PREDICTING THE EMERGENCE OF PIPERAQUINE-RESISTANT *PLASMODIUM FALCIPARUM* MALARIA IN AFRICA

Laura M. Hagenah, Kyra A. Schindler, Jennifer L. Small-Saunders, Kathryn Wicht, David A. Fidock

Columbia University Irving Medical Center, New York, NY, United States

Global efforts to control and eliminate *Plasmodium falciparum* (Pf) malaria have been thwarted by the emergence of resistance to first-line antimalarials. Resistance to piperaquine (PPQ) in Southeast Asia is primarily mediated by mutations in the drug efflux transporter PfCRT. In Africa, PPQ has been identified as a promising partner drug for chemoprevention with artemisinin-based combination therapies, based on its potency against asexual blood stage parasites, extended plasma half-life (2-3 weeks), and good safety profile. However, the emergence of artemisinin-resistant parasites in areas in Africa increases selective pressure for PPQ resistance, so it will be important to predict whether resistance can arise in this region. Here we have used gene editing to introduce the most common chloroquine-resistant *pfcrt* alleles in Africa into Dd2 (Asian) parasites: GB4 (Dd2 without N326S/I356T), Cam783 (Dd2 without N326S), and FCB (Dd2 without I356T). We then edited the most prevalent PPQ-resistant PfCRT mutations from Southeast Asia (T93S and I218F) into Dd2$^{GB4,\ Cam783,\ or\ FCB\ crt}$ parasites. In PPQ survival assays, these mutations only confer high-grade PPQ resistance (~10% survival at 200 nM) on the FCB PfCRT background. Parasites expressing GB4+T93S or Cam783+T93S exhibited increased survival only at lower PPQ concentrations (~25 nM). This suggests that N326S, absent in both GB4 and Cam783 but present in Dd2 and FCB, is necessary for these mutations to confer PPQ resistance. All T93S and I218F mutant parasites showed increased susceptibility to chloroquine and monodesethyl-chloroquine, relative to parental Dd2. Ongoing fitness assays will reveal the impact of our set of mutant *pfcrt* alleles on parasite growth rates *in vitro*. The interplay between the degree of drug resistance and parasite fitness is an important determinant of which strains can dominate regionally. Our findings help proactively predict the emergence of PPQ resistance in Africa, which is especially relevant to global health efforts to identify region-specific antimalarial treatments and to combat the spread of multidrug-resistant Pf parasites.

Triple artemisinin combination therapies (TACT) are currently being evaluated to replace artemisinin combination therapies (ACT) due to the burgeoning spread of antimalarial drug resistance. Since artemisinin derivatives have short serum half-lives, there is a greater demand on partner drugs to clear residual infections. Partner drugs, and antimalarials in general, often act on heme detoxification pathways leading to potential cross resistance and failure of clinically relevant drugs. To ensure the long-term success of TACTs, ideal partner drugs will have high synergy or produce collateral sensitivity, such that resistance to one drug results in greater sensitivity to the other. Identification of ideal drug combinations would rely on knowledge of the genetic determinants affecting susceptibility to each drug individually and in combination. To achieve this, we tested 102 unique recombinant progeny from a *Plasmodium falciparum* genetic cross in a high throughput screen against 14 drug combinations and used the result to carry out quantitative trait loci (QTL) mapping. The cross utilized a multidrug resistant, KEL1/PLA1 parasite isolated from western Cambodia in 2016, representing a contemporary Southeast Asian genetic background. The second parent is a drug sensitive, African parasite isolated from Malawi in 2016. With the recent emergence of Kelch13 mutations in east Africa, this cross will be valuable to assess the function and interactions of mutations associated with drug resistance in an African genetic background. Results for the piperaquine/amodiaquine drug combination identified a highly significant locus on chromosome 7 centered on *pfcrt*, as well as two significant loci on chromosome 10, a suggestive locus on chromosome 2 and a minimal signal on chromosome 14. Results for piperaquine/pyronaridine in combination also produced a very similar linkage scan to piperaquine/amodiaquine. Further investigation into these loci using unique progeny with varying Plasmepsin copy numbers and *pfcrt* alleles will elucidate their potential interactions that result in differential drug response.

0003

DECREASED EX VIVO SUSCEPTIBILITY OF *PLASMODIUM FALCIPARUM* TO BOTH DIHYDROARTEMISININ AND LUMEFANTRINE IN NORTHERN UGANDA

Patrick K. Tumwebaze[1], Melissa D. Conrad[2], Martin Okitwi[1], Stephen Orena[1], Oswald Byaruhanga[1], Thomas Katairo[1], Jennifer Legac[2], David Giesbrecht[3], Sawyer Smith[3], Frida G. Ceja[4], Samuel L. Nsobya[1], Jeff Bailey[3], Roland A. Cooper[4], Philip J. Rosenthal[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California, San Francisco, San Francisco, CA, United States, [3]Brown University, Providence, RI, United States, [4]Dominican University of California, San Rafael, CA, United States

The emergence of artemisinin (ART) resistance (delayed clearance after therapy) in northern (N) Uganda may facilitate selection of *Plamodium falciparum* resistant to ART-based combination therapy (ACT) partner drugs, as seen in southeast Asia. We compared genotypes and drug susceptibility phenotypes of *P. falciparum* isolates collected in June-July, 2021 from Tororo and Mbale, Districts in eastern (E) Uganda, where markers of ART resistance have been uncommon, and Agago District in N Uganda, where the resistance-associated PfK13 469Y and 675V mutations have emerged. Genotypes were determined using molecular inversion probe techniques. Drug susceptibilities were measured with IC_{50} (SYBR green) and ring survival assay (RSA) methods. We successfully assayed ring survival, IC_{50}s, and K13 genotypes in 75, 74, and 84 samples, respectively. As seen previously, the prevalences of PfK13 mutations associated with ART resistance were higher in N than E Uganda (469Y 33% vs. 7%, p = 0.01; 675V 16% vs. 4%, p = 0.16). Increased copy number of the *pfmdr1* and *pmp-2/3* genes was very uncommon. Susceptibilities to dihydroartemisinin (DHA) by RSA and to chloroquine, monodesethyl amodiaquine, piperaquine, mefloquine, DHA, quinine, and pyronaridine by IC_{50} were similar in the two regions. However, susceptibility to lumefantrine (LM) was decreased in N (IC_{50} 14.6 nM for 49 samples) compared to E (7.0 nM for 25 samples) Uganda (p <0.0001). 14 of 49 isolates from N, but none of 25 from E Uganda had LM IC_{50} >20 nM (p=0.002). The 469Y mutation was associated with abnormal DHA RSA (median survival 1.7% for WT, 2.5% for mixed, and 7.3% for pure mutant isolates; p = 0.01 for WT vs pure mutant) and trended toward elevated LM IC_{50} (11.4 nM for WT, 11.8 nM for mixed, and 14.8 nM for pure mutant isolates; p = 0.09). Significant associations were not seen for the 675V mutation, but sample size was limited (only two pure mutant 675V parasites were studied). Our results indicate loss of activity of both DHA and LM in N Uganda and suggest concern regarding the activity of artemether-LM, the first-line antimalarial in Uganda. Studies to assess the antimalarial efficacy of ACTs in N Uganda are urgently needed.

0004

IDENTIFICATION OF PIPERAQUINE RESISTANCE IN SOUTH AMERICA HIGHLIGHTING AN EVOLUTION OF MOLECULAR MARKERS CONTRASTING WITH THE SOUTHEAST ASIAN SITUATION

Plasmodium falciparum malaria (*Pf*) is nowadays treated using six artemisinin-based combination therapies (ACTs) recommended by the WHO. Their efficiency is threatened by the emergence of parasite resistance. Recently, the combination dihydroartemisinin - piperaquine (DHA-PPQ) has been discontinued in Southeast Asia following the emergence of parasites resistant to both DHA and PPQ. In French Guiana, South America, we identified piperaquine resistance at a prevalence of 45.3% based on *in vitro* survival assays (n=86). This resistance was significantly associated with the mutation PfCRT^{C350R} and *Pfpm2/3* gene amplifications (p<0.001). It was also responsible for therapeutic failures in patients. However, no signs of artemisinin partial resistance (phenotype or genotype) were detected. Genomic data identified recurrent *de novo* emergence of this mutation. It has already spread at the sub-regional level in the Guiana Shield and requires improved guidelines for treatment recommendations. A temporal analysis was also performed to understand PPQ resistance evolution over a 20-year period. It revealed the emergence of PfCRT^{C350R} mutation, first, followed, years later, by the amplification of *Pfpm2/3*. *In vitro* assay results suggested that PfCRT^{C350R} mutation is required for PPQ resistance in this region. This situation will be compared to the evolution of resistant markers described in Southeast Asia to emphasize the different mutational pathways and genetic architectures of drug resistance in different parasite genetic backgrounds.

A. Lusingu[1]

[1]National Institute for Medical Research, Tanga, United Republic of Tanzania, [2]National Malaria Control Programme, Dodoma, United Republic of Tanzania, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Tanzania Medicines and Medical Devices Authority, Dar es Salaam, United Republic of Tanzania, [5]Global Health Institute, University of Antwerp, Antwerp, Belgium

In high malaria endemic areas of sub-Saharan Africa, school-age children (5-15 years) have become increasingly more vulnerable and contribute significantly as reservoirs to onward malaria transmission in the population. An effectiveness-implementation hybrid trial was conducted to evaluate the implementation of the intermittent preventive treatment of malaria in schoolchildren (IPTsc) using Dihydroartemisinin-Piperaquine(DP), for evidence of the operational feasibility and effectiveness of IPTsc on clinical malaria incidence at a high endemic area in Handeni District Council (DC), Handeni Town Council (TC), and Kilindi DC of Tanga region, Tanzania. Wards in the three study districts were the randomisation unit (clusters). Each ward was randomised to implement IPTsc or not (control). All schoolchildren in primary schools located in the IPTsc arm were given DP three times a year in liaising with transmission seasonality. For the impact of the intervention, in each district, 24 randomly selected wards (12 per study arm, one school per ward) were chosen as representatives. Three rounds of drug dispensing (in Aug 2020, Nov 2020, and Mar 2021), covered 127 primary schools with around 80,000 schoolchildren involved. The average respective coverage of completed dose per round was; 77% (range 68%-83%), 76% (range 69%-82%), and 79%(range 77%-83%). The drugs were well tolerated by the schoolchildren. For impact evaluation, 3752 schoolchildren (1971 DP arm and 1781 control arm) were enrolled. Baseline asymptomatic malaria parasitaemia was 58% for Handeni DC, 20% for Kilindi DC, and 18% for Handeni TC. The average attributable reduction of malaria parasitaemia across all districts was 62% and the effectiveness of IPTsc in preventing clinical malaria over the course of a year was 41% (95%CI 31%-49% *p<0.001*). Implementation of IPTsc was feasible and well accepted by the communities and teachers. IPTsc reduces malaria parasitemia, prevents clinical malaria, and is feasibly implementable through schoolteachers. The addition of IPTsc to school health policy is desirable in improving the health and academic achievement of schoolchildren.

THE POTENTIAL IMPACT OF POINT-OF-CARE RESISTANCE DIAGNOSTICS ON SPREAD OF ANTIMALARIAL RESISTANCE WITHIN A MULTI-DRUG POPULATION TREATMENT STRATEGY

Lucy Okell[1], Oliver Watson[2], Darlington Akogo[3], Emmanuel Adabor[3], Gina Cuomo-Dannenburg[1], Kenny Malpartida-Cardenas[1], Jamal-Deen Abdulai[3], Jesus Rodriguez Manzano[1], Xavier Palmer[4], Issah Samori[1], Robert Verity[1], Pantelis Georgiou[1], Aubrey Cunnington[1]

Rapid 'resistance diagnostic' tests are an emerging technology consisting of user-friendly sample-to-result DNA tests, which detect not only malaria infection, but also drug resistance-associated mutations in the parasite. These point-of-care tests could allow clinicians to choose an antimalarial according to the resistance profile of a patient's infection. This technology has direct benefits for the patient, but also has potential to alter spread of resistance if the diagnostics become widely used. Here, we use multi-strain malaria transmission models tracking sensitive and resistant parasites over time to test the potential for resistance management by diagnostics. First, we explore proof-of-principle within an ODE deterministic model framework. If two drugs, A and B, are used in a standard multiple first-line therapy population treatment strategy, and allocated to patients at random, resistance to each drug will eventually spread to 100% frequency. By contrast, in an idealised scenario where resistance diagnostics are used to guide all treatment decisions and operate perfectly (i.e. patients with the strain resistant to drug A are always given drug B instead, and vice versa), the advantage of single-drug resistance is negated and resistant strains cannot spread. We are currently developing an individual-based model to include real-life factors such as imperfect sensitivity of the diagnostic, lower coverage of diagnostic use (currently ~40% for standard RDTs in many areas), lower test sensitivity for minor clones within multi-clonal infections, varied and off-policy informal antimalarial use, residual drug levels, partial resistance and multi-drug resistance among others. Nonetheless in initial results we so far find that resistance diagnostics could substantially increase the useful lifespan of an antimalarial drug compared to a standard multiple first line therapy policy. Furthermore, they may allow continued use of drugs to which there is moderate resistance already present, conserving efficacy of newer antimalarials.

CONTRASTING DRUG POLICY INTERVENTIONS TO DELAY THE FIXATION OF 561H ARTEMISININ RESISTANT *PLASMODIUM FALCIPARUM* IN RWANDA

Robert Zupko, Haojun Li, Tran Dang Nguyen, Thu Nguyen-Anh Tran, Kien Trung Tran, Maciej F. Boni

Pennsylvania State University, University Park, PA, United States

While artemisinin combination therapies (ACTs) have been instrumental in reducing the global public health burden due to malaria, the identification of 561H artemisinin-resistant *Plasmodium falciparum* in Rwanda is the latest signal that the parasite is rapidly evolving resistance. The lack of a WHO approved replacement for ACTs necessitates the need for a drug policy intervention to delay the spread and fixation of 561H while simultaneously meeting the public health goal of effective treatment of uncomplicated malaria. In this study, we employed a national-scale, individually-based stochastic model of malaria, calibrated for the ground conditions in Rwanda to evaluate various drug policy interventions. Following model validation, we developed a menu of interventions based upon four broad policy interventions: artemether-lumefantrine (AL) extension, AL replacement, multiple first-line therapies (MFT), and drug rotation. We found that over short time horizons (i.e., three to five years) options incorporating dihydroartemisinin-piperaquine (DHA-PPQ) minimizes treatment failures, although the evolution of partner drug resistance to piperaquine results higher treatment failures over a ten-year time horizon. In contrast, policy options incorporating artesunate-amodiaquine (ASAQ) or AL had higher treatment failure rates in the short term, while having a two-fold or better difference in treatment failures over the long-term, compared to full DHA-PPQ deployment. These findings highlight the need for awareness both the time horizons involved, and partner drug resistance when developing drug policy responses to the of artemisinin resistance while awaiting the deployment of next generation therapies for uncomplicated malaria.

0008

MATERNAL CHILD HEALTH VULNERABILITY DURING THE COVID-19 PANDEMIC IN LUSAKA, ZAMBIA

Joelle Rosser[1], Christabel Phiri[2], Duncan Chanda[2]

[1]Stanford University, Stanford, CA, United States, [2]University of Zambia School of Medicine, Lusaka, Zambia

Infectious disease outbreaks and natural disasters often have indirect impacts on essential health services, which can lead to significant excess morbidity and mortality. Anecdotal experience, qualitative studies, and mathematical modeling studies have raised serious concerns about the potential impact of the COVID-19 pandemic on essential health services in sub-Saharan Africa, but quantitative estimates of service disruption remain limited. We quantified the change in health service utilization for a variety of health services at a referral hospital in Lusaka, Zambia. We compared the monthly number of patients receiving various services before and after the start of the COVID-19 pandemic by student's t-test. The most dramatic decreases in utilization were found to be in child weight checks (-56.6% [95% CI: -37.5%, -75.7%]) and the number of cervical cancer screenings performed (-43.3% [95% CI: -21.9%, -64.7%]). Obstetric services and childhood vaccinations demonstrated more modest declines. Our study provides quantitative measures for the decline in several health service which can be used for modeling the long-term impacts of the pandemic. Our findings also highlight the particular vulnerability of preventative health services during disaster scenarios.

0009

IMPACT OF COMMON GENETIC VARIANTS ON CYTOKINE RESPONSE HETEROGENEITY UPON BCG VACCINATION IN INFANTS FROM GUINEA-BISSAU

Collins K. Boahen[1], Simmone J.c.f.m. Moorlag[1], Kristoffer Jarlov Jensen[2], Vasiliki Matzaraki[1], Stephanie Fanucchi[3], Ivan Monteiro[4], Charlotte De Bree[1], Ezio T. Fok[5], Leo A.b. Joosten[1], Musa Mhlanga[5], Peter Aaby[4], Christine Stabell Benn[6], Mihai G. Netea[1], Vinod Kumar[1]

[1]Department of Internal Medicine and Radboud Center for Infectious Diseases (RCI), Radboud University Medical Center, Nijmegen, Netherlands, [2]Center for Clinical Research and Prevention, Frederiksberg and Bispebjerg Hospital, Frederiksberg, Denmark, [3]Lemba Therapeutics, Nijmegen, Nijmegen, Netherlands, [4]Bandim Health Project, Indepth Network, Bissau, Guinea-Bissau, [5]Epigenomics & Single Cell Biophysics Group, Department of Cell Biology FNWI, Radboud Institute for Molecular Life Sciences (RIMLS), Nijmegen, Netherlands, [6]Danish Institute for Advanced Study, University of Southern Denmark, Odense, Denmark

Mycobacterium tuberculosis (TB) continues to be one of the leading causes of mortality worldwide. Over 25% of TB deaths occur in the African Continent. Bacillus Calmette-Guerín (BCG) being TB vaccine also provides non-specific protective effects against other infections through "trained innate immunity". Several studies have demonstrated that the host genetic variation has a strong influence on the immune response, e.g to influenza, Hepatitis B or measles vaccination. However, which genetic variants affect cytokine responses to secondary infections upon BCG vaccination is unknown. Moreover, while studies in European populations have demonstrated the role of genetic polymorphisms in the inter-individual variability in cytokine responses upon stimulation, it is not clear whether these findings are transferable to non-Europeans. We utilized an African trial cohort (Guinea-Bissau) of low-birth-weight (<2.5 kg) infants (~400

samples) randomized to BCG vaccination or no BCG-vaccination. In vitro stimulation of whole blood was done using five different stimuli followed by seven different cytokine measurements. We performed genome-wide SNP cytokine QTL (cQTL) mapping followed by pathway enrichment and functional annotation. The results were compared using a European BCG-vaccinated adult cohort (n=300).In the African samples, we identified 9 independent cQTLs ($P < 5 \times 10^{-8}$) affecting cytokine responses specifically in the BCG group but not in the control group. Interestingly, these cQTLs show pleiotropic effects. Also, nominal cQTLs ($p < 0.05$) between European and African samples showed very limited overlap (1.4% to 1.5%), indicating either age or ethnicity-associated genetic effects. We identified several causal genes at these loci and implicated complement pathway in regulating cytokine response after BCG vaccination, which was confirmed through functional validation. Our study shows that distinct genetic loci affect cytokine response in BCG-vaccinated African infants; the same associations were not seen in otherwise similar BCG-unvacciantedinfants or in European BCG-vaccinated adults.

0010

TRADITIONAL UVULECTOMY: PREVALENCE AND ASSOCIATED FACTORS IN A PREGNANCY BIRTH COHORT IN NORTH SHEWA ZONE, ETHIOPIA

Bezawit M. Hunegnaw[1], Yahya Mohammed[2], Frederick G. B. Goddard[3], Mesfin Zeleke[2], Chalachew Bekele[2], Grace J. Chan[4], Delayehu Bekele[5]

[1]Department of Pediatrics and Child Health, St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, [2]BIRHAN HDSS, St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, [3]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States, [4]Division of Medicine Critical Care, Boston Children's Hospital, Harvard Medical School; Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States, [5]Department of Obstetrics and Gynecology, St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia

Traditional uvulectomy is a procedure which consists of cutting part or all of the uvula. It takes place in informal settings in the community without any clinical assessment or indication, usually for fear of obstructed breathing in infants leading to death. The procedure is performed by local traditional healers using unsterilized sharp equipment and is known to expose individuals to complications such as excessive bleeding, sepsis, tetanus and infectious diseases like Hepatitis and HIV. Despite efforts to counsel and educate the community on the dangers of this practice, it still persists in some developing countries. In Ethiopia, this practice is commonly observed in the Amhara region where the community attributes nearly all infant and neonatal illnesses to uvular swelling or elongation. This region also bears one of the highest infant and neonatal morbidity and mortality rates in the country. Few hospital-based studies have been conducted to describe prevalence and complications of this practice but there is dearth of information on the magnitude of this problem in the community. The BIRHAN pregnancy and birth cohort study is based in the Amhara region and follows a cohort of children from birth up to two years of age through scheduled visits on days 6, 28 and 42 after birth as well as months 6, 12 and 24. This study aims to assess the prevalence and timing of traditional uvulectomy among a largely rural community and describe social, obstetric and neonatal factors associated with the observation of this practice. A total of 2,290 live births were enrolled and followed during the period of December 2018 to December 2021. The prevalence of traditional uvulectomy in the study population was high at 14.1%; n=322. Of those who were subject to the procedure, 8.7%; n= 28 were performed by day 6 of birth and 74.2%; n=239 were done by the age of 12 months. Further analysis will describe factors associated with this harmful practice. The results of this study will help to describe the current burden of this problem as well as identify risk populations and areas for targeted interventions that will help to reduce neonatal and early childhood morbidity and mortality.

0011

ASSOCIATIONS BETWEEN BRAIN VOLUMETRY IN CHILDHOOD AND EARLY CHILDHOOD STUNTING

Beena Koshy[1], Samuel Berkins[1], Roshan Livingstone[1], Anitha Jasper[1], Arpan Banerjee[2], Rebecca Scharf[3], Venkata Raghava Mohan[1], Sushil John[1], Jaya Prakash Muliyil[1], Gagandeep Kang[1]

[1]Christian Medical College, Vellore, Tamil Nadu, India, Vellore, India, [2]National Brain Research Centre, Gurgaon, India, [3]University of Virginia Children's Hospital, Virginia, VA, United States

Early childhood stunting affects over 200 million young children worldwide and is associated with suboptimal childhood development and cognition. There are limited data on the effects of early childhood stunting on human brain volumetry. We evaluated childhood brain volumes at 9 years of age and its association with stunting at 2 years, in a community-based birth cohort in Vellore, south India. Volumetric T1 weighted magnetic resonance imaging (MRI) images were acquired using Siemens Skyra 3T MRI scanners without sedation, and automated segmentation performed using FreeSurfer version 6. For analysis, volumes of total brain, cerebellum, regional cerebral cortices, subcortical brain structures and corpus callosum at 9 years were compared between those stunted and not stunted at 2 years of age using univariate analysis with further adjustments for age, sex, and total brain volume. Of 251 new-borns recruited into the MAL-ED birth cohort, 205 (81.7%) children were available for the 9-year follow-up. Of 178 children included in this analysis, 83 (46.6%) children were stunted at 2 years. Children stunted at 2 years of age had smaller left and right cerebellar cortices when compared to those not stunted (left - 52,032 mm^3 Vs 53,348 mm^3; p = .03 and right - 52,369 mm^3 Vs 53,688 mm^3; p = .04 respectively), when adjusted for age, sex, and total brain volume. Stunted children also had significantly smaller posterior corpus callosum when compared to those not stunted (744 mm^3 Vs 783 mm^3 respectively; p = .04). Follow up of an Indian birth cohort showed that early childhood stunting was associated with lower childhood cerebellar cortical brain volumes which may influence information integration and motor co-ordination, as well as smaller posterior corpus callosum which could affect higher order association brain regions. Future research should explore concurrent and predictive nutrition-brain associations in children.

0012

CHARACTERIZING THE BURDEN OF HYALINE MEMBRANE DISEASE AMONG DECEASED INFANTS ENROLLED IN THE KENYA CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE NETWORK (CHAMPS) PROGRAM

Harun Odhiambo Owuor[1], Sammy Khagayi[1], Aggrey Igunza[1], Preston Izulla[2], John Wagai[2], Sarah Ngere[1], Dickens Onyango[3], Elizabeth Oele[1], Richard Omore[1], Victor Akelo[4]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Adroitz consultants limited, Nairobi, Kenya, [3]Kisumu County Health Department, Kisumu, Kenya, [4]Centers for Disease Control and Prevention, Kisumu, Kenya

Hyaline membrane disease (HMD) is a life-threatening clinical syndrome whose true prevalence is still unknown in many African countries. Furthermore, diagnosis and therapy remain a challenge in developing countries. Child Health and Mortality Prevention Surveillance (CHAMPS) is a multi-country surveillance program that systematically identifies causes of under-five mortality from defined catchment areas in seven countries. Here, we described prevalence, diagnosis, management, and maternal risk factors for hyaline membrane disease among neonates enrolled in the CHAMPS Kenyan site. Causes of death (COD) were determined by a panel of experts using data from post-mortem conducted through minimally invasive tissue specimen testing, clinical records, and verbal autopsy. Between May 2017 and April 2021, 124 deceased neonates had their COD determined. Thirty (24.2%) had HMD as immediate COD or other significant condition causing death. Slightly more than half (17 [56.6%]) had a clinical diagnosis of HMD antemortem—none of the cases had the often routinely required investigations such as chest X-ray, electrocardiogram, blood culture or blood gases analyses done prior to

death. Supplemental oxygen was given in all cases, with the amount of oxygen administered being sup-optimal (0.5L/min). No case received surfactant replacement therapy, continuous positive airway pressure, mechanical breathing machine, and endotracheal tube placement. HMD was commonest in neonates with low birth weight (26 [86.6%]) and preterm births (25 [83.3%]). The prevalence of HMD is high among Kenya CHAMPS cases, with significant antemortem gaps in diagnosis and clinical management of cases identified. Given medical complexity of diagnosing and managing children with HMD, a high index of clinical suspicion coupled with training on optimal management can be considered to reduce HMD associated neonatal deaths.

Discharge against medical advice (DAMA) is a known risk factor for adverse outcomes in children. An improved understanding of its impact on outcomes and its risk factors is essential to the development of programs to address DAMA. The aim of this study was to (1) assess the impact of DAMA on post-discharge outcomes and (2) to identify key socioeconomic and clinical risk factors for DAMA. This secondary analysis of a multisite observational study included children 6-60 months of age hospitalized with suspected or proven infections enrolled from July 2017 to July 2019. Children received follow-up for 6 months after discharge to determine outcome. Seventy-seven clinical and socio-demographic variables, collected at admission, were assessed as potential risk factors. Univariate logistic regression was performed to identify significant risk factors for DAMA, as well as its impact on post-discharge readmission and mortality. Of the 3,673 children who survived to hospital discharge, 483 (13%) were discharged against medical device, and 53 (11%) of them died within 6 months. DAMA was highly associated with post-discharge mortality (HR: 3.62, 95% CI: 2.60-5.05). Malnutrition, HIV and anemia were key clinical risk factors of DAMA, while lower maternal education, higher distance from hospital, and the children being brought to the hospital by their father (compared to their mother) were key social risk factors. DAMA is common and is a key risk factor for poor post-discharge outcomes. Programs to address DAMA, especially for socially vulnerable children, are urgently required.

0014

CLINICAL DECISION SUPPORT ALGORITHM ADHERENCE AT A PEDIATRIC TELEMEDICINE AND MEDICATION DELIVERY SERVICE IN A LOW-RESOURCE SETTING

Molly Klarman[1], Katelyn E. Flaherty[1], Xiaofei Chi[1], Youseline Cajsuma[1], Lerby Exantus[2], Jason Frieson[3], Valery M. Beau de Rochars[1], Chantale Baril[2], Torben Becker[1], Matthew J. Gurka[1], Eric J. Nelson[1]

[1]Univeristy of Florida, Gainesville, FL, United States, [2]Université d'État d'Haiti-Faculté de Médecine et de Pharmacie, Port-au-Prince, Haiti, [3]Trek Medics International, Washington, DC, United States

In low-resource settings the application of telemedicine coupled with medication delivery has considerable potential to overcome healthcare access barriers. We piloted a telemedicine and medication delivery service (TMDS) called 'MotoMeds' for pediatric patients with acute illness at night in Haiti. In this study, a paper-based clinical decision-support algorithm was developed for call center case management. We assessed the algorithm's performance by comparing call center exams with paired in-person exams (reference standard). In this sub-analysis, algorithm adherence was the primary outcome measure. Inclusion criteria were age 10 years or less and parental contact with a TMDS provider. Workflow: A parent of an ill child contacted the call center. A TMDS provider used the algorithm to gather information to triage the child for danger signs and generate an assessment and plan. Cases included a severity (mild, moderate, severe) and disposition assessment; plans included oral or topical medications and/or oral fluids. For households within the delivery zone, a provider and driver transported medications/fluids to the child's home where the paired exam was performed. Two independent physicians reviewed the charts for algorithm non-adherence: severity mis-categorizations, failure to identify danger signs, prescription of a non-indicated antibiotic and/or failure to prescribe an indicated antibiotic. A total of 382 cases were enrolled; 86% (327) of cases at the call center and 88% of cases (296) at the household exhibited full adherence. Among cases with deviations, mis-categorization between mild and moderate severity was the most common type at both the call center (13%, 48) and household (10%, 35). A missed danger sign occurred in <1% (1) of cases at the call center and 3% (10) of cases at the household. Prescription of non-indicated antibiotics occurred in 1% (5) and 5% (16) of cases and failure to prescribe an antibiotic occurred in 1% (2) and <1% (1) of cases at the call center and household, respectively. The data reveal areas for improvement and suggest adherence can be optimized with digitization, a critical step towards scalability.

0015

WHOLE PROTEOME DIFFERENTIAL SCREENING IDENTIFIES HELMINTH DEFENSE MOLECULE AS NOVEL SCHISTOSOMIASIS JAPONICA VACCINE CANDIDATE

Amanda E. Ruiz[1], Sunthorn Pond-Tor[1], Ronald Stuart[1], Mario Jiz[2], Blanca Jarilla[2], Jennifer Friedman[1], Hai Wei Wu[1], Jonathan D. Kurtis[1]

[1]Brown University, Providence, RI, United States, [2]Research Institute of Tropical Medicine, Manila, Philippines

To identify vaccine candidates for Schistosomiasis japonica, differential screening of an adult worm cDNA library was employed using sera and epidemiologic data from a praziquantel treatment reinfection cohort (N = 300) in a holoendemic region of the Philippines. This approach enables the identification of schistosome antigens recognized by antibodies expressed by resistant, but not susceptible, individuals. 1 x 106 clones were differentially screened of which 32 were recognized by antibodies in both resistant sera (RS) and susceptible sera (SS), 38 were recognized by antibodies in SS, and five were uniquely recognized by RS. Of the five uniquely recognized clones, four were identified as SjHDM-1, a helminth innate immune cell modulator. The population profile of rSjHDM-1-specific antibodies in the praziquantel treatment reinfection cohort was assessed using a bead-based assay. Cohort participants demonstrated a 2.7-fold increase in rSjHDM-1-specific IgG antibody responses compared to SWAP-

specific IgG responses (p<0.0001) and a 3.7-fold increase compared to SEA-specific IgG responses (p<0.0001). Compared to North American controls, study participants displayed a significant increase of rSjHDM-1-specific IgG antibody responses (p=0.007). Immunofluorescence staining of SjHDM-1 in adult *Schistosoma japonicum* worms exhibited localization to the tegument in female and male worms. Mouse protection studies will be conducted to characterize SjHDM-1 as a vaccine candidate, with efficacy assessed in a buffalo challenge study. SjHDM-1 yields promise as a novel schistosome vaccine antigen given its host immune accessibility and its antigen-specific IgG profile in holoendemic populations.

0016

MATERNAL SCHISTOSOMIASIS AND ALTERATIONS IN BREAST MILK COMPOSITION

Meagan Amelia Barry[1], Zorimel Vargas[2], Veronica Tallo[3], Marianne J. Sagliba[3], Amabelle J. Amoylen[3], Jennifer F. Friedman[1], Emily A. McDonald[1]

[1]The Warren Alpert Medical School of Brown University, Providence, RI, United States, [2]The Center for International Health Reserach, Rhode Island Hospital, Providence, RI, United States, [3]Research Institute of Tropical Medicine, Manila, Philippines

Human breast milk is the preferred nutritional source for babies and is recommended for at minimum 6 months and, ideally, up to 24 months. Breastfeeding is associated with reduced risks of infant acute otitis media, gastroenteritis, and lower respiratory tract infections. Human milk is composed of macronutrients including carbohydrates such as lactose, micronutrients, and components conferring immune protection including immunoglobulins, predominantly secretory IgA. IgA-secreting plasma cells of the breast are thought to originate in the intestine. In a mouse model of schistosomiasis, egress of eggs through the gut lymphoid tissue led to vascular remodeling and a reduction in secretory IgA producing lymphocytes. The effect of maternal schistosomiasis on human breast milk composition has yet to be investigated. To elucidate this question, a cohort of 240 pregnant women in Leyte, Philippines were enrolled and followed until their infants were 2 years of age. Helminth infection was evaluated by Kato-Katz method at enrollment (less than 20 weeks gestation) and at 32 weeks gestation. Women were offered anthelmintic treatment, but all declined. Breast milk samples were evaluated at periodic time points throughout the study. At six months postpartum, exclusively breastfeeding women who were infected with *Schistosoma japonicum* were found to have a 29% decrease in IgA in their breastmilk (p<0.05). We postulate that this is the result of damage to the gut lymphoid tissue during schistosome egg migration. Additionally, in mothers with evidence of gut integrity disruption and bacterial translocation, as measured by endotoxin in blood collected at 32 weeks gestation, there was an association with both decreased IgA (p<0.01, R^2=0.024) as well as decreased lactose content (p<0.01, R^2=0.023) in the breastmilk at 6 months postpartum. This is the first study to investigate alterations in human breast milk, in particular demonstrating impairment in the immune properties of breast milk, in maternal schistosomiasis. Future work will investigate associations between altered milk components and infant growth in the context of maternal schistosomiasis.

COMPARATIVE GENOMICS AND GENETIC MAPPING BUILT ON A NEW SNAIL MODEL PROVIDE INSIGHTS INTO SCHISTOSOME-RESISTANCE IN THE SNAIL *BIOMPHALARIA GLABRATA*

Lijing Bu[1], Daibin Zhong[2], Lijun Lu[1], Eric S. Loker[1], Guiyun Yan[2], **Si-Ming Zhang**[1]

[1]University of New Mexico, Albuquerque, NM, United States, [2]University of California Irvine, Irvine, CA, United States

Schistosomiasis, caused by Schistosoma parasites transmitted by freshwater snails, still plagues 237 million people in the world. *Biomphalaria glabrata* has served as the only model snail for studies of schistosomes in snails. To better understand schistosome vector snail biology and help develop innovative snail control strategies, we have developed a new snail model consisting of two homozygous *B. glabrata* lines (iM line and iBS90) with sharply contrasting schistosome-resistance phenotypes. We produced and compared high-quality genome sequences for iM line and iBS90 which were assembled from 255 (N50 = 22.7 Mb) and 346 (N50 = 19.4 Mb) scaffolds, respectively. Using F2 offspring bred from the two lines and the newly generated genome sequences, we constructed 18 linkage groups covering 96% of the genome and identified three new QTLs (quantitative trait loci), two involved in snail resistance and one relating to body pigmentation. This study provides excellent genomic resources for understanding complex vector snail biology, reveals genomic difference between resistant and susceptible lines, and offers novel insights into genetic mechanism of snail resistance to schistosomiasis.

0018

INTERLEUKIN-4-INDUCING PRINCIPLE FROM *SCHISTOSOMA MANSONI* EGGS IS IMPORTANT IN BLADDER CANCER: DNA RECOGNITION AND BINDING SPECIFICITY OF THE *S. HAEMATOBIUM* HOMOLOGUE

Derick Osakunor[1], Trevor Siggers[2], Olivia Lamanna[1], Kenji Ishida[1], Heather Hook[2], Michael Hsieh[1]

[1]Children's National Hospital, Washington, DC, United States, [2]Boston University, Boston, MA, United States

Urogenital schistosomiasis, caused by *Schistosoma haematobium* is the most common form of schistosomiasis worldwide and is well-known for its association with bladder cancer; incidence rates estimated at about 3-4 cases per 100,000. However, the underlying mechanisms for the causal link between *S. haematobium* and bladder cancer, are poorly understood. Interleukin-4-inducing principle from *Schistosoma mansoni* eggs (IPSE) is the most abundant secreted protein from eggs of all schistosome species and plays a major role in modulating host pathology. We have previously demonstrated that H-IPSE, the *S. haematobium* homolog of IPSE, is internalized by both endothelial and urothelial cells, drives endothelial and urothelial proliferation, and is thus involved in *S. haematobium*-related carcinogenesis. Here, we used Protein binding microarray (PBM) technology and bioinformatics approaches to determine the specific DNA binding motifs of H-IPSE, and the downstream transcriptional events that result. Our results showed that DNA binding of H-IPSE is highly specific, and a DNA-binding motif of GGGTGGG was determined. The GGGTGGG sequence is recognized by the transcription factors PuF and Sall2, which are involved in tumor suppression. Concurrent experiments with M-IPSE (the *S. mansoni* homolog) showed that M-IPSE has the DNA binding motif resembling GGGGGAAAA and is different from H-IPSE, although similar in their affinity for G-rich sequences. Together, our results enabled us to identify novel targets of H-IPSE and its role in carcinogenesis and tumor progression through DNA recognition and binding of transcription factor sequence motifs involved in tumor suppression, and thus expand the understanding of the *S. haematobium*-associated pathology. The differences in DNA binding motifs for H-IPSE and M-IPSE may likely explain the unique carcinogenic properties of S. *haematobium* but not *S. mansoni*.

HARNESSING THE POTENTIAL OF ANTI-GLYCAN ANTIBODIES INDUCED IN SCHISTOSOMIASIS FOR DEVELOPMENT OF HIGHLY SENSITIVE AND SPECIFIC SEROLOGICAL TOOLS

Anna O. Kildemoes[1], Tom Veldhuizen[1], Lisette van Lieshout[1], Daniel Camprubí-Ferrer[2], Jose Munoz[2], Leo Visser[1], Sammy M. Njenga[3], Meta Roestenberg[1], Angela van Diepen[1], Cornelis H. Hokke[1]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]Barcelona Institute for Global Health, Barcelona, Spain, [3]Kenya Medical Research Institute, Nairobi, Kenya

The WHO 2030 roadmap for schistosomiasis clearly identifies an expanded portfolio of highly sensitive and specific diagnostic tools as essential

for continued and sustained progress towards elimination. Serological assays are excellent for sensitive detection of primary infections with schistosomes and for schistosomiasis surveillance in very low endemic, near- and post-elimination settings. However, many existing assays are based on crude soluble egg, cercarial or worm antigen preparations, which suffer from batch-to-batch variation and contain cross-reactive epitopes. Many glycan elements present in the schistosome glycoprotein and glycolipid repertoire elicit high antibody titres upon infection. Here we aim to exploit the antigenicity of glycan motifs for development of highly sensitive and specific schistosomiasis serology, while also benefitting from the added advantage of glycans being highly stable compared to protein antigens. Tailor-made glycan microarrays combined with well-characterised sample sets (n>500 individuals) were used to evaluate target performance. Sensitivity was determined using two controlled human schistosome infection (CSI) studies, primary infection samples from travellers, and samples from schistosomiasis endemic areas. Specificity was confirmed using helminth naïve and soil-transmitted helminth positive samples. From >80 targets, a single native schistosome glycan performed with high sensitivity and specificity for both IgG and IgM (≥95%). Observations from natural primary (traveller) and low dose CSI (10-30 cercariae) single exposure infections show dose dependent timing of IgG response initiation. Current preliminary data indicates that synthetic glycans can mimic the native material. In conclusions, a glycan target candidate for development of highly sensitive and specific schistosomiasis diagnostic tool(s) with use cases for travellers and in low endemic, near and post-elimination settings has been identified. Importantly, the glycan antigen shows promise for scalable production and hence future standardised test development.

SOIL-TRANSMITTED HELMINTHIASIS IS NO LONGER A PUBLIC HEALTH PROBLEM IN BURKINA FASO

Clarrise Bougouma[1], Hamado Ouedraogo[1], Christophe Nassa[1], Fanny Yago-Wienne[2], Dieudonné Naré[2], Micheline Kalkoundo/Ouedraogo[2], **Lucien Mano**[2], Yaobi Zhang[3], Benoit Dembele[4], Steven D. Reid[3], Angela Weaver[3], Anna Phillips[5], Jennifer Magalong[5]

[1]NTD Control Program - Ministry of Health, Ouagadougou, Burkina Faso, [2]Helen Keller International, Ouagadougou, Burkina Faso, [3]Helen Keller International, New York, NY, United States, [4]Helen Keller International, Regional Office for Africa, Dakar, Senegal, [5]Family Health International 360, Washington, DC, United States

Baseline mapping conducted between 2004 and 2005 showed Burkina Faso was endemic for soil-transmitted helminths (STH) and co-endemic with schistosomiasis (SCH) and lymphatic filariasis (LF) in a number of health districts. Overall, 48 out of 70 health districts (HDs) had STH prevalence among school age children (SAC) ranging 1.8-48.7%. Mass drug administration (MDA) for STH started in 2001 in the Sud-Ouest region and reached all endemic HDs by 2005, integrated with LF and/or SCH MDA. Population 5 years and older were targeted with albendazole during LF/MDA and SAC were targeted with albendazole during SCH/MDA and since 1999, deworming of children under five years has been conducted biannually with vitamin A supplementation (VAS) campaigns. To assess multiple years of treatment on STH endemicity, impact assessments were conducted in 2016-2019 during both SCH sentinel site surveys and LF transmission assessment surveys (TAS) with support from USAID's END in Africa and Act | West programs. SCH-STH surveys were carried out in 77 sentinel and spot check sites, with a total of 11,065 children aged 5 to 15 years evaluated. TAS-STH integrated surveys were conducted in 20 LF evaluation units (EUs), with a total of 6,927 children aged 6 to 7 evaluated in 650 sites. Kato-Katz was used to diagnose STH infections in stool. In total, 727 sites across 66 HDs were assessed by either SCH-STH or TAS-STH surveys, although only 48 of these were endemic for STH at baseline. The STH prevalence findings ranged from 0.00 to 4.49% (median prevalence 0.00%). Among them, 12 HDs evaluated through TAS-STH surveys were classified as having a prevalence of <2%, and 30 HDs were classified as having a prevalence between 2% and 10%. No moderate or heavy intensity infection was found in any HD. The results showed that multiple years of deworming may have successfully eliminated STH as a public health problem in Burkina Faso. STH MDA is no longer needed, but to maintain the progress made in controlling STH, targeted deworming will be implemented in collaboration with the Nutrition Directorate and the Family Health Directorate for pregnant women and women of childbearing age at health facilities.

0021

CIRCULATING ANODIC ANTIGEN (CAA) AS A DIAGNOSTIC MARKER FOR MEASURING TREATMENT SUCCESS IN UROGENITAL SCHISTOSOMIASIS

Yabo J. Honkpehedji[1], Jacob Gerstenberg[1], Jean-Claude Dejon-Agobe[1], Raphael Rakotozandrindrainy[2], Rivo Rakotoarivelo[3], Mandranto Rasamoelina[4], Elisa Sicuri[5], Daniela Fusco[6], Paul Corstjens[7], Pytsje T. Hoekstra[8], Andrea Kreidenweiss[9], Govert J. van Dam[8], Ayola A. Adegnika[1]

[1]Centre de Recherche Medical de Lambarene, Lambarene, Gabon, [2]Université d'Antananarivo, Antananarivo, Madagascar, [3]Université de Fianarantsoa, Fianarantsoa, Madagascar, [4]Centre d'Infectiologie Charles Mérieux, Antananarivo, Madagascar, [5]Fundación Privada Instituto de Salud Global Barcelona, Barcelona, Spain, [6]Bernhard-Nocht-Institut für Tropenmedizin, Hamburg, Germany, [7]Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands, [8]Department of Parasitology, Leiden University Medical Center, Leiden, Netherlands, [9]Institut für Tropenmedizin, Universität Tübingen, Tübingen, Germany

Monitoring of anthelmintic efficacy constitutes a challenge, as diagnostics are mainly based onmeasuring the excretion of eggs. Therefore, sensitive and accurate tools are needed to improve theassessment of the efficacy of anthelmintic interventions. Diagnosis of schistosomiasis is alsocomplemented by the detection of *circulating anodic antigen* (CAA), an antigen that is released by*Schistosoma* worms into the bloodstream of the host and excreted via urine. As part of the freeBILy-GAB study, we compared CAA detection in urine vs. urine filtration method to assess the efficacy ofpraziquantel treatment for urogenital schistosomiasis during pregnancy. We evaluated the efficacy ofpraziquantel (40mg/kg single dose) within 82 infected pregnant women. Schistosomiasis wasdiagnosed and monitored through urine filtration and CAA detection multiple days post-treatment. Detection of CAA was based on an up-converting reporter particle-based lateral flow test. Wecalculated cure rates (CR), geometric mean (GM), and intensity reduction rate (IRR) for bothprocedures. CRs by microscopy were higher compared to that of CAA detection at days 21 (96.8% vs.81.1%) and 41 (96.8% vs. 80.3%) following treatment. Decrease of urine CAA levels appeared to befaster than urine egg counts, as CAA GM dropped below the positivity threshold 4-6 days aftertreatment, while the GM of egg counts only reached negativity after 14-21 days. Egg count IRRcontinued to increase after treatment for many days and reached the WHO threshold of 90% fortreatment success on day 14. Meanwhile, CAA IRR remained lower, showed greater dispersal and thesteady decline reversed on day 28. The CAA is a prospective tool for monitoring praziquantel-basedtreatment. The CAA detects the effect of treatment at an earlier time point as compared tomicroscopy. However, we recorded higher variability of CAA levels during follow up where wesuspected that antigen levels would remain at a low level. The CAA detection might be more sensitiveto immature worms than egg-based microscopy, therefore detecting treatment failure or reinfection more accurately.

0022

COMMUNITY-WIDE DEWORMING LEADS TO A LOWER BURDEN OF STH INFECTION IN SCHOOL-AGED CHILDREN COMPARED WITH SCHOOL-BASED DEWORMING ALONE: RESULTS ROM THE COMMUNITY-DEWORMING AGAINST SOIL-TRANSMITTED HELMINTHS (CODE-STH) TRIAL

Clare E. F. Dyer[1], Dinh Ng Nguyen[2], Naomi E. Clarke[1], Sze Fui Hii[3], H. M. P. Dilrukshi Herath[3], Handan Wand[1], Luc E. Coffeng[4], Darren J. Gray[5], Archie C. A. Clements[6], Roy M. Anderson[7], John M. Kaldor[1], Rebecca J. Traub[3], Susana Vaz Nery[1]

[1]University of New South Wales, The Kirby Institute, Sydney, Australia, [2]Tay Nguyen University, Faculty of Animal Sciences and Veterinary Medicine, Buôn Ma Thuột, Vietnam, [3]The University of Melbourne, Faculty of Veterinary and Agricultural Sciences, Melbourne, Australia, [4]Erasmus MC University Medical Center, Rotterdam, Netherlands, [5]Australian National University, Research School of Population Health, Canberra, Australia, [6]Curtin University, Faculty of Health Sciences, Perth, Australia, [7]Imperial College London, Department of Infectious Disease Epidemiology, School of Public Health, London, United Kingdom

STH infections cause significant morbidity worldwide. The main control strategy is deworming of school-aged children (SAC). Community-wide deworming may reduce reinfection in SAC further as reducing the STH reservoir in adults may also reduce transmission. CoDe-STH is the first trial in the world comparing school-based versus community-wide deworming on STH infections in SAC. It is the largest ever trial using qPCR for STH diagnostics. Conducted in 64 primary schools in Dak Lak province, Vietnam, over 21,000 albendazole doses were given to SAC in both trial arms, and over 70,000 doses given to community members in the intervention arm at baseline. Stool samples were collected from SAC in both arms at baseline and at 1 year. More than 15,000 samples were analysed by qPCR. The primary outcome was prevalence of *Necator americanus*, the dominant STH species in the region; the main secondary outcome was infection intensity of *N. americanus*. Generalised linear mixed models with an interaction term of arm/timepoint were used to compare study outcomes. Unadjusted and adjusted odds ratios (OR) of *N. americanus* infection in SAC did not differ between trial arms at follow-up indicating that community-wide deworming had no impact on reducing reinfection of SAC one year after deworming. However, the odds of high/moderate intensity *N. americanus* infection was significantly lower in the community arm (uOR 0.29, p=0.001; aOR 0.30, p=0.001), demonstrating that community-wide deworming meant reinfections in SAC one year after deworming were of a lower intensity. In a sensitivity analysis, whereby schools with baseline *N. americanus* prevalence of <5% were excluded, the incident rate ratio (IRR) of infection intensity was also significantly lower in the community group (uIRR 0.42, p=0.008; aIRR 0.48, p=0.009). CoDe-STH is the first demonstration that community-wide deworming lowers burden of STH infection in SAC more than school-based deworming alone. This trial demonstrates the health benefit of expanding deworming programs to include the wider community after 12 months and only one round of treatment.

0023

GENETIC DIFFERENCES AMONG HUMAN TRICHURIS POPULATIONS WITH DIFFERING RESPONSES TO ALBENDAZOLE-IVERMECTIN COMBINATION TREATMENT

Abhinaya Venkatesan[1], Rebecca Chen[1], Brenna Reimer[1], Somphou Sayasone[2], Said Ali[3], Jean Coulibaly[4], Chandni Patel[5], Sophie Welsche[5], Ladina Keller[5], Eveline Hürlimann[5], Jennifer Keiser[5], John Gilleard[1]

[1]University of Calgary, Calgary, AB, Canada, [2]Lao Tropical and Public Health Institute, Vientaine, Lao People's Democratic Republic, [3]Public Health Laboratory Ivo de Carneri, Zanzibar, United Republic of Tanzania, [4]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire, [5]Swiss Tropical and Public Health Institute, Basel, Switzerland

Trichuris trichiura, one of the most important Soil Transmitted Helminth (STH) species, infects over 500 million people globally. Mass drug administration treatment programs use either albendazole or mebendazole but these benzimidazole drugs have very low efficacy against *T. trichiura,* with egg reduction rates (ERR) typically below 50%. Combination albendazole-ivermectin treatment has shown considerable improvement in efficacy. An albendazole-ivermectin combination treatment trial was performed in three regions - Laos, Tanzania, and Cote d'Ivoire, revealing high efficacy with ERR above 98% in Tanzania and Laos but much lower efficacy in Cote d'Ivoire with ERR below 70%. To explore whether this difference in efficacy could be due to genetic differences in the parasite populations, we performed Illumina short-read deep amplicon sequencing of multiple mitochondrial and ribosomal DNA loci on *T. trichiura* PCR positive fecal samples from the three regions. Primers targeting the mitochondrial *nad1*, *nad4, cox-1,* and the major β-tubulin gene generated haplotypes mapping to the appropriate reference sequences from all the samples from Tanzania and Laos, but not from Cote d'Ivoire. Phylogenetic analysis of the ribosomal ITS-1 and ITS-2 loci revealed that haplotypes from the samples in Cote d›Ivoire clustered separately from those found in Tanzania and Laos populations in a clade containing *Trichuris* sequences from non-human primates and *Trichuris suis*. This study demonstrates that the *Trichuris* population in Cote d›Ivoire is genetically divergent to those from Tanzania and Laos, likely a cryptic species, and has a lower sensitivity to albendazole-ivermectin combination treatment.

0024

HUMAN GUT MICROBIOME CHANGES ARE ASSOCIATED WITH SINGLE DOSE ALBENDAZOLE TREATMENT OUTCOMES OF HOOKWORM INFECTIONS

Francis A. Appiah-Twum[1], Jewelna E B. Akorli[1], Lydia Okyere[2], Kate Sagoe[1], Irene Owusu Donkor[1], Michael Cappello[3], Michael D. Wilson[1]

[1]Department of Parasitology, Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, [2]Department of Pathobiology, University of Illinois, Urbana, IL, United States, [3]Department of Pediatrics, Yale School of Medicine, Yale University, New Haven, CT, United States

Microbes play an important role in human gut homeostasis, metabolic, immunologic and physiopathology of the body. Active helminth infections cause host gut dysbiosis, which should restore after successful treatment. Our longitudinal study conducted during 2018-2021 in the Kintampo North Municipality in Ghana recorded low cure rates with treatment with a single dose of 400 mg albendazole in some communities. To investigate the involvement of the gut microbiome we obtained fecal samples from consented hookworm positive participants who were either successfully treated or failed. At each sampling event, the samples were collected prior to and 10-14 days post albendazole treatment. We used 16S rRNA amplicon sequencing of DNA extracted from stool to investigate the composition and biodiversity of the gut microbiota and to identify potential microbial biomarkers associated with treatment outcomes. The results showed significant variation in microbiota diversity between individuals successful and unsuccessful after albendazole treatment (ADONIS; R^2= 0.10 p= 0.001). A significant compositional increase in Firmicutes (Metastats; p= 0.005) was observed among individuals who failed treatment and a corresponding increase in Proteobacteria (Metastats; p= 0.04) within cured individuals. The diversity analysis also revealed a significant increase in microbial diversity (ANOSIM; R= 0.21, p= 0.001) among successfully treated individuals. This study suggests a relationship between human gut microbiota and albendazole therapy outcomes of hookworm infection. Moving forward, we will conduct further studies to hone in on specific biomarkers identified within this study to establish their potential for assessment of pharmacological responses to anthelminthic therapies.

0025

THE BENZIMIDAZOLES OXFENDAZOLE AND FLUBENDAZOLE ELIMINATE ADULT FILARIAE OF *LITOMOSOIDES SIGMODONTIS* IN AN IMMUNE SYSTEM-DEPENDENT MANNER

Frederic Risch, Johanna F. Scheunemann, Julia J. Reichwald, Benjamin Lenz, Alexandra Ehrens, Marianne Koschel, Achim Hoerauf, **Marc P. Hübner**

University Hospital Bonn, Bonn, Germany

Preclinical research is hampered by the fact that drugs with known efficacy in human filarial patients as well as filarial rodent models are less active *in vitro* and require increased concentrations for efficacy. In the present study, we investigated to what extent the efficacy of the benzimidazoles flubendazole and oxfendazole in the *Litomosoides sigmodontis* mouse model depends on the immune system. Both flubendazole and oxfendazole are direct acting drugs and treatment with either compound can lead to complete elimination of adult worms in the *L. sigmodontis* mouse model after subcutaneous (flubendazole) or oral (oxfendazole) application. Wild-type BALB/c, eosinophil-deficient dblGATA, IL-4R/IL-5-deficient, antibody-deficient μMT, and B-, T-, and NK-cell-deficient RAG2/IL-2Rγ mice were infected with *L. sigmodontis*. Following adult worm development (35 dpi), mice were treated with optimal and suboptimal doses of flubendazole subcutaneously and oxfendazole orally, respectively, and worm burdens were determined 70 days post infection and compared to vehicle controls. In a separate experiment, animals were treated with a combination of oxfendazole and IL-4, IL-5, or IL-33 for 3 days. Wild-type animals showed a reduction in adult worm burden of >98% compared with vehicle controls after 5-day treatment with flubendazole and oxfendazole. In contrast, treatment with either benzimidazole in knockout mice resulted in no reduction (RAG2/IL-2Rγ) or significantly impaired reduction in worm burden (dblGATA, IL-4R/IL-5$^{-/-}$, μMT). In addition, the efficacy of a suboptimal 3-day treatment with oxfendazole (17% reduction in adult worms) was increased to 70% reduction in adult worms when combined with IL-5, but not IL-4 (37%) and IL-33 (39%). Our results suggest that various components of the immune system support the filaricidal effect of benzimidazoles *in vivo* and represent a way to increase treatment efficacy *in vivo* and may allow the development of *in vitro* assays with a better prediction of drug efficacy.

PROCESS DEVELOPMENT OF SJ-P80: A LOW-COST TRANSMISSION-BLOCKING VETERINARY VACCINE FOR ASIATIC SCHISTOSOMIASIS

Adebayo J. Molehin[1], Sean A. Gray[2], Darrick Carter[2], Afzal A. Siddiqui[3]

[1]Midwestern University, Glendale, AZ, United States, [2]PAI Life Sciences Inc, Seattle, WA, United States, [3]Texas Tech University Health Sciences Center, Lubbock, TX, United States

Asiatic schistosomiasis caused by *Schistosoma japonicum* is a neglected tropical disease resulting in significant morbidity to both humans and animals - particularly bovines - in endemic areas. Infection with this parasite leads to less healthy herds, causing problems in communities which rely on bovines for farming, milk and meat production. Additionally, excretion of parasite eggs in feces perpetuates the life cycle and can lead to human infection. We endeavored to develop a minimally purified, inexpensive, and effective vaccine based on the 80 kDa large subunit of the calcium activated neutral protease (calpain) from *S. japonicum* (Sj-p80). Here we describe the production of veterinary vaccine-grade Sj-p80 at four levels of purity and demonstrate in a pilot study that minimally purified antigen provides protection against infection in mice when paired with a low-cost veterinary adjuvant, Montanide™ ISA61 VG. Preliminary data demonstrate that the vaccine is immunogenic with robust antibody titers following immunization, and vaccination resulted in a reduction of parasite eggs being deposited in the liver (23.4-51.4%) and intestines (1.9-55.1%) depending on antigen purity as well as reducing the ability of these eggs to hatch into miracidia by up to 31.6%. We therefore present Sj-p80 as a candidate vaccine antigen for Asiatic schistosomiasis which is now primed for continued development and testing in bovines in endemic areas. A successful bovine vaccine could play a major role in reducing pathogen transmission to humans by interrupting the parasitic life cycle and improving quality of life for people living in endemic countries.

0027

INTERLEUKIN-4-INDUCING PRINCIPLE OF *SCHISTOSOMA MANSONI* EGGS (IPSE), A SCHISTOSOME IMMUNOREGULATORY PROTEIN, PREVENTS SEPSIS

Ioannis Koutroulis, Wade O'Brien, **Michael Hsieh**

Children's National Hospital, Washington, DC, United States

Urogenital and hepatoenteric schistosomiasis transmission depend upon the successful transit of eggs across the bladder and intestinal walls, respectively. However, egg passage disrupts local tissues and can lead to bacterial translocation, sepsis, and host death, an undesirable outcome for schistosomes that rely on continuous oviposition to maximize reproductive success. There is evidence that schistosomes may immunoregulate their hosts to prevent sepsis. *Schistosoma mansoni*-infected mice develop endotoxemic sepsis and die if their myeloid cells lack the IL-4 receptor. Mice whose bladders are injected with *Schistosoma haematobium* eggs also develop endotoxemia and die if phagocytic cells are depleted. *Schistosoma* eggs secrete large amount of the interleukin-4-inducing principle of *S. mansoni* eggs (IPSE). These findings led us to hypothesize that IPSE may be a schistosome molecule that prevents host sepsis. To test this hypothesis, mice underwent intravenous IPSE or vehicle injection followed by intraperitoneal injection with cecal slurry a day later to induce sepsis. Mice were then assigned clinical sepsis scores every 2 hours for 18 hours in a blinded fashion (maximum score of 28). Both groups of mice had similar baseline scores. Whereas mice given vehicle injections developed progressively severe sepsis with an average score of 16 at 18 hours, IPSE-treated mice did not exceed a score of 14 at any time point. Additionally, at time of euthanasia (18 hours post-sepsis induction), there was a decrease in average sepsis scores in the IPSE-treated group compared to vehicle-treated mice, that continued to have a worsening clinical course. A 48-plex cytokine analysis of mouse plasma collected at time of euthanasia was performed using the Luminex platform. This revealed significant changes in multiple cytokines, consistent with IPSE's known immunoregulatory mechanisms. These findings support the hypothesis that IPSE may contribute to prevention of schistosomiasis-associated sepsis likely via preconditioning, and suggest that IPSE could be developed as a therapeutic agent for other forms of sepsis.

ECO-CLIMATIC FACTORS SHAPING THE DISTRIBUTION OF *ANOPHELES COLUZZII* AND *AN. GAMBIAE* MALARIA VECTORS AND OF THEIR PUTATIVE HYBRIDS ACROSS THEIR SYMPATRIC RANGE

Beniamino Caputo[1], Leonardo Frosi[1], Chiara Virgillito[1], Carlo Maria De Marco[1], Verena Pichler[1], Federico Filipponi[2], **Alessandra della Torre**[1]

[1]University of Rome Sapienza, Rome, Italy, [2]Institute for Environmental Protection and Research (ISPRA), Rome, Italy

Anopheles coluzzii (CO) and *An. gambiae* (GA), the main Afrotropical malaria vectors, have recently diverged and believed to be isolated due to imperfect pre-mating isolation mechanisms, as shown by records of putative hybrids (H) characterized by heterozygous CO/GA genotypes of diagnostic markers in chromosome-X centromeric region. We here report the results of the systematic review of the existing (2001-2021) literature on field samples of CO, GA and H distribution across their sympatric range in west and central Africa. This allowed to create a database with >170k individuals from >1,900 sampling sites; of these individuals approximately 119k were collected and identified as adults, 5k as larvae and 47k were collected as larvae, but genotyped after emergence in the laboratory.

Overall, H-frequency was highest in the far-west region (up to 25%), 10-fold lower (up to 1.9%) in western countries and again 10-fold lower (<0.2%) in central Africa. Unexpectedly, H-frequency was overall lower in samples collected as larvae but emerged in the lab and genotyped as adults (which we expected to have escaped selective mechanism against H-larvae in the field), than in samples collected as adults. Preliminary results of Generalized Additive Model carried out on the latter sample highlight temperature and rainfall (and not land cover) as major climatic determinants of H-frequencies. In addition, it is predicted that H-frequency is higher where CO and GA frequencies are balanced and in proximity to the coast, confirming at continental level previous results from Burkina Faso and far-west region, respectively.

LOCAL THERMAL ADAPTATION IN MOSQUITO POPULATIONS AND THE POTENTIAL IMPLICATIONS FOR IMPACTS OF CLIMATE CHANGE

Nina L. Dennington[1], Matthew B. Thomas[2], Marissa Grossman[1]

[1]The Pennsylvania State University, University Park, PA, United States, [2]The University of York, York, United Kingdom

Local thermal adaptation in mosquito populations and the potential implications for impacts of climate change Environmental temperature impacts many aspects of mosquito life history. Consequently, there is considerable concern that increases in temperature due to climate change could lead to shifts in the dynamics and distribution of *Aedes aegypti*, the primary vector of arbovirus diseases like dengue, Zika, and yellow fever. Many current mechanistic models that examine the effects of temperature on transmission tend to assume there are 'average' thermal performance curves that are representative for a given vector species. However, this 'one size fits all' assumption ignores the potential for local thermal adaptation to create population-level differences in thermal performance. In this study, we explored thermal performance of five field populations of *Ae. aegypti* from Mexico, together with a standard laboratory strain. We reared these six populations at a range of temperatures between 13°C and 37°C to generate thermal performance curves for a suite of life-history traits including development rate, fecundity, and survival. We then integrated these traits into a composite fitness measure to characterize the effects of temperature on overall population growth rates. The results provide strong evidence for the potential for local thermal adaptation in *Ae. aegypti* populations and challenge the prevailing of application of 'one size fits all' thermal performance models to explore the current and future impact of climate on mosquito borne diseases.

WHY DO HUMANS DIFFER IN ATTRACTIVENESS TO MALARIA MOSQUITOES?

Marieke M. de Swart[1], Niels O. Verhulst[2], Joop J.A. van Loon[3], Leo A.B. Joosten[4], Hauke Smidt[1], Constantianus J.M. Koenraadt[1]

[1]Laboratory of Entomology, Wageningen University, Wageningen, Netherlands, [2]Institute of Parasitology, National Centre for Vector Entomology, Vetsuisse and Medical Faculty, University of Zürich, Zürich, Switzerland, [3]Laboratory of Entomology, Wageningen University and Research, Wageningen, Netherlands, [4]Department of Internal Medicine and Radboud Center for Infectious Diseases, Radboud University Medical Center, Nijmegen, Netherlands

Malaria morbidity and mortality have increased in the past years, underlining the need for fundamental knowledge to develop new or improved vector surveillance and control tools, such as odour-baited traps. Malaria mosquitoes are attracted to humans using cues such as volatiles emanating from the human body. Earlier research has shown that human individuals differ in their attractiveness to the malaria mosquito *Anopheles coluzzii*, which correlates with human skin microbial composition. The human skin interacts in a complex manner with the immune system that on one hand defends the skin against pathogens and on the other hand facilitates the balance of commensal bacteria. However, it is unknown which selection pressure drives this preference from mosquitoes for specific humans. We hypothesize that mosquitoes prefer those humans whose blood is most beneficial for their reproduction and/or survival. To test this hypothesis, an observational study with 49 human subjects was conducted. During four visits, *An. coluzzii* mosquitoes were allowed to take blood meals from subjects *in vivo* and *in vitro*. Odour samples and skin swabs for analysis of microbial composition were collected from each subject during each visit. After feeding, mosquito oviposition and survival were monitored up to 14 days after feeding. Furthermore, from whole blood of the subjects, peripheral blood mononuclear cells were isolated and then stimulated *in vitro* with three selected species of commensal bacteria to study individual variation in cytokine production as immunological parameters. Individual attractiveness of the human odour samples to *An. coluzzii* mosquitoes was studied in a dual-choice olfactometer. Preliminary results show substantial variation across participants in the parameters measured. Statistical modelling is ongoing to investigate effects of subject traits on mosquito attraction and reproduction.

GENOTYPING OF *ANOPHELES* MOSQUITO BLOOD MEALS REVEALS NONRANDOM HUMAN HOST SELECTION: IMPLICATIONS FOR *PLASMODIUM FALCIPARUM* TRANSMISSION, MALAWI

Rex B. Mbewe[1], John B. Keven[2], Charles Mangani[3], Mark Wilson[4], Themba Mzilahowa[5], Don Mathanga[5], Clarissa Valim[6], Miriam K. Laufer[7], Edward D. Walker[8], Lauren M. Cohee[7]

[1]Malawi University of Business and Applied Sciences, Blantyre, Malawi, [2]University of California, Irvine, CA, United States, [3]Kamuzu University of Health Sciences, Blantyre, Malawi, [4]University of Michigan, Ann Arbor, MI, United States, [5]Kamuzu University of Health Sciences, Malaria Alert Center, Blantyre, Malawi, [6]Boston University School of Public Health, Boston, MA, United States, [7]University of Maryland School of Medicine, Baltimore, MD, United States, [8]Michigan State University, East Lansing, MI, United States

Genotyping of human blood in arthropod vector blood meals allows identification of individual humans who were fed upon. This approach has improved understanding of parasite transmission in several vector-borne disease systems, including malaria. We used microsatellite-based genotyping to identify which humans were naturally transmitting *Plasmodium falciparum* to *Anopheles* vector mosquitoes. Household surveys (n=46) were conducted in two districts of moderate-to-high malaria transmission in southeastern Malawi. Demographic information and blood spots on filter paper were collected from consented participants. Indoor resting, blood-fed, female *Anopheles* mosquitoes were repeatedly sampled from inside participants' houses every two weeks during peak transmission (Jan-Apr 2020) by pyrethroid spray catches and CDC light traps. Genomic DNA from human blood spots and mosquito blood meals was genotyped and unique profiles identified and matched using a program in RStudio. *P. falciparum* DNA was detected in human and mosquito samples by PCR. Human blood was detected in 370 mosquito samples, of which 12% (n=44) contained more than one human genotype. Few individuals contributed most of the blood meals to the *Anopheles* vector population. 46 unique human genotypes from the at-risk human participants (n=250) were found among the 370 mosquito blood meals. The number of blood meals taken from individual people ranged from 1 to 49. More blood meals (60%) came from males than females even though males were a smaller fraction of the population. Among blood meals that matched genotyped participants, vectors fed more frequently on school-age children (SAC) (6-15 years old) than younger children and adults. Mosquitoes that had fed upon male SAC had the highest *P. falciparum* infection prevalence in their abdomens. Results support the hypothesis that SAC, particularly males, are important reservoirs of *P. falciparum* transmission from humans to mosquitoes. Thus, interventions aimed at reducing *P. falciparum* transmission should preferentially target this population.

0032

DOES HOST PREFERENCE DRIVE OBSERVED FEEDING PATTERNS OF *AEDES ALBOPICTUS* ACROSS GEOGRAPHIC POPULATIONS?

Kara Fikrig[1], Noah Rose[2], Nathan Burkett-Cadena[3], Basile Kamgang[4], Paul Leisnham[5], Jamie Mangan[1], Alongkot Ponlawat[6], Sarah Rothman[5], Tanise Stenn[3], Carolyn S. McBride[2], Laura C. Harrington[1]

Aedes albopictus is an invasive mosquito species capable of transmitting over 20 different pathogens with a variety of reservoir hosts. Its capacity to transmit these pathogens in nature is unclear, in part due to uncertainty surrounding its feeding behavior. Blood meal analyses from field-captured mosquitoes have shown vastly different feeding patterns, with a range of anthropophagy and host diversity levels. We sought to investigate whether innate host preference influences observed feeding patterns in nature. Low generation *Aedes albopictus* colonies were established with field-collected mosquitoes from 3 locations with high reported anthropophagy (Thailand, Cameroon, and Florida) and 3 locations with low reported anthropophagy (New York, Maryland, and Virginia). These mosquitoes were compared against anthropophilic (Thai *Ae. aegypti*) and zoophilic (Ugandan *Ae. aegypti*) control colonies. Host preference was assessed via dual-port olfactometer, which allows simultaneous presentation of two hosts (human arm and guinea pig). After 10 minutes of odor exposure, the number of mosquitoes that chose each host were recorded. All 6 *Ae. albopictus* colonies were significantly less likely ($P < 0.05$) to choose human than Thai *Ae. aegypti* (anthropophilic control) and did not exhibit significantly different host choice from the Ugandan *Ae. aegypti* (zoophilic control). There were no significant differences in host choice between low anthropophagy and high anthropophagy *Ae. albopictus* colonies. Our results suggest that differences in natural feeding patterns were not driven by differences in innate host preference for this species. Variation in feeding patterns are more likely the result of differences in host availability in each location. Our work is the first to compare *Ae. albopictus* and *Ae. aegypti* host preference directly and provides insight into differential vectorial capacity and human feeding risk.

0033

EXPANDED GEOGRAPHIC DISTRIBUTION AND HOST PREFERENCE OF *ANOPHELES GIBBINSI* (*AN. SPECIES 6*) IN NCHELENGE DISTRICT, ZAMBIA

Mary E. Gebhardt[1], Rachel S. Krizek[1], Maureen Coetzee[2], Lizette L. Koekemoer[2], Yael Dahan-Moss[2], David Mbewe[3], James Sichivula Lupiya[3], Mbanga Muleba[3], Jennifer C. Stevenson[4], William J. Moss[1], Douglas E. Norris[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Tropical Diseases Research Centre, Ndola, Zambia, [4]Macha Research Trust, Choma, Zambia

Nchelenge District in northern Zambia suffers from holoendemic malaria transmission despite a decade of yearly IRS and ITN distributions. One hypothesis for this lack of impact is that some vectors may forage in the early evening or outdoors. *Anopheles gibbinsi* was identified in early evening mosquito collections and we gleaned further insight into this taxon, including characterizing its genetic identity, feeding preferences and potential role as a malaria vector. Mosquitoes were collected with CDC light traps in indoor sitting rooms, outdoor gathering spaces and animal pens from 16:00-22:00. Host detection by PCR, COI and ITS2 PCR, and CSP ELISA were performed on all samples morphologically identified as *An. gibbinsi* (n = 453), and a subset of specimens (n = 24) were selected for COI and ITS2 sequencing. Comparison of COI and ITS2 *An. gibbinsi* reference sequences to the NCBI database revealed >99% identity to "*An. sp. 6*" from Kenya. More than 97% of specimens were morphologically and molecularly consistent with *An. gibbinsi*. Specimens were primarily collected in animal pen traps (59.2%), followed by traps outdoors near where humans gather (24.3%), and traps set indoors (16.5%). Host DNA detection revealed a high propensity for feeding on goats, but 5% of specimens with detected host DNA (n = 4) had fed on humans. None of the specimens were positive for *Plasmodium falciparum* sporozoites. In order to determine risk factors for increased abundance of *An. gibbinsi,* a negative binomial generalized linear mixed-effects model was performed. Animal pens and inland households >3 km from Lake Mweru were both associated with increased *An. gibbinsi* abundance. This is the first report of *An. gibbinsi* in Nchelenge District, Zambia. This study provided a species identity for "*An. sp. 6*" from sequences deposited in the NCBI database - a species implicated in malaria transmission in Kenya. Composite data suggest that this species is largely zoophilic and exophilic, but opportunistically feeds on humans and ingests the malaria parasites they carry. This species should continue to be monitored in Zambia and neighboring countries as a potential malaria vector.

0034

ANOPHELES LEUCOSPHYRUS GROUP PHYLOGENY REVEALS ORIGINS OF THE MAJOR FOREST MALARIA VECTORS IN SOUTHEAST ASIA

Upasana Shyamsunder Singh[1], Katy Morgan[1], Pradya Somboon[2], Thaung Hlaing[3], Aparup Das[4], Jane M. Carlton[5], **Catherine Walton**[1]

[1]University of manchester, Manchester, United Kingdom, [2]Chiang Mai University, Chiang Mai, Thailand, [3]Department of Medical Research, Yangon, Myanmar, [4]ICMR National Institute of Research in Tribal Health, Jabalpur, India, [5]New York University, New York, NY, United States

The *Anopheles leucosphyrus* group of mosquitoes belonging to the *Neomyzomia* series has a wide range spanning from southwestern India to mainland and insular Southeast Asia (SEA). The group comprises 20 known species to date, all of which are highly forest dependent typically breeding in forest ground pools. Many species within the group including *An. baimaii*, *An. dirus*, *An. scanloni*, *An. cracens* and *An. balabacensis* are highly competent vectors of human malaria in India and SEA. Other members of the group such as *An. macarthuri*, *An. pujutensis*, and *An. nemophilous* spread primarily simian malaria and feed preferentially on monkeys. Using a phylogenomics approach involving the whole genome sequencing of 10 species of both human and simian/ape feeding species we studied the evolution of host feeding in the group. The phylogeny revealed a single origin of a human blood feeding clade that contains most species of the *Anopheles dirus* complex, major vectors of human forest malaria in Southeast Asia. The estimated timing of this switch indicates this occurred in response to early hominin dispersals to SEA rather than to the more recent arrival of anatomically modern humans. This phylogeny coupled with an understanding of host switching therefore serves as an archaeological tool that can date and place the arrival of early hominins. Host switching from primates to hominins most likely occurred in insular Southeast Asia where the majority of ancestral monkey and ape feeding species are found. Following the host switching event, human-feeding mosquitoes spread from insular to mainland SEA during the Pleistocene when there were multiple phases when the Sunda Shelf was exposed joining the islands of Borneo, Sumatra and Java to the mainland. Dispersal across the mainland was associated with multiple speciation events likely involving adaptation to different habitats. These recently derived species continue to have a strong preference for human blood making them extremely effective malaria vectors in the forested regions of SEA.

0035

MOXIDECTIN COMBINATION THERAPY FOR LYMPHATIC FILARIASIS IS SUPERIOR TO IVERMECTIN PLUS ALBENDAZOLE FOR CLEARANCE OF MICROFILAREMIA AT 12 MONTHS POST-TREATMENT

Catherine M. Bjerum[1], Benjamin Koudou[2], Pascal Gabo[3], Allassane Ouattara[2], Peter U. Fischer[4], Gary J. Weil[4], Christopher L. King[1], Philip J. Budge[4]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Centre Suisse de Recherches Scientifiques, Abidjan, Côte D'Ivoire, [3]Centre Hospitalier Régional d'Agboville, Agboville, Côte D'Ivoire, [4]Washington University in St. Louis, St. Louis, MO, United States

An improved treatment regimen for lymphatic filariasis (LF) that provides prolonged microfilaria (Mf) clearance could accelerate LF elimination by reducing the number of rounds of mass drug administration required to interrupt transmission. We now report preliminary efficacy data from the first randomized clinical trial of moxidectin combination therapy for LF. We enrolled 121 patients with *W. bancrofti* night blood counts of >40 Mf/mL into four treatment arms: (i) ivermectin + albendazole (IA, current standard of therapy), (ii) ivermectin + diethylcarbamazine (DEC) + albendazole (IDA), (iii) moxidectin + albendazole (MoxA), and (iv) moxidectin + DEC + albendazole (MoxDA). To date, 105 participants (87%) have been reevaluated 12 months post-treatment. Complete Mf clearance was achieved and sustained through 12 months in 100% of MoxA (15/15) and MoxDA (20/20) participants, compared with 19/22 (86%) IDA and 6/21 (29%) IA (control) participants ($p<0.001$). Semiquantitative filariasis test strip (FTS) scores, (related to adult worm burdens) decreased in 8 (36%) IDA and 9 (45%) MoxDA participants, compared to 2 (13%) MoxA and 1 (5%) IA participants ($p=0.008$). Among those with scrotal worm nests detectable by ultrasound at baseline, 11/12 (92%) IA participants had detectable worm nests at 12 months vs 3/10 (30%) after IDA, 3/8 (38%) after MoxA, and 4/10 (40%) after MoxDA ($p = 0.01$). These data show that MoxA is superior to IA and comparable to IDA and MoxDA for sustained clearance of Mf through 12 months post-treatment. Greater reduction in FTS scores after treatments that included DEC is consistent with that drug's known macrofilaricidal effect. IDA, MoxDA, and MoxA all appear superior to IA for inactivating adult worm nests. The primary endpoint for the study (24 months) has not yet been reached. However, these preliminary data suggest that a single dose of MoxA may lead to prolonged Mf clearance without DEC. That would be a game-changer for LF elimination programs in onchocerciasis-endemic countries where IDA cannot be used because of safety concerns.

0036

PARTIAL MACROFILARICIDAL ACTIVITY OF IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE COMBINATION TREATMENT FOR HUMAN ONCHOCERCIASIS

Nicholas Opoku[1], Kerstin Fischer[2], Bettina Dubben[3], Charles Goss[4], Mahmood A. Seidu[5], Nicole Fetcho[2], Achim Hoerauf[3], Christopher L. King[6], Gary J. Weil[2], **Peter U. Fischer**[2]

[1]University of Healthand Allied Sciences, Saint Louis, Ghana, [2]Washington University School of Medicine, Saint Louis, MO, United States, [3]IMMIP, University of Bonn, Bonn, Germany, [4]Biostatistics Division, Washington University School of Medicine, Saint Louis, MO, United States, [5]University of Ghana, Accra, Ghana, [6]Case Western Reserve University, Cleveland, OH, United States

Onchocerciasis ("river blindness") has been targeted for elimination. New treatments that kill or sterilize female worms could accelerate this process. Prior studies have shown that a triple drug treatment comprised of ivermectin plus diethylcarbamazine and albendazole (IDA) leads to prolonged clearance of microfilaremia in persons with lymphatic filariasis. We now report results from a randomized clinical trial that compared the macrofilaricidal effects of IDA vs. a comparator treatment (ivermectin plus albendazole, IA) in persons with onchocerciasis. The study was performed in the Volta region of Ghana. Persons with microfiladermia and palpable subcutaneous nodules were pre-treated with two doses of ivermectin (150 ug/kg) that were separated by 6 months prior to treatment with either a single dose of IA (150 ug/kg, 400 mg), a single dose of IDA (IDA1, 150 ug/kg, 6mg/kg, 400 mg) or 3 daily doses of IDA (IDA3). These treatments were tolerated equally well, and there were no severe or serious adverse events. Skin microfilariae were cleared or greatly reduced by all three treatments for 18 months, at which time nodules were excised for histological assessment. Nodules were barcoded, embedded in paraffin, and at least two sections per nodule were stained, scanned and analyzed by two independent assessors. 64% (127 of 198) adult female worms were alive in 116 nodules recovered from 41 IA recipients. 52% (142 of 274) of female worms in 149 nodules from 47 IDA1 recipients and 53% (159/300) worms in 167 nodules from 47 IDA3 recipients were alive. This reduction in female worm viability after IDA (IDA1 and IDA3) vs IA was statistically significant. 28% of female worms in nodules from IA recipients were alive and fertile at 18 months compared to only 15% after IDA1 and 12% after IDA3. Results from this pilot study suggest that IDA was superior to IA for killing or sterilizing female *O. volvulus* worms. These results are superior to those reported to date with other short term oral treatments. However, additional studies will be needed to confirm these promising findings.

0037

SAFETY AND PHARMACOKINETICS OF A SINGLE ORAL DOSE OF MOXIDECTIN IN SUBJECTS AGED 4 TO 17 YEARS WITH (OR AT RISK OF) ONCHOCERCIASIS, TO IDENTIFY AN OPTIMAL DOSE FOR TREATMENT OF CHILDREN 4 TO 11 YEARS: RESULTS OF AN OPEN LABEL STUDY

Nicholas O. Opoku[1], Felix Doe[2], Melinda Lowe[3], Kashyap Patel[4], Craig Rayner[4], Annette C. Kuesel[5], Sally Kinrade[3]

[1]School of Public Health University of Health and Allied Sciences (UHAS), Hohoe, Ghana, [2]Hohoe Municipal Hospital, Hohoe, Ghana, [3]Medicines Development for Global Health, Southbank, Australia, [4]Certara, Princeton, NJ, United States, [5]World Health Organization Special Programme for Research and Training in Tropical Diseases (TDR), Geneva, Switzerland

Community-directed treatment with ivermectin over decades has controlled and eliminated onchocerciasis in some foci, but alternative strategies are required to achieve elimination across Africa. Moxidectin (MOX), a milbemycin-class macrocyclic lactone with broad activity against filarial and ecto-parasites, has demonstrated superior skin microfilariae suppression compared to ivermectin. MOX 8 mg is approved by the United States Food and Drug Administration for the treatment of onchocerciasis in patients 12 years and older. However, to achieve onchocerciasis elimination, all age groups that serve as a reservoir for infection should be included in treatment programs. We are conducting a prospective, age-stratified, adaptive, open-label, single-dose, pharmacokinetic (PK) and safety study at the University of Health and Allied Sciences Research Centre, Hohoe, Ghana. The study aims to determine the PK of MOX in children and adolescents aged 4 to 17 years and select a suitable dose to treat children younger than 12 years. Participants from villages in the Kpassa sub-district in Nkwanta North, an area endemic for onchocerciasis, were recruited into three age-based cohorts: 12 to 17 years (Cohort I, n=9), 8 to 11 years (Cohort II, n=18) and 4 to 7 years (Cohort III, n=9). Cohort I and the first 9 participants in Cohort II were enrolled concurrently and received 8 mg MOX, based on simulations in a population PK (popPK) model. PK sampling and safety follow-up was completed to Week 24. Following Day 28 PK sample analysis, a Safety Monitoring Board review of safety, non-compartmental PK and updated popPK modelling incorporating body weight effects on clearance recommended evaluating a 6 mg dose in children 8 to 11 years (Cohort II, n=9) and initiating evaluation of a 4 mg dose in children 4 to 7 years (Cohort III). As of 31 Mar 2022, all subjects have been dosed and PK sampling and safety monitoring is continuing. MOX was well-tolerated with only mild or moderate adverse events, all assessed as unrelated to treatment, reported to date. The results of Week 24 follow-up and PK sample analysis for all participants, to be completed in August 2022, will be presented.

0038

AUTOMATED ANALYSIS OF HISTOLOGICAL SLIDES FROM ONCHOCERCA NODULES USING ARTIFICIAL INTELLIGENCE (AI)

Janina M. Kuehlwein[1], Daniel A. Kuehlwein[2], Julia Poplawska[3], Bettina Dubben[1], Kerstin Fischer[4], Marcel Bergmann[5], Marlene Rickmers[6], Matthias Schmid[6], Alexander Y. Debrah[7], Sabine Specht[8], Achim Hoerauf[1], Ute Klarmann-Schulz[1]

[1]Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany, [2]Capgemini, Cologne, Germany, [3]Capgemini, Wrocław, Poland, [4]Washington University School of Medicine, St. Louis, MO, United States, [5]Capgemini, Hamburg, Germany, [6]Institute for Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Bonn, Germany, [7]Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, [8]Drugs for Neglected Diseases Initiative, Geneva, Switzerland

Onchocerciasis is a neglected tropical disease caused by the filarial worm *Onchocerca volvulus*. The adult worms reside in nodules under the human host's skin, where they can reproduce for 15 years. Macrofilaricidal drugs that kill or sterilize adult worms are urgently needed to eliminate onchocerciasis by 2030. One hurdle to rapid drug development is the histological evaluation of the nodules, which can only be done by a few experts worldwide. We aim to automate this time-consuming task by developing an AI tool that is faster and less dependent on human assessors. Over 1,000 digitalized nodule slides were used to train separate AI models to detect worm sections (Faster R-CNN) and subsequently classify the detected sections (EfficientNet). First, binary classification models (e.g., alive vs. dead and unclear) were trained on the following attributes: vitality, sex, presence of *Wolbachia* (endosymbiotic bacteria) and fertility of female worms. Then, these models were refined with more classes per attribute (e.g., alive vs. dead vs. unclear). In addition, a classification model was trained to detect microfilariae (Mf) in the nodule tissue. Most models reached accuracies of over 90%: detection of worm sections 92% mAP; classification on single sections for vitality: 96.9%, sex: 98.1%, *Wolbachia*: 90.0% and fertility: 95.1%. The recently started training to detect Mf in the nodule tissue showed an accuracy of around 80%. Preliminary data on the refined models indicate a similar performance to the binary models. Finally, all models were combined in a single tool that provides a complete nodule analysis. The first test with binary classification on 15 images, which were not included in the training, showed 81.4-98.6% agreement between a human expert and the AI, depending on the attribute. The first validation of the combined tool shows similar results as the individual models. Based on these results, the focus is now on the tool's robustness to ensure similar outcomes on new data from different sources. After validation and approval of the tool for clinical trials, the human experts will focus on the quality checks of the AI and the assessment of complex cases.

0039

NINETEEN ONCHOCERCIASIS BIOMARKER CANDIDATES IDENTIFIED DIRECTLY IN HUMAN SERUM AND URINE

Bruce A. Rosa, Kurt Curtis, Petra Erdmann Gilmore, John Martin, Qiang Zhang, Robert Sprung, Gary J. Weil, R. Reid Townsend, Peter U. Fischer, Makedonka Mitreva

Washington University in St Louis School of Medicine, St. Louis, MO, United States

Onchocerca volvulus, the causative agent of onchocerciasis, infects over 20 million people and can cause severe dermatitis and ocular conditions including blindness. Current mass drug administration treatments do not kill female *O. volvulus* worms, and common diagnostic tests cannot reliably assess the viability of adult worms. This lack of sensitivity for active infections presents an urgent need for better diagnostic tests to monitor the efficacy of new treatments and ongoing mass drug administration. Serum samples from individuals infected with *O. volvulus* (n = 8), and from uninfected individuals (n = 7) were examined by deep scale proteomics, including the use of a timsTOF Pro mass spectrometer. Data were interrogated for *O. volvulus* proteins present in infected but not uninfected samples. Among all detected proteins, 19 high-priority candidate biomarkers were identified in the serum of 3 or more *O. volvulus*-infected samples (not present in uninfected) that were supported by two or more unique peptides. Comprehensive functional annotation, RNA-seq based transcriptional profiling and taxonomic conservation/diversification characterized the detected proteins in more detail. 15 peptides from 11 of the top 19 proteins were validated by parallel MS/MS (Orbitrap) with isotope-labeled synthetic peptides. One candidate was detected with eight unique peptides in five different serum samples. Additional MS/MS samples have shown that peptides from 4 of the top 6 candidate biomarkers were also detected in urine samples from onchocerciasis patients. We are now working to develop practical assays for the most promising candidates that may be useful for diagnosis of active infections and for monitoring efficacy of new treatments in clinical trials.

CHARACTERIZING VIRAL-SPECIFIC B CELL RESPONSES IN HUMAN FILARIAL INFECTION USING VIRSCAN, A NOVEL SEROSURVEY TOOL

Gayatri Sanku[1], Limin Wang[2], Xin Wei Wang[3], Thomas Nutman[1]

[1]National Institutes of Health, Laboratory of Parasitic Disease, Bethesda, MD, United States, [2]National Institute of Health, Bethesda, MD, United States, [3]National Institutes of Health, Bethesda, MD, United States

Filarial infections have been shown to alter bystander CD4+ and CD8+ T cell memory responses to a variety of non-filarial antigens including virally-encoded proteins. We have previously found that in filarial-cytomegalovirus (CMV) coinfections, filarial infections may limit the ability of T-effector cell to transition to long lived memory cells; moreover, these infections appear to induce T cell exhaustion that may insufficient control of persistent antigens. To understand whether these T cell-associated outcomes of filarial infections extend to the B cell compartment, serum from 20 healthy and 186 *Loa loa*-infected individuals were assessed using VirScan, a viral peptide phage display library, that allows for the simultaneous assessment of human immunoglobulin G (IgG) response to all major viruses of humans (n=206) through sequencing of the immunoprecipitated phage. By comparing total IgG raw read counts among all samples tested, it could be seen that there was significant virus-specific seroreactivity to 135 distinct viral species. Among the 20 most prevalent viruses recognized by human IgG in all subjects, the filarial-infected individuals demonstrated markedly lower viral-specific IgG responses for Human herpesvirus 6A (p=.022), Enterovirus B (p=0.004), Rhinovirus A (p=.007), and Rhinovirus B (p=.004)) when compared to the healthy individuals. When testing for differences among microfilariae positive (Mf+) and microfilariae negative (Mf-) Loa loa- infected individuals, viral-specific IgG raw read counts were significantly lower among Mf+ patients for Rhinovirus A (p=0.005). We are further analyzing the diversity of viral epitopes among filarial-infected individuals to determine how broadly epitope restriction occurs at the B cell level. Our data suggest filarial infections may modify not only T cell-based viral bystander responses, but also those driven by B cells.

0041

TOWARDS TELOMERE TO TELOMERE FILARIAL GENOMES

Sasisekhar Bennuru, Thomas B. Nutman

NIAID/NIH, Bethesda, MD, United States

Filarial genomics have largely accelerated over the last decade with the rapid advances in sequencing technologies and genome assembly pipelines. Among the filarial worms, *Brugia malayi* and *Onchocerca volvulus* genomes are at near chromosomal level. Because repetitive elements are part of the filarial genomes that we frequently exploit for molecular diagnostics we sought to better characterize the organization of these and other non-coding DNAs. Over the last decade, the *L. loa* genome improved from 5443 contigs (SOLID 454) to 2250 contigs

(Illumina and PacBio) with scaffold N50 values ~175-180 Kb. Using ultra-high molecular weight (UHMW) DNA extracted from microfilaria of *L. loa* obtained during apheresis of a single patient, we performed long-read sequencing using Oxford nanopore technology (ONT). The ONT reads (~130 x coverage) with average read N50 values ~40-60 Kb were assembled with multiple long-read assemblers (e.g. FLYE, CANU, WENGAN, SHASTA, WTDBG2, NECAT, NEXTDENOVO, RAVEN). After merging the best assemblies and removal of haplotigs, we condensed the genome to 12 contigs with scaffold N50 ~16 Mb. 6 of the 12 contigs were smaller repeat elements that comprised ~0.6% of the 91.8 Mb assembled genome, while the 6 larger contigs and the mitochondrial genome made up 99.3% of the genome. Synteny with other filarial genomes and Nigon element mapping resulted in the identification of 5 autosomes and an X-chromosome, with BUSCO scores of ~99%. Moreover, all the 6 chromosomes had the canonical telomeric repeats "TTAGGC" at both ends. Long-read sequencing and assembly of the Brugia malayi and Wuchereria bancrofti is in progress and will be compared to the Loa loa chromosome level assembly.

0042

WHAT PREDICTS PEOPLE'S ADHERENCE TO COVID-19 MISINFORMATION? A RETROSPECTIVE STUDY USING A NATIONWIDE ONLINE SURVEY AMONG ADULTS RESIDING IN THE UNITED STATES

Sooyoung Kim, Ariadna Capasso, Tyler Headley, Shahmir Ali, Ralph DiClemente, Yesim Tozan

New York University School of Global Public Health, New York, NY, United States

Tackling infodemics with flooding misinformation is key to managing the COVID-19 pandemic. Yet only a few studies have attempted to understand the characteristics of the people who believe in and adhere to misinformation. Our study objective was to identify the factors associated with adherence to certain types of COVID-19 misinformation among US adults during the early phase of the pandemic. We used the data from an online survey that was administered in April 2020 to 6,518 English-speaking adult participants in the United States. We created binary variables to represent four misinformation categories related to COVID-19: general COVID-19-related, vaccine/anti-vaccine, COVID-19 as an act of bioterrorism, and mode of transmission. Using binary logistic regression and the LASSO regularization, we then identified the important predictors of adherence to each type of misinformation. Nested vector bootstrapping approach was used to estimate the standard error of the LASSO coefficients. About 30% of our sample reported adhering to at least one type of COVID-19-related misinformation. Adherence to one type of misinformation was not strongly associated with adherence to other types. We also identified 58 demographic and socioeconomic factors that predicted people's susceptibility to at least one type of COVID-19 misinformation. Different groups, characterized by distinct sets of predictors, were susceptible to different types of misinformation. There were 14 predictors for general COVID-19 misinformation, 23 for COVID-19 vaccine, 37 for COVID-19 as an act of bioterrorism, and 14 for mode of COVID-transmission. Our findings confirm the existence of groups with unique characteristics that adheres to different types of COVID-19 misinformation. Findings are readily applicable by policymakers to inform careful targeting of misinformation mitigation strategies.

0043

SUPPLY OR SERVICE? FACTORS AFFECTING DELIVERY OF INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA IN PREGNANCY IN DRC

Radha Rajan[1], Kathryn Sugg[1], Florence Mpata[2], Eric Sompwe Mukomena[3]

[1]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [2]Breakthrough ACTION DRC, Kinshasa, Democratic Republic of the Congo, [3]National Malaria Control Program - DRC, Kinshasa, Democratic Republic of the Congo

National data suggested many missed opportunities for delivery of intermittent preventive treatment for malaria in pregnancy (IPTp) during ANC visits in DRC. This study, conducted in March 2021 in the Lualaba and Tanganyika provinces, examined ANC registry records, conducted facility assessments, and used qualitative methods to triangulate on data quality and reasons for missed IPTp delivery. While ANC registry findings revealed missed IPTp provision at 44% of all ANC visits, data quality sub-analyses suggest frequent under recording of IPTp provision along with ample missing data. Specifically, data quality verifications revealed 41% variation between clients recorded receiving SP compared to observed, and 19% variation between those recorded vs. recalling receipt of SP during their ANC visit. In both cases, registries under-recorded SP provision compared to the data verification approach. Two strong predictors of SP provision at every ANC visit were stock in a pharmacy/storeroom (OR 6.99, SE 1.00) and having 1+ supervisory visits in the past year (OR 2.35, SE 0.30), while not receiving SP stock in the past month or longer significantly reduced odds of SP provision at every ANC visit (OR 0.60, SE 0.06). Qualitative data reiterated challenges with record keeping as providers noted they have many forms to complete and an inadequate number of staff to do the work correctly. Providers also described challenges in counseling clients on how to manage common side-effects of SP. From facility inventories, the study found major SP supply disruptions between September 2020 and January 2021, coinciding with the emergence of COVID-19 in DRC. The study findings underscore problems with data recording, counseling efficacy, and SP stock management that overemphasize the scope of missed opportunities for IPTp delivery while suggesting the necessity of interventions to improve IPTp provision. Provincial malaria control staff reviewed the data and offered potential recommendations, including increased supervision of ANC providers, job aids to support counseling about management of side-effects, and improved IPTp stock alert and restocking systems.

0044

IS IT POSSIBLE TO ACCURATELY PREDICT RISK OF PRETERM DELIVERY IN A RURAL SETTING IN ETHIOPIA?

Clara Pons-Duran[1], Bryan Wilder[1], Bezawit Mesfin Hunegnaw[2], Sebastien Haneuse[1], Frederick GB Goddard[1], Delayehu Bekele[2], Grace J. Chan[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia

Prematurity is the principal cause of death among children under five years, globally leading to over 900,000 deaths per year. To effectively reduce the prevalence of preterm deliveries, interventions should be targeted at high-risk pregnancies. However, most proposed predictive models for preterm birth require information collected with tools that are not available in low-resource areas. We evaluated whether risk of preterm delivery can be predicted using readily available data. This study uses data from a maternal and child health cohort in North Shewa, Ethiopia. All women were enrolled in the cohort between December 2018 and March 2020. The study outcome was preterm delivery, defined as any delivery occurring before week 37 of gestation regardless of vital status of the fetus or neonate. Sociodemographic, clinical, environmental, and pregnancy-related factors were included in the models. Predictors that were not available but important for risk prediction — mainly ultrasound measurements and biomarkers — were not considered. Both standard

time-to-event analysis methods (Cox and accelerated failure time models) and machine learning models (decision tree ensembles) were used to predict the risk of preterm delivery. Model discrimination was estimated using the area-under-the-curve (AUC). A total of 2493 pregnancies were included in the analysis. Of those, 138 women were censored for being lost to follow-up before delivery. The predictive performance of all models was poor. The AUC was highest for the tree ensemble classifier (0.59, 95%CI [0.56, 0.63]). When models were calibrated so that 90% of women who experienced a preterm delivery were classified as high risk, at least 80% of those classified as high risk did not experience preterm delivery. Neonatal sex, multiple gestation and education were among the factors which contributed most strongly to the models. It may not be possible to accurately predict risk of preterm delivery without collecting key predictors such as cervical length or fetal fibronectin during pregnancy, and the feasibility and cost-effectiveness of collecting such data in low-resource areas should be explored.

0045

COST EFFECTIVENESS ANALYSIS OF EXPANDING TUBERCULOSIS PREVENTIVE THERAPY TO HOUSEHOLD CONTACTS AGED 5-14 YEARS IN THE PHILIPPINES

Ghassan Ilaiwy[1], Jessica L. Keim-Malpass[1], Romella Tuppal[2], Alexander F. Ritua[2], Flordeliza Bassiag[2], Tania A. Thomas[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Isabela State University, Echague, Philippines

There has been limited uptake of the newest national guidelines encouraging the expansion of tuberculosis preventive therapy (TPT) to children aged 5-14 years who are household contacts (HHCs) of index pulmonary tuberculosis (TB) cases. In this analysis we provide input on the most cost-effective strategy to expand latent TB testing and treatment among HHCs aged 5-14 years of index TB patients in the Philippines. In the model, eligible HHCs are screened for latent TB infection (LTBI) with either tuberculin skin test (TST) or interferon gamma release assay (IGRA) and those who test positive will then be simulated to receive one of the following strategies: 6 months of daily isoniazid (6H), 3 months of daily isoniazid plus rifampicin (3HR), 3 months of weekly isoniazid and rifapentine (3HP) or the current practice of no testing or treatment for LTBI (NTT). The analysis adds up the projected costs of the program to the Philippines public healthcare system and compares them to the quality-adjusted life years (QALY) gained over a time horizon of 20 years. An intervention will be considered cost-effective if its incremental cost-effectiveness ratio (ICER) falls below the Philippines gross domestic product per capita of $3,298.33. Our model estimates that expanding TPT coverage to HHCs aged 5-14 years would be cost effective when using TST. The most cost-effective strategy combines TST with 6H with an ICER of 2,296 $/QALY gained (Uncertainty range: 1,274 - 4,875), closely followed by combining TST with 3HP which had an ICER of 2,374 $/QALY gained (Uncertainty range: 1,343-4,923). In a high prevalence scenario with LTBI prevalence exceeding 50% among HHCs, all testing and regimen combinations became cost-effective with TST and 6H again achieving the lowest ICER. These findings were robust to sensitivity analyses over a wide range of parameter values. In conclusion, expanding TPT coverage to HHCs aged 5-14 years is cost effective when using TST and 6H closely followed by a strategy combining TST and 3HP especially in a high prevalence scenario. IGRA cost will require significant reduction to achieve results similar to TST.

0046

ELUCIDATING PNEUMOCOCCAL MIGRATION IN SOUTH AFRICA USING GENETIC AND HUMAN MOBILITY DATA

Sophie Belman[1], Noémie Lefrancq[2], Shabir A. Madhi[3], Anne von Gottberg[4], Mignon du Plessis[4], Stephen D. Bentley[1], Henrik Salje[2]

[1]Wellcome Sanger Institute, Hinxton, Saffron Walden, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]University of the Witwatersrand, Johannesburg, South Africa, [4]Centre for Respiratory Diseases and Meningitis, National Institute for Communicable Diseases, Johannesburg, South Africa

Streptococcus pneumoniae is a globally endemic, human obligate bacteria, and a leading cause of pneumonia and meningitis worldwide. The pneumococcal conjugate vaccine targets a subset of the 100 pneumococcal serotypes. Despite the enormous public health burden, the extent and mechanisms of pneumococcal spread across spatial scales remains largely unknown, as does the variability of spread driven by the vaccine. We analyzed 6910 geolocated whole genome pneumococcal genome sequences from patients, collected from 2000-2014 from throughout South Africa. We developed mechanistic phylogeographic models to reconstruct pathogen spread, incorporating the generation time distribution, human mobility data provided by Facebook, population size, and underlying heterogeneities in sampling. We found that pairs of sequences that had a most recent comment ancestor (MRCA) within one year were separated by an average of 186km, rising to 287km for pairs separated by 10 years. We were able to accurately recover this pattern of spatial spread using our mechanistic model. We estimated that most transmission events were local (85% within municipality), with occasional long-distance transmissions, mainly between population hubs. Overall, the pneumococcus was 20 times more likely to have travelled to a major population hub (population >3-million) than elsewhere after one year of sequential person-to-person transmission. We found that the introduction of the vaccine in 2009 had a marked impact on serotype distribution. Serotypes not included in the vaccine were subsequently more mobile, with individuals infected by non-vaccine types being located in significantly more municipalities after just 2 years of transmission than individuals infected by the serotypes in the vaccine. Although most transmission events remain local in South Africa there is variability in its rate of spread determined by serotype fitness. Our framework provides an opportunity to explore whether similar patterns of spread are observed elsewhere with differing mobility patterns as well as the impact of vaccine introductions on patterns of spread across pneumococcal serotypes.

SAVING YOUNG LIVES: TRIAGE AND MANAGEMENT OF SEPSIS IN CHILDREN USING SMART TRIAGE

Yashodani Pillay[1], Dustin Dunsmuir[1], Katija Pallot[1], Matthew O. Wiens[1], Collins Agaba[2], Annette M. Nabweteme[3], Jessica Rigg[4], Stefanie K. Novakowski[1], Abner V. Tagoola[5], Niranjan Kissoon[1], Mark J. Ansermino[1]

[1]University of British Columbia, Vancouver, BC, Canada, [2]World Alliance for Lung and Intensive Care Medicine in Uganda (WALIMU), Kampala, Uganda, [3]World Alliance For Lung and Intensive Care Medicine in Uganda (WALIMU), Kampala, Uganda, [4]Centre for International Child Health, Vancouver, BC, Canada, [5]Jinja Regional Referral Hospital, Jinja, Uganda

Sepsis is the leading cause of child death and disability. Triage can improve outcomes by detecting those most at-risk, but is not the norm in many low- and middle- income countries. We evaluated whether Smart Triage, a digital triage platform, improves time to treatment for children with sepsis at a regional referral facility in Eastern Uganda. Smart Triage includes a mobile triage application integrating pulse oximetry and a clinical risk prediction model, a Bluetooth patient and treatment tracking system, and a clinical dashboard. Model development was completed using a baseline cohort enrolled from March 2020 to March 2021 and usability testing was done with healthcare workers prior to implementing the platform. From April 2021 to December 2021 all children presenting to the outpatient department (OPD) with an acute illness were triaged and stratified as emergency, priority, or non-urgent based on anthropometric data, vital signs and pulse oximetry, using the model integrated into the mobile application. Our primary outcome was time to first treatment. In the baseline cohort, 1,612 children were triaged, with a 22.4% (95% CI 20.4 to 24.3) admission rate. After implementation, 1,948 children were triaged, with a 15.0% (95% CI 13.4 to 16.6) admission rate. The mean time to treatment decreased by 20%, from 5.1 hours (95% CI 4.7

to 5.5) to 4.1 hours (95% CI 3.9 to 4.4).e improvement was greater for emergency cases. These results indicate that risk stratification at triage using a simple digital triage tool can reduce the time to treatment and improve the quality of care for children with sepsis.

DEVELOPMENT OF A NON-CONTACT HANDWASHING DEVICE TO PREVENT THE SPREAD OF COMMUNICABLE DISEASES IN NIGERIA

Padraic S. Casserly[1], David Fadare[1], Akinwale Coker[1], Rahaman Abu[1], Luke Ajuka[1], Olusola Oke[1], Erioluwa Morenikeji[1], Ademola Dare[1], Adetunji Lana[1], Chibueze Achi[1], Timothy Akinremi[1], Amos Adeleye[2], Olusola Idowu[2], Olabanji Olayinka[2], Mamoudou Maiga[3], Robert Murphy[3]

[1]University of Ibadan, Ibadan, Nigeria, [2]University College Hospital, Ibadan, Nigeria, [3]Northwestern University, Evanston, IL, United States

According to a report issued by UNICEF on World Water Day 2022, Nigeria has the world's highest number of deaths from waterborne disease among children under five years old. The factors contributing to this problem are numerous, but among the reasons is a lack of adequate handwashing infrastructure. To address this deficiency, public and private institutions have deployed their own makeshift solutions. The most common solution consists of a bucket of water, mounted at hand height, with a tap fixed at the bottom of the bucket. When the tap is opened by hand, water flows out of the bucket and on to the user's hands which are placed beneath the tap. The user can then wash his/her hands. This solution, called a Veronica Bucket, grew immensely in popularity following the outbreak of the Covid-19 pandemic as proper hand-hygiene was identified as an important strategy in stemming the spread of the coronavirus. However, this solution, while simple and effective, does have several drawbacks. Firstly, users must physically manipulate the tap on the Veronica bucket to access flowing water. This task serves as a small, yet real, hurdle in using the handwashing solution. The tap can also serve as a point of transmission for communicable diseases. Another deficiency with the Veronica Bucket is that the dispensation of soap is not inherently built into the design. A drop of soap diluted in water is sufficient to rupture and kill many types of viruses and bacteria, but the Veronica Bucket does not dispense soap. And users of the Veronica Bucket can choose to wash their hands for only several seconds rather than the 40 seconds advised by the WHO. To address these problems, a team of engineering faculty, students, and staff at the University of Ibadan in Ibadan, Nigeria, developed a device which replaces the manually operated tap on a Veronica Bucket. This battery-powered and rechargeable device automatically detects when a user places his/her hands underneath the bucket and then dispenses water and liquid soap on to the user's hands. The device then pauses, allows the user to lather with soap, and then distributes water from the bucket for rinsing. The entire operation takes 40 seconds.

0049

PARTICIPATORY APPROACH IN MODELLING OF THE POTENTIAL IMPACT OF INTERVENTIONS ON THE COVID19 EPIDEMIC IN THE KYRGYZ REPUBLIC

Ainura Moldokmatova

University of Oxford, Oxford, United Kingdom

Modelling of potential effects of non-pharmaceutical interventions and vaccination on the course of COVID-19 pandemic was widely applied in informing the global health strategies in light of the novelty of the disease and related uncertainties and unknowns. Along with many other countries, Kyrgyzstan constantly needed prompt evidence, prognosis and projections of the disease spread and mortality. Vaccination was expected to dramatically change the epidemic, however, the initial demand in the world exceeded manufacturing capacities, and thus, it caused new challenges in the country in planning the vaccination with limited delivery. The Kyrgyz modelling group in cooperation with International COVID-19 Modelling (CoMo) Consortium and the Kyrgyz Ministry of Health (MoH) conducted two modelling rounds. Such participatory approach allowed us to promptly share our projections with key decision-makers, including MoH and the Cabinet of Vice-Prime Minister. Eventually, we proposed several scenarios of lockdown release interventions and vaccination strategies. Each scenario projected the potential impact of interventions on the course of the epidemic, mortality and health system. However, the policy decisions were driven not only by existing evidence and research tools but also by social pressure. Thus, our proposed "managed lockdown release" scenario was acknowledged as an optimal approach to balance between health and economic/social destruction. However, the decision was to fully release the lockdown due to the above pressures, which was followed by a significant wave of morbidity and mortality as projected in our baseline scenario "full release". Considering the above, our group decided to share the information on the importance of social distancing, mask-wearing, vaccination and other interventions with a broader audience via participating in public discussions, press conferences and other mass media channels. I believe, through such a participatory approach we managed to significantly contribute to informing the national policy decisions and improving the public acceptance of related public health interventions.

THE DEVELOPMENT OF A MACHINE LEARNING-DRIVEN CLINICAL DECISION SUPPORT TOOL FOR THE MANAGEMENT OF DENGUE IN VIETNAM

Damien K. Ming[1], Bernard Hernandez[1], Nguyen Quang Huy[2], Luu Phuoc An[2], Ho Quang Chanh[2], Dong Thi Hoai Tam[2], Nguyen Tuan[2], Cameron P. Simmons[3], Bridget Wills[2], Pantelis Georgiou[1], Alison H. Holmes[1], Sophie Yacoub[2]

[1]Imperial College London, London, United Kingdom, [2]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam, [3]Institute of Vector-Borne Disease at Monash University, Melbourne, Australia

Seasonal dengue epidemics exert significant pressure on healthcare settings worldwide. Clinical decision-making is a dynamic process and central to patient outcomes. However existing tools and guidelines tend to be static, and focus mainly on early management. The adoption of appropriate clinical decision-support systems (CDSS) at patient point-of-care could improve the quality and consistency of care delivery. We present work in the development of a CDSS intended for use by clinicians managing dengue in Vietnam. This work is done in the context of a multi-disciplinary collaboration in the application of technological innovations in low- and middle-income country settings. We performed process mapping, task analysis and semi-structured interviews at the Hospital for Tropical Diseases (HTD), Ho Chi Minh City, Vietnam in order to understand and characterise clinician needs for the management of acute febrile illnesses. In parallel, clinical data from 4,131 patients admitted with dengue were used to train a set of machine learning models to predict clinical outcomes. Workshops and focus groups adopting human-centred design principles informed the development of CDSS prototypes. We identified potential areas in the patient pathway at the HTD where CDSS introduction could be impactful. Clinical decision-making for acute infection is complex and variation in approaches to patient management and risk assessment are described. The optimal functions for the CDSS were identified and prioritised in small group sessions - a system emphasising usability, ease of access to guidelines, dashboard summary functions and risk prediction for shock have been chosen for incorporated into a web-based CDSS, accessible through desktop and mobile devices. Translation of these findings into a CDSS is currently underway and usability testing in end-users in Vietnam planned for Q3 2022.

0051

CHALLENGES FOR PRECISE ESTIMATION OF CHILD IMMUNIZATION COVERAGE AND DROP-OUT RATE IN MANDERA COUNTY IN KENYA

Bentinck S. Ochieng'[1], Misiko T. Linda[1], Hassan Mumin[1], Cynthia A. Ngesa[1], Rashed Shah[2]

[1]Save the Children International Kenya, Nairobi, Kenya, [2]Save the Children US, Washington, DC, United States

Precision in estimating child immunization coverage and drop-out rates is dependent on census data, specifically on estimating population in an area which leads to set the target for immunizing children in that particular area. Achieving the precision in child immunization report becomes challenging more specifically in the area where in- and out-migration rate is higher, for example in areas with abundant nomadic population or in the informal settlement or slum areas. Child immunization coverage in such areas often suffers low precision which may include coverage estimates far beyond or below 100%. Similarly, inaccuracy in drop-out reporting is also noticed in reported immunization data from those areas. We conducted a community population based survey in 2020 in three sub-counties (Mandera North, Mandera South and Mandera West) in Kenya and compared the survey results with reported data through District Health Information System (DHIS) for same period. Our survey results revealed fully immunization coverage among children below 1 year as 61% which was reported through DHIS data as 97.6%; a similar difference was shown for DPT-Hepatitis-Hib drop-out rate, while survey result (17.6%) and DHIS data (4.3%) were compared. The DHIS sets immunization targets using census data which are obtained usually every 10 years. Census data are then used to project population data in a specific area for later years until another round of census is conducted. Such projections often misestimate real population data which leads to under- or over-estimated coverage and drop-out rate in a specific area. The significant differences we found between survey results and DHIS reported data between child immunization coverage and drop-out rates are greatly misleading the project managers and implementers in those sub-counties to plan the implementation focus, especially for prioritizing needs to address the real inadequacy of immunization services in the area.

0052

MULTIAGENT SIMULATION MODEL OF THE COVID-19 EPIDEMIC PROCESS WITH SOCIAL FACTORS

Olga Salun[1], Dmytro Chumachenko[2], Olena Muradyan[3], Tetyana Chumachenko[1]

[1]Kharkiv National Medical University, Kharkiv, Ukraine, [2]National Aerospace University "Kharkiv Aviation Institute", Kharkiv, Ukraine, [3]V.N. Karazin Kharkiv National University, Kharkiv, Ukraine

Agent-based approach to simulation is an effective tool for studying the spread of COVID-19. Modeling makes it possible to identify the parameters that affect the development of the epidemic process and to understand social aspects influencing COVID-19 propagation. To build a multi-agent model of the epidemic process, we used data provided by the Public Health Center under the Ministry of Health of Ukraine on the incidence of COVID-19 distributed by age and incorporated the results of a sociological study on adherence to vaccination against COVID-19 and other control measures (437 blood plasma donors, 797 healthcare workers, 150 students). The agent-based model was realized using C# language. The objects of the model were age, gender, and knowledge base, including adherence to vaccination and readiness to comply with control measures. We simulated the spread of COVID-19 through an artificial population with the same characteristics of our study population. Transmission occurred probabilistically based on traits of the individual agents (e.g., vaccination status and adherence, control measure acceptance, age, etc.). The model was verified by comparing the retrospective forecast with registered cases of COVID-19. The simulation results showed that the population can be divided into three groups concerning vaccination: skeptics (43%), conformists (32%), and loyalists (25%). This division is observed in all three groups of respondents (plasma donors, healthcare workers, and students). But within each social group, the ratio of these subgroups varied. Using sociological data and methods of intelligent decision-making in conditions of uncertainty, we found that attitude to vaccination correlates with the attitude to compliance with control measures. Our model allows us to study the effectiveness of control measures, accounting for important individual traits such as attitudes toward vaccination, which is an important advantage over other models. The model can also be useful in the development of educational programs aimed at certain social groups.

0053

SYSTEMATIC REVIEW OF MATHEMATICAL MODELING OF INFECTIOUS DISEASE WITH HUMAN MOVEMENT DATA

Aniruddha Deshpande, Kristin Nelson

Emory University, Atlanta, GA, United States

Human movement plays a key role in determining the dynamics of infectious disease epidemiology. Population mixing rates and travel affect the rate of epidemic growth, distribution of infections, and total population size. Therefore, we conducted a systematic review of studies using human movement data in mathematical mechanistic models of infectious disease. We searched PubMed until July 11th, 2021, and retrieved over 1,700 articles. After review, we identified 107 articles that met inclusion criteria. We extracted metadata for each included article including modeling approach, type of mobility data used, location of study, and disease system of interest. Airborne transmission was the most studied transmission route with COVID19 with 62% of studies and influenza being the most frequently studied diseases with 23% of the articles[NK1] . Historically, census data or population counts were the most utilized data types to parameterize movement models, but location-based services - software monitoring location date -- are increasingly common[NK2] . Considering this, most studies were set in the US, Europe, and China. While mobility is fundamental to all infectious disease, the literature has been skewed to disease systems and locations where such studies are the most easily implemented - airborne transmission in high-income settings. [NK3] This highlights the need to increase the study of the role of human movement in infectious disease dynamics in Africa, Asia, and Latin America as they bear disproportionate burden. Furthermore, research needs to expand beyond airborne transmission as enteric and vector-borne diseases comprise a large proportion of the burden of infectious diseases and human movement has implications on population dynamics for these diseases. Our review provides an atlas of current literature as a reference to enable future studies by showcasing implementation of in areas of greatest burden.

COMPARATIVE REPRESENTATIVENESS OF A MOBILE PHONE-BASED VS. IN PERSON SURVEY-BASED COVERAGE EVALUATION SURVEYS FOLLOWING MASS DRUG ADMINISTRATION FOR SOIL-TRANSMITTED HELMINTHS: INDIA

Rohan Michael Ramesh[1], William Edward Oswald[2], Gideon John Israel[1], Kumudha Aruldas[1], Sean Galagan[3], Arianna Rubin Means[3], Hugo Legge[2], Saravanakumar Puthupalayam Kaliappan[1], Judd L. Walson[3], Katherine Elizabeth Halliday[2], Sitara S.R. Ajjampur[1]

[1]Christian Medical College, Vellore, India, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]University of Washington, Seattle, WA, United States

With increasing mobile phone subscriptions in low- and middle-income countries, telephone-based surveys are becoming increasingly popular for public health programs and research. Despite advantages, such as cost-effectiveness, time efficiency, reach, sharing of information, and comparable quality to in-person data collection, systematic exclusion of participants without access to mobile phones, or for other reasons, may limit representativeness. For DeWorm3, a large, ongoing randomized,

controlled multi-country trial including India, we regularly conducted coverage evaluation surveys to measure coverage of mass drug administration in two sub-sites, Timiri (rural area), and Jawadhu hills (tribal area), located in south India. The COVID-19 pandemic led to a nationwide lockdown in 2020, which necessitated a change in protocol to use a mobile phone-based survey instead of in-person coverage surveys. Here we examine the representativeness of the mobile phone-based survey to the previous in-person survey conducted in 2019. During the in-person survey, 88% of sampled households participated, while only 57% of sampled households participated in the phone-based survey. Notably, 17% of households in 2020 were not able to be contacted at all, as they did not provide a telephone number during the census. Larger households, households with higher socioeconomic status, and those with younger, more educated household heads were over-represented in the phone-based survey. Non-response in the phone-based survey, defined as households that refused to participate or were unable to consent or could not be contacted, was lower in Jawadhu hills, higher in households from the poorest SES quintile, and lower in households with heads who completed secondary school or higher education. Phone-based interviews took a shorter time, but more attempts were required to complete surveying all household members. The in-person coverage evaluation survey better represented the population than the phone-based survey, though the latter permitted an assessment of treatment coverage when circumstances during the pandemic precluded household visits.

WORLD HEALTH ORGANIZATION COORDINATED SCIENTIFIC ADVICE FOR HEALTH PRODUCT RESEARCH AND DEVELOPMENT

Mercedes Perez Gonzalez, Marion Laumonier, Vasee Moorthy, Deus Mubangizi, Anna Laura Ross

World Health Organization, Geneva, Switzerland

The current global disease landscape is an ever-evolving challenge to health product developers focusing their efforts on tackling the prevention, treatment and control of tropical infectious diseases. Vaccines, diagnostics, medicines and vector control products adapted to the specific context in which they are intended to be used are key to reducing the overall burden of infectious diseases and incorporating specifications to meet these requirements needs to happen at the research & development (R&D) stage. The World Health Organization (WHO) Science Division has a mandate to optimize R&D processes, including the provision of scientific advice to external parties to support the development of appropriate health products in areas of unmet public health needs. Product developers may contact WHO to obtain Coordinated Scientific Advice (CSA), a new standardized service for joint advice delivered by WHO Prequalification and the WHO disease-focused technical department(s). CSA is open to innovative products and existing products when new data are generated for a new indication, for example. The entire process is expected to take approximately ten weeks and the outcome is a consolidated WHO advice report. CSA is confidential and prospective in nature. The optimal time for a CSA is before the start of pivotal phase III trials but will ultimately depend on the needs of the product developer. WHO is conducting a time-limited pilot and inviting product developers to apply. The overall impact will be evaluated through user feedback, follow-up of the product development, future relevant guidelines and prequalification outcomes. Initial observations show particular interest from developers across different disease areas and different health product categories. CSA provides comprehensive advice to developers to best anticipate applications for WHO prequalification and policy recommendations, aiming to improve quality of submissions through adequate study design and accelerate timely access to quality priority health products.

DEVELOPING A COMMUNITY OF PRACTICE FOR NEGLECTED TROPICAL DISEASE (NTD) PROGRAM MANAGERS IN AFRICA

Arianna Means[1], Sultani H. Matendechero[2], Maria Cecilia Cesar de Almeida[3], Traore Mahamadou[4], Gilbert Baayenda[5], Karsor K. Kollie[6], Massitan Dembele[4], Clarisse Bougouma[7], Agazi Fitsum Gebreselassie[8], Jusufu Paye[1], Phaedra Henley[8]

[1]University of Washington, Seattle, WA, United States, [2]National Public Health Institute, Ministry of Health, Nairobi, Kenya, [3]Neglected Tropical Disease Program, National Public Health Institute, Luanda, Angola, [4]NTD Programme, Ministry of Health, Bamako, Mali, [5]Vector Borne and Neglected Tropical diseases Division, Ministry of Health, Kampala, Uganda, [6]Neglected Tropical Disease Programme, Ministry of Health, Monrovia, Liberia, [7]National Programme for the Control of Neglected Tropical Diseases, Ouagadougou, Burkina Faso, [8]Center for One Health, University of Global Health Equity, Kigali, Rwanda

Neglected tropical disease (NTD) Program Managers have numerous responsibilities including coordination and partnerships, resource mobilization, intervention and service delivery, and data management, surveillance, monitoring, evaluation and research. In 2019, a group of Program Managers in Africa advocated for opportunities to collaborate and learn from one another in deriving best practices to overcome shared professional challenges. In 2020, the African NTD Community of Practice (CoP) for Program Managers in Africa was launched to support the pursuit of this goal. The purpose of this abstract is to describe the process of co-designing the CoP in partnership with Program Managers. In 2020, a CoP Development Team based at the University of Washington (USA) and University of Global Health Equity (Rwanda) met with a group of nine Program Managers to begin learning about Program Manager priorities for an African Program Managers CoP. Over a series of three meetings, Program Managers were presented with key decisions to make for the CoP, including voting on features to include in an online CoP and other design components. After the co-design meetings were concluded, a Beta version of an online CoP was developed that included features that Program Managers met consensus on. In February 2021, the Program Managers participated in one-to-one usability testing exercises with CoP facilitators. During these meetings, Program Managers navigated the Beta CoP using a "talk aloud" method. Experiences and feedback from the usability testing were pooled and used to refine the platform, particularly to improve the translation features that allow Program Managers to communicate with one another in their own language without any need for manual translation. The final CoP, named Kikundi, includes key features such as direct messaging, group messaging, discussion forums, curated resources, a Program Manager directory, program updates, an NTD events calendar, and professional development trainings. By engaging in a rigorous co-design process, the CoP is well matched to meet Program Manager needs moving forward.

0057

COMMUNITY READINESS ASSESSMENT OF MALNUTRITION AND DIETARY INCLUSION OF RICE BRAN IN RURAL SOUTHWEST GUATEMALA

Roberto Delgado-Zapata[1], Diva M. Barrientos[2], **Annika Weber**[3], Melissa Fineman[1], Andrea Jimenez-Zambrano[4], Brigitte Pfluger[5], Maureen Cunningham[6], Elizabeth P. Ryan[3], Molly M. Lamb[1]

[1]Colorado School of Public Health, Aurora, CO, United States, [2]Centro del Desarrollo Humano Fundación para la Salud Integral de los Guatemaltecos, Guatemala, Guatemala, [3]Colorado State University, Fort Collins, CO, United States, [4]University of Colorado, Aurora, CO, United States, [5]Laney Graduate School, Emory University, Atlanta, GA, United States, [6]Childrens Hospital Colorado, Aurora, CO, United States

Rice bran is a globally accessible, nutrient-rich agricultural co-product of rice processing that can support nutrient absorption and reduce frequency of, and recovery time from, diarrhea episodes. Rice bran is underutilized in regions where the vicious cycle of malnutrition and diarrheal disease

contribute to increased childhood morbidity and mortality. This study assessed baseline community readiness to address malnutrition in rural Guatemalan households, in a region where 40% of children suffer from chronic malnutrition. In September 2021, thirteen key respondents of varied social roles and demographics residing in the Trifinio region of southwest Guatemala were selected. In-person semi-structured interviews were conducted in Spanish using the Community Readiness Model with 6 domains: (A) Community efforts, (B) Community knowledge of efforts, (C) Leadership, (D) Community climate, (E) Knowledge about the issue, and (F) Resources for efforts. Interviews were recorded and observational field notes were taken by a second Spanish speaking team member. Interview responses were scored by a native Guatemalan Spanish speaker who did not conduct the interviews. The overall readiness score was 4.26 (SD 1.52). This score indicates the community is in the pre-planning stage for addressing malnutrition, in which there is clear recognition that something must be done about the issue of childhood malnutrition, and there is awareness of groups addressing diarrhea and child growth faltering, but efforts to address malnutrition are not yet focused or detailed. Rice Bran was not consumed as part of the diet in this community. To address malnutrition beyond the "pre-planning stage" in this community, we need to reduce stigma and raise general awareness of rice bran and malnutrition among local leaders. Local focus groups on dietary habits across the lifespan may also inform household-level interventions. In an effort to develop a sustainable malnutrition prevention intervention, we have initiated a 3-month feasibility trial of household-level dietary rice bran supplementation.

