebaza<sup>2</sup>, Francesca Aweeka<sup>4</sup>, Sunil Parikh<sup>3</sup>

<sup>1</sup>Yale University, New Haven, CT, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>Yale School of Public Health, New Haven, CT, United States, <sup>4</sup>University of California San Francisco, San Francisco, CA, United States

*In vitro* and *in vivo* studies have demonstrated that mutations in certain *Plasmodium falciparum* putative transporters, particularly *pfmdr1* and *pfcr1* are key mediators in resistance to many of the long-acting partner drugs used in artemisinin-based combination therapies (ACTs). In addition, recent *in vitro* data suggests that changes in *pfmdr1* may mediate resistance to the antiretroviral lopinavir/ritonavir (LPV/r). The impact of HIV infection, antiretroviral regimen, as well as the impact of long-acting partner drug

pharmacokinetics on the selection of drug resistant mutations in recurrent malaria has not been clearly elucidated. We conducted a prospective PK/PD study of artemether-lumefantrine in HIV-uninfected and HIV-infected children on three 1st-line antiretroviral regimens in a high endemic region of eastern Uganda. Drug levels were quantified at multiple time points, key molecular markers of drug resistance (*pfcr1* K76T, *pfmdr1* N86Y, *pfmdr1* Y184F) were assessed using a ligase detection reaction-fluorescent microsphere assay, *pfmdr1* copy number using real time PCR, and parasites were genotyped using six polymorphic markers to determine multiplicity of infection. Recurrent malaria (either clinical or parasitological failure) by day 42 was observed in 187 of 355 children. Drug levels in those with recurrent malaria varied dramatically between treatment groups (median day 7 lumefantrine in HIV-uninfected children, and HIV-infected children on efavirenz-, nevirapine-, and lopinavir/ritonavir-based ART were 345, 107, 515, and 620 ng/mL, respectively). Thus far, paired genotyping of baseline and recurrent infections for *pfmdr1* N86Y, *pfmdr1* Y184F, and *pfcr1* K76T has been completed in 75, 90, and 65 children, respectively. The prevalence of mutant alleles at baseline and the time of recurrent malaria was 18% and 4%, 67% and 68%, and 77% and 69%, for *pfmdr1* 86Y, *pfmdr1* 184F, and *pfcr1* 76T, respectively. Genotyping will be completed in all children, and the association of lumefantrine drug exposure and the selection of drug resistant markers at all putative drug resistance markers will be presented.

## 1903

### ELECTROCARDIOGRAPHIC EFFECTS OF THE ANTIMALARIAL DRUG DIHYDROARTEMISININ-PIPERAQUINE

Joel Tarning<sup>1</sup>, Thanaporn Wattanakul<sup>1</sup>, Rita Baiden<sup>2</sup>, Markus Winterberg<sup>1</sup>, Bernhards Ogutu<sup>2</sup>, Fred Binka<sup>2</sup>

<sup>1</sup>Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>INDEPTH Network, Accra, Ghana

Concerns have been raised regarding the potential for the antimalarial drug dihydroartemisinin-piperazine to cause cardiotoxicity. Pharmacokinetic samples and electrocardiogram (ECG) measurements were obtained from a total of 1,000 patients, enrolled in a multi-centre trial in Burkina Faso, Mozambique, Ghana, and Tanzania [INDEPTH study]. All patients had uncomplicated *P. falciparum* malaria and received a standard 3-day treatment of dihydroartemisinin-piperazine. Nonlinear mixed-effects modelling was used to describe the relationship between piperazine exposure and QT-prolongation in order to evaluate the cardiovascular safety in patients with uncomplicated malaria. Both QTc-prolongation ( $\Delta$ QTc) and absolute QTc-intervals (QTc) were evaluated with separate modelling approaches. Linear and non-linear effects models, the impact of a circadian rhythm, and clinical covariates were evaluated with a stepwise modelling approach. A three-compartment disposition model with three transit absorption compartments described the piperazine concentration-time profile well. Body weight was included as an allometric function on all clearance and volume parameters, resulting in lower drug exposure in small children. The effect of piperazine on  $\Delta$ QTc was described by a linear relationship, resulting in a 6.14 msec QTc-prolongation per 100 ng/mL increase in population piperazine concentration. The effect of piperazine on the absolute QTc-interval was best described by a nonlinear model resulting in a maximum population QT-prolongation of 48.1 msec. The developed pharmacokinetic-pharmacodynamic model described the relationship between piperazine concentrations and  $\Delta$ QTc/QTc intervals effectively. The model demonstrated that an increased piperazine concentration was directly related to a prolongation of the QTc interval. However, the prolongation estimated from the model was considered to have an acceptable safety profile in the clinical setting of life-saving malaria treatment.

## 1904

**SURINAME ON THE ROAD TO ZERO MALARIA; AN EPIDEMIOLOGIC DESCRIPTIVE STUDY**

Hedley Cairo, **Helene Hiwat**, Loretta Hardjopawiro  
*Ministry of Health Malaria Program, Paramaribo, Suriname*

Until 2004 malaria in Suriname showed a high disease burden with high *Plasmodium falciparum* (Pf) proportions. In 2004, Coartem® was introduced as first line treatment for Pf infections. Since then malaria control activities were scaled up and included improved access to diagnosis and treatment and mass distribution of Long Lasting Insecticide treated Nets. The population at risk is about 80,000 people and can be stratified as stable Maroon and Amerindian tribal communities and mobile migrant gold miner populations (MMP). This study describes the malaria epidemiology in Suriname between 2000 and 2015. Surveillance data were obtained from national healthcare providers, analyzed and described. Epidemiologic parameters were calculated. The trend of confirmed malaria cases shows peaks of cases until 2004. The highest peak, 15,967 cases, was observed in 2001. From 2004 onwards a steep decline is observed, reaching a nadir of 308 cases in 2014 (decrease of 98.1%). The Pf to non-Pf ratio has declined by 89.6% from 4.8 in 2000 to 0.5 in 2015. With both Pf and *Plasmodium vivax* (Pv) cases declining. Since 2011 cases among children below 14 years of age were very few. Hospital admissions for malaria have decreased enormously by 97.1% from 377 in 2003 to 11 in 2015. The proportion of admissions due to Pv infections increased from 13.4% in 2001 to 45.5% in 2015. Also, a shift in at risk populations was observed from stable communities to MMP populations. Deaths due to malaria have dropped from 24 in 2000 to 0 in 2015. In the current near elimination setting, management of imported cases has become increasingly important. In 2015 the proportion of imported cases was 73.5% of the total number of cases diagnosed. The majority originated from French Guiana as a consequence of cross-border moving miners. Suriname is on the brink of elimination. Artemisinin Combination Therapy as first line treatment for Pf infections and improved access to diagnosis and treatment have contributed to the malaria reduction. However, the high proportion of imported malaria poses the risk of re-introduction in areas which are currently malaria free. A regional approach is required to deal with this.

## 1905

**MALARIA ELIMINATION: ENGAGING COMMUNITIES THROUGH NATIONWIDE CAMPAIGNS**

Diouf<sup>4</sup>, Moussa Diop<sup>3</sup>, Ernest Kakoma<sup>5</sup>, Oumar Sarr<sup>2</sup>, Cheikh S. Senghor<sup>4</sup>, Chilumba Sikombe<sup>1</sup>, Fagueye Sonko<sup>3</sup>, Stacey Naggiar<sup>1</sup>, Pauline Wamulume<sup>5</sup>, Hana Bilak<sup>6</sup>, Philippe Guinot<sup>3</sup>, Todd Jennings<sup>1</sup>

<sup>1</sup>PATH MACEPA, Lusaka, Zambia, <sup>2</sup>National Malaria Control Program, Senegal, Dakar, Senegal, <sup>3</sup>PATH MACEPA, Dakar, Senegal, <sup>4</sup>Ministry of Health, Senegal, Dakar, Senegal, <sup>5</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia, <sup>6</sup>PATH MACEPA, Geneva, Switzerland

Malaria elimination requires political commitment, sustained funding, and a package of technical tools. Elimination will be impossible without engaging the direct beneficiaries: affected communities. These communities should not be considered merely as recipients of priority funding, but rather, as critical partners. PATH-MACEPA has worked with national malaria programs in Senegal and Zambia to create community demand for malaria elimination strategies, tailoring approaches as needed. In Senegal, the “Zéro Palu, je m’engage” campaign was launched in 2014 to bring together citizens at all levels of the country in the fight against malaria. One of the campaign’s initiatives is the deployment of “community champions” to facilitate malaria elimination interventions at the community level. These community champions are sponsored by private-sector companies, showcasing how public-private partnerships

can collaborate to eliminate malaria one community at a time. In Zambia, the “Malaria Ends with Me” slogan was first used in 2015 during a mass drug administration (MDA) trial. This trial presented challenges around the acceptability of a new approach, including giving a new drug to people who “felt fine”. Community engagement activities likely contributed to a low refusal rate of less than 1% by the end of the study. When MDA results demonstrated the issue of not finding people at home, community engagement was expanded to target mobile populations, school children, and religious leaders. As malaria decreases, identifying, treating, and following up each case is essential. Case investigation relies on neighbors of an “index case” accepting testing and treatment. In Senegal last year, close to 2,500 index cases led to investigations; out of over 51,600 people, only 143 refused to be tested. In Zambia, villages select individuals to serve as community health workers who test, treat, and track local and imported infections, while in Senegal, volunteers in malaria-free communities motivate travelers to get tested to avoid local spread of infection. These examples show the power of communities taking malaria elimination into their own hands.

Zanzibar aims to eliminate malaria locally-acquired malaria by 2018, following sharp declines in malaria morbidity and mortality since 2000. Interventions introduced and maintained in Zanzibar included universal diagnostic testing and artemisinin-based combination therapy (ACT) for case management of uncomplicated malaria from late 2003, and insecticide-treated nets and indoor residual spraying from 2006. These interventions were scaled up rapidly across both islands of Zanzibar: Pemba and Unguja. Evaluating the impact of these interventions on malaria burden using probabilistic methods is not possible due to the lack of contemporaneous control groups that did not receive interventions. We present analysis of routine health information management system (HMIS) data using a plausibility approach to estimate the impact of interventions applied during 2000–2015. An interrupted time series model was used to analyze changes in confirmed malaria incidence from 129 public outpatient facilities in Zanzibar. In addition, modeled counterfactuals were generated to estimate the number of malaria cases averted due to introduction of interventions. After accounting for climate variability, seasonality, testing rates, and outpatient attendance, the average monthly incidence rate declined following introduction of ACTs in 2003 compared to the pre-ACT period (incidence rate ratio, IRR 0.976). After vector control was introduced in 2006, the trend increased compared to the pre-vector control period (IRR 1.0184), but maintained an overall decline (IRR 0.9918). The combination of case management with ACTs and vector control is

estimated to have averted, on average, 8394 malaria cases per year during 2006–2015 across Zanzibar, while ACTs alone averted, on average, 1999 malaria cases per year during 2004–2005. This study presents a relatively simple yet rigorous approach to the use of routine HMIS data in evaluating the impact of malaria interventions.

## 1907

### EVIDENCE OF TRANSMISSION DECLINE DURING MASS DRUG ADMINISTRATION TRIALS IN SOUTHERN ZAMBIA THROUGH PARASITE GENOMICS: AN EXAMPLE OF BARCODING AND ITS UTILITY FOR MALARIA PROGRAMS

**Sarah K. Volkman**<sup>1</sup>, Rachel Daniels<sup>2</sup>, Hawela Moonga<sup>3</sup>, Conceptor Mulube<sup>4</sup>, Brenda Mambwe<sup>4</sup>, John M. Miller<sup>4</sup>, Richard W. Steketee<sup>5</sup>, Adam Bennett<sup>6</sup>, Thomas P. Eisele<sup>7</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health/Broad Institute/Simmons College, School of Nursing and Health Sciences Collaboration, Boston, MA, United States, <sup>2</sup>Harvard T.H. Evaluation of changing genomic diversity of malaria parasite infections could provide critically sensitive measures of changing transmission dynamics. The Zambian Ministry of Health is exploring mass drug administration (MDA) with dihydroartemisinin-piperazine in combination with vector control to accelerate malaria elimination efforts. As part of a monthly sampled cohort of individuals followed over 18 months (December 2014–May 2016) from a community randomized controlled MDA trial in 60 health facility catchment areas in Southern province, parasites were assessed for patterns in genetic relatedness. Molecular barcode analysis was performed on *Plasmodium falciparum* genetic material extracted from discarded rapid diagnostic tests. Across 231 RDT positive samples with molecular barcodes over the study period, the proportion of monogenomic samples at baseline was 36%, and this increased substantially in the first six months of the study (final results will be available for presentation). Multiple instances of identical molecular barcodes were identified and fell into four types: those collected at the same month/time interval, those collected following the same MDA round, those from samples collected between MDA treatment rounds, and those collected from different clusters. Assessment of samples from individuals who were slide positive two months after treatment revealed that all of these infections were new parasite infections, since multiple positions of the 24-SNP molecular barcode were distinct between the sample pairs. These results suggest that genetic characterization of infections allows measures of increasing monogenomic infections and documentation of incident infections and possibly their source; these changes may correlate with both control efforts and with transmission decline. These findings support the use of parasite genomics to track changes in the parasite populations in response to the deployment of elimination programs; as transmission is reduced to very low levels, these metrics may be more sensitive to change than traditional tools.

## 1908

### PCR INCIDENCE OF *PLASMODIUM FALCIPARUM* INFECTIONS IN COHORT SAMPLES OVER TIME DURING A MALARIA MDA RANDOMIZED CONTROL TRIAL IN SOUTHERN PROVINCE ZAMBIA

**Mulenga Mwenda**<sup>1</sup>, Sandra Chishimba<sup>1</sup>, Brenda Mambwe<sup>1</sup>, Conceptor Mulube<sup>1</sup>, Victor Chalwe<sup>2</sup>, Hawela Moonga<sup>3</sup>, Busiku Hamainza<sup>3</sup>, Richard W. Eisele<sup>7</sup>, John M. Miller<sup>1</sup>, Daniel J. Bridges<sup>1</sup>

<sup>1</sup>PATH MACEPA, Lusaka, Zambia, <sup>2</sup>Zambia Ministry of Health, Mansa, Zambia, <sup>3</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia, <sup>4</sup>PATH MACEPA, Seattle, WA, United States, <sup>5</sup>PATH, Seattle, WA, United States, <sup>6</sup>Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, <sup>7</sup>Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

As part of a comprehensive package of interventions for achieving malaria elimination in Southern Zambia, a community randomized control trial was carried out in 60 health facility catchment areas (HFCAs) to assess the effectiveness of mass drug administration (MDA) on malaria prevalence and incidence. HFCAs were randomized to receive MDA (treatment given to all individuals), focal MDA (treatment given to all individuals living in a house where anyone tested positive), or standard malaria control activities that included high vector control coverage and community case management (control). A subset of individuals (all ages) in each HFCA was enrolled into a longitudinal study involving monthly visits where individuals were tested for malaria using the SD Bioline *P.f* RDT (and treated with artemether-lumefantrine if positive) as well as the collection of a dried blood spot (DBS) and (in some cases) a blood slide. A total of approximately 34,000 individual cohort visits were performed over the 18-month lifespan of the trial. To better understand malaria incidence in the different arms of the study, all available DBS are being tested by PET-PCR—a real-time fluorogenic primer-based PCR assay that detects the presence of *Plasmodium* at the genus and species level with a sensitivity many fold higher than that of conventional point-of-care diagnostics. From these data, we determined the level of (i) RDT subpatent parasite carriage, (ii) PCR microscopy and RDT concordance, and (iii) non-*Plasmodium falciparum* species prevalence. To date, 10,218 RDT-negative and 69 RDT-positive DBS were assayed by PET-PCR, representing the first six months of the samples collected, of which 2% were PCR-positive. The negative predictive value (NPV) of the RDT tests was found to be 99.7% while the positive predictive value (PPV) was 56.5%. The high NPV and the low PPV respectively showed that the RDT is highly specific but has moderate sensitivity. The implication of these findings on elimination strategies will be discussed.

## 1909

### PREVENTING REESTABLISHMENT OF MALARIA IN RECENTLY-ELIMINATED AREAS: A MODELING STUDY OF REACTIVE CASE DETECTION AND ADAPTIVE RESPONSE

**Jaline Gerardin**<sup>1</sup>, Caitlin A. Bever<sup>1</sup>, Daniel Bridenbecker<sup>1</sup>, Thomas P. Eisele<sup>2</sup>, John M. Miller<sup>3</sup>, Philip A. Eckhoff<sup>1</sup>, Edward A. Wenger<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling, Seattle, WA, United States, <sup>2</sup>Tulane University, New Orleans, LA, United States, <sup>3</sup>PATH-MACEPA, Lusaka, Zambia

After elimination, areas with substantial vectorial capacity remain susceptible to reestablishment of malaria transmission through importation of infections. What types of operations are effective at preventing resurgence? What are the features of an effective surveillance system? How do programmatic needs differ based on local conditions such as pre-elimination transmission intensity, population density, and importation rate? To address these questions, we simulated malaria transmission

at the household level with an agent-based mathematical model and investigated the effects of various case management rates, maintenance of vector control, features of reactive case detection programs, and larger-scale drug- and insecticide-based responses on outbreak management and prevention of resurgence in three representative communities in southern Zambia. We find that excellent surveillance is a necessary condition for preventing reestablishment, and we predict that many areas of sub-Saharan Africa will require continued refreshing of vector control until elimination is achieved on a broader regional scale and importation becomes unlikely. The intensity of reactive activities needed to maintain elimination varies with both local receptivity and local configuration of households, with densely populated areas requiring larger radius of follow-up activities. Since asymptomatic infections remain likely when infections are imported into areas with substantial lingering immunity, adaptive responses where mass drug campaigns are triggered when clinical case counts surpass a pre-determined threshold can be a powerful tool for managing outbreaks. These results suggest a general set of guidelines for programs seeking to maintain elimination in areas that remain vulnerable to importation pressure.

## 1910

### DEVELOPING A NATIONAL MALARIA ELIMINATION INVESTMENT CASE: A FRAMEWORK AND APPLICATION

**Anton L.V. Avancena**<sup>1</sup>, Arian Hatefi<sup>2</sup>, William Parr<sup>3</sup>, Rima Shretta<sup>1</sup>

<sup>1</sup>University of California San Francisco Global Health Group, San Francisco, CA, United States, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Parr and Associates, Picton, New Zealand

The World Health Organization's *Global Technical Strategy for Malaria 2016-2030* calls for malaria elimination in at least 35 countries by 2030. To achieve this ambitious target, national malaria programs will require adequate financial resources to interrupt local transmission and prevent reintroduction. Donor funding for malaria elimination, however, has decreased in recent years, and competing priorities, coupled with a low priority given to malaria as a result of reduced transmission rates, often lead governments to withdraw funding for malaria at a critical juncture. Historical evidence suggests that ill-timed downsizing of malaria programs can lead to deadly and costly resurgences. To sustain political and financial commitment, policymakers responsible for resource allocation must be convinced of the economic returns of eliminating malaria. An investment case can present the rationale for investing in clear and concise terms. Building on existing literature, we developed a framework for national malaria elimination investment cases. The framework has four sections, namely (1) proposed investment, (2) rationale for investing, (3) financial landscape, and (4) issues to consider. The framework, when properly adapted, can help malaria programs gather and generate evidence on the costs, benefits, risks, and financial viability of national malaria elimination. We applied this framework to Papua New Guinea, a malaria endemic country that has aligned itself with the regional goal of making Asia Pacific malaria-free by 2030. Using the outputs of a dynamic transmission model, we estimated the total cost of eliminating malaria to be US\$454 million (range: US\$282-701 million) in 2016-2030, or \$30 million on average per year. This is roughly US\$14 million more than what was spent on malaria control in 2015. Elimination by 2030 can save over 14,500 lives and avert over 7.8 million cases. The net economic benefits of elimination compared to a business-as-usual scenario is roughly US\$5 billion (range: US\$4-7 billion). The median return on investment is 17, indicating that the incremental costs of elimination greatly outweigh its costs.

## 1911

### HIGH LEVEL EFFICACY IN HUMANS OF A NEXT-GENERATION *PLASMODIUM FALCIPARUM* ANTI-SPOROZOITE VACCINE: R21 IN MATRIX-M™ ADJUVANT

**Navin Venkatraman**<sup>1</sup>, Georgina Bowyer<sup>1</sup>, Nick J. Edwards<sup>1</sup>, Oliver Griffiths<sup>1</sup>, Jonathan Powlson<sup>1</sup>, Daniel Silman<sup>1</sup>, Richard Morter<sup>1</sup>, Pedro M. Blagborough<sup>4</sup>, Rachel Roberts<sup>1</sup>, Alison M. Lawrie<sup>1</sup>, David J. Lewis<sup>5</sup>, Saul N. Faust<sup>2</sup>, Sarah Gilbert<sup>1</sup>, Katie J. Ewer<sup>1</sup>, Adrian V. Hill<sup>1</sup>

<sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>NIHR/Wellcome Trust Southampton Clinical Research Facility, Southampton, United Kingdom, <sup>3</sup>Novavax, Gaithersburg, MD, United States, <sup>4</sup>Imperial College, London, United Kingdom, <sup>5</sup>NIHR/Wellcome Trust Imperial Clinical Research Facility, London, United Kingdom

It remains a global health priority to develop a durable and highly efficacious malaria vaccine. The most advanced malaria vaccine candidate, RTS,S/AS01 has completed Phase III testing in a multicentre study across several African sites and demonstrates low-level (~30%) efficacy against clinical malaria in children aged 5-17 months after a three dose schedule. Efficacy wanes rapidly over time and there remain some safety concerns that require further assessment in the planned pilot deployment trials due to commence in Africa in 2018. There is a need to improve on RTS,S/AS01 to achieve WHO development goals of a durable vaccine with >75% efficacy. RTS,S comprises recombinant particles expressing the central repeat and the C-terminus of the circumsporozoite protein (CSP) fused to Hepatitis B surface antigen (HBsAg). R21 has been developed at the Jenner Institute, University of Oxford. This is an improved HBsAg-CSP-based construct, but without any unfused HBsAg protein which is present at a four-fold molar excess in RTS,S particles. This excess of HBsAg was required for RTS,S to form a particle; however, R21 forms particles without excess HBsAg by utilizing the better expressing yeast, *Pichia pastoris*. Matrix-M (MM) is a promising, novel saponin-based adjuvant that has been tested safely with vaccines for a number of diseases in over 1000 subjects. We previously showed that R21 administered with MM is safe and has comparable immunogenicity at much lower doses compared to RTS,S/AS01: 10µg doses of R21/MM induced the same antibody titres to the CSP repeat as 50µg of RTS,S/AS01B. Durable humoral responses at 6 months were higher for the 10µg than the 50µg dose of R21/MM. We report a Phase IIa efficacy trial using controlled human malaria infection in healthy UK adult volunteers. Three doses of 10µg R21 adjuvanted with MM given 4 weeks apart demonstrated high level sterile efficacy [(81.8%; n=11); p=0.0009]. Furthermore, we observed significantly reduced reactogenicity compared to reported data on the standard RTS,S/AS01 regimen. These data provide strong support for this R21/MM vaccine to be evaluated further in African adults, children and infants.

Wellcome Trust Clinical Research Facility, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, <sup>5</sup>Clinical Biomanufacturing Facility, Oxford, United Kingdom, <sup>6</sup>GlaxoSmithKline Vaccines, Wavre, Belgium, <sup>7</sup>Leidos Life Sciences, Fredrick, MD, United States, <sup>8</sup>United States Agency for International Development, Washington, DC, United States

The development of an effective blood-stage malaria vaccine holds significant promise, not only for reducing the morbidity and mortality associated with malaria, but also for reducing transmission, either alone or as a crucial component of a multi-stage vaccine. The reticulocyte-binding protein homologue 5 (RH5) is the most promising blood-stage *P. falciparum* candidate antigen to date. It is essential for parasite survival and erythrocyte invasion, has limited polymorphism, and antibodies induced by RH5 in preclinical *in vitro* studies overcome two of the long-standing difficulties associated with other merozoite antigens: first, they can block erythrocyte invasion to high efficiency (requiring lower antibody concentrations); and second, cross-inhibit all *P. falciparum* lines and field isolates tested to-date. Efficacy has been shown against a stringent heterologous strain blood-stage challenge in an *in vivo* Aotus monkey-*P. falciparum* challenge model, following vaccination with RH5 protein. Protection was strongly correlated with anti-RH5 serum IgG antibody concentration and *in vitro* functional growth inhibition activity (GIA). Here we report on a first-in-human Phase Ia clinical trial (NCT02927145) of the recombinant protein RH5.1 delivered with GSK's adjuvant AS01B to 48 healthy, malaria-naïve UK adult volunteers (four groups of n=12). Group 1 receive a lead-in dose (2 µg) of RH5.1 (given 3 times 4 weeks apart) before dose escalation to 10 µg in Group 2, and then 50 µg in Group 4 (same schedule). Group 3 receive 50 µg twice 4 weeks apart followed by a delayed, fractional dose (10 µg) boost at 6 months. All groups receive the same dose (0.5 mL) of AS01B. This is the first RH5 protein/adjuvant vaccine to be tested in humans. The vaccine is well tolerated at all doses. There have been no safety concerns and no SAEs to-date. T cell, B cell and serum antibody responses have been assessed by ELISpot, flow cytometry and quantitative ELISA and purified IgG is tested for anti-parasitic function using the *in vitro* GIA assay. These promising data will be presented and RH5.1/AS01B will be tested for efficacy in a Phase IIa blood-stage CHMI trial in late 2017.

## 1913

### INTEGRATED ANALYSIS OF ANTIBODY, CYTOKINE AND T CELL RESPONSES INDUCED BY RTS,S/AS01E VACCINATION WITHIN THE AFRICAN PEDIATRIC PHASE 3 TRIAL: SEARCHING FOR CORRELATES OF PROTECTION

<sup>1</sup>ISGlobal, Barcelona, Spain, <sup>2</sup>Manhiça Health Research Center, Manhiça, Mozambique, <sup>3</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>4</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>5</sup>Antigen Discovery Inc., Irvine, CA, United States, <sup>6</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>7</sup>Indiana University, Bloomington, IN, United States, <sup>8</sup>Michigan State University, East Lansing, MI, United States, <sup>9</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

The RTS,S/AS01E malaria vaccine is the most clinically advanced, however there is still a need to better characterize and integrate antibody and cellular immune responses elicited upon vaccination to understand its moderate and short-lasting protection. We assessed the antibody and cellular responses to the RTS,S/AS01E antigens circumsporozoite protein (CSP) and Hepatitis B surface antigen (HBsAg) at baseline and one month post primary vaccination by luminex and intracellular cytokine

staining and flow cytometry in RTS,S-vaccinated and control-vaccinated children recruited in two of the African sites of the phase III trial: Manhiça (Mozambique) and Bagamoyo (Tanzania). We aimed to explore the association between antibody and cellular responses induced by the vaccine, focusing on specific cell types and cytokines of the T helper phenotype. RTS,S vaccination induced polyfunctional CSP- and HBsAg-specific CD4+ T cells and antibodies of different isotypes/subclasses and degrees of avidity to multiple CSP B cell epitopes (NANP, C-terminal and full length). RTS,S-vaccinated children had significantly higher frequencies of CSP- and HBsAg-specific CD4+ T cells producing IL-2, TNF-α and CD40L and HBsAg-specific CD4+ T producing IFN-γ and IL-17 than controls or baseline frequencies; these responses were confined in central and effector memory compartments. Additionally, effector memory CD4+ T cells producing IL-4 and IL-21 were detected for both vaccine antigens. Furthermore, we identified distinct profiles of antigen-specific cytokine responses associated with RTS,S vaccination and protection/risk of malaria. We will present data on the correlation between such cytokine profiles and antibody responses induced by the vaccine in African children. Data thus far show that RTS,S/AS01E vaccine induces antibody and T cell responses of higher quality and complexity than previously thought. The joint analysis of responses detected in memory CD4+ T and B cell compartments may provide better correlates of RTS,S/AS01-induced immunity and duration of protection that may guide development of second generation improved candidates.

### IGG PROTEOMICS AND BCR SEQUENCING OF SPECIFIC B CELLS FOR ANTIBODY REPERTOIRE ASSESSMENT AFTER MALARIA TRANSMISSION BLOCKING VACCINATION IN MALIAN ADULTS

<sup>1</sup>National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>2</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States, <sup>3</sup>Malaria Research and Training Center, Bamako, Mali, <sup>4</sup>Adaptive Biotechnologies Corp, Seattle, WA, United States

Transmission blocking vaccines induce antibodies that target sexual-stage antigens expressed by the parasite in the mosquito. Antibodies against Pfs25 and Pfs230, molecules present on the surface of the sexual stages of *Plasmodium falciparum*, can reduce parasite burden in the mosquito. Antibody repertoire analyses, performed by BCR sequencing and/or proteomics of serum IgG, have been employed to evaluate vaccine responses. Here, we used a Pfs25 tetramer to sort Pfs25-specific single B cells (Pfs25+, CD3-, CD19+, CD20+) generated after a fourth dose of Pfs25-EPA immunization in Malian adults, and sequenced light and heavy chain of antibody from these cells. In a second approach, Pfs25-specific antibodies were affinity-purified from plasma of vaccinees and analysed by mass spectrometry. For peptide analysis, we used an *in-house* database, generated by immunosequencing a 130-nt fragment of the CDR3 region of the IgH from PBMCs from the same donors. We compared two groups of samples: those with antibodies able to reduce parasite burden in the midgut of a mosquito; and those without such antibody activity. For both groups, we compared IgG sequence alignment/coverage using the PBMC immunosequencing database, CDR3 length, and post-translational modifications. Our results showed that all Pfs25-IgG samples from the high antibody activity group yielded peptides matching CDR3 region sequences generated from study PBMC. Coverages higher than 75% were found only in the high antibody activity group. Hexose was found as post-translational modification only in peptide sequences from the high antibody activity group, suggesting a glycosylation process. CDR3 length did not differ between high and low activity groups. These preliminary analyses demonstrate that proteomics techniques can detect specific IgGs from the vaccine trial. For the BCR sequencing of antigen-specific

single cell, we were able to find information about heavy and light chain for dozens of cells per sample. We will combine all datasets (CDR3 sequencing; BCR sequencing of single cell; MS/MS analysis) to define BCR repertoire, expansion, and hypermutation after vaccination.

## 1915

### DIFFERENTIAL IMMUNE-RESPONSIVENESS TO PFSPZ VACCINE IN MALARIA-NAÏVE, SEMI-IMMUNE AND IMMUNE POPULATIONS FROM INFANCY TO ADULTHOOD

Sanaria is developing whole *Plasmodium falciparum* (Pf) sporozoite (SPZ) vaccines spurred by an international scientific alliance of ~200 investigators from ~40 organizations in ~20 countries. Unprecedented clinical outcomes have resulted from 14 PfSPZ-based Vaccine trials conducted to date; >90% protection against controlled human malaria infection has been achieved in 6 clinical trials in the USA, Germany, Mali, and Tanzania. The high level of observed efficacy must necessarily rely on and be defined by wide-ranging and robust induction of immune responses. T cell responses directed against infected hepatocytes are considered to be the primary mediators of protection, but antibodies against PfSPZ have also been implicated, and may also be a marker for T cell responses. We have systematically assessed antibody levels against, 1) the most-abundant protein on PfSPZ, the circumsporozoite protein (CSP), by ELISA; 2) whole PfSPZ surface antigens by an automated immunofluorescence assay (aIFA); and live PfSPZ by inhibition of sporozoite invasion (ISI) of hepatocytes, on a high throughput platform, for all trials. In semi-immune Tanzanian adults the median antibody responses to PfCSP by ELISA, were 6.5-10 times lower than in malaria naïve Americans, but higher than in immune Malians who received the same immunization regimen. T cell responses implicated in durable protection in the face of waning antibodies, followed the same trend. Overall, the lower vaccine specific immune responses correlated with poor protective efficacy in adult Tanzanians. Most notably though, antibody responses increased in magnitude in younger age groups in Tanzania with 6-12 month olds attaining highest levels, similar to those in naïve adults in the USA. Future systems-based analyses, are expected to highlight the immunological underpinnings driving differential responsiveness to PfSPZ Vaccines across age-groups and exposure levels, and how to overcome immune dysregulation in adults due to long term exposure to malaria.

## 1916

### HUMAN TO MOSQUITO TRANSMISSION OF *PLASMODIUM VIVAX* GAMETOCYTES DURING CONTROLLED HUMAN MALARIA INFECTION AND DEVELOPMENT OF *VIVAX* SPOROZOITES

**Katharine A. Collins**<sup>1</sup>, Hayley Mitchell<sup>1</sup>, Matthew Adams<sup>1</sup>, Melanie Rampton<sup>1</sup>, Gregory J. Robinson<sup>1</sup>, Claire Wang<sup>2</sup>, Stephan Chalou<sup>3</sup>, Jörg J. Möhrle<sup>3</sup>, James S. McCarthy<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>QPID Pty Ltd, Brisbane, Australia, <sup>3</sup>Medicines for Malaria Venture, Geneva, Switzerland

*Plasmodium vivax* is a major cause of morbidity and the most globally widespread malaria parasite. However, the development of drugs and vaccines to control *P. vivax* infection has been limited in comparison to progress with *P. falciparum*. This is largely due to the inability to continuously culture the parasites *in vitro*, thus hindering the evaluation of interventions against asexual parasite cultures, preventing the *in vitro* generation of gametocytes for transmission blocking studies, and limiting the production of sporozoites that could be used to infect hepatocytes for the evaluation of hypnozoites. Here we describe the iterative development of a safe and reproducible clinical trial system using *P. vivax*-infected erythrocytes to initiate a blood stage infection in malaria-naïve volunteers (n=32), that could potentially be exploited to study all stages of *P. vivax* parasite biology. We demonstrate the ability to monitor the development and clearance of asexual parasitemia and gametocytemia with qPCR and RT-qPCR, respectively. *P. vivax* gametocytes were detected in all volunteers and were successfully transmitted to *Anopheles* mosquitoes using direct skin feeding assays (DFA) and direct membrane feeding assays (DMFA). Transmission success was related to the level of gametocytemia and the prevalence of infection was up to up 63% after DFA and up 12% after DMFA. Membrane feeding assays were also performed following the enrichment of gametocytes and resulted in 93% of the mosquitoes infected with up to 10 oocysts/midgut and ~4,300 sporozoites/infected mosquito. This work demonstrates the potential utility of *P. vivax* controlled human malaria infection as a model to evaluate asexual stage and transmission blocking interventions. Furthermore, this system could facilitate the study of multiple *P. vivax* parasite stages by providing a source of gametocytes for standard membrane feeding assays and generating sporozoites to enable the evaluation of hypnozoites. This system is amenable to further optimisation and thus may provide an opportunity to support the development of drugs and vaccines against all stages of *P. vivax*.

## 1917

### A NOVEL HIGHLY PROTECTIVE *PLASMODIUM* ANTIGEN - A *FALCIPARUM* VACCINE CANDIDATE

Richie<sup>3</sup>, Robert Gerbasi<sup>1</sup>, Emily Smith<sup>1</sup>, Keith Limbach<sup>1</sup>, Eileen D. Villasante<sup>1</sup>

<sup>1</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>2</sup>The University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Sanaria Inc., Rockville, MD, United States

The development of an effective malaria vaccine depends upon inducing an immune response capable of preventing infection, disease, and transmission. A malaria vaccine is feasible as radiation-attenuated sporozoites (RAS) elicit sterile protection in mice and humans. While both RTS,S and whole sporozoite vaccines show potential, these vaccines may not achieve the long-term efficacy and cross-strain protection necessary. Alternative pre-erythrocytic (PE) antigens must therefore be identified, characterized and evaluated as single or multi-component subunit

vaccines. Recently, we screened a panel of new *Plasmodium yoelii* (Py) PE antigens for their ability to recall T cell responses from RAS-immunized mice. Vaccines expressing antigens that were positive in this screen were then systematically evaluated for the ability to induce sterilizing protection in mice against a sporozoite challenge, identifying viable candidates for the development of a vaccine. We adopted a matrix strategy to test a large number of antigens in combinations of three, with and without PyCSP in mice. The immunization regimen consisted of priming with DNA and boosting with adenovirus 5 (Ad5) constructs. As a result of these studies, we have identified a novel PE antigen (E140) capable of consistently inducing 100% sterilizing protection in inbred and outbred mice (alone or in combination with other PE antigens), against a sporozoite challenge. PyE140 immunization of mice induced high titer antibodies to sporozoites, liver, and schizont stages, which correlate with protection. We have further examined the duration of the PyE140 protection, routes of immunization, blood stage challenge, and antigen localization on these parasite stages. In addition to these results, preliminary *P. falciparum* E140 immunogenicity data will be presented. These data support the advancement of the *P. falciparum* E140 ortholog in a subunit malaria vaccine.

## 1918

### HELMINTH INDUCED ALTERATIONS IN T CELL, B CELL, DENDRITIC CELL AND MONOCYTE SUBSETS AND THEIR REVERSAL FOLLOWING TREATMENT

**Anuradha Rajamanickam**<sup>1</sup>, Saravanan Munisankar<sup>1</sup>, Yukthi Bhootra<sup>1</sup>, Dolla Chandrakumar<sup>2</sup>, Thomas B Nutman<sup>3</sup>, Subash Babu<sup>1</sup>

<sup>1</sup>NIH-ICER-National Institute for Research in Tuberculosis, Chennai, India, <sup>2</sup>National Institute for Research in Tuberculosis, Chennai, India, <sup>3</sup>Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland, USA, Chennai, India

Although helminth infections are known perturb innate and adaptive immune responses, whether these alterations are related to expansion of particular cell populations or to alterations of specific cell function is unknown. Thus, we enumerated the numbers of a variety of T cell, B cell, monocyte and dendritic cell (DC) subsets in a group of individuals with asymptomatic, *Strongyloides stercoralis* (Ss) infection (INF) and a group of uninfected controls (UN). These cell frequencies were also repeated in the INF individuals 6 months following anthelmintic treatment. Our data show that Ss infection is characterized by significantly increased number of naïve (CD45RA+ CCR7+ p=0.0135), effector (CD45RA-CCR7- p=0.0088) and regulatory (CD4+ CD25+ Foxp3+ CD127dim p=0.0404) CD4+ T cells in comparison to UN individuals. In contrast, there were no significant differences in the number of cells in the CD8+ T cell compartments between the groups. Ss infection was also characterized by significantly increased numbers of naïve B cells (CD45+ CD19+ CD21+ CD27- p=0.0188) and significantly decreased numbers of immature (CD45+ CD19+ CD21+ CD10+ p<0.0001) and activated memory (CD45+ CD19+ CD21- CD27+ p<0.0001) B cells. INF was also associated with increased numbers of myeloid (Lin- HLA-DR+ CD11c+ p<0.0001) and plasmacytoid (Lin- HLA-DR+ CD123+ p<0.0001) DCs as well as increased numbers of non-classical (CD45+ HLA- DR+CD14dimCD16hi p=0.030) but decreased numbers of intermediate monocytes (CD45+ HLA-DR+ CD14hi CD16dim p=0.0041). Anthelmintic treatment resulted in a significant reversal of the cell frequencies to those seen in uninfected populations. Thus, Ss infection leads to alterations in the numbers of T cell, B cell, DC and monocyte subsets, alterations that revert toward "normal" and after anthelmintic treatment.

## 1919

### IMMUNOLOGIC IMPACT OF ASCARIASIS ON THE HOST LUNG

**Jill Weatherhead**<sup>1</sup>, Leroy Versteeg<sup>1</sup>, John Knight<sup>1</sup>, Ana Maria Jaramillo<sup>2</sup>, Amy Coffey<sup>1</sup>, Dana Hydell<sup>1</sup>, Burton Dickey<sup>2</sup>, Bin Zhan<sup>1</sup>, Maria Elena Bottazzi<sup>1</sup>, Coreen Beaumier<sup>1</sup>, David Corry<sup>1</sup>, Peter Hotez<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>University of Texas M.D. Anderson, Houston, TX, United States

Ascariasis (roundworm) is the most common intestinal helminth infection globally and accounts for significant morbidity including allergic airway disease. This study aims to evaluate the lung immunologic changes that occur during *Ascaris* infection in a murine model. We hypothesize that *Ascaris* infected mice will demonstrate a type 2 immune response consistent with allergic airway disease. Balb/c mice were administered *Ascaris suum* embryonated eggs by oral gavage. Plethysmography was completed and respiratory system resistance (RRS cm H<sub>2</sub>O·s·ml<sup>-1</sup>) was measured on day 12 post-infection. Bronchoalveolar lavage (BAL) was collected and total cell counts were determined using cytospin and microscopy. BAL fluid and lung tissue were collected for cytokine analysis using Luminex MAGPIX®. Additional lung tissue was used for histopathologic evaluation (H&E, PAS, and PAFS stains). *A. suum* infected mice had severe airflow resistance compared to controls (p= 0.0087). Total immune cell counts in BAL were significantly elevated in *Ascaris* infected compared to controls (2,637,714 vs 167,500; p< 0.001) including macrophages (p = 0.0047), lymphocytes (p = 0.0159), neutrophils (p < 0.0001) and eosinophils (p= 0.0012). *Ascaris* infected mice had a robust type 2 cytokine inflammatory response in both the BAL fluid and lung tissue including Interleukin-4 (IL-4) (p < 0.01; p< 0.01), IL-5 (p< 0.001; p< 0.001), IL-13 (p< 0.001; p< 0.01) relative to controls. On histopathology, *Ascaris* infected mice demonstrated severe neutrophilic and eosinophilic inflammatory infiltrate, goblet cell metaplasia, mucin production and smooth muscle hypertrophy consistent with a type 2 mediated immune response. We found that ascariasis causes profound airway hyper-responsiveness and type 2 inflammatory lung pathology consistent with severe allergic airway disease. Further evaluation of the immunologic molecular mechanism by which *Ascaris* induces allergic airway disease will allow for recognition of novel therapeutic targets. Interventions to reduce *Ascaris* infection have the potential to prevent significant morbidity in millions of children around the world.

## 1920

### ALLERGIC SENSITIZATION COINCIDENT WITH HELMINTH INFECTION DRIVES A TH2-DOMINATED IMMUNE RESPONSE THAT LIMITS PARASITE BURDEN

**Pedro H. Gazzinelli-Guimaraes**, Thomas B. Nutman

National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

More than three billion people worldwide are infected with helminth parasites and/or suffer from allergic diseases. A common feature of atopic disorders and helminth infections is their association with type 2 immune responses; however, the impact of helminth infections on allergic diseases is based largely on epidemiological studies. Previously, we have demonstrated that parasite- and allergen-specific CD4+ T cell responses in subjects with filarial infections and coincident allergic sensitization (filarial [Fil]+ allergy [A]+) have hyperreactive parasite Ag-specific Th2-associated immune responses, when compared to 3 appropriate control groups (Fil-A-, Fil-A+, Fil+A-), which correlated with serum IgE levels and levels of circulating activated eosinophils. To better understand the mechanisms underlying the augmented TH2-associated immune responses seen at the helminth/allergy interface and how it might influence the parasitologic outcome of the helminth infection, we used a murine model of house dust mite (HDM)-induced allergic asthma and coincident helminth infection (*Ascaris spp*). Our data show that HDM sensitization prior to infection with *Ascaris* led to a strong Th2 response (IL-4, IL-13, IL-10) in the lung with

markedly increased BAL cellularity (primarily eosinophils and macrophages) compared with non-HDM-sensitized mice. Moreover HDM-sensitization prior to *Ascaris* infection led to a 66% reduction in the number of lung-stage *Ascaris* larvae. Moreover, when airway reactivity and pulmonary mechanics were evaluated, the HDM-allergic and *Ascaris*-infected mice had a marked increase in the Forced Vital Capacity and a significant reduction in the lung resistance compared with the non-HDM sensitized but *Ascaris*-infected mice. Our data, therefore, suggest that allergic sensitization coincident with helminth infection leads to a TH2- dominated immune response that not only limits parasite burdens but may also be involved in tissue remodeling allow more quick resolution of the local inflammation-associated morbidity.

## 1921

### TAXONOMIC AND FUNCTIONAL MICRO BIOME ASSEMBLAGES IN INDIVIDUALS INFECTED WITH STHS

**Makedonka Mitreva**<sup>1</sup>, Bruce Rosa<sup>1</sup>, Taniawati Supali<sup>2</sup>, Lincoln Gankpala<sup>3</sup>, Erliyani Sartono<sup>4</sup>, Yenny Djuard<sup>2</sup>, Kerstin Fischer<sup>1</sup>, Rahul Tyagi<sup>1</sup>, Fatoma Bolay<sup>3</sup>, Peter Fischer<sup>1</sup>, Maria Yazdanbakhsh<sup>4</sup>  
<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>Universitas Indonesia, Jakarta, Indonesia, <sup>3</sup>Liberian Institute for Biomedical Research, Charlesville, Liberia, <sup>4</sup>Leiden University Medical Center, Leiden, Netherlands

To understand the dysbiosis associate with soil transmitted helminth (STH) infections in the human gut ecosystem we compared microbial community taxonomic and functional assemblages among infected and uninfected individuals and before and after anthelmintic treatment. We focused on identifying and validating biologically meaningful associations by: a) comparing the microbiome of moderate/heavy infected individuals to uninfected individuals, b) validating the findings using subjects from different geographical cohort, c) identifying STH-discriminatory taxa (including those conserved among subjects from the different cohorts), d) delineating microbiome assemblages after de-worming, and, e) identifying microbiome-encoded biological functions associated with infection. While answering these questions, technical aspects were also considered to understand how study design, diagnostic accuracy, precise STH burden estimation and depth of coverage affect optimal profiling of the microbiome. We identified twelve bacterial taxa associated with infections in these two geographically very distinct cohorts, including taxa previously related to reducing gut inflammation (*Olsenella*), being increased in other disease states (*Flavonifactor*) or nematode infections (*Enterococcus*). We also identified taxa that responded to treatment, including *Clostridium XVIII*, which was also lower in infected individuals but recovered abundance after treatment, and *Butyricimonas*, which is a butyrate-producing bacteria (butyrate is inhibitor of gut inflammation). Among functional categories identified as associated with hookworm infection was mucin-type O-glycan biosynthesis, indicating that hookworm infection results in changes to the mucosal layer, which is needed for the parasite to penetrate in order to attach on the lining of the intestine and feed on blood. These findings have important implications for designing mechanistic studies to fully understand the STH-microbiome interactions that could facilitate development of affordable microbiome driven intervention for sustainable STH control.

## 1922

### COMPARISON OF WHOLE GENOME TO 16S SEQUENCING ANALYSIS OF INTESTINAL MICROBIOME IN ARGENTINIAN CHILDREN WITH HELMINTH AND PROTOZOA INFECTIONS

**Ashish Damania**<sup>1</sup>, Rubén Cimino<sup>2</sup>, Alejandro Krolewiecki<sup>2</sup>, Laurie Mazzola<sup>3</sup>, Joanna Bybee<sup>3</sup>, Barton Slatko<sup>3</sup>, Rojelio Mejia<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Universidad Nacional de Salta Argentina, Salta, Argentina, <sup>3</sup>New England Biolabs, Inc., Ipswich, MA, United States

Next generation sequencing for microbiome analysis is commonly performed using 16S rRNA gene sequencing or whole genome shotgun sequencing (WGS) method. We carried out both WGS and 16S sequencing on human fecal samples from a 122 Argentinian cohort study focusing on two groups- helminth infected (*Ascaris*, *Ancylostoma*, *Necator*, *Strongyloides*, and *Trichuris*) versus no-parasite groups verified by multi-parallel real-time quantitative PCR. WGS had higher resolution allowing the reads to classify to the bacterial strain level and in some cases even sub-strain level. 16S sequencing could not resolve further than genus level. Shannon alpha diversity metric comparing only bacterial reads within groups showed no statistically significant difference for helminth infected group ( $p = 0.999$ ) and for no-parasite group ( $p = 0.400$ ) indicating that either method has similar sensitivity to detect alpha diversity differences. However, WGS has a significant increase in "difference of means" (DOM) as compared to 16S rRNA gene sequencing, with a delta gap increase of  $1.49 \times 10^{-3}$  proportion of reads (medians of  $5.3 \times 10^{-5}$  versus  $-0.001437$  respectively,  $p = 0.0001$ ). DOM is a measure of the change in proportion of specific bacterial sequences for helminth and no-parasite groups. It provides information on the capacity of an assay to discriminate between 2 experimental groups and small effect size. The WGS method provides rich metagenomic information compared to 16S rRNA sequencing. Metagenomic information for 16S rRNA reads can be inferred using PICRUST software through taxonomic information, but it lacks the direct evidence of genes found in WGS. As such, 16S sequencing is computationally inexpensive, while WGS data is challenging to manage relying on software using complex algorithms to analyze data. Our data shows that WGS offers higher taxonomic resolution and discrimination along with metagenomic information while 16S provides a reasonable option if the taxonomy and diversity are the primary focus of a study. This study provides important information for potential tropical medicine research in selecting the optimal assay based on function and price.

## 1923

### WHOLE GENOME SEQUENCING OF ASCARIS LUMBRICOIDES WORMS REVEALS CHANGES IN SPACE AND TIME

**Alice V. Easton**<sup>1</sup>, Eric Dahlstrom<sup>2</sup>, Stephen F. Porcella<sup>2</sup>, Rita G. Oliveira<sup>3</sup>, Jianbin Wang<sup>4</sup>, Shenghan Gao<sup>4</sup>, Richard E. Davis<sup>4</sup>, Sammy M. Njenga<sup>5</sup>, Charles Mwandawiro<sup>5</sup>, Joanne P. Webster<sup>6</sup>, Roy M. Anderson<sup>3</sup>, Thomas B. Nutman<sup>1</sup>

<sup>1</sup>Helminth Immunology Section, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Research Technology Branch, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rocky Mountain Laboratories, Hamilton, MT, United States, <sup>3</sup>Department of Infectious Disease Epidemiology, Faculty of Medicine, Imperial College London, London, United Kingdom, <sup>4</sup>Department of Biochemistry and Molecular Genetics, University of Colorado School of Medicine, Aurora, CO, United States, <sup>5</sup>Eastern and Southern Africa Centre of International Parasite Control (ESACIPAC), Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, <sup>6</sup>Department of Pathobiology and Population Science and London Centre for Neglected Tropical Disease Research (LCNTDR), The Royal Veterinary College, Hawkshead Lane, Hatfield, Hertfordshire, United Kingdom

As deworming becomes more common, more health departments and global health organizations are looking for "end game" strategies. A

greater understanding of who infects whom in settings where helminth prevalence is low but persistent could make deworming results more sustainable. Of 530 *Ascaris lumbricoides* adult worms collected at two time-points (baseline and 3 months after treatment) in five villages in rural western Kenya, the whole genomes of 77 were sequenced using Illumina paired-end sequencing. Reads were processed and mapped onto a new reference *A. lumbricoides* genome assembled from the reads from the germline DNA from one of the 77 worms. SNPs were called relative to the reference genome, and nearly one million variants were identified. Neighbour Joining clustering was done repeatedly based on sampling 200,000 single-nucleotide polymorphisms (SNPs) at a time. Significant clustering was found within villages and from the same time-point, but not within houses or at the individual level. Furthermore, genetic distance between worms was significantly associated with geographical distances between host residences ( $r=0.22$ ,  $p=0.001$ ) suggesting that worms in different villages may be partially reproductively isolated from each other. The genomic data indicated that worm populations changed post-treatment, which is corroborated by independently collected morphological data. Nevertheless, many members of the original population(s) were still present 3 months post-treatment. In environments such as this one, where worm transmission appears to cluster within villages, the village may be the appropriate unit for deworming programs to target. These data also stress the importance of monitoring genomic changes in worm populations following treatment.

## 1924

### THE EFFECT OF SOIL-TRANSMITTED HELMINTHS ON CHILD DEVELOPMENT: IS IT MEDIATED BY ANEMIA?

**Brittany Blouin**

*McGill University, Montreal, QC, Canada*

It has been hypothesized that soil-transmitted helminths (STHs) adversely affect child development and that this effect is mediated by anemia (i.e. STH infections cause anemia and anemia affects development). However, no formal mediation analysis has yet been performed to investigate this hypothesis. The current objective, therefore, was to investigate the extent to which the effect of STH infection on child development is due to mediation by anemia. A longitudinal cohort study was conducted in Iquitos, Peru between September 2011 and July 2016. Children were recruited at one year of age and followed-up yearly to five years of age. Every year, STH infection was measured using the Kato-Katz technique and child development was measured with the Wechsler Preschool and Primary Scale of Intelligence (WPPSI) in a random sample of 880 children. Anemia was measured at 3, 4 and 5 years of age. STH infection and anemia were categorized into the number of times each child was detected STH infected/anemic throughout the study. A total of 781 children completed the WPPSI at five years. In multivariable linear regression analyses, children found STH-infected more times had statistically significantly lower WPPSI scores at five years of age compared to children who were never found infected (adjusted  $\beta$  values (95% CI) for the total net effect of 1, 2, 3, 4-5 detected infections compared to never infected, respectively: -1.7 (-3.9, 0.6); -3.9 (-6.3, -1.5); -4.4 (-6.9, -2.0), -2.9 (-5.5, -0.3)). Decomposition of the total net effect of STH infection on child development revealed that, although anemia was found to have an independent effect on child development (data presented elsewhere), the observed STH effects were not notably due to mediation by the number of times found anemic. The percent of the total net effect of STH infection on child development that was due to mediation by anemia was: 12%, 3%, 5% and 7% for 1, 2, 3 and 4-5 STH infections, respectively. These results suggest that other mechanisms, such as malnutrition and inflammatory and immunological responses, should be investigated as possible explanations for the effect of STH infection on child development.

## 1925

### A CLOUD-BASED EPIDEMIOLOGICAL SURVEILLANCE PLATFORM WITH APPLICATION TO CHAGAS DISEASE VECTOR CONTROL

**Jennifer Kate Peterson<sup>1</sup>**, Sasha Gutfraind<sup>2</sup>, Erica Billig<sup>1</sup>, Claudia Arevalo Nieto<sup>3</sup>, Gian Franco Condori<sup>3</sup>, Narender Tankasala<sup>2</sup>, Justin Sheen<sup>1</sup>, Ricardo Castillo<sup>1</sup>, Priyanka Anand<sup>1</sup>, Michael Z. Levy<sup>1</sup>

<sup>1</sup>*University of Pennsylvania, Philadelphia, PA, United States*, <sup>2</sup>*University of Illinois at Chicago, Chicago, IL, United States*, <sup>3</sup>*Universidad Cayetano Heredia, Lima, Peru*

Epidemiological surveillance is a critical mission in public health, providing advanced warning and prevention at the earliest stages of an epidemic. In the case of vector-borne diseases, surveillance often requires surveying a large number of sites over an expansive area for disease vectors. Ideally, surveillance site selection would be informed by historical and epidemiological data integrated in some way to generate prediction of local risk. To this end, we developed an epidemiological app that we call EpiReportR. EpiReportR is a versatile and user-friendly platform that addresses a variety of spatial epidemiological problems. Implemented in the open source language R, EpiReportR provides neighborhood maps for use by health inspectors during door to door surveillance for domesticated *Triatoma infestans*, the vector of Chagas disease. In the maps, each house appears as a point that is colored according to its relative risk of infestation with the insect and the maps are updated in real time based on field results. EpiReportR also includes tools for electronic data collection, eliminating the laborious digitalization of paper forms following data collection. EpiReportR also provides a number of other capabilities for spatial epidemiology work, including access to predictive spatial models, analytic capabilities, and visualization. The cost and expertise required for EpiReportR are minimal, and modification of the app requires only knowledge of R and SQL. The app is fully-functional across computers and mobile devices, open source, and can be easily adapted to a variety of epidemiological scenarios. EpiReportR is currently being used for Chagas disease entomological surveillance by health inspectors in nine districts of Arequipa, Peru, and data is currently being collected on its use.

## 1926

### MOLECULAR EPIDEMIOLOGY OF CUTANEOUS LEISHMANIASIS AMONG REFUGEES IN NORTH LEBANON

**Dima El Safadi<sup>1</sup>**, Waleed Al-Salem<sup>2</sup>, Alvaro Acosta-Serrano<sup>3</sup>, Monzer Hamze<sup>1</sup>

<sup>1</sup>*Laboratory of Health and Environmental Microbiology (LMSE), Doctoral School for Sciences and Technology, Faculty of Public Health, Lebanese University, Tripoli, Lebanon*, <sup>2</sup>*Saudi Ministry of Health, Riyadh, Saudi Arabia*, <sup>3</sup>*Department of Parasitology and Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Cutaneous leishmaniasis (CL) is the most prevalent neglected tropical disease in the conflict zone in the Middle East, which currently affects more than hundred thousands of refugees annually. In Lebanon, whose population has increased ca. 25% because of mass migration from Syrian conflict zones has historically had a very low annual incidence of CL; however, recent outbreaks of CL are being reported by hospitals among Syrian refugees. Here our study is designed to investigate the current situation of CL among refugees in North Lebanon. The pilot study was carried out at Al-Bachaer medical center situated in North Lebanon from 1st December till 1st April 2017. 36 patients infected by CL have been diagnosed by dermatologist according to clinical symptoms. The majority of patients (78%) are younger than 18 years. Needle aspirations were taken for direct smear to seen under microscopy. In addition, Isohelix swab has been taken for each patient then all swabs have been processed for molecular diagnosis. *Leishmania* species were identified by PCR-RFLP analysis of the ribosomal Internal Transcribed Spacer 1 (ITS1). The refugees had displaced from endemic and non-endemic areas of North Syria. Most of refugees had migrated from Edleb (52.7%; 19/36), followed by Hama

(22.2%; 8/36), Rakkah (8.3%; 3/36), Aleppo (11.1%; 4/36), Homos (5.5%; 1/36) and Tartous (2.7%; 1/36). All these patients are living in the poorest region of North Lebanon where environmental factors could drive infectious disease particularly CL as it would be favorite ecology for sand flies to breed and transmit. As clinical manifestation, the lesions were mainly located in the facial area. Nodular and papular lesions, with or without ulceration, were the most predominant lesion types (44.4% 16/36). On molecular level, 15 samples (41.6%; 15/36) were positive for *Leishmania* sp. and patients were mainly coming from Edleb, Hama, Rakka and Aleppo. Possibility of local transmission is observed through female patient who settled in Lebanon for 4 years and then noticed the appearance of ulcerative lesion after more than 42 months of settling in Lebanon. CL infection was confirmed by microscopy and PCR.

## 1927

### FIELD TRIAL TO ASSESS LEISHMANIASIS VACCINE EFFECTIVENESS AS A POTENTIAL IMMUNOTHERAPY IN ASYMPTOMATIC DOGS

**Angela J. Toepp**<sup>1</sup>, Mandy Larson<sup>1</sup>, Tara Grinnage-Pulley<sup>1</sup>, Geneva Wilson<sup>1</sup>, Carolyne Bennett<sup>1</sup>, Adam Lima<sup>1</sup>, Michael Anderson<sup>1</sup>, Hailie Fowler<sup>1</sup>, Bryan Anderson<sup>1</sup>, Molly Parrish<sup>1</sup>, Kelsey Willardson<sup>1</sup>, Germine Alfonse<sup>1</sup>, Jane Jefferies<sup>2</sup>, George Seier<sup>3</sup>, Javan Esfandiari<sup>4</sup>, Caitlin Cotter<sup>5</sup>, Radhika Gharpure<sup>5</sup>, Christine Petersen<sup>1</sup>

<sup>1</sup>The University of Iowa, Iowa City, IA, United States, <sup>2</sup>Noah's Ark Animal Clinic, Kansas City, MO, United States, <sup>3</sup>Cobb Ford Pet Health Center, Prattville, AL, United States, <sup>4</sup>ChemBio Diagnostic Systems, Inc., Medford, NY, United States, <sup>5</sup>Johns Hopkins University, Baltimore, MD, United States

Visceral Leishmaniasis is targeted for elimination on the Indian subcontinent. One of the greatest challenges to date for achieving this goal is how to stem transmission from asymptomatic-infected people. Studies indicate that vaccination could prevent transmission from asymptomatic-infected individuals by boosting nascent immunity. Due to inherent risks of vaccinating already exposed populations, no study has evaluated the ability of a vaccine to decrease VL in asymptomatic-infected individuals. Dogs are the predominant reservoir host for *L. infantum*, with similar immunopathogenesis of disease to people. A vaccine trial in dogs would show proof of principle to decrease parasite load and progression to VL. We report efficacy results from a double blind, randomized, vaccine field trial to prevent VL progression. 557 *Leishmania*-negative or asymptomatic dogs were enrolled. *Leishmania* infection status was determined via qPCR, serology, and clinical data. Non-clinical dogs had less than two clinical signs of VL and were diagnostic positive. Dogs were vaccinated 3 times at 14 day intervals and followed every 3 months for 12 months. To provide a standard that will allow comparison to human clinical trials, a data safety-monitoring board evaluated the statistical plan and nine-month interim data. Analyses include comparison between treatment groups for overall clinical score to evaluate disease progression, seroconversion, *L. infantum* qPCR positivity, time to event analyses for clinical disease and death, and vertical transmission. Xenodiagnosis was performed on a subset of dogs to evaluate vector transmissibility. This trial, the first to vaccinate asymptomatic dogs, demonstrated that vaccinating asymptomatic infected animals was safe. Preliminary results indicate that vaccination decreased all-cause mortality. Results demonstrate ability of this novel vaccine/immunotherapy to alter seropositivity and parasitemia, which correlates directly with likelihood of transmission. This study underscores the need for vaccines that target asymptomatic leishmaniasis as part of the toolbox to promote eradication goals globally.

## 1928

### LOCAL DYNAMICS, SPATIAL INTERACTIONS AND DISPERSAL ROUTES OF VISCERAL LEISHMANIASIS IN 45 MUNICIPALITIES OF SÃO PAULO STATE, BRAZIL

**Elivelton Da Silva Fonseca**, Raul Borges Guimarães  
São Paulo State University, Presidente Prudente, Brazil

Visceral leishmaniasis (VLeish) has a worldwide distribution with Brazil harboring 90% of cases in Latin America. The appearance of endemic areas depends on the adaptation of sandflies to naïve ecological niches. The disease has been a major health concern in São Paulo state since 1998 and its continuing expansion is not so far clearly comprehended. We hypothesize that Tobler's first law of geography can be applied to justify the spatial interactions of many transmission sites of the vector and reported cases in São Paulo. The overall goal is to analyze dispersion routes by spatial modeling and spatial interactions of VLeish, and to demonstrate that VLeish risk can be measured effectively using spatial interactions theory, elucidating active cores and residual borders of transmission. 45 municipalities in western São Paulo were selected due the consistency of the databases, and because they belong to an important hub in the state. The databases consisted of: (i) *entomological data and notification* – Superintendence of Control of Endemics (SUCEN) and The Center of Epidemiological Surveillance (VL and CL); (ii) *environmental data – Moderate-Resolution Imaging Spectroradiometer (MODIS) – Land Surface Temperature (LST), Normalized Difference Vegetation Index (NDVI)*; (iii) *socioeconomic variables* – Human Development Index (HDI) and the Index of Social Vulnerability (ISV). Using multi-criteria analysis was possible to group the results in: I – Core of VLeish or presence of vector *Lu. longipalpis*, especially in the west, and presence of vegetation remnants. II – The active border of high transmission, presence of *Lu. longipalpis*, hot and humid climate, medium social vulnerability, presence of native remaining refuges of vegetation. III – VLeish residual border, absence of vectors *Lu. longipalpis*, wet weather, native vegetation. IV – Low incidence of VLeish, absence of *Lu. longipalpis*. The potential for transmission of leishmaniasis does not imply the occurrence in these areas, bearing in mind that evidence was assessed for a number of other factors that may enhance the transmission cycle.

## 1929

### USING DYNAMIC MODE DECOMPOSITION TO PRIORITIZE REGIONAL SCREENING FOR HAT IN THE DEMOCRATIC REPUBLIC OF CONGO

**Cody A. Palmer**<sup>1</sup>, Joshua L. Proctor<sup>1</sup>, Matthew Steele<sup>2</sup>, Crispin Lumbala<sup>3</sup>, Caitlin A. Bever<sup>1</sup>

<sup>1</sup>Institute For Disease Modeling, Bellevue, WA, United States, <sup>2</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States, <sup>3</sup>Programme National de Lutte contre la Trypanosomiase Humaine Africain (PNLTHA), Kinshasa, Democratic Republic of the Congo

The WHO has set a goal to eliminate Human African Trypanosomiasis (HAT) as a public health problem by 2020. With limited means available, a major challenge is to prioritize the distribution of resources to the areas that are most at risk of continued transmission. Overall, reported HAT cases in the Democratic Republic of Congo (DRC) have steadily declined in recent years. Dynamic Mode Decomposition (DMD) is an equation free method with the ability to find coherent spatial-temporal patterns in data arising from nonlinear systems. We applied DMD to ten years of active and passive screening data from DRC as a fast, data-driven method for identifying areas which have deviated from the national trend. Not only do the results select specific *foci* of interest for increased future screening or surveillance, but they may also highlight features of potentially problematic regions where little screening has been performed in the past. In particular, DMD pinpointed *foci* along riverine transportation routes, which supports further analysis of the role of migration in maintaining transmission. We

discuss some of the limitations to this method, what efforts can be made to improve its use in the future, and how it might be complemented by epidemiological modeling.