0058

HEALTH CARE SEEKING BEHAVIOR FOR ILLNESSES IN CHILDREN AGED UNDER FIVE YEARS IN WESTERN KENYA: A QUALITATIVE STUDY

Sarah Hawi Ngere[1], Victor Akelo[2], Sammy Khagayi[1], Ken Ondeng'e[1], Maryanne Nyanjom[1], Peter Otieno[1], Dickens Onyango[3], Beth A. Tippett Barr[2], Richard Omore[1]

[1]Kenya Medical Research Institute (KEMRI-CGHR), Kisumu, Kenya, [2]U.S. Centers for Disease Control and Prevention, Kisumu, Kenya, [3]Kisumu County Department of Health, Kisumu, Kenya

Health care seeking behavior by caregivers for childhood illnesses is an important determinant of child survival, and delayed healthcare is associated with high child mortality. Acquiring health information and making use of the information can moderate inaccurate assessment and response to childhood diseases. The Child Health and Mortality Prevention Surveillance (CHAMPS) Kenya team assessed factors affecting caregivers' Health care seeking behavior for childhood illness in western Kenya by conducting a qualitative study of 88 community members between April 2017 and February 2018 using purposive sampling in an informal urban settlement in Kisumu County, and in rural Siaya County. Key informant interviews, semi-structured interviews and focus group discussions were audio-recorded and transcribed. All participants provided verbal consent. Data management was completed on *Nvivo 11*. Iterative analysis process was utilized and themes were identified and collated. Our findings reveal three broad thematic areas: cultural beliefs, religious beliefs and economic factors. Often, caregivers prefer not to take children with measles symptoms to the hospital because of a belief that the child will die upon medical intervention. In other instances, caregivers would take their children to traditional healers for illness believed to be caused by witchcraft. Caregivers would seek prayers for their children illness and wellbeing because of the belief in the healing power of prayers. Caregivers low income and perception of prohibitive cost of clinical care attributes to seeking over the counter medication first, which further delays care. Pain relievers were the most commonly reported medication purchased by caregivers to relieve symptoms of illness in children. To improve timely health care seeking behavior, it is important to increase health literacy in caregivers and improve their ability to accurately assess the timing and importance of clinical health care. Education should include a focus on danger signals in childhood illness which should prompt immediate clinical healthcare-seeking.

0059

ATTITUDES AND EXPERIENCES REGARDING MENSTRUAL HYGIENE MANAGEMENT AMONG MOZAMBICAN OF SCHOOL-AGE GIRLS

Helena Boene[1], Yolanda Maússe[1], Carlota Muianga[2], Tomohiko Morita[2], Naima Magaio[2], Eusebio Macete[1], Brecht Mommen[2], Khatia Munguambe[1]

[1]Manhica Health Research Center (CISM), Manhica village, Mozambique, [2]United Nations Children Fund, Maputo city, Mozambique

Some scientific evidence suggests that poor Menstrual Hygiene Management (GHM) is a factor that influences absenteeism and poor school performance among girls. There is little research related to GHM in Mozambique. This study aimed to understand the challenges faced by school-age girls in the practice of GHM in Mozambique. A mixed study was conducted in the provinces of Inhambane, Tete and Nampula in 2018/19. Were conducted 12 observations in schools, 24 interviews with teachers and 60 focus group discussions with different community members. Interviews were recorded and transcribed before the thematic analysis using Nvivo 12. Data from observations was entered in Ms Excel and frequencies of each indicator was generated. Menstruation is perceived as a sign of growth, a passage into adulthood. Menstruation information is obtained from teachers, mothers and other actors who are not necessarily prepared to respond to girls' needs. Menstruating girl does not necessarily miss classes, but may be temporarily absent from the classroom or school. Norms and practices associated with menstruation guide behaviour during this period which include negative perceptions about menstruation and the culture of silence around the subject. The schools have robust structures, but the bathrooms were not aligned with the type of construction of the other school structures. Schools lack basic hygiene conditions, with a lack of water and soap. The lack of privacy in the bathrooms, the discomfort of colic, the fear of being discovered are some of the challenges faced by girls during menstruation. Posing risks for girls to miss school. The main source of information about menstruation is the school. Cultural norms and practices associated with menstruation guide secret behaviour resulting in limited exchange of information about menstruation and menstrual hygiene. The lack of hygiene and sanitation conditions is one of the challenges faced by girls in school during menstruation. Teachers do not have accurate information on menstruation and menstrual hygiene and training is needed in this area.

0060

IS 'SPEEDING UP' A FEASIBLE AND BENEFICIAL LONG-TERM STRATEGY IN DRUG AND VACCINE DEVELOPMENT? OPPORTUNITIES, RISKS, BENEFITS AND DRAWBACKS OF SYSTEMATIC ACCELERATION

Hanna K. de Jong[1], Sabine M. Hermans[1], Mariëtte A. van den Hoven[2], Martin P. Grobusch[1]

[1]Centre for Tropical Medicine and Travel Medicine, Department of Infectious Diseases, Division of Internal Medicine, Amsterdam UMC, Location University of Amsterdam, Amsterdam, Netherlands, [2]Department of Ethics, Law and Humanities, Amsterdam UMC, Location Vrije Universiteit Amsterdam, Amsterdam, Netherlands

The covid-19 pandemic has shown that the acceleration of clinical trials of both vaccines and pharmacotherapeutics is feasible and may not lead to unfavorable registration process outcomes. Clinical trial and registration trajectory, from beginning to end, would have normally taken at least a decennium, while the first covid-19 vaccines were developed in less than two years. Similar accelerations of clinical trials have been preceded a few times, mainly in situations of global health emergencies: the Ebola vaccine clinical trialing during the West African Ebola virus disease outbreak in 2013-2016; and fast-tracking of multidrug-resistant tuberculosis (MDR-TB) clinical drug development (bedaquiline, delamanid) when the MDR-TB epidemic became a global emergency. These successful examples of clinical trial accelerations could be used to identify the components which are beneficial and essential in enabling acceleration of clinical trials,

such as resources, priority (i.e., covid-19 is a public health risk for high income countries) and risk assessment (i.e., introducing mRNA vaccines posed a potentially higher safety risk due to more 'unknowns' than introducing an existing vaccine platform with more safety experience). Once these components are determined, a new clinical trial trajectory could be developed in which time and eventually costs might be reduced in comparison to the current clinical trial trajectories. We hypothesize that it should be possible to re-model the clinical trial trajectory in a - flexible - scheme also for diseases and settings beyond emergency responses, thereby benefiting global health by making pharmaceutical development more accessible. We are currently testing this hypothesis by means of a literature search in which we will examine examples of acceleration of drug and vaccine development for global health programs such as are mentioned earlier, and use the gained knowledge to re-model the current clinical trial trajectory. Results of the work currently underway will be presented during the meeting.

0061

ASSESSING THE ECONOMIC IMPACT OF COVID-19 IN THE LARGEST TOWNSHIP IN SOUTH AFRICA: SOWETO

Dineo A. Thaele, Portia C. Mutevedzi, Pedzisai Ndagurwa, Nyasha Mutanda, Issac Choge, Cleopas Hwinya, Selamola Tloubatla, Shabir Madhi

Vaccines and Infectious Diseases Analytics Research Unit, Johannesburg, South Africa

The implementation of lockdown measures posed a huge threat to economies globally, more so in resource limited settings such as South Africa. In March 2020, following the initial Covid-19 cases in South Africa, a hard lockdown was implemented with only essential services and workers allowed to operate. In the third quarter of 2021, the unemployment rate was reported at 34.9%, the highest official unemployment rate recorded since 2008. Furthermore, South Africa is experiencing food insecurity due to COVID-19 and high inflation rates, with about 16% of the population reported to have experienced food insecurity. This study aims to examine the economic impact of COVID-19, using data from CHAMPS Soweto/Thembelihle Health Demographic Surveillance Site collected during the level three and four lockdown period February 2021 - June 2021. The outcome variable economic impact is defined as any individual reporting loss of income or who perceived basic needs (i.e. medicine, food) as expensive. Analysis included descriptive and adjusted logistic regression to identify factors associated with economic impact of COVID-19. Among adults aged 18-59 years (55 542), 29% reported having experienced economic impact of COVID-19. About 18% (10 041) experienced loss of income and 15 932 (29%) reported that basic needs were expensive during the COVID-19 period. Those permanently employed (OR 3.74, CI 3.56-4.92) and those temporarily employed (OR 4.04 CI 3.79-4.31) were at a higher risk of experiencing the economic impact of COVID-19 compared to those who were students. By age group, those who were between 51-55 years (OR 1.93, CI 1.76-2.11) and 56-59 years old (OR 2.03; CI 1.84-2.25) were more likely to experience the economic impact of COVID-19 compared to those 19-24 years. We show that COVID-19 has severe economic impact on the Soweto population; a community already struggling socio-economically. These findings show the need to balance outbreak response with economic productivity. There is now an urgent need to create employment and business opportunities as well as to subsidize the food basket.

0062

COMPARISON OF PREGNANCY AND BIRTH OUTCOMES USING ARCHIVAL MEDICAL RECORDS BEFORE AND DURING THE FIRST WAVE OF THE COVID-19 PANDEMIC IN KINSHASA, DEMOCRATIC REPUBLIC OF CONGO: A DESCRIPTIVE, LONGITUDINAL ANALYSIS

Patrick J. Arena[1], Camille Dzogang[2], Adva Gadoth[1], Dalau M. Nkamba[3], Nicole A. Hoff[1], David Kampilu[2], Michael Beya[2], Hui-Lee Wong[4], Steven A. Anderson[4], Didine Kaba[3], Anne W. Rimoin[1]

[1]UCLA Fielding School of Public Health, Los Angeles, CA, United States, [2]UCLA-DRC Health Research and Training Program, Kinshasa, Democratic Republic of the Congo, [3]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [4]U.S. Food and Drug Administration, Silver Spring, MD, United States

Little research has been conducted on the impact of the coronavirus disease 2019 (COVID-19) pandemic on either pregnancy/birth outcomes or the ability of archival medical records to capture such outcomes. Our study objective is to compare the frequency of preterm birth (PTB), stillbirth, low birth weight (LBW), small for gestational age (SGA), microcephaly, and neonatal bloodstream infection (NBSI) before and during the COVID-19 pandemic in Kinshasa, Democratic Republic of Congo. We conducted a facility-based retrospective cohort study in which identified cases of pregnancy/birth outcomes were tabulated at initial screening and subcategorized according to level of diagnostic certainty using Global Alignment of Immunization Safety Assessment in pregnancy (GAIA) definitions. Documentation of birth complications, delivery type, and maternal vaccination history were also evaluated. The frequency of each pregnancy/birth outcome was compared in the pre- (i.e., July 2019-February 2020) and intra-COVID-19 (i.e., March-August 2020) periods via two-sample *z*-test for equality of proportions. In total, 14,300 birth records were abstracted. Pregnancy/birth outcomes were identified among 22.0% and 14.3% of pregnancies in the pre- and intra-COVID-19 periods, respectively. For stillbirth, LBW, SGA, microcephaly, and NBSI, estimates were similar across study periods. However, the frequency of PTB in the intra-COVID-19 period was significantly lower than that reported in the pre-COVID-19 period (8.6% vs. 11.5%, $p < 0.0001$). Furthermore, the level of diagnostic certainty declined slightly across all outcomes from the pre- to the intra-COVID-19 period. Nonetheless, diagnostic certainty was especially low for certain outcomes (i.e., stillbirth and NBSI) regardless of period; other outcomes (i.e., PTB and LBW) had moderate to high levels of diagnostic certainty. Results were mostly consistent when the analysis was focused on the facilities designated for COVID-19 care. Overall, our study adds crucial real-world data to the literature regarding the impact of the COVID-19 pandemic on maternal/neonatal services and outcomes in Africa.

0063

CONGENITAL BIRTH DEFECTS AMONG PERINATAL DEATHS: FINDINGS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) BANGLADESH

Afruna Rahman[1], Kyu Han Lee[2], Muntasir Alam[1], Mohammad Zahid Hossain[1], Kazi Munisul Islam[1], Mohammad Sabbir Ahmed[1], Rajib Biswas[1], Shovo Debnath[1], Afsana Afrin[1], Emily S. Gurley[2], Shams El Arifeen[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States

Nearly 240,000 newborns die globally per year within the first 28 days of life from congenital birth defects (CBD). About 90% of children born with CBDs come from low- and middle-income countries. Worldwide CBDs contribute to over 20% of stillbirth and neonatal deaths. CHAMPS is a multi-country program aiming to recognize and track the causes of stillbirths and childhood deaths in seven countries, through postmortem minimally invasive tissue sampling (MITS) and other information. We aimed to estimate the prevalence and explore the common presentations of CBDs using MITS in Bangladesh. From March 2018 to February 2022, an expert

panel determined the causes for 298 perinatal deaths based on data from MITS, histopathology, molecular and microbiological diagnostics, clinical data abstraction, photographs and verbal autopsies. We found 21 (7%) cases with CBDs in the causal chain and, of these, 10 (48%) were stillbirths and 11 (52%) were early neonatal deaths. A CBD was considered the underlying cause in 10 deaths and antecedent or morbid cause in 11 others. Congenital malformation syndrome affecting multiple systems (7/21), neural tube defect (NTD) (3/21) and malformation of the musculoskeletal system (4/21) were the most common. Anencephaly and gastroschisis were the main NTD and musculoskeletal system abnormality, respectively. Shared maternal characteristics include maternal age <30y (91%), hypertension (19%), previous delivery of a baby with congenital abnormality (9%), and gestational diabetes (5%). Twelve mothers had a history of ultrasound investigation during pregnancy; and the CBD was detected in ultrasound reports of six cases. Seventeen mothers (68%) received at least one ANC visit. The panel opined 60% of cases were preventable (6 out of 10 where congenital malformation was the underlying condition) through preconception counselling, folic acid supplementation, or ultrasound for pregnancy profile for early detection. Our findings highlight the need for appropriate folic acid supplementation, quality antenatal care during pregnancy and strengthening research on major CBDs to understand the risk factors for prevention.

0064

CHARACTERISTICS OF CALLERS WHO SOUGHT FREE HEALTH SERVICES FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) CALL CENTRE IN BALIAKANDI, A RURAL SUB-DISTRICT OF BANGLADESH

Qazi Sadeq ur Rahman[1], Kazi Munisul Islam[1], Kyu Han Lee[2], Abu Md Saleheen[1], Afruna Rahman[1], Sanwarul Bari[1], Emily Gurley[2], Shams El Arifeen[1], Mohammad Zahid Hossain[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [2]Bloomberg School of Public Health Johns Hopkins University, Baltimore, MD, United States

In September 2017, Child Health and Mortality Prevention Surveillance (CHAMPS) Bangladesh established a 24/7 physician's operated call-in centre to address illness-related inquiries for Baliakandi population, which is a rural subdistrict in Bangladesh. It is specially designed to assess illness of under-5 children and maternal complication. Physicians provide advice to the family for management of illness and refer to appropriate health facility. All calls are recorded, and referrals are followed up using an android application. Caller information was later linked with ongoing Demographic Surveillance System (DSS) covering 56005 ever-married women of reproductive age and 22395 under-5 children. This study assessed the characteristics of callers taking recent data between January to December 2021. Call centre received total 3160 calls from Baliakandi residents on selected period where 2256 (71%) were health-related calls of any nature. Among 2256 calls, 1802 (80%) calls were for illness; 813 (45%) calls were for under-5 children and 449 (25%) were for maternal complications. 791 (63%) illness-related calls from total 1262 for under-5 children and pregnant/postpartum women could be linked to DSS; of them 477 (60%) calls were from households (HH) of fourth and highest wealth quintile; 456 (58%) were from HHs where mothers had education for more than 10 years; and majority of calls (73%) from HHs with younger mothers (15-29 years). Out of 791, 30 maternal and under-5 children complications were urgently referred to health facility for immediate management. 14 (47%) of them visited recommended hospital. Among non-compliance of referral (16), 14 (88%) women had secondary or higher level of education and 8 (50%) HHs were from fourth quintile group. They preferred to have treatments at home or in private hospital. 465 (58%) mothers who used the call centre services had higher education and 585 (74%) HHs using call centre were from middle to higher quintile groups. Considering the high non-usage of the call centres, we recommend further studies to identify the barriers for using call-in centre services and recommended referral facilities.

0065

ACCELERATING UNIVERSAL HEALTH COVERAGE THROUGH CONTINUOUS PERFORMANCE IMPROVEMENT OF PRIVATE HEALTH FACILITIES IN BENIN

Karamatou Bangbola[1], Gninoussa Akadiri[1], **Mariam D. Bahova**[1], Sandra Djalle Incardona[1], Jordan M. Smith[1], Josea Ratsirarson[1], Heloise Gayet[1], Erin Mohebbi[2], Margaret Chappell[2], Jean Placide Agbogba[2]

[1]Medical Care Development Inc, Silver Spring, MD, United States, [2]Abt Associates, Rockville, MD, United States

In Benin, 65% of people seek care in private health facilities (PHFs) and 14% of women give birth in PHFs. However, all Ministry of Health (MOH) capacity building interventions are aimed at public health facilities. The unfavorable regulatory environment, coupled with a low demand for, and awareness of, quality services, contribute to an inefficient and uneven quality of services in the private sector. To improve the quality of reproductive, maternal, newborn and child health care (RMNCH) in the PHFs, USAID's Benin Private Sector Health Partnership Activity project worked with the MOH to conduct a capacity building intervention composed of (i) training nurses, midwives and clinicians using a High Impact Intervention Package (PIHI in French) on key RMNCH topics, followed by (ii) evaluation visits to assess their performance using a dedicated clinical checklist and provide tailored recommendations. The PIHI training was provided to 157 staff from 120 PHFs in 9 districts, and a pool of 45 evaluators were trained on the evaluation process to conduct the intervention from August 2020 to September 2021. The PHFs received a baseline visit and up to 3 evaluation visits during the intervention period. Scores for PHFs receiving at least 2 visits (N=118) increased by 15.94% (95% CI 13.75-18.11, p<0.0001) from 41.25% at baseline to 57.19% during the follow-up visit. Scores for PHFs receiving 4 visits (N= 36) increased (p<0.0001) from 40.70%, at baseline to 54.55%, 66.99%, and 68.81% during the 3 follow-up visits, respectively. The difference in scores between the 3rd and 4th visit was not statistically significant (p=0.39). Of the 118 PHFs receiving at least one follow-up visit, only 3 PHFs (0.03%) scored at least 80% at baseline for satisfactory quality services compared to 27 PHFs (22.81%) at the final visit. These results suggest that this approach can effectively improve the quality of services provided in a sector that has long been neglected and needs stronger support to help achieve universal health coverage in Benin. The many lessons learned in this project could be useful for other countries where PHFs play a similarly important role in service coverage.

0066

EXTREMOPHILES AND THE SEARCH FOR EXTRA-TERRESTRIAL LIFE.

Cornelius C. Nwora

Texas Southern University, Houston, TX., Houston, TX, United States

Extremophiles - are species of microorganisms that have adapted themselves to live in extremes of cold or hot temperatures like hot springs and glacial environments. How they uniquely survive the harshness of those environments - in niches, on fossil remains, rocks and now in outer space, have been the subject of much research for Microbiologists, environmentalists, archeologists, modern astronauts and scientists searching for life outside of our planet - Earth. Several spore-forming *Bacillus* species (*B. stearothermophilus, B. subtilis, B. coagulans, B. cereus, B. anthracis*, etc.) have long been isolated from the soil and identified as contaminants of food and water reservoirs. Majority of industrially useful microorganisms have been isolated from the soil where they uniquely contribute to enriching the soil - trapping and transforming the energy of the sun into useful nutrients. Their survival has been attributed to their unique ability to produce dipicolinic acid, a calcium ion chelator found only in spores. Recently, some novel microbial species have been isolated from the International Space Station (ISS) and belong to the - Methylobacteriaceae family. Of these, *Methylorubrum rhodesianum* was the first to be named and a close specie with *Methylobacterium indicum*.

"The new strains may be "bio-technologically useful genetic determinant" to assist with the growth of plants in space. Another extremophile named - *Deinococcus radiodurans* which was exceptionally resistant to high levels of radiation and pressures simulated to International Space Station conditions has also been isolated. These and a few other such endeavors stand out to usher a new era of research that help scientists to try to understand extra-terrestrial life and the peculiar traits needed to enable humans learn to adapt to life outside of our planet - Earth.

0067

SARS-COV-2 SEROPREVALENCE, COVID-19 VACCINATION, AND HESITANCY IN AGRICULTURAL WORKERS IN RURAL GUATEMALA

Diva Mirella Barrientos[1], Lyndsay Krisher[2], Alex Cruz -Aguilar[3], Daniel Pilloni-Alessio[4], Luis E. Crisostomo-Cal[4], Edgar A. Castañeda-Sosa[5], Jaime Butler-Dawson[6], Daniel Olson[7], Lee S. Newman[6], Edwin J. Asturias[7]

[1]Fundacion para la Salud Integral de los Guatemaltecos, Guatemala, Guatemala, [2]Colorado School of Public Health, Aurora, CO, United States, [3]Pantaleon, S.A., Guatemala, Guatemala, Guatemala, [4]Pantaleon, S.A. Guatemala, Guatemala, Guatemala, [5]Hospital Herrera Llerandi Clinical Laboratory, Guatemala, Guatemala, [6]Center for Health, Work & Environment, Colorado School of Public Health, Aurora, CO, United States, [7]Center for Global Health, Colorado School of Public Health, Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO, United States

During the COVID-19 pandemic, serological tests to screen populations have provided better estimates of the cumulative incidence of infection. In addition, little is known about the confidence, acceptability, and uptake of COVID-19 vaccines in rural areas of low and middle-income countries. This study evaluated the seroprevalence of SARS-CoV-2 in agricultural workers in rural Guatemala, their COVID-19 vaccine uptake and vaccination attitudes. A cross-sectional study was undertaken from August to November of 2021 in agricultural workers at a sugar plantation in rural Guatemala. A questionnaire was used to collect demographic, previous COVID-19 infection, attitudes towards and receipt of COVID-19 vaccines. Serological testing was performed to detect SARS-CoV-2 IgM and IgG using STANDARD™ Q COVID-19 IgM/IgG Plus assay. Of 4,343 workers, 1,279 (29.4%) were seropositive for SARS-CoV-2 IgG and/or IgM compared to 2.3% reporting having COVID-19 infection in the past; 85% had received the first dose of the COVID-19 vaccine and 21.9% the second dose at the time. The majority were men (99.5%), who worked in the sugar cane fields (99.9%), with an average age of 34 years. Vaccine refusal was 0.6%, and 13.9% expressed some degree of vaccine hesitancy. Vaccine hesitancy and refusal was inversely associated with uptake of any dose of COVID-19 vaccine and their interest in protecting the family, coworkers, and their community. Most non-hesitant workers (57.3%) reported receiving enough information about COVID-19 vaccines, compared to 39.1% of those with some hesitancy and 15.4% of those refusing ($p<0.001$). Most workers trusted health care providers and the Ministry of Health on COVID-19 vaccine information, followed by their employer; vaccine refusers were significantly likely to trust on their family, friends, or religious leaders. Agricultural workers in countries like Guatemala, have suffered high incidence of asymptomatic and undetected SARS-CoV-2 infection. Most have received the COVID-19 vaccine, but there are moderate degrees of vaccine hesitancy that require better public health information to overcome it.

0068

SOCIOECONOMIC DISRUPTIONS CREATED BY THE COVID-19 PANDEMIC IN AN URBAN SLUM COMMUNITY

Hojeong Kwon[1], Nivison Nery Jr[2], Juan P. Aguilar Ticona[2], Emilia M.M.A. Belitardo[2], Renato Victoriano[3], Rôsangela O. Anjos[3], Moyra M. Portilho[3], Mayara C. de Santana[3], Laiara L. dos Santos[3], Daiana de Oliveira[3], Olatunji Johnson[4], Mitermayer G. Reis[1], Guilherme S. Ribeiro[3], Derek A.T. Cummings[5], Albert I. Ko[1], Federico Costa[1], Mariam Fofana[1]

[1]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [2]Instituto de Saúde Coletiva, Universidade Federal da Bahia, Salvador, Brazil, [3]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Salvador, Brazil, [4]Department of Mathematics, University of Manchester, Manchester, United Kingdom, [5]Department of Biology, University of Florida, Gainesville, FL, United States

Urban slum communities are particularly vulnerable to the socioeconomic disruptions created by the COVID-19 pandemic. We sought to evaluate the impact of the pandemic and emergency social protection interventions on employment and food security among inhabitants of an urban slum community in Salvador, Brazil. Additionally, we assessed the impact of "Auxilio Emergencial", a financial assistance program created to alleviate the economic impact of COVID-19 emergency among informal workers. We conducted household-based surveys before (September to November 2019) the emergence of COVID-19, and after the first (November 2020 to February 2021) and second (July to October 2021) COVID-19 epidemic waves in Brazil. Of the 2988 individuals who participated in at least one of the surveys, 1,726 (57.8%) were female, and most self-identified as Black (48.3%) or Brown (44.9%). The prevalence of unemployment among women increased from 52.0% in the first pre-pandemic survey to 61.7% and 68.1% in the second and third surveys. Among men, unemployment increased from 30.9% in the first survey to 35.4% and 45.9% in the second and third surveys. Based on a standardized 2-item screening tool, 50.7% of households reported food insecurity in the pre-pandemic survey. Overall, 632/943 (67.0%) households reported receiving support through Auxilio Emergencial during the second survey. Between the first and second surveys, the prevalence of food insecurity decreased by 5.1% (95% CI -13.2 – 2.9%) among households receiving Auxilio Emergencial, whereas it increased by 6.0% (95% CI -5.1 – 17.1%) among non-recipient households. These findings indicate that, within this setting of informal settlements and high socioeconomic deprivation, women were particularly vulnerable to economic instability during the COVID-19 pandemic. Although social support programs partially alleviated food insecurity among recipients, the overall prevalence of food insecurity remained high in this population. This highlights the need for additional social protection interventions to mitigate economic and food insecurity in urban slum communities.

GENOMIC CHARACTERIZATION OF *KLEBSIELLA PNEUMONIAE* ISOLATES FROM DEATHS IN CHILDREN UNDER 5 YEARS OF AGE IDENTIFIED THROUGH THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) NETWORK

Eungi Yang[1], Maureen Diaz[2], Ashutosh Wadhwa[2], Muntasir Alam[3], Mustafizur Rahman[3], Md Saiful Islam[3], M Ishrat Jahan[4], Ikechukwu U. Ogbuanu[5], Karen Kotloff[6], Milagritos D. Tapia[6], Samba O. Sow[6], Victor Akelo[7], Dickens Onyango[8], Shams El Arifeen[3], Emily Gurley[9], Dianna M. Blau[2], Jonas Winchell[2]

[1]Centers for Disease Control and Prevention/IHRC Inc., Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]International Centre for Diarrhoeal Diseases Research, Dhaka, Bangladesh, [4]Kumamoto University, Kumamoto, Japan, [5]Crown Agents, Freetown, Sierra Leone, [6]Division of Infectious Disease and Tropical Pediatrics Center for Vaccine Development and Global Health University of Maryland School of Medicine, Baltimore, MD, United States, [7]US Centers

for Disease Control and Prevention-Kenya, Kisumu, Kenya, [8]Kisumu County Department of Health, Kisumu, Kenya, [9]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Klebsiella pneumoniae (KP) was identified as the predominant organism attributed to deaths at Child Health and Mortality Prevention Surveillance (CHAMPS) sites in sub-Saharan Africa and South Asia. Recent data indicate a rise in multidrug resistant and hypervirulent KP. We performed genomic characterization of KP isolates from CHAMPS cases to investigate diversity, virulence, and antimicrobial resistance (AMR) with the goal of informing development of vaccines and other therapeutics. KP isolates cultured from post-mortem blood and/or cerebrospinal fluid (CSF) specimens from Bangladesh (n=19), Mali (n=13), Kenya (n=32) and Sierra Leone (n=13) underwent whole genome sequencing (WGS) at icddr,b and CDC, Atlanta. Sequence types (STs) were determined using Institute Pasteur multi-locus sequence type database. Clinically relevant information, including K (capsular polysaccharide) and O (lipopolysaccharide) antigen loci, AMR elements, and virulence factors, was extracted using KP specific genomic tools Kleborate and Pathogen watch. Among 77 isolates identified as KP by various microbiological methods at CHAMPS site laboratories, 61 (79%) were identified as KP by WGS. Among these, 35 STs were identified, including novel types in Sierra Leone (n = 1) and Mali (n = 5). In total, 34 K-loci and 6 O-loci types were detected. Diverse K-loci (5-13 unique types) were observed within each country. O1/O2v1 comprised the majority of isolates in Bangladesh (57%), Kenya (48%), and Sierra Leone (50%) while O1/O2v2 was dominant in Mali (66%). Over 60% of strains from Bangladesh and Sierra Leone possessed yersiniabactin siderophores, a virulence factor common among hospital-associated KP strains. Extended-spectrum beta-lactamase genes were detected in 40-100% of KP isolates from each country; a carbapenem resistance gene was identified in 57% of Bangladeshi isolates. Virulence factors and AMR are common among KP isolates associated with child deaths in low-and-middle-income countries. Ongoing surveillance utilizing genomics tools is crucial for the development of vaccine candidates and antimicrobial treatments for this important pathogen.

0070

INTEGRATED DELIVERY OF HOUSEHOLD MALARIA INTERVENTIONS DURING THE COVID PANDEMIC IN ZAMFARA STATE, NIGERIA

Temitope Ogunbi[1], Bako Kantiok[2], Idowu Akanmu[1], Linda Osaji[1], Angela Acosta[3], Foyeke Oyedokun-Adebagbo[4], Olufunmilayo Sanni Adeniyi[5], Ian Tweedie[1], Bolatito Aiyenigba[1]

[1]Breakthrough ACTION-Nigeria, Johns Hopkins Bloomberg School of Public Health, Abuja, Nigeria, [2]Breakthrough ACTION Nigeria, Johns Hopkins Bloomberg School of Public Health, Abuja, Nigeria, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]United States Agency for International Development, Abuja, Nigeria, [5]National Malaria Elimination Programme, Abuja, Nigeria

Globally, 2/3 of the additional malaria deaths recorded in 2020 were attributed to service disruptions from COVID-19. To prevent further delays in the implementation of planned campaigns for life-saving interventions such as insecticide treated nets (ITN) and seasonal malaria chemoprevention (SMC), the Government of Zamfara State, Nigeria and its partners creatively reorganized ITN & SMC delivery as an integrated campaign, despite the involvement of different target groups and commodities. However, implementing a mass campaign had the potential to increase the number of COVID-19 cases. We deployed a combined ITN-SMC campaign involving modified community and house-to-house commodity distribution strategies, and integrated COVID-19, SMC, and ITN-related messaging. The strategy included fixed distribution posts in selected areas (80% of nets) and door to door distribution in others (20% of nets) tailored to local logistical challenges and the capacity of authorities to manage gatherings. To reduce crowding, the number of days for net distribution was extended from five to ten. A multi-channel demand creation strategy as well as advocacy was used to ensure political, community and media support for the campaign. Messages focused on the importance of malaria prevention; correction of myths and misconceptions for ITNs, SMC, and COVID-19; and prompt care-seeking in the COVID-19 context. Bottom-up mechanisms were put in place to minimize the spread of rumors. These efforts yielded impressive results; 2.9 million ITNs reached beneficiaries, and 1,030,000 SMC doses were administered to eligible children (91% coverage). There was an unprecedented level of government buy-in at all levels (at least $353,925). The net card redemption rate was 96%, and net use rates among children under five, pregnant women and the general population was 90%, 92% and 74% respectively. The COVID-19 infection live count in Zamfara State did not spike during the campaign period. This experience shows that with some modifications, mass distribution campaigns and the promotion of healthy malaria behaviors can successfully continue despite the COVID-19 pandemic.

0071

EFFECTS OF CLIMATIC FACTORS ON COVID19 TRANSMISSION IN ETHIOPIA

Fitsum Bekele Endeshaw[1], Fentabile Getnet Yimer[1], Solomon Kibret Birhanie[2]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]Program in Public Health, University of California, Irvine, CA, United States

Climate conditions may affect the transmission and pathophysiology of respiratory tract infections in many ways. However, its impact on the COVID-19 pandemic's propagation is not well studied. This study aimed to evaluate the effects of environmental parameters such as temperature, rainfall, relative humidity, sunshine length, and wind speed on COVID-19 daily cases in Addis Ababa, Ethiopia. Data for confirmed COVID-19 cases between 10th March 2020 and 31st October 2021 were obtained from the National Data Management Center at the Ethiopian Public Health Institute. Data for climatic factors were obtained from the Ethiopia National Meteorology Agency. The Spearman rank correlation test was used to estimate the correlation between daily confirmed COVID-19 cases and climatic factors, and the log-link negative binomial regression model was used to fit the effect of climatic factors on COVID-19 transmission, from lag0 to lag14 days. A total of 245,101 COVID-19 cases were reported in Addis Ababa during the study period, with a median of 337 and a maximum of 1903 new cases per day. A significant association between COVID-19 cases and humidity was observed with a 1% increase in relative humidity was associated with a 1.1% [IRRs (95%CI): 0.98, (0.97-0.99)] and 1.2% [IRRs (95% CI): 0.98, (0.97-0.99)] decrease in COVID-19 cases for 4 and 5 lag days prior to detection, respectively. The highest increase in the effect of wind speed and rainfall on COVID-19 was observed at 14 lag days prior to detection with IRRs of 1.854 (95%CI: 1.26 - 2.74) and 1.078 (95%CI: 1.04 - 1.12), respectively. The lowest IRR was 1.109 (95%CI: 0.93-1.31) and 1.007 (95%CI: 0.99-1.02) both in lag 0, respectively. The transmission of COVID-19 was substantially associated with climate factors in Addis Ababa, Ethiopia. The number of reported cases has shown seasonal variations, the highest in rainy and the lowest in dry seasons. This highlights COVID-19 prevention and control strategies should consider seasons. Further study might be required to understand the virological and pathophysiologic impact of climatic factors in Ethiopia.

0072

HISTORICAL GOLD MINING INFECTIOUS DISEASE EPIDEMICS IN AUSTRALASIA

G. Dennis Shanks

Australian Defence Force Malaria and Infectious Disease Institute, Enoggera, Australia

Lethal infectious disease epidemics have historically occurred in military, refugee and mining camps where crowded conditions promote the spread of enteric, respiratory and insect-borne infections. The early history of gold mines around Palmer River, Queensland in the 1870s, Kalgoorlie, Western Australia in the 1890s and Papua on the island of New Guinea in the 1910s are recounted specifically as it relates to infectious disease deaths.

Despite large diagnostic gaps, it is likely that malaria was the predominate problem in Palmer River, typhoid in Kalgoorlie and bacillary dysentery in Papua. Nearly two-thirds of all recorded deaths in the Palmer River district from 1873-1883 were due to infections predominately "fevers". Typhoid fever likely killed >2000 Australians in the early phases of the Western Australian goldfields in the 1890s. Severe dysentery outbreaks killed up to a majority of the local workforce in the Lakekema goldfields of Papua resulting in the colonial authorities stopping mining activity in the second decade of the twentieth century. In the absence of public health measures and specific chemotherapy, large mortality rates in miners reflected the over-riding economic drivers of gold miners and their lack of any understanding of microbial disease and its interruption by public health measures. Similar infectious disease epidemics are likely to reoccur when large numbers of impoverished miners use low-technology methods to work alluvial gold deposits in conflict areas as has been seen in modern Africa and Latin America.

0073

EXEMPLARS IN DIAGNOSTICS: LESSONS FROM PROGRAMS OR INNOVATIONS THAT HAVE CLOSED THE GAP IN DIAGNOSTICS SERVICE DELIVERY

Mikashmi Kohli[1], Grace Umutesi[2], David Phillips[2], Nathaniel Gerthe[2], Sydney Yang[2], Jacob Bigio[3], Ezekiel Boro[1], Madhukar Pai[4], Kekeletso Kao[1]

[1]FIND, the global alliance for diagnostics, Geneva, Switzerland, [2]Gates Ventures, Seattle, WA, United States, [3]Research Institute of the McGill University Health Centre and McGill International TB Centre, Montreal, QC, Canada, [4]Canada Research Chair in Epidemiology & Global Health, McGill International TB Centre, McGill School of Population and Global Health, McGill University, Montreal, QC, Canada

Forty seven percent of the global population have little or no access to appropriate diagnostic services. Access to appropriate diagnostics for 6 conditions (HIV, TB, Malaria, HBV, hypertension, and diabetes) could prevent 1.1 million premature deaths in low- and middle-income countries (LMICs) every year, while inappropriate diagnosis results in poor health outcomes, increases the cost of care, and contributes to the development of antimicrobial resistance. Moreover, many countries have yet to develop country-specific diagnostic strategic plans and national essential diagnostics lists (EDLs). The Exemplars in Global Health (EGH) program seeks to address this challenge by studying country or global-programs and innovations that contributed to closing the gap in diagnostics. Diagnostics alone cannot help strengthen any disease program and the outcome measures are interlinked to the downstream processes in the cascade of care, such as linkage to treatment, follow up etc. Therefore, we used empirical analysis, structured interviews with experts, policy analysis to assess the success of diagnostics. Early findings highlight the importance of point-of-care and self-testing, use of digital solutions to retain people in the care cascade, multi-disease testing platforms and integrated testing strategies. In partnership with downstream audiences, including country decision-makers, norm-setting bodies, and funders, findings from this project will be disseminated and learnings from success stories will be leveraged where appropriate, to support the successful implementation of diagnostic programs in comparable settings.

0074

COVID-19 LOCKDOWNS AND FOOD INSECURITY: ASSESSING HOUSEHOLD INDICATORS OF VULNERABILITY IN HARAR AND KERSA, ETHIOPIA

Jonathan Andrew Muir[1], Merga Dheresa[2], Nega Assefa[2], Tamirat Getachew[2], Solveig A. Cunningham[1]

[1]Emory University, Atlanta, GA, United States, [2]Haramaya University, Harar, Ethiopia

COVID-19 is associated with one of the largest disruptions to life in the 21st century. To quell disease spread, national governments implemented lockdowns that likely created hardships for households around the world. To improve knowledge of the consequences of these lockdowns, we examined food insecurity and economic hardships such as job loss or business closure during the pandemic in a remote region of Ethiopia. Data were collected from Health and Demographic Surveillance Systems in Harar and Kersa, Ethiopia, using a cross-sectional survey that was implemented between August and September 2021. The questionnaire was administered to a simple random sample of 880 households (5 households were excluded as respondents were less than 18 years old). Of 875 households, 139 (15.9 %) reported not having enough food to eat since March 2020, an increase of 5.8 % from households that reported not having enough food to eat prior to the pandemic. In bivariate logistic regression analyses, households were less likely to have reported food insecurity if they lived in urban compared to rural areas (OR = 0.54, p-value = 0.001) and more likely to have reported food insecurity if they had more than 8 household members (OR = 3.27, p-value = 0.021). After adjusting for additional covariates, households were less likely to have reported food insecurity if they had a household member with secondary level education or greater compared to no education (AOR = 0.28, p-value = 0.003) or reported a monthly household income greater than 4,000 Birr (highest quartile) compared to households with a monthly income less than 1,350 Birr (lowest quartile) (AOR = 0.29, p-value = 0.005). Households were more likely to have reported food insecurity if they had a family member lose employment (AOR= 2.33, p-value <0.001) or reported an increase in local food prices (AOR= 4.00, p-value <0.001). These results are consistent with the premise that the pandemic exacerbated socioeconomic inequalities to increase disparities in food security. This knowledge will help inform future policies seeking to mitigate disease outbreaks without fomenting other unintended hardships or health problems.

0075

MOLECULAR EPIDEMIOLOGY OF *UREAPLASMA* SPECIES ISOLATED FROM NEONATES IN THE GLOBAL MULTI-CENTER CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE NETWORK (CHAMPS)

Jessica L. Waller[1], Eungi Yang[2], Lava Rishishwar[3], Vasanta Chivukula[4], Maureen H. Diaz[1], Jonas Winchell[1], Child Health and Mortality Prevention Surveillance Consortium[5]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]IHRC and Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]IHRC and Applied Bioinformatics Laboratory, Atlanta, GA, United States, [4]ASRT, Inc and Applied Bioinformatics Laboratory, Atlanta, GA, United States, [5]Emory Global Health Institute, Atlanta, GA, United States

Ureaplasma species, including *U. urealyticum* and *U. parvum,* are infectious causes of stillbirth, neonatal sepsis, and preterm labor. Recent studies in South Asia and South Africa suggest *Ureaplasma* species are an underrecognized cause of neonatal infections in low- and middle-income countries. Diagnostic testing of neonatal clinical specimens for *Ureaplasma* is rarely done, and bacterial factors associated with birth complication and infection remain unclear. We performed additional testing on post-mortem blood, cerebrospinal fluid (CSF), and tissue specimens from Child Health and Mortality Prevention Surveillance (CHAMPS) cases in South Africa from May 2017 to January 2018. *Ureaplasma* species were initially detected by real-time reverse transcription polymerase chain reaction (RT-PCR) using custom TaqMan Array Cards. Specimens from CHAMPS cases in which *Ureaplasma* was detected in one or more specimen types were transferred to the Centers for Disease Control and Prevention (CDC) for culture, real-time PCR, and whole genome sequencing (WGS). Ten isolates (5 *U. urealyticum*, 5 *U. parvum*) were recovered from 22 primary specimens, including lung tissue (n=5), blood (n=2), and CSF (n=3), from 6 cases where *Ureaplasma* was detected but not attributed to the cause of death. Genome assemblies were generated for 8 isolates and species identified by WGS matched real-time PCR species identification for all isolates. Expanded multi-locus sequence typing revealed diversity of isolates. Four (50%) isolates matched known sequence types (STs) (STs 38, 95, 48) which clustered in clonal complexes corresponding to species. Of these, 2 isolates from 2 different cases matched the same ST (ST 38). Novel allelic profiles were identified in the remaining 4 (50%) isolates. Sequence

evaluation for antimicrobial resistance revealed 1 isolate as tetracycline resistant through *tet (M)* gene acquisition. Analysis of additional specimens from cases enrolled at all CHAMPS sites is ongoing to further investigate the molecular epidemiology of *Ureaplasma* spp. and to identify relevant features that may contribute to poor clinical outcomes.

0076

SEROPREVALENCE BASED MAP OF VULNERABILITY TO ZIKA VIRUS BASED ON ENVIRONMENTAL SUITABILITY

Yannik Roell, Thomas Jaenisch

University of Colorado, Aurora, CO, United States

The 2015-17 Zika virus (ZIKV) epidemic in the Americas subsided faster than expected and evolving population immunity was postulated to be the main reason. Herd immunization is suggested to occur around 60-70% seroprevalence, depending on demographic density and climate suitability. However, this was only documented for a few cities in South America, meaning a substantial portion of the population might still be vulnerable to a future Zika virus outbreak. The aim of our study was to determine the vulnerability of populations in South America and Africa by comparing the environmental suitability of ZIKV transmission to the observed seroprevalence, based on published and unpublished studies. We collected seroprevalence and geospatial data of 89 unique locations from 34 studies. Extracting the environmental suitability at each location and converting to a hypothetical expected seroprevalence, we were able to determine the discrepancy between observed and expected. This discrepancy was used to evaluate the level of risk that each location still has for an outbreak to occur. Of the 89 unique locations, 58 (65%) exhibited an expected seroprevalence higher than what was observed. 19 locations (21%) even showed a discrepancy of -0.5 or less as an indicator of high risk. The considerable heterogeneity between environmental suitability and seroprevalence potentially leaves a large population vulnerable to future infection. Vulnerability seems to be especially pronounced at the fringes of the environmental suitability for ZIKV (e.g., Sao Paulo, Brazil). The discrepancies between observed and expected seroprevalence raise the question why the ZIKV epidemic stopped with large populations unaffected. This lack of understanding also highlights that future ZIKV outbreaks currently cannot be predicted with confidence.

0077

A SUSPECTED CASE OF EBOLA IN BURKINA FASO: WHAT IF IT HAD BEEN TRUE?

M'winmalo Inès Evelyne DA

Jhpiego, Ouagadougou, Burkina Faso

On August 22 2021, in a sub-regional context marked by a recent outbreak of Ebola Virus Disease (EVD) in the Republic of Guinea and a suspected imported case in the Republic of Côte d'Ivoire, a 22-year-old male patient who returned from Côte d'Ivoire was received at the Bogodogo University Hospital (CHU B) and was suspected to be a case of Ebola. An after action review (AAR) that focused on seven (07) thematic areas (coordination and finance; surveillance; risk communication and community engagement; laboratory system; infection prevention and control; case management and continuity of services; logistics and procurement) was conducted. The methods consisted of a workshop with the direct stakeholders of emergency management. Group work by thematic areas was carried out, followed by restitution in large group. The results of this after action review show many shortcomings: i) A long diagnostic delay (34 hours for the transport of samples to the hemorrhagic fever reference laboratory, which only had outdated reagents and therefore could not be used, 146 hours to obtain the final results); ii) Chaotic management of the suspected case (more than 150 direct contacts, absence of an isolation room requiring hospitalization in the COVID19 resuscitation room, inadequate training of personnel in the surveillance of MVE: unarmed personnel not knowing what to do, insufficient sample-takers, absence of legal texts for the mobilization of EIRs for the management of health emergencies, absence of standard operating procedures for the notification of cases of MVE according to the one-health approach, absence of a crisis communication plan).Taking into account all these criteria, and a virus reproduction rate equal to 2, approximately we would 302 cases would be confirmed on the evening of August 28th 2022. In 6 days this epidemic could have reached all continents. The question is: if nothing is done, is the world prepared for the worst? It is urgent and imperative to strengthen the preparation of teams to manage public health emergencies in countries like Burkina Faso.

0078

USING OUTREACH TRAINING AND SUPPORTIVE SUPERVISION (OTSS) TO IMPROVE THE QUALITY OF INTEGRATED HEALTH SERVICES IN BENIN

Jocelyn Akakpo[1], Hortense Kossou[1], Marie-Agnès Agboton-Zouménou[1], Serge Zountcheme[1], Senan Lorens Zinsalo[2], Floride Niyuhire[1], Thomas Hall[3], Timothé Chevaux[3], Ahmed Saadani Hassani[4], Patrick Condo[5], Bertille A. Onambele[6], William E. Houndjo[7], Cyriaque Affoukou[7], Alain Aissan[7]

[1]Management Sciences for Health, Cotonou, Benin, [2]Management Sciences for Health, Natitingou, Benin, [3]Management Sciences for Health, Medford, MA, United States, [4]Centers for Disease Control and Prevention, Cotonou, Benin, [5]U.S. President's Malaria Initiative, Cotonou, Benin, [6]US Agency for International Development, Cotonou, Benin, [7]National Malaria Control Program, Ministry of Health, Cotonou, Benin

In Benin, improving maternal and child health services is a priority as 72% of people seeking care at a health facility are women and children under five. Routine supervision is key to improved quality service delivery. The outreach training and supportive supervision (OTSS) tool, developed to support quality improvement of malaria case management, was adapted by the Integrated Health Services Activity (IHSA) to be used for integrated supervision of health workers (HWs) in four departments: Alibori, Atacora, Oueme and Plateau. This tool allows health facility (HF) management teams to provide oversight and coaching for maternal and newborn health (MNH), family planning (FP), gender-based violence (GBV), infection control, and malaria services. These teams conduct quarterly OTSS visits to HFs, visiting each HF at least annually, providing advice and training to HWs on key technical elements of prevention, diagnostics, and treatment. Based on identified gaps, an action plan is developed and then monitored by the HF coordination doctor. Between Oct 2019-Sep 2021, the OTSS tool was used at 287 of the 298 HFs (96%) of the four IHSA-supported departments, at least once a year with more frequent follow-up at underperforming sites, enabling the supervision of 1,277 HWs on MNH, FP, malaria, and GBV. During the same period in those departments, the following results were obtained from the national health information system and were analyzed using a chi-square test. The proportion of fever cases tested for malaria increased from 82% to 92% ($p<0.001$). The proportion of HFs meeting the minimum standard (80%) of correct malaria testing and treatment increased from 70% to 79% ($p<0.05$). Pregnant women receiving at least three intermittent preventive treatment doses under direct observation increased from 7% to 30% ($p<0.01$). Women with obstetric complications who received appropriate care increased from 25% to 86% ($p<0.01$). Further investigation is required to determine if other factors pre- and post- intervention may have affected these results. However, systematic, integrated supervision may contribute to improved HW performance.

0079

ANALYSIS OF EBOLA VIRUS EPIDEMIC PREPAREDNESS AND ASSOCIATED CAPACITIES IN THE DEMOCRATIC REPUBLIC OF CONGO

Sarah R. Tritsch[1], Wolfgang Munar[1], Placide Mbala K[2], Gerry Makaya[3], Abigail J. Porzucek[1], John D. Klena[4], Francis Mbuyi[3], Virgil Tsoni[2], Norbet Soke[4], Jean Claude Makangara[2], Amuri Aziza[2], Eddy Lusamaki[2], Pauline Musuamba[2], John Otshudiema[5], Richard Luce[4], Prosper Amedee Djiguimde[5], John Kombe[6], Gervais Folefack[5], Steve Ahuka-Mundeke[2], Joel M. Montgomery[4], Jean-Jacques Muyembe[2], Peter Fonjungo[4], Christopher N. Mores[1]

[1]George Washington University, Washington, DC, United States, [2]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, [3]Vysnova Partners Inc, Landover, MD, United States, [4]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]World Health Organization, Geneva, Switzerland, [6]DGLM, Ministry of Health, Kinshasa, Democratic Republic of the Congo

Several approaches and tools to assess country-level preparedness to public health emergencies exist. The World Health Organization's International Health Regulations (2005) and the Joint External Evaluations (JEE) were developed to inform National Action Plans for Health Security. However, these assessments and their associated recommendations tend to represent, at best, national aggregates that do not consider regional contexts, capabilities, and resources. The Democratic Republic of Congo (DRC) is the second largest and one of the poorest countries in Sub-Saharan Africa. Ebola Virus Disease (EVD) outbreaks are common in the DRC, where the 13th outbreak was recently declared over. Civil unrest, overlapping emergencies competing for political attention, intense poverty, and a fragmented health care system reduce DRC's capability to respond to public health emergencies. Under such conditions, the implementation of preparedness measures becomes an imperative for controlling EVD outbreaks before they reach an uncontrollable magnitude. We posit that low-income countries and fragile states would benefit from a scaled down version of the JEE to determine the most critical points of preparedness that need to be addressed. Because diagnostics are one of the most fundamental components of outbreak response, building and maintaining resilient laboratory capacity networks should be considered a priority when planning responses to outbreaks. This analysis looks at the preparedness of the DRC to respond to EVD outbreaks, and how to assess and incorporate subnational-specific barriers and facilitators when performing preparedness assessments and implementing standards. In addition, we look at how resilient laboratory capacity networks can be leveraged not only to specifically strengthen preparedness to EVD outbreaks, but also as an investment in strengthening DRC's overall health system.

HOW FAMILIES REACT TO RECEIVING CAUSE OF DEATH INFORMATION OF CHILDREN ENROLLED IN CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) IN MOZAMBIQUE: RAPID QUALITATIVE ASSESSMENT

Amílcar Magaco[1], Yury Macete[1], Raquel Mucor[1], Antonio Calia[1], Quique Bassat[2], Inacio Mandomando[1], Maria Maixenchs[2], Khatia Munguambe[1]

[1]CISM, Manhica, Mozambique, [2]ISGlobal, Barcelona, Spain

A child death is a huge tragedy for parents and family members. Unfortunately, families in low and middle-income countries (LMIC) still face excess infant mortality. The Child Health and Mortality Prevention Surveillance (CHAMPS) uses minimally invasive tissue sampling (MITS) to determine causes of death (CoD) in children under-5 years. CoD results, in addition to being used to suggest health interventions to reduce child mortality, are delivered to the child's parents so that they know the specific CoD, which may help them to deal with the loss and to seek medical follow up when necessary. This study aims to explore the experiences of parents and relatives of deceased children on the procedure for delivering CoD results. A rapid qualitative assessment was carried out using semi-structured interviews with parents and relatives of deceased children and systematic observations during the delivery of CoD results. Data were independently coded by two researchers, summarized in an MS Excel matrix and submitted to content analysis. The delivery of CoD results is a symbolic moment marked by memories and a mixture of feelings such as sadness, pain, relief and satisfaction for the parents and relatives of deceased children. These results, although they bring memories and emotions, are important for the bereaveds' closure. They are useful for medical follow-up when necessary and to minimize family tension and conflicts due to accusations that the child died as a result of witchcraft. Delays in delivery of results cause anxiety and frustration, making some parents turn to traditional healers to consult them on the child's CoD and apply traditional therapies for the mother to become pregnant again and give birth to a healthy baby. Learning about the CoD is good and necessary for parents and relatives of deceased children who consented to the MITS procedure, but delays in delivering results cause anxiety and frustration to them. These findings suggest the importance of delivering CoD results promptly, and we recommend that after delivering of CoD results, a medical and psychological families follow-up, especially to the mothers of the deceased children.

0081

INVESTIGATION OF THE GASTROENTERITIS DISEASE OUTBREAK AT LUVEVE SUBURB IN BULAWAYO PROVINCE - ZIMBABWE, 2020

Mandlenkosi King Moyo

Africa University, Bulawayo, Zimbabwe

On the 21st of May 2020, health department authorities were notified that residents in Luveve suburb at Emakhandeni District were reporting diarrheal incidences, turbid and foul-smelling water. To investigate, a study was conducted which probed into the cause and latent risk factors associated with the gastroenteritis disease outbreak at Luveve suburb. The study was an unmatched case-control study grounded on a structured questionnaire administered to 106 randomly sampled residents presenting with diarrhea (cases) and 106 neighbors of diarrheal patients (controls) as on May-June 2020. The minimum sample size was calculated on Epi Info version 7.2 software using the Fleiss method assuming a 95% confidence level, 80% power, 1:1 ratio of cases to control and odd ratio of 2.30. The cases were selected from a line-list generated at Luveve clinic. Univariate analysis and multivariate logistic regression were used to predict being a diarrheal case using Epi Info version 7.2 software. The stool samples results yielded *Shigella dysenteria, Salmonella typhi* and *Shigella sonnei.* From the univariate analysis the risk factors which emerged significant (p<0.05) were drinking municipal water and reporting sewage bursts. The significant protective factors were drinking stored water, reporting treating water and drinking one glass. However, in the multivariate logistic regression, drinking municipal water (aOR 5.0, 95% CI [1.2-14.1], p<0.003), reporting sewage bursts (aOR 4.5, 95% [1.4-14.1], p<0.010) and drinking five glasses of municipal water emerged as risk factors. The protective factors were drinking from water which was stored prior to the outbreak (aOR 0.3, 95% CI [0.1-0.7], p<0.003) and drinking treated water (aOR 0.3, 95% CI [0.1-0.8], p<0.012). The strategies to improve water quality should consider employing the use of aqua tablets to treat water and the issuance of a boil notice to the residents of the affected area. The emergent risk factors such as drinking municipal water and reporting sewage burst point to the need for provision of an alt.ernative water source and issuing of a water avoidance notice to the affected residents.

0082

INFECTIOUS BITES: A MULTIDISCIPLINARY APPROACH FOR BIOCONTAINMENT PREPAREDNESS

Maria G. Frank, Adam Sorenson, Jacob Wiersch, Jacob Fray, Caroline Persson, Kelly Medero, Adam Beitscher

Denver Health Hospital Authority, Denver, CO, United States

In 2015, and in response to the Ebola Outbreak in West Africa, the U.S. Department of Health and Human Services designated ten health departments and associated partner hospitals to become regional treatment centers for patients with highly infectious diseases (RESPTC) and reinforce the nation's infectious disease response capability. Our institution carries the RESPTC denomination and our multidisciplinary High-risk Infections Team (HITeam), which encompasses a skillfully trained and engaged group of nurses, physicians, respiratory therapists, paramedics, pharmacists, infection control, research and laboratory specialists, emergency management, engineering and environmental services; works, learns, trains and thrives collectively with the aim of providing excellent clinical care to our patients while assuring safety of the team. We developed a collaborative, multidisciplinary didactic series on specific biocontainment topics showcasing the unique expertise of our team members. Our series thus far has reviewed topics such as South American Hemorrhagic Fevers, Nipah Virus, Crimean-Congo Hemorrhagic Fever, Lassa Fever, Hantavirus infections, Personal Protective Equipment and Ebola virus. Our sessions usually include a clinical presentation discussed by a physician, laboratory diagnostics by our laboratorians, bedside care and infection prevention by a nurse, and available and developing treatments by a pharmacist; if a clinical trial is available for a specific pathogen, our research nurse will provide a process overview. Although these series are planned by our HITeam members, they are available institution-wide. With the potential for an influx of highly infectious pathogens in the healthcare setting, identifying, training and engaging stakeholders uniquely equipped to provide excellent care is cardinal. Our Infectious Bites series can be used as a model for inter-professional work in Biocontainment preparedness and foster lasting partnerships at an institutional, regional and national level.

COVID-19, BURIAL SITE SURVEILLANCE TO MEASURE EXCESS MORTALITY IN KARACHI, PAKISTAN

Abdul Momin Kazi[1], Fauzia Aman Malik[2], Nazia Ahsan[1], Obianuju Genevieve Aguolu[2], Saima Jamal[1], Waliyah Mughis[1], Muhamamad Taha Faruqui[1], Ayub Khan[1], Saad Bin Omer[2]

[1]Aga Khan University, Karachi, Pakistan, [2]Yale University, New Haven, CT, United States

In Pakistan, the government system for documenting fatalities and determining their causes is ineffective, leaving essential data on which to base health initiatives. In this regard we are collecting information to monitor unanticipated disparities in fatalities and their reasons, using burial ground surveillance and verbal autopsy methods, in order to measure the population-level impact of the COVID-19. This study is an observational surveillance consisting of retrospective data of 36 months and prospective data of 12 months within morgues and graveyards in Karachi, Pakistan. Ethnographic approach has been used in this study to collect data via IDIs, observations, formal and informal interview, with the community to facilitate the surveillance process. Surveillance process includes, data from graveyard registries, and verbal autopsy using the WHO verbal autopsy questionnaire. In addition e-questionnaires with geo-tagging and dashboard displaying mortality data against various variables consisting of graphs/ charts and scorecards have been created to visualize the real time data connected to a centralized system. At the conclusion of the study, this database and system, together with all records, will be handed over to a government body. The preliminary results show that out of the total deaths (N=22828), the highest number of deaths occurred in 2021 (n=12016), with a peak occurring in the month of August (n=2054), followed by 2019 (n=4021) and 2020 (n=3742). 556 deaths have been reported due to Covid-19. Males mortality prevalence was observed to be higher than females (males:56%, females:41%). Out of six districts of Karachi, Karachi West reported the highest proportion of mortalities (486.4/100,000). Themes obtained from qualitative data include (i) information about the graveyards, (ii) burial process (iii) record keeping system (manual/ computerized). The initial findings indicate the digitization of graveyard death registries to improve national mortality surveillance, which is required at every level of the health system in order to create the vital health intelligence needed for monitoring, policy, and planning.

0084

THE REMOTE EMERGING DISEASE INTELLIGENCE-NETWORK (REDI-NET): FROM CONCEPT TO ACTIVE SURVEILLANCE IN BELIZE

Benedicte Fustec[1], Caroline Pitts[1], Marie C. Pott[2], Alvaro Cruz[2], Uziel Romero[2], Hsiao-Mei Liao[3], Le Jiang[3], Yvonne-Marie Linton[4], John P. Grieco[1], Nicole L. Achee[1]

[1]Department of Biological Sciences, Eck Institute for Global Health, University of Notre Dame du Lac, Notre Dame, IN, United States, [2]Belize Vector and Ecology Center, Orange Walk Town, Belize, [3]Naval Medical Research Center, Diagnostics and Surveillance Department, Silver Spring, MD, United States, [4]The Walter Reed Biosystematics Unit, Smithsonian Institution, Suitland, MD, United States

The past decades have seen a dramatic increase of emerging and/or re-emerging infectious diseases worldwide, and more outbreaks will be foreseen in the future. Yet, proactive surveillance is still limited by the lack of expertise and capacity to provide reliable data in an actionable time frame across at-risk locations. The Remote Emerging Disease Intelligence-NETwork (REDI-NET) project was launched to enhance current surveillance efforts to detect, predict and contain potential emerging infectious disease threats in an efficient and timely manner. Specifically, consortium partners have established a complete set of robust standard operating procedures, including those for standardized field sample collection, storage and metagenomic next-generation sequencing (mNGS) to capture a broad spectrum of pathogens circulating in Kenya, Belize and Florida. In Belize, active surveillance was performed monthly from ten routine sampling sites within four of the six political districts, including Corozal, Orange Walk, Stann Creek and Toledo District, during November 2021 to March 2022. Field collections involved capturing four sample types including water, sediment, leeches and ticks to serve as sentinels for pathogens existing in water bodies (environmental biosurveillance) and/or blood meals of hematophagous invertebrates (invertebrate xenosurveillance). Here we report on viral and non-viral (e.g., bacterial, parasitic) pathogens detected using mNGS based on MinION/GridION sequencers (Oxford Nanopore Technologies) demonstrating the success of remote field and laboratory data acquisition by the REDI-NET program to validate an operational framework for reliable risk estimates on emerging pathogens.

0085

PERCEPTIONS AND LEVELS OF COMPLIANCE WITH ANTI-COVID-19 MEASURES IN SOUTHERN RURAL MOZAMBIQUE: THE CASE OF CONFINEMENT, SOCIAL DISTANCING, FREQUENT HAND WASHING, AND FACE MASK WEARING IN THE DISTRICT OF MANHICA

Ariel Quingue Nhacolo, Amilcar Magaco, Felizarda Amosse, Aura Hunguana, Teodomiro Matsena, Arsenio Nhacolo, Quique Bassat, Charfudin Sacoor, Inacio Mandomando, Khatia Munguambe

Manhica Health Research Center, Manhica, Mozambique

This study assesses community perceptions and implementation of the measures recommended by the government of Mozambique to prevent COVID-19 in rural areas of southern Mozambique, taking immobility, quarantine, social distancing, frequent hand washing, and mask wearing as the key practices to measure; using data from a cross-sectional household survey that was conducted in the district of Manhica in 2020.

A total of 768 heads of households were interviewed - of which 98% said that they had heard of coronavirus, but this percentage drops to 92% when asked about COVID-19, which suggests that this disease was better known as coronavirus than COVID-19. Sixty-three (63.0%) of households did not have devices for hand washing or disinfection, and of those who had devices, 68.8% had no water and 68.8% had no soap in these devices. Almost all households (98.9%) had masks, but the ratio of masks per household member aged 6+ years) was only 1.0. Of those who said they had heard of coronavirus, 44.4% defined it fairly, but 45.1% said did not know how to define it. Perception of concepts - 37.0% of the respondents defined quarantine well, 29.2% said quarantine was staying at home, and 31.5% said did not know. Thirty-seven (37.0%) defined correctly social distancing, but 32.0% gave inconclusive answers such as "stay away from others". Immobility - 37.8% defined it fairly, but 40.9% said it was just staying at home, and 18% said did not know. The question "what do you mean by avoiding crowded places" gave the following responses: avoiding places with 10+ people (10.7%), with 20+ people (10.2%), with 50+ people (9.1%), don't know (8.5%), other definitions (39.8%). Participant's self-assessment of his/her degree of compliance with anti-Covid measures (on a scale of 0%, 25%, 50%, 75% and 100%) - 39.8% said cannot stay at home, 54.2% avoid travelling at 100%, 50% wear masks in crowded places at 100%. There is a need to react to these findings by increasing efforts to disseminate information and raise awareness at community level to improve compliance with the COVID-19 prevention measures.

0086

INSECT REPELLANT OR INSECTICIDE? EFFICACY, SAFETY, AND TOXICITY

James H. Diaz

Louisiana State University Health Sciences Center, New Orleans, LA, United States

Insect repellants are chemical or organic agents that discourage insect contact by creating toxic atmospheres above applied skin to discourage insect bites and arthropod-borne infectious disease transmission. Unlike repellants, insecticides are chemicals that kill insects on contact. A convenience sample survey queried Internet search engines to identify case reports and series, entomological investigations, and toxicological studies on chemical and plant-based insecticides and repellants to determine their efficacy, safety, and toxicity. Citronella, IR3535, permethrin-treated clothing, and oil of lemon eucalyptus (p-menthane-3, 8-diol, or PMD) do not provide acceptable coverage over a broad enough range of insects. Picaridin is an effective alternative for N-diethyl-3-methylbenzamide (formerly N, N-diethyl-m-toluamide, or DEET). Unlike DEET, picaridin offers effective insect protection without toxicities in children and during pregnancy and does not damage plastics or clothing. Mite infections, including scabies, are best treated with topical or oral invermectin, an antiparasitic, rather than topical permethrin, an insecticide. Lice infections require physical removal of viable nits and treatment with oral or topical ivermectin rather than topical treatment with insecticides, such as lindane, malathion, or permethrin. Permethrin-impregnated clothing does provide contact-level insecticidal effects and offers better and longer duration protection against encephalitis and malaria-transmitting mosquitoes than topical DEET or picaridin alone. In special cases, where environmental exposures to disease-transmitting trombiculid mites, biting midges, sandflies, or blackflies occur, topical insect repellents containing IR3535, picaridin, or PMD offer better topical protection than DEET alone. Combinations of permethrin-impregnated clothing and either topical DEET or picaridin are recommended for the best protection from mosquitoes and ticks. Topical and oral ivermectin preparations are recommended over lindane and malathion for treating lice and mite infections, including scabies.

CLOSE ENCOUNTERS OF THE ENVENOMATING KIND: MISSIONARIES, INSECTS, AND THE SCRAMBLE FOR AFRICA, 1885 - 1914

David Adams[1], Michael Kent[2]

[1]National University of Ireland-Galway, Galway, Ireland, [2]Point University-Savannah, Savannah, GA, United States

Close Encounters of the Envenomating Kind: Missionaries, Insects, and the Scramble for Africa, 1885 – 1914 Encounters with envenomating insects of all kinds were, and remain, common in sub-Saharan regions throughout Africa. As Europeans, whether secular, military, or religious, pushed more deeply into these areas, these meetings grew increasingly likely. Missionaries who worked for the Church Missionary Society (CMS), an evangelical Anglican organisation founded in 1804, provide an excellent case in point. They provide vivid, sometimes humorous, and sometimes tragic, encounters with arthropods from ants to spiders. Naïve newcomers, blissfully ignorant of hazards that might await them in the bush, faced particular risk. Relying on published and archival contemporary accounts by CMS missionaries during the late 19th century Scramble for Africa, this presentation will highlight encounters, both comical and tragic, with envenomating insects in sub-Saharan Africa.

MOLECULAR DETECTION OF CRIMEAN-CONGO HAEMORRHAGIC FEVER VIRUS IN ARTHROPOD VECTORS AND SEROLOGICAL EVIDENCE IN PASTORALISTS' LIVESTOCK IN NORTH CENTRAL NIGERIA

Olanrewaju Eyitayo Igah[1], Chinonyerem Chinyere[1], Ismaila Shittu[1], Clement A. Meseko[1], Ndudim I. Ogo[1], Audu J. Natala[2], Junaidu Kabir[2]

[1]National Veterinary Research Institute, Jos, Nigeria, [2]Ahmadu Bello University, Zaria, Nigeria

Crimean - Congo haemorrhagic fever virus (CCHFV) is a tick-borne viral haemorrhagic disease that is highly pathogenic in humans with enzootic cycle between tick vectors and animal hosts. Human infection with CCHFV takes the clinical form of viral haemorhagic disease, a major health condition but with limited testing in Nigeria. This is the only recent work done since 1970 when it was first conducted to detect the circulation of the virus in ticks in Northern Nigeria and the role they play in the distribution of the virus. In this study, blood samples were collected from 333 pastoralists' cattle in North Central Nigeria and 1,470 ticks were picked from the animals. For serology, Enzyme Linked Immuno Sorbent Assay was performed using a double antigen multi species ELISA kit with sensitivity and specificity of 98.9% and 95% respectively both at 95% confidence interval to detect IgG antibody to CCHFV in plasma while RT-qPCR virological technique was used to identify viral antigen in ticks that were pooled based on location and genus followed by homogenization and RNA extraction from each tick pool. Four species of ticks were morphologically identified to parasitize cattle in the sampled location namely; *Boophilus decoloratus* (34.6%), *Hyalomma truncatum* (32.9%), *Amblyomma variegatum* (24.6%) and *Rhipicephalus sanguineus* (8%). Of the 41 pools of tick tested for CCHF, one (1) pool of 35 *Boophilus* ticks (2.4%) was positive for CCHF virus with qPCR cycle threshold of 33.3%. The seroprevalence of CCHFV was found to be 67%. In Kaduna state, 85 of 108 samples tested positive (78.7%) while in Plateau state 138 of 225 samples tested positive (61.3%). Although *Hyalomma spp*. is documented to be the main vector of CCHFV, in the present investigation, *Boophilus* species was identified to play a role as reservoir of CCHF. The high seroprevalence of CCHF in livestock underscores the public health risk associated with CCHFV at the human-animal interface in Nigeria.

0089

BACTERIAL PRODUCTS FROM MOSQUITO MIDGUT MICROBIOTA NEGATIVELY IMPACT PREVALENCE AND INFECTION INTENSITY OF *PLASMODIUM FALCIPARUM* IN *ANOPHELES GAMBIAE*

Esinam Abla Akorli[1], Jewelna Akorli[1], Lisa Ranford-Cartwright[2]

[1]Noguchi Memorial Institute for Medical Research, Legon, Ghana, [2]University of Glasgow, Glasgow, United Kingdom

Novel mosquito-borne disease control ideas include the use of bacterial symbionts to reduce transmission. Bacteria belonging to the family Enterobacteriaceae have shown promise in limiting *Plasmodium* intensity in the *Anopheles* vector. However, it remains unclear whether the interaction between bacteria and parasite is a direct cell-to-cell or indirect through secreted products. This study aimed at determining if naturally-occurring bacteria release substances that can disrupt mosquito stages of *P. falciparum* development. *Enterobacter cloacae* and *Serratia marcescens* bacterial species were isolated from field-caught *Anopheles gambiae* mosquitoes in Ghana. Media from liquid cultures of these bacteria were filtered, lyophilized and dissolved in sterile phosphate buffered saline (PBS). Their impact on the prevalence and intensity of infection with *Plasmodium falciparum* in the mosquito was assessed by introducing these bacterial products in a blood meal containing gametocytes grown *in vitro*, and feeding via membrane feeders to *An. gambiae* mosquitoes. Mosquitoes were dissected 10-11 days post-infection and oocysts were counted. Mosquitoes fed an infectious blood meal containing *S. marcescens* product had a significantly reduced prevalence of *P. falciparum* infection (P=0.00119) and infection intensity (P=7.85 x10^{-12}) compared to the control with lyophilized LB medium added. The addition of products from *E. cloacae* cultures however had no significant effect on prevalence of infection (P=0.306) or infection intensity (P=0.152). These products released by symbiotic bacteria can be used as potential transmission blocking agents to reduce the burden of malaria.

0090

ECO BIOTRAPS - AN INNOVATIVE ADJUNCT VECTOR CONTROL GREEN DEVICE FOR INTEGRATED VECTOR MANAGEMENT

Susanta K. Ghosh[1], Nitin Khope[2], Prasad Phadke[2]

[1]National Institute of Malaria Research, Bangalore, India, [2]Ecobio Consulting Private Limited, Ahmedabad, India

Vector-borne diseases are endemic in more than 100 countries and affect approximately half of the world's population. Mosquitoes are the deadliest animal in the world killing 1 million people annually. Malaria, Dengue, Chikungunya, Lymphatic Filariasis, Zika, Japanese Encephalitis, Yellow Fever are all transmitted by several species of mosquitoes. The existing methods of vector control need innovation. Eco Biotrap is one such tool that can be integrated under the integrated vector management. Eco Biotraps are inexpensive, just-add-water, biodegradable, easy to deploy in rural and urban settings that have been shown to be an mosquitocidal and larvicidal device.When filled with water, the Biotraps mimics the breeding sites of female mosquitoes, and once a mosquito approaches to lay eggs, a WHO approved mosquito insecticide embedded inside, ensures a 100% eggs do not turn into adults, thereby eliminating breeding.Eco Biotraps are easy to use, convenient to deploy, 100% biodegradable after 4-6 weeks with no recollection needed, affordable and the insecticide does not come in direct human contact. In addition, Eco Biotraps can be deployed very easily without training, so that a coordinated response could involve local stakeholders. We believe that Eco Biotraps would be an effective adjunct vector control device along with other vector control methods like long lasting insecticide treated nets (LLINs), and also indoor residual sprays (IRS) for control and elimination of mosquito borne diseases. Each Eco Biotrap holds 2-liter water and can be placed at different places in and around households and in neighborhoods. Preliminary studies indicated >95% larvae are eliminated using the traps. Details can be assessed at www.ecobiotraps.com.

0091

CDC BOTTLE BIOASSAY ASSESSING THE PATTERN OF THE INSECTICIDE SUSCEPTIBILITY OF *PHLEBOTOMUS ARGENTIPES* IN SRI LANKA

Dulani R. K. Pathirage[1], Sanath C. Senanayake[2], B.G.D. Nissanka K. de Silva[3], Nadira D. Karunaweera[2]

[1]Faculty of Medicine , University of Colombo, Colombo, Sri Lanka, [2]Faculty of Medicine , Colombo, Colombo, Sri Lanka, [3]Faculty of Applied Sciences, University of Jayewardenepura, Nugegoda, Sri Lanka

Phlebotomus argentipes is the incriminated vector of *Leishmania donovani,* the causative organism of leishmaniasis. A proper understanding of the insecticide susceptibility pattern in the vector isimportant prior to planning and implementing a successful vector control program. Thus, the present study was conducted to assess the insecticide susceptibility levels of sand fly vectors in Sri Lanka. *P. argentipes* flies originated from those in the wild and were reared at the insectary of the Department of Parasitology, Faculty of Medicine, Colombo was exposed to malathion (0.005, 0.0075, 0.01, 0.05 µgml-1), propoxur (0.0125, 0.006875, 0.125 µgml-1) and lambdacyhalothrin (12.5 and 1.25 µgml-1) insecticides using standard guidelines of CDC bottle bioassay established for mosquitoes. Dead flies were counted every 2 minutes until all perished. Each concentration of insecticides was tested with four replicates. The total percentage mortality (Y-axis) against time (X-axis) was plotted in a graph with all replicates considered together using a linear scale. The results were validated with the control mortalities using Abbott's formula. Levels of resistance were calculated according to the WHO set standards. Resistant values obtained for the tested sandfly populations, were below 0.006875µgml-1 (25% mortality), 0.005µgml-1 (30% mortality) and 1.25µgml-1 (66% mortality) respectively for propoxur, malathion and lambdacyhalothrin. Overall, the Sri Lankan populations of *P. argentipes* can be considered susceptible to the tested insecticides, when compared to the discriminating dosages specified for either anopheline or aedine mosquitoes. However, the observed level of 80% mortality of flies when exposed to 0.0075µgml-1 of malathion suggests the possibility of resistance that needs to be confirmed with further experiments. Research is continuing to test further diagnostic dosages and study genetic markers such as kdr mutations associated with insecticide resistance in *P. argentipes* in Sri Lanka.

0092

METAGENOMIC STUDY OF BLOOD-MEAL HOSTS AND PARASITES OF TSETSE FLY IN TANZANIA

Ju Yeong Kim, Tai-Soon Yong

Department of Environmental Medical Biology, Institute of Tropical Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

Tsetse flies can transmit *Trypanosoma* spp. that cause trypanosomiasis in humans, wild animals, and domestic animals. Amplicon deep sequencing of the 12S rRNA gene can be used to detect mammalian tsetse hosts and the 18S rRNA gene can be used to screen eukaryotic pathogens, including *Trypanosoma* spp. Tsetse flies were collected from the Serengeti National Park (n=48), Maswa Game Reserve (n=42), and Tarangire National Park (n=49) in Tanzania. Amplicon deep sequencing targeting mammal-specific 12S rRNA and 18S rRNA genes was performed to screen the blood-feeding hosts of tsetse flies and eukaryotic parasites in tsetse flies, respectively. Various mammals were found to be blood feeding hosts of the tsetse flies, including humans, common warthogs, African buffalos, mice, giraffes, African elephants, waterbucks, and lions. African buffaloes were detected more frequently as a blood-feeding source (P=0.0010) in Serengeti. 18S rRNA gene deep sequencing showed that six tsetse samples harbored the *Trypanosoma* gene, which was identified as *T. godfreyi* and *T. simiae* in subsequent ITS1 gene sequencing. This study may provide essential data for formulating better strategies to control African trypanosomiasis.

0093

COMMUNITY-LED SKIN SURVEILLANCE TO ASSESS AND COMBAT THE BURDEN OF SKIN INFECTIONS SUCH AS SCABIES IN REMOTE AUSTRALIAN ABORIGINAL COMMUNITIES

Hannah Mary Milroy Thomas, Rebecca Famlonga, Abbey Ford, Asha Bowen

Telethon Kids Institute, Nedlands, Australia

Reducing the burden of scabies is important to improve health and wellbeing for Australian Aboriginal children living in remote communities. Scabies infections are intensely itchy, and scratching can lead to secondary bacterial infections such as impetigo which in turn contribute to chronic diseases, including Rheumatic Heart Disease. We have been using school-based surveillance to assess the burden of skin infections such as scabies in nine remote Australian Aboriginal communities. Research like ours, and downstream service provision to tackle this burden, often relies on extensive travel by clinicians and researchers. This is time consuming, expensive, and frequent fly-in visitors may not always be in the best interests of a remote community (as has been the case during the COVID-19 pandemic). Therefore, in 2022 we are implementing and evaluating a co-designed virtual skin surveillance methodology with a focus on local capacity building and empowerment. In partnership with communities and schools, this program offers training opportunities for community-based individuals to conduct skin surveillance with virtual support from an experienced skin health researcher. Implementation concurrently with 'old way' (travel-reliant) surveillance in 2022 allows us to assess the comparative sensitivity of this approach, and extensive yarning with community members allows us to explore and learn from the experiences of those who participate, privileging community voices in our evaluation of this new approach to skin health research. If found to be effective and acceptable, this work will be translated to inform the development of a culturally sensitive remote schools training package, with the aim of empowering individuals to deliver genuinely community-led approaches to recognising and combatting the burden of skin infections such as scabies.

0094

RETROSPECTIVE AND LESSONS LEARNED FROM THE CONSTRUCTION AND COMMISSIONING OF AN ACL-3 INSECTARY

Erin Lauer[1], Amanda D. Rice[2], Robert A. Dettmann[1], Adam E.J. Fleming[1], David R. Gillum[2], Kelly N. Kim[1], Irene A. Mendoza[2], Gregory L. Powell[2], Giorgio Scarpellini[2], Rocco Casagrande[1]

[1]Gryphon Scientific, Takoma Park, MD, United States, [2]Arizona State University, Tempe, AZ, United States

Arthropods are vectors for many pathogens that significantly harm human and animal health globally, and research into vector-borne diseases is critical work of public health importance. The size, mobility, and life cycle of arthropods present unique risks for containment, and so, insectary laboratories are essential to the safe handling of arthropod-borne hazards. In 2018, the School of Life Sciences at Arizona State University (ASU) recognized the need for an insectary to support their expanding research mission and began the process to deliver a Level 3 arthropod containment (ACL-3) facility to investigators. Four years later, the insectary has yet to be commissioned. At the request of the ASU Environmental Health and Safety team (EHS), Gryphon Scientific, an independent team with biosafety and biological research expertise, studied the project lifecycle through the design, construction, and commissioning of the ACL-3 facility with the goal of identifying lessons learned from the delayed timeline. We interviewed involved personnel to glean in-depth insight from all perspectives. Here, we propose to present the synthesized findings that could benefit the biosafety of future insectary laboratories. The major themes include: the operational implementation of ACL requirements; gaps in available resources; prioritizing expertise over cost-savings; early involvement of safety personnel; and communication needs of a stratified team. The available guidance on construction of ACL laboratories was found not to be specific enough to address some risks inherent in the research, so several mitigations were designed by the ASU team that addressed the residual risk. These mitigations, which should be considered for wider implementation in ACL-3 facilities elsewhere, will be discussed. Completion of the ACL-3 insectary at ASU was delayed, but the team thoroughly assessed potential risks and enabled appropriate practices for the safe handling of arthropod vectors. By promoting these lessons learned, we hope to bolster the biosafety of forthcoming insectaries and to offer helpful guidance to EHS teams undertaking their construction.

THE TICK CELL BIOBANK: TICK AND INSECT CELL LINES FOR STUDY OF TROPICAL DISEASE AGENTS AND VECTOR CONTROL

Lesley Bell-Sakyi[1], Jing Jing Khoo[1], Catherine Hartley[1], Low Van Lun[2], Alistair Darby[1], **Ben Makepeace**[1]

[1]University of Liverpool, Liverpool, United Kingdom, [2]University of Malaya, Kuala Lumpur, Malaysia

Blood-feeding arthropods transmit numerous viral, bacterial, protozoan and helminth disease-causing agents, as well as causing irritation or direct damage to their vertebrate hosts. Arthropod cell lines are valuable tools for research on disease and vector control. The Tick Cell Biobank (TCB) is the world's only dedicated culture collection for generation, storage and distribution of cell lines derived from ticks and blood-feeding insects, and provision of training in arthropod cell line maintenance and application. The TCB hosts 70 cell lines derived from ixodid and argasid ticks (including tropical vector species of the genera *Amblyomma*, *Dermacentor*, *Hyalomma*, *Rhipicephalus* and *Ornithodoros)* and a growing panel of cell lines derived from mosquitoes (*Culex* and *Aedes*), biting midges (*Culicoides*), sand flies (*Lutzomyia* and *Phlebotomus*), triatomine bugs (*Rhodnius* and *Triatoma*) and tsetse flies (*Glossina*). TCB Outposts in Malaysia, Kenya and Brazil are facilitating uptake of arthropod cell line technologies in Asia, Africa and South America. Research in the TCB focuses on genotypic and phenotypic characterisation of selected tick and insect cell lines and determining their susceptibility to, and interaction with, a range of intracellular bacterial pathogens and symbionts including species and strains of *Anaplasma*, *Ehrlichia*, *Rickettsia*, *Spiroplasma* and *Wolbachia*. Recent in-house and collaborative research highlights include establishment of a *Phlebotomus papatasi* cell line naturally infected with *Wolbachia;* isolation in tick cells of *Wolbachia* from Malaysian cat fleas; and detection of short virus-derived DNA forms of the RNA orthonairovirus, Crimean-Congo hemorrhagic fever virus, that appear to play a role in maintenance of persistent infection in tick cells.

COMPARISON OF DIFFERENT MOSQUITO TRAPS FOR ZOONOTIC ARBOVIRUS VECTORS IN PAPUA NEW GUINEA

Joelyn Goi[1], Melanie Koinari[2], Muker Sakur[1], Rebecca Vinit[1], William Pomat[1], David Williams[3], Stephan Karl[2]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Australian Institute of Tropical Health and Medicine, James Cook University, QLD, Australia, [3]CSIRO, Australian Centre for Disease Preparedness, Geelong, Victoria, Australia

Little is known about zoonotic arboviruses and their vectors in Papua New Guinea (PNG). Vector surveillance is important to control mosquito-borne diseases. Incrimination and surveillance of zoonotic arbovirus vectors is important for the control of important diseases such as Japanese Encephalitis. In the present study, we compared the efficacies of three types of mosquito-trapping devices BG-Sentinel traps (BGS), CDC light traps with incandescent light (CDC_I) and CDC light traps with UV light (CDC_UV) to determine their suitability and cost-effective surveillance tool of key vectors of neglected zoonotic arboviral diseases in PNG. The study was conducted in various commercial chicken and pig farms in Central and Morobe provinces of PNG. All traps were used without lures.

Traps were placed outside animal houses for two periods of 5 consecutive days. The captured mosquitoes were identified by species, counted and species-specific capture rates were compared among trap types. A total of 13,788 mosquitoes were caught, including vectors belonging to the genera *Aedes, Anopheles and Culex*. Mosquito species captured included *Ae albopictus, Ae. aegypti, An. bancrofit, An. farauti, An. koliensis, An. longirostris, An. punctulatus, Cx annulirostris, Cx. gelidus, Cx. quinquefasciatus and Cx. Sitiens*. Of 13,788 mosquitoes, CDC_I trap caught 7.9%, BGS caught 14.5% and CDC_UV caught 77.6%. Median trapping rates showed significant difference among traps and ranging from species and farms. Culex was the most predominant genus caught in all the traps. BGS caught significantly more *Culex quinquefasciatus* than the two other two traps. CDC_UV captured the highest abundance, highest species richness and exhibited the highest overall *Culex* mosquito capture rates compared to BGS and CDC_I. This study represents the first assessment of mosquito trapping devices for zoonotic arbovirus vectors in PNG livestock farms. We recommend CDC_UV traps for future research and programmatic monitoring and surveillance of infectious arboviral vector programs in PNG.

ENTOMOLOGICAL AND EPIDEMIOLOGICAL FACTORS OF VISCERAL AND CUTANEOUS LEISHMANIASIS OUTBREAK IN KAJIADO WEST, KENYA

Damaris Matoke-Muhia[1], Barrack O. Omondi[2], Steve Kiplagat[2], Johnstone Ingonga[1], Mwatela Kitondo[3], Hellen Nyakundi[3], Jandouwe Villinger[2], Richard Wamai[4], Daniel K. Masiga[2]

[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, [3]African Centre for Community Investments in Health, Baringo County, Kenya, [4]Northeastern University, Boston, MA, United States

The Kajiado-West sub-county in Kenya, recently emerged as a new focus for visceral (VL) and cutaneous leishmaniasis (CL). We investigated entomological and epidemiological factors contributing to VL and CL occurrence to establish transmission hotspots and inform control strategies. We conducted a cross-sectional survey in four villages: Esonorua, Oldonyo Nyokie, Musenke and Shompole. Suspected VL and CL cases were screened using rK39 and microscopy. We did *Leishmania* parasite speciation by ITS1 PCR and sequencing. The entomological survey was conducted in November 2021 and February 2022 using CDC and Lumin-8 light traps. Regional taxonomic keys and *COX1* PCR were used for sandfly identification. 100 cases (males 56, females 44) were examined for VL infections. Overall, VL seroprevalence in the sub-county was 10%; the highest and lowest seroprevalences occurred in Esonorua (5%; n=5) and Shompole (1%; n= 1), respectively. 80% (n=8) of the VL patients were <15 years, with more infections in males (75%; n=6) than females (25%; n=2). There was no significant association between age group or gender and VL seropositivity. The overall CL prevalence in the sub-county was 36.4% (8/22), *L. tropica* was identified as the causative agent. We sampled 4,781 sandflies and identified 1,627 comprising four *Phlebotomus* spp. and eight *Sergentomyia* spp. The *Phlebotomus* spp. included *Ph. martini* (8.4%; n=136), *Ph. saevus* (2.3%; n= 38), *Ph. orientalis* (1.2%; n= 19), and *Ph. guggisbergi* (0.1%; n=1). We detected *L. tropica* DNA in *S. clydei* (n=3) and *Ph. saevus* (n= 1) while *L. donovani* was detected exclusively in *S. clydei* (n= 18). Overall, *L. donovani* and *L. tropica* infection rates in sandflies were 4% (18/450) and 0.7% (3/450), respectively. In conclusion, *L. donovani* and *L. tropica* are the main *Leishmania* spp circulating in the sub-county. Their presence in humans and sandflies indicates continuous transmission of the disease. *L. tropica* and *L. donovani* detection in *S. clydei* implicate the sandfly as a vector, however, requires further investigation. Factors behind the recent outbreak after long dormancy remain to be explored.

0098

AN UNUSUAL CASE OF HOME INFESTATION AND ALLERGIC REACTIONS ASSOCIATED WITH *ORNITHODOROS* SP. (IXODIDA: ARGASIDAE) IN COSTA RICA

Adriana Troyo[1], Jacqueline Camacho-Leandro[1], Esteban Brenes-Céspedes[2], Diana Rojas-Araya[1], Ólger Calderón-Arguedas[1]

[1]Laboratorio de Investigación en Vectores (LIVE), Centro de Investigación en Enfermedades Tropicales (CIET), Facultad de Microbiología, Universidad de Costa Rica, San José, Costa Rica, [2]Pest Control Division, BMF Soluciones, Heredia, Costa Rica

Infestation of homes with *Ornithodoros* spp. (Ixodida: Argasidae) and human biting depends on the particular species as well as nesting behavior and availability of hosts. Some species transmit pathogens like *Borrelia* spp. that cause tick-borne relapsing fever, and bites can cause toxicosis. Currently, there are only two such reports in Costa Rica: one includes two incidents associated with *O. kelleyi* (1979 and 1980), and the other cites a case by *Ornithodoros* sp. without dates. In February 2022, an infestation by argasid ticks was reported in a two-story mountain home in Heredia, Costa Rica. The owners, who visit occasionally, had been experiencing bites and allergic reactions for several months, including localized inflammation at the site, but also swelling, rashes, and itching in other parts of the body. They were treated with antihistamines. At the house, biting was concentrated in one room (second floor), where ticks were later found. There was no sign of recent animal activity, although pest control treatments were applied in the past 2 years for rodents, bats, and arthropods. Adults and nymphs (>60) were collected, as well as larvae (from aspirated material). Larvae were mounted in Hoyer's medium and identified as *O. kelleyi* according to taxonomic keys. However, larvae were smaller (body and scutum length= 0.8-0.86 and 0.305-0.325 mm, respectively, vs. 0.95-1.04 and 0.331-0.357 mm for *O. kelleyi*) and the apical 3/3 dentition comprised ~60% of the hypostome (distal third in *O. kelleyi*), with 8-9 denticles in the inner row (5-8 in *O. kelleyi*). Reports of bats and *O. kelleyi* in houses are not uncommon in North America, while human-biting seems less frequent. Interestingly, the only report of *O. kelleyi* south of Mexico is the one from Costa Rica, although *Ornithodoros puertoricensis, O. rudis*, and *O. talaje* are also known to bite humans in Central America. Given that these ticks may pose a risk to human health and that information on *Ornithodoros* spp. in Central America is scarce, further morphological and molecular analyses are being conducted to confirm the identity of the species associated with this case, as well as the main vertebrate host involved.

ECO-FRIENDLY ALTERNATIVE MALARIA CONTROL STRATEGIES: INSECTICIDAL ACTIVITY OF *AEOLLANTHUS PUBESCENS* LEAF ESSENTIAL OIL AGAINST *ANOPHELES GAMBIAE*

Oswald Yedjinnavenan Djihinto[1], Roméo B. Bohounton[1], Luc S. Djogbénou[1], Oronce S-L Dedome[2], Pierre M. Sovegnon[1], Bruno Barea[3], Aristide Adomou[4], Pierre Villeneuve[3], Fidèle P. Tchobo[2]

[1]Tropical Infectious Diseases Research Centre (TIDRC), University of Abomey-Calavi, Cotonou, Benin, [2]Laboratory of Study and Research of Applied Chemistry, Polytechnic School of AbomeyCalavi, Cotonou, Benin, [3]CIRADPERSYST-UMR IATE, Montpellier, France, [4]Laboratoire de Botanique Et Écologie Végétale (LaBEV), University of Abomey-Calavi, Cotonou, Benin

The excessive use of synthetic insecticides is responsible for many cases of resistance in insects. Therefore, the use of natural molecules of ecological interest with insecticidal properties turns out to be an alternative approach to the use of synthetic insecticides. This study aims at investigating the larvicidal, adulticidal activity and the chemical composition of the essential oil of *Aeollanthus pubescens* on the major malaria vector, *Anopheles gambiae*. Three reference strains of *Anopheles gambiae* sensu stricto (Kisumu, Kiskdr and Acerkis) were used in this study. The leaves of *A. pubescens* were collected in southern Benin. The standard WHO guidelines for larvicide evaluation were used and the chemical composition of

the essential oil was analysed by gas chromatography coupled to mass spectrometry. Adult mosquitoes were exposed to the net pieces coated with the essential oil for 3 min using the WHO cone bioassay method. Probit regression analysis was used to determine lethal concentrations (LC_{50}) and time to knockdown (KDT_{50}). The Log-rank test was performed to evaluate the difference in survival between the strains. Fourteen (14) components were identified representing 98.3% of the total of oil content. The major components were carvacrol (51.1%), thymyle acetate (14.0%) and ɣ-terpinene (10.6%). The essential oil has shown larvicidal properties with LC_{50} of 29.6, 22.9, and 28.4 ppm respectively on Kisumu, Acerkis and Kiskdr strains. With the net pieces treated at 165 µg/cm^2, the KDT_{50} of both Acerkis (1.71 s, Z =3.34, $p < 0.001$) and Kiskdr (2.67 s, Z =3.49, $p < 0.001$) individuals were significantly lower than that of Kisumu (3.8 s). The lifespan of the three mosquito strains decreased respectively to 1 day for Kisumu ($\chi2 = 99$, df = 1, $p < 0.001$), 2 days for Acerkis ($\chi2 = 117$, df = 1, $p < 0.001$) and 3 days for Kiskdr ($\chi2 = 96.9$, df = 1, $p < 0.001$). Our findings show that the *A. pubescens* essential oil has a larvicide and adulticide properties against the malaria vector *An. gambiae* s.s. This bio-insecticidal activity may be a promising discovery for the control of the resistant malaria-transmitting vectors.

A FIELD BIOASSAY FOR ASSESSING IVERMECTIN BIO-EFFICACY IN MALARIA VECTORS

Kelly Ominde[1], Yvonne Kamau[2], Jonathan Karisa[2], Martha Muturi[2], Mercy Tuwei[1], Zedekiah Ondieki[2], Joseph Mwangangi[2], Caroline Kiuru[3], Caroline Wanjiku[2], Lawrence Babu[2], Carlos Chaccour[3], Marta Maia[4]

[1]KEMRI Wellcome Trust Research Programme and Pwani University, Kilifi, Kenya, [2]KEMRI Wellcome Trust Research Programme, Kilifi, Kenya, [3]IS Global, Barcelona, Spain, [4]KEMRI Wellcome Trust Research Programme, Kilifi, Kenya and University of Oxford, Centre for Global Health and Tropical Medicine, Nuffield Department of Medicine, Oxford, United Kingdom

Ivermectin (IVM) mass drug administration is currently under evaluation as a complementary malaria vector control tool. Mosquitoes ingesting blood from treated hosts suffer reduction in survival. Estimating bio-efficacy of IVM on wild-caught mosquitoes requires they ingest IVM in a bloodmeal either through a membrane or direct-feeding on a treated host. The latter, has ethical implications, the former results in very low feeding rates. Therefore, there is need to develop a safe and effective method for monitoring IVM bio-efficacy in wild mosquitoes. Our study exposed insectary-reared *Anopheles gambiae s.s* to five IVM doses: 85, 64, 43, 21, 11 and 0 ng/ml (control) in three different types of solutions: i) blood, ii) 10% glucose, and iii) blood in 10% glucose mixture in four ratios: 1:1, 1:2, 1:4, and 1:8 fed through a filter paper. Following treatments, mosquito survival was monitored for 28-days. Shortly after ingesting the meal, a pool of mosquitoes was sacrificed and weighed to determine mean weights of each meal type. Regardless of solution used, higher IVM doses resulted in significant reduction in survival. However, mortality rates for each IVM dose differed by solution. IVM was most lethal in a bloodmeal and least lethal in sugar solution, and when administered in sugar-blood mixture resulted in effects closer to bloodmeal. Larger blood meals was ingested compared to sugar or sugar-blood mixtures. However, meal sizes of mosquitoes fed on sugar and sugar-blood mixtures were similar despite pronounced difference in mortality rates. Ivermectin bio-efficacy differs depending on meal type used to deliver the drug. Meal volumes do not explain differences in lethality of IVM when comparing different meal types, further research is needed to understand the underlying mechanism. None of the solvents tested here performed better than blood but 1:4 sugar-blood mixture was comparable to blood. Given that the assay is sugar feeding based and wild-caught readily sugar feed, the mixture, is a good candidate for field-based bio-efficacy monitoring. To ascertain utility in the field, the mixture is currently being tested on field-collected mosquitoes.

PHENOTYPIC, GENOTYPIC AND BIOCHEMICAL CHANGES DURING PYRETHROID RESISTANCE SELECTION IN *ANOPHELES GAMBIAE* MOSQUITOES

Maxwell G. Machani[1], Eric Ochomo[1], Daibin Zhong[2], Goufa Zhou[2], Xiaoming Wang[2], Andrew Githeko[1], Guiyun Yan[2], Yaw Afrane[3]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]University of California, Irvine, CA, United States, [3]University of Ghana, Ghana, Ghana

The directional selection for insecticide resistance due to indiscriminate use of insecticides in public health and agricultural system favors an increase in the frequency of insecticide-resistant alleles in the natural populations. Similarly, removal of selection pressure generally leads to decay in resistance. Past investigations on the emergence of insecticide resistance in mosquitoes mostly relied on field survey of resistance in vector populations that typically had a complex history of exposure to various public health and agricultural pest control insecticides in nature, and thus the effect of specific insecticides on rate of resistance emergence or resistance decay rate is not known. This study examined the phenotypic, genotypic, and biochemical changes that had occurred during the process of selection for pyrethroid resistance in *Anopheles gambiae*, the most important malaria vector in Africa. In parallel, we also examined these changes in resistant populations when there is no selection pressure applied. Through repeated deltamethrin selection in adult mosquitoes from a field population collected in western Kenya for 12 generations, we obtained three independent and highly pyrethroid-resistant *An. gambiae* populations. Three susceptible populations from the same parental population were generated by removing selection pressure. These two lines of mosquito populations differed significantly in monooxygenase and beta-esterase activities, but not in *Vgsc* gene mutation frequency, suggesting metabolic detoxification mechanism plays a major role in generating moderate-intensity resistance or high-intensity resistance. Pre-exposure to the synergist piperonyl butoxide restored the susceptibility to insecticide among the highly resistant mosquitoes, confirming the role of monooxygenases in pyrethroid resistance. The rate of resistance decay to become fully susceptible from moderate-intensity resistance took 15 generations, supporting at least 2-years interval is needed when the rotational use of insecticides with different modes of action is considered for resistance management.

INSECTICIDE RESISTANCE SURVEILLANCE OF MALARIA VECTORS IN PAPUA NEW GUINEA 2017 - 2022

Solomon Lagur[1], Michelle Katusele[1], Joelyn Goi[1], Muker Sakur[1], Lemen Kilepak[1], Samuel Demok[1], Stephen Gideon[2], Leo Makita[3], Petrina Johnson[4], Leanne Robinson[5], Moses Laman[2], Stephan Karl[4], Christine Pombreaw[1], Rebecca Vinit[1], Lincoln Timinao[1]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Papua New Guinea Institute of Medical Research, Port Moresby, Papua New Guinea, [3]National Department of Health, Port Moresby, Papua New Guinea, [4]Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia, [5]Burnet Institute, Melbourne, Australia

Anopheles farauti, An. koliensis and *An. punctulatus* are the 3 major malaria vectors in Papua New Guinea (PNG), and determining their distribution and susceptibility to insecticides is important for informing public health vector control strategies. Previous insecticide resistance (IR) data in 2018 reported these species to be susceptible to deltamethrin, lambdacyhalothrin and dichlorodiphenyltrichloroethane (DDT) across 4 provinces of PNG. This study presents an update of IR status of malaria vector populations in 9 provinces of PNG. IR monitoring was conducted between 2017 to 2022. Mosquitoes were collected as larvae from georeferenced natural habitats and reared to adults. 3-5 days old adults were tested against 4 insecticide classes (Carbamates, Organochlorines, Organophosphates, and Pyrethroids) using standard WHO tube bioassays to assess knockdown kinetics and 24-hour mortality. The samples

were then morphologically identified, and stored in ethanol for further laboratory analysis. A total of 12,972 female Anopheles mosquitoes were tested, controls included. All 3 species showed susceptibility to all 8 insecticides tested, except *An. koliensis*, which showed resistance to DDT, having 33.3% mortality, and lambdacyhalothrin, 83.3% mortality, in East Sepik province. Phenotypic resistance also shown in *An. punctulatus* population to DDT in Milne Bay, having 88.2% mortality, and lambdacyhalothrin in West Sepik, 87.5% mortality. Possible phenotypic resistance to DDT in the *An. farauti* population was also observed in Madang, Milne Bay and Western provinces (94.4-96.8% mortality), as well as to lambdacyhalothrin in the *An. punctulatus* population of East New Britain, East Sepik and Madang provinces (92.7-96.3% mortality). We now report evidence of phenotypic resistance in *An. koliensis* and *An. punctulatus* to DDT and lambdacyhalothrin in 3 provinces of PNG, as well as possible resistance in all 3 major Anopheles species to the same 2 insecticides, in several provinces. In particular, pyrethroid resistance is of concern given that the national malaria control program relies on pyrethroid treated long-lasting insecticidal nets.

RESULTS OF THE 2021 ANNUAL VECTOR CONTROL REPORT IN MAINLAND TANZANIA

Matt Worges[1], Hannah Koenker[2], Benjamin Kamala[3], Deo Mwingizi[3], David Dadi[3], Ato Selby[3], Dana Loll[4], Peter Gitanya[5], Charles Dismas Mwalimu[5], Frank Chacky[5], Naomi Serbantez[6], Ruth Msola[3], Josh Yukich[1]

[1]USAID Tanzania Vector Control Activity, Tropical Health, New Orleans, LA, United States, [2]USAID Tanzania Vector Control Activity, Tropical Health, Baltimore, MD, United States, [3]USAID Tanzania Vector Control Activity, Johns Hopkins University Center for Communication Programs, Dar es Salaam, United Republic of Tanzania, [4]USAID Tanzania Vector Control Activity, Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, [5]Tanzania National Malaria Control Program, Ministry of Health, Dar es Salaam, United Republic of Tanzania, [6]U.S. President's Malaria Initiative, USAID, Dar es Salaam, United Republic of Tanzania

Malaria is a leading cause of morbidity and mortality among children under 5 and pregnant women in Tanzania. The National Malaria Control Program (NMCP) must have readily available, digestible data to adjust their strategies and operations to maximize impact. The PMI-funded Tanzania Vector Control Activity (TVCA) worked with the NMCP to compile and synthesize the most current entomological, epidemiological, and other relevant data in addition to conducting an overview of the effectiveness of ongoing vector control interventions in mainland Tanzania. Council-level monthly malaria case data (confirmed positives) were pulled from the Tanzania DHIS2 from 2018 to 2021 and transformed to rates per 1,000 population. Slope equations from linear best fit lines and simple linear regression were used to determine if case data were steady, decreasing, or increasing. Nets per capita were derived from ITN distribution data and net decay rates, then converted to population ITN access at council level. Indoor residual spraying timing and insecticide resistance data were mined from reports covering 2011 to 2021. At the end of 2021, about one-third (n=62) of the councils had malaria incidence below 30 cases per 1,000 population, 16% were between 30 and 60, a quarter between 60 and 120 and another quarter above 120. Most councils (79 of 184; 42.9%) showed decreasing monthly malaria case incidence trends as well as at least 51-80% bed net population access with no evidence of insecticide resistance (even if driven by the overall lack of widespread resistance data). Even among the 39 mainland councils with evidence of pyrethroid resistance, ITN access was above 50% and malaria case incidence was either declining or holding steady in 36 (92.3%). A slight majority of councils fell into the 51-80% bed net access range and were noted as having a decreasing trend in monthly malaria case incidence (98 of 184; 53.3%). These results are being used to guide NMCP decision making for vector control activities including quantification of ITNs to be distributed.

0104

IVERMECTIN RESISTANCE MECHANISMS IN ECTOPARASITES: A SCOPING REVIEW

Joanna Furnival-Adams[1], Caroline Kiuru[1], Marta Maia[2], Carlos Chaccour[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]KEMRI Wellcome Trust Research Programme, Kilifi, Kenya

Mono-therapeutic ivermectin mass drug administration (MDA) has been used for many years to control both human and veterinary parasites. This approach has provoked concern regarding its potential to increase selection pressure and accelerate the development of resistance in target and non-target organisms. Although widespread ivermectin resistance has been observed in veterinary parasite populations, until now there have been few and contended reports of resistance in human parasites. With ivermectin MDA now being investigated for efficacy and safety as a malaria control tool, it is important to consider potential resistance mechanisms that may develop in ectoparasites such as headlice and bed bugs, that may also inform our predictions of resistance mechanisms in mosquitoes. The aim of this scoping review was to map existing knowledge of resistance mechanisms in these organisms and to attempt to predict potential resistance mechanisms to ivermectin that may develop in the future. We searched databases including MEDLINE, PubMed and Web of Science using relevant search terms, and included studies that describe a validated mechanism of resistance in ectoparasites. We conducted a quality assessment for each of the included studies and results were summarised in terms of organism, resistance mechanism, degree of resistance, geographic location, and where possible, gene target. Predicting mechanisms of ivermectin resistance in mosquitoes will facilitate the development of molecular assays and enable preparedness of monitoring and evaluation strategies.

0105

WIND TUNNEL STUDIES ON THE IMPACT OF INSECTICIDE TREATED MATERIALS (ITMS) ON *AEDES AEGYPTI* HOST LOCATION BEHAVIOR

Ashwaq Alnazawi[1], P. mccall[2], David Weetman[3]

[1]MoH, Jeddah, Saudi Arabia, [2]Liverpool school of Tropical Medicine, Liverpool, United Kingdom, [3]Liverpool school of tropical medicine, Liverpool, United Kingdom

Insecticide treated materials (ITMs) offer a simple yet effective method to reduce domestic infestations of disease vectors. However, their use against *Aedes aegypti* is complicated by the development of insecticide resistance. The study aimed to investigate whether resistant and susceptible *Ae. aegypti* strains exhibit behavioural differences during host-seeking at insecticide-treated netting and how they respond to host behind an ITM barrier containing holes.Two experimental assays were developed based on host seeking and final stage host feeding behaviours in three strains of *Ae. aegypti,* New Orleans (pyrethroid-susceptible), Jeddah and Makkah (pyrethroid-resistant). Individuals were exposed to Insecticide treated and untreated materials and their host feeding behaviour was assessed based on groups of 5 mosquitoes, attempting to reach and feed on human bait. Host seeking behaviour was assessed using a wind tunnel, with individuals flying upwind and allowed to pass through holed material. Behavioural events were recorded over 10 and 20 min respectively and logged manually. A significant reduction in time spent resting, probing or bouncing was seen with treated compared to untreated materials. However, no difference was observed between resistant and susceptible strains. After contact with treated nets, all strains of mosquito were seen to favour resting at a distance from the treated surface. In the wind tunnel, hole entry was seen to vary between mosquito strains, along with a significant reduction in the number of mosquitoes that passed through treated compared to untreated material (P<0.0005). This effect was significantly greater for the susceptible strain compared to the resistant strains(P<0.01) with this also being reflected in post-exposure knock-down and mortality.These results demonstrate how physiological resistance may

enable mosquitoes to more easily pass through holed treated materials due to increased resilience to the insecticide rather than through altered behaviour, with patterns of behaviour being similar or not varying consistently between strains.

0106

MULTIPLE MECHANISMS MEDIATING INSECTICIDE RESISTANCE IN *AEDES AEGYPTI* AND *AE. ALBOPICTUS* MOSQUITO POPULATIONS FROM CAMEROON

Borel Djiappi Tchamen[1], Stella Nana-Ndjangwo[2], Mavridis Konstantinos[3], Balabanidou Vasileia[4], Roland Bamou[1], Parfait Awono-Ambene[5], Timoléon Tchuinkam[6], John Vontas[7], Christophe Antonio-Nkondjio[8]

Insecticide resistance is an increasing threat limiting the efficacy of vector control measures worldwide. Alongside Anopheline and *Culex* species, *Aedes* species including *Aedes aegypti* (Linnaeus, 1762) and *Ae. albopictus* (Skuse, 1894) from urban settings of Cameroon becoming resistant to pyrethroids and DDT. The F1 progeny of these *Aedes* species collected in Douala, Yaoundé and Dschang from August to December 2020 were tested using WHO tube assays with four insecticides : deltamethrin 0.05%, permethrin 0.75%, DDT 4% and bendiocarb 0.1%. TaqMan, qPCR, RT-qPCR assays and Cuticular Hydrocarbons (CHCs) identification and quantitation by GC-MS and GC-FID were used to detect kdr mutations, expression profiles of eight detoxification genes and implication of cuticle tickness respectively in insecticide resistance. *Ae. aegypti* mosquitoes from Douala were found resistant to DDT, permethrin and deltamethrin also three kdr mutations (F1534C, V1016G and V1016I) were detected in *Ae. aegypti* populations from Douala and Dschang. The kdr allele F1534C was predominant (90%) in *Ae. aegypti* ffrom Douala and was detected for the first time in *Ae. albopictus* (2.08%). P450s genes, Cyp9J28 (2.23-7.03 folds), Cyp9M6 (1.49-2.59 folds), Cyp9J32 (1.29-3.75 folds) and GSTD4 (1.34-55.3 folds) were found overexpressed in the Douala and Yaoundé *Ae. aegypti* populations. Furthermore, we found substantially higher CHC content in *Ae. aegypti* from Douala, compared to susceptible control mosquitoes (38% increase in mean CHC amounts). The large distribution of insecticide resistance in *Ae. aegypti* and *Ae. albopictus* populations calls for alternative strategies towards the control and prevention of arboviral diseases in Cameroon.

0107

RESPONSE OF *ANOPHELES FUNESTUS* S.L. AND *AN. GAMBIAE* S.L. TO DIFFERENT INSECTICIDES IN MALAWI

Leonard C. Dandalo[1], Martin Chiumia[2], Fred Sande[2], Charlotte Banda[2], Ganizani Kapito[2], Medson Kamwana[2], Lusungu Chamdimba[2], Abdoulaye Bangoura[1], Jules Nahimana[1], Miriam Mokuena[3], Pius Masache[4], Monica Bautista[4], Tyson Volkmann[4], John E. Gimnig[5], Adeline Chan[5], Lilia Gerberg[6], Yemane Yihdego[3], Shadreck Mulenga[7], Michael Kayange[7], Themba Mzilahowa[2]

[1]U.S. President's Malaria Initiative VectorLink Project, Abt Associates, Lilongwe, Malawi, [2]Malaria Alert Centre, Kamuzu University of Health Sciences, Blantyre, Malawi, [3]U.S. President's Malaria Initiative VectorLink Project, Abt Associates, Rockville, MD, United States, [4]U.S. President's Malaria Initiative/U.S. Agency for International Development, Lilongwe, Malawi, [5]U.S. President's Malaria Initiative, Entomology Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]U.S. President's Malaria Initiative/U.S. Agency for International Development, Washington, DC, United States, [7]National Malaria Control Programme, Community Health Sciences Unit, Lilongwe, Malawi

Insecticide-treated bed nets (ITNs) and indoor residual spraying (IRS) are the primary malaria vector control interventions in Malawi. *Anopheles funestus* s.l. and *An. gambiae* s.l. are the main malaria vectors targeted by these interventions. However, prolonged use of insecticides may lead to the emergence and spread of insecticide resistance in the target vectors. From July 2018 to December 2022, susceptibility of the two main malaria vector populations to different insecticides was monitored in Malawi. Larval and adult mosquitoes were sampled and reared from sentinel sites in Karonga, Nkhata Bay, Nkhotakota, Kasungu, Salima, and Chikwawa districts, and the resultant F1 progeny were tested for their susceptibility to different classes of insecticides. CDC bottle assays and WHO tube assays were used to determine the frequency of phenotypic resistance. Intensity of pyrethroid resistance was assessed. Both *An. funestus* s.l. and *An. gambiae* s.l. across the six sentinel sites were highly resistant to pyrethroids (permethrin, deltamethrin, and alpha-cypermethrin) even after increasing the diagnostic dose by 2 to 10-fold. However, pre-exposure of both species to piperonyl butoxide (PBO) restored their susceptibility status to the diagnostic dose of the pyrethroids. Both species were fully susceptible to pirimiphos-methyl (organophosphate), chlorfenapyr (pyrrole), and clothianidin (neonicotinoid). These data have led the National Malaria Control Programme to adjust its ITN distribution policy from using standard pyrethroid only treated nets to nets with PBO and/or other dual active ingredient ITNs. Further, pirimiphos-methyl and clothianidin are also being used in rotation for IRS as part of the insecticide resistance management strategy in Malawi. Continued monitoring of the insecticides used in IRS and ITNs is important for early detection and containment of insecticide resistance.

Centro de Investigaciones Regionales "Dr. Hideyo Noguchi", Universidad Autónoma de Yucatán, Merida, Mexico

Current methods to control Aedes aegypti, the major vector of dengue, Zika, and chikungunya, have proven insufficient in preventing disease outbreaks. A promising new approach termed targeted indoor residual spraying (TIRS) consists of the selective application of residual insecticides on *Aedes aegypti* indoor resting sites, such as exposed lower sections of walls (< 1.5m), under furniture, and on dark surfaces. TIRS is a novel approach for *Ae. aegypti* control that has two major enhancements to existing practice; it exploits mosquito behavior to target insecticide applications and it is being applied preventively (before transmission season) rather than reactively (in response to reported cases). Here, we present the design and preliminary entomological findings of the TIRS trial, a two-arm, parallel, cluster randomized controlled trial quantifying the efficacy of TIRS in reducing the burden of laboratory-confirmed *Aedes*-borne viral clinical disease. Preliminary results after the first year of applying pirimiphos-methyl (Actellic 300CS, Syngenta) in ~8,000 houses were estimated by measuring indoor adult *Ae. aegypti* density through Prokopack aspirator collections in a sub-sample of 1,500 houses monitored monthly for 6 months covering the arbovirus transmission season. The overall effect across 6 months post-TIRS application showed a 77.4% reduction in positivity (calculated as the total number of houses positive for adult *Ae. aegypti*) in the TIRS arm compared to the control arm. Furthermore, we observed a waning in bioefficacy as the insecticide residual effect diminished over time. Results from a satisfaction and perceived effectiveness survey applied to 750 TIRS-treated households showed that 88% reported a reduction in the number of indoor mosquitoes and 96% would recommend the TIRS intervention to others. Our preliminary findings suggest a high and sustained effectiveness of TIRS for the control of indoor *Ae. aegypti* and high levels of satisfaction and uptake by the community. Epidemiological data collection is ongoing and will be analyzed for the primary endpoint when the predefined number of clinical endpoints is reached.

The combination of *Wolbachia*-based incompatible insect technique (IIT) and radiation-based sterile insect technique (SIT) can be used for population suppression of *Aedes aegypti*. We implemented open-field mass-releases of *w*AlbB-infected *Ae. aegypti* males, as part of an Integrated Vector Management (IVM) plan lead by the Mexican Ministry of Health, to suppress natural populations of *Ae. aegypti* in a suburban setting in south Mexico. A controlled before-and-after quasi-experimental study was developed in two suburban localities of Yucatan (México): San Pedro Chimay (SPC), which received IIT-SIT, and San Antonio Tahdzibichen as control. Release of *w*AlbB *Ae. aegypti* males at SPC extended for 6 months (July-December 2019), covering the period of higher *Ae. aegypti* abundance. Entomological indicators included egg hatching rates and outdoor/indoor adult females collected at the release and control sites. Approximately 1,270,000 lab-produced *w*AlbB-infected *Ae. aegypti* males were released in a 50-ha area. The efficacy of IIT-SIT in suppressing indoor female *Ae. aegypti* density (quantified from a generalized linear mixed model showing a statistically significant reduction in treatment versus control areas) was 90.9% a month after initiation of the suppression phase, 47.7% two months after (when number of released males was reduced to match local abundance), 61.4% four months after (when normal 10:1 ratio of releases was re-established), 88.4% five months after and 89.4% at six months after the initiation of the suppression phase. Our study, the first open-field pilot implementation of Wolbachia IIT-SIT in Mexico and Latin-America, confirms that inundative male releases can significantly reduce natural populations of *Ae. aegypti* within a IVM plan implemented by Ministry of Health personnel.

FIRST DETECTION OF THE KNOCKED DOWN RESISTANCE *(KDR)* MUTATION, L1014F, IN THE THREE MAJOR MALARIA VECTOR SPECIES IN PAPUA NEW GUINEA

Michelle N. Katusele[1], Solomon Lagur[1], Muker Sakur[1], Lincoln Timinao[1], Elma Nate[1], Lisa Reimer[2], Moses Laman[1], Stephan Karl[1]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Liverpool School of Tropical Medicine, Liverpool, Papua New Guinea

Malaria vector control in Papua New Guinea (PNG) is primarily pyrethroid treated long-lasting insecticide nets that are routinely distributed since 2005. Routine insecticide resistance monitoring reported that the three major malaria vector species, *Anopheles punctulatus, An. farauti* and *An. koliensis* are pyrethroid susceptible. Recent data suggest that these vector populations have developed phenotypic resistance to dichlorodiphenyltrichloroethane (DDT) and a possible cross-resistance to the pyrethroid insecticide, lambdacyhalothrin. In an effort to understand the underlying molecular mechanisms conferring this resistance, we conducted a molecular analysis of resistant and susceptible mosquito phenotypes tested against several pyrethroids and DDT from 2018 to 2021. All DDT, deltamethrin and lambdacyhalothrin resistant phenotypes and a subset of susceptible phenotypes in routine World Health Organization susceptibility bioassays were analyzed. Genomic DNA was extracted from these mosquitoes using standard methods. A PCR detecting the L1014F *kdr* mutation in *An. punctulatus* group was used to differentiate mutant alleles from the susceptible wild type alleles. A total of 25 resistant and 63 susceptible phenotypes were used in the preliminary analysis. We detected both the heterozygous and homozygous resistant alleles at a frequency of 0.30 and 0.01 respectively, and the homozygous wild type allele at 0.69. All resistant phenotypes had either the heterozygous (96%) or homozygous resistant allele (4%). Susceptible phenotypes had either the heterozygous allele (4.55%) or the wild type allele (95.45%). L1014F mutation was mostly detected in *An. punctulatus* (88%), 8% in *An. koliensis* and in a single *An. farauti* specimen (4%). We report for the first time the presence of the common *kdr* resistant mutation, L1014F, which confers pyrethroid and DDT resistance, in the three major malaria vector species in PNG. Further analysis to determine the magnitude of L1014F resistant mutation within the malaria vector population is ongoing and is crucial to inform the national malaria control program on effective control strategies.

0111

IMPACT OF DUAL ACTIVE INGREDIENT INSECTICIDE-TREATED NETS CONTAINING ALPHA-CYPERMETHRIN PLUS PYRIPROXYFEN ON THE MORTALITY, FERTILITY, AND FECUNDITY OF PYRETHROID-RESISTANT *ANOPHELES GAMBIAE* S.L. IN BENIN

Martin Akogbéto[1], Keller Alphonse Konkon[1], David Zoungbédji[1], Steve Hougbe[1], Virgile Gnanguénon[2], Germain Gil Padonou[1], Patrick Condo[2], A. Saadani Hassani[2], Daniel Impoinvil[3]

[1]CREC, Cotonou, Benin, [2]USAID, Cotonou, Benin, [3]CDC, Atlanta, GA, United States

To mitigate the widespread resistance of malaria vectors to pyrethroids, new generation insecticide-treated nets (ITNs) have been developed. One of these new generation ITNs is the Royal Guard® net, which combines alpha-cypermethrin with a juvenile hormone analog, pyriproxyfen (PPF), which disrupts female reproduction and fertility of eggs. This study evaluated the impact of PPF ITNs on the mortality, fertility, and fecundity of *Anopheles gambiae* s.l. from Benin after exposure. Three populations of *An. gambiae* s.l. (Kisumu susceptible strain and two wild Benin resistant populations from Cotonou and Seme-Podji) were exposed for 3 minutes to either new PPF ITNs, standard alpha-cypermethrin ITNs (SAC; [Royal Sentry® net]), and an untreated net and evaluated using a protocol developed by Innovation-To-Impact (Liverpool, UK). Mosquito mortality was recorded 24, 48, and 72 hours after net exposure. Ovary dissections and identification of Christopher's stages in 75% of the surviving mosquitoes were used to determine the impact of PPF on ovary development and fertility rates. The abdomens of the remaining 25% of the surviving mosquitoes were dissected, and the number of eggs was counted to determine fecundity. Mortality rates of *An. gambiae* Kisumu exposed to PPF ITNs were 100% after exposure. Mortality rates of wild *An. gambiae* s.l. populations exposed to PPF ITNs from Cotonou and Seme were 29% and 13%, respectively, and 3% and 1% for those exposed to SAC ITNs, respectively, after 72 hours of observation. While the mortality rate of the wild resistant *An. gambiae* s.l. after exposure to the PPF ITNs was low, all surviving mosquitoes dissected were infertile (100%), and no eggs were observed in the abdomens of the remaining 25% of *An. gambiae* s.l. dissected for oviposition and fecundity measurements. The PPF ITN inhibited the reproduction of pyrethroid-resistant mosquitoes, suggesting that PPF ITNs may be an effective vector control tool in Benin.

0112

AGE GRADING OF *ANOPHELES GAMBIAE SENSU STRICTO* MOSQUITOES USING MALDI TOF MS PROTEIN PROFILING

Mercy Tuwei, Jonathan Karisa, Martha Muturi, Kelly Ominde, Marta Ferreira Maia

KEMRI-Wellcome-Trust Research Programme, Kilifi, Kenya

Malaria is transmitted by the bite of an infected female *Anopheles* mosquito. Transmission can only occur if a mosquito survives the extrinsic incubation period of 10 to 14 days. Assessing the age structure of mosquito populations could help in evaluating the impact of control methods. Traditional techniques are cumbersome and subjective. Malaria vectors have been shown to undergo proteomic changes as they age. MALDI-TOF is a mass spectrometry technique that uses laser technology for protein profiling and identification. This study aimed to determine if MALDI-TOF MS is capable of distinguishing different age groups of *Anopheles gambiae s.s.* mosquitoes based on their protein profiles. *Anopheles gambiae sensu stricto* mosquitoes (Kilifi strain) were reared in a laboratory controlled environment at KEMRI-Wellcome Trust insectary. Mosquito were reared to different physiological and chronological ages. The individual life history of each mosquito was recorded including mating, blood-feeding and oviposition. Approximately 100 mosquitoes per group of distinct physiological and chronological age were processed using MALDI TOF MS. Principal components analysis was used to explore differences in each group's spectrum profiles. Age-grading databases were created using ClinProTools and validated with spectra of unknown age. The study is ongoing. We expect to present the protein profiles of different ages of mosquitoes and database accuracy. We also aim discussing whether the method is worth exploring more widely in the field. The information will be used to validate the importance of MALDI-TOF MS as a new tool for entomological surveillance.

0113

ELECTRONIC MOSQUITO BARRIERS: A NON-CHEMICAL INSECT REPELLING TECHNOLOGY USING ELECTRIC FIELDS

Ndey Bassin Jobe[1], Ulla Gordon[2], Farooq Tanveer[2], Andreas Rose[2], Krijn Paaijmans[1]

[1]Center for Evolution and Medicine, School of Life Sciences, Arizona State University, Tempe, AZ, United States, [2]Biogents AG, Regensburg, Germany

Decades of research have made great advances in controlling mosquitoes that transmit infectious diseases with insecticides. But our overreliance on insecticides raises concerns for our environment, our health and the development of insecticide resistance. As such, there is a critical need for novel non-chemical technologies to control insects. High voltage electric fields (EFs) provide great promise, but EF-insect science remains in its infancy. I will present the electric field concept, how insects respond to EFs, and preliminary data on how they prevent both host-seeking (feeding) and water-seeking (ovipositioning) mosquitoes from entering spaces. This first non-chemical insect repellent technology is safe and can be incorporated in window/door/eaves openings, larger fences, storm drains and water tanks to prevent mosquito from biting or laying eggs.