## 1930

### USE OF SALIVA FOR LARGE SCALE *TRYPANOSOMA CRUZI* SCREENING

Lea C. Oliveira<sup>1</sup>, Carlos H. Moreira<sup>1</sup>, Claudia D. Lorenzo<sup>2</sup>, Ana L. Bierrenbach<sup>1</sup>, Erika R. Manuli<sup>1</sup>, Natália B. Pereira<sup>1</sup>, Flavia C. Salles<sup>1</sup>, Marcela Souza-Basquera<sup>1</sup>, **Ester C. Sabino<sup>1</sup>**

<sup>1</sup>Laboratory of Parasitology (LIM46), Institute of Tropical Medicine, University of São Paulo, São Paulo, Brazil, <sup>2</sup>Federal University of São João Del Rei, Divinópolis, Brazil

Vector control for Chagas disease was aggressively addressed during 1990s, and in 2006, Brazil was certified as free of vector transmission caused by the main vector *Triatoma infestans*. Nevertheless, residual infestation and recolonization can occur, threatening the long-term success of the vector control. Large scale serological surveys using blood collection are complex to perform and have been used only focally to monitor areas where sporadic acute cases were detected. The development of an antibody detection method based on saliva would facilitate large scale and systematic screening of children in endemic regions. The aim of this study was to evaluate if plasma could be replaced by saliva in commercial available T cruzi EIA. We have collected saliva from 100 T.cruzi infected patients and 50 healthy individuals using Sallivete®, Sarsted. Five assays were evaluated (ARCHITECT Chagas – Abbott; Chagas REC – INVITRO; GOLD ELISA Chagas – REM; ELISA recombinant v.4.0 – Wiener and ELISA Chagas III – Grupo Bios S.A – Diasorin). Test parameters such as sample and conjugate dilutions, incubation time and conjugate manufacturer were modified. A better discrimination between Chagas patients and controls were achieved using the ELISA recombinant v.4.0 – Wiener kit under the following conditions: no sample dilution, no conjugate dilution, sample and conjugate incubation period of 60 minutes and a cut-off of two standard deviation above the mean of the controls. Under these conditions the assay sensitivity and specificity were 97% and 100% respectively, showing that saliva could replace plasma for large screening surveys in endemic areas.

### POLICY RECOMMENDATIONS FOR REACHING ELIMINATION OF VISCERAL LEISHMANIASIS ON THE INDIAN SUBCONTINENT: A COMPARISON OF MULTIPLE TRANSMISSION MODELS

**Epke A. Le Rutte<sup>1</sup>**, Lloyd A. Chapman<sup>2</sup>, Luc E. Coffeng<sup>1</sup>, Graham F. Medley<sup>3</sup>, José A. Ruiz Postigo<sup>4</sup>, Deirdre T. Hollingsworth<sup>2</sup>, Sake J. de Vlas<sup>1</sup>

<sup>1</sup>Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, <sup>2</sup>Warwick University, Warwick, United Kingdom, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>World Health Organisation, Geneva, Switzerland

Introduction: On the Indian subcontinent (ISC), visceral leishmaniasis (VL) is targeted for elimination as a public health problem by 2020. The elimination target is defined as an annual VL incidence of <1 per 10,000 capita at (sub-)district level. Interventions focus on vector control, surveillance and on diagnosing and treating VL cases. Aim: To explore whether and within which timeframe current interventions may lead to reaching the VL elimination target. Methods: We present multiple mathematical models of VL transmission on the ISC with structural differences regarding the main reservoir of infection, including those with a prominent role of asymptomatic infection. We compare their predictions for achieving the WHO VL elimination targets with ongoing and alternative treatment and vector control strategies. Results: All the transmission models suggest that the WHO elimination target will be met in Bihar, India, before or close to 2020 in sub-districts with a pre-control

incidence of 10 VL cases per 10,000 people per year or less, when current interventions (60% coverage of indoor residual spraying (IRS) of insecticide and an average delay of about 40 days from onset of symptoms to treatment) are maintained. Conclusion: Increasing the IRS coverage and to a lesser extent reducing the time from onset of symptoms to treatment will both decrease the time to elimination. However, in all cases the models suggest there is likely to be ongoing transmission after 2020 and so control measures will have to be kept in place for several years to achieve the longer-term aim of breaking transmission.

## 1932

### A LONGITUDINAL ASSESSMENT OF GAMETOCYTE PRODUCTION AND INFECTIVITY IN CHRONIC AND ACUTE *PLASMODIUM FALCIPARUM* INFECTIONS

**Aissata Barry<sup>1</sup>**, Bronner Goncalves<sup>2</sup>, Moussa W. Guelbeogo<sup>1</sup>, Alphonse Ouedraogo<sup>1</sup>, Issiaka Soulama<sup>1</sup>, Issa Nebie<sup>1</sup>, Amidou Diarra<sup>1</sup>, Kjerstin Lanke<sup>3</sup>, Mireille Ouedraogo<sup>1</sup>, Desire Kargougou<sup>1</sup>, Zongo Zoumanaba<sup>1</sup>, Chris Drakeley<sup>2</sup>, Alfred B. Tiono<sup>1</sup>, Teun Bousema<sup>3</sup>

<sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Radboudumc, Nijmegen, Netherlands

Gametocytes are essential for onward transmission to mosquitoes. In *Plasmodium falciparum*, gametocytes appear 10-12 days after asexual parasites and often circulate at very low densities. It is currently unclear whether individuals are infectious to mosquitoes before symptoms arise or before malaria infections are detectable by microscopy. We assessed gametocyte production and infectivity in two cohorts in Burkina Faso. In the first cohort, children (5-10 years) were cleared of pre-existing infections and were subsequently weekly monitored by molecular methods for incident infections. Upon first detection of infection, sampling was performed daily and monitoring continued for 42 days. Mosquito feeding assays were performed at day 0 (day of detection of infection), d14 and d35. The second cohort was identical in design but malaria infections were not cleared. Intensive follow-up commenced once an asymptomatic infection was detected for 2 consecutive months (a chronic infection). 51 acute and 39 chronic *P. falciparum* infections were monitored for asexual parasite and gametocyte dynamics and infectivity to mosquitoes. Only 13% (7/51) of children with acute infections remained fever free after the first detection of malaria infection by nPCR, whilst 72% (28/39) of all children with chronic malaria infections remained asymptomatic during 42 days of intensive monitoring. Although mature gametocytes were detected at low densities, none of children with acute malaria infections infected mosquitoes compared to 69% (27/39) of children with chronic infections. Of the latter, some were infectious at 2 or 3 occasions during the 35-days of intensive follow-up and infected up to 98% of mosquitoes. Taken together, our results suggest that intensive monitoring allows the detection of symptomatic malaria before infected individuals become infectious to mosquitoes. Asymptomatic malaria-infected children, on the other hand, are often infectious for several weeks; their identification will be key to the success of malaria elimination strategies.

## 1933

### MALARIA BURDEN THROUGH ROUTINE REPORTING: RELATIONSHIPS BETWEEN INCIDENCE ESTIMATES

**Simon P. Kigozi<sup>1</sup>**, Ruth N. Kigozi<sup>2</sup>, Arthur Mpimbaza<sup>3</sup>, Asadu Sserwanga<sup>3</sup>, Joaniter Nankabirwa<sup>4</sup>, Sarah Staedke<sup>1</sup>, Moses Kamya<sup>4</sup>, Grant Gorsey<sup>5</sup>, Rachel Pullan<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Malaria Consortium, Kampala, Uganda, <sup>3</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>4</sup>College of Health Sciences Makerere

University, Kampala, Uganda, <sup>5</sup>University of California San Francisco, San Francisco, CA, United States

Malaria burden remains high in Uganda, ranked 4th by number of cases and 11th by number of deaths worldwide and accounting for 30-50% of outpatient visits. The burden is estimated using routine surveillance for planning, implementation, and evaluation of public health practice. Standard routine measures of burden include total suspected or cases, and test positivity rate (TPR) as incidence proxies. Additional estimates of incidence commonly used are evaluated in this study. We aim to explore relationships between incidence estimates from routine data to improve interpretation of burden reported through routine reporting. Three high-level facilities located at varied malaria endemicities in Uganda (Nagongera, Walukuba & Kihhi) were included. Study participants were children under 11 years suspected to have malaria, and seen between Oct-2011 and Jun-2016. Estimates of incidence (TPR, malaria positive fraction - MPF, mean incidence (reported case) rate - MIR, and standardized incidence ratio - SIR) were derived and pairwise relationships between them explored. Nagongera, Walukuba & Kihhi HCIV saw 46,049 (79%), 31,861 (52%) and 32,675 (78%) study participants of which 33.3%, 34.0% and 60.7% respectively, had home village recorded as located within the facility's sub-county. Strong nonlinear relationships were observed between MPF and MIR over time (monthly). And, positive linear relationships observed between MPF and SIR over time (Coef=0.140,  $p < 0.001$ ; Coef=0.215,  $p = 0.002$ ; Coef=0.198,  $p < 0.001$ ). Similarly, weaker linear relationships were observed across space (Coef=-0.012,  $p = 0.785$ ; Coef=-0.013,  $p = 0.589$ ; Coef=-0.026,  $p = 0.133$ ). Burden over time is not implied across space. Improved interpretation of burden requires an account for both time and space/location. Full results will be presented at the conference.

## 1934

### LONGITUDINAL CLINICAL AND MOLECULAR ANALYSIS OF ASYMPTOMATIC MALARIA INFECTION IN MALAWI

Andrea Geri Buchwald<sup>1</sup>, Miriam Ismail<sup>1</sup>, Courtney Aceto<sup>2</sup>, Alaina Halbach<sup>1</sup>, Alick Sixpence<sup>3</sup>, Mabvuto Chimunya<sup>3</sup>, Millius Damson<sup>3</sup>, John D. Sorkin<sup>4</sup>, Karl Seydel<sup>5</sup>, Don Mathanga<sup>3</sup>, Terrie E. Taylor<sup>6</sup>, Miriam K. Laufer<sup>1</sup>

<sup>1</sup>Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Stevenson University, Baltimore, MD, United States, <sup>3</sup>Malaria Alert Center, University of Malawi College of Medicine, Blantyre, Malawi, <sup>4</sup>University of Maryland Baltimore and Baltimore Veterans Affairs Medical Center GRECC, Baltimore, MD, United States, <sup>5</sup>Michigan State University, East Lansing, MI, United States, <sup>6</sup>Michigan State University College of Osteopathic Medicine, East Lansing, MI, United States

In Malawi, asymptomatic *Plasmodium falciparum* infections are common and may drive transmission. The frequency, persistence, and clinical outcome of asymptomatic infections is unknown. Although school aged children (SAC) carry the majority of prevalent infections, this may be due to increased exposure to infection or a prolonged duration of asymptomatic infections. Whether and how many asymptomatic infections progress to clinical disease and eventually prompt treatment is unknown. We characterize the age-specific dynamics of asymptomatic infections in a high-transmission setting and examine the association between asymptomatic infection and clinical disease. In total, 120 participants, aged 1-50 years, with uncomplicated malaria (treated with artemether-lumefantrine) were enrolled and followed monthly for up to two years. Samples from all visits were tested for parasites using both microscopy and qPCR. Genotyping with *m*sp1 and *m*sp2 was used to characterize the complexity of each infection. Molecular force of infection was defined as the number of unique infecting genotypes/person/year. Analysis has been completed for 1702 person months of follow up time. Asymptomatic infections were detected in 23% of visits. Asymptomatic infection, the longest of which persisted for 16 months, was associated with increased time to next clinical malaria (HR 0.45,  $p < 0.001$ ) in all ages. The mean duration of persistence of individual infections will be calculated by age.

Overall, 785 incident infections were detected; 35% at a visit when no symptoms were reported. We found SAC are a distinct risk group, and have a significantly higher molecular force of infection (IRR 2.4,  $p < 0.001$ ) than other age groups. In our setting, clinical malaria was more likely to be due to newly acquired infection (OR 4.6, 95%CI 2.5-8.5) than to a persistent infection. Asymptomatic infections constitute a significant reservoir of *P. falciparum* in Malawi and may be protective against clinical malaria.

## 1935

### TRACKING MALARIA: PREGNANT WOMEN AS A SENTINEL POPULATION FOR MALARIA SURVEILLANCE

Nina C. Brunner<sup>1</sup>, Frank Chacky<sup>2</sup>, Renata Mandike<sup>2</sup>, Ally Mohamed<sup>2</sup>, Christian Lengeler<sup>1</sup>, Fabrizio Molteni<sup>1</sup>, Manuel W. Hetzel<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland, <sup>2</sup>National Malaria Control Programme, Ministry of Health, Community Development, Gender, Elderly and Children, Dar Es Salaam, United Republic of Tanzania

With increasing spatial heterogeneity of malaria transmission and an age shift of the disease burden towards older children and adults, pregnant women attending antenatal care (ANC) have been proposed as a pragmatic sentinel population for malaria surveillance. However, the representativeness of routine ANC prevalence data and how it is related to the prevalence in other population subgroups has yet to be investigated. For this study, we obtained monthly ANC malaria prevalence data from all Tanzanian health facilities reporting to the national data warehouse DHIS2 between January 2014 and May 2016. Among 4,354,911 pregnant women attending ANC, 49.6% were tested for malaria. The average malaria infection prevalence in pregnant women was 7.6% (95% CI 7.2-7.9) with little monthly variation. In 2015, malaria prevalence was generally higher in school children and in children aged 6-59 months than in pregnant women, with substantial variability between regions and districts. A high correlation was found between regionally aggregated ANC prevalence and prevalence in children aged 6-59 months (Spearman rho:  $p = 0.90$ ;  $p < 0.0001$ ) as well as school children (regional:  $p = 0.84$ ;  $p < 0.0001$ ; district:  $p = 0.80$ ;  $p < 0.0001$ ). On the other hand, correlation was low with district aggregated prevalence predicted by the Malaria Atlas Project ( $p = 0.56$ ;  $p < 0.0001$ ). In all comparisons, the correlation was substantially better in districts or regions with one rainy season compared to areas with biannual rain. The results of this study provide strong support for using pregnant women attending ANC as a sensible and pragmatic sentinel population to assess malaria trends in Tanzania. However, ANC malaria prevalence cannot be used to directly predict the prevalence in other population subgroups. Further work is required to identify covariates that influence the relationship between ANC and other population subgroup prevalences particularly in areas of more intense seasonality.

## 1936

### COMBINING LONG-LASTING INSECTICIDAL NETS AND INDOOR RESIDUAL SPRAYING FOR MALARIA PREVENTION IN ETHIOPIA: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Eskindir Loha<sup>1</sup>, Wakgari Deressa<sup>2</sup>, Taye Gari<sup>1</sup>, Meshesha Balkew<sup>2</sup>, Oljira Kenea<sup>2</sup>, Tarekegn Solomon<sup>1</sup>, Alemayehu Hailu<sup>2</sup>, Bjarne Robberstad<sup>3</sup>, Meselech Assegid<sup>2</sup>, Hans J. Overgaard<sup>4</sup>, Bernt Lindtjorn<sup>3</sup>

<sup>1</sup>Hawassa University, Hawassa, Ethiopia, <sup>2</sup>Addis Ababa University, Addis Ababa, Ethiopia, <sup>3</sup>University of Bergen, Bergen, Norway, <sup>4</sup>Norwegian University of Life Sciences, Aas, Norway

Long lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) are effective tools to prevent malaria, but the effectiveness of combining the two are not yet fully understood. This study compared the separate versus combined effect of LLINs and IRS on malaria incidence and anemia. This cluster randomized controlled trial was done in the Adami Tullu

district in south-central Ethiopia for 119 weeks, from September 2014 to January 2017. Prior to the trial, we did a pilot study to estimate the sample size, and registered 8 malaria episodes per 10,000 person-weeks of observation (PWO). 6072 households (HHs) were randomly assigned to four intervention arms: LLINs + IRS, LLINs, IRS, and no intervention implemented by the project (control). The primary outcome was malaria incidence. Analysis was based on an intention-to-treat principle. Each arm had 44 clusters with an average of 35 HHs per cluster; the total population was 34,548. PermaNet 2.0 LLINs were distributed in September 2014, and IRS (with propoxur) was carried out yearly. Active and passive case detection were done weekly. Malaria was diagnosed using a rapid diagnostic test (CareStart™). Anemia was assessed through yearly surveys on children. The yearly rainfall was 60% of expected in 2015 (El Niño effect), entomological studies were simultaneously conducted. Results The overall malaria incidence was 2.91 per 10,000 PWO (37% of pre-intervention incidence), and similar in the four arms with 2.99 (LLINs + IRS), 2.92 (LLINs), 3.01 (IRS) and 2.72 (control). Generalized estimation equation showed that LLINs did not provide individual protection. Entomological findings showed greater outdoor mosquito human-biting activities than indoor. The yearly mean hemoglobin concentrations were similar among the trial arms. Conclusions The malaria incidence was low and similar in the intervention arms. The severe drought might have contributed in too few malaria cases to evaluate the interventions. However, residual transmission could be an important cause of malaria transmission in the area. Our results could be relevant for situations with low malaria incidence.

## 1937

### DEVELOPMENT OF A NOVEL GENOTYPING AND MATHEMATICAL ALGORITHM FOR ESTIMATION OF MULTIPLICITY OF INFECTION OF MALARIA PARASITES

Rebecca M. Mitchell<sup>1</sup>, Zhiyong Zhou<sup>2</sup>, Sheila Sergent<sup>2</sup>, Mili Sheth<sup>2</sup>, Vishal Nayak<sup>2</sup>, Mike Frace<sup>2</sup>, Bin Hu<sup>2</sup>, Scott Sammons<sup>2</sup>, Simon Kariuki<sup>3</sup>, Meghna Desai<sup>2</sup>, Ymir Vigfusson<sup>1</sup>, Ya Ping Shi<sup>2</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>KEMRI, Kisumu, Kenya

Multiple strain infections with malaria parasites in humans are common in endemic areas, and quantifying the multiplicity of infection can be used as a surrogate marker for transmission intensity. Here we present a novel multiplex polymerase chain reaction and next-generation sequencing approach for differentiating *Plasmodium falciparum* malaria strains within a host. This novel method allows recovery of information for all 24 SNP sites (identified by Daniels et al 2008, Malaria Journal) using 3 multiplex PCRs. The disambiguation algorithm relies on consistent amplicon ratios across SNP sites to search through all possible amplicon ratios and barcodes to identify up to 4 strains and their frequencies within a sample. Both the laboratory and analytic pipelines were developed using a collection of spiked laboratory isolates consisting of whole blood and cultured ring-stage parasites with known SNP barcodes and frequencies. We assessed multi-strain infections in available smear-positive samples from four population surveys in western Kenya from 1996 (n=64) and after scale up of malaria interventions in 2001 (n=64), 2007 (n=47) and 2012 (n=67). Over this time period, prevalence of infection in young children (<5 years old) dropped from approximately 80% at baseline to 26% in 2008 and plateaued at 40% in 2009 through 2012. Over time, the proportion of lower-diversity infections with only one or two strains in a sample among smear-positive samples increased (p<0.001, Wald test for regression coefficient) (Over time: 1 strain: 7.8%, 9.3%, 27.7%, 26.9%; ≤2 strains: 23.4%, 37.5%, 36.2%, 50.7%; ≤3 strains: 51.6%, 67.2%, 59.6%, 76.1%). Proportion of samples with four or more strains decreased over time (48.4%, 32.8%, 40.4%, 23.9%) (p=0.013 via Wald test). These trends indicate that even during the plateau in prevalence from 2009 and 2012, the total infection complexity was decreasing as reflected by within-host strain diversity. This approach provides a tool to

measure dynamics of transmission intensity and to evaluate the impact of targeting interventions over time, information that is critical in planning malaria control interventions.

A renewed emphasis on malaria control in Papua New Guinea (PNG) has resulted in a significant overall reduction in the prevalence and incidence of malaria. However these reductions have not been uniform in all areas and recent data suggests a trend toward increased incidence of malaria in some locations. A suite of health facility surveillance and community-based surveys, undertaken throughout the past decade, combine sensitive serological and molecular diagnosis of infections with operational, demographic, human and vector behavioural and spatial data. Across all sites and surveys, the reductions had been very pronounced for *P. falciparum* (Pf), with qPCR prevalence declining from >50% to <10% in community surveys. In children 1-5 years, the molecular force of blood-stage infection (molFOB) declined from 5.9/child/year (2006) to 1.6 /child/year (2013) and the incidence of clinical episodes from 2.0 (2006) to 0.1 (2013) episodes/child/year. For *P. vivax* (Pv), qPCR prevalence declined from 42% (2006) to 13% (2010) before returning to 20% (2014) in communities on the north coast of Madang Province. In 1-5 year old East Sepik children, PCR prevalence ranged from 60% and 65% in 2006 to 2008 respectively, to 18% in 2013, whilst molFOB dropped from 14.0/child/year (2006) to 2.4/child/year (2013) and the incidence of clinical episodes declined from 2.0 to 1.1 to 0.1/child/year. Parasite densities decreased 5-fold, with 72% of Pf and 87% of Pv infections submicroscopic in 2013/14. Very recent surveys on north coast Madang indicate that whilst Pv prevalence remained unchanged at 20%, Pf has resurged to a prevalence of 30%. The relationship between low-density asymptomatic infections, parasite genotypes and population level immunity will be presented, as well as a detailed analysis of the relationship between host and vector behavior and infection status. Understanding the highly dynamic nature of malaria transmission in PNG and the driving factors is critical to inform appropriate surveillance and intervention strategies to sustain the gains made with a decade of malaria control in PNG and advance towards elimination.

### GENETIC RELATEDNESS OF *VIBRIO CHOLERAE* ISOLATES WITHIN AND BETWEEN HOUSEHOLDS DURING OUTBREAKS IN DHAKA, BANGLADESH

Household contacts of cholera patients have a 100 times higher risk of developing a cholera infection than the general population. To compare the genetic relatedness of *Vibrio cholerae* isolates from infected household contacts and water sources within patient households, we performed whole-genome-sequencing (WGS) and multilocus-variable-number tandem-repeat analysis (MLVA) on isolates across three cholera outbreaks in Dhaka, Bangladesh. The WGS analyses revealed that 80% of households had water isolates that were more closely related to clinical isolates from the same household than to any other isolates. While in another 20% of households an isolate from a person was more closely related to clinical isolates from another household than to water isolates from their own household. The mean pairwise differences in single nucleotide variant (SNV) counts for isolates from the same household were significantly lower than those for different households (2.4 vs. 7.7  $p < 0.0001$ ), and isolates from the same outbreak had significantly fewer mean pairwise differences compared to isolates from different outbreaks (mean: 6.2 vs. 8.0,  $p < 0.0001$ ). Based on MLVA in outbreak 1 we observed that the majority of households had clinical isolates with MLVA genotypes unrelated to water source isolates from the same household. While in outbreak 3 the majority of households had clinical and water source isolates with the same MLVA genotypes. The beginning of outbreak 2 resembled outbreak 1 and the latter part resemble outbreak 3. We validated our use of MLVA by comparing it to WGS. Consistent with WGS results, the number of pairwise differences in the five MLVA *loci* for isolates within the same household was significantly lower than isolates from different households (mean 1.6 vs. 3.0, ( $p < 0.0001$ )), and isolates from the same outbreak had significantly fewer *loci* differences compared to isolates from different outbreaks (mean 2.5 vs. 3.2,  $p < 0.0001$ ). These results suggest that transmission patterns for cholera are a combination of person to person and water to person cholera transmission with the proportions of the two modes varying within and between outbreaks.

Natural *Vibrio cholerae* infection provides durable protective immunity, while vaccines composed of killed whole cell *V. cholerae* may result in more limited protection. To better understand the difference in the innate immune response to live toxigenic *V. cholerae* O1 versus killed organisms, we used human macrophage cell culture to identify pathways that discriminate between responses to stimulation. To screen for differences in gene expression, we used RNAseq to examine the complete transcriptome, and found that expression of IL-23 was 28-fold higher in cells exposed to

live *V. cholerae* compared to killed organisms. Next, we found that IL-23 release from human macrophages was also higher in cells exposed to live versus killed *V. cholerae*, measured by enzyme-linked immunosorbent assay (mean difference 4.3 ng/ml, CI 3.5-6.2,  $p < 0.001$ ). In addition to IL-23, IL-1 $\beta$  and IL-6 expression were also increased, comprising a group of cytokines known to act together to promote Th17 CD4+ responses. The IL-23 response was dependent on stimulation by live *V. cholerae* with enzymatically active toxin, because the stimulation effect was markedly reduced in both an isogenic cholera toxin mutant and in cells stimulated with killed organism and exogenous holotoxin, but could be restored with exogenous holotoxin plus the cholera toxin mutant strain of *V. cholerae*. Prior studies demonstrate that Th17 immune responses are prominent in natural *V. cholerae* infection and lacking in persons vaccinated with whole-cell killed *V. cholerae*. B cell memory responses are promoted by Th17 CD4+ cells, and through this mechanism, IL-23 may contribute to long-term immunity to *V. cholerae*.

#### DEVELOPMENT OF A NEW DIPSTICK FOR RAPID DETECTION OF *VIBRIO CHOLERAE* O1 IN ACUTE WATERY DIARRHEAL STOOLS

Md. Abu Sayeed<sup>1</sup>, Jakia Amin<sup>2</sup>, Kamrul Islam<sup>1</sup>, Motaher Hossain<sup>1</sup>, Nishat Sultana<sup>2</sup>, Noor Jahan Akter<sup>2</sup>, Farhana Khanam<sup>1</sup>, Jason R. Andrews<sup>3</sup>, Edward T. Ryan<sup>4</sup>, Firdausi Qadri<sup>1</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Incepta Pharmaceuticals Ltd, Savar, Dhaka, Bangladesh, <sup>3</sup>Stanford University School of Medicine, Stanford, California, CA, United States, <sup>4</sup>Massachusetts General Hospital, Boston, MA, United States

Cholera is a severely dehydrating diarrheal disease that results in approximately 3-5 million cases and over 100,000 deaths per year globally. Cholera is caused mainly by *Vibrio cholerae* O1, and less commonly by *V. cholerae* O139. Recognizing cholera cases early, especially in an initial phase of an epidemic, and in areas where cholera has not previously circulated is a high public health priority. Laboratory capacity in such settings is usually limited. To address this, we have recently developed an immunochromatographic lateral flow device (dipstick), Cholkit, for rapid diagnosis of cholera cases. The dipstick contains a monoclonal antibody to the O-specific polysaccharide (OSP) component of *V. cholerae* O1 lipopolysaccharide that recognizes both Inaba and Ogawa serotypes. We tested the Cholkit dipstick using fresh stool specimens of 76 adults and children presenting with acute watery diarrhea to the International Centre for Diarrhoeal Disease Research in Dhaka, Bangladesh (icddr,b). We compared Cholkit's performance with those of microbial culture, PCR (rfb and ctxA genes) and Crystal VC, the latter a commercially available dipstick designed to detect both *V. cholerae* O1 and O139. We found that all stool specimens with a positive culture for *V. cholerae* O1 (n=19) were positive by Cholkit. We then used Bayesian latent class modeling to estimate sensitivity and specificity of each diagnostic assay. The sensitivity of Cholkit, microbiological culture, PCR, and Crystal VC was 98% (95% CI: 88-100), 71% (95% CI: 59-81), 74% (95% CI: 59-86) and 98% (95% CI: 88-100), respectively. The specificity for *V. cholerae* O1 was 97% (95% CI: 89-100), 100%, 97% (95% CI: 93-99) and 98% (95% CI: 92-100), respectively. Of note, two Crystal VC assays were positive for *V. cholerae* O139, although neither stool sample was confirmed by culture or PCR, and *V. cholerae* O139 is not recognized to be circulating in Dhaka at present. Conclusion: the Cholkit dipstick is simple to use, requires no dedicated laboratory capacity, and has a sensitivity and specificity of 98% and 97%, respectively. Cholkit warrants further development and evaluation.

Cholera has become endemic in Haiti since its introduction in 2010. A killed whole cell bivalent oral cholera vaccine (BivWC) has now been used in multiple countries; however, a complete understanding of the immune response to this vaccine is still lacking. To determine whether this vaccine generates detectable circulating memory B cell (MBC) responses, we followed a cohort of 73 Haitian adults who received two doses of BivWC (Shanchol) for 1 year following vaccination. We assessed immune responses at day 0 (baseline), day 7 (7 days after the first vaccination), day 21 (7 days after the second vaccination), and again on days 44, 90, 180, and 360 following the initial vaccination. We observed a significant increase in circulating IgA MBC responses targeting the O-specific polysaccharide (OSP; Ogawa and Inaba) of *Vibrio cholerae* O1, starting 21 days following vaccination. We also observed an increase in the level of circulating IgG memory B cells targeting V. cholerae O1 Ogawa OSP at day 44 following vaccination; the Ogawa serotype has been the predominant circulating strain of V. cholerae in Haiti since the introduction of cholera there in 2010. These results provide evidence that the bivalent oral cholera vaccine is capable of inducing and boosting systemic memory B cell responses targeting V. cholerae.

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Massachusetts General Hospital, Boston, MA, United States, <sup>3</sup>National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, United States, <sup>4</sup>Merck & Co., Inc., Kenilworth, NJ, United States, <sup>5</sup>Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>6</sup>PaxVax, Inc., Redwood City, CA, United States, <sup>7</sup>University of Vermont College of Medicine, Burlington, VT, United States, <sup>8</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States

Cholera is a dehydrating diarrhea caused by *Vibrio cholerae* O1/O139. The mediator(s) of protective immunity against cholera are not well defined. A growing body of evidence suggests that protection may be afforded by antibodies targeting V. cholerae O-specific polysaccharide (OSP). A single-dose live attenuated oral cholera vaccine was recently FDA-approved in the U.S (CVD 103-HgR, Vaxchora; PaxVax). Oral vaccination with CVD 103-HgR was associated with protection against experimental wild type

challenge against cholera in North American volunteers. Protection was associated with vibriocidal seroconversion observed ten days after vaccination. The vibriocidal response is largely comprised of IgM responses against V. cholerae LPS. Protection against cholera is serogroup specific, and serogroup-specificity is defined by the OSP component of LPS. We were therefore interested in assessing whether OSP antibody responses occurred after vaccination with CVD 103-HgR, and whether such responses correlate with protection against disease. In brief, adult North American volunteers (n=46) were immunized with 5×10<sup>8</sup> colony-forming units (CFU) of CVD 103-HgR and then challenged with approximately 1×10<sup>5</sup> CFU of wild-type V. cholerae O1 El Tor Inaba strain N16961, either 10 or 90 days post vaccination. Vaccination was associated with induction of significant increases in IgM and IgA anti-OSP antibody levels by day 10 after vaccination that fell back to baseline by day 90 in the absence of challenge. There was significant boosting of anti-OSP IgM and IgA responses and development of IgG anti-OSP responses following day 90 challenge, but no boosting following day 10 challenge. IgM and IgA anti-OSP responses on day 10 following vaccination were associated with protection against moderate or severe diarrhea following wild type challenge (Spearman r=-0.44, p=0.002; r=-0.362, p=0.01). Conclusion: Oral vaccination with live attenuated cholera vaccine CVD 103-HgR (Vaxchora) induces antibodies that target V. cholerae OSP, and these anti-OSP responses correlate with protection against experimental challenge with V. cholerae O1.

## 1944

**EPIDEMIC CHOLERA AND MICRONUTRIENT DEFICIENCY — GRANDE SALINE, HAITI, 2011**

**Sae-Rom Chae**<sup>1</sup>, Jacques Boncy<sup>2</sup>, Gerard A. Joseph<sup>2</sup>, Parminder S. Suchdev<sup>1</sup>, Sunkyung Kim<sup>1</sup>, Eric D. Mintz<sup>1</sup>, Brendan R. Jackson<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Laboratoire National de Santé Publique, Port-au-Prince, Haiti

Epidemic cholera typically affects vulnerable communities with unsafe water and poor nutrition. Most *Vibrio cholerae* infections are asymptomatic, and risk of symptomatic cholera is thought to increase with micronutrient deficiencies. Cholera was introduced to Haiti for the first time in October 2010. In March–April 2011, we conducted a cross-sectional seroepidemiologic survey in Grande Saline, Haiti, to assess risk factors for symptomatic infection, including micronutrient deficiencies. We tested sera of participants ≥2 years of age for ferritin, a marker of iron deficiency; retinol-binding protein (RBP), a marker of vitamin A deficiency; and C-reactive protein (CRP) and alpha-1-acid glycoprotein (AGP), markers of inflammation. We adjusted ferritin and RBP for CRP and AGP using a multiple linear regression model from a previous study to account for potential confounding effects of inflammation. We used multivariable logistic regressions to examine associations between self-reported cholera diagnosis or V. cholerae seropositivity and micronutrient deficiencies, adjusting for age, sex, and education. Of 772 participants tested (age range 2–90 years; 3% <5 years), 150 (21%) reported a cholera diagnosis during October 2010–April 2011; 466 (60%) were seropositive. Low ferritin (<12 µg/L for age <5 years, <15 µg/L for age ≥5 years) was found in 19%; 3% had low RBP (<0.7 µmol/L). Elevated CRP or AGP (>5 mg/L or >1 g/L, respectively) was found in 20%. No associations between self-reported cholera diagnosis and low micronutrient measures were observed. Participants with low ferritin had higher odds of seropositivity than those with normal ferritin levels (odds ratio 2.1; P <0.001). The association between seropositivity and iron deficiency suggests a higher risk of cholera infection among people with malnutrition, though symptomatic infection was not associated; however, causality cannot be inferred. Improved access to nutritious foods and safe water are critical in impoverished communities, and further studies to better characterize the relationship between symptomatic cholera and micronutrient deficiencies are warranted.