0114

INCREASE IN THE MALARIA ENTOMOLOGICAL INOCULATION RATE FOLLOWING THE WITHDRAWAL OF INDOOR RESIDUAL SPRAYING IN ATACORA, BENIN

Rock Aikpon[1], Cyriaque Affokou[1], Germain Gil Padonou[2], Patrick Condo[3], Ahmed Saadani Hassani[4], Daniel Impoinvil[5], Aurore Ogouyemi Hounto[1], Martin Akogbéto[2]

[1]Ministry of Health Benin/ National Malaria Control Program, Cotonou, Benin, [2]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [3]3US President's Malaria Initiative (PMI), US Agency for International Development (USAID), Cotonou, Benin, Cotonou, Benin, [4]US President's Malaria Initiative (PMI), US Centers for Disease Control and Prevention (CDC), Cotonou, Benin, Cotonou, Benin, [5]US Presidents' Malaria Initiative, Entomology Branch, US Centers for Disease Control and Prevention (CDC), Atlanta, Georgia

The National Malaria Control Program (NMCP) withdrew indoor residual spraying (IRS) from the Atacora department in northern Benin after six consecutive years (2011-2016) of implementation in the region, with the expectation that past IRS campaigns significantly reduced seasonal malaria transmission. An IRS withdrawal strategy, comprised of enhanced surveillance, reinforced case management, and availability of insecticide-treated bednets (ITNs) through continuous channels, was done to maintain the suppression of malaria. The entomological inoculation rate (EIR), a measure of exposure to infectious mosquitoes, was evaluated before and after IRS withdrawal to measure malaria rebound. Monthly mosquito collections by human landing captures (HLCs) were done in two Atacora districts (Natitingou and Toukountouna). Entomological monitoring occurred during the last IRS campaign year (2016) and two years after the IRS withdrawal (2018), both times from January to December. Technical constraints prevented entomological assessment in 2017. Two years after IRS withdrawal, the average EIR increased in the two survey districts. In 2016, the cumulative EIR was 17.2 infected bites/year in Natitingou and 24.8 infected bites/year in Toukountouna. In 2018, the EIR significantly increased ($p<0.0001$) from 94.9 infected bites/year in Natitingou to 129.2 infected bites/year in Toukountouna. While the EIR increased significantly after IRS withdrawal, it is not clear if mitigation measures were insufficient in this seasonal malaria transmission setting or if other factors, such as rainfall, ITN coverage, or insecticide resistance accounted for the increased EIR. The lack of control districts also limits the interpretation of the result.

While EIR is an accepted vector-based transmission indicator, human malaria cases are the definitive measure of impact. Thus, additional investigation with robust epidemiological and entomological monitoring may provide a better indication of whether IRS withdrawal led to malaria rebound.

0115

METABOLIC BASIS OF PYRETHROID RESISTANCE IN *AEDES AEGYPTI* FROM CENTRAL AMERICA AND THE DOMINICAN REPUBLIC

Juan C. Lol[1], David Castañeda[1], Marlyn Vásquez[2], Miguel Reyes[2], Haroldo Monterroso[2], Carlos Estupinian[3], Eduardo Romero[3], Yeni Henríquez[4], Emperatriz Lugo[5], David Soto[5], Camila Conejo[6], Ariana Barboza[6], Carlos Aguilar[7], Daniel O'Reilly[8], Marina Monserrate[8], Julio Batista[9], Cesar Burgos[9], Audrey Lenhart[10], Norma Padilla[1]

[1]Laboratorio de Entomología Médica y Malaria, Centro de Estudios en Salud, Universidad del Valle de Guatemala, Guatemala, Guatemala, [2]Ministerio de Salud Pública y Asistencia Social, Guatemala, Guatemala, [3]Dirección de Salud Ambiental, Unidad de Vigilancia de Enfermedades Transmitidas por Vectores, Ministerio de Salud, San Salvador, El Salvador, [4]Unidad de Vigilancia de la Salud, Región Sanitaria Metropolitana, Secretaría de Salud, Tegucigalpa, Honduras, [5]Dirección de Entomología Médica, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [6]Centro Nacional de Referencia en Entomología, Instituto Costarricense de Investigación y Enseñanza en Nutrición y Salud, Tres Ríos, Cartago, Costa Rica, [7]Programa Nacional de Manejo Integrado de Vectores, Ministerio de Salud, San José, Costa Rica, [8]Departamento de Control de Vectores, Ministerio de Salud, Ciudad de Panamá, Panama, [9]Centro de Prevención y Control de Enfermedades Transmitidas por Vectores y Zoonosis, Ministerio de Salud Pública, Santo Domingo, Dominican Republic, [10]Centers for Disease Control and Prevention, Atlanta, GA, United States

Insecticide-based interventions have been central to the prevention and control of *Aedes*-borne diseases. However, resistance to DDT, permethrin and deltamethrin was documented during 2017-2018 in *Aedes aegypti* across Central America and the Dominican Republic. Molecular assays detected the presence of multiple *kdr* mutations (V410L, V1016I and F1534C) in the region, which partially explains the phenotypic resistance observed. However, metabolic mechanisms conferring pyrethroid resistance in *Ae. aegypti* remain poorly characterized. Thus, we aimed to elucidate the metabolic basis of pyrethroid resistance across the region. Mosquito eggs were collected across Central America and the Dominican Republic between 2021 and 2022. The insecticide susceptibility profiles, the intensity of resistance, and the potential role of detoxification enzymes were determined using CDC bottle bioassays. Expression levels of six cytochrome P450 genes (CYP6BB2, CYP6Z8, CYP9J10, CYP9J28, CYP9J32 and CYP9M6) were measured by RT-qPCR in pyrethroid-resistant populations. Bioassays confirmed resistance to DDT, permethrin and deltamethrin, and increased activity of detoxification enzymes (esterases, cytochrome P450s and glutathione-S-transferases) was associated with phenotypic resistance to permethrin and deltamethrin. Gene expression analyses revealed significant ($p<0.05$) overexpression of CYP9J10 and CYP9M6 in the pyrethroid-resistant populations. These findings are the first report of specific metabolic genes associated with pyrethroid resistance in Central America and the Dominican Republic. Moreover, the results highlight the urgent need to implement an integrated approach for insecticide resistance management using molecules without potential cross-resistance in the region or other non-chemical alternatives. Operational failure of the insecticide-based control interventions must be also measured to preserve the efficacy of the insecticides available in the future.

0116

STATUS OF INSECTICIDE RESISTANCE IN MALARIA VECTORS IN THREE PROVINCES IN ZAMBIA: INFORMING THE NATIONAL INSECTICIDE RESISTANCE MANAGEMENT PLAN

Mohamed N. Bayoh[1], Nduka Iwuchukwu[1], Rabecca Ngwira[1], Emmanuel Kooma[2], Allison Belemvire[3], Paul Psychas[4], Daniel Impoinvil[5], Kelley Ambrose[6], Aklilu Seyoum[6]

[1]PMI VectorLink Project, Abt Associates, Lusaka, Zambia, [2]National Malaria Elimination Program, Lusaka, Zambia, [3]U.S. President's Malaria Initiative, USAID, Washington, DC, United States, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [5]U.S. President's Malaria Initiative, Malaria Branch, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]PMI VectorLink Project, Abt Associates, Rockville, MD, United States

The emergence of insecticide resistance (IR) is a threat to the effectiveness of indoor residual spraying (IRS) and insecticide-treated nets (ITNs). Zambia's National IR Management Plan recommends rotating IRS insecticides every two years; but, due to a lack of viable options, many districts in 2022 will use clothianidin (CN) for the 4th or 5th consecutive year. Pirimiphos-methyl (PM) was used widely for IRS from 2012 to 2018 but will not be reintroduced given its shorter than anticipated residual efficacy (3-5 months). DDT has been used from 2020 to 2021 in several districts where there is susceptibility. In addition, Zambia's National Malaria Elimination Program plans to shift its primary vector control strategy to universal coverage with PBO or dual active ingredient ITNs in 2023. Routine IR data collected by PMI in 2021 was reviewed to inform decision-making. Susceptibility testing of *Anopheles funestus* s.l. and *An. gambiae* s.l. to all WHO prequalified ITN pyrethroids and IRS insecticides (DDT, PM CN) was done in 3 provinces (Luapula, Eastern, Copperbelt) using WHO tube and CDC bottle assays. *An. funestus* s.l. and *An. gambiae* s.l. were fully susceptible to 2.0% CN, 100 µg chlorfenapyr, and 0.25% PM in all three provinces. A mix of susceptibility and resistance to 4.0% DDT was found in *An. funestus* s.l. in Luapula and Copperbelt (mortality 89-100%), while *An. gambiae* s.l. in Eastern Province were fully susceptible (mortality 100%). Both species were resistant to 0.05% deltamethrin, 0.75% permethrin, and 0.05% alpha-cypermethrin in Luapula and Copperbelt; a mix of resistance and susceptibility was noted for *An. gambiae* s.l. in Eastern Province. Alpha-cypermethrin had the lowest mortalities (44% for *An. funestus* s.l., 27% for *An. gambiae* s.l.). Susceptibility restoration by PBO pre-exposure in pyrethroid-resistant mosquitoes ranged from 85% to 100% from mortality levels as low as 32%. Despite the susceptibility of local vectors to clothianidin, its continued deployment raises concern for the emergence of resistance and should continue to be monitored. PMI's routine IR testing will continue to focus on current and emerging vector control insecticides.

0117

HETEROGENEITY OF INSECTICIDE SUSCEPTIBILITY FROM SIX ECOLOGICAL ZONES IN NIGERIA SUGGEST A HIGHLY EVOLVING *ANOPHELES GAMBIAE* S.L. POPULATION UNDER SELECTION PRESSURE

Annual insecticide resistance monitoring is an essential tool to guide improved malaria vector control decisions. However, the value of collecting and analyzing this data over time and in several locations has not been justified. We investigated patterns of mosquito susceptibility to pyrethroid insecticides (permethrin, deltamethrin, and alpha-cypermethrin) based on data collected from 2016-2020 under the U.S. Presidents' Malaria Initiative VectorLink project in Nigeria. Mortality data were grouped into six ecological zones and subjected to one-way analysis of variance. Monitoring sites with at least four years of consecutive resistance data for all three pyrethroids were included. The range of mortality rates of *An. gambiae* s.l. mosquitoes exposed to permethrin, deltamethrin and alpha-cypermethrin were 5-100%, 33-100% and 16-100%, respectively. The proportion of local government areas (LGAs) that reported *An. gambiae* s.l. resistance to all three pyrethroids in a given year fluctuated over the period of interest—the percent of LGAs reporting resistance to permethrin, deltamethrin, alpha-cypermethrin ranged from 54.2-94.2%, 29.2-57.4%, and 15.9-29.2%, respectively. Significantly high variation ($p \leq 0.05$) in the mortality rates of *An. gambiae* s.l. mosquitoes exposed to the three pyrethroid insecticides was found in the mangrove, rainforest, transitional forest, Sudan savannah, and Guinea savannah ecozones, indicating ongoing insecticide selection pressure. In contrast, variation in the mortality of *An. gambiae* s.l. exposed to pyrethroids was not significant ($p \geq 0.05$) in the Sahel savannah ecozone, which suggests less intensive insecticide selection pressure in this ecozone. Outcomes from analyzing several years of data provide a clear and consistent distinction in the response of *An. gambiae* s.l. mosquitoes to pyrethroids. Such information may be used for evidence-based decision making, particularly given the need to consider scaling up new types of nets, such as PBO and dual active ingredient nets, for malaria vector control across the diverse ecozones and mosquito population resistance profiles of Nigeria.

0118

COMBINING MULTIPLE METHODS OF NEXT GENERATION SEQUENCING ENHANCES UNDERSTANDING OF INSECTICIDE RESISTANCE MECHANISMS IN PERMETHRIN RESISTANT *ANOPHELES COLUZZII* DISPLAYING REDUCED PBO-SYNERGY FROM MAFERINYAH, GUINEA

Bethanie J. Pelloquin[1], Moussa Sylla[2], Noboru Minakawa[3], Mark Rowland[1], Susana Campino[1], Thomas Walker[1], Louisa A. Messenger[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Centre de Formation et de Recherche en Santé Rurale de Mafèrinyah, Conakry, Guinea, [3]Nagasaki University, Nagasaki, Japan

Resistance to insecticides may severely threaten the long term efficacy of malaria vector control programmes. The synergist piperonyl butoxide (PBO) restores pyrethroid susceptibility by inhibiting mosquito detoxification enzymes and has been incorporated into some insecticidal nets. However, reduced PBO synergy has been reported in *Anopheles*. Next generation sequencing methods (NGS) enable detection of emerging resistance mechanisms, unlike targeted assays which are used in routine entomological surveillance and are rapidly outdated as mosquitoes evolve. This study uses NGS to characterise resistance mechanisms in an F1 population of field caught, permethrin resistant *Anopheles (An.) coluzzii* from Maferinyah, Guinea which displayed reduced PBO-synergy. We performed whole genome sequencing (WGS), whole transcriptome sequencing (RNA-Seq) and 16S rRNA sequencing on permethrin exposed *An. coluzzii* who did and did not experience PBO synergy. We developed a bioinformatics pipeline which can be used to identify single nucleotide polymorphisms (SNPs), insertions, deletions, copy number variants (CNVs) and chromosomal inversions from WGS data; expression of candidate genes from RNA-Seq data and abundance of microbes from 16S data. Preliminary data analysis revealed that microbial profiles vary with PBO exposure and resistance status, with PBO-exposed mosquitoes having significantly lower microbial diversity and mosquitoes with restored susceptibility having an increased abundance of *Staphylococcus spp.* and *Chromobacterium spp*. No SNPs were found to be significantly associated with PBO resistance suggesting that other genomic mutations such as CNVs may be driving resistance. Further analysis of WGS data will identify the impact of CNVs, which are thought to play a larger role in resistance but are more difficult to identify. RNA-Seq data will identify differentially expressed genes (including metabolic or cuticular) which may be contributing to reduction in synergy. Using NGS to identify population-specific markers of resistance will enable the development of up-to-date assays which can be widely used in the field.

EARLY BIO-EFFICACY LOSS OF NETS MASS DISTRIBUTED FOR MALARIA VECTOR CONTROL IN MADAGASCAR: IMPLICATIONS FOR MALARIA PREVENTION STRATEGY

Thiery Nepomichene[1], Rico Randrenjarison[1], Bakoly Rahaivondrafahitra[2], Jacky Raharinjatovo[2], Isabel Swamidoss[3], Carla Mapp[3], Laurent Kapesa[4], Jocelyn Razafindrakoto[4], Anna Bowen[5], Allison Belemvire[6], Sarah Zohdy[7], Stephen Poyer[8], Romain Girod[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Population Services International Madagascar, Antananarivo, Madagascar, [3]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]U.S. President's Malaria Initiative, USAID, Antananarivo, Madagascar, [5]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Antananarivo, Madagascar, [6]U.S. President's Malaria initiative, USAID, Washington, DC, United States, [7]U.S. President's Malaria Initiative, Entomology Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [8]Population Services International, Washington, DC, United States

In September 2018, the National Malaria Control Program and partners conducted a campaign to distribute insecticide-treated nets (ITNs) across Madagascar. Bio-efficacy of ITNs was tested upon arrival in Madagascar and after distribution. We conducted chemical analyses of insecticide residue on ITNs using HPLC and standard WHO cone bio-assays using a fully-susceptible strain of *Anopheles arabiensis*. Thirty DawaPlus® 2.0 and PermaNet® 2.0 ITNs were tested on arrival and 12, 24, and 36 months after distribution. DawaPlus® 2.0 nets were collected from three districts with differing climates: Bekily (semi-arid), Farafangana (humid), and Maintirano (tropical), while PermaNet® 2.0 nets were from sub-humid Taolagnaro district. On arrival, mosquito mortality rates observed from DawaPlus® 2.0 (86.4%) and PermaNet® 2.0 nets (83.6%) were above the WHO threshold of 80.0%. At 12, 24, and 36 months after distribution, mosquito mortalities induced by both DawaPlus® 2.0 and PermaNet® 2.0 were <56% for all districts. Moreover, knock-down effect was below the WHO threshold of 95.0% for both DawaPlus® 2.0 and PermaNet® 2.0 nets for all districts and time points. Finally, the deltamethrin residue on each ITN was also below the expected values of 80mg/m² for DawaPlus® 2.0 and 55mg/m² for PermaNet® 2.0; regardless of ITN age, the concentration of deltamethrin was <66mg/m² for DawaPlus® 2.0 and <36mg/m² for PermaNet® 2.0 ITNs. According to manufacturers, ITNs are effective for ≤36 months, thus, mass distribution campaigns are organized every three years. However, the DawaPlus® 2.0 and PermaNet® 2.0 ITNs showed a loss of bio-efficacy within one year of distribution. This bio-efficacy loss could be due to a manufacturing problem, to poor storage and transportation conditions, or to use and maintenance practices in Madagascar. Understanding and correcting the root causes is critical to guide corrective actions such as improving manufacturing, replacing ITNs more frequently, and increasing education on ITN care.

COMPARATIVE TRANSCRIPTOMIC ANALYSIS OF INSECTICIDE RESISTANT *AEDES AEGYPTI* FROM PUERTO RICO REVEALS INSECTICIDE-SPECIFIC PATTERNS OF GENE EXPRESSION

Dieunel Derilus[1], Lucy Mackenzie Impoinvil[1], Jonathan Gerhart[2], Muturi J. Ephantus[1], Janet McAllister[3], Joanie Kenney[3], Steven E. Massey[4], Ryan Hemme[5], Linda Kothera[3], Audrey Lenhart[1]

[1]Entomology Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Division of Bacterial Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [4]Biology Department, University of Puerto Rico, Rio Piedras Campus, San-Juan, PR, United States, [5]Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Dengue Branch, San Juan, PR, United States

Aedes aegypti transmits major arboviruses of public health importance, including dengue, chikungunya, Zika, and yellow fever. The use of insecticide represents the cornerstone of vector control, and insecticide resistance (IR) in *Ae. aegypti* has become widespread. Here, we applied Illumina RNA-Seq to study the gene expression patterns in *Ae. aegypti* populations from 2 sites (Manati and Isabela) in Puerto Rico (PR). *Aedes aegypti* populations were phenotyped as either malathion, alpha-cypermethrin or lambda-cyhalothrin resistant, and transcriptomes of these phenotypes were compared against non-insecticide exposed individuals from the same populations as well as the insecticide susceptible Rockefeller reference strain. The analysis showed that cytochrome P450s were the predominant over-expressed detoxification genes across all resistant phenotypes, with CYP6Z7, CYP28A5, CYP9J2, CYP6Z6, CYP6BB2, CYP6M9, and two CYP9F2 orthologs commonly over-expressed in mosquitoes that survived exposure to all three insecticides (independent of geographical origin), suggesting their association with both pyrethroid and organophosphate resistance. Some detoxification genes were uniquely overexpressed in mosquitoes that survived exposure to malathion (CYP6BY1), alpha-cypermethrin (GSTD1), and lambda-cyhalothrin (CYP4H29, GSTE6), suggesting that their overexpression is associated with resistance to specific insecticides. For 4 out of 6 Resistant vs Susceptible comparisons, the gene ontology (GO) terms associated with monooxygenase, ironbinding, and passive transmembrane transporter activities were significantly enriched in the list of upregulated genes, indicating the potential contribution of these molecular activities to IR in this species. Interestingly, for all experiments, the downregulated genes that were significantly enriched were GO terms associated with chitin binding and chitinase activities. This RNA-Seq analysis presents a detailed picture of gene expression patterns and provides evidence for the molecular basis of pyrethroid and organophosphate resistance in *Ae aegypti* populations from PR.

0121

USING BAYESIAN STATE-SPACE MODELS TO UNDERSTAND THE POPULATION DYNAMICS OF THE DOMINANT MALARIA VECTOR, *ANOPHELES FUNESTUS* IN RURAL TANZANIA

Halfan S. Ngowo[1], Fredros O. Okumu[1], Emmanuel E. Hape[1], Issa H. Mshani[1], Heather M. Ferguson[2], Jason Matthiopoulos[2]

[1]Ifakara Health Institute, Ifakara, United Republic of Tanzania, [2]University of Glasgow, Glasgow, United Kingdom

It is often assumed that the population dynamics of the malaria vector *Anopheles funestus*, its role in malaria transmission and the way it responds to interventions are similar to the more elaborately characterized *An. gambiae*. However, *An. funestus* has several unique ecological features that could generate distinct transmission dynamics and responsiveness to interventions. The objectives of this work were to develop a model which will; 1) reconstruct the population dynamics, survival, and fecundity of wild *An. funestus* populations in southern Tanzania, 2) quantify impacts of density dependence on the dynamics, and 3) assess seasonal fluctuations in *An. funestus* demography. A Bayesian State Space Model (SSM) based on mosquito life history was fit to time series data on the abundance of female *An. funestus* collected over 2 years in southern Tanzania. Prior values of fitness and demography were incorporated from laboratory-reared first generation progeny of wild *An. funestus*. The model was structured to allow larval and adult fitness traits to vary seasonally in response to environmental covariates, and for density dependency in larvae. The model accurately reconstructed the seasonal population dynamics of *An. funestus* and generated biologically-plausible values of their survival larval, development and fecundity in the wild. This model suggests that *An. funestus* survival and fecundity annual pattern was highly variable across the year, but did not show consistent seasonal trends either rainfall or temperature. While the model fit was somewhat improved by inclusion of density dependence, this was a relatively minor effect and suggests that this process is not as important for *An. funestus* as it is for *An. gambiae*. The model's ability to accurately reconstruct the dynamics and demography of *An. funestus* could potentially be useful in simulating the response of these populations to vector control techniques deployed separately or in combination. The observed and simulated dynamics also suggests that *An. funestus* could be playing a role in year-round malaria transmission, with any apparent seasonality attributed to other vector species.

0122

THE HUMAN-BAITED HOST DECOY TRAP (HDT) IS AN EFFICIENT SAMPLING DEVICE FOR EXOPHAGIC *ANOPHELES ARABIENSIS* WITHIN IRRIGATED LANDS IN SOUTHERN MALAWI

Kennedy K. Zembere[1], James Chirombo[1], Peter Nasoni[2], Daniel P. McDermott[3], Lizzie T. Divala[1], Frances M. Hawkes[4], Christopher M. Jones[3]

[1]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [2]Illovo sugar estate, Chikwawa, Malawi, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]University of Greenwich, London, United Kingdom

Irrigation schemes provide an ideal habitat for *Anopheles* mosquitoes particularly during the dry season. Reliable estimates of outdoor host-seeking behaviour are needed to assess the impact of vector control options, and this is particularly the case for *Anopheles arabiensis* which displays a wide range of behaviours that circumvent traditional indoor-insecticide based control. In this study we compared the sampling efficiency of the host decoy trap (HDT) with the human landing catch (HLC) and Suna trap in a repeated Latin square design in two villages (Lengwe and Mwanza) on an irrigated sugar estate in southern Malawi. Over the course of 18 trapping nights, we caught 379 female *Anopheles*, the majority of which were identified as *An. arabiensis*. Across both villages, there was no detectable difference in *Anopheles* catch between the HDT compared with the HLC (RR = 0.85, $P = 0.508$). The overall sensitivity of the HLC was greater than the Suna trap regardless of mosquito density (Lengwe, $\alpha = 2.75$, 95% credible interval: 2.03–3.73; Mwanza, $\alpha = 3.38$, 95% credible interval: 1.50–9.30) whereas the sensitivity of the HDT was only greater than the Suna trap when mosquito numbers were high (Lengwe, $\alpha = 2.63$, 95% credible interval: 2.00–3.85). We conclude that the HDT is an effective sampling device for outdoor host seeking *An. arabiensis* in southern Malawi. The presence of *An. arabiensis* in irrigated lands during the dry season poses a challenge for ongoing indoor vector control efforts.

SPATIO-TEMPORAL CLUSTERS AND PATTERNS OF SPREAD OF DENGUE, CHIKUNGUNYA, AND ZIKA IN COLOMBIA

Laís P. Freitas[1], Mabel Carabali[1], Mengru Yuan[1], Gloria I. Jaramillo-Ramirez[2], Cesar G. Balanguera[2], Berta N. Restrepo[3], Kate Zinszer[1]

[1]Université de Montréal, Montreal, QC, Canada, [2]Universidad Cooperativa de Colombia, Villavicencio, Colombia, [3]Universidad CES, Medellín, Colombia

Colombia has one of the highest burdens of arboviruses in South America. The country was in a state of hyperendemicity between 2014 and 2016, with co-circulation of several *Aedes*-borne viruses, including a syndemic of dengue, chikungunya, and Zika in 2015. We analyzed the cases of dengue, chikungunya, and Zika notified in Colombia from January 2014 to December 2018 by municipality and week. The trajectory and velocity of spread was studied using trend surface analysis, and spatio-temporal high-risk clusters for each disease in separate and for the three diseases simultaneously (multivariate) were identified using Kulldorff's scan statistics. During the study period, there were 66,628, 77,345 and 74,793 cases of dengue, chikungunya, and Zika, respectively, in Colombia. The spread patterns for chikungunya and Zika were similar, although Zika's spread was accelerated. Both chikungunya and Zika mainly spread from the regions on the Atlantic coast and the south-west to the rest of the country. We identified 21, 16, and 13 spatio-temporal clusters of dengue, chikungunya and Zika, respectively, and, from the multivariate analysis, 20 spatio-temporal clusters, among which 7 were simultaneous for the three diseases. For all disease-specific analyses and the multivariate analysis, the most-likely cluster was identified in the south-western region of Colombia, including the Valle del Cauca department. The results further our understanding of emerging *Aedes*-borne diseases' trajectory in Colombia and provide useful information on the identified spatio-temporal disease-specific and multivariate clusters of dengue, chikungunya, and Zika, that can be used to target interventions. To our knowledge, this is the first time that the co-occurrence of all three diseases in Colombia was explored using multivariate scan statistics.

APPLICATION OF A SPATIALLY EXPLICIT SAMPLING DESIGN TO IDENTIFY HETEROGENEITIES IN THE DISTRIBUTION OF MOSQUITOES

Brigid J. Kemei[1], Daniel McDermott[2], Janet Midega[3], Seline Omondi[1], Maurice Ombok[1], Joseph Mwangangi[3], David Weetman[2], Luigi Sedda[4], Martin Donnelly[2], Eric Ochomo[1]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Department of Vector Biology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, United Kingdom, [3]Centre for Geographic Medicine Research, Kenya Medical Research Institute, Kilifi, Kenya, [4]Lancaster Ecology and Epidemiology Group, Lancaster Medical School, Lancaster University, United Kingdom

The quality of data collected in any entomology study is heavily reliant upon the sampling design. In Kenya, the Division for National Malaria Program uses health facility data to select three sub-counties within the County that have high, medium, and low transmission, and the surveillance teams then perform convenience sampling within the selected sub-counties. This means that harder-to-reach areas may never be sampled and the surveillance is likely to be focused within a small geographical area within the sub-County. This study reports on the practical application of a stratified lattice and close pair sampling design for evaluating the spatial distribution of mosquito abundance. Sampling was conducted in Kilifi County in the coastal region of Kenya. Thirty sampling points were selected across 3 predefined ecotypes. CDC light trap collections were made at 4 households at each sampling point fortnightly over 2 months. A spatial negative binomial GLMM of the *Anopheles funestus sl*, *An. gambiae s.l.* and *Culex* spp. abundance was conducted using the sdmTMB package in R and predicted abundance mapped across the study area. *An. funestus s.l* was the dominant malaria vector in the region followed by *An. gambiae s.l.* Modelling indicates the presence of spatial correlation in the sampled mosquito abundance and a significant association for the Anopheles spp. with proximity to freshwater sources. This relationship was not mirrored in the Culex spp. which showed relative ubiquity throughout the study region. The environmental stratification was not significant. In conclusion**,** the stratified inhibitory lattice with close pairs sampling design established a clear relationship with the two primary vector species and the proximity to water. The ability of the design to isolate this relationship and produce spatial prediction maps with a balanced number of locations over the study region allows for the tailoring of vector control efforts in this area.

CHECKMATE OR STALEMATE? MODELLING DENSITY-DEPENDENCE & ALLEE EFFECTS IN THE MALARIA VECTOR CONTROL ENDGAME

Andrea M. Kipingu[1], Daniel T. Haydon[2], Paul C.D Johnson[2], Samson S. Kiware[1], Mafalda Viana[2]

[1]Ifakara Health Institute, Dar ES Salaam, United Republic of Tanzania, [2]University of Glasgow, Glasgow, United Kingdom

Understanding the interplay between vector control and malaria mosquito population dynamics is critical to assess and improve vector control. Mosquito populations are regulated through a range of biotic and abiotic mechanisms, and among them, density-dependence is thought to be widespread. Density-dependence means per capita growth rate should be fastest when density is very low, for instance through competition for larval habitat that is alleviated as population size goes down. Although, an opposing scenario is also possible where small mosquito populations experience Allee effects*,* defined as positive density-dependence, in which per capita growth rate reduces as population declines. Here, we aim to identify the trade-offs between density-dependence and Allee effects, and how they might be impacted by interventions such as larvicides. Learning how to exploit this trade-off could make the difference between extinction or persistence (checkmate or stalemate). We developed a deterministic-stochastic simulation based on a stage-structured population model. The model follows a mosquito life cycle stages with life history traits such as adult and larval survival and fecundity defined as a function of density, larvicides and environmental variables. We included density-dependence as a predictor of larval stage and Allee effects as a predictor of adult mosquito fecundity rate. With density-dependence and Allee effects at levels that lead to a stable population, results indicate that there is at least 56% and 21% decline in average number of adult mosquitoes at a 100% and 50% coverage of larvicides respectively. However, if density-dependence increases by 50% and the intervention is short termed, the mosquito population bounces back to similar or higher levels than before. In contrast, if Allee effects are increased by only 36%, the population will decline 3 times faster. This indicates that density-dependence and Allee effects could be used to drive the population to extinction when used in combination to larvicides as an intervention.

0126

CHANGING SPECIES COMPOSITION OF POTENTIAL MALARIA VECTORS IN MEGHALAYA, NORTHEAST INDIA

Upasana Shyamsunder Singh[1], Preeti Acharya[2], Tulasi Karumuthil[2], Sonal Kale[2], Jonathan Huck[1], Tucker Gilman[1], Mark L. Wilson[3], Anne Kessler[4], Jane M. Carlton[4], Aparup Das[2], Sandra Albert[5], Catherine Walton[1]

[1]Department of Earth and Environmental Sciences, University of Manchester, Manchester, United Kingdom, [2]ICMR-National Institute of Research in Tribal Health, Jabalpur, India, [3]School of Public Health,

University of Michigan, Ann Arbor, MI, United States, [4]Department of Biology, New York University, New York, NY, United States, [5]Indian Institute of Public Health-Shillong, Shillong, India

Malaria in India is declining, in part due to use of long lasting insecticide treated nets (LLINs) and vector control. The north-eastern (NE) region of India contributes ~10% of the nation's malaria burden, with Meghalaya state specifically continuing to experience low-level endemicity and occasional seasonal epidemics. The important mosquito vectors in NE India have long been considered to be *Anopheles baimaii* and *An. minimus*, both associated with forest habitats. Local deforestation and increased rice growing, along with widespread LLIN use, may be changing vector species composition. Understanding if and how vector species composition is changing is critical to successful malaria control. In a biodiverse setting like Meghalaya, where >24 *Anopheles* mosquito species have been recorded, accurate morphological identification of all species is logistically challenging. To accurately determine *Anopheles* species richness in the West Khasi Hills (WKH) and West Jaintia Hills (WJH) districts, adult and larval mosquitoes were collected and identified using molecular methods of allele-specific PCR and cytochrome oxidase I DNA barcoding. In 14 villages across both districts, we identified high species richness; 19 species in total. Molecular findings indicated that *An. minimus* and *An. baimaii* were rare, while five other species (*An. maculatus*, *An. pseudowillmori*, *An. jeyporiensis*, *An. nitidus* and *An. peditaeniatus*) were abundant. *An. maculatus* was highly prevalent in WKH (39% of light trap collections) and *An. pseudowillmori* in WJH (45%). Larvae of these five species were found in rice fields suggesting that land cover change is influencing species composition change. Our analysis investigates how changing land cover may affect malaria risk, including assessment of the spatial relationship between mosquito host-seeking, malaria cases, and land cover categories. Results suggest that rice fields are contributing to the observed abundance of *An. maculatus* and *An. pseudowillmori* which could be playing a role in malaria transmission, either independently due to their high abundance, or in combination with *An. baimaii* and/or *An. minimus*.

0127

ELECTROPENETROGRAPHY FOR THE STUDY OF PROBING BEHAVIORS OF A DISEASE VECTOR MOSQUITO *CULEX TARSALIS* COQUILLETT (DIPTERA: CULICIDAE)

Anastasia M. W. Cooper[1], Dana N. Mitzel[2], Kristopher Silver[1]

[1]Kansas State University, Manhattan, KS, United States, [2]National Bio and Agro-Defense Facility, Manhattan, KS, United States

*Culex tarsalis*mosquitoes are capable of vectoring numerous pathogens affecting public andanimal health. Unfortunately, probing behaviors of mosquitoes are poorly understoodbecause they occur in opaque tissues. Electropenetrography (EPG) has thepotential to elucidate these behaviors by recording the electrical signalsgenerated during probing. We used an AC-DC EPG with variable input resistors(Ri levels) to construct a waveform library for *Cx. tarsalis* feeding onhuman hands. EPG waveforms representing different probe phases werecharacterized and defined by visual and video observations of biologicalactivities and analyzed for differences in appearance at four Ri levels and twocurrent types to identify electrical origins. The optimal settings for EPG recordingsof *Cx. tarsalis* probing on human hands was 150 millivolts of alternatingcurrent with 10^7 Ohms of resistance. Waveforms for *Cx. tarsalis*included those previously observed and associated with probing behaviors in *Aedesaegypti*: waveforms J (surface salivation), K (stylet penetration throughthe skin), L (type 1 and 2, search for a blood vessel/ingestion site), M (type1 and 2, ingestion) and N (an unknown behavior which may be a resting anddigestion phase before stylet withdrawal). However, we also observed additionalvariations in the waveforms that are not exhibited by *Ae. aegypti* thatwe named type 3 L waves, type 3 and 4 M waves, and type 1 and 2 N waves. Thisinvestigation enhances our understanding of mosquito probing behaviors. Weexpect it to facilitate future pathogen acquisition and transmission studiesand help identify new pest and disease management targets.

0128

MALARIA VECTOR MOSQUITOES LIVE LONGER AND LAY MORE EGGS AROUND IRRIGATION SCHEMES IN ETHIOPIA

Dawit Hawaria Logita[1], Solomon Kibret[2], Delenasaw Yewhalaw[3], Guiyun Yan[2]

[1]Yirgalem Hospital Medical College, Yirgalem, Ethiopia, [2]University of California at Irvine, Irvine, CA, United States, [3]Jimma University, Jimma, Ethiopia

Water resource development projects like irrigated agriculture are key to ensuring economic growth and food security in Africa. However, such development projects cause environmental modification that could potentially favor vector-borne diseases transmission like malaria. This study aimed at assessing the effects of environmental modification due to irrigation practices on malaria vector mosquito development and survivorship in Ethiopia. The study was conducted in two agroecosystems, irrigated and non-irrigated areas, in western Ethiopia. Monthly larval surveys were conducted between 2017 and 2020. Life-table experiments were done to examine the effect of environmental modification on survivorship and development of both immature and adults *An. arabiensis.* Habitat diversity, larval abundance, pupation rate, development time of immatures, and adult longevity and fecundity were compared between the two agroecosystems. The irrigated agroecosystem was significantly associated with larval anopheline occurrence. The estimated mean survival time of female *Anopheles arabiensis* in the irrigated and non-irrigated areas was 37.9 and 31.3 days, respectively. The study found that fecundity of *An. arabienis*, was 96.2% higher in the irrigated agroecosystem than in the non-irrigated area. The findings of this study underscore that irrigation in semi-arid areas of Ethiopia increases the survival and fecundity of the major malaria vector, *An. arabiensis*.

0129

THE ORIGIN OF *AEDES ALBOPICTUS* INVADED MOZAMBIQUE

Sarina Yamashita[1], Kyoko Futami[1], Nelson Cuamba[2], Noboru Minakawa[1]

[1]Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, [2]National Malaria Control Programme, Maputo, Mozambique

Asian tiger mosquito, *Aedes albopictus*, is known as a main vector of various arboviruses. This species was originally described from Asia, but it has spread to several non-native geographical regions through the international movements of people and commodities. In Africa, although this mosquito has already established in West Africa, its established population had not been reported from the continental part of East Africa until it was confirmed in an urban neighbourhood of Maputo City in 2015. Since *Ae. albopictus* occurs in Madagascar, we hypothesized that the Mozambique population was introduced from the island. To confirm this, we identified the origin and invasion pathways with mitochondrial gene cytochrome c oxidase subunit 1 (CO1). The mosquito specimens were collected with ovitraps in Matola, a city adjacent to Maputo, Mozambique. We compared the CO1 gene sequences of the specimens with those from Madagascar and other countries that were available in GenBank. The genetic analysis revealed a total aligned length of 1,320 bp in which 7 variable sites were observed and 8 haplotypes were determined. One of the haplotypes was new and the other 7 haplotypes matched up with those reported from Malaysia. The population genetic structure was also similar to those found in Singapore and Hangzhou (a tropical region of China). These results indicate that the Mozambique population of *Ae. albopictus* was not originated in Madagascar, but in Southeast Asia.

0130

EFFECT OF CO-INFECTIONS ON THE TRANSMISSION OF CHIKUNGUNYA, MAYARO AND UNA VIRUSES BY *AEDES AEGYPTI* MOSQUITOES

Tessa Visser[1], Haidong Wang[2], Sandra Abbo[3], Chantal Vogels[4], Gorben Pijlman[3], Constantianus Koenraadt[1]

[1]Laboratory of Entomology, Department of Plant Sciences, Wageningen University & Research, Wageningen, Netherlands, [2]School of Public Health and Emergency Management, South University of Science and Technology, Shenzhen, China, [3]Laboratory of Virology, Department of Plant Sciences, Wageningen University & Research, Wageningen, Netherlands, [4]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States

Chikungunya (CHIKV), Mayaro (MAYV) and Una (UNAV) are mosquito-borne alphaviruses that are currently co-circulating in Latin America. Each of these viruses shares its geographical and ecological niche with the mosquito vectors that can transmit it. CHIKV is mainly transmitted by the urban yellow fever mosquito *Aedes aegypti.* MAYV is mainly maintained in a sylvatic cycle between *Haemagogus* spp. mosquitoes and several vertebrates, but studies have shown that MAYV can also be transmitted by *Ae. aegypti*. UNAV is very closely related to MAYV and CHIKV, and although the vector species are unknown, it has been isolated from *Aedes* spp. Despite the potential challenge to public health, we fundamentally know little about co-infections in humans and mosquitoes. In particular, we do not know the impact of alphavirus co-infections on transmission by *Ae. aegypti*. We investigated the vector competence of *Ae. aegypti* co-infected with CHIKV, MAYV and UNAV. The mosquitoes were given an infectious bloodmeal in our BSL-3 facility and were incubated for 10 days at 28ºC, 70% relative humidity. After RNA extractions on collected mosquito bodies and saliva, the presence and relative RNA quantity of each of the viruses in co-infected mosquitoes was determined by qPCR. We show that UNAV can be experimentally transmitted by *Ae. aegypti*. Experiments exposing the mosquitoes to a single virus show a difference in infection rates (57-76%) but not in transmission rates (11-13%). Exposing the mosquitoes to all possible combinations of the three viruses with equal virus titers increased infection rates (67-97%). Co-infections do, however, not seem to affect transmission rates (12-20%). Further analysis of the qPCR results will elucidate if one of the viruses is more dominant than the others. Vector competence is only one of the factors that contributes to transmission potential. To determine how alphavirus infection can impact the mosquito's host-seeking behaviour, we will study the response of virus-infected *Ae. aegypti* to human odours in an olfactometer. Altogether our results contribute to our knowledge on the vectorial capacity of *Ae. aegypti* for alphavirus transmission.

0131

ECOLOGICAL DETERMINANTS AND RECORDED DISTRIBUTION OF *ANOPHELES STEPHENSI* IN ETHIOPIA

Meshesha Balkew[1], Dereje Dengela[1], Gedeon Yohannes[1], Ephrem Abiy[1], Amha Worku[1], Dejene Getachew[2], Solomon Yared[3], Peter Mumba[4], Sheleme Chibsa[4], Eric Tongren[5], Melissa Yoshimizu[6], Aklilu Seyoum[7], Cecilia Flatley[7], Sarah Zohdy[8], Seth R. Irish[8]

[1]PMI VectorLink Project, Abt Associates, Addis Ababa, Ethiopia, [2]Dire Dawa University, Dire Dawa, Ethiopia, [3]Jigjiga University, Jigjiga, Ethiopia, [4]U.S. President's Malaria Initiative, USAID, Addis Ababa, Ethiopia, [5]U.S. President's Malaria Initiative, US Centers for Disease Control and Prevention, Addis Ababa, Ethiopia, [6]U.S. President's Malaria Initiative, USAID, Washington, DC, United States, [7]Abt Associates, PMI VectorLink Project, Rockville, MD, United States, [8]U.S. President's Malaria Initiative, Entomology Branch, US Centers for Disease Control and Prevention, Atlanta, GA, United States

Entomological surveillance conducted on *Anopheles stephensi* from August 2018 to December 2020 in Ethiopia enabled mapping of the extent of detection sites, data on sporozoite infections, blood meal sources & susceptibility to insecticides. In 2021, monitoring was expanded to previously uninspected sites to characterize breeding habitats & assess larval indices. These data serve as a baseline before a planned larviciding intervention. A site was considered positive whenever larvae were found, reared to adults & identified to the species. Larval density, container indices, relative breeding indices & adults' susceptibility to insecticides were determined. *Anopheles stephensi* was detected in 22 urban & 23 peri-urban/rural sites in Afar, Amhara, Dire Dawa, Oromia, & Somali regions. In these locations, *Anopheles stephensi* was found to breed in artificial containers such as cisterns, covered *birkas* (household water storage), water tanks & smaller vessels. Natural breeding habitats such as puddles, rain pools, rock pools & hoof prints were also found with *An. stephensi* larvae in Dire Dawa. In four towns in the eastern part of the country, concrete cisterns comprised 49-79% of all containers, whereas *birkas* were mostly found in the Somali region & comprised up to 77% of the breeding habitats. Adults were mainly caught in animal sheds. The water in breeding containers was stagnant, clean rain/tap water, sometimes with algal growth. The mean larval density ranged from 1.5 to 3.0 larvae/dip/day. The relative breeding index was 50-80%, while the relative habitat index was 0.8-1.0. *Aedes aegypti* larvae was found in 40% of containers positive for *An. stephensi*. Populations of *An. stephensi* were susceptible (> 98% mortality) to chlorfenapyr & clothianidin but resistant (<90% mortality) to deltamethrin, permethrin, alpha-cypermethrin, pirimiphos-methyl, propoxur, & bendiocarb. In conclusion, *An. stephensi* is widely distributed in Ethiopia, where it exists, prefers to breed in container habitats. Further surveillance should continue to elucidate the extent of distribution & if additional natural breeding habitats support larval development.

0132

HIGHER INFESTATION RATES OF THE VECTOR *AEDES AEGYPTI* IN RURAL AREAS THAN IN URBAN AREAS IN MANAGUA, NICARAGUA

Harold Suazo Laguna[1], José Victor Zambrana[1], Jacqueline Mojica Diaz[1], Maria Mercedes López Quintero[1], Jorge Ruiz Salinas[1], Kathyrn Hacker[2], Aubree Gordon[2], Eva Harris[3], **Josefina Coloma**[3]

[1]Sustainable Sciences Institute, Managua, Nicaragua, [2]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [3]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

Surveillance and control of *Aedes aegypti*, primarily responsible for the transmission of dengue, chikungunya, and Zika viruses, continue to be a public health priority in many countries worldwide. We initiated a cohort study of 2,134 participants in Managua, Nicaragua, to investigate arboviral infections and disease across a gradient of urbanicity. To create a spatially representative sampling design, we used satellite imagery to define the sampling area in rural and urban areas in District III using impervious surfaces (man-made structural features) as a proxy for potentially inhabited sampling locations, which were then selected randomly, taking into account close-pair points and allowances for misclassification and inaccessibility. Two entomological surveys were conducted in the context of this A2CARES study. The first measured larval and pupal stages in 10% of the dwellings (167 households in rural and 470 in urban study areas) using a systematic sampling design. The second targeted 50% of the 1,000 cohort houses (250 households in rural and 250 in urban areas) selected with a random spatial distribution method. We measured multiple entomological indices including Breteau, pupae per 100 persons (PPP) or per 100 containers, and adult mosquito indices. The first survey yielded Breteau indices of 35.3 (95% Confidence Interval 26.9-45.6) in rural vs. 19.6 (15.8-24.2) in urban areas; p=0.0003, and PPP indices of 13.8 (11.1-16.8) in rural vs. 9.6 (8.4-11-0) in urban areas; p=0.0034; while in urban areas, the container productivity was significantly higher. In the second survey, the PPP index was 24.5 (21.7-27.6) in rural and 4.5 (3.4-5.8) in urban areas; p=0.0003. With respect to the mean numbers of adult *Ae. aegypti* captured per 100 homes, we found 32.0 (25.4-39.8) in rural vs. 16.0 (11.4-21.8) in urban areas (p<0.0001). Thus, contrary

to assumptions, we found higher infestation rates of *Ae. aegypti* in rural areas compared to urban areas using different sampling methodologies and multiple entomological indices.

0133

EVALUATION OF DIFFERENT TRAPPING METHODS FOR THE COLLECTION OF *ANOPHELES* MOSQUITOES IN WESTERN KENYA

Jackline Jeruto Kosgei[1], Seline Omondi[1], Vincent Moshi[1], Daniel McDermott[2], Martin Donnelly[2], Collins Ouma[3], John E. Gimnig[4], Bernard Abong'o[1], Eric Ochomo[1]

[1]Kenya Medical Research Institute (KEMRI), Kisian station, Kisumu city, Kenya, Kisumu, Kenya, [2]Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, United Kingdom, Liverpool, United Kingdom, [3]Maseno University, Maseno, Kenya, Maseno, Kenya, [4]Centres for Disease Control and Prevention, Atlanta, Georgia, United States of America, Atlanta, GA, United States

Entomological surveillance is essential for monitoring the impact of control tools and is mostly conducted using human landing catches (HLCS) or CDC-light traps (CDC-LT). HLCs may expose collectors to potentially infectious mosquito bites. To assess the optimal approach for mosquito surveillance for a large-scale trial of attractive targeted sugar baits, we compared five trapping methods indoors and outdoors in western Kenya. Five mosquito sampling methods—CDC-L), UV light traps (UV-LT), aspiration, HLC, and malaise trapping were evaluated in villages of Asembo, in Siaya County, western Kenya between July and September 2020. CDC-LTs, UV-LTs, and HLCs were conducted in three locations of the same compound (inside houses; outside 10 meters from the house; and outside 10 meters from the compound boundary). Collections were rotated through houses following a five-by-five Latin-square design. Mosquito densities, species abundance, and sporozoite infectivity rates were compared across all sampling methods. Data analysis was performed using R statistics software version 4.1.2. A total of 5483 *Anopheles* mosquitoes were sampled from 868 trapping efforts: 246 CDC-LTs, 237 UV-LTs, 223 aspirations, 148 HLCs, and 14 malaise traps. *Anopheles funestus* constituted 3824, (69.74%) of the sampled *Anopheles* mosquitoes. Compared to HLC, indoor aspiration captured highest number of *An. funestus,* mean=8.82 (RR =12.74, 95% CI 6.02-24.58, P <0.001) followed by indoor UV-LT, mean=4.26, (RR= 5.13, 95% CI 2.80-9.39, P <0.001) and indoor CDC-LT mean=2.30 (RR= 3.00, 95% CI 1.63-5.53, P <0.001). Similarly, outdoor UV-LT and CDC-LT collected a higher number of *Anopheles* mosquitoes across all species when compared to outdoor HLC. Hourly biting rates in UV-LT and CDC-LT indicated different peaks compared to HLC. *An. funestus* were primarily caught indoors. *An. arabiensis* and *An. coustani* were mostly collected outdoors with UV-LTs. The UV-LT and CDC-LT were superior to HLC both indoors and outdoors. Differences in hourly biting by different collection methods indicate the need to further investigate the behaviour of *An. funestus*.

0134

FACTORS ASSOCIATED WITH QUALITY OF LIFE IN CHRONIC CHIKUNGUNYA RHEUMATISM IN GUADELOUPE

Fabrice Simon[1], Rémi Bossy[2], Anne-Laurence Demoux[2], Julien Dezaunay[3], Nadia Rugard[3], Denise Federico[4], Giulia Calusi[4], **Hugh Watson**[5], Franciane Gane-Troplent[3]

[1]Emerging Virus Unit, Aix-Marseille University, Marseille, France, [2]Aix-Marseille University, Marseille, France, [3]Université des Antilles, Guadeloupe, France, [4]Aptuit (Verona) Srl, Verona, Italy, [5]Evotec ID, Lyon, France

Chronic chikungunya disease is associated with a poor quality of life and symptoms not restricted to the musculoskeletal system. A cohort of patients with chronic chikungunya disease in Guadeloupe were evaluated in order to identify the main factors determining quality of life. Sixty-one patients were followed up a mean of 36 months after chikungunya infection. Patients underwent comprehensive examination for musculoskeletal involvement, assessment of subjective symptoms, and the impact on mood, physical activity and quality of life (SF12). Spearman correlations and multivariate regression analysis were performed using a multiple imputations technique, for handling missing data, followed by stepwise procedure to determine the main predictors of quality of life. Patients had extensive musculoskeletal involvement shown by high scores for the number of tender joints (9±4) and stiff joints (5±4). Patient symptom scales (% ±SD) revealed high scores for pain (62% ±24), stiffness (76% ±17) and fatigue (57% ±24), while SF12 physical and mental component scores showed a poor overall health-related quality of life. Measures of joint pain, stiffness impact and inflammation were found to contribute to impaired quality of life scores in 81%, 48% and 30% of the regression model iterations, respectively. In addition, fatigue and disturbed sleep appeared to be important predictors for physical aspects of quality of life, appearing in 39% and 100% of model iterations, respectively. The emergence of anxiodepressive syndromes post-chikungunya infection was also strongly associated with both physical and mental component scores of SF12. These data confirm that musculoskeletal symptoms are not the only determinants of quality of life in chronic chikungunya disease. Follow-up of patients should include assessment and management of fatigue, poor sleep quality and anxiodepressive syndromes.

0135

GENETIC DETERMINANTS OF A CHIKUNGUYNA VIRUS OUTBREAK IN NORTHEAST BRAZIL

Chilinh Nguyen[1], Gregory D. Ebel[1], Ernesto TA Marques[2], Cynthia Braga[3], Thomas Jaenisch[4], Brian D. Foy[1], Tereza Magalhaes[5]

[1]Center for Vector-Borne Infectious Disease, Colorado State University, Fort Collins, CO, United States, [2]Infectious Disease and Microbiology Department, University of Pittsburgh, Pittsburgh, PA, United States, [3]Department of Parasitology, Instituto Aggeu Magalhães, Fundação Oswaldo Cruz, Recife, Brazil, [4]Center for Global Health, Colorado School of Public Health, Aurora, CO, United States, [5]Department of Preventive and Social Medicine, School of Medicine, Universidade Federal da Bahia, Salvador, Brazil

Chikungunya virus (CHIKV) is a virus transmitted by *Aedes* mosquitoes that causes significant morbidity in humans. The heterogenous transmission dynamics and epidemiology of CHIKV infections seen in different locations are thought to be associated with complex interactions of multiple genetic, ecological, and social determinants that are poorly understood. Understanding these determinants on a fine, local scale is critical to better predicting and controlling future CHIKV outbreaks. We aim to understand viral genetic determinants associated with transmission and human disease across a 1-year outbreak period in an urban area in northeast Brazil that has been a hotspot for arbovirus transmission. We sampled blood from chikungunya disease patients over the duration of this CHIKV outbreak from a 100 km^2-municipality within the Recife Metropolitan Region (RMR) that ultimately infected more than half of the city. From this cohort, we are in the process of sequencing CHIKV from 132 serum samples from well-characterized clinical cases. This data set offers us the opportunity to explore key unanswered questions regarding the underlying genetic factors that contributed to this intense and prolonged CHIKV outbreak in Brazil. We plan to identify the CHIKV genotypes circulating within the study population during the outbreak period and their prevalence over time. We will characterize the evolutionary dynamics of the genotype(s) as the virus first adapted to the region and as selective pressure from increasing population immunity to CHIKV occurred over time. We will also determine associations of viral genotypes or genetic variants with differential clinical symptoms of infected patients. We expect that more than one genotype was circulating during this outbreak, that we will see evidence of CHIKV evolution/adaptation over the span of the outbreak and that clinical symptoms of our cohort will associate with certain genotypes or virus variants. These data will contribute to a better understanding of CHIKV transmission dynamics and pathogenesis.

0136

SEROSURVEILLANCE OF CHIKUNGUNYA INFECTIONS AMONG U.S. MILITARY PERSONNEL DEPLOYING IN THE AMERICAS, 2013 - 2020

Simon Pollett[1], Charlotte Lanteri[1], Brett Forshey[2], Stephanie Trefry[3], Evandro Winkelmann[3], Farooq Nasar[3], Michael McCracken[3], Kevin Taylor[2], Sithembile Mabila[2], Carlos Morales[1], David Tribble[1], Timothy H. Burgess[1], Gregory Gromowski[3]

[1]Infectious Disease Clinical Research Program, Department of Preventive Medicine, Uniformed Services University, Bethesda, MD, United States, [2]Armed Forces Health Surveillance Division, Silver Spring, MD, United States, [3]Viral Diseases Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Examining the risk and risk factors of chikungunya virus (CHIKV) infection during military deployment is important for CHIKV prevention efforts in any population. We leveraged the U.S. Department of Defense Serum Repository (DoDSR) to identify post-deployment CHIKV seropositivity in U.S. Military personnel deployed in the Americas during and after the CHIKV epidemic. The DoDSR comprises > 60 million sera from U.S. military members undergoing routine HIV screening . We selected DoDSR sera collected after n = 1500 deployments to Belize (n = 205), Colombia (n = 250), Curacao (n = 100), El Salvador (n = 225), Honduras (n = 250), Guatemala (n = 220), and Puerto Rico (n = 250) between 2013-2020. Post-deployment sera were screened for anti-CHIKV antibodies with a Vero cell-based microPRNT80, and confirmation using a CHIKV PRNT50 and a CHIKV/Mayaro Virus (MAYV) PRNT50 ratio ≥ 4. We analyzed 1500 deployments (including n = 13 individuals with > 1 deployment) with a median deployment duration of 0.5 years (IQR 0.25 - 0.75 years, range < 0.25 - to 4.5 years). Screening CHIKV microPRNT80 post-deployment sera positivity frequency was 25/1500 (1.7%). 18 (1.2%) met a CHIKV/MAYV PRNT50 ratio threshold to confirm CHIKV seropositivity. No sera met positivity criteria for MAYV infection, although n = 7 CHIKV screen-positive sera were equivocal for both MAYV and CHIKV. When constrained to deployments overlapping with the peak CHIKV Americas epidemic period (2014-2015), CHIKV seropositivity frequency remained low (0.9%). Post-deployment CHIKV seropositivity correlated with deployment length (p = 0.0001). Post-deployment seropositivity frequencies by country of deployment were: Belize (0/205, 0%), Colombia (0/250, 0%), Curacao (0/100, 0%), El Salvador (0/225, 0%), Guatemala (1/220, 0.5%), Honduras (3/250, 1.2%), and Puerto Rico (14/250, 5.6%). In conclusion**,** among those deploying to CHIKV endemic countries in the Americas between 2013-2020, post-deployment CHIKV seropositivity was low and correlated with deployment length. This may reflect effective vector avoidance or heterogeneity in CHIKV exposure in deployed personnel.

0137

ENDEMIC TRANSMISSION OF CHIKUNGUNYA VIRUS IN SOUTHERN THAILAND

Kathryn B. Anderson[1], Aaron Farmer[2], Darunee Buddhari[2], Sarunyou Chusri[3], Taweewun Hunsawong[2], Butsaya Thaisomboonsuk[2], Tippa Wongstitwilairoong[2], Chonticha Klungthong[2], Piyawan Chinnawirotpisan[2], Stefan Fernandez[2]

[1]SUNY Upstate Medical University, Syracuse, NY, United States, [2]Armed Forces Research Institute for Medical Sciences, Bangkok, Thailand, [3]Prince of Songkhla University, Songkhla, Thailand

Chikungunya virus (CHIKV) infections are distributed across the globe, causing significant and, often, lasting morbidity. CHIKV vaccines are in development, but their evaluation is limited by the unpredictability of CHIKV transmission, which classically manifests as explosive epidemics separated by variable interepidemic periods. A passive surveillance study for undifferentiated febrile illness was established in southern Thailand in 2012 and is ongoing. Among 1473 individuals with paired acute and convalescent specimens, 391 (26.5%) had molecular or serological evidence of acute CHIKV infection. The proportions of participants confirmed to have CHIKV infection differed by year, being highest during epidemic periods (39.2% in 2018-2019, corresponding to a large regional CHIKV outbreak, compared to 18.9% in the inter-epidemic period 2012-2017). The highest burden of CHIKV infection was observed in younger adults, which may reflect age-related differences in exposure patterns and / or differences in the frequencies and manifestations of CHIKV-related disease. In phylogenetic analysis, the large epidemic of 2018-2019 in Thailand represented monophyletic expansion of a clade that was first identified in Africa, South Asia, and Singapore in 2015. Thai sequences from the inter-epidemic period were interspersed with those from other South and Southeast Asian CHIKV, suggesting frequent introductions and regional mixing. These data indicate possible stable endemicity of CHIKV in the study area, though additional studies are needed to confirm these findings and to discern whether this persistence reflects widespread, low-level transmission or migrating bursts of focal epidemic activity. For episodic pathogens such as CHIKV, intensified detection and study of endemic hot spots may hold the key to proactive preparation and countermeasure development, rather than reactive attempts at mitigation, for future epidemics.

0138

LONGITUDINAL AND TRANSVERSAL STUDIES OF CHIKV SEROPREVALENCE IN SOUTHEAST BRAZIL REVEALS A CRYPTIC CIRCULATION OF THE VIRUS

Nathalia Zini[1], Matheus Ávila[2], Maisa Carla Parra[2], Livia Sacchetto Pengo[1], Andreia Negri[3], Bruno Henrique Milhim[1], Rafael Alves da Silva[1], Gislaine Celestino da Silva[1], Alice Freitas Versiani[4], Ana Carolina Bernardes Terzian[5], Cassia Fernanda Estofolete[1], Nikolaus Vasilaskis[6], Mauricio Lacerda Nogueira[1]

[1]Laboratório de Pesquisas em Virologia, Departamento de Doenças Dermatológicas, Infecciosas e Parasitárias, Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil, [2] Laboratório de Pesquisas em Virologia, Departamento de Doenças Dermatológicas, Infecciosas e Parasitárias, Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil, [3]Vigilância Epidemiológica Municipal, São José do Rio Preto, São José do Rio Preto, Brazil, [4]Department of Pathology, University of Texas Medical Branch, Galveston, Texas, U.S.A., São José do Rio Preto, Brazil, [5]Instituto René Rachou, Fundação Osvaldo Cruz, Belo Horizonte, Minas Gerais, Brazil., São José do Rio Preto, Brazil, [6]Department of Pathology, University of Texas Medical Branch, São José do Rio Preto, Brazil

Chikungunya vírus (CHIKV) and Mayaro vírus (MAYV) are arthropod-borne viroses of Alphaviruses genus transmitted by Aedes sp. genus mosquitões. In 2015 CHIKV was the first detected in São José do Rio Preto (SJdRP) and in the period between 2015-2020 the surveillance program notified a total 463 suspect cases and 41 confirmed cases in the city. The study aimed to investigate the presence of CHIKV antibodies in a cohort study participants (a 4 year follow-up of 341 subjects) and in the samples from a panel from the arboviruses surveillance program of the city during a dengue outbreak in 2019. We analyzed 341 serum paired samples of the cohort study (2015-2019), and 497 dengue-negative samples (2019) of a dengue outbreak using anti-CHIKV IgM/IgG by ELISA. After that, equivocal and positive samples in ELISA were confirmed by Plaque Reduction Neutralization Test (PRNT80), showing low cross reactivity with MAYV and a low prevalence of MAYV in southeast Brazil. Demographics data were associated with serological results and analyzed. A positive sample by Rt-qPCR to CHIKV was sequenced and subsequently submitted to a phylogenetic analysis. The total prevalence of anti-CHIKV IgM/IgG positive was 7.9% and 2.3% in the cohort study and 4.4% and 8.9% in samples from dengue-suspects subjects. During the cohort study (4 year), the incidence was 20.6/1,000 habitants and the attack rate was 2.1%. The phylogenetic analisys identified that the genotype CHIKV present in the municipally was the ECSA lineage, wich was associated with outbreaks in our country. Using both a longitudinal cohort and transversal studies the data showed a cryptic circulation of CHIKV the data showed a cryptic circulation of CHIKV in SJdRP, since no epidemic associated to this vírus since its introduction in 2015, as seen in most places in the world. This data reinforces the importance of arboviruses surveillance and especially in

the contexto of a new arboviruses introduction in a region wich can lead to na outbreak due to the know emerging and epidemic potential of the vírus.

0139

ALPHAVIRUS SEROPOSITIVITY IN ACUTE FEBRILE PATIENTS DURING A DENGUE OUTBREAK IN AN ARBOVIRUS ENDEMIC AREA IN PERU

Francesca Falconi-Agapito[1], Xiomara Merino[1], Fiorella Torres[2], Connie Fernández[3], Kevin K. Ariën[4], Michael Talledo[1]

[1]Institute of Tropical Medicine Alexander von Humboldt, Lima, Peru, [2]Hospital Santa Gema Yurimaguas, Yurimaguas, Peru, [3]Hospital Santa Gema Yurimaguas, Lima, Peru, [4]Institute of Tropical Medicine Antwerp, Antwerp, Belgium

The Peruvian Amazon is endemic for different arthropod-borne viruses (arboviruses) mainly those transmitted by mosquitos. Yearly outbreaks and/or epidemics are reported for which the main etiological agent is dengue virus (DENV), followed by the flaviviruses Zika (ZIKV), and yellow fever, and the alphaviruses chikungunya (CHIKV) and mayaro (MAYV). Despite febrile patients (FPs) present with nonspecific symptoms early in the acute phase of the disease, the simultaneous screening of arboviruses is poorly evaluated, and then the co-infection or prevalence of less-frequent arboviruses is generally missed. CHIKV is currently the most prevalent alphavirus, however the circulation of the antigenically related virus MAYV pose a problem for serodiagnosis, similar to the one described for flaviviruses. In this study, we evaluated the presence of the antigenically-related alphaviruses CHIKV and MAYV in 148 acute serum samples from dengue-suspected cases during a DENV outbreak in Yurimaguas, an arboviral endemic city at the Peruvian Amazon, between 2018 and 2019. Viral RNA was evaluated using a multiplex RT-PCR for the detection of DENV, ZIKV and CHIKV, while IgM and IgG antibodies (Abs) were assessed using ELISA tests from Euroimmun for DENV, ZIKV, CHIKV and MAYV. By using RT-PCR, DENV was detected in 51.4% (76/148) of patients, while all samples were negative to ZIKV and CHIKV. The identification of MAYV by RT-PCR is under evaluation. Higher positivity rates were observed for IgG Abs in comparison to IgM in the ELISA assays, thus for DENV 79.1% vs 29.7%, for ZIKV 43.2% vs 2.7%, for CHIKV 24.3% vs 7.4% and for MAYV 29.1% vs 6.1% of patients were positive for IgG and IgM respectively. Three FPs were simultaneously positive to CHIKV and MAYV for IgM, while 29 were positive for CHIKV and MAYV for IgG. These findings highlight the need (i) to further investigate the presence of possible arboviral co-infections in FPs and also (ii) to assess the potential cross-reactivity of Abs raised against related alphaviruses such as CHIKV and MAYV in areas with reported co-circulation of different arboviruses and their implications in the diagnosis and management of FPs.

0140

THE CHIKUNGUNYA VIRUS: A REEMERGING CAUSE OF ACUTE FEBRILE ILLNESS IN THE HIGH JUNGLE OF NORTHERN PERU

Miguel A. Aguilar Luis[1], Yordi Tarazona-Castro[2], Lucinda Troyes-Rivera[3], Wilmer Silva-Caso[1], Johanna Martins-Luna[2], Victor Zavaleta-Gavidia[4], Felipe Cabellos-Altamirano[3], Hugo Carrillo-Ng[1], Luis J. del Valle[5], Sungmin Kym[6], Sebastian Miranda-Maravi[2], Saul Levy-Blitchtein[7], Juana Del Valle-Mendoza[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Instituto de Investigación Nutricional, Lima, Peru, [3]Dirección Subregional de Salud de Jaén, Ministerio de Salud, Cajamarca, Peru, [4]Dirección Regional de Salud Cajamarca, Ministerio de Salud, Cajamarca, Peru, [5]Universitat Politècnica de Catalunya, Barcelona, Peru, [6]Chungnam National University School of Medicine, Daejeon, Republic of Korea, [7]Vall d'Hebron Hospital Universitari, Barcelona, Spain

The Chikungunya virus (CHIKV) is an emerging arthropod-borne virus (arbovirus) that causes undifferentiated acute febrile illness in Peru. We performed a study to identify the prevalence of CHIKV in febrile patients. A cross sectional study was conducted in the province of Jaen, Cajamarca's state, located in the high jungle of northern Peru. Patients attending primary care health centers within Cajamarca's Regional Health Direction were enrolled between June 2020 through June 2021. Patients were included with a acute febrile illness (AFI). Serum sample collection was performed on all patients and the diagnosis of CHIKV was performed using real-time RT-PCR and detection of IgM antibodies by ELISA assay. A total of 1047 patients with AFI were enrolled between June 2020 and June 2021. Identification of CHIKV was carried out in 130 patients (12.42%), of which 84 (8.02%) were diagnosed by RT-PCR, 42 (4.01%) by IgM ELISA detection and 4 (0.38%). by both assays. Most of the patients with CHIKV infection corresponded to the 18-39 years old (46.92%), followed by the 40-59 years old (23.85%) and those with 60 years or older (12.31%). Also, a greater proportion of female patients was identified (53.07%). The most common clinical symptoms in the whole study population were headache (85.67%), myalgias (71.35%) and arthralgias (64.76%). In the case of patients with CHIKV the most common symptoms were headache (84.62%), myalgias (70.77%) and arthralgias (64.62%). Most positive cases for CHIKV occurred during the months of May (23.08%), March (20.00%) and February (13.85%) of 2021. In conclusion, we report a considerable frequency of CHIKV infections in patients with AFI from the high jungle in northern Peru. These findings should raise awareness that CHIKV is a pathogen with continuous transmission in different regions of Peru. Epidemiological surveillance should be strengthened with reliable diagnostic techniques, given that clinical symptoms may be nonspecific.

0141

DETECTION OF SARS-COV-2 ANTIBODIES IN FEBRILE PATIENTS FROM AN ENDEMIC REGION OF DENGUE AND CHIKUNGUNYA IN PERU

Yordi Tarazona-Castro[1], Lucinda Troyes-Rivera[2], Johanna Martins-Luna[1], Felipe Cabellos-Altamirano[2], **Miguel Angel Aguilar-Luis**[3], Hugo Carrillo-Ng[1], Luis J. del Valle[4], Sungmin Kym[5], Sebastian Miranda-Maravi[1], Wilmer Silva-Caso[3], Saul Levy-Blitchtein[6], Juana M. del Valle-Mendoza[3]

[1]Instituto de Investigación Nutricional, Lima, Peru, [2]Dirección Subregional de Salud de Jaén, Ministerio de Salud, Jaen, Peru, [3]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [4]Universitat Politècnica de Catalunya, Barcelona, Spain, [5]Chungnam National University School of Medicine, Daejeon, Republic of Korea, [6]Vall d'Hebron Hospital Universitari, Barcelona, Spain

The rapid expansion of the novel SARS-CoV-2 virus has raised serious public health concerns due to the possibility of misdiagnosis in regions where arboviral diseases are endemic. We performed the first study in northern Peru to describe the detection of SARS-CoV-2 IgM antibodies in febrile patients with a suspected diagnosis of dengue and chikungunya fever. A consecutive cross-sectional study was performed in febrile patients attending primary healthcare centers from April 2020 through March 2021. Patients enrolled underwent serum sample collection for the molecular and serological detection of DENV and CHIKV. Also, serological detection of IgM antibodies against SARS-CoV-2 was performed. 464 patients were included during the study period, of which (40.51%) were positive for one pathogen, meanwhile (6.90%) presented co-infections between 2 or more pathogens. Most patients with monoinfections were positive for SARS-CoV-2 IgM with (73.40%), followed by DENV 18.09% and CHIKV (8.51%). The most frequent co-infection was DENV + SARS-CoV-2 with (65.63%), followed by DENV + CHIKV and DENV + CHIKV + SARS-CoV-2, both with (12.50%). The presence of polyarthralgias in hands (43.75%, $p<0.01$) and feet (31.25%, $p=0.05$) were more frequently reported in patients with CHIKV monoinfection. Also, conjunctivitis was more common in patients positive for SARS-CoV-2 IgM (11.45%, $p<0.01$). The rest of the symptoms were similar among all the study groups. SARS-CoV-2 IgM antibodies were frequently detected in acute sera from febrile patients with a clinical suspicion of arboviral disease. The presence of polyarthralgias in hands and feet may be suggestive of CHIKV infection.

These results reaffirm the need to consider SARS-CoV-2 infection as a main differential diagnosis of acute febrile illness in arboviruses endemic areas, as well as to consider co-infections between these pathogens.

0142

LONGITUDINAL ANALYSIS OF PLATELET INDICES AND RED-CELL DISTRIBUTION WIDTH AND ITS CORRELATION WITH THROMBOCYTOPENIA IN DENGUE PATIENTS: A CASE-CONTROL STUDY

Muhammad Sohaib Asghar[1], Muhammad Junaid Tahir[2], Farah Yasmin[1], Najeebullah Chughtai[3], Syed Jawad Haider Kazmi[3], Rabail Yaseen[1]

[1]Dow University of Health Sciences, Karachi, Pakistan, [2]Lahore General Hospital, Lahore, Pakistan, [3]Liaquat National Hospital and Medical College, Karachi, Pakistan

Emerging evidence suggest association of certain platelet indices with degree of thrombocytopenia in dengue patients. However, there is paucity of longitudinal follow-up of these parameters with decline and recovery of platelet counts. The objectives were to determine the differences of red cell distribution width-standard deviation (RDW-SD), red blood cell distribution width-coefficient of variation (RDW-CV) and platelet indices including platelet distribution width (PDW), mean platelet volume (MPV), platelet-large cell ratio (P-LCR), and plateletcrit (PCT) among dengue and non-dengue patients. Analysis was done in dengue patients of longitudinal 7-days follow-up for correlation with platelet counts. This case-control study was conducted upon retrospectively collected data of admitted patients in a tertiary care hospital. Cell counts were collected from hospital's medical record of 131 dengue patients and 131 non-dengue patients via CELL-DYN Ruby automated Hematology Analyzer by Abbott (IL, USA). Mann-Whitney U test and Spearman's correlation coefficients were applied. The mean age was 35.25 ± 15.08 and 30.72 ± 13.63 in controls and cases respectively (p=0.106). Baseline characteristics including gender (p=0.247) and comorbidities were similar in both groups. Mean PDW, MPV and P-LCR were found higher in dengue patients while PCT was found lower (p<0.001). In non-dengue patients, only RDW-SD (r-0.236) and PCT (r+0.951) were found correlating with platelet counts, while RDW-SD (r+0.245), RDW-CV (r=0.371), P-LCR (r-0.400), MPV (r-0.252) and PCT (r+0.842) were found correlating in dengue cases. In longitudinal analysis of dengue cases, RDW-SD and RDW-CV remain decreasing with platelets till day 2, and then start increasing with rising platelets at day 7. PCT remained positively correlated till day 7. MPV became positively correlated on day 2. PDW became negatively correlated at day 6 with rising platelets. CIn conclusion, platelet indices and RDW on days 2, 6 and 7 of in-hospital stay were found predictive of dengue-related thrombocytopenia, hence they are useful parameters for dengue recovery.

SOLUBLE SUPPRESSOR OF TUMORIGENICITY (SST2) PREDICTS SEVERE DENGUE AND CARDIAC DYSFUNCTION

Andrew Teo[1], **Po Ying Chia**[2], Tsin Wen Yeo[1]

[1]Lee Kong Chian School of Medicine, Singapore, Singapore, [2]National Centre for Infectious Diseases, Singapore, Singapore

Dengue can be complicated by severe disease including cardiac dysfunction. The lack of reliable prognostic biomarker poses a challenge in managing dengue patients. We investigated the functionality of soluble suppressor of tumorigenicity (sST2) as a predictive marker of severe dengue. Plasma samples came from a longitudinal cohort (with study visits in the febrile, critical and recovery phaes) of slightly older adult dengue patients recruited between 2016-2019 in Singapore. Cardiac parameters: stroke index (SI), cardiac index (CI) and Granov-Goor Index (GGI) were measured with a bioimpedance device at the different phases for dengue participants and once for the controls. Plasma levels of sST2, Troponin T and NT-proBNP were measured via ELISA. A total of 120 subjects, 36 dengue fever (DF), 43 dengue with warning signs (DWS), 11 severe dengue (SD) and 30 controls were assayed. In the febrile, critical, and early recovery phases, sST2 levels were significantly elevated in dengue participants and with greater disease severities (P<0.001 for all). sST2 concentrations were negatively correlated with SI (r=-0.48; P<0.001), CI (r=-0.26; P=0.02) and GGI (r=-0.44; P<0.001) in the critical and phase. sST2 levels in the febrile and critical phases, were positively correlated to troponin-T (r=0.44, P<0.001; r=0.22, P=0.03 respectively) and NT-proBNP (r=0.21, P=0.03; r=0.35, P<0.001 respectively). Interestingly, ROC analysis demonstrated sST2 as a good biomarker of SD in the critical phase, (AUROC 0.79, P<0.001). In conclusion, sST2 levels were raised in dengue patients especially in SD. Furthermore, sST2 levels were associated with markers of cardiac impairment. sST2 may be a useful prognostic biomarker of severe dengue.

0144

A FATAL CASE OF DENGUE HEMORRHAGIC FEVER ASSOCIATED WITH DENGUE VIRUS 4 (DENV-4) IN BRAZIL GENOMIC AND HISTOPATHOLOGICAL FINDINGS

Mariana Cunha[1], Thais Coletti[2], Juliana Guerra[1], Cesar Ponce[1], Natalia Fernandes[1], Rodrigo Resio[1], Ingra Morales[2], Flavia Salles[2], Daniel Ferreira Neto[3], Ester Sabino[2]

[1]Adolfo Lutz Institute, Sao Paulo, Brazil, [2]Instituto de Medicina Tropical, Sao Paulo, Brazil, [3]Ministerio da Saude, Brasilia, Brazil

Dengue infection is the most prevalent arthropod-borne viral disease in subtropical and tropical regions of the world, whose primary vector is *Aedes aegypti* mosquitoes. The mechanisms of dengue virus (DENV) pathogenesis are little understood because we have no animal models of disease; only humans develop symptoms and research has been limited to studies involving patients. DENV is very diverse: there are four antigenic groups (serotypes) and three to five genetic groups (genotypes) within each serotype. Thus, it has been difficult to evaluate the relative virulence or transmissibility of each DENV genotype as both of these factors are important determinants of epidemiology and their measurement is complex because the natural cycle of this disease involves human-mosquito-to-human transmission. Samples from serum, brain, cerebellum, heart, lungs, liver and kidneys from a 13-old male patient that died with hemorrhagic manifestations were sent for differential diagnosis at Adolfo Lutz using both classical virological methods (RT-qPCR, virus isolation, ELISA and hemagglutination inhibition test) and immunohistochemistry (IHQ). A DENV serotype 4 was detected by a DENV multiplex RT-qPCR, and a full genome was obtained from C6/36 cell supernatant using Minion. Lesions were described in heart, liver, lung and kidney with positive IHQ in endothelial cells of brain, cerebellum, heart and kidney, and also in Hepatocytes and Kuppfer cells. Sequencing revealed a DENV-4 genotype II showing an unique non synonymous mutation on position I759M (envelope protein - steam region), however, electrostatic changes in these protein were not significant. Here we report a whole genome of a fatal case caused by a DENV-4 genotype II showing hemorrhagic lesions in several organs in a DENV endemic area of Brazil, with a positive immunohistochemistry on several endothelial cells, liver and kidney, in a patient with no signs of previous DENV infection.

0145

DENGUE VIREMIA KINETICS AND ITS EFFECT ON CLINICAL OUTCOMES

Nguyen Lam Vuong[1], Nguyen Than Ha Quyen[1], Nguyen Thi Hanh Tien[1], Nguyen Minh Tuan[2], Duong Thi Hue Kien[1], Phung Khanh Lam[1], Dong Thi Hoai Tam[1], Tran Van Ngoc[3], Thomas Jaenisch[4], Cameron P. Simmons[5], Bridget A. Wills[4], Sophie Yacoub[1], Ronald B. Geskus[1]

[1]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam, [2]Children's Hospital No. 1, Ho Chi Minh City, Vietnam, [3]Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, [4]University of Oxford, Oxford, United Kingdom, [5]Monash University, Clayton, Australia

Dengue incidence has been increasing for the last four decades and has been identified as one of the top 10 threats to global health by the WHO.

Higher viremia levels in the early phase are associated with more severe dengue outcome, but data on overall viremia kinetics and its effect on clinical outcomes remain limited. We analysed a pooled dataset of 2340 laboratory-confirmed dengue patients from three prospective observational studies performed between 2000 and 2016 in Ho Chi Minh City, Vietnam. The studies enrolled both pediatric and adult patients presenting within three days after fever onset (illness day 1, 2 or 3). All had daily viremia data from enrolment. Viremia levels were measured by RT-PCR. Clinical endpoints included severe dengue (based on the WHO 2009 classification) and predefined moderate-severe plasma leakage. We investigated the trajectory of viremia over time and how it differed by age, sex, serotype and immune status using a mixed-effects model with zero-inflation to account for undetectable values. On each illness day we assessed the effect of viremia on clinical endpoints by logistic regression. We found that viremia rapidly decreased after symptom onset and was detectable in only one case after illness day 8. Viremia kinetics differed by serotype, immune status, and age ($p < 0.0001$): DENV-1, primary infection (for DENV-1 and 3) and older age had highest viremia and took the longest to become undetectable. The effect of viremia on the endpoints did not differ by age, sex, serotype, and host immune status. Higher viremia levels on any illness day increased the risk of developing severe dengue and plasma leakage but effect sizes were modest (ORs [95% CIs] were 1.27 [1.04; 1.56] and 1.24 [1.10; 1.41] per each 10-log increase) compared with the effects of a secondary immune response (ORs [95% CIs] were 73.1 [9.91; 540] and 2.31 [1.49; 3.04], respectively). The findings will be of use for planning antiviral therapeutic trials as well as for incorporation into electronic clinical decision support systems.

0146

AN UPDATED ASSESSMENT OF DENGUE ALGORITHMS INTEGRATED INTO FIVE SOUTHEAST ASIAN INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI) GUIDELINES

Stephanie Petzold[1], Kerstin Rosenberger[1], Martin W. Weber[2], Jacqueline Deen[3], Thomas Jaenisch[1]

[1]Heidelberg Institute of Global Health, University Hospital, Heidelberg, Germany, [2]WHO Regional Office for Europe, Office for quality of care, Athens, Greece, [3]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines, Manila, Philippines

During the early stages of dengue fever, clinicians need to identify children who might develop severe disease course and need referral. The WHO Integrated Management of Childhood Illness (IMCI) algorithms currently, don't include dengue in the generic IMCI algorithm. However, the management of dengue has been incorporated into several IMCI country adaptations. We aimed to evaluate the dengue algorithms incorporated into IMCI guidelines in Southeast Asian countries. The study methodology comprised three components. First, we investigated dengue fever algorithms incorporated into five Southeast-Asian country IMCI guidelines through a desk-based analysis. Second, we conducted an expert survey to elicit opinions regarding the incorporation of dengue in IMCI. Third, we compared our findings with data from a multicentre study on dengue risk assessment, management and surveillance (IDAMS). There was considerable variation in the classification schemes across the guidelines investigated. Generally, the guidelines did not differentiate between a screening tool to identify dengue versus warning signs for progression to severe dengue. There was a consensus by expert to include dengue and to extend the age range for IMCI guidelines since dengue is relevant for children beyond 5 years of age. Using data from the IDAMS study, we found that the likelihood of virologically confirmed dengue increased after three days of persistent fever but nearly half of the patients (366 out of 910) who had fever for only one day had virologically confirmed dengue. This study supports the extension of the IMCI age range for dengue assessment beyond 5 years of age. Because of the challenge of distinguishing dengue from other febrile illnesses, conducting laboratory testing for dengue is important to do at an early stage during the course of the illness. Testing only children with persistent fever for 3 days may lead to an underdiagnosis of dengue among those with acute febrile illness but the cost-effectiveness and public health benefits of earlier testing needs further assessment.

0147

CHANGES IN THE TRANSMISSION INTENSITY OF DENGUE VIRUS ACROSS ECOLOGICALLY DIVERSE REGIONS OF ECUADOR AND ASSOCIATED RISK FACTORS

Leah Katzelnick[1], Emmanuelle Quentin[2], Savannah Boerger[3], Thien-An Ha[4], Paulina Andrade[4], Joseph Eisenberg[3], Patricio Ponce[5], Josefina Coloma[4], Varsovia Cevallos[5]

[1]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Centro de Investigación en Salud Pública y Epidemiología Clínica, Universidad UTE, Quito, Ecuador, [3]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [4]School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [5]Centro de Investigación en Enfermedades Infeciosas y Vectoriales (CIREV), Instituto Nacional de Investigación en Salud Pública (INSPI), Quito, Ecuador

In the 20th into the 21st century, viruses transmitted by *Aedes aegypti* mosquitoes have worsened in previously affected areas and expanded into new regions. Dengue is one of the few tropical diseases with an increasing global burden over the last 20 years. The ecological and demographic drivers of dengue virus (DENV) can be studied in Ecuador, a South American country with multiple distinct regions. Here, we used province-level age-stratified dengue incidence data from 2000-2019 and catalytic models to estimate the force of infection of DENV over decades and across geographically diverse provinces in Ecuador. We identify provinces at different stages of establishing endemic DENV transmission. Coastal provinces with the largest and most connected cities had the earliest and highest increase in DENV transmission intensity, starting around 1980 and continuing to the present. In contrast, remote and rural areas with reduced access, like the northern coast and the Amazon regions, experienced a rise in DENV transmission and endemicity only in the last 10 to 20 years. The newly introduced chikungunya and Zika viruses have distinct age-specific incidence distributions consistent with recent emergence across all provinces. We then evaluated factors associated with geographic differences in vector suitability and arbovirus disease in the last 10 years by modeling 11,693 *A aegypti* presence points and 73,550 cases. In total, 54% of the population of Ecuador lives in areas with high risk of *Ae. aegypti,* including in the provinces we identified as experiencing recent increases in DENV transmission intensity. Most suitable provinces had hotspots for arbovirus disease risk, with population size, elevation, sewage connection, trash collection, and access to water as important determinants. Our investigation serves as a case study of the changes driving the expansion of DENV and other arboviruses globally and provides an approach for identifying areas at early stages of establishing endemic transmission that should be targeted for intense preventative efforts to avert future epidemics.

0148

THE ROLE OF ANTIGENIC AND GENETIC DIVERSITY IN DRIVING THE INFECTION AND DISEASE RISKS OF DENGUE VIRUS

Lin Wang[1], Angkana T. Huang[1], Leah C. Katzelnick[2], Ana Coello Escoto[2], Rachel Sippy[1], Richard Jarman[3], Stefan Fernandez[4], Irina Maljkovic Berry[3], Simon Cauchemez[5], Derek A. T. Cummings[6], Henrik Salje[1]

of Research, Silver Spring, MD, United States, [4]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [5]Institut Pasteur, Paris, France, [6]University of Florida, Gainesville, FL, United States

Despite the substantial global burden, the infection and disease risks from dengue virus (DENV) remain not well understood. Co-circulation of four serotypes and resulting human multiple infections increase the complexity. DENV's infection and disease processes are driven by multiple competing factors, including the antigenic and genetic evolution of DENV and the effects of pre-existing immunity. These factors are often analyzed separately using different data sources. It remains unclear how heterogeneous data from case-based surveillance and viral surveillance could be combined together to assess DENV's infection and disease risks in the community. Here we analyzed 12,389 laboratory-confirmed secondary DENV cases collected from a children's hospital in Bangkok from 1994 to 2014. We used their information of infecting year, age, and serotype. To capture antigenic diversity within the population, we build a three-dimensional antigenic map using data from a large antigenic testing program that systematically tested the neutralization ability of 348 different DENV strains isolated in Thailand from 1994 to 2014 against a suite of reference sera. We further increased the resolution of the population antigenic profile in any year by placing an additional 2242 sequenced viruses onto the map, based on genetic similarity. Using Bayesian methods to incorporate year, age, serotype, and antigenic information, we jointly estimated the yearly serotype-specific force of infection, degree of cross-protection, and most importantly, the infection and disease risks over antigenic distance. We reconstructed the age- and serotype-specific distributions of incident cases per year. Our model selection suggests that the full model incorporating all available information has the highest predictive power. Our study provides a unified framework to integrate heterogeneous data from case-based surveillance and viral surveillance for assessing the infection and disease risks of DENV in the community.

ESTIMATING PATHOGEN FITNESS FROM GENETIC DATA

Noemie Lefrancq[1], Angkana T. Huang[1], Derek A. T. Cummings[2], Julian Parkhill[1], Henrik Salje[1]

[1]University of Cambridge, Cambridge, United Kingdom, [2]University of Florida, Gainesville, FL, United States

Subclinical infections and co-circulating lineages commonly hide the underlying dynamics of dengue fever from surveillance systems. Therefore, the role of different lineages in driving epidemics remains largely unknown. Models informed by pathogen sequences can help. Here we develop a light analytical framework that makes use of genetic data and quantifies the fitness of individual mutations in a population. We extend a recently developed isolate-specific, genetic distance-based measure of epidemic success. We derive an expected value of this index given the underlying level of transmission in the population. By fitting this index for each isolate, we estimate their effective reproduction number R(t). Through this framework, we are able to assess which genetic markers are significantly linked to dengue virus fitness, without specifically looking at known circulating genotypes. Using simulated data, we demonstrate the validity of our approach. We simulate an endemic transmission and generate sequences for each infected individual. We let some mutations be significantly more fit in the population than others. We then sample the sequences generated with a range of procedures, mimicking common surveillance system biases (e.g., uneven sampling by location and year). We show our method can efficiently and accurately recover isolate fitness, as well as decipher the contribution of the different variants to fitness. Next, we apply this method to dengue virus sequences from Thailand (n = 726 over 18 years). This novel method provides an exciting way to quickly assess pathogen fitness from phylogenetic trees, and is highly relevant for pathogen surveillance.

0150

PROFILE AND DYNAMICS OF THE ANTIGEN-SPECIFIC BINDING ANTIBODY RESPONSE AND ANTIBODY-DEPENDENT COMPLEMENT DEPOSITION ACTIVITY AFTER PRIMARY AND SECONDARY DENGUE VIRUS TYPE 1 AND TYPE 3 INFECTIONS

Sandra Bos[1], Jose Victor Zambrana[2], Antonio Gregorio Dias Jr.[1], Elias M. Duarte[1], Julia Huffaker[1], Reinaldo Mercado-Hernandez[1], Lakshmanane Premkumar[3], Angel Balmaseda[4], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Department of Microbiology and Immunology, University of North Carolina, Chapel Hill, NC, United States, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Dengue is the most medically important mosquito-borne viral disease and a major public health concern worldwide, with the four dengue virus serotypes (DENV1-4) being responsible for 50-100 million cases annually. DENV immunity is complex, and antibodies generated after a primary infection with one serotype can cross-react with other serotypes, leading to either protection, increased risk of symptomatic infection or enhanced disease severity upon subsequent infection. In this study, we investigated the quality and dynamics of antibodies generated after DENV1 and DENV3 primary and secondary infections over time. We analyzed samples collected at 14-28 days, as well as 3, 6, and 18 months post-infection from a long-standing pediatric dengue hospital-based study in Managua, Nicaragua, using a newly developed multiplex Luminex assay and an antibody-dependent complement deposition (ADCD) assay. Here, we describe the binding and isotype profile of antibodies targeting the envelope protein (E), E domain III (EDIII), and non-structural protein 1 (NS1) of DENV1-4 and ZIKV, as well as the ADCD activity to each antigen. Notably, we found that antibodies generated after primary DENV1 infection bind and deposit complement on DENV3 EDIII but not on DENV3 NS1, whereas upon primary DENV3 infection, ADCD activity was observed on DENV1 NS1 but not on DENV1 EDIII. We also observed that ADCD activity mediated by anti-DENV3 NS1 antibodies wane faster after a secondary DENV3 infection compared to a secondary DENV1 infection. This study reveals that the binding profile and ADCD activity of the anti-DENV antibody response differ by infection history and infecting serotype, resulting in a fingerprint unique to each serotype.

0151

DETERMINANTS OF SYMPTOMATIC DENGUE VIRUS INFECTION IN A PEDIATRIC COHORT IN NICARAGUA

Jose Victor Zambrana[1], Leah C. Katzelnick[2], Jorge Ruiz Salinas[1], Guillermina Kuan[1], Angel Balmaseda[1], Eva Harris[3]

[1]Sustainable Sciences Institute, Managua, Nicaragua, [2]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

Dengue is the most medically important arbovirus worldwide, affecting more than 140 countries, with 50-100 million cases each year. The determinants of symptomatic dengue virus (DENV) infections among individuals and communities are of public health importance and are relevant for vaccine development to create strategies to lessen the burden of dengue. Previous studies have reported varying DENV symptomatic-inapparent infection ratio (S:I ratio) year-by-year and varying predictors of the S:I ratio, including age, time since the last infection, prior DENV immunity, and spatial location. Here we evaluated 3,720 DENV infections in children 2-17 years old in the Pediatric Dengue Cohort Study (PDCS) in Managua, Nicaragua, from 2004 to 2020. We analyzed the S:I ratio of DENV infections by demographic factors, immune response, prior DENV antibody titer, predominant circulating serotype, and epidemic year. A

Least Absolute Shrinkage and Selection Operator (LASSO) regression was used for feature selection to capture the most important variables determining the S:I ratio. In addition, we performed a spatial analysis of the S:I ratio in the DENV2 epidemic in 2019 in the same cohort. The yearly S:I ratio ranged greatly, from 1:1 to 1:17, with the highest yearly S:I ratios coinciding with the largest DENV epidemics. In our analysis of determinants of the S:I ratio, we found older age, epidemic year, prior intermediate DENV titer, time since the last infection, prior DENV and ZIKV infection, and spatial household location as significant predictors of greater symptomatic infection. The feature selection analysis showed epidemic year as the most important variable for predicting the S:I ratio, followed by prior intermediate DENV titer and older age, which predicted a higher S:I ratio. In this study, we cover a broad range of individual and ecological factors over a long period of time, and our results suggest that the yearly size of the epidemic, changes in individual-level immunity, and key demographic characteristics shape the varying determinants of DENV S:I ratios.

0152

THE INFLAMMASOME IS ACTIVATED BY DENGUE VIRUS NONSTRUCTURAL PROTEIN 1 AND PLAYS A PROTECTIVE ROLE DURING VIRAL INFECTION

Marcus P. Wong, Evan Y.W. Juan, Phoebe Wang, Sophie F. Blanc, Scott B. Biering, P. Robert Beatty, Eva Harris

Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

Dengue virus (DENV), consisting of serotypes 1-4, is the most medically important flavivirus, causing an estimated 50-100 million dengue cases globally every year. Most symptomatic DENV infections present as an acute febrile illness that is self-limited though debilitating; however, some cases progress to severe and potentially fatal complications that include vascular leakage leading to hemorrhage and hypovolemic shock. DENV nonstructural protein 1 (NS1) is secreted from infected cells and has been implicated as a major driver of dengue pathogenesis, activating immune cells and acting directly on endothelial barriers, causing them to become pathologically hyperpermeable. While recent work has delved into the mechanisms behind the endothelial cell-intrinsic pathway of DENV NS1-induced vascular leak, much less is known about how DENV NS1 interacts with immune cells and what role this activation plays in DENV infection. We have discovered that DENV NS1 can trigger activation of the inflammasome, a family of cytosolic innate immune sensors that react to danger-associated molecular patterns. DENV NS1 induces the release of the pro-inflammatory cytokine IL-1β in human and murine monocytes in a caspase-1 dependent manner that is independent of the sensor NLRP3. Additionally, we found that caspase-1-deficient, but not NLRP3-deficient, mice are more susceptible to infection in a murine model of DENV infection. These results indicate that the inflammasome acts as a sensor of the DENV viral toxin NS1 and plays a protective role during DENV infection. Work is ongoing to identify the inflammasome that senses DENV NS1 and investigate the mechanisms by which inflammasome activation leads to host defense against DENV infections.

0153

CONSISTENCY OF ESTIMATES OF THE INTENSITY OF DENGUE VIRUS INFECTION FROM SEROLOGICAL AND PASSIVE CASE SURVEILLANCE STUDIES

Angkana T. Huang[1], Darunee Buddhari[2], Gabriel Ribeiro dos Santos[1], Surachai Kaewhirun[3], Sopon Iamsirithaworn[3], Direk Khampaen[3], Aaron Farmer[2], Stefan Fernandez[2], Stephen J. Thomas[4], Isabel Rodriguez Barraquer[5], Anon Srikiatkhachorn[2], Derek A. T. Cummings[6], Timothy Endy[7], Alan L. Rothman[8], Henrik Salje[1], Kathryn Anderson[4]

[1]University of Cambridge, Cambridge, United Kingdom, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Ministry of Public Health, Nonthaburi, Thailand, [4]State University of New York Upstate Medical University, Syracuse, NY, United States, [5]University of California, San Francisco, CA, United States, [6]University of Florida, Gainesville, FL, United States, [7]Coalition for Epidemic Preparedness Innovations, Manlius, NY, United States, [8]University of Rhode Island, Kingston, RI, United States

Force of infection (FOI) is an important metric when designing and implementing interventions. Ideally, FOI would be calculated using serologic data from highly powered prospective cohort studies, directly measuring rates at which naive individuals seroconvert to the pathogen of interest. However, because this approach is resource intensive, FOI is typically inferred from mathematical models applied to cross-sectional seroprevalence or passive surveillance case datasets. Consistency of FOI estimates from these different approaches remains poorly understood. Here, we use data from a series of cohort studies in Kamphaeng Phet, Thailand (1998-2016: total 10159 individuals, 59801 bleeds with hemagglutination inhibition antibody measurements to all four dengue serotypes) and case data from the provincial hospital (1994-2019, n=12222). We built a suite of models to estimate the annual FOI between 1998 and 2018, considering the cohorts as both longitudinal measures (multiple samples per individual) and cross-sectional data (single sample per individual). By comparing the consistency of the estimates and modifying models to reconcile the discrepancies, we gained insight into key drivers of dengue risk. We found broad concordance in the timing of peaks and troughs of FOI in the different approaches but with significant differences in their magnitude. It was only when incorporating two key extra components that we were able to reconcile these differences. Firstly, we allowed for differences in the risk for infection by age, highlighting how the risk of infection among susceptible individuals is highest for 12-15 year olds. Secondly, we allowed for serological responses to be 'lost' after a first infection (i.e., falling to levels below 1:40), which we estimate occurs in 65% of primary infections. Our findings suggest that all approaches including seroconversion rates will need to be interpreted with caution. Specifically, age structure differences between individuals under study and the general population and effects of antibody kinetics on observed seroconversions will need to be considered.

0154

DENGUE VIRUS DAILY DIARY (DENV-DD) - A NEW PATIENT-REPORTED OUTCOME (PRO) TOOL MEASURING DENGUE SYMPTOM INTENSITY: FINDINGS FROM A DEN-3 HUMAN CHALLENGE STUDY

Morgan Marks[1], Amy Jones[2], Frances White[3], Helen Kendal[3], Verity Smith[3], Jane Wells[4], Charlotte Panter[3], Beth-Ann Coller[1], Justin O'hagan[1], Richard Jarman[5], Michael Koren[5], Lisa Ware[6], Todd Saretsky[1], Tim Endy[6], Stephen Thomas[6]

[1]Merck and Co. Inc., Kenilworth, NJ, United States, [2]Adelphi Values Lts., Bollington, United Kingdom, [3]Adelphi Values Ltd., Bollington, United Kingdom, [4]Adelphi Values Ltd., Kenilworth, United Kingdom, [5]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [6]State University of New York, Upstate Medical University, Syracuse, NY, United States

Dengue is the most common arboviral infection worldwide. Infection can result in a febrile illness with headache, abdominal, muscle/bone pain, rash or diarrhea. Understanding the patient's experience of dengue illness can provide insight on the unmet individual/public health burden of dengue. We describe frequency and intensity of self-report dengue signs/symptoms in a DEN-3 human challenge study using a novel PRO tool, the Dengue Virus Daily Diary (DENV-DD). Healthy adults were challenged with a single dose of DEN-3 ($1.4*10^3$ pfu/ml; CH53489) and asked to complete the DENV-DD daily for 28 days during follow-up. The DENV-DD uses a 4-point intensity scale for 24 symptoms ("not at all" to "a lot"), global symptom intensity ("good" to "very bad") and global impact ("not at all" to "very hard" to do usual activities). Treatments taken and temperature were also self-recorded. Clinical measures and viral RNA were collected routinely through day 28 follow-up. For each participant, a daily mean symptom rating was estimated by averaging individual symptom intensity. PRO completion, response distributions/patterns and relationships

with clinical/lab characteristics were explored. Nine volunteers (Mean age: 33; 5 female; 8 white) were challenged. Daily completion rate was high (90%). Most signs/symptoms occurred between Days 4-14 (86%). Tiredness, body hurting, back hurting and body weakness were the most common symptoms and had the highest intensity. We identified a positive relationship between fever intensity and temperature as well as between global impact and mean symptom ratings. We also observed a positive relationship between clinical and PRO-measured symptom intensity. Viral replication and mean symptom rating both peaked between Days 4-12. We demonstrated the use of the DENV-DD to capture a wide range of signs/symptoms associated with dengue illness in the context of a well-established human challenge model. Validation of this tool in a natural dengue infection setting is underway. Self-reported measures of dengue illness are helpful to assist with public health monitoring and vaccine clinical endpoint development.

0155

DENGUE IN US STATES AND TERRITORIES, 2018-2020

Aidsa Rivera[1], Dania Rodriguez[1], Torres C. Brenda[1], Nicole P. Lindsey[2], Laura E. Adams[1]

[1]Centers for Disease Control and Prevention, Dengue Branch, San Juan, Puerto Rico, [2]Centers for Disease Control and Prevention, Arboviral Diseases Branch, Fort Collins, CO, United States

Dengue virus (DENV) is an arbovirus associated with high morbidity that can result in severe disease or death. In the U.S., dengue cases are reported to ArboNET, the national arboviral surveillance system. This analysis describes trends and characteristics of dengue cases reported to ArboNET during 2018-2020. Dengue cases met the dengue clinical criteria definition with either (*i*) DENV nucleic acid detected by RT-PCR in a clinical specimen; or (*ii*) detection of anti-DENV IgM in serum. A total of 3,449 DENV cases were reported to ArboNET; 2,311 (67%) were travel associated and 1,138 (33%) were locally acquired. Locally acquired cases were reported from Puerto Rico (n=861; 76%), American Samoa (n=150; 13%), Florida (n=90; 8%), Guam and Texas (n=15 each; 1%), and the US Virgin Islands (n=3; 0.3%). Fifty-eight percent of travel-associated cases were submitted by four states: Florida (n=514; 22%), California (n=455; 20%), New York (n=223; 10%) and Texas (n=141; 6%). The largest number of DENV cases was reported in 2019 (n=1,593; 46%), followed by 2020 (1,217; 35%) and 2018 (n=639; 19%). A quarter of all dengue cases were from Puerto Rico (n=875; 25%), most of which occurred in 2020 (n=780; 89%). Half of all dengue cases occurred among males (n=1,725; 50%) and case-patients with known race were white (n=1,132; 56%), Asian (n=303; 15%), Native Hawaiian or Other Pacific Islander (n=176; 9%), Black or African American (n=120; 6%), and other (n=261; 13%). DENV case-patient median age was 34 (IQR 17-53) years. Approximately 40% (n=1,389) of DENV patients were hospitalized, and three fatal cases were reported. Of 585 cases with reported serotype, the majority were DENV-1 (n=461; 79%), followed by DENV-2 (n=67; 12%), DENV-3 (n=53; 9%), and DENV-4 (n=4; <1%). The proportion of DENV-1 cases increased by year (46%, 61%, and 89%). Dengue continues to be a public health threat in the U.S. both for travelers and people living in endemic areas. Disease monitoring through surveillance is critical to support effective control and prevention measures, including education to healthcare providers, travelers, and people living in areas with dengue transmission.

INDIVIDUAL, HOUSEHOLD, AND COMMUNITY DRIVERS OF DENGUE VIRUS INFECTION RISK IN KAMPHAENG PHET PROVINCE, THAILAND

Gabriel Ribeiro dos Santos[1], Darunee Buddhari[2], Sopon Iamsirithaworn[3], Direk Khampaen[3], Alongkot Ponlawat[2], Thanyalak Fansiri[2], Aaron Farmer[2], Stefan Fernandez[2], Stephen Thomas[4], Isabel Rodriguez Barraquer[5], Anon Srikiatkhachorn[3], Angkana T. Huang[1], Derek A T Cummings[6], Timothy Endy[4], Alan L. Rothman[7], Henrik Salje[1], Kathryn Anderson[4]

[1]University of Cambridge, Cambridge, United Kingdom, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Ministry of Public Health, Nonthaburi, Thailand, [4]SUNY, Syracuse, NY, United States, [5]University of California, San Francisco, CA, United States, [6]University of Florida, Gainesville, FL, United States, [7]University of Rhode Island, Providence, RI, United States

Dengue is endemic in many tropical and subtropical regions. In settings with high levels of transmission, it remains unclear which are the main risk factors that alter individual infection risk. To explore the drivers of infection, we tested blood taken from individuals living in multigenerational households in Kamphaeng Phet province, Thailand, for DENV antibodies (N=2376, mean age 31y). Seropositivity ranged from 45.4% among those age 1-5y to 99.5% for those >30y. We explored the drivers of infection risk by fitting spatially explicit serocatalytic models. Using this regression framework, we incorporated individual and household characteristics from questionnaires as well as data from entomological surveys. We estimated that 11.8% of the susceptible population gets infected annually, with less than 2% of all infections detected by the passive surveillance systems. We estimated the average basic reproductive number (R0) to be 2.60 across the province. We found 37.5% of the variance in seropositivity was explained by unmeasured household-level effects with only 4.2% explained by spatial differences between households. Door screens appear to have a protective effect but the number of adult mosquitoes trapped in the households at random timepoints was not significantly linked to infection risk. The serostatus of individuals from the same household were significantly correlated with a 1.26 odds ratio of being seropositive if another individual in the household was seropositive rather than seronegative. This correlation remained significant when individuals were separated by up to 15 years in age. This correlation structure vanished when considering groups of households located within 500m from each other instead. These findings show that despite highly endemic transmission, persistent differences in infection risk exist across households, the reasons for which remain further investigation.

0157

MOSQUITO SALIVARY SECRETIONS DISRUPT ENDOTHELIAL CELL PERMEABILITY AND MAY FACILITATE FLOOD FEEDING AND PATHOGEN TRANSMISSION

Paola Valenzuela Leon[1], Gaurav Shrivastava[1], Ines Martin-Martin[2], Eric Calvo[1]

[1]National Institute of Allergy and Infectious Diseases (NIAID), Rockville, MD, United States, [2]Carlos III Health Institute, Madrid, Spain

Mosquito blood feeding is an essential process for reproduction and the vehicle for pathogens transmission to vertebrate hosts. During blood feeding, the host's hemostatic system is activated resulting in platelet aggregation, vasoconstriction, coagulation, inflammation, and cell recruitment to the bite site. Mosquitoes have evolved an array of bioactive salivary compounds that counteract the hemostatic system of their hosts. These salivary molecules have also been implicated in pathogen transmission and establishment in their vertebrate hosts. Mosquito saliva increases the migration of neutrophils, macrophages, and monocytes to the bite site; the recruitment of these cells is accompanied by increased endothelial permeability. However, the role of mosquito saliva on endothelial permeability is not well understood. Here, we evaluated the

effect of salivary gland extracts (SGE) of three major disease vectors: *Culex quinquefasciatus, Anopheles gambiae*, and *Aedes aegypti* on endothelial permeability in vitro and in vivo. Our results show that SGE of *Ae. aegypti* and *Cu. quinquefasciatus* significantly increased the endothelial permeability in vivo while *An. gambiae* SGE showed a modest increase in permeability. Similar results were obtained in FITC-Dextran Trans-Epithelial in vitro assays. Human Primary Dermal Microvascular Endothelial Cells (HDMVECn) treated with SGE resulted in a higher leakage of Dextran. We measured the expression of 84 genes related to endothelial cells biology by qPCR. HDMVECn treated with *Ae. aegypti* SGE resulted in upregulation of Tissue factor, CCL2, KIT, PECAM-1, and Selectin-E genes. Leukocyte recruitment in vitro experiments also shows that mosquito SGE increases cell transmigration. These results demonstrate that mosquito SGEs have a profound effect on endothelial cell integrity and immune response leading to the upregulation of several pro-inflammatory genes. Identifying individual salivary proteins responsible for these activities may lead to a transmission-blocking approach to mosquito-borne diseases.

0158

LONGITUDINAL ASSESSMENT OF DENGUE NS1-SPECIFIC HUMORAL IMMUNE MEMORY IN HUMAN COHORTS FOLLOWING PRIMARY DENGUE INFECTION

Zoe L. Lyski[1], Brian Booty[1], Courtney A. Micheletti[1], Samantha R. Osman[1], Rachel Rodríguez-Santiago[2], Vanessa Rivera-Amill[2], William B. Messer[1]

[1]Oregon Health and Science University, Portland, OR, United States, [2]Ponce Health and Science University, Ponce, Puerto Rico

The four serotypes of dengue virus (DENV 1-4) are considered the most important vector-borne viral pathogens effecting humans worldwide. Following DENV infection, naïve host B-cells expand, produce, and secrete DENV-specific antibodies (Abs) that recognize viral antigens, specifically epitopes present on the surface of whole virus and secreted non-structural protein 1 (NS1). After viral clearance, some of these B-cells become long-lived plasma cells (LLPCs) which secrete Abs into the serum, while others become memory B cells (MBCs) that remain in circulation, quiescent, but poised to respond and expand on repeat infection. The humoral response against some antigens, such as measles, is long-lived (the lifetime of an individual), while against others is much shorter. The durability and breadth of DENV whole virus specific Abs has been widely interrogated, however the durability and breadth of NS1-specific Abs and memory B-cells remains largely uncharacterized. Here we quantify DENV NS1-specific Abs, both LLPC and MBC-derived, in humans following DENV infection in a longitudinal manner. Using peripheral blood mononuclear cells (PBMCs) and matched serum samples from DENV immune donors with times post-infection ranging from <1-43 years, we interrogated the durability and breadth of the NS1-specific antibody response. LLPC-derived Abs were quantified by ELISA against DENV (1-4) NS1 and endpoint titers were calculated. NS1-specific MBC frequencies were determined by limiting dilution assay wherein, PBMCs from human subjects with history of prior DENV infection were stimulated *in vitro* to become antibody-secreting cells and the resulting Abs were assessed for DENV (1-4) NS1 specificity by ELISA. Using this approach, we identified DENV (1-4) NS1 homotypic and cross-reactive Abs, both LLPC and MBC-derived, that remain in circulation years to decades after infection in subjects from both endemic and non-endemic transmission settings. To more rigorously interrogate the change in NS1-specific Abs and MBCs overtime we also determined measles-specific antibody titers and MBC frequencies in the same samples.

0159

INVESTIGATING THE TRANSCRIPTIONAL RESPONSE OF HUMAN ENDOTHELIAL CELLS UPON TREATMENT WITH WILDTYPE DENGUE VIRUS NONSTRUCTURAL PROTEIN 1 AND A GLYCOSYLATION MUTANT

Felix Pahmeier[1], Scott B. Biering[1], Dustin R. Glasner[2], Yale A. Santos[2], Charles Y. Chiu[2], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Department of Laboratory Medicine, University of California, San Francisco, San Francisco, CA, United States

Members of the *Flaviviridae* family pose a major public health challenge; infection and case numbers have been steadily increasing in recent years. During flavivirus infection, the nonstructural protein 1 (NS1) is secreted from infected cells. The level of soluble NS1 in the bloodstream has been shown to correlate with flavivirus disease severity, and vaccination of mice with NS1 has been shown to be protective from lethal flavivirus challenge. Mechanistically, NS1 from different flaviviruses has been shown to specifically bind to human tissue-derived endothelial cells in a manner that reflects disease tropism. The interaction with the endothelium leads to the disruption of intercellular junctions and the endothelial glycocalyx, ultimately resulting in endothelial barrier dysfunction. Here, we investigate the transcriptional response of endothelial cells upon dengue virus (DENV) NS1 treatment and compare the gene expression changes induced by the wildtype protein and a mutant (N207Q) that was previously shown not to trigger endothelial hyperpermeability. To investigate both pathogenic barrier breakdown and its recovery, we determined differentially expressed genes 6 and 24 hours post-treatment of human pulmonary microvascular endothelial cells by RNA sequencing. We found 359 and 146 genes that were differentially regulated at 6 and 24 hours post-treatment, with an enrichment for factors associated with inflammatory and growth factor signaling. We validated these findings by quantitative reverse transcriptase-PCR and investigated the differential gene expression of several factors, including the putative NS1 receptor beta-2-adrenergic receptor, in endothelial cells derived from the lung, umbilical vein, dermis, brain and liver. Further, we are identifying genes whose regulation is conserved across flaviviruses (DENV, Zika virus, West Nile virus) and those that are regulated differentially. The insights provided by this study will help understand the pathogenic cascade triggered by NS1 and open avenues for the development of high-throughput assays for the evaluation of compounds inhibiting these processes.

0160

CHARACTERISING CLIMATE DEPENDENCIES IN VECTOR BIONOMICS AND MOSQUITO-PATHOGEN INTERACTIONS FOR GLOBAL DENGUE VIRUS TRANSMISSION

Victoria Cox, Wes Hinsley, Neil Ferguson, Samir Bhatt, Ilaria Dorigatti

MRC Centre for Global Infectious Disease Analysis, School of Public Health, Imperial College London, London, United Kingdom

Climatic relationships with *Aedes aegypti* life-traits and subsequently dengue virus transmission have been shown to be non-linear. The turning point values of these relationships (for example the optimum temperature for the extrinsic incubation period) are usually based on laboratory derived data. Previous work has demonstrated that laboratory and field derived estimates are substantially different, for example the additional *Aedes* mortality rate in the field is estimated to be 0.179 $days^{-1}$. A greater understanding of the mechanisms underlying the climatic relationships with dengue transmission in the field is essential, particularly given the likelihood that the spatiotemporal distribution of dengue will vary with the changing climate in the coming decades. The aim of this study is to reconstruct 'epidemiologically-derived' relationships between climate and mosquito life-traits using mechanistic epidemiological modelling. We use a Bayesian modelling approach to estimate the turning point values of several mosquito life-trait climate relationships determining

survival, feeding behaviour, development, and reproduction. We calibrate mechanistic models which explicitly incorporate temperature-, humidity- and rainfall-dependent mosquito compartments to the force of infection of dengue previously calculated using catalytic models applied to case notification and serology data in 349 global locations. In preliminary work we estimated a higher minimum and lower maximum threshold in the function describing the temperature-dependent mosquito mortality, compared to laboratory derived values, which suggests mosquitoes cannot survive at as a wide a range of temperatures in the field as is currently suggested from laboratory data. Subsequent work will refine our understanding of the quantitative relationships between multiple mosquito life-traits and climate in real-world settings, which should facilitate improved accuracy in future mechanistic dengue transmission models.

0161

LONG TERM HUMORAL IMMUNOGENICITY OF LIVE ATTENUATED AND PURIFIED INACTIVATED DENGUE VACCINES

Michael A. Koren, Simon Pollett, Rafael De La Barrera, Richard G. Jarman

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Dengue vaccine development is challenging due to concerns about waning immunity and the potential for vaccine induced disease enhancement. The Walter Reed Army Institute of Research has developed several potential dengue vaccine products including a tetravalent live attenuated vaccine platform (TDENV), a purified formalin-inactivated tetravalent vaccine (DPIV) and an alternative heterologous sequential prime boost utilizing both the DPIV and TDENV (ADVP). In this study, we called back volunteers who had previously participated in vaccine trials involving these vaccines 4-14 years prior, in order to evaluate long term immunogenicity. We recruited a total of 54 subjects from 4 different studies using these investigational products. 30 subjects recruited were from the ADVP prime boost study, 22 subjects from DPIV studies and 2 subjects from TDENV. Subjects underwent a single sera collection between 2019-2020. Neutralizing antibody titers were measured via a microneutralization assay. ADVP recipients demonstrated long term detectable tetravalent neutralizing antibody titers that varied significantly (p=0.008) by regimen received (DPIV-TDENV 66-83% and TDENV-DPIV 0-36%). DPIV with ASO3B adjuvant recipients from years 2015-2017 demonstrated 56-100% tetravalent seropositivity with those who received 3 doses maintaining 100% tetravalent seropositivity. None of three DPIV with Aluminum hydroxide adjuvant recipients who received vaccine between years 2011-2012 maintained tetravalent seropositivity. Both recipients of the 2 dose TDENV regimen given between years 2006-2008 maintained tetravalent seropositivity. Geometric mean neutralizing antibody titers per serotype were highest in the DPIV-TDENV 0, 6 month group (118-233) and recipients of three doses of DPIV (348-779). Overall these results demonstrate variable maintenance of durable neutralizing antibody titers for these vaccine platforms, with notably higher geometric mean titers and tetravalent seropositivity rates in the 0,6 month DPIV/TDENV and 3 dose DPIV cohorts and highlight that maintenance of humoral immunogenicity beyond 10 years is possible.

0162

REFINING EFFICACY ESTIMATES OF A SECOND-GENERATION DENGUE VACCINE

Bethan N. Cracknell Daniels, Neil Ferguson, Ilaria Dorigatti

Imperial College London, London, United Kingdom

It is an exciting time for dengue vaccine development, with one licenced vaccine candidate (Dengvaxia) and two second generation candidates currently in phase III clinical trials. Presently however, Dengvaxia is not in widespread use due to the absence of accurate diagnostics enabling the rapid detection of seropositive subjects ahead of vaccination. A second-generation vaccine developed by Takeda Pharmaceutical is currently in the fourth year of its phase III trial, and overall results thus far show that this new candidate is efficacious against symptomatic dengue. However, efficacy has also decayed with time and is thought to vary with the infecting dengue serotype, reflecting the difficulty of eliciting a balanced tetravalent immune response. The vaccine's efficacy may also vary by the baseline serostatus and age of the vaccine recipients, although small sample sizes limit interpretation. In this study, we assess the extent to which published clinical trial data can be used within Bayesian survival models to refine vaccine efficacy estimates by serotype, baseline serostatus, age and disease severity. These models are also being used to test different hypotheses about the vaccine's mechanism of action, which will be used to evaluate the potential population-level impact of vaccination. As licensure is currently being sought, refined characterisation of the vaccine's complex efficacy profile is vital.

0163

TAK-003 DRIVES SUSTAINED AFFINITY MATURATION OF POLYCLONAL ANTI-DENGUE ANTIBODY RESPONSES AGAINST ALL FOUR DENGUE SEROTYPES IN PARTICIPANTS ACROSS A WIDE AGE RANGE AND IRRESPECTIVE OF BASELINE SEROSTATUS

David Dominguez[1], Isamu Tsuji[1], Jonathan Hernandez[1], Vianney Tricou[1], Shibadas Biswal[1], Mayuri Sharma[1], DEN-301 and DEN-304 Study Groups[2]

[1]Takeda Pharmaceuticals Inc., Cambridge, MA, United States

Dengue is a mosquito-borne disease caused by four dengue virus serotypes (DENV-1-4) with half of the world's population at risk. Therefore, a safe and effective dengue vaccine is an unmet clinical need. Neutralizing antibody titers are a common measure of immunity to flavivirus vaccines. However there is increasing evidence that additional aspects of antiviral immune responses may contribute to vaccine-elicited immunity. The degree of antiviral antibody affinity maturation, driven by vaccination or natural infection is considered an important arm of protective antiviral immune response. Takeda's tetravalent dengue vaccine candidate (TAK-003) has been shown to trigger tetravalent seropositivity and neutralizing antibodies in children, adolescents, and adults during two Phase 3 clinical trials conducted in dengue-endemic and non-endemic regions (DEN-301, NCT02747927; DEN-304, NCT03423173, respectively). To assess the magnitude of avidity index, a measure of the degree of polyclonal antibody affinity maturation in response to vaccination with TAK-003, we utilized an anti-dengue IgG avidity assay employing bio-layer interferometry and dengue virus-like particles (VLPs). Avidity index was calculated as: antiviral IgG response/dissociation constant, k_{off}. The magnitude of affinity maturation was measured pre- and post-vaccination in samples from study participants from both phase 3 clinical trials. Vaccination with TAK-003 stimulated robust tetravalent polyclonal antibody affinity maturation against all DENV serotypes across a wide age range of vaccine recipients, irrespective of baseline serostatus. Additionally, vaccine-driven antibody affinity maturation evolved rapidly and was sustained over time post-vaccination in baseline seropositive and seronegative pediatric, adolescent and adult participants from both endemic and non-endemic countries. Further characterization is currently underway to assess the relationship between vaccine-driven anti-dengue antibody affinity maturation and outcome of subsequent dengue infection.

Dengue fever continues to be one of the main public health threats globally and poses a health risk to U.S. military personnel deployed to dengue endemic areas. For the past few decades, Cameroon has continued to experience sporadic outbreaks of arboviral infections including dengue fever. Here, we describe for the first time, the phylogeny and origin of complete dengue viral genomes isolated from Cameroon. Samples collected between 2017-2018 during dengue virus (DENV) outbreaks in Cameroon were screened for DENV using reverse transcription polymerase chain reaction (RT-PCR), followed by whole genome sequencing of positive samples. Bayesian inference phylogenetic approach based on the Bayesian Markov chain Monte Carlo (MCMC) method was used to determine the time of the most recent common ancestor (TMRCA) and evolution rates of the Cameroon dengue virus strains. Sample analysis yielded six near-complete DENV-1 genomes. Phylogenetic analysis revealed that the strains from the current study belong to an emerging sub-lineage of DENV-1 genotype V and form a monophyletic taxon with a 2012 strain from Gabon. The TMRCA of the Cameroon strains was estimated to have existed around 2010 with a 95% highest posterior density (HPD) interval of 2008-2013. The strains appear to be evolving at 5.04 x 10^{-4} nucleotide substitutions per site per year (95% HPD interval of 4.12 x 10^{-4} and 5.97 x 10^{-4}). Our study showed that an emerging sub-lineage of the dengue DENV-1 genotype V was responsible for the 2017-2018 outbreaks in Cameroon. Our results highlight the need for constant genomic surveillance on DENV and other arboviruses to determine the viral origin and routes of propagation, and consequently aid in understanding their evolutionary dynamics to enhance preparedness for future outbreaks.

0165

MOLECULAR CHARACTERIZATION OF CIRCULATING VIRUSES IN AN OUTBREAK OF YELLOW FEVER FROM OCTOBER 2021 TO FEBRUARY 2022 IN COMMUNITIES IN GHANA

Joseph H.K. Bonney[1], Bright Agbodzi[1], **Terrel Sanders**[2], Samuel Dadzie[1], Dennis Laryea[3], Franklin Aseidu-Bekoe[3]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]US Naval Medical Research Unit No. 3 Ghana Detachment, Marion, SC, United States, [3]Ghana Health Service, Accra, Ghana

Yellow fever is an acute viral hemorrhagic disease transmitted by infected *Aedes spp.* mosquitoes. Disease severity ranges from self-limited febrile illness to hemorrhagic syndrome with jaundice, multiple organ failure and death. During outbreaks, severe cases are more likely to be detected and reported. From October 2021 to February 2022, an outbreak of Yellow Fever in some communities in Ghana resulted in 70 confirmed cases with 35 deaths (case-fatality, 50%). In all, a total of 188 clinical specimens of human sera were collected within the period of the outbreak and submitted to the Noguchi Memorial Institute for Medical Research (NMIMR) for testing. Large proportions (65%) of the cases were sent from communities within the Savannah region where the outbreak started in a predominantly unvaccinated nomadic community. The recorded age range was from 4 months to 70 years, and they mostly presented with symptoms of body pain, fever, abdominal pain, vomiting, jaundice, and bleeding from the gums. Information from this genomic surveillance of YF during this recent outbreak will better inform US AFRICOM regarding the risks to Force Health Protection (FHP) when deployed in austere settings like Ghana. Molecular amplification methods were used on de-identified specimens collected during the outbreak and subsequently produced full-length sequences of three confirmed cases. Phylogenetic analysis characterized the three under the West African genotype II strains and they shared a close homology with sequences from Cote d'Ivoire and Senegal. The utility of the more sensitive advanced molecular diagnostic techniques deployed for the laboratory testing during this outbreak investigations made it distinctive from the serological assays previously used. It enabled us to characterize the circulating strains and for the first time deposited YF strains from Ghana at the GenBank. To change the trend of YF outbreaks in Ghana and elsewhere, public health authorities must increase efforts to ensure that individuals and groups in difficult-to-access areas and at highest risk of exposure are educated about the potential risk of YF infection and vaccinated.

0166

SEROPREVALENCE OF CHIKUNGUNYA, DENGUE AND WEST NILE VIRUS INFECTIONS AMONG PATIENTS WITH FEBRILE ILLNESS IN SOME HEALTHCARE FACILITIES IN GHANA

Clara Yeboah[1], **Terrel Sanders**[2], Janice Tagoe[1], Selassie Kumordjie[1], Eric Behene[1], George Boateng-Sarfo[1], Edward O. Nyarko[3], William Ampofo[1], Naiki Attram[2], Chaselynn Watters[2], Anne T. Fox[2], Shirley Nimo-Paintsil[2]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]US Naval Medical Research Unit No. 3 Ghana Detachment, Accra, Ghana, [3]37 Military Hospital, Ghana Armed Forces, Accra, Ghana

The re-emergence of vector-borne diseases has highlighted arboviruses, which includes Chikungunya, Dengue and West Nile viruses, as a major public health concern globally. They are known to be endemic in many parts of the world, including Ghana, and affect military personnel deployed to these endemic regions. The non-specific clinical manifestations that are like other endemic diseases such as malaria, with fever being a major symptom, make the diagnosis of these infections very challenging. There is limited data on circulating arboviruses in Ghana; hence, this study sought to determine the seroprevalence of Chikungunya, Dengue and West Nile virus among febrile patients in select clinics in Ghana. This cross-sectional study was a hospital-based surveillance study which used questionnaires to collect demographic data from febrile patients. Case definition for enrolling patients (5 to 65 years) was fever and/ or history of fever. Serum samples were tested for IgM and IgG antibodies of selected arboviruses using commercially available ELISA kits. Of the 280 serum samples obtained from study participants, 132 (47.1%) demonstrated exposure to at least one or all three of the arboviruses tested. Ninety-nine (35.4%), 64 (22.9) and 50 (17.9%) were exposed to Dengue, Chikungunya and West Nile virus, respectively. Among the patients that were exposed, the most prevalent dual exposure observed was Dengue and West Nile virus 56 (20%). Adults were more likely to be exposed to Dengue (OR=6.7, 95%CI=3.3-3.8), Chikungunya (OR=2.8, 95%CI=1.3-6.3) and West Nile virus (OR=4.1, 95%CI=1.9-9.1) than children. Using the multinomial logistic regression model, adults were found to have a higher likelihood of being exposed to one or multiple arboviral infections. The predominant arboviral infection detected among febrile patients in Southern Ghana was Dengue fever. Some patients showed exposure to two or all three viruses tested. Adults were more exposed to any or all three arboviruses. These findings suggest the circulation of these arboviruses, which should be included during differential diagnosis of febrile patients in Ghana.