## 1945

**WHO IS AT RISK OF CHOLERA IN AFRICA? QUANTIFYING POTENTIAL VACCINE DEMAND AND IMPACT POLICY-RELEVANT SPATIAL LEVELS**Sean M. Moore<sup>1</sup>, Andrew S. Azman<sup>2</sup>, Heather S. McKay<sup>2</sup>, Justin Lessler<sup>2</sup><sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Africa is subject to high-mortality cholera epidemics and areas of persistent incidence. Oral cholera vaccine (OCV) is becoming an important tool for cholera control as increased production has led to a growing interest in proactively vaccinating populations at high risk for infection. However, despite increases in OCV availability, the number of OCV doses available (~10 million in 2017) is too low to conduct large, generalized campaigns in at-risk countries. To prioritize the use of current supplies and quantify future production needs it is important to identify populations living at high risk of cholera infection who would derive the most benefit from prophylactic OCV use. Using cholera incidence reports from 2010-2016 over multiple spatial scales, we map the incidence of cholera in 20x20 km grid scales throughout Africa. To provide risk estimates at a policy-relevant scale, we identify districts (2nd ISO administrative level) with a significant at-risk subpopulation that comprises either  $\geq 10\%$  of a district's population or is  $\geq 100,000$  people. Based on these criteria, 69.2 (95% CrI: 49.8-89.2) million people live in high-risk districts in Africa based on an annual incidence threshold of  $\geq 1$  per 1,000, and an additional 141.5 (95% CrI: 106.7-184.0) million people live in moderate-risk districts with incidence between 1 per 1,000 and 1 per 10,000. Assuming only direct vaccine protection at levels consistent with a recent meta-analysis, vaccinating everyone living in moderate- and high-risk areas could directly prevent more than 582,000 (95% CrI: 339,000-1,044,000) cases over a five-year period, but would require 421.5 (95% CrI: 313.0-546.4) million doses, more than 50x the global annual production of OCVs in 2016. However, if districts are sequentially prioritized by incidence rate, 50% of these cases could be prevented with only 12% of the OCV doses (50.7 million doses, 95% CrI: 49.0-54.2 million), and 95% could be prevented with only 51% of the required doses (214.5 million doses, 95% CrI: 205.1-232.6 million).

## 1946

**MALARIA TRANSMISSION AT THREE SENTINEL SITES IN WESTERN KENYA FROM 2002 TO 2016: THE RESURGENCE AND CAUSALITY ANALYSIS**Guofa Zhou<sup>1</sup>, Guiyun Yan<sup>1</sup>, Andrew K. Githeko<sup>2</sup>, Harrysone E. Atieli<sup>2</sup><sup>1</sup>University of California Irvine, Irvine, CA, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya

The long-lasting insecticidal nets (LLINs), indoor residual spraying of insecticide (IRS) and artemisinin-based combination therapy (ACT) have been scaled up in Africa to control and eliminate malaria in the past decade. These intervention measures have led to overall significant declines in malaria burden. However, several studies have also documented little change in some sites in Africa. High-quality evidence for malaria burden changes and especially the mechanisms underlying these changes are often lacking. We conducted a long-term evaluation of malaria transmission dynamics in three sentinel sites with varying transmission intensity in western Kenya. The 15-year longitudinal monthly observational study found that in two highland sites, currently indoor resting vector density has resurged to the level of 2004-2005, the period before the LLIN mass distribution. Parasite prevalence remained unchanged at two sites since 2009 and bounced back to the level of 2005 at one site. We investigated the potential causes of the resurgence, including LLIN coverage rate, vector insecticide resistance, vector species composition shift, insecticidal decay effect of the LLINs, and climatic anomaly. Generalized additive model was used to determine the relative

contributions of different factors through a stepwise feeding procedure. The results indicated that indoor resting *Anopheles gambiae* s.l. density was mainly affected by long-term trend and annual variability of climate regardless of study sites, whereas density and proportion of indoor resting *An. funestus* were correlated with resistance level and climatic factors. Parasite prevalence were strongly correlated with insecticide resistance, *An. funestus* indoor resting density, LLIN killing ability and climatic factors. The results suggested that insecticide resistance and shift of vector species became key factors affecting malaria control in this highly endemic area of Africa.

## 1947

**HIGH PLASMODIUM FALCIPARUM OOCYST LOADS IN NATURALLY INFECTED MOSQUITOES IN AFRICA**Anais Bompard<sup>1</sup>, Dari F. Da<sup>2</sup>, Serge Yerbanga<sup>2</sup>, Isabelle Morlais<sup>1</sup>, Thierry Lefèvre<sup>1</sup>, Thomas S. Churcher<sup>3</sup>, Anna Cohuet<sup>1</sup><sup>1</sup>Institut de Recherche pour le Développement, Montpellier, France,<sup>2</sup>Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso,<sup>3</sup>MRC Centre for Outbreak Analysis and Modelling, Infectious Disease Epidemiology, Imperial College, London, United Kingdom

The population dynamics of human-to-mosquito malaria transmission in the field has important implications for the genetics, epidemiology and control of malaria. The number of *Plasmodium falciparum* oocysts in naturally infected mosquitoes in the wild is poorly understood, though past work indicates that most mosquitoes have only one or two oocysts. The per bite mosquito force of infection (the mean number of oocysts gained from an infectious bite) is also unclear despite the force of infection influencing factors such as the efficacy of novel transmission blocking interventions currently under development. Here a yearlong analysis of malaria transmission in three sites in Burkina Faso and Cameroon is reported. Naturally fed mosquitoes were caught inside houses and dissected to assess the prevalence and intensity of oocysts and sporozoites 3 and 7 days after collection. Cross-sectional surveys of the resident human population were carried out to determine the prevalence and intensity of sexual and asexual parasites. Results show that oocysts intensity in naturally infected mosquitoes is substantially higher than previous estimates. In the rainy season infected mosquitoes had on average 9-18 oocysts per mosquitoes 3 days after collection, with one mosquito harboring 786 oocysts. Multivariate analysis indicated that village, season and bednet use in the local population to be associated with the prevalence and intensity of oocysts and the sporozoite rate. A dynamical mathematical model of transmission was used to estimate the per-bite transmission probability, the proportion of superinfections and average parasite exposure per bite for each location. The implications of high parasite exposure on biology of transmission and the development and use of transmission blocking interventions in the field are discussed.

## 1948

**IMPACT OF PYRETHROID EXPOSURE ON RESISTANT MOSQUITO FITNESS**Alida Kropf<sup>1</sup>, Behi Kouadio Fodjo<sup>2</sup>, Marius Zoh Gonze<sup>2</sup>, Bassirou Bonfoh<sup>2</sup>, Chouaibou Mouhamadou<sup>2</sup><sup>1</sup>MIE, Bouake, Côte D'Ivoire, <sup>2</sup>CSRS, Abidjan, Côte D'Ivoire

The use of insecticides is the current backbone of vector control. But, it is widely believed that the current rise and spread of insecticides resistance in mosquito population could compromise its efficacy as exposures to LLINs or IRS are no longer able to kill their target. However very little is known about the long-term effect of insecticide exposure on resistant mosquito. We here hypothesize that mosquitoes that have survived insecticide exposure will have a reduced fitness, which may be expressed in a shorter lifespan, reduced blood-feeding success or reduced egg output. We tested this hypothesis in an experimental design where we measured different life history traits on 2 groups of resistant mosquitoes. One group was exposed repeatedly to insecticides before being allowed to have a

blood meal while the other group acted as our control was not exposed. The experiment was conceived in order to recreate a situation as close to reality as possible, using a pure *An. gambiae* s.s resistant strain, Tiassale S molecular form and a bed net furnished and distributed to the populations by the National Malaria Control Program in Côte d'Ivoire. Each measured life trait after each exposure has subsequently been broken down into a gonotrophic cycle and the parameters were compared within and between the different gonotrophic cycles for each mosquito group. We were able to put in evidence a sub-lethal effect of pyrethroid exposure on resistant mosquitoes. Affected were life traits such as the blood feeding, the egg laying, immediate mortality and delayed mortality. As all of these traits play a major role in the transmission and thus the epidemiology of malaria. They were, in a second step, included into a vectorial capacity model (MacDonald Ross formula). These results help understanding why vector control remains somewhat effective in reducing malaria transmission and that finally the impact of resistance on vector control may be much less than previously assumed.

## 1949

### TARGETING CATTLE FOR MALARIA ELIMINATION: MARKED REDUCTION OF *ANOPHELES ARABIENSIS* SURVIVAL FOR OVER SIX MONTHS USING A SLOW-RELEASE IVERMECTIN FORMULATION

Kija Ng'habi<sup>1</sup>, Gloria Abizanda<sup>2</sup>, Marta Alustiza<sup>2</sup>, Gerry Killeen<sup>1</sup>, Fredros Okumu<sup>1</sup>, **Carlos J. Chaccour**<sup>2</sup>

Behavioural plasticity has allowed malaria vectors to avoid home-centered vector control strategies such as, Indoor residual spraying and insecticide-treated nets which are both remarkably effective and affordable. This unsuppressed large population is now responsible for residual malaria transmission, a major challenge in elimination efforts. Partial zoophily is the key factor in residual malaria transmission as evidenced by large proportion of mixed cattle and human blood meals in a number of vector species. Mosquitoes that feed on peridomestic livestock tend to avoid contact with insecticides, reproduce and survive to continue transmission once human blood is available again. Modelling shows that targeted use of veterinary endectocides (drugs that kill mosquitoes feeding on treated subjects) could result in incremental transmission reduction after roll-out of long-lasting insecticidal nets, indoor residual spraying and other core vector control tools. Veterinary endectocides hold potential to become a complementary strategy for malaria elimination. We conducted a trial of a long-lasting, implantable veterinary formulation of ivermectin that can sustain mosquito-killing levels of this drug for more than months. 3 calves were randomly assigned to be implanted with five silicon rods or nothing as control. 50 *Anopheles arabiensis* (triplicates) females were fed on their flanks every 2 weeks. Mosquito mortality was then assessed by counting and removing the dead for 10 days. Our results show a marked and significant reduction in *Anopheles arabiensis* survival that does not decay in magnitude even six months after implantation. Slow release ivermectin formulations could complement on the success achieved by home-centered measures and aid malaria elimination.

### INVESTIGATING THE ACTIVITY OF THE MACROCYCLIC LACTONES IVERMECTIN AND MOXIDECTIN AGAINST MALARIA VECTORS

Cielo Pasay<sup>1</sup>, Paul Mills<sup>2</sup>, Milou Dekkers<sup>3</sup>, Romal Stewart<sup>4</sup>, Leon Hugo<sup>4</sup>, Oselyne Ong<sup>4</sup>, Chen Wu<sup>4</sup>, Greg Devine<sup>4</sup>, James McCarthy<sup>1</sup>

<sup>4</sup>Mosquito Control Laboratory, QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia

Livestock that live in close proximity to human hosts are alternative blood sources for many malaria vector mosquito species. In such areas, treating peri-domestic animals with insecticides such as ivermectin or moxidectin may reduce the mosquito population, hence reduce transmission of malaria. Moxidectin has the theoretical advantage of increased lipophilic properties and longer half life. The aim of this study was to investigate the efficacy of these two macrocyclic lactones with known activity against arthropod ectoparasites. Activity was tested against the dominant malaria mosquito vector in Oceania, namely *Anopheles farauti*. Initially, activity of these drugs was tested against colony mosquitoes by membrane feeding assays where the drugs were prepared in the blood meals. Drug levels were measured in the plasma and red cell compartments in the blood meals and IC50 and IC90 levels determined. Subsequently, in-vivo efficacy was investigated by conducting a clinical trial where pigs were treated with ivermectin and moxidectin in doses appropriate for human administration. Then *An. farauti* mosquitoes were allowed to feed on the pigs. Drug levels in the skin and blood of the pigs and mosquito mortality were monitored. Results of both the *in vitro* and *in vivo* experiments will be presented. Results of this study will assist in evaluating the potential of an innovative malaria control strategy utilising domestic animals for mosquito vector control applicable in the field setting.

## 1951

### THE CONTRIBUTION OF SYMPTOMATIC AND ASYMPTOMATIC INFECTIONS TO THE INFECTIOUS RESERVOIR OF *PLASMODIUM FALCIPARUM* AND *P. VIVAX* IN ETHIOPIA

Fitsum G. Tadesse<sup>1</sup>, Wakweya Chali<sup>1</sup>, Kjerstin Lanke<sup>2</sup>, Hassen Mamo<sup>3</sup>, Abraham Aseffa<sup>1</sup>, Robert Sauerwein<sup>2</sup>, Delenasaw Yewhalaw<sup>4</sup>, Chris Drakeley<sup>5</sup>, Endalamaw Gadissa<sup>1</sup>, Teun Bousema<sup>2</sup>

<sup>1</sup>Armauer Hansen Research Institute, Addis Ababa, Ethiopia, <sup>2</sup>Radboud UMC, Nijmegen, Netherlands, <sup>3</sup>Addis Ababa University, Addis Ababa, Ethiopia, <sup>4</sup>Jimma University, Jimma, Ethiopia, <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The level of asymptomatic malaria infections is considerably higher than previously thought. Whether these infections need to be targeted to further strengthen control efforts/accelerate malaria elimination needs detailed investigation. In this study we performed detailed assessments of parasite carriage and transmissibility to mosquitoes to investigate the relative contribution to malaria transmission of clinical and asymptomatic malaria. We successfully performed mosquito feeding assays using locally reared *A. arabiensis* mosquitoes on clinical malaria episodes detected by the routine health system (n=41) and asymptomatic malaria infections detected by microscopy (n=41) and PCR (n=88) in Adama, central Ethiopia. Membrane feeding experiments yielded 5,000 mosquito observations. Mosquito infection was investigated using CSP based ELISA on 20-30 mosquitoes per experiment that were sacrificed 12 days post feeding; infection was confirmed with 18S gene based qPCR. Microscopy and PCR revealed 8.4%(41/487) and 26.5%(129/487) asymptomatic infections, respectively. Most of the infections were attributed to Pv 60.0%(98/164), while only 31.7%(52/164) were due to Pf. Among the feeding experiments analyzed so far, 2 out of 8 asymptomatic Pf carriers were infectious to mosquitoes (5 and 30% infected mosquitoes) but none of the clinical patients (0/8) were found infectious. Among 13 Pv carriers, 2/5 asymptomatic individuals were infectious to mosquitoes (5.5 and 25% infected mosquitoes) while 7/8 symptomatic individuals were infectious to mosquitoes and infected on average 57% of mosquitoes. Transmission data on an additional 4000 mosquitoes from 140 individuals will be completed in the coming months. Preliminary results from this study demonstrate that asymptomatic Pf infections play significant role in the maintenance of the infectious reservoir whereas clinical malaria cases are particularly relevant for Pv transmission. The findings fill an

important knowledge gap on the relative contribution of symptomatic and asymptomatic individuals in an area of moderate-low transmission of vivax and falciparum malaria.

## 1952

### OUTDOOR PRIMARY AND "SECONDARY" VECTORS CONTRIBUTING TO RESIDUAL TRANSMISSION IN ZAMBIA

Jennifer C. Stevenson<sup>1</sup>, Mbanga Muleba<sup>2</sup>, Limonty Simubali<sup>3</sup>, Twig Mudenda<sup>3</sup>, Esther Cardol<sup>4</sup>, James Lupiya<sup>2</sup>, David Mbewe<sup>2</sup>, Christine M. Jones<sup>1</sup>, Giovanna Carpi<sup>1</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>3</sup>Macha Research Trust, Choma, Zambia, <sup>4</sup>Radboud University, Nijmegen, Netherlands

Historically data across much of sub-Saharan Africa showed high levels of exposure to malaria mosquitoes indoors in the middle of the night. The use of insecticide-treated nets and indoor spraying of insecticides targeting these behaviors have been attributed to 70% of over 600 million cases of malaria averted between 2000-2015 in this region. Despite the impressive gains and continued high coverage of interventions, malaria transmission persists in many areas. Contributing factors to this residual transmission may be the persistence of vectors with altered behaviors; those that evade contact with insecticides can maintain transmission. To assess the contribution of outdoor foraging of anopheline vectors to malaria transmission, light trap collections of mosquitoes were made in sites of low and high malaria transmission in Zambia. Collections targeted to areas within homesteads frequented by residents in the evening or night were compared in a Latin Square design. In Macha, the low transmission site, southern Zambia, light traps were set outdoors next to kitchens, animal shelters and exit points from homesteads. Here, hourly collections at kitchens indicated sizable exposure to anophelines prior to when residents entered houses, however larger catches were made from animal shelters; collections were 26-fold those next to kitchens. Of the mosquitoes caught near animals, 63% were of the species *Anopheles squamosus*, previously shown to be a potential malaria vector in the area. In the high transmission site, Nchelenge, northern Zambia, light traps were set outdoors where food is cooked at night, next to animal pens and at wash rooms. Highest catches were made where people gather at night with 2.4-fold the catch of traps set next to animals. 85% were identified as *An. funestus* s.l. Data from these divergent sites show potential exposure to a variety of vectors outdoors in both pre-elimination and holoendemic malaria sites in Zambia. These findings stress the necessity for combining malaria interventions targeting both indoor and outdoor foraging mosquitoes as the dominant vectors and their associated behaviors may be difficult to predict.

## 1953

### IMPACT OF PNEUMOCOCCAL CONJUGATE VACCINE ON INVASIVE PNEUMOCOCCAL DISEASE IN THE GAMBIA: POPULATION-BASED SURVEILLANCE OVER 9 YEARS

Grant Mackenzie<sup>1</sup>, Philip Hill<sup>2</sup>, David Jeffries<sup>1</sup>, Ilias Hossain<sup>1</sup>, Malick Ndiaye<sup>1</sup>, Henry Badji<sup>1</sup>, Usman Ikumapayi<sup>1</sup>, Rasheed Salaudeen<sup>1</sup>, Sheikh Jarju<sup>1</sup>, Martin Antonio<sup>1</sup>, Lamin Ceesay<sup>3</sup>, Dawda Sowe<sup>3</sup>, Momodou Jasseh<sup>1</sup>, Kim Mulhollan<sup>4</sup>, Maria Knoll<sup>5</sup>, Orin Levine<sup>6</sup>, Stephen Howie<sup>7</sup>, Richard Adegbola<sup>8</sup>, Brian Greenwood<sup>9</sup>, Tumani Corrah<sup>1</sup>

<sup>1</sup>Medical Research Council Unit, The Gambia, Banjul, Gambia, <sup>2</sup>University of Otago, Dunedin, New Zealand, <sup>3</sup>Ministry of Health, Gambia Government, Banjul, Gambia, <sup>4</sup>Murdoch Childrens Research Institute, Melbourne, Australia, <sup>5</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>6</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States, <sup>7</sup>University of Auckland, Auckland, New Zealand,

<sup>8</sup>GlaxoSmithKline, Wavre, Belgium, <sup>9</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

*Streptococcus pneumoniae* is a major cause of child mortality. Pneumococcal conjugate vaccines (PCV) have reduced the incidence of invasive pneumococcal disease (IPD) in affluent countries. Many low-income countries have introduced PCV, yet data on vaccine impact from these settings are lacking. We measured the impact on IPD of Gambia's PCV program which introduced PCV7 in Aug 2009 without a catch-up program and PCV13 in May 2011. We conducted standardized population-based surveillance for suspected meningitis, sepsis or pneumonia among those aged  $\geq 2$  months in the Basse Health & Demographic Surveillance System (BHDSS) in rural Gambia. Sterile site samples were analysed by conventional microbiology and pneumococcal isolates were serotyped by latex agglutination. The rate of enrolment per unit population varied over time, so we adjusted annual counts of IPD to the mean rate of enrolment of patients with suspected meningitis, sepsis or pneumonia. Incidence was calculated using BHDSS mid-point population estimates. We published results to the end of 2014. Here we report updated results to the end of 2016. We investigated 24 179 patients, identifying 372 cases of IPD. The baseline incidence of vaccine-type IPD in the 2-23 month age group from May 12, 2008 to May 11, 2010 was 195 and fell to 14 per 100,000 person-years in 2015/16; incidence of non-vaccine type IPD increased from 49 to 74 per 100,000 person-years; all IPD decreased from 253 to 88 per 100,000 person-years. In the 2-4 year age group the incidence of vaccine-type IPD fell from 99 to 15 per 100,000 person-years; non-vaccine type IPD increased from 14 to 18 per 100,000 person-years; all IPD decreased from 113 to 33 per 100,000 person-years. In the 5-14 year age group the incidence of all IPD decreased from 12 to 1 per 100,000 person-years. In the  $\geq 15$  year age group the incidence of all IPD fell from 9 to 1 per 100,000 person-years. Of 25 cases of vaccine-failure, 11 occurred within 12 months of the 3rd dose of PCV and 14 occurred more than 12 months after the 3rd dose of PCV. Overall cases of IPD have fallen by around 65% in the under 5 year age group and herd protection effects are evident in older children and adults.

## 1954

### SAFETY, TOLERABILITY AND EFFICACY OF A THREE-DOSE REGIMEN OF RADIATION ATTENUATED *PLASMODIUM FALCIPARUM* NF54 SPOROZOITES (PFSPZ VACCINE) IN HEALTHY MALIAN ADULTS

Mahamadou S. Sissoko<sup>1</sup>, Sara A. Guindo<sup>1</sup>, M'Bouye Doucoure<sup>1</sup>, Boucary Ouologuem<sup>1</sup>, Souleymane Traore<sup>1</sup>, Boubacar Fomba<sup>1</sup>, Sidiki Perou<sup>1</sup>, Eric R. James<sup>4</sup>, Tooba Murshedkar<sup>4</sup>, B. Kim Lee Sim<sup>4</sup>, Peter F. Billingsley<sup>4</sup>, Thomas L. Richie<sup>4</sup>, Stephen L. Hoffman<sup>4</sup>, Patrick E. Duffy<sup>2</sup>, Ogobara Doumbo<sup>1</sup>

<sup>1</sup>MRTC, University of Science, Techniques and Technologies, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>3</sup>BRB/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, <sup>4</sup>Sanaria Inc., Rockville, MD, United States

A double blind, randomized clinical trial was conducted in Mali, West Africa to assess a 3-dose regimen of Sanaria® PfSPZ Vaccine (1.8x10<sup>6</sup> PfSPZ) administered by direct venous inoculation against natural malaria exposure over 6 months of surveillance. An open label dose escalation pilot study was completed first and demonstrated the safety and tolerability of PfSPZ Vaccine (4.5x10<sup>5</sup>, 9x10<sup>5</sup>, and 1.8x10<sup>6</sup> PfSPZ). After establishing safety and tolerability, the targeted dose (1.8x10<sup>6</sup> PfSPZ) was then administered at 0, 8, 16 weeks to the main cohort (n=120) in a double blind, randomized, placebo-controlled trial starting in Mar 2016.

Participants received artesunate/amodiaquine to eliminate Pf before first and last vaccination. The incidence and severity of local and systemic AEs occurring within 7 days after each dose were solicited. During the malaria transmission season (Aug-Dec 2016), volunteers were examined and blood smears obtained every 2 weeks for 24 weeks in total; the primary efficacy endpoint was detection of first positive blood smear following third vaccination. 60 subjects received at least one dose of PfSPZ Vaccine and 60 subjects received placebo. 57 (95%) received all 3 doses of PfSPZ Vaccine and 55 (91.7%) subjects received normal saline placebo. We detected no significant differences in local or systemic AEs or laboratory abnormalities between PfSPZ Vaccine and placebo groups. The primary efficacy endpoint was the time-to-infection during the transmission season. 55 subjects in the PfSPZ Vaccine group and 54 subjects from the placebo group were evaluable for per protocol analysis. Of these participants, 42 (77.8%) from the placebo group and 32 (58.1%) from the vaccine group developed Pf infection. Per protocol, the vaccine efficacy was 51% ( $p=0.004$ , 95% CI 20-70) by time-to-infection analysis (ITT 39%,  $p=0.033$ ) and 24% ( $p=0.031$ , 95% CI 2-41) by proportional analysis (ITT 22%,  $p=0.041$ ). PfSPZ Vaccine was well tolerated and safe at higher doses. This 3-dose vaccine regimen of PfSPZ Vaccine showed similar protection against Pf infection as previously reported in African adults receiving a 5-dose regimen.

## 1955

### HEPATITIS C, SYPHILIS, AND G6PD DEFICIENCY IN CAMEROONIAN BLOOD DONORS

**Stephanie M. Lauden**<sup>1</sup>, Stella Chongwain<sup>2</sup>, Anzeh Achidi<sup>2</sup>, Ethan Helm<sup>2</sup>, Sarah Cusick<sup>1</sup>, Amelia Krug<sup>1</sup>, Tina Slusher<sup>1</sup>, Troy Lund<sup>1</sup>

<sup>1</sup>University of Minnesota, Minneapolis, MN, United States, <sup>2</sup>Mbingo Baptist Hospital, Mbingo, Cameroon

Glucose-6-phosphate dehydrogenase (G6PD) deficiency, the most common genetic condition in the world, remains a well-known risk factor for hemolytic anemia and kernicterus in newborns. A wide range of prevalence has been reported in Africa, though little is known about the region of Cameroon. To identify prevalence of G6PD deficiency in Cameroon and correlate with demographic, hematologic, and infectious markers. Blood was collected at Mbingo Hospital, a large referral center in Northwest Cameroon, as part of a previously established hospital blood donor program. Demographic information, ABO, hemoglobin, and infectious markers [syphilis (RPR), hepatitis C virus (antigen), hepatitis B (HBsAg), HIV] were performed per hospital donor screening protocol. Samples were frozen, with freezer temperatures maintained between -20 and -80C. G6PD testing was then completed in batch with thawed samples. Deficiency was determined using the Beutler Fluorescent spot test. We compared prevalence rates of each infection among G6PD-deficient vs non-deficient males by chi-square. We screened 747 blood donors and identified 40 (5%) deficient donors. Out of 539 (72%) males, 38 (7%) had G6PD deficiency. The prevalence of HCV in G6PD-deficient males versus non-deficient males was 8.3% vs. 1.3% ( $p = 0.02$ ). The prevalence of RPR positivity was 13.5% vs. 5.4% in G6PD-deficient vs non-deficient males ( $p = 0.05$ ), respectively. We found no significant difference in rates of hepatitis B virus or HIV in G6PD-deficient versus sufficient males. ABO typing in G6PD-deficient males showed 16.2% A, 18.9% B, 66.2% O, and 2.7% AB, similar to that of the study cohort ( $p = 0.93$ ). This is the first study to correlate G6PD deficiency with infectious markers. This raises important questions regarding the relationship between G6PD deficiency, hepatitis C virus, and syphilis. Further investigation is required to evaluate whether G6PD deficiency represents an independent risk factor for the development of hepatitis C and syphilis.

## 1956

### OUTCOMES OF A PILOT HYDROCELE SURGERY CAMP IN ETHIOPIA

**Andualem Deneke**<sup>1</sup>, Fikreab Kebede<sup>2</sup>, Belete Mengistu<sup>2</sup>, Biruk Kebede<sup>2</sup>, Tigist Hirpa<sup>2</sup>, Molly Brady<sup>3</sup>, Sunny Mante<sup>4</sup>, Zeina Sifri<sup>5</sup>, Scott McPherson<sup>6</sup>

<sup>1</sup>Surgical Society of Ethiopia, Addis Ababa, Ethiopia, <sup>2</sup>RTI International, Addis Ababa, Ethiopia, <sup>3</sup>RTI International, Washington, DC, United States, <sup>4</sup>African Filariasis Morbidity Project, Accra, Ghana, <sup>5</sup>Helen Keller International, Washington, DC, United States, <sup>6</sup>RTI International, Research Triangle Park, NC, United States

Globally an estimated 19.5 million men suffer from hydrocele due to lymphatic filariasis. Two major challenges in addressing the burden of hydrocele are patient identification and access to safe hydrocele surgery. In Ethiopia, LF patient estimates for three regions suggest 1,245 suspected hydrocele patients (0.04% of population), likely an underestimate due to stigma. Trained health extension workers developed patient line listings going door-to-door with color photos depicting hydroceles to aid in identification. A hydrocele surgery camp was then piloted at one hospital in collaboration with local and federal authorities and with support from the USAID-funded MMDP Project. Clinical officers screened 252 patients and confirmed 198 hydrocele cases (79%). Eight surgeons or surgical officers participated in a five-day training in resection (excision) surgery using theory-based modules and the Filariace Anatomical Surgical Task Trainer (FASTT) simulator. Trainees practiced on the FASTT simulator before operating on live patients. Each trainee then performed at least five live surgeries under the supervision and support of a master trainer. Over the 11-day period of the training and camp, 175 hydrocele surgeries were performed. All patients were hospitalized for three days and received a nine-day course of antibiotics, starting one day before surgery. At day five post-surgery, when 154 (88%) patients were followed up by trained community clinical workers, no patients were found with hematoma or infection. However, by day 14, out of 167 patients followed up, one (0.6%) had a hematoma and 19 (11.4%) had infections. This may indicate a need for improved post-surgical care. All patients with complications were referred to local health facilities. Other studies have found rates of complications ranging between 3-7% at day five, and increasing at later follow up. Critical to the camp's success was the standardized training, appropriate use of antibiotics, and routine patient follow up. Based on the ease of identifying a cohort of patients and the small number of post-operative complications, this strategy may be applicable in other countries.

## 1957

### IDENTIFYING CLINICAL PREDICTORS FOR PROGRESSION TO CHRONIC KIDNEY DISEASE IN MESOAMERICAN NEPHROPATHY

**Rebecca S. Fischer**<sup>1</sup>, Chandan Vangala<sup>1</sup>, Sreedhar Mandayam<sup>1</sup>, Denis Chavarria<sup>2</sup>, Kristy O. Murray<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Gerencia de Salud Ocupacional, Nicaragua Sugar Estates Limited, Chichigalpa, Nicaragua

Mesoamerican nephropathy (MeN) is a mysterious kidney disease of unknown etiology. The epidemic, to which greater than 20,000 deaths are owed, is unrelenting across Central America. MeN primarily affects young agricultural workers who lack traditional risk factors for kidney disease. MeN has been characterized as a chronic kidney disease (CKD), but we recently identified an acute phase of MeN, involving acute kidney injury with interstitial nephritis. The goal of this analysis is to pinpoint clinical characteristics of acute MeN that predict progression to CKD. Using univariate analysis, we compared patients with acute MeN who developed CKD to those who did not to identify clinical risk factors for CKD. Physicians at a private hospital in Nicaragua completed case reports detailing acute clinical encounters on cases of MeN and provided follow-up data on subsequent CKD diagnoses. From Feb 2015-Jan

2017, 468 cases of acute MeN were reported, mostly male (91%) and young (median age 27 yrs). Most (92%) had acute kidney injury (AKI). Frequent symptoms were fever (62%), nausea/vomiting (72%), back pain (61%), and headache (52%). Leukocytosis (80%), neutrophilia (84%), lymphopenia (53%), elevated C-reactive protein (76%), and anemia (59%) were common, along with leukocytes (99%) and leukocyte casts (30.2%) in urine. 30 patients (6%) progressed rapidly (median 90 days) to CKD, with half (51%) progressing to  $\geq$ Stage 3 CKD. We found that age  $>$ 25 years (Prevalence Ratio [PR] 2.90 [1.03, 8.19],  $p=0.045$ ), hyperuricemia (2.56 [1.26, 5.21],  $p=0.010$ ), anemia (3.37 [1.31, 8.67],  $p=0.012$ ) and hyponatremia (PR 3.20 [1.46, 7.02],  $p=0.004$ ) were associated with CKD. Leukocytosis (PR 0.39 [95%CI 0.19, 0.81],  $p=0.012$ ) and leukocyturia (PR 0.36 [0.17, 0.75],  $p=0.006$ ) during the acute phase of MeN were found to be protective. Our data suggest that acute systemic inflammation during acute MeN may mediate progression to CKD. Our ongoing longitudinal analysis will enhance our understanding of clinical events during disease progression and shed light on the mechanism of injury. This is the first of clinical factors associated with CKD and with recovery in MeN.