0167

DETERMINING THE VECTOR COMPETENCE OF JAPANESE MOSQUITOES FOR JAPANESE ENCEPHALITIS VIRUS

Astri Nur faizah[1], Daisuke Kobayashi[1], Yukiko Higa[1], Faustus Akankperiwen Azerigyik[1], Kentaro Itokawa[1], Takashi Tomita[1], Kazuhiro Hirayama[2], Haruhiko Isawa[1]

[1]National Institute of Infectious Diseases, Tokyo, Japan, [2]The University of Tokyo, Tokyo, Japan

The ability of a mosquito to be infected with and later transmit the arthropod-borne virus to susceptible hosts is called vector competence. Results from the vector competence studies have been used to incriminate mosquito species in arbovirus transmission cycles, in combination with virus detection in field-captured individuals and their vertebrate host feeding patterns. Despite being widely known as *Culex*-borne (mainly *Culex tritaeniorhynchus*), the Japanese encephalitis virus had been inferred by some studies to also be vectored by *Culex pipiens* and *Aedes*

albopictus. Here, we examined the two mosquito species, *Culex pipiens* form *molestus* (CPM) and *Aedes albopictus* (AAL) originating from Japan, to find out their level of susceptibility and to clarify whether both species could serve as a Japanese Encephalitis virus (JEV) vector in their respective area of distribution in Japan. Laboratory colonies of the two mosquito species were starved overnight and blood-fed the next day using a Hemotek membrane feeder in a dark or lighted room. At 7 and 14 days post-infection (dpi), the mosquitoes were harvested for their body parts and saliva to evaluate infection, dissemination, and transmission rates. Results showed infection rates of 28 and 25% across time points in CPM after exposure to JEV G-I and G-III, respectively. Whereas the transmission rates were observed in G-I (2.5%) but not in G-III exposed CPM. In AAL, as much as 53% of mosquitoes were infected after exposure to JEV G-III at 14dpi. We are currently assessing the infection, dissemination, and transmission rates in both colonies after the exposure to various JEV genotypes to determine the whole picture of their vector competencies. The JEV G-I presence in the saliva suggested the occurrence of virus transmission by CPM, along with the possibility of the mosquito species being refractory to JEV G-III. Nevertheless, this study adds up the knowledge pool of two mosquito species' roles in the JEV transmission cycle in Japan and highlights the information of species that should be included in mosquito control programs.

0168

CHARACTERIZATION OF UNIQUE POWASSAN VIRUS ISOLATES FROM NEW YORK STATE

Rachel E. Lange[1], Kiet A. Ngo[2], Joseph G. Maffei[2], Cheri A. Koetzner[2], Rene Hull[3], Amy B. Dean[3], Melissa Prusinski[4], Bryon Backenson[4], Alan P. Dupuis[2], Laura D. Kramer[2], Alexander T. Ciota[2]

[1]University at Albany School of Public Health and Wadsworth Center, Albany, NY, United States, [2]The Arbovirus Laboratory, Wadsworth Center, New York State Department of Health, Albany, NY, United States, [3]Laboratory of Viral Disease, Wadsworth Center, New York State Department of Health, Albany, NY, United States, [4]Bureau of Communicable Disease Control, New York State Department of Health, Albany, NY, United States

Powassan virus (POWV, family *Flaviviridae*), first isolated in Canada in 1958, is a reemerging tickborne virus endemic in the U.S., Canada, and Russia. In 1997, a POWV-like agent was isolated from *Ixodes scapularis* in New England and determined to be genetically distinct from the original POWV isolate. This revealed the existence of two lineages: lineage I, POWV (POWV-1) and lineage II, deer tick virus (DTV). It is suggested that POWV-1 is maintained between *I. cookei* and groundhogs and *I. marxi* and squirrels, while DTV is maintained in a cycle between *I. scapularis* and small mammal hosts. This distinction suggests an evolutionary progression of either POWV-1 or DTV into unique transmission cycles and subsequent evolution of divergent lineages. Tick, mammalian, and human case isolates from New York State (NYS) are typically identified as DTV, but for the first time in 45 years three POWV-1 isolates were detected, including the first known isolation of POWV-1 from *I. scapularis*. This study aimed to investigate genotypic and phenotypic characteristics of recent NYS isolates in distinct hosts through sequence analysis and replication kinetics *in vitro* and *in vivo*. Genetic data revealed distinctions between POWV-1 isolates from both *I. scapularis* and *I. cookei* compared to historic POWV-1 isolates. Of note, a DTV isolate from a recent NYS human case displayed POWV-1-like mutations that had not been previously identified in DTV. *In vivo* growth kinetics in *I. scapularis* revealed intermediate fitness for an *I. scapularis*-derived POWV-1 isolate and increased fitness in the NYS human isolate relative to isolates of both lineages. These data suggest a possible role of lineage-specific mutations in increased viral fitness that influence host-specific adaptations and continued emergence of POWV in the Northeast.

0169

ESCAPE OF ARBOVIRUSES FROM MOSQUITO SALIVARY GLANDS INTO SALIVA

Emily Gallichotte, Landon Williams, Gregory Ebel

Colorado State University, Fort Collins, CO, United States

Arboviruses, such as Zika virus (ZIKV), West Nile virus (WNV) and chikungunya virus (CHIKV) are transmitted by mosquitoes, leading to millions of infections worldwide each year. When a mosquito feeds on an infected host, the virus must infect the midgut, escape the midgut, infect the salivary glands, escape the salivary glands and be present in the saliva at sufficient levels to infect a new host when the mosquito takes its next bloodmeal. Each of these steps present barriers to transmission, with escape from the salivary glands serving as the strongest barrier for many arboviruses. We sought to measure the role of escape from the salivary glands on transmission, and the relationship between level of virus in salivary glands and saliva in three mosquito-virus pairs; ZIKV and CHIKV in *Aedes aegypti* and WNV in *Culex quinquefasciatus*. For ZIKV, we found a strong salivary gland escape barrier. Within mosquitoes that had virus present in their saliva, there was a strong positive relationship between level of virus in the saliva and salivary glands. However, there were many mosquitoes with high levels of virus in the salivary glands, and no virus present in saliva. Within the salivary glands, virus must first pass through the basal lamina, then infect acinar cells and shed into apical cavities, before being transported to the saliva via the salivary duct. We will use fluorescent microscopy to determine if level of virus in the saliva correlates with localization and or/accumulation of virus in the proper compartments of the salivary glands. These experiments will further define virus-vector interactions, and identify additional barriers to transmission across arboviruses and their mosquito vectors.

0170

CCL3, CCL5, IL15, IL1RA, AND VEGF ARE USEFUL BIOMARKERS TO DISCRIMINATE CLASSES OF ADVERSE EVENTS FOLLOWING 17DD YF PRIMARY VACCINATION ACCORDING TO CAUSE SPECIFIC DEFINITIONS

Jordana Rodrigues Barbosa Fradico[1], Ana Carolina Campi-Azevedo[1], Elaine Spezialli Faria[1], **Izabela Mauricio de Rezende**[2], Betania Paiva Drumond[3], Janaina Fonseca Almeida[4], Roberta Barros da Silva[4], Sandra Maria Deotti Carvalho[5], Andrea Teixeira-Carvalho[1], Olindo Assis Martins-Filho[1], Collaborative Yellow Fever Group[6]

[1]Grupo Integrado de Pesquisas em Biomarcadores, Instituto René Rachou, Fundação Oswaldo Cruz FIOCRUZ Minas, Belo Horizonte, Brazil, [2]Stanford University School of Medicine, Stanford, CA, United States, [3]Laboratório de Vírus, Departamento de Microbiologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [4]Secretaria de Estado de Saúde de Minas Gerais, Belo Horizonte, Brazil, [5]Departamento de Imunização e Vigilância das Doenças Transmissíveis, Secretaria de Vigilância em Saúde, Ministério da Saúde, Brasilia, Brazil

Yellow fever (YF) is a viral hemorrhagic vectorborne disease considered one of the most lethal viral infections. The largescale vaccination coverage is essential to controlling disease spread and the reemergence of the YF epidemic. The YF vaccine is well tolerated, and adverse events following YF immunization (YEL AEFI) are usually mild and occasionally reported. Several hypotheses have already been proposed to explain the basis of the YEL AEFI, but the precise mechanisms involved in the development of these events remain unknown. In the present study, a range of serum biomarkers was quantified in suspected cases of YEL AEFI to propose a reliable laboratory algorithm to discriminate confirmed YEL AEFI cases ("A1" class) from those with other illnesses ("C" class). The analysis of serum biomarkers, including chemokines, inflammatory and regulatory cytokines, and growth factors, was performed using the BioPlex Pro Human Cytokine 27plex Assay. Our findings demonstrated that increased levels of CXCL8, CCL2, CXCL10, IL1β, IL6, and TNFα were observed in YEL AEFI ("A1" and "C" classes) as compared to primary vaccines without YEL AEFI [PV(day

3-28)] and reference range (RR) controls. Notably, increased levels of CCL3, CCL4, CCL2, CCL5, IL1β, IL15, IL1Ra, and GCSF were found in "A1" as compared to "C" class. Venn diagrams analysis allowed the preselection of biomarkers for further investigation of performance indices. Data demonstrated that CCL3, CCL5, IL15, and IL1Ra presented high global accuracy (AUC = 1.00) to discriminate "A1" from "C". Decision tree was proposed with a reliable algorithm to distinguish YEL AEFI cases according to cause specific definitions with outstanding overall accuracy (91%). CCL3, CCL5, IL15, and IL1Ra appear as root attributes to identify "A1" followed by VEGF as branch nodes to discriminate Wild Type YFV infection ("C(WTYFV)") from cases with other illnesses ("C*"). Together, these results demonstrated the applicability of serum biomarker measurements as putative parameters toward establishing accurate laboratory tools for complementary differential diagnosis of YEL AEFI cases.

0171

MURINE MODELS OF POWASSAN VIRUS DISEASE REVEAL A ROLE FOR CD8+ T CELLS IN PROTECTION AND PATHOGENESIS

E. Taylor Stone[1], Mariah Hassert[1], Elizabeth Geerling[1], Colleen Wagner[1], James D. Brien[1], Gregory D. Ebel[2], Alec J. Hirsch[3], Jessica L. Smith[3], Cody German[3], Amelia K. Pinto[1]

[1]Saint Louis University School of Medicine, Saint Louis, MO, United States, [2]Colorado State University, Fort Collins, CO, United States, [3]Vaccine & Gene Therapy Institute, Oregon Health & Sciences University, Beaverton, OR, United States

Powassan virus (POWV) is a tick-borne flavivirus which causes fatal meningoencephalitis in 10-15% of reported human cases, but for which there are no approved vaccinations or therapeutics. Concomitant with this high fatality rate are predictions that incidence of POWV infection is expected to increase as the warming climate expands the range of *Ixodes* ticks capable of transmitting the virus to humans in North America. With the goal of establishing the correlates of protection for POWV to aid the development of efficacious POWV vaccines, we used C57BL/6 mice as a model of POWV infection. Using this model, we have identified two murine CD8 T cell epitopes and two CD4 T cell epitopes. We also provide evidence that CD8 T cells may potentiate immunopathogenesis during POWV-infection. Conversely, CD8 T cells also appear to be important for control of viral replication in the peripheral and central nervous system organs. Identification of beneficial and detrimental aspects of POWV-immune protection is significant as it will aid in the design of POWV vaccines.

0172

PHARMACOKINETIC AND PHARMACODYNAMIC PROPERTIES OF SOFOSBUVIR AND DACLATASVIR FOLLOWING A RESPONSE GUIDED TREATMENT OF HEPATITIS C

Richard M. Hoglund[1], Barnaby Flower[2], Leanne McCabe[3], Azim Ansari[4], Chau Le Ngoc[5], Phuong Nguyen Thi Ngoc[5], Le Manh Hung[6], Le Thanh Phuong[6], Thuan Dang Trong[6], Thu Vo Thi[5], Hang Vu Thi Kim[5], Evelyne Kestelyn[5], Sarah L. Pett[3], Guy Thwaites[5], Nguyen Van Vinh Chau[6], David Smith[4], Eleanor Barnes[4], Hugo Turner[7], Motiur Rahman[5], Ann Sarah Walker[2], Jeremy Day[5], Graham S. Cooke[2], Joel Tarning[1]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, Thailand, [2]Department of Infectious Disease, Imperial College London, London, United Kingdom, [3]MRC Clinical Trials Unit at UCL, University College London, London, United Kingdom, [4]University of Oxford, Oxford, United Kingdom, [5]Oxford University Clinical Research Unit (OUCRU), Ho Chi Minh City, Vietnam, [6]Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, [7]MRC Centre for Global Infectious Disease Analysis, School of Public Health, Imperial College London, London, United Kingdom

Treatment of Heptatis C is of today still very expensive, which hinders potential elimination of the diseases. A contributing factor to the high cost is the long treatment regimen, for example, the standard treatment with sofosbuvir and daclatasvir is a twelve-week regimen. Shorter regimens have been evaluated but have shown low cure rates. However, a promising alternative would be response-guided therapy, in which the choice of treatment duration is guided by early virologic response. In the current study, Hepatitis C infected Vietnamese adults with mild liver disease received either a 4-week or an 8-week treatment with sofosbuvir and daclatasvir, based on their day 2 virologic response. Treatment failures were retreated with a standard 12-week regimen. A total of 52 patients were enrolled in the study and had bloods sample taken for pharmacokinetic analysis at baseline, day 14 and at the end of treatment. In addition, 40 of these patients participated in a pharmacokinetic sub-study in which 5 additional blood samples were taken after the first dose and at day 28. Drug levels of sofosbuvir, its metabolite GS-331007, and daclatasvir were quantified using liquid chromatography tandem mass-spectrometry. The pharmacokinetic properties were evaluated using a non-compartmental analysis as well as a modelling approach, and drug exposure were linked to therapeutic outcome. Treatment failures were only seen in the 4-week arm, showing that virologic response on day 2 is not enough to archive a successful treatment. The pharmacokinetic analysis was successfully performed and, using the non-compartmental analysis results, no significant correlation between drug exposure and therapeutic outcome were seen.

A HUMAN SKIN MODEL OF ARBOVIRUS INFECTION FOR ASSESSING THE IMPACT OF MOSQUITO SALIVARY FACTORS AT THE MOSQUITO-VIRUS-HOST INTERFACE

Allen T. Esterly, Megan G. Lloyd, Prashant Upadhyaya, Jennifer F. Moffat, Saravanan Thangamani

SUNY Upstate Medical University, Syracuse, NY, United States

Mosquito-borne viruses inflict a significant burden on human health all over the world. Viruses such as Zika virus (ZIKV), West Nile virus (WNV), or Mayaro virus (MAYV) are transmitted at the mosquito-host interface during blood feeding. Not only do pathogen immune evasion strategies influence the initial infection and replication of pathogens delivered, but arthropod salivary factors also influence initial infection and replication. Single cell type in-vitro cultures provide limited ability to study the microenvironment of virus delivery and subsequent infection. To study complex interactions between viral, mosquito, and host factors, we describe a proof-of-concept model for arbovirus infection using adult human skin ex-vivo with ZIKV (flavivirus) and MAYV (alphavirus). Histological analysis showed viability of skin to 4 days post-surgical removal in culture. Arboviruses replicated in human skin up to 4 days post infection and shed into culture media. Proinflammatory cytokine and chemokine genes, such as IFN-β and CCL20, were elevated in infected skin relative to uninfected controls. Genes for intracellular pattern recognition receptor molecules RIG-I and MDA5 were increased after MAYV and ZIKV infection. Interferon-induced transmembrane proteins (IFITMs) were significantly upregulated during MAYV infection in skin. Immuno-histochemical detection of virus antigen in skin showed disseminated virus throughout skin tissue. This model brings physiological relevance to studying the impact of infection on skin cell populations and the influence of arthropod salivary molecules during virus delivery.

0174

A NS4A ZIKA VIRUS MUTANT DEMONSTRATES ENHANCED VIRULENCE IN MICE

Anna S. Jaeger[1], Jeffrey Marano[2], Kasen Riemersma[3], Elise Pritchard[1], James Weger-Lucarelli[2], Thomas C. Friedrich[3], Matthew T. Aliota[1]

[1]University of Minnesota, Twin Cities, MN, United States, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, [3]University of Wisconsin-Madison, Madison, WI, United States

Zika virus (ZIKV) is now in a post-pandemic period, for which the potential for re-emergence and future spread is unknown. Adding to this

uncertainty is the unique capacity of ZIKV to directly transmit between human hosts via sexual transmission. Recently, we demonstrated that direct transmission of ZIKV between vertebrate hosts resulted in ZIKV strains with increased mortality in mice and increased transmission in mosquitoes, suggesting that human-only transmission chains could pose a threat for enabling the emergence of more virulent ZIKV strains. Coincident with this change in phenotype was the emergence of three amino acid substitutions (NS2A-A117V, NS2A-A117T, and NS4A-E19G) shared among all vertebrate-passaged lineages. To understand the contribution of these genetic changes to the virulence phenotype, we engineered these amino acid substitutions singly and in combination into a Zika virus infectious clone. Ifnar1-/- mice were then subcutaneously inoculated with 10^3 PFU of each of these viruses, or a wild-type infectious clone (WT-IC) control. Infection with the NS4A-E19G mutant resulted in significantly enhanced mortality and significantly higher viremia at 4 days post infection (dpi) compared to the NS2A-117 mutants or the WT-IC. The double mutant viruses (NS4A-E19G/NS2A-A117V and NS4A-E19G/NS2A-A117T) also caused enhanced mortality and similarly increased viremia at 4dpi compared to the NS2A single mutants or the WT-IC. These results suggest that the NS4A-E19G substitution contributes to the enhanced virulence phenotype observed in serially-passaged viruses. Data are forthcoming, but we are now performing experiments to understand the potential mechanisms by which the NS4A substitution aids in more effective viral evasion or regulation of the immune response in mice, and to assess the role of these substitutions in increased mosquito transmission potential. Defining the genetic determinants of enhanced ZIKV virulence and their underlying mechanisms could inform better surveillance for variants of concern and provide insights into future ZIKV evolution.

INVESTIGATING THE ROLE OF TEMPERATURE IN THE TRANSMISSION DYNAMICS OF FLAVIVIRUSES IN COLOMBIA

Andrew C. Glover, Ilaria Dorigatti, Neil M. Ferguson

Imperial College London, London, United Kingdom

Previous studies have investigated fitting various *Aedes* spp. mosquito life traits to temperature-dependent functions. However, as the underlying studies are typically laboratory-based, they may not be indicative of field-settings. Here, we show analytically that small adjustments within the reported credible intervals of the parameterization of these thermal responses can yield markedly different transmission dynamics of *Aedes*-borne flaviviruses. We then demonstrated this mechanistically through a stochastic, temperature-dependent metapopulation model applied to Colombia. In doing so, we accounted for patch connectivity through a radiation model and calibrated mean mosquito carrying capacities across the spatial grid from previous maps of dengue force of infection estimates to allow for spatial variation in the baseline level of *Aedes* spp. environmental suitability. We then utilized fine-scale historical temperature data to investigate various combinations of previously proposed thermal responses, and scalings of them, for different entomological and epidemiological parameters, for both dengue and Zika. While accounting for under-reporting, model fits were assessed against municipality-level time series incidence data across Colombia through a Bayesian framework using a Dirichlet-multinomial likelihood function to account for overdispersion. When applied in an epidemic context, our model demonstrated high predictive accuracy of the timings of the 2015-16 Zika outbreak across different departments, even though the outbreak was relatively heterogenous across space. Our model also had strong predictive accuracy in an endemic context for dengue, where it accurately predicted the timing of the 2010 outbreak. However, it also predicted a dengue outbreak in 2015-16 that was not observed, which coincided with the Zika outbreak. This corroborates other studies that highlighted dengue incidence was atypically low in Latin America following the Zika outbreak, and highlights the need for an improved understanding of potential biological mechanisms that may suppress dengue incidence when Zika is co-circulating.

0176

ADAPTIVE IMMUNE RESPONSES TO WEST NILE VIRUS CROSS-REACT WITH USUTU VIRUS

Megan B. Vogt[1], Rebecca Salgado[1], Seth A. Hawks[1], Claire Y.-H. Huang[2], Nisha K. Duggal[1]

[1]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, [2]Centers for Disease Control and Prevention, Division of Vector-Borne Diseases, Fort Collins, CO, United States

Usutu virus (USUV) is a mosquito transmitted flavivirus that originated in Africa. Since USUV emerged in Europe in 2001, it has caused numerous mass bird die-offs and >100 human infections, including several cases of encephalitis. USUV shares approximately 76% amino acid identity with West Nile virus (WNV), a closely related flavivirus. Previously, we showed WNV vaccination protects against lethal USUV infection of African (Uganda 2012) or European (Spain 2009) isolates and significantly reduces viremia in an immunodeficient mouse model. Protection was greater against Spain 2009. Here, we investigated whether WNV mediated cross-protection against USUV is antibody or T cell mediated. To determine whether WNV specific antibodies neutralize USUV, we performed plaque reduction neutralization tests on convalescent sera from humans who had symptomatic WNV infections against WNV or multiple USUV strains, including Uganda 2012 and Spain 2009. We found the geometric mean $PRNT_{50}$ titers of these sera samples against WNV was 1:300, while the titers against most USUV strains, including Uganda 2012, were approximately 1:60. The titer against Spain 2009 isolate was 1:265. These results indicate that natural WNV infection produces antibodies that can neutralize USUV *in vitro*. Passive transfer studies are ongoing to determine whether these titers can protect against USUV disease *in vivo*. To determine whether T cells from WNV exposed individuals can recognize USUV, we isolated splenocytes from WNV vaccinated mice and stimulated them with WNV or USUV. Splenocytes stimulated with WNV produced approximately 1650pg/mL of IFNγ, and splenocytes stimulated with two different USUV strains (Uganda 2012 or Spain 2009) produced 250-730pg/mL of IFNγ, indicating that WNV vaccinated T cells do respond to USUV virus. In the future, we will perform adoptive transfer studies to determine whether WNV specific T cells are protective against USUV infection *in vivo*. Understanding the mechanisms behind cross-protective immune responses between WNV and USUV will be crucial to assessing risk of USUV disease in WNV endemic areas and developing therapeutics against USUV.

Among the zoonotic arboviruses detected in Brazil, since 2004, several studies have provided serological evidence regarding the circulation of West Nile Fever Virus (WNV) in mammal and bird reservoirs. Recently genomic monitoring activities in horses, also revealed the circulation of WNV in several states located in southeastern and northeastern Brazilian regions. This highlights how pivotal it is investigating the unnoticed circulation of WNV in horses, as this host' infections may precede human cases of encephalitis. Here using a nanopore sequencing approach we obtain WNV complete genome sequences from two states located in northeast Brazil (Bahia and Ceará). A total of 54 suspicious WNV samples collected between 2017 to 2020 from horses with encephalitis were screened. Viral RNA was extracted from samples (brain and spinal cord) using Kit QIAamp Viral RNA Mini Kit (Qiagen). A multiplex PCR using a primer scheme based was then performed in order to amplify the entire coding region of WNV. Samples with DNA concentration >2ng/ul were then submitted to nanopore sequencing using the MinION. Basecalling of raw files and barcode demultiplexing were performed using Guppy, and the consensus sequences generated by de novo assembling using Genome Detective. Phylogenetic inferences were then performed. Our results revealed that genomes generated in this study belonged to Lineage 1a. The ML reconstruction revealed that our newly isolates were scattered through the tree highlighting that multiple introduction events have occurred trough time. Together, our results reinforce the necessity to improve the profile of epidemiological and genomics investigation towards zoonotic arbovirus in Brazil, increasing priority of WNV genomic surveillance in equines with encephalitis in order to follow the dispersion of WNV through the country.

0178

HARMONIZATION OF MULTIPLE SARS-COV-2 REFERENCE MATERIALS USING THE WHO IS (NIBSC 20/136). RESULTS AND IMPLICATIONS

[1]University of Colorado, Aurora, CO, United States, [2]Wadsworth Center, New York State Department of Health, Albany, NY, United States, [3]Brigham and Women's Hospital, Department of Pathology,, Boston, MA, United States, [4]Brigham and Women's Hospital, Division of Rheumatology, Inflammation and Immunity, Harvard Medical School, Boston, MA, United States, [5]BioDesix Inc., Boulder, CO, United States, [6]BioDesix Inc, Boulder, CO, United States, [7]Division of Infectious Diseases, Wadsworth Center, New York State Department of Health,, Albany, NY, United States, [8]INSTAND e.V., Society for Promoting Quality Assurance in Medical Laboratories, Duesseldorf, Westphalia, Germany, [9]ThermoFisher Scientific, Waltham, MA, United States, [10]Division of Infectious Diseases, Wadsworth Center, New York State Department of Health, Albany, NM, United States, [11]Division of Infectious Diseases, Wadsworth Center, New York State Department of Health,, Albany, NM, United States, [12]Oneworld Accuracy, Vancouver, BC, Canada

There is an urgent need for harmonization between SARS-CoV-2 serology platforms and assays prior to defining appropriate correlates of protection and as well inform the development of new rapid diagnostic tests that can be used for sero-surveillance as new variants of concern (VOC) emerge. We compared multiple SARS-CoV-2 serology reference materials to the WHO IS to determine their utility as secondary standards, using an international network of laboratories with high-throughput quantitative serology assays. This enabled the comparison of quantitative results between multiple serology platforms. Between April and December of 2020, thirteen well-characterized and validated SARS-CoV-2 serology reference materials were recruited from six different providers to qualify as secondary standards to the WHO International Standard. All samples were tested in parallel with NIBSC 20/136 and parallel line assays were used to compute the relevant potency and binding antibody units. All samples saw varying levels of concordance between diagnostic methods at specific antigen-antibody combinations. Seven of the 12 candidate materials had high concordance for the Spike-IgG analyte (%CV between 5% and 44%). In conclusions**,** despite some concordance between laboratories, qualification of secondary materials to a WHO IS using arbitrary IU or BAU/mL does not provide any benefit to the reference materials overall, due to the lack of consistent agreeable IU or BAU/mL conversions between labs. Secondary standards should be qualified to well-characterized reference materials, such as the WHO IS, using serology assays that are similar to the ones used for the original characterization of the WHO IS.

0179

ZIKA VIRUS: INTERIM FINDINGS IN THE SINDH REGION OF PAKISTAN

Khekashan Imtiaz[1], Erum Khan[1], Kelli Barr[2], Joveria Farooqi[1], Akbar Kanji[1], Zahida Azizullah[1], Maureen T. Long[3]

[1]The Aga Khan University, Karachi, Pakistan, [2]University of South Florida, Florida, FL, United States, [3]University of Florida, Gainesville, FL, United States

Globally, the Zika virus (ZIKV) has emerged as a cause of acute febrile illness in children and adults. In Pakistan, the detection of ZIKV antibodies has been reported. However, the validity of this data is questionable given the current understanding of flaviviral antigenic cross-reactivity. To confirm ZIKV circulation in the Sindh region of Pakistan, patients presenting to healthcare with a febrile illness were evaluated using ZIKV nucleic acid, IgM antibodies, and neutralization assay. Patients were recruited after taking formal consent from referral hospitals situated in 4 rural and one urban center in the Sindh region of Pakistan. All samples were tested for flaviviruses including Dengue, Zika, West Nile, and Japanese Encephalitis Virus using a commercial IgM capture ELISA kit and singleplex real-time PCR. For the confirmation of IgM positivity, the plaque reduction neutralization test (PRNT) was performed on selected Zika IgM positive samples to measure neutralizing antibodies. A total of 745 samples were collected from acute febrile patients admitted over a period of three years (2015-17), IgM ELISA and RT-PCR were for ZIKV and three other commonly circulating Flavivirus, DENV, WNV, and JEV. A total of 203 patients showed IgM positivity for the ZIKV. Of these 19.59% (n=146) were also positive for either DENV, WNV, and JEV. 7.6% (n=57) samples were showed IgM positivity exclusively for ZIKV and no cross-reactivity was noticed. These were considered as presumptive ZIKV Positive samples. Twenty-two samples of the Zika presumptive positive samples were further tested for confirmation using PRNT, Vero cell lines were infected with ZIKV; plaques were counted at day 5 post-infection. Serum samples with 50% reduction of the number of plaques at titers ≥10 were recorded as positive according to the CDC. The study provides evidence that the ZIKV has been circulating in Pakistan during the time of global transmission of this virus. Serologic cross-reactivity is a significant barrier to diagnosis in endemic areas where multiple flaviviruses co-circulate, serological diagnostics should be run in parallel with related co-circulating viruses.

0180

DEVELOPMENT OF A RECOMBINANT VSV VECTORED VACCINE AGAINST NIPAH VIRUS DISEASE

Thomas P. Monath[1], Richard A. Nichols[2], D. Gray Heppner[1], Tracy Kemp[1], Lynda Tussey[1], Kelly Scappaticci[2], Joseph Crowell[2], Thaddeus Pullano[2], Joan S. Fusco[2]

[1]Crozet Biopharma LLC, Lexington, MA, United States, [2]Public Health Vaccines LLC, Cambridge, MA, United States

Nipah virus (NiV) is a bat-borne henipaviral zoonosis causing outbreaks of lethal encephalitis and pneumonia in South and Southeast Asia. Development of a vaccine is a high priority for WHO and for the Coalition

for Epidemic Preparedness Innovations (CEPI), which is funding this work. A recombinant vesicular stomatitis virus (rVSV) expressing the glycoprotein (GP) of Ebola virus (rVSV-EBOV GP) has been approved for preventive immunization against Ebola (Ervebo®, Merck & Co.). The rVSV-EBOV vector was modified through reverse genetics to express an additional glycoprotein (G) of NiV. The rVSV EBOV GP NiV G vaccine candidate (code name PHV02) is a chimeric virus with tropism and immunological properties derived from the wild-type VSV parent, the rVSV-EBOV vector and the NiV transgene donor. Here we describe the characteristics of the vector and vaccine candidate relevant to clinical and environmental safety, immunogenicity and efficacy. The PHV02 vaccine candidate was shown to be highly attenuated in hamsters, ferrets and nonhuman primates. Hamsters and African green monkeys inoculated with the vaccine developed NiV neutralizing antibodies and were solidly protected against lethal NiV challenge. PHV02 virus inoculated intracerebrally in cynomolgus macaques was not neurovirulent and induced significantly lower histopathological scores than yellow fever 17D vaccine used as an active control. A biodistribution study in ferrets inoculated IM showed no neuroinvasion. Robust manufacturing methods have been developed and clinical immunological tests qualified. Based on the promising profile in animal models, this novel PHV02 NiV vaccine candidate has now entered clinical trials under an US FDA Investigational New Drug Application (IND).

SARS-COV-2 TRANSMISSION DYNAMICS IN SCHOOLS FROM A SMALL MUNICIPALITY OF BUENOS AIRES PROVINCE, ARGENTINA

Favio Crudo[1], Mariana Fernandez[1], Paz Zaldivar[2], Karina A. Cardone[2], Fernando Spina Markmann[2], María H. Irigoyen[3], Lucía G. Vaulet[3], Marcelo Rodríguez Fermepín[3], Roberto Chuit[4], Marcelo C. Abril[5], **Maia V. Periago**[6]

[1]Fundación Mundo Sano/ADESAR, Buenos Aires, Argentina, [2]Health Secretariat of San Antonio de Areco, San Antonio de Areco, Argentina, [3]Laboratory of Immunology and Clinical Virology/ INFIBIOC, University of Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina, [4]Institute of Epidemiological Research, National Academy of Medicine, Ciudad Autónoma de Buenos Aires, Argentina, [5]Fundación Mundo Sano, Ciudad Autónoma de Buenos Aires, Argentina, [6]CONICET/Fundación Mundo Sano, Ciudad Autónoma de Buenos Aires, Argentina

There has been a lot of controversy around the effect of school closing on the spread of SARS-CoV-2 in the population, especially during a time when vaccines were not available. Studies conducted in different regions of the world, exposed conflicting results; most of them were based on government collected data. To safely return to schools in a municipality from the Province of Buenos Aires (Argentina) when few vaccines were available and with Delta as the predominant variant of concern (VOC), a surveillance protocol for a safe return to schools was established in San Antonio de Areco (SAA) at the initial, primary and secondary level. The objective of this study was to analyze the transmission dynamics of SARS-CoV-2 between cases and contact in SAA, though monitoring of infection in suspected cases and contacts through RT-PCR from nasopharyngeal swabs using individual samples and pools. The protocol was applied from March 8th, 2021, one week after the beginning of the school year, until the 22nd of May 2021, in all the SAA schools. In total, 920 tests were performed to all suspected cases and contacts related to schools (students, teachers and staff). From the total number of enrolled students (n=5297), 172 cases were confirmed as positive (3.3%), with a greater proportion of positives at the high school level; while the prevalence in teachers and staff was 10% (87/876). The predominant epidemiological nexus, both in students as well as teachers and staff, was the home/family setting. When considering only those cases where transmission occurred in the educational context, the proportion of cases in student was reduced to 0.21% and to 1.1% in teachers and staff. Therefore, it appears that the school is not a driver of infection in the community and what seems to be important to consider is the presence of health measures in schools, the state of transmission in the rest of the population, and the VOC circulating.

HUMORAL AND CELLULAR IMMUNE MEMORY TO FOUR COVID-19 VACCINES

Daniela Weiskopf, Zeli Zhang, Jose Mateus, Camila Coelho, Jennifer Dan, Carolyn Rydyznski-Moderbacher, Rosa I. Galvez, Fernanda H. Cortez, Alessandro Sette, Shane Crotty

La Jolla Institute for Immunology, La Jolla, CA, United States

Multiple COVID-19 vaccines, representing diverse vaccine platforms, successfully protect against symptomatic COVID-19 cases and deaths. Head-to-head comparisons of T cell, B cell, and antibody responses to diverse vaccines in humans are likely to be informative for understanding protective immunity against COVID-19, with particular interest in immune memory. Here, SARS-CoV-2-spike—specific immune responses to Moderna mRNA-1273, Pfizer/BioNTech BNT162b2, Janssen Ad26.COV2.S and Novavax NVX-CoV2373 were examined longitudinally for 6 months. 100% of individuals made memory $CD4^+$ T cells, with cTfh and CD4-CTL highly represented after mRNA or NVX-CoV2373 vaccination. mRNA vaccines and Ad26.COV2.S induced comparable $CD8^+$ T cell frequencies, though memory $CD8^+$ T cells were only detectable in 60-67% of subjects at 6 months. Ad26.COV2.S was not the strongest immunogen by any measurement, though the Ad26.COV2.S T cell, B cell, and antibody responses were relatively stable over 6 months. A differentiating feature of Ad26.COV2.S immunization was a high frequency of $CXCR3^+$ memory B cells. mRNA vaccinees had substantial declines in neutralizing antibodies, while memory T cells and B cells were comparatively stable over 6 months. These results of these detailed immunological evaluations may also be relevant for vaccine design insights against other pathogens.

0183

CHADOX1-VACCINATED SARS-COV-1 SURVIVORS EXHIBIT A BROAD SPECTRUM OF PROTECTION AGAINST SARS-COV-2 VARIANTS

Sheng-Yu Huang[1], Ing-Kit Lee[2], Shin-Ru Shih[1], Shu-Min Lin[3], Chung-Guei Huang[3]

[1]Chang Gung University, Taoyuan, Taiwan, [2]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, [3]Chang Gung Memorial Hospital, Taoyuan, Taiwan

The last outbreak of severe acute respiratory syndrome-coronavirus (SARS-CoV-1) disease had occurred between November 2002 and August 2003, and it led to 8,098 suspected SARS cases, 774 SARS-related deaths (case fatality rate: 9.6%) and spread to 32 different countries. To investigate whether there is an advantage in protection against SARS-CoV-2 infection after SARS-CoV-1 infection compared to uninfected people 19 years later. In this study, we collected the serum samples of individuals who had been infected with SARS-CoV-1 19 years ago and have received either one or two doses of the AstraZeneca (AZ) vaccine against coronavirus disease-2019 (COVID-19). To ensure accurate comparison and analysis, we investigated cases with similar intervals between AZ vaccination and blood draw from those who had never been infected with SARS-CoV-1. We observed that after AZ vaccination, the neutralizing antibody expressions were significantly higher in the SARS-CoV-1-infected group compared to those in the uninfe cted group. Incidentally, in Taiwan, approximately 78 and 30% of the people remained negative with respect to the neutralizing antibody expression after receiving the first and second dose of the AZ vaccine, respectively. The pseudovirus neutralization (NT) assay revealed that sera from the SARS-CoV-1 survivors completely (100%) neutralized the Wuhan, Alpha, Gamma, and Delta variants after the first AZ vaccination. However, only 66% of the cases could neutralize the Beta and Omicron variants. In contrast, for the uninfected group, only the Wuhan and Gamma variants could be 100% neutralized after the administration of the first AZ vaccine. Unfortunately, the neutralizing ability for the other variants was completely absent in this group. After the second AZ vaccination, the SARS-CoV-1 survivors could neutralize all COVID-19 variants, whereas 16% of the casess in the uninfected group still failed to

neutralize the Beta and Omicron variants. Therefore, the AZ-vaccinated SARS-CoV-1 survivors have a broad spectrum of protection against the SARS-CoV-2 variants compared to the uninfected group.

INFLUENCE OF AGE ON MSK SEQUELAE IN EBOLA SURVIVORS IN EASTERN SIERRA LEONE

Anna C. Sanford[1], Nell G. Bond[1], Emily J. Engel[1], Lansana Kanneh[2], Michael A. Gbakie[2], Fatima K. Kamara[2], Donald S. Grant[2], John S. Schieffelin[1]

[1]Tulane University, New Orleans, LA, United States, [2]Kenema Government Hospital, Kenema, Sierra Leone

Ebola virus disease (EVD) survivors have presented with specific post-Ebola sequelae, collectively termed post-Ebola syndrome. Musculoskeletal (MSK) complaints are some of the most common complaints in post-Ebola syndrome. Here, we explore the influence of age on MSK signs in EVD survivors. Data was collected as part of an ongoing cohort study in Eastern Sierra Leone. Survivors completed questionnaires and physical exams at baseline and follow-up visits. Survivors were grouped by reproductive age categories: < 15 years of age, female reproductive age (15-40 years), and > 40 years of age. Date of first visit ranged from March 2016 to September 2020 and occurred 2.63 years after discharge from Ebola treatment unit (ETU), on average. At first visit, more female than male EVD survivors had MSK signs on physical exam (24.9% vs 22.4%), however this difference was not significant. Survivors 15-40 years of age were significantly more likely to display MSK signs on physical exam at first visit than those < 15 years (p = .008). Survivors > 40 years of age were not significantly more likely to demonstrate MSK signs than those < 15 years (p=.250). When grouped by sex, women 15-40 years of age were significantly more likely to demonstrate MSK signs on exam than women < 15 years (p=.040). Women > 40 years of age were not significantly more likely to demonstrate MSK signs than those < 15 years (p=.419). Our finding that EVD survivors 15-40 years of age were significantly more likely to demonstrate MSK signs on physical exam was surprising, as we expected survivors > 40 years of age to present with more MSK signs. Age may play a role in the development of MSK signs in post-Ebola syndrome. Studies into the immune response to EVD by age group and sex could provide insight into the pathogenesis of MSK sequelae in EVD survivors.

CROSS-REACTIVITY OF DENGUE ANTIBODY TO SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS 2

Kamonthip Rungrojcharoenkit, Taweewun Hunsawong, Darunee Buddhari, Rungarun Suthangkornkul, Jindarat Lohachanakul, Kedsara Tayong, Kanittha Sirikajornpan, Prinyada Rodpradit, Chonticha Klungthong, Thomas S. Cotrone, Stefan Fernandez, Anthony R. Jones

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) outbreaks continue to increase globally, including areas where dengue virus (DENV) in endemic. Accuracy and early diagnosis are important factors to control these SARS-CoV-2 outbreaks. Serological cross-reactivity between DENV and SARS-CoV-2 virus have been reported in the endemic areas of arbovirus infections, and this can lead to misdiagnosis for both diseases and misunderstanding about potential cross-protection. Here, we demonstrated the potential cross-reactivity of DENV antibodies with SARS-CoV-2 using well-characterized acute and convalescent samples collected before SARS-CoV-2 outbreak including normal human serum (n=6), Febrile illness (n=23), primary DENV (n=20) and secondary DENV (n=20). The majority of anti-SARS-CoV-2 antibodies-positive samples (using an in-house ELISA) would cross react and appear as secondary DENV infections (7.2% of positive rate). We found poor correlation between DENV IgM antibody and in-house spike-RBD ELISA. Among ELISA positive samples, none of them was positive against live SARS-CoV-2 microneutralization assay. These data indicates a potential of cross-reactivity of binding antibody but not neutralizing antibody.

0186

REACTIVITY OF SARS COV 2 SPIKE PROTEIN AND ITS RBD AND P3 DOMAINS TO SERA OF COVID 19 AND PRE COVID 19 PATIENTS IN MALI

Abdouramane Traore[1], Saidou Balam[1], Drissa Konate[1], Bourama Traore[1], Merepen Agnès Guindo[1], Fousseyni Kane[1], Housseini Dolo[1], Salimata Kante[1], Seidina Diakite[1], Fatoumata Kasse[1], Mamoudou Kodio[1], Boubacar Drame[1], Yaya I Coulibaly[1], Ousmane Faye[1], Seydou Doumbia[1], Giampietro Corradin[2], Mahamadou Diakite[1]

[1]USTTB, Bamako, Mali, [2]University of Lausanne, Lausanne, Switzerland

The SARS-CoV-2 Spike protein and its receptor binding domain (RBD) play an essential role in the invasion of the virus into the host cell. P3 is a segment representing 6% of the length of the S protein, located in the RBD domain, which is recognized by the ACE2 (Angiotensin-converting enzyme 2) protein. The aim of this study was to evaluate antibodies (IgG) specific for S, RBD, and P3 of SARS-CoV-2 in specimens from patients hospitalized for COVID-19 and from pre-COVID-19 donors collected prior to the outbreak of COVID-19 in Mali. Sera from COVID-19 patients (N=266) at the Bamako Dermatology Hospital (HDB) in 2020 and from donors collected in Dangassa, a rural endemic area (N=283) in 2018, were tested to S, RBD, and P3 antigens using ELISA. Seroprevalence was 80.5% for Spike antigen (Ag), 71.1% for RBD and 31.9% for P3 at HDB. In pre-COVID-19 samples from Dangassa, the seroprevalence was 21.9%, 6.7% and 8.8% respectively for the same antigens. The presence of antibodies against SARS-CoV-2 in pre-CoVID-19 samples suggests the existence of cross-reactivity with other SARS viruses and/or other pathogens in endemic areas like *Plasmodium*.

0187

ASSESSMENT OF LONG-TERM IMMUNE RESPONSE FOLLOWING VACCINATION WITH THE RVSVΔG-ZEBOV-GP EBOLA VACCINE IN HEALTHCARE WORKERS IN HIGH-RISK DISTRICTS IN UGANDA

Michelle A. Waltenburg[1], Amy Whitesell[1], Luke Nyakarahuka[2], Jimmy Baluku[2], Markus Kainulainen[1], Jackson Kyondo[2], Sam Twongyeirwe[2], Sophia Mulei[2], Alex Tumusiime[2], John D. Klena[1], Christina Spiropoulou[1], Joel M. Montgomery[1], Julius J. Lutwama[2], Stephen Balinandi[2], Trevor Shoemaker[1], Caitlin Cossaboom[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Uganda Virus Research Institute, Entebbe, Uganda

The rVSVΔG-ZEBOV-GP Ebola vaccine (rVSV-ZEBOV) is a live recombinant vesicular stomatitis virus (VSV) vaccine containing the Ebola virus (species *Zaire ebolavirus;* EBOV) glycoprotein (GP) in place of the VSV GP. Since August 2018, rVSV-ZEBOV has been used in response to four Ebola virus disease (EVD) outbreaks in the Democratic Republic of Congo and neighboring countries, including Uganda. Data on the immune response duration following rVSV-ZEBOV vaccination are critical to inform recommendations on future use, including booster doses, in high-risk areas to help curtail further epidemics and ensure healthcare workers (HCWs) are protected. This study aimed to assess knowledge, attitudes, and practices related to EBOV, vaccination, and infection prevention and control among vaccinated and unvaccinated HCWs in three high-risk districts in Uganda (Kasese, Kabarole, and Bundibugyo Districts). We also sought to determine the prevalence of anti-EBOV IgG and assess risk factors for EBOV seropositivity among participants. We administered surveys and collected blood samples to test for the presence of EBOV-specific IgG antibodies. Laboratory testing is ongoing; here we present a descriptive analysis of survey data. Overall, 565 HCWs were enrolled, of which 210 (37%) were vaccinated. Knowledge that rVSV-ZEBOV only protects against EBOV was low among vaccinated (32%; 62/192) and

unvaccinated (7%; 14/200) HCWs. Most vaccinated (91%; 192/210) and unvaccinated (92%; 326/355) HCWs indicated that they would want to receive a booster or initial dose of rVSV-ZEBOV, respectively. Safety concerns (e.g., vaccine-related adverse events) was the most reported reason (60%; 28/47) for hesitancy in receiving a dose of rVSV-ZEBOV. As Uganda has experienced outbreaks of *Sudan ebolavirus* and *Bundibugyo ebolavirus*, for which rVSV-ZEBOV does not protect against, our data underscore the importance and challenges of risk communication to HCWs, and the need for continued vigilant infection prevention and control practices when working with suspect EVD patients. The results of this study will also help characterize immune response following vaccination.

0188

HUMORAL RESPONSES ELICITED BY VARIOUS SARS-COV-2 VACCINES IN MOUSE MODELS OF DIABETES

Olivia Smith, Brent Fujimoto, Teri A. Wong, Albert To, Troy Odo, Axel T. Lehrer

University of Hawaii Manoa, Honolulu, HI, United States

The COVID-19 pandemic has resulted in an unprecedented burden to health systems, caused economic and social disruption, and led to a staggering number of deaths. Individuals with Type 2 diabetes mellitus (T2DM) are more susceptible to severe COVID-19 disease, accounting for 33% of hospitalizations in the United States, while those with obesity and morbid obesity, account for over 60% of the COVID-19 hospitalizations. T2DM affects 6.28% of the world's population and roughly 30 million people in the United States. Additionally, previous literature suggests reduced vaccine efficacy in individuals with T2DM. Considering how T2DM is a risk factor for severe COVID-19, as well as drastic increases in health disparities, it is important to understand how this metabolic syndrome affects the immunity generated by SARS CoV-2 vaccines and to understand COVID-19 hospitalization prevention within these populations. It is hypothesized that humoral immune responses elicited by differing vaccine platforms, including mRNA and subunit protein vaccines, will be decreased in mice with altered metabolic states compared to healthy control counterparts. To address this objective, an optimized multiplex bead-based immunoassay was used to delineate the humoral immunogenicity to SARS CoV-2 vaccine platforms in diabetic mouse models as well as anti-SARS CoV-2 Spike binding, a partial correlate of protection for SARS CoV-2. Preliminary results suggest a decrease in humoral responses in T2DM and obese mouse models after completing 2-dose regimens of two adjuvanted subunit protein vaccines and the mRNA vaccine. However, the promising new protein subunit vaccine, adjuvanted with CoVaccine HT, elicits greater humoral responses compared to Alum adjuvanted and mRNA vaccines in mice with altered metabolic states. As a partial correlate of protection for SARS CoV-2, these humoral responses can be used to determine the efficacy of varied vaccines in diabetic mouse models and could also be used for future vaccine development or even in vaccine and prevention interventions within populations of those with T2DM and obesity.

0189

A NOVEL METHOD FOR ESTIMATING VACCINE EFFICACY AGAINST INFECTION AND DISEASE PROGRESSION: APPLICATION TO A COVID-19 VACCINE TRIAL

Lucy R. Williams[1], Merryn Voysey[2], Andrew J. Pollard[2], Nicholas C. Grassly[1]

[1]Imperial College London, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom

Vaccines can impact multiple aspects of the natural history of an infectious disease, providing protection against different stages of disease progression. Vaccine efficacy (VE) is typically evaluated independently for each disease outcome, but this can cause biased estimates and misleading interpretation of VE against some outcomes. We propose an integrated analysis of all outcomes based on a Markov model of disease natural history that adjusts for these biases. The model is implemented as a hierarchical multivariate multivariable generalised regression in RStan. The number of infections and disease cases is a function of VE, test sensitivity and specificity, adherence to testing, force of infection (FOI) and the probability of progression to each stage of severity. We tested the model using simulated data and then applied it to data from COV002, a phase 3 trial of the ChAdOx1 nCoV-19 (AZD1222) vaccine against COVID-19. In this trial, symptomatic cases were detected through testing in response to symptom-reporting while asymptomatic/pre-symptomatic cases were detected with weekly testing regardless of symptom status. Accounting for imperfect test characteristics and differences in adherence to weekly testing, our model estimated ChAdOx1 nCoV-19 VE against infection (VE_{in}) at 48% (95% CI 38-57) and against progression to symptoms (VE_{pr}) at 45% (95% CI 31-71). This implies a VE against symptomatic infection of 71.4% (95% CI 63-78), consistent with published trial estimates. Adjusting for test specificity made negligible difference, while accounting for a lower probability of detecting asymptomatic relative to symptomatic infections decreased estimated VE_{in}, particularly in subgroups with poorer testing adherence. The FOI and probability of symptom development, p_s, were higher in participants aged <55 years (FOI 0.37/year [95% CI 0.33-0.41], p_s 0.54 [95% CI 0.48-0.59] than ≥55 years (FOI 0.26/year [95% CI 0.21-0.32], p_s 0.33 [95% CI 0.24-0.45]). Our model framework can be used to analyse vaccine trial data with multiple disease outcomes and demonstrates the robustness of the trial-reported estimates for ChAdOx-1 nCoV-19.

0190

SARS-COV-2 SEROPREVALENCE IN RURAL & URBAN POPULATIONS IN GHANA

Irene Owusu Donkor[1], Jewelna Akorli[1], Millicent Opoku[1], Yvonne Ashong[1], Nana Efua Andoh[1], Jeffrey Sumboh[1], Kojo Mensah Sedzro[1], Abuaku Benjamin[1], Vincent Munster[2], Kwadwo Ansah Koram[1]

[1]Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, [2]Rocky Mountain Laboratories, Hamilton, MT, United States

Ghana officially announced its first case of COVID-19 on March 12, 2020 after which a nationwide age-stratified cross-sectional study was conducted from February until December 2021 to assess the severity of COVID-19 transmission. Study sites were selected based on disease burden stratification high, medium, low and very low zones according to real-time disease reports gathered. Probability Proportional to Size was applied within each geographic zone and 20 households selected from 300 Enumeration Areas (geographic area covering an average of 180 households). Naso/oropharyngeal swabs and venous blood were collected from 5898 consented participants (one per household). Swabs were tested using quantitative reverse-transcription PCR (qRT-PCR), and serum was tested using the WANTAI ELISA total IgG/IgM assay. The overall seroprevalence was 67.9%, with the highest rate in Greater Accra (76.0%) a high burden zone. Seroprevalence was higher in the urban population (70%) compared to the rural population (62.7%). Seroprevalence was lowest in young children, highest in teens and young adults, and slightly decreased in older age groups (5-9 years, 52.2%; 10-14, 63.9%; 15-19, 72.6%; 30-39, 72.5%; 50-59, 70.0%; 60-69, 69.2%; and 70+, 69.0%). There were no significant differences by gender. A total of 5389 participants were unvaccinated, and 65% were seropositive in this group. Of the 4,003 seropositive individuals, 69.2%were asymptomatic and 26.4% did not adhere to infection prevention guidelines. Of the 2219 samples tested using qRT-PCR so far, 6.9% were positive for the *E* gene only, 58.7% were positive for the *N* gene only, and 9.6% were positive for both. Confirmatory testing with qRT-PCR showed an overall infection rate of 7.6%. (29.7% *E* gene only, 1.2% *N* gene only, and 42% *E+N* genes). These results indicate that more than half of the sampled population has been exposed to the SARS CoV-2 virus since it was first reported, putting Ghana in the medium to high COVID-19 burden category. Infection rate was quite low compared to seroprevalence during the sampling period.

0191

KAPOSI'S SARCOMA-ASSOCIATED HERPESVIRUS SHEDDING IN SALIVA AND CERVICAL SECRETIONS IN TANZANIAN WOMEN

Anna M. Mertelsmann[1], Crispin Mukerebe[2], Donald Miyaye[2], Peter Shigella[2], Loyce Mhango[2], Peter Lutonja[2], Paul L. Corstjens[3], Claudia de Dood[3], Soledad Colombe DVM[4], Christine Aristide[5], Maureen M. Ward[5], Myung Hee Lee[5], Johb M. Changalucha[2], Jennifer A. Downs[5]

[1]NYP Weill Cornell, New York, NY, United States, [2]Mwanza Intervention Trials Unit/National Institute for Medical Research, Mwanza, United Republic of Tanzania, [3]Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands, [4]Institute of Tropical Medicine, Antwerp, Belgium, [5]Center for Global Health, Weill Cornell Medicine, New York, NY, United States

In endemic areas, Kaposi's sarcoma-associated herpesvirus (KSHV) transmission occurs to a significant degree via saliva, typically during childhood. Factors leading to KSHV viral reactivation and salivary shedding remain poorly understood. Preliminary data suggest that *Schistosoma mansoni* infection, which has been associated with impaired viral control, may contribute to KSHV reactivation. However, in those studies clear evidence for this impact was limited due to a focus on seroprevalence or small sample size. We sought to determine the relationship between active *S. mansoni* or *S. haematobium* infection and KSHV shedding.We quantified KSHV DNA in stored saliva and cervical swab samples from two cohorts of women living in areas of Tanzania with endemic *S. mansoni* or *S. haematobium* by real-time polymerase chain reaction. Chi-squared and Fisher's Exact tests were used to determine differences in clinical and demographic factors between those who were and were not shedding KSHV. Among the 99 women from the *S. mansoni* area, 6 (6.1%) had detectable KSHV in saliva, of whom 3 had *S. mansoni* infection. There was no difference in frequency of KSHV salivary shedding between the *S. mansoni* infected (n=39) and uninfected (n=60) groups. Women with KSHV salivary shedding more frequently reported infertility than those not shedding KSHV (80% versus 19.5%, p=0.009). Among the 43 women from the *S. haematobium* area, 7 (15.9%) had detectable KSHV in saliva, of whom 4 had *S. haematobium* infection. There was no difference in frequency of KSHV salivary shedding between the *S. haematobium* infected (n=18) and uninfected (n=25) groups. No woman had KSHV detected in her cervical sample. In conclusion, in this population with high KSHV seroprevalence, we provide the first report that *S. haematobium* infection was not associated with KSHV salivary shedding, and provide additional evidence for the same in *S. mansoni* infection. Interestingly, KSHV salivary shedding was associated with infertility, a known effect of another herpesvirus, HHV-6. Our results contribute to knowledge about the epidemiology and transmission of KSHV infection in an East African population.

0192

A SARS-COV-2 ANTIBODY LATERAL FLOW ASSAY PROVIDES A SEMIQUANTITATIVE ASSESSMENT OF ANTI-SPIKE ANTIBODY RESPONSES AFTER SARS-COV-2 VACCINATION

Sarah E. Greene, Rachel M. Presti, Alfred H.j. Kim, Gary J. Weil

Washington University in St Louis, St. Louis, MO, United States

Inexpensive, simple SARS-CoV-2 diagnostic tests can be useful tools for responding to the COVID-19 pandemic, especially in outpatient or low resource settings. Prior studies have shown that some SARS-CoV-2 antibody lateral flow assays (LFA) are sensitive for detecting antibodies within weeks after infection. This study tested samples from immunocompetent adults and those with chronic inflammatory disease (CID) who were taking a variety of immunosuppressive agents, before and after SARS-CoV-2 vaccination. We used the LFA COVIBLOCK Covid-19 rapid test cassette to detect antibodies to the SAR-CoV-2 spike (S) protein receptor binding domain. These results were compared with results obtained by anti-S ELISA and a SARS-CoV-2 viral particle neutralization assays. The LFA detected anti-S antibodies in 31/31 (100%) of the immunocompetent and 119/137 (86.9%) of the CID participants. Furthermore, the LFA detected anti-S antibodies in 28/28 (100%) of the immunocompetent and 112/116 (96.6%) of the CID participants who had detectible anti-S antibodies by ELISA. Semiquantitative LFA scores were significantly lower in samples from participants with CID. Semiquantitative LFA scores were significantly correlated with anti-S antibody ELISA OD values (Spearman coefficient r=0.92) and were also correlated with SARS-CoV-2 viral particle neutralization results. This simple LFA test appears to be a practical alternative to laboratory-based assays for detecting anti-S antibodies in individuals or populations. This type of test may be most useful for testing people in outpatient or resource-limited settings.

0193

INTERFERENCE OF COXSACKIEVIRUSES ON AZD1222 VACCINATION

Han-Pin Chang

Chang Gung University, Taoyuan City, Taiwan

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has infected over 470 million patients while taking the lives of more than 6 million. Despite preventive measures, the number of patients has kept growing worldwide. Currently, it is assumed that the most effective way to fight the virus is by an effective vaccination. It has been shown in many pieces of research that vaccines could induce innate and adaptive immune responses and reduce disease severity. In Taiwan, the common vaccines are Pfizer-BioNTech (BNT), Moderna(mRNA-1273), Medigen, and Oxford-AstraZeneca COVID-19 vaccine (AZD1222). Our laboratory has been performing neutralizing antibody titer ELISA assays for vaccinated Taiwanese. Results have shown that Taiwanese vaccinated with the AZD1222 vaccine have a scattered range of antibody titer, with a lower seropositive rate than other vaccines. Because coxsackieviruses use the same CAR receptor as the AZD1222 vaccine, and coxsackievirus infection often occurs locally. Therefore, we speculate that neutralizing antibodies produced by coxsackievirus infection may interfere with AZD1222 induced antibody titer. We performed Neutralization Titer Assays with coxsackievirus B viruses (CVB) using vaccinated serum. Results showed a positive correlation between CVB neutralization antibody titers and AZD1222 vaccination titers. To exclude the influence of other factors in serum and different viral-associated pathways in cells, we used the characteristics of CHO cells that do not express any known receptor for AZD1222 to engineer a CHO cell that stably expresses the CAR receptor. Then we used purified CVB neutralizing antibodies to test whether the infectivity of adenovirus is affected. This study may give us a clue why antibody responses differ among vaccinees of AZD1222 in Taiwan.

0194

SURVEILLANCE FOR ARBOVIRUSES AND LEPTOSPIROSIS AMONG NON-MALARIAL OUTPATIENTS WITH ACUTE FEBRILE ILLNESS IN AREAS AFFECTED BY CYCLONES IDAI AND KENNETH IN MOZAMBIQUE

Vanio Andre Mugabe[1], Osvaldo Frederico Inlamea[2], Sadia Ali[2], Plácida Maholela[2], Bibiana Melchior[2], Argentina Felisbela Muianga[2], John Oludele[2], Andarusse Sumail[2], Virgílio António[2], Vanessa Onofre Monteiro[2], Inocêncio Chongo[2], Uriel Kitron[3], Guilherme Sousa Ribeiro[4], Eduardo Samo Gudo[2]

[1]Universidade Licungo - Mozambique, Quelimane, Mozambique, [2]Instituto Nacional de Saúde, Maputo, Mozambique, Maputo, Mozambique, [3]Emory University, Atlanta, GA, United States, [4]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Salvador, Brazil

The floods associated with the landfall of cyclones Idai and Kenneth in Mozambique between March and April 2019 had a major impact on the country's public health and placed the population at risk for vector- and rodent-borne diseases. Aiming to improve the diagnostic capacity, yield information to guide public health responses, and assess potential short-term effects of cyclones Idai and Kenneth on arboviruses (dengue,

Zika, and chikungunya) and leptospirosis, we established a clinical and laboratory surveillance for non-malarial acute febrile illness in six health units located in different districts within the two provinces (Sofala and Cabo Delgado) most affected by the cyclones. Patients were tested by real-time reverse transcriptase polymerase chain reaction (qRT-PCR) for dengue (DENV), Zika (ZIKV) and chikungunya (CHIKV) viruses and by enzyme immunoassay (ELISA) to detect nonstructural DENV protein 1 (NS1) and DENV, ZIKV, CHIKV, and Leptospira IgM antibodies. From April to September 2019, we enrolled 305 patients aged ≥15 years, of which 58.4% were women and the median age was 30 years (IQR: 23 - 41 years). All patients were qRT-PCR negative for arboviruses. Three (1.0%) patients were positive by DENV NS1 ELISA, of which one also had positive IgM against DENV and CHIVK. In addition, specific IgM antibodies against DENV, ZIKV, CHIKV or Leptospira were found in the serum of 104 (34.1%) patients. Of them, 73 (23.9%) had evidence of a recent single infection, 19 (6.2%) had evidence of a recent infection by more than one arbovirus, and 12 (3.9%) had dual recent infection by an arbovirus and Leptospira. Our results indicate that vector- and rodent-borne diseases happened in all districts under investigation on wake of cyclones Idai and Kenneth, including some regions of the country where cases had not been previously detected. Although the absence of baseline, long-term surveillance data hampered assessing the impact of cyclones Idai and Kenneth on vector- and rodent-borne transmission, the investigation provided useful information to respond to post-cyclone emergency purposes.

0195

HIGH SEROPREVALENCE RATES OF SARS-COV-2 SPECIFIC IGG ANTIBODY IN SITAKUNDA, CHATTOGRAM, BANGLADESH

Taufiqur R. Bhuiyan

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

We report results from serial population representative SARS-CoV-2 serosurveys in the Sitakunda subdistrict in the South-West Bangladesh. We used digitized satellite imagery to select a random sample of the population, asked all individuals ≥1 years old from selected household to participate in the study and used the Wantai total Ab assay to measure total antibodies against the SARS-CoV-2 RBD. From March through June 2021, we surveyed 2,307 individuals and estimated an adjusted (for assay performance and household clustering) seroprevalence of 64% of whom very few (5.4%; n=125) were vaccinated. After this serosurvey, a large epidemic of the Delta variant hit the area and we revisited all enrolled households from September to October, 2021. We found that 68% of those seronegative in the first serosurvey seroconverted in the three-month period between rounds. 12% of these individuals who seroconverted were vaccinated with at least one dose of Covid-19 vaccine, and 28.3% of those who seroconverted reported having an onset of at least one covid-related symptom since the first serosurvey. We estimated an adjusted seroprevalence after the Delta wave of 83.6%. We then revisited households in Jan-Feb 2022 after the Omicron wave and are currently testing these samples with the same methods and plan to estimate seroprevalence, seroincidence and seroreversion rates over the full time period.

0196

ANTI-VIRAL ACTIVITY OF FDA-LICENSED DRUGS ON ARBOVIRAL INFECTION *IN VITRO*

Jindarat Lohachanakul, Kamonthip Rungrojcharoenkit, Kedsara Tayong, Rungarun Suthangkornkul, Prapapun Ong-ajchaowlerd, Suttikarn Apichirapokey, Thongchai Khiankaew, Chutithorn Tawilert, Stefan Fernandez, Anthony R. Jones, Thomas S. Cotrone, Taweewun Hunsawong

Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Chikungunya virus (CHIKV) and Zika virus (ZIKV) are mosquito-borne viruses. There is currently no licensed vaccine or specific treatment available for either viruses. In this study, we investigated anti-viral activity of FDA-approved drugs including Favipiravir, Arbidol, Ivermectin B1a, Milbemycin oxime, Niclosamide, and Telmisartan on arboviral infection. The concentrations of each drug were selected based-on toxicity assay results in *Aedes albopictus*-derived cell line, C6/36 cells, to investigate the effect on CHIKV 181 clone 25 (vaccine strain) and ZIKV (Puerto Rico strain, Asian genotype) infections at MOI of 0.1. The half-maximal inhibitory concentration (IC50) values against CHIKV infection were 59.2, 24.3, 3.5, 26.4, 20.1 and 1.0 µg/ml for Favipiravir, Arbidol, Ivermectin B1a, Milbemycin oxime, Niclosamide, and Telmisartan, respectively. Among all, we observed only two drugs had any inhibitory effect on ZIKV infection including Arbidol and Ivermectin B1a with IC50 values of 2.5 and 0.3 µg/ml, respectively. These data indicate a potential inhibitory effect of these drugs against CHIKV and ZIKV replications which and may be considered as candidates for testing in animal model and future clinical evaluation.

0197

DETECTION OF RESPIRATORY VIRUSES IN HEALTHY CHILDREN IN THE ERA OF THE COVID-19 PANDEMIC

Flavian Akite, Patrick Ansah

Navrongo Health Research Center, Navrongo, Ghana

Respiratory viruses are known to be detected in children irrespective of their health status. Two or more of these viruses can be detected simultaneously for one person although this might not change the severity of infections. While some studies suggest that the Covid-19 pandemic has suppressed the presence of these respiratory viruses as a result of the strict regulations implemented, much is not known about Ghana where the pandemic was less prevalent, and regulations were not strictly adhered to. The main aim of this study was to determine the viruses in circulation among healthy children during the Covid-19 pandemic. Nasopharyngeal samples were collected from 382 children between the ages of one and twelve years. These were transported in a viral transport medium and stored in a -20°C freezer. The samples were analysed for the presence of five respiratory viruses using Multiplex PCR. A questionnaire was administered to collect the demographic characteristics of participants. After the analysis, 65 samples (17.0%) were positive for at least one respiratory virus. The prevalence of viruses detected are as follows: 8.9% for SARS-CoV-2, 4.4% for Influenza Virus (A and B), 3.1% for Respiratory Syncytial Virus, 2.8% for parainfluenza viruses (1, 2 and 3), and 1% for Adenovirus. Ten samples (2.6%) were positive for two or more of the viruses under investigation. None of these participants presented signs of respiratory infections at the time of sample collection. This data suggests the presence of respiratory viruses in healthy children in Ghana. These viruses are co-circulating with a high prevalence of Covid-19. This data shows that there is a potential threat to disease outbreaks.

0198

MODELLING LASSA FEVER IN NIGERIA AND INVESTIGATION OF THE ECOLOGICAL CHARACTERISTICS OF THE DISEASE RESERVOIR

James McKendrick, Warren Tennant, Michael J. Tildesley

Warwick University, Coventry, United Kingdom

Lassa fever is a viral haemorrhagic disease caused by infection with *Lassa mammarenavirus* and is endemic to many regions within West Africa. During the first four months of 2018, Nigeria experienced an unprecedented epidemic of Lassa fever resulting in a total of 633 confirmed cases and 171 deaths. Annual epidemics occurring at the same time of year have since followed, and the main drivers of these annual outbreaks are yet to be fully identified. The rodent *Mastomys natalensis* serves as the primary reservoir of the virus, and their ecology and behaviour has been linked to the distinct spatial and seasonal patterns of Lassa fever incidence. In this presentation we show that the population dynamics of the rodents are a key driver of the observed seasonality in cases. Using a vector transmission model with a periodic birth rate in the rodent population, we are able to replicate the trends in

the confirmed case data from 2018-2020 supplied by the Nigeria Centre for Disease Control. Furthermore, we investigate how the choice of contact-density function describing the disease transmission rate between rats affects the overall epidemiological dynamics of Lassa fever in human hosts. When applying an Approximate Bayesian Computation method of model selection, we conclude that the system supports a sigmoidal shape function for the rodent-to-rodent transmission rate. The resulting posterior parameter distributions indicate that the rodent reservoir spikes in population before the increase in reported cases, therefore our research suggests disease management could be improved by focusing efforts on reducing the number of interactions between humans and rodents, particularly at the end of a calendar year.

PROTEIN-PROTEIN CONJUGATION ENHANCES IMMUNOGENICITY OF SARS-COV-2 RECEPTOR BINDING DOMAIN VACCINES

Puthupparampil V. Scaria[1], Christopher G. Rowe[2], Beth B. Chen[2], Thayne H. Dickey[2], Jonathan P. Renn[2], Lynn E. Lambert[2], Emma K. Barnafo[2], Kelly M. Rausch[2], Niraj H. Tolia[2], Patrick E. Duffy[2]

[1]LMIV/NIAID/NIH, Bethesda, MD, United States, [2]NIAID/NIH, Bethesda, MD, United States

The emergence SARS-CoV-2 in late 2019 and the ensuing pandemic have propelled an unprecedented effort to develop vaccines to contain virus spread or prevent disease. This resulted in numerous effective vaccines that are currently deployed, and candidates currently being evaluated. While vaccines based on mRNA and adeno viral vector platforms were highly effective and faster to develop, protein subunit vaccines also showed success. Many of the vaccines currently approved for human use target the Spike protein of the corona virus isolate from the early stage of the pandemic. Nevertheless, they afford significant protection against serious illness from newer variants, albeit with reduced effectiveness. Despite the success of new vaccines, the need for effective and affordable vaccines persists, especially in the developing world. More recent efforts target the receptor binding domain (RBD) of the Spike protein to focus the immune response to this domain and enhance neutralizing antibody generation that interrupts the ACE2 interaction. We adapted our protein-protein conjugate vaccine technology to generate a vaccine based on RBD antigen. RBD was conjugated to a carrier protein, EcoCRM, to generate two types of conjugates: crosslinked and radial conjugates. In the crosslinked conjugate, antigen and carrier are chemically crosslinked while in the radial conjugate, antigen is conjugated to the carrier by site specific conjugation. These conjugates were tested in mouse immunogenicity studies with two different adjuvants used in human vaccines, Alhydrogel® and AS01. With AS01, both conjugates showed enhanced immunogenicity in mice compared to RBD. Antibody subclass analysis showed a Th1 biased antibody response. In hACE2 binding inhibition and pseudo-virus neutralization assays, sera from mice vaccinated with the radial conjugate demonstrated strong functional activity. Immune sera obtained with the radial conjugate yielded strong virus neutralization activity in different variants of SARS-CoV-2 including WA1, Delta and Omicron. Further studies are underway to evaluate this conjugate in non-human primates.

IMPLEMENTATION OF DIRECT DETECTION BY NANOPORE SEQUENCING OF POLIOVIRUS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Tresor Mampuela Kabeya[1], Alex Shaw[2], Catherine Pratt[3], Emmanuel Lokilo[1], Catherine Troman[2], Yogolelo Riziki[4], Marcelline Akonga[4], Bibiche Nsunda[4], Yvonne Lay[4], Elie Pukuta[4], Aziza Amuri[4], Raphael Lumembe[4], Jean-claude Makangara[4], Joyce Akello[2], White Bailey[3], Eddy Lusamaki[4], Steeve Ahuka[4], Nick Grassly[2], Placide Mbala[4]

[1]National Institute for Biomedical Research, kinshasa, Democratic Republic of the Congo, [2]Imperial College London, London, United Kingdom, [3]University of Nebraska, Nebraska, NE, United States, [4]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo

Delayed detection of poliovirus transmission has been described as one of the greatest risks to polio eradication. Direct detection of poliovirus from stool by nested PCR and nanopore sequencing (DDNS) offers a real opportunity to reduce the delivery time of results for the response to polio epidemics. We tested samples in 2 stages in this study: a retrospective arm in which we tested stools from suspected subjects with polioviruses by cell culture; a prospective arm including all samples received during the 4 months of the study as part of the surveillance of acute flaccid paralysis in the Democratic Republic of the Congo (DRC). A total of 2552 chloroform-treated stools were collected and analyzed in the laboratory with DDNS following the protocol protocols.io (https://dx.doi.org/10.17 504/protocols.io.b5pyq5pw) in parallel with cell culture, intra typic differentiation (ITD), and Sanger sequencing. Our results showed non-inferior sensitivity and specificity of DDNS compared with cell culture for both Sabin and vaccine-derived polioviruses. The generated sequences are very consistent between DDNS and traditional Sanger sequencing of cell culture supernatant (average similarity of 99.9%). DDNS PV1 sequences were obtained at a shorter median of 7 days after sample receipt in comparison with 33 days for cell culture, ITD and Sanger sequencing. DDNS allowed early detection of the new emergence of circulating vaccine-derived poliovirus 2 (cVDPV2) in Maniema province. These data showed that DDNS is sensitive, specific, and accurate, and also enables early identification of important viruses, a key component of the GPEI strategy for 2022-2026.

0201

PHARMACOVIGILANCE OF COVID-19 VACCINES IN SUB-SAHARAN AFRICA - A COHORT EVENT MONITORING STUDY OF THE SAFETY OF THREE COVID-19 VACCINES IMPLEMENTED IN GABON IN ADULTS AGED 18 YEARS AND ABOVE

Ghyslain Mombo-Ngoma[1], Anthony Mintsa[1], Frederique Mbang Abba[1], Christelle Akagha Konde[2], Julienne Atsame[3], Lisbeth Akebayeri[4], Arsene Ifoudji Makao[5], Linda Ibinga[6], Carinne Eyi Zang[7], Bertrand Lell[1], Marielle K. Bouyou-Akotet[8]

[1]Centre de Recherches Medicales de Lambaréné (CERMEL), Lambaréné, Gabon, [2]Centre Hospitalier Universitaire d'Owendo, Owendo, Gabon, [3]Ministère de la santé, Libreville, Gabon, [4]Hopital de la coopération sinogabonaise, Libreville, Gabon, [5]Centre Hospitalier Universitaire de Libreville (CHUL), Libreville, Gabon, [6]Hopital d'Instruction des Armées, Akanda, Gabon, [7]Centre Hospitalier Universitaire Mere Enfant Fondation Jeanne Ebori, Libreville, Gabon, [8]Université des Sciences de la Santé (USS), Owendo, Gabon

Like all countries around the world, African countries have also suffered the Covid-19 pandemic with several waves. It was on this order that when the first vaccines became available, the countries of sub-Saharan Africa also considered vaccinating their populations against Covid-19. The monitoring of vaccines against COVID-19 is a major challenge, in particular to guarantee their effectiveness in the population as well as to identify any adverse effects that may not have been observed during clinical trials, in particular the rare (<1/1000) or delayed effects. The objective of this analysis is to assess the safety of the Covid-19 vaccines

deployed in Gabon during the national immunisation campaign. In Gabon, a national vaccination committee (COPIVAC) has been set up to coordinate the national anti-Covid-19 vaccination campaign, with a pharmacovigilance subcommittee responsible for evaluating the safety of use of vaccines. deployed in Gabon, ensuring continuous monitoring of foreseeable or unexpected adverse effects. A national database has been set up on RedCap with active and passive detection of minor and severe adverse events post-immunization (AEFI). The vaccination campaign began on March 25, 2021, targeting adults aged 18 and over who would have given informed consent after eligibility assessment. As of March 28, 2022, 450,722 injections of the Sinopharm/BBIBP, BionTech/Pfizer, Janssen and Moderna vaccines have been administered in a population with a proportion of 73% (326,497) men and around 94% (425,359) aged between 18 and 59 years. A total of 6863 AEFIs were recorded including deaths. Systemic events such as headache, fatigue, fever and local and general pain were the most common. Adverse manifestations were mostly minor and transient. The few deaths observed were either due to Covid-19 or to other conditions not related to the vaccines. In conclusion, a pharmacovigilance system for monitoring the safety of Covid-19 vaccines in Gabon has been set up and the it has shown that vaccines against Covid-19 were well tolerated with good safety.

0202

DETERMINANTS OF COVID-19 VACCINATIONS AMONG A STATE-WIDE YEAR-LONG SURVEILLANCE INITIATIVE IN A CONSERVATIVE SOUTHERN STATE

Lidia Gual-Gonzalez, **Maggie S. J. McCarter**, Kyndall C. Braumuller, Stella Self, Connor H. Ross, Chloe Rodriguez-Ramos, Virginie G. Daguise, Melissa S. Nolan

The University of South Carolina, Columbia, SC, United States

More than 350 million cases and 5 million deaths from COVID-19 have been recorded worldwide. With growing concern, and therefore increased public health measures for controlling the pandemic, came increased skepticism by a growing subset of the United States' population. Vaccine hesitancy has become a leading barrier in COVID-19 control and prevention. Given the intricate nature of this important barrier, a single statistical analysis methodology fails to address all eventualities of this complex issue. This study utilized multiple distinct, analytical approaches to understand vaccine motivations and population-level trends. With 14,915 surveys from a year-long, state-wide surveillance initiative, we performed three robust statistical analyses to evaluate vaccine hesitancy: principal component analysis, survival analysis, and spatial-time series analysis. The analytic goal was to utilize complementary mathematical approaches to identify overlapping themes of vaccine hesitancy and vaccine trust in a highly conservative US state. Principal component analysis showed four components correlated within the variables: vaccine mistrust and information garnered through various forms of media, and trust in both the science and safety behind the COVID-19 vaccine and the government. Spatial time series showed that overall, there was an increased tendency in vaccination rates towards the end of the study, as well as more positive vaccination perception. Finally, emerging hotspot analysis for vaccination status showed most areas had oscillating hot spots throughout the past year, indicating heterogeneity of vaccination status among the local population. The results indicate information source, and the population's trust in the science and approval behind the vaccine research influences vaccine receipt. Findings coincide with previous research on predictors of vaccine hesitancy and receipt. This multifaceted statistical approach allowed for methodologically rigorous results that public health professionals and policy makers can directly use to improve vaccine interventions.

0203

LOWER SEVERITY OF DENGUE FEVER TO PEOPLE WITH COVID 19 VACCINE FULL DOSES

Osa Rafshodia Rafidin, Sylvia Gusrina, Yuliana Fitriady

Health City Office of Samarinda, Samarinda, Indonesia

Dengue fever is rising in the early 2022 at Samarinda City, East Borneo of Indonesia. The trend within the last 2 years of Covid19 Pandemic, Dengue fever is at minimal level of cases. These are the side effect of under reporting cases during pandemic. Within January 2022 to March 2022, there are 721 cases reported, with 10 deaths, 71 cases with high severity cases, 640 with mild symptoms. The age under 18 years old are the most cases, following 18 - 40 years old, and over 40 years old with the highest percentage of deaths. Indonesia start Covid19 Vaccine at January 2021, with the age over 60 years old as priority to get it. In the middle of 2021, the government increase the participant to age over 40 years old, and at the late 2021, the government expand the criteria to age over 18 years old. At the early 2022, the government introduce Covid19 vaccine for under 18 years old. Until the end of March 2022, the Coverage for under 18 years old is 78% for Samarinda City. As the dengue fever and dengue haemorrhagic fever risen, 52 cases with high severity cases are among age under 18 years old, and received only dose 1 at the time they were sick. 19 cases with high severity cases are among age 18 - 40 years old without any Covid19 Vaccine received. 7 deaths cases are among 18 - 40 years old without any vaccine received, 3 deaths are among age over 60 years old. In conclusion, people who has no Covid19 Vaccine are more statistically significant to be more severe illness when they got Dengue Fever infection.

"KUTETEZA": IMPLEMENTATION OF A VILLAGE-LED COVID-19 PREVENTION INTERVENTION IN RURAL MALAWI

Donnie Mategula[1], Sepeedeh Saleh[1], Ana Ibarz-Pavón[1], Mphatso Phiri[1], Marlen Chawani[1], Latif Ndeketa[1], Melody Sakala[1], Wongani Nyangulu[1], Henry Sambakusi[1], Mwiza Sambo[1], Robert Mataya[2], Titus Divala[1], Keneth Maleta[1], Moses Kumwenda[1], Chimwemwe Ligomba[1], Amos Nyaka[3], Clara Sambani[3], Steve Vinkhumbo[4], Dominic Nkhoma[5], Bridget Malewezi[6], Liz Corbett[1], Anja Terlouw[1]

[1]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [2]. Kamuzu University of Health Sciences, Blantyre, Malawi, [3]Society of Medical Doctors (SMD), Lilongwe, Malawi, [4]Ministry of Disability and Elderly, Lilongwe, Malawi, [5]Ministry of Health, Lilongwe, Malawi, [6]Society of Medical Doctors (SMD), Malawi, Lilongwe, Malawi

The COVID-19 epidemic in Malawi started in April 2020, with 85,667 cases and 2,626 deaths recorded nationally to date. Data suggest that the Malawi epidemic has largely centred around urban settings, but the true extent of rural spread - exposing the elderly in these communities - is less clear. The likelihood of SARS-COV-2 remaining an endemic pathogen means an effective long-term response is vital. The "Kuteteza" project (meaning "to protect" in Chichewa) is a community-based intervention using shielding of the elderly and additional strategies to mitigate the impacts of COVID-19 in rural and peri-urban Malawi. We partnered with government and district-level staff in the Blantyre and Mangochi districts. After engagement with village leaders, local volunteers and community members identified elderly residents and rearranged living spaces, ensuring continued provision of basic needs. Masks, handwashing stations, and soap were provided to shielding households. Context-responsive community engagement reinforced COVID-19 prevention during peak risk periods. Government ministry collaboration allowed extra support to key vulnerable groups, with food packages for instance. The project involved 25 villages. Multi-level stakeholder engagement was pivotal in developing and establishing the work, and strong district health office support was integral to implementation. Team members contributed to national meetings, aligning the project with national guidance and stakeholder actions. Established partnerships with relevant ministries resulted in the incorporation of shielding in the Malawi COVID-19 response plan. In 'Kuteteza' villages, handwashing stations and soap were used, and there

was awareness of COVID-19 prevention measures. Further experiences and evaluation results will be presented, including learning points for future outbreak responses. Through effective stakeholder engagement and contribution to national response strategy, the Kuteteza project raised awareness and supported populations at a critical time in the pandemic. These approaches can be incorporated in future epidemic and emergency responses.

0205

SEROPREVALENCE AND FACTORS CORRELATED WITH SARS-COV-2 INFECTION IN KAMPHAENG PHET, THAILAND

Darunee Buddhari[1], Sopon Iamsirithaworn[2], Surachai Kaewhiran[3], Taweewun Hunsawong[1], Anthony R. Jones[1], Aaron R. Farmer[1], Stefan Fernandez[1], Clarence Tam[4], Timothy P. Endy[5], Stephen J. Thomas[6], Kathryn B. Anderson[6]

[1]USAMD-AFRIMS, Bangkok, Thailand, [2]Ministry of Public Health, Nonthaburi, Thailand, [3]Ministry of Public Health, Kamphaeng Phet, Thailand, [4]National University of Singapore, Singapore, Singapore, [5]Coalition for Epidemic Preparedness Innovations, Washington, DC, United States, [6]State University of New York Upstate Medical University, Syracuse, NY, United States

Thailand initially experienced a delayed onset of SARS-CoV-2 pandemic activity but has since accumulated over 3 million infections to date. Defining seroprevalence over time and risk factors for infection are important for understanding SARS-CoV-2 transmission dynamics and informing control strategies. We present early findings from an ongoing population-based, prospective serological study of SARS-CoV-2 in Kamphaeng Phet, Thailand, nested within an ongoing multigenerational family cohort study for dengue virus (DENV) infection that began in 2015. For this sub-study, 1199 individuals enrolled from 231 multigenerational families from July to November 2021. The median age was 26 (range 0 to 96 years) and 59.2% were female. Seropositivity was determined by using AFRIMS in-house IgA and IgG ELISA to the spike protein's receptor binding domain of SARS-CoV-2. During enrollment, 29.0% reported a history of prior SARS-CoV-2 vaccination. The primary vaccines in use for a first dose were Sinovac (22.6%), AstraZeneca (2.8%), Pfizer (2.2%), and Sinopharm (1.3%). The majority of vaccinated individuals were seropositive for SARS-CoV-2 (58.9%), with the lowest seropositivity identified among those vaccinated with a single dose of Sinovac (16.8%). 5.1% of enrollees without a history of vaccination were seropositive on enrollment. Seropositivity was highest in unvaccinated adults aged 19-59 years (8.7% versus 2.2% and 4.5% in children and the elderly, respectively, p<0.01). Among adults, those who had completed high school or college were more likely to be seropositive than lower levels of education (p=0.01). Unvaccinated individuals with SARS-CoV-2 Seropositivity were less likely to have had an acute DENV infection identified during the course of the DENV cohort study (OR = 0.38, p=0.09). In this ongoing study of SARS-CoV-2 transmission within households in Thailand, we report early evidence of heterogeneity in risk of infection and a potential inverse association between risks of DENV and SARS-CoV-2 infection. These findings could inform mitigation measures for both of these viruses and represent an important area for further study.

0206

INHIBITORY EFFECT OF CONCOMITANTLY ADMINISTERED RABIES IMMUNOGLOBULINS ON THE IMMUNOGENICITY OF COMMERCIAL AND CANDIDATE HUMAN RABIES VACCINES IN HAMSTERS

Marie-Clotilde Bernard, Florence Boudet, **Andrea C. Pineda-Pena**, Françoise Guinet-Morlot

Sanofi, Marcy L'Etoile, France

The World Health Organization protocol for rabies post-exposure prophylaxis (PEP) recommends extensive wound washing, immediate vaccination, and administration of rabies immunoglobulin (RIG) in severe category III exposures. Some studies have shown that RIG can interfere with rabies vaccine immunogenicity to some extent. We investigated the interference of RIG on a next generation highly purified Vero cell rabies vaccine candidate (PVRV-NG) versus standard-of-care rabies vaccines in a previously described hamster model. The interference of either human (h) or equine (e) RIG on the immune response elicited by PVRV-NG, a commercial purified Vero cell rabies vaccine (PVRV), and a commercial human diploid cell rabies vaccine (HDCV) was evaluated using the 4-dose Essen PEP regimen (vaccine administered via intramuscular (IM) route at Days 0, 3, 7, 14; RIG administered at Day 0 at a distinct IM site). The anti-rabies seroneutralizing titers and specific serum IgM titers were measured by fluorescent antibody virus neutralization (FAVN) test and enzyme-linked immunosorbent assay (ELISA), respectively, for the vaccines administered with or without RIG. For both read-outs, the RIG interference on PVRV-NG, observed transiently at Day 7, was in the same range as that on PVRV and tended to be lower than that on HDCV. More precisely, antibody titers at D7 were statistically significantly decreased for PVRV-NG, PVRV and HDCV co-administered with hRIG compared to vaccine alone: 1) reduction of FAVN titers by 2.2-fold (p-value= 0.01), 3.6-fold (p-value<0.001) and 10.5-fold (p-value<0.001), respectively; 2) reduction of IgM ELISA titers by 1.9, 2.1 and 3.9-fold (p-values<0.001), respectively. Similar trends were observed with eRIG when tested with PVRV-NG and PVRV vaccines. In summary, the results generated in the hamster model showed that RIG induced similar or less interference on the immunogenicity of PVRV-NG than the standard-of-care vaccines.

0207

COMPARISON OF ONE SINGLE ANTIGEN ASSAY AND THREE SARS-COV-2 MULTI-ANTIGEN IGG ASSAYS IN NIGERIA

Nnaemeka C. Iriemenam[1], Fehintola Ige[2], Stacie Greby[1], Olumide O. Okunoye[1], Mabel Uwandu[2], Maureen Aniedobe[2], Nwando Mba[3], Nwachukwu William[3], Akipu Ehoche[4], Augustine Mpamugo[4], Andrew Mitchell[5], Kristen Stafford[5], Andrew Thomas[6], Temitope Olaleye[6], Oluwaseun Akinmulero[6], Ndidi Agala[6], Ado Abubakar[6], Ajile Owens[7], Sarah Gwyn[7], Eric Rogier[7], Venkatachalam Udhayakumar[7], Laura Steinhardt[7], Diana Martin[7], McPaul Okoye[1], Rosemary Audu[2]

[1]Centers for Disease Control and Prevention, Abuja, Nigeria, [2]Nigerian Institute of Medical Research, Lagos, Nigeria, [3]Nigeria Centre for Disease Control, Abuja, Nigeria, [4]University of Maryland, Baltimore, Abuja Office, Abuja, Nigeria, [5]University of Maryland, Baltimore, Baltimore, MD, United States, [6]Institute of Human Virology, Abuja, Nigeria, [7]Centers for Disease Control and Prevention, Atlanta, GA, United States

Determining an accurate estimate of SARS-CoV-2 seroprevalence has been challenging in African countries where malaria and other pathogens are endemic. Single-antigen assays have shown cross-reactivity and may not provide accurate SARS-CoV-2 seroprevalence estimates in these countries. We assessed the performance of one single-antigen assay and three SARS-CoV-2 multi-antigen IgG assays in a Nigerian population endemic for malaria. De-identified NIMR plasma from SARS-CoV-2 RT-PCR positive and pre-pandemic negative panels were used to evaluate the performance of the four assays (RightSign™ COVID-19 IgG/IgM (RDT), Tetracore® FlexImmArray™ SARS-CoV-2 Human IgG Antibody Test, Luminex xMAP® SARS-CoV-2 multi-antigen IgG assay, and a CDC SARS-CoV-2 multi-antigen IgG bead assay). The 2018 NAIIS pre-pandemic plasma panels were used to assess potential cross-reactivity by testing specimens with known reactivity to malaria. Overall sensitivity with NIMR specimens was 64.0% (95% CI: 53.7-73.2), 80.5% (70.0-88.1), 84.8% (75.9-91.0), and 95.9% (89.3-98.7) for RightSign, FlexImmArray, Luminex xMAP, and CDC assay, respectively. Specificity with NIMR plasma specimens was 100% (95% CI: 95.4-100) for RightSign, 98.0% (92.3-99.7) for Luminex xMAP, and 100% (95.3-100) for FlexImmArray and CDC assay. When stratified by days post RT-PCR confirmation, sensitivity for <15 days was 58.3%% (44.9-70.7), 75% (60.1-85.9), 83.1% (70.6-91.1), and 93.1% (82.5-97.8), while ≥15 days was 72.5% (55.9-84.9), 88.2% (71.6-96.2), 87.5% (72.4-95.3), and 100% (89.1-100) for RightSign, FlexImmArray, Luminex xMAP, and CDC assay, respectively. Specificities using NAIIS panels were 100.0% (97.7-100.0), 97.5% (93.9-99.6), 99% (96.1-99.8) and 100% (97.6-100)

for RightSign, FlexImmArray, Luminex xMAP, and CDC assay, respectively. Results showed higher sensitivity with the multi-antigen versus the single-antigen SARS-CoV-2 assay. Multi-antigen assays performed well in Nigeria, even with samples with known malaria reactivity, and might provide more accurate measures of COVID-19 seroprevalence and vaccine efficacy than single antigen assays.

0208

CLINICAL AND EPIDEMIOLOGICAL RISK FACTORS FOR COVID19 AMONG CASES SEEKING CARE IN LIBERIA, A MULTI-CENTERED, RETROSPECTIVE, OBSERVATIONAL STUDY

Wahdae mai Harmon Gray[1], Mukhtar Adeiza[2], Heounohu Hessou[2], Jerry Brown[2], Keith L. Gray[1], Laura A. Skrip[1]

[1]University of Liberia, Monrovia, Liberia, [2]14th Military Covid Treatment Unit, Monrovia, Liberia

Identifying clinical and epidemiological risk factors for COVID-19 is crucial for informingmeasures to reduce the burden of the pandemic locally. In Liberia, limited research has been conducted to inform clinical management, facilitate targeted preventive messaging within communities, and forecast resource needs. This research seeks to identify the clinical and epidemiological risk factors for COVID-19 morbidity and mortality among cases seeking care in Liberia. Data on confirmed COVID-19 cases who sought care between March 2020 and September 2020 were extracted from medical charts at health facilities in Liberia. Due to data quality issues associated with paper charts, data required cleaning to remove duplicates per three sets of pre-specified assumptions. The statistical analysis was implemented on the resulting three datasets as a sensitivity analysis. Associations between epidemiological, clinical, and demographic variables and indicators of disease severity (management with breathing support and survival status) were assessed using simple and multivariable logistic regression. Data from 1591 confirmed cases across 14 counties were analyzed. The median age was 38 years (IQR: 27-50), and the majority were male (n=1050, 64.7%). Rates of CPAP use for breathing support and case fatality were 5.3% and 5.3%, respectively. In the multivariable analysis, comorbid diabetes and hypertension and increasing age were associated with increased odds of CPAP use. Recent travel history, increasing age, and need for breathing support were associated with increased odds of mortality. Nearly 48% of raw case entries in the database warranted cleaning due to identification as duplicates. We identified epidemiological and clinical patient characteristics associated with increased odds of need for breathing support and mortality due to COVID-19 in a resource-poor setting. We also highlighted enormous data collection and management challenges that warranted intense data cleaning and, importantly, affected the ability to do real-time analyses for informing clinical management at the peak of the outbreak.

0209

CHARACTERIZATION AND EVALUATION OF THE EFFICACY OF THERAPEUTIC ANTIBODIES FOR THE PREVENTION OF SARS-COV-2 (OMICRON) INFECTION AND DISEASE IN THE HAMSTER MODEL

Yu Cong[1], Erin Kollins[1], Russ Byrum[1], Saurabh Dixit[1], Sanae Lembirik[1], Lou Huzella[1], Donna Perry[1], Scott Anthony[1], David Drawbaugh[1], Amanda Hischak[1], Nejra Isic[1], Marisa St Claire[1], Ann Eakin[2], Karl Erlandson[3], Connie Schmaljohn[1], Michael R. Holbrook[1]

[1]NIAID Integrated Research Facility at Fort Detrick, Fort Detrick, MD, United States, [2]NIAID Division of Microbiology and Infectious Diseases, Bethesda, MD, United States, [3]Biomedical Advanced Research and Development Authority, Washington, DC, United States

The emergence of multiple variants of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has challenged the utility of vaccines and several therapeutic antibodies, as specific mutations within the viral spike protein has led to a decrease or complete loss of potency. The omicron variant (B.1.1.529), currently an urgent global health concern, further limited therapeutic options. In the absence of clinical information, it's critical to characterize the hamster model of SARS-CoV-2 respiratory disease for potential countermeasures against omicron. Here, the authentic infectious omicron BA.1 and BA.1.1 isolates were evaluated in hamsters for lung infection, clinical disease, and pathology. We observed attenuated pathogenicity, compared to previous SARS-CoV-2 variants, with no clinical signs of disease, limited (or no) weight loss, and reduced lung disease when evaluated by histopathology. Despite the limited clinical burden, we observed a marked and significant viral burden in the upper and lower respiratory tracts, allowing us the ability to assess medical countermeasures using viral load reduction. The prophylactic efficacy of nine therapeutic antibodies that neutralized omicron *in vitro* was evaluated against BA.1 or BA.1.1 infection in hamsters. We found that most of the monoclonal antibodies restricted viral infection in the upper and lower respiratory tract and limited the lung pathology of hamsters exposed with BA.1 or BA.1.1. These findings demonstrate that the attenuated replication and pathogenicity of BA.1 and BA.1.1 in the hamster model parallels human clinical data and most of the therapeutic monoclonal antibodies tested here maintain potency against omicron BA.1 and BA.1.1.

0210

COVID-19 VACCINE HESITANCY AMONG ADULTS AGED 18 YEARS AND ABOVE RESIDING IN THE LARGEST TOWNSHIP IN SOUTH AFRICA

Nyasha Mutana, Pedzisai Ndagurwa, Dineo Thaele, Cleopas Hwinya, Shabir A. Madhi, Portia C. Mutevedzi

South African Medical Research Council Vaccines and Infectious Diseases Analytics Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, Johannesburg, South Africa

South Africa has experienced severe Covid-19 pandemic, with 2 waves prior to and 2 waves post Covid-19 vaccine availability. Despite vaccines being the most promising covid-19 prevention strategy, vaccine uptake in South Africa has been low, with 43.5% of adults aged 18 years and above fully vaccinated as of 25 March 2022, similar to other African countries. Vaccine hesitancy threatens the success of Covid-19 vaccine programs more so in countries like South Africa where vaccines are readily available free of charge. The objective of this study is to examine the level and determinants of Covid 19 vaccine hesitancy among adults (18 years and above) residing within the CHAMPS Soweto/Thembelihle Health and Demographic Surveillance (CHAMPS-SaT HDSS), Johannesburg, South Africa. The study includes 72766 adults from the surveillance total population of ~120 000 individuals. Descriptive statistics were used to examine proportion of people not vaccinated, and multivariate logistic regression modeling identified factors associated with non-vaccination. Further, we explored reasons given for non-vaccination to determine vaccine hesitancy. Seventy-nine percent (57 875) of the study sample was not vaccinated. Among those who were not vaccinated, 38% were undecided, 25% did not want the vaccine and 37% cited other reasons. The odds of not being vaccinated were lower among those with secondary (OR 0.60 CI 0.64 - 0.75) and higher education (OR 0.38 CI 0.34 - 0.43) compared to those with primary or less education. Those aged 35-49 years (OR 0.36 CI 0.34 - 0.38), 50-64 years (OR 0.15 CI 0.14 - 0.15) and 65+ years (OR 0.11 CI 0.10 - 0.12) were less likely to be unvaccinated compared those aged 18-34 years. Being employed (OR 0.65 CI 0.56 - 0.76) was associated with lower odds of not being vaccinated compared to being unemployed. There is evidence of vaccine hesitancy among adults who are not vaccinated within the CHAMPS-SaT HDSS site with significant socio-economic and demographic differences. There is need for more campaigns in townships like Soweto and Thembelihle to increase vaccine uptake and demystify myths that exist around Covid 19 vaccines.

0211

DIVERGENT RHABDOVIRUS DISCOVERED IN A PATIENT WITH NEW ONSET NODDING SYNDROME

Gasim Abd-Elfarag[1], Arthur Edridge[1], Martin Deijs[2], Maarten Jebbink[2], Michael van Hensbroek[1], Lia van der Hoek[3]

[1]Center for Global Child Health, Amsterdam UMC, Amsterdam, Netherlands, [2]Laboratory of Experimental Virology, Amsterdam UMC, Amsterdam, Netherlands, [3]Laboratory of Experimental Virology Center for Global Child Health, Amsterdam UMC, Amsterdam, Netherlands

A divergent rhabdovirus was discovered in the bloodstream of a 15-year-old girl with Nodding syndrome from Mundri West County in South Sudan. Nodding syndrome is a progressive degenerative neuropathy of unknown cause affecting thousands of individuals in Sub-Saharan Africa. The index case was previously healthy until she developed head-nodding seizures four months prior to presentation. Virus discovery by VIDISCA-NGS on the patient's plasma detected multiple sequence reads belonging to a divergent rhabdovirus. The viral load was 3.85 × 103 copies/mL in the patient's plasma and undetectable in her cerebrospinal fluid. Further genome walking allowed for the characterization of full coding sequences of all the viral proteins (N, P, M, U1, U2, G, U3, and L). We tentatively named the virus "Mundri virus" (MUNV) and classified it as a novel virus species based on the high divergence from other known viruses (all proteins had less than 43% amino acid identity). Phylogenetic analysis revealed that MUNV forms a monophyletic clade with several human-infecting tibroviruses prevalent in Central Africa. A bioinformatic machine-learning algorithm predicted MUNV to be an arbovirus (bagged prediction strength (BPS) of 0.9) transmitted by midges (BPS 0.4) with an artiodactyl host reservoir (BPS 0.9). An association between MUNV infection and Nodding syndrome was evaluated in a case–control study of 72 patients with Nodding syndrome (including the index case) matched to 65 healthy households and 48 community controls. No subject, besides the index case, was positive for MUNV RNA in their plasma. A serological assay detecting MUNV anti-nucleocapsid found, respectively, in 28%, 22%, and 16% of cases, household controls and community controls to be seropositive with no significant differences between cases and either control group. This suggests that MUNV commonly infects children in South Sudan yet may not be causally associated with Nodding syndrome.

0212

HUMANIZED SCFV ANTIBODIES FOR COVID-19 THERAPY

Adinarayana Kunamneni, Ravi Durvasula

Mayo Clinic, Jacksonville, FL, United States

Effective therapies are urgently needed for COVID-19. Due to structurally analogous regions of the Ebola virus glycoprotein (GP) and SARS-CoV-2 spike (S) protein, we rapidly identified two murine anti-EBOV scFv antibodies generated from ribosomal display by re-testing against the receptor binding domain (RBD) variants of the SARS-CoV-2 spike (S) glycoprotein that prevents SARS-CoV-2 from infecting cultured cells. Murine scFv antibodies are relatively easy to produce but are severely restricted for therapeutic use by their immunogenicity in humans. Production of human antibodies has been problematic. Humanized antibodies can be generated by introducing the six hypervariable regions from the heavy and light chains of a murine antibody into a human framework sequence and combining it with human constant regions. We humanized, with the aid of computer modeling, a murine scFv antibody against the S RBD variants. The binding, virus neutralization, and cell protection results all indicate that humanized antibodies (HC2-LC1 and HC3-LC3) have retained the binding activities and the biological properties of the murine scFv antibodies.

AEDES-BORNE ARBOVIRUS SEROPREVALENCE IN A COHORT OF CHILDREN FROM MERIDA, MEXICO: A BASELINE ANALYSIS OF THE TARGETED INDOOR RESIDUAL SPRAYING (TIRS) TRIAL

James T. Earnest[1], Henry Puerta-Guardo[2], Yerun Zhu[1], Oscar D. Kirstein[1], Gloria A. Barrera-Fuentes[2], Azael Che-Mendoza[2], Amy M. Crisp[3], Norma Pavia-Ruz[2], Salha Villanueva-Jorge[4], Pilar Granja-Perez[4], Ira M. Longini[3], Natalie E. Dean[1], Elizabeth Halloran[5], Lance A. Waller[1], Audrey Lenhart[6], Pablo Manrique-Saide[2], Guadalupe Ayora-Talavera[2], Matthew H. Collins[1], Gonzalo Vazquez-Prokopec[1], Hector Gomez-Dantes[7]

[1]Emory University, Atlanta, GA, United States, [2]Universidad Autonoma de Yucatan, Merida, Mexico, [3]University of Florida, Gainesville, FL, United States, [4]Public Health Services of Yucatan, Merida, Mexico, [5]University of Washington, Seattle, WA, United States, [6]U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]National Institute of Public Health, Cuernavaca, Mexico

Aedes borne viruses (ABVs) place a significant strain on public health resources globally. Vector control is an important public health strategy to control and prevent ABV infections. The Targeted Indoor Residual Spraying (TIRS) project is a cluster-randomized controlled trial to study the epidemiologic impact of novel vector control techniques in preventing illness due to ABVs in the city of Merida, Yucatan, Mexico. We selected 50 geographical neighborhood clusters that were randomly allocated to either the control or intervention arms of the trial and enrolled a cohort of 4,600 children aged 2-15 living in these clusters. We collected socio-economic and demographic data and serum samples during enrollment in 2021. Baseline seroprevalence of IgG antibodies against dengue, Zika, and chikungunya viruses was determined for n=1400 (~30%) enrolled participants. We found that 44.2% of children were seropositive for antibodies against dengue viruses, 21.5% against Zika virus, and 24.1% against chikungunya virus. No significant differences in ABV-seroprevalences between the control and intervention arms were detected, confirming balance between the arms at baseline. Our data indicated that a significant number of children were exposed to Zika virus, most likely during the pandemic of 2015-2016, and nearly half were previously exposed to one or more dengue serotypes. A subset of 225 randomly selected TIRS participants was tested by focus reduction neutralization tests (FRNTs) to determine dengue serotype specificity. Interestingly, compared to FRNT data collected from a similar (by age and location) population in 2016, the TIRS cohort showed a significantly lower frequency of dengue reactivity to any serotype (90% vs 37%). The results from these studies suggest low levels of recent exposure to dengue viruses and may be informative to predicting the susceptibility of the population of Merida to future outbreaks.

0214

COMPREHENSIVE MUTAGENESIS OF SARS-COV-2 S PROTEIN TO MAP ANTIBODY EPITOPES AND IDENTIFY RESIDES ESSENTIAL FOR FUNCTION

Edgar Davidson[1], Jazmean K. Williams[1], Christopher N. Selverian[1], Shruthi Kannan[1], Hayley Crawford[1], Nathan A. Krump[1], Colleen Fenn[1], Ross Chambers[1], James E. Crowe Jr[2], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Departments of Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN, United States

To characterize the immune response to SARS-CoV-2 infection, we created a comprehensive Ala-scan mutation library (>1240 mutations) of the SARS-CoV-2 S protein. We use this library to epitope map anti-SARS-CoV-2 monoclonal antibodies (MAbs) by high-throughput, rapid screens of MAb binding to each mutant S protein. Individual mutant expression plasmids transfected into human cells achieve native protein expression and folding, immunoreactivity of MAbs to each mutant S protein is

quantified by high-throughput flow cytometry, allowing us to identify the S protein epitope residues with the highest energetic contributions to MAb binding. We have mapped over 100 MAbs targeting the S protein, identifying conformational epitopes in the S1 receptor binding domain (RBD) and N-terminal domain (NTD), and in S2, helping characterize MAbs that neutralize and protect in animal models of disease. To provide critical reagents for analyses of MAb or serum immune responses to SARS-CoV-2 infection, we developed a pseudotyped lentiviral reporter virus system for SARS-CoV-2, with reporter virus particles (RVPs) displaying S protein. These replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2) and reproducible virus neutralization assays with luminescent or fluorescent readout. We have produced over 60 SARS-CoV-2 RVP types incorporating variant S proteins. We also used our MPS antibody isolation platform to obtain MAbs against S protein, some of which neutralize the major Omicron variants. We used RVP technology to screen the S protein mutant library for infectivity, to identify residues critical for virus infectivity whose mutation eliminates virus infectivity but does not impact S protein expression, antigenicity, or reporter virus budding. To identify uncharacterized SARS-CoV-2 cellular binding factors we are assaying wild-type SARS-CoV-2 RVP infectivity in non-permissive cells expressing our membrane proteome array (MPA) of 6,000 unique human membrane proteins. Similar experiments with other viruses have yielded previously unidentified candidate membrane proteins that enable virus infectivity.

RELATIONSHIP BETWEEN THE VACCINATION AGAINST COVID19 AND THE INCIDENCE OF IMPORTED CASES AND HOSPITALISATIONS IN THE CAPITAL CITY OF GABON, CENTRAL AFRICA

Sydney Maghendji Nzondo[1], Romain R. Tchoua[2], Guy P. Obiang Ndong[3], Julienne Atsame[4], Anthony Mintsa Menie[3], Reinne Moutongo Mouandza[1], Jack Mari Ndong Ngomo[1], **Marielle K. Bouyou-Akotet**[1]

[1]Université des Sciences de la Santé, Libreville, Gabon, [2]COVID-19 committee, Libreville, Gabon, [3]Ministry of Health, Libreville, Gabon, [4]Infectious Diseases National Control Programme, Libreville, Gabon

Several reports showed that Sinopharm, Pfizer BioNtech and Janssen vaccines are safe and effective for preventing COVID-19-related serious illness, hospitalization, and death. Data on vaccine effectiveness are scarce in Central Africa. This incidence rate of COVID-19 imported cases and hospitalised case was compared between vaccinated and non vaccinated individuals. Results. Using national data, from October to December 2021 ; the incidence rate of hospitalizations significantly decreased among the vaccinated individuals although that of laboratory-confirmed cases remained high during epidemic peaks. Although less vaccinated, younger children were not a higher risk of being infected. Data on each vaccine specific effectiveness are being analyzed. The number of vaccinated individuals with a positive PCR test significantly decreased among the group of vaccinated individuals.

SUSCEPTIBILITY OF *PLASMODIUM FALCIPARUM* ISOLATES FROM EASTERN UGANDA TO ANTIMALARIAL COMPOUNDS UNDER DEVELOPMENT

Oriana Kreutzfeld[1], Patrick Tumwebaze[2], Martin Okitwi[2], Stephen Orena[2], Oswald Byaruhanga[2], Thomas Katairo[2], Melissa D. Conrad[1], Stephanie A. Rasmussen[3], Jennifer Legac[4], Ozkan Aydemir[5], David Giesbrecht[5], Samuel L. Nsobya[2], Maelle Duffey[6], Jeffrey A. Bailey[5], Roland A. Cooper[3], Philip J. Rosenthal[1]

[1]University of California, San Francisco, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Dominican University of California, San Rafael, CA, United States, [4]University of California, San Francsico, CA, United States, [5]Brown University, Providence, RI, United States, [6]Medicines for Malaria Venture, Geneva, Switzerland

Malaria, especially *Plasmodium falciparum* infection, remains an enormous problem, and its treatment and control are seriously challenged by drug resistance. New antimalarial drugs are needed. To characterize the pipeline of lead antimalarials under development, we assessed *ex vivo* drug susceptibilities to compounds targeting *P. falciparum* cytochrome b (PfCYTb), dihydroorotate dehydrogenase (PfDHODH), elongation factor 2 (PfEF2), phenylalanine t-RNA sythetase (PfPheRS) and phosphatidylinositol 4-kinase (PfPI4K) for 688 fresh *P. falciparum* clinical isolates collected in eastern Uganda from 2015-2021. Drug susceptibilities were assessed with 72 h growth inhibition (IC_{50}) assays using SYBR green. In general, field isolates were highly susceptible, with median IC_{50}s in the low nM range for compounds targeting PfCYTb (ELQ300, 13 nM); PfDHODH (DSM265, 3.6 nM; DSM421, 20 nM; DSM632, 9.8 nM; DSM705, 11 nM; DSM1049, 22 nM; BRD1331 13 nM), PfEF2 (DDD498, 0.6 nM); PfPheRS (BRD5018, 1.6 nM); and PfPI4K (MMV048, 60 nM; UCT943, 11 nM). Median IC_{50} values were near those reported previously for laboratory strains, but outliers with decreased susceptibilities were identified. Positive correlations between IC_{50} results were seen for compounds with shared targets. We also sequenced potential resistance mediators to search for polymorphisms previously selected *in vitro* and to determine genotype-phenotype associations. We identified many polymorphisms in target genes, generally in <10% of samples, but except for those in PfPI4K, none were previously selected *in vitro* with drug pressure or associated with decreased *ex vivo* drug susceptibility. Three mutations (N957H, I876V and Y883H) in PfPI4K were associated with slightly decreased susceptibility to MMV048 (median IC_{50} WT vs mutant: 55 nM vs 74 nM for N957H, 61 nM vs 75 nM for I876V, and 60 nM vs 77 nM for Y883H). Overall, Ugandan *P. falciparum* isolates were highly susceptible to 11 compounds under development as next-generation antimalarials, consistent with a lack of pre-existing or novel resistance-conferring mutations in circulating Ugandan parasites.

ASSESSMENT OF *PLASMODIUM FALCIPARUM* ARTEMISININ RESISTANCE INDEPENDENT OF *KELCH13* POLYMORPHISMS AND WITH ESCALATING MALARIA IN BANGLADESH

Maisha Khair Nima[1], Angana Mukherjee[1], Saiful Arefeen Sazed[2], Muhammad Riadul Haque Hossainey[3], Ching Swe Phru[2], Fatema Tuj Johora[4], Innocent Safeukui[1], Barbara Calhoun[1], Wasif Ali Khan[2], Mohammad Shafiul Alam[2], Kasturi Haldar[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]icddr,b, Dhaka, Bangladesh, [3]George Washington University, Washington, DC, United States, [4]Georgia State University, Atlanta, GA, United States

Emerging resistance to artemisinin drugs threatens the elimination of malaria. Resistance is widespread in South East Asia (SEA) and Myanmar. Neighboring Bangladesh, where 90% of infections occur in the Chittagong Hill Tracts (CHTs), lacks recent assessment. We undertook a prospective study in the sole district-level hospital in Bandarban, a CHT district with low population densities but 60% of reported malaria cases. Thirty patients presented with malaria in 2018. An increase to 68 patients in 2019 correlated with the district-level rise in malaria, rainfall, humidity, and temperature. Twenty-four patients (7 in 2018 and 17 in 2019) with uncomplicated *Plasmodium falciparum* mono-infection were assessed for clearing parasites after starting artemisinin combination therapy (ACT). The median (range) time to clear half of the initial parasites was 5.6 (1.5 to 9.6) h, with 20% of patients showing a median of 8 h. There was no correlation between parasite clearance and initial parasitemia, blood cell counts, or mutations of *P. falciparum* gene *Pfkelch13* (the molecular marker of artemisinin resistance [AR]). The *in vitro* ring-stage survival assay (RSA) revealed one (of four) culture- adapted strains with a quantifiable resistance of 2.01% ± 0.1% (mean ± standard error of the mean [SEM]). Regression analyses of *in vivo* and *in vitro* measurements of the four CHT strains and WHO-validated K13 resistance mutations yielded good correlation (R^2=0.7; ρ =0.9, $P < 0.005$), strengthening

evaluation of emerging AR with small sample sizes, a challenge in many low/moderate-prevalence sites. There is an urgent need to deploy multiple, complementary approaches to understand the evolutionary dynamics of the emergence of *P. falciparum* resistant to artemisinin derivatives in countries where malaria is endemic. DOI: 10.1128/mbio.03444-21

EFFECTIVENESS OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY WITH SULFADOXINE-PYRIMETHAMINE IN IMPROVING PARASITOLOGICAL AND CLINICAL OUTCOMES IN SOUTHERN MOZAMBIQUE

Glória Matambisso[1], Nanna Brokhattingen[2], Sónia Maculuve[1], Pau Cístero[2], Henriques Mbeve[1], Anna Escoda[2], Gizela Bambo[1], Judice Miguel[1], Elena Buetas[2], Ianthe Jong[2], Boaventura Cuna[1], Cardoso Melembe[1], Nelo Ndimande[1], Gemma Porras[2], Haily Chen[2], Eusébio Macete[1], Alfredo Mayor[2]

[1]CISM, Maputo, Mozambique, [2]ISGlobal, Barcelona, Spain

In 2014 Mozambique adopted the WHO intermittent preventive treatment in pregnancy (IPTp) policy, which recommends the use of IPTp with sulfadoxine-pyrimethamine **(**SP) for all HIV negative (HIV^-) pregnant women attending antenatal care (ANC). However, the effectiveness of IPTp-SP is threatened by the spread of SP resistance, and a continuous monitoring of IPTp-SP effectiveness is necessary to inform programmatic decisions. We conducted a three-year prospective observational study beginning two years after the policy implementation in Mozambique, at heath facilities in Magude (low malaria transmission area), Manhiça (low to moderate transmission) and Ilha Josina (high transmission). A form including the number of IPTp-SP doses registered from the woman's antenatal booklet was filled out. Finger-prick peripheral blood samples onto filter papers collected at delivery visits were analyzed by real-time quantitative polymerase chain reaction (qPCR) to assess the presence of *Plasmodium falciparum* (*Pf*), as well as by quantitative suspension array technology for antimalarial antibodies. Especially in Ilha Josina, *Pf* positivity rate by qPCR at delivery was lower in the group receiving the recommended three or more IPTp-SP doses (6.2%) than in the group receiving less than three doses (14.3%; p=0.019). The seroprevalence of pregnancy-specific antibodies was higher in the group not receiving the recommended number of doses than in the full IPTp-SP group in the three study areas. This probably reflects the higher *Pf* positivity rate in this group. An association between anemia and receiving less than three doses was found in Manhica and Magude. Similarly, receiving fewer than three doses was associated with low birth weight in Manhica and Ilha Josina. Our findings indicate that three or more doses of IPTp-SP is effective in reducing *Pf* positivity rate in high transmission settings, although pregnancy-specific seroprevalence also suggests an impact in low transmission settings. Following the IPTp-SP policy improves the health of the women and their infant even in contexts of high prevalence of molecular markers of SP resistance.

The *Plasmodium falciparum multidrug resistance transporter 1* gene (*pfmdr1*) is associated with altered response to artemisinin-based combination therapies (ACTs), particularly those containing the partner drugs lumefantrine and amodiaquine (i.e., artemether-lumefantrine (AL) and artesunate-amodiaquine (ASAQ)). Past studies of *pfmdr1* single nucleotide polymorphisms (SNPs) at codons 86, 184, and 1246 have shown different treatment responses to AL and ASAQ. To determine whether patients infected with parasites carrying specific *pfmdr1* SNPs are at increased risk of recurrent parasitemia or treatment failure, patient data on molecular markers of *P. falciparum* from 16 therapeutic efficacy studies in 13 African countries from 2013 to 2019 were analyzed. The Mantel-Haenszel (MH) method was used to create forest plots displaying the common effect odds ratio by treatment arm for each specific study and the pooled MH odds ratio by treatment arm when the data from all studies were compiled. This odds ratio represented the odds of recurrent infections with a specific allele compared to the odds of successfully treated infections with that same allele in pre-treatment samples. For patients treated with AL, the odds of the N86 allele in recurrent infections was 5.24 (95% CI 2.69, 10.20) times higher than the odds of the N86 allele in pre-treatment infections successfully cleared. For those treated with ASAQ, the odds of the 86Y allele in recurrent infections was 2.65 (95% CI 1.21, 5.79) times higher than the odds of the 86Y allele in pre-treatment infections successfully cleared. There were no statistically significant associations detected between recurrent infections and *pfmdr1* codons 184 and 1246. These results support prior studies that suggested: 1) patients given AL infected with parasites carrying N86 were at a significantly greater risk of recurrent infection; 2) patients given ASAQ infected with parasites carrying 86Y were at a significantly greater risk of recurrent infection. These findings suggest that ACT choice and *pfmdr1* genotype may influence treatment outcome after *P. falciparum* infection.

Surveillance of molecular markers of antimalarial resistance in *Plasmodium falciparum* is an effective strategy to detect emerging resistance to current treatments. This study aimed to analyze the profile of the mutations associated with *Plasmodium falciparum* resistance to anti-malarial drugs in Mozambique in 2015 and 2018. A total of 1877 dried blood spots were collected in Maputo, Gaza, Inhambane, Sofala, Tete, Zambézia and Cabo Delgado provinces in the context of therapeutic efficacy studies, cross-sectionals in the community and pregnant women at health facilities in 2015 (543 samples) and 2018 (1334 samples). Whole genome sequencing of these samples was performed for detection of drug resistance mutations in Kelch type protein 13 (*pfkelch13*), multidrug resistance gene 1 (*pfmdr1*), dihydrofolate reductase (*pfdhfr),* dihydropteroate synthase (*pfdhps*) and chloroquine transporter gene (*pfcrt*) genes. No mutations related to artemisinin resistance were detected in the *pfkelch13* gene. Mutations on codons 74-76 in *pfcrt* gene were only observed in 2015 in Maputo (2%) and Gaza (9%) provinces. Mutation in codon 86 of *pfmdr1* gene was only found in Gaza province (8%) in 2015. Mutation in codon 184 of *pfmdr1* gene was common in all provinces (ranging from 54-61% in 2015 and 50-65% in 2018). Prevalence of quintuple mutants in *pfdhfr/pfdhps* was 70% in 2015 and 80% in 2018, and was highest in Maputo province and lowest in Cabo Delgado province. Mutation in the codon 436 of *pfdhps* gene was only observed in Cabo-Delgado, suggesting local selection of this mutation in Northern Mozambique. This data, the most comprehensive in the country, provides key information for the rationale use of antimalarials for malaria control and elimination.

0221

GENETIC DIVERSITY OF DRUG RESISTANCE GENES IN *PLASMODIUM MALARIAE* AND *P. OVALE*

Reinhard Kobbie Danku, Alamissa Soulama, Felix Ansah, Yaw Aniweh

West African Center for Cell Biology of Infectious Pathogens, Accra, Ghana

Although malaria remains a public health concern in sub-Saharan Africa, recent global concerted anti-malarial efforts have significantly reduced the burden. Unfortunately, the efforts are *Plasmodium falciparum*-focussed with the neglect of *P. malariae* and *P. ovale.* If malaria is to be eliminated and eradicated, there is the need to target all forms of human malaria-causing *Plasmodium* species. The true contribution of *P. malariae* and *P. ovale* to malaria worldwide is unknown mainly because they are frequently misdiagnosed; due to their characteristic low parasitemias, frequent mixed-species infection, and the subpar performance of malaria gold standard diagnostic tool. With antimalarial drug resistance posing a threat to the no malaria agenda, there is the need to periodically surveil and assess the genetic effect of drug pressure on the circulating *Plasmodium* species. Hence, this study seeks to analyse the genetic diversity of P. *malariae* and *P. ovale* drug resistance genes (multidrug resistance gene and Kelch-13 propeller gene) using Sanger sequencing. The resulting data will be instrumental in the development of future antimalarial drugs.

0222

EX-VIVO SUSCEPTIBILITY OF *PLASMODIUM FALCIPARUM* ISOLATES TO STANDARD ANTIMALARIALS IN BOBO-DIOULASSO, BURKINA FASO

Anyirekun Fabrice Somé[1], R. Serge Yerbanga[1], Zachari Kabré[1], Fofana Aminata[1], Thomas Bazié[1], Jenny Legac[2], Jean-Bosco Ouédraogo[1], Philip J. Rosenthal[2], Roland A. Cooper[3]

Malaria remains the leading cause of morbidity and mortality in Burkina Faso. The country utilizes artemether-lumefantrine, artesunate-amodiaquine, and recently dihydroartemisinin-piperaquine as first line therapies for uncomplicated malaria. Seasonal malaria chemoprevention (SMC) with amodiaquine plus sulfadoxine-pyrimethamine is implemented country-wide in children 5 years and under during the transmission season. With concerns regarding potential resistance to many classes of antimalarials, monitoring the efficacy of available antimalarial drugs is a high priority. To assess susceptibilities of malaria parasites to standard antimalarials, we measured ex vivo IC_{50}s for 11 compounds utilizing 79 isolates collected from patients presenting with uncomplicated *Plasmodium falciparum* malaria in Bobo Dioulasso from July to December, 2021. Assays utilized a standard 72 h growth inhibition microplate assay with SYBR Green detection, with results compared to those with laboratory-adapted control parasite strains. Isolates (median IC_{50} [range], nM) were generally highly sensitive to: chloroquine (10 [3.7 – 423]), monodesethylamodiaquine (24 [0.6 – 206]), piperaquine (4.4 [1.2 – 47]), lumefantrine (6.5 [0.5 – 38]), mefloquine (4.7 [0.3 – 30]), atovaquone (0.2 [0.01 – 1.0]), dihydroartemisinin (4.1 [1.1 – 25]), cycloguanil (774 [3.6 – 8265]), pyronaridine (4.5 [0.4 –15]) and quinine (40 [1.5 – 166]). With a few exceptions, parasites were highly resistant to pyrimethamine (29,845 [33 – 116,400]). These IC_{50} values were similar to those reported from our recent ex vivo studies in eastern Uganda, and suggested good antimalarial efficacy of all tested drugs except pyrimethamine. However, it is noteworthy that the median IC_{50} for monodesethylamodiaquine was greater than that recently reported in Uganda (7.1 [1.1 - 202]; $p < 0.0001$), possibly related to widespread use of amodiaquine as part of SMC in Burkina Faso. Genotyping of isolates from Burkina Faso to characterize key mutations associated with antimalarial drug resistance is currently underway.

and Technology, Dar es Salaam, Tanzania, Dar es Salaam, United Republic of Tanzania, [6]National Institute for Medical Research, Tanga, United Republic of Tanzania

In Tanzania, the Ministry of Health is planning to introduce seasonal malaria chemoprevention (SMC) in malaria endemic areas with very strong seasonal transmission pattern as a measure to decrease burden of infection in children. This study assessed the effectiveness of dihydroartemisinin-piperaquine (DP) as SMC for control of malaria in two districts of Masasi and Nanyumbu Mtwara region, southern Tanzania. Between March and June 2021 children aged 3-59 months in selected wards were enrolled in an open cluster randomized (intervention and control) study. Children in the interventional clusters were administered monthly with a full course of DP for three consecutive months regardless of the malaria infection status, whereas those in the control clusters were treated according to the national treatment guidelines once they got infected. The primary outcome was malaria prevalence as assessed by using malaria rapid diagnostic tests (mRDT) at the end of transmission season. The drug was well tolerated with no serious adverse events. Before intervention: malaria prevalence by mRDT was 23.69% (167/705) in Nanyumbu district and 12.60% (206/1635) in Masasi district. Following the intervention, malaria prevalence in Nanyumbu district declined to 9.20% (55/598), ($x2$=48.07, p<0.001), whereas in Masasi it declined to 6.80 (101/1486) ($x2$=29.55, p<0.001). Also, following the intervention there was significant decline in anaemia prevalence in the interventional clusters, whereas in the control clusters it increased. The SMC using dihydroartemisinin-piperaquine was safe and effective for seasonal malaria chemoprevention in Masasi and Nanyumbu districts.

0224

SEASONAL MALARIA CHEMOPREVENTION IN BURKINA FASO: IMPACT ON *PLASMODIUM FALCIPARUM* GENETIC DIVERSITY AND RESISTANCE PROFILE

Issiaka Soulama[1], Séni Nikiema[2], Salif Sombié[3], Samuel Sindie Sermé[4], Noélie Henry/Béré[4], Désiré Kargougou[3], Sam Aboubacar Coulibaly[3], Alfred B. Tiono[3], Florencia Djigma[2], Sodiomon B. Sirima[4], Jacques Simporé[2]

In Burkina Faso, the implementation of seasonal malaria chemoprevention (SMC) as a malaria prevention strategy started in 2014 and is now being implemented countrywide since 2019. Unfortunately, there is no routine malaria molecular surveillance to measure the impact of SMC on the genetic diversity of malaria parasites including resistance profiling, some characteristics of which are strongly correlated with the dynamics of the level of transmission and resistance.The present study was thus designed to measure the effect of SMC on malaria prevalence, complexity and polyclonality of infection, and the dynamic of resistance markers during the four months of the SMC in children in Saponé Health District located in the South-Central Region of Burkina Faso.This was a cohort study of 220 children aged from 3 to 59 months followed up during the 4 months (July-October 2020) of the SMC. Demographic, clinical and biological data were collected. Blood samples were taken before each of the 4 round visits for microscopic diagnosis and molecular typing by PCR.The mean age was 32,7 months. A gain of hemoglobin rate was effective from 10.2 g/dl to 10.8 g/dl respectively from July to October. The geometry mean of *P. falciparum* density statistically (p<0.05) increased from July (3390tf/ul) to October (5170tf/ul). We observed an increase in the parasite prevalence by PCR from July to October, 6% to 34% respectively. While there is trend of reduction in the prevalence of FC27 *msp2* alleles the results showed an increase of the RO33 *msp1* alleles from July to October. However, there was no significant difference in the complexity of the infection between the 1st and 4th round passages (p>0,05). Interestingly, there is an increase in monoclonal infection prevalence. The analysis of the resistance profile showed a significant reduction of the prevalence of the *pfmdr1*_86Y mutation opposed to a high prevalence of the *pfcrt*76T mutation at the end of the rounds.The results show an impact of SMC on the parasite diversity but especially a different dynamic at the level of resistance markers which would be interesting to monitor.

0225

NEXT-GENERATION SEASONAL MALARIA CHEMOPREVENTION: MODELLING THE PUBLIC HEALTH IMPACT OF NEW MEDICAL INTERVENTIONS

Lydia Braunack-Mayer[1], Thiery Masserey[1], Narimane Nekkab[1], Josephine Malinga[1], Swapnoleena Sen[1], André-Marie Tchouatieu[2], Sherrie L. Kelly[1], Melissa A. Penny[1]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Medicines for Malaria Venture, Geneva, Switzerland

Seasonal malaria chemoprevention (SMC) is a cornerstone of malaria control in settings with intense malaria transmission, administered monthly to children throughout the malaria season. However, the spread of partial resistance to sulfadoxine-pyrimethamine, which in combination with amodiaquine is the standard of care for SMC, threatens SMC's effectiveness. Guidance for developing new or repurposing existing drugs for SMC is needed and, yet, little is known about how different product characteristics contribute to SMC's effectiveness. We combined an individual-based mathematical model of malaria transmission with pharmacokinetics/pharmacodynamics models and statistical analysis to estimate the public health impact of next-generation SMC. Global sensitivity analyses identified trade-offs between a next-generation intervention's efficacy, prophylaxis period, and program coverage, and optimisation identified minimum criteria to achieve target malaria morbidity reductions. With this approach, framed by expert engagement, we provide modelling evidence to inform the iterative process of selecting seasonal chemoprevention candidates. Our preliminary findings indicate that high SMC coverage and lasting protection between rounds are critical for morbidity reduction. When four SMC rounds are equally spaced over four months and deployed to children under five or ten years, a drug elimination half-life of more than 15 days is required to achieve target clinical incidence and severe disease reductions of 85% to 80% (measured over the intervention period in the target population) in low to very high malaria transmission settings, respectively. Over 40% of children should receive all SMC rounds and 90% at least one round to achieve these targets. As a result, minimum criteria for SMC duration of protection should be set to facilitate next-generation SMC's effectiveness, alongside increasing access and uptake. Drug developers and funders should support the generation of evidence on duration through studies of pharmacokinetic/pharmacodynamic properties and malaria challenge trials or early clinical studies.

After recovery from severe anaemia, preschool children recently discharged from hospital are at high risk of dying or being readmitted in the first six months after discharge. Monthly post-discharge malaria chemoprevention (PDMC) has been shown to reduce this risk substantially. We conducted a systematic review and meta-analysis to determine the efficacy of PDMC. Three double-blind, placebo-controlled trials from Malawi, Kenya, Uganda and the Gambia, involving 3,663 children with severe anaemia, met the eligibility criteria. PDMC consisted of either monthly sulfadoxine-pyrimethamine (SP) until the end of the malaria transmission season (average: 3.1 doses per child, Hb<7 g/dL) (N=1,200, the Gambia), monthly artemether-lumefantrine (AL) given at 4 and 8 weeks post-discharge (N=1,414, Malawi, Hb<5 g/dL), or monthly dihydroartemisinin-piperaquine given at the end of the 2nd, 6th, and 10th week post-discharge (N=1,049, Uganda and Kenya, Hb<5 g/dL). Fixed-effects meta-analysis was used to generate pooled effect estimates. PDMC was associated with a relative risk reduction of 77% (95% CI 30-92) in mortality during the intervention period ending 4 weeks after the last PDMC course (primary outcome) ($p=0.01$, $I^2=0\%$), 58% (48-66) in all-cause readmissions ($p<0.001$, $I^2=87\%$), 68% (54-78) in readmissions due to severe malaria ($p<0.001$, $I^2=93\%$), 62% (44-74) in readmissions due to severe anaemia ($p<0.001$, $I^2=69\%$), 24% (17-31) in non-severe all-cause out-patient visits ($p<0.001$, $I^2=10\%$), and 57% (50-64) in uncomplicated clinical malaria ($p<0.001$, $I^2=71\%$). The reduction was restricted to the intervention period and not sustained in the three months after protective drug levels had waned. In malaria-endemic Africa, PDMC reduces mortality and readmissions in recently discharged children who have recovered from severe anaemia and can be a valuable strategy for management of this high-risk group following discharge from hospital.

Resistance of *Plasmodium falciparum* parasites to dihydroartemisinin-piperaquine (DHA-PPQ) has spread throughout the Greater Mekong Sub-Region. To address this threat to malaria control and elimination, new drug combinations, which, ideally, kill asexual blood stage parasites, block transmission, prevent reinfections and provide radical cure by eliminating *P. vivax* hypnozoites are urgently needed. In 2018, a new 8-aminoquinoline drug, tafenoquine (TQ) was approved by the U.S. FDA for chemoprophylaxis and radical cure. Although TQ has a poor blood stage activity, it possesses gametocytocidal and hypnozoitocidal activities. Methylene blue (MB) is an old antimalarial drug with potent blood stage and gametocytocidal activity, and may be a suitable partner drug for TQ. We therefore evaluated the antimalarial activity of TQ in combination with MB. When tested *in vitro* against *P. falciparum* lines, W2 (chloroquine and pyrimethamine-resistant) and VPA02 (a recent isolate from Vietnam, resistant to DHA, PPQ and mefloquine), MB synergised the antimalarial activity of TQ against blood stage parasites using fixed-ratio drug combinations with summary fractional inhibitory concentrations of 0.33±0.09 and 0.42±0.10, respectively. Exposure of parasites to concentrations of 1000 or 4000 nM of TQ alone for 72 h did not inhibit growth of either W2 or VPA02 line, respectively. However, addition of MB (range 1.6 - 800 nM) to fixed TQ concentrations (range 125 to 4000 nM), markedly enhanced TQ activity compared to those of MB or TQ alone. Furthermore, we conducted *ex vivo* assays using plasma samples collected from 11 human volunteers after single oral doses of TQ (200 mg to 600 mg) with TQ concentrations ranging from 233 to 870 nM. While plasma physiological TQ concentrations were not sufficient to fully inhibit parasite growth, addition of MB (≥25 nM) resulted in complete inhibition of W2 and VPA02 parasite growth. These findings demonstrate that addition of MB enhances the activity of TQ against asexual blood stages of *P. falciparum* parasites and provide the impetus for further clinical evaluation of TQ-MB combinations for malaria treatment and elimination.

0228

ANALYSIS OF THE PREVALENCE OF MOLECULAR MARKERS IN *PFCARL* ASSOCIATED WITH RESISTANCE TO GANAPLACIDE (KAF156) IN FIELD SAMPLES FROM AFRICA

Evangelia Alexiou[1], Aminatou Kone[2], Billy Ngasala[3], Andreas Mårtensson[4], Abdoulaye A. Djimdé[2], Jose P. Gil[1]

[1]Karolinska Institute, Stockholm, Sweden, [2]University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, [3]Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania, [4]Uppsala University, Uppsala, Sweden

Malaria case management has been one of the major pillars for the disease's control and is strongly dependent on the efficacy of the developed antimalarials. For several years now the highly efficacious artemisinin-based combination therapies (ACTs) have been the first-line treatment for uncomplicated *Plasmodium falciparum* malaria. Recent evidence, though, exhibit an increase in the parasite's resistance towards several artemisinin derivatives and other antimalarial agents, including Artesunate-Mefloquine and Dihydroartemisinin (DHA)-Piperaquine combination therapies. This creates the need for new alternatives for the future of malaria's control and elimination. Currently, a novel therapy including KAF156 (Ganaplacide), an imidazolpiperazine, in combination with a new formulation of Lumefantrine, is being proposed for the replacement of ACTs in the treatment of uncomplicated *P. falciparum* malaria. However, recently, parasite resistance to KAF156 has been developed in vitro, involving point mutations in *pfcarl* (*P. falciparum* cyclic amine resistance locus gene), namely M81I, S1076I/N and I1139K. An important concern is whether these mutations are already naturally present in African parasite populations. In this work we have developed new PCR-RFLP protocols for the identification of these SNPs, and tested in a sizable (n=531) sample of infections from two different geographical locations, Bangamoyo, Tanzania and Bougoula-Hameau, Mali. In the former set of infections we have also preliminarily analysed the hypothesis of lumefantrine driven selection of *pfcarl* SNPs by genotyping the baseline (n=266) and the recurrent infections (n = 37) of an Artemether-Lumefantrine (AL) efficacy trial. We did not find evidence for the presence of any of the aforementioned mutations that have been associated with resistance to KAF156, leading to the conclusion that if present they should be at frequencies significantly below 1%.

0229

THERAPEUTIC EFFICACY OF DIHYDROARTEMISININ PIPERAQUINE COMBINATION IN THE TREATMENT OF UNCOMPLICATED MALARIA IN THREE MALARIA SENTINEL SITES IN GHANA

Benjamin Kwaku Abuaku[1], Paul Boateng[2], Nancy Odurowah Duah-Quashie[1], Nana Yaw Peprah[2], Neils Ben Quashie[3], Alexander Asamoah[2], Eunice Obeng Amoako[1], Keziah Laurencia Malm[2], Kwadwo Ansah Koram[1]

[1]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Accra, Ghana, [2]National Malaria Control Programme, Public Health Division, Ghana Health Service, Accra, Ghana, [3]Centre for Tropical Pharmacology and Therapeutics, University of Ghana Medical School, Accra, Ghana

In 2020, Dihydroartemisinin-Piperaquine (DHAP) was adopted as a second line antimalarial for uncomplicated malaria in Ghana, following a review of the country's antimalaria medicines policy. Available data obtained in 2007

had shown DHAP therapeutic efficacy of 93.3% using a 28-day follow-up schedule. In 2020, the standard 42-day follow-up schedule for DHAP was used to estimate current efficacy levels in three malaria sentinel sites representing the three main ecological zones of the country- savannah, forest, and coastal. PCR genotyping distinguished between recrudescence and re-infection using merozoite surface protein 2 (MSP2)-specific primers: FC27 and 3D7. Per protocol analysis showed day-28 efficacy of 100% in all three sentinel sites. Day-42 PCR-corrected efficacy ranged between 90.3% (95% CI: 80.1 - 96.4) in the savannah zone to 100% in the forest and coastal zones, yielding a national average of 97.0% (95% CI: 93.4 - 98.8). We conclude that DHAP is highly efficacious in the treatment of uncomplicated malaria in Ghana. This data will serve as baseline for subsequent DHAP efficacy studies in the country.

0230

MONITORING MOLECULAR MARKERS OF *PLASMODIUM FALCIPARUM* DRUG RESISTANCE TO EVALUATE DRUG-BASED MALARIA INTERVENTIONS IN SENEGAL FROM 2000 TO 2020

Yaye Dié Ndiaye[1], Wesley Wong[2], Abdoulaye Tine[1], Mouhammad Sy[1], Tolla Ndiaye[1], Amy Gaye[1], Mame Fama Ndiaye[1], Mariama Toure[1], Nogaye Gadiaga[1], Aita Sene[1], Awa Bineta Deme[1], Baba Dieye[1], Mamadou Samb Yade[1], Khadim Diongue[1], Fatou Ba Fall[3], Doudou Sene[3], Medoune Ndiop[3], Ibrahima Diallo[3], Mame Cheikh Seck[1], Aida Sadikh Badiane[1], Jules François Gomis[1], Mouhamadou Ndiaye[1], Mamadou Alpha Diallo[1], Ibrahima Mbaye Ndiaye[1], Bronwyn MacInnis[4], Sarah Volkman[2], Dyann Wirth[2], Daouda Ndiaye[1]

[1]CIGASS/Cheikh Anta Diop University, Dakar, Senegal, [2]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [3]Senegal National Malaria Control Program, Dakar, Senegal, [4]The Broad Institute, Cambridge, MA, United States

Senegal is a malaria-endemic country that has implemented successive antimalarial drug-based strategies for two decades, with intermittent preventive treatment of malaria in pregnancy with sulfadoxine-pyrimethamine (SP) since 2003, treatment with artemisinin-based combination therapies including artesunate amodiaquine (AS-AQ) and artemether-lumefantrine (AL) since 2006, and seasonal malaria chemoprevention (SMC) with SP-AQ for children under age 10 since 2014. Drug pressure may select resistant alleles and risk loss of drug efficacy. Annual therapeutic efficacy studies (TES) and surveillance of molecular markers of drug resistance are done to monitor and guide drug interventions. We genotyped drug resistant alleles of *Pfcrt*, *Pfmdr1*, *Pfdhfr*, *Pfdhps*, *Pfk13* from 3,804 samples (collected 2000 – 2020) from febrile patients with malaria at health facilities in Kedougou and Kolda (high transmission; SMC started in 2014); Diourbel and Kaolack (moderate transmission; SMC started in 2019); and Thies and Pikine (low transmission, no SMC). The triple DHFR mutant haplotype (N51I/C59R/S108N) was >80% by 2020 for all sites, regardless of SMC use. In Kedougou, while the DHPS A581G allele was detected once in 2017, the prevalence of the DHPS A437G allele decreased from 86.8% to 48.1% from 2015 to 2020. No PfK13 mutations of concern were detected . PfMDR1 N86Y remains below 25% in all sites, while PfMDR1 Y184F is >50% in all sites. The most common PfMDR1 haplotype is $N_{86}F_{184}D_{1246}$, followed by $N_{86}Y_{184}D_{1246}$ (wildtype). While PfCRT K76T has remained low (< 20%) in Diourbel, Kaolack, and Kolda), it increased from 10% to 35% in Kedougou (2015 to 2020), and in Thies, it increased rapidly after 2014, reaching > 90% in 2020. The unexpected rise of PFCRT K76T in Thies and Kedougou, the increase in the triple DHFR, and decrease in the DHPS A437G mutant under increasing SP-AQ pressure in Kedougou may relate to modulation of resistance or the fitness costs of specific drug resistance alleles. Different drug-based interventions in different transmission contexts modulate increases or decreases in molecular markers of resistance and warrant ongoing surveillance.

0231

PLASMODIUM FALCIPARUM DRUG RESISTANCE MARKER SELECTION AFTER REPEATED DIHYDROARTEMISININ-PIPERAQUINE TREATMENT IN AFRICA: A CASE STUDY FOR THE ANALYSIS OF LONG HALF-LIFE ANTIMALARIALS IN HIGH TRANSMISSION SETTINGS

Leyre Pernaute-Lau[1], Mamadou Tékété[2], Abdoulaye A Djimdé[2], Steffen Borrmann[3], Pedro Gil[1]

[1]Karolinska Institutet, Stockholm, Sweden, [2]University of Science, Techniques and Technologies of Bamako, Bamako, Mali, [3]University of Tübingen, Tübingen, Germany

In 2020 infections with the parasite *Plasmodium falciparum* accounted most of the 241 million malaria cases, majority of them in the African continent. Dihydroartemisinin-piperaquine (DHA-PPQ) is being incorporated in African national control programs and it has been proposed for mass drug administration strategies. Although PPQ resistance has been already reported in SouthEast Asia, in Africa high-transmission settings the selection of resistance markers remains unclear. We analysed data from 224 patients receiving DHA-PPQ enrolled in a randomized clinical trial performed in southern Mali from 2012 to 2014. The WANECAM project included an active follow-up of 63 days and a distinctive long passive follow-up of two years. In this unique trial, we monitor the spread of molecular markers of resistance in 675 malaria infections by genotyping *pfcrt*, *pfmdr1* along the recurrent episodes and by analysing copy number distribution of *pfmdr1, pfpm2* and *pfpm3* genes in the context of time-to-reinfection.Out of all genotyped Single Nucleotide Polymorphisms (SNPs), *pfcrt* 76T and 356T were associated with significantly decreased times to re-infection compared with the wildtype infections [means (days) wildtype *versus* mutant: 155.2 *vs* 109, $P<0.001$; 138.6 *vs* 113.8, $P<0.05$, respectively]. In addition, *pfpm2* multicopy infections, not present in the baseline but being selected in surprisingly early recurrent infections. Furthermore, there is a significant increased tendency in *pfpm3* copy number variation along the trial. All SNPs under analysis were associated with less than 100 days recurrent infections, suggesting this period as the window of selection for the mutations.The unique longer follow-up of the trial allowed to capture some potentially resistance parasite populations being selected in the background, under the partner drug prolonged pressure. Thereby, new approaches need to be followed when analysing long half-life partner drugs aiming to captured resistance parasites selection early on time, especially in the context large-scale preventive interventions.

0232

DNA CONTAMINATION DURING EXTRACTION OF DRIED BLOOD SPOTS FROM WHATMAN FILTER PAPER

Hamma Maiga, Patrick J. Gorres, Patrick E. Duffy

Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Dried blood spots (DBS) on filter paper (confetti) are one of the most common methods used to collect and extract DNA from field samples for molecular epidemiology of malaria studies. This DNA extraction step may be challenging, particularly in resource limited regions where scissors are used to cut the filter papers with the possibility of introducing contamination between samples due to poor scissor cleaning. Many methods use 70% ethanol to clean the scissors. However, there is limited evidence that ethanol or other solutions used to clean the scissors optimally reduce sample contamination. This work aimed to provide such evidence. DBS were prepared from 3 drops of blood from two *Plasmodium falciparum* cultures (20-0119-0 and 20-2091-0 isolates) spotted on filter paper. All samples were dried for 24 hours at room temperature. We examined three solutions (Water, Ethanol and DNase) to clean scissors between spots during the DNA extraction. For each cleaning solution, two blank confettis were used as negative controls. DBS were cut into small pieces with scissors and transferred into 1.5-mL

microtubes. Parasite DNA was extracted using QIAamp kit and eluted in water. Parasite-infected and negative control samples were analyzed by PCR-based genotyping of the merozoite surface proteins 1 & 2 (*msp-1* and *msp*-2), and the *P. falciparum* chloroquine resistance transporter *(Pfcrt)* genes. A total of 15 samples were analyzed. Based on *msp*1 and *msp*2 amplification (3 for each cleaning solution, n=9), *P. falciparum* was detected on the blank confetti when scissors were washed with Ethanol. Based on *Pfcrt* amplification (2 for each cleaning solution, n=6), DNA of *P. falciparum* was detected on the blank confetti when scissors were cleaned with Ethanol and Water. We did not detect any DNA of any genes on the negative control confettis when the scissors were cleaned with DNase. In conclusion, scissors cleaned with DNase prevented cross-contamination between samples during processing of dried blood spots. Ethanol cleaning of scissors, which is commonly used, fails to completely avert cross-contamination.

0233

CHARACTERIZATION OF GENES IN *PLASMODIUM FALCIPARUM* MUTANTS ASSOCIATED WITH ALTERED SENSITIVITY TO ARTEMISININ

Caroline Simmons[1], Justin Gibbons[1], Min Zhang[1], Jenna Oberstaller[1], Camilla Pires[1], Chengqi Wang[1], Shulin Xu[1], Debora Casandra[1], Andreas Seyfang[1], Thomas Otto[2], Julian Rayner[3], John Adams[1]

[1]University of South Florida, Tampa, FL, United States, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom

Artemisinin combination therapies have led to a significant decrease in *Plasmodium falciparum* malaria mortality, but emerging artemisinin resistance (ART-R) that has reached Sub-Saharan Africa threatens to reverse these gains. ART-R that originated in SE Asia was first linked to polymorphisms in the Kelch propeller protein (K13) and now appears fixed in parasites of this region. Subsequently, several other seemingly unrelated genetic mutations are being linked to altered ART sensitivity. In earlier studies, we identified *P. falciparum* mutants created by *piggyBac* mutagenesis with increased sensitivity to ART, including a mutant of K13 with a single transposon integrated near the putative transcription start site. In this study, we characterize a similar ART-sensitive mutant in a gene defined as a "*Plasmodium*-conserved gene of unknown function", now functionally linked to K13 as the Kelch13 Interacting Candidate 5 protein (KIC5). RNAseq analysis of the KIC5 mutant during intraerythrocytic asexual development identified transcriptional changes associated with DNA stress response and altered mitochondrial metabolism, linking dysregulation of the KIC5 gene to the parasite's ability to respond to ART exposure. Through characterization of the KIC5 transcriptome, we hypothesize that this gene may be essential under ART exposure to manage gene expression of the wild-type stress response at early ring stage, thereby providing a better understanding of the parasite's processes that can alter ART sensitivity and resistance.

0234

EVALUATE THE ROLE OF CYTOKINES AND CHEMOKINES IN THE DEVELOPMENT OF COMPLICATIONS IN MALARIA CAUSED BY *PLASMODIUM VIVAX*

Catalina Tovar Acero[1], Javier Ramírez Montoya[2], María C. Velasco[2], Paula A. Avilés-Vergara[1], Juan Rivera-Correa[3], Dina M. Ricardo-Caldera[1], Ana Rodríguez[4], María F. Yasnot-Acosta[2]

[1]Universidad del Sinú, Montería, Colombia, [2]Universidad de Córdoba, Montería, Colombia, [3]Autoimmunity and Inflammation Program, Hospital for Special Surgery; Department of Medicine, Weill Cornell Medicine, New York, NY, United States, [4]New York University, New York, NY, United States

Plasmodium vivax can cause complicated manifestations, the mechanisms that lead to this situation are not entirely clear. The presence of parasite and parasite-derived components triggers the inflammatory response, which is characterized by the production of pro- and anti-inflammatory molecules. These molecules may be responsible for the damage observed in different affected organs in complicated malaria. Evaluate the role of cytokines and chemokines in the development of complications in malaria caused by. Thirteen cytokines and chemokines were quantified in 106 people with malaria (severe and not severe) and 50 controls, with bead-based multiplex assay. The study variables were analyzed by non-parametric tests were carried with Prima and R statistical software. Fitting models with interaction to study the complication probability, using Lasso Regression with readjustment of Gamlss models of binomial family. IL-10, IL-6 and IFNg had higher concentration in the severe malaria group (<0.0001) and lower concentration of TGF-b (<0.0001), compared with non-severe malaria group and control group. IL-10, IL-6, IFNg showed a negative correlation with platelet count in severe malaria, IL-6 and IFNg specifically with severe thrombocytopenia; and a positive correlation between IFNg and transaminases, and IL-2 and creatinine. Lasso regression model suggests that IL-4, IL-10, CCL2 and TGF-β might be developed as prognostic for severity in *P. vivax* malaria. The inflammatory response during *P. vivax* infection can mediate the development of hematological, renal, and hepatic complications. TGF-b to protect against the development of complicated forms of *P. vivax* malaria.

0235

K13-ASSOCIATED ENDOCYTIC STRUCTURES IN *TOXOPLASMA* ARE REQUIRED FOR PLASMA MEMBRANE HOMEOSTASIS RATHER THAN PARASITE GROWTH

Brandon Mercado-Saavedra, Ludek Koreny, Ross F Waller

University of Cambridge, Cambridge, United Kingdom

Toxoplasma gondii is an obligate intracellular parasite that belongs to the phylum Apicomplexa. These parasites include both *Plasmodium*, responsible for malaria, and *Toxoplasma,* responsible for toxoplasmosis, which has a mortality rate that has significantly increased in the past years in low and lower-middle-income countries. There has been increasingly widespread resistance to the frontline antimalarial, artemisinin, and the protein K13 has attracted much attention in *Plasmodium* research because it is associated with both artemisinin-resistance and the endocytic process by which the parasite feeds on red blood cells through the cytostome. We identified that K13 in *Toxoplasma* also which raised the questions: Is a cytostome-equivalent structure present in *Toxoplasma*, and is endocytosis required for this parasite's growth in *Toxoplasma*? We found that K13 co-locates with other endocytosis-related proteins (DrpC, EPS15, and AP2) as well as others not previously implicated in endocytosis but also associated with artemisinin-resistance (e.g., UBP1). This putative endocytic structure is present at the parasite's inner membrane complex (IMC) in both mother and forming daughter cells, indicating that it is formed early in the development of the IMC even before contact with the plasma membrane during daughter parasite maturation. Live-cell imaging shows that this structure and its constituent proteins are stable features of the IMC. Depleting most of these proteins results in strong growth phenotypes, manifesting as extra-parasitic cytosolic extensions within the parasitophorous vacuole, swollen parasites, and a failure of the ordered rosette organization of the vacuole. However, the replication rate was not significantly affected with K13 protein depletion. Our results show that while endocytosis is essential for *Toxoplasma's* intracellular survival, unlike in *Plasmodium*, its more significant role might be plasma membrane homeostasis rather than parasite nutrition. Further understanding of this endocytic structure and its contribution to endocytosis will bring insights into a novel mechanism to tackle toxoplasmosis.

MODELS OF MALARIA-INDUCED ACUTE KIDNEY INJURY

Johanna Bensalel[1], Angelica P. Piña[2], Kiara Hernandez[2], Winifred Prempeh[2], Daniela Basave[2], Alberto Lazaro[3], Julio Gallego-Delgado[1]

[1]The Graduate Center of CUNY and Lehman College, New York, NY, United States, [2]Lehman College, Bronx, NY, United States, [3]Hospital General Universitario Gregorio Marañón and Universidad Complutense de Madrid, Madrid, Spain

In 2020, there were an estimated 241 million cases of malaria and 627,000 deaths, of which most are in children. Until the most recent decade, the impact of malaria-induced acute kidney injury (MAKI), one of the complications of severe malaria (SM), was severely underestimated and research in this area has been neglected. However, it has been reported that 40-60% of SM patients present with MAKI and it is in fact, the strongest predictor of death in children with SM. Almost half of these cases result in renal failure and MAKI has been associated with chronic kidney disease and other long term complications. There are currently no specific therapies to treat this complication, as the molecular pathways implicated in this pathology remain unknown, and there are no suitable rodent models that replicate the condition in humans. The purpose of this study is to develop an *in vivo* model that resembles the pathology in MAKI patients, specifically exhibiting signs of acute tubular necrosis (ATN), the hallmark of MAKI. In this study, unilateral nephrectomies were performed on wild type mice prior to infection with *Plasmodium berghei NK65*, a rodent-infecting *Plasmodium* species. The removal of one kidney and subsequent infection has resulted in development of kidney injury in mice within 14 days, evident by elevated levels of acute kidney injury (AKI) biomarkers including urinary neutrophil gelatinase-associated lipocalin (NGAL), serum cystatin C, serum lactate dehydrogenase (LDH), and serum potassium ion concentrations. Expression of AKI-associated proteins kidney injury molecule 1 (KIM-1), caspase-3, matrix metalloproteinase-9 (MMP-9), tumor necrosis factor-like weak inducer of apoptosis (TWEAK), and retinol-binding protein-4 (RBP4) was also increased in renal tissue. Establishment of this *in vivo* model of MAKI is critical to the scientific community as it can be used to elucidate the molecular pathways implicated in MAKI, delineate the development of the disease, identify biomarkers for early diagnosis and prognosis, and test potential adjunctive therapies.

0237

IMPACT OF *PLASMEPSIN II* COPY NUMBER ON THE FITNESS OF PIPERAQUINE-RESISTANT PFCRT MUTANT *PLASMODIUM FALCIPARUM* IN CAMBODIA

William Witt[1], Biraj Shresta[1], Nonlawat Boonyalai[2], Paphavee Lertsethtakarn[2], Sohei Hom[3], Piyaporn Sai-ngam[2], Chaiyaporn Chaisatit[2], Sasikanya Thaloengsok[2], Lychhea Huot[2], Brian A. Vesely[2], Michele D. Spring[2], John S. Griesenbeck[2], Dysoley Lek[3], Mariusz Wojnarski[2], Norman C. Waters[2], Shannon Takala Harrison[1]

[1]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Bacterial and Parasitic Diseases Department, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]National Center for Parasitology Entomology and Malaria Control, Phnom Penh, Cambodia

Plasmodium falciparum resistance to piperaquine was reported in Cambodia within two years of the 2010 country-wide switch to dihydroartemisinin-piperaquine as the first line therapy. Initial genotype-phenotype association studies identified amplified *plasmepsin II* (*pfpm2*) gene copy number as a potential molecular marker of piperaquine resistance. Subsequent genome-wide studies identified associations between mutations within the *P. falciparum* chloroquine resistance transporter (*pfcrt*) gene and parasite piperaquine susceptibility. Gene-editing studies indicated that these PfCRT mutations could confer piperaquine resistance in the absence of amplified *pfpm2,* but often at a fitness cost, and hypothesized that amplified *pfpm2* may have a compensatory effect in piperaquine-resistant PfCRT mutant parasites. To test this hypothesis, we compared the fitness of Cambodian field isolates harboring piperaquine-resistance-conferring PfCRT mutations (i.e., F145I, G353V, H97Y, or I218F) with different *pfpm2* copy number (i.e., 1, 2, or >2 copies). Cryopreserved *P. falciparum* isolates collected from patients in Cambodia were culture adapted and their growth rates compared to an eGFP+ Dd2 line using flow cytometry, with assays performed in triplicate. We observed that the Dd2 line outcompeted all the PfCRT mutant strains, regardless of *pfpm2* copy number; however, some strains were outcompeted more rapidly than others. In particular, PfCRT mutant parasites with *pfpm2* copy number >2 were more rapidly outcompeted compared to parasites with 2 *pfpm2* copies, particularly in parasites harboring the G353V and I218F mutations, which have been shown to confer a lesser fitness cost to the parasite in isogenic lines. Although the genetic background of these field isolates may differ, our analysis suggests that, in the absence of drug, *pfpm2* copy number >2 imposes a significant fitness cost to the parasite, as opposed to a compensatory effect, potentially explaining the rapid decrease in high *pfpm2* copy number parasites with the removal of piperaquine pressure.

CHARACTERISATION OF *PLASMODIUM YOELII* 17XL INFECTED MICE AS A TRANSLATIONALLY RELEVANT MODEL OF MALARIA INDUCED ENDOTHELIAL GLYCOCALYX DEGRADATION

Athina Georgiadou[1], Nuri Han[1], Zeina Fahmy[1], Orestis Katsoulis[1], Sophie Walsh[1], Andrew Teo[2], Adrian Najer[3], Tsin Wen Yeo[2], Aubrey Cunnington[1]

[1]Section of Paediatric Infectious Disease, Department of Infectious Disease, Imperial College London, London, United Kingdom, [2]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore, [3]Department of Materials, Imperial College London, London, United Kingdom

The endothelial glycocalyx is a mesh-like structure of glycoproteins and proteoglycans which covers the luminal surface of vascular endothelial cells and plays crucial roles in maintaining the function and integrity of the vascular endothelium. In malaria, multiple pathological processes converge on the vascular endothelium, including inflammatory activation, oxidative damage, activation of coagulation pathways, and sequestration of parasite infected red cells. Recent evidence indicates that glycocalyx degradation occurs in human malaria and the extent of glycocalyx degradation is associated with severity of disease. Thus, preserving and restoring the endothelial glycocalyx may be promising therapeutic approaches. We have recently used comparative transcriptomics to identify *Plasmodium yoelii* 17XL (Py17XL) infection in C57BL/6 mice as a translationally relevant model for the most severe manifestations of *P. falciparum* malaria in children. Here we show that endothelial glycocalyx degradation in Py17XL infection, indicated by plasma levels of syndecan-1, exceeds that in other commonly used mouse models (*Plasmodium yoelii* 17XNL, *Plasmodium berghei* ANKA). This was corroborated by extensive loss of glycocalyx immunofluorescence staining on the surface of vascular endothelial cells in tissue sections. Artesunate treatment of Py17XL infected mice attenuated glycocalyx degradation, suggesting that it is being driven by a process related to parasite load. Glycocalyx degradation in Py17XL was positively correlated with malaria severity markers of parasitemia and lactate and negatively correlated with haematocrit, consistent with human studies. Glycocalyx degradation was also accompanied by pathological changes in multiple organs including brain, lung, liver and kidneys. These findings suggest that the Py17XL mouse model is promising for translational studies of the mechanisms of glycocalyx degradation and potential adjunctive treatments to preserve or restore the glycocalyx layer.

0239

AN UNKNOWN TRANSMISSION BOTTLENECK FOR MALARIA? QUANTIFYING SPOROZOITE EXPELLING IN RELATION TO OOCYST LOADS IN MOSQUITOES INFECTED BY CULTURED GAMETOCYTES AND NATURAL GAMETOCYTE CARRIERS

Chiara Andolina[1], Wouter Graumans[1], Geert-Jan van Gemert[1], Moussa Guelbeogo[2], Sore Harouna[2], Ismail Onyige[3], Daniel Ayo[3], Joseph Okoth[3], Jordache Ramjith[1], Rianne Stoter[1], Marga Vegte-Bolmer[1], Martina Pangos[4], Melissa Conrad[5], John Rek[3], Moses Kamya[6], Alfred B Tiono[2], Photini Sinnis[7], Katharine Collins[1], Sarah G Staedke[8], Kjerstin Lanke[1], Teun Bousema[1]

[1]Radboudumc, Nijmegen, Netherlands, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]Department of Plastic and Reconstructive Surgery, Trieste, Italy, [5]Department of Medicine, San Francisco General Hospital, University of California, San Francisco, CA, United States, [6]Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, [7]Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [8]Department of Clinical Research, London School of Hygiene and Tropical Medicine, London, United Kingdom

It is currently unknown whether all *Plasmodium falciparum* infected mosquitoes are equally infectious. We assessed sporogonic development using cultured gametocytes and natural infections in Burkina Faso and Uganda. We quantified the number of sporozoites expelled into artificial skin in relation to intact oocysts, ruptured oocysts, and (residual) salivary gland sporozoites. Sporozoites were quantified by highly sensitive qPCR; intact and ruptured oocysts by fluorescence microscopy following anti-circumsporozoite antibody staining. Overall, 62% (45/72) of *P. falciparum* N54 and 60.7% (34/56) of N135-infected *Anopheles stephensi* mosquitoes expelled sporozoites. The geometric means of expelled and residual salivary gland sporozoites were 184 (IQR 45.7-659) and 31,779 (IQR 15,740-99,790), respectively. There was a strong correlation between ruptured oocyst number and salivary gland sporozoite load (ρ=0.74; p<0.001), but no statistically significant correlation between salivary gland sporozoite load and the number of sporozoites ejected. In Burkina Faso we performed 56 membrane feedings with *Anopheles coluzzii* mosquitoes on natural gametocyte carriers. We found that among those mosquitoes that were salivary gland sporozoite positive, 97.2% (36/37) ejected sporozoites with a geometric mean of 420 sporozoites ejected (IQR 116-2779) and 35,149 of residual sporozoites (IQR 20,310-164,900). Experiments in Uganda with *Anopheles gambiae* mosquitoes yielded similar results. Although some mosquitoes carried high numbers of sporozoites in their salivary glands, a minority were expelled and the size of the sporozoite inoculum was highly heterogenous. We observed no clear threshold sporozoite density necessary for successful expelling suggesting that all *P. falciparum* infected mosquitoes are potentially infectious mosquitoes.

CLOSING THE GAPS - DELAYED TREATMENT OF MALARIAL-FEVER IN CHILDREN UNDER 5 YEARS

Jailos Lubinda, Susan F. Rumisha, Paul Castle, Akriti Sharma, Paulina Dzianach, Peter W. Gething, Daniel J. Weiss

Telethon Kids Institute, Malaria Atlas Project, Perth, Australia

Infants and children under 5 years old remain at great risk of malaria and also bear over 80% of all malaria deaths. Based on malaria morbidity and mortality estimates, over half a million children died from malaria in 2020 alone. Malaria case management, particularly early diagnosis and prompt, effective treatment, remains a priority and vital component of malaria control and elimination strategies. Early diagnosis and treatment of malaria reduce disease, prevent deaths, and reduce transmission. Delaying effective treatment with antimalarials can cause infections to progress to severe illness and death, especially for *Plasmodium falciparum*. While WHO recommends that all suspected malaria cases be confirmed using parasite-based early diagnostic testing and receive effective treatment prompt (within 24-48hrs from the onset of malaria symptoms), no recent studies provide the current global state of prompt treatment. This study assessed the global malaria treatment delay across 110 malaria endemic countries utilizing data from demographic health surveys and malaria indicator surveys (DHS/MIS) between 2005 and 2021 on the "time to receipt of the 1st antimalarial". Results revealed that huge progress had been made both in and outside sub-Saharan Africa (SSA) during the study period. Prompt treatment was generally higher outside SSA. Nonetheless, the study detected country and region-specific disparities in treatment timings with 23.4% (global), 21% (outside), and 27.2% (within SSA) of children with fever delayed in receiving treatment, respectively. The WHO AFRO region had the highest treatment delay (27.2%) than SEARO with the lowest (17%). During the same period, country delays ranged between 5% (Maldives) to nearly 70% for Haiti. These findings imply that over 130 000 deaths among children may arise from potential treatment delays. With the much-desired acceleration of the malaria elimination agenda and meeting the GTS goal of reducing malaria mortality rates by ≥90% by 2030, the lenses of malaria control efforts should not ignore early diagnosis and prompt treatment to avoid preventable deaths and to decrease the risk of onward transmission.

0241

PLASMODIUM FALCIPARUM DDI1 IS AN ESSENTIAL RETROVIRAL ASPARTYL PROTEASE WHICH REPAIRS ARTEMISININ DAMAGES IN THE MALARIA PARASITE

Noah Machuki Onchieku[1], Damaris Matoke-Muhia[1], Pawan Malhotra[2]

[1]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [2]International Centre for genetic Engineering & Biotechnology (ICGEB), New Delhi, India

The human malaria parasite, *Plasmodium falciparum*, has a complex stage-specific biology in a wide spectrum of human host and mosquito vector environments. This diversity requires swift transformation mechanisms to maintain cellular and proteome homeostasis. To maintain the homeostasis, the parasite utilizes the ubiquitin-proteasome system (UPS) to degrade and recycle the proteins. Most of the UPS components have informed development of many clinical inhibitors, especially in the treatment of different types of cancer. It is feasible, therefore, to speculate that the human malaria parasite UPS presents great opportunities for development of rational antimalarial drugs. Here, we identified and characterized the proteasome shuttle proteins; *Pf*Ddi1, *Pf*Rad23 and *Pf*Dsk2 as potential targets for known and novel antimalarial drugs. Using *in silico* analysis, we showed that while the three proteins belong to the ubiquitin like (UBL)–ubiquitin associated (UBA) domain family, *Pf*Ddi1 has an additional domain with a typical D[S/T]G aspartyl triad signature. Our enzyme activity assays demonstrated that *Pf*Ddi1 is an active retroviral aspartyl (A2) protease that hydrolyzes polyubiquitin and retropepsin substrates, an activity that is blocked by artemisinin, the mainstay antimalaria drug. In addition, immunofluorescence assays (IFA) showed that while the *Pf*Ddi1 localizes predominantly in the parasite cytoplasm, *Pf*Rad23 and *Pf*Dsk2 oscilates between the nucleus and cytoplasm. Our TUNEL assays and Western blot analyses demonstrated that artemisinin leads to DNA fragmentation and increased polyubiquitination in the parasite, which enhances the recruitment of *Pf*Ddi1 into the nucleus. On the other hand, functional complementation studies in *Sacharomyces cerevisiae* cells demosntrated that the *Pf*Ddi1, *Pf*Rad23 and *Pf*Dsk2 proteins are functional homologs of the yeast proteins, and Ddi1-deficient yeast cells have increased excretion of proteins to the media, and are more susceptible to artemisinin pressure.

0242

BRAIN ALTERATIONS IN ADULT NONCEREBRAL FALCIPARUM MALARIA

Sanjib Mohanty[1], Praveen K. Sahu[1], Rajyabardhan Pattnaik[2], Megharay Majhi[2], Himanshu Gupta[3], Arjen M. Dondorp[4], Lukas Pirpamer[5], Angelika Hoffmann[6], Sam C. Wassmer[7]

[1]CWS Hospital, Rourkela, India, [2]Ispat General Hospital, Rourkela, India, [3]GLA University, Mathura, India, [4]MORU, Bangkok, Thailand, [5]Medical University of Graz, Graz, Austria, [6]University Hospital Bern, Inselspital, University of Bern, Bern, Switzerland, [7]London School of Hygiene & Tropical Medicine, London, United Kingdom

Cerebral malaria in adults is associated with brain hypoxic changes on magnetic resonance (MR) images and has a high fatality rate. Findings of neuroimaging studies suggest that brain involvement also occurs in patients with uncomplicated malaria (UM) or severe noncerebral malaria (SNCM) without coma, but such features were never rigorously characterized. UM and SNCM patients underwent MR imaging on admission and up to 72 hours later, as well as plasma analysis. Apparent diffusion coefficient (ADC) maps were generated, with values from 5 healthy individuals serving as controls. Patients with SNCM had a wide spectrum of cerebral ADC values, including both decreased and increased values compared with controls. Patients with low ADC values, indicating cytotoxic edema, showed hypoxic patterns similar to cerebral malaria despite the absence of deep coma. Conversely, high ADC values, indicative of mild vasogenic edema, were observed in both patients with SNCM and patients with UM. Brain involvement was confirmed by elevated circulating levels of S100B. Creatinine was negatively correlated with ADC in SNCM, suggesting an association between acute kidney injury and cytotoxic brain changes. Brain involvement is common in adults with SNCM and a subgroup of hospitalized patients with UM, which warrants closer neurological follow-up. Increased creatinine in SNCM may render the brain more susceptible to cytotoxic edema.

Cerebral malaria (CM) is a common presentation of severe *Plasmodium falciparum* infection and remains an important cause of death in the tropics. Key aspects of its pathogenesis are still incompletely understood, but severe brain swelling identified by magnetic resonance imaging (MRI) was associated with a fatal outcome in African children. In contrast, our MRI findings in Indian patients suggest distinct pathogenic patterns between pediatric and adult CM, with a stronger cytotoxic component in the latter groups. Using MRI and blood profiling databases, we investigated features associated with brain swelling in our cohort of pediatric and adult patients with CM in Rourkela, India, and compared them with an African pediatric CM cohort in Malawi. We determined that higher plasma *Plasmodium falciparum* histidine-rich protein 2 levels and elevated var transcripts that encode for binding to endothelial protein C receptor (EPCR) were linked to CM at both sites. Machine learning models trained on the African pediatric cohort could classify brain swelling in Indian children CM cases but showed a weaker performance for adult classification, due to overall lower parasite var transcript levels in this age group and more severe thrombocytopenia in Rourkela adults. Overall, these findings provide evidence that higher parasite biomass and a subset of Group A-EPCR binding variants are common features in children and adult CM cases, despite age-related differences in their degree of brain swelling.

0244

BREADTH AND ABUNDANCE OF *PLASMODIUM FALCIPARUM* RIFIN AND STEVOR EXPRESSION IS ASSOCIATED WITH CEREBRAL MALARIA IN MALIAN CHILDREN

Jonathan G. Lawton[1], Albert E. Zhou[1], Drissa Coulibaly[2], Emily M. Stucke[1], Rafal Sobota[1], Savy M. Sebastian[1], Bryan Cummings[1], Ankit Dwivedi[1], Antoine Dara[2], James B. Munro[1], Abdoulaye K. Koné[2], Karim Traoré[2], Bouréima Guindo[2], Bourama M. Tangara[2], Amadou Niangaly[2], Issa Diarra[2], Modibo Daou[2], Youssouf Tolo[2], Mody Sissoko[2], Kieran Tebben[1], Matthew B. Laurens[1], Amed Ouattara[1], Bourema Kouriba[2], Ogobara K. Doumbo[2], Shannon Takala-Harrison[1], Christopher V. Plowe[1], Joana C. Silva[1], Mahamadou A. Thera[2], Mark A. Travassos[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]University of Sciences, Techniques and Technologies, Bamako, Mali

The *Plasmodium falciparum* RIFIN and STEVOR variant surface antigen families are displayed on the surface of infected erythrocytes, where they mediate adhesion to nearby uninfected erythrocytes, cellular invasion, and inactivation of immune cells. While these *in vitro* findings suggest a role in severe malaria pathogenesis, little is known about RIFIN and STEVOR expression in clinical malaria episodes. We hypothesized that severe infections have greater breadth and abundance of RIFIN and STEVOR expression compared to uncomplicated infections, defining breadth as the number of unique variants expressed in an infection. Using Illumina short-read RNA-sequencing, we measured RIFIN and STEVOR expression in blood samples from Malian children with three clinical malaria phenotypes, including 14 cases of cerebral malaria (CM), 10 cases of severe malarial anemia (SMA), and 24 uncomplicated malaria (UM) controls matched to cases on age, sex, ethnicity, and residence. We used a custom bioinformatics pipeline to assemble *de novo* RIFIN and STEVOR transcripts. We also aligned sequence reads to the 3D7 reference genome for differential expression analysis of thirteen "strain-transcendent" RIFINs and STEVORs that are uniquely conserved across *P. falciparum* strains. Within each sample, the breadth ($p<0.001$) and abundance ($p<0.001$) of RIFIN transcripts were significantly higher than that of STEVOR transcripts. CM cases expressed more unique RIFIN ($p=0.009$) and STEVOR ($p=0.01$) variants and had higher RIFIN ($p=0.001$) and STEVOR ($p=0.01$) expression abundance compared to UM infections. SMA cases did not differ from UM controls in terms of RIFIN or STEVOR expression levels. A subset of strain-transcendent RIFINs and STEVORs was significantly upregulated in severe infections, although none were differentially expressed in CM or SMA alone. These findings suggest that RIFINs and STEVORs may be important for CM pathophysiology and that certain conserved targets are promising candidates for vaccine development. Further study is needed to determine whether these antigens induce immune protection against severe disease.

0245

ACCURACY OF DIAGNOSIS AMONG CLINICAL MALARIA PATIENTS: COMPARING MICROSCOPY, RDT, AND A HIGHLY SENSITIVE QUANTITATIVE PCR AND THE IMPLICATIONS OF SUB-MICROSCOPIC INFECTIONS

Stephen Opoku Afriyie[1], Thomas Kwame Addison[1], Yilekal Gebre[2], Abdul-Hakim Mutala[1], Kwasi Baako Antwi[1], Abbas Dawood Ackom[1], Kofi Agyapong Addo[1], Austine Tweneboah[1], Cristian Koepfli[2], Kingsley Badu[1]

[1]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]University of Notre Dame, Notre Dame, IN, United States

The World Health Organization recommends parasitological confirmation of all suspected malaria cases by microscopy or rapid diagnostic tests (RDTs) before treatment. These conventional tools are widely used for point-of-care diagnosis in spite of their poor sensitivity at low parasite density. Several studies have compared the diagnostic accuracy of microscopy and RDT using standard 18S rRNA PCR as reference with varying outcomes. Here, we present for the first time in Ghana, the accuracy of diagnosis of microscopy and RDT using highly sensitive *var*ATS qPCR as reference in a clinical setting. 1,040 febrile patients were recruited from two primary healthcare centers in the Ashanti Region of Ghana and tested for malaria by microscopy, RDT, and *var*ATS qPCR. The sensitivity, specificity, and predictive values were assessed using *var*ATS qPCR as gold standard. Kappa (κ) values were calculated to determine the level of agreement between the tests. Parasite prevalence was 17.5%, 24.5%, and 42.1% by microscopy, RDT, and *var*ATS qPCR respectively. Using qPCR as the standard, RDT was more sensitive (55.7% vs 39.3%), marginally less specific (98.2% vs 98.3%), and had higher positive (95.7% vs 94.5%) and negative predictive values (75.3% vs 69.0%) than microscopy. RDT showed better diagnostic agreement (κ=0.571) with *var*ATS qPCR than microscopy (κ=0.409). Parasite prevalence and density was significantly higher ($p<0.0001$) among the 5-14 age group than the <5, 15-30, and >30 age groups across all the tests. RDT outperformed microscopy for the diagnosis of *Plasmodium falciparum* malaria in the study area. However, both diagnostic methods missed over 40% of clinical cases that were detected by *var*ATS qPCR. Novel tools are needed to ensure prompt diagnosis of all clinical malaria cases.

0246

MOLECULAR CHARACTERIZATION OF RESIDUAL PARASITAEMIA ON DAYS-3 AND 14 AFTER ARTEMETHER-LUMEFANTRINE OR PYRONARIDINE-ARTESUNATE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN NIGERIA

Roland Ibenipere Funwei[1], Olusola Ojurongbe[2], Oladapo Walker[1], Catherine O. Falade[3]

[1]Babcock University, Ilishan-Remo, Nigeria, [2]Ladoke Akintola University of Technology, Ogbomoso, Oyo state, Nigeria, [3]University of Ibadan, Ibadan, Nigeria

Microscopic evaluation of parasite clearance is widely utilised as the gold standard in antimalarial drug efficacy trials. However, sub-microscopic residual parasitaemia after artemisinin-based combination therapy (ACT) may signal reduced parasite responsiveness. PCR-determined residual parasitaemia was evaluated on days 3 and 14 post-treatment with artemether-lumefantrine (AL) or pyronaridine-artesunate (PA) in children aged 3 -144 months. One hundred and twenty (AL: n = 60, PA: n = 60) days 3 and 14 dried blood spots, negative by microscopy, were analysed for residual parasitaemia of *falciparum* species using nested PCR. The allelic similarity of parasite clones of the residual parasitaemia on days 3 and 14 were determined with the corresponding day-0 isolates using merozoite surface proteins1 (*msp1*) (K1, RO33, MAD20) and *msp2* (3D7, FC27) families and glutamate-rich protein (*glurp*). The enrollees' mean age (month) was 80 ± 38 and 81 ± 40 for AL and PA, respectively. In all, 45% (AL) and 35% (PA) of enrollees were febrile (≥ 39°C) at baseline. The geometric mean parasite densities were 28,380 (95% CI: 18,625-41,481) and 25,411 (95% CI: 16,949-38,836) for AL and PA. Parasite and fever clearance times were optimal for both treatment arms. However, persistent PCR-determined sub-microscopic residual parasitaemia at day three post ACT treatment was 83 and 88% for AL and PA, while 64% and 36% were parasitaemic on day 14 for AL and PA respectively. Microscopy-confirmed gametocytaemia persisted from days 0 -7 and 0 -21 for AL and PA. When the alleles of day three versus day 0 were compared according to base pairs sizes, 59% of the parasites shared identical alleles for *glurp*, 36% for 3D7 and FC27, while K1 was 77%, RO33 64% and MAD20 23%. Similarly, Day 14 versus day 0 was 36% (*glurp*), 64% (3D7), 32% (FC27), 73% (K1), 77% (RO33) and 41% (MAD20) respectively. PCR-determined sub-microscopic residual parasitaemia on days 3 and 14 following AL or PA treatment was detected with identical parasite clones, which may compromise ACTs efficacy. Further studies are needed to characterize the viability status of these PCR-confirmed residual parasites.

0247

IMPLEMENTATION OF COMMUNITY CASE MANAGEMENT OF MALARIA IN MALARIA ENDEMIC COUNTIES OF WESTERN KENYA, ARE COMMUNITY HEALTH VOLUNTEERS UP TO THE TASK IN DIAGNOSING MALARIA

Enock Oburi Marita

Formerly Amref Health Africa, Nairobi, Kenya

Community case management of malaria (CCMm) is an equity-focused strategy that complements and extends the reach of health services by providing timely and effective management of malaria to populations with limited access to facility-based healthcare. In Kenya, CCMm involves use of malaria rapid diagnostic tests (RDT) and treatment of confirmed uncomplicated malaria cases with artemether lumefantrine (AL) by community health volunteers (CHVs). Test positivity rate (TPR) from CCMm reports collected by Ministry of Health in 2018 was twofold compared to facility-based reports for the same period. This necessitated the need to evaluate the performance of CHVs in conducting malaria RDTs. The study was conducted in four counties within the malaria endemic lake zone in Kenya with a malaria prevalence in 2018 of 27%; the national prevalence of malaria was 8%. Multi-stage cluster sampling and random selection were used. Results from 200 malaria RDTs performed by CHVs were compared with test results obtained by experienced medical laboratory technicians (MLT) performing the same test under the same conditions. Blood slides prepared by the MLTs were examined microscopically later as a backup check of the results. A kappa score was calculated to assess level of agreement. Sensitivity, specificity, positive and negative predictive values were calculated to determine diagnostic accuracy. The median age of CHVs was 46 (IQR: 38, 52) with a range [26, 73] years. Females were 72% of the CHVs. Test positivity rates for MLTs was 42% and for CHVs was 41%. The kappa score was 0.89 indicating an almost perfect agreement in mRDT results between CHVs and MLTs. The overall sensitivity and specificity between the CHVs and MLTs were 95.0% (95% CI: (87.7, 98.6) and 94.0% (95% CI; 88.0, 97.5) respectively. Engaging CHVs to diagnose malaria cases under CCMm yielded results which compared well with the results of qualified experienced laboratory personnel. CHVs can reliably continue to offer malaria diagnosis in the community setting. The reported TPR difference between CHV and facility-based testing needs to be explored.

REVISITING A NEGLECTED SYMPTOM: CLINICAL EXPERIENCE USING THE HYFE COUGH TRACKER IN MALARIA PATIENTS

Valeria López[1], Amelia Houana[2], **Isabel Sánchez Olivieri**[3], Antonio Macucha[2], Hansel Mundaca[4], Vegovito Vegove[2], Eldo Elobolobo[2], Carlos Chaccour[3]

[1]Universidad Central de Venezuela, Caracas, Bolivarian Republic of Venezuela, [2]Centro de Investigación de Salud de Manhica, Maputo, Mozambique, [3]Clínica Universidad de Navarra, Pamplona, Spain, [4]Barcelona Institute for Global Health, Barcelona, Spain

Malaria remains the most important human parasitic disease causing over 240 million cases and 600.000 deaths in 2020. Acute respiratory distress can be present in up to 40% of children with severe malaria and up to 50% of patients have a cough of new onset. In spite of these notable respiratory features, the diagnosis of malaria remains blood-based which fundamentally restricts diagnosis to individual interactions with a health care worker. The usage of devices that can monitor and analyze coughs with artificial intelligence software is an entirely new, low-cost, non-invasive tool. This can be leveraged for malaria screening and differential diagnosis with bacterial pneumonia and other key respiratory conditions possibly improving the use of antimicrobials in settings with limited resources. To assess the presence of cough as one of the symptoms of malaria, we used a smartphone-based App (Hyfe cough tracker) in our clinical practice in the community health center of Mopeia, Mozambique. We attended clinically 63 children (1months - 11 years) who consulted for malaria (33) or any respiratory symptoms (30). As part of the clinical examination, the children were monitored for 30 minutes with a smartphone running Hyfe placed in a shoulder pouch. Overall, 63% of children had at least one episode of cough, this was similar in both groups. Patients with a positive malaria test had a median of 4 episodes/30min and those consulting with respiratory complaints had a median of 2. Malaria patients had an almost two-fold probability to experience more than 10 episodes of cough/30min than patients with other respiratory diseases. These results stress the importance of respiratory symptoms in malaria patients and open the door to better quantify cough as a biomarker for this disease.

MALARIA DIAGNOSIS IN SALIVA BY DROPLET DIGITAL PCR (DDPCR) TARGETING NON-RIBOSOMAL MULTICOPY TARGETS

Gabriel L. Costa[1], Denise A. M. Alvarenga[1], Anna Caroline C. Aguiar[2], Jaime Louzada[3], Dhélio B. Pereira[4], Tatiana Flávia P. de Oliveira[5], Antônio Augusto F. Júnior[5], Luzia H. Carvalho[1], Cristiana F. A. de Brito[1], **Tais N de Sousa**[1]

[1]Instituto René Rachou, Fundação Oswaldo Cruz (FIOCRUZ), Belo Horizonte, Brazil, [2]Bioscience Department, University of São Paulo (USP), Santos, Brazil, [3]Federal University of Roraima, Boa Vista, Brazil, [4]Center for Research in Tropical Medicine (CEPEM), Porto Velho, Brazil, [5]Laboratório Federal de Defesa Agropecuária de Minas Gerais (LFDA/MG), Pedro Leopoldo, Brazil

Accurate diagnosis of malaria is fundamental for the adequate treatment of patients, prevention of mortality and disease control. Light microscopy is the gold standard for diagnosis; however its low limit of dectection may lead to a misdiagnosis of mixed infections and loss of low-density infections of *Plasmodium*. By using multicopy targets and highly sensitive molecular techniques, it is possible to change this scenario. This study evaluated the performance of droplet digital PCR (ddPCR) to detect non-ribosomal multicopy targets of *P. vivax* (Pvr47) and *P. falciparum* (Pfr364) in saliva samples. A total of 471 samples of blood, whole saliva and buccal swab (157 samples of each) were collected of individuals from the Brazilian Amazon region between 2017 and 2020. The sensitivity of qPCR in saliva was 77%; however, it was only 47% in buccal swab. Parasite DNA was not detected in saliva samples in low-density infections (<1500 parasites/µL) compared with the detection in blood samples. ddPCR showed increased sensitivity for detecting *Plasmodium* in the blood and swabs (99% in blood, 73% in saliva, and 59% in swabs). Noticeably, ddPCR detected a higher proportion of mixed infections in the blood (15%), saliva (9%) and swabs (18%) than qPCR. Our data showed that the differences between ddPCR and qPCR were the result of a higher number of *P. falciparum* infections detected by ddPCR. There was a moderate correlation between parasite densities estimated by the different methods in blood. Whereas a significant correlation was observed for all analysis performed for *P. vivax*, only density estimates obtained by qPCR and LM correlate to each other for *P. falciparum*. Our findings highlight the possibility of using non-invasive sample collection methods for malaria diagnosis by targeting multicopy sequences combined with highly sensitive molecular methods.

PERFORMANCE AND USABILITY EVALUATION OF POINT-OF-CARE TESTS FOR GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY IN MAE SOT, THAILAND

Stephanie Zobrist[1], Cindy Chu[2], Rebecca Green[1], Podjanee Jittamala[3], Laypaw Archasukan[4], Candy Beau[4], Kan Choun[4], Gornpan Gornsawun[4], Emily Gerth-Guyette[1], Paw Khu Moo[4], Kle Bah Wah[4], Tha Gay Wah[4], Sampa Pal[1], Francois Nosten[2], Gonzalo J. Domingo[1], Germana Bancone[2]

[1]PATH, Seattle, WA, United States, [2]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University and the Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Mae Sot, Thailand, [3]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [4]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand

Radical cure of *Plasmodium vivax* malaria requires elimination of liver-stage parasites through treatment with 8-aminoquinolines. However, individuals with glucose-6-phosphate dehydrogenase (G6PD) deficiency—a commonly inherited enzyme disorder—are at increased risk of hemolysis following exposure to these drugs. Point-of-care (POC) diagnostics for G6PD deficiency are critical to expand access to safe treatment options for *P. vivax*. Several POC G6PD diagnostics have been developed, and data on test performance and usability are needed to inform further product development and facilitate uptake. Between November 2021 and March 2022, a study was conducted in Mae Sot, Thailand, to evaluate the performance and usability of three POC G6PD tests: two versions of a quantitative biosensor test and one qualitative rapid test. Healthy adults were recruited for the diagnostic accuracy study at clinics and through an enriched sample of participants with known G6PD status. Venous blood was collected and transferred to the central hematology laboratory where G6PD and hemoglobin measurements were obtained from the index tests, Fluorescent Spot Test, HemoCue® 301+, and a quantitative G6PD spectrophotometric reference assay. Index tests were run in duplicate in temperature-controlled and uncontrolled settings. To assess usability, intended users of POC G6PD tests were trained on test procedures and surveyed on key product features. Three-hundred participants were enrolled in the diagnostic accuracy study, including 35 G6PD deficient males and females (11.7%), 20 G6PD intermediate females (6.7%), and 245 G6PD normal males and females (81.7%). Diagnostic performance of the index tests in terms of sensitivity and specificity for G6PD deficients and intermediates will be reported. 15 health care workers participated in the usability assessment. Scores from the assessments, alongside qualitative user perceptions and experiences with the tests will also be presented. These data provide insights into key performance and usability considerations to inform product development of POC diagnostics for G6PD and expand access to radical cure.

0251

GENETIC DIVERSITY OF HISTIDINE-RICH PROTEIN 2 AND 3 GENES IN *PLASMODIUM FALCIPARUM* POPULATIONS IN GHANA AND ITS IMPLICATIONS FOR THE USE RAPID DIAGNOSTIC TESTS FOR MALARIA INFECTIONS

Nancy Odurowah Duah-Quashie[1], **Philip Opoku-Agyeman**[1], Selassie Bruku[1], Tryphena Adams[1], Kwesi Z. Tandoh[1], Nana Aba A. Ennuson[1], Sena A. Matrevi[1], Benjamin Abuaku[1], Neils B. Quashie[1], Chaselynn Watters[2], David Wolfe[3], Hugo Miranda Quijada[3], Terrel Sanders[3]

[1]Noguchi Memorial Institute for Medical Research, College of Health Sciences, Accra, Ghana, [2]US Naval Medical Research Unit no.3, Ghana Detachment, Accra, Ghana, [3]US Naval Medical Research Unit no. 3, Ghana Detachment, Accra, Ghana

Plasmodium falciparum histidine-rich protein 2 (*Pfhrp2)* based rapid diagnostic tests (RDTs) are extensively used to diagnose malaria worldwide. RDTs targeting *Pfhrp2* antigen cross react with *Pfhrp3* because they share structural similarities and this complements the detection of the parasites. However, the use of the test is being compromised by reports indicating the occurrence of deletions of the *Pfhrp2* and *Pfhrp3* genes in some parasites and the consequent false negative test results. We therefore, sought to detect reported deletions and genetic diversity of *Pfhrp2* and *Pfhrp3* genes (exon 2) using the parasite isolates from children ≤9 years with uncomplicated malaria from 10 sentinel sites during 2016 to 2020 transmission seasons. Both genes were amplified using nested PCR and repeated runs with no amplification indicated the presence of the deletion in the genes. Successfully amplified genes were sequenced using the Sanger method. Deletions were observed in 32.6% (569/1745) and 21.2% (402/1894) of the samples for *Pfhrp2* and *Pfhrp3* genes respectively. Sequencing was done for 1152 *Pfhrp2* and 1248 *Pfhrp3* amplicons however analysis was done with 824 and 901 good sequences. *Pfhrp2* repeat polymorphisms were dominantly of types 2 (AHHAHHAAD) and 7 (AHHAAD). Variant repeat polymorphisms were also observed in types 1, 2, 3, 7, 10, 12, 13, however 2 and 7 had most variants of 31 and 18 respectively. For the *pfhrp3* repeat types, 16 (AHHAAN), 17 (AHHDG) and 18 (AHHDD) were the dominant types observed. Number of variants of these three types were 32, 22 and 20 respectively. *Pfhrp2* polymorphisms showed more diversity than *pfhrp3* in Ghanaian isolates. The implication of our findings of the high frequencies of the *Pfhrp2* and *Pfhrp3* gene deletions as well as the variants of main epitopes of the monoclonal antibodies for the RDT (types 2 and 7) in our isolates could be suggestive of decreasing sensitivity of the tests in diagnosing malaria infections in Ghana and this is further discussed.

0252

REDUCTION OF CLINICAL MALARIA CASES FROM 2014 TO 2021 IN MAINLAND TANZANIA: A COMPARISON OF TRENDS BY HEALTH FACILITY OWNERSHIP

Osia Mwaipape[1], Joseph J. Joseph[1], Humphrey Mkali[1], Abdul-wahid Al-mafazy[1], Anna Mahendeka[2], Sijenunu Aron[2], Frank Chacky[2], Jeremiah Ngondi[3], Chonge Kitojo[4], Naomi Serbantez[4], Erik Reaves[5], Claud John[6], Donal Bisanzio[3], Samwel Lazaro[2]

[1]RTI International -Tanzania Office, Dar es Salaam, United Republic of Tanzania, [2]National Malaria Control Program, Dodoma, United Republic of Tanzania, [3]RTI International, Washington, DC, United States, [4]US President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, [5]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania, [6]Ministry of Health, Dodoma, United Republic of Tanzania

Malaria remains a public health problem in Tanzania and a leading cause of morbidity and mortality with pregnant women and children under five years being the most vulnerable. There has been a gradual decrease in clinical malaria cases (presumptive without testing) largely due to implementation of policies and guidelines on malaria diagnosis and treatment of only malaria confirmed cases with artemisinin-combination therapy (ACT). This study aimed to investigate trends of clinical malaria cases reported by health facilities from 2014 to 2021. Monthly health facilities data were downloaded from the district health information system (DHIS2) and analyzed using Stata software. Descriptive statistics were used to explore the time trends and compare data by health facility type (Public, Defense, Private, Parastatal and Faith-based). Differences across health facility types were compared using test of proportions. The number of clinical malaria cases reported from 2014 to 2021 decreased by 99.7% (2,591,519/2,599,990) in OPD while clinical malaria admissions decreased by 97.9% (119,095/121,635). The proportion of clinical malaria cases decreased from 36.3% (2,599,990/7,156,298) in 2014 to 0.2% (8,471/4,279,835) in 2021 for OPD, and from 35.6% (121,635/341,978) in 2014 to 1.3% (2,540/193,148) in 2021 for IPD. Compared to other facility types, Public Health facilities consistently reported a significantly lower proportion of clinical cases (p=<0.001). There were differences in the proportion of clinical cases across other facility types; however, the difference was not statistically significant. The findings suggest that public health facilities adhere consistently to the National Guidelines for Diagnosis and Treatment of Malaria. This might be attributed to investments and improvements in training, supervision, commodities, and other malaria supplies to public health facilities. Further efforts are needed to improve malaria diagnosis and treatment practices in Defense, Parastatal, Private and Faith-based facilities.

0253

SUPPLY AND DEMAND SIDE FACTORS INFLUENCING UPTAKE OF MALARIA TESTING SERVICES IN THE COMMUNITY; LESSONS FOR SCALE-UP FROM A CLUSTER-RANDOMIZED, COMMUNITY BASED TRIAL

Joseph Kipkoech Kirui[1], Josephine Malinga[2], Edna Sang[3], George Ambani[1], Lucy A. Abel[1], Erick Nalianya[3], Jane Namae[4], Mathew Boyce[5], Jeremiah Laktabai[4], Diana Menya[1], Wendy O'Meara[6]

[1]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [2]Duke Global Health Institute, Durham, North Carolina, USA, ELDORET, Kenya, [3]Duke Global Inc, Kenya, Eldoret, Kenya, [4]School of Medicine, Moi University College of Health Sciences, Eldoret, Kenya, [5]Georgetown University, Washington, DC, United States, [6]Academic Model Providing Access to Healthcare, Eldoret, Kenya, Durham, NC, United States

Maximizing the impact of community-based programs requires understanding how the supply of, and demand for, the intervention interact at the point of delivery. We present results from a large-scale community health worker study designed to increase the availability of and demand for malaria diagnostic testing in a rural, malaria-endemic region in western Kenya between 2015 and 2017. Community Health Workers (CHWs) provided free malaria Rapid Diagnostic Test(mRDT) in the community. Those with a positive malaria test were provided with a discounted first-line antimalarial over-the-counter. We conducted a community-based survey of household members with fever in the last four weeks to collect individual study outcomes at 12- and 18-months post-implementation. In addition, we collected monthly testing data from the 244 participating CHWs and also conducted semi-structured interviews with a random sample of 70 CHWs. From the survey, 55% (n=948/1738) reported having a malaria test for their recent illness with 38% having been tested by a CHW. Being aware of a local CHW (Adj. OR=1.50, 95% CI:1.10-2.04) and belonging to a wealthy household (Adj. OR=1.53, 95% CI:1.14-2.06) were associated with higher malaria testing uptake from any source. Poorer households were more likely to receive a test from a CHW. School-aged children between 5-17 years were more than twice as likely to be tested by a CHW (Adj. OR=2.39 95% CI:1.43-4.01). Both confidence in AL treatment (Adj. OR=2.75, 95% CI:1.54-4.92) and perceived accuracy of an RDT performed by a CHW (Adj. OR =2.43, 95% CI:1.12-5.27) were strongly and positively associated. Scale-up of community-based malaria testing intervention through CHWs is feasible and effective at reaching the poorest households. In order to maximize the impact of such interventions, it is important to recognize factors that may restrict both delivery and demand for such services.

0254

PLASMODIUM 18S RRNA BIOMARKER CLEARANCE AFTER FDA-APPROVED ANTIMALARIAL TREATMENT IN CONTROLLED HUMAN MALARIA INFECTION TRIALS

Christopher R. Chavtur[1], Weston J. Staubus[1], Mabel Ho[1], Dianna Hergott[1], Annette M. Seilie[1], James Kublin[2], Ming Chang[1], Sean C. Murphy[1]

[1]University of Washington, Seattle, WA, United States, [2]Fred Hutch Cancer Research Center, Seattle, WA, United States

Controlled human malaria infection (CHMI) studies at non-endemic sites are now widely used to evaluate candidate anti-malaria drugs and vaccines prior to larger field studies in endemic regions. Historically, thick blood smears (TBS) were used in CHMI studies to detect infection after challenge and to confirm the clearance of parasites after treatment. In the past several years, more sensitive molecular biomarkers, such as Plasmodium 18S rRNA, have been qualified by the US FDA for detection of infection after challenge and have supplanted TBS for this purpose. However, the FDA has not formally qualified such biomarkers for confirming clearance of parasites after treatment. We compiled and analyzed post-treatment TBS and 18S rRNA quantitative reverse transcription PCR (qRT-PCR) data acquired from 142 P. falciparum infected participants across 7 CHMI studies conducted at our center over the past decade. For studies where infections were protocol-defined by TBS positivity (treatment densities of 5,000 to 200,000 estimated parasites/mL(p/mL)), the 18S rRNA biomarker cleared from peripheral blood in an average of 3.5 ± 0.2 days, which was significantly longer than the mean time to a negative TBS (1.8 ± 0.2 days). In studies where infections were protocol-defined by qRT-PCR positivity (treatment densities between 20 to 40,000 p/mL), biomarker clearance averaged 3.3 ± 0.1 days, which was not significantly different from TBS-defined studies. However, across all studies, the time to 18S rRNA biomarker negativity after treatment was directly correlated to the parasite density at the time of treatment, with significantly longer clearance times for participants with higher densities at treatment ($p = 0.001$). Thus, initiating treatment earlier leads to faster biomarker clearance. The data defines the expected clearance kinetics in treated CHMI study participants and will help identify conditions that deviate from this normal clearance to further increase the safety of such studies. Overall, the Plasmodium 18S rRNA can be relied upon to confirm the adequacy of treatment in CHMI studies at non-endemic sites.

IMPLEMENTATION OF PROFICIENCY TESTING IN ZANZIBAR SUPPORTS QUALITY IMPROVEMENT FOR MALARIA MICROSCOPY AT FACILITY LEVEL

Saidi Mgata[1], Saidi Mohamed[2], Bimkubwa Khamis[2], Safia Mohamed[2], Stella Makwaruzi[3], Goodluck Tesha[3], Mohamed Ali[2], Rodgers Mwinga[4], Albert Ikonje[5], Sigsibert Mkude[1], Naomi Serbantez[5], Chonge Kitojo[5]

[1]PMI Impact Malaria, PSI, Dar es salaam, United Republic of Tanzania, [2]Zanzibar Malaria Elimination Programme, Zanzibar City, United Republic of Tanzania, [3]PMI Impact Malaria, Jhpiego, Dar es salaam, United Republic of Tanzania, [4]PMI Impact Malaria, MCDI, Kisumu, Kenya, [5]U.S. President's Malaria Initiative, USAID, Dar es salaam, United Republic of Tanzania

Quality assured malaria microscopy remains the 'gold standard' for diagnosing malaria. However, in limited resource settings like Tanzania, the accuracy of microscopy results remains a great challenge. To build microscopists' competence and improve the accuracy of test results, refresher trainings and provision of external quality assessment, which includes proficiency testing, onsite supportive supervision, and blind rechecking, are essential. During 2021, the Zanzibar Malaria Elimination Programme with support from U.S. President's Malaria Initiative Impact Malaria project provided basic Malaria Diagnostic Refresher Training (bMDRT) to 60 laboratory technologists from the two Zanzibar islands of Unguja and Pemba and distributed malaria proficiency testing (PT) panels to 44 health facilities. The aim of the PT was to evaluate the performance of laboratory technicians in public and private laboratories at health facilities in Zanzibar. Two rounds of PT panels were distributed between June and December 2021. The laboratory technicians were assessed on their competence for parasite detection (PD) and species identification (ID). The results were compared with validated results at the central laboratory and feedback was given to the facility. The results show an improving trend of PD and ID competencies for consecutive rounds. On average, PD improved from 74% to 90% and ID from 28% to 50% from Round 1 to 2. The next steps are to expand the number of microscopists trained and to continue doing further rounds of PT.

0256

DISTINGUISHING MALARIA-CAUSED COMA FROM NON-MALARIA CAUSED COMA: THE CONTRIBUTION OF MALARIAL RETINOPATHY

Bo Zhang[1], Yuzhou Lin[2], Dylan S. Small[3], Karl B. Seydel[4], Terrie E. Taylor[4]

[1]Fred Hutchinson Cancer Research Center, Seattle, WA, United States, [2]Harvard University, Boston, MA, United States, [3]University of Pennsylvania, Philadelphia, PA, United States, [4]Michigan State University, East Lansing, MI, United States

The World Health Organization (WHO) defines a child as suffering from cerebral malaria (CM) if they are in coma, have malaria parasites in their blood, and have no alternative cause of the coma. In malaria endemic areas there is often a large proportion of children with asymptomatic parasitemia. When comatose, this group confounds the CM definition as it mis-classifies children with asymptomatic parasitemia and other causes of coma as having CM. An autopsy study showed that approximately 25% of the children who died of WHO-defined cerebral malaria did not have malaria parasites in their brain and had evidence of another coma-inducing etiology that was not appreciated prior to death. If it could be determined prior to death whether a child's coma is caused by malaria parasites or another pathology, treatment might be improved. Prior studies justified the discriminative power of platelet and white blood cell counts in diagnosing severe malaria. One important biomarker of CM is CM-specific retinopathy consisting of a set of malarial-specific retinal changes. CM can be classified as retinopathy-positive and retinopathy negative. This study aimed to quantify the power of malarial retinopathy in discriminating malarial- from non-malarial coma. Our study cohort consists of 1228 patients. We assume there are two latent classes among these patients, corresponding to malarial- and non-malarial coma, and that the parasite protein *Plasmodium falciparum* histidine-rich protein-2 (*Pf*HRP2) follows a log-normal distribution in each latent class. We implemented a Gaussian mixture model based on the $\log_{10}$-scale *Pf*HRP2, and find that 10% of patients had non-malarial coma. We then explored the diagnostic power of retinopathy by building logistic regression classifiers using a combination of patients' platelet counts, white blood cell counts, peripheral parasitemia, and retinopathy. We found that the platelets plus retinopathy model significantly improved the discriminative power of the platelets plus white blood cell model (AUROC: 0.830 vs. 0.752, p-value = 0.038).

0257

THE COMMCARE MOBILE APPLICATION IMPROVES THE QUALITY OF MALARIA CARE IN CHILDREN UNDER FIVE YEARS OLD AT THE COMMUNITY LEVEL IN MADAGASCAR

Stéphanie Ranaivo[1], Haja Andriamiharisoa[1], Feno Rakotoarimanana[1], Andritiana Tsarafihavy[1], Serge Raharison[1], Aishling Thurow[2], Laurence Laumonier-Ickx[2], Thomas Hall[2], Laurent Kapesa[3], Jocelyn Razafindrakoto[4], Solofo Razakamiadana[4], Azzah Al-Rashid[4]

[1]Management Sciences for Health, Antananarivo, Madagascar, [2]Management Sciences for Health, Medford, MA, United States, [3]President's Malaria Initiative, Antananarivo, Madagascar, [4]USAID/ Madagascar, Antananarivo, Madagascar

Community health volunteers (CHVs) in Madagascar serve as first-line health care providers for many communities located more than five kilometers from a basic health center. The USAID-funded Accessible Continuum of Care and Essential Services Sustained (ACCESS) Program, led by Management Sciences for Health and in partnership with Dimagi, supports the Ministry of Public Health of Madagascar to introduce the use of the CommCare mobile application to improve the quality of care provided by CHVs. With the help of built-in algorithms, the application provides step-by-step instructions to the CHVs on case management, including malaria testing and treatment for children under five years of age (CU5); collects individual case management data; and automatically generates monthly activity reports. ACCESS compared monthly community activity report data from October 2020 to September 2021 within the 12 districts covered by CommCare in the four target regions of Atsinanana, Atsimo Andrefana, Fitovinany, and Vatovavy. The malaria testing and treatment rate for CU5 among 1,891 CommCare users was measured and compared with that of the 2,530 other CHVs in the same regions and districts and for the same period using a chi-squared test. Data from October 2020 to September 2021 was extracted from CommCare and ACCESS District Health Information Software II platforms. The rate of fever cases tested by rapid diagnostic test (RDT) was significantly higher among CHVs using CommCare (96% [7212/7499)]) compared to all other CHVs in the four regions (69% [44,367/64,023]) (p=0.001). Similarly, the treatment rate of positive cases with artemisinin-based combination therapy (ACT) is higher among CHVs using CommCare (86% [3541/4231]), compared to CHVs not using CommCare in the same area (81% [23,753/29178]) (p<0.001). No differences in RDT and ACT supplies between users and non-users were noted. These data therefore suggest that CommCare users have a higher rate of compliance with testing and treatment guidelines than non-users, improving the quality of uncomplicated malaria management in CU5.

0258

DELETIONS OF *PLASMODIUM FALCIPARUM PFHRP2* AND *PFHRP3* GENES FROM PARTICIPANTS IN ANTIMALARIAL EFFICACY TRIALS IN ANGOLA, GUINEA, AND UGANDA 2017-2020

Jessica N. McCaffery[1], Douglas Nace[1], Pedro R. Dimbu[2], Alexandre Delamou[3], Abdoul H. Beavogui[4], Chris Ebong[5], Mateusz Plucinski[1], Eric S. Halsey[1], Eric Rogier[1]

[1]CDC, Atlanta, GA, United States, [2]National Malaria Control Program, Luanda, Angola, [3]Centre National de Formation et de Recherche en Santa Rurale, Mafèrinyah, Guinea, [4]Centre National de Formation et de Recherche en Santè Rurale, Mafèrinyah, Guinea, [5]Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda

HRP2-based rapid diagnostic tests (RDTs) are widely used across sub-Saharan Africa to diagnose *P. falciparum* malaria, but the emergence of *pfhrp2* and *pfhrp3* (*pfhrp2/3)* gene deletions threatens their utility. In response to this threat, the WHO set a local prevalence of 5% *pfhrp2* deletions as the threshold for switching away from HRP2-only RDTs. In this study, dried blood spots (DBS) were collected from children under 12 years of age with *P. falciparum* mono-infection during enrollment in an antimalarial efficacy study. All children had symptoms of malaria and microscopically-confirmed *P. falciparum* infection of at least 1000 parasites/ul blood. A multiplex bead-based antigen detection assay screened these samples to identify low levels of HRP2/3 antigen expression relative to pan-*Plasmodium* lactate dehydrogenase and aldolase. Samples with low HRP2/3 expression in relation to pan-*Plasmodium* antigens were selected for *pfhrp2/3* genotyping. Before *pfhrp2/3* genotyping, a *Plasmodium* PCR speciation assay and *pfmsp1* and *pfmsp2* PCRs were used to assess DNA quantity and quality. A total of 610 DBS from three sites in Angola, 846 from four sites in Guinea, and 589 from three sites in Uganda were screened. Genotyping samples with low HRP2/3 antigen profile revealed two *pfhrp2*-single deletions (0.3%) and two *pfhrp3*-single deletions (0.3%) in Angola. Analysis of HRP2/3-low samples from Guinea revealed one *pfhrp2/3* dual deletion (0.1%), one *pfhrp2*-single deletion (0.1%), and one *pfhrp3*-single deletion (0.1%). In Uganda, one *pfhrp2*-single deletion (0.2%) and four *pfhrp3*-single deletions (0.7%) were observed. Of the samples included in this study, *pfhrp2/3* dual-deletions were only observed in one sample from Guinea. While not able to provide *pfhrp2/3* deletion prevalence estimates for an entire country, this report provides evidence that symptomatic *P. falciparum* infections from the study sites in these three countries show high levels of HRP2 and HRP3 expression, supporting the utility of HRP2-based RDTs in the study sites.

DEVELOPMENT AND VALIDATION OF AN AFFORDABLE AND FULLY AUTOMATED MICROSCOPE SYSTEM FOR MALARIA DIAGNOSIS AND RESEARCH

Hongquan Li, Kajal Maran, Jassi Pannu, Rinni Bhansali, Lucas Valenzuela, Ethan Li, Maxime Voisin, Hazel Soto-Montoya, Manu Prakash

Stanford University, Stanford, CA, United States

Despite the widespread use of RDT and the accelerated adoption of molecular tests, malaria microscopy remains an indispensable tool for malaria diagnosis, case management, treatment efficacy studies, vaccine trials and epidemiological research. The role microscopy needs to play is even more important with the rise of pfHRP2/3 deletion and the spread of drug resistant mutations. However, manual microscopy is labor intensive and error-prone - while the detection limit of manual microscopy is thought to be around 10-100 parasites/microliter, a 2019 work that surveyed 10 studies reported sensitivity ranging from 40% to 80% at 1000 parasites/ul. To address this challenge, we have developed a fully motorized, computer-vision based system for automated detection of malaria parasites in both asextual and gametocyte stages. The solution uses DAPI staining, which costs less than $0.02/test reagent-wise and stains rapidly (in 2 minutes). Use of fluorescence allows sensitive and specific detection with 10x-20x objectives that have 25-100 times larger field of views compared to traditionally used 100x oil immersion objectives. With both transmitted light and fluorescent contrast, the system is capable of screening 500,000 - 2,000,000 red blood cells per minute, with expected detection limit below 10 parasites/ul. Results from ongoing validation studies in India and Uganda will be shared.

As countries push toward elimination of *Plasmodium vivax*, treatment of liver stage parasites with primaquine or tafenoquine is increasingly important. Both drugs are associated with hemolytic anemia (HA) in individuals with decreased glucose-6-phosphate dehydrogenase (GP6D) activity levels, a genetically determined trait commonly found throughout the Mekong Subregion. To mitigate this risk, several countries, including Cambodia, require *P. vivax* infected individuals be screened for G6PD deficiency before receiving primaquine. The gold standard assay for G6PD activity requires spectrophotometry which is not universally accessible in many malaria-endemic areas. Point-of-care (POC) testing provides an alternative, but several methods in use do not reliably detect individuals with intermediate levels of G6PD activity who may be at risk for primaquine-induced HA. Quantitative POC assays have been developed to address this gap. We enrolled 966 individuals seeking care for febrile illness from November 2020 to September 2021 in seven health facilities located in Kampong Speu Province, Cambodia, to determine the performance of the quantitative STANDARD™ G6PD (SD Biosensor) POC assay when used by local clinic staff. G6PD activity and hemoglobin concentration in capillary blood were measured on-site using the POC assay. Reference values for each participant were obtained by spectrophotometry and hematology analysis of a corresponding venous specimen. Using the manufacturer-recommended thresholds for G6PD deficiency, the sensitivity of the POC assay was 92.8% (95% confidence interval (CI): 88.8-96.8%) among men and 93.5% (CI 80.7-100%) among women. The negative predictive value for men was estimated to be 98.3% (CI 97.3-99.2%) and 99.3% (CI 98.0-100%) for women. Receiver operator curves for men and women had areas under the curve of 0.97 (CI 0.946-0.995) and 0.945 (CI 0.915-0.974), respectively. These results add to a growing body of literature that suggests this POC assay is capable of quickly and accurately identifying those at increased risk of primaquine-induced HA, potentially increasing access to *P. vivax* radical cure.

QUANTITATIVE PCR ASSAY FOR DIAGNOSIS OF *PLASMODIUM FALCIPARUM* INFECTIONS TO MONITOR SEASONAL MALARIA CHEMOPREVENTION (SMC) EFFECTIVENESS IN MALI

Bourama Traoré[1], Fousseyni Kané[2], Zahra Razook[3], Mahamoudou B Touré[2], Soumba Keita[2], Daouda Sanogo[2], Drissa Konaté[1], M'Baye Thiam[2], Bindongo Dembele[2], Ayouba Diarra[2], Hamady Coulibaly[2], Nafomon Sogoba[1], Alyssa E. Barry[4], Mahamadou Diakité[2], Seydou Doumbia[2]

[1]International Center for Excellence in Research (ICER-Mali)/USTTB, Bamako, Mali, [2]University Clinical Research Center (UCRC) Mali/USTTB and West African International Center for Excellence in Malaria Research (ICEMR-WA), Mali/USTTB, Bamako, Mali, [3]Deakin University, Geelong, Victoria, AUSTRALIA and Burnet Institute, Melbourne Victoria, AUSTRALIA, Geelong, Australia, [4]Deakin University, Geelong, Victoria and Burnet Institute, Melbourne Victoria, Geelong, Australia

Malaria diagnosis relies on Giemsa-stained blood smears using microscopy and the Rapid diagnostic tests (RDTs) for detecting *Plasmodium* antigens in endemic setting. However, the sensitivity of these methods decreases as parasitemia falls below the detection threshold of 100 parasites/µL for microscopy, and 50 parasites/µL for RDTs. In addition, false positives are observed, particularly after treatment, as parasite antigens detected can remain in the circulation following parasite clearance. This study aimed to assess the molecular prevalence of malaria infection after provision of Seasonal Malaria Chemoprevention among school aged children in Koulikoro, Mali. DNA was extracted from blood spots on filter paper and stored at –20°C until used. For quantification by qPCR, we used an assay targeting the 18s rRNA gene. Serial dilution of cloned *P. falciparum* 18sRNA from 10^5 copies/µl to 5 copies/µl were prepared and use as positive control and to derive a standard curve for quantification of parasite copy number. Based on the optimized qPCR, 54.5% (364/667) of blood samples were positive for *P. falciparum*. More than half of the positive samples (56%, 167/298) presented with low parasite density (below 5 copies /µL). High disagreement rates between the two diagnostic methods with regard to positive parasitemia was observed with 61/667 samples positive at microscopy but negative by qPCR, and 134/667 samples positive at *P. falciparum* by qPCR but negative by microscopy. A sensitivity and specificity were 45% and 79% respectively in microscopy compared to qPCR. Kappa statistics showed poor agreement between the two diagnostic techniques (Kappa=0.24). The ability of microscopy to detect true positives was estimated at 69% compared to qPCR with statistical significance (P<0.0001). This study demonstrates the importance to implement molecular monitoring for *Plasmodium* infections for better characterization of epidemiologic strata and to detect possible resistance to treatment.

0262

EFFICACY AND SAFETY OF IVERMECTIN FOR THE TREATMENT OF *PLASMODIUM FALCIPARUM* INFECTIONS IN ASYMPTOMATIC GABONESE ADULTS - A RANDOMIZED, DOUBLE-BLIND, PLACEBO CONTROLLED TRIAL

Dorothea Ekoka Mbassi[1], Ghyslain Mombo-Ngoma[1], Jana Held[2], Dearie G. Okwu[3], Wilfrid Ndzebe-Ndoumba[3], Laura C. Kalkman[3], Franck A. Ekoka Mbassi[1], Lais Pessanha de Carvalho[2], Juliana Inoue[2], Malik A. Akinosho[4], Lia B. Dimessa-Mbadinga-Weyat[4], Emmanuel K. Yovo[4], Benjamin Mordmüller[5], Ayôla A. [1]Bernhard-Nocht-Institute for Tropical Medicine, Hamburg, Germany, [2]Institute of Tropical Medicine, Tübingen, Germany, [3]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, [4]Centre de Recherches Médicales de Lambaréné, Lambaréné, Germany, [5]Radboud University Medical Centre, Nijmegen, Netherlands

New antimalarials are needed to improve malaria control and elimination. Mosquitoes feeding on ivermectin-treated hosts die and it has *in vitro* anti plasmodial activity. Ivermectin's *in vivo* efficacy against blood stage infection is unknown. We assessed the efficacy and tolerability of ivermectin for the treatment of *Plasmodium falciparum* infections in asymptomatic Gabonese adults. We conducted a phase 2a monocentric clinical trial. It consisted of a safety dose-escalation phase followed by a randomized, double-blind, placebo-controlled trial. Asymptomatic adults with *P. falciparum* parasitemia of 200-5000 parasites/µl residing in Lambaréné, Gabon, were enrolled. In the dose-escalation phase, groups of 5 participants received 200 µg/kg ivermectin q.d. for 1, 2 or 3 days. Subsequently, 34 participants were randomized to 300 µg/kg ivermectin or placebo q.d. for three days. Primary efficacy outcome was the time to 90 % parasite reduction for at least 8 hours by microscopy. Safety outcomes were the number of drug-related serious adverse events and grade 3 adverse events (trial registration: PACTR201908520097051). Out of 49 participants who received at least one dose of placebo or ivermectin, 39 completed the trial as per protocol. At baseline, the median age (IQR) was 25 (20-40) years, there was more male than female participants (63% vs 37%). The median *P. falciparum* parasite load was 599 (314-1102) Pf/µL. No severe or serious adverse events were observed. 3d-300µg/kg IVM showed no significant activity against blood stage parasites compared to placebo-control one-week post-treatment (RD = 0·04, 95% CI -0·18 - 0·27). In this trial, ivermectin did not reduce *P. falciparum* parasitaemia in asymptomatic individuals. Due to its mosquitocidal effects, ivermectin is still an effective altruistic therapy for the protection of other community members by reducing transmission. A dose-dependent effect of ivermectin on *plasmodium* cannot be ruled out.

0263

IVERMECTIN AND PREGNANCY, SAFETY EVIDENCE FROM THE BOHEMIA CLUSTER RANDOMIZED TRIAL IN MOZAMBIQUE

Patricia Nicolas[1], Julia Montana[1], Amelia Houana[2], Anotonio Macucha[2], Hansel Mundaca[1], Aina Casellas[1], Jenisse Mbanze[2], Paula Ruiz-Castillo[1], Samuel Martinho[2], Humberto Munguambe[2], Marta Ribes[1], Saimado Imputiua[2], Vegobito Vegove[2], Victor Mutepa[2], Arlindo Soares[2], Aida Xerinda[2], Eldo Elobolobo[2], Felix Hammann[3], Felisbela Materula[2], Francisco Saute[2], Regina Rabinovich[1], Carlos Chaccour[1]

[1]Barcelona Institute for Global Health - Campus Clinic, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique, [3]Inselhospital Bern, Bern, Switzerland

Ivermectin has been used for over 35 years in mass drug administration campaigns for neglected tropical diseases. In this context, women of reproductive age are screened and excluded based on self-reported pregnancy status. This approach is justified based on the known risk of blindness and disability related to onchocerciasis and lymphatic filariasis. Despite uncertainty on the safety of ivermectin during pregnancy, the documented experience of more than 900 pregnant women inadvertently exposed and the biological basis of active xenobiotic pumps in the placenta suggest that administration during pregnancy may not entail an increased risk of adverse pregnancy outcome. As ivermectin is under evaluation as a potential novel tool for malaria vector control, the risk benefit for pregnant women must be reassessed in the context of this potential new indication, which would have a personal benefit but obtained indirectly through a community effect as it works by reducing the vector population at community level. The BOHEMIA project, funded by Unitaid, includes a large-scale cluster-randomized trial in the highly malaria endemic district of Mopeia, Zambezia province, Mozambique. The primary objective of the trial is to assess the efficacy and safety of three rounds of mass drug administration with ivermectin with a single dose of 400 mcg/kg, monthly during the rainy season. Women of child bearing age are only included for treatment after a negative pregnancy test. Nonetheless, it remains possible for women to become pregnant while the drug is still circulating at physiologically relevant concentrations. All women found pregnant within four weeks of dosing are followed until pregnancy outcome. Here we present key relevant data obtained during the first six months of the trial including: acceptability of pregnancy testing in the context of malaria-aimed MDA, appropriateness of self-reported pregnancy status as a screening method, and early safety results in women dosed peri-conception.

0264

IMPACT OF MASS DRUG ADMINISTRATION OF IVERMECTIN ON MALARIA TRANSMISSION IN RURAL MOZAMBIQUE, EFFICACY RESULTS FROM THE BOHEMIA CLUSTER RANDOMIZED TRIAL

Carlos Chaccour[1], Patricia Nicolas[2], Samuel Martinho[2], Julia Montana[2], Aina Casellas[1], Jenisse Mbanze[2], Paula Ruiz-Castillo[1], Amelia Houana[2], Humberto Munguambe[2], Arlindo Soares[2], Marta Ribes[1], Saimado Imputiua[2], Vegovito Vegove[2], Victor Mutepa[2], Almudena Sanz[2], Mussa Sale[2], Felisbela Materula[2], Mary Mael[1], Mary-Ann Richardson[1], Aida Xerinda[2], Antonio Macucha[2], Eldo Elobolobo[2], Urs Duthaler[3], Caroline Jones[4], Kang Xia[5], Marta Maia[4], Cassidy Rist[6], Felix Hammann[7], Hansel Mundaca[2], Regina Rabinovich[1], Francisco Saute[2]

Mass drug administration with ivermectin has been proposed as a complementary strategy to reduce malaria transmission. The BOHEMIA project, funded by Unitaid, includes a large-scale cluster-randomized trial in the highly endemic district of Mopeia, Zambezia province, Mozambique. The local malaria prevalence in children under five years of age is 75% by RDT and the dominant vectors are *Anopheles arabiensis* and *Anopheles funestus*. The rainy season spans from December to May and transmission occurs year-round with a peak in May. The primary objective of the trial is to assess the efficacy and safety of three rounds of ivermectin mass drug administration with a single monthly dose of 400 mcg/kg for three months during the rainy season. The target population is all above 15 kg of weight, key exclusion criteria are pregnancy, current use of medications with potential drug-drug interactions, and severe illness. The primary efficacy outcome measure is malaria incidence in children under five years of age as determined by active case detection at community level. There are three intervention groups: (A) ivermectin is administered to eligible humans only, (B) ivermectin is administered to eligible humans and livestock, and (C) albendazole is administered to eligible humans as control group. The clinical trial was launched on March 14, 2022. The target enrollment is 35,000 participants for treatment and 3,000 children for the active case detection cohort divided in 159 clusters. The differential incidence between intervention and control clusters will be compared with a regression model using generalized estimating equations with exchangeable correlation structure that considers the cluster design effect. We present data on enrollment, acceptability, and efficacy obtained during the first six months of the trial.

0265

SAFETY OF MASS DRUG ADMINISTRATION OF IVERMECTIN TO DECREASE MALARIA TRANSMISSION IN MOZAMBIQUE, RESULTS FROM THE BOHEMIA CLUSTER RANDOMIZED TRIAL

Carlos Chaccour[1], Patricia Nicolas[2], Amelia Houana[2], Antonio Macucha[2], Hansel Mundaca[2], Julia Montana[2], Aina Casellas[1], Jenisse Mbanze[2], Paula Ruiz-Castillo[1], Samuel Martinho[2], Humberto Munguambe[2], Marta Ribes[1], Saimado Imputiua[2], Vegovito Vegove[2], Victor Mutepa[2], Felisbela Materula[2], Mary Mael[1], Mary-Ann Richardson[1], Aida Xerinda[2], Eldo Elobolobo[2], Felix Hammann[3], Regina Rabinovich[1], Francisco Saute[2]

[1]Barcelona Institute for Global Health - Campus Clinic, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça, Mopeia, Mozambique, [3]University Hospital Bern, Bern, Switzerland

Ivermectin has an outstanding safety profile at the recommended doses for the current approved indications. For neglected tropical diseases, ivermectin is usually administered once a year at doses around 150-200 mcg/kg. For the intended use case of reducing malaria transmission, pharmacokinetic and epidemiologic modelling predict the need for higher doses in order to have an impact of public health value. Recently-finished or ongoing field trials have mostly centered around monthly administration during three months of the rainy season with treatment schemes ranging from a single dose of 400 mcg/kg once a month to three consecutive daily doses of 300 mcg/kg once a month. The BOHEMIA project, funded by Unitaid, includes a large-scale cluster-randomized trial in the highly endemic district of Mopeia, Zambezia province, Mozambique. The target population is all above 15 kg of weight, key exclusion criteria are pregnancy, current use of medications with potential drug-drug interactions, and severe illness. There are three intervention groups: in group (A) ivermectin is administered to eligible humans only, in group (B) ivermectin is administered to eligible humans and livestock, and in group (C) albendazole is administered to eligible humans as control. The primary safety outcome measure is the differential incidence of adverse and severe adverse events between the ivermectin and albendazole groups. This is captured by active follow up of all treated participants who keep a diary for the six days after treatment and are visited monthly by a field worker.

Robustness is added by passive detection of adverse events at all health facilities in the district and a toll-free number available throughout the study period. The trial was launched on March 14, 2022 and aims at recruiting 35,000 participants for treatment. Here we present safety data obtained during mass drug administration.

0266

EVALUATION OF IVERMECTIN AS AN ANTIMALARIAL THERAPY AGAINST *PLASMODIUM FALCIPARUM* LIVER STAGE

Pradeep Annamalai Subramani[1], Surendra Kumar Kolli[1], Justin Nicholas[1], Samantha Barnes[1], Phornpimon Tipthara[2], Joel Tarning[3], Kevin Kobylinski[4], John H. Adams[1]

[1]University of South Florida, Tampa, FL, United States, [2]Mahidol Oxford Tropical Medicine Research Unit, Mahidol University, Bangkok, Thailand, [3]Mahidol Oxford Tropical Research Unit, Mahidol University, Bangkok, Thailand, [4]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Malaria remains a major global public health threat due to prevalence of drug-resistances and failure to frontline antimalarial therapy, hindering the global efforts to control and eliminate the disease. Almost none of the available antimalarial drugs are efficacious against the liver stage of *Plasmodium falciparum*, which is the initial stage of infection that leads to disease causing blood stage infection. The only currently FDA-approved class of drug capable of eliminating *Plasmodium* liver stage parasites are the 8-aminoquinolines and this drug class has its own limitations due to potential hemolytic activity in people with favism and therefore not suitable for mass drug administration (MDA). Due to these limitations, there is a critical need for safer and more efficacious drugs that can prevent liver stage development of malaria parasites. Ivermectin is an approved broad spectrum antiparasitic drug that has been proposed as a novel malaria transmission control tool to kill mosquito vectors that transmit malaria and aid malaria elimination. Recent studies have revealed ivermectin inhibit liver-stage development of *P. berghei*, a rodent malaria laboratory model, suggesting this drug may be an effective antimalarial drug. However, ivermectin is known to be metabolized by cytochrome 3A4, which exhibits polymorphism among different individuals to potentially alter efficacy against *Plasmodium*, emphasizing the importance of understanding the metabolism of ivermectin and its metabolites. We have established a robust invitro liver assay to study the liver stage development of human malaria parasites in primary human hepatocytes that can be used to evaluate the potential impact of these metabolic differences on ivermectin's anti-liver stage efficacy. This model can be used to evaluate the metabolism of ivermectin in hepatocytes from different donors and its efficacy against *P. falciparum* liver stages.

0267

REGULATORY PATHWAY FOR REPURPOSING IVERMECTIN FOR MALARIA: CHALLENGES AND SOLUTIONS

Regina Rabinovich, Mary Ann Richardson, Carlos Chaccour

Barcelona Institute for Global Health - Campus Clinic, Barcelona, Spain

Repurposing an "antique" drug for a novel malaria indication - as a complementary vector control tool- involves challenges in terms of regulatory and technical review. Regulation of drug and vector control tools are traditionally done by separate groups. However, ivermectin for malaria requires regulatory review as a drug for product quality, as well as an anti-vector product for efficacy. Ivermectin, although used broadly in Africa for several NTDs, has not been licensed, as it has been provided as a donated product for those campaigns for about 30 years. The BOHEMIA project, designed to evaluate the efficacy of ivermectin MDA in two countries, has challenged both global and national regulatory agencies to integrate and address several unique issues including the regulatory pathway for industry and key issues such as the need for pregnancy testing, dose optimization and generic supply for the potential new indication. We will describe the pathway that has evolved, the key issues identified, and propose options to resolution as the clinical trials are completed.

0268

EFFECT OF PRIMAQUINE DOSE ON THE RISK OF RECURRENCE IN PATIENTS WITH UNCOMPLICATED *PLASMODIUM VIVAX*: A SYSTEMATIC REVIEW AND INDIVIDUAL PATIENT DATA META-ANALYSIS

Robert J. Commons[1], Megha Rajasekhar[2], Julie A. Simpson[2], Ric Price[1], WWARN Vivax Primaquine Efficacy, Tolerability and Safety Study Group[3]

[1]Global Health Division, Menzies School of Health Research, Darwin, Australia, [2]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia, [3]WorldWide Antimalarial Resistance Network (WWARN), Oxford, United Kingdom

Despite clinical use for over 60 years, the optimal dose of primaquine for *Plasmodium vivax* radical cure is unknown. Most endemic countries recommend a total primaquine dose of 3.5 mg/kg administered over 14 days. To directly inform global and national malaria treatment guidelines, we investigated the effect of the total dose of primaquine mg/kg on the risk of *P. vivax* recurrence. Efficacy studies of uncomplicated *P. vivax* including a treatment arm with daily primaquine, published between January 2000 and March 2021, were identified and individual patient data from eligible studies pooled using standardised methodology. The effect of receiving primaquine and primaquine mg/kg dose on the incidence risk of *P. vivax* recurrence between days 7 and 180 were derived using Cox regression analyses. Of 60 eligible studies, 23 studies enrolling 6,879 patients from 16 countries were available for analysis: 1,470 (21.4%) patients were not treated with primaquine, 29 (0.4%) received very low dose (<2 mg/kg) primaquine, 2,567 (37.3%) low dose (2 to <5 mg/kg) primaquine and 2,813 (40.9%) high total dose primaquine (>=5 mg/kg). The risk of recurrence by day 180 was 50.8% [95%CI 48.0-53.7] without primaquine, 19.3% [17.0-21.8] following low dose primaquine and 8.2% [7.1-9.4] following high dose primaquine. After controlling for confounders, the rate of first recurrence was greater in patients treated with low versus high dose primaquine (Adjusted Hazard Ratio (AHR)=2.2 [1.6-2.9]) and this was observed for both low (AHR for low versus high dose primaquine =2.3 [1.5-3.4]) and high relapse periodicity regions (AHR=1.9 [1.1-3.3]). In patients treated with primaquine, a 1 mg/kg increase in primaquine total dose was associated with an AHR of 0.8 [0.7-0.9], although the benefit of increasing primaquine dose reduced for total doses greater than 6 to 7 mg/kg. The widely recommended low total dose primaquine regimen (3.5 mg/kg) provides suboptimal anti-relapse efficacy and this is apparent in most vivax-endemic regions.

0269

AGE-DOSED SINGLE LOW DOSE PRIMAQUINE IN FALCIPARUM-INFECTED AFRICAN CHILDREN WITH G6PD DEFICIENCY IS WELL TOLERATED AND SAFE

Walter Taylor[1], Peter Peter Olupot-Olupot[2], Marie Onyamboko[3], Pimnara Peerawaranun[1], Winifred Were[2], Cate Namayanja[2], Peter Onyas[2], Harriet Titin[2], Joy Baseke[2], Rita Muhindi[2], Daddy Kayembe[3], Pauline Ndjowo[3], Sophie Ugoya[4], Arjen Dondorp[1], Joel Tarning[1], Mehul Dhorda[1], Chiraporn Taya[1], Grace Abongo[2], Charles Okalebo[2], Tom Williams[5], Caterina Fanello[3], Kathryn Maitland[5], Mavuto Mukaka[1], Nicholas Day[1]

[1]MORU, Bangkok, Thailand, [2]Mbale Clinical Research Institute, Mbale, Uganda, [3]KIMORU, Kinshasa, Democratic Republic of the Congo, [4]KEMRI-Wellcome Trust, Kilifi, Kenya, [5]Imperial College of Science & Technology, London, United Kingdom

In 2012, the WHO i recommended the use of single low dose primaquine (SLDPQ) for blocking *Plasmodium falciparum* transmission. Most treatment guidelines in Sub Saharan Africa have not included SLDPQ for

the management of uncomplicated malaria. This is partly because of a paucity of data appraising the safety and efficacy of SLDPQ in glucose-6-phosphate dehydrogenase deficiency (G6PDd). We, therefore, investigated SLDPQ safety in G6PDd falciparum-infected children. We conducted a randomised, double blind, placebo-controlled, trial in Ugandan and Congolese children aged 6m–11y with baseline haemoglobin concentrations ≥ 6 g/dL, treated with artemether-lumefantrine or dihydroartemisinin-piperaquine and age-dosed SLDPQ/placebo. The primary endpoint was the development of profound (Hb < 4 g/dL) or severe anemia (Hb < 5 g/dL) with clinical features of severe malaria by Day 21; the non-inferiority margin in genotypically-confirmed G6PDd patients was 3%, assuming a 1.5% rate in the placebo arm. 1137 children were recruited: 239 A^- G6PDd hemizygous males & 45 A^- homozygous females (G6PDd group), 119 A^- heterozygous females, 418 normal males, 299 normal females, and 17 of unknown genotypic status. Median age was 5 years. Three patients met the primary end point: G6PDd group 0/133 (placebo) vs. 1/151 (0.67%): Δ= -0.66 [(-1.96–0.63)%, p=0.347] and nonG6PDd group: 1/430 (0.23%, placebo) vs. 1/407 (0.25%, SLDPQ): Δ= -0.014 [(-0.68 –0.65)%, p=0.958]. Nine patients (5 placebo) were transfused in the first week; four had G6PDd. Placebo-SLDPQ early vomiting rates were 49 (1.58%)/3103 treatments vs. 43 (1.38%)/3103 treatments (p=0.599). Although too few events of the stringently-defined safety endpoint precluded demonstrating non-inferiority of SLDPQ, age-dosed SLDPQ was safe with a similar blood transfusion rate as placebo. This study adds substantial evidence for drug policy and should serve as a paradigm across Sub Sharan Africa.

0270

THE TOLERABILITY OF ASCENDING DOSE PRIMAQUINE IN HEALTHY VOLUNTEERS WITH GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY IN THAILAND

Podjanee Jittmala[1], Borimas Hanboonkunupakarn[1], Kittiyod Poovorawan[1], James Watson[2], Parinaz Mehdipour[3], Julie Simpson[3], Nicholas Day[2], Kesinee Chotivanich[1], Cindy Chu[2], Germana Bancone[2], Joel Tarning[2], Francois Nosten[2], Sasithon Pukrittayakamee[4], Nicholas White[2], **Walter Taylor**[2]

[1]Mahidol University, Bangkok, Thailand, [2]MORU, Bangkok, Thailand, [3]Melbourne University, Melbourne, Australia, [4]Mahidol university, Bangkok, Thailand

Plasmodium vivax represents some 2% of the global malaria burden and is the most common species outside of subSaharan Africa. *P. vivax* elimination rests on eliminating the hypnozoite reservoir that is the source of recurrent blood stage infections called relapses. Primaquine and tafenoquine are recommended for treating liver hypnozoites but both cause dose dependent acute haemolysis in individuals with glucose-6-phosphate dehydrogenase deficiency (G6PDd), necessitating pretreatment G6PDd testing. A primaquine regimen that could be used without G6PDd testing would be a substantial advance. Exploiting the primaquine dose haemolysis relationship, we conducted an adaptive challenge study of ascending dose primaquine (ADPQ) to determine whether we could produce a gradual, well tolerated haemolysis in healthy G6PDd males. Starting with a 20-day regimen of 7.5, 15, 22.5 & 30 mg/d, each for 5 days, subsequent changes to the PQ dose and number of days of a given dose within each cycle depended on the results of daily haemoglobin (Hb) concentrations and predefined rules for continuing or stopping PQ. We recruited 23 G6PDd males aged 18–55 (median 32) years with G6PD Viangchan (*n*=12 subjects), Canton (4), Mahidol (3), Orissa (1), Chinese-5 (1), Aures (1), and Union (1). 5 ADPQ regimens were tested: 3 x 20 days (*n*=9 subjects), 16 days (4), 15 days (10). Median (range) Day 0 Hb was 14.3 (11.4–15.8) g/dL. All subjects had Hb declines that nadired at the end of dosing. The 15 & 16d regimens produced a significantly (0=0.018) greater median fractional fall vs. 20d regimens: 26.7 (14.5–34.1)% vs. 19.6 (14.1–27.1)% for respective median nadir Hbs of 10.5 (9.2–11.70) and 11.7 (10.8–12.2) g/dL. Reticulocyte responses were rapid, peaking at 14.9 and 6.8% on Days 11 and 16 for the 15-16 and 20-day regimens, respectively. PQ was well tolerated. One subject stopped early because of fatigue and another for unexplained rises in ALT (445 IU/L) and AST (AST 220 IU/L). ADPQ induced a tolerated haemolysis. Data modelling is ongoing to suggest a regimen for testing in the field.

0271

EFFECT OF PRIMAQUINE DAILY DOSE ON TOLERABILITY AND SAFETY IN PATIENTS WITH UNCOMPLICATED *PLASMODIUM VIVAX*: AN INDIVIDUAL PATIENT DATA META-ANALYSIS

Megha Rajasekhar[1], Robert J. Commons[2], Julie A. Simpson[1], Ric N. Price[2], WWARN Vivax Primaquine Efficacy, Tolerability and Safety Study Group[3]

[1]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Victoria, Australia, [2]Global Health Division, Menzies School of Health Research and Charles Darwin University, Darwin, Northern Territory, Australia, [3]WorldWide Antimalarial Resistance Network (WWARN), Oxford, United Kingdom

Despite greater efficacy, the use of high doses of primaquine (PQ) for radical cure of *Plasmodium vivax* is confounded by poor gastrointestinal (GI) tolerance and concerns of haematological safety. We investigated the relationship between the daily dose of PQ on GI tolerability and haematological safety. Individual patient data were pooled from clinical efficacy studies of patients with uncomplicated *P. vivax* including a treatment arm with PQ, published between January 2000 and March 2021. GI intolerance was defined as the presence of vomiting, diarrhoea, or anorexia between days 2 and 14. Haematological safety was defined as maximum absolute reduction in haemoglobin (Hb) levels on days 2-14 vs. day 0 and fractional fall in Hb ≥25% to less than 7g/dl. Data were available from 33 studies in which 1470 patients received no PQ, 2242 received low daily dose PQ (<0.375 mg/kg/day), 2880 received intermediate daily dose (≥0.375 to <0.75 mg/kg/day) and 1554 received high daily dose (≥0.75 mg/kg/day). Compared to no PQ, patients treated with low, intermediate and high daily doses had higher odds of GI intolerance (OR 1.39 [95%CI: 0.92,2.09], 1.57[1.19,2.08] and 2.29[1.72,3.05] respectively). The risk of Hb falling by ≥25% to <7 g/dL was 0.1% (1/1218) in patients not treated with PQ, 0.0% (0/1260) in patients treated with low daily dose PQ , 0.3% (5/1771) after intermediate dose and 0.7% (10/1461) after high dose PQ. After controlling for baseline Hb and other covariates there was no association between PQ daily dose and maximum absolute reduction in Hb between days 2 and 14 (high dose vs no PQ: 0.08 g/dL [-0.03, 0.18]). Higher daily doses of PQ were associated with more frequent GI symptoms, though further analyses including individual-level data on food co-administration are warranted. In patients not known to be G6PD deficient (<30% activity), there was no direct association between high daily PQ doses and adverse haematological outcomes.

0272

DEVELOPING PRIMAQUINE FOR MALARIA ELIMINATION WITH A HOLISTIC APPROACH

Julie Nguyen Ngoc Pouplin[1], Developing Paediatric Primaquine (DPP) Consortium[2], Thoopmanee Kaendiao[3], Walter R. Taylor[4]

[1]Reseau Medicaments et Developpement (ReMeD), Bordeaux, France ,[3]Mahidol Oxford Tropical Medicine Research Unit (MORU), Bangkok, Thailand, [4]University of Oxford, Oxford, United Kingdom

Primaquine is an old drug which has a key role in malaria elimination as radical cure and transmission blocking. It is a WHO essential drug and has been recommended for decades by the WHO for the control and, more recently, elimination of *Plasmodium vivax* and *P. falciparum*. Despite this, its deployment at global level is low. Reasons for this gap between policy and practice are complex; the main challenges include the: i) absence of quality-assured, child friendly, PQ dosage forms, ii) limited interest from pharma, iii) fear of haemolysis in G6PD deficient patients, iv) paucity of evidence to inform safe and efficacious regimens, and v) lack of a supply chain plan to ensure optimal and sustainable

global distribution. To overcome these challenges and engage directly with pharma, we set up the Developing Paediatric Primaquine (DDP) consortium with European Union funding, that integrates multidisciplinary expertise from pharmaceutical development to field implementation. The key aim is to prequalify child-friendly and adult primaquine, followed by registration in malaria endemic countries. DPP core activities include: i) a bioequivalence study vs. Sanofi reference 15mg primaquine, ii) showing pharmaceutical equivalence of the paediatric line extension (7.5, 5, 3.75, 2.5 mg), iii) formulation work to mask primaquine's bitterness using a sensory approach, iv) initiating granule development as the optimal dosage form for better palatability, acceptability and marketing, iv) two field trials (radical cure & infectivity) to validate the safety, efficacy and acceptability of the paediatric line, and v) evaluate packaging designs. We will present and discuss our activities to date, including the challenges we have faced in a niche area of malaria elimination. As a small academia-NGO led consortium, we believe that our holistic strategy to see primaquine used for malaria elimination is timely and brings an important dynamic and new activities that complements the activities of bigger actors in malaria elimination.

0273

PRIMAQUINE TREATMENT IN LACTATING WOMEN IS SAFE FOR THE BREASTFED INFANT

Joel Tarning, Thanaporn Wattanakul, Mary E. Gilder, Warunee Hanpithakphong, Htun H. Win, Naw Hilda, Cindy S. Chu, Germana Bancone, Verena I. Carrara, Nicholas J. White, François Nosten, Rose McGready, Richard M. Hoglund

Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Primaquine and tafenoquine are the only available drugs providing radical cure of *Plasmodium vivax* malaria. However, these drugs are contraindicated in breastfeeding women as they cause acute hemolysis in glucose-6-phosphate dehydrogenase (G6PD) deficient individuals, and the excretion into breast milk and thus infant exposure are unknown. Healthy G6PD normal breastfeeding women with previous *P.vivax* infection and their healthy G6PD normal infants were enrolled in this trial. Mothers received primaquine 0.5 mg/kg/day for 14 days. Drug concentrations of primaquine and carboxyprimaquine were measured in maternal venous, capillary and breast milk samples as well as in infant capillary samples. Population pharmacokinetic-pharmacodynamic modelling and simulation were used to evaluate the drug exposure in mothers and breastfeeding infants. Venous and capillary concentration-time data in lactating mothers were modelled simultaneously by a drug-metabolite model with a flexible first-pass metabolism of primaquine into carboxyprimaquine. Drug concentration data in breast milk was characterized by estimating the distribution of drugs from blood to a separate breastmilk compartment. A mechanistic breastfeeding model was constructed based on the average breastmilk volume consumed during a feed and the feeding pattern in this population. Drug exposures were then simulated in all infants and compared to measured drug concentration-time data. Simulated and measured primaquine and carboxyprimaquine concentrations were negligibly low in breastfeeding infants. The estimated primaquine dose received by infants, based on breast milk levels, was <1% of the standard dose of 0.5 mg/kg. Primaquine should not be withheld from breastfeeding mothers due to safety concerns of G6PD-deficient infants or young children.

0274

PRIMAQUINE PHARMACOKINETICS AS TRANSMISSION BLOCKING IN FALCIPARUM-INFECTED AFRICAN CHILDREN

Mavuto Mukaka[1], The Primaquine in Africa group[2]

[1]*MORU, Bangkok, Thailand*

Single low dose primaquine (SLDPQ) is recommended for transmission blocking but few pharmacokinetic (PK) data exist in acute paediatric *Plasmodium falciparum*. Rich blood sampling [baseline, +1, 1.5, 2, 4, 8, 12, 24 hours] was performed in Congolese and Ugandan children 6 months—11 years with acute uncomplicated *P. falciparum*, diagnosed by malaria slide or rapid diagnostic test, who were treated with 3-day dihydroartemisinin-piperaquine or 3-day artemether-lumefantrine. SLDPQ was dosed by age, using 2.5, 5 and 7.5 mg tablets, on Day 0: 6m—<1y: 1.25 mg, 1—5y: 2.5 mg, 6—9y: 5 mg, 10—11y: 7.5 mg. PQ and carboxyPQ PK were determined by noncompartmental analysis. Of 1,137 recruited patients, 258 of median age 5 [interquartile range (IQR) 3—7] years underwent PK analysis: 14 were aged 6m—<1y, 129 1—5y, 83 6—9y and 32 10—11y. Administered mg/kg PQ doses ranged from 0.10—0.40, IQR 0.16—0.25, median 0.21. SLDPQ was well tolerated; early vomiting occurred in 30/1137 (2.64%) and the 7-day transfusion rate was 0.88% in the SLDPQ (5/569) and placebo (5/568) recipients (p=1.0). Overall median maximum concentration (Cmax) was 103.0 (IQR 71.7—139.0, range 2.3—447) ng/mL, reached (Tmax) at median 2 (range 1.0—8.0) hours. Median (range) PQ—carboxyPQ exposures ($AUC_{0\text{-last}}$) were 713.2—3,157.7 (6m—<1y), 577.3—2,428.3 (1—5y), 893.4—4,273.8 (6—9y), and 931.0—4,522.9 (10—11y) ng*h/mL; respective median half-lives were 4.7 (2.4—75.4) and 17.5 (4.5—180.2) hours. Primaquine clearance increased with increasing age but was highest in the youngest children when adjusted by body weight. This well tolerated age-dosed SLDPQ regimen was characterised by wide interindividual variability in Cmax but less variability in $AUC_{0\text{-last}}$. The median dose of 0.21 mg/kg leaves scope for an increase in dose. More PK data in the youngest children would add weight to dosing recommendation in this group, which experiences higher clearance/kg. Our data will be included in pharmacokinetic pharmacodynamic models of haemoglobin changes and gametocyte carriage to define dose response relationships and inform optimal age and weight-based dosing.

The emergence and spread of antimalarial drug resistance pose a threat to global efforts to control and eliminate malaria, and the discovery and development of new antimalarials with novel mode of action is an urgent priority. We have discovered a novel class of drug-like inhibitors of *Plasmodium falciparum* growth that blocked parasite egress from infected erythrocytes and subsequent invasion of released merozoites. These new compounds are potent inhibitors of the essential *Plasmodium* aspartic proteases plasmepsin IX and X (PMIX and PMX) and block multiple stages of the parasites lifecycle. The discovery of PMX-specific (WM4) and PMIX/X (WM382) dual inhibitors has also provided tools to investigate the function of these aspartic proteases to show that PMIX and PMX are master modulators of merozoite invasion and direct maturation of proteins required for invasion, parasite development and egress. Enzyme kinetic and determination of the 3-dimensional structure of protease-drug complexes have identified the molecular interactions responsible for specificity involved in the inhibition of these proteases by WM382 and WM4. In addition, attempts to select resistant *P. falciparum in vitro,* demonstrated a high barrier for the development of resistance against these compounds.This new class of PMIX- and PMX-inhibitors with dual-targeting activity, novel mode of action, ability to disrupt multi-lifecycle stages of *Plasmodium* parasites both *in vitro* and *in vivo,* and high resistance threshold, provides promising drug candidates for treatment and prevention of malaria infections.

0276

MALARIA BURDEN IN AREA WITH HIGH BED NET OWNERSHIP IN NORTH EASTERN TANZANIA

Debora Charles Kajeguka[1], Robert Kaaya[2], Filemoni Tenu[2], Emmanuel Mkumbo[1], Francis Mponela[1], Anna Kaaya[1]

[1]Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, [2]Pan-African Malaria Vector Control Consortium, Moshi, Tanzania, Moshi, United Republic of Tanzania

Several interventions have been made to eliminate Malaria in Tanzania including use of insecticide-impregnated bed nets and artemisinin combination therapy. Nevertheless, malaria is still high in some parts of the country. We assessed the burden of malaria in terms of prevalence as well explored about bed net ownership and utilization.Three cross sectional surveys were conducted in June 2021, September 2021 and January 2022. A total of 457 participants were recruited. The study included children aged between 2-10 years and adolescents/adults aged 11-70 years. The study was conducted in Bondo site which comprises of Bondo, Kwadoya, Ngojoro and Kwamgwe villages in Handeni Tanga Tanzania.A face-to-face interview were conducted. A pre-tested questionnaire was used to collect demographic information, bed net use, bed net ownership and factors for malaria exposure. The developed questionnaire was uploaded in the system and data was collected electronically using Open Data Kit application. The blood sample from the finger-prick was used to test malaria parasites using malaria rapid diagnostic test.The prevalence of malaria was 32.8% (150), 21.7% (99), and 22.1% (101) in cross-sectional 1,2 and 3 respectively. Seventy percent (106), 66.7% (66) and 68.3% (69) who were malaria positive (by MRDT) used a Insecticide-treated bed nets in cross-sectional 1,2 and 3 respectively, less than 0.05.This study highlight that Insecticide-treated bed nets usage were signifcantly associated with malaria positivity. In order to achieve malaria elimination, we advocate malaria campaigns targeting proper usage of Insecticide treated bed nets.

MODELLING THE OPTIMAL ALLOCATION OF GLOBAL MALARIA FUNDING FOR ERADICATION

Nora Schmit, Matteo Pianella, Hillary M. Topazian, Giovanni D. Charles, Peter Winskill, Katharina Hauck, Azra C. Ghani

Imperial College London, London, United Kingdom

Large reductions in the global malaria burden have been achieved in the last decades, but plateauing funding poses a challenge for progressing towards eradication. We aimed to determine the optimal strategy to allocate global resources to achieve the ultimate aim of malaria eradication whilst minimising clinical burden. Using existing mathematical models of *Plasmodium falciparum* and *Plasmodium vivax* transmission, we determined the funding allocation for the distribution of insecticide-treated nets (ITNs) across countries that maximised the long-term reduction in global malaria cases from a baseline of no ITN coverage as an indicator of the eradication goal. We compared the impact of this optimal strategy on clinical case incidence and the population at risk of malaria at alternative global budgets and with different allocation strategies - including prioritising settings of high or low transmission intensity or allocating funding proportional to the malaria burden at the baseline (year 2000). The optimal strategy was closely aligned with an allocation framework that prioritises funding for high-transmission settings, resulting in case reductions of 79% (optimal strategy) and 71% (prioritising high-transmission settings) at intermediate budget levels. Allocation strategies that have the greatest impact on cases were associated with lesser near-term impact on the global population at risk, highlighting a trade-off between reducing burden and "shrinking the map" through a focus on malaria elimination. The optimal funding distribution prioritised high ITN coverage in high-transmission settings endemic for only *P. falciparum*, whilst maintaining lower levels in low-transmission settings. However, at high budgets, almost 75% of funding was targeted at low-transmission settings co-endemic for *P. falciparum* and *P. vivax*. These results support current global strategies to prioritise funding to the high-burden *P. falciparum*-endemic settings in sub-Saharan Africa to minimise clinical malaria burden but illustrate the trade-off against competing goals of advancing elimination and addressing the burden of *P. vivax*.