## 1958

### A NOVEL, PORTABLE INFRARED 3D SCANNER QUICKLY PROVIDES ACCURATE LIMB VOLUME AND CIRCUMFERENCE MEASUREMENTS IN PATIENTS WITH FILARIAL LYMPHEDEMA

Channa Yahathugoda<sup>1</sup>, Michael Weiler<sup>2</sup>, Ramakrishna Rao<sup>3</sup>, Lalindi Da Silva<sup>1</sup>, Mirani Weerasooriya<sup>1</sup>, Gary Weil<sup>3</sup>, **Philip J. Budge<sup>3</sup>**

<sup>1</sup>University of Ruhuna, Galle, Sri Lanka, <sup>2</sup>LymphaTech, Atlanta, GA, United States, <sup>3</sup>Washington University in St. Louis, St. Louis, MO, United States

Despite progress in reducing transmission of lymphatic filariasis (LF), millions remain affected by filarial lymphedema. Current tools for measuring lymphedema include water displacement (WD), limb circumference (LC), and ultrasound skin thickness (UST). Each of these methods has drawbacks: WD is difficult to perform in the field, LC measurements are cumbersome and variable, and UST measurement is difficult to standardize and requires expensive equipment. A portable infrared scanner has recently been developed that can quickly and accurately measure limb volumes. We compared the scanner with the above-mentioned modalities in patients with filarial lymphedema. Six examiners were trained in each modality over a 2-day period that was followed by a test period with 52 patients. Limbs were measured by 2 (WD) or 3 (each other modality) separate examiners. Limbs with differing grades of lymphedema were examined (N = 28, 19, 20, 21, 2, 4, and 10 for grades 0-6, respectively). Limb volumes ranged from 1.6L to 11.0L and circumference ranged from 17.8 to 71.1 cm. The portable scanner calculated limb volume and circumference measurements that correlated nearly perfectly with WD ( $r^2 = 0.997$ ) and LC values ( $r^2 = 0.992$ ) over the entire range measured. The scanner required an average of 2.2 min to acquire measurements for both legs, compared to 17.4, 7.5, and 31.7 min, respectively, for WD, LC, and UST. Coefficients of variation for limb volume measurements performed by 2 (WD) or 3 (scanner) examiners were 1.4% for WD and 2.2% for the 3D scanner. CVs for circumference measurements were 1.8% by tape measure and 1.6% by scanner. UST was the least precise measure tested; median inter-observer variability was 5.5% (IQR 3.2% - 9.1%; range 0.2% - 42.0%). These results show that accurate and precise lower extremity volume and circumference measurements can be obtained in approximately 2 minutes with a non-invasive, portable scanner. This technology has the potential to revolutionize assessment and monitoring of lymphedema in the clinic and in the field.

## 1959

### ABORTION RATE IS MUCH HIGHER THAN MICROCEPHALY RATE IN ZIKA VIRUS INFECTIONS OCCURRING IN THE FIRST TRIMESTER OF PREGNANCY

Danillo L. Espósito<sup>1</sup>, Adriana A. Ferreira<sup>1</sup>, Flávia M. Moraes<sup>1</sup>, Michelli R. Persona<sup>1</sup>, Beatriz dos Ribeiro<sup>1</sup>, Suzi V. Fábio<sup>2</sup>, Luzia Márcia R. Passos<sup>2</sup>, Ana Alice M. Castro e Silva<sup>2</sup>, **Benedito A. Fonseca<sup>1</sup>**

<sup>1</sup>School of Medicine of Ribeirão Preto, Ribeirão Preto, S.P., Brazil, <sup>2</sup>Ribeirão Preto Health Department, Ribeirão Preto, S.P., Brazil

Zika virus (ZIKV) infections in pregnant women have been associated to an increased number of severe malformations, such as, microcephaly and arthrogryposis. Much of this knowledge has been acquired through clinical studies but very few prospective studies have been done in cohorts of pregnant women, and this type of study is crucial to define ZIKV infections as the cause of congenital disease. In our prospective study, a cohort of pregnant women admitted to the study, independently of their stage of pregnancy, was followed up to the end of pregnancy. The primary goal of the study was to detect infections in these women and to compare the pregnancy outcomes of women infected or not with ZIKV. Pregnant women presenting with a zika-like disease, with duration of less than four days, were evaluated and followed by an ObGyn physician and zika diagnosis was performed by RT-PCR. STORCH syndrome was investigated in every case. From February 2016 to March 2017, 1,125 pregnant women were admitted to the study and 268 became sick during the follow-up (70, 102 and 96 on the first, second and third trimester, respectively). According to these trimesters, ZIKV-infections were detected in 42, 74, and 62 pregnant women and it was evident that the zika-related complications were only observed when infection occurred in the first and second trimester. Adverse pregnancy outcomes of ZIKV-positive mothers included 4 microcephaly, two newborns with normal cephalic perimeter but with cerebral calcifications, one arthrogryposis, and most important, 9 abortions, while outcomes of ZIKV-negative mothers included two microcephaly and two abortions. The newborn with arthrogryposis died a few hours after birth. One of the abortion cases associated to ZIKV-negative patients was from a 42-year-old patient and the other was from a patient infected with dengue-1 virus. Although the number of symptomatic pregnant women was not very large, it was clear that ZIKV infections were associated to a higher number of microcephaly and, most important, to a much higher rate of abortion, especially when the infection occurred in the first trimester of the pregnancy.

Using traps for surveillance of vector and pathogen populations is an important component of many vector management programs, however this technology has remained largely unchanged over many years. It is inaccessible in developing countries and limited in developed countries, largely due to costs and personnel requirements. Project PREMONITION has developed an autonomous mosquito trap that captures live mosquitoes

individually for higher-throughput lower-cost mosquito surveillance and pathogen discovery. The PREMONITION trap uses infrared sensors and algorithms to identify flying insects by wing beat frequency, capable of capturing only target mosquito species and reducing non-targeted captures. In addition to recording putative species identification, abiotic data such as precise time of capture, temperature, humidity and ambient light, are recorded effectively providing foraging activity parameters throughout the collection period. Due to a unique design, each specimen is tagged with the data it produced, enabling new bioinformatics analyses. Field trials of the PREMONITION trap were conducted in Houston, Texas, in summer 2016 to evaluate trap performance under native environmental conditions. We performed 87 deployments across 20 sites in Houston. Over 20 GB of mosquito data paired with high-resolution environmental data were collected and analyzed. Over 22,000 mosquito events were detected and key species activity was captured at the sub-minute temporal scale. Data showed over 90% accuracy at identifying *Culex* and *Aedes* mosquitoes at the genus level. The resulting bionomic data provide unprecedented insight to the diurnal and nocturnal activity of these vectors.

### PREVENTING MALARIA PARASITE TRANSMISSION WITH TRANSGENIC ENTOMOPATHOGENIC FUNGI

**Brian Lovett**<sup>1</sup>, Etienne Bilgo<sup>2</sup>, Abdoulaye Diabate<sup>2</sup>, Raymond J. St. Leger<sup>1</sup>

<sup>1</sup>University of Maryland, College Park, MD, United States, <sup>2</sup>Centre Murazl IRSS, Bobo-Dioulasso, Burkina Faso

We compared arthropod genes encoding insect-specific sodium, potassium and calcium channel blockers for their ability to improve the efficacy of *Metarhizium* against insecticide-resistant anophelines. Toxins increased lethality to mosquitoes at spore dosages as low as one conidium per mosquito. One of the most potent strains, expressing the EPA approved Hybrid (Ca<sup>++</sup>/K<sup>+</sup> channel blocker), was studied for efficacy in a MosquitoSphere in Burkina Faso. We found that suspending *Metarhizium* in locally produced sesame oil and spreading that on netting or black sheets achieves a long-term effect in the MosquitoSphere. Compared to the wild-type fungus, Met-Hybrid killed anopheline mosquitoes in half the time and at much lower spore doses in semi-field conditions, which increased the percent of lethality of infected mosquitoes and the effective persistence of the pathogen. The results surpass the WHO threshold for successful vector control agents. Met-Hybrid also has important pre-lethal effects that include sexual transmission and reduced blood feeding by infected mosquitoes. This NIH funded, international effort represents an important step in the progression of transgenic mosquito control technologies into field application.

## 1962

### MITIGATION OF PYRETHROID-RESISTANT *Aedes aegypti* USING PRE-SEASON, NON-PYRETHROID INDOOR RESIDUAL SPRAYING

**Mike W. Dunbar**<sup>1</sup>, Pablo Manrique-Saide<sup>2</sup>, Anuar Medina<sup>2</sup>, Azael Che-Mendoza<sup>3</sup>, Felipe Dzul-Manzanilla<sup>4</sup>, Fabian Correa-Morales<sup>4</sup>, Guillermo Guillermo-May<sup>2</sup>, Wilbert Bibiano-Marin<sup>2</sup>, Valentín Uc-Puc<sup>2</sup>, Eduardo Geded-Moreno<sup>2</sup>, José Vadillo-Sánchez<sup>2</sup>, Hugo Delfín-González<sup>2</sup>, Abdiel Martin-Park<sup>2</sup>, Gabriela González-Olvera<sup>2</sup>, Jorge Palacio-Vargas<sup>4</sup>, Scott Ritchie<sup>5</sup>, Audrey Lenhart<sup>6</sup>, Gonzalo M. Vazquez-Prokopec<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Autonomous University of Yucatan, Merida, Mexico, <sup>3</sup>Ministry of Health, Veracruz, Mexico, <sup>4</sup>Ministry of Health, Merida, Mexico, <sup>5</sup>James Cook University, Townsville, Australia, <sup>6</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Prevention of *Aedes*-transmitted viruses (dengue, chikungunya, Zika) relies strongly on reactive vector control interventions (e.g., indoor space spraying, ultra-low volume spraying, thermal fogging) in response

to symptomatic cases, yet these methods are less effective against indoor-resting *Aedes aegypti* and of limited impact in mitigating rapidly propagating outbreaks. Additionally, the evolution of pyrethroid resistance further reduces the efficacy of vector control. Indoor residual spraying of insecticides (IRS) can effectively prevent transmission, although it is time consuming and difficult to deploy during outbreaks. Applying IRS using non-pyrethroid insecticides before the start of the transmission season may both reduce vector populations and mitigate the effect of pyrethroid resistance. We compared the entomological efficacy of IRS when applied two months before peak transmission within Merida, Mexico, an area with high prevalence of pyrethroid resistance. A randomized controlled trial was performed to compare the efficacy of IRS with Bendiocarb, to which *Ae. aegypti* is susceptible, to an untreated control. Houses were sampled for presence and abundance of *Ae. aegypti* 15 days before and 15 days, one, two, and three months after IRS. All indices of adult *Ae. aegypti* (e.g., proportion of houses positive, total abundance, and abundance of bloodfed females) were reduced immediately following application of IRS with Bendiocarb compared to the untreated control and reductions remained three months post application, well beyond the peak transmission period. Mean abundance of *Ae. aegypti* per house was reduced from 2.0 ± 0.3 (untreated) to 0.48 ± 0.1 (Bendiocarb) 15 days post IRS. Lower abundance per house with IRS was consistent 3 months post spraying, 0.59 ± 0.1 (untreated) to 0.26 ± 0.1 (Bendiocarb). These data indicate that early application of IRS with non-pyrethroid insecticides can effectively reduce populations of pyrethroid-resistant *Ae. aegypti* throughout the transmission season and merit more thorough explorations on the epidemiological impact of preventive vector control with residual insecticides.

## 1963

### EPI INFOTM FOR MOSQUITO SURVEILLANCE: A FREE MOBILE APPLICATION AND ANALYSIS DASHBOARD TO IMPROVE FIELD DATA COLLECTION AND PROVIDE AUTOMATED ANALYSIS THAT ENABLES DATA-DRIVEN DECISION MAKING FOR VECTOR CONTROL

**Rebecca S. Levine**, Daniel Impoinvil, Asad Islam, Mohammed Lamtahri, Jose Aponte, Sachin Agnihotri, Matthew Burrows, Audrey Lenhart

Centers for Disease Control and Prevention, Atlanta, GA, United States

The Zika virus outbreak in the Americas highlighted capacity gaps of many vector surveillance programs in the region to rapidly conduct mosquito surveillance for supporting the vector control measures necessary to halt the outbreak. As a result, many countries employed generalized vector control, with patchy data on mosquito abundance, densities, or resistance to insecticides, which prevented them from more efficiently targeting their efforts. To improve the tools available for supporting decision making for outbreak control, the US Centers for Disease Control and Prevention (CDC) developed a tablet-based, mobile application for mosquito surveillance and a desktop data analysis dashboard, using existing free Epi Info™ software. The mobile app allows users to enter mosquito surveillance and control data directly in the field. In addition to a module collecting demographic information, the app consists of four modules: mosquito trapping (multi-day, for ovitraps and adult traps), mosquito surveys (single day, for immature surveys and aspiration), cone bioassays (for monitoring insecticide-treated surfaces), and vector control (for recording vector control actions, including efficacy studies). GPS coordinates, dates, and times are automatically collected, and sampling locations can be captured automatically using scanned barcodes. Field-collected data sync with the master database upon the tablet's detection of a wireless connection, and are uploaded immediately to the analysis dashboard. The dashboard automatically calculates relevant mosquito indices, places sampling locations on a map, and presents the user with graphical representations of trends over time, all of which can be filtered by dates and locations of interest. The dashboard is designed for use by mosquito surveillance and control personnel to make operational decisions based on data that is collected in near-real time. Using the Epi Info™ app and dashboard

eliminates the need for paper-based mosquito surveillance systems, enabling programs to more rapidly make data-driven vector control decisions. The app is freely available in multiple languages.

## 1964

### NEXT GENERATION MOSQUITO SURVEILLANCE TECHNIQUE: THE NEAR INFRA-RED SPECTROSCOPY

**Maggy Sikulu-Lord**<sup>1</sup>, Robert Wirtz<sup>2</sup>, Leon Hugo<sup>3</sup>, Jill Ulrich<sup>1</sup>, Gregor Devine<sup>3</sup>, Milali P. Masabho<sup>4</sup>, Rafael de Freitas<sup>5</sup>, Floyd Dowell<sup>6</sup>

<sup>1</sup>The University of Queensland, St. Lucia, Australia, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>4</sup>Marquette University, Milwaukee, WI, United States, <sup>5</sup>Instituto Oswald Cruz-Fiocruz, Rio de Janeiro, Brazil, <sup>6</sup>USDA, Kansas City, KS, United States

Mosquito control programs need high throughput, rapid and cost effective surveillance tools to estimate the impact of interventions, determine exposure risk and direct interventions to disease hot spots. Traditional surveillance tools such as those that estimate mosquito survival or those that detect infections in mosquitoes are either laborious, technically demanding or costly. Our team is currently testing the applicability of the near infrared spectroscopy (NIRS) as an alternative surveillance technique for malaria, dengue and Zika control programs. NIRS can predict the age and species of the major malaria vector, *Anopheles gambiae* s.s. and *An. arabiensis* simultaneously with accuracies of up to 90% and can predict the age of laboratory reared *Anopheles stephensi* and *Ae. Aegypti* with accuracies of up to 95%. Prediction of the 1) presence or absence of Wolbachia in *Aedes aegypti* was up to 96% accurate and 2) presence of dengue in laboratory reared *Ae. aegypti* was 91% accurate. Other applications that NIRS has shown potential include detection of Plasmodium parasites in *Anopheles* and Zika virus in *Ae. Aegypti* mosquitoes. The team is exploring alternative analysis options such as artificial neural networks to improve the predictive accuracy of NIRS. NIRS has shown potential as an alternative surveillance tool for mosquito control programs. It is a non-destructive one stop shop surveillance technique that can be used to measure multiple characteristics of a mosquito sample such as infection and age with just a single, 3-second reading of the mosquito. The technique does not require reagents to operate and hundreds of samples can be scanned and analyzed immediately. However, for operational use, NIRS requires field validation.

## 1965

### CHARACTERIZING THE BEHAVIOR OF SUSCEPTIBLE AND RESISTANT STRAINS OF ANOPHELES GAMBIAE AT THE LLIN INTERFACE USING SIMPLE NEW LABORATORY VIDEO TESTS

**Angela Hughes**, Hilary Ranson, Philip McCall  
*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

The central role of long-lasting insecticidal nets (LLINs) in malaria prevention in Africa is threatened by pyrethroid resistance. Investigating how mosquito populations interact with different LLIN types is fundamental to understanding the nature of resistance, evaluating new net treatments and managing future resistance emergences. We used two new simple bench top tests, the Cone Video test and the Thumb test, to explore detailed behavioral events associated with insecticide exposure, in two insecticide susceptible and two resistant strains of *Anopheles gambiae* at three LLIN types (PermaNet® 2.0, Olyset® and Duranet®). The Cone Video test employs scan sampling to quantify activity during a standard WHO cone test (resting on net, cone or in flight; 5 mosquitoes; 3min) using a cellphone camera. In all tests, susceptible and resistant mosquitoes rested preferentially on untreated and treated netting except for susceptible mosquitoes on Olyset®, where net contact was significantly reduced compared with other LLINs. Non-contact assays suggest this reduced contact was due to irritancy induced by contact with the net surface rather than repellency; interestingly this effect was not seen in

pyrethroid resistant populations. Reduction in net contact correlated with mortality post-exposure. The Thumb test video records detailed events of a single mosquito at a human-baited LLIN interface, with or without blood feeding. Here, susceptible and resistant mosquito strains readily fed through all LLIN types though the duration of the blood meal was reduced in both strain types when feeding through an LLIN compared to an untreated net. The results of both assays will be compared and considered in relation to behavioral data from other studies. The results demonstrate the potential of these simple assays for increasing understanding of the repellent or contact irritant properties of existing and new insecticides or LLINs, and the full characterization of their modes of action.

## 1966

### DELTA METHRIN RESISTANCE IN Aedes Aegypti RESULTS IN VECTOR CONTROL FAILURE IN MERIDA, MEXICO

**Gonzalo M. Vazquez-Prokopec**<sup>1</sup>, Anuar Medina-Barreiro<sup>2</sup>, Azael Che-Mendoza<sup>3</sup>, Felipe Dzul-Manzanilla<sup>3</sup>, Fabian Correa Morales<sup>3</sup>, Guillermo Guillermo-May<sup>2</sup>, Wilbert Bibiano-Marin<sup>2</sup>, Valentin Uc-Puc<sup>2</sup>, Eduardo Geded-Moreno<sup>2</sup>, Jose Vadillo-Sanchez<sup>2</sup>, Scott A. Ritchie<sup>4</sup>, Audrey Lenhart<sup>5</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Autonomous University of Yucatan, Merida, Mexico, <sup>3</sup>Centro Nacional de Programas Preventivos y Control de Enfermedades (CENAPRECE), Mexico City, Mexico, <sup>4</sup>James Cook University, Cairns, Australia, <sup>5</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Insecticide resistance has emerged as a worrisome outlook for the implementation of insecticide-only approaches to vector control. Particularly for *Aedes aegypti*, it is generally argued that this rapid rise of insecticide resistance may compromise the effectiveness of control programs. Yet, empirical evidence of such negative operational impact is lacking. We present results from a randomized controlled trial performed in the city of Merida, Mexico, quantifying the efficacy of indoor residual spraying (IRS) against adult *Ae. aegypti* in houses treated with either deltamethrin (to which local *Ae. aegypti* expressed a degree of resistance) or bendiocarb (to which local *Ae. aegypti* were susceptible) as compared to untreated control houses. This trial was designed to quantify the operational impact of deltamethrin resistance on the efficacy of insecticide applications to control *Ae. aegypti*. Indoor residual spraying (an effective method to control *Ae. aegypti*) was performed from October 31 to November 22, 2015 and aimed at full coverage of entire city blocks and close entomological monitoring consisting of indoor adult collections using Prokopack aspirators at 2 weeks prior to spraying (baseline) and at 15 days, and 1, 2 and 3 months post-spraying. While no statistical differences between treatment and control houses were found for all adult *Ae. aegypti* infestation indices at baseline, post-spraying *Ae. aegypti* infestation and abundance were significantly lower in houses treated with bendiocarb compared to untreated houses (odds ratio <0.75, P<0.05; incidence rate ratio < 0.65, P<0.05) whereas no statistically significant difference was detected between the untreated and the deltamethrin-treated houses. On average, bendiocarb spraying reduced *Ae. aegypti* abundance by 60% during a 3-month period. Results demonstrate that vector control efficacy can be significantly compromised when the insecticide resistance status of *Ae. aegypti* populations is not taken into consideration.

## 1967

**TOXOCARA INFECTION IN AN ECUADORIAN BIRTH COHORT: FROM BIRTH TO 5 YEARS OF AGE**

Yisela Oviedo<sup>1</sup>, Martha Chico<sup>1</sup>, Maritza Vaca<sup>1</sup>, Sofia Loor<sup>1</sup>, Mauricio L. Barreto<sup>2</sup>, Neuza Alcantara-Neves<sup>2</sup>, Philip Cooper<sup>3</sup>

<sup>1</sup>Fundacion Ecuatoriana Para Investigacion en Salud, Quito, Ecuador, <sup>2</sup>Universidade Federal da Bahia, Salvador, Brazil, <sup>3</sup>Universidad Internacional de Ecuador, Quito, Ecuador

Human infection with toxocarasis is a systemic zoonotic helminth infection with worldwide distribution but which is most prevalent among populations living under conditions of poor hygiene in tropical regions. Infection is acquired through accidental exposure to embryonated eggs of *Toxocara canis* and *Toxocara cati*, excreted in the faeces of the definitive hosts, dogs and cats, respectively. Although *Toxocara* infections can be transmitted through the intrauterine route in natural and paratenic hosts, there are few data on possible *in utero* transmission in humans. Further, there is limited information from humans on the burden of disease morbidity attributable to these infections in endemic populations. To address these questions, we have been using data and stored samples from an ongoing birth cohort, the ECUAVIDA cohort, of 2404 newborns and their mothers recruited in a rural District of Esmeraldas Province in coastal Ecuador. For the present analysis, plasma samples collected from a sample of 290 mothers and their children at birth (cord blood), 7, 13, 24, 36, and 60 months were analyzed for the presence of IgG antibodies to *Toxocara canis* excretory-excretory substances (TES) by ELISA. TES-specific antibodies were detected in 80.3% of mothers and in 84.1%, 0%, 9.3%, 48.4%, 64.9%, and 80.9% of children at 7, 13, 24, 36, and 60 months, respectively. The incidence rate of infection was greatest during the second year of life (39.3% of seronegatives) and seroprevalence reached that of the children's mothers (i.e. >80%) by 5 years of age. Significant risk factors for infection varied by age but consistently included household dogs and or cats. Our data indicate lack of *in utero* transmission of *Toxocara* infection in a hyper-endemic region of Ecuador with rapid acquisition of infection between 7 months and 24 months of age. Future analyses will estimate the burden of disease that can be attributed to *Toxocara* infection in this cohort.

## 1968

**SEROPREVALENCE OF ANTIBODIES TO TOXOCARA SPECIES IN THE UNITED STATES AND ASSOCIATED RISK FACTORS, 2011-2014**

Eugene W. Liu<sup>1</sup>, Holly M. Chastain<sup>1</sup>, Sun Hee Shin<sup>1</sup>, Ryan Wiegand<sup>1</sup>, Deanna Kruszon-Moran<sup>2</sup>, Sukwan Handali<sup>1</sup>, Jeffrey L. Jones<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention - National Center for Health Statistics, Hyattsville, MD, United States

Toxocarasis results from infection with larval stages of a dog and cat intestinal nematode and causes human morbidity. Current US estimates of *Toxocara* exposure are over 17 years old. We used a multiplex bead based assay (Tc-CTL-1MBA) with purified *Toxocara canis* antigen to estimate *Toxocara* antibody seroprevalence in serum of 13,509 persons six years and older from the National Health and Nutrition Examination Survey (NHANES), 2011-2014 and identified seropositivity risk factors. We tested a subset of 500 samples with the *T. canis* enzyme immunoassay test previously used in NHANES III (1988-1994) to estimate seroprevalence had the prior survey samples been tested by Tc-CTL-1MBA. The age standardized estimate of *Toxocara* seroprevalence was 5.0% (95% confidence interval [CI], 4.2%-5.8%), lower than previously reported in 1988-1994 even accounting for increased Tc-CTL-1MBA specificity. Risk factors for seropositivity from multiple logistic regression were older age (odds ratio [OR], 2.1; 95%CI, 1.1-3.9 in 50-59 year olds; OR, 1.7; 95%CI, 1.0-2.8 in 60-69 year olds; and OR, 2.6; 95%CI, 1.5-4.7 in ≥70 year olds versus 6-11 year olds), non-Hispanic Black race/Hispanic origin (OR, 1.4;

95%CI, 1.0-2.0 versus non-Hispanic White), male sex (OR, 1.9; 95%CI, 1.6-2.2), living below poverty level (OR, 1.9; 95%CI, 1.4-2.6), a household with >0.5 persons per room (OR, 1.3; 95%CI, 1.0-1.6), less than college education (OR, 1.9; 95%CI, 1.5-2.4), and birth outside the United States (OR, 3.6; 95%CI, 2.6-5.1). *Toxocara* seroprevalence estimates in 2011-14 were lower than in a study from NHANES III, 1988-94, but seropositivity risk factors remained the same. These findings could help frame prevention efforts.

## 1969

**CHARACTERIZING SOIL-TRANSMITTED HELMINTH SINGLE AND MULTIPLE INFECTIONS RESPONSE TO TREATMENT WITH BENZIMIDAZOLES AND OTHER DRUGS**

Piero L. Olliaro<sup>1</sup>, Michel Vaillant<sup>2</sup>, Aissatou Diawara<sup>3</sup>, Eliézer K. N'Goran<sup>4</sup>, Shaali Ame<sup>5</sup>, Xiao-Nong Zhou<sup>6</sup>, Marco Albonico<sup>7</sup>, Benjamin Speich<sup>8</sup>, Stefanie Knopp<sup>8</sup>, Peter Steinmann<sup>8</sup>, Juerg Utzinger<sup>8</sup>, Jennifer Keiser<sup>8</sup>

<sup>1</sup>Special Programme for Research and Training in Tropical Diseases (World Health Organization/TDR), Geneva, Switzerland, <sup>2</sup>Luxemburg Institute of Health, Luxembourg, Luxembourg, <sup>3</sup>Biology program, Division of Science and Mathematics, New York University Abu Dhabi (NYUAD), Abu Dhabi, United Arab Emirates, <sup>4</sup>Université Félix Houphouët-Boigny de Cocody-Abidjan, Abidjan, Côte D'Ivoire, <sup>5</sup>Public Health Laboratory-Ivo de Carneri, Chake Chake, United Republic of Tanzania, <sup>6</sup>National Institute of Parasitic Diseases, Chinese Center for Disease Control and Prevention, Shanghai, China, <sup>7</sup>Centre for Tropical Diseases, Negrar, Verona, Italy, <sup>8</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

The benzimidazoles albendazole and mebendazole are given as preventive chemotherapy to school-aged children or entire communities for soil-transmitted helminthiasis caused by *Ascaris lumbricoides* (Al) *Trichuris trichiura* (Tt) and hookworm (Hw). Efficacy varies with the species, location and time. A database made of 12 clinical trials of albendazole (alone and combinations), mebendazole (alone and combinations), other treatments, or placebo was analysed to characterise infections and study treatment effects on individual and multiple species. Baseline infection intensities were expressed as eggs per gram of faeces (EPG); treatment outcomes were expressed as egg reduction rates using arithmetic means (ERR) and as distribution of individual-participant ERR (where no change or an increase was expressed as 0%). 4,981 patients were diagnosed with 9,525 infections overall with one (35%) or several STH species (65%): Al 21%, Tt 45% and Hw 34%. Baseline infection intensity was significantly higher for each STH species in co-infections than mono-infections. The ERR met the WHO minimal efficacy criteria of >95% for Al, >50% for Tt and >90% or >70% for Hw in just 55% of studies of albendazole and mebendazole alone or in combination, independent of whether mono- or multiple-infections. Considering individual responses, placebo achieved 100% ERR (hence cure) in 19% of Al and 11% of Tt and Hw infections. Albendazole alone gave ERR=0 in 1%, 27% and 8% of Al, Tt and Hw infections, and ERR=100% in 79%, 52% and 45%, respectively. The equivalent figures for mebendazole are 2%, 22% and 26%; and 93%, 25% and 21%. All treatments were compared through network meta-analysis. Co-infections were frequent and had higher infection intensities, but did not influence treatment performance. Just over half of treatments meet the WHO minimal efficacy criteria. Individual ERR response distributions allow identifying the proportions of suboptimal responders and comparing treatment performances.

## 1970

**A SINGLE DOSE OF IVERMECTIN, DEC PLUS ALBENDAZOLE IS SUPERIOR TO DEC PLUS ALBENDAZOLE FOR TREATMENT OF TRICHURIS TRICHIURA IN INDONESIA**

Taniawati Supali<sup>1</sup>, Yenny Djuardi<sup>1</sup>, Michael Christian<sup>1</sup>, Elisa Iskandar<sup>1</sup>, Roosпита Maylasari<sup>1</sup>, Sarah Wondmeh<sup>2</sup>, Gary J. Weil<sup>2</sup>, Peter U. Fischer<sup>2</sup>

<sup>1</sup>University of Indonesia, Jakarta, Indonesia, <sup>2</sup>Washington University School of Medicine, St. Louis, MO, United States

*Trichuris trichiura* is a prevalent soil transmitted helminth (STH) in Indonesia and known for its poor susceptibility to common anthelmintics including benzimidazoles. Therefore, lymphatic filariasis (LF) elimination programs using diethylcarbamazine (DEC) combined with albendazole (DA) may have suboptimal effects on STH. Recently, a new regimen combining ivermectin, DEC and albendazole (IDA) was studied in a large community clinical trial for LF. As part this study, we have compared the efficacy of a single dose of IDA and DA against STH infection. Residents in a village in Southwest Sumba District were treated either with IDA or DA. A total of 262 participants provided stool samples at two time points, before treatment and two to four weeks after treatment. The presence of STH and the fecal egg count per gram (EPG) were determined using the Kato-katz method. Baseline infection rates for *Ascaris lumbricoides*, hookworm, and *Trichuris trichiura* in the study area were 30.5%, 75.6%, and 78.2%, respectively. There were no significant differences of STH prevalence rates between the IDA and DA groups at baseline. Following treatment, prevalence of any STH infection differed significantly between the two groups (85.5% vs 51.5%, respectively), especially for *T. trichiura* (67.7% vs 12.0%). Reduction of infection intensity for each species was significant in both groups (all  $p < 0.0001$ ). The STH cure rate (CR) was significantly higher in the IDA group (48.1%) compared to the DA group (13.3%,  $p < 0.0001$ ). Analysis by species showed only for *T. trichiura* a significant difference in the CR (IDA 89.1% vs DA 26.5%) as well as in the incidence of new infections (IDA 15.9% vs DA 46.2%). The egg reduction rate (ERR) of *T. trichiura* was also higher in the IDA compared to the DA group (94.1% vs 40.1%). The triple drug therapy using IDA showed higher efficacy against *T. trichiura* compared to the current standard regimen for LF elimination using DA. This result supports the inclusion of ivermectin in LF and STH elimination programs in Indonesia.