0278

EFFECTIVENESS OF REACTIVE STRATEGIES FOR MALARIA TRANSMISSION: SYSTEMATIC REVIEWS AND META-ANALYSES OF REACTIVE CASE DETECTION AND TREATMENT, REACTIVE DRUG ADMINISTRATION, AND REACTIVE INDOOR RESIDUAL SPRAYING

Laura C. Steinhardt[1], John E. Gimnig[1], Achyut KC[1], Amanda Tiffany[2], Elizabeth Quincer[3], Leah Loerinc[3], Taiwo Samson Awolola[1], Daniel Impoinvil[1], Sarah Zohdy[1], Nicholas Laramee[4], Amy Large[4], Kim A. Lindblade[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]WHO, Geneva, Switzerland, [3]Emory School of Medicine, Atlanta, GA, United States, [4]Emory Rollins School of Public Health, Atlanta, GA, United States

Many countries pursuing malaria elimination implement 'reactive' strategies targeting household members and neighbors of index cases to reduce transmission. These strategies include reactive case detection and treatment (RACDT, testing and treating those positive), reactive drug administration (RDA, providing antimalarials without testing), and reactive indoor residual spraying (RIRS, spraying insecticide in/near index case houses). We conducted systematic reviews of RACDT, RDA, and RIRS. Two reviewers screened titles/abstracts and full-text records using defined criteria (**P**atient=those in malaria-endemic/receptive areas; **I**ntervention= RACDT, RDA, or RIRS; **C**omparison=standard of care; **O**utcome=malaria incidence/prevalence) and abstracted data for meta-analyses. The GRADE approach was used to rate certainty of evidence (CoE) for each outcome. For RACDT and RDA, 1,339 records yielded 5 RACDT studies (3 cluster-randomized controlled trials [cRCTs] and 2 non-randomized studies [NRS]) and 7 RDA studies (6 cRCTs and 1 NRS); 3 cRCTs comparing RDA to RACDT were included in both reviews. For RIRS, 457 records yielded 2 cRCTs. Compared to RDA, RACDT was associated with non-significantly (NS) higher parasite prevalence (odds ratio [OR]=1.85; 95% confidence interval [CI]: 0.96-3.57; 1 study) and malaria incidence (rate ratio [RR]=1.30; 95% CI: 0.94-1.79; 3 studies); both very low CoE. Compared to control or RACDT, RDA was associated with NS lower parasite incidence (RR=0.73; 95% CI: 0.36-1.47; 2 studies, moderate CoE), prevalence (OR=0.78; 95% CI: 0.52-1.17; 4 studies, low CoE), and malaria incidence (RR=0.93; 95% CI: 0.82-1.05; 6 studies, moderate CoE). Compared to no RIRS, RIRS showed lower parasite prevalence (RR=0.32; 95% CI: 0.13-0.80; 1 study, high CoE) and NS lower malaria incidence (RR=0.65; 95% CI: 0.38-1.11; 1 study, moderate CoE); compared to proactive IRS, RIRS was not inferior for malaria incidence (mean difference=0.10; 95% CI: -0.38-0.58; 1 study, moderate CoE). Evidence for reactive strategies' impact on malaria transmission is limited, especially for RACDT, but suggests RDA and RIRS might be more effective.

0279

ADHERENCE OF TREATMENT PRESCRIPTIONS TO GUIDELINE RECOMMENDATIONS IN PATIENTS WITH MALARIA IN REAL-WORLD SETTING: INSIGHTS FROM A PROSPECTIVE, MULTICENTRE OBSERVATIONAL STUDY IN SUB-SAHARAN AFRICA

Vito Baraka[1], Pedro Aide[2], Quique Bassat[2], Abel Nhama[2], Agatha David[3], Samwel Gesase[4], Jonathan Gwasupika[5], Sebastian Hachizovu[5], Geofrey Makenga[1], Christian Ruchaho Ntizimira[6], Orikomaba Obunge[7], Kitoto Antoinette Tshefu[8], Marc Cousin[9], Nekoye Otsyula[10], Rashidkhan Pathan[11], Céline Risterucci[9], Guoqin Su[12], Christine Manyando[5]

[1]National Institute for Medical Research, Tanga Centre, Tanga, United Republic of Tanzania, [2]Centro de Investigaçao em Saude de Manhiça (CISM), Maputo Province, Mozambique, [3]Nigerian Institute of Medical

Research, Lagos, Nigeria, [4]National Institute for Medical Research, Korogwe, United Republic of Tanzania, [5]Tropical Diseases Research Centre, Ndola, Zambia, [6]African Center for Research on End-of-Life Care, Kigali, Rwanda, [7]Center for Malaria Research and Phytomedicine (CMRAP), University of Port Harcourt, Port Harcourt, Nigeria, [8]The Hospital Center of Mont Amba Kinshasa, Kinshasa School of Public Health, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [9]Novartis Pharma AG, Basel, Switzerland, [10]Novartis Pharma Services Inc., Nairobi, Kenya, [11]Novartis Healthcare Pvt. Ltd., Hyderabad, India, [12]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

To understand the gap between guidelines and local clinical practice for diagnosis and treatment of malaria, the patient characteristics, diagnostic approach, treatment, and adherence to standard guideline recommendations were assessed in an observational study (October 2020 to March 2021). A total of 1001 patients, with symptoms suggestive of malaria, visiting a health care facility were prospectively enrolled across 11 sites in six countries in sub-Saharan Africa. The median age of patients was 11 years (range: 2 weeks to 91 years) with more patients coming from rural (44.9%) than urban (30.6%) or suburban areas (24.5%). Overall, 735 (73.4%) patients had confirmed malaria (based on local practice) at baseline (uncomplicated malaria: 598 [81.4%] and severe malaria: 137 [18.6%]); of whom 533 (72.5%) were administered a rapid malaria diagnostic test. At the community level, 57% of patients sought advice or received treatment for malaria and 56.1% of patients took one or more drugs for their illness before coming to the study site. In terms of early access to care, 44% of patients travelled to the site 48 hours or more after symptom onset. In patients with uncomplicated malaria, the most prescribed treatments were artemisinin-based combination therapies (ACTs; n=564 [94.3%]), primarily artemether-lumefantrine (82.3%), in line with the WHO treatment guidelines. In addition, these patients also received antipyretics (85.6%) and antibiotics (42.0%). However, in those with severe malaria, only 66 (48.2%) patients received parenteral treatment followed by an oral ACT as per WHO guidelines whereas 62 (45.3%) received parenteral treatment only. The present study's findings suggest that the prescribed treatment in most patients with uncomplicated malaria, but not of those with severe malaria, was in alignment with the WHO recommended guidelines in sub-Saharan Africa.

0280

MALARIA KNOWLEDGE, PREVENTION PRACTICES, AND CARE-SEEKING BEHAVIOR AMONG FOREST-GOERS IN CAMBODIA: A MIXED-METHODS FORMATIVE ASSESSMENT

Sochea Phok[1], Kemi Tesfazghi[2], Erica Felker-Kantor[2], Andy Tompsett[2], Boukheng Thavrine[3], Po Ly[3], Huy Rekol[3], Siv Sovannaroth[3], Meas Tha[3], Saad Hassan[4], Avery Avrakotos[5], Jim Malster[2]

[1]Population Services International Cambodia, Phnom Penh, Cambodia, [2]Population Services International, Washington, DC, United States, [3]National Center for Malaria Control, Parasitology and Entomology, Phnom Penh, Cambodia, [4]U.S. President's Malaria Initiative, USAID, Phnom Penh, Cambodia, [5]U.S. President's Malaria Initiative, USAID, Washington, DC, United States

Consistent use of long-lasting insecticide treated nets/hammocks (LLIN/LLIHN), early diagnosis, and treatment are central to reducing malaria burden. As malaria cases decrease in Cambodia, forest-goers are most at risk of malaria due to their proximity to the forest, working during peak biting times, frequent mobility, and distance from health services. The study aimed to understand forest-goers' knowledge, attitudes, and practices related to malaria prevention and care-seeking and to identify key behavioral determinants of LLIN/LLIHN use and care-seeking within 24 hours of fever onset. A mixed-methods study design consisting of a cross-sectional survey and qualitative in-depth interviews was implemented in Kampong Chhnang and Pursat provinces. Survey participants (N=654) were recruited using respondent driven sampling. Findings were analyzed using univariate and bivariate analysis and multivariate weighted logistic regression. Interviews (N=28) were coded and analyzed using thematic content analysis. All study participants had heard of malaria and 98% knew that malaria was transmitted by mosquitoes. Although LLIN/LLIHN ownership was high (94%) and 99% of participants perceived LLIN/LLIHN use as an important malaria prevention measure, only 76% reported using one during their last visit to the forest. Only 57% of participants sought care within the recommended 24 hours of fever onset during their last febrile illness. In controlled regression models, perceived community social norms were significantly associated with LLIN/LLIHN use (OR: 2.7, 96%CI:1.99-2.64) and care-seeking within 24 hours of fever onset (OR: 1.7, 95%CI:1.00-2.88). Social support from other forest-goers was significantly associated with LLIN/LLIHN use (OR: 4.9, 95%CI: 1.32-18.12). The study identified rates of LLIN/LLIHN use and delayed care-seeking behaviors as concerns to address to meet malaria elimination goals. Social and behavior change activities may consider incorporating social norms and social support as mechanisms for behavior change given the identified positive correlations with LLIN/LLIHN use and prompt care-seeking behavior.

0281

TRIALS OF IMPROVED PRACTICES TO ASSESS COMMUNITIES' INITIAL REACTION TO A SPATIAL REPELLENT PRODUCT IN BUSIA, WESTERN KENYA

Sheila Ekodir[1], Prisca A. Oria[1], Julius I. Odero[1], April Monroe[2], Eric Ochomo[1], Steven A. Harvey[3]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Spatial Repellents (SR), a potential complementary malaria prevention tool, are designed to protect a space from mosquitoes. Trials of Improved Practices (TIPs) is being implemented to complement an ongoing cluster randomized trial testing the efficacy of an SR product in Busia, western Kenya. TIPs captures end-user experiences, perceived efficacy, acceptability, and recommendations over time. One week after installation, semi-structured double-blinded interviews were conducted with 30 purposively selected participants from 12 intervention clusters (SR and placebo) to capture participants' first reaction to the intervention applied in their home. Two months after installation, a second interview was completed to capture blinded perceptions of the product after two cycles of product replacement. During the first visit, most participants mentioned a perception that the product was effective, reporting fewer mosquitos. As a result, some households reported stopping use of other mosquito control tools. During the second visit, some reported mosquitoes had started to return due to perceived differences in intervention effectiveness from the beginning of the 28-day installation period to the end. Participants had positive views of the intervention, noting benefits of protection outside of sleeping hours, when nets provide protection, and not requiring daily action. Most liked the product appearance and some suggested increasing what they perceived as an active ingredient to make it last longer and installing products in additional locations such as bathrooms. Participants also requested biodegradable products, rather than plastic. Initial TIPS interviews provided an in-depth understanding of end users' initial preferences and can inform communication to study communities to promote continued use of core interventions. To capture participants' reaction over time, participants will be interviewed again at 6, 12, 18 and 24 months. These interviews will provide important data for comparing perceptions of SR product feasibility, effectiveness, and acceptability to actual household allocation following trial unblinding.

0282

DYNAMICS OF *PLASMODIUM FALCIPARUM* AFEBRILE MALARIA IN SOUTHERN MOZAMBIQUE

Arlindo Chidimatembue[1], Henriques Mbeve[1], Meritxell Molinos[1], Nelo Ndimande[1], Pedro Aide[1], Pio Vitorino[1], Quique Bassat[2], Francisco Saute[1], Alfredo Mayor[2]

[1]Manhica Health Research Centre, Maputo, Mozambique, [2]ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain

Peaceful coexistence with the infected host is a common but poorly understood phenomenon for many human pathogens, including *Plasmodium falciparum* (*Pf*). The persistence of *Pf* afebrile infections and the continuous production of gametocytes may constitute a primordial source for ongoing transmission that may compromise the success of elimination initiatives. To date, few data are available regarding the progression of afebrile *Pf* infections in order to design effective interventions that can successfully detect and tackle this parasite reservoir. In this study, healthy individuals aged 5 - 60 years residing in Manhiça District were screened at the household level using a Histidine Rich Protein-2 based rapid diagnostic test (RDT) from SD Bioline. All RDT positive cases were also microscopically confirmed and closely followed for 28 days with daily visits during the first 4 days and weekly until day 28 during the rainy season (October-April) in 2020-21 and 2021-22. Antimalarial treatment was only provided at the end of follow-up or if clinical symptoms appeared before day 28. The average age of participants at enrollment was 18 years. The median body temperature was 36.4°C, and the average body weight was 41.3 kg. The geometric mean parasite density on day 0 was 1944 parasites/µL measured by microscopy. This analysis used data from 107 of the 146 individuals enrolled and excluded individuals with >2 missed follow-up visits. Parasite densities in 52 of the 107 participants (48.6%) decreased to microscopically undetectable levels. In 19 participants (17.8%), parasite densities drastically reduced and stabilized at low-density levels (below 100 parasites/µL). In 26 participants (24.3%), parasite densities were maintained at densities above 100 parasites/ µL. Ten participants (9.3%) developed a fever during the first week of follow-up. Therefore, approximately one-quarter of the afebrile RDT-detectable infections maintain densities with a high potential for transmission. The ongoing molecular characterization will provide further insights into the spontaneous clearance of afebrile infections in areas of low malaria transmission.

0283

REACHING POPULATIONS AT RISK OF MALARIA EQUITABLY: CHALLENGES AND PROSPECTS TO MALARIA ELIMINATION IN NEPAL

Chuman L. Das[1], Suman Thapa[2], Gokarna Dahal[1], Sashi Kandel[1], Uttam R. Pyakurel[1], Krishna Aryal[2], Sambhu Jha[2], Dinesh Koirala[2], Pramin Ghimire[2], Eric Swedberg[3], Erica Wetzler[4], Sara Canavati[3]

[1]Epidemiology and Disease Control Division (EDCD), Ministry of Health, Kathmandu, Nepal, [2]Save the Children International, Kathmandu, Nepal, [3]Save the Children US, Washington, DC, United States, [4]World Vision US, Federal Way, WA, United States

Nepal is among six countries in the Asia Pacific that have made significant progress in policy milestones and its made tremendous progress in malaria elimination from over 42,000 reported cases in 1985 to only 390 cases in 2021. However, significant challenges persist to achieving a *"malaria free Nepal by 2025"*. We aim to outline the challenges and prospects for equitably achieving malaria elimination in Nepal, which can be applied to other countries. Firstly, the high proportion of vivax malaria (~80%), calls for innovative tools to address low-density infections and community mobilization to support drug adherence. Secondly, the importation of cases from India, which along with improved transport networks, leads to outbreaks and re-introduction of malaria in previously malaria-free areas. Additionally, malaria vectors are prevalent in many areas, and climatic and cultural factors promote human-vector contact, breeding, and transmission. Low private-sector engagement has resulted in limited involvement in malaria treatment and surveillance of PHFs and little ownership at provincial/local levels. To address these challenges, the National Program is focusing on the 1-3-7 surveillance strategy, improved cross border collaboration with India (including origin, travel, destination, and return interventions), LLIN/IRS coverage in areas with high receptivity and vulnerability, private sector involvement and community management of malaria. Prospects for malaria elimination include implementation of radical cure for *Plasmodium vivax*, including G6PD testing, and community transmission blocking interventions for *P. falciparu*m. Nepal established a national malaria elimination task force at the central level and is in the process of planning a provincial level task force to track, monitor, and resolve issues related to elimination efforts. If the current trends continue, epidemiological models project that there will be zero indigenous cases by 2023. Nepal needs to re-evaluate its current surveillance strategy, focusing on targeted community management of malaria and on targeted interventions to address imported malaria.

0284

DEFINING MALARIA OPERATIONAL RESEARCH AND PROGRAM EVALUATION PRIORITIES FOR SUB-SAHARAN AFRICA: RESULTS FROM A BROAD STAKEHOLDER CONSULTATION PROCESS

Roger Tine[1], Evelyn Ansah[2], Samantha Herrera[3]

[1]Université Cheikh Anta Diop, Dakar, Senegal, [2]University of Health and Allied Sciences, Ho, Ghana, [3]PMI Insights Project, Washington, DC, United States

Policy, strategy, and operational decisions should be grounded in evidence to reignite gains and accelerate progress toward improved malaria control and elimination. The U.S. President's Malaria Initiative (PMI) Insights Project, together with the Université Cheikh Anta Diop of Dakar, conducted a broad stakeholder consultation to identify pressing evidence gaps in malaria control and elimination policy, strategy, and guidelines across sub-Saharan Africa (SSA), and develop a priority list of country-driven malaria operational research (OR) and program evaluation (PE) topics to address the gaps. Five key stakeholder groups were engaged in the process: national malaria programs (NMPs), research institutions in SSA, funding agencies, WHO representatives in SSA, and global technical partners supporting malaria program implementation and research. Stakeholders were engaged through individual or small group interviews and an online survey, and asked about key operational challenges faced by NMPs, pressing evidence gaps in current strategy and implementation guidance, and priority OR and PE questions to address the challenges and gaps. Altogether, 47 interviews were conducted with 82 individuals and 46 global technical partners providing input through the online survey. A total of 33 emergent OR and PE topics were identified through the consultation process, and then evaluated and prioritized by an external evaluation committee made up of experts from NMPs, research institutions, and WHO across SSA. The resulting prioritized OR and PE topics predominantly focus on generating evidence needed to close gaps in malaria control and elimination intervention coverage, address persistent challenges faced by NMPs in the implementation of core strategic interventions, and inform the effective deployment of new tools. The prioritized research list is intended to serve as a key resource for informing OR and PE investments, thereby ensuring future investments focus on generating the evidence needed to strengthen national strategies and program implementation and facilitating a more coordinated and impactful approach to malaria OR and PE.

0285

COMMUNITY HEALTH WORKER RESILIENCE IN THE FIGHT AGAINST MALARIA AMIDST COVID-19: A CASE STUDY FROM EASTERN PROVINCE, ZAMBIA

Marie-Reine I. Rutagwera[1], Bupe M. Kabamba[1], Mathews Monde[1], Enock Banda[1], Sarah Shankwaya[1], Webby E. Phiri[1], Chabu C. Kangale[1], Caroline Phiri-Chibawe[1], Travis Porter[2], John M. Miller[3], Busiku Hamainza[4]

[1]PAMO Plus, Lusaka, Zambia, [2]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States, [3]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, [4]Zambia Ministry of Health (MOH) National Malaria Elimination Centre (NMEC), Lusaka, Zambia

Zambia's Ministry of Health (MOH) has deployed 16,500 community health workers (CHWs) nationwide since 2011, of which 2,932 are providing malaria community case management (CCM) in Eastern Province. In 2019, the COVID-19 (COVID) pandemic spread throughout the world with Zambia recording its first case in March 2020. Between May 2020 and March 2022, Eastern Province recorded 36.3 COVID cases per 1,000 population, the third highest province in Zambia. The health system shifted its focus to pandemic control, and supply chains were disrupted, resulting in a considerable disruption to delivery of national health services, threatening the CHW program. This case study assesses CHW resilience amidst COVID by reviewing CHW malaria service provision data and commodity availability in Eastern Province from 2019 (prior to COVID) to 2021. Data describing passive number tested, positive, and treated cases were extracted from the health management information system. Changes in annual malaria test positivity rate of 39% (pre-COVID) vs 55% and 45% (2020 and 2021) in Eastern Province suggest potential changes in malaria treatment seeking during the pandemic. However, during this time CHWs increased the number of people tested for malaria—423,944 in 2019 (pre-COVID), 744,531 in 2020, and 834,505 in 2021. CHWs also maintained high annual treatment rates among confirmed cases—97%, 98%, and 97%, respectively—referring untreated cases onward to health facilities. Despite challenges posed by COVID, the CHW program remained resilient and maintained malaria service coverage. This could be attributed to the availability of commodities, COVID sensitization, continuity of program support by the national malaria program and cooperating partners, prioritization of CCM of malaria by the MOH, interest expressed by CHWs to serve their communities, and the trust communities have in the CHWs. Where the districts are adequately stocked and malaria commodities made available to CHWs, CHWs can continue to provide life-saving health services amidst a pandemic, and potentially shore up declines in treatment seeking at health facilities.

0286

EVALUATING THE 1-3-7 SURVEILLANCE FOR MALARIA ELIMINATION STRATEGY IN LAO PDR

Saysana Phanalasy[1], Boualam Khamlome[2], David Sintasath[3], Thipphasone Vilaysouk[4], Jehan Ahmed[5], Tabitha Kibuka[5], Kemi Tesfazghi[1]

[1]PMI Impact Malaria, Vientiane, Lao People's Democratic Republic, [2]Center for Malariology, Parasitology, and Entomology, Vientiane, Lao People's Democratic Republic, [3]U.S. President's Malaria Initiative, United States Agency for International Development, Regional Development Mission for Asia, Bangkok, Thailand, [4]U.S. President's Malaria Initiative, United States Agency for International Development, Vientiane, Lao People's Democratic Republic, [5]PMI Impact Malaria, Washington, DC, United States

Between 2000 and 2020, the annual number of probable and confirmed cases of malaria in Lao People's Democratic Republic (PDR) fell by 99 percent, from 279,903 to 3,537. The National Strategic Plan for Malaria Control and Elimination (2021-2025) calls for malaria elimination by 2030. To reinforce efforts towards malaria elimination, Lao PDR adopted a 1-3-7 approach in 2020 under which cases are reported within 1 day, investigated within 3 days, and foci are responded to within 7 days. Health workers in 125 malaria elimination districts (out of a total of 148 districts) were trained by the national program on the approach throughout 2020. In 2021, U.S. President's Malaria Initiative (PMI) Impact Malaria Laos assessed the implementation of the 1-3-7 approach by evaluating the technical, programmatic, and human resource feasibility and appropriateness of the strategy. The assessment determined the type and level of human, material, and financial resources required for effective implementation, and identified factors and barriers to the successful implementation at each level of the health system. In total, 68 semi-structured key informant interviews were conducted with health workers at the provincial, district, and health facility levels. Findings suggest that streamlining the case notification and classification processes could reduce travel and workload on overburdened staff. Innovative mechanisms leveraging digital tools could ease and improve case notification, investigation, and response where geographical access is difficult. Readily available financial resources at the lowest health level could support field activities related to case investigation and response. The availability of training and resources were identified as areas where targeted response packages could be developed. In conclusion, the assessment found that implementation of the 1-3-7 strategy in Lao PDR is appropriate and feasible but can be further optimized with some modest adaptations.

0287

MALARIA BURDEN AND MALNUTRITION WITHIN MANANJARY DISTRICT, MADAGASCAR: AN ANALYSIS OF SPATIO-TEMPORAL PATTERNS AND THE POTENTIAL IMPACT OF IMPROVED MULTISECTORAL PROGRAMMING

Mahery Rebaliha[1], **Joseph Lewinski**[2], Benjamin Rice[3], James Hazen[1], Christopher Golden[4], Suzanne Van Hulle[2], Virginie Andreas Nambinin Ralisoa[1], Elanirina Andrianoelivololona[1]

[1]Catholic Relief Services, Antananarivo, Madagascar, [2]Catholic Relief Services, Baltimore, MD, United States, [3]Princeton University, Princeton, NJ, United States, [4]Harvard University School of Public Health, Cambridge, MA, United States

Little is known about the interactions between food security, moderate acute malnutrition (MAM), and malaria prevalence. In Madagascar, undernurishment is among the highest in sub-Saharan Africa (42%) and malaria incidence is high (71.6 per 1000). In the peri-costal district of Manjaray, malnutrition and malaria incidence are higher than the national average. To better understand this complex interaction, a prospective study of 10 cohorts (n = 2485, all ages, 171-292 individuals per site) was launched in 2021. Mobile clinical teams conduct monthly visits to cohort communities collecting malaria prevalence, anthropomorphic, micronutrient, and household level questionnaire data related to nutritional status, food access, malaria infection status, and use of prevention measures. Baseline malaria and nutrition prevalence showed spatial differences between nearby communities. MAM prevalence was 5.48% overall (range between sites: 2.14% to 12.45%, n = 2301). Indicating food insecurity is common, a large proportion of households reported reducing the number of meals (37.72%, n = 517) or portion size at mealtime (29.98%, n = 517) in the past week. Disruptive but not uncommon, two cyclones hit Manajary consecutively within four weeks in February 2022 creating widespread damage, population displacement, and geographical changes. Routine temporal changes coupled with severe weather events have created difficulties in food security and access to malaria treatment and prevention resources. Our growing understanding of the shared drivers between malaria and nutritional outcomes suggests the need for better coordination among community-based nutrition and health systems. Using the mobile and community coordination approaches outlined here will enable better multisectoral policy at the national level to be developed and help reduce food insecurity and malaria prevalence.

IMPROVING MALARIA SURVEILLANCE DATA AS MALARIA INTERVENTION IN CENTRAL UGANDA

Patricia Mukose

Malaria Consortium, Kampala, Uganda

Surveillance data collected from health facilities is critical for early outbreak detection, planning and decision making for effective malaria control and programming. The quality of this data, more so in developing countries is however often limited to allow use for the intended purposes. Reporting rates are often so low to make meaningful deductions from the data. The USAID's Malaria Action for Districts in mid-central Uganda operated in Kyotera, Sembabule, Lwengo, Rakai, Lyantodde, Bukomansibi, Kalangala, Kalungu and Masaka dsitricts implemented a package of interventions to improve surveillance data quality and its use in this area. The package included on-site mentorships, performance review meetings, support supervision as well as regular data review and cleaning exercises. Presented here is analysis of the quality of weekly malaria surveillance data submitted into District Health Information System (DHIS2) from health facilities in the focus area during implementation of these interventions from July 2017 to September 2020. The study assessed completeness data using the indicator: proportion of health facilities reporting weekly malaria surveillance data into DHIS2. In the focus area.Results showed that a total of 400 facilities reported into the DHIS2 in the study period. The proportion of facilities reporting weekly malaria surveillance data increased from 68.5% in Jul - Sep 2017 to 84.7% in Jul - Sep 2018 to 92.3% in Jul-Sep 2019 and 89.2% in Jul-Sep 2020. The slight reduction in Jul-Sep 2020 might be due to the lock-down instituted in the country to fight against the corona pandemic. With this data at least three malaria upsurges in the region were detected early to enable timely response.Malaria control in developing countries like Uganda has suffered from low reporting rates of weekly surveillance data yet it is a cornerstone for saving of lives through early detection. This study suggest that, with interventions as described, health facilities can be empowered to provide quality weekly data.

0289

PLASMODIUM FALCIPARUM MSP1 AND *MSP2* GENETIC DIVERSITY IN *P. FALCIPARUM* SINGLE AND MIXED INFECTION WITH *P. MALARIAE* AMONG THE ASYMPTOMATIC POPULATION IN SOUTHERN BENIN

Romuald Agonhossou[1], Romaric Akoton[1], Hamirath Lagnika[2], Oswald Djihinto[2], Pierre Sovegnon[2], Helga Saizonou[2], Luc S. Djogbenou[3]

[1]Fondation pour la Recherche Scientifique (FORS)/ Centre de Recherche pour la lutte contre les Malaides Infectieuses Tropicales (CReMIT), Cotonou, Benin, [2]Centre de Recherche pour la lutte contre les Malaides Infectieuses Tropicales (CReMIT), Cotonou, Benin, [3]Centre de Recherche pour la lutte contre les Malaides Infectieuses Tropicales (CReMIT)/ Institut Régional de Santé Publique (IRSP/Ouidah), Cotonou, Benin

Plasmodium falciparum and *P. malariae* infections are very common in malaria-endemic countries. However, very little is known about their interactions especially the effect of *P. malariae* on *P. falciparum* genetic diversity. This study aimed to assess *P. falciparum* genetic diversity in *P. falciparum* and mixed infection *P. falciparum/ P. malariae* isolates among the asymptomatic populations in Southern Benin. Two hundred and fifty blood samples (125 of *P. falciparum* and 125 *P. falciparum/ P. malariae* isolates) were analyzed by a nested PCR amplification of *msp1* and *msp2* genes. The R033 allelic family was the most represented for the *msp1* gene in mono and mixed infection isolates (99.2% vs 86.4%) while the K1 family had the lowest frequency (38.3% vs 20.4%). However, with the *msp2* gene, the two allelic families displayed similar frequencies in *P. falciparum* isolates while the 3D7 allelic family was more represented *in P. falciparum/P. malariae* isolates (88.7%). Polyclonal infections were also observed to be lower (62.9%) in *P. falciparum/P. malariae* isolates ($p < 0.05$). Overall, a total of 96 individual alleles were identified (47 for *msp1* and 49 for *msp2*) in *P. falciparum* isolates while a total of 50 individual alleles were identified (23 for *msp1* and 27 for *msp2*) in *P. falciparum/ P. malariae* isolates. The Multiplicity of Infection (MOI) was lower in *P. falciparum/ P. malariae* isolates ($p < 0.05$). This study revealed a lower genetic diversity of *P. falciparum* in *P. falciparum/ P. malariae* isolates using *msp1* and *msp2* genes among the asymptomatic population in Southern Benin.

0290

NATIONWIDE FACILITY-LEVEL MALARIA INCIDENCE USING AVAILABLE ROUTINE DATA, MALAWI, 2018—2021

Collins Kwizombe[1], **Tyson Volkmann**[2], John Painter[3], Austin Gumbo[4], Michael Kayange[4]

[1]US President's Malaria Initiative, USAID, Lilongwe, Malawi, [2]US President's Malaria Initiative, CDC, Lilongwe, Malawi, [3]US President's Malaria Initiative, CDC, Atlanta, GA, United States, [4]National Malaria Control Programme, Lilongwe, Malawi

Increasingly, sub-national data are pursued to inform decisions about allocating limited resources for geographically specific malaria control interventions. In some countries, routine data are unavailable, and acquiring these data requires collection of non-routine data through resource-intensive strategies. To calculate facility-level malaria incidence in Malawi, malaria case reports and facility-level catchment population estimates from the national DHIS2 were used. Facilities were included if they reported a catchment population estimate and submitted 100% of monthly reports for any year from 2018 to 2021. To obtain incidence denominators, facility population counts were summed by district and compared to 2021-adjusted National Statistics Office (NSO) district estimates to determine their accuracy (acceptable if variation ≤5%). To obtain facility-level incidence, mean case counts were divided by the adjusted facility-level population estimate. Of 1,008 facilities listed in DHIS2, 647 (64%) met the criteria for inclusion; 67 were excluded due to lack of population data, and 294 for lacking monthly reports. A mean of 3.5 years of data were included per facility. Estimated facility population data for 24/28 districts (86%) summed to within 5% of the 2021-adjusted NSO district population estimates, and the national population coverage for the facilities included was 96%. 27 million total confirmed malaria cases were included (90% of all cases reported during the analysis period). Four-year mean facility-level malaria incidence ranged from 12/1,000 to 3,329/1,000 population (median value: 381/1,000; 25th/75th percentile: 208/650). Facility-level standard deviation by district ranged from 136-583/1,000. Available facility-level population estimates were accurate compared to a standard, and data availability permitted the systematic calculation of incidence for most facilities. If these results accurately represent geographic incidence variation, these data could be mapped and higher risk areas identified. Monitoring routine data may help identify local trends and inform targeted control strategies.

0291

THE POSITIVE EXTERNALITIES FOLLOWING INDOOR RESIDUAL SPRAYING (IRS) IN NGOMA DISTRICT, RWANDA

Michee S. Kabera[1], Marcel Manariyo[2], Emmanuel Hakizimana[1], Aimable Mbituyumuremyi[1], Aline Uwimana[1], Noella Umulisa[2], J Louis Mangala[1], Kaendi Munguti[3]

[1]Rwanda Biomedical Center, Kigali, Rwanda, [2]JPHIEGO, Kigali, Rwanda, [3]USAID, Kigali, Rwanda

Positive externality occurs when an unrelated activity causes a benefit to a third party. Ngoma district, located in Eastern province of Rwanda, received the first round of indoor residual spraying (IRS) in April 2019 with the support of the Government of Rwanda and The Global Funds and a coverage rate of 98.9%. The district has fifteen health centers (HCs) and 1,419 Community Health Workers (CHWs) providing malaria case management. Comparative data analysis from the Routine Health Management Information System, twelve months before and after the first round of IRS, showed a decrease from 510,881 to 348,078 in the average outpatient's department (OPD) malaria case consultations (a 46%

decrease). The average daily OPD cases was 95 per HC before IRS and 64 after IRS (a 33% decrease). Assuming the time spent for OPD consultation of 10 minutes per patients, each HC gained approximately 5 hours per day, equivalent to 62% of an 8-hour working day of a nurse. Similarly at community level, the yearly number of consultations dropped from 1,023,644 to 222,995 cases (a 78% decline), with an average monthly number of consultations per CHWs estimated at 60 cases before and 14 after IRS (a 77% decrease). Discussions with community members suggested an economic effect due to averted malaria cases (direct and opportunity costs of seeking care such as travel, waiting time and loss of productivity due to illness). In addition, based on discussions with health workers at the HCs and communities, this subsequently led to reduced workload. Therefore, IRS not only reduced malaria incidence, saving lives, but also had a positive effect of reducing workload of health workers who are already overburdened with other health related activities. This may increase patient satisfaction by reducing the waiting time of consultation and increase quality of services.

0292

MONITORING MALARIA OUTCOMES IN REMOTE RAINFOREST REGIONS OF GUYANA

Camille Adams[1], Bolanle Olapeju[2], Joann Simpson[1], Gabrielle Hunter[2], Sean Wilson[1], Lyndsey Mitchum[2], TrishAnne Davis[2], Jennifer Orkis[2], Douglas Storey[2]

[1]Breakthrough ACTION, Georgetown, Guyana, [2]Johns Hopkin University, Baltimore, MD, United States

Malaria is endemic in the hinterlands of Guyana, especially in remote gold mining regions. The Ministry of Health (MoH), Breakthrough ACTION Guyana, and the Pan American Health Organization (PAHO) trained volunteers near remote mining areas to provide rapid malaria testing and treatment to miners. Key programmatic indicators included the use of insecticide treated nets (ITN), prompt care-seeking, self-medication, and treatment adherence rates among miners. A new monitoring system was created to fill a critical information gap between local and regional services and management. It used exit interviews with miners who sought malaria services and field visits to volunteer testers by MOH supervisors who used a standardized monitoring tool, co-designed with MoH, PAHO, and mining camps. Regional Ministry teams were trained to analyze the monitoring data to inform restocking of test kits, treatment drugs, and counseling aids during quarterly field visits and provide needed feedback. This monitoring revealed challenges including lack of data entry/analysis capacity in regional offices, limited funds for transportation/logistics, and hesitancy of miners to be interviewed. These challenges were overcome with training of the MOH staff/volunteer testers and adjusting timelines to address logistic barriers. Monitoring data revealed improved outcomes. Of miners who accessed testing services, 43% had sought care promptly, 88% did not self-medicate, 73% adhered to treatment and 24% slept under an ITN, compared to 37%, 44%, 44% and 33% miners respectively before the scale up of the program. The decline in ITN use is presumably due to MOH challenges in ITN acquisition and distribution. Use of systematic monitoring enabled timely decisions for mid-course corrections and strategic prioritization of local capacity needs to ensure sustainability.

0293

ACCEPTABILITY OF WOMEN ATTENDING ANTENATAL CARE AS A SENTINEL SURVEILLANCE POPULATION FOR MALARIA IN GEITA REGION, TANZANIA

Courtney Emerson[1], Ulimboka Stephen[2], Ruth Lemwayi[2], Alen Kinyina[2], Samwel L. Nhiga[3], Sijenunu Aaron[3], Japhet Simeo[4], Chonge Kitojo[5], Erik Reaves[6], Mary Drake[2], Julie R. Gutman[1], Peter J. Winch[7]

[1]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Jhpiego, Dar es Salaam, United Republic of Tanzania, [3]National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, [4]Regional Health Management Team, Geita Region, United Republic of Tanzania, [5]U.S. President's Malaria Initiative, USAID, Dar es Salaam, United Republic of Tanzania, [6]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania, [7]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Measurement of malaria prevalence in communities is conventionally estimated through infrequent cross-sectional household surveys that do not provide continuous information regarding longitudinal malaria parasitemia in the community. Recent studies have suggested that malaria parasitemia prevalence among women attending antenatal care (ANC) correlates with prevalence among children under 5 years old and that pregnant women could be a sentinel population for tracking malaria prevalence over time. However, acceptability of collecting malaria risk factor data during ANC visits is unknown. A tablet-based questionnaire was introduced at 40 healthcare facilities in Geita Region, Tanzania, which included 15 questions on insecticide-treated net ownership and use and care-seeking for febrile children. Facilities were chosen that had 15 to 120 first ANC visits per month. To assess perspectives regarding wider introduction of the questionnaire, 21 semi-structured interviews were held with health care workers (HCWs) and managers at 12 facilities. Thirty pregnant and recently delivered women participated in focus group discussions at 7 facilities to assess the acceptability of spending additional time answering questions about malaria risk. All pregnant women felt that introduction of ANC surveillance and spending 10 more minutes with HCWs answering questions about their health would be neutral or beneficial. They perceived being asked about their health as standard of care. HCWs and managers felt that introduction of ANC surveillance was within the scope of practice of HCWs. Nine of 21 perceived that it could potentially benefit the health of women. Six HCWs expressed concern about staffing shortages and need for reimbursement for extra time and noted that management of data and records occurs after hours when patients have departed. Pregnant women and HCWs generally perceived ANC surveillance for malaria as acceptable and mostly positive. To be seen as a part of standard practice, and not an additional activity, efforts will be needed to ensure HCWs perceive a benefit for ANC clients and that concerns regarding staffing are addressed.

0294

A NOVEL APPROACH FOR DETECTING MALARIA HOTSPOTS IN AREAS OF VERY LOW TRANSMISSION AND ITS APPLICABILITY FOR IMPROVING SURVEILLANCE AND RESPONSE ACTIVITIES IN MOZAMBIQUE

Arnau Pujol[1], Glória Matambisso[2], Beatriz Galatas[3], Sónia Maculuve[2], Pau Cisteró[1], Henriques Mbeve[2], Judice Miguel[2], Boaventura Cuna[2], Cardoso Melembe[2], Nelo Ndimande[2], Llorenç Quintó[1], Humberto Munguambe[2], Helena Martí-Soler[1], Júlia Montaña[1], Lidia Nhamussua[2], Wilson Simone[2], Fabião Luis[2], Arantxa Roca-Feltrer[4], Gillian Stresman[5], Pedro Alonso[3], Baltazar Candrinho[2], Eusébio Macete[2], Francisco Saúte[2], Caterina Guinovart[1], Pedro Aide[2], Alfredo Mayor[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique, [3]World Health Organization, Geneva, Switzerland, [4]Malaria Consortium, London, United Kingdom, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

Identifying malaria hotspots in time and space allows us to detect malaria reservoirs in elimination settings and key areas for targeted interventions. The commonly used SatScan hotspot detector identifies circular or elliptical areas with higher malaria prevalence than statistically expected, but it is limited by the irregular distribution of human populations. Methods that account for population distribution while maintaining operational feasibility are needed to improve the effectiveness of targeted interventions. We present a new method to detect hotspots that accounts for population density by linking Plasmodium falciparum positive cases between them when they are closer than a given distance

of programmatic relevance, identifying structures of any shapes and sizes. The cases closest to the hotspot members are used to estimate the statistical significance of the hotspot. The method can identify persistent hotspots that also evolve in time. We compared this method with SatScan, showing a better capacity to adapt to the population distribution and the specifics of the programmatic focus. We applied the method to two different scenarios in southern Mozambique. First, hotspots were identified from clinical cases passively detected at health facilities in a low transmission setting where reactive surveillance was conducted between 2018 and 2020 (Magude District). Most of the hotspots persisted for less than two weeks, but we identified a hotspot that persisted for two months. Secondly, we applied the method to data from community-based cross-sectional surveys and pregnant women attending antenatal care (ANC) visits from two districts between 2016 and 2019 (Magude and Manhiça Districts). We identified hotspots from ANC data missed by cross-sectional surveys. This suggests that ANC data may improve the hotspot detection with respect to cross-sectional surveys, showing the potential of pregnant women as a sentinel group for malaria surveillance. The method can be easily applied to reactive surveillance in low transmission settings and integrated in surveillance systems to quickly detect outbreaks for rapid responses.

0295

MAPPING MALARIA PREVALENCE IN SUB-SAHARAN AFRICA WITH DEEP LEARNING AND SATELLITE IMAGERY

Iwona Hawryluk[1], Elizaveta Semenova[2], Xenia Miscouridou[2], Thomas A. Mellan[1], Samir Bhatt[1]

[1]Imperial College London, London, United Kingdom, [2]University of Oxford, London, United Kingdom

Maps of an infectious disease are integral to guiding public health policy. For vector-borne diseases such as malaria, statistical methods and location-specific information on the environment can be fitted to prevalence data. Typically prevalence data is collected through time-consuming and resource-intensive household surveys, which cannot be as regular as routinely collected data from health facilities. Statistical models are therefore critical to fill in the data gaps. Recent advances in computation and machine learning theory combined with publicly available satellite imagery can help address this problem. Although the use of satellite imagery has been a long-standing topic in epidemiological studies, practitioners rely on manually extracting the predictors such as temperature from the image and rarely consider very high resolutions (pixel sizes &lt 1km). Here we present a new approach, based on using raw satellite images as input data. In this work, we used Deep Learning models to predict the prevalence of malaria across the whole of sub-Saharan Africa. The model was trained using Demographic and Health Survey (DHS) prevalence data and corresponding satellite images covering approx. 6x6km areas for each of the DHS locations. We applied Convolutional Neural Networks to unprocessed images taken as the model input to automatically detect different malaria predictors, such as forests, water bodies or settlements. The model was able to estimate the malaria prevalence with a mean absolute error of around 13%, systematically achieving better performance than the benchmark linear model with the regular suite of environmental covariates. We tested various sources of openly available satellite data, as well as combining the image input with numeric socioeconomic and environmental covariates. We show that using raw satellite images can aid the mapping of infectious diseases while avoiding the subjective step of manual predictor extraction. This can help to quantify the prevalence of malaria in locations that are difficult to survey in traditional ways and thus to provide more targeted interventions in places which need it the most.

0296

OPTIMIZING THE DELIVERY OF ROUTINE MALARIA DATA QUALITY ASSESSMENTS: A MULTI-LEVEL LOGISTIC REGRESSION MODEL TO INFORM INSTITUTIONALIZED APPROACH IN MOZAMBIQUE

Ann-Sophie Stratil[1], Maria Rodrigues[2], Sarmento Armando[2], Sergio Gomane[2], Kulssum Mussa[3], Baltazar Candrinho[3], Arantxa Roca-Feltrer[1]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Maputo, Mozambique, [3]National malaria control programme, Ministry of Health, Maputo, Mozambique

While quality of surveillance data is essential for malaria programmes, the accuracy of reported data remains low. Many countries now strive to institutionalize routine data quality assessments (DQAs) as a key approach to improve data accuracy. Mozambique has been implementing this since 2019 with a selection of health facilities (HFs) receiving DQAs with differing frequencies. These are aimed at improving the accuracy of monthly malaria reports at HFs - containing aggregated data from register books - before being entered into the national health information system. Despite this being a resource-intensive exercise, the influence of different operational factors on the impact of DQAs including baseline accuracy, location and size of HFs, frequency of and lag between DQAs has never been systematically investigated. This is the first analysis aiming to inform an optimized operational delivery of routine DQAs. A 2-level logistic regression model of 650 DQAs, delivered from 10/2019 to 12/2021 and clustered within 175 HFs across 13 districts, was fitted in relation to operational factors outlined above. A binary outcome was used where in an 'accurate' monthly report >90% of confirmed malaria cases matched the number of cases reported in the register book. Controlling for operational factors, each DQA doubled the odds of an accurate report (OR 1.74 [1.38-2.20]). While most factors had no significant influence, the impact of each DQA was significantly higher if baseline accuracy was low: for baseline accuracies of 80-90%, each DQA tripled the odds of an accurate report; for baseline accuracies of <80%, each DQA quadrupled the odds. If baseline accuracy was ≤90%, the probability of an accurate report at the next visit was sustainably over 80% after the 2nd follow-up DQA. This is the first time the impact of routine DQAs was quantified in relation to various operational factors. This approach showed that after establishment of baseline accuracy, resources in Mozambique should focus on 2 follow-up DQAs to HFs where baseline accuracy is ≤90% to sustain data quality. Similar approaches will help to optimize the delivery of routine DQAs in other countries.

MALNUTRITION AND RISK OF MALARIA IN CHILDREN UNDER 5 YEARS IN BURKINA FASO: A LONGITUDINAL STUDY

Elisabeth A. Gebreegziabher[1], Boubacar Coulibaly[2], Clarisse Dah[2], Ali Sié[2], Mamadou Bountogo[2], Mamadou Ouattara[2], Idrissa Kouanda[2], Guillaume Compaoré[2], Mariam Seynou[2], Eric Nebie[2], Elodie Lebas[1], David Glidden[1], Thomas M. Lietman[1], Catherine E. Oldenburg[1]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso

The association between malaria and malnutrition is complex. Using data from a randomized controlled trial of 450 children 0-5 years of age in Burkina Faso, we examined the effect of malaria on anthropometric measures at 2 weeks and six months, the effect of malnutrition at baseline on incidence of malaria among those with no malaria at baseline, and whether age of child modifies the effect of malnutrition on risk of malaria. Malaria status (based on parasitemia on a smear), weight, height, mid-upper arm circumference (MUAC), Height-for-Age Z Score (HAZ), Weight-for-Age Z Score (WAZ), and Weight-for-Height Z score (WHZ) of children were measured at baseline, 2 weeks and 6 months. We used generalized estimating equations (GEE) adjusted for sex, age, breastfeeding, maternal

education, and study treatment (Azithromycin vs. placebo) for both analyses. We used GEE models that include the interaction term to assess effect modification by age on the multiplicative scale and relative excess risk due to interaction (RERI) on the additive scale. There were 51 kids (13.8%) with incident malaria among those with no malaria at baseline. There were no statistically significant differences in anthropometric measures between those with and without malaria. Among those with no malaria at baseline, there were no statistically significant differences in risk of malaria by baseline anthropometric measures. Age (0-30 months and 30-60 months) modified the effect of baseline weight and height on incidence of malaria on multiplicative scale and the effect of baseline weight, height, HAZ, WAZ, and WHZ on the additive scale. Among those 0-30 months, for each kg increase in weight, the risk of malaria increased by 19% (RR: 1.19 95% CI (1.05 to 1.36)); and for each cm increase in height, it increased by 7% (RR: 1.07 95% CI (1.03 to 1.12)) but did not increase for those 30-60 months. The effect of malnutrition on incidence of malaria may vary by age. The risk of malaria increased with increasing anthropometric measures among kids 0-30 months while it slightly decreased for kids aged 30-60 months. Underweight, stunted or wasted kids 30-60 months had the highest risk of malaria.

0298

MAPPING HOUSE LOCATION WITH REMOTE SENSING AND DEEPING LEARNING METHODS IN RURAL KENYA AND ETHIOPIA

Ming-Chieh Lee, Guiyun Yan

University of California, Irvine, Irvine, CA, United States

The human population represents one of the most critical variables in assessing exposure to vector-borne pathogens in rural African countries. Accurate information on the house location and house roof materials can improve modeling disease transmission risk and help plan interventions for malaria diseases. However, obtaining precise information in vast rural areas of Africa with no prior detailed mapping effort is labor-intensive, expensive, and time-consuming. High-resolution remote sensed images are helpful, but the traditional imagery analysis or manually identify methods need skilled technicians and are prone to human errors due to the morphological resemblance in visual of ground objects to human dwellings. Therefore, we utilized remote sensing and deep learning methods to detect the human house locations and roof materials in multiple study sites in western Kenya and Ethiopia. Using high resolution, multi-band pan-sharpened Pléiades satellite images with labeled dwellings from the ground survey, the Mask R-CNN, a deep convolutional neural network for object detection, was used to generate low-level features and high-level features. In addition, bounded box regression and classification were conducted. The model was trained on a 0.1° x 0.1° satellite image for each site with a total of 25,000 labeled houses and validated on the other adjacent 0.1° x 0.1° areas. The model yielded an overall accuracy of 85% in the area and 95% on the corrugated iron sheet roof-type houses. A combination of remote sensing and deep learning methods is valuable for detecting house location and roof materials, estimating population density, and the population under risk in rural Africa.

0299

CAREGIVERS' PERCEPTION OF RISK FOR MALARIA, HELMINTH INFECTION AND MALARIA-HELMINTH CO-INFECTION AMONG CHILDREN LIVING IN URBAN AND RURAL SETTINGS OF SENEGAL: A QUALITATIVE STUDY

Muhammed Olanrewaju Afolabi[1], Ndéye Mareme Sougou[2], Aminata Diaw[2], Doudou Sow[3], Isaac A. Manga[2], Ibrahima Mbaye[4], Brian Greenwood[1], Jean Louis A. Ndiaye[4]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Université Cheikh Anta Diop, Dakar, Senegal, [3]Université Gaston Berger de Saint-Louis, Saint-Louis, Senegal, [4]Université de Thies, Thies, Senegal

Malaria parasites and worms frequently co-exist in children living in low- and middle-income countries where existing vertical control programmes for the control of these two conditions are not operating at optimal levels. This gap necessitates the development and implementation of strategic interventions to achieve effective control and eventual elimination of these co-infections. Central to the successful implementation of any intervention is its acceptance and uptake by caregivers whose perception about the risk for malaria-helminth co-infection has been little documented. Therefore, we conducted a qualitative study to understand the caregivers' perspectives about the risk as well as the behavioural and social risk factors promoting malaria-helminth co-infection among pre-school and school-aged children living in endemic rural and urban communities in Senegal. In June and December 2021, we conducted individual and group interviews, and participant observations, among 100 primary caregivers of children recruited from Saraya villages in southeast Senegal and among leaders and teachers of Koranic schools in Diourbel, western Senegal. Our findings showed that a majority of the study participants in the two settings demonstrated a high level of perception of risk for malaria and acceptable awareness about handwashing practices, but had misconceptions that malaria-helminth co-infection was due to a combination of excessive consumption of sugary food and mosquito bites. Our observations revealed many factors in the house structures, toilet practices and handwashing with ashes and sands, which the caregivers did not consider as risks for malaria-helminth co-infections. These findings underscore the need to promote caregivers' awareness about the existence and risk of malaria-helminth co-infection in children. This approach would assist in addressing the caregivers' misconceptions about the occurrence of the co-infection and could enhance their uptake of the strategic interventions targeted at achieving control and subsequent elimination of malaria and helminth co-infection.

SEVERE ILLNESS DANGER SIGNS AMONG MALARIA POSITIVE CHILDREN: AN ANALYSIS OF HOUSEHOLD SURVEY DATA FROM 21 MALARIA ENDEMIC COUNTRIES IN SUB-SAHARAN AFRICA BETWEEN 2011-2020

Cameron Taylor[1], Joanna Lowell[2], Gisele Dunia[3], Sorrel Namaste[1], Yazoume Ye[4]

[1]The DHS Program, ICF, Rockville, MD, United States, [2]The DHS Program, Vysnova Partners, Rockville, MD, United States, [3]The DHS Program, EnCompass, Rockville, MD, United States, [4]ICF, Rockville, MD, United States

Diagnosing a child with severe malaria or another illness is difficult since symptoms of severe malaria can be clinically indistinguishable from other illnesses. In areas of high malaria transmission, where asymptomatic parasitemia is common, malaria may be incidental to other severe illnesses. An accurate diagnosis of severe illness among malaria positive children is critical to the treatment of sick children. Most data about severe illness come from children presenting to the formal healthcare system, there is little data about children who have not yet sought care. This analysis examined data from 42 Demographic and Health Surveys (DHS) and Malaria Indicator Surveys (MIS) across 21 countries in sub-Saharan Africa between 2011 and 2020. The outcome of interest is the presence of severe illness. This is defined as children age 6-59 months who were RDT-positive for malaria with at least one caregiver-reported severe illness sign/symptom, including extreme weakness, loss of consciousness, difficult breathing, seizures, abnormal bleeding, jaundice, heart problems, dark urine, or severe anemia (hemoglobin levels <7.0 g/dL, via a HemoCue device). The study includes a weighted descriptive country-level analysis and a multilevel mixed-effects logistic regression model to assess the determinants of severe illness. In examining all children tested for malaria (n=209,405), 24.8% were positive by RDT. Among children RDT-positive for malaria, 17.1% (95% CI: 16.4-17.8) had at least one severe illness sign/symptom, with variations between surveys. Severe illness symptoms were significantly associated with gender, age, and wealth quintiles. Children surveyed between 2016 and 2020 were significantly less likely to report at least one severe illness sign/symptom than those surveyed between 2011 and 2015 (AOR: 0.83; 95% CI: 0.78-0.88). In examining caregiver-reported severe illness danger signs and presence of severe

anemia, this analysis provides additional insights to the level of severe illness among malaria positive children at the population level. This estimate can help guide referral and management of severe illness in children.

PREVALENCE OF ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTION IN SCHOOLS IN THREE DISTRICTS IN SENEGAL (2021)

Mame Cheikh Seck[1], Julie Thwing[2], Aliou Ndiaye[3], Jules Gomis[3], Mouhamadou Ndiaye Ndiaye[1], Mamadou Alpha Diallo[1], Ibrahima Mbaye Ndiaye[3], Aida Sadikh Badiane[1], Mouhamad Sy[3], Tolla Ndiaye[3], Amy Gaye[3], Yaye Die Ndiaye[3], Mariama Toure[3], Aita Sene[3], Awa Deme[3], Baba Dieye[3], Mamadou Samb Yade[3], Mamane Nassirou Garba[3], Khadim Diongue Diongue[1], Doudou Sene[4], Medoune Diop[4], Ibrahima Diallo[4], Seynabou Gaye[4], Fatou Ba Fall[4], Bronwyn MacInnis[5], Sarah Volkman[5], Dyann Wirth[5], Daouda Ndiaye[1]

[1]University of Cheikh Anta Diop, Dakar, Senegal, [2]Malaria Branch, Center for Global Health, US Centers for Disease Control and Prevention, Atlanta, GA, USA, Dakar, GA, United States, [3]International Research & Training Center in Applied Genomics and Health Surveillance (CIGASS), Cheikh Anta Diop University, Dakar, Senegal, [4]Senegal National Malaria Control Program, Dakar, Senegal, [5]Harvard T.H. Chan School of Public Health, Boston, MA, United States

Malaria is endemic in Senegal, with a reported incidence of 31.2 per 1000 residents in 2021. Malaria transmission is highly seasonal, peaking in October and November, and is highest in southeast Senegal. The three southeastern regions recorded 79% of all cases and 44% of deaths in 2021. Seasonal malaria chemoprevention (SMC) has been implemented in Senegal for children up to ten years since 2014, necessitating evaluation of parasite prevalence among school-aged children and children under five years to monitor SMC impact. In low and moderate transmission contexts, school-aged children have higher parasite prevalence than children under five years but may be symptomatic less often and may constitute the majority of the parasite reservoir. In November 2021, we conducted a cross-sectional survey of school-aged children in two conventional and three residential, religious schools in Diourbel region (low-moderate transmission), five schools in Tambacounda region (moderate transmission), and, four schools in Kedougou region (high transmission), all of which are targeted for SMC. Data on demographics and preventive measures were collected, along with rapid diagnostic test (RDT) and dried blood spots (DBS) for molecular analyses. We enrolled 3,748 children 6-14 years old, including 920 children from residential, religious schools and 979 pupils from conventional schools in Diourbel, 852 in Tambacounda, and 982 in Kedougou. Of these, 40.8% were female, 46.9% were aged 5-9 years, and 53.1% were aged 10 or more years. Among children aged 5-9 years, 95% reported having received SMC. RDT positivity rates were 4.5% and 1.5%, respectively, in residential religious schools and conventional schools in Diourbel; 5.2% in Tambacounda schools, and 17.2% in Kedougou schools. Parasite prevalence was comparable among children 5-9 years (7.0%) and children aged 10 or more years (7.4%). School surveys are an important tool to monitor parasite prevalence among school-aged children. Results from molecular analysis will also be presented. Data from the school surveys will be compared with health facility and household data collected from the same study sites.

0302

THE EFFECTS OF METEOROLOGICAL FACTORS AND GEOGRAPHICAL ELEVATION ON MALARIA INCIDENCE IN ELIMINATION TARGETED DISTRICT OF ETHIOPIA

Desalegn Dabaro Dangiso[1], Zewdie Birhanu[2], Abiyot Negash[2], Dawit Hawaria[1], Delenasaw Yewhalaw[2]

[1]Yirgalem Hospital Medical College, Yirgalem, Ethiopia, [2]Jimma University, Jimma, Ethiopia

Ethiopia has made significant strides in the fight against malaria. The country has now adopted & is implementing the global malaria elimination program, which is expected to be completed by 2030. The success of the elimination attempt, on the other hand, can be influenced by multiple factors. Climate & environmental conditions can be one of the most significant factors affecting the progress of elimination. As a result, the study aimed to investigate the burden & transmission drivers of malaria in one of the country's elimination targeted districts. From 2010 to 2017, all febrile patients in the district's health facilities were diagnosed for malaria using a microscope & Rapid Diagnostic Test. The malaria data were collected from the malaria registers, the meteorological data from the country's National Meteorological Agency, & the geographic coordinates of each village. The data were entered using EpiData 3.1, & analyzed by R version 4.0.0. During the study period, a total of 135,607 patients were diagnosed, with 29,554 (21.8%) of them being confirmed malaria cases. Only two species, *Plasmodium falciparum* & *Plasmodium vivax*, were identified, with 56.3 % & 38.4 %, respectively. The rest 5.2 % was a mixed infection. A time series plot revealed a significant reduction in malaria, with a clear downward trend in case numbers. In a Negative Binomial Regression, the transmission season, rainfall, temperature, elevation, & the patient's sex & age were found to be predictors of disease incidence & spatial distribution. An ARIMA (2, 1, 2), the best fit model for point prediction of potential malaria incidence in 2030, the target year for elimination, projected that the monthly incidence will fluctuate around 88 cases. Finally, the results showed a significant reduction in malaria morbidity in the district. The results of the predictive model, on the other hand, raised doubts about whether the elimination goal will be reached within the time frame. Thus, achieving the elimination goal would necessitate an equitable distribution & efficient use of current interventions, as well as the development of evidence-based interventions.

0303

POTENTIAL MALARIA IMPACT OF THE GRAND ETHIOPIAN RENAISSANCE DAM ON MALARIA TRANSMISSION IN ETHIOPIA

Fentabil Getnet Yimer[1], Fitsum Bekele Endeshaw[1], Shewayiref Geremew[1], Solomon Kibret[2]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]2Program in Public Health, University of California Irvine, Irvine, CA, United States

Ethiopia is building a mega dam, called the Grand Ethiopian Renaissance Dam (GERD), on the Nile River. The effect of this dam on malaria risk of the population around the impoundment has not been well explored. Better understanding of the potential malaria risk helps design proper malaria control measures to safeguard public health. In this view, this study assessed malaria incidence and its correlation with environmental factors in western Ethiopia and demonstrated how GERD might impact malaria dynamics in the area. Multiple data sources were used including District Health Information Software 2 (DHIS2) malaria case data of three districts covered by GERD reservoir (2018 to 2021), district population data, Remote sensed environmental data, climate data, and published articles on the impact of dams on malaria epidemiology. Malaria incidence rates and trends in the setting were summarized; the non-parametric Spearman rank test was used to test the correlation of malaria incidence with environmental factors, and Mann-Kendall Trend and Sen's Slope tests to estimate the impact of dams on local climate (the example of Gibe dam in Ethiopia), and finally, the impact of GERD on malaria was demonstrated. The annual malaria incidence in GERD-covered districts ranged from 103

to 780 per 1,000 populations at risk with a fluctuating trend between 2018 and 2021. The environmental factors associated with increased malaria incidence were normalized difference vegetation index (ρ=0.64, P<0.001), rainfall (ρ=0.547, P<0.001) and enhanced vegetation index (ρ=0.68, P<0.000). Twenty years of data (10 years before and 10 after the Gibe dam) shows that it significantly increased rainfall and temperature in the area. Malaria remains high in the GERD districts. The Dam could create a favourable environment for mosquito breeding if proper vector control is not placed. Hence, incorporating malaria control measures in reservoir management such as suppressing shoreline breeding habitats and creating a buffer zone for population settlement should be prioritized to prevent unprecedented malaria epidemics in the dam area.

[1]Malaria Branch, Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]National Malaria Control Program, Ministry of Health, Luanda, Angola, [4]National Malaria Control Program, Ministry of Health, Cotonou, Benin, [5]Unit of Clinical Pharmacology and Pharmacovigilance University of Kinshasa; Department of Pharmacology and Therapeutics, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [6]Ethiopian Public Health Institute, Addis Ababa, Ethiopia; University of North Carolina, Chapel Hill, USA, Addis Ababa, Ethiopia, [7]Centre National de Formation et de Recherche en Santé Rurale de Maferinyah, Forecariah, Guinea, [8]Institut Pasteur de Madagascar, Antananarivo, Madagascar; Faculté des Sciences, Université de Toliara, Toliara, Madagascar, [9]The National Malaria Control Program, Antananarivo, Madagascar, [10]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [11]Malaria and Other Parasitic Diseases Division, Rwanda Biomedical Centre, Kigali, Rwanda, [12]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [13]Department of Pathology, College of Health Science, Makerere University Kampala, Kampala, Uganda

The differentiation of recurrent malaria infections as a reinfection or recrudescence during a therapeutic efficacy study (TES) in high malaria transmission areas has implications for the periodic monitoring of antimalarial efficacy. Various *Plasmodium falciparum* molecular markers have been used to achieve this, including genotyping of polymorphic surface antigen coding genes (*msp1*, *msp2*, and *glurp*) and highly polymorphic neutral microsatellites. Recently, WHO updated the recommended TES genotyping methods to include a combination of *msp1*, *msp2*, and 1-3 neutral microsatellites. However, the optimal neutral microsatellites have not been specified and will be dependent on the malaria transmission level of a country or region. To address this, a database of seven neutral microsatellite markers (Poly-α, PfPK2, TA1, TA109, C3M69, C2M34, and 2490) from multiple TESs was compiled and analyzed to determine the sensitivity and diversity of each microsatellite marker. This included data from 41 collection sites in ten African countries (Angola, Benin, DRC, Ethiopia, Guinea, Madagascar, Mozambique, Rwanda, Tanzania, and Uganda) with 1283 pretreatment samples collected between 2016 and 2020. Sensitivity was assessed by calculating the locus-specific multiplicity of infection. Genetic diversity at each locus was estimated by Shannon's diversity index (H). Among the seven markers genotyped collectively as part of these studies, the most discriminant marker was Poly-α, followed by PfPK2 and TA1, based on both high sensitivity and diversity. C2M34 had higher diversity but was less sensitive than TA1. The TA109, C3M69, and 2490 loci had the lowest sensitivity and diversity scores. This study provides scientific evidence for the selection of Poly-α, PfPK2, and TA1 as the most sensitive and diverse microsatellite markers in the classification of reinfections versus recrudescent infections, an analysis integral to TESs.

0305

A PROSPECTIVE STUDY OF *PLASMODIUM FALCIPARUM* GENOMIC INTELLIGENCE IN MOZAMBIQUE

Clemente da Silva[1], Neide Canana[2], Eduard Rovira-Vallbona[3], Arantxa Roca-Feltrer[2], Alexandra Wharton-Smith[2], Arlindo Chidimatembue[1], Caitlin Bever[4], Caterina Guinovart[3], Joshua L. Proctor[4], Airone Ringuissa[2], Maria Rodrigues[2], Paulo Arnaldo[5], Simone Boene[1], Pedro Aide[1], Sonia Enosse[2], Craig Bonnington[2], Andres Aranda-Diaz[6], Bryan Greenhouse[6], Baltazar Candrinho[7], Francisco Saute[1], Alfredo Mayor[3]

[1]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, [2]Malaria Consortium, Maputo, Mozambique, [3]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [4]Institute for Disease Modeling (IDM), USA, CA, United States, [5]Instituto Nacional de Saúde, Maputo, Mozambique, [6]University of California San Francisco (UCSF), California, CA, United States, [7]National Malaria Control Program (NMCP), Ministry of Health, Mozambique, Maputo, Mozambique

The integration of genomic data into routine surveillance activities has the potential to increase actionable intelligence for making programmatic decisions on the optimal mix of control and elimination measures. With the aim of informing Mozambique's national malaria control and elimination strategy, we are conducting a prospective genomic surveillance study targeting different settings and populations. The specific objectives are to: 1) monitor molecular markers of drug and diagnostic resistance; 2) characterize transmission sources in low transmission areas; 3) estimate transmission levels and the effectiveness of antimalarial interventions; and 4) assess the value of pregnant women as sentinel population. Sampling will take place in households and health facilities in 19 districts across 9 provinces, representing different transmission strata and geographical areas. Dried blood spots and rapid diagnostic tests will be collected during the rainy and dry seasons from consenting patients of all ages (low transmission areas) or 2-10 year-old children (medium-to-high transmission settings) seeking care for malaria symptoms and from pregnant women attending their first antenatal clinic visit. Samples will also be collected in the context of interventions such as mass drug administration, seasonal malaria chemoprevention, indoor residual spraying, and intermittent preventive treatment in infants, to assess the impact of these on the *Plasmodium falciparum* molecular epidemiology. We will use a multiplex amplicon-based next generation sequencing approach targeting informative single nucleotide polymorphisms, structural variants and microhaplotypes. Genetic data will be incorporated into epidemiological and transmission models to identify the most informative relationship between genetic features and malaria epidemiology such as sources of transmission and programmatic effectiveness of interventions. Strategic genomic information will be ultimately integrated into the national malaria information and surveillance system to improve the use of the genetic information for programmatic decision-making.

SPATIOTEMPORAL MAPPING OF MALARIA INCIDENCE IN SUDAN USING ROUTINE SURVEILLANCE DATA

Ahmed Elabbas Mustafa Elagali[1], Asmaa Elagali[2], Peter Gething[1], Daniel Weiss[1], Ayman Ahmed[3], Hassan Ismail[4], Mustafa Abubakr[5], Abdalla Ahmed Mohammed[6], Ewan Cameron[1], Nada Makki[7]

[1]Telethon Kids Institute, Perth, Australia, [2]Omdurman Islamic University, Khartoum, Sudan, [3]Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan, [4]Neglected Tropical Diseases Control Division, Federal Ministry of Health, Khartoum, Sudan, [5]Department of the Integrated

Vector Management (IVM), Federal Ministry of Health, Khartoum, Sudan, [6]Diseases Control Directorate, Federal Ministry of Health, Khartoum, Sudan, [7]Health Information Management and Statistics, Federal Ministry of Health, Khartoum, Australia

Malaria is a serious threat to global health, with over 95% of the cases reported in 2020 by the World Health Organization in African countries, including Sudan. Sudan is a low-income country with a limited healthcare system and a substantial burden of malaria. The epidemiology of malaria in Sudan is rapidly changing due to factors including the rapidly developing resistance to drugs and insecticides among the parasites and vectors, respectively; the growing population living in humanitarian settings due to political instability; and the recent emergence of *Anopheles stephensi* in the country. These factors contribute to changes in the distribution of the parasites species as well as malaria vectors in Sudan, and the shifting patterns of malaria epidemiology underscore the need for investment in improved situational awareness, early preparedness, and a national prevention and control strategy that is updated, evidence-based, and proactive. A key component of this strategy is accurate, high-resolution endemicity maps of species-specific malaria. Here, we present a spatiotemporal Bayesian model, developed in collaboration with the Sudanese Ministry of Health, that predicts a fine-scale (1km X 1km) clinical incidence and seasonality profiles for *Plasmodium falciparum* and *Plasmodium vivax* across the country. We use monthly malaria case counts for both species collected via routine surveillance between January 2017 and December 2019, as well as a suite of high-resolution environmental covariates to inform our predictions. These epidemiological maps provide a useful resource for strategic planning and cost-effective implementation of malaria interventions, thus informing policymakers in Sudan to achieve success in malaria control and elimination.

0307

IMPLEMENTING A SIMPLIFIED, AUTOMATED ALGORITHM TO CLASSIFY MALARIA CASES IN SOUTHERN LAOS AND IDENTIFY HOTSPOTS OF TRANSMISSION

Abhishek Gupta[1], Rafael Jairah Jr Matoy[1], Fraterne Kagame[1], Phoutnalong Vilay[2], Odai Sichanthongthip[2], Nontokozo Mngadi[1], Julia Dunn[1], Viengphone Sengsavath[2]

[1]Clinton Health Access Initiative, Vientiane, Lao People's Democratic Republic, [2]Center of Malariology, Parasitology and Entomology, Vientiane, Lao People's Democratic Republic

Malaria in Laos has decreased by 86% over the last twenty years and has become increasingly focalized in hotspots, particularly in southern Laos. Laos has adopted the 1-3-7 approach for malaria elimination in low burden districts, including case notification by day 1, case investigation and classification (CICC) by day 3 and response by day 7. CICC is completed by the health facility, not necessarily the point of care (POC), which can slow down the process and increase the work burden, making it difficult to expand to areas with a higher number of cases. We conducted a pilot to demonstrate the feasibility of CICC, without the target of within 3 days, at POCs in high burden districts by adding two questions on infection and travel history to the existing malaria case register form (CRF). Data were entered every month at the district level into a pilot DHIS2 module to classify cases using an automated algorithm. After the pilot, we examined the CICC rates, surveyed staff, and conducted a sink-source analysis. The pilot ran from April to September 2021, alongside routine surveillance activities, in 24 POC in high burden provinces of Salavan, Savannakhet, and Attapu. Out of 114 cases reported on the national malaria information system in the pilot sites, 101 (89%) cases were investigated and classified on DHIS2, exceeding the 85% target. On a scale of 1 to 5, the survey showed that most POC and district staff agreed that the components of the pilot were comprehensive (4.4), easy to implement (4.1), received adequate support (4.8), and acceptable given their workload (5.0). Attapu had the highest number of cases overall (46/101), and the highest number of local cases, 36 (84%), with 5 (12%) imported and 2 (5%) relapse cases. 3 of 5 imported cases were from a different district within the province. Meanwhile, Salavan reported the most imported cases (18/101), with 13 of the cases being imported from Sekong, a province not included in the pilot. Overall, these results suggest that it is feasible to conduct CICC at the POC and scale up to high burden districts. This would provide a greater understanding of transmission patterns allowing for better targeting of interventions.

0308

EXPOSURE PATTERNS OF HUMANS TO MALARIA VECTORS IN WESTERN KENYA AND IMPLICATIONS FOR MALARIA CONTROL

Julius Ichodo Odero[1], Bernard Abong'o[1], Prisca A. Oria[1], Sheila Ekodir[1], Vincent Moshi[1], Steven A. Harvey[2], Eric Ochomo[1], John E. Gimnig[3], Nicole L. Achee[4], John P. Grieco[4], April Monroe[5]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Division of Parasitic Diseases and malaria, Centers for Disease Control (CDC) and Prevention, Atlanta, GA, United States, [4]University of Notre dame, Department of Biological Sciences, Eck Institute for Global Health, Notre Dame, IN, United States, [5]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States

Despite sustained implementation of insecticide-treated nets (ITNs), malaria remains a leading cause of morbidity and mortality in western Kenya. Night-time entomological and human behavioral data were collected as part of a cluster-randomized clinical trial evaluating the efficacy of a spatial repellent to correlate exposure patterns of household residents to malaria vectors and potential gaps in bite prevention. Human landing collections and direct observation of household member behavior, related to indoor or outdoor location and ITN use, were conducted in 48 households in Busia County western Kenya from May to August 2021, prior to SR distribution. Data was collected hourly, between 1700 and 0700 hours, indoors and outdoors. Captured mosquitoes were assessed for species determination, sporozoite infection and parity status. Entomological and human behavioral data were layered to estimate exposure to anopheline bites. *Anopheles gambiae s.l*. species complex and *An. funestus* comprised the majority of anophelines collected. Indoor biting rates were 59% and 71%, respectively. However, when accounting for overlayed indoor and outdoor resident location, an estimated 97% of bites occurred indoors. Using an ITN while sleeping was estimated to prevent 80% of bites for *An. gambiae s.l.* and 83% of bites for *An. funestus*. Remaining exposure for ITN users occurred largely indoors in the evening and early morning hours. For both ITN users and non-users, most exposure to malaria vectors within the household space was estimated to occur indoors, suggesting the added value of complementary indoor-oriented interventions such as spatial repellents. Additional research is needed to better understand potential gaps in protection away from home. Differences between unadjusted anopheline vector biting rates and human behavior-adjusted indicators highlight the importance of integrating entomological and human behavioral data for a comprehensive understanding of malaria risk including how exposure patterns may change by time, cultural contexts, and in response to new malaria control interventions.

IMPROVING ROUTINE MALARIA DATA QUALITY THROUGH DATA REVIEW MEETINGS IN THE FAR NORTH AND NORTH REGIONS OF CAMEROON FROM 2019

Fottsoh Arnold[1], Olivier Kakesa[2], Jean FOSSO[3], Achu Dorothy Fosah[3], Jean-Marie Tsachoung[4], Souleymanou Souleymanou[5], Yazoume Ye[6]

[1]ICF International, Maroua, Cameroon, [2]ICF International, Yaounde, Cameroon, [3]National Malaria Control Program, Yaounde, Cameroon, [4]ICF International, Garoua, Cameroon, [5]U.S. President's Malaria Initiative, Yaounde, Cameroon, [6]ICF International, USA, MD, United States

In the North and Far North regions of Cameroon, malaria burden remains high compared to other regions. In the 2019-2023 National Malaria Strategic Plan, surveillance is considered as a specific intervention aimed at

producing quality data for decision making. However, the collection and use of quality malaria data remains a challenge. To address this issue, the NMCP and partners have been conducting regular data review meetings to improve routine data quality in the North and Far North regions since 2019. These meetings consist of checking data consistency between District Health Information Software 2 (DHIS2) and source documents, making corrections and visualizing keys malaria indicators. We assessed the contribution of these data reviews to the change in quality of malaria data in these regions. We extracted DHIS2 data Jan 2011 - Dec 2021 on two malaria indicators: number of suspected malaria cases (SM) and number of suspected malaria cases tested with rapid diagnostic test or microscopy (SMt). We performed an interrupted time series analysis comparing data consistency before and after the introduction of data review meetings in january 2019. To measure change, we calculated the change in mean inconsistency per report submitted after data review meetings were introduced using a Bayesian negative binomial model adjusted for secular trend and seasonality. Data review meetings were associated with 71% (incidence rate ratio [IRR]: 0.29 [95% CI: 0.067–1.253]) reduction of mean data inconsistency of SM and SMt in Far North region and 78% (IRR: 0.22, [95% CI: 0.042–1.234]) reduction in North region. Adding data review meetings at the district level further reduced data inconsistency by 91% (IRR: 0.09 [95% CI: 0.019–0.438]) for both indicators in Far North region and 69% (IRR: 0.31 [95% CI: 0.047–2.283]) in North region. Holding these meetings at the district level only was associated with an 83% and 68% reduction of mean data inconsistency in Far North and North regions respectively. Regular data review meetings at regional and district levels likely contributed to improving malaria data quality and should be maintained and institutionalized.

0310

THE IMPACT OF THREE YEARS OF INDOOR RESIDUAL SPRAYING (IRS) INTERVENTION ON CONTROLLING MALARIA DISEASE IN KAMONYI DISTRICT, RWANDA

Protais Kayijuka[1], Michee S. Kabera[1], Marcel Manariyo[2], Jean Louis N. Mangara[1], Emmanuel Hakizimana[1], Dunia Munyakanage[1]

[1]Rwanda Biomedical Center, Kigali, Rwanda, [2]Jhpiego, Kigali, Rwanda

Following the upsurge of malaria occurred earlier in the last decade, the Government of Rwanda and its Partners have been combining efforts based on local evidences and increasing the coverage of interventions for effective malaria control countrywide. The primary vector-control interventions deployed in Rwanda for the management of insecticide resistance are Indoor Residual Spraying (IRS) with non-pyrethroid insecticides and Long Lasting Insecticidal Nets (LLINs). The IRS intervention targets the districts with high burden of malaria transmission with a rotation of insecticide every two years. The Kamonyi district is bordering with Kigali-City, in West, and benefited the IRS intervention with annual round from 2019. The insecticide used was Fludora Fusion WP-SB 56.25 in 2019 and 2020 and Actellic 300 CS in 2021 with an annual coverage of more than 98.50% of the targeted structures. This abstract assesses the impact of IRS in malaria control in Kamonyi district for the three consecutive years of its implementation. A comparative analysis of data extracted from the Routine Health Management Information System (RHMIS) of the Ministry of Health was performed on the average of outpatients and inpatients malaria cases or deaths for the three years before IRS (2016-2018) and the three years during the IRS intervention (2019-2021) in Kamonyi district. The analysis showed that in the last three years before spraying, simple malaria cases were 625,149 while the number of severe malaria was 1,464 cases and 37 malaria deaths. After the implementation of IRS in the three years (2019-2021), malaria decreased respectively to 528,786 (15%) for simple malaria cases, 501 (66%) for severe malaria and 10 cases (73%) of malaria deaths. The malaria incidence was dropped down from 599 (z-score: 0.87) in 2019 to 229 (z-score: -1.83) in 2021. The IRS using new generation of insecticides with high coverage contributed to reduce simple malaria incidence and importantly severe malaria cases and related death in Kamonyi district.

0311

APPLYING A STANDARDIZED, MOLECULAR ENTOMOLOGY DATA LABELING SYSTEM IN GHANA TO EFFECTIVELY INTEGRATE INTO CENTRAL DHIS2 DATABASE

Marianne Parrish[1], Allison Hendershot[1], Yemane Yihdego[1], Osei Akuoko[2], Edem Obum[2], Bryan Fei[2], Matthew Boddie[1], Melissa Yoshimizu[3], Jennifer Armistead[3], Matthew Kirby[1], Kathryn Stillman[1]

[1]PMI VectorLink Project, Abt Associates, Rockville, WA, United States, [2]PMI VectorLink Project, Abt Associates, Accra, Ghana, [3]U.S. President's Malaria Initiative, USAID, Washignton, DC, United States

To reverse the rising trend in malaria cases, the U.S. President's Malaria Initiative's (PMI) flagship vector control program—the VectorLink project—uses entomological data to identify the mosquito vector, characterize its behavior, monitor susceptibility to insecticides, and measure the quality and impact of vector control interventions. By integrating molecular analysis as part of entomological monitoring, the project possesses a more granular understanding of species diversity, parasitic infection rates, and distribution of genetic markers for insecticide resistance towards more targeted vector control measures. However, molecular data management is complex, often fragmented, inconsistently used, and rarely integrated into existing information systems. To combat this, the PMI VectorLink project piloted a mosquito labelling system for molecular data in Ghana that tracks mosquito samples from the field to the laboratory, linking the entomological field and bioassay data set to the molecular data set through a central DHIS2 database to increase data utility. In mid-2022, a dual code system with scannable labels, unique identifiers, and central registration was implemented along with an archival system to account for previously collected mosquitoes from each month in 2022. A subset of collected mosquitoes were labelled with a piloted unique identifier and sent to the laboratory for molecular analysis. This pilot allowed for identification of system and workstream implementation weaknesses, including monitoring the integrity of pooled samples to ensure downstream use, and the roll-out established new roles and responsibilities for molecular data management. Based on the success of the pilot, by the end of the year, the labeling system will expand to include all insecticide resistance samples in Ghana. With this progress, all field and laboratory entomology data collected in 2022 for Ghana will be managed within the central database, VectorLink Collect, which facilitates transfer to the Ghana DHIS2 national health information system.

A NON-PARAMETRIC APPROACH TO ESTIMATE MULTIPLICITY OF INFECTION AND PATHOGEN HAPLOTYPE FREQUENCIES

Loyce Kayanula[1], Kristan Schneider[2]

[1]African Institute for Mathematical Sciences, Limbe, Cameroon, [2]Hoschule Mittweida, Mittweida, Germany

Global efforts to monitor the spread of infectious diseases, particularly by molecular surveillance, led to tremendously reduced morbidity and mortality. However, there are still many confounding factors in molecular surveillance. Observing the presence of multiple genetically-distinct variants (lineages) within an infection (often referred to as multiplicity of infection - MOI) is common in many infectious diseases such as malaria. MOI is an epidemiologically and clinically relevant quantity as it scales with transmission intensity and might impact the clinical pathogenesis of the disease. In malaria, MOI is considered an important quantity, and a variety of methods to estimate it exists. A limitation of many statistical methods is the underlying assumption that MOI follows a Poisson distribution. For diseases like malaria, this assumption has been questioned because mosquito biting rates follow a negative binomial distribution, which better captures heterogeneity in biting rates in the vector population. We could show that maximum-likelihood estimation under this more general distribution leads to the same estimates as the Poisson model. To resolve this structural limitation, we provide a nonparametric approach to estimate haplotype frequencies and the multiplicity of infection (MOI). The unique characteristic of this approach is that it allows capturing overdispersion in

the distribution of MOI. E.g., in the case of malaria, overdispersion arises from seasonal fluctuation in transmission intensities or heterogeneous mosquito biting rates. In particular, we outline the underlying statistical model and show how the maximum-likelihood estimate of haplotype frequencies and the distribution of MOI can be obtained using the Expectation-Maximization (EM) algorithm. We report on the accuracy and precision of the proposed method (i.e., bias and variance of the estimator) based on a simulation study. Finally, we apply the method to estimate the distribution of MOI from malaria molecular data from endemic areas in Cameroon and Kenya.

0313

INVESTIGATION OF INCREASED MALARIA CASES IN SOLWEZI AND KALUMBILA DISTRICTS, NORTH-WESTERN PROVINCE OF ZAMBIA, SEPTEMBER, 2021

Danny Sinyange[1], Lwito S. Mutale[1], Japhet Chiwaula[2], Kentzo Mumba[2], Stephen Bwalya[2], Busiku Hamainza[2]

[1]Zambia Field Epidemiology Training Programme, Lusaka, Zambia, [2]Zambia National Malaria Elimination Centre, Lusaka, Zambia

North western province has been receiving financial and material support from First Quantum Minerals (FQM) alongside with government towards malaria control and elimination in Kalumbila and Solwezi districts since 2014. Despite the yearly support, malaria morbidity remains high. We conducted an investigation to establish the existence of an outbreak and the possible risk factors. Purposively, we sampled six health facilities from each district based on proximity to FQM mining sites, high malaria burden, past issues with data quality and at least one FQM owned facility from each district. We conducted data quality audits (DQA) for first and second quarter, 2020 to determine that there are no data quality errors and that the incidence is significantly abnormally high. We calculated epidemic thresholds from the third quartile of 5-year historic data. We collected qualitative data on malaria interventions and environmental factors using key informant interviews. We used RStudio to run spearman's correlation to compare trends in malaria incidence with rainfall pattern. The DQA revealed low overall data accuracy below 70%. Malaria case incidence in 2020 surpassed epidemic thresholds in both districts. A statistically significant positive monotonic relationship was found between rainfall and malaria incidence per 1000 population (rho=0.524, p-value < 0.001). A malaria outbreak was observed in Solwezi and Kalumbila districts in 2020. Poor data quality and reporting limits the ability of district health offices to detect and timely respond to outbreaks, so we encouraged health facilities to hold regular data audits to improve data entry, storage, and reporting. We recommended the sites rely also on patterns of rainfall as an early warning system and strengthen malaria epidemic preparedness and response at district level.

0314

THE RELATIONSHIP BETWEEN HOUSING, OCCUPATION, AND EDUCATION AND MALARIA RISK IN RURAL MOZAMBIQUE

Kelly M. Searle[1], Dominique E. Earland[1], Anísio Novela[2], Albino F. Bibe[3], João L. Ferrão[4]

[1]University of Minnesota School of Public Health, Minneapolis, MN, United States, [2]Sussundenga Rural Health Center, Sussundenga, Mozambique, [3]Sussundenga Secondary School, Sussundenga, Mozambique, [4]Superior Institute of Sciences and Education, Beira, Mozambique

Housing construction is a known risk factor for *Plasmodium falciparum* infection. The hypothesized mechanism for this risk is that poor construction materials provide access for infectious mosquitos. However, different parts of the house structure (walls, roof, windows, eaves, and floors) have shown varying associations with malaria risk across different settings. It has been hypothesized that housing structure mediates the true association between income and malaria infection. This study investigated the complex relationships between housing construction, occupation, and education. We conducted a community-based, cross-sectional study of malaria prevalence and risk in Sussundenga Village, Mozambique from December 2020-February 2021. Ninety-eight (98) households with 302 residents completed the study. The overall malaria prevalence by rapid diagnostic test (RDT) was 31%. Rudimentary floor construction [OR: 2.1 (1.3-3.5)] and open windows [OR: 1.95 (1.2-3.3)] were independently associated with malaria infection. When adjusted for individual level confounders (age, insecticide treated net use, and number of residents per household) rudimentary roof [OR: 2.5 (1.1-5.5)], wall [OR: 1.8 (1.0-3.0)], floor [OR: 1.9 (1.2-3.3)] construction and open windows [OR: 2.0 (1.2-3.5)] were all associated with malaria infection. When education level (primary, secondary, tertiary) of the head of household and occupation (full-time, part-time) was added to the model, all associations between household structure were nullified except for rudimentary roof structure, suggesting the association between education and occupation is partially mediated by housing structure. While not statistically significant, the association between education and malaria infection was most strongly mediated by housing structure (18%: roof type, 28%: wall type, 44%: roof type, and 16%: windows). These results show that both education and occupation play an important role in household-level protection against malaria infection. This is partially mediated through housing structure, which is the primary risk factor for infection at the household level.

0315

TRANSITIONING MALARIA SURVEILLANCE IN ZANZIBAR FROM MALARIA EARLY EPIDEMIC DETECTION SYSTEM (MEEDS) TO INTEGRATED DISEASE SURVEILLANCE AND RESPONSE (IDSR) SYSTEM: AN ON-GOING SYSTEM EVALUATION

Laura Mercedes Castro[1], Wahida S. Hassan[2], Abdul-Wahid H. Al-Mafazy[3], Faiza B. Abbas[2], Mohamed H. Ali[2], Mohamed Ali Ali[2], Erik Jason Reaves[4]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [3]Research Triangle Institute (RTI) International, Zanzibar, United Republic of Tanzania, [4]U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Dar Es Salam, United Republic of Tanzania

A timely, complete, and actionable malaria surveillance system is critical to Zanzibar's success in malaria elimination. Zanzibar currently has two parallel weekly facility-based, passive surveillance systems that capture similar key malaria indicators: Malaria Early Epidemic Detection System (MEEDS) and Integrated Disease Surveillance and Response (IDSR). Zanzibar is in the process of streamlining malaria surveillance by discontinuing MEEDS and transitioning solely to IDSR in mid-2022. We assessed the performance of the IDSR and compared its performance to MEEDS to identify strengths, weaknesses, and lessons learned that stakeholders can leverage to support the successful transition from MEEDS to IDSR. We analyzed malaria indicators reported through the MEEDS and IDSR systems during January - August 2021 to estimate the number of reporting facilities, completeness, and timeliness (submitted by specified weekday), and describe data quality. We conducted key interviews with national and district-level staff, and health workers from 74 randomly selected health facilities from Unguja and Pemba islands, on knowledge of malaria case management and the strengths, challenges, and available resources to support malaria surveillance. Preliminary quantitative findings indicate lower data timeliness (77.2%) and completeness (93.4%) in IDSR when compared to the well-established MEEDS (81.4% and 99.2%, respectively). Initial qualitative findings suggest that most respondents are aware of malaria case management and have the key resources needed for IDSR and MEEDS reporting. However, there are gaps in the processes used for compiling weekly reports (e.g., lack of standardization for tallying complex IDSR indicators for aggregate data, numerous data sources from which patient information must be abstracted, including manually created laboratory books). These gaps have made it difficult to reproduce weekly reports during the data quality assessment. The final analysis will guide recommendations to strengthen the IDSR to improve long-term success as Zanzibar transitions surveillance systems for malaria elimination.

0316

GOLD MINERS SHOOT UP MALARIA TRANSMISSION IN INDIGENOUS AREAS OF RORAIMA, BRAZIL

Jacqueline de Aguiar Barros[1], Fabiana Granja[2], Pedro Pequeno[2], Paola Marchesine[3], **Maria de Fatima Ferreira-da-Cruz**[4]

[1]Coordenação de Vigilância Sanitária/ Coordination of Health Surveillance, Roraima, Brazil, [2]Universidade Federal de Rondonia / Federal University of Roraima, Roraima, Brazil, [3]General Coordination of Surveillance of Zoonoses and Vector-Transmitted Diseases, Brasilia, Brazil, [4]Fundação Oswaldo Cruz, Rio de Janeiro, Brazil

This descriptive study, based on secondary data, was carried out with the objective of knowing when, where, and who falls ill with malaria in Roraima, a Brazilian state, from 2010 to 2019. During this period, 113,326 autochthonous cases, 3,409 hospitalizations, and 54 deaths from malaria were reported. The annual parasitic incidence and the number of hospitalizations showed significant changes over the period, but without significantly affecting the number of deaths. The increase in the proportion of *P. falciparum* infections was significant throughout the study but did not influence hospitalization and death figures. Cases imported from Venezuela had increased significantly since 2016 and those with transmission in rural, urban, and settlement areas have decreased between 2010 and 2014. But, malaria prevalence in indigenous and mining areas has been increasing since 2014. The way gold miners cause dramatic changes in the environment, where mining wells produce a multitude of breeding sites, added to the behavior of miners who work with little clothes, at times of greater vector activity, together with the presence of asymptomatic carriers of the disease, contribute to the high incidence of malaria in mining sites. Besides that, the great mobility of miners facilitates the renewal of the susceptible population by the constant entry and exit of infected or not infected people. We conclude that the presence of miners in Yanomami indigenous areas is a reality that has been contributing to the increase of malaria cases in Roraima. In this way, the need to implement health policies that also meet this contingent is reinforced, and it is necessary to include other government bodies in the discussion on mining in indigenous lands which, like any other economic activity, must take into account the principles of sustainability, preservation of biodiversity and guaranteeing the cultural and social rights of indigenous peoples to ensure the social well-being and health of the entire indigenous and non-indigenous population.

0317

ASYMPTOMATIC *PLASMODIUM* PREVALENCE IN HIGH-RISK POPULATIONS IN MONDULKIRI, CAMBODIA

Dyna Doum[1], David Mclver[2], Allison Tatarsky[2], Neil F. Lobo[3]

[1]Health Forefront Organization, Phnom Penh, Cambodia, [2]Malaria Elimination Initiative (MEI), University of California, San Francisco (UCSF), San Francisco, CA, United States, [3]Eck Institute for Global Health (EIGH), University of Notre Dame, South Bend, IN, United States

Though malaria remains one of the most serious public health issues globally and is a leading cause of mortality in many developing countries, many areas are moving towards local elimination. Knowledge of both symptomatic and asymptomatic malaria point prevalence on a subnational scale allows the estimation of the number of parasites present in the transmission system enabling the targeting and tailoring of resources towards greater impact and better use of available capacity - especially in lower transmission areas. Malaria incidence or prevalence is typically based on symptomatic reporting of patients in conjunction with a positive malaria diagnostic - conventionally RDTs or microscopy. Asymptomatic malaria parasites carriers usually do not report for malaria diagnosis, resulting in this proportion of infections not being reported, even though they may serve as a significant reservoir of parasites. *Plasmodium* detection by PCR is much more sensitive than RDT or microscopy, particularly in low density or mixed infection cases, and it is valuable for the accurate collection of malaria epidemiological data. This study aimed to determine the PCR-based point prevalence of malaria infection by parasite species in forest rangers, forest dwellers, and forest goer populations, which are at high risk of malaria infection. A cross-sectional survey was performed during the high transmission season in November and December 2021, in Mondulkiri province, Cambodia. Blood samples collected on filter papers from participants were screened for *Plasmodium spp.* using PCR. The primary outcome measure of estimated mean malaria infection prevalence (by parasite species) per target population was determined. This result will allow the estimation of the amount of the reservoir in the high-risk populations and help implement an effective malaria control program toward achieving malaria elimination.

0318

INFORMING STRATIFIED MALARIA CONTROL FOR HIGHEST IMPACT: A SEMI-MECHANISTIC, MULTI-METRIC, BAYESIAN GEOSTATISTICAL MODELLING FRAMEWORK TO SUPPORT MALARIA CONTROL PLANNING IN MOZAMBIQUE

Tasmin L. Symons[1], Justin J. Millar[2], Punam Amratia[1], Baltazar Candrinho[3], James M. Colborn[4], Dominic Lucero[5], Mark Connell[1], Daniel J. Weiss[6], Peter W. Gething[6], Ewan Cameron[6]

[1]Telethon Kids Institute, Perth, Australia, [2]PATH, Seattle, WA, United States, [3]National Malaria Control Programme, Ministry of Health, Maputo, Mozambique, [4]Clinton Health Access Initiative, Maputo, Mozambique, [5]Clinton Health Access Initiative, Gaborone, Botswana, [6]Telethon Kids Institute & Curtin University, Perth, Australia

The burden of malaria is disproportionately felt in a small number of high-burden countries, with ten African nations accounting for ~66% of global cases in 2017. Following large reductions in burden early this century, since 2015 progress has stalled, leading WHO and RBMP to coordinate the High Burden to High Impact initiative - a country-led program centred around a new paradigm in malaria control: intervention mixes which are efficiently targeted using a deep understanding of human, vector, and parasite ecologies. For such an approach to be feasible, programs require timely and accurate estimates of spatio-temporal variance in risk. The traditional data used in malaria risk estimation - cross-sectional parasite rate surveys - are spatially rich but infrequent. However, ongoing investment in strengthened routine health surveillance systems has resulted in an improved stream of robust, near-real-time, longitudinal information on the burden of malaria in health facilities. Synthesising these sources of data, each giving a partial but complementary view of the full picture, is key to producing these maximally accurate spatio-temporal estimates of malaria infection and morbidity. Here we present a new modelling framework to achieve this synthesis. We highlight Mozambique here thanks to its wide-reaching National Health Service and range of transmission settings. After adjusting incidence rates for variations in access to care and data quality, the framework jointly infers *Pf*PR and incidence, with a mechanistic model of fever aetiology determining a plausible mapping between community PR and observed cases in clinics. This extension of geostatistical techniques allows for the explicit inclusion of the prophylactic effect of antimalarials; and the role of non-malarial fevers prompting otherwise asymptomatic *Pf* infections to seek care. The outputs of this framework offer transformational improvements in risk stratification for malaria control planning: it provides detail on seasonal variation in burden, a country-specific *Pf*PR-incidence relationship; and a suite of spatio-temporally granular maps with principled uncertainty.

0319

CHARACTERIZING CASES OF FATAL SEVERE MALARIA IN THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) SITES OF MANHIÇA AND QUELIMANE, MOZAMBIQUE

Rosauro Varo[1], Elisio Xerinda[2], Sara Ajanovic[1], Natalia Rakislova[1], Carla Carrilho[3], Juan Carlos Hurtado[1], Milton Kincardett[2], Dercio Jordao[2], Dianna M. Blau[4], Khátia Munguambe[2], Inácio Mandomando[2], Quique Bassat[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique, [3]Service of Pathology, Maputo Central Hospital, Maputo, Mozambique, [4]Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

More than 5 million deaths occur annually in children <5 years of age globally, with malaria accounting for approximately 8% of these deaths. In 2020, there were 2-4M severe malaria cases and 627,000 malaria deaths worldwide, with 94% of these deaths occurring in Sub-Saharan Africa, mainly affecting children <5 years of age. Between December 2016 and December 2021, as part of the Child Health and Mortality Prevention Surveillance (CHAMPS) network, minimally invasive tissue sampling (MITS) were conducted postmortem in Manhiça and Quelimane district areas to ascertain the cause of death of 505 children <5 years of age and stillbirths, after written informed consent was obtained. Of those deaths, 43 (8,5%) were in infants and 73 (14,4%) were in children aged 12-<60 months. For each case, clinical, microbiological, molecular, histopathological and verbal autopsy data were reviewed by a multidisciplinary panel of local experts who determined the chain of events leading to death using the WHO ICD-10 coding system. Of 116 deaths in infants/children with a cause of death determined, malaria was in the causal chain leading to death in 20 (17%), being in 17 (15%) considered the underlying cause (2 infants and 15 children between 12 and 60 months). Of these malaria deaths 15 (75%) were specified as cerebral malaria and 10 children had more than one cause of death determined. Among these malaria deaths with multiple causes, 3 were HIV positive, 5 had also pneumonia (2 aspiration pneumonia, 1 pneumonia due to *H. influenzae*, 1 pneumonia due to gram-negative bacteria and 1 polymicrobial pneumonia (*S. pneumoniae, H. influenzae, M. catarrhalis*), 1 had polymicrobial sepsis (*S. pneumoniae, K. pneumoniae, Salmonella spp*), 1 had anemia and 1 had hypoglycemia. Considering other significant conditions contributing to death we found: anemia, acute gastroenteritis, aspiration pneumonia, acute malnutrition, hypoglycaemia and HIV exposure. Malaria remains a leading cause of death in children in Mozambique. Understanding the full chain of events leading to death and associated conditions could help to guide better strategies for research and mortality prevention.

0320

AN EVOLUTION FROM A PREDOMINANT K1 ALLELIC VARIANT TO MAD20 OF MSP1 GENE BETWEEN 2015 TO 2019 IN METEHARA, SOUTHEAST ETHIOPIA

Abeba G. Reda[1], Alebachew A. Messele[2], Hussein H. Mohammed[1], Ashenafi AS Assefa[1], Lemu L. Golassa[3], Hassen Hs Mamo[4]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]Aklilu Lemma Institute of Pathobiology, Addis Ababa, Ethiopia, [3]Aklilu Lemma Institute of Pathobiology, Addis Ababa University, Addis Ababa, Ethiopia, [4]Department of Microbial, Cellular and Molecular Biology, Addis Ababa University, Addis Ababa, Ethiopia

In this study, we try to investigate the temporal dynamics of genetic diversity and multiplicity as a result of evolutionary change in the genes that contribute to *Plasmodium falciparum* infection. We used a cross-sectional study design to carried out. From eighty-three dry blood spots from malaria patients who were screened for *P. falciparum* mono-infection by QPCR Eighty three confirmed P. falciparum were genotyping to merozoite surface protein 1,2 and glutamate-rich protein using nested PCR. Seventy (84.3%) of the isolates were successfully genotyped for all three target genes in In 2015 and 2019, the allelic distributions of the three genes differed significantly (P= 0.001). Overall, the most common allelic families for msp1 and msp2 were K1 and FC27 respectively. For glurp, eight distinct genotypes were identified. Genotyping of msp1, msp2 and glurp was 25 (86.2%), 25 (86.2%) and 24 (82.2%) respectively. K1, MAD20 and RO33 all have 19(65.5%), 3(10.3%) and 3(10.3%) msp1 allelic families respectively. Over all the multiplicity of infection was 1.67 (95 percent CI 1.54-1.74) and the heterozygosity index for msp1, msp2, and glurp was 0.48, 0.70, and 0.55 respectively. This study provides current information on the genetic diversity of P. falciparum populations in five-year intervals, The progression of the dominant K1 variant from 2015 to MAD20 variant in 2019 was observed in this study.

0321

USING TREE-BASED IDENTITY-BY-DESCENT SEGMENTS TO EVALUATE THE EFFECT OF DIRECTIONAL SELECTION ON THE ESTIMATION OF RECENT EFFECTIVE POPULATION SIZE AND POPULATION STRUCTURE IN *PLASMODIUM FALCIPARUM*

Bing Guo[1], Michele D. Spring[2], Mariusz Wojnarski[2], Brian A. Vesely[2], Joana C. Silva[1], David Serre[1], Norman C. Waters[2], Shannon Takala-Harrison[3], Timothy D. O'Connor[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Intensive malaria elimination efforts to counter the spread of multidrug-resistant *Plasmodium falciparum* (*Pf*) have led to a dramatic decrease in malaria cases in the Greater Mekong Subregion, with a corresponding reduced parasite effective population size (N_e) and more fragmented population structure. Estimates of parasite population demography are critical for monitoring sources and sinks of malaria transmission and the impact of targeted interventions in reducing malaria. Identity-by-descent (IBD) has been widely used in human studies to estimate N_e and population structure in recent time scales. However, strong positive selection related to antimalarial drug resistance in *Pf* can potentially cause inaccurate estimation of parasite demography. Here, we simulated positive selection using coalescent (msprime) and forward simulators (SLiM), implemented a tree-based true IBD-estimation algorithm, and directly evaluated how selection affects IBD-based demography estimation in *Pf*. With high-quality IBD as input, we found that selection strength, duration, and starting frequency of the selected allele all affect IBD coverage (enrichment by position) and length distribution, and thus estimation of parasite N_e (IBDNe). The effects are further aggravated when reductions in N_e occur in recent time frames. We found that removing IBD segments within the high-IBD region associated with selection can reduce selection-induced bias in N_e estimation. By simulating a multi-subpopulation model, we found that strong positive selection increases within and inter-population IBD sharing and blurs underlying structure; however, IBD filtration allows identification of finer-scale, more accurate population structure. We have jointly called variants from whole genome sequence data for >2300 Southeast Asian *Pf* isolates from MalariaGen *Pf* v6 and in-house data sets. We will evaluate the effects of drug resistance-related positive selection on the estimation of *Pf* demography by including and excluding regions predicted to be under selection and examine the necessity of selection-adjusted genomic analysis for low transmission settings.

CHROMOSOME SPLITTING OF *PLASMODIUM BERGHEI* USING THE CRISPR/CAS9 SYSTEM

Daniel Addo-Gyan[1], Haruka Matsushita[1], Sora Enya[1], Nishi Tsubasa[2], Yuda Masao[2], Naoaki Shinzawa[1], Shiroh Iwanaga[3]

[1]Tokyo Medical And Dental university, Tokyo, Japan, [2]Mie University, Mie, Japan, [3]Osaka University, Osaka, Japan

Spatial arrangement of chromosomes is responsible for gene expression in *Plasmodium* parasites. However, methods for rearranging chromosomes have not been established, which makes it difficult to investigate its role in detail. Here, we report a method for splitting chromosome in rodent malaria parasite by CRISPR/Cas9 system using fragments in which a telomere and a centromere were incorporated. The resultant split chromosomes segregated accurately into daughter parasites by the centromere. In addition, elongation of de novo telomeres were observed, indicating its proper function. Furthermore, chromosome splitting had no effect on development of parasites. Splitting of the chromosome is expected to alter its spatial arrangement, and our method will thus be useful for investigating its biological role related with gene expression.

MICROSATELLITE CHARACTERIZATION AND ANTIGENIC SEQUENCING OF KENYAN *PLASMODIUM FALCIPARUM* FIELD ISOLATES FOR DOWN SELECTION OF NEW STRAINS FOR USE IN CONTROLLED HUMAN MALARIA INFECTION (CHMI) STUDIES

Mariah Desroches[1], Elgin Akin[1], Janette Moch[1], Ben Andagalu[2], Alexander Pichugin[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]United States Army Medical Research Directorate - Kenya Medical Research Institute, Nairobi, Kenya

The development of an effective malaria vaccine would be monumental in helping control and eliminate malarial infections, which are a global risk to human health. Due to the low efficacy of the current malaria vaccines, it is essential that challenge strains used during vaccine and drug trials accurately reflect the genetic diversity of *Plasmodium falciparum* strains in the field. Currently, only four *Pf* strains are being used as challenge strains during Controlled Human Malaria Infection (CHMI) studies that test vaccine and drug efficacy. In order to identify additional strains for future use in CHMI studies that reflect the genetic diversity present in the field, we are receiving blood samples from subjects infected with *Pf* from clinical sites in Colombia, Ghana, Kenya, and Thailand with the intent to identify a strain that is genetically distinct from the current *Pf* challenge strains for use in CHMI studies. To date, eight isolates have been received from USAMRD-Africa in Kenya. *Pf* strains from these samples have been successfully culture adapted and genetically characterized by both microsatellite (MS) analysis of twelve loci and Sanger sequencing of the genes CSP, AMA1, MSP1, and MSP2. Two of the eight samples were found to be polyclonal and were subsequently cloned via limiting dilutions in an effort to isolate parasites into monoclonal cultures. The cloned cultures were reassessed via MS analysis to ensure they were singularly clonal before proceeding with antigenic sequencing. In total, twelve different strains have been identified, assayed via MS analysis, and sequenced. All twelve Kenyan strains were genetically distinct from 3D7 and 7G8, the current strains used for CHMI studies, based on targeted sequencing. In addition, they appear to cluster similarly with other East and West African *Pf* strains based on genetic distance matrices constructed from sequencing data. These strains will ultimately be compared against new isolates, tested for drug susceptibility and gametocyte formation, optimized for infection of mosquitos, assayed for liver cell infectivity, and considered for future *Pf* strains in CHMI trials.

0324

FROM SNPS TO MICROHAPLOTYPES - SEARCHING FOR GEOGRAPHIC SIGNALS IN *PLASMODIUM FALCIPARUM* DNA

Debayan Datta[1], Andres Aranda-Diaz[2], Arnau Pujol Vallribera[1], Eduard Rovira Vallbona[1], Simone Boene[3], Clemente da Silva[3], Arlindo Chidimatembue[3], Gloria Matambisso[3], James Colborn[4], Sofonias Tessema[5], Nicholas Hathaway[2], Rose Zulliger[6], Pedro Aide[3], Abuchahama Saifodine[7], Baltazar Candrinho[8], Francisco Saute[3], Bryan Greenhouse[2], Alfredo Mayor[1]

[1]ISGlobal, Hospital Clínic – Universitat de Barcelona, Barcelona, Spain, [2]EPPIcenter Research Program, Division of HIV, Infectious Diseases, and Global Medicine, Department of Medicine, UCSF, San Francisco, CA, United States, [3]Centro de Investigação em Saúde de Manhiça (CISM), Manhica, Mozambique, [4]Clinton Health Access Initiative, Maputo, Mozambique, [5]Institute of Pathogen Genomics, Africa Centres for Disease Control and Prevention, Addis Ababa, Ethiopia, [6]U.S. President's Malaria Initiative, USAID, Washington, DC, United States, [7]U.S. President's Malaria Initiative, USAID, Maputo, Mozambique, [8]National Malaria Control Programme, Ministry of Health, Maputo, Mozambique

Modeling *Plasmodium falciparum* spatial population structure may contribute to strategies for malaria elimination by helping identify the origin and spread of infections. The wealth of next generation sequencing data that has been acquired from natural infections in endemic areas presents an opportunity to understand geographical patterns of parasite populations in great detail. Here, we use a machine learning algorithm to evaluate the spatial structure of *Plasmodium falciparum* infections in Mozambique. We used whole genome sequencing data from 832 samples from 7 provinces of Mozambique collected between 2015 -2019, and extracted allelic information from high quality SNPs and microhaplotypes with high diversity. We calculated genetic distances between pairs of samples using SNP genotypes, and performed Principal Coordinates analysis on the genetic distance matrix. We then applied the Random Forests machine learning algorithm on microhaplotype alleles to classify samples based on geographical location. We assessed allele contribution to geographic differentiation using the variable importance rank from the Random Forests classifier. Our results show that using either whole-genome level high quality SNPs or a selection of high-diversity microhaplotypes, samples can be classified at a regional level between Northern and Southern Mozambique. However, at the province level, the classifier fails to accurately predict sample location. While this regional structure may be sufficient to infer parasite importation in elimination settings in southern Mozambique, further analyses are ongoing to identify whether finer-scale population structure is reproducibly detectable at the province level among *Plasmodium falciparum* isolates in Mozambique, using existing and prospectively collected data.

0325

PLASMODIUM FALCIPARUM GENETIC DIVERSITY IN COINCIDENT HUMAN AND MOSQUITO HOSTS

Zena Lapp[1], Andrew A. Obala[2], Lucy Abel[3], David A. Rasmussen[4], Kelsey M. Sumner[5], Elizabeth Freedman[1], Steve M. Taylor[1], Wendy Prudhomme-O'Meara[1]

[1]Duke University, Durham, NC, United States, [2]Moi University, Eldoret, Kenya, [3]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [4]North Carolina State University, Raleigh, NC, United States, [5]University of North Carolina, Chapel Hill, NC, United States

Population genetic diversity of *Plasmodium falciparum* antigenic loci is high despite large bottlenecks in population size during the parasite life cycle. The extent of this diversity in human blood-stage infections, following expansion from a small number of liver-stage schizonts, has been well described. However, little is known about parasite genetic diversity in the vector, where a similar bottleneck and expansion occurs following parasite mating and where parasite genotypes from several different human infections may accumulate. We assessed parasite genetic diversity within human and mosquito *P. falciparum* infections collected

from the same households during a 14-month longitudinal cohort study using amplicon deep-sequencing of two antigenic gene fragments (*ama1* and *csp*). To a prior set of infected humans (n = 1175/2813 with 86.2% sequencing success) and mosquito abdomens (n = 199/1448 with 95.5% sequencing success), we added *ama1* and *csp* haplotypes from infected mosquito heads (n = 134/1448 with 98.5% sequencing success). Across all sample types we observed 456 *ama1* and 289 *csp* unique haplotypes. Only 20.0% (*ama1*) and 21.5% (*csp*) of these haplotypes were shared between humans and mosquitoes, although these made up 89.4% (*ama1*) and 93.9% (*csp*) of the total set of sequenced haplotypes. While both hosts contained many rare haplotypes, population genetic metrics indicated that the overall and sample-level parasite populations were more diverse in mosquitoes than in humans, and infections were more likely to harbor a dominant haplotype in human than in mosquito infections (as determined by the proportion of sequenced reads). Finally, within a given mosquito there was little overlap in genetic composition of the abdomen and head, suggesting that infections may be cleared from the abdomen during the course of a mosquito's lifespan. Taken together, our observations provide evidence for the role of the mosquito vector in maintaining the diversity of malaria parasite populations.

0326

NOVEL MOLECULAR INVERSION PROBES FOR HIGH-THROUGHPUT GENOTYPING OF *PLASMODIUM VIVAX* POPULATIONS

Zachary R. Popkin-Hall[1], Karamoko Niaré[2], Rebecca DeFeo[2], Abebe A. Fola[2], Özkan Aydemir[3], Claudia F. Gaither[1], David J. Giesbrecht[2], Jeffrey A. Bailey[2], Jonathan J. Juliano[1], Hugo O. Valdivia[4]

Over the last decade, genomic epidemiology of *Plasmodium falciparum* has become a useful tool for studying population movement, antimalarial resistance, importation, and other issues around elimination. Molecular inversion probes (MIPs) provide a highly multiplex and highly scalable genotyping approach that has provided valuable information about *P. falciparum* population genomics in Central Africa, East Africa, and the Horn of Africa. MIPs enable genome-wide coverage in an efficient and affordable fashion. *Plasmodium vivax* is the most widespread human malaria pathogen, with a global distribution, including in sub-Saharan Africa. In many areas where *P. falciparum* control is working, *P. vivax* has become an emerging malaria threat. As a result, there has been a recent proliferation in global *Plasmodium vivax* genomics studies, as well as a superior genome assembly from a Papua New Guinean isolate. Leveraging the success of MIPs in *P. falciparum*, we have developed MIP panels for the investigation of *P. vivax* populations. These four MIP panels include one containing 741 probes spanning multiple known genes of interest (e.g. reticulocyte binding proteins, Duffy binding proteins, potential vaccine targets, potential drug resistance genes, and diversity markers) and three MIP panels containing 1,625 probes designed using SNPs generated from all known published *P. vivax* genomes as well as newly generated genomes from Peru and the DRC. The SNP panels include a panel based on high F_{ST} SNPS that differentiate populations from different global geographic regions and two panels based on neutral SNPs. Using these panels, we have investigated the population structure from 689 Peruvian *P. vivax* samples collected by NAMRU in the region around Iquitos. We describe local connectivity between different populations of parasites as well as diversity in proteins involved in invasion, resistance, and vaccine candidates.

0327

STRONG FINE-SCALE SPATIAL AND TEMPORAL STRUCTURE OF RESIDUAL *PLASMODIUM FALCIPARUM* IN ZANZIBAR DETECTED THROUGH MULTIPLEXED AMPLICON SEQUENCING AND MINION SEQUENCING

Aurel Holzschuh[1], Anita Lerch[1], Bakar S. Fakih[2], Logan Stuck[3], Abdul-wahid H. Al-mafazy[4], Abdullah Ali[5], Manuel W. Hetzel[2], Joshua Yukich[3], Cristian Koepfli[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [3]Tulane University, New Orleans, LA, United States, [4]Research Triangle Institute (RTI) International, Zanzibar, United Republic of Tanzania, [5]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania

Over the past 15 years, Zanzibar has made great strides towards malaria elimination; yet progress has stalled despite access to efficacious antimalarials and good vector control coverage. Reactive case detection (RCD) using RDTs is routinely conducted by the Zanzibar Malaria Elimination Program (ZAMEP). To better understand residual *Plasmodium falciparum* transmission dynamics, we characterized the genetic diversity of parasites circulating within 5 districts covering both main islands. We sequenced 518 *P. falciparum* dried blood spot (DBS) samples at 35 loci using a novel, highly multiplexed droplet digital PCR (ddPCR)-based high-throughput amplicon deep sequencing method. Sequencing data was obtained at high coverage (median 98.6%) in DBS with ≥10 parasites/μL. The parasite population in Zanzibar was highly diverse (average H_E = 0.73) and 70% of infections were polyclonal. Infections in people with a recent travel history could not be distinguished from infections in individuals who had not traveled but had a significantly higher MOI. Strong fine-scale spatial and temporal structure in local parasite populations was observed, with two clearly separated clusters on Pemba Island. Relatedness analysis by identity-by-descent (IBD) revealed multiple near-clonal clusters in villages, linked to clinical cases. Travel history combined with genomic data revealed spread of these infections over the archipelago. No *kelch13* mutations were identified, but high prevalence of known resistance-associated mutations in *dhfr*, *dhps*, *mdr1*, and *mdr2* genes. No *hrp2/hrp3* deletions were found. A smaller panel of 6 highly informative microhaplotypes and 6 full-length drug-resistance markers was optimized for *MinION* sequencing and is currently being evaluated for in-country sequencing in Zanzibar. In conclusion, high-resolution *P. falciparum* genotyping identified pronounced population structure in Zanzibar. Closely related parasites within households point to clinical cases as important identifiers of transmission. Targeted interventions should be tested for the control of isolated parasite populations on the archipelago.

0328

RELATEDNESS OF *PLASMODIUM FALCIPARUM* WITH *PFHRP2* AND *PFHRP3* DELETIONS IN THE HORN OF AFRICA COMPARED TO OTHER GLOBAL ISOLATES

Eric Rogier[1], Jessica N. McCaffery[1], Mohamed Mohamed[2], Camelia Herman[1], Doug Nace[1], Rachel Daniels[3], Naomi Lucchi[1], Sophie Jones[1], Ira Goldman[1], Michael Aidoo[1], Qin Chang[4], Edie Kemenang[5], Ghasem Zamani[5], Venkatachalam Udhayakumar[1], Jane A. Cunningham[6]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Hôpital Général Peltier, Djibouti City, Djibouti, [3]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [4]Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia, [5]World Health Organization, Eastern Mediterranean, Switzerland, [6]World Health Organization, Geneva, Switzerland

Deletions of *pfhrp2 (*and paralogue *pfhrp3*, *pfhrp2/3*) genes threaten HRP2/3 antigen-based rapid diagnostic test (RDT) diagnosis of *Plasmodium falciparum.* Though *pfhrp2/3* deletions have been found in *P. falciparum* populations in different parts of the world, the high prevalence of deletions in the Horn of Africa (HoA) have provoked recommendations for alternate diagnostics for detecting *P. falciparum* infection in Ethiopia,

Eritrea, and Djibouti. It is unclear if deletions in the *pfhrp2/3* genes observed in different global settings are a result of parasite importation events or *de novo* gene deletions on endemic background lineages. Molecular data for a panel of seven *P. falciparum* neutral microsatellite (NMS) genomic markers was gathered for *P. falciparum* samples from three countries in the HoA and 11 other global locations for a total of 622 specimens. Relatedness among isolates was assessed by *pfhrp2/3* genotype through principal component analysis (PCA) and estimates for Hendrick Pairwise G_{ST}. Regardless of *pfhrp2/3* genotype, *P. falciparum* within the HoA was more related to other African isolates compared to Asian and New World parasites. For isolates showing *pfhrp2* deletions, Ethiopian, Djiboutian, and Eritrean parasites were all closely related (Pairwise G_{ST} <0.85) compared to *pfhrp2* deleted strains from Sudan, Peru, and Suriname (Pairwise G_{ST} >0.92), with similar findings in comparing strains with *pfhrp3* single deletions. Within the HoA, the relatedness of Ethiopian and Djiboutian gene deleted isolates was highest (Pairwise G_{ST}=0.68) compared with Eritrean and Djiboutian (Pairwise G_{ST}=0.77) or Eritrean and Ethiopian (Pairwise G_{ST}=0.84) isolates. *P. falciparum* with deletions in *pfhrp2/3* genes appear to have arisen *de novo* within background lineages in the HoA, and the evidence from this current study do not support the hypothesis that these parasites have been imported from other global sites. Ethiopian and Djiboutian deleted parasites within the HoA appear to have the most recent common ancestor.

0329

TARGETED NEXT GENERATION GENOMIC SURVEILLANCE APPROACHES TO CHARACTERIZE *PLASMODIUM VIVAX* RELATEDNESS

Sasha V. Siegel[1], Roberto Amato[1], Mariana Kleinecke[2], Georgia Whitton[1], Jutta Marfurt[2], Hidayat Trimarsanto[3], Richard Pearson[1], Angela Rumaseb[2], Ric N. Price[2], Sarah Auburn[2]

[1]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [2]Global and Tropical Health Division, Menzies School of Health Research and Charles Darwin University, Darwin, Australia, [3]Eijkman Institute for Molecular Biology, Jakarta, Indonesia

Critical knowledge gaps remain in *Plasmodium vivax* epidemiology, largely due to the challenge of defining parasite relapse periodicity - this requires characterization of recurrent parasitemia that arise from either relapses from dormant hypnozoites, recrudescences, or reinfections. Molecular approaches in combination with relatedness inference and time-to-event analysis between the infective episodes offer great potential to resolve this. We have used microhaplotype markers to create a genotyping barcode for defining relatedness between recurrent infections. Using a global collection of 1,895 *P. vivax* genomes, we have selected 92 short (200 base pair) microhaplotype barcoding regions containing several high-diversity SNPs (single nucleotide polymorphisms) that overcome limitations of standard biallelic SNP barcodes (global mean diversity = 0.78), in addition to 4 putative drug resistance assay amplicon targets (PvMDR1, DHPS) and 2 mitochondrial amplicons that discriminate *Plasmodium* species. Our 98-assay Illumina panel successfully reconstructed relatedness relationships of 11 *P. vivax* recurrent pairs, and correctly classified geographical clustering of diverse populations from 17 different countries. In this presentation we will present evidence that the panel performs well in connectivity analyses with sufficient resolution to identify a major clonal outbreak in Malaysia, and subtle substructure in the region that were previously only possible with whole genome sequencing approaches. The assay panel is being refined and optimized to genotype parasite isolates from diverse geographical regions, which will be analyzed and contextualized using and end-to-end surveillance platform and will inform epidemiology and programmatic strategies for *P. vivax* control and elimination efforts.

0330

ESTIMATING MULTIPLICITY OF INFECTION FROM MULTIPLE GENETIC MARKERS

George Kamanga, Kristan A. Schneider

Hochschule Mittweida University of Applied Sciences, Mittweida, Germany

Estimating multiplicity of infection (MOI)from multiple genetic markers The importance of estimating multiplicity of infection (MOI) as part of molecular surveillance of infectious diseases is well recognized, particularly in malaria. Here, MOI is defined as the number of super-infections due to the occurrence of multiple infectious events. Due to the lack of translational tools required for mainstream use by researchers with varying expertise, MOI estimates are often based on heuristic approximations, which are simple to use but biased. This is particularly true when estimating MOI based on molecular information from several genetic/ molecular markers (multi-locus data). Such data is often characterized by two problems: (i)missing data at one or more markers is common; (ii) the number of possible haplotypes (and hence parameters to be estimated) increases geometrically with the number of markers. In particular, although the availability of several markers increases the granularity for molecular surveillance, sample size is depleted due to missing information while the number of parameters increases. This problem is avoided when estimating MOI for each molecular marker separately. However, the estimates vary between the markers, and the variance for each marker can be substantial, leading to little confidence in the estimates. To overcome these drawbacks, we propose a maximum-likelihood method to estimate MOI from several markers, which disregards haplotype structure by treating the markers as independent. The method yields one estimate for the distribution of MOI and the marginal frequencies at each marker locus. The method avoids the problem of over parameterization and the depletion of sample size due to missing data. The maximum-likelihood estimate is readily obtained by the EM-algorithm, which is implemented in an easy-to-use R-script. Based on numerical simulations, we report the accuracy and precision of this method (i.e., bias and variance of the estimator). As examples we apply the method to malaria molecular data from Kenya and Cameroon to estimate the distributionof MOI and allele frequency spectra.

0331

A FORWARD GENETIC SCREEN REVEALS *PLASMODIUM FALCIPARUM* GENES LINKED TO SURVIVAL IN SICKLE-TRAIT CELLS

Camilla V. Pires[1], Jenna Oberstaller[1], Chengqi Wang[1], Min Zhang[1], Thomas D. Otto[2], Julian C. Rayner[3], Steve M. Taylor[4], John H. Adams[1]

[1]University of South Florida, Tampa, FL, United States, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom, [4]Duke University, Durham, NC, United States

Malaria causes over a half million deaths and >200 million cases of clinical disease annually, but sickle-trait cell (HbAS), representing individuals heterozygous for sickle hemoglobin, confers strong protection against lethal *Plasmodium falciparum* malaria, reducing the risk of severe, life-threatening malaria by over 90%. The mechanisms of this protection remain incompletely understood, but the redox imbalance of sickle-trait cells creates an intraerythrocytic oxidative stress microenvironment that limits parasite growth and virulence. A major protective role of HbAS arises from a cascade of events that starts with the redox imbalance and leads to aberrant intraerythrocytic actin remodeling in infected HbAS RBCs and reduced cytoadherence. Here, we applied a forward-genetic screen approach using *P. falciparum* mutants created by random *piggyBac (pB)* mutagenesis to elucidate genotype-phenotype associations of molecular mechanisms of parasite responses and survival in sickle-trait cells. We performed a sickle-trait *pB* screen by comparing survival in RBCs with HbAS and HbAA control of a 128-mutant *P. falciparum* library with broad genome-wide GO coverage. After cultivating *in vitro* over three and six parasite life cycles, we used Quantitative Insertion Site Sequencing counts of each *pB* insertion within the 128-*pB* library to score each

mutant's phenotype growth response in sickle-trait cells compared to that under ideal culture conditions. Our results revealed parasite sensitivity to sickle-trait cells is linked to cythoadhesion, redox response, exported protein, lipid metabolism, transcription, and translation. Notably, these adaptive response mechanisms in *P. falciparum* to survive in HbAS RBCs overlap with those we have previously observed as to oxidative stress sensitive phenotypes. This first small-scale screen of sickle-trait cells bring important insights to understand the host-parasite interactions and parasite survival mechanisms associated with HbAS that may help guide future development of therapies to treat or prevent severe, life-threatening falciparum malaria.

0332

EFFICACY OF ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN DJOUGOU AND POBÈ IN THE REPUBLIC OF BENIN, 2020

Irene Cavros[1], Augustin Kpemasse[2], Ahmed Saadani Hassani[3], Alexis Sacca Yarou Maye[2], Ramani Saliou[2], Patrick Condo[4], Cyriaque Dossou Affoukou[2], Rotimi Adjamonsi Ewedje[5], Boucheix Houndekon[5], Yaye D. Ndiaye[6], Awa Bineta Deme[6], Daouda Ndiaye[6], Aurore Ogouyemi Hounto[2]

[1]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Benin Ministry of Health, National Malaria Control Program, Cotonou, Benin, [3]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Cotonou, Benin, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Cotonou, Benin, [5]Benin Ministry of Health, Cotonou, Benin, [6]International Research and Training Center in Applied Genomics for Health Surveillance, Dakar, Senegal

In Benin, malaria is the leading cause of childhood morbidity and mortality; early diagnosis and treatment with an effective antimalarial is a key strategy for malaria prevention and control. Artemether-lumefantrine (AL), an artemisinin-based combination therapy, was introduced in 2005 as the first-line treatment for uncomplicated *Plasmodium falciparum* malaria. In accordance with the World Health Organization (WHO) recommendation for regular monitoring of the efficacy of antimalarial treatments, a therapeutic efficacy study of AL was conducted. Between June and December of 2020, febrile patients aged 6-59 months with confirmed malaria (2,000-200,000 parasites/μL) were treated with AL for 3 days. Clinical and parasitological response was monitored in a 28-day in vivo efficacy trial in two sentinel sites in Benin: Djougou in the northwest and Pobè in the southeast. Polymerase chain reaction (PCR) using *msp1*, *msp2*, and *glurp* was used to distinguish recrudescence from reinfection in treatment failures to calculate PCR-corrected day 28 treatment efficacy. Molecular analysis of *K13* gene mutations at codon C580Y associated with artemisinin resistance was also performed. A total of 187 patients were included in the study, with zero lost to follow up. There were 7 clinical/parasitological failures (5 in Pobè and 2 in Djougou.) The day 28 uncorrected AL efficacy per site was 96.5% (111/115) in Pobè and 93.0% (67/72) in Djougou. PCR-corrected AL efficacy per site was 99.1% (114/115) in Pobè and 95.8% (69/72) in Djougou. The analysis of *K13* codon C580Y showed no evidence of mutations. Results from this study exceed the WHO's 90% acceptable treatment efficacy threshold, indicating that AL, the current first line treatment for malaria in Benin, remains effective. However, continued monitoring of clinical and parasitological efficacy of antimalarials and molecular resistance markers every two years is important to ensure treatments remain efficacious and to allow Benin's Ministry of Health to continue to make informed treatment policy decisions for malaria control.