## 1971

**SOIL-TRANSMITTED HELMINTH INFECTION AND MASS DRUG ADMINISTRATION IN MYANMAR: ARE ADULTS PERPETUATING TRANSMISSION?**

Julia C. Dunn<sup>1</sup>, Alison A. Bettis<sup>1</sup>, Nay Yee Wyine<sup>2</sup>, Aye Moe Moe Lwin<sup>3</sup>, Nay Soe Maung<sup>3</sup>, Roy M. Anderson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Myanmar NTD Research Collaboration, Yangon, Myanmar, <sup>3</sup>University of Public Health, Yangon, Myanmar

Myanmar has had ongoing mass drug administration (MDA) programmes against soil-transmitted helminths (STH) and lymphatic filariasis (LF) for at least 14 years. Data reported to the WHO preventive chemotherapy (PCT) databank show national coverage of the STH MDA programme, annually treating school-aged children (SAC) with albendazole, has been above 75% since 2006. However, national coverage of the separate LF MDA programme, which annually treats the whole community with albendazole and DEC, has only been above 75% since 2014. Few epidemiological studies include adults, preferring to focus on SAC. However, MDA compliance is usually lower in the older age groups and it is possible that treatment is insufficient in these age groups to adequately reduce prevalence and intensity. Our epidemiology study, conducted in two villages in lower Myanmar that have received four years of MDA ( $n=659$ ), recorded an overall prevalence of 20.5% STH infection, with 16.9% STH infection in adults. Whilst STH infection remains higher in SAC (28.5%),

there is a substantial burden of infection in adults. Prevalence of infection with any STH is statistically different between pre-SAC, SAC and adults ( $p=0.002$ ). The most prevalent STH species overall, and in each age group, was *Trichuris trichiura*. Only 6.33% of infected adults were infected with more than one STH species. When analysing STH prevalence in adults alone ( $n=467$ ) we found no statistical difference between the study villages, sex of study participant, education level or whether the participant shared a household with children. However, there was a statistically significant difference between stratified age groups within the adult age class ( $p=0.002$ ), with prevalence decreasing as adult age group increased. In conclusion, despite adults in these Myanmar communities receiving annual MDA for four years, STH prevalence is surprisingly high. Further study is required to better understand STH infection in adults if country NTD control programmes plan on targeting elimination. Adults are likely acting as an important reservoir of infection, perpetuating transmission in the community.

## 1972

**ENZYME-LINKED IMMUNOSORBENT ASSAY AS AN ENDGAME DIAGNOSTIC METHOD FOR SOIL-TRANSMITTED HELMINTH INFECTIONS**

Rita G. Oliveira<sup>1</sup>, Alice V. Easton<sup>2</sup>, Poppy H. Lamberton<sup>3</sup>, Johnny Vlaminck<sup>4</sup>, Coreen M. Beaumier<sup>5</sup>, Jimmy H. Kihara<sup>6</sup>, Sammy M. Njenga<sup>6</sup>, Charles S. Mwandawiro<sup>6</sup>, Peter Geldhof<sup>4</sup>, Chris Drakeley<sup>7</sup>, Simon J. Brooker<sup>8</sup>, Roy M. Anderson<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>National Institutes of Health, Washington, DC, United States, <sup>3</sup>University of Glasgow, Glasgow, United Kingdom, <sup>4</sup>Ghent University, Merelbeke, Belgium, <sup>5</sup>Baylor College of Medicine, Houston, TX, United States, <sup>6</sup>Kenya Medical Research Centre, Nairobi, Kenya, <sup>7</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>8</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States

With the success of mass deworming programmes against soil-transmitted helminths (STH) and the known limitations of the current techniques, improved diagnostic methods are necessary to ensure detection of low-intensity infections. Immunoassays measuring antibody titres against specific STH antigens can provide a new way of measuring programme impact and recording rates of reinfection. A study was conducted in Bungoma District, western Kenya, where blood and stool samples were collected from 2273 individuals during two cross-sectional surveys in Mar-Apr and Aug-Sep 2014. Stool samples were analysed using duplicate Kato-Katz and intensity of infection recorded as eggs-per-gram (EPG). Plasma was extracted from the blood samples and analysed by indirect enzyme-linked immunosorbent assay (ELISA) to measure antibody titres against two *Necator americanus* recombinant proteins (Na-ASP-2 and Na-SAA-2) and two *Ascaris* antigens, A. suum haemoglobin (AsHb) and A. lumbricoides extract. Prevalence and intensity of infection were analysed together with antibody seroprevalence against the four antigens, searching for correlations between EPG and antibody titres at individual and community level, as well as changes in seroprevalence post-community-wide deworming. Despite a positive correlation between the age-prevalence profile of *N. americanus* and seroprevalence of Na-ASP-2, no other correlations were found between infection status or EPG levels and antibody titres, and no significant changes in seroprevalence were found three months after deworming treatment. There was also some evidence of cross-reactivity between the four antigens tested. Immunoassays might be used as alternative diagnostic methods in populations targeted by deworming programmes, but cross-reactivity between species and difficulties in distinguishing between past, prepatent and current infections remain. Their use might be limited to an analysis of community-wide exposure rather than accurate individual diagnosis of present or past infection. In the endgame, seroconversion in young children could be a good marker of continued exposure to infection.

## 1973

**POOL THE STOOL: POOLING STOOL SAMPLES AS A STRATEGY FOR INCREASING THE EFFICIENCY AND EFFECTIVENESS OF REAL-TIME PCR FOR SOIL-TRANSMITTED HELMINTHS (STH)**

Marina Papaïakovou<sup>1</sup>, Nils Pilotte<sup>1</sup>, Yan Hu<sup>2</sup>, Raffi V. Aroian<sup>2</sup>, Judd L. Watson<sup>3</sup>, Steven A. Williams<sup>1</sup>

<sup>1</sup>Smith College, Northampton, MA, United States, <sup>2</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>3</sup>University of Washington, Seattle, WA, United States

Due to mass-drug administration (MDA) efforts the incidence of soil-transmitted helminth (STH) infection is declining in many countries. As such declines occur, the need for cost-effective and sensitive strategies capable of monitoring the changing rates of infection is becoming increasingly critical. While PCR-based molecular techniques have repeatedly demonstrated their improved diagnostic capacities, the costs of DNA-isolation and subsequent PCR screening can be prohibitively high. Accordingly, sample pooling strategies, capable of reducing the costs associated with such screening efforts, would provide one means of potentially overcoming these economic obstacles. Such strategies have previously been utilized for the molecular testing of urine, blood and vector insect samples, and the capacity to detect soil-transmitted helminths in pooled stool samples has been previously evaluated using microscopy-based diagnostic techniques. In this study, we aimed to demonstrate that a similar pooling approach would not substantially reduce the sensitivity of real-time PCR-based detection of soil-transmitted helminths, when compared with the testing of individual human stool samples. Accordingly, pools of 5, 10 and 20 samples with a series of known egg-per-gram (epg) concentrations, 0 epg (control), 20 epg, 50 epg, 100 epg and 200 epg were prepared for six human-infecting species of STH (*Necator americanus*, *Ancylostoma duodenale*, *Ancylostoma ceylanicum*, *Strongyloides stercoralis*, *Trichuris trichiura* and *Ascaris lumbricoides*). Samples underwent DNA isolation, and resulting extracts were tested using previously validated and published multi-parallel real-time PCR assays for the detection of each species of STH. Results of testing have enabled us to identify the largest pool sizes that can be tested while still maintaining the required sensitivity at low epg concentrations. These results will help to guide programmatic decision making efforts with respect to sample pooling strategies, as the need to reduce the cost and labor associated with STH control efforts becomes increasingly pressing.

## 1974

**IMAGE-BASED TECHNOLOGY IDENTIFIES CANDIDATES FOR THE IN VITRO SINGLE-TREATMENT OF *TRYPANOSOMA CRUZI* AND *TRYPANOSOMA BRUCEI* PARASITES FROM THE MMV PATHOGEN BOX COLLECTION OF COMPOUNDS**

Melissa L. Sykes

Eskitis Institute for Drug Discovery, Brisbane, Australia

Chagas disease, endemic to 21 countries in the Americas, is caused by the protozoan parasite *Trypanosoma cruzi* and is recognized by the World Health Organisation as one of the world's 17 most neglected tropical diseases. The disease causes some 14 000 deaths per year and a further 8 million people are threatened with *T. cruzi* infection. Treatment of Chagas disease is limited to the drugs which have associated side effects and display lack of efficacy against the chronic phase of the disease. *Trypanosoma brucei* sub-species cause Human African Trypanosomiasis (HAT), endemic to 36 countries within sub-Saharan Africa. This disease moves through clinically distinct clinical phases and in the latter, parasites cross the blood brain barrier and infection is difficult to treat. In addition, treatment regimens are complicated and not effective against all species. To identify much-needed new compounds with activity against *T. cruzi*, a phenotypic, high-content, 384-well image-based assay was developed to identify *T. cruzi* amastigotes within host cells following compound

exposure. In the same well, the effect of compound activity on host cells is determined. This assay was used to profile the activity of the Medicines for Malaria (MMV) Pathogen Box collection, containing 400 compounds selected for chemical diversity and drug-like properties. Fifteen compounds exhibited selective and unpublished activity against the parasite and 12 of these compounds were also active against *T. brucei* parasites. The majority of the IC50 values of these compounds were sub- $\mu$ M and provide a resource of potential new targets shared by these kinetoplastid parasites. To establish the most effective molecules for prioritisation, compound time to kill and maximum efficacy were investigated. As a preliminary identification of the mode of action, the impact of these molecules on parasite mitochondrial health and replication were investigated utilising Mitotracker Red and nucleoside analogues, respectively. Novel to *T. cruzi* drug discovery, nucleoside analogues were coupled with click chemistry for the image-based assessment of parasite replication.

## 1975

**ANTI-LEISHMANIAL LUCIFERASE BASED IN VITRO HIGH THROUGHPUT SCREENING OF INTRACELLULAR AMASTIGOTES OF GEOGRAPHICALLY DIVERSE PARASITES**

Mozna Khraiweh, Erica Penn, Susan Leed, Juan Mendez, Chad Black, Mara Kreishman-Deitrick, Mark Hickman, Brian Vesely  
Walter Reed Army Institute of Research, Silver Spring, MD, United States

Leishmaniasis is a neglected vector-borne tropical disease caused by a protozoan of the genus *Leishmania*. The clinical spectrum of leishmaniasis ranges from self-healing cutaneous ulcers to an irreparable damage of the soft and cartilaginous tissues and even to fatal systemic illness. Most of the drugs available today are difficult to use, have unpleasant side effects, and have variable efficacy. Consequently, there is a continued search for safer, less expensive and more effective drugs. Experimental Therapeutics' (ET) mission is to develop drugs to treat cutaneous leishmaniasis for US service members. ET's testing paradigm focuses primarily on evaluating compounds' activity on *L. major*, starting with *in vitro* IC50s of intracellular amastigotes. Promising compounds from the *L. major* screen can now be evaluated further on a geographically diverse set of parasites. In this study, a pLEXY-hyg based vector was used to generate *Leishmania* parasites that constitutively express the firefly luciferase gene. These nine transgenic species (*L. major*, *L. guyanensis*, *L. infantum*, and *L. mexicana*, and *L. panamensis*, *L. donovani*, *L. tropica*, *L. amazonensis*, and *L. peruviana*) were evaluated in comparison to their wild type counterparts and characterized for their utility for use in a high throughput screening format to find novel, broad-spectrum anti-Leishmanial compounds with activity against geographically diverse parasites.

## 1976

**COORDINATE REGULATION OF CELLULAR PROCESSES BY INOSITOL PHOSPHATES DURING *TRYPANOSOMA BRUCEI* LIFE CYCLE DEVELOPMENT**

Ken Stuart, Atashi Anupama, Igor Cestari

Center for Infectious Disease Research, Seattle, WA, United States

*Trypanosoma brucei* changes surface protein, metabolism and morphology during its life-cycle. In the mammalian host bloodstream forms (BFs) differentiate into stumpy BFs, then to procyclic forms (PFs) in the fly midgut and to other stages in the salivary gland. We showed that the inositol phosphate pathway helps regulate these developmental steps. Three genes that affect PI(4,5)P2, function in regulating surface protein expression and antigenic variation. Knockdown of inositol polyphosphate 5-phosphatase (IP5Pase), which dephosphorylates Ins(1,4,5)P3, (a product of the above enzymes) results in a cell density dependent differentiation of slender to stumpy BFs. Knockdown of inositol polyphosphate multikinase (IPMK), which phosphorylates Ins(1,4,5)P3, results in differentiation of BF to PF. This differentiation changes surface protein (VSG loss and procyclin expression), cell morphology, and the transcriptome. RNAseq following IPMK knockdown in BFs shows upregulated stage-specific gene sets

including those for sugar and amino acid transporters, cAMP signaling, oxphos, and specific RNA-binding proteins. MS analysis found that the IPMK substrate Ins(1,4,5)P3 affinity enriched proteins that function in signaling, protein synthesis and degradation whereas the IPMK product Ins(1,3,4,5)P4 enriched proteins that function in energy metabolism. In BFs IPMK and IP5Pase knockdowns, respectively, increased ATP production and decreased pyruvate release. Importantly, this increased ATP production was blocked by oxphos inhibitors showing de novo production of a functional oxphos system. Thus, IPMK functions in the regulation of the metabolic switch between glycolysis and oxphos and affects differential editing of mt mRNAs that encode oxphos components. IPMK knockdown also increased sensitivity to citrate/cis-aconitate induced differentiation, whereas by affecting cellular metabolite levels. These data indicate that inositol phosphates are part of the cellular regulatory network that controls *T. brucei* differentiation and development in a coordinated fashion during its life cycle.

## 1977

### UNDERSTANDING THE TRYPANOSOME LYTIC FACTOR (TLF) MEDIATED KILLING OF *LEISHMANIA* SP.

Jyoti Pant<sup>1</sup>, Maria Nelson<sup>2</sup>, Mert K. Keceli<sup>3</sup>, Jayne Raper<sup>1</sup>

<sup>1</sup>The Graduate Center, City University of New York, New York, NY, United States, <sup>2</sup>City University of New York, New York, NY, United States, <sup>3</sup>Hunter College, New York, NY, United States

Trypanosome Lytic Factor (TLF) is an innate immunity factor originally discovered for its ability to protect against *Trypanosoma brucei* subspecies. Recently, we have shown TLF can ameliorate infections by cutaneous *Leishmania* sp. in macrophages and mice. Here, we investigated if TLF is effective at killing *Leishmania* sp. within neutrophils; one of the first cells to take up the parasites *in vivo*. We found that depleting neutrophils in TLF expressing mice exacerbates the infection indicating that TLF effectively kills parasites within neutrophils. *In vitro* experiments suggest that this TLF mediated killing of *Leishmania* sp. metacyclic promastigotes occurs due to the direct interaction of TLF and *Leishmania* within the acidic phagosome of phagocytic cells. *In vitro* we find that metacyclics are killed by a two step process designed to mimic neutrophil uptake or macrophage uptake: TLF is first incubated in acidic media (pH 5.6 mimics the phagosome), which promotes the association of APOL1, the pore-forming protein of TLF, to the metacyclics. Then parasites are switched to neutral media to mimic the escape from neutrophil phagosomes and release into the serum. Herein, we find the parasite number is reduced but not eliminated. Alternatively if parasites are further acidified to pH 4.5 to mimic the parasitophorous vacuole of macrophages that amastigotes reside in, the metacyclics are completely lysed. Yet *in vivo* in presence of TLF, *Leishmania* can grow and cause disease. We propose this is due to the timely differentiation to amastigotes, the form that proliferates in macrophages *in vivo*. We find that axenic amastigotes are completely resistant to TLF *in vitro*. Preliminary data suggest that difference in surface glycoproteins composition between the metacyclics and amastigotes leads to difference in susceptibility of parasites to TLF.

### INTERFERING POLYAMINES METABOLISM IN TRYPANOSOMATIDS, A VALID APPROACH FOR DRUG DEVELOPMENT

Esteban A. Panozzo Zenere<sup>1</sup>, Exequiel O. Porta<sup>1</sup>, Diego Benitez<sup>2</sup>, Shane Wilkinson<sup>3</sup>, Sigrid C. Roberts<sup>4</sup>, Marcelo Comini<sup>2</sup>, Gut Jiri<sup>5</sup>, Juan Engel<sup>5</sup>, James McKerrow<sup>5</sup>, Babu Tekwani<sup>6</sup>, Guillermo R. Labadie<sup>1</sup>

<sup>1</sup>IQUIR, Rosario, Argentina, <sup>2</sup>Institute Pasteur, Montevideo, Uruguay, <sup>3</sup>Queen Mary University of London, London, United Kingdom, <sup>4</sup>Pacific University of London, Oregon, OR, United States, <sup>5</sup>University of California

San Francisco, San Francisco, CA, United States, <sup>6</sup>University of Mississippi, Mississippi, MS, United States

Chagas disease, leishmaniasis and sleeping sickness represent the major health condition with a wide range of disability for people who are infected with parasites from the family of trypanosomatids (*Trypanosoma cruzi* TC, *Leishmania donovani* LD, and *T. brucei* TB). Despite years of extensive research in this field, there is still no new therapeutic drug available in the market yet. Thus, for these neglected diseases a new era of antiparasitic medicine is required. To serve this purpose, we developed a strategy to build compounds in a very inexpensive synthesis process, with very high yields and Selectivity Index. In this present work we found that our compounds were very active against *T. cruzi* (N,N'-bis(isopropyl) bencyl-1,4 diamine, IC50 = 370 nM epi.) *L. donovani* (N,N'-bis(4-Bencyloxy-3-Methoxy)bencyl-1,10 diamine, IC50 = 16nM), or *T. brucei* (N,N'-bis(isopropyl)bencyl-1,4 diamine, IC50 = 29 nM bloodstream form). Interestingly, our studies showed that these compounds respond differently on each parasite and that is related to their structural features, like the selectivity toward TB or TC that could be rationalized in terms of certain physical-chemical properties. Additionally, the collection was also tested on the intracellular life stage of LD and TC. Having in mind the polyamine nature of the library prepared, different experiments related to polyamine metabolism and transport were conducted. Selected hits that also shown good parameters on ADME-Tox (in silico) were assayed against trypanothion synthetase of the three parasites studied and rescue experiment with polyamines metabolites were performed in LD. Finally, we designed and synthesized a fluorescent analog of the most active compounds and the incorporation and localization was studied in the TC amastigotes. We can conclude through analysis of this library that we have found some serious candidate for LD, TB and TC chemotherapy. We all the information collected, the action mechanism is not clear yet, but the compounds are multitarget including the transport process. More studies will be required to find the molecular target/s and action mechanism.

## 1979

### INCIDENCE OF SALMONELLA BACTEREMIA AMONG YOUNG CHILDREN IN SUB-SAHARAN AFRICA: MAL055 RTS,S/AS01 SALMONELLA ANCILLARY STUDY

Calman A. MacLennan<sup>1</sup>, Ryan Wiegand<sup>2</sup>, Nelli Westercamp<sup>2</sup>, Simon Kariuki<sup>3</sup>, Clinical Trials Partnership Committee Investigators<sup>4</sup>

<sup>1</sup>University of Oxford, Oxford, United Kingdom, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Kenya Medical Research Institute/Centers for Disease Control and Prevention, Kisumu, Kenya, <sup>4</sup>Clinical Trials Partnership Committee, Kisumu, Kenya

Salmonella enterica is a major cause of bacterial bloodstream infections in Africa, manifesting as typhoid fever and invasive nontyphoidal Salmonella (iNTS) disease. Robust up-to-date epidemiological data to support the development and implementation of new interventions including vaccines are currently lacking. Our aim was to determine incidence of Salmonella bacteremia in children under five years of age across sub-Saharan Africa using data from the phase 3 RTS,S/AS01 malaria vaccine trial (NCT20866619). Children aged 6-12 weeks (n=6537) and 5-17 months (n=8922) from 11 sites were recruited and randomized to receive RTS,S/AS01 or comparator vaccines. They were followed up for a median of 38 and 48 months respectively between 2009 and 2014. Blood cultures were performed for all children with fever leading to hospital admission. 257 microbiologically-confirmed cases of Salmonella bacteremia were detected during 50,280 person years of observation (PYO), with an overall incidence of 534 cases/100,000 PYO (95%CI 471-604). Incidence of bacteremia due to Salmonella Typhi (n=32, 12.5% of Salmonella bacteremias) was 66.5 (95%CI 45.5-93.9), and that for nontyphoidal Salmonella (NTS; n=222, 86.4%) was 461 (95%CI 402-526) cases/100,000 PYO. 90% (n=200) of the 222 cases of iNTS disease were due to two serovars of Salmonella, S. Typhimurium (n=136, 61%) and S. Enteritidis (n=64, 29%). Incidence of Salmonella bacteremia varied from 0 in Bagamoyo, Tanzania; Kilifi, Kenya; and Lamberene, Gabon, to 1280 (95%CI 961-1660) in Kintampo, Ghana,

and 1780 (95%CI 1420-2200) in Siaya, Kenya. NTS bacteremia, but not typhoid fever, was significantly associated with the number of malaria episodes during the trial, but NTS bacteremia was not reduced by RTS,S/AS01 compared with comparator vaccines (incidence rate ratio = 0.83 (95%CI 0.63-1.10)). These findings confirm Salmonella as a major and persistent cause of bacteremia among children under five years of age across sub-Saharan Africa with *S. Typhimurium*, Enteritidis and Typhi as the three commonest serovars. A vaccine able to protect against these serovars could have a major public health impact.

## 1980

### UNDERSTANDING THE POTENTIAL VALUE OF NEW DIAGNOSTICS FOR ENTERIC FEVER: INSIGHTS FROM DECISION ANALYTIC MODELING

Jason R. Andrews<sup>1</sup>, Paul Arora<sup>2</sup>, Isaac I. Bogoch<sup>3</sup>, Edward T. Ryan<sup>4</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, <sup>3</sup>University of Toronto, Toronto, ON, Canada, <sup>4</sup>Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

Enteric fever is responsible for an estimated 11.9 million illnesses and 129,000 deaths annually. Currently available diagnostics have limited accuracy, resulting in empirical management in which individuals with disease fail to receive appropriate antibiotics, while others receive unnecessary treatment. Several promising new typhoid diagnostics are in the development pipeline. Additionally, host immune biomarkers have demonstrated good accuracy in distinguishing bacterial from viral infections. To evaluate the potential clinical impact and cost-effectiveness of these new diagnostics, we developed a decision-analytic and cost-effectiveness model, simulating the treatment of individuals with acute febrile illnesses. We parameterized the model with disease, treatment, demographic, and cost data from studies in South Asia. In the base case, we assumed that 13% of patients had enteric fever; 26% had other bacterial infections (*Rickettsia*, leptospirosis, *E. coli*, *Strep* spp, etc); and 50% had viral infections. We use disability weights from the Global Burden of Disease study and mortality estimates from recent meta-analyses. We compared five diagnostic and treatment strategies: no diagnostics; Tubex TF (a rapid typhoid serodiagnostic); new rapid typhoid diagnostics; C-reactive protein (CRP); a new bacterial/viral biomarker. Multiway sensitivity analysis and probabilistic uncertainty analysis were performed, with variable importance evaluated by calculating partial rank correlation coefficients. In a population of 10,000 patients with acute febrile illnesses, Tubex TF and a new typhoid diagnostic would avert 132 and 525 DALYs, respectively, and averting \$23,000 and \$103,000 in healthcare costs. However, CRP or a new bacterial/viral biomarker would avert additional disability and costs compared with typhoid-specific diagnostics. In conclusion, while new typhoid diagnostics could yield health gains in endemic settings, biomarkers that distinguish bacterial from viral infections would have greater clinical impact and potentially yield cost-savings due to averted healthcare expenditures.

## 1981

### COMPARISON OF STRATEGIES AND THRESHOLDS FOR VI CONJUGATE VACCINES AGAINST TYPHOID FEVER: A COST-EFFECTIVENESS MODELING STUDY

Nathan C. Lo<sup>1</sup>, Ribhav Gupta<sup>1</sup>, Jeffrey D. Stanaway<sup>2</sup>, Denise O. Garrett<sup>3</sup>, Isaac I. Bogoch<sup>4</sup>, Stephen P. Luby<sup>1</sup>, Jason R. Andrews<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States, <sup>3</sup>Typhoid Programs, Sabin Vaccine Institute, Washington, DC, United States, <sup>4</sup>University of Toronto, Toronto General Hospital, Toronto, ON, Canada

Typhoid fever remains a major public health problem globally. While new Vi conjugate vaccines hold promise for averting disease, the optimal programmatic delivery remains unclear. We aimed to identify the strategies

and associated epidemiologic conditions under which Vi conjugate vaccines would be cost-effective. We developed a dynamic, age-structured transmission and cost-effectiveness model that simulated vaccination strategies with a typhoid Vi conjugate vaccine. We simulated a 10-year vaccination program through: (i) routine immunization of infants (<1 years) through the Expanded Program on Immunization (EPI) at 85% coverage; and (ii) EPI plus a catch-up campaign in school-aged children (5-15 years) at 75% coverage. Direct vaccination costs were estimated at a total of US\$ 3.50 per child for EPI and US\$ 4.00 per child for school catch-up based on literature and the recently approved rotavirus vaccine. We assumed a 1% case fatality rate for typhoid fever. The incremental cost-effectiveness ratio (ICER) was calculated in 2016 US\$ per disability-adjusted life year (DALY) averted. We defined strategies as highly cost-effective if the ICER was less than the GDP per capita of a low-income country (US\$1,035). Vi conjugate typhoid vaccines were highly cost-effective by routine immunization through EPI in settings with an annual incidence above 40 cases per 100,000, and for the combined strategy (EPI plus a catch-up campaign) in settings with an annual incidence above 100 cases per 100,000. The incidence threshold was highly sensitive to the typhoid-related case fatality rate, which contributed the majority of disease burden. Typhoid Vi conjugate vaccines would be highly cost-effective in low-income countries in medium incidence settings (40 annual cases per 100,000). These results were sensitive to case fatality rates, underscoring the need to consider rising antimicrobial resistance in the global vaccination strategy.

## 1982

### RICKETTSIAL INFECTIONS AS A MAJOR ETIOLOGY OF ACUTE FEBRILE ILLNESS: A PROSPECTIVE STUDY IN NORTHERN SABAH, BORNEO, EAST MALAYSIA

Megan E. Reller<sup>1</sup>, Mathew Grigg<sup>2</sup>, Timothy William<sup>3</sup>, Tsin Yeo<sup>4</sup>, Emily G Clemens<sup>5</sup>, J. Stephen Dumler<sup>5</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>Menzie School of Health Research, Darwin, Australia, <sup>3</sup>Queen Elizabeth Hospital, Sabah, Malaysia, <sup>4</sup>Nanyang Technological University, Singapore, <sup>5</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Serosurveys have documented rickettsioses in Malaysia, with *Orientia tsutsugamushi* (OT, the agent of scrub typhus) most frequent in urban and spotted fever group rickettsiosis (SFGR) in rural areas. However, SFGR and related typhus group rickettsioses (TGR) are not nationally reported and OT rarely (2 in both 2014 and 2015, incidence of 0.1 cases/million). In Sabah, 1 OT case in 2015 suggests an incidence of 0.3 cases/million. Rickettsioses remain unsuspected and untreated by regimens for acute febrile illness (AFI). We enrolled patients in 2 district hospitals in northern Sabah, Borneo, East Malaysia (Kudat, 2014 est. pop. 86,634 and Kota Marudu, 2014 est. pop. 69,163) from Dec 2013-Jan 2015. Acute and convalescent (paired) sera were obtained from febrile (38°C) patients without malaria. Sera (convalescent and if positive, acute) were screened for IgG (1:80) to OT, SFGR (*Rickettsia conorii*), and TGR (*R. typhi*) by IFA and then titrated to 2,560. Unpaired and selected paired acute-phase sera were screened (1:40) for IgM by IFA. An IgG titer  $\geq 160$  defined seroprevalent infection. A 4-fold IgG titer rise to  $\geq 160$  confirmed acute infection; those IgM-positive alone were probable. Of 123 convalescent sera, 21, 8 and 4 had acute infections with OT, SFG, and TG (12, 1 and 3 seroconversions) and 21, 8, and 9, respectively, seroprevalent infections; none were IgM-positive. Of 148 unpaired acute-phase sera, 1 was IgM-positive for OT, 3 for SFG, and 5 for TG. Overall, 33/123 (27%) had confirmed acute rickettsioses and 38 (31%) seroprevalent infections; 71 (58%) had confirmed acute or past rickettsioses (42 [34%] OT, 16 [13%] SFGR, 13 [11%] TGR). For OT, this results in an adjusted incidence of ~141 cases/million population in the region studied, and in Sabah of 6.5 cases/million (23-fold increase from Ministry of Health estimates). Acute-phase IgM was insensitive for the detection of acute rickettsioses. Since distinguishing acute and past infections requires convalescent sera and rickettsioses require specific therapy, further prospective studies that include paired serology are needed to determine the toll of untreated rickettsioses across Malaysia.

### TIMING AND SPATIAL HETEROGENEITY OF LEPTOSPIROSIS TRANSMISSION IN NORTHEAST THAILAND

Katharine A. Owers<sup>1</sup>, Soawapak Hinjoy<sup>2</sup>, James E. Childs<sup>1</sup>, Vincent Herbreteau<sup>3</sup>, Peter J. Diggle<sup>4</sup>, Albert I. Ko<sup>1</sup>

<sup>1</sup>Yale School of Public Health, New Haven, CT, United States, <sup>2</sup>Bureau of Epidemiology, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, <sup>3</sup>IRD, ESPACE-DEV (IRD, UM2, UR, UAG), Saint-Pierre, France, <sup>4</sup>Division of Medicine, Lancaster University, Lancaster, United Kingdom

Thailand experienced an explosive country-wide outbreak of leptospirosis in the late 1990s, followed by high endemic transmission. The key barrier to effective control has been a lack of knowledge about the factors driving the timing and spatial distribution of this persistent transmission. We obtained data on weekly leptospirosis incidence in the 320 districts of northeastern Thailand between 2000 and 2014 from the Thai passive notifiable disease surveillance system (R506). We modeled incidence using a spatiotemporally explicit Poisson model and first examined the effects of current and lagged rainfall and temperature (Thai Meteorology Department). We then collected data on environmental covariates—land use (Thai Land Development Department), livestock and irrigation (FAO), NDVI, NDWI, and elevation (Google Earth Engine)—and evaluated their effects on spatial variation in incidence. Between 2000 and 2014, 53,719 cases of leptospirosis were reported in northeastern Thailand. The timing of peak incidence varied between early August and mid-October and did not coincide with periods of rice planting or harvesting. Instead, weekly incidence was strongly associated with rainfall and temperature in the current and two prior weeks. Districts with high flooding propensity (NWDI, OR = 95.24 per 0.01 index point), a high percentage of rice paddies (OR = 1.057 per %), and low cattle density (OR = 0.98 per head) had significantly higher leptospirosis incidence. We also encountered significant spatiotemporal residuals in our model that appear to represent focal outbreaks. Our study found that rainfall and temperature, not specific events in the agricultural cycle, were the main determinants of peak transmission. We also identified specific environmental features associated with persistent high transmission which may serve as targets for prevention. However, in addition to this endemic pattern, outbreaks contribute to the burden of leptospirosis. Understanding the sources of these epidemics will be important for leptospirosis control in this region.

### 1984

### DNA AND RNA SEQUENCING-BASED METAGENOMICS FOR UNBIASED PATHOGEN DETECTION AMONG TANZANIAN ADULTS WITH UNDIFFERENTIATED FEBRILE ILLNESS

Matthew P. Rubach<sup>1</sup>, Erin H. Graf<sup>2</sup>, Kornelia Edes<sup>2</sup>, Holly M. Biggs<sup>1</sup>, Willbroad Saganda<sup>3</sup>, Bingileki F. Lwezaula<sup>3</sup>, Venance P. Maro<sup>4</sup>, John A. Crump<sup>1</sup>, Robert Schlager<sup>2</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>University of Utah, Salt Lake City, UT, United States, <sup>3</sup>Mawenzi Regional Referral Hospital, Moshi, United Republic of Tanzania, <sup>4</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania

In cohort studies of febrile illness in the tropics, conventional infectious disease diagnostics achieve a laboratory-confirmed diagnosis for only 40–50% of participants. We assessed the ability of unbiased next-generation sequencing-based metagenomics to identify an etiologic pathogen in Tanzanian patients with undifferentiated febrile illness (UFI, defined as the subset of febrile patients enrolled into our fever study who had no cough, diarrhea, stiff neck, or symptoms localizing to skin, soft tissue, joint or bone). Utilizing plasma samples from 65 UFI patients (median age 37 [interquartile range 23–45] years, 41 [63%] females) who had negative aerobic blood culture and negative malaria blood smear results, we performed RNA and DNA sequencing on the Illumina NextSeq and analyzed the sequencing output with Taxonomer, an ultra-rapid, web-based metagenomics data analysis tool. This unbiased metagenomics

approach detected an etiologic pathogen in 17 (26%) patients. *Plasmodium falciparum* was detected in 2 patients. Bacterial pathogens were detected in 8 patients: Enterobacteriaceae (n=3), Legionella spp. (n=2), and Mycobacterium sp., Pantoea sp., and Stenotrophomonas maltophilia (n=1 patient, respectively, for the latter 3 bacteria). Parvovirus B19 was detected in 7 patients. HIV was identified in 6 patients (subtype D, n=3; subtype C, n=2; subtype A1, n=1), and viruses of unclear pathogenicity were detected in 11 patients (anellovirus, n=7; and GB virus C, n=4). Independent molecular testing is underway to confirm the presence of each etiologic pathogen in the original plasma sample. Our findings indicate that among patients presenting with febrile illness in the tropics, unbiased metagenomics can increase the proportion of patients with a laboratory-confirmed diagnosis. Identification of unsuspected parvovirus B19 illness is consistent with findings from a metagenomics study of febrile illness in Kenya. Metagenomics pathogen detection has the potential to become an important diagnostic modality for epidemiologic surveillance of fever in the tropics.

### 1985

### SYSTEMIC INFLAMMATION AND NEURODEVELOPMENTAL OUTCOMES IN BANGLADESHI INFANTS GROWING UP IN ADVERSITY

Nona M. Jiang<sup>1</sup>, Fahmida Tofail<sup>2</sup>, Jennie Z. Ma<sup>1</sup>, Rashidul Haque<sup>2</sup>, Beth D. Kirkpatrick<sup>3</sup>, Charles A. Nelson, III<sup>4</sup>, William A. Petri, Jr.<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>University of Vermont, Burlington, VT, United States, <sup>4</sup>Boston Children's Hospital, Harvard Medical School, Boston, MA, United States

Hundreds of millions of children who grow up in poverty do not meet their full developmental potentials, which in turn affects their academic performance and future earnings. The identification of biomarkers that predict future neurodevelopmental outcomes offers a promising approach toward allowing for early identification of at-risk children. We previously published a study linking systemic inflammation to the neurodevelopment of children from a slum community in Dhaka, Bangladesh. We have validated our initial findings of systemic inflammation and neurodevelopment in a second cohort in Dhaka. We have also implemented advanced neuroimaging testing in these children via EEG, NIRS, and fMRI. We sought to determine whether elevated levels of the inflammatory markers CRP and soluble CD14 (sCD14) are associated with neurodevelopmental outcomes in Bangladeshi children. 422 infant-mother pairs from an urban slum in Dhaka, Bangladesh were enrolled at birth and followed prospectively. Inflammation was measured with sCD14, IL-1 $\beta$  and IL-6 at 18 weeks, and CRP at 6, 18, 40, and 53 weeks. Psychologists assessed cognitive, language, motor, and social emotional development using the Bayley Scales of Infant and Toddler Development at 78 and 104 weeks of age. We tested for the ability of inflammatory markers to predict developmental outcomes, independent of known predictors. Every 10 pg/mL increase in sCD14 was associated with a 1.1 to 2.0 decrement in cognitive and motor scores at 78 weeks and in all domains at 104 weeks. The cumulative number of CRP elevations that a child experienced in the first year of life, as well as IL-1 $\beta$  and IL-6 at 18 weeks of age, were also negative predictors of Bayley Scales results (all  $p < 0.05$ ). In conclusion, elevated CRP, sCD14, IL-1 $\beta$  and IL-6 were associated with lower neurodevelopmental outcomes. Our findings implicate a role of inflammation in the neurodevelopment of children growing up in adversity and identify a strategy to predict children at-risk for developmental impairment. Further studies are needed to identify cut-off levels of these biomarkers at which targeted interventions should be implemented.

**SURVEILLANCE OF MALARIA AMONG UNITED STATES PEACE CORPS VOLUNTEERS USING ELECTRONIC MEDICAL RECORDS**

Elizabeth Davlantes<sup>1</sup>, Lauren Lewis<sup>1</sup>, Susan Henderson<sup>2</sup>, Rennie Ferguson<sup>2</sup>, Kathrine Tan<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>Peace Corps, Washington, DC, United States

The United States Peace Corps has conducted surveillance for malaria and other diseases among Peace Corps Volunteers (PCVs) since 1985. In 2015, the surveillance system was incorporated into an electronic medical records (EMR) system. Peace Corps Medical Officers (PCMOs), who provide local medical support, chart clinical diagnoses and report surveillance data in the EMR, which is also retrievable at headquarters. We evaluated the utility of this new integrated system for malaria surveillance. We administered an email survey targeting all PCMOs and conducted semi-structured phone interviews with seven headquarters staff working with the EMR. We assessed the utility of four surveillance case definitions for malaria, including their sensitivity and positive predictive value. We compared clinical information in the EMR for all malaria cases captured between January and June 2016. Of 131 PCMOs, 77 (59%) responded to the survey. Of 53 respondents who work in malarious nations, 98% believe that most PCVs contact them when concerned that they have malaria. However, there was a gap between the number of cases documented in the EMR charts and the number of cases reported through the surveillance system. Of 134 cases with a malaria clinical diagnosis between January and August 2016, only 58 (43% sensitivity) were reported to the surveillance system by PCMOs. Headquarters staff estimate that 60% of all malaria cases in the surveillance system are identified by PCMOs, while 40% are added during data cleaning. However, cleaning is labor intensive (requiring up to 50 hours per month). Among the 48 cases in the EMR identified as malaria during the review period, positive predictive value was 67%. The EMR is an important tool for surveillance of malaria among PCVs and, with refinements in data quality and case definitions, could serve as a model for other multinational organizations wishing to monitor and protect the health of their staff.

Resilience, GA, United States

The clinical symptoms of malaria in naïve individuals has long been known to be associated with changes in multiple physiological parameters, such

as temperature and respiration. To better assess the clinical impact of malaria infections, an integrative analysis of multiple physiological signals was conducted using a stringent experimental animal model system as a part of the Host Acute Models of Malaria to study Experimental Resilience (HAMMER) project. Time series data including blood pressure, temperature, activity, and ECG was collected from nonhuman primates (*Macaca mulatta* and *Macaca fascicularis*) infected with *Plasmodium knowlesi* using customized telemetry implants. The customized telemetry devices allowed nearly uninterrupted *in vivo* collection of time series data during pre-infection, liver, and blood stages at high frequencies ranging from 1 to 1,000 Hz based on data type. This type of continuous data capture has not been previously used to study malaria infections. Multiple methods were used to conduct feature selection for pattern classification between stages of infection using the high-resolution time series data collected in the study. Our analysis reveals that there were perturbations to the physiological signals and circadian rhythms during the liver and blood stages. Changes in activity, temperature and ECG between pre-infection and the liver stage were detected highlighting novel characteristic physiological signals that may be unique to the liver stage development. However, the underlying physiological mechanisms remain unclear. Our study highlights and quantifies the association of various physiological signals with malaria progression in nonhuman primates providing the basis for a predictive model identifying the onset of malaria symptoms in humans.

A bespoke spatial decision support system (SDSS) was piloted in Phu Yen Province, Vietnam to support the implementation of malaria surveillance as a core intervention activity. This paper examines the development and user acceptance of SDSS surveillance tools to address key challenges to elimination in Vietnam and the Greater Mekong Subregion (GMS) including locating active malaria transmission, guiding targeted response interventions, and supporting the identification and investigation of suspected forest transmission sites and associated high risk populations. A customized SDSS was developed for three communes in Phu Yen. Village health workers conducted household geographic reconnaissance (GR) operations to map and enumerate all households in the study site. Detected malaria cases were recorded in the SDSS from 2015–2016 and auto-georeferenced to household residence locations. Case data were utilized in the SDSS to guide and map village level targeted response interventions. Remote area sleeping site surveys were also conducted during the study period and analyzed in the SDSS. User acceptability survey and in-depth interviews were conducted with SDSS stakeholders in March 2017. A total of 4,667 households with 17,563 people were mapped during baseline GR operations. During the study period, 128 malaria cases were reported and automatically mapped in the SDSS. Twelve village level targeted response interventions were conducted, testing a total of 872 people. Of those, 361 were investigated during remote-area sleeping site assessments. Intervention and remote-area sleeping site data were mapped and analyzed in the SDSS. Overall, very

high acceptability (100%) of the SDSS was reported by Vietnamese malaria personnel (n=16). Key areas identified for improvement included data collection form standardization and further training and support. The pilot SDSS provided an effective and acceptable operational tool for Vietnam's malaria personnel to implement the surveillance. Study findings call for further operational research, streamlining and wider rollout of SDSS surveillance approaches throughout Vietnam and the GMS.

## 1989

### CLIMATE VARIABILITY AND MALARIA TRANSMISSION IN ETHIOPIA: APPLICATION OF A NEW CLIMATE DATASET FOR DISTRICT-BASED MALARIA ELIMINATION STRATEGY

**Aduugna Woyessa<sup>1</sup>**, Aisha Owusu<sup>2</sup>, Madeleine Thomson<sup>2</sup>, Dereje Dilu<sup>3</sup>, Hiwot Solomon<sup>3</sup>

<sup>1</sup>*Ethiopian Public Health Institute, Addis Ababa, Ethiopia*, <sup>2</sup>*International Research Institute for Climate and Society, Palisades, NY, United States*, <sup>3</sup>*National Malaria Control Program, Federal Ministry of Health of Ethiopia, Addis Ababa, Ethiopia*

In Ethiopia, the influence of climate variability on malaria transmission and relationship of El Niño Southern Oscillation (ENSO) with malaria epidemics in the past is well documented. The National Malaria Control Program (NMCP)/Ministry of Health has been collaborating with the National Meteorological agency (NMA) since 2001 and demanding better tools to use climate information for decision-making at local level. However, the use of climate information for decision-making was impractical due to the complex nature of climate and its association with malaria in Ethiopia. The recent impetus of researchers in developing a new climate dataset known as Enhanced National Climate Services (ENACTS), a collaborative initiative between the NMA and International Research Institute for Climate and Society (IRI), helped to address the expectations of NMCP for a malaria elimination strategy. This strategy relies on a strong surveillance system at the lower administrative and planning units (districts). Thus, a district-based malaria surveillance suite was developed to inform the malaria community about climate. The proxy surveillance suite for malaria is designed to support implementation of malaria elimination through online information on (1) significant trends in three distinct seasons (March-April-May, July-August-September, October-November-December); (2) current and recent rainfall (decadal and cumulative); (3) climate suitability for malaria transmission; and (4) probabilities of temperature and rainfall occurrence associated with ENSO events. The development of the current proxy suite is a vital step for NMA in addressing the expectations of malaria community.

## 1990

### IN-HAND, IN-FIELD, IN-TIME DATA: EFFECTIVELY DIRECTING MOP-UPS IN AN INDOOR RESIDUAL SPRAY CAMPAIGN

**Anne C. Martin<sup>1</sup>**, Derek Pollard<sup>1</sup>, Silvia Renn<sup>1</sup>, Busiku Hamainza<sup>2</sup>, David Larsen<sup>3</sup>, Anne Winters<sup>1</sup>

<sup>1</sup>*Akros, Lusaka, Zambia*, <sup>2</sup>*National Malaria Elimination Center, Government of Zambia, Lusaka, Zambia*, <sup>3</sup>*Syracuse University, Syracuse, NY, United States*

Household-level interventions are necessary for many health and development challenges, and their success relies on informed decisions using timely and accurate data. Indoor Residual Spraying (IRS) is a key control intervention for malaria, and, with billions of dollars invested by the President's Malaria Initiative, is an enormous household level intervention. What's more, WHO recommends reaching 85% of households with IRS in a given area to successfully protect populations. Such significant investment and strict metrics for success, demand strategic technical approaches to optimizing implementation. mSpray, is an electronic data capture tool that improved data availability in the 2016 IRS campaign in Luapula Province. mSpray incorporates satellite enumeration in planning IRS, geospatial tracking in spray activities, and monitoring by district officers in daily planning. The key to mSpray's success is the use of

the technology in the field, in real-time, to uncover, correct, and respond to otherwise invisible enumeration errors. These corrections informed district officers in their daily planning for deployment of IRS spray teams. Officers reviewing coverage data for spray areas could see which spray areas had not reached adequate coverage and needed to be revisited. The number and success of revisits, then, acts as a proxy indicator for the effect of data-based decision-making. In 2016 in Luapula, 66.5% of spray areas were revisited. In these areas, spray effectiveness increased, on average, by an absolute 29.4 percentage points. This is incredibly significant in an intervention that requires reaching 85% coverage to deliver any effect. While mop-ups are recommended practice, they do add costs due to additional spray days. Additional investigation is needed to understand the cost-benefit of mSpray to guide decision making, as well as the costs of revisits and the level of communal protection additional spray coverage actually affords. This presentation will discuss the use of the tool, the data use culture it propagated, the results, and potential future and further applications.

## 1991

### TOWARDS INCORPORATION OF MALARIA CONTROL INTO PLANNING AND MANAGEMENT OF WATER INFRASTRUCTURE

**Jonathan Lautze<sup>1</sup>**, Solomon Kibret<sup>2</sup>, Matthew McCartney<sup>3</sup>, Luxon Nhamo<sup>1</sup>

<sup>1</sup>*International Water Management Institute, Pretoria, South Africa*, <sup>2</sup>*University of California, Irvine, CA, United States*, <sup>3</sup>*International Water Management Institute, Vientiane, Lao People's Democratic Republic*

There is growing acceptance that dams generally lead to elevated malaria risk in Africa. However, the aggregate effect of such dams on malaria - as well as the variables that enhance or attenuate this effect - are not thoroughly understood. This report highlights our work identifying the cumulative impact of large dams on malaria at present, as well as future impacts in the context of climate change, in Africa. The report also identifies key risk factors for elevated malaria transmission around dams and outlines how such risk factors can strengthen approaches to water resources planning and management. Methodologically, the work overlays locations of large and small dam reservoirs with data from Malaria Atlas Project (MAP) to determine impacts in communities close to v. far from reservoir shorelines. Population projections and malaria incidence estimates were used to predict future population at risk of malaria around large dams in IPCC Representative Concentration Pathways (RCP). A set of additional attributes are then considered to determine the degree to which they explain evidenced levels of malaria transmission around the reservoirs. Such additional parameters will include: i) dam size, ii) average slope along reservoir shoreline, iii) poverty levels in surrounding communities, iv) level of malaria transmission stability in which a dam is located. Results show that: i) at least 1.1 million people contract malaria each year due to their proximity to reservoirs, and as many as 15 million are at risk, ii) the size of the currently-affected population is likely to triple in the current century as a function of population growth and climate change - without even considering effects of new dam construction. Ultimately, formulation of control strategies that optimally respond to the elevated risk of malaria around dams will rest on identification and comprehension of how various risk factors combine with the presence of water reservoirs to affect malaria transmission. This report therefore reflects on work underway that assigns importance to key risk factors and describes relationships according to which their impact is manifested.

### BED NET EFFECTIVENESS VARIES BY INSECTICIDE ACROSS AFRICA: A LARGE, POPULATION-BASED OBSERVATIONAL STUDY

**Mark M. Janko**, Michael E. Emch, Steven R. Meshnick  
*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Insecticide-treated bed nets (ITNs) are critical for malaria control, and the World Health Organization estimates 68% of cases averted between 2001 and 2015 are due to ITNs. Continued success of ITNs depends on the continued efficacy of insecticides. However, resistance to pyrethroids has emerged across Africa. Monitoring resistance and developing countermeasures presents challenges. For example, insecticide resistance is geographically heterogeneous, and monitoring activities occur at only a small number of sites, limiting generalizability to a country's population. Further, resistance monitoring is dependent on bioassays, which cannot detect mosquito behavioral changes, or control for other factors important to transmission. Here, we address some of these limitations. Our aim was to assess the effect of bed nets treated with different insecticides on malaria risk across sub-Saharan Africa. We used data from 168,118 children younger than 5 years of age from 33 Demographic and Health Surveys (DHS) and Malaria Indicator Surveys (MIS) across sub-Saharan Africa from 2009 to 2016. We coded bed net use according to the insecticide used in the net, and used mixed effects logistic regression to estimate the association between sleeping under a net treated with different insecticides and odds of malaria infection, adjusting for potential confounders and stratifying by country and year. The two most widely used insecticides are deltamethrin (n=45,401) and permethrin (n=31,111). Sleeping under a deltamethrin-treated net was associated with odds of malaria infection ranging from 0.45 (95% CI 0.25 - 0.80, Gambia 2013) to 1.12 (0.92 - 1.35, Burkina Faso 2010). For permethrin-treated nets, odds of infection ranged from 0.40 (0.18 - 0.88, Burundi 2012) to 1.23 (0.86 - 1.77, Nigeria 2015). In conclusion, bed net effectiveness depends on insecticide used, and varies between countries and over time. Government and non-governmental organizations need to consider which insecticide is used in making decisions regarding bed net distributions to reduce malaria transmission. DHS and MIS surveys are valuable tools that can aid in such decision-making.

1993

### PTEX COMPONENT EXP2 IS REQUIRED FOR PROTEIN EXPORT AND SMALL MOLECULE TRANSPORT ACROSS THE MALARIA PARASITE VACUOLE MEMBRANE

**Josh Beck**<sup>1</sup>, Matthias Garten<sup>2</sup>, Svetlana Glushakova<sup>2</sup>, Armiyav S. Nasamu<sup>1</sup>, Jacquin C. Niles<sup>3</sup>, Joshua Zimmerberg<sup>2</sup>, Daniel E. Goldberg<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>Massachusetts Institute of Technology, Cambridge, MA, United States

Intraerythrocytic malaria parasites reside within a parasitophorous vacuolar membrane (PVM) generated during host cell invasion. Erythrocyte remodeling and nutrient acquisition requires export of effector proteins and import of small molecules across this barrier between the parasite surface and host cell cytosol. The Plasmodium translocon of exported proteins (PTEX) is crucial for protein export across the PVM, however the molecular basis of an observed PVM nutrient channel remains unknown. PTEX consists of three core proteins including the AAA+ ATPase chaperone HSP101 and two novel proteins known as PTEX150 and EXP2, hypothesized to serve a structural role and to form a membrane-spanning channel, respectively. While the critical importance of HSP101 and PTEX150 to protein export has been demonstrated, the contribution of EXP2 to parasite biology has remained obscure. To interrogate EXP2 function in *Plasmodium falciparum*, we employed the recently developed TetR-DOZI-apptamer system to achieve regulatable EXP2 translation. EXP2

knockdown revealed a critical role in protein export and blood-stage parasite survival. The expression timing and protein levels of HSP101 and PTEX150 are closely mirrored, peaking early in the ring stage. In contrast, EXP2 expression peaks in trophozoites, corresponding to an increased ratio of EXP2 to other PTEX components in the later part of the developmental cycle and implying a stoichiometry mismatch that suggests EXP2 may serve multiple roles in PVM biology. Accordingly, cell-attached patch clamp recordings on the PVM of extruded parasites revealed that the presence of the PVM nutrient channel is also dependent upon EXP2 expression levels. Importantly, inactivation of HSP101 blocks protein export but does not impact this channel. Collectively, our results suggest that EXP2 serves dual roles as a protein-conducting pore in the context of PTEX and as a channel to facilitate small molecule passage across the PVM independent of HSP101. Our data may indicate a seemingly unprecedented dual functionality for a pore operating in its endogenous context.

1994

### LINKING EPCR-BINDING PFEMP-1 TO BRAIN SWELLING IN PEDIATRIC CEREBRAL MALARIA

**Anne Kessler**<sup>1</sup>, Selasi Dankwa<sup>2</sup>, Maria Bernabeu<sup>2</sup>, Visopo Harawa<sup>3</sup>, Samuel Danziger<sup>2</sup>, Fergal Duffy<sup>2</sup>, Sam Kampondeni<sup>4</sup>, Michael Potchen<sup>5</sup>, Nicholas Dambrauskas<sup>2</sup>, Vladimir Vigdorovich<sup>2</sup>, Brian Oliver<sup>2</sup>, Noah Sather<sup>2</sup>, Ian MacCormick<sup>3</sup>, Wilson Mandala<sup>3</sup>, Stephen Rogerson<sup>6</sup>, John Aitchison<sup>2</sup>, Terrie Taylor<sup>4</sup>, Sarah Hochman<sup>7</sup>, Wenzhu Mowrey<sup>1</sup>, Karl Seydel<sup>4</sup>, Joseph Smith<sup>2</sup>, Kami Kim<sup>1</sup>

<sup>1</sup>Albert Einstein College of Medicine, Bronx, NY, United States, <sup>2</sup>Center for Infectious Disease Research, Seattle, WA, United States, <sup>3</sup>Malawi-Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, <sup>4</sup>Blantyre Malaria Project, Blantyre, Malawi, <sup>5</sup>University of Rochester Medical Center, Rochester, NY, United States, <sup>6</sup>University of Melbourne, Melbourne, Australia, <sup>7</sup>New York University Langone Medical Center, New York, NY, United States

Brain swelling is a key pathogenic process in pediatric cerebral malaria (CM), but the underlying mechanisms are incompletely understood. It is thought that sequestration in the brain microvasculature mediated by the variant parasite antigen PfEMP-1 is essential for disease. Prior var/PfEMP1 expression studies have identified a subset of parasites in severe pediatric malaria that bind endothelial protein C receptor (EPCR), a receptor on endothelial cells involved in blood-brain barrier regulation. We combined extensive clinical data, including MRI imaging, retinal funduscopy, and Pfhyp2-based estimates of parasite biomass, with var expression analysis and machine learning approaches to identify host and parasite factors associated with (1) stringently defined cerebral malaria [WHO criteria plus malarial retinopathy (Ret+CM)] and (2) pediatric CM cases with brain swelling. Increased brain volume/swelling was independently diagnosed and scored by two radiologists blinded to the clinical status of each case, and an onsite ophthalmologist performed retinal examinations to identify malarial-specific retinopathy. Using the aforementioned approaches, EPCR-binding PfEMP-1, high parasite biomass, and low platelet counts were strong indicators of Ret+CM and brain swelling. Of the EPCR-binding PfEMP-1 measured, CIDR $\alpha$ 1.1 (DC8) was highly expressed in Ret+CM cases, and CIDR $\alpha$ 1.7 (group A) had the strongest association with severe swelling and fatality. We then identified a CIDR $\alpha$ 1.7 domain expressed in brains of fatal (Malawian) CM cases that blocks EPCR's natural ligand (APC) from binding and inhibits the barrier protective properties of EPCR in human brain endothelial cells. Next generation sequencing of expressed var tags confirmed the contribution of CIDR $\alpha$ 1.7 in severe/swelling CM cases. Overall, our study suggests that *P. falciparum* interference with EPCR function is associated with Ret+CM and brain swelling in pediatric CM. This strengthens the rationale for targeting adjunctive treatments on restoring EPCR protective pathways in pediatric CM.

1995

### THE BONE MARROW AS A MAJOR RESERVOIR FOR *PLASMODIUM VIVAX* INFECTION

*Plasmodium vivax* is a major cause of malaria morbidity within and outside of Africa. Malaria transmission stages, or gametocytes, appear in blood circulation 3-5 days after the first asexual parasites are detected microscopically, and therefore transmission can occur well before the patient is symptomatic. It is assumed that both *P. vivax* asexual and gametocytes stages do not require tissue sequestration for development and therefore are present in circulation throughout their cycle. However, this hypothesis has not been rigorously tested. We recently discovered a significant bone marrow and spleen reservoir for *P. falciparum* gametocytes and the rodent malaria parasite *P. berghei*, suggesting that the reticulo-endothelial system may represent a conserved parasite reservoir across *Plasmodium* spp. The goal of the present study was to systematically assess *P. vivax* circulation dynamics and sequestration sites both in the non-human primate model and in human infections. Comparative transcriptional analysis of *P. falciparum* versus *P. vivax* gametocytes demonstrated a conserved cascade of stage specific gene expression until maturity despite significantly different cycle length. A subset of conserved asexual and gametocyte stage markers was successfully validated by quantitative Real-Time PCR (qRT-PCR) and antibody assays in peripheral blood samples from infected Aotus monkeys. To investigate possible tissue specific sequestration of *P. vivax* parasites during infection, we performed detailed histological analyses of asexual and gametocyte stages across organs. Analysis across 13 infected primates provided strong evidence for major accumulation of both asexual and gametocyte stages in the hematopoietic system of the bone marrow. Parallel transcriptional analysis of parasites in patient blood samples confirmed absence of these stages in circulation. These data suggest that the bone marrow plays an essential role in proliferation and transmission of malaria parasites.

1996

### FUNCTIONAL CONSERVATION OF AN ESSENTIAL HOST CELL INVASION LIGAND BETWEEN *PLASMODIUM FALCIPARUM* AND *P. VIVAX*, AND A PLATFORM TO ACCELERATE VACCINE DEVELOPMENT.

Damien R. Drew, Paul R. Sanders, Gretchen Weiss, Paul R. Gilson, Brendan S. Crabb, James G. Beeson

The Burnet Institute, Melbourne, Australia

Malaria caused by *Plasmodium vivax* is a major global health problem and the predominant form of malaria in many regions. Knowledge of key molecular events of host-cell invasion by *P. vivax* to guide vaccine and therapeutic development is limited, and lags behind that of *P. falciparum*, partly due to an inability to readily culture *P. vivax* *in vitro*. Apical Membrane Antigen 1 (AMA1) is a leading *P. falciparum* vaccine candidate and an orthologue is present in *P. vivax*, however, whether its function is conserved, or how it differs, has not been established. We report that AMA1 of *P. vivax* can functionally complement *P. falciparum*

AMA1 in invasion of erythrocytes. We generated novel chimeric parasites in which Pf-AMA1 was replaced with PvAMA1 in *P. falciparum* parasites; we observed efficient invasion with no observable change in growth or invasion phenotype. Antibodies raised against recombinant PvAMA1 specifically inhibited invasion of the chimeric parasites expressing PvAMA1, confirming that PvAMA1 plays an important role in parasite invasion. Furthermore, this established the approach as a powerful platform to accelerate vaccine and drug development. We established that the interaction of AMA1 with RON2 protein is involved in invasion for both *Plasmodium* species, and identified key structural determinants for invasion. Results indicate significant molecular flexibility in the AMA1-Ron2 interaction that enables conserved function despite substantial sequence divergence. These insights open new opportunities for vaccine and therapeutic development against *P. vivax*.

1997

### NANO-SCALE IMAGING REVEALS HOST CELL REMODELLING AND KNOB ASSEMBLY MECHANISMS IN *PLASMODIUM FALCIPARUM*

Oliver Looker<sup>1</sup>, Emma McHugh<sup>1</sup>, Boyin Liu<sup>1</sup>, Adam Blanch<sup>1</sup>, Shannon Kenny<sup>1</sup>, Dean Andrew<sup>1</sup>, Eric Hannsen<sup>2</sup>, Paul McMillan<sup>3</sup>, Leann Tilley<sup>1</sup>, Matthew W. Dixon<sup>1</sup>

<sup>1</sup>Department of Biochemistry and Molecular Biology, Bio21 Institute, University of Melbourne, Melbourne, Australia, <sup>2</sup>Melbourne Advance Microscopy Facility, Bio21 Institute, University of Melbourne, Melbourne, Australia, <sup>3</sup>Biological Optical Microscopy Platform, Bio21 Institute, The University of Melbourne, Melbourne, Australia

Survival of the human malaria parasite *Plasmodium falciparum* within the host relies on its ability to drastically alter its red blood cell (RBC) host. Parasite derived modifications of the RBC membrane skeleton alter the deformability properties of the RBC. These modifications underpin cytoadherence based virulence and severe disease states such as cerebral and placental malaria. This adhesion is driven by the assembly of a parasite derived structure at the RBC membrane skeleton called the knob which acts as a scaffold for the presentation of the major virulence antigen PfEMP1 at the RBC surface. The knob is composed of the knob associated his-rich protein (KAHRP) and together with PfEMP1 they form the virulence complex. In this work, we have defined the protein trafficking networks and the structural remodelling events that underpin parasite virulence. Using a mass spec based approach, we identify the protein composition of important PfEMP1 trafficking structures called Maurer's clefts. We GFP tagged 9 of the most abundant proteins and using an immunoprecipitation and mass spectrometry approach we assembled a comprehensive protein interaction network of proteins at the Maurer's clefts, which includes the virulence protein PfEMP1. We have developed a correlative light and electron microscopy technique, which combines dSTORM super resolution microscopy and scanning electron microscopy, to visualise host cell remodelling events. Using this technique, we have tracked the trafficking of KAHRP to the RBC membrane skeleton and its sequential assembly into donut shaped structures which insert into the membrane forming the knobs. Further to this we also track the delivery of PfEMP1 to the virulence complex.

1998

### ROLE OF THE AMP-ACTIVATED PROTEIN KINASE (AMPK) PATHWAY IN SCHISTOSOME DEVELOPMENT AND HOST-PARASITE INTERACTIONS

Kasandra Hunter, Stephen Davies

Uniformed Services University of the Health Sciences, North Bethesda, MD, United States

Schistosomes are obligate parasites, exhibiting auxotrophy for many compounds that must be acquired from the host in order to support parasite growth and development. In addition to key nutrients such as fatty acids, cholesterol and glucose, schistosome development appears to

require other signals from the host, as parasite growth and reproductive capacity are significantly attenuated in certain lines of gene-targeted mice. We previously found that impaired growth and reproduction of *Schistosoma mansoni* in immunodeficient mice correlated with reduced expression and activity of the parasite cAMP-dependent protein kinase (PKA). As PKA is a central regulator of cell metabolism and schistosomes utilize a combination of glycolysis, fatty acid oxidation and oxidative phosphorylation to meet their bioenergetic needs, we hypothesized that schistosomes from immunodeficient mice might also exhibit alterations in signaling pathways that regulate energy metabolism. First, we show that adult schistosomes express an AMP-activated protein kinase (AMPK), a heterotrimeric enzyme that is central to regulating energy metabolism at the cellular level in other eukaryotes. Second, we provide evidence that expression of the catalytic alpha subunit is developmentally regulated during the life cycle. Third, we show that schistosome AMPK activity is sensitive to changes in the worm's environment, suggesting a mechanism by which schistosome metabolism may be responsive to host factors. Finally, we provide evidence that AMPK expression is attenuated in parasites isolated from immunodeficient mice, suggesting the host exerts significant influence over the regulation of schistosome energy metabolism. Studies are underway to determine how schistosome AMPK expression and activity are modulated by environmental signals. Elucidating how schistosome energy metabolism is regulated and how external factors influence parasite energy metabolism may reveal opportunities to disrupt transmission of these important pathogens.

## 1999

### ATYPICAL PHARMACOLOGY OF SCHISTOSOME TRPA1-LIKE ION CHANNELS

Swarna Bais, Corbett T. Berry, Xiaohong Lu, Gordon Ruthel, Bruce D. Freedman, **Robert M. Greenberg**

*University of Pennsylvania, Philadelphia, PA, United States*

Praiquantel is effectively the only drug currently available for treatment and control of schistosomiasis, and there is an urgent need for new antischistosomal. Ion channels are validated targets for current anthelmintics. Transient receptor potential (TRP) channels comprise a diverse family of ion channels that are critical for transduction of sensory signals, as well as a variety of other functions. However, the properties of TRP channels remain largely unexplored in schistosomes and other parasitic helminths. Schistosome genomes predict representatives of most TRP channel subfamilies, but not TRPV, the vanilloid receptor family involved in nociception, inflammatory signaling, thermoreception, and other sensory functions. Despite the absence of TRPV channels, both adult and larval schistosomes display dramatic hyperactivity in response to selective activators of mammalian TRPV1 such as capsaicin and resiniferatoxin. Capsaicin also induces rapid, long-lasting separation of paired adult males and females, perhaps indicating a nociceptive effect. Capsaicin-induced worm hyperactivity exhibits TRPV1-like pharmacology and is virtually eliminated by knockdown of SmTRPA, a schistosome TRPA1-like channel (other TRPA1 channels are not sensitive to capsaicin). The effect of SmTRPA knockdown is selective, with no significant effect on hyperactivity induced by serotonin. The TRPA1 activator AITC also elicits significant hyperactivity that is abolished by knockdown of SmTRPA1, indicating that SmTRPA exhibits mixed TRPV1/TRPA1-like pharmacology. Consistent with our results on whole schistosomes, both capsaicin and AITC elicit an influx of Ca<sup>2+</sup> in mammalian cells expressing SmTRPA, as measured by Ca<sup>2+</sup> imaging. These results indicate that at least one schistosome TRP channel has atypical pharmacological sensitivities that could potentially be exploited for selective targeting by new antischistosomal. We further hypothesize that some sensory functions normally mediated by the missing TRPV channels may be fulfilled instead by schistosome TRP channels from other subfamilies.