Genetic epidemiology can reveal parasite population structure, transmission intensity, and provide actionable data to assess malaria interventions. Coupled with geographic information, genomic data can further identify transmission hotspots, spatial connectivity, and parasite movement by humans or mosquitos over time and space. We carried out longitudinal genomic surveillance (8 visits over 2 years) in a cohort of 70 participants from across Thiès, Senegal—a region of very low malaria transmission (EIR <1). Genetic identity by state (IBS), was established using a 24-SNP molecular barcode, identity by descent (IBD) was calculated from whole genome sequence data, and a hierarchical Bayesian regression model was used to establish genetic and spatial relationships. Participants were living in "daaras" (religious boarding schools); only 16.9% participants reported bednet use; and 4 participants were re-infected over the follow-up period. Limited genetic diversity [nucleotide diversity (SNPϖ) = 0.274; He = 0.371 (0.341, 0.401); genotypic richness index R of 0.425], and a high frequency of monogenomic infections (90.5% (67/74)) were observed. Genomic haplotypes were shared within and persist across malaria transmission seasons (8 haplotypes shared between 40 patients). Genetically similar parasites were clustered within households and parasite genetic similarity declined with increasing distance. There was a significant positive association between physical and genetic distance by year with a 31% [95% credible interval, (11. 58)] per km increase in separation in 2015 and a 16% [95% credible interval, ((2.31)] per km increase in 2016. A similar trend was observed when the data were analyzed within a year with an increase of 4% [95% credible interval, (0.8)] per km increase in separation. IBD analysis of haplotypes persisting for multiple years showed that identical parasites (clonal by IBS) were generally identical across the

whole genome, sharing from 70 – 100% of their genome sequence. This works shows how genomic and epidemiologic data can be used for surveillance and detection of fine-scale malaria transmission patterns.

0334

ASSESSMENT OF THE IMPACT OF PREGNANCY AND MALARIA INFECTION ON THE VARIATION OF NEUTROPHIL LEVELS IN WOMEN FROM SAN, MALI

Severely decreased neutrophils levels can have life-threatening implications. Probably due immunological and hormonal changes, pregnant women are more likely to get malaria than non-pregnant women. It is essential to understand whether pregnancy induces changes in neutrophil levels and thereby poses a threat to the health of gravidae. This is a cross-sectional analytical study assessing the impact of malaria in pregnancy on neutrophil level variation. The study was conducted in San Health District (Mali) and involved pregnant women infected or not by Plasmodium falciparum and non-pregnant healthy volunteers. Subjects were categorised as having neutropenia, normal neutrophil levels and neutrophilia. A linear regression model allowed to determine factors associated with neutrophil level variations in pregnant women. White blood cells mean count (4416.3, SD= 1313.8) while lower in healthy non-pregnant subjects, decreased from pregnant women without malaria infection (7673.8, SD= 10515.6) to pregnant women with malaria infection (5493.2, SD= 1528.6). Pregnant women in the malaria infected and non-infected groups had each 48.5% (98/ 202) cases of neutrophilia (48.5%). Surprisingly, 67 of the 71 cases of neutropenia (94.4%) observed in this study were in apparently healthy non-pregnant individuals. Categorising gestational age, the mean percentage of neutrophils level was significantly lower ($p<0.001$) in the first trimester (49.92%) compared to the second trimester of pregnancy (62.01%). A linear regression model showed that compared to early pregnancy, the second (OR= 3.301e+05, $p= 0.001$) and the third trimester (OR= 5.36e+05, $p< 0.001$) were strongly associated with an increase in neutrophil levels. The model also showed that each increase in malaria parasite density multiplies the neutrophil levels by 1.0001 times (OR= 1.0001, $p< 0.001$). In conclusion, data from Mali shows benign neutropenia in healthy non-pregnant people. This study suggests that, in absence of malaria infection, the second trimester of pregnancy is strongly associated with an increase in neutrophil levels.

EVALUATION OF NATURALLY ACQUIRED IMMUNITY AGAINST NOVEL *PLASMODIUM VIVAX* PRE-ERYTHROCYTIC ANTIGENS IN HUMAN POPULATION FROM LOW ENDEMIC MALARIA REGION

Julio A. Ventocilla[1], L. Lorena Tapia[2], Joao Aguiar[3], Brandon K. Wilder[2]

[1]Vysnova Partners Inc / NAMRU-6, Lima, Peru, [2]U.S. Naval Medical Research Unit No.6, Lima-Peru (NAMRU-6), Lima, Peru, [3]Naval Medical Research Center (NMRC) and CAMRIS International Inc., Maryland, MD, United States

Plasmodium vivax (*Pv*) represents the most geographically widespread human malaria. Targeting the pre-erythrocytic (PE) stage of the parasite life cycle is especially appealing for *Pv* vaccines as even a partially-protective intervention could reduce the hypnozoite reserve responsible for disease and transmission. Here, we explore naturally acquired immunity to a panel of *Pv* PE antigens as a first step to enable vaccine development and to better understand naturally acquired PE immunity. To this end, we screened samples from *Pv* infected individuals from a low endemic malaria region in the Peruvian Amazon Basin for immunity to 12 *Pv* PE antigens by ELISA and ELISpot assays. In these samples, all PE antigens showed positive antibody reactivity with prevalence of 58-99%. The magnitude of the IgG antibody response against PE antigens was lower compared with blood stage antigens MSP-1 and DBP-II although in general, titers persisted better for PE antigens (average decrease of 6% for PE antigens and 43% for MSP1 over 6 months). A significant correlation between IgG antibodies levels and number of previous malaria episodes was observed only for blood stage antigens. Volunteers with high IgG responses to PE and Blood stage antigens showed a significantly lower parasitemia compared with low IgG responders (1921 vs 4663 par/µl, $p=0.014$). Analysis between antibody levels and parasitemia against 5 PE antigens showed a significant but low-medium negative correlation (Rho: 0.23-0.39,$p<0.05$). Our ELISpot analysis showed a positive T cell response in 35% vs 9-35% of total volunteers against blood stage antigen MSP1 and PE antigens, respectively, with no correlation with IgG responses. These results demonstrate clear humoral and T cell responses against *Pv* PE antigens in individuals naturally infected with *P. vivax*. In addition, these results provide data on some characteristics of antibodies to PE antigens (immunogenicity, durability, boosting after malaria episodes and correlations with parasitemia at time of disease) that should be further explored to inform selection of novel PE antigens for use in the development of new malaria vaccine candidates.

INITIAL RTS,S/AS01 ANTIBODY RESPONSE AND EFFICACY ARE POSITIVELY ASSOCIATED WITH MALARIA TRANSMISSION INTENSITY

Griffin J. Bell[1], Stephaney Gyaase[2], Bright Adu[3], Benedicta Mensah[3], Karamoko Niare[4], David Dosoo[2], Paulin Essone[5], Varun Goel[6], Kenneth Wiru[2], Musah Osei[2], Fabrice Mougeni[5], Cyrus Sinai[6], Portia Kamthunzi[7], Selidji Todagbe Agnandji[5], Tisungane Mvalo[7], Anita Ghansah[3], Jeffrey Bailey[4], Michael Emch[1], Kwaku Poku Asante[2]

[1]UNC Gillings School of Global Public Health, Chapel Hill, NC, United States, [2]Kintampo Health Research Centre, Kintampo, Ghana, [3]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [4]Brown University, Providence, RI, United States, [5]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, [6]UNC Chapel Hill, Chapel Hill, NC, United States, [7]UNC Project - Malawi, Lilongwe, Malawi

RTS,S/AS01 has recently been recommended by WHO for widespread implementation in medium to high malaria transmission settings. Previous analyses have noted lower vaccine efficacies in higher transmission settings, potentially due to "rebound malaria," which occurs over multiple years due to the development of immunity due to natural infections in those not vaccinated with RTS,S/AS01. To investigate other potential mechanisms behind the lower efficacy in high transmission areas, we examine initial vaccine efficacy (against the first case of malaria so as to exclude the rebound effect) and vaccine antibody response using data from three study areas (Kintampo, Ghana; Lilongwe, Malawi; Lambarene, Gabon) from the 2009-2014 phase III trial. Our key exposures are parasitemia during vaccination, age at vaccination, and malaria transmission intensity computed using ecological variables from sixteen geospatial datasets, three surveys, and data from the phase III trial. We calculate vaccine efficacy (one minus hazard ratio) using a cox-proportional hazards model. We find that antibody response was highest in older children in high transmission settings and in children who had parasitemia during vaccination. We find that vaccine efficacy was lowest in children in low transmission settings (0.25 cases per person-year) with no parasitemia during vaccination: 30.77% (95% CI: 19.94%, 40.14%). Children in high transmission settings (but with no parasitemia during vaccination)

had increased efficacy against the first case of malaria: 51.13% (45.86%, 55.89%) and 59.95% (53.65%, 65.40%) in 2 and 3 cases per person-year settings, respectively. Among those with parasitemia during vaccination, efficacy varied little within levels of transmission intensity: 58.44% to 59.55%. These results suggest that vaccine efficacy may improve due to infections before and during vaccination, reinforcing that rebound malaria is the main reason for lower efficacy in high transmission settings. These results may be reassuring for implementation in high transmission settings and may build evidence for innovative vaccine dosing strategies.

CROSS REACTIVITY OF *PLASMODIUM FALCIPARUM* ANTIGENS PF27, PF43, PF45 WITH THEIR ORTHOLOGS PV27, PV43, PV45 OF *P. VIVAX* TO SERA FROM DONORS LIVING IN KÉNIÉROBA, MALI

Salimata Kante[1], Saidou Balam[1], Drissa Konate[1], Merepen dite Agnes Guindo[1], Abdouramane Traore[1], Assitan Dembele[1], Seidina AS Diakite[1], Fatoumata Kasse[1], Karim Traore[1], Larissa Denou[1], Seydou Doumbia[1], Giampietro Corradin[2], Mahamadou Diakite[1]

[1]USTTB, Bamako, Mali, [2]University of Lausanne, Lausanne, Swaziland

Antigenic polymorphism of *Plasmodium falciparum* represents a major challenge for the development of an effective malaria vaccine. Bioinformatics tools remains a realistic approach to identify new antigens that can be used as potential vaccine candidates. In addition, the presence of homologies between *P. falciparum* (Pf) and *P. vivax* (Pv) proteins offers the prospect to develop multi-species and cross-protective vaccines. This study aimed to assess the cross-reactivity of *P. falciparum* Pf27, Pf43 and Pf45 antigens with their *P. vivax* orthologs Pv27, Pv43 and Pv45 to sera from donors living in Kéniéroba, a *P. falciparum* endemic area located at 55 km south-west of Bamako, Mali. Antigenic peptides covering the above orthologs Pf and Pv protein sequences were tested for IgG antibody levels by ELISA on sera samples from children (n = 41) and adults (n = 48). The seroprevalence for Pv27 was 42.7% vs. 29.2% for Pf27; 12.4% for Pf43 vs. 6.7% for Pv43, and 13.5% for Pv45 vs. 11.2% for Pf45. Seropositivity to Pf27 (56.1%, p = 0.0001), Pv27 (87.8%, p = 0.0001), Pv45 (29.3%, p = 0.0001) was significantly higher in children. A significant correlation was found between antibodies against *P. falciparum* antigens with their *P. vivax* orthologs in both children and adult sera ($p < 0.05$). The antibodies titers to Pf43 (p = 0.0001), Pv43 (p = 0.0002), Pf45 (p = 0.001) and Pv45 (p = 0.0001) were significantly higher in adults. Sera from children and adult donors reacted well to the couple Pf27/Pv27. The high seroprevalence suggests existence of cross-reactivity between *P. falciparum* antigens and their orthologs *P. vivax* that should be tested as potential vaccine candidates.

TRANSCRIPTOME ANALYSIS OF ADAPTIVE IMMUNE RESPONSE TO CHAD63 MVA ME-TRAP VACCINE

Lamin Camara

MRC Unit The Gambia at LSHTM, Banjul, Gambia

Malaria is still a major cause of mortality and morbidity in Africa despite various efforts to control it. This bottleneck has mainly been attributed to the complex life cycle of *Plasmodium* parasite and the high level of genetic diversity which allows it evade host immune system[1,2]. While a significant amount of effort is currently being directed towards the development of antimalarial vaccines, those so far developed including RTS,S at phase III trials have registered low efficacy levels[3]. There is therefore an urgent need for development of a high-efficacious malaria vaccine. Previous results have reported promising immunogenicity with chimpanzee adenovirus 63 (ChAd63) vector followed by modified vaccinia Ankara (MVA), both encoding multiple epitope string thrombospondin-related adhesion protein (ME-TRAP) in African adults and pediatric populations. Early cellular responses of prime-boost approaches with ChAd63 MVA ME-TRAP are correlated with elevated levels of both T cells and antibodies, particularly CD8+ effector and effector memory responses to vaccination. While the vaccine efficacy of these heterologous prime-boost regimens has been extensively studied, transcriptomic correlates of immunogenicity and efficacy is yet to be characterized. Transcriptomic analyses to vaccine responses have reliably been used to provide a global picture of the immune mechanisms and type of responses a vaccine induces. With this in mind, this project will utilize samples from previous studies that investigated the immunogenicity of ChAd63 MVA ME-TRAP and correlate it to transcriptomic signatures induced during the immunization to inform vaccine efficacy.

INCREASED PLASMA LEVEL OF INTERLEUKIN-8 IS ASSOCIATED WITH FATAL OUTCOME IN CHILDREN WITH CEREBRAL MALARIA

Bertin Vianou[1], Jade Royo[2], Manfred Accrombessi[1], Elisée Kinkpé[3], Linda Ayédadjou[4], Farid Boumediene[5], Daniel Ajzenberg[5], Jules Alao[4], Ida Dossou-Dagba[3], Gwladys Bertin[6], Sandrine Houzé[7], Jean-François Faucher[8], Agnès Aubouy[2]

[1]Institut de Recherche Clinique du Bénin, Cotonou, Benin, [2]PHARMADEV UMR 152, Institut de Recherche pour le Développement (IRD), Toulouse, France, [3]Paediatric Department, Calavi Hospital, Calavi, Benin, [4]Paediatric Department, Mother and Child University and Hospital Center (CHU-MEL), Cotonou, Benin, [5]Tropical Neuroepidemiology, INSERM UMR 1094, Limoges, France, [6]UMR261 MERIT, IRD, Université de Paris, Paris, France, [7]French Malaria Reference Center, Hôpital Bichat, APHP, Paris, France, [8]Infectious diseases and tropical medicine department, Limoges University Hospital, Limoges, France

Malaria remains a major public health problem despite major scientific advances. WHO reports 241 million cases of malaria in 2020 compared to 227 million cases in 2019, with more than 400,000 deaths attributed to malaria each year, mainly among children in Sub-Saharan Africa. Cerebral malaria (CM) is one of the most severe forms of malaria and remains fatal in 15 to 40% of cases. Despite the administration of effective anti-malarial drugs, it unfortunately leads to very high mortality rates. Although the late management of these cases contributes to the severity of the disease, it seems that the disruption of the cellular immune response also contributes to the fatal outcome due to blood-brain barrier damage. Cytokines, chemokines and lipid mediators are key molecules in the intercellular dialogue. Therefore, our study aimed to study such plasma and urine markers in CM patients and identify markers of death. The study was conducted in Beninese children presenting with CM. Plasma and urine samples were collected at inclusion and following clinical management at Day 3 and Day 30. Using Luminex technology, levels of 17 markers of pro-and anti-inflammatory responses were simultaneously measured in plasma. For urine markers, levels were measured using commercial enzyme immunoassays kits. Socio-demographic, clinical and biological data were analyzed by univariate analysis and logistic regression. A total of 70 CM cases were included, corresponding to 50 children who survived and 20 who died. Multivariate linear regression analysis revealed a strong correlation between increased plasma IL-8 and death. Plasma IL-8 concentration ≥ 57.5 pg/ml increased dramatically the risk of mortality during CM [adjusted OR = 15.3, 95% CI 2.75-85.4, P = 0.002]. By contrast, the other plasma and urine markers measured were not associated to death outcome. Interestingly, plasma TNF-α, IL-6, IL-10, CXCL10 and ICAM-1 decreased gradually from Day 0 to Day 30, whereas CXCL5, CCL17 and CCL22, suggesting deleterious and protective roles, respectively. This study highlighted plasma IL-8 as a marker of death in childhood cerebral malaria.

INVESTIGATION OF MONOCYTE GENE REGULATORY NETWORKS BEFORE, DURING, AND AFTER ACUTE MALARIA USING SINGLE CELL TRANSCRIPTOMICS AND EPIGENOMICS

Katherine Dobbs[1], Adam Pelletier[2], Paula Embury[1], Yelenna Skomorovska-Prokvolit[1], Sidney Ogolla[3], James Kazura[1], Arlene Dent[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]RPM Bioinfo Solutions, Montreal, QC, Canada, [3]Kenya Medical Research Institute, Kisumu, Kenya

Acute malaria is associated with systemic inflammation and altered monocyte functions. In addition, longer-term changes in innate immune homeostasis may follow acute malarial illness. We collected peripheral blood mononuclear cells (PBMC) from a 7-yr-old boy from western Kenya at 3 timepoints: healthy baseline (Pf PCR neg), 7 wks later during an episode of uncomplicated malaria, and 6 wks after treatment and clinical recovery. PBMC nuclei were analyzed simultaneously for transcriptomes and chromatin accessibility at the single cell level (10X Multiome ATAC+Gene Expression). Single cell identities were inferred from the Human Cell Atlas. Among monocytes, there were 701 differentially expressed genes (DEG) in baseline vs. malaria, 197 DEG in malaria vs. recovery, and 75 DEG in recovery vs. baseline (FDR<0.01). Inflammation-related DEG with higher expression at recovery vs. baseline included *IL1B, NLRP3, LYN, NAMPT, NFKB1,* and *CD80*; DEG with lower expression at recovery vs. baseline included *PPARG, TGFB1,* and *CXCR4*. ATAC (Assay for Transposase Accessible Chromatin) data revealed increased peak size in the *IL1B* promoter in recovery vs. baseline monocytes, indicating open chromatin at this locus that is consistent with higher *IL1B* transcription at recovery. Gene set enrichment analysis of recovery vs. baseline monocytes showed enrichment in the "Reactome Immune System" pathway, containing the upregulated genes reported above, as well as in the "Benporath MYC Max Targets" pathway. Transcription factor (TF) activity was compared across timepoints by analyzing ATAC peak data for enrichment in TF motifs. The most statistically significant difference in TF activity between recovery vs. baseline was for *SPI1*. *SPI1* encodes PU.1, a critical regulator of monocyte development. Of the DEG in recovery vs. baseline in the "MYC Max Targets" pathway, 81% are known *SPI1* targets. Collectively, these data suggest longer-term malaria-induced changes in monocyte gene regulatory networks controlled by *SPI1* that may be related to augmented inflammatory signaling. Future experiments will address temporal stability of chromatin changes.

0341

THE ANALYSIS OF CROSS-REACTIVITY OF INHIBITORY ANTIBODY AND MEMORY B CELL RESPONSES TO DUFFY BINDING PROTEIN II VARIANTS AFTER *PLASMODIUM VIVAX* INFECTION

Pongsakorn Thawornpan[1], Siriruk Changrob[1], Piyawan Kochayoo[1], Kittikorn Wangriatisak[1], Chayapat Malee[1], Francis B. Ntumngia[2], Sai Lata De[2], Eun-Taek Han[3], John H. Adams[2], Patchanee Chootong[1]

[1]Department of Clinical Microbiology and Applied Technology, Faculty of Medical Technology, Nakhon Pathom, Thailand, [2]Department of Global Health, University of South Florida, Tampa, FL, United States, [3]Department of Medical Environmental Biology and Tropical Medicine, School of Medicine, Kangwon National University, Gangwon-do, Republic of Korea

Duffy binding protein region II (DBPII) of *Plasmodium vivax* is a critical microneme protein involved in parasite invasion, thereby being chosen as a potential vaccine candidate. However, a major challenge for vaccine design remains as the highly polymorphic nature of this protein often misdirects immune response to be strain-specific. Details of cross-reactive humoral immunity to DBPII variants have therefore become an important focus for the development of broadly protective vaccine. Here, we demonstrated the presence of cross-reactive inhibitory antibody against a panel of Thai DBPII variants (DBL-THs) at post-infection phase of *P. vivax*. The cross-reactivity of inhibitory antibodies against DBL-TH variants was determined in immunized mice and in infected individuals (n=15) by *in vitro* erythrocyte binding inhibition assay. Using anti-DBL-TH sera at 50% inhibitory concentration (IC50), anti-DBL-TH2 sera showed cross inhibition while anti-DBL-TH5 exhibited strain-specific inhibition. In *P. vivax* patients at 12-month post-infection, 6 subjects produced and maintained cross-reactive inhibitory antibodies against more than three DBL-TH variants, whereas all subjects showed no inhibition to reference strain Sal I. To explore cross-reactive memory B cell (MBC) responses against DBL-TH variants, *P. vivax*-infected subjects recovered for 1-3 months (n=8) were tested. The plasma samples from 5 subjects showed broadly inhibition. However, MBC-derived IgG of these patients after 11-day MBC cultures revealed the strain-specificity to DBL-TH antigens. Altogether, this study demonstrated the potential capability of DBL-TH variants in eliciting broadly inhibitory antibodies both in animal and human models. Cross-reactive antibodies with varying inhibitory activities could persist for 12 months after parasite clearance. However, MBC responses to DBP-TH variants were stain-specific. These findings will guide the design of long-lasting, broadly protective DBPII-based vaccine against vivax malaria.

0342

DISTINCT TRANSCRIPTIONAL RESPONSES ASSOCIATED WITH VACCINATION STATUS AND PROTECTION OUTCOMES AFTER MALARIA CHALLENGE

Understanding immune mechanisms that mediate malaria protection is critical for improving vaccine development. Vaccine strategy using radiation-attenuated *Plasmodium falciparum* sporozoite (PfRAS) induces high level of sterilizing immunity against malaria and serves as a valuable tool for the study of protective mechanisms. To identify vaccine-induced and protection-associated responses during malarial infection, we performed transcriptome profiling of whole blood and high dimensional flow cytometry profiling of PBMC from volunteers receiving either suboptimal dose of PfRAS or noninfectious mosquito bites followed by controlled human malaria infection (CHMI) challenge. Whole blood transcriptome analysis revealed that gene sets associated with interferon responses and T and B cell signatures were upregulated and downregulated, respectively, in protected vaccinees one day following CHMI. Dynamic transcriptome changes were observed in non-protected vaccinees that were similarly shared with mock-vaccinated individuals after CHMI and were characterized with downregulation of innate cell signatures and inflammatory responses. Additionally, immunophenotyping data showed that there was a long-term expansion of the vδ2+ subset of γδ T cell in individuals who developed blood-stage parasitemia, even after treatment and resolution of infection. Our data provide key insights in understanding immune mechanistic pathways of PfRAS-induced protection and infective CHMI. We demonstrate that protective immunity by PfRAS is associated with early changes in interferon and adaptive immune responses.

0343

DYSFUNCTIONS OF REGULATORY T AND B CELLS ASSOCIATED TO THE RISK OF NENATAL SEPSIS IN MALARIA ENDEMIC AREA IN BENIN

Darius Sossou[1], Sem Ezinmegnon[2], Komi Gbedande[2], Gino Agbota[2], Rodolphe Ladepko[2], Manfred Accrombessi[2], Achile Massougbodji[2], Jules Alao[3], Valérie Briand[1], Pierre Tissières[4], Karen Brengel-pesce[5], Marine Mommert[5], Nadine Fievet[1]

[1]Université de Paris Cité, MERIT, Institute of Research for Development (IRD), Paris, France, [2]CERPAGE, Université d'Abomey-Calavi, Faculté des Sciences de la Santé, Calavi, Benin, [3]Pediatric Department, Mother and

Child University and Hospital Center (CHUMEL), Cotonou, Benin, [4]Institute of Integrative Biology of the Cell (I2BC), CNRS, CEA, University Paris Saclay, Gif-sur-Yvette, France, [5]Département « Medical Diagnostic Discovery » de bioMérieux, Paris, France

Regulatory T and B cells (Tregs & Bregs) play a prominent role in tolerating the haploidentical mother *in utero,* and at birth, an essential role in the tolerance and control of immune responses to pathogens. Malaria in pregnancy (MiP) alters the newborn immune development and is a risk factor predisposing to malaria and also to other infections during the first year of life. Based on the specific interactions between MiP and prematurity, it is essential to understand the dysfunctions of regulatory immunity in relation to the risk of sepsis in a group of newborns affected by MiP and/or prematurity. Tregs and Bregs might be impacted by MiP or prematurity and consequently associated to a risk of sepsis and infections during the first 3 months of life. This study aims to identify biomarkers of regulatory T and B for diagnosis and prognosis of neonatal sepsis in West Africa where sepsis, MiP and prematurity remain a major public health problem. A cohort of 580 newborns was followed with a full clinical from birth to 3 months in Benin. Mononuclear cells from cord blood of neonates with the most discriminating clinical profiles in terms of occurrence of sepsis, prematurity and MiP are selected. We are evaluating the phenotypes and frequencies of different subpopulations of Tregs and Bregs with immunosuppressive function markers. We focused the immunological analysis on the subgroup of neonates according to the occurrence of sepsis or not in order to assess the outcome of sepsis. Our preliminary results show that neonates who developed sepsis within 72 hours were born with significantly decreased FoxP3 expression on Tregs and higher Breg frequencies. Also, the frequencies of *de novo* generation of Recent Thymus Emigrant Tregs was lower and is compensated by a higher production of peripherally induced Tregs whose Th1 stability and suppressive power are often impaired. Our preliminary results suggest that neonates at risk of developing sepsis were born with an altered phenotypic profile compared to non-sepsis neonates. Ongoing analysis of functional markers are performed to evaluate the impact of MIP and preterm neonates on Treg and Breg and the risk of sepsis in early life.

FACTORS ASSOCIATED WITH HUMAN IGG ANTIBODY RESPONSE TO *ANOPHELES ALBIMANUS* SALIVARY GLAND EXTRACT: ARTIBONITE DEPARTMENT, HAITI, 2017

Alicia Jaramillo-Underwood[1], Daniel Impoinvil[1], Alice Sutcliffe[1], Karen E. S. Hamre[1], Vena Joseph[2], Lotus van den Hoogen[3], Jean Frantz Lemoine[4], Ruth A. Ashton[2], Michelle A. Chang[1], Alexandre V. Existe[4], Jacques Boncy[4], Chris Drakeley[3], Gillian Stresman[3], Thomas Druetz[5], Thomas Eisele[2], Eric Rogier[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti, [5]University of Montreal School of Public Health, Montreal, QC, Canada

Malaria prevalence in Haiti is low, often not exceeding 1% rapid diagnostic test (RDT) positivity throughout the country. In malaria low-transmission settings, serological data can provide an accurate estimation of human exposure both to the malaria vector and the parasite. This study utilized data from a 2017 cross-sectional easy access group survey conducted in southern Artibonite department, Haiti. Participant enrollment occurred at places of congregation: schools, health facilities, and churches. Enrolled persons of all ages completed a questionnaire and provided a blood sample for malaria RDT and later serological assays. A multiplex bead-based assay was developed to simultaneously detect IgG to *Anopheles albimanus* salivary gland extract (SGE) and 23 *Plasmodium falciparum* antigens among 4,185 participants enrolled. Logistic regression estimated odds of an above-median ("high") IgG response against SGE by adjusting for individual-level covariates, IgG against *P. falciparum* antigens, and environmental covariates of enrollment sites. When compared to participants >15 years, children under 5 years and 6-15 years old were found to have 3.7- (95% CI: 2.3, 6.0) and 5.4-fold (95% CI: 3.7, 7.9) increase in odds, respectively, of high anti-SGE IgG. Seropositivity to *P. falciparum* CSP, Rh2_2030, and SEA-1 antigens was significantly associated with high IgG response against SGE, with CSP and SEA-1 having a positive association. Enrollment at study sites under 200m was associated with significantly higher anti-SGE IgG levels compared to elevations above 200m. The ability to approximate population exposure to malaria vectors through SGE serology data is strongly dependent on age categories—possibly pointing towards differing immunological responses to salivary antigens with age. SGE antigens can be easily integrated into a multiplex serological assay with other targets for malaria parasites. Characterization of factors associated with IgG response to SGE can advance understanding of how anopheline salivary antigens can be used as a biomarker for malaria risk.

0345

COMPARATIVE IMMUNOGENETICS OF SEVERE MALARIAL ANEMIA IN PRIMATE MODEL

Mohammed Yaro[1], Robert Morrison[1], Isha Pandey[1], Sachy Orr-Gonzales[1], Lynn E. Lambert[1], Amber I. Raja[2], Patrick E. Duffy[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]The London School of Hygiene and Tropical Medicine, London, United Kingdom

Rhesus and cynomolgus macaques present contrasting pathogenesis to *Plasmodium coatneyi* malarial infection with the former but not the latter recapitulating the features of severe malarial anemia (SMA) seen in children. The underlying molecular mechanisms of SMA in children or macaques are not fully understood. Published results indicate that SMA in macaques are associated with activated $CD8^+$ and $CD4^+$ T-lymphocytes, and preliminary data from our group suggest that $CD8^+$ T-lymphocyte depletion alleviates SMA in rhesus. In order to elucidate the mechanism of the cellular immune response and the contributions of major histocompatibility (MHC) and killer cell immunoglobulin-like receptors (KIR) genomic regions in SMA, we analyzed transcription profiles in Rhesus and Cynomolgus during *P. coatneyi* infection. Our results indicate that four MHC allelic profiles in class I and II regions were common between the two macaques. Serological specificities for two other MHC alleles are strongly associated with resistance to SMA compared to only one that is associated with susceptibility. Understanding the immunogenetics of severe malarial pathogenesis in macaque model may offer us better insight into the characteristic antimalarial immune responses that contribute to SMA in children.

0346

PLASMODIUM FALCIPARUM INFECTIONS INDUCE TRANSCRIPTIONAL AND SPATIAL CHANGES IN HOFBAUER CELLS ASSOCIATED WITH IMPAIRED FETAL DEVELOPMENT

Ricardo Ataide[1], Martin N. Mwangi[2], Ernest Moya[2], Mike Liomba[2], Glory Mzembe[2], Gomezgani Mhango[2], Katherine Fielding[1], Rebecca Harding[1], Kamija S. Phiri[2], Sant-Rayn Pasricha[1]

[1]Population Health and Immunity, The Walter and Eliza Hall Institute, Melbourne, Australia, [2]Training Research Unit of Excellence (TRUE), Blantyre, Malawi

Plasmodium falciparum infections during pregnancy cause placental damage. Placentas exposed to *P. falciparum* accumulate and retain parasite-derived hemozoin (Hz). Hofbauer cells (HBCs) are fetal tissue macrophages that play a role in placental development. We hypothesized that HBCs are differentially activated in placentas with *P. falciparum* Hz and contribute to the risk of small-for-gestational-age and low birth weight. Leveraging clinical and demographic data from a trial of iron in pregnancy in Malawi (ACTRN12618001268235) we applied spatial transcriptomics and multiplexed imaging to interrogate *in situ* expression and spatial interactions of HBCs in placentas with or without Hz. We used the GeoMx Digital Spatial Profiler (NanoString) on FFPE sections of placenta

to identify differentially expressed genes (DEGs) in HBCs. In addition, we used multiplexed Opal staining on tissue microarrays to identify, quantify and validate HBC markers and assess population enrichment and proximity/distance to other cell populations and to maternal and fetal circulation. Early results show that women whose placentas have Hz delivered smaller babies (mean difference (MD), [95% Confidence Interval]: -378.0 g, [-61.4 to -694.6]). Human Phenotype Ontology analysis shows genes upregulated in HBCs from placentas with Hz are implicated in pathways leading to abnormal cerebral vasculature morphology and brain immune cell activation. In addition, placentas with Hz tend to show HBCs at higher frequencies (+4.8%, [-4.5 to 14.1]) and closer in contact to maternal vasculature (-2.8 µm, [-9.3 to 3.8]). Hofbauer cells are activated in placentas with *P. falciparum* Hz and remain differentially activated through to delivery. Differentially expressed genes in HBCs may reflect a close transcriptional profile to brain microglia and be markers of brain development. Further spatial analyses between tissues with or without Hz will provide insights into the interaction of HBCs with their environment. Transcriptional and spatial profiles of HBCs associate with detrimental fetal outcomes and may represent an early accessible marker of cognitive development.

0347

GUT MICROBIOTA INFLUENCES SUSCEPTIBILITY TO *PLASMODIUM FALCIPARUM* MALARIA

Aly Kodio[1], Drissa Coulibaly[1], Safiatou Doumbo[1], Salimata Konaté[1], Abdoulaye Kassoum Koné[1], Souleymane Dama[1], Amadou Niangaly[1], Mamadou Lamine Tall[2], Ahmed Mohamed Konaté[1], Coralie L'Ollivier[2], Anthony Levasseur[2], Fadi Bittar[2], Abdoulaye Djimdé[1], Ogobara K. Doumbo[1], Didier Raoult[2], Mahamadou Ali Thera[1], Stéphane Ranque[2]

[1]MRTC, Bamako, Mali, [2]IHU Méditerranée Infection, Aix Marseille université, Marseille, France

The gut microbiota has recently been associated with malaria susceptibility/resistance in animal models and humans, but the impact of the gut microbiota on the risk of malaria attacks remains to be evaluated. The objective was to evaluate the influence of the gut microbiota on malaria attacks and asymptomatic carriage of Plasmodium in children in a malaria endemic area, Mali.Three hundred healthy children were included in a 16 month cohort study in Bandiagara. The community structure of intestinal bacteria and fungi of the children was characterized by 16S, ITS metagenomics from stool collected at inclusion. Clinicians monitored for malaria attacks. Asymptomatic Plasmodium carriage was assessed by qPCR.During the study, 107 vs 82 children had at least one malaria attack and one asymptomatic *Plasmodium* episode, respectively. Higher bacterial richness was associated with susceptibility to episodes of asymptomatic and malaria attacks while fungal diversity and richness were relatively homogeneous in children with and without *P. falciparum* infection. Linear discriminant analysis of the effect size of operational taxonomic units showed that: 17 bacteria including Clostridiaceae, Eubacteriaceae, Senegalimassilia sp and 7 fungi including *Dioszegia fristigensis*, *Ogataea polymorpha* were associated with susceptibility, whereas 8 bacteria including *Bifidobacterium* spp, *Weissela confusa* and 3 fungi including *Malassezia* sp., *Niesslia exosporoides*, were associated with malaria resistance. In addition, 15 bacteria including *Coproccus eutactus*, *Klebsiella pneumoniae* and 13 fungi including *Wallemia mellicola* were associated with susceptibility while 19 bacteria including *Bifidobacterium* spp, *Bacteroides fragilis* and *Lactobacillus ruminis* and 3 fungi including *Cryptococcus neoformans* were associated with resistance to asymptomatic Plasmodium episodes.Further studies are needed to confirm these findings, which provide an avenue for strategies to reduce malaria risk by modulating components of the gut microbiota in vulnerable populations.

0348

ASSESSING SOCIOECOLOGICAL RISK FACTORS FOR MALARIA AND SCHISTOSOMIASIS AMONG CHILDREN IN MISUNGWI, TANZANIA, AN AREA OF CO-ENDEMICITY

Claudia Duguay[1], Jacklin F. Mosha[2], Natacha Protopopoff[3], Franklin W. Mosha[4], Cindy Feng[5], Alphaxard Manjurano[2], Alison Krentel[1], Manisha A. Kulkarni[1]

[1]University of Ottawa, Ottawa, ON, Canada, [2]National Institute for Medical Research Mwanza Research Centre, Mwanza, United Republic of Tanzania, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, [5]Dalhousie University, Halifax, NS, Canada

More than 240 million malaria cases are reported annually, with over 600,000 deaths, mostly in Sub-Saharan Africa (SSA). In addition, Neglected Tropical Diseases, which include schistosomiasis, affect over 1.7 billion people worldwide with more than 200 million people in SSA requiring preventive treatment in 2019. Malaria and schistosomiasis transmission and infection are both dependent on environmental determinants that create favorable conditions for vectors and parasites, and on social determinants, i.e. demographic and socioeconomic factors and behaviors related to disease exposure. In the present study, we investigated factors that are independently and jointly associated with malaria, schistosomiasis, and co-infection among school-aged children. A cross-sectional study was conducted in January 2022 in Misungwi, Tanzania, that sampled 4,200 children aged 6 months to 14 years old. Malaria rapid diagnostic tests (RDTs) were administered for all children (n=4200) while novel schistosomiasis IgM/IgG RDTs were administered for a sample of the children 5 years and older (n=1300). The prevalence of malaria, seroprevalence of schistosomiasis, and co-infection were 31% (1301/4240), 93% (1038/1115), and 38% (428/1115), respectively. Mixed effects regression analyses will be used to assess associations between risk of infection or co-infection and hypothesized individual-, household- and community-level risk factors: low socioeconomic status, poor housing and/or sanitation, poor disease-related knowledge, higher ambient temperature, and closer proximity to Lake Victoria. Spatial cluster analyses will be used to identify hotspots of disease exposure. This study will improve our understanding of social and environmental factors that are associated with malaria, schistosomiasis, and co-infection to inform potential entry points for integrated disease prevention and control.

0349

KNOWLEDGE, ATTITUDE, AND PRACTICES (KAP) ON MALARIA PREVENTION AMONG ADOLESCENTS LIVING IN AN AREA OF PERSISTENT TRANSMISSION IN SENEGAL: A CROSS-SECTIONAL STUDY

Fassiatou Tairou[1], Saira Nawaz[2], Marc Christian Tahita[3], Babacar Faye[1], Roger C K Tine[1]

[1]Université Cheikh Anta Diop of Dakar, Dakar, Senegal, [2]Ohio state university, center for health outcomes and policy evaluation studies, New Albany, OH, United States, [3]Clinical Research Unit of Nanoro, Nanoro, Burkina Faso

Despite decrease of malaria burden due to the scaling up of control measures, transmission is still persistent in the southern part of Senegal with many cases among adolescents. This is challenging for the country in the pre-elimination stage of malaria as these adolescents will contribute significantly to onward transmission. Therefore, this present study assesses the Knowledge, Attitude, and Practices (KAP) of adolescents living in the health district of Saraya, regarding malaria. A community-based cross-sectional survey was conducted. Households were selected using multistage sampling method. Socio-demographic data, household assets, and KAP were assessed using an electronic questionnaire. Factors associated with adolescents' prevention practices were assessed using logistic regression analysis. Overall, 391 adolescents were included in the study. Nearly, one-third of the participants had good knowledge and good practice of prevention while three-quarters had a positive attitude

and good care-seeking behavior regarding malaria. Multivariate analysis revealed that primary (aOR=5.43, p=0.002) or secondary education (aOR=10.41, P=0.000) level is associated with good knowledge while male individuals have lower knowledge compared to female ones (aOR=0.40, P=0.001). The rich (aOR=0.29, P=0.015), the poor (aOR=0.13, P=0.000), and the poorest (aOR=0.18, p=0.001) were less likely to have a positive attitude towards malaria compared to the richest. Those with a positive attitude were two times the odds (aOR=2.32, P=0.011) of reporting good malaria prevention practices compared to a negative attitude. In contrast, the rich (aOR=0.40, P=0.018), the medium (aOR=0.32, P=0.03) and the poor (aOR=0.44, P=0.035) wealth index are less likely to apply good practices of malaria prevention compared to the richest. The odds of good care-seeking behavior was lower among poor adolescents. Adolescents' knowledge level and their practice on malaria prevention were poor. Programs aiming to improve access to health care services and to increase sensitization among adolescents to raise awareness on malaria prevention are urgently needed.

0350

IMPROVED ADHERENCE TO TEST, TREAT, AND TRACK (T3) MALARIA STRATEGY AMONG OVER-THE-COUNTER MEDICINE SELLERS (OTCMS) THROUGH INTERVENTIONS IMPLEMENTED IN SELECTED RURAL COMMUNITIES OF FANTEAKWA NORTH DISTRICT, GHANA

Olajoju Temidayo Soniran[1], Benjamin Abuaku[2], Collins Ahorlu[2]

[1]Akanu Ibiam Federal Polytechnic, Unwana, Afikpo, Nigeria, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Prompt diagnosis and treatment of malaria prevents a mild case from developing into severe disease and death. Unfortunately, parasitological testing of febrile children is greater in the public and formal private sector than in the informal private sector where some people with malaria-like symptoms first seek treatment. This study aimed at improving adherence to the test, treat, track (T3) policy among OTCMS through interventions that could be scaled-up easily at the national level was conducted in some rural communities of Ghana. Interventions were evaluated using a two-arm, cluster randomized trial across 8 rural communities (4 clusters per arm), in two adjacent districts (Fanteakwa North and Fanteakwa South districts) of Ghana. A total of 12 OTCMS (7 in the intervention arm and 5 in the control arm) in the selected communities participated in the study. Five (5) interventions were implemented for 12 months in the intervention arm only. The primary outcome was the proportion of children under 10 years with fever or suspected to have malaria visiting OTCMS and subjected to a parasitological test before treatment. Outcomes were measured using mystery client surveys supplemented by a household survey. Data was analyzed using chi-square test or fisher exact test. Following implementation of interventions, mystery client survey showed that OTCMS' adherence to malaria protocol in the intervention arm (66.7%) was significantly higher ($p<0.05$) compared to the control arm (40%). Household surveys in the intervention arm showed that caregivers self-treating their children or visiting drug vendors significantly decreased from 8.6% and 13.8% to 3.9% and 3.2% in favor of visits to OTCMS shops for treatment. From our findings, interventions targeting OTCMS have the potential of improving management of uncomplicated malaria in rural communities with limited access to quality healthcare, thus reducing morbidity and mortality rates.

0351

UNDERSTANDING PSYCHOSOCIAL DETERMINANTS OF MALARIA BEHAVIORS IN LOW TRANSMISSION SETTINGS: A SYSTEMATIC REVIEW

Albert Casella[1], April Monroe[1], Michael Toso[1], Gabrielle Hunter[1], Carol Underwood[1], Ruchita Pillai[1], Jayme Hughes[2], Lynn Van Lith[1], Stella Babalola[1]

[1]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [2]Johns Hopkins University, Baltimore, MD, United States

Human behavior plays an important role in malaria elimination, including acceptance and use of prevention measures and prompt care seeking for fever. These behaviors depend in part on psychosocial factors such as knowledge, attitudes, perceived risk, and perceived community norms. The current state of research on these factors in low malaria transmission settings, including sampling approaches and association with key behaviors, is unknown. To address this gap, Breakthrough ACTION conducted a systematic review of recent peer-reviewed and grey literature in low transmission settings (as defined in the WHO Framework for Malaria Elimination and key terms) using PRISMA guidelines. Records were screened (n=966) and retained publications (n=96) analyzed to assess sampling approaches, data collection instruments, and factor behavior associations. Purposive and cluster random sampling were common study designs. Knowledge, attitudes, and perceived risk were commonly measured variables, but measurement was incongruent across studies. Perceived response efficacy, perceived self efficacy, and perceived community norms were rarely measured, although recent evidence within high-transmission context suggests they influence behavior. Positive associations between malaria knowledge, favorable attitudes, and behavior were consistently found. A subset of studies (n=19) focused on populations at increased risk of transmission such as miners and forest workers, where rates of correct knowledge tended to be lower than others. Currently, there is insufficient evidence to assess the relationship between other psychosocial factors and behavior in low transmission settings, a gap that offers opportunities for innovative social and behavior change programming. Results of this review highlight the need for malaria research to employ more consistent, comprehensive measures of psychosocial constructs that shape behavior, and offer promising existing instruments and sampling approaches. Interventions seeking to address remaining gaps toward malaria elimination should consider the pivotal role of psychosocial factors.

0352

SOCIODEMOGRAPHIC TRENDS IN MALARIA KNOWLEDGE AND IMPLICATIONS FOR BEHAVIOR CHANGE INTERVENTIONS IN ZANZIBAR

Faiza B. Abbas[1], Emmanuel Kigadye[1], Fauzia Mohamed[1], Samson Kiware[2], April Monroe[3], Mwinyi Khamis[4]

[1]Open University of Tanzania, Dar es salaam, United Republic of Tanzania, [2]Ifakara Health Institute, Dar es salaam, United Republic of Tanzania, [3]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [4]Zanzibar Malaria Elimination Program, Zanzibar, United Republic of Tanzania

Zanzibar is among the few places within East Africa that have documented a significant reduction of malaria morbidity and mortality. Despite tremendous gains over the past decade, malaria transmission still persists in Zanzibar. This study aimed at understanding levels of malaria knowledge to provide recommendations that can be used to reinforce and scale-up targeted malaria social and behavior change interventions. A descriptive cross-sectional survey was conducted through an administered questionnaire to 431 households selected randomly. The interviewees were the heads of household or representative adults above 18 years. This study investigated the levels of knowledge about the causes, symptoms, and prevention of malaria in areas with high (> 1.9 per 1,000) and low (<1 per 1000) incidence of local malaria cases. The Principal Component Analysis (PCA) was used to compute the composite variable of each

category. Descriptive statistics were calculated to understand variables of interest between low and high transmission areas. Multinomial logistic regression model was used to compare knowledge on malaria based on key variables. Respondent age, education level, and wealth status were significantly associated with variations in the level of malaria knowledge. Old age was found to be significantly associated with low knowledge of malaria (P<0.001). The majority of study participants who had secondary and higher education levels had good knowledge of malaria (P<0.006). Participants characterized as middle-income had good knowledge compared to those characterized as low-income (P<0.001). Low levels of malaria knowledge were documented among the elderly and populations with lower education and income levels. There is a need to extend mobilization, advocacy, and expand channels of communication to reach all community members. The reported gaps in knowledge are important to consider when designing strategies to engage communities in malaria elimination in Zanzibar. Tailored social and behavioral change interventions aiming to increase malaria knowledge could enhance the uptake of malaria prevention services in the community.

WHAT IS THE MALARIA COST BURDEN AND WHO BEARS IT? A COST-OF-ILLNESS STUDY IN UGANDA

Katherine Snyman[1], Catherine Pitt[2], Samuel Gonahasa[3], Jane Namuganga[3], Joaniter I. Nankabirwa[3], Emmanuel Arinaitwe[3], Catherine Maiteki-Sebuguzi[3], Henry Katamba[4], Jimmy Opigo[4], Moses R. Kamya[3], Grant Dorsey[1], Sarah G. Staedke[2]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]Ministry of Health (MOH/NMCP), Kampala, Uganda

In Uganda, the burden of malaria remains high, and treatment imposes a large economic burden on households and the health system. Cost-of-illness studies can guide development of efficient and equitable control programs and decisions on allocation of scarce resources. However, a gap in this evidence exists for Uganda and elsewhere in Africa. To evaluate the societal and provider cost of malaria illness and to assess the distribution of the economic burden of malaria in Uganda through an equity lens, we conducted a cost-of malaria illness study from November 2021 to May 2022 in 10 randomly selected public health facilities in 10 districts of Uganda. These sites have been established as Malaria Reference Centres for the LLINEUP2 trial, a study to evaluate the impact of long-lasting insecticidal nets (LLINs) distributed through the 2020-2021 national campaign in Uganda. Provider costs for diagnostics, drugs, health worker time and overheads were collected from health facility registers; observations and a time-in-motion study were also conducted. Care-seeking behavior and household expenditure on malaria treatment including out-of-pocket payments, transportation and productivity losses were collected from cross-sectional surveys conducted in 3,200 households across all 64 LLINEUP2 trial communities in 32 districts of Uganda. Average values overall, and by geographic, socio-economic and age subgroups, were estimated for household-level and individual-level access to treatment, quality of treatment and cost burden. Preliminary results indicate that the average household cost of a malaria episode was $15.32 (95% CI: $13.79-16.85), with 84% of costs attributed to productivity losses. Household average cost per episode varied by region (max: Acholi $19.28 ; min: Bunyoro $13.88) and age of patient (under 2 years $5.77 less; p-value: 0.04). We will present final results of this analysis which will inform resource-allocation decisions about malaria control by providing an average cost of malaria treatment, which can be applied in economic evaluations and for policymaking in Uganda and across Africa.

0354

TRANSCRIPTIONAL PROFILING OF PRIMARY SIMIAN HEPATOCYTES INFECTED WITH THE REPLICATING FORM OF THE MALARIA PARASITE *PLASMODIUM CYNOMOLGI*

Gabriel Mitchell[1], Guglielmo Roma[2], Annemarie Voorberg-van der Wel[3], Martin Beibel[2], Anne-Marie Zeeman[3], Sven Schuierer[2], Laura Torres[1], Erika L. Flannery[4], Clemens H.M. Kocken[3], Sebastian A. Mikolajczak[4], Thierry T. Diagana[4]

[1]Open Innovation at Novartis Institute for Tropical Diseases, Novartis Institutes for BioMedical Research, Emeryville, CA, United States, [2]Chemical Biology and Therapeutics, Novartis Institutes for BioMedical Research, Basel, Switzerland, [3]Department of Parasitology, Biomedical Primate Research Centre, Rijswijk, Netherlands, [4]Novartis Institute for Tropical Diseases, Novartis Institutes for BioMedical Research, Emeryville, CA, United States

The simian parasite *Plasmodium cynomolgi* develops into replicating schizonts and dormant hypnozoites during the infection of hepatocytes and is used as a model organism to study relapsing malaria. Using FACS-purification of cells infected with GFP-expressing parasites, we previously reported the transcriptional profiling of *P. cynomolgi* liver stages and revealed many important biological features of the parasite but left out the host response to malaria infection. Here, we aligned our published RNA sequencing data obtained from primary simian hepatocytes infected with *P. cynomolgi* to the reference rhesus monkey genome rheMac7 and quantified the expression of host genes in comparison to either uninfected samples or uninfected bystander cells. Although the dataset could not be used to study hypnozoite-infected cells because of sample contamination, we found that it provides a snapshot of the transcriptional response of hepatocytes to *P. cynomolgi* schizonts at 9-10 days post-infection. Our results show that schizont-infected cells modulate the expression of genes associated with multiple host processes in comparison to uninfected samples, including the upregulation of pathways involved in the response to DNA damage, cell division and the response to viral infection and cytokines, and the downregulation of metabolic genes. Results also identified host pathways more specifically modulated in schizont-infected cells in comparison to uninfected bystander cells, such as the upregulation of genes associated with the Rho GTPase cycle and membrane trafficking, and the downregulation of genes associated with protein translation. This study constitutes a valuable resource characterizing the hepatocyte response to *P. cynomolgi* infection and provides a framework to build on future research that aims at understanding hepatocyte-parasite interactions during relapsing malaria infection.

0355

AN INSIGHT OF THE PERCEPTION OF FRANCOPHONE AFRICAN IMMIGRANTS ON MALARIA-RELATED KNOWLEDGE OF HEALTHCARE PROFESSIONALS IN WESTERN CANADIAN MINORITY REGIONS

Sedami Gnidehou[1], Kongnon Sangué Coulibaly[2], Youssef Ahmed[3], Rémi Vincent[3], Ali Ahmed[3], Srilata Ravi[3], Michael Hawkes[4]

[1]Campus Saint- Jean and Department of Medical Microbiology and Immunology, University of Alberta, Edmonton, AB, Canada, [2]Faculty of Science, University of Alberta, Edmonton, AB, Canada, [3]Campus Saint-Jean, University of Alberta, Edmonton, AB, Canada, [4]Pediatrics, Faculty of Medicine, University of Alberta, Edmonton, AB, Canada

Despite decades of study, malaria remains one of the world's greatest killers, with populations living in Sub-Saharan African (SSA) regions being at the highest risk. However, the disease is not restricted to SSA. Promoted by population movements, imported malaria (IM) or travel-associated malaria is a growing public health threat in many industrialized non-endemic countries including Canada. Similar to European countries and the United States, Canada's reported IM cases are densely concentrated within regions exhibiting a steady growth of immigrants especially from SSA. Studies have demonstrated that Canadian health practioners malaria

knowledge can be incomplete, affecting traveler's confidence when seeking for medical advice before a trip to malaria endemic settings. Remarkably, the number of immigrants, especially French-Speaking immigrants from SSA (FISSA) has significantly increased in Edmonton, a predominant English-speaking Canadian city. Thus, challenges related to trust in health professional malaria knowledge when trying to access pre-travel medical advice may increase this population's susceptibility to IM infections. We used a structured survey to assess a Healthcare Competency Perception (HCP) index score (negative, neutral and positive scores) and malaria related healthcare statements within a cohort of 382 FISSA (48% female; 52% male) living in Edmonton. We observed that while 264/382 (69%) of FISSA were satisfied with the healthcare they received in Canada, confidence in the healthcare system's ability to treat and deal with malaria effectively appear to be significantly lower, with only 148/382 (39%) receiving a positive score on the HCP index. Moreover, in comparison with other respondents, respondents with a positive HCP index score were significantly more likely to visit a hospital or a doctor if they or their family member were sick after coming back from a trip to an endemic region (OR 2.98, 95% CI 1.23-8.33). This study suggests that low confidence in healthcare workers may be a barrier to health-seeking behaviour post-travel for FISSA.

0356

COMMUNITY EDUCATION, PERCEPTION AND BEHAVIORAL CHANGE ARE THE KEY DETERMINANTS OF MALARIA OUTBREAK AT DOLONIBASTI SUB-CENTRE OF UDALGURI DISTRICT, ASSAM, NORTH-EAST INDIA

Hari Shankar[1], Rahim Ali Ahmed[2], Syed Shah Areeb Hussain[3], Ananta Swargiary[4], Avdhesh Kumar[5], Harpal Singh Suri[2], Kuldeep Singh[3], Afluza Begum[6], Joy Kumar Chakma[1], Neelima Mishra[3], Praveen K. Bharti[3]

[1]Indian Council of Medical Research, New Delhi, India, [2]National Vector Borne Disease Control Programme, Assam, India, [3]ICMR – National Institute of Malaria Research, New Delhi, India, [4]Bodoland University, Assam, India, [5]National Vector Borne Disease Control Programme, New Delhi, India, [6]Bhattadev University, Assam, India

Despite the malaria control efforts like long-lasting insecticidal nets distribution, rounds of indoor residual spray, introduction of bi-valent rapid diagnostic tests and artemisinin combination therapy; malaria remained consistent in Dolonibasti sub-centre (outbreak region) of district Udalguri and followed by an outbreak in 2008. This necessitates us to investigate the factors driving the malaria transmission and outbreak. We collected malaria epidemiological data for the years 2008-2018 of Udalguri district and Orang block primary health centre (BPHC) covering outbreak region, as well as yearly (2011-2018) and monthly (2013-2018) data of outbreak region. An entomological survey, Knowledge, Aptitude and Practices study among malaria cases (n=120) from outbreak region was conducted. Annual (2011-2018) and monthly (January, 2013-December 2018) meteorological data was collected for the point location of outbreak region. Overall, annual parasite incidence (API) was declined in Udalguri by 82% but Orang BPHC and specifically outbreak region remained unaffected with the previous intervention efforts from the Government. Out of 2130 confirmed cases in outbreak region, 55% were adults (n=1176) and rest were children. *Anopheles minimus* was the major vector with 28.6% positivity and high larval density in paddy fields/drainage area. Annual relative humidity was associated with rise in malaria cases, API (r_s=0.69, 90%CI; p=0.06) and slide positivity rate (r_s=0.83, 95%CI; p=0.01). Older people were less educated (r_s=-0.66; p=0.00), had lesser knowledge about malaria cause (r_s=-0.42; χ^2=21.80; p=0.00) and prevention (r_s=-0.18; p=0.04). Malaria control practices were followed by those having knowledge about cause of malaria (r_s=0.36; χ2=13.50; p=0.00) and prevention (r_s=0.40; χ2=17.71; p=0.00). Education, though influenced the adoption of malaria control measures, but its magnitude was relatively weak. This shows that formal education can help in improving the malaria control practices but only to a certain extent, and more concerted efforts are needed to educate the community towards malaria control practices.

0357

IMPROVEMENTS IN THE INTEGRATED DISEASE SURVEILLANCE AND RESPONSE (IDSR) SYSTEM FOR MALARIA SURVEILLANCE IN MAINLAND TANZANIA

Joseph Joachim Joseph[1], Humphrey Mkali[1], Ssanyu Nyinondi[1], Osia Mwaipape[1], Samwel N. azaro[2], Franky Chacky[2], Anna Mahendeka[2], Khalifa Munisi[2], Sijenunu Aaron[2], Ally Mohamed[2], Abdul-wahid Al-mafazy[1], Chonge Kitojo[3], Naomi Serbantez[3], Erik Reaves[4], Claud John[5], Donal Bisanzio[6], Erin Eckert[6], Richard Reithinger[6], Jeremiah M. Ngondi[6]

[1]RTI International, Dar es salaam, United Republic of Tanzania, [2]National Malaria Control Program, Dodoma, United Republic of Tanzania, [3]United States Agency for International Development (USAID), Dar es salaam, United Republic of Tanzania, [4]U.S President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es salaam, United Republic of Tanzania, [5]Ministry of Health, Dodoma, United Republic of Tanzania, [6]RTI International, Washington, DC, United States

Tanzania has made remarkable progress in reducing malaria burden and aims to transition from malaria control to sub-national elimination. In 2013, electronic weekly and monthly reporting systems using the District Health Information System-2 were introduced. Weekly reporting was implemented through the Integrated Disease Surveillance and Response (eIDSR) system using mobile phones and progressively scaled-up from 67 health facilities (HFs) in 2013 to >7,000 HFs (100%) by 2020. This study aimed to describe the implementation of eIDSR and compare the accuracy of malaria indicators between weekly and monthly data to ascertain its usefulness for malaria outbreak detection and case-based surveillance (CBS) in low transmission areas. The indicators included were number of patients tested for malaria, number of confirmed malaria cases, and number treated presumptively for malaria (clinical cases). The analysis described the trend of reporting, testing, test positivity, and incidence per 1000 population. Comparisons of weekly and monthly reporting rates and incidence were performed for 2020 and 2021 and were stratified by malaria epidemiological strata (parasite prevalence: very low <1%, low 1≤5 %, moderate 5≤30%, and high >30%). Between 2020 and 2021, overall weekly reporting rates increased from 90.2% to 93.9%, while monthly reporting rates were 98.9% in 2020 and 98.7% in 2021. Overall reporting rates and timeliness of weekly reports were highest in very low strata. Confirmed malaria incidence from weekly data was 87.0 per 1000, which was 17.5% lower than monthly data in 2020, and 66.3 per 1000, which was 12.4% lower in 2021. For 2020 and 2021, incidences were the same across weekly and monthly data in the very low strata. Weekly reporting improved steadily over time, while reporting rates and malaria incidence were lower compared to monthly. Nonetheless, the concurrence of weekly and monthly annual reporting rates and incidence in very low strata suggests that eIDSR could be useful for early outbreak detection, and the eIDSR platform could reliably be expanded by adding more indicators and modules for CBS in very low epidemiological strata.

0358

CATALYTIC ROLE OF GOVERNANCE IN IMPROVING UPTAKE OF MALARIA IN PREGNANCY INTERVENTIONS: EXPERIENCES FROM PARTICIPATION OF COUNTY LEADERSHIP IN QUALITY IMPROVEMENT (QI) IN IPTP UPTAKE IN VIHIGA COUNTY, KENYA

Beth Marigu Barasa[1], Augustine Ngindu[1], Dickson Mwakangalu[1], Alphonce Nyakech[1], Eric Sikuku[2], Hellen Agisa[2], Gladys Tetteh[3], Lolade Oseni[3], Daniel Wacira[4]

[1]U.S. President's Malaria Initiative Impact Malaria Project, Nairobi, Kenya, [2]County Department of Health, Vihiga County, Mbale, Kenya, [3]U.S. President's Malaria Initiative Impact Malaria Project, Jhpiego, Baltimore, MD, United States, [4]U.S. President's Malaria Initiative, USAID, Nairobi, Kenya

Malaria in pregnancy (MiP) is associated with poor pregnancy outcomes including anaemia, intrauterine growth restriction, low birth weight,

stillbirths, and maternal and neonatal death. To reduce these effects, WHO recommends the use of insecticide-treated nets (ITNs), a minimum of 3 doses of sulfadoxine-pyrimethamine (SP) starting at 13 weeks gestation, and prompt diagnosis and treatment of malaria during pregnancy. The Impact Malaria (IM) project baseline assessment 2019 indicated that in Vihiga County the uptake of the second and third dose of Intermittent Preventive Treatment for Malaria in pregnancy (IPTp2 and IPTp3) was 50% and 35% respectively. To improve this, IM supported a Quality Improvement (QI) learning session for 23 health care providers (Emuhaya Sub-County 10 and Sabatia Sub County 13). The session focused on the use of QI tools to conduct root-cause analysis to identify the bottlenecks to scaling up MiP interventions and generating and monitoring change ideas and improvement. Two follow-up sessions were conducted 3 months apart to review the implementation of the solutions. The leadership provided support for the establishment and revival of QI teams. The key causes of low performance included frequent SP stockouts, non-functional Directly Observed Therapy (DOT) corners, poor community linkages with health facilities (HFs), and inadequate documentation of IPTp doses. County leadership delegated authority to facility in-charges to purchase SP using facility funds when the central level experienced stockouts. Health care providers established 14 QI teams in the facilities to address causes of missed opportunities including the provision of safe water for DOT corners and the revival of facility-community linkages. The Sub-County managers established a WhatsApp group for monitoring weekly IPTp uptake in the 23 HFs. Uptake of IPTp2 and IPTp3 improved from 50% to 92 % and 32 % to 77% respectively from January 2021 to December 2021. Understanding of the causes of bottlenecks at all service delivery levels by county leadership enabled locally developed, pragmatic solutions that led to an increase in intervention coverage.

0359

MALARIA AND ECONOMIC GROWTH IN IVORY COAST

Octavie Francine Yao[1], Omer Kouakou[2]

[1]Programme Nationale de Lutte Contre Le Paludisme, Abidjan, Côte D'Ivoire, [2]Universite Alassane Ouattara, Bouake, Côte D'Ivoire

The objective of our study was to determine the effect of malaria incidence on economic growth in Côte d'Ivoire over the period 1971-2019. To achieve this objective, we used the ARDL model using ordinary least squares (OLS) estimator on data from the WDI (2019). The results of the ARDL model showed that in the short term, malaria incidence, gross fixed capital formation, and trade openness positively influence economic growth while mortality rate negatively influences it. In the long run, while malaria incidence, labor force, and public expenditure contribute positively to growth, mortality and morbidity deteriorate it.

ASSOCIATION OF ANTHELMINTHIC TREATMENT WITH MALARIA PREVALENCE: A SECONDARY DATA ANALYSIS OF THE SUSSUNDENGA MALARIA STUDY

Joseph A. Akambase[1], João L. Ferrão[2], Albino F. Bibe[3], Anísio Novela[4], Dominique E. Earland[1], Kelly M. Searle[1]

[1]University of Minnesota School of Public Health, Minneapolis, MN, United States, [2]Superior Institute of Science and Education (ISCED), Beira, Mozambique, [3]Sussundenga Secondary Schoo, Sussundenga, Mozambique, [4]Sussundenga Rural Health Center, Sussundenga, Mozambique

Malaria remains a serious public health problem in Sub-Saharan Africa. Hence, the need for complementary malaria control strategies. Community mass treatment with Ivermectin, an anthelminthic has emerged in recent times as an effective vector control tool. However, reported effects of other classes of anthelminthic such as the benzimidazoles on the prevalence of malaria in observational settings are conflicting. We explored the relationship between treatment with anthelminthic and the prevalence of malaria in Sussundenga village, Mozambique. We used data from a cross-sectional community-based survey designed to study malaria risk in Sussundenga village. Participants were asked if they had ever received an anthelminthic and were tested for P. falciparum malaria using a rapid diagnostic test (RDT). With logistic regression models, we tested the association between outcome of malaria rapid diagnostic test and patient characteristics to determine independent predictors of malaria prevalence. Similarly, the differences between anthelminthic group and anthelminthic-unexposed group were investigated using simple logistic regression models. 277 participants were included in the analysis. 77% reported ever receiving an anthelminthic. Malaria prevalence by RDT was 30%. Age, ITN use and heads of households of participants with full-time jobs were identified as independent predictors of malaria prevalence. There was no statistically significant association between prior receipt of anthelminthic and malaria prevalence after adjusting for age, ITN use and household heads with full-time jobs (OR = 1.21, p = 0.5573; aOR = 1.37, p= 0.3569). This finding was consistent regardless of the timing of anthelminthic administration ((OR = 0.44, 95% CI, 0.09 - 2.09, p = 0.3032; aOR = 0.35, 95% CI, 0.07 - 1.80, p = 0.2099) We found no statistically significant association between prior receipt of anthelminthic and malaria prevalence by RDT. Age, ITN use and heads of households of participants with full-time jobs predict malaria prevalence.

0361

PLASMODIUM VIVAX AND SARS-COV-2 CO-INFECTION IN VENEZUELA: A CASE SERIES FROM THE MALARIA HOTSPOT IN LATIN AMERICA

David A. Forero-Peña[1], Fhabián S. Carrión-Nessi[1], Óscar D. Omaña-Ávila[1], Daniela L. Mendoza-Millán[1], Iván A. Escalante-Pérez[1], Sinibaldo R. Romero Arocha[1], Melynar Chavero[1], Luisamy Figuera[1], Andrea L. Maricuto[1], Natasha A. Camejo-Ávila[1], Diana C. Freitas-De Nobrega[1], Rosa Contreras[2], Jaime Torres[2], Óscar O. Noya-González[2]

[1]Biomedical Research and Therapeutic Vaccines Institute, Ciudad Bolívar, Bolivarian Republic of Venezuela, [2]"Dr. Félix Pifano" Tropical Medicine Institute, Central University of Venezuela, Caracas, Bolivarian Republic of Venezuela

Malaria-endemic areas are not spared from the impact of coronavirus disease 2019 (COVID-19), leading to co-infection scenarios where overlapping symptoms pose serious diagnostic challenges. Current knowledge on *Plasmodium* and severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) co-infection remains limited, especially in Latin America, where *P. vivax* infection is more prevalent than in other global regions. We present here a case series of 12 patients with *P. vivax* and SARS-CoV-2 co-infection seen at two main malaria referral centres of the Capital District and Bolivar state, Venezuela between March 13, 2020 and December 31, 2021. Nine out of 12 patients had moderate to severe COVID-19 disease. All patients with severe COVID-19 disease received steroids, supplemental oxygen, and anticoagulants. Three patients had mild COVID-19 disease, two of whom were managed as inpatients because one was a pregnant woman and one was an infant. Patients' mean age was 42 (SD 18) years. Eight of the patients were men, four were hypertense, one suffered from asthma, and one was diabetic. Fever (12/12), chills (11/12), dry cough (9/12), headache (7/12), and diaphoresis (6/12) were the most frequent symptoms reported. Elevated AST/ALT levels, thrombocytopenia, severe anaemia, and thrombocytosis were the most relevant laboratory abnormalities documented. Mean time span between symptom onset and a positive test for SARS-CoV-2 infection based on RT-PCR or a positive microscopy for *Plasmodium* spp. was 6.3 (SD 3.4; range: 3-15) days and 3.3 (SD 3.4; range: 1-13) days, respectively. Nine patients had previous *P. vivax* malaria episodes (range: 1-11), three of whom within the past six months (possible relapse cases). All patients recovered uneventfully. Mean hospital stay was 11.5 (SD 7.2; range: 3-24) days. In malaria-endemic regions, suspected COVID-19 patients should also be monitored for malaria diagnosis without delays due to overlapping symptoms. *P. vivax* and SARS-CoV-2 co-infection could increase the severity of the disease rapidly. Future studies about the pathophysiology and lasting effects of malaria and COVID-19 co-infection are needed.

0362

DETERMINANTS OF MALARIA-RELATED COMMODITIES STOCKOUTS IN THE FOURTH QUARTER OF 2019, AT THE 34 HEALTH ZONES' DISTRIBUTION WAREHOUSES

Mario Edgard Badet[1], Virgile Gnaguenon[2], Eugène Montcho[2], Patrick Condo[2], Cyriaque Dossou Affoukou[1]

[1]Programme Notional de Lutte contre le Paludisme, Cotonou, Benin, [2]U.S. President's Malaria Initiative, USAID, Cotonou, Benin, Cotonou, Benin

In order to identify potential determinants of commodities stock-outs, we conducted a descriptive cross-sectional analysis regarding the 34 health zones' distribution warehouses (HDW). The evaluation focused on 2019 fourth quarter's data and took place from June 15 to 26, 2020. The dependent variable is 'a minimum of a-day stockout' of any given commodity in the fourth quarter of 2019. We also used the following independent variables: quarantine of commodities, availability of commodities at the central procurement office, compliance with delivery dates, availability of financial resources for the purchase of commodities, availability of means of transport of the commodities for the HDW, and lastly the HDW's managers' command of supply chain management processes, which is routinely assessed by using a standardized technical guide to interview the managers. Using a logistic regression model, the dependent variable was weighed against each of the independent variables. The significance threshold was set at the conventional value of 0.05. A proportion of 63.64% of the HDWs had experienced at least a-day commodity stockout in the fourth quarter of 2019. These stockouts were found to be significantly associated with the lack of command of supply chain management processes standards by the HDW managers (P value= 0.017), availability of commodities at the central procurement centers (P value= 0.001), quarantine of commodities (P value = 0.032), non-compliance with delivery dates (P value = 0.011). More efforts are needed to address aspects including HDW managers' capacity building, availability of commodities at the procurement central offices, quality control and routine monitoring processes.

0363

THE USE OF OUTCOME HARVESTING TO EVALUATE THE INTEGRATION OF PRIVATE SECTOR MALARIA CASE MANAGEMENT TO NATIONAL HEALTH SYSTEMS IN VIETNAM

Trung Thanh Nguyen

Population Service International (PSI) Vietnam, Hanoi, Vietnam

Since 2016, PSI has implemented the Greater Mekong Sub-Region Elimination of Malaria through Surveillance project which supports National Malaria Programs (NMPs) in Cambodia, Lao PDR, Myanmar, and Vietnam to engage private health care providers in the provision of quality malaria case management and the generation of data that is integrated into national surveillance systems. The project is currently transitioning activity management to NMPs in each country. In Vietnam, the project was evaluated in 2021 using Outcome Harvesting (OH). OH is an evaluation approach to identify, describe, and verify outcomes from development interventions through key informant interviews and desk reviews. OH is appropriate for evaluation in dynamic, uncertain situations, but is rarely used in malaria programs. Between July and September 2021, 26 outcomes were harvested following reviews of project documentation, national malaria policies, guidelines and interviews with program staff. Outcomes were verified through interviews with NMP staff, provincial Center for Disease Control staff and private providers working with the project. Verified outcomes demonstrated that the project succeeded in influencing stakeholders in target areas. The evaluation generated evidence related to an increased quality of malaria service provision within the private sector and increased integration of private sector data into provincial surveillance systems. National policy changes were also attributed by respondents to the project, including the inclusion of private providers in national training, commodity supply and supervision activities. At the community level, OH demonstrated changes in preferences for place of treatment. The results of this evaluation, demonstrate that the GEMS program contributed to changes in the national context, stakeholder behavior and provider practice, leading to the successful transition of private sector to NMP oversight. These results reaffirm the need for comprehensive engagement of national and subnational stakeholders when transitioning public health programs to government oversight.

0364

FACTORS ASSOCIATED WITH IPTP UPTAKE AMONG PREGNANT WOMEN IN MADAGASCAR

Bakoly Nirina Rahaivondrafahitra[1], Vololoniala Aimée Ravaoarinosy[2], Jacky Raharinjatovo[1], Mickael Randriamanjaka[1], Mohamed Patrice Diallo[1], Laurent Kapesa[3], Solofo Razakamiadana[4], Jocelyn Razafindrakoto[4], Anna Bowen[5]

[1]Population Services International (PSI), Antananarivo, Madagascar, [2]National Malaria Control Program Madagascar, Antananarivo, Madagascar, [3]President's Malaria Initiative, Antananarivo, Madagascar, [4]USAID, Antananarivo, Madagascar, [5]President's Malaria Initiative, Antananarivo, Madagascar

In 2016, the World Health Organization (WHO) recommended that all pregnant women benefit from 8 antenatal care contacts and receiving monthly intermittent preventive treatment (IPTp) with sulfadoxine pyrimethamine (SP) starting the second trimester of the pregnancy, with at least 3 doses of IPTp before delivery. USAID, through IMPACT (Improving Market Partnerships and Access to Commodities Together), with the NMCP (National Malaria Control Program) implemented a household survey to measure IPTp uptake (defined as receiving at least three doses of SP during pregnancy) and to identify predictors associated with IPTp-3 uptake. A cross-sectional household survey was conducted (March 2021) in 10 USAID-supported regions among women who had given birth in the last 12 months. A total of 44 enumeration areas (EA) were randomly selected using probability proportionate to size from the general census (2018). A representative sample of 3,751 households were systematically selected using census conducted in each EA, allowing to find 616 women having given birth in the last 12 months. Data were analyzed using STATA version 13.0. Logistic regression adjusting for age, marital status, number of children, education level, and location was used to identify factors associated with IPTp uptake. IPTp uptake among the target group was 46.8% [95%CI= 37.4-56.4%]. Regression analysis identified three predictors associated with IPTp uptake: i) women who understand how to take IPTp than those who do not (aOR=2.80; 95%CI=1.67-4.71), ii) women receiving at least one IPTp dose under direct observation of the health provider were more likely to receive the three doses than those who did not (aOR=2.73; 95%CI=1.49-5.04), and iii) women in the 4th and 5th quintiles for socio-economic status were more likely to complete the three doses than those who are not (aOR=2.20; 95%CI=1.34-3.85). The results help identify factors that may be addressed in the communication strategy: providing instruction on how to take the SP, targeting poorest women (free service), and ensuring provider training on direct observation.

0365

UNDERSTANDING ANTENATAL SERVICE QUALITY THROUGH SUPPORTIVE SUPERVISION DATA IN TANZANIA

Goodluck Tesha[1], Stella Makwaruzi[1], Saidi Mgata[2], Kanuth Dimoso[2], Charlotte Eddis[3], Adam Nothem[3], Jadmin Mostel[3], Katherine Wolf[4], Sigsibert Mkude[2], Abdallah Lusasi[5], Samwel Lazaro[5], Sijenunu Mwaikambo[5], Albert Ikonje[6], Chonge Kitojo[6], Naomi Serbantez[6]

[1]PMI Impact Malaria, Jhpiego, Dar es salaam, United Republic of Tanzania, [2]PMI Impact Malaria, PSI, Dar es salaam, United Republic of Tanzania, [3]PMI Impact Malaria, PSI, Washington, DC, United States, [4]PMI Impact Malaria,

Jhpiego, Baltimore, MD, United States, [5]National Malaria Control Program, Ministry of Health, Dodoma, United Republic of Tanzania, [6]U.S. President's Malaria Initiative, USAID, Dar es salaam, United Republic of Tanzania

Malaria in pregnancy (MIP) is a major global public health problem associated with increased maternal anemia, spontaneous abortion, and infant and maternal death. The Tanzania Ministry of Health delivers MIP and other antenatal care (ANC) services to pregnant women through an integrated ANC platform guided by the National Malaria Control Program and the Reproductive and Child Health Department. The U.S. PMI Impact Malaria project, in collaboration with regional and council health management teams, reviewed records of women who had delivered in three project-supported regions using a structured assessment tool during malaria service and data quality improvement (MSDQI) supportive supervision at ANC between October 2020 and December 2021. The ANC register was used to track adherence to guidelines as reflected in the records. The team assessed recording of the following at first ANC: gestation age, hemoglobin, malaria RDT, iron/folic acid and ITN provision; as well as visit number and number of IPTp doses throughout the pregnancy. Records of 5079 women who attended ANC were reviewed and found the interventions delivered and documented as follows: 96% gestation age, 94% RDT results, 94% ITN provided, 86% iron/folic acid, 44% Hemoglobin level and 59% IPTp3+. Many who received IPTp3+ attended first ANC between 13-26 weeks, had gravida 2-4 and made 4-6 ANC visits. Women who attended first ANC very late in their pregnancy had significantly higher odds of only getting IPTp1 compared to women who attended first ANC at ≤12 weeks (Month (M) 7: OR1.8; M8: OR2.4). Women who began ANC ≥13 weeks had significantly higher odds of getting IPTp3 compared to those beginning ≤12 weeks (M4: OR2.0; M5: OR2.1, M6: OR1.5). ANC intervention coverage was high, indicating high-quality integrated services. The data has identified a challenge in adherence to guidelines in provision of IPTp, root cause analysis will be conducted to identify the root cause of the problem and develop plans to address it.

0366

THREE DELAYS OF MALARIA CARE-SEEKING: COMPARING STRUCTURAL AND PSYCHOSOCIAL FACTORS INFLUENCING PROMPT CARE-SEEKING IN MALAWI

Bolanle Olapeju[1], Michael Bride[1], Tyson Volkmann[2], Shelby Cash[3], Edson Dembo[4], Michael Kayange[5], Austin Gumbo[5], Taonga Mafuleka[5], Nyanyiwe Mbeye[6], Jennifer Boyle[1], Chime Mukwakwa[1], Alfred Mang'ando[1], Joseph Sakala[1]

[1]Johns Hopkins University Center for Communications Programs, Baltimore, MD, United States, [2]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Lilongwe, Malawi, [3]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]U.S. President's Malaria Initiative, USAID, Lilongwe, Malawi, [5]National Malaria Control Program, Lilongwe, Malawi, [6]Kamuzu University of Health Sciences, Lilongwe, Malawi

The three-delays (1st- deciding to seek, 2nd- getting to, and 3rd- receiving adequate) care model was used to explore delay-related factors influencing prompt care-seeking for children under five with fever to inform the design of effective social and behavior change (SBC) interventions. We analyzed responses from 913 female caregivers in a nationally representative cross-sectional survey conducted in Malawi in 2021. The outcome variable was prompt care-seeking from a qualified provider. Delay factors included: 1st level- knowledge, attitudes towards malaria, the perception that prompt care-seeking is effective, perceived malaria susceptibility and discussion of malaria with family or friends; 2nd level- proximity to facility, transportation, and urban versus rural location; 3rd level- perceptions of provider knowledge, perceived quality of care, and perceived availability of commodities. Logistic regressions explored the association of delay factors at each level with prompt care-seeking, controlling for contextual variables. Delay factors were summed into three continuous variables to compare their relative associations with prompt care-seeking. Statistically significant factors associated with prompt care-seeking included knowledge of malaria, positive attitudes towards care-seeking, and recent discussion of malaria with family or friends (aOR ranging 1.22-1.42)[1] at the 1st level, and proximity to a health facility (aOR: 1.46; 95% CI: 1.06-2.00) at the 2nd level. Each additional positive factor present in the 1st level increased the odds of prompt care-seeking by 29% (aOR: 1.29; 95% CI: 1.16-1.44), while additional factors at the 2nd and 3rd levels had no effect. Amidst the backdrop of free malaria services in Malawi, key correlates of prompt care-seeking for fever were primarily psychosocial factors occurring at the 1st delay phase that may be addressed with community-based SBC interventions. Interventions may use a mix of SBC approaches to address key correlates of care-seeking, including improved knowledge, attitudes, and household discussions about prompt care-seeking for fever.

0367

PERFORMANCE OF COMMUNITY HEALTH INFLUENCERS, PROMOTERS AND SERVICES (CHIPS) ON CASE MANAGEMENT OF UNCOMPLICATED MALARIA

Dawit Getachew[1], Muhammad Abubakar Kumo[1], Hussaini Tijjani[2], Akinyeye Abiodun Ojo[1], Nihinlola Mabogunje[1], Olusola Oresanya[1], Kolawole Maxwell[1]

[1]Malaria Consortium, Abuja, Nigeria, [2]State Primary Health Care Management Board, Kano, Nigeria

Nigeria has the second highest childhood mortality in the world. Most of these deaths are preventable through proven and cost-effective interventions. Substantial inequalities still exist in child health outcomes based on differences in economic status, education, place of residence and sex. Kano State has one of the highest malaria prevalence and under-five mortality in the country. The Nigerian Ministry of Health adopted a new community health workers' model called Community Health Influencers, Promoters, and Services (CHIPS) to improve access to and quality of primary health care in rural communities and also contribute to the attainment of UHC. Support to the National Malaria Programme2 (SuNMaP2) supported the introduction of CHIPS in hard-to-reach communities in Kano through harmonization of integrated community case management (iCCM) and CHIPS modules, training of 1,130 CHIPS agents (99% female) and provision of malaria and non-malaria commodities with proper linkage to health facilities for clinical mentoring, supportive supervision and data collection. A performance assessment of 320 CHIPS agents was conducted in Kano focusing on four thematic areas: service provision; use of CHIPS guideline and job aids; patient's records management; and stock management. The assessment showed that job aids for malaria rapid diagnostic test (RDT) and rectal artesunate were available and in use by 84.3% of CHIPS agents. About 90% of children under five with confirmed malaria were treated with artemisinin-based combination therapy (ACT) by CHIPS agents. Patient's record management was good, with 85.1% of them having updated household record information. 88.7% of the CHIPS agents maintained good stock management practices including use of inventory control card and First-Expiry-First-Out (FEFO) method. Overall, 85% of CHIPS agents were performing according to standards. We recommend that routine supervision that includes observation of case management of malaria should be done more regularly in all CHIPS implementing localities. Linkages between facility based and community-based malaria treatment should also be strengthened.

0368

THE CONTRIBUTION OF THE U.S. PMI IMPACT MALARIA PROJECT IN BUILDING THE CAPACITY OF MATERNITY PROVIDERS ON MALARIA IN PREGNANCY IN MALI

Fatoumata Sidibe[1], Abdrahamane Diallo[2], Samba Coumare[1], Chebou Diallo[1], Mariam Sylla[1], Beh Kamaté[1], Curt von Boguslawski[3], Lansana Sangaré[4], Patricia Gomez[5], Charlotte Eddis[6], Thierno Ba[6], Fady Touré[7], Aissata Kone[7], Fatimata Toure[8], Mamadou Ouane[1]

[1]PMI Impact Malaria, PSI, Bamako, Mali, [2]PMI Impact Malaria, Jhpiego, Bamako, Mali, [3]Population Services International (PSI), Bamako, Mali, [4]U.S. President's Malaria Initiative, USAID, Bamako, Mali, [5]PMI Impact Malaria, Jhpiego, Baltimore, MD, United States, [6]PMI Impact Malaria, PSI, Washington, DC, United States, [7]National Malaria Control Program, Ministry of Health, Bamako, Mali, [8]Sub-Directorate of Reproductive Health, Ministry of Health, Bamako, Mali

In Mali in 2018 there were no specific malaria in pregnancy (MIP) training materials, nor did the outreach training and supportive supervision (OTSS) approach include MIP. Maternity providers referred pregnant women who tested positive for malaria to the outpatient clinic for treatment. In 2019, the U.S. President's Malaria Initiative Impact Malaria (IM) project supported the National Malaria Control Program and the Sub-Directorate of Reproductive Health to produce specific training materials on MIP prevention and management and respectful antenatal care (trainer's guide and reference manual), and developed MIP checklists to integrate into OTSS, part of the upgrade to OTSS+. These documents and checklists were validated by the MIP technical working group (TWG) and disseminated through cascade training to maternity providers in five regions: Ségou, Mopti, Kayes, Koulikoro, and Bamako. A total of 1,121 maternity providers were trained in 2019 and in 2021: 34% midwives, 32% obstetric nurses, 31% matrons, and 3% other cadres, from 1,063 health facilities including 958/1,408 Community Health Centers and 42/62 Referral Health Centers which is equivalent to 68% of functional public health facilities in the country. During these combined trainings (classroom theory and clinical practice), participants scored an average of 75% at pre-test and 97% at post-test. After these trainings, OTSS+ visits assessed the competence of a subset of 282 trained providers in the regions of Ségou and Mopti in 2019. Overall, 53% of providers met the competency score of 90% in MIP prevention, and 60% of providers reached a score of 90% in MIP treatment. When IM moved to Kayes, Koulikoro, and Bamako in 2020, a baseline OTSS+ round was conducted before the MIP training in 2021. In 2021, after the training, OTSS+ reached 294 of the trained providers, 58% of whom reached the competency threshold in MIP prevention vs. 22% at baseline, and 47% of them reached the competency threshold in MIP treatment vs. 17% at baseline. The MIP TWG subsequently endorsed a change in practice such that all trained maternity providers now treat MIP in the maternity department.

0369

ENGINEERING A TRANSGENIC ASAIA BOGORENSIS STRAIN TO CONTROL AN EFFECTOR PLASMID WITH A CONDITIONAL ORIGIN OF REPLICATION FOR PARATRANSGENESIS USE

Anna Manges

Duquesne University, Pittsburgh, PA, United States

Malaria is a dangerous vector-borne disease caused by parasitic protists of the genus *Plasmodium* and transmitted through the bite of infected female *Anopheles* mosquitoes. In 2020, over 600,000 deaths from malaria were reported. Due to its severity, many strategies to mitigate and combat the spread of malaria are currently in place. However, the emergence of resistance to insecticides and anti-plasmodial treatments calls for additional methods for reduction of malaria infection. Paratransgenesis is the genetic engineering of symbiotic bacteria that live in the mosquito midgut to secrete anti-plasmodial effector peptides. Paratransgenesis has the potential to kill *Plasmodium* parasites prior to human infection. The pi protein, Pir, is necessary for the replication of oriR6K plasmids. By inserting *pir* into the *Asaia bogorensis* chromosome, an oriR6K effector plasmid will be able to replicate in the engineered bacterial strain only, preventing its horizontal transfer to unintended hosts. To this end, *pir* with three variable ribosome binding sites (RBSs) have been inserted into a neutral phage site within the *Asaia* chromosome. These variable RBSs have been shown to control low, medium, and high oriR6K plasmid copy numbers within the respective transgenic strains. By supplementing Pir in trans, the plasmid will be unable to replicate in unintended hosts, preventing its transfer to other organisms in the mosquito midgut environment. The use of three separate RBSs also allows for replication of the plasmid at optimal levels for survival and competitiveness of the transgenic strains. Thus, this provides the first step towards a plasmid-based paratransgenesis system that will not be transferred to other bacteria within the mosquito midgut.

0370

EFFECT OF FIVE ROUNDS OF SEASONAL MALARIA CHEMOPREVENTION IN CHILDREN AGED BETWEEN 5 AND 14 YEARS IN DANGASSA MALI

Drissa Konate[1], Sory Ibrahim Diawara[1], Nafomon Sogoba[1], Jeffrey G. Shaffer[2], Bourama Keita[1], Abdourhamane Cisse[1], Ilo Dicko[1], Ibrahim Sanogo[1], Merepen dite Agnes Guindo[1], Abdouramane Traore[1], Salimata Kante[1], Assitan Dembele[1], Fatoumata Kasse[1], Larissa Denou[1], Seidina AS Daikite[1], Karim Traore[1], SIdibe M'Baye Thiam[1], Vincent Sonogo[3], Ayouba Diarra[1], Mahamoudou Toure[1], Jules Mihigo[4], Celia Diane[4], Seydou Doumbia[1], Mahamadou Diakite[1]

[1]FMOS/USTTB, Bamako, Mali, [2]School of Public Health and Tropical Medicine, Tulane University, Tulane, LA, United States, [3]NMCP, Bamako, Mali, [4]PMI, Bamako, Mali

Despite a significant reduction in malaria burden in children under five years of age, the large-scale implementation of seasonal malaria chemoprevention (SMC) remains a considerable challenge in areas with long periods of seasonal malaria transmission, such as Dangassa Mali. Low coverage, shifting malaria risk in children at least five years of age, and rebound effects in malaria incidence after SMC stoppage are primarily reported in areas with long-term malaria transmission. An open randomized study was conducted to assess the effect of an additional round of the current SMC regimen in older children in Dangassa, Mali, where malaria transmission is highly seasonal. Poisson regression models were used to estimate the reduction in malaria incidence in the intervention group compared to a control group. Overall, a downward trend in participation rates was observed from August (94.3%) to November (87.2%) respectively. One month following the fourth SMC round, the risk of malaria incidence was similar in both comparison groups (IRR=0.66, 95%CI [0.35-1.22]). In December, a decrease of 51% in malaria incidence was observed in the intervention group compared to the control group after adjusting for age and long-lasting insecticidal net use (IRR=0.49, 95%CI [0.26-0.94]). A reduction of approximately 17% in malaria incidence was observed after the fifth round in the intervention group as compared with the control group. Implementing a fifth round of SMC in Dangassa has shown a significant reduction in malaria incidence. These results suggest a critical need to extend SMC to children aged at least five years and include five cycles of treatment in areas with extended transmission seasons, such as Dangassa. **Keywords**: Malaria, Incidence, Seasonal malaria chemoprevention, Mali.

FACTORS ASSOCIATED WITH RECEIVING LONG-LASTING INSECTICIDE TREATED NETS AT REPRODUCTIVE AND CHILD HEALTH CLINICS IN MAINLAND TANZANIA

Mponeja P. Gitanya[1], Israel P. Nyarubeli[2], Heavenlight Paul[2], Stella Kajange[3], Ally Mohamed[1], Samwel Lazaro[1], Sijenunu Aroni[1], David Dadi[4], Benjamin Kamala[4], Naomi Serbantez[5], Deogratius Mwingizi[4], Hannah Koenker[6], William Kisinza[7]

[1]National Malaria Control Program Tanzania, Ministry of Health, Dodoma, United Republic of Tanzania, [2]Department of Environmental and Occupation Health, Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania, [3]President Office Regional Authority and Local Government, Dar es Salaam, United Republic of Tanzania, [4]USAID-Tanzania Vector Control Activity/Johns Hopkins Centre for Communication Programs, Dar es Salaam, United Republic of Tanzania, [5]US President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, [6]Tropical Health LLP, Baltimore, MD, United States, [7]Amani Research Centre of the National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

Mass distribution of Long-Lasting Insecticidal Nets (LLINs) is an effective malaria prevention intervention. Tanzanian policy is for every pregnant woman attending first antenatal clinic (ANC) and every child receiving their first measles-rubella vaccination to be given a free LLIN. However, routine data shows that not all eligible pregnant women and children get an LLIN at these visits. This study aimed to determine factors influencing the uptake of LLINs in these two vulnerable groups. A health facility-based cross-sectional survey was conducted from July and September 2021 in Mainland Tanzania in 60 health facilities randomly selected from ten districts in five regions representing five different transmission strata and rural and urban areas. The study involved 1320 pregnant women attending first ANC and 1320 children attending first measles-rubella vaccination services. Chi-square tests followed by a modified Poisson regression model were used to identify factors associated with LLIN uptake in both groups separately. About three quarters (N= 980) of pregnant women received an LLIN at their first ANC. This was highest in Babati district (94.6%) and lowest in Mbogwe District (56.7%). Increasing age (p= 0.015), number of children per woman (p= 0.033), number of ANC visits (p= 0.010), and the previous experience of sleeping under a mosquito net (p<0.001) were associated with receiving an LLIN at the visit. Seventy one percent (N=938) of caretakers received an LLIN at their child's immunization visit. This was highest in Kaliua (94.1%) and lowest in Ilala (43.7%). Increasing caretakers' age (p<0.001), higher level of education of caregiver (p<0.001), previous experience of sleeping under a mosquito net (p = 0.037), and previous exposure to health education on LLIN (p<0.001) were associated with receiving an LLIN at the visit. The rates of pregnant women and caretakers of young children receiving LLINs at first ANC and measles-rubella immunization visits were unsatisfactory. The study findings may be used to strengthen education and mentorship programs at all health facilities for both women of childbearing age and health care providers.

0372

IMPACT OF PROACTIVE COMMUNITY CASE MANAGEMENT ON MALARIA AND ANEMIA PREVALENCE AMONG PREGNANT WOMEN IN BANKASS, MALI, 2020

Kassoum Kayentao[1], Saibou Doumbia[2], Jane Yang[3], Djoumé Diakité[2], Stephanie Rapp[4], Caroline Whidden[2], Emily Treleaven[5], Julie Thwing[6], Ari Johnson[7]

[1]Mali Research and Training Center, Bamako, Mali, [2]MUSO, Bamako, Mali, [3]MUSO, San Francisco, CA, United States, [4]MUSO, Abidjan, Côte D'Ivoire, [5]University of Michigan, Ann Arbor, MI, United States, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]University of California, San Francisco, San Francisco, CA, United States

Malaria and anemia in pregnancy remain common in Mali despite the scale-up of control interventions. We conducted a cross-sectional study to assess whether proactive home visits by Community Health Workers (CHWs) are more effective than conventional, passive workflow in reducing the prevalence of malaria and anemia among pregnant women in rural Bankass, Mali. The study was nested in a three-year (2017-2020) cluster-randomized controlled trial assessing the impact of proactive community case management in reducing under-five mortality among 137 village-clusters randomized to proactive home visit intervention (household visit by CHW at least two times per month) or passive control arms (CHW services provided at a fixed site in the community). CHWs in both arms provided illness management, including malaria rapid diagnostic tests (RDT) and antimalarial treatment for those with positive tests, follow-up care, health education, and reproductive, maternal, and newborn care and referral services. At the end line survey, all pregnant women were tested for malaria using RDTs and anemia. Women who reported completing a pregnancy in the last year were asked about receiving three or more doses of intermittent preventive treatment in the pregnancy (IPTp3+). At end line, 1848 pregnant women were interviewed (control N = 859, intervention N = 989). The prevalence of malaria was similar in the intervention and control arms (16.1%, 95% CI 13.8-18.4 and 17.6%, 95% CI 15.0-20.7, respectively). The prevalence of moderate or severe anemia (hemoglobin < 10 g/dL) was also similar in the intervention and control arms (38.0%, 95% CI 34.8-41.3 and 42.1%, 95% CI 37.4-46.8, respectively). Among 207 women who reported completing a pregnancy in the last year and provided information on IPTp3+, 67.0% (95% CI 56.4-77.5) received three or more doses of IPTp3 in the intervention arm compared to 51.0% (95% CI 42.7-59.3) in the control arm (OR 1.95, p = 0.022). Proactive home visits were not associated with a significant reduction of malaria and anemia prevalence among pregnant women, but improved the coverage of at least three doses of IPTp compared with passive workflow.

0373

FACTORS ASSOCIATED WITH EARLY UPTAKE OF INTERMITTENT PREVENTIVE THERAPY IN PREGNANCY IN BUSIA DISTRICT, UGANDA

Thomas Katairo[1], Philip Orishaba[2], Wani Muzeyi[3], Emmanuel Arinaitwe[1], Moses R. Kamya[1], Nelson Kalema[4], Joaniter I. Nankabirwa[1]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]The Centre for Rapid Evidence Synthesis, Kampala, Uganda, [3]Clinical Epidemiology Unit, Kampala, Uganda, [4]Infectious Diseases Institute, Kampala, Uganda

In areas with moderate to high malaria transmission, the World Health Organization recommends monthly Intermittent Preventive Therapy in Pregnancy (IPTp) with sulphadoxine-pyrimethamine (SP) beginning in the fourth gestational month. Women who begin IPTp during the fourth month, compared to later during pregnancy, have better birth outcomes; however, the factors affecting early IPTp uptake are largely unknown. 467 pregnant women attending antenatal care at Busia Health Centre IV and Masafu Hospital, both in eastern Uganda, were enrolled using an explanatory sequential mixed methods design. Qualitative data were gathered through in-depth and key informant interviews. We used modified Poisson regression with clustered robust standard errors at hospital level to predict prevalence ratios (PR). Overall, 30% (95% CI= 26.0%-34.3%) of pregnant women initiated IPTp during the fourth month. Participant age 15-24 years (aPR=1.03; 95% CI=1.01-1.06), being a Protestant (aPR= 1.26; 95% CI= 1.05-1.52), being married (aPR= 1.20; 95% CI= 1.03-1.17), using insecticide treated nets (aPR= 1.11; 95% CI= 1.02-1.20) and listening to a radio more than once a week (aPR=1.46; 95%CI=1.21-1.76) were associated with increased prevalence of early IPTp initiation while being a trader (aPR= 0.47; 95% CI= 0.41-0.55), being a Moslem (aPR= 0.26; 95% CI= 0.22-0.30), having been separated/divorced/widowed (aPR= 0.93; 95% CI=0.87-0.99), being in a wealthy category (aPR=0.65; 95% CI= 0.62-0.67) and having knowledge about IPTp (aPR= 0.23; 95% CI= 0.18-0.28) were associated with reduced prevalence of early IPTp initiation. In qualitative assessments, discouragement from the mother-in-law, a lengthy turn-around time, and IPTp knowledge gaps were

all identified as barriers to IPTp uptake. The government and its partners should consider redoubling their social mobilization efforts, such as radio broadcasts, to educate communities about the importance of early initiation of IPTp.

0374

FACTORS ASSOCIATED WITH SEASONAL MALARIA CHEMOPREVENTION (SMC) COVERAGE ACROSS ALL CYCLES AND ADHERENCE TO DAY 2 AND 3 MEDICATION: A MULTI-YEAR REVIEW OF INDEPENDENT HOUSEHOLD MONITORING SURVEYS FROM TWO COUNTRIES

Charlotte Eddis[1], Thierno Ba[1], Christophe Tchadjeu[2], Chebou Diallo[3], Samba Coumare[3], Beh Kamate[3], Jean Yves Mukamba[2], Dorothy Achu[4], Lia Florey[5], Jadmin Mostel[1]

[1]PMI Impact Malaria, PSI, Washington, DC, United States, [2]PMI Impact Malaria, PSI ACMS, Yaounde, Cameroon, [3]PMI Impact Malaria, PSI, Bamako, Mali, [4]National Malaria Control Program, Ministry of Health, Yaounde, Cameroon, [5]U.S. President's Malaria Initiative, USAID, Washington, DC, United States

Seasonal Malaria Chemoprevention (SMC) consists of the intermittent administration of antimalarial medications during the rainy season to prevent clinical malaria. Full treatment courses of sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) are given to children aged 3-59 months at 28-day intervals. SP and AQ are given on day 1 as directly observed treatment by community distributors, and caregivers administer another two AQ doses on subsequent days unobserved. To ascertain factors associated with coverage of SP and AQ on day 1 and adherence to day 2 and 3 AQ the NMCPs, supported by the U.S. PMI Impact Malaria, conducted independent household monitoring surveys in Cameroon and Mali. In Cameroon, 96% of nearly 2 million children targeted were reached in all 4 cycles in 2020 (93% of nearly 1 million in Mali) per caregiver declaration and 95% took their second and third dose during each cycle (97% in Mali) per caregiver declaration. In Cameroon, the most cited reason for a child not being treated in cycle 1- home not visited by a distributor - dropped from 50% to 30% in cycle 4 . Children treated in cycle 4 had significantly lower odds of having side effects (except for loss of appetite) than children treated in cycle 1. Even though children under one year old had higher odds of side effects than children over one year old, it did not affect adherence to medication on day 2 and 3. Ineligibility of the child on day 1 of each cycle due to fever (they do not test for malaria as part of their campaign) decreased from 22% of all reasons for not being treated in cycle 1 to 14% in cycle 4 of 2020 in Cameroon, while in Mali it increased from 10% to 26% that year. This may be due to differences in campaign start dates, as Cameroon starts cycle 1 at the beginning of July, and Mali at the end of July. In Mali, which does test as part of the campaign, the proportion of positives out of suspected cases tested increased from cycle to cycle in both under-fives and over fives in both 2019 and 2020. Analyses are ongoing, and the results may be used to tailor the delivery and communications strategies to each country.

KNOWLEDGE AND PRACTICES ON MALARIA AMONG COMMUNITIES INVOLVED IN A SEASONAL MALARIA CHEMOPREVENTION STUDY IN NANYUMBU AND MASASI DISTRICTS, TANZANIA

Sylvia F. Mkalla[1], Billy E. Ngasala[2], Richard O. Mwaiswelo[3], Bruno P. Mmbando[4], Frank Chacky[5]

[1]Directorate of Research, Coordination, and Promotion, Tanzania Commission for Science and Technology, Dar es Salaam, Tanzania, Dar es Salaam, United Republic of Tanzania, [2]MUHAS, Dar es Salaam, United Republic of Tanzania, [3]Department of Microbiology, Immunology and Parasitology, Hubert Kairuki Memorial University, Dar es Salaam, Tanzania, Dar es Salaam, United Republic of Tanzania, [4]Tanga Research Centre, National Institute for Medical Research, Tanga, Tanzania,, Tanga, United Republic of Tanzania, [5]National Malaria Control Programme, Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, Dodoma, United Republic of Tanzania

Utilization of malaria interventions are influenced by the level of knowledge and perception of the community on the infection and the availability of the interventions. This study assessed knowledge, perception, and utilization of malaria control tools in Masasi and Nanyumbu districts, Tanzania, areas with seasonal malaria transmission. A community-based cross-sectional survey among heads of households of under-five children conducted between August and September 2020. A structured questionnaire was administered to the heads of the households to gather information on knowledge and perception of malaria infection and utilization of the available malaria interventions. Screening of malaria infection was carried out on children aged between 3 and 59 months using a malaria rapid diagnostic test (mRDT). A total of 1556 household heads were interviewed, 1167 (75.0%) were male, and 1067 (68.6%) were couples. Only 47.3% and 13.8% of the household heads had moderate and adequate knowledge on malaria infection and control, respectively. The level of knowledge on malaria infection and control was significantly influenced by gender and level of education of the household head, and the number of under-five children in the household. Likewise, about 95% of the household heads perceived sleeping under the bed net to be beneficial. Majority of the household (95.9% (1492/1556) reported using bed nets as malaria intervention, but only 84.0% (1305/1556) of the households had bed nets. In this area with seasonal transmission about half of household heads had a moderate level/adequate of knowledge on malaria infection and control interventions.

0376

COMPARING CHEMOPREVENTION APPROACHES FOR SCHOOL-BASED MALARIA CONTROL IN MACHINGA DISTRICT, MALAWI

Alick Sixpence[1], Wangisani Kumalakwaanthu[1], Alfred Matengeni[1], Laurence S. Magder[2], Karl B. Seydel[3], Miriam K. Laufer[4], Don P. Mathanga[1], Lauren M. Cohee[4]

[1]Malaria Alert Centre, Kamuzu University of Health Science, Blantyre, Malawi, [2]Department of Epidemiology & Public Health, University of Maryland, Baltimore, MD, United States, [3]Department of Osteopathic Medical Specialties, College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, [4]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Prevalence of *Plasmodium falciparum* (*Pf*) infection in school-age children (5-15 years, SAC) is often higher than in younger children and adults. Asymptomatic infection and uncomplicated malaria disease lead to decreased school attendance, impaired cognitive function, and continued parasite transmission. School-based preventative treatment is a promising strategy to reduce the burden of malaria among SAC. However, optimal design of an intervention is not clear. We aim to compare intermittent preventive treatment (IPT), in which all students receive treatment to both clear parasites and provide a period of prophylaxis, and intermittent screening and treatment (IST), in which only students with a positive test are treated. In February 2022, we enrolled 745 primary school students in a 3-arm randomized controlled clinical trial: IPT, IST, and control. All students in the IPT arm and students with positive high-sensitivity rapid diagnostic test (hsRDT) in the IST arm were treated. Girls <10 years old and all boys were treated with dihydroartemisinin-piperaquine (DP). Older girls were treated with chloroquine as DP is contraindicated in the first trimester of pregnancy. The intervention will be performed three times during the peak malaria transmission season (Feb-June). Outcomes including *Pf* infection, clinical malaria, anemia, school attendance and household infection prevalence will be assessed 6-8 weeks after the final intervention. At each visit, students are interviewed about symptoms and treatment history and a fingerprick blood sample is obtained to characterize *Pf* infection. At baseline, mean hemoglobin level was 12.7g/dL (SD:1.3); 8.0% of students were anemic (<11g/dL); 30% reported fever

in the last 48hrs; 49% reported sleeping under a bednet the night prior to the interview. *Pf* infection prevalence by hsRDT in the IST arm was 47.9%. Full baseline, follow-up and outcome results will be presented. Thus far our study confirms the high prevalence of *Pf* infection in SAC. Results of this trial will inform the design of school-based malaria chemoprevention programs.

ACCOUNTING FOR REGIONAL TRANSMISSION VARIABILITY AND THE IMPACT OF MALARIA CONTROL INTERVENTIONS IN GHANA: A POPULATION LEVEL MATHEMATICAL MODELLING APPROACH

Timothy A. Awine

Navrongo Health Research Centre, Navrongo, Ghana

Background: Assessing the effectiveness of malaria control measures in Ghana will require taking transmission dynamics of the disease into account given the influence of climate variability in the region of interest. The impact of preventative interventions on malaria incidence and the prospects of meeting program timelines in Ghana have been investigated using mathematical models based on regionally diverse climatic zones. Methods: An ordinary non-linear differential equation model with its associated rate parameters was developed incorporating the transitions between various disease compartments for three ecological zones in Ghana. Model parameters were estimated using data captured on the District Health Information Management System in Ghana from 2008 to 2017.The impact of insecticide treated bed nets and indoor residual spraying on the incidence of malaria were simulated at various levels of coverage and protective effectiveness in each ecological zone. To fit the model, Approximate Bayesian Computational sampling approach was adopted. Results: Increasing the coverage levels of both long lasting insecticide treated bed nets or indoor residual spraying activities without a corresponding increase in their proper use or patronage does not impact highly on averting predicted incidence of malaria in Ghana. Improving on the protective efficacy of long lasting insecticide treated bed nets through proper usage could lead to substantial reductions in the predicted incidence of malaria. Similar results were obtained with indoor residual spraying across all zones. Conclusions: Projected goals set in the National Strategic plan for malaria control 2014-2020 as well as WHO targets for malaria pre-elimination by 2030 are only likely be achieved if a substantial improvement in treated bed net usage is achieved coupled with targeted deployment of indoor residual spraying with high efficacy.

COMPARATIVE ANALYSIS OF FACILITY AND COMMUNITY DISTRIBUTION OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY: EVIDENCE FROM MATERNITY RECORD BOOKLET IN OHAUKWU, EBONYI STATE NIGERIA

Charity Anoke[1], Bright Orji[1], Emily Bryce[2], Elizabeth Oliveras[2], Joseph Enne[1], Elizabeth Njoku[1], Lawrence Nwankwo[3], Emmanuel Ugwa[4], Bartholomew Odio[1], Herbert Onuoha[1], Christina Maly[2], Emmanuel Otolorin[1], Elaine Roman[2], Oniyire Adetiloye[1]

[1]Jhpiego, Abuja, Nigeria, [2]Jhpiego, Baltimore, MD, United States, [3]Ebonyi State Ministry of Health, Abakaliki, Nigeria, [4]Federal Medical Center, Birnin Kudu, Jigawa State, Birnin Kudu, Nigeria

Nigeria has the highest malaria burden globally, contributing to 31.9% of global malaria deaths, and is one of the two countries with the greatest burden of malaria during pregnancy. According to the 2018 Nigeria Demographic and Health Survey (DHS), even though up to 57% of pregnant women attend ANC four or more times, only 17% received three or more doses of IPTp as recommended by the WHO. Nigeria supported this demonstration project of CHWs in delivering intermittent preventive treatment of malaria in pregnancy (IPTp) at the community-level, complementing IPTp at antenatal care (ANC) in three districts. Data were extracted from 735 maternity record booklets (MRB) at 25 public health facilities in Ohaukwu for women presenting for ANC between April and September of 2019. The MRB allowed for the longitudinal analysis of client-level data that is not available from routine data sources. Sixty percent of women received IPTp doses only in the community, while 28% received IPTp only at ANC and 12% received IPTp in both locations. One-way ANOVA and post-hoc Tukey tests were used to examine the difference in mean number of ANC visits and number of IPTp doses between the three groups. The mean number of ANC visits was significantly higher in the group of women receiving IPTp at both locations compared to those only receiving IPTp in the community (0.89 ± 0.18 visits, $p<0.01$) and those only receiving IPTp during ANC (0.61 ± 0.20 visits, $p<0.01$). There was no statistically significant difference in the mean number of ANC visits between the groups receiving IPTp only in one location (0.29 ± 0.13 visits, $p=0.077$). The difference in number of doses was statistically significant across all groups, whereby women in the facility-only group received the fewest IPTp doses. Receipt of IPTp in both locations was associated with both greater numbers of ANC visits and IPTp doses. Only receiving IPTp in the community was not associated with a decrease in ANC attendance. These data suggest complementing ANC-based IPTp distribution with community-based distribution is beneficial.

0379

LONG-TERM IMPACT OF SEASONAL MALARIA CHEMOPREVENTION (SMC) ON MONTHLY DISTRICT- AND CLINIC-LEVEL MALARIA CASES IN CHILDREN AGED UNDER FIVE USING ROUTINE CLINICAL DATA, 2013-2018

Sol Richardson[1], Cheick S. Compaore[2], Benoît Sawadogo[2], Monica A. de Cola[1], Gauthier Tougri[3], Christian Rassi[1], Arantxa Roca-Feltrer[4]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Ouagadougou, Burkina Faso, [3]Ministry of Health, Burkina Faso, Ouagadougou, Burkina Faso, [4]Malaria Consortium, Maputo, Mozambique

Since its recommendation by the World Health Organization in 2012, seasonal malaria chemoprevention (SMC) targeting children aged 3-59 months with administration of sulfadoxine-pyrimethamine plus amodiaquine (AQ) in four-cycle annual rounds during the high transmission season has been scaled up across Sahelian countries. As SMC in Burkina Faso has matured, it has been delivered over eight consecutive years in some areas. We investigated whether impact of SMC on monthly district-level counts of suspected and confirmed malaria cases among children aged 0-59 months in Burkina Faso remained consistent between annual rounds. Data were extracted from the national Health Management Information System, covered 64 districts with at least one year of SMC delivery and spanned 2013-2018. We fitted quasi-Poisson generalized additive mixed models with cyclic cubic spline terms for each district to adjust for seasonality in cases, and random intercept terms for years within districts. Models included interactions between periods of SMC delivery and number of annual SMC rounds previously delivered in that district by year to test for differences in effect between years. SMC delivery was significantly associated with lower adjusted monthly district-level counts of cases (rate ratio: 0.23, 95% CI: 0.22-0.24, $p<0.0001$), corresponding to a 77% reduction. Interaction terms indicated reductions of 84%, 93%, 94% and 96% in monthly malaria cases in areas with one, two, three and four previous rounds respectively, and a significant improvement in effect with successive rounds. The results highlight the effectiveness of SMC in Burkina Faso and are consistent with trials showing a 75% reduction in confirmed cases. It may be hypothesized that increasing effectiveness of SMC over time reflects increasing coverage and adherence to AQ administration. Next steps include obtaining additional clinical data from Burkina Faso, Togo and other Sahelian countries; fitting models to clinic-level data using a supercomputer; estimating impact in districts with five annual SMC cycles; and investigating potential SMC "rebound effects" in children aged over five years.

0380

OPTIMIZING THE ROLE OF LEAD MOTHERS IN SEASONAL MALARIA CHEMOPREVENTION (SMC) CAMPAIGNS: INSIGHTS FROM FORMATIVE RESEARCH IN KANO STATE, NORTHERN NIGERIA

Ekechi Okereke[1], Helen Smith[2], Chibuzo Oguoma[1], Olusola Oresanya[1], Maxwell Kolawole[1], Ashiru Rajab[3], Emmanuel Shekarau[4], Festus Okoh[4], Erica Vigano[5], Laura Donovan[5], Charlotte Ward[6], Kevin Baker[5]

[1]Malaria Consortium, Abuja, Nigeria, [2]International Health Consulting Services Ltd, Liverpool, United Kingdom, [3]Kano State Ministry of Health, Kano, Nigeria, [4]National Malaria Elimination Programme, Abuja, Nigeria, [5]Malaria Consortium, London, United Kingdom, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

Seasonal malaria chemoprevention (SMC) is effective in preventing malaria. Lead mothers (LMs) are community health volunteers that undertake health promotion activities during SMC campaigns aimed at ensuring caregivers' compliance with administering the complete dosage for SMC. The LMs approach is used in several SMC implementing states across Nigeria, however, there is lack of evidence about structure or impact of this approach. We sought to better understand the current role of LMs and identify areas for improvement by obtaining feedback from stakeholders, to possibly improve SMC outcomes in Nigeria. Formative research, utilizing qualitative methods, was undertaken in Kano State, northern Nigeria. Twenty semi-structured interviews were conducted with stakeholders from National, State, Local government health systems as well as from the community. Transcription and thematic analysis were conducted on the qualitative data. Study findings indicate that recruitment and supervision guidelines for LMs should be reviewed and strengthened within the SMC programme in Nigeria. There is also a clear need to improve the knowledge and skills of LMs through adequate training, so that they better deliver targeted health messages to caregivers during SMC campaigns. Appropriate job aids such as flipbooks, should be developed and provided to LMs. In addition to their current role, LMs should discuss other malaria prevention interventions [beyond SMC] with caregivers, encourage better nutrition and sanitation practices within households as well as promote better health-seeking behaviour among community members. To promote sustainability, respondents also noted policy-makers should work to transition the role of LMs to the Community Health Influencers Promoters Services (CHIPS) agents during SMC campaigns; since CHIPS agents have government policy and funding support, in contrast to the current LMs intervention which is not sustainable and heavily supported by donor organizations. In addition to feedback from some study respondents that CHIPs agents have more training and capacity to contribute to the SMC programme than the current LMs.

0381

SAFETY AND EFFICACY OF DIHYDROARTEMISININ-PIPERAQUINE FOR SEASONAL MALARIA CHEMOPREVENTION IN SCHOOL AGED CHILDREN, MALI

Karim Traore, Drissa Coulibaly, Bourema Guindo, Abdoulaye Kassoum Kone, Kindie Kouriba, Souleymane Traore, Fayçal Maiga, Moussa Djimde, Mahamadou Ali Thera

Malaria Research and Training Center, Bamako, Mali

Implementation of Seasonal malaria chemoprevention (SMC) with Sulfadoxine pyrimethamine and Amodiaquine (SP-AQ) has reduced malaria burden in children under 5 but contrasted with increased cases in school-aged children. Extending SMC to school-aged children will contribute to reduce malaria morbidity and transmission. SP-AQ currently used for SMC are threatened by apparition of resistance. Alternative drug is needed in case of spread of SP-AQ resistance strains. We assessed the safety and efficacy of DHA-PQ for SMC in school-aged children in Bandiagara. A double-blind randomized controlled trial was conducted with 345 participants from 6-15 years old randomized in ratio 1:1:1 in 3 arms to receive either DHA-PQ or SP-AQ or albendazole. Albendazole used in control group was administrated to all participants to reduce treatment bias. Four SMC rounds were conducted from September to December and participants were followed to assess safety and efficacy of the drugs. The adverse events frequently reported were abdominal pain (12.87% vs 45%), headaches (15.44% vs 26.08%), vomiting (9.35% vs 22.42%) and nausea (6.14% vs 14.65%) respectively in DHA-PQ and SP-AQ arms. In SP-AQ arm adverse events increased significantly with age. Biological analysis showed that the median (Q1-Q3) ALT level was higher in DHA-PQ arm (15.55 IU/l, 12.2-21.70) compared to SP-AQ and control arms with 12.00 IU/l (9.0-16.70) and 12.70 IU/l (9.4-16.45) respectively ($p = 0.0006$). The mean of hemoglobin was similar in the 3 treatment arms. Prevalence of clinical malaria was lower in both DHA-PQ and SP-AQ arms (1.5%) compared to the control arm (15.9%). Prevalence of malaria infection was higher in the control arm (40.4%) compared to the DHA-PQ (9.9%) and SP-AQ (6.1%) arms. Kaplan Meier model showed that in subsequent rounds of MSC the presence of parasitemia was more frequent in control arm. Gametocyte density was higher in control arm (mean = 44.4 ± 0.0) and lower in SP-AQ and DHA-PQ arm (0.4 ± 1.8 and 0.3 ± 1.2) respectively. DHA-PQ showed high efficacy and good safety in SMC in school aged children and may be an alternative to SP-AQ for SMC.

0382

FACTORS AFFECTING COVERAGE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY AND INFANCY UNDER PROGRAMMATIC CONDITIONS: A SYSTEMATIC REVIEW

Olusola B. Oresanya[1], Seyi Soremekun[2], Bilal Avan[2], Omowunmi Omoniwa[1], James Tibenderana[3], Joana Schellenberg[2]

[1]Malaria Consortium, Abuja, Nigeria, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Malaria Consortium, London, United Kingdom

Despite the efficacy of Intermittent preventive treatment in infancy (IPTi) with Sulphadoxine-Pyrimethamine and WHO's recommendation, its adoption has been slow across Africa; only Sierra Leone attempted implementing at scale. One of the many bottlenecks to IPTi policy uptake is its limited efficacy and the lack of demonstrable impact in real world settings, which is dependent on the coverage of the intervention. Missed opportunities for IPTi uptake during immunization clinics causing low coverage, have been demonstrated. This review, planned for June 2022, seeks to systematically identify and synthesize evidence on the barriers to achieving high coverage of IPTi and the determinants of coverage drawing from literature on IPTi and lessons from implementation of IPTp, a similar but more widely implemented intervention. Search will include electronic bibliographic databases, grey literature and bibliographies of retrieved articles. Inclusion criteria: quantitative, qualitative, or mixed methods research studies; studies assessing barriers to, facilitators of, or determinants of uptake or coverage of IPTp or IPTi; reports; peer-reviewed or grey literature; and sub-Saharan African region. Search will include concepts like 'Intermittent preventive treatment', 'Factor', 'Barrier', 'Determinant', 'infant', 'routine immunization clinic', 'malaria', 'coverage', 'Policy uptake' etc. The search strategy will be run on databases, lists of titles and abstracts of articles retrieved will be exported to Endnote library and duplicates removed, and eligible full articles meeting inclusion criteria will be retrieved. Quality assessment of the studies will be done using the relevant checklists to deal with the risk of bias. A descriptive analysis of the selected studies will be done with a narrative synthesis to bring the findings together. Data extraction will be aided by a tool and verified by a second reviewer. Pre-existing themes used by the authors will be identified and stratified based on user or provider perspectives. This review will contribute to the development of a logic model for optimal IPTi coverage when implemented at scale.

0383

SULFADOXINE PYRIMETHAMINE/AMODIAQUINE (SPAQ) ADMINISTRATION DURING SEASONAL MALARIA CHEMOPREVENTION (SMC) CAMPAIGNS IN BURKINA FASO: PRACTICES AND CHALLENGES

Cheick Compaore[1], Adama Traore[1], Benoit Sawadogo[1], Clotaire Tapsoba[1], Gauthier Tougri[2]

[1]Malaria consortium, Ouagadougou, Burkina Faso, [2]MoH, NMCP, Ouagadougou, Burkina Faso

Malaria transmission in Burkina Faso is seasonal, with peaks observed during the rainy season. Seasonal malaria chemoprevention (SMC) is positioned as a major prevention intervention to reduce the burden of malaria. The results of a study conducted in 2020 on the implementation of SMC in the context of COVID 19, as well as the various campaign reports, showed that caregivers had difficulties administering SMC drugs (SPAQ) to their children. We conducted an exploratory study to identify &lt role models &gt within the communities, that is, individuals who exhibit uncommon, positive behaviours that aid the successful administration of SPAQ. These behaviours were then shared with other community members through interactive monthly sessions (e.g. roleplay and story-telling). The health district of Saponé, located in the Center South region, served as the framework for this study. Role models were identified through focus group discussions and key informant interviews were conducted to further explore their beneficial behaviours. Many themes as caregiver's perception on malaria, adverse event of SMC and SPAQ administering practice for children aged under five by caregiver, had been identified. In general, caregiver have a good perception of SMC and quote that the number of their visit in the health facility because of malaria, decreases and their expense for health service fees also. However, even if they do not observe adverse effect of SPAQ to their own children, they said that their neighborhood mentioned vomiting, diarrhea and lethargy as adverse effect. Caregivers described many practices related to SPAQ administration; some flatter the child with candy or threaten children with injection. The most commonly reported behaviour was mixing SPAQ with food or drink (e.g. porridge or tea) prior to administration. The role model approach allowed good engagement of community members at throughout the study. However, the efficiency of these practices on malaria incidence needs to be explored by a further study.

0384

RESULTS OF THE ROLE MODEL STUDY TO EXPLORE CAREGIVER ADMINISTRATION OF SULFADOXINE-PYRIMETHAMINE (SP) &LT AMODIAQUINE (AQ) DURING SEASONAL MALARIA CHEMOPREVENTION (SMC) CAMPAIGNS &GT CHAD

Narcisse Tounaikok[1], Laura Donovan[2], Kevin Baker[2], Erica Viganò[2], Adama Traore[3], Cheick Compaore[3], Beakgoube Honore[1], Nodjiyam Dingamtel[1], Fantche Awokou[4], Muhammad Shafique[5]

[1]Malaria Consortium, N'Djamena, Chad, [2]Malaria Consortium, London, United Kingdom, [3]Malaria Consortium, Ouagadougou, Burkina Faso, [4]Malaria Consortium, Lome, Togo, [5]External consultant, Islamabad, Pakistan

Seasonal malaria chemoprevention (SMC) is an intervention recommended by WHO since 2012 to prevent malaria cases in children under five. It consists of intermittent administration of a full course of sulfadoxine-pyrimethamine (SP) plus amodiaquine (AQ) [SPAQ] to children aged 3-59 months during peak malaria transmission season. The first dose of SPAQ is administered by caregivers under the direct supervision of Community Distributors (CDs), while dose 2 and 3 of AQ are left for caregivers to administer. Previous studies found that, some caregivers skip doses or sometimes children refuse to take SPAQ, not allowing for complete administration of the full drug course. The Role Model study provided a promising social and behavioral change approach to addressing community challenges and finding existing local solutions. The study was conducted in Tersefe (Chad). The area comprised of 14 villages with a total population of 14,442, including 2838 children under five. Data were collected through focus group discussions (FGDs) with female and male caregivers and CDs and in-depth interviews (IDIs) with potential Role Models identified. The villages were divided into three clusters according to their distance from the health center. An equal number of FGDs and IDIs were conducted in each cluster. The study identified easily replicable Role Model behaviors existing within communities. Among others, these included strategically placing blister packs next to commonly used household products to be reminded of administration, having family members support primary caregivers, providing rewards to children, as well as practicing other malaria prevention strategies. Role Model volunteers identified during the study were trained and held sessions in their respective communities to promote positive behaviors prior to the 2022 SMC campaign. The evaluation FGDs conducted with caregivers at the end of the study showed that the approach is feasible and accepted by communities. Results and related messaging are being integrated into the 2022 SMC campaign to improve the administration of SPAQ.

A PHASE 1, OPEN-LABEL, DOSE ESCALATION AND ROUTE OPTIMIZATION TRIAL WITH CONTROLLED HUMAN MALARIA INFECTION TO EVALUATE PROTECTIVE EFFICACY OF AN ANTI-MALARIA HUMAN MONOCLONAL ANTIBODY IN HEALTHY MALARIA-NAÏVE ADULTS

Kirsten E. Lyke[1], Andrea A. Berry[1], Kaitlin Mason[1], Sudhaunshu Joshi[1], Biraj Shrestha[1], Kathleen A. Strauss[1], Matthew Adams[1], LaSonji A. Holman[2], Floreliz Mendoza[2], Ingelise J. Gordon[2], Jittawadee Murphy[3], Andrezza Campos Chagas[3], Emily Coates[2], Nina M. Berkowitz[2], Martin Gaudinski[2], Lesia Dropulic[2], Robert A. Seder[2]

[1]University of Maryland, Baltimore, MD, United States, [2]Vaccine Research Center, NIAID, NIH, Bethesda, MD, United States, [3]Entomology Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States

Human monoclonal antibodies (mAb) may offer an important new tool to reduce malaria morbidity and mortality. The antimalarial mAb, CIS43, was derived from a protected subject immunized with *Plasmodium falciparum* (Pf) whole-sporozoite (SPZ) vaccine, targets a conserved epitope within the junctional region of Pf circumsporozoite protein, and was modified with an LS mutation found to increase antibody half-life (CIS43LS). The mAb has been found to confer high level protection at doses of 20 or 40 mg/kg intravenously (iv) following controlled human malaria infection (CHMI). To assess whether CIS43LS could mediate protection at lower doses and by a subcutaneous (sc) route of administration, malaria-naïve volunteers aged 18-50 years received mAb at doses of 1 (n = 7), 5 (n = 4), and 10 (n = 3) mg/kg iv and 5 (n = 4) and 10 (n = 4) mg/kg sc. Pharmacokinetic (Pk) assessments and safety analysis were performed. Volunteers underwent CHMI by the bites of five mosquitoes infected with 3D7 strain Pf at approximately 8 weeks following mAb inoculation. Six additional naïve control volunteers underwent CHMI simultaneously. Volunteers were followed daily from Days 7-18 with qualitative PCR used for Pf detection. Volunteers were treated with atovaquone-proguanil or terminally treated at Day 21. The mAb inoculation was safe and well tolerated with mild adverse events reported. No serious adverse events occurred. All 6 controls and 4 of 7 volunteers dosed at 1 mg/kg (57%) developed parasitemia following CHMI. No volunteers developed parasitemia following dosing at 5 mg/kg iv (0/4), 5 mg/kg sc (0/4), 10 mg/kg iv (0/3) and 10 mg/kg sc (0/4). The mean prepatent period for volunteers infused 1 mg/kg mAb was 11.75 (range 11-12) days vs. 7.67 (range 7-9) days in controls (P< 0.0001). Pk analysis to determine antibody levels of CIS43LS at the time of CHMI are underway. We conclude that volunteers dosed at 5 mg/kg or greater by iv or sc were protected following CIS43LS inoculation at 8 weeks. These findings show that mAbs can mediate protection at low doses and by the sc route providing data that this approach may be useful across a number of clinical use cases.