### DECODING GONAD-SPECIFIC AND PAIRING-DEPENDENT GENE EXPRESSION IN *SCHISTOSOMA MANSONI* BY COMPARATIVE TRANSCRIPTOMICS DELIVERED MOLECULAR INSIGHTS RELEVANT FOR BASIC AND APPLIED RESEARCH

**Christoph G. Greveling**<sup>1</sup>, Steffen Hahnel<sup>1</sup>, Thomas Quack<sup>1</sup>, Nicolas J. Wheeler<sup>2</sup>, Timothy A. Day<sup>2</sup>, Florian Sessler<sup>3</sup>, Nancy Holroyd<sup>4</sup>, Matthew Berriman<sup>4</sup>, Zhigang Lu<sup>1</sup>

<sup>1</sup>*Justus-Liebig-University Giessen, Germany, Giessen, Germany*, <sup>2</sup>*Iowa State University, Ames, IA, United States*, <sup>3</sup>*Wellcome Trust Sanger Institute, Hinxton, United Kingdom*, <sup>4</sup>*Wellcome Trust Sanger Institute, Giessen, United Kingdom*

Schistosomes are exceptional trematodes that live dioeciously. To achieve sexual maturation and reproduction, female worms have to be constantly paired with males. Although males are sexually mature before pairing, we assumed that the male-female interaction of schistosomes is a bidirectional process, which is supported by former studies investigating pairing-induced gene expression. However, not much is known about the complexity of transcriptional processes following pairing, especially with respect to the gonads. Based on a recently established organ-isolation approach, we performed comparative transcriptomics with RNA of ovaries and testes from both paired and unpaired adult *S. mansoni*. By RNAseq we identified >7,000 transcripts in the gonads of both sexes. Although transcript levels of the majority of these genes (4,100) were pairing-unaffected in both gonads, 243 (testes) and 3,600 (ovaries) transcripts occurred pairing-dependently. Among these, 309 and 42 differentially expressed genes (DEGs) showed ovary-specific and testis-specific transcription, respectively. Furthermore, 436 transcripts occurred testis-specifically but pairing-independently. KEGG pathway mapping confirmed roles of these DEGs in transcription/translational, cellular, and signal transduction processes as well as energy metabolism. Among others we identified genes with preferential or specific expression in the gonads, and whose functions are associated to stem-cells/neoblasts or neural processes. Comparisons to work on neuropeptidergic signaling in planarian showed interesting parallels but also remarkable differences highlighting the importance of the nervous system for flatworm gonad differentiation. In-depth analyses exhibited new aspects of GPCRs, which represent the largest receptor family in schistosomes. Furthermore, GPCRs are interesting as potentially druggable targets for novel intervention strategies that are urgently needed. Overall, our datasets reveal yet unknown aspects of schistosome reproductive biology and will be relevant for basic as well as applied, exploitable research initiatives.

### THE MICROBIOME IN THE COURSE OF URINARY SCHISTOSOMIASIS AND INDUCED PATHOLOGIES

Adewale Adebayo<sup>1</sup>, Mangesh Survayanshi<sup>2</sup>, Shrinkath Bhute<sup>2</sup>, Raphael Isokpehi<sup>3</sup>, Atinuke Agunloye<sup>1</sup>, **Chiaka Anumudu**<sup>1</sup>, Yogesh Shouche<sup>2</sup>

<sup>1</sup>*University of Ibadan, Ibadan, Nigeria*, <sup>2</sup>*National Centre for Cell Science, Pune, India*, <sup>3</sup>*Bethune Cookman University, Daytona Beach, FL, United States*

Research on the molecular mechanisms influencing the outcomes of bladder pathologies by *Schistosoma haematobium* is urgently needed to develop new diagnostics, therapeutics and infection prevention strategies. We sought to determine the microbiome features and changes in urine during urogenital schistosomiasis and induced bladder pathologies. Study participants were recruited from Eggua, southwestern Nigeria and screened for schistosomiasis infection and bladder pathologies by urine microscopy and ultrasonography respectively. Microbiome sequencing, pre-processing of microbiome sequences and data analytics of microbiome sequence data collection were performed using relevant bioinformatic tools and analytical software. Seventy study participants (36 males and

34 females, between ages 15 and 65) were categorised into four groups according to status of schistosomiasis infection and bladder pathology. Data analytics of the next-generation sequencing reads revealed that Proteobacteria and Firmicutes dominate and influence microbiome structure of urine samples from non-infected persons and persons with urogenital schistosomiasis. Furthermore, gender and age could influence taxa abundance independent of infection or bladder pathology. Several taxa distinguished *Schistosoma haematobium* induced bladder pathologies from infection alone and from healthy persons, including known immune-stimulatory taxa such as *Fusobacterium*, *Sphingobacterium* and *Enterococcus*. Two of these significant taxa, *Sphingobacterium* and *Aerococcus* were projected as markers of infection, while several genera including potentially beneficial taxa such as *Trabulsiella* and *Weissella*, were associated with the non-infected. Finally, expected changes in protein functional categories were observed to relate to cellular maintenance and lipid metabolism. The urinary microbiome is a factor to be considered in developing biomarkers, diagnostic tools, and new treatment for urinary schistosomiasis and induced bladder pathologies.

## 2002

### HELMINTHS INDUCE PERSISTENT EPIGENETICALLY-MEDIATED PERTURBATIONS IN THE TUBERCULOSIS IMMUNE RESPONSE

**Andrew DiNardo**<sup>1</sup>, Godwin Mtetwa<sup>2</sup>, Temhlanga Mndzebele<sup>2</sup>, Gugu Maphalala<sup>3</sup>, Tomoki Nishiguchi<sup>1</sup>, Rojelio A. Mejia<sup>1</sup>, Alexander Kay<sup>2</sup>, Emily M. Mace<sup>1</sup>, George Makedonas<sup>1</sup>, Anna Mandalakas<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Baylor-Swaziland Children's Foundation, Mbabane, Swaziland, <sup>3</sup>Swaziland National Tuberculosis Laboratory, Mbabane, Swaziland

Helminth infection is associated with an increased rate of TB progression and decreased TB immunity but the mechanism and duration of helminth-induced immune perturbation remains uncertain. There is burgeoning knowledge that the epigenetic code, post-translational modifications of DNA and its surrounding chromatin structure, determines immune phenotype. Murine models show that Schistosoma-infected mice undergo epigenetically mediated immune perturbations. DNA methylation epigenetically silences immune function by coiling DNA into a transcriptionally inactive state. In a cohort of TB-exposed children, we performed urine and stool ova and parasite (O&P) exam, helminth PCR and serology to characterize participants' helminth status. DNA methylation of 94 immune regulatory genes was measured using methylation-sensitive endonuclease digestion followed by qPCR. Helminth and DNA methylation results were correlated with downstream flow-cytometry based immune profiling. Compared to uninfected controls, active or remote Schistosomiasis was associated with a  $\geq 20\%$  increase in DNA methylation of 4 pioneer or transcription factors as well as 4 surface receptors ( $p < 0.005$ ; Sidak-Bonferroni). The increased DNA methylation persisted for 6 months after empiric anti-helminth therapy. One intracellular protein and 1 transcription factor were hypo-methylated  $\geq 10\%$  compared to healthy-controls. Schistosoma infection and DNA methylation correlated with decreased mycobacteria induced CD4+ T cell production of IFN- $\gamma$ ; and TNF and increased CD4 IL-4 and PD-1 ( $p < 0.005$ ). In addition, schistosomiasis was associated with decreased Natural Killer cell (CD56+) perforin and increased monocyte IL-10 production ( $p < 0.0001$ ). In conclusion, Schistosomiasis induces persistent and profound epigenetic changes characterized by DNA hypermethylation that is correlated with a perturbed mycobacteria-specific immunity including decreased cell-mediated CD4+ T cells and Natural Killer cells with an increase in immune tolerant response in CD4+ cells and monocytes.

## 2003

### DICHOTOMOUS EFFECTS OF IL-4 AND IL-10 ON HUMAN SCHISTOSOMIASIS IMMUNE RESPONSES

**Huldah Sang**<sup>1</sup>, Rachael Hamilton<sup>2</sup>, Isaac Onkanga<sup>1</sup>, Bartholomew Ondigo<sup>1</sup>, Thomas Schneider<sup>2</sup>, Maurice Odieri<sup>1</sup>, Pauline Mwinzi<sup>1</sup>, Lisa Ganley-Leal<sup>2</sup>

<sup>1</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>STC - Biologics, Cambridge, MA, United States

IL-4 and IL-10 have dichotomous effects on immune responses in human schistosomiasis and in other chronic inflammatory diseases. In general, IL-4 pathways are associated with resistance to infection with schistosomes, whereas those driven by IL-10 are associated with reduced protection. This dichotomy is reflected in immune responses, such as IgE regulation and CD23 expression by B cells, which are positively and negatively regulated by IL-4 and IL-10, respectively. We thus sought to define the global effects of IL-10 and IL-4 on B cell activation and differentiation to better understand the mechanisms of host immunity. Reflecting global effects on resistance to infection, we report that IL-4 and IL-10 have highly dichotomous effects on human B cells. Relatively high doses of IL-4 decrease expression of homing receptors associated with secondary lymph node entry and exit, including CCR7, CXCR5, and CXCR4, whereas IL-10 increased levels. In contrast, IL-4 increased molecules associated with enhanced antigen capture and antigen presentation, while IL-10 generally reduced these receptors. In addition, IL-4 exposed cells responded to *E. coli* LPS by increasing direct  $\mu$  to e class switch. Overall, these results suggest that *in situ* B cell differentiation, as well as T cell activation, may take place under conditions with high concentrations of IL-4. IL-4 appears to favor an environment for B cells to activate a higher repertoire of T cells through enhanced antigen capture and presentation towards a more complex response. In addition, IL-4 mediated rapid low affinity IgE production likely aids in the amplification of antigen capture and production of high affinity and broader range of IgE later in the response. In contrast, despite rapid migration to the lymph nodes, IL-10 may result in reduced local antigen capture, leading to an overall reduced affinity of IgE, which has been shown to be associated with susceptibility to schistosome infection.

### DEVELOPMENT OF AN INTERLEUKIN-4-INDUCING PRINCIPLE OF SCHISTOSOMA MANSONI EGGS (IPSE)-SPECIFIC PCR PLATFORM TO QUANTIFY EGG BURDENS ASSOCIATED WITH SCHISTOSOMIASIS

**Dannah Farah**<sup>1</sup>, Evaristus Mbanefo<sup>2</sup>, Michael Hsieh<sup>3</sup>

<sup>1</sup>The George Washington University School of Medicine and Health Sciences, Washington, DC, United States, <sup>2</sup>Biomedical Research Institute, Rockville, MD, United States, <sup>3</sup>Children's National Medical Center, Washington, DC, United States

Schistosomiasis is a neglected tropical disease (NTD) affecting between 200-500 million people worldwide. The two species causing most human cases of schistosomiasis are *Schistosoma mansoni* and *S. haematobium*. The gold standard for diagnosis is detection of parasite eggs in stool using the Kato-Katz method. Counting eggs passed in stool is labor-intensive with poor sensitivity. Other alternatives like the circulating anodic (CAA) and cathodic (CCA) antigen detection assays do not quantify egg burdens, which remain an important indicator of individual morbidity associated with schistosomiasis. The interleukin-4-inducing principle of *S. mansoni* eggs (IPSE) is the most abundant secreted protein from schistosome eggs. We hypothesize that the mRNA transcripts of IPSE may be found in the stool, urine, body fluids, and host tissues, and that these transcripts can be specifically targeted as a quantitative molecular biomarker of egg burdens in individuals affected by schistosomiasis. Liver tissue and stool samples were collected from *S. mansoni* and *S. haematobium* infected mice and hamsters, respectively. A standard curve was generated by qPCR

amplification of IPSE mRNA from known concentrations of parasite egg RNA. The resultant proportional equation was applied to assess correlation between concentrations of parasite RNA in samples with egg counts by microscopy. Preliminary results showed a positive correlation between increasing concentrations of IPSE RNA and the number of eggs counted in both stool and liver tissue samples of *S. mansoni* infected mice. Our next steps are to optimize this assay using *Schistosoma haematobium* infected hamsters, and to develop this assay as a morbidity assessment tool in field settings.

### ESSENTIAL ASPECTS OF RNA METABOLISM FOR *P. FALCIPARUM* BLOOD-STAGE SURVIVAL

Jenna Oberstaller<sup>1</sup>, Min Zhang<sup>1</sup>, ChengQi Wang<sup>1</sup>, Thomas D. Otto<sup>2</sup>, Xiangyun Liao<sup>1</sup>, Justin Swanson<sup>1</sup>, Swamy R. Adapa<sup>1</sup>, Kenneth Udenze<sup>1</sup>, Iraad F. Bronner<sup>2</sup>, Suzanne Li<sup>1</sup>, Hannah Haines<sup>1</sup>, Julian C. Rayner<sup>2</sup>, Rays H.Y. Jiang<sup>1</sup>, John Adams<sup>1</sup>

<sup>1</sup>Department of Global Health, College of Public Health, University of South Florida, Tampa, FL, United States, <sup>2</sup>Malaria Programme, Wellcome Trust Sanger Institute, Genome Campus, Hinxton, Cambridgeshire, United Kingdom

Post-transcriptional and translational regulatory mechanisms have been shown to play important roles in *Plasmodium* gene expression, particularly during the sexual stages and the mosquito-to-human host transition. The role of these mechanisms during the blood stage has been less certain though mounting evidence suggests their utilization, particularly for invasion-related genes that appear to be regulated in a just-in-time fashion at the protein level. We have recently achieved *P. falciparum* blood-stage saturation-level mutagenesis with the recovery of ~38,000 single-insertion *piggyBac* transposon mutants, allowing us to assign probability scores for the essentiality of nearly all *P. falciparum* genes based on whether or not the coding sequence could be disrupted. We found that the essential genome is highly enriched for RNA-metabolic processes; >40% of the previously identified *P. falciparum* blood stage RNA-associated proteome are highly likely to be essential, with essentiality scores of RNA-binding proteins associated with centers for RNA degradation (P-bodies), translational regulation (stress granules), the exosome (involved in RNA surveillance and processing), or splicing being among the top quartile of all *P. falciparum* genes. In addition to conserved RNA metabolism genes, we identified ~50 uncharacterized potential RNA-binding proteins with no human orthologs that are likely to be essential. We report further validation and characterization of one such putative RNA-binding protein via complementary molecular techniques. Taken together, these observations suggest the essentiality of post-transcriptional regulatory mechanisms to ensure the parasite's survival in the blood stage, and further interrogation of these putative essential regulatory proteins promises important insights into *Plasmodium* biology and possible avenues for intervention.

<sup>1</sup>Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>The Walter and Eliza Hall Institute of Medical Research, Parkville, VIC, Australia, <sup>3</sup>Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom, <sup>4</sup>Immune Disease Institute, Harvard Medical School,

Boston, MA, United States, <sup>5</sup>Malaria Evolution in South Asia (MESA)-International Centers of Excellence in Malaria Research (ICEMR), Goa Medical College, Bambolim, India, <sup>6</sup>Department of Cell Biology, Harvard Medical School, Boston, MA, United States, <sup>7</sup>Department of Chemistry, University of Washington, Seattle, WA, United States, <sup>8</sup>Department of Parasitology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

The two major malaria parasite species, *Plasmodium falciparum* and *P. vivax* have distinct red blood cell (RBC) tropisms: *P. falciparum* can invade RBCs of any age while *P. vivax* is restricted to invading the youngest RBCs known as reticulocytes. Parasites make use of invasion ligand proteins to target and bind to proteins on the RBC surface known as host receptors, many of which have yet to be identified. *P. falciparum* has two essential host receptors: basigin/BSG and CD55. There is only one known host receptor for *P. vivax*, the Duffy Antigen Receptor for Chemokines (DARC), but this gene does not mediate reticulocyte tropism. Reticulocytes and erythrocytes do not have nuclei precluding direct genetic analysis, therefore we exploited an immortalized cell line, JK-1, to produce nucleated RBCs (that we term jkRBCs) that enable production of *in vitro* genetic mutants to identify and validate candidate host receptors. We were able to enrich a synchronous population of jkRBCs using a combination of epigenetic modifiers and density gradient sedimentation. Via quantitative surface proteomics and flow cytometry we demonstrate that all known *P. falciparum* host receptors are found at levels comparable to RBCs, and that *P. falciparum* invasion into jkRBCs is on par with invasion into RBCs. In order to validate the requirement of DARC for *P. vivax*, we overexpressed this gene under the control of the  $\beta$ -globin promoter, resulting in >3-fold higher invasion using *P. vivax* isolates from Brazil and India. Using the CRISPR/Cas9 system, we have been able to generate gene knockouts in the JK-1 cells. We generated gene mutants for a candidate *P. vivax* host receptor, transferrin receptor/TFRC/CD71. Mutant TFRC JK-1 cells are strongly inhibited for *P. vivax* invasion but do not show any defects in *P. falciparum* invasion. In addition, we also observed that knockouts of BSG and CD55 had no effect on *P. vivax* invasion, suggesting that the two parasite species use different invasion pathways. We have identified reticulocyte-specific genes by quantitative surface proteomics and we are in the process of generating and screening gene knockouts in order to identify novel *P. vivax* host receptors.

### METABOLISM AND WHIPWORM INFECTION: MTOR, AND THE LARGE NEUTRAL AMINO ACID SLC7A5, INFLUENCE RESISTANCE TO THE INTESTINAL DWELLING NEMATODE TRICHURIS MURIS

Maria Z. Krauss<sup>1</sup>, Kevin N. Couper<sup>2</sup>, Richard K. Grencis<sup>1</sup>

<sup>1</sup>Wellcome Centre for Cell Matrix Research, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom, <sup>2</sup>Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom

*Trichuris trichiura* (whipworm) is a gastrointestinal dwelling nematode that infects approximately 500 million people worldwide. *T. muris* occurs naturally in mice and is very closely related to the human whipworm, making it a great model to dissect the immune response against the parasite. In wild type mice, infection with a high dose of *T. muris* eggs leads to resistance and worm expulsion, which is dependent on a CD4+Th2 response and production of interleukin (IL)-13. Parasitic infection places metabolic demands on the host and it is well established that metabolic changes are essential in promoting T cell activation and effector function. T cells up-regulate glycolysis, glucose and amino acid uptake to support the new metabolic demand. The large neutral amino acid transporter Slc7a5 has been shown to be necessary for activation of mTORC1, a nutrient/energy/redox sensor critical for T cell differentiation into effector cells. We have found that during the early stages of a high dose *T. muris* infection (up to day 21), mice that lack Slc7a5 in CD4+ T cells have significantly

delayed worm expulsion, impaired production of antibodies, and lower levels of IL-13. Their CD4+ T cells also have reduced glycolytic rates when compared to cells from cohoused infected wild type mice. However, at later stages of infection (day 30+), antibody and IL-13 levels recovered alongside the ability to expel parasites. The critical role of mTOR in CD4+ T cells was shown in mice lacking mTOR in CD4+ T cells that failed to expel a high dose of parasites and developed long term chronic infection. Also, *in vitro* incubation with mTOR inhibitors blocks the production of most cytokines (including IL-10, IL-13, IL-17A and IFN- $\gamma$ ) in CD4+ T cells from infected animals. Our study shows that mTOR is essential for the proper functioning of T cells during *T. muris* infection and importantly, that amino acid uptake by CD4+T cells can profoundly influence the development of effective resistance to this parasite.

## 2008

### BONE MARROW-DERIVED MONOCYTES MEDIATE HOST PROTECTIVE RESPONSES TO *TRICHINELLA SPIRALIS*

**Chandler Sy**, Everett Henry, Juan Manuel Inclan Rico, Mark Siracusa

*The Rutgers Graduate School of Biomedical Sciences (GSBS), Newark, NJ, United States*

Helminth parasites are amongst the most abundant of all chronic human infections. Protective immunity to helminths is associated with the development of CD4+ T helper type 2 (TH2) cell responses and production of type 2 cytokines. Recent studies have found that alternatively activated (M2) macrophages play a crucial role in promoting both anti-helminth immunity and wound healing responses following infection. However, the contributions of tissue-resident versus inflammatory monocyte-derived macrophages remain unclear. Here, we show that mice depleted of macrophages or bone marrow-derived monocytes exhibit reduced TH2 cytokine-mediated immunity to *T. spiralis*. Specifically, both the nonspecific depletion of macrophages via treatment with clodronate liposomes as well as the depletion of CCR2+ bone marrow-derived monocytes via a diphtheria toxin inducible system resulted in reduced TH2 responses, a loss of intestinal M2 macrophages, a dramatic decrease in weight, and increased mortality. This increase in mortality and morbidity was not the result of either increased gut pathology or liver dysfunction. However, mice depleted of CCR2+ monocytes exhibited increased expression of tumor necrosis factor (TNF)- $\alpha$  in their brains. In conclusion, these data suggest that CCR2+ bone marrow-derived monocytes perform essential host protective responses and regulate inflammatory cytokine production in the central nervous system following *T. spiralis* infection.

### SINGLE-CELL RNA-SEQ REVEALS HIDDEN SIGNATURE OF SEXUAL COMMITMENT IN MALARIA PARASITES

**Christopher Nötzel**<sup>1</sup>, Asaf Poran<sup>2</sup>, Omar Aly<sup>2</sup>, Nuria Mencia-Trinchant<sup>2</sup>, Chantal T. Harris<sup>1</sup>, Monica L. Guzman<sup>3</sup>, Duane C. Hassane<sup>2</sup>, Olivier Elemento<sup>2</sup>, Björn F. C. Kafsack<sup>1</sup>

<sup>1</sup>*Department of Microbiology and Immunology, Weill Cornell Medicine, New York, NY, United States*, <sup>2</sup>*Institute for Computational Biomedicine, Department of Physiology and Biophysics, Weill Cornell Medicine, New York, NY, United States*, <sup>3</sup>*Division of Hematology and Medical Oncology, Department of Medicine, Weill Cornell Medicine, New York, NY, United States*

*Plasmodium falciparum* parasites have to balance continuous asexual replication within red blood cells with differentiation into non-replicating sexual stages, called gametocytes. Commitment to either fate is already determined during the preceding cell cycle that begins with invasion by a single, asexually-committed merozoite and ends, 48-hours later, with a schizont releasing newly formed merozoites, all of which are committed to either continued asexual replication or differentiation into gametocytes. Sexual commitment requires activation of *ap2-g*, the transcriptional master regulator of sexual development, from its epigenetically silenced state

during asexual replication. Expression of AP2-G during this "commitment cycle" poises gene expression in nascent merozoites to initiate sexual development through a hitherto unknown mechanism. In order to maintain a persistent infection, *ap2-g* expression is limited to a sub-population of parasites (1-30%, depending on genetic background and growth conditions). As sexually-committed schizonts comprise only a sub-population and are morphologically indistinguishable from their asexually-committed counterparts, defining their characteristic gene expression has been difficult using traditional, bulk transcriptome profiling. To determine the transcriptional changes induced by AP2-G within this sub-population, we applied highly-parallel, single-cell RNA sequencing (scRNA-seq) to malaria cultures undergoing sexual commitment. In this first application of scRNA-seq to eukaryotic pathogens, we surveyed over 19,000 single parasite transcriptomes from a conditional AP2-G knockdown (AP2-G-DD) line and NF54 wildtype parasites in multiple stages of development and found that sexually committed, AP2-G<sup>+</sup> mature schizonts specifically up-regulate additional regulators of gene expression, including AP2 transcription factors, histone modifying enzymes, and regulators of nucleosome positioning. These epigenetic regulators likely act to poise the expression of genes necessary for initiation of gametocyte development in the subsequent cell cycle.

### PLASMEPSINS IX AND X ARE ESSENTIAL AND DRUGGABLE MEDIATORS OF MALARIA PARASITE EGRESS AND INVASION

**Armiyaw S. Nasamu**<sup>1</sup>, Svetlana Glushakova<sup>2</sup>, Ilaria Russo<sup>3</sup>, Barbara Vaupel<sup>1</sup>, Anna Oksman<sup>1</sup>, Arthur S. Kim<sup>1</sup>, Daved H. Fremont<sup>4</sup>, Niraj Tolia<sup>5</sup>, Josh R. Beck<sup>1</sup>, Marvin J. Meyers<sup>6</sup>, Jacquin C. Niles<sup>7</sup>, Joshua Zimmerberg<sup>2</sup>, Daniel E. Goldberg<sup>1</sup>

<sup>1</sup>*Department of Medicine, Division of Infectious Diseases, Washington University School of Medicine, St. Louis, MO, United States*, <sup>2</sup>*Section on Integrative Biophysics, Eunice Kennedy Shriver National Institute of Child Health and Development, National Institutes of Health, Bethesda, MD, United States*, <sup>3</sup>*Faculty of Biology, Medicine and Health, School of Biological Sciences, Division of Infection Immunity and Respiratory Medicine, University of Manchester, Manchester, United Kingdom*, <sup>4</sup>*Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO, United States*, <sup>5</sup>*Department of Molecular Microbiology, Washington University School of Medicine, St. Louis, MO, United States*, <sup>6</sup>*Center for World Health and Medicine, St. Louis University School of Medicine, St. Louis, MO, United States*, <sup>7</sup>*Department of Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA, United States*

Proteases of the malaria parasite *Plasmodium falciparum* have long been investigated as drug targets. The *P. falciparum* genome encodes ten aspartic proteases called plasmepsins, which are involved in diverse cellular processes. Most have been studied extensively but the functions of plasmepsins IX and X (PMIX and X) were unknown. Here, we show that PMIX is essential for erythrocyte invasion, acting on rhoptry secretory organelle biogenesis. In contrast, PMX is essential for both egress and invasion, controlling maturation of the subtilisin-like serine protease SUB1 in exosome secretory vesicles. We have identified compounds with potent antimalarial activity targeting PMX, including a compound known to have oral efficacy in a mouse malaria model.

## 2011

### SPECIES SPECIFIC TRYPANOSOME RESISTANCE IS GOVERNED BY APOL1 VARIATION IN BABOONS

**Joey Verdi**, Russel Thomson, Jayne Raper

*Hunter College, CUNY, New York, NY, United States*

Some primates maintain resistance to infection by *Trypanosoma brucei* via the protective effects of the primate-specific protein apolipoprotein L-1 (APOL1). APOL1 circulates in plasma on high-density lipoprotein complexes called trypanosome lytic factors that are endocytosed by the

parasites. Once inside the parasite, the APOL1 forms cation selective pores in membranes leading to ion dysregulation followed by osmotic lysis. The human infective *T. b. rhodesiense* and *T. b. gambiense* have independently evolved APOL1 resistance mechanisms. All screened baboon (*Papio spp.*) APOL1s lyse *T. b. rhodesiense* by evading the parasites resistance mechanism, whereas *T. b. gambiense* has variable resistance to baboon APOL1s. *Papio cynocephalus* baboons are susceptible to *T. b. gambiense* infection *in vivo*, while *P. papio* and *P. hamadryas* baboons are resistant. Whole genome sequencing has recently revealed that the APOL1 gene is highly polymorphic in the human population, with some African-specific variants of APOL1 providing increased resistance to trypanosomes. The differential response to *T. b. gambiense* infection among baboon species may be a result of APOL1 polymorphism in the baboon lineage. By analyzing baboon genome sequencing data, we have identified putative APOL1 sequences in all baboon species, revealing a high degree of APOL1 variation within the *Papio* genus. Indeed, recombinant *P. cynocephalus* APOL1 is significantly less lytic to trypanosomes *in vitro* than *P. hamadryas* APOL1, and transiently transgenic mice expressing APOL1 constructs that resemble *P. cynocephalus* APOL1 are more susceptible to infection than mice expressing *P. hamadryas* APOL1. These data suggest that APOL1 variance governs susceptibility/resistance to trypanosome infection in primate hosts.

*Trypanosoma cruzi* faces various environmental challenges as it propagates from an insect vector to a mammalian host during its life cycle. To cope with these environmental challenges, *T. cruzi* has developed robust compensatory mechanisms; however, the sensory machinery utilized to detect variations in the extracellular conditions remains unknown. In all cell types, mechanosensation is responsible for detecting changes in pressure, osmolarity, and fluidity of the membrane. In addition mechanosensation is associated with increase in biofilm formation, quorum sensing and activation of virulence-related genes. In *T. cruzi*, we have identified and characterized a mechanosensitive channel (TcMCS) that shares structural and functional traits with the small conductance mechanosensitive channel, MscS of *E. coli*. The presence of homologues suggests a conserved mechanism for osmoadaptation in other protozoan parasites. Single-channel electrophysiological characterization of TcMCS using *E. coli* spheroplast showed a tension-dependent activation within the range similar to bacterial MscS channels. A linear non-rectifying conductance of 0.4 nS suggests a pore that is permeable to ions, amino acids and compatible osmolytes that can be transported across membranes in the course of adaptation. Immunofluorescence studies show that TcMCS is differentially localized in the three main life stages of *T. cruzi* with localization on the contractile vacuole and the plasma membrane. Gene knockout mediated by CRISPR-Cas9 caused severe defects in morphology and impaired growth and infectivity of the parasites. Under hyposmotic stress, cells overexpressing TcMCS swell significantly less and knockout mutants swell significantly more and are not able to recover. Known mechanosensitive channel blockers including gadolinium, cause significant differences in the parasite's ability to detect and compensate its volume under osmotic stress. TcMCS knockdown mutants showed major defects in metacyclogenesis and intracellular replication. Overall, our results support the physiological role of TcMCS in *T. cruzi* osmoregulation and infectivity.

### A NATURAL MOUSE MODEL FOR CRYPTOSPORIDIOSIS

Adam Sateriale<sup>1</sup>, Jan Slapeta<sup>2</sup>, Rodrigo Baptista<sup>1</sup>, Jessica Kissinger<sup>1</sup>, Carrie Brooks<sup>1</sup>, Gillian Herbert<sup>1</sup>, Ravi Pulusu<sup>1</sup>, Boris Striepen<sup>1</sup>

Cryptosporidiosis is a leading cause of diarrhea and an important contributor to global infant mortality. There are no efficacious drugs or vaccines available and our knowledge of *Cryptosporidium* biology to drive their development is scant. *Cryptosporidium* research is greatly hindered by the lack of a continuous tissue culture system and poor animal models. To develop a more facile mouse model of *Cryptosporidium* infection, we have isolated a strain of *Cryptosporidium tyzzeri* (*C. parvum* mouse genotype I) from naturally infected *Mus domesticus*; strains which we now maintain continuously in our animal facility. De novo assembly of the *C. tyzzeri* genome shows 96% overall nucleotide identity to *C. parvum* and *hominis* and a high degree of synteny. The highest burden of *C. tyzzeri* infection is found in the distal ileum of the mouse small intestine, yet there is also significant infection of the jejunum and duodenum, similar to what is seen in human cryptosporidiosis. Perhaps of greatest importance, *C. tyzzeri* produces significant infections in healthy C57/BL6 mice. These infections produce high parasite burden but are self-limiting, and mice that have cleared *C. tyzzeri* appear resistant to future infection. Using CRISPR directed homology repair we have genetically engineered *C. tyzzeri* strains to express reporter genes for *in vivo* imaging and localization. In summary, we now have access to a natural mouse model that closely resembles the human infection in which both host and parasite are genetically tractable. We envision this model will lead to better understanding of cryptosporidiosis susceptibility, resolution, and subsequent protection in the context of a functioning immune system.

## 2014

### THE TRICHOMONASVAGINALIS HOMOLOGUE OF HUMAN MACROPHAGE MIGRATION INHIBITORY FACTOR INDUCES THE PARASITE SURVIVAL DURING NUTRIENT STARVATION

Yi-Pei Chen<sup>1</sup>, Patricia J. Johnson<sup>2</sup>

<sup>1</sup>Molecular Biology Institute, University of California Los Angeles, Los Angeles, CA, United States, <sup>2</sup>Molecular Biology Institute, Department of Microbiology, Immunology and Molecular Genetics, University of California Los Angeles, Los Angeles, CA, United States

*Trichomonas vaginalis* is responsible for the most prevalent non-viral sexually transmitted disease worldwide, yet the mechanisms used by this parasite to establish and maintain infection are poorly understood. We and collaborators have previously identified a *T. vaginalis* homologue (TvMIF) of a human cytokine, the macrophage inhibitory factor (HuMIF). TvMIF has been shown to "mimic" HuMIF by activating signaling pathways stimulated by HuMIF to increase cell growth and inhibit apoptosis in human host cells. To interrogate a possible role of TvMIF in parasite survival during infection, we asked whether overexpression of TvMIF (TvMIF-OE) confers an advantage to the parasite under nutrient stress by comparing the survival of TvMIF-OE parasites relative to wild type parasites. We found that TvMIF-OE survive significantly better than wild type parasites, when starved of serum, the source of lipids and other nutrients required by the parasite. We also observed that addition of exogenous recombinant TvMIF increases the survival of the TvMIF-OE parasites in the absence of serum. Recombinant HuMIF likewise increases the parasite survival in the absence of serum, indicating that the parasite may hijack this host survival factor to resist its own death. We hypothesize that TvMIF inhibits parasite apoptosis under stress conditions to maximize survival awaiting more favorable conditions. Using two methods to measure apoptosis, TvMIF-OE parasites were found to undergo less apoptosis than wild type parasites grown without serum. Reactive oxygen species (ROS) were also found to

be inhibited by the overexpression of TvMIF under serum starvation. We are currently attempting to identify the pathway(s) activated in *T. vaginalis* by TvMIF to compare these with known apoptosis or other signaling pathways. These studies are likely to reveal both similarities and differences in survival mechanisms used by this unicellular eukaryotic parasite and its multicellular human host.