THE ROLE OF CELL-TRAVERSAL PROTEIN FOR OOKINETES AND SPOROZOITES IN STERILE IMMUNITY INDUCED BY RADIATION-ATTENUATED SPOROZOITE VACCINES IN THE NATURAL HOST

Solomon Conteh

National Institutes of Health, Bethesda, MD, United States

*Pf*SPZ Vaccine, a promising malaria vaccine consisting of radiation-attenuated *Plasmodium falciparum* (*Pf*) sporozoites (RAS), provides sterile and partial protection against controlled human malaria infection (CHMI) and natural infection in humans, respectively. It presents a wide range of antigens, but it is unclear whether Cell-Traversal Protein for Ookinetes and Sporozoites (CelTOS) plays a major role in RAS-induced protection. Studies in mice have shown that anti-CelTOS response elicited by direct or passive immunization can inhibit parasite infection. Here, we investigated the role of CelTOS in RAS-induced protection using *Grammomys surdaster* thicket rats (TR), a natural host *for Plasmodium*, and C57BL/6 mice, a non-natural host. Two transgenic *Plasmodium berghei* ANKA (*Pb*) parasites *Pb*PfCelTOS and *Pb*PvCelTOS (wherein PbCelTOS was replaced with PfCelTOS and PvCelTOS, respectively) were used as both RAS immunogens and sporozoite (SPZ) challenge strains to assess homologous (ho) and heterologous (ht) protection. TR and mice received 3 doses of 50K RAS and 10K RAS, respectively, at least 3 weeks apart followed by ho challenge (same parasite) or ht challenge (transgenic parasite, different CelTOS sequence). *Pb*PfCelTOS RAS immunization conferred the same ho and ht (Pb) protection in mice and TR 100% (10/10) and 42.6% (6/14) respectively. *Pb*PvCelTOS RAS immunization conferred the same ho and ht (Pb and PbPfCelTOS) protection in mice, 100% (10/10); but different in TR, 60% (6/10) ho protection and only 30% (3/10) ht protection. This suggests CelTOS responses are required for full protection in outbred TR but not in inbred mice. We observed lower efficacy of SPZ vaccines in the natural host compared to the non-natural host, consistent with previous studies, and this more potent immunity in mice might mask any contribution of CelTOS responses to protection. More studies are needed to confirm these preliminary results, but the findings suggest that CelTOS contributes to sterile immunity in the natural host, and generally support efforts to identify novel antigens for subunit pre-erythrocytic malaria vaccines.

0387

EXPERIENCE WITH THE CRYOGENIC COLD CHAIN FOR DISTRIBUTION OF PFSPZ VACCINES

Eric R. James, Dimitri Koutzoumis, Diana Perez, Kerri Springer, Yonas Abebe, B Kim Lee Sim, Stephen L. Hoffman

Sanaria Inc, Rockville, MD, United States

Experience with the Ebola and SARS-CoV-2 RNA vaccines has expanded the repertoire of cold chain options for vaccine distribution to include ultra-low freezer storage and dry ice distribution. The immunogen in PfSPZ platform products (PfSPZ Vaccine, PfSPZ Challenge, PfSPZ-LARC2 Vaccine) is *Plasmodium falciparum* (Pf) sporozoites (SPZ), which, being eukaryotic organisms, must therefore be stabilized by cryopreservation. Distribution occurs through a liquid nitrogen (LN2) vapor phase (LNVP) cold chain that maintains temperature below -150 °C. There are several veterinary vaccines distributed using LN2 or LNVP and the huge livestock breeding, human IVF and expanding CAR-T/cellular therapies industries employ LNVP for distribution. Cryopreserved products are stable essentially indefinitely. It is surprising, therefore, that manufacturers of human vaccines have not also moved to cryogenic distribution yet: the main reason may be that the standard vaccine vial does not work below -80 °C. We have solved this issue by creating a cryovial with a heat-annealed foil-seal-protected septum that maintains CCI in LNVP and functions like a standard vaccine vial once thawed. This cryovial has now been introduced into our manufacturing process. For the Phase 1 and 2 trials, over 550 shipments supplying >38 clinical trials at 14 sites in the USA, Europe and Africa have used our LNVP cold chain to date. Additionally, volunteer samples (sera and cells) are often reverse shipped in LNVP dry shippers as dry ice is frequently difficult and/or expensive to obtain in Africa whereas LN2 is more widely available. The LNVP dry shippers range in static hold time between ~10 days to 50 days and payload capacities range from 259 to 1,554 cryovials, and they require no electricity and are thus highly suited for extending distribution down the last mile to remote locations. Our LNVP distribution experience is being translated into expanded distribution network designs for Phase 3 clinical trials and into post-launch distribution models for malaria elimination campaigns and for travel medicine clinics.

PFSPZ-LARC2 GMP MANUFACTURE AND CLINICAL ASSESSMENT OF A GENETICALLY MODIFIED PFSPZ VACCINE ATTENUATED AT THE LATE-LIVER STAGE

B. Kim Lee Sim[1], Debashree Goswami[2], Jeremy Guth[1], Yonas Abebe[1], Asha Patil[1], Tooba Murshedkar[1], Thomas L. Richie[1], Ashley M. Vaughan[3], Stefan H.I. Kappe[3], Stephen L. Hoffman[1]

[1]Sanaria Inc, Rockville, MD, United States, [2]Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States, [3]Center for Global Infectious Disease Research, Seattle Children's Research Institute and Department of Pediatrics, University of Washington, Seattle, WA, United States

In 2020 malaria caused 627,000 deaths, the greatest numbers of annual deaths since 2012. There is an urgent unmet medical need for a malaria vaccine that prevents infection and disease in individuals and can be deployed in mass vaccination programs for malaria elimination. Of vaccines under development, only Sanaria's PfSPZ vaccines have the efficacy against Pf infection to be considered for prevention of Pf infection in individuals and for geographically focused Pf malaria elimination campaigns. Sanaria's 1st generation vaccine, Sanaria® PfSPZ Vaccine, is composed of radiation-attenuated *Plasmodium falciparum* (Pf) sporozoites (SPZ), which arrest early in the liver stage. The immunogen of Sanaria's 2nd generation vaccine, Sanaria PfSPZ-CVac (Chemoprophylaxis Vaccine) is infectious PfSPZ, which replicate in the liver, biologically amplifying the immunogen load by up to 50,000-fold, and then are killed in early blood stage by an anti-malarial drug like chloroquine (CQ). PfSPZ-CVac (CQ) provides 100% vaccine efficacy (VE) against heterologous controlled human malaria infection (CHMI) 12 weeks after vaccination using only 22% of the PfSPZ dose used in PfSPZ Vaccine which achieves 80% VE at 9-10 weeks against heterologous CHMI. Thus, PfSPZ-CVac (CQ) is more protective than PfSPZ Vaccine, at ~1/5 the dose (=cost). However, administration of infectious PfSPZ has safety concerns. To retain the enhanced potency of PfSPZ-CVac and eliminate its potential drawbacks, 2 genes, *Pfplasmei2 and Pflinup* were deleted from Pf (NF54 strain) leading to complete parasite arrest at the late liver stage. PfSPZ-LARC2 parasites invade and develop to the late liver stage *in vitro*, and are tested for full arrest and absence of blood stage infection in FRG mice with humanized livers. We have produced a master cell bank (MCB) of PfLARC2, and it is now being manufactured in compliance with GMPs to produce PfSPZ-LARC2 Vaccine, which will be assessed for safety and efficacy in clinical trials in the 2nd half of 2022. We expect PfSPZ-LARC2 Vaccine to mirror PfSPZCVac (CQ) efficacy without safety concerns. Thus, it is our best and essentially ideal PfSPZ vaccine candidate.

PLASMODIUM VIVAX SPOROZOITES FOR CONTROLLED HUMAN MALARIA INFECTION

Sumana Chakravarty[1], Natasha KC[1], Gigliola Zanghi[2], Stefan H. I. Kappe[2], Ashley M. Vaughan[2], B. Kim Lee Sim[1], Stephen L. Hoffman[1]

[1]Sanaria Inc., Rockville, MD, United States, [2]Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States

One of Sanaria's goals is to develop a vaccine against *Plasmodium vivax* (Pv) malaria, the most wide-spread cause of malaria-associated

morbidity outside of Africa. Using sporozoite (SPZ)-based vaccines, we aim to prevent all blood stage infections with Pv. We also aim to produce quality-controlled stocks of aseptic, purified, cryopreserved PvSPZ (PvSPZ Challenge) to promote well-controlled, reproducible studies in Pv including controlled human malaria infection (CHMI). We have overcome the significant challenge of propagating the life cycle of Pv *in vitro*, by growing Pv blood stages in *Saimiri boliviensis* (Sb) instead and have produced multiple stocks of purified, cryopreserved PvSPZ from mosquitoes fed on Pv-infected Sb blood, vialing as many as 80 million PvSPZ from 2000 mosquitoes in 1 day. In addition, we have 1) Developed assays to test and characterize PvSPZ for infectivity *in vitro* in monolayer and in micro-patterned co-cultured primary human hepatocytes over 3-21 days; 2) Tested the functional activity of drugs on inhibiting liver stage parasite development *in vitro;* 3) Infected NHPs *in vivo*; 4) Demonstrated that vialed, cryopreserved PvSPZ, Chesson strain infect humanized FRG KO huHep mice and produce hypnozoites *in vivo*. In compliance with regulatory standards for human use we have further 5) Standardized methods to propagate Pv in Sb maintained in specific pathogen free (SPF) colonies; 6) Vialed and cryopreserved aseptic, purified, infectious PvSPZ from aseptic mosquitoes fed on Pv-infected SPF blood; 7) Established conformance of the aseptic PvSPZ products of 5 pilot runs to in-process asepticity, *in vitro* potency, and release criteria; 8) Produced a master cell bank; 9) Prepared a pre-IND package ready for submission to the FDA and 10) Anticipate equivalent infectivity of aseptic PvSPZ in FRGKO huHEP mice. This enabling technology is now intended for initial CHMI trials planned in Germany and the US. PvSPZ Challenge also forms the basis of a powerful vaccine approach to preventing Pv malaria when administered with anti-malarial chemoprophylaxis, the PvSPZ **c**hemoprophylaxis **vac**cine (PvSPZ-CVac).

SEMI-AUTOMATED PRODUCTION OF ASEPTIC MOSQUITOES FOR THE MANUFACTURE OF PFSPZ VACCINES

Abraham Eappen[1], Donald Ward[1], Ravi Chauhan[2], Morgan Douglas[1], Nicole Encardes[1], William DeMore[2], Ben Lane[2], Kim Lee Sim[3], Stephen L. Hoffman[1], Peter Billingsley[1]

[1]Sanaria Inc., Rockville, MD, United States, [2]KeyTech, Baltimore, MD, United States, [3]Protein Potential, LLC., Rockville, MD, United States

Sanaria has moved to Phase 3 GMP compliant manufacturing of Sanaria® PfSPZ Vaccine to support licensure applications and commercialization. *Plasmodium falciparum* sporozoites (PfSPZ) are manufactured using aseptic *Anopheles stephensi* mosquitoes. To meet the needs of the extensive world markets, at an affordable price, the scale of manufacturing must be greatly increased and cost of goods (COGs) reduced. Some of the most labor- and space-intensive steps in PfSPZ manufacture are production of aseptic Pf-infected mosquitoes. Mosquito eggs are disinfected in bulk, hatched, and then seeded into flasks containing mosquito growth medium that allows the larvae to grow to pupae under aseptic conditions. The pupae are harvested and transferred to Big Adult Mosquitoes Containers (BAMC), in which adult mosquitoes emerge and maintained through Pf- gametocyte feeding and harvest of PfSPZ. Currently, these steps are all performed manually. Exploiting the biology of newly emerged adult mosquitoes, we developed a container that will allow the movement of aseptic mosquitoes from culture flasks to BAMC aseptically. Using this as proof concept, we have designed a re-usable bioreactor container that will allow for the production of 3x the number of *A. stephensi* pupae than our current culture container. This container will allow for aseptic media changes outside of a biosafety cabinet and will eliminate the need for manual harvesting of pupae and transfer into BAMCs by inclusion of a novel aseptic connection of the bioreactor container to a modified BAMC. Mosquito pupae will eclose within the larval bioreactor container, and newly emerged adults will fly upward into the attached modified BAMC. The modified BAMC can be disconnected aseptically within a biosafety cabinet without mosquito escape with the inclusion of a shutter that can be closed prior to the disconnection of the BAMC from the bioreactor. Progress on the effectiveness of this bioreactor will be reported. This Bioreactor based semi-automated aseptic mosquito production will reduce the cost of mosquito production by at least 50%.

IN VITRO PRODUCED *PLASMODIUM FALCIPARUM* SPOROZOITES: GENE EXPRESSION AND IN *VITRO* INFECTIVITY AND CELLULAR IMMUNOGENICITY OF CRYOPRESERVED PARASITES

Abraham Eappen[1], Tao Li[1], Alemtaye Yossef[1], Gigliola Zanghi[2], Natasha KC[1], Ayyappan Rathakrishnan[1], Ehud Inbar[1], Sumana Chakravarty[1], Maria Belmonte[3], Martha Sedegah[4], Tint Wai[1], Stefan H. I. Kappe[5], MingLin Li[1], Lixin Gao[1], Robert Morrison[2], Peter Billingsley[1], B. Kim Lee Sim[1], Stephen Hoffman[1]

[1]Sanaria Inc., Rockville, MD, United States, [2]Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States, [3]Naval Medical Research Center / Henry M. Jackson Foundation, Silver Spring / Bethesda, MD, United States, [4]Malaria Department, Naval Medical Research Center, Silver Spring, MD, United States, [5]Seattle Children's Research Institute, University of Washington, Seattle, WA, United States

Sanaria has developed methods to mass produce *Plasmodium falciparum* (Pf) sporozoites (SPZ) *in vitro* (iPfSPZ) in bioreactors without mosquitoes to replace mosquito-produced PfSPZ (mPfSPZ) in our PfSPZ-vaccines. Using a mini bioreactor, we produced up to 4.5 x 10^8 iPfSPZ per culture, and in a bioreactor that was 6.25 times larger, we produced up to 1.5 x 10^9 iPfSPZ per culture. As we move toward a final method of production and product, we have been characterizing the iPfSPZ. In RNA-seq, of the 50 genes most highly expressed in mPfSPZ, 32 had higher expression levels in mPfSPZ than in iPfSPZ and 18 had greater expression in iPfSPZ. For PfCSP, PfSSP2/TRAP, PfCelTOS, and PfAMA, all of which had lower expression in iPfSPZ, the results were confirmed by qRT-PCR with iPfSPZ having 64%, 75%, 81% and 76% the level of expression of mPfSPZ respectively. In a 6-day *in vitro* hepatocyte potency assay, cryopreserved iPfSPZ produced 95% the numbers of late liver schizonts expressing PfMSP1 as did fresh iPfSPZ, and cryopreserved mPfSPZ produced 82% the numbers as did fresh mPfSPZ. Both fresh (20% more) and cryopreserved (33% more) iPfSPZ produced more late liver stage schizonts than did mPfSPZ. When mice were immunized with fresh or cryopreserved iPfSPZ or mPfSPZ and assessed for T cell responses to stimulation with Pf-infected erythrocytes, there was no significant differences between responses in iPfSPZ or mPfSPZ immunized mice, although responses were higher overall in mPfSPZ immunized mice. PfCSP and other protein expression in iPfSPZ is lower in mPfSPZ than expected by gene expression studies. We speculate that absence of mosquito extracellular proteins and lipids in our cultures impairs optimal formation of the oocyst capsule leading to sub-optimal uptake of nutrients by the *in vitro* oocysts, and this is a reason for the reduced protein expression levels. We are focusing on optimization of iPfSPZ production in bioreactors by addition of extracellular proteins and other nutrients. The goal is inexpensive, large-scale manufacture of the iPfSPZ needed for mass vaccination programs to eliminate Pf malaria.

0392

PROTECTIVE TARGETS OF SPOROZOITE-BASED WHOLE ORGANISM MALARIA VACCINES IDENTIFIED FROM GENOME-WIDE SIEVE ANALYSIS OF *PLASMODIUM FALCIPARUM* ISOLATES FROM FIELD EFFICACY TRIALS

Ankit Dwivedi[1], Ryan Scalsky[1], Thomas Stabler[2], James B. Munro[1], Olukemi O. Ifeonu[1], Biraj Shrestha[1], Sudhaunshu Joshi[1], Alphonse Ouedraogo[3], Alfred Tiono[3], Drissa Coulibaly[4], Amed Ouattara[1], Thomas L. Richie[5], B. Kim Lee Sim[5], Christopher V. Plowe[1], Kirsten E. Lyke[1], Shannon Takala-Harrison[1], Stephen L. Hoffman[5], Mahamadou Thera[4], Sodiomon B. Sirima[3], Matthew B. Laurens[1], **Joana C. Silva**[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]Swiss Tropical and Public Health Institute, Base, Switzerland, [3]Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso, [4]Malaria Research and Training Center, University of Sciences, Techniques and Technologies, Bamako, Mali, [5]Sanaria Inc, Rockville, MD, United States

Identification of protective targets of *Plasmodium falciparum* (Pf) sporozoite (SPZ)-based immunization will elucidate the genomic architecture of whole organism vaccine-induced protection and may lead to novel vaccine formulations with broader efficacy. PfSPZ-based malaria vaccines have shown significant, but partial vaccine efficacy (VE) against endemic malaria in field studies. Furthermore, clinical trials in which VE was assessed against controlled human malaria infection using either homologous or heterologous strains revealed that these vaccines are susceptible to allele-specific efficacy, the process by which vaccine protection is strongest against pathogen strains immunologically similar to the vaccine strain at protective loci. Here, we take advantage of allele-specific efficacy in field trials of PfSPZ-based vaccines to identify candidate targets of vaccine-induced protection. These target loci will be those in which allele frequencies differ significantly between infections in vaccinees and controls, with the vaccine allele depleted in the vaccine arm, due to the vaccine sieve effect. One study, in Burkina Faso, used Sanaria® PfSPZ Vaccine, composed of radiation attenuated SPZs of the PfNF54 strain, while the second study used Sanaria® PfSPZ CVac, consisting of fully infectious PfNF54 SPZs administered under the cover of the chemoprophylactic chloroquine. Both studies were randomized, double-blind, placebo-controlled trials in malaria-experienced adults. Sieve analyses in the Malian trial revealed 179 non-synonymous (NSYN) sites significantly differentiated between vaccinees and controls, in 145 protein-coding loci. In Burkina Faso, 358 significantly differentiated NSYN sites in 295 loci were identified. Products of these loci are enriched for functions such as host cell binding, including proteins intrinsic to or anchored in the cellular membrane. The intersection of both sets of loci resulted in 36 protein-coding genes, including those encoding a well-characterized sporozoite antigen, an exported protein, and several membrane-associated conserved proteins and variant surface antigens.

0393

SEASONAL VACCINATION WITH THE RTS,S/AS01E MALARIA VACCINE GIVEN WITH OR WITHOUT SEASONAL MALARIA CHEMOPREVENTION: EXTENSION OF A RANDOMIZED, DOUBLE-BLIND PHASE 3 TRIAL UNTIL CHILDREN REACH THE AGE OF FIVE YEARS

Jean-Bosco Ouedraogo[1], Alassane Dicko[2], Issaka Zongo[3], Issaka Sagara[2], Matthew Cairns[4], Serge Yerbanga[3], Djibrilla Issiaka[2], Charles Zoungrana[3], Youssoufa Sidibe[2], Amadou Tapily[2], Koual Sanogo[2], Mahamadou Kaya[2], Hama Yalcouye[2], Oumar Dicko[2], Modibo Diarra[2], Kalifa Diarra[2], Ismaila Thera[2], Alassane Haro[3], Abdoul Aziz Sienou[3], Amagana Dolo[2], Paul Snell[4], Jane Grant[4], Paul Milligan[4], Opokua Ofori-Anyinam[5], Cynthia Lee[6], Christian Ockenhouse[6], Halidou Tinto[3], Abdoulaye Djimde[2], Daniel Chandramohan[4], Brian Greenwood[4]

[1]INSTech, Bobo-Dioulasso, Burkina Faso, [2]Malaria Research & Training Centre, Bamako, Mali, [3]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]GSK Vaccines, Rixensart, Belgium, [6]PATH, Seattle, WA, United States

An individually-randomized, controlled trial involving 5920, 5-17 month old children undertaken in Mali and Burkina Faso showed that seasonal malaria vaccination (SMV) with the RTS,S/AS01$_E$ vaccine was not inferior to seasonal malaria chemoprevention (SMC) and that the combination of SMV and SMC was superior to either intervention given alone, reducing the incidence of uncomplicated malaria, severe malaria and deaths attributable to malaria over a period of three years by about 70%. Because SMC is recommended until the age of five years, the trial has been extended for a further two years to determine whether administration of SMV with RTS,S/AS01$_E$ until children reach the age of five years is non-inferior to SMC alone in preventing clinical malaria, and whether administration of the combination of these two interventions is superior to either intervention alone in preventing clinical malaria and other severe outcomes (Clinicaltrials.gov NCT04319380). 5033 children enrolled in the initial phase of the study received study interventions in 2020. In 2021, 2289 children who were ≤5 years received the interventions and 2106 children who had reached the age of 5 did not receive interventions but remained under surveillance. The primary endpoint of the both the extension study and overall trial is a clinical episode of malaria with a parasite density of ≥5000 parasites per µl, detected at study health facilities. The prevalence of malaria parasitaemia has been measured among all children in the trial at the end of each transmission season. Sera have been collected for determination of anti-CSP antibody concentrations before and after vaccination in a randomly selected subset of approximately 400 children each year. Data collection was completed on 31 March 2022. Analysis of data will be completed by September 2022 and the results will be presented at the conference.

0394

MALARIA SYMPTOMS IN RELATION TO DETECTION OF PARASITEMIA BY QUANTITATIVE REAL-TIME PCR AND MICROSCOPY IN CONTROLLED HUMAN MALARIA INFECTION TRIALS AT WALTER REED ARMY INSTITUTE OF RESEARCH

Brennan R. Cebula, Jason A. Regules, James E. Moon

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Plasmodium 18S rRNA/DNA quantitative real-time PCR (qRT-PCR) is a promising diagnostic alternative to microscopy for controlled human malaria infection (CHMI) studies that has recently received biomarker qualification through the U.S. Food and Drug Administration for use in this context at non-endemic sites. Compared to microscopy, qRT-PCR has demonstrated earlier detection of parasitemia allowing for treatment before symptoms develop, which can reduce the duration and resources needed for post-exposure monitoring in CHMI studies. qRT-PCR also mitigates the inter-observer variability inherent to malaria microscopy which can result in errors in clinical trials and affect outcomes. Walter Reed Army Institute of Research (WRAIR) has assessed qRT-PCR in recent CHMI studies alongside microscopy. We report time-to-positivity for qRT-PCR and microscopy in comparison with time-to-onset, duration, and subject reported severity for malaria symptoms in a total of 23 control subjects infected with *Plasmodium falciparum* from two CHMI studies conducted at WRAIR. Our results were largely consistent with those of previous similar studies, with qRT-PCR detecting parasitemia a mean 4.37 days before microscopy and a mean 3.76 days prior to symptom onset. We also detected a statistically significant positive correlation between fever duration and severity, and negative correlation between headache duration and severity. While our study is limited by the small number of subjects and the short duration of symptoms, it does reinforce the growing evidence for the use of qRT-PCR in CHMI and provides further insight into malaria symptomology.

0395

IMPLEMENTATION POTENTIAL AND PUBLIC HEALTH IMPACT OF FIRST-GENERATION MALARIA VACCINES

Josephine Malinga, Narimane Nekkab, Lydia Braunack-Mayer, Sherrie L. Kelly, Melissa A. Penny

Swiss Tropical and Public Health Institute, Allschwil, Switzerland

Following decades of vaccine development, in 2021 WHO gave a recommendation of the first malaria vaccine, RTS,S, for paediatric use and seasonal vaccination against *P. falciparum* for children in moderate to high transmission areas. As global malaria burden reduction has stalled, there are renewed efforts to optimize current strategies and develop new interventions to accelerate progress towards elimination, including for RTS,S and other malaria vaccines. To support better understanding of the role of vaccines, we used an individual-based model of malaria transmission combined with statistical approaches to identify factors driving public heath impact in seasonal and perennial settings. We assessed the potential impact of a first-generation vaccine by exploring trade-offs between key vaccine characteristics such as efficacy and duration, alongside population-level characteristics of vaccination coverage and deployment strategies. We modelled RTS,S deployed as part of the Expanded Programme on Immunization in children 6-9 months, with annual boosters until age five co-administered with a blood-stage antimalarial. We found vaccine anti-infective initial efficacy and duration similarly drive impact in the first year. At least a 50% burden reduction is predicted if new vaccines achieve initial efficacy of >90% and half-life >12 months, but impact is limited if coverage is inadequate. We found there is potential for multi-seasonal protection if half-life duration can be extended beyond 10-12 months, however, there's little understanding of mechanisms with which long-term protection is conferred. Our modelling implies that extending antibody half-life by 3-5 months longer than RTS,S may result in sustained impact in the year following seasonal vaccination. Such a vaccine, combined with antimalarials or other interventions may reduce severe disease, mortality, and interrupt transmission. To maximize public health impact of next-generation vaccines, priority use-cases and target settings should be ranked through stakeholder engagement, considering the impact that can be achieved with improved first-generation vaccines.

0396

DIFFERENTIAL SEX-SPECIFIC IMMUNE RESPONSES FOLLOWING PRIME-AND-TRAP VACCINATION ALTERS PROTECTION AGAINST MALARIA IN MICE

Caroline J. Duncombe, Felicia N. Watson, Anya C. Kalata, Melanie J. Shears, Sean C. Murphy

University of Washington, Seattle, WA, United States

Generating liver resident-memory CD8$^+$ T (T_{RM}) cells is critical for effective liver-stage malaria vaccines. The role of biological sex in liver-stage vaccine protection is understudied. Here we report sex-specific immune responses and protection outcomes for the two-step heterologous 'Prime-and-Trap' liver-stage malaria vaccine designed to induce liver T_{RM} cells. The Prime-and-Trap strategy combines peripheral sporozoite antigen DNA priming with a single intravenous dose of liver-homing radiation-attenuated sporozoites (RAS) to direct and "trap" activated and expanding T cells in the liver. This strategy induces robust liver CD8$^+$ T_{RM} cell responses and confers sterile protection in the *Plasmodium yoelii* (Py) rodent malaria model in female BALB/cj mice. However, when tested in male BALB/cj mice, this vaccine induces fewer liver CD8$^+$ T_{RM} cells that yield lower rates of protection from sporozoite challenge. We examined sex-divergent immune responses in the spleen and liver following each step of the Prime-and-Trap regimen. The frequency of antigen-specific CD8+ IFN-γ T cells were lower in male mice following gene gun prime and RAS trap compared to female mice. Sexually dimorphic activation of certain immune pathways appears to drive attenuated downstream retention of T_{RM} cells in the liver, leading male mice to generate sub-optimal immune responses that yields less effective protection from challenge. Our findings emphasize the importance of incorporating biological sex as a variable when designing and evaluating liver-stage malaria vaccines.

Plasmodium vivax (Pv) vaccine development research is lagging far behind *P. falciparum* (Pf). In 2020, there were 241 million malaria cases worldwide, of which Pv-infection accounted for 3%. Very recently, we have developed a multistage Pf vaccine based on LC16m8Δ (m8Δ)/ adeno-associated virus (AAV) effective both for pre-erythrocytic (100% protection) and sexual stages (>99% transmission blocking; TB). The present study aims to applicate this vaccine platform for the development of a Pv multi-stage vaccine with high protection levels and TB efficacy. We developed a Pv vaccine [m8Δ/AAV-Pv(s25-CSP)] harboring the fusion gene encoding the pre-erythrocytic stage antigen PvCSP and the sexual stage antigen of Pvs25. Its protective and TB efficacies were assessed by PvCSP transgenic (TG) sporozoite challenge and direct membrane feeding assay (DMFA) using blood from Pv-infected patients in Brazil, respectively. The vaccine elicited robust PvCSP- and Pvs25-specific antibodies with titer of more than 10^5 and achieved high sterile protection up to 90% protection against PvCSP-TG sporozoites challenge. The vaccine also provided a high level of TB efficacy (>90%). In this study, we have successfully applied the new vaccine platform consisting of m8Δ/AAV for developing a Pv multistage vaccine. We are planning to evaluate its safety and immunogenicity in a non-human primate model.

The *Plasmodium falciparum* circumsporozoite protein (CSP) is an effective antigen for malaria vaccination. Antibodies targeting the junction between the CSP N-terminus and central repeat region can provide sterilizing protection. Full length recombinant CSP (rCSP) vaccines may offer an advantage over CSP-based vaccines that do not include the junctional region, including RTS,S and R21. We present clinical trial results of immunogenicity and efficacy against controlled human malaria infection (CHMI) for a full-length rCSP vaccine given with adjuvant, Glucopyranosyl

Lipid A-liposome *Quillaja saponaria* 21 formulation (GLA-LSQ). Twenty healthy, malaria-naïve Baltimore participants aged 18-45 years old were enrolled into two dosing arms: 60 µg rCSP + 5 µg GLA-LSQ (high dose, n = 10) and 10 µg rCSP + 5 µg GLA-LSQ (low dose, n = 10) given on days 1, 29, and 85. Vaccinated participants and six unvaccinated infectivity controls underwent CHMI 28 days after third vaccinations. Study endpoints included anti-CSP IgG antibody and time to *P. falciparum* asexual parasitemia following CHMI. The high dose group had higher geometric mean anti-rCSP IgG fold rise (day of CHMI/baseline, 236.2-fold, 95% CI: 32.4, 1721.1) than the low dose group (55.4-fold, 95% CI: 8.3, 370.0). All vaccinated participants developed *P. falciparum* asexual parasitemia following CHMI (vaccine efficacy: 0%). No difference in median time to parasitemia existed: parasitemia was detected eight days after CHMI in all groups. Median peak parasite density (cycle threshold) was 34.45 (IQR: 32.25, 35.45) in the high dose group, 33.40 (IQR: 33.00, 33.80) in the low dose group, and 32.20 (IQR: 31.70, 33.30) in infectivity controls. While the vaccine was highly immunogenic, the lack of vaccine efficacy suggests that the vaccine construct and schedule given did not induce functional antibodies that reduce parasitemia or provide sterile protection. Further dissection of the immune responses to this vaccine may help define protective responses for future CSP-based vaccines.

Malaria is a leading cause of morbidity and mortality. There is an urgent need for additional tools, e.g. a highly effective malaria vaccine, if we are to continue towards the ambitious goal of malaria parasite eradication. The possibility of a malaria vaccine was first realized in the 1940s, however a vaccine capable of inducing long-lasting protective immunity remains elusive. We have shown that a chemically attenuated whole parasite blood-stage vaccine, consisting of blood-stage malaria parasites attenuated with the seco-cyclopropyl pyrrolo indole analogue, Tafuramycin-A (TF-A), offers strong protection against homologous and heterologous challenge in rodent models of malaria. Additionally, a single dose of TF-A attenuated ring-stage *Plasmodium falciparum* 7G8 parasites was shown to be safe and immunogenic in malaria-naïve human volunteers, inducing a broad parasite-specific cellular immune response. The protective efficacy of this vaccine candidate has now been evaluated in malaria-naïve volunteers. Three doses of chemically attenuated *P. falciparum* 7G8 trophozoite-stage malaria parasites were administered one month apart to the vaccine group (n=5). The control group (n=2) were unvaccinated. One month after the final vaccine dose, vaccinated and control study participants were challenged with 1,800 *P. falciparum* 7G8 parasitised red blood cells. Two out of five participants in the vaccinated group did not develop blood-stage parasitemia, as detected by qPCR. The blood of these two participants supported the growth of the parasite *in vitro*. The remaining participants (both vaccinated and control) developed blood-stage parasitemias that required intervention with Riamet to resolve the infection. Parasite-specific antibody and cellular responses were measured and will be presented. This is the first time, to our knowledge, that a blood-stage malaria vaccine has completely prevented the development of blood-stage parasitemia in humans. This data provides proof-of-principle for the whole parasite blood-stage malaria vaccine approach in humans.

The Malaria Vaccine Technology Roadmap 2013 aims to develop safe and effective anti-malarial vaccines by 2030. It targets a minimum of 75% protective efficacy. Recently, we have developed a highly effective multi-stages vaccine against both the pre-erythrocytic and sexual stages of *Plasmodium falciparum.* This multi-stage vaccine encodes a pre-erythrocytic stage antigen circumsporozoite protein (PfCSP) and one sexual stage antigens s25 (Pfs25). The combination between the pre-erythrocytic vaccine (PEV; i.e. anti-PfCSP) effect and transmission-blocking vaccine (TBV; i.e. anti-Pfs25) effect brings the synergy to enhance the vaccine more potent in malaria prevention than a single antigen target strategy. In this study, we evaluated the effects of immunization against the PEV and TBV stages singly, and the effects of combining vaccine moieties as part of a multi-stage vaccine. The single vaccine moieties indicated 100% protection as PEV against PfCSP-transgenic *P. berghei* sporozoites and more than 90% oocyst reduction in mosquito midgut as TBV against Pfs25-transgenic *P. berghei*. Next, we evaluated the synergy of TBV+PEV on a double transgenic *P. berghei* expressing both PfCSP and Pfs25. We performed the assay in conditions that weaken our vaccine effect to measure the benefit of synergy. As a result, while the individual efficacy decreased to about 50% in TBV and about 60% in PEV respectively, the synergy of TBV+PEV remained over 90%. These findings propose the potential of our vaccine as a" next-generation malaria vaccine" to achieve the landmark goals of the malaria vaccine technology roadmap.

Ivermectin (IVM) is an endectocide currently being considered for malaria vector control through mass drug administration (MDA) campaigns. Its mode of action is independent of vector behavior or insecticide resistance therefore having the potential to directly address residual malaria transmission. Several trials using different IVM dose regimens are underway. Evidence from IVERMAL study indicates that 300mcgIVM/Kg given once a day for three days results in a significant reduction in mosquito survival up to 28 days. However, MDA strategies may operationally struggle to deliver high coverage and adherence rates using a 3-day long regimen. For this reason, we designed an open-lab randomized controlled trial (RCT) to compare the pharmacokinetics (PK) and mosquitocidal effect of single high-dose of IVM 400mcg/Kg to the 3-day regimen of 300mcg/Kg of IVM. Furthermore, we investigated the mosquitocidal activity of albendazole as a potential comparator for future trials. Healthy participants were randomized to receive either 1) Single-dose oral IVM 400 mcg/Kg; 2) Oral IVM 300 mcg/Kg given once a day for

three consecutive days; 3) single-dose oral 400mg albendazole; or 4) no treatment. Participants were followed-up for 28-days post-treatment with blood samples drawn at regular intervals and fed through a membrane to *Anopheles gambiae* s.l. which were observed for mortality for 28-days. Plasma concentrations of IVM at each timepoint were determined using HPLC. We present here the mosquito and PK results. Data will be presented in form of Kaplan-Meier curves. Survival rates between groups will be compared using log rank tests. PK parameters will be derived using observed data (Cmax, Tmax) and non-compartmental analysis of the concentration-time profiles. The results will inform the design of IVM MDA interventional trials and implementation strategies. The PK results could form estimates of the expected impact of ivermectin on mosquito populations and malaria transmission using mathematical models.

Once a key pillar of malaria control, housing modification remains underutilized in most endemic areas. In advance of a cluster-randomised trial to evaluate the impact of housing modification on malaria incidence in Uganda, we conducted a pilot study to assess the acceptability, feasibility, durability, cost, and entomological impact of four types of housing modifications. Between January-July 2021, 200 houses were randomized to 1) full screening: screening eaves or ceilings, windows, and ventilation openings, and patching holes in the walls; 2) partial screening: screening eaves or ceilings; 3) eave tubes; 4) eave ribbons; or 5) control arm. Evaluations included baseline and endline household surveys, monthly entomological surveys, installation process and cost analysis, and qualitative evaluation. All four interventions were acceptable, feasible, and had a significant entomologic impact. Full screening was most accepted, used locally available materials, and gave the highest reductions in vector density compared to the control arm (for *Anopheles gambiae*, density ratio: full screening 0.25 [95% CI 0.12; 0.53]; partial screening 0.36 [95% CI 0.17; 0.76]; eave tubes 0.45 [95% CI 0.21; 0.99]; eave ribbons 0.39 [95% CI 0.17; 0.90]; similar results for *An. funestus*). Eave tubes were most feasible, quickest to install (on average, per house: eave tubes 3.9hr; full screening 7.65hrs; partial screening 7.73hrs; eave ribbons 13.2hr), were durable, and had the second-lowest cost (average societal, economic cost per house projected to trial conditions: partial screening $42.41; eave tubes $45.25; full screening $87.70; eave ribbons $102.27). Partial screening was well-received initially but showed poor durability and was redundant for houses with closed eaves. Eave ribbons were moderately accepted and durable but time-consuming, labour-intensive to install, and expensive. Full screening and eave tubes were selected for further evaluation in an ongoing large-scale trial. Beyond informing the trial intervention selection, the pilot has contributed to the wider knowledge base for a range of housing modifications for malaria prevention.

EXPLORING THE IMPACT OF CONTROL INTERVENTIONS ON INSECTICIDE-RESISTANT MOSQUITOES THROUGH IMPROVED BIOLOGICAL REALISM IN MALARIA MODELS

Melissa A. Iacovidou[1], Priscille Barreaux[2], Simon E. F. Spencer[1], Matthew B. Thomas[3], Erin E. Gorsich[1], Kat S. Rock[1]

[1]University of Warwick, Coventry, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University of York, York, United Kingdom

Mathematical models of malaria often assume age-independent mortality rates of mosquitoes despite evidence that senescence can occur. In this study, we investigate whether the age-independent assumption yields quantitatively different results in assessing the impact of interventions to control malaria and subsequent policy recommendations arising from modelling. Firstly, we use survival data on insecticide-resistant *Anopheles gambiae s.l.* to fit age-independent and age-dependent mortality functions to mosquitoes exposed and not exposed to insecticide-treated nets (ITNs). By incorporating age dependency, we obtain biologically realistic survival functions and explore the effects of insecticide exposure on mosquito mortality rates. We calculate the expected number of infectious bites a mosquito takes in its lifetime, and, by extension, the vectorial capacity. We observe a significant decrease in the predicted vectorial capacity when mosquitoes are exposed to ITNs and a further reduction when age-dependent mortality rates are included. Next, we extend a Ross-Macdonald-type host-vector model to include the more biologically realistic mortality functions by formulating an age-structured system, with the age-structure present in the mosquito compartments. Using our previously parameterised survival functions, we compare the dynamics with the age-independent system (with constant mortality), which is most commonly utilised. In addition, to further increase biological realism in the model, we use an Erlang distribution for the extrinsic incubation period (EIP), and, again, compare results against the more frequently used distributions (such as fixed EIP). We explore the predicted impact of ITNs in the model from a pre-control baseline and increased mortality as observed in the experimental mosquito data. We outline the circumstances in which the standard non-age-structured model gives alternative results or recommendations for malaria control measures and highlight the importance of collecting detailed age-structured vector data for parameterising malaria models for different vector species and climates.

ASSESSING NATIONAL VECTOR CONTROL MICRO-PLANNING IN ZAMBIA USING THE 2021 MALARIA INDICATOR SURVEY

Irene Kyomuhangi[1], Andrew Andrada[1], Zhiyuan Mao[1], Derek Pollard[2], Christina Riley[2], Adam Bennett[3], Busiku Hamainza[4], Hannah Slater[3], Justin Millar[3], John M. Miller[5], Thomas P. Eisele[1], Kafula Silumbe[4]

[1]Tulane University, New Orleans, LA, United States, [2]AKROS, Lusaka, Zambia, [3]PATH, Seattle, WA, United States, [4]National Malaria Elimination Centre, Lusaka, Zambia, [5]PATH, Lusaka, Zambia

In 2020 the Zambia National Malaria Elimination Centre (NMEC) targeted the distribution of long-lasting insecticidal nets (LLINs) and indoor-residual spraying (IRS) campaigns based on sub-district micro-planning. Detailed population and structure count maps were developed and reviewed with district health office staff to assign areas to receive either LLIN or IRS at health facility catchment level, using a 'mosaic' approach. The objective of this analysis is to assess how well the micro-planning was followed in distributing LLINs and IRS. The analysis compared coverage of the interventions among household clusters in the 2021 National Malaria Indicator Survey (MIS), against the micro-plan area under which the households fell. The 2021 MIS was implemented in April-May, and the sample included 202 standard enumeration areas that served as 'clusters' selected at first stage with probability of selection proportional to cluster population size. A total of 4,155 households across all clusters were sampled via simple random sampling at second stage. Household

LLIN and IRS coverage was ascertained with a standardized questionnaire. The proportion of households with ≥1 LLIN, and those which received IRS within the past 12 months were estimated for each cluster and overlayed onto microplanning maps. Preliminary results from the analysis suggest that overall LLIN and IRS coverage may have declined compared to previous years. The proportion of households that received their assigned intervention under the micro-plan was 70.5% (95%CI: 67.9, 73.1) for LLIN-assigned households and only 47.7% (95% CI: 45.7, 49.7) for IRS-assigned households. Overall coverage across the sampled population, regardless of the micro-plan, was 53.3% (95% CI: 49.6, 56.9) for LLINs compared to 39.0% (95%CI: 35.7, 42.1) for IRS, while 70.6% (95% CI: 67.5, 73.6) of households received either intervention compared to 29.4% (95% CI: 26.4, 32.5) who received neither. We will also present the factors contributing to adherence or non-adherence to the micro-plan, with the aim of informing future micro-planning exercises by the Zambia NMEC, as well as other national programs.

DEVELOPING FIELD-DEPLOYABLE RT-PCR TOOL FOR MOSQUITO INSECTICIDE RESISTANCE SURVEILLANCE

Mahdiyeh Bigham[1], Maria Luisa Simoes[1], Camille Wouters[1], Yuemei Dong[1], Armel Tedjou[2], Francesco Buongiorno[3], Lorenzo Colombo[3], Andrea Nardi[3], Stefano Lo Priore[3], Charles Wondji[2], George Dimopoulos[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Centre of Research in Infectious Diseases (CRID), Yaounde, Cameroon, [3]Hyris Ltd, London, United Kingdom

We are developing a field-deployable molecular diagnostic system to survey insecticide-resistance at field conditions. Insecticide resistance surveillance is a key component of malaria vector control and can be performed through lengthy phenotypic assays and PCR-based molecular assays. However, even the molecular assays require transporting of collected mosquitoes to centralized laboratories for testing, thereby representing a major rate-limiting step that can even lead to months-long delays in obtaining crucial information. We are developing a qPCR-based diagnostic assays for *Anopheles gambiae* target site and metabolic resistance-type insecticide resistance markers using the field-deployable portable bCUBE qPCR system. We specifically focused on the *An. gambiae* knockdown resistance genes (L1014F, L1014S, N1575Y), Ace-1 (G119S), RDL (A296S), GST (I114T-GSTe2), and P450 (CYP4J5 -L43F, Coeae1d). The qPCR genotyping assay combines a modified allele-specific primer with a common wild-type primer to distinguish resistant from wild-type SNPs. We designed multiple primer pairs for the different SNPs and selected combinations that can discriminate the markers. Discrimination of SNPs is determined by the melting curves, enabling the determination of homozygous, or heterozygous insecticide resistance alleles in the field-caught *An. gambiae* from Cameroon. We also explore the identification of resistance SNPs in pooled samples to enable a greater throughput. The insecticide surveillance system is designed for autonomous operation and will also generate data that will enhance our understanding of insecticide resistance dynamics in mosquito populations.

SEASONAL DYNAMICS OF AN EMERGING AFRICAN MALARIA VECTOR, *ANOPHELES STEPHENSI*: IMPLICATIONS FOR MALARIA CONTROL

Charles Whittaker[1], Ellie Sherrard-Smith[1], Peter Winskill[1], Gina Cuomo-Dannenburg[1], Patrick Walker[1], Azra Ghani[1], Samir Bhatt[2], Thomas Churcher[1], Arran Hamlet[1]

[1]Imperial College London, London, United Kingdom, [2]University of Copenhagen, Copenhagen, Denmark

Increasing urbanisation has contributed to reductions in malaria burden across sub-Saharan Africa with urban areas typically experiencing lower levels of transmission. Recent invasion and proliferation of the urban malaria vector *Anopheles stephensi* across the Horn of Africa threatens this progress. Understanding the vector's seasonal dynamics in these settings represents a crucial input to its control, given that the effectiveness of many malaria control interventions depends on timing delivery relative to seasonal peaks in transmission. Here we collate longitudinal catch-data for the species from across South Asia and the Middle East to better understand these dynamics and explore their implications for malaria transmission in urban settings across the Horn of Africa where the disease is currently largely absent. Our analyses reveal pronounced variation in the extent and timing of seasonality across *Anopheles stephensi* populations, ranging from single seasonal peaks to bimodality and near-perennial patterns of abundance. This diversity is underpinned by patterns of land use, as well as variation in seasonal patterns of rainfall and temperature across locations. Dynamics frequently differ between rural and urban settings, suggesting structural differences in how these environments shape patterns of vector abundance. Integrating these seasonal profiles with a model of malaria transmission, we show that the impact of IRS is highest in settings with the highest seasonality, but that crucially, achieving this impact requires an understanding of when *Anopheles stephensi* populations are likely to peak. Our results highlight a critical lack of studies from the Horn of Africa able to directly inform this understanding, underscoring the need for longitudinal entomological monitoring of the vector across the region.

0407

EVALUATING THE ASSOCIATION BETWEEN NEXT GENERATION LONG-LASTING INSECTICIDE TREATED NETS WITH PIPERONYL BUTOXIDE AND MALARIA PARASITE PREVALENCE AMONG CHILDREN UNDER FIVE IN ZAMBIA

Andrew Andrada[1], Zhiyuan Mao[1], Irene Kyomuhangi[1], Emmanuel Kooma[2], Ketty Ndhlovu[2], Busiku Hamainza[2], Adam Bennett[3], Hannah Slater[3], Justin Millar[3], John M. Miller[4], Kafula Silumbe[4], Thomas P. Eisele[1]

[1]Center for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]National Malaria Elimination Centre, Lusaka, Zambia, [3]PATH, Seattle, WA, United States, [4]PATH Malaria Control and Elimination Partnership in Africa, Lusaka, Zambia

Zambia recently began introducing new long-lasting insecticide treated nets (LLINs) containing piperonyl butoxide (PBO) to improve community protections against pyrethroid resistant vectors and to reduce malaria infections. PBO inhibits a mosquito's ability to break down insecticides and acts as a synergist to improve the efficacy of insecticides. The National Malaria Elimination Centre began mass distributing these PBO nets in 2020 to seven out of the ten provinces in Zambia. We used the 2021 Zambia Malaria Indicator Survey to investigate associations between LLINs and malaria parasite prevalence identified through rapid diagnostic tests among children under five. We assessed RDT positivity among LLIN households and PBO households using a logistic regression, controlling for indoor residual spraying and community LLIN density. Other covariates included in the model are urbanicity, household socioeconomic status, parental education, gender, and age of the children. Our preliminary results show a significant inverse relationship between having LLINs and malaria parasite prevalence. Among those with LLINs, PBO nets further decreased the likelihood of an RDT positive test (OR: 0.60, 95% CI: 0.43 to 0.82). Plasmodium falciparum parasite rates estimated by the Malaria Atlas Project at the cluster level will be later added to the analysis to control for variation in malaria endemicity. This analysis is one of the first opportunities to evaluate these next generation PBO LLINs after actual malaria program implementation and scale-up. Initial results from this evaluation are encouraging and highlight possible effects PBO nets may have on the reduction of malaria parasite prevalence in Zambia.

0408

THE SYMBIOTIC TC1 BACTERIUM IS A NOVEL MOSQUITO-BASED MALARIA INTERVENTION TOOL

Wei Huang[1], Janneth FI Rodrigues[2], **Marcelo Jacobs-Lorena**[1]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]GlaxoSmithKline, Tres Cantos, Spain

The intolerable burden of malaria demands the urgent development of novel approaches to fight this deadly disease. We describe the properties of a non-modified symbiotic bacterium – TC1 - originally isolated from mosquitoes that had lost the ability to sustain the development of *Plasmodium falciparum* parasites. TC1 is a potent inhibitor of *Plasmodium* development in mosquitoes via secretion of an inhibition factor that blocks early stages of *Plasmodium* development. We have identified the inhibitor as a small hydrophobic compound that can penetrate the cuticle and inhibit *Plasmodium* development on mosquito contact. TC1 does not impose a fitness cost to the mosquito, as it does not affect mosquito survival, blood feeding behavior, fertility, or fecundity. TC1, and its secreted molecule constitute a novel tool for malaria intervention.

0409

EFFECT OF DELTAMETHRIN-PIPERONYL BUTOXIDE (PBO) INSECTICIDE-TREATED NETS ON MALARIA CASE INCIDENCE AND ENTOMOLOGICAL INDICATORS IN EBONYI, NIGERIA

Kelly M. Davis[1], Adedayo O. Oduola[2], Lazarus M. Samdi[3], Petrus U. Inyama[3], Ifeanyi Okeke[3], Jesse C. Uneke[4], Lawrence Nwankwo[5], Perpetua Uhomoibhi[6], Adedapo Adeogun[7], Okefu O. Okoko[8], Kelley Ambrose[9], Uwem Inyang[10], Melissa Yoshimizu[11], Aklilu Seyoum[9], Sarah Burnett[1]

Pyrethroid resistance has been widely documented throughout Nigeria, threatening the effectiveness of insecticide-treated nets (ITNs), the primary malaria vector control intervention in the country. New types of ITNs, such as pyrethroid nets treated with piperonyl butoxide (PBO), have been developed to address this resistance. Based on entomological evidence collected under the U.S. President's Malaria Initiative VectorLink project, the National Malaria Elimination Program in Nigeria deployed 1.7 million PBO ITNs in Ebonyi State in November 2019. A study using an interrupted time series approach was designed to evaluate the epidemiological and entomological impact of the PBO ITN campaign using routine data from December 2017 to November 2021. Monthly data on confirmed malaria cases were obtained from the national HMIS and incidence rates were calculated at the ward level. Entomological impact was determined by collecting data on indoor and outdoor human biting rates and indoor resting density of *Anopheles* mosquitoes in Ezza North Local Government Area. Annual malaria case incidence increased from 14.5 cases per 1,000 population to 18.7 between the first and second years of the pre-distribution period (rates calculated from December to November each year), before falling to 16.6 in the first year post-distribution and then to 7.3 the following year. The indoor biting rate decreased from 0.6 bites/person/night pre-distribution (June-October 2019) to 0.2 in the first year post-distribution and then to 0.0 the following year. The outdoor biting rate decreased from 2.9 bites/person/night during the pre-distribution period to 1.4 in the first year post-distribution and then to 1.3 the following year. Average indoor resting density decreased from 9.8 mosquitoes/room/night during the pre-distribution period to 3.6 during the first year post-distribution before increasing slightly to 5.0 in the second year. While these initial results show a promising impact of PBO ITNs, final analyses are ongoing. Results from the final model will be presented to provide a clearer understanding of the impact of PBO ITNs in pyrethroid-resistant areas.

EXPLORING THE EFFECT OF WOLBACHIA-INDUCED IMMUNITY GENES ON *PLASMODIUM FALCIPARUM* SUPPRESSION IN *ANOPHELES STEPHENSI*

Tanaya Sheth[1], Shengzhang Dong[1], Qiang Sun[2], Zhiyong Xi[2], George Dimopoulos[1]

[1]W. Harry Feinstone Department of Molecular Microbiology and Immunology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [2]Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, United States

Malaria causes an estimated 240 million cases every year with about half million deaths annually. Due to the heavy disease burden and the lack of effective vaccines, resistance of the parasite to drugs and resistance of the mosquitoes to insecticides, the development of novel malaria control strategies is becoming increasingly important. *Wolbachia*, an intracellular bacterium is known to infect about 66% arthropod species. While it successfully naturally infects mosquito species such as *Aedes albopictus*, infection in *Anopheles* spp. is not widely known. Previous studies have shown that *An. stephensi* transinfected with *Wolbachia* are more resistant to *Plasmodium* infection. The interaction between *Plasmodium*, *Anopheles* and the *Wolbachia* is complex, and the mechanism by which *Wolbachia* renders the mosquito more resistant to parasite infection largely remains unknown. To explore this, we compared transcriptome of midguts and carcasses between *Wolbachia* infected and uninfected *An. stephensi*. Our data have shown that many immunity genes, like thioester-containing proteins (TEPs) and other components of the complement-like system, are upregulated upon *Wolbachia* infection in both midguts and carcasses. The effect of these candidate *An. stephensi* immunity genes on *P. falciparum* infection is investigated using dsRNA-mediated gene silencing. Results obtained from this study will further elucidate the *Anopheles-Wolbachia-Plasmodium* tripartite interactions and inform the development of *Wolbachia*-based malaria control.

0411

IMPLEMENTATION OF COMMUNITY-BASED LARVAL SOURCE MANAGEMENT FOR ENHANCING MALARIA CONTROL IN MAINLAND TANZANIA. A PROCESS NARRATION

Denis Richard Kailembo[1], Noela Kisoka[1], Sumaiyya Thawer[1], Fabrizio Molteni[1], Christian Lengeler[2], Yahya Derua[3], Tegemeo Gavana[4], Prosper Chaki[4], Stella Kajange[5], Samwel Lazaro[6], Jubilate Bernard[6], Charles Dismas[6]

[1]Swiss Tropical and Public Health Institute, Dar es Salaam, United Republic of Tanzania, [2]University of Basel, Basel, Switzerland, [3]National Institute for Medical Research - Amani Center, Muheza, United Republic of Tanzania, [4]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [5]President's Office - Regional Administration and Local Governments, Dodoma, United Republic of Tanzania, [6]National Malaria Control Program - Ministry of Health, Dodoma, United Republic of Tanzania

In mainland Tanzania, implementation of insecticide treated nets and indoor residual spraying has helped in reducing malaria prevalence from 18.1% (2008) to 7.5% (2017). In enhancing malaria control, the country is planning to deploy Larval Source Management (LSM). LSM is the management of water bodies that are potentially mosquito breeding sites. WHO recommends LSM as a supplemental vector control intervention, suitable mostly in urban settings and where breeding habitats are few, fixed and findable. Little evidence is available on LSM implementation in rural settings. Tanzania is piloting routine LSM implementation in three councils: Handeni DC, Lushoto DC and Tanga CC, selected to represent both rural and urban settings, as well as different malaria risk strata: low (1-≤5 *Pf*$PR_{5\text{-}10yrs}$), moderate (5-≤30 *Pf*$PR_{5\text{-}10yrs}$) and high (>30% *Pf*$PR_{5\text{-}10yrs}$). Implementation follows a community-based approach set up following

extensive consultations between Ministry of Health, implementing partners and research institutions. Two community owned resource persons implement LSM at the ground level, supervised by officers at village, ward and council levels using existing local government structures. The country uses two biolarvicide products that are produced locally by Tanzania Biotech Products Limited; *Bacillus thuringiensis var. israelensis* (Bti) and *Bacillus sphaericus* (*Bs*). LSM is conducted in all selected areas following a temporal approach based on rainfall patterns. Implementation is guided by standard operating procedures through the following phases: advocacy, training, logistical set-up, mapping, baseline data collection, application, monitoring and evaluation. All councils have conducted baseline data collection and biolarviciding is expected to start in May 2022. This implementation experience using exclusively governmental mechanisms as well as locally produced biolarvicides is expected to contribute important real-world experience on the potential of this form of vector control across a range of ecologies and transmission situations. We will be reporting on this experience after six months of implementation.

0412

ONE-HALF OF BYSTANDER EXPOSURES OF ENTERIC PATHOGENS TO ANTIBIOTICS WERE DUE TO RESPIRATORY ILLNESSES, ONE-QUARTER DUE TO DIARRHEAL ILLNESSES

Stephanie A. Brennhofer[1], James A. Platts-Mills[1], Joseph A. Lewnard[2], Elizabeth T. Rogawski McQuade[3]

[1]University of Virginia, Charlottesville, VA, United States, [2]University of California – Berkeley, Berkeley, CA, United States, [3]Emory University, Atlanta, GA, United States

During the course of treating a diarrheal or respiratory illness, pathogens carried subclinically at the time of treatment can be exposed to antibiotics, resulting in bystander selection pressure for antimicrobial resistance. We quantified and attributed exposures to antibiotics for subclinical enteric pathogens by type of illness. We included 15697 antibiotic courses amongst 1715 children in the MAL-ED birth cohort. We calculated the proportion and incidence per 100 child-years that bystander exposures to antibiotics for enteric pathogens were due to the treatment of acute lower respiratory infection (ALRI), dysentery, diarrhea, upper respiratory tract infection (URTI), and other causes for all courses of antibiotics and specifically for fluoroquinolone and macrolide courses. We identified subclinical infections by linking the most recent stool within 30 days to the start of an antibiotic course. Any pathogen exposed to an antibiotic course and was not the cause of the diarrheal illness was considered a bystander pathogen. For all bystander pathogens, more than one-third of antibiotic courses given were attributed to the treatment of URTIs; this proportion increased to one-half when ALRIs were included. Diarrheal and dysentery illnesses accounted for nearly one-quarter of antibiotic exposures, however, dysentery illnesses accounted for only a small proportion (<3%) for each bystander pathogen. When antibiotic courses were subset to fluoroquinolone or macrolide use, respiratory infections (ALRI and URTI) continued to account for nearly 50% of courses, however, the proportion of antibiotic courses attributed to diarrheal and dysentery illnesses increased to over one-third for all bystander pathogens. Half of subclinical enteric pathogen exposures to antibiotics occurred during the treatment of respiratory infections. Interventions focused on the reduction of antibiotics during respiratory illnesses would not only reduce exposure of respiratory pathogens to antibiotics, but could have a profound effect on bystander exposure to antibiotics for enteric pathogens and thus, the development of antimicrobial resistance.

0413

OPTIMIZING ISOLATION OF *VIBRIO CHOLERAE* FROM STORED VOMIT AND STOOL SAMPLES

Chelsea N. Dunmire[1], Denise Chac[1], Fahima Chowdhury[2], Ashraful I. Khan[2], Taufiqur R. Bhuiyan[2], Regina C. LaRocque[3], Jason B. Harris[3], Edward T. Ryan[3], Firdausi Qadri[2], Ana A. Weil[1]

[1]University of Washington, Seattle, WA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Massachusetts General Hospital, Boston, MA, United States

The gold standard for isolation of *Vibrio cholerae* (Vc), the causative agent of cholera, is culture of fresh stool in alkaline peptone broth for enrichment of *Vibrio* species and sub-culture on a selective media, such as thiosulphate citrate bile salts (APW>TCBS). However, for isolation of Vc from stored clinical samples, this method is often low yield. We compared isolation methods using clinical samples from 20 cholera patients who had Vc positive stool cultures, collected in Dhaka, Bangladesh at the International Centre for Diarrhoeal Disease Research, Bangladesh. One aliquot of both vomit and stool was frozen unprocessed and another was stored with ~30% glycerol added. Samples were stored at -80C for one year. We then attempted to isolate Vc from the vomit and rice-water stool samples by 1) direct plating on Luria-Bertani (LB) agar, 2) TCBS agar, and 3) tryptic soy agar (TSA) +5% blood, and 4) inoculation into APW enrichment and 5) inoculation into LB broth with subsequent plating for methods 4 and 5 onto both LB agar and TCBS agar. Successful isolation was defined as recovery of 10 or more Vc colonies from a vomit or rice water stool sample. Vc was isolated successfully from 4/20 (20%) unprocessed vomit samples and 7/13 (54%) glycerol vomit samples. Among stool, 6/20 (30%) unprocessed and 5/10 (50%) glycerol samples resulted in Vc isolation. Use of glycerol to store vomit did not increase the yield of APW>TCBS but did increase stool Vc isolation using this method. Sample pH and the colony forming unit count from the time of sample collection did not predict success in Vc recovery. We found that direct plating of stored clinical samples onto TSA+ 5% blood plates was as successful and less labor and resource intensive as the gold standard method of APW>TCBS. APW>TCBS and TSA+5% blood direct plating resulted in catching >80% of successful isolations. Multiple media types may be needed to recover the most possible Vc from stored samples, and isolation using TSA+5% blood plating may save time and resources.

0414

EFFECT OF A HOMESTEAD FOOD PRODUCTION PROGRAM ON THE PREVALENCE OF DIARRHEA AND ACUTE RESPIRATORY INFECTION IN CHILDREN IN SYLHET, BANGLADESH: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

Nathalie J. Lambrecht[1], Anna A. Müller-Hauser[1], Shafinaz Sobhan[1], Wolf-Peter Schmidt[2], Tarique Md. Nurul Huda[3], Jillian L. Waid[4], Sabine Gabrysch[4]

[1]Institute of Public Health, Charité – Universitätsmedizin Berlin, Berlin, Germany, [2]Department of Disease Control, London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [4]Research Department 2, Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany

Nutrition-sensitive agricultural interventions may reduce child illness by improving child nutrition and increasing caregivers' knowledge of optimal health and hygiene practices. The impact of such interventions on child illness has not yet been rigorously evaluated. We assessed the impact of a multi-year Homestead Food Production intervention on diarrhea and respiratory infections in children. The Food and Agricultural Approaches to Reducing Malnutrition (FAARM) cluster-randomized controlled trial enrolled over 2,700 married women and their children under three years of age in 96 clusters in Sylhet Division, Bangladesh. The intervention promoted home gardening and small-scale poultry rearing alongside child nutrition and health counseling over three years (2015-2018). From

mid-2017, an additional food hygiene training was delivered over eight months to reduce food contamination. Caregiver-reported diarrhea and symptoms of acute respiratory infection (ARI) were recorded every two months from 2015 up to one year post-intervention. We assessed the effect of the intervention on 7-day period prevalence of diarrhea and ARI using mixed-effects logistic regression with settlement-level random effects. Overall, we analyzed 32,465 observations of 3,262 children 0-36 months old. The 7-day period prevalence of diarrhea across all survey rounds was 4.0% in the control group and 3.8% in the intervention group. There was no relevant overall effect of the intervention on diarrhea prevalence (Odds Ratio [OR]: 0.92, 95% CI: 0.71 to 1.19) nor any effect by year of intervention. There was also no difference in the 7-day period prevalence of ARI between the control (25.5%) and intervention (26.0%) groups (OR: 1.00, 95% CI: 0.72 to 1.39). Our results show that a three-year Homestead Food Production intervention with food hygiene training in Bangladesh had no effect on child diarrhea or ARI. Nutrition-sensitive agricultural interventions may need to incorporate more comprehensive public health measures to achieve immediate improvements in child health outcomes.

0415

INTERACTIONS OF A COMMENSAL GUT MICROBIOME MEMBER WITH *VIBRIO CHOLERAE*

Patricia M. Silva[1], Denise Chac[1], Chelsea N. Dunmire[1], Mia Gwyneth Dumayas[1], Ashraful I. Khan[2], Taufiqur R. Bhuiyan[2], Fahima Chowdhury[2], Regina C. LaRocque[3], Jason B. Harris[3], Edward T. Ryan[3], Firdausi Qadri[2], Ana A. Weil[1]

[1]University of Washington, Seattle, WA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh (icddrb), Dhaka, Bangladesh, [3]Massachusetts General Hospital, Boston, MA, United States

Cholera is a diarrheal disease caused by the intestinal bacterium *Vibrio cholerae* (Vc). Cholera affects millions of patients each year and is transmitted in contaminated food or water. Vc infected patients can be asymptomatic or develop severe acute diarrheal symptoms. We previously used metagenomic sequencing to characterize the gut microbiota of persons exposed to Vc in Dhaka, Bangaldesh, and in a machine learning analysis we found that *Rothia mucilaginosa* (Rm) was more likely to be present in Vc infected persons (22.7%, 5/22) compared to uninfected persons (11.1%, 4/36, P=0.01, Mann Whitney U-test). We have previously found that other commensal gut microbes associated with cholera impact Vc biofilm formation through bacterial cell-to-cell interaction. In this study, we investigated how a Rm strain isolated from this study population might impact Vc virulence. We co-cultured Rm with Vc at 37C for six hours and quantified biofilm biomass using a microtiter dish assay with crystal violet staining. We found that Rm spent-cell supernatant (SCS), but not heat-killed Rm or Vc:Rm co-culture, increased Vc biofilm formation compared to Vc in fresh media (P=0.002, unpaired t test). Rm SCS had no impact on Vc growth by colony forming unit count. To further characterize the Rm metabolites in SCS that are impacting Vc biofilm production, we will evaluate the effects of Rm SCS fractions on Vc biofilm production, including using Vc biofilm mutants. In conclusion, we found that metabolites from Rm, a native member of the gut microbiota, can increase formation of biofilm for this enteric pathogen. Because biofilm is a known virulence factor in Vc infection, this interaction has the potential to affect patient clinical outcomes.

0416

ESTIMATING THE PROPORTION OF SUSPECTED CHOLERA CASES THAT REPRESENT TRUE *VIBRIO CHOLERAE* INFECTIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Kirsten E. Wiens, Hanmeng Xu, Kaiyue Zou, Maya N. Demby, Elizabeth C. Lee, Andrew S. Azman

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Current estimates of cholera burden rely on clinical diagnosis of cases that present with acute watery diarrhea (i.e., suspected cholera cases), with rare laboratory confirmation. Typical suspected cholera case definitions have high sensitivity but low specificity, and definitions can vary by location across seasons. In this study we use existing data from multiple locations to estimate the relationship between suspected and confirmed cholera cases and identify factors that may explain variation in positivity rates. Specifically, we conduct a systematic review of published research and surveillance studies conducted during 2000-2022 that tested at least 10 suspected cholera cases for the presence of *Vibrio cholerae* O1 or O139 using culture, PCR and/or a rapid diagnostic test (RDT). In total, we include 102 studies from 28 countries. Using a random-effects meta-analysis, we estimate that the proportion of suspected cholera that represents true *V. cholerae* infection is 39% (95% Confidence Interval 34%-44%) by culture, 44% (26%-64%) by PCR, and 55% (44%-65%) by RDT. We also find substantial variation in positivity rates between studies (I^2 values: 99% for culture, 97% for PCR, and 98% for RDT). In addition, we investigate how positivity rates are influenced by season, cholera endemicity, outbreak vs. routine surveillance, suspected case incidence rate, geographic region, walking time to health facilities in catchment area, study methodology, and sensitivity/specificity of the laboratory test. Finally, we discuss how our findings will help to refine global estimates of cholera burden while informing new strategies for laboratory testing of suspected cholera cases.

INVESTIGATING THE IMPACT OF SOCIAL AND ENVIRONMENTAL EXTREMES ON CHOLERA TIME VARYING REPRODUCTIVE NUMBER IN NIGERIA

Gina E C Charnley[1], Sebastian Yennan[2], Chinwe Ochu[2], Ilan Kelman[3], Katy A M Gaythorpe[1], Kris A. Murray[4]

[1]Imperial College London, London, United Kingdom, [2]Nigeria Centre for Disease Control, Abuja, Nigeria, [3]University College London, London, United Kingdom, [4]MRC Unit The Gambia at London School of Hygiene and Tropical Medicine, Fajara, Gambia

Cholera is one of the most reported enteropathogens and was re-introduced to Africa in the 1970s during the seventh and ongoing cholera pandemic. Since its re-introduction it has caused significant mortality and morbidity, especially in the most vulnerable people such as children under five. Nigeria currently reports the second highest number of cholera cases in Africa, with numerous socioeconomic (poverty, water, sanitation) and environmental (climate, waterbodies) risk factors. Less investigated is the role of extreme social (i.e., conflict) and extreme environmental (i.e., floods, droughts) events, despite recent work showing their potential importance and the frequency of these events in Nigeria. To address this gap, we analysed cholera data provided by the Nigeria Centre for Disease Control, with covariate data from a range of sources. We estimated time varying reproductive number (R) from confirmed cholera incidence in Nigeria for 2018 and 2019 and used a machine learning approach (Random Forest) to evaluate its association with extreme events (conflict, flood, drought) and pre-existing vulnerabilities such as poverty, sanitation and healthcare. The best fit model in terms of predictive power included monthly conflict events, the Palmers Drought Severity Index, access to sanitation and Multidimensional Poverty Index. We used historical exposure periods, split by month and state and R threshold (R = >1 or <1) to evaluate the relationships between the covariates and R. We used the historical median values and error to inform hypothetical exposure periods and to create a traffic-light system for cholera outbreak risk, highlighting

environmental and social thresholds for outbreaks to occur. By varying the exposure periods, we showed that reduced poverty and greater access to sanitation lessened vulnerability to increased cholera risk caused by extreme events (conflicts, floods and drought). The work presented here shows the need for sustainable development to increase community resilience to disasters; beyond this, increasing adaptation capabilities improves overall health and quality of life.

0418

MODELING ACQUISITION AND CLEARANCE DYNAMICS OF CAMPYLOBACTER IN CHILDREN IN LOW- AND MIDDLE-INCOME COUNTRIES

Dehao Chen[1], Arie H. Havelaar[1], James A. Platts-Mills[2], Yang Yang[1]

[1]University of Florida, Gainesville, FL, United States, [2]University of Virginia, Charlottesville, VA, United States

Undertaken in eight settings in low- and middle-income countries (LMIC) with high child diarrhea and malnutrition burdens, MAL-ED was a study unveiling associations between the cumulative burden of enteric infections and malnutrition in children under two. Colonization by zoonotic enteric pathogens from livestock feces, especially *Campylobacter* spp., has been identified as an important risk factor of malnutrition in children in LMIC. Here, we developed a two-stage time-inhomogeneous Markov model for the dynamics of *Campylobacter* acquisition and clearance among children. This model was validated using simulation studies and applied to the longitudinal data from MAL-ED. Acquisition of *Campylobacter* was slower than clearance in India, Nepal, South Africa, Brazil, and Peru over the whole 24-month study period, while the two rates were comparable and crossed over during the study period in Bangladesh, Pakistan, and Tanzania. We further estimated the average acquisition interval and duration of colonization for each month and obtained the median of these monthly averages for each country. For the whole study period, Bangladesh and Brazil had the shortest and longest median acquisition intervals (22 days and 254 days), while South Africa and Tanzania had the shortest and longest median durations of colonization (10 days and 49 days). The force of infection is inversely proportional to the acquisition interval. Using site-specific model-estimated parameters, we simulated the underlying acquisition and clearance dynamics and their realized longitudinal trends of *Campylobacter* prevalence, which were consistent with the observed prevalence trend at each site, suggesting adequate goodness of fit. Our work suggests further research to incorporate host-specific characteristics and site-specific environmental features into the model to identify risk drivers for the acquisition/clearance dynamics of *Campylobacter*, which may explain the heterogeneity across sites found in this study and inform intervention strategies.

0419

ASSESSMENT OF GUT MICROBIOME IN ANGOLAN SICKLE CELL DISEASE CHILDREN. EFFECT OF HYDROXYUREA TREATMENT

Miguel Brito[1], Mariana Delgadinho[1], Catarina Ginete[1], Brigida Santos[2], Jocelyne Vasconcelos[2]

[1]H&TRC - Health and Technology Research Center, Escola Superior de tEcnologia da Saude de Lisboa, Instituto Politécnico de Lisboa, Portugal, Lisbon, Angola, [2]Centro de Investigaçã em Saúde de Angola, Bengo, Angola

In Sub-Saharan Africa Sickle cell disease (SCD) can contribute up to 80% of under-5 mortality. Clinical manifestations are very heterogeneous and the intestinal microbiome has recently been reported to be crucial in the modulation of inflammation, cell adhesion and induction of aged neutrophils, key interveners of recurrent vaso-occlusive crises. Since gut bacteria can regulate aged neutrophils, defects in either the integrity of the intestinal walls or a chronic disequilibrium of the microbiota are very likely to emerge in SCD patients. Moreover, it has been suggested that Hydroxyurea (HU) shows a multimodal action and may reduce microbiome dysbiosis and aged neutrophils. In this context, we aimed to understand how SCD and HU treatment modulates the microbiome and if these changes could be related with disease severity.

A SCD pediatric population, was studied before and after 6 months of continuous HU treatment. A total of 66 stool samples were collected, DNA was extracted, quantified and the bacterial 16SRNA gene for the V3-V4 regions was sequenced by NGS. Microbiome taxonomic profiling analysis was performed with the EzBioCloud pipeline and differences between the two groups were assessed with the Statistical Analysis of Metagenomic Profiles (STAMP) software, using Welch's t-test. Significant associations were observed in alpha-diversity between the two groups, with higher values for the children naïve for HU, namely in OTU species count ($p<0.001$), phylogenetic diversity ($p=0.004$) and microbial richness ($p<0.001$), which was calculated by the ACE, Chao1 and Jackknife indices. We also noticed that children after HU treatment had higher proportions of some bacteria associated with health, including Blautia luti, Roseburia inulinivorans, Lactobacillus rogosae and Faecalibacterium, when compared to the beginning of the study. Additionally, the proportion of Firmicutes phylum was significantly lower before HU.

This was the first study to report gut microbiome changes before and after HU treatment in SCD children. Overall, our findings provide a rationale for further research about gut microbiota dysbiosis in this population.

0420

EVALUATE SNP BASED NOVEL DIAGNOSTIC ASSAY FOR ENTERIC FEVER DETECTION IN LIMITED RESOURCE SETTINGS

Sadia Isfat Ara Rahman[1], Farhana Khanam[1], Ankur Mutreja[2], Zoe Dyson[2], Gordon Dougan[2], Firdausi Qadri[1]

[1]icddrb, Dhaka, Bangladesh, [2]University of Cambridge, Cambridge, United Kingdom

Enteric fever, caused by *Salmonella enterica* serovars Typhi, Paratyphi A, remains a major cause of morbidity and mortality in low and middle-income countries (LMIC). The diagnosis of enteric fever has become difficult due to nonspecific clinical syndrome of typhoid and paratyphoid infection from other febrile illnesses. Moreover, the lack of robust, reliable, accurate currently available diagnostic methods and the emergence of fluoroquinolone-resistant, multi-drug resistant, extensively drug-resistant *S. Typhi* highlights the urgent need for highly sensitive molecular techniques. The wide advent of whole genome sequencing (WGS) approach has introduced a robust SNP based genotyping scheme 'GenoTyphi' that can identify specific SNP for H58 and other emerging lineages. Here we implemented WGS data to evaluate the performance of a rapid, reliable, and cost-effective genome-based diagnostic approach for *S.* Typhi including globally dominant H58 lineage and *S.* Paratyphi A detection that can be used as part of routine diagnostics in limited-resource settings including Bangladesh. An in-house built conventional PCR was carried out on a collection of blood culture positive Bangladeshi *S.* Typhi, *S.* Paratyphi A strains by utilizing *in silico* designed primer sets that target unique genes for *S.* Typhi, H58 Typhi, and *S.* Paratyphi A detection and comparison on the specificity was made with standard blood culture method. Our PCR results showed that SSPA2308, STY2513, STY0307 target genes demonstrated 100% specificity for blood culture positive *S.* Paratyphi A (22/22, 100%), *S.* Typhi (20/20,100%), H58 *S.* Typhi (20/20, 100%) DNA respectively. Moreover, WGS data of 202 Bangladeshi *S.* Typhi strains revealed that the majority of the *S.* Typhi (83/202, 41.1%) belonged to the H58 lineage in which 89.2% of H58 Typhi acquired MDR genes. Besides, *S.* Typhi and *S.* Paratyphi A detection, this genome-based diagnostic approach has added a new dimension to designing unique markers for MDR-associated H58 lineage detection and has the potential to inform local treatment algorithms based on regional antibiotic susceptibilities.

0421

DIGESTIVE TOLERABILITY AND ACCEPTABILITY OF FIBERSOL-2 IN HEALTHY AND DIARRHEAL CHILDREN 1-3 YEARS OLD AT A RURAL FACILITY, BANGLADESH: RESULTS FROM A FOUR ARM EXPLORATORY STUDY

Abu Sadat Mohammad Sayeem Bin Shahid, Abu Syed Golam Faruque, Mohammod Jobayer Chisti

icddr,b, Dhaka, Bangladesh

Fibersol-2 is a fermentable, non-viscous dextrin which has some beneficial effects on human health. We aimed to evaluate its digestive tolerability and acceptability in terms of reducing abdominal symptoms, like pain, distension, rumbling, and bloating in healthy and diarrheal children, as well as improvement in stool consistencies in diarrheal children 1-3 years old. Sixty children of either sex, 1-3 years old, thirty each at hospital and home, were included into this exploratory study having four groups (healthy/low, healthy/high, diarrheal/low and diarrheal/high) during the period of 1st August to 23rd October 2017 to find out the digestive tolerability of Fibersol-2 by administering its low (2.5g) and high (5g) doses twice daily with 50 ml drinking water during the intervention period of seven days. Age was significantly associated in the model in relation to the factors, dose and status of all the four groups (p=0.026). There was no change in stool consistency among healthy children throughout the study period and among diarrheal children, the median duration of resolution of diarrhea was [3.9 (2.9, 5.1) days vs. 3.5 (2.0, 8.0) days; p=0.885] in low dose and high dose groups, respectively. Significant difference was observed in terms of abdominal pain (27% vs. 7%, p=0.038) and distension (40% vs. 0%, p<0.001) in diarrheal children, compared to healthy children during the pre-intervention period. We also observed significant difference in respect of abdominal distension (23% vs. 0%, p=0.011), rumbling (27% vs. 0%, p=0.005) and bloating (43% vs. 3%, p=0.001) in diarrheal children, compared to healthy children during the intervention period. However, no significant difference was observed in connection with abdominal pain (p=0.347) and distension (p=0.165) during the pre-intervention period, compared to the intervention period in diarrheal children. Moreover, no significant difference was observed during the post intervention period for the diarrheal and healthy children. Fibersol-2 was found to be well tolerated in healthy and diarrheal children of 1-3 years old.

GUT MICROBIOTA-DERIVED LIPIDS CORRELATE WITH ORAL CHOLERA VACCINE RESPONSES AND THESE LIPIDS IMPACT INNATE IMMUNE RESPONSES IN *VITRO*

Denise Chac[1], Chelsea N. Dunmire[1], Fahima Chowdhury[2], Ashraful I. Khan[2], Taufiqur R. Bhuiyan[2], Edward T. Ryan[3], Regina C. LaRocque[3], Jason B. Harris[3], Firdausi Qadri[2], Ana A. Weil[1]

[1]University of Washington, Seattle, WA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Massachusetts General Hospital, Boston, MA, United States

Oral cholera vaccines (OCV) are critical for cholera control yet immune responses to vaccination vary, and host factors and demographic variances do not fully explain these differences. Gut microbes are known regulators of mucosal immune function, and we have observed correlations between gut microbes and responses to OCV. Our prior microbiome study of stool from OCV recipients demonstrated that specific gut microbes predict O-specific polysaccharide memory B cell responses (OSP MBC) after vaccination and a common factor among these microbes is the ability to produce unique sphingolipids.To investigate this correlation, we conducted lipid profiling on fecal extracts from OCV recipients in Dhaka, Bangladesh, and found increased ceramides (a precursor to sphingolipids that can be made by bacteria) among individuals with OSP MBC responses compared to vaccine recipients without OSP MBC responses (P=0.03, Mann-Whitney test). We next isolated gut microbes known to produce sphingolipids from the stool of persons living in Dhaka, Bangladesh, and tested them for the presence of serine palmitoyltransferase (SPT), the gene that enables ceramide and sphingolipid production in bacteria. One of the microbes that we found to be *spt+* is *Bacteroides xylanisolvens.* We extracted lipids from *B. xylanisolvens* culture using the Bligh-Dyer method and measured immune responses to these lipids in our macrophage model derived from the human monocytic cells. When SPT activity in the bacterial culture was inhibited, the proinflammatory response from our model was increased. For example, interleukin-6 was significantly increased in response to stimulation with the non-sphingolipid-containing lipid layers of *B. xylanisolvens* compared to those with sphingolipids (P<0.0001, t test).We have identified sphingolipid-producing microbes that correlated with OSP MBC responses in OCV recipients and found that the presence of these sphingolipids may impact innate immune responses. Our studies may contribute to the development of microbe-derived molecules that enhance immune responses to OCV.

Tiono[1], Shrimati Datta[2], Yuanyuan Liang[2], Ifayet Mayo[2], Jennifer Oshinsky[2], Kathleen J. Tracy[2], Tsion Girmay[2], Marcela Pasetti[2], Kathleen M. Neuzil[2], Sodiomon B. Sirima[1], Matthew B. Laurens[2]

[1]Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso, [2]University of Maryland School of Medicine,, Baltimore, MD, United States

Typhoid conjugate vaccines (TCV) have demonstrated efficacy against typhoid fever. A recent study showed TCV-induced IgA and IgG responses to *Salmonella Typhi* Vi polysaccharide correlate with protection in a controlled human infection model. The aim of this study was to measure anti-Vi IgG and IgA responses at 28 days and 30-35 months post-vaccination in children 15–23 months of age. We randomized children 2:1 to receive single-dose TCV or inactivated polio vaccine (IPV). We compared anti-Vi IgG and IgA responses at 28 days and 30-35 months after vaccination using Vi-coated plates and reagents (Binding Site, San Diego, CA) based on a protocol adapted from the commercial VaccZyme assay. Seroconversion was defined as ≥ 4-fold increase in titer.150 children were recruited and enrolled. At day 28 post-vaccination, anti-Vi IgG seroconversion was 94·9% (95%CI 88·4-98·3%) in TCV recipients compared to 3·9% (95%CI 0·5-13·5%) in the IPV group. Anti-Vi IgG GMT at day 28 in the TCV group was 3210·1 EU/ml (95%CI 2311·7-4457·6) versus 5·3 EU/ml (95%CI 4·1-6·9) in the IPV group. At 30-35 months, the same trend for %IgG seroconversion was observed, with 88·7% (95%CI 79·0-95·1) in the TCV group compared to 6·8% (95%CI 1·4-18·7) in IPV recipients; however, GMT decreased to 79·3 EU/ml (95%CI 63·1-99·6) in the TCV group versus 5·7 EU/ml (95%CI 4·4-7·3) in the IPV group. Participants who received TCV achieved higher anti-Vi IgA GMT (41·1 EU/ml, 95%CI 33·8-49·9) at day 28 than IPV recipients (1·7 EU/ml, 95%CI 1·5-1·8). Analyses of anti-Vi IgA immunogenicity at 30-35 months post-vaccination are ongoing. TCV conferred similarly strong anti-Vi IgA and IgG responses at 28 days post-vaccination in children vaccinated at 15-23 months of age. However, the anti-Vi IgG responses decreased at 30-35 months. Results confirm TCV is highly immunogenic in this population. The durability of the immune response is also demonstrated, but a correlate of TCV protection is unknown. Future studies should continue to investigate vaccine-induced protective responses and consider the need for, and timing of, routine booster vaccination in target populations.

0424

ASSOCIATION BETWEEN ANTE-NATAL SYPHILIS TEST RESULTS AND BIRTH OUTCOMES IN WESTERN KENYA

Jeremiah Laktabai[1], Victoria Mobley[2], Wendy P. O'Meara[3], Steve M. Taylor[4]

[1]Moi University, Eldoret, Kenya, [2]Division of Public Health, Department of Health and Human Services, Durham, NC, United States, [3]Duke Global Health Institute, Durham, NC, United States, [4]Duke University School of Medicine, Durham, NC, United States

Maternal syphilis remains a major contributor to poor pregnancy outcomes. Syphilis point-of-care tests are now employed for pregnancy screening, but the effect of screening on outcomes is unclear. We enrolled women presenting to routine antenatal care clinic in a matched case-control study at a single site in western Kenya. Syphilis point of care test-positive women were matched 1:2 with test-negative women on gravidity, gestational age, and HIV status, and followed through delivery. A confirmatory treponema pallidum hemagglutination assay (TPHA) testing was done for all participants at enrollment while syphilis serum testing was performed serially during subsequent antenatal clinic visits. Pregnancy outcomes were assessed up to 1 month after delivery and compared using prevalence ratios. We enrolled 51 syphilis test-positive (cases) and 100 test-negative (controls) women at a mean of 22 weeks gestation; 24% were HIV-positive and 40% were paucigravid. A positive TPHA was more common among cases than controls ($p < 0.001$). Only 2 women met the definition for incident syphilis. Pregnancy outcomes were available for 147 women. The prevalence of low birthweight was higher among cases (15.2%) than controls (5.4%; $p = 0.052$). Among the 109 women with concordant point of care and TPHA results at antenatal clinic enrollment, the prevalence of low birth weight was significantly higher among test-positive (25%) than test-negative (4.9%) women (adjusted PR 5.84; 95% CI 1.08, 31.5). Despite treatment with penicillin, latent syphilis at antenatal care enrollment was associated with a more than 5-fold increased risk of low birth weight. Alternate implementation strategies for point of care testing may be necessary to realize the potential of antenatal syphilis screening to improve pregnancy outcomes.

0425

THE EXCESS BURDEN OF INPATIENT BLOODSTREAM INFECTIONS CAUSED BY ANTIBIOTIC RESISTANT BACTERIA IN LMICS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Kasim Allel[1], Jennifer Stone[2], Eduardo E. Undurraga[3], Lucy Day[1], Leesa Lin[1], Luis Furuya-Kanamori[4], Laith Yakob[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]School of Population Health, Australian National University, Canberra, Australia, [3]Pontificia Universidad Catolica, Santiago, Chile, [4]UQ Centre for Clinical Research, Faculty of Medicine, The University of Queensland, Herston, Australia

Bloodstream infections (BSIs) produced by antibiotic-resistant bacteria (ABR) cause a substantial burden of disease worldwide. However, the magnitude is unclear in low-and-middle income countries as most appraisals come from high-income settings where reduced exposure to antibiotic reservoirs exists. The aim of this meta-analysis was to quantify the excess mortality, length of stay (LOS), ICU admission, and economic costs attributable to BSIs produced by ABR among adult inpatients. A systematic literature review was conducted following the PRISMA guidelines (PROSPERO registration: CRD42021264056). Three reviewers searched three medical databases (PubMed, SCIELO and Scopus; initial search n=11327) without date or language restrictions to determine differences in outcomes for BSIs caused by resistant versus susceptible bacteria. Costs estimates for outcomes were sourced either from WHO-CHOICE, or failing that, from the literature and inflated to 2020 USDs. The final included studies (n=95) showed significantly increased mortality (OR=1.51, 95%CI=1.3-1.7), LOS (SMD=0.47, 95%CI=0.1-0.7), and ICU admission (OR=1.93, 95%CI=1.5-2.5) for resistant versus susceptible BSIs. *Enterobacteriaceae*, *A. baumanii* and *S. aureus* in upper middle-income countries from the African and Western Pacific regions accounted for the highest overall burden. Excess hospital-related costs were estimated at $7378 (95% CI: $4085-$10672) for resistant BSIs. We provide a comprehensive evaluation of the excess burden of BSIs produced by AMR in low-resourced settings. We observed wide heterogeneity between WHO region, income group, and pathogen-drug combinations. Our results are critical for the design of country-specific policies, specifically related to infection prevention and surveillance and the production of new targeted antibiotics and vaccines. Nonetheless, there are still data gaps in AMR literature and surveillance capacity; improved technological development for data collection and culture within healthcare systems are crucial to tackle AMR BSIs.

0426

INAPPROPRIATE USE OF ANTIBIOTICS AMONG CHILDREN IN THE COMMUNITY OF THREE LOW- AND MIDDLE-INCOME COUNTRIES

Antoine Ardillon[1], Lison Ramblière[2], Agathe de Lauzanne[3], Perlinot Herindrainy[4], Jean-Baptiste Diouf[5], Andrianirina Zo[6], Touch Sok[7], Laurence Borand[3], Fatoumata Sarr[8], Muriel Vray[8], Jean-Marc Collard[4], Elisabeth Delarocque-astagneau[9], Didier Guillemot[1], **Bich-Tram Huynh**[1]

[1]Institut Pasteur, Paris, France, [2]Institut Pasteur, Antony, France, [3]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [4]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [5]Centre Hospitalier Roi Baudouin, Dakar, Senegal, [6]Institut Pasteur, Antananarivo, Madagascar, [7]Ministry of health, Phnom Penh, Cambodia, [8]Institut Pasteur de Dakar, Dakar, Senegal, [9]University saint Quentin-INSERM, Montigny le Bretonneux, France

Antibiotics resistance is a global public health issue, particularly in low- and middlle-income countries (LMICs) where children bear the highest burden of bacterial infection. Inappropriate use of antibiotics is a major contributor to antibiotic resistance. However, such data are lacking at the community level in low- and middlle-income countries, where the majority of the population is treated outside the hospital. We aimed to characterize the pattern of inappropriate antibiotics use among outpatient children and to identify associated determinants in Madagascar, Senegal and Cambodia. We used data from a child cohort (BIRDY cohort, 2012-2018) conducted both in urban and rural areas of these 3 countries. Children were followed-up from birth up to the age of 24 months to document all their infectious episodes. All symptoms, diagnosis and antibiotics received were documented. We defined inappropriate use as unnecessary use of antibiotics based on the diagnosis of probable bacterial infection. We performed mixed logistic models to identify determinants associated with inappropriate use of antibiotic. Among the 3710 children included, there was 29% (3,448/11,762) consultations with antibiotic prescription. Amoxicillin accounted for 36% of all prescriptions. We found that 57.0%, 15.5% and 57.2% of prescriptions were inappropriate in Cambodia, Madagascar and Senegal, respectively. Bronchiolitis was the most common indication followed by gastroenteritis and rhinopharyngitis with 43.9%, 35.5% and 20% of inappropriate prescription, respectively. Being older than 3 months (aOR ranging from 1.93 [1.65-2.25] to 4.1 [3.1-5.5]) and a diagnosis with a higher severity score (2.1[1.7-2.4] to 3.6 [2.7-4.7]) were associated with an increased risk of inappropriate prescription in the 3 countries. Also, children from urban site were less at risk of receiving an inappropriate prescription (0.2 [0.1-0.3] to 0.5[0.4-0.6]). Our findings show a significant proportion of inappropriate use of antibiotics and underscore the importance of implementing local programs to optimize antibiotic prescriptions at the community level.

0427

NEAR-TERM PREGNANT WOMEN IN THE DOMINICAN REPUBLIC EXPERIENCE HIGH RATES OF GROUP B *STREPTOCOCCUS* RECTOVAGINAL COLONIZATION

Katherine M. Laycock[1], Francia Acosta[2], Sandra Valera[3], Ana Villegas[3], Elia Mejia[3], Christian Mateo[3], Rosa Felipe[3], Anabel Fernández[4], Megan Job[5], Andrew P. Steenhoff[4], Adam J. Ratner[5], Sarah Geoghegan[6]

[1]Division of Infectious Diseases, Children's Hospital of Philadelphia, Philadelphia, PA, United States, [2]Niños Primeros en Salud, Consuelo, Dominican Republic, [3]Hospital Materno Infantil San Lorenzo de Los Mina, Santo Domingo, Dominican Republic, [4]Global Health Center, Children's Hospital of Philadelphia, Philadelphia, PA, United States, [5]Division of Pediatric Infectious Diseases, Grossman School of Medicine, New York University, New York, NY, United States, [6]Division of Paediatric Infectious Diseases, Children's Health Ireland at Crumlin and Temple Street, Dublin, Ireland

Group B *Streptococcus* (GBS) colonizes an estimated 18% of pregnant women worldwide and is an important cause of stillbirth and serious infection and death in neonates. Populations in low- and middle-income countries (LMICs) experience higher disease burdens and larger gaps in care. Region-specific data on GBS colonization rates and serotype distribution among pregnant women in LMICs are critically needed to inform effective prevention measures like intrapartum antibiotic prophylaxis (IAP) and vaccine development. The Caribbean region has the highest colonization rates identified worldwide. In the Dominican Republic (DR), the only prior study of maternal GBS colonization included women presenting in labor at all gestational ages and identified GBS colonization in 44%, the highest rate ever reported. We sought to determine the rate of GBS colonization among near-term pregnant women in the DR. Spanish-speaking pregnant women at 35 weeks or greater gestation who presented to an urban tertiary referral hospital in Santo Domingo for routine antenatal care between September 2021 and March 2022 were enrolled for rectovaginal sampling. One flocked swab in Liquid Amies medium (COPAN ESwab) was used for anterior vaginal and rectal sampling. Medium was then incubated in chromogenic Strep B Carrot Broth (Hardy Diagnostics) per manufacturer instructions, and color change indicated a positive result. Of 720 near-term pregnant women approached during the study period, 350 women were enrolled. Rectovaginal sampling using carrot broth identified GBS colonization in 26%. In the first 240 enrolled, GBS colonization was not significantly associated with past GBS history, antibiotic use in pregnancy, or vaginal douching practices. Analysis of additional demographic factors and GBS serotype distribution is ongoing. The GBS colonization rate in this cohort of near-term Dominican pregnant women exceeds the global average, highlighting the potential impact of a safe, effective GBS vaccine and the need for further work on the feasibility of routine GBS screening and IAP to reduce neonatal morbidity and mortality in the DR and other resource-limited areas.

DETECTION OF *ORIENTIA TSUTSUGAMUSHI* INFECTION FROM STILLBIRTH CASES: FINDING FROM CHAMPS STUDY IN BANGLADESH

Muntasir Alam[1], Afruna Rahman[1], Arpita Shyama Deb[1], M Ishrat Jahan[1], Shafina Jahan[1], Kyu Han Lee[2], Mohammad Zahid Hossain[1], Shams El Arifeen[1], Mustafizur Rahman[1], Emily S Gurley[2]

[1]icddr,b, Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Orientia tsutsugamushi (OT) is a mite-born obligate intracellular gram-negative bacterium known to cause scrub typhus, a febrile illness endemic in the Asia-Pacific region. Surveillance from Bangladesh from 2009-08 identified that 9% of all patients hospitalized for febrile infections had scrub typhus. Signs and symptoms of illness are non-specific can lead to multiple organ failure and death in up to 30% of cases. OT infection during pregnancy can cause stillbirth, preterm labor, small size for gestational age, or low birth weight. Diagnosis is difficult and research about infections during pregnancy is limited. Here we report three stillbirths from rural Bangladesh where OT was identified using molecular testing. The Child Health and Mortality Prevention Surveillance (CHAMPS) program investigates causes of stillbirths and under-5 deaths in Bangladesh and other countries. Post-mortem blood, cerebrospinal fluid (CSF), nasopharyngeal swabs, and rectal swabs are collected and tested using multiple diagnostic platforms such as microbial culture and TaqMan Array Card Real-Time PCR. Tissues are collected using minimally invasive tissue sampling and reviewed using histopathology. From August 2017 to Aug 2021 specimens from 115 stillbirths were collected; OT was identified by real-time PCR in CSF from 3 cases (2%); one also had the organism detected in blood. Ct for all specimens ranged between 31-34. All three stillbirths were preterm, macerated, low birth weight and detected before delivery (antepartum). Gross observation indicated hepatomegaly and nose bleeding for two cases. For two cases the mother reported febrile illness with shivering 3-4 days before the period of delivery and both received antimicrobial therapy. The expert panel in Bangladesh did not consider the organism as a contributor to the demise of these fetuses, despite the real time PCR results, due to relatively higher Ct value and because stillbirths associated with OT have not been previously described in Bangladesh. The real burden and impact of OT infection among pregnant women in Bangladesh deserves further investigation.

0429

RECOGNISING SEPSIS AS A HEALTH PRIORITY IN SUB-SAHARAN AFRICAN COUNTRY: LEARNING LESSONS FROM ENGAGEMENT WITH GABON'S HEALTH POLICY STAKEHOLDERS

Bayode Romeo Adegbite[1], Paul Kawale[2], Levi Kalitsilo[2], Shevin T. Jacob[3], Jamie Rylance[4], Ayola Akim Adegnika[1], Martin Grobusch[1]

[1]Centre de Recherches Médicales de Lambaréné, Lambarene, Gabon, [2]African Institute for Development Policy, Lilongwe, Malawi, Malawi, [3]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, Uganda, Uganda, [4]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, Malawi, Malawi

Sepsis is a life-threatening condition due to organ dysfunction, resulting in a dysregulated host response to infection. It has been recognized as a global health priority by the United Nations World Health Assembly, which adopted a resolution in 2017 to improve sepsis prevention, diagnosis, and management globally. Low- and middle-income countries such as Gabon govern limited resources both human and material, and the health system is challenged by many infectious diseases. This study investigated how sepsis is prioritized in Gabon. From May to November 2021, we conducted a qualitative study on health care stakeholders at the local, regional, and national levels. Stakeholders included the Ministry of Health (MOH), ethics/regulatory bodies, research institutions, training institutions, referral hospitals, international funders, and media. Twenty-three multisectoral stakeholders were interviewed. Respondents indicated that sepsis is not yet prioritized in Gabon due to the lack of evidence of its burden. They also suggest that the researchers should focus on linkages between sepsis and the countries' existing health sector priorities to accelerate sepsis prioritization in health policy. Stakeholder awareness and engagement might be accelerated by involving the media in the generation of communication strategies around sepsis awareness and prioritization. There is a need for local and national evidence to be generated by researchers and taken up by policymakers, focusing on linkages between sepsis and a country's existing health sector priorities. MOH should set sepsis reporting structures and develop appropriate sepsis guidelines for identification, management, and prevention.

0430

BIOMARKERS OF AETIOLOGY IN HOSPITALISED CHILDREN WITH SEVERE ACUTE INFECTIONS

Jacqueline Waeni[1], Elijah Gicheru[1], Martin Mutunga[1], Boniface Gichuki[1], James Njunge[1], Daniel O'Connor[2], James Nokes[1], Charles Sande[1]

[1]KEMRI Wellcome Trust, Kilifi, Kenya, [2]University of Oxford, Oxford, United Kingdom

Despite the improvement in global health over the last three decades, sepsis are still a major cause of morbidity and mortality globally and especially in children under 5 years. Sepsis is a heterogeneous syndrome caused by a dysregulated host response to infection. Different pathogens cause infections that manifest with sepsis-like symptoms thus limiting symptomatic clinical diagnosis. Determining the aetiology of sepsis remains a global challenge. This complicates care decisions, leading to increased antimicrobial resistance and mortality. Preventing death and long-term morbidity due to infectious diseases requires better diagnostics. Understanding the molecular processes that underlie different aetiologies would enable initiation of appropriate and timely treatment. We aimed to characterise the host response in plasma of children under 5 years admitted at the Kilifi County Hospital with severe acute infections. Admission levels of plasma proteins were determined using untargeted liquid chromatography tandem mass spectrometry (LC-MS/MS). Protein profiles of children with bacterial infections (N = 63) were compared with those of children who had viral infections (N=75). Healthy children (N=20) were used as controls. Using linear models, we assessed the relationship between baseline plasma proteins and infection. Bioinformatic analysis of differentially expressed proteins showed elevation acute phase proteins such as C-reactive protein in children with bacterial infections. In addition, angiotensinogen, lipopolysaccharide binding protein and Serpin Family A Member 1 were associated with bacterial infections while Apolipoprotein A-2, and paraoxonase-1 were associated with viral infections. Acute phase responses and neutrophil degranulation were enriched in bacterial infections while platelet degranulation was negatively associated with bacterial infections. These results show the changes plasma protein levels and biological processes during bacterial and viral sepsis that can be leveraged to design biomarkers and future interventions of sepsis.

0431

IMMUNOGENICITY OF A PSORALEN-INACTIVATED WHOLE-CELL *NEISSERIA GONORROHOEA* VACCINE IN MICE

Leigh Ann Sanders[1], Almutasem Hamed[1], Todd A. Ponzio[1], Thomas F. Wierzba[1], Maria Blevins[1], Elizabeth B. Norton[2], Appavu K. Sundaram[3], Daniel F. Ewing[3], Kevin R. Porter[3], David Caudell[1], Marlena Westcott[1], John W. Sanders[1]

[1]Wake Forest University School of Medicine, Winston-Salem, NC, United States, [2]Tulane University, New Orleans, LA, United States, [3]Naval Medical Research Center, Silver Spring, MD, United States

Gonorrhea is a major global health threat compounded by increasing multidrug resistance. There is currently no vaccine. We examined a method of inactivating *N. gonorrhoeae* (GC) with 4-aminomethyl-4,5', 8-trimethylpsoralen (AMT), a psoralen derivative, and UVA light (PUVA) to introduce DNA crosslinks, disabling DNA replication without altering the proteins on the cell surface. This inactivation technique protects protein epitopes and produces "killed but metabolically active" bacteria which could allow for the development of a more robust vaccine than other inactivation methods. GC strain FA1090 was inactivated using either 2 cycles of AMT at a dose of 40 ug/ml and 1 Joule/cm^2 of UVA or formalin (10% for 2 hours at room temperature). Four groups of 7-8 mice received a 0.1 ml injection containing 5 x 10^6 CFU equivalents of PUVA or formalin inactivated bacteria with or without 0.25 µg dmLT, a mucosal adjuvant, on days 0 and 21. Sera was analyzed for antibody response (IgM+G+A) by whole cell ELISA using GC as the coating antigen. Histopathologic exam of colorectal tissue collected on day 35 was performed. Significantly higher titers were demonstrated for PUVA-GC than formalin-GC ($p = 0.0009$), PUVA-GC vs PUVA-GC+dmLT ($p<0.0001$), formalin-GC vs formalin-GC+dmLT ($p=0.009$) and PUVA-GC+dmLT vs formalin-GC+dmLT ($p<0.0001$). Notably the nonadjuvanted PUVA-GC vaccine induced significantly higher titer antibodies than the adjuvanted formalin-GC vaccine ($p = 0.0005$). Histologically, both vaccines induced increased cellularity composed predominantly of tightly packed lymphocytes within the colonic lymphoid aggregates, but the lymphoid aggregates were more cellular and organized in the PUVA-GC+dmLT compared to the formalin-GC+dmLT group. This study demonstrates a proof of concept for an PUVA inactivated gonorrhea vaccine. The vaccine elicited a robust humoral response and promising mucosal changes in the mouse model. Future studies are planned to further characterize the immune response and evaluate protection.

0432

DEEP NECK INFECTIONS IN DIABETIC PATIENTS: A COMPARATIVE STUDY WITH NON-DIABETIC PATIENTS

Debasmita Dubey, Smarita Lenka, Santosh Kumar Swain

IMS and SUM Hospital, Bhubaneswar, India

The global burden of diabetes, as well as diabetic-related comorbidities, is steadily rising. Infections are more common in people with diabetes. Deep neck infections, especially in immunocompromised hosts such as diabetic patients, can be fatal if life-threatening complications arise. Due to a growing concern regarding antibiotic resistance, we aim to investigate if there has been a change in the microbiology and antibiotic sensitivity of deep neck infection February 2019- January 2020 infections in diabetic and non diabetic patients group over the period of one year. Study was conducted 150 consecutive patients with deep neck infection treated in the Otolaryngology / Head & Neck Surgery Department of IMS & SUM Hospital, Bhubaneswar, Odisha. Out of which 47 patients were diabetic and 103 were non diabetic group. Demographics, clinical features and microbiological data, etiology, duration of hospital stay and other complications were analyzed. Among the 150 patients (47 diabetic and103 non-diabetics) with deep neck infection, Clinical samples were obtained from 150 patients, and were identified by conventional method and Vitek 2 sytem. Antibiotic profiling also done by Vitek 2 system. *Streptococcus pyogenes* is the common bacteria found in non-diabetic cases and *Pseudomonas aeruginosa, Klebsiella pneumonniae* were predominant in diabetic patients with infection. Diabetic patients are more likely to develop abcesses than non-diabetic patients. In the diabetes group, surgical drainage was performed more frequently than in the nondiabetic group. The diabetic group had a longer hospital stay, more problems, and more tracheostomy or intubation than the nondiabetic group. In both groups, odontogenic and upper airway infection were the most frequent infections. Diabetes mellitus patients are more likely to have infection. When dealing with deep neck infections in patients with diabetes mellitus, we should pay special care because these patients are more likely to have longer stay in the hospital. Empirical antibiotics should cover *K. pneumoniae* and *P. aeruginosa* in patients with deep neck infection who have diabetes mellitus.

0433

DEVELOPMENT OF DEEP GENOME MINING BASED DIAGNOSTICS FOR CURABLE SEXUALLY TRANSMITTED INFECTIONS

Clement Shiluli[1], Bernard Kanoi[1], Michael Maina[1], Shwetha Kamath[2], Ibrahim Ndirangu[1], Srinivasa L. Raju[2], **Jesse Gitaka**[1]

[1]Mount Kenya University, Thika, Kenya, [2]Jigsaw Bio Solutions Ltd, Bangalore, India

Gonorrhea, caused by *Neisseria gonorrhoeae* (NG) accounted for approximately 87 million cases globally in 2016. Although the disease is a major global burden causing adverse outcomes including ectopic pregnancies, pelvic inflammatory disease and infertility the most preferred laboratory method for diagnosis is bacterial culture. However, basic sample handling can make culture unreliable. Several other methods

available for NG diagnosis include molecular methods, which are less labor intensive and are accurate. However, are not widely field deployable especially in low resource settings. In this study, we leveraged genome-mining approaches to select identical multi repeat sequences (IMRS) distributed throughout the NG genome to design primer pair that target numerous regions. Genomic DNA was extracted from bio-banked NG positive urethral swabs, and 10-fold serially diluted (100pg/µl to 1×10^{-3} pg/µl) and used as DNA template for PCR reactions using the IMRS primers. As a control, conventional PCR with 16s RNA primers was also run, and both assay products resolved on agarose gel. We observed that the IMRS PCR assay was more sensitive with a lower limit of detection of 0.006 pg/µl, representing >1052 times better sensitivity. The IMRS assay was comparable ($P \geq 0.1573$) to the conventional 16s RNA PCR in detecting cultured NG from infected patients. We further showed that Loop-mediated isothermal amplification (LAMP) using IMRS PCR primers is both reliable and sensitive for detecting cultured and field NG isolates. Put together, algorithm-based de novo genome mining of IMRSs as amplification primers can serve as a novel platform technology for developing ultrasensitive diagnostics for NG genome and potentially a wide range of infectious pathogens. In addition, there is a potential to implement this concept in miniaturized, point-of-care, isothermal, microfluidic platforms and laboratory-on-a-chip diagnostic devices.

0434

A MENINGOCOCCAL MENINGITIS RAPID DIAGNOSTIC TEST IN CEROBROSPINAL FLUID (CSF)

Savannah Marie Rubin, Cheikh Tidiane Diagne, Oumar Ndiaye

Institut Pasteur of Dakar, Dakar, Senegal

Meningitis is a devastating infectious disease and remains a major public health challenge. *Neisseria meningitis* (Nm), causing meningococcal meningitis, is the pathogen with the potential to produce large epidemics within countries in the meningitis belt of sub-Saharan Africa. Meningococcal meningitis being a deadly disease, is associated with high mortality (up to 50% when untreated) and survivors are often left with crippling neuro developmental sequelae. Early diagnosis and prompt application of specific antimicrobial therapy are the most important measures to save lives and reduce complications. The use of laboratory methods has become necessary as it can inform decision-makers of the Nm serogroup involved. However, countries most affected face real limitations in laboratory diagnostics. A Point of Care (POC) device that would be rapid, cheap and simple enough to be performed in local health structures is needed. To meet this demand, a rapid diagnostic test (RDT) to enable identification of six serogroups of Nm from the cerebrospinal fluid (CSF) is being developed. This test is composed of two strips in the same cassette. The serogroups A, C and W135 will be detected on one strip whilst B, Y and X will be detected using another one. Currently in phase 2 of development (optimization phase), the prototypes are being tested with different concentration of polysaccharides with promising results (a detection limit of 0.5ng/ml per serogroup except for Y 0.75 ng/ml and A 1ng/ml with an optimization that is ongoing). On the other hand, samples from hospitals are being collected and characterized (gold standard methods) for the next step of validation. This RDT could be useful both as a first-line diagnostic tool for epidemiological surveillance of outbreaks and at the patient's bedside for improved case management.

0435

COMMUNITY SURVEY OF LEPROSY, SCHISTOSOMIASIS, STRONGYLOIDIASIS, SARS-COV-2, AND ASSOCIATIONS WITH WASH AND SES IN EASTERN MINAS GERAIS, BRAZIL

Emma R. Nedell[1], Heloine M. Leite[2], Pedro H. F. Marçal[3], Brooke L. Lappe[4], Dirce R. de Oliveira[3], Marcos D. S. Pinheiro[3], Erica B. M. Silva[3], Julie A. Clennon[5], Thomas R. Ziegler[6], Jeffrey M. Collins[7], Lance A. Waller[8], José A. Ferreira[9], Lucia A. O. Fraga[3], Jessica K. Fairley[7]

[1]Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Universidade Federal de Juiz de Fora-Campus GV, Governador Valadares, Brazil, [3]Universidade Vale do Rio Doce, Governador Valadares, Brazil, [4]Gangarosa Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [5]Department of Environmental Sciences, Emory College of Arts and Sciences, Emory University, Atlanta, GA, United States, [6]Division of Endocrinology, Department of Medicine, Emory University School of Medicine, Atlanta, GA, United States, [7]Division of Infectious Diseases, Department of Medicine, Emory University School of Medicine, Atlanta, GA, United States, [8]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [9]Faculdade da Saúde e Ecologia Humana, Vespasiano, Brazil

Neglected tropical diseases (NTDs), including Hansen's disease (HD), or leprosy, and soil-transmitted helminths, remain public health concerns in Brazil. This cross-sectional serosurvey aims to assess the burden of and risk factors for HD and parasitic infections in municipalities in Minas Gerais, while also measuring SARS-CoV-2 seroprevalence. Participants aged 3 years and older were randomly sampled from neighborhoods in Governador Valadares, Inhapim, and Turmalina. A survey assessing demographics, water, sanitation, and hygiene (WASH), and environmental conditions was administered. Blood spots were collected and tested for antibody reactivity to *Mycobacterium leprae* (LID-1), *Schistosoma mansoni* (SEA), *Strongyloides* spp. (NIE), and SARS-CoV-2 using a multiplex beaded assay (MBA). Descriptive and bivariate analyses were conducted. Initial results include survey data on 594 individuals, of which serological data was available for 220 participants. The mean age was 51.5 years and 66.3% were female with 23.4% black, 21.4% white, and 54.1% mixed race. Most participants (74.8%) had an elementary school education or less and 37.3% made below minimum wage (approximately 8 USD per day). Two-thirds (65.4%) of survey participants self-reported ever having been diagnosed with a parasitic infection and 20 (3.4%) self-reported past history of HD. Four (1.8%) were positive for anti-LID-1, 28 (12.7%) were positive for anti-SEA, and 12 (5.5%) were positive for anti-NIE. One hundred eighty-two (82.7%) were positive for SARS-CoV-2 antibodies via either infection or vaccination. Occupational or recreational contact with bodies of water was found to be associated with self-reported history of a parasitic infection (OR=1.72; 95% CI: 1.11, 2.69). Using a public faucet as a source for cooking water was found to be associated with self-reported HD diagnosis (OR=10.27; 95% CI: 2.27, 46.39). These initial findings begin to characterize the burden of NTDs with further analyses of the associations of WASH, socioeconomic status, and seroreactivity of the full sample expected.

0436

EXPLORING THE BIOACTIVITY OF *KHAYA SENEGALENSIS* (DESR.) A. JUSS. FOR COMBATING MULTIPLE DRUG-RESISTANT *STAPHYLOCOCCUS AUREUS* INFECTIONS

Sylvester Kaminta, Daniel Boamah, Borge L. Frimpong, Henry Brew-Daniels, Susana O. Dapaah, Seyiram Kumordzie, Paa K. Gordon, Benjamin A. Dadzie

Centre for Plant Medicine Research, Mampong-Akuapem, Ghana

Since antiquity, antibacterial agents have been a blessing in the fight against diversified bacterial infections saving millions of lives. However, despite efforts to combat infections caused by multiple drug-resistant

Staphylococcus aureus (MDRSA), infections due to MDRSA is still on the rise and remain a significant public health burden globally. Currently, effective antibiotics to address this urgent need are limited, warranting the search for new compounds using the medicinal approach to discover antimicrobial therapies. Here, we investigated the bactericidal effect of cold macerated 70% ethanolic stem bark extract of *Khaya senegalensis* (KS) on twenty MDRSA isolates, using the agar well-diffusion and micro-broth dilution techniques. The test organisms were challenged with two-fold dilution concentrations of extract, 100 to 6.25 mg/mL and 50 to 0.02 mg/mL for the agar well-diffusion and micro-broth dilution assays, respectively. Our work showed that the ethanolic extract from KS inhibited all the tested organisms with appreciable inhibition zones ranging from 18.3 ± 0.6 to 8.3 ± 0.6 mm in a dose-dependent manner compared to Ciprofloxacin (15 µg/mL) 15.3 ± 0.6 to 19.0 ± 0.0 mm. Also, the extract showed promising activity against the MDRSA strains with very low minimum bactericidal concentrations of 0.39 to 1.56 mg/mL. Further studies on phytochemical screening and bioassay-guided fractionation of extract from KS to isolate the bioactive compounds are ongoing.

0437

COMMON ENVIRONMENTAL EXPOSURES IN INDIVIDUALS WITH HANSEN'S DISEASE IN THE SOUTHERN UNITED STATES

Danielle M. Chaney[1], Jessica K. Fairley[2]

[1]Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Division of Infectious Diseases, Department of Medicine, Emory School of Medicine, Atlanta, GA, United States

Hansen's disease (HD), or leprosy, is a disease caused by *Mycobacterium leprae* and less commonly, *Mycobacterium lepromatosis*. There are approximately 250,000 new cases of HD each year globally, and an estimated 150 new cases annually in the United States. A recent increase in case reports from Florida and other southern states suggest a rise in locally acquired infection. The 9-banded armadillo (*Dasypus novemcintus*) is the only known natural reservoir in North America and a likely source of zoonotic transmission in Gulf states. *Mycobacterium leprae* has also been shown to survive in free-living amoebae in soil. The objective of this study is to describe common exposures among patients with suspected locally acquired HD infections. We designed and conducted a phone survey for past and current non-immigrant patients of the Emory HD Program. Survey questions included states of residence, foreign residence, occupation, outdoor activities, and exposure to armadillos. A descriptive analysis was performed to identify commonalities among the participants. Preliminary results include 5 individuals who were diagnosed with HD. The median age of patients was 70 years old. 2 patients resided in Florida at the time of the survey and 3 resided in Georgia. However, 2 of the patients residing in Georgia had previously lived in Florida and continue to visit the state. 3 of the patients lived internationally, although none in a country with endemic HD. 2 of the patients had physical contact with armadillos and the other 3 reported seeing armadillos around their home. All participants reported spending at least 3-5 hours per week outdoors and taking part in activities such as gardening, hiking, golf, and kayaking. 4 of the 5 participants had associations with central and northern Florida and contact with armadillos or soil that could potentially be contaminated with armadillo bodily fluids. The information from this study starts to explore common exposures among non-immigrant US patients with HD. Further research and a larger patient sample is needed to better understand the association between these risk factors and HD.

0438

EFFECT OF EFFLUX PUMP INHIBITORS ON CLINICAL STRAINS OF MULTIRESISTANT *KLEBSIELLA PNEUMONIAE*

Wilmer Silva-Caso[1], Giancarlo Perez-Lazo[2], Isaac Peña-Tuesta[3], Liliana Morales-Castillo[4], Johanna Martins-Luna[3], Adriana Morales-Moreno[2], Miguel Angel Aguilar-Luis[1], Hugo Jove-Químper[4], Fernando Soto-Febres[2], Juana Del Valle-Mendoza[1]

[1]School of Medicine, Research and Innovation Center of the Faculty of Health Sciences, Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Unidad de Enfermedades Infecciosas, Hospital Nacional Guillermo Almenara, Lima, Peru, [3]Laboratorio de Biologia Molecular, Instituto de Investigación Nutricional, Lima, Peru, [4]Servicio de Microbiología, Hospital Nacional Guillermo Almenara, Lima, Peru

The study was undertaken to evaluate the effect of the inhibitors phenylalanine-arginine β-naphthylamide (PAβN) and carbonyl cyanide 3-chlorophenylhydrazone (CCCP) in isolated multiresistant clinical strains of *K. pneumoniae* from hospitalized patients in Lima, Peru. Cross-sectional study that included 16 clinical samples collected from hospitalized patients in Lima, Peru. *Klebsiella pneumoniae* was identified by the MicroScan WalkAway system. Samples were cultured on BHI agar, analyzed by Universal 16S PCR, and confirmed by genetic sequencing. The minimum inhibitory concentration (MIC) for the studied antibiotics was determined by the broth microdilution method. A range of concentrations from 0.25 µg/ml to 256 µg/ml was used in a 96-well microplate with 100 µl Muller-Hinton broth.The activity of the efflux pumps was evaluated by adding the inhibitors phenylalanine-arginine β-naphthylamide (PAβN) and carbonyl cyanide 3-chlorophenylhydrazone (CCCP). The change from 4 to more dilutions in the MIC was considered as a criterion of significance. The non-susceptibility rates obtained by MIC were the following: amikacin (1, 6.25%), ciprofloxacin (10, 62.50%), piperacillin/tazobactam (0, 0%), tigecycline (11, 68.75%), cefepime (6, 37.50%) and colistin (4, 25%). In the presence of PAβN, a significant increase in amikacin susceptibility was obtained in 1 strain (6.25%), ciprofloxacin in 3 (18.75%), piperacillin/tazobactam in 1 (6.25%), tigecycline in 4 (25%), cefepime in 2 (12.50%) and colistin in 4 (25%). The addition of CCCP led to a significant increase in the susceptibility of ciprofloxacin, tigecycline and cefepime in 3 (18.75%) strains, piperacillin/tazobactam in 2 (12.50%) and colistin in 1 (6.25%). No significant inhibitory effects on the MIC of amikacin were seen in the presence of CCCP. In conclusion, the use of PAβN and CCCP can enhance the antibiotic effect of ciprofloxacin, piperacillin/tazobactam, tigecycline, cefepime, and colistin in clinical strains of *K. pneumoniae*. Efflux pump inhibitors may be useful in treating multidrug-resistant *K. pneumoniae*.

0439

RELATIONSHIP BETWEEN ACUTE FEBRILE ILLNESS AND EMERGING AND RE-EMERGING BACTERIAL PATHOGENS IDENTIFIED IN PATIENTS AT A HEALTH FACILITY IN THE PERUVIAN JUNGLE

Wilmer Silva-Caso[1], Miguel Angel Aguilar-Luis[1], Johanna Martins-Luna[2], Giancarlo Perez-Lazo[3], Fernando Soto-Febres[3], Carmen Tinco-Valdez[2], Naysha Mallqui-Espinoza[4], Mercedes Vilcapoma-Balbin[5], Erika Misaico-Revate[6], Hugo Carrillo-Ng[2], Juana Del Valle-Mendoza[1]

[1]School of Medicine, Research and Innovation Center of the Faculty of Health Sciences, Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Laboratorio de Biologia Molecular, Instituto de Investigación Nutricional, Lima, Peru, [3]Unidad de Enfermedades Infecciosas, Hospital Nacional Guillermo Almenara, Lima, Peru, [4]Univesidad Nacional Agraria de la Selva, Huánuco, Peru, [5]Centro de Salud Las Palmas, Huánuco, Peru, [6]Hospital de Tingo María, Ministerio de Salud del Peru, Huánuco, Peru

The study was undertaken to determine the relationship between acute febrile illness and emerging and re-emerging bacterial pathogens identified in patients treated in the Leoncio Prado health network. Observational, descriptive, comparative, cross-sectional studies were conducted. A

secondary database obtained from an initial study carried out in the health establishment of the Leoncio Prado Health Network is analyzed. All samples were analyzed by polymerase chain reaction (PCR) to determine the presence of infectious bacterial agents. A surveillance strategy for febrile syndromes based on the patient's symptoms was established. Of the 279 samples analyzed, 23 (8.2%) were positive for infection by *Rickettsia spp*. As for the positive samples for *Leptospira spp.*, there were a total of 15 (5.4%). Women had a higher frequency of infection by *Rickettsia spp.*, 13 (53.3%) while men had a higher frequency of infection by *Leptospira spp.* 10 (66.7%). Fever was present in all patients, the most common general symptom reported was headache with a frequency of 100.0% (n = 23) and 86.7% (n = 13) followed by myalgia with 91.3% (n = 21).) and 66.7%(n=10) for *Rickettsia* + and *Leptospira* + respectively. The finding shows an epidemiological precedent for these pathogens in the region. The frequencies of infection by *Rickettsia spp*. and *Leptospira spp.* indicate that these emerging and re-emerging bacterial pathogens do not play a predominant role in the etiology of acute febrile syndrome in the region studied.

0440

SPATIOTEMPORAL DISTRIBUTION AND DETERMINANTS OF SCRUB TYPHUS IN THAILAND

Reiden Magdaleno[1], Abigail Collingwood[1], Richard P. Fiorella[2], Edward Ionides[3], Kevin M. Bakker[4]

[1]University of Michigan School of Public Health, Ann Arbor, MI, United States, [2]Department of Geology and Geophysics, University of Utah, Salt Lake City, UT, United States, [3]Department of Statistics, University of Michigan, Ann Arbor, MI, United States, [4]Department of Epidemiology, University of Michigan, Ann Arbor, MI, United States

Scrub typhus is an important vector-borne infectious disease with more than one billion people at risk and approximately one million annual cases. In Thailand, scrub typhus incidence has increased significantly over the past two decades. Despite recent efforts towards understanding transmission dynamics, comprehensive provincial level analyses to identify risk areas and identify the mechanisms driving transmission are lacking. Here, we incorporate high resolution case data from Thailand to understand the spatiotemporal dynamics and associated meteorological determinants of scrub typhus. To explore the relationship between meteorological factors, such as cloud cover, specific humidity, relative humidity, temperature, and precipitation with scrub typhus, data were fitted with linear regression models for hypothesis testing and analyzed using Pearson correlation. Cross-correlation was used to identify lagged relationships, and nonlinear relationships discovered were fitted with LOESS. The mountainous provinces in the northern and northeastern regions of Thailand had the highest incidence of scrub typhus, with peaks in cases occurring between July and October. High-risk provinces included Chiang Rai, Chiang Mai, Mae Hong Son, Nan, and Tak, which experience similar meteorological conditions. We found that relative and specific humidity, which are both influenced by temperature, explained much of the observed incidence. Additionally, we discovered a 4-5 month lag between when the temperature first increased above the minimum optimum temperature for vector larval activity and egg-hatching rate and peak incidence. Increases in humidity, which chigger mites rely on for water source, and average temperatures around 23°-25°C, which are optimum for egg-hatching rate and larval activity, can be used as thresholds for when scrub typhus transmission is likely increasing. This work can inform public health officials when and where prevention and control efforts need to be focused.

0441

ETIOLOGICAL AGENTS OF DIARRHEAL DISEASES DETECTED AMONG UNDER-5 DEATHS IN MANHIÇA AND QUELIMANE DISTRICTS, MOZAMBIQUE IN THE CHAMPS NETWORK, 2017-2021

Percina Chirinda[1], Eva Dora João[1], Filomena Manjate[1], Avertino Benedito[1], Rita Mabunda[1], Nelio Nobela[1], Marcelino Garrine[1], António Sitoe[1], Elísio Xerinda[1], Dianna Blau[2], Quique Bassat[3], Inácio Mandomando[1]

[1]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [2]Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]ISGlobal, Hospital Clínic - Universitat de Barcelona;, Barcelona, Spain

Diarrhea is the 3rd leading cause of mortality in children under-5 globally, being responsible for 525,000 deaths worldwide each year; however, there is a scarcity of studies that evaluate the role of specific pathogens in death among children under 5. In this analysis, we aim to study etiological agents causing diarrhea detected in deceased children in Manhiça and Quelimane districts, Mozambique from January 2017 - April 2021. Real-time polymerase chain reaction for detection of enteric pathogens in post-mortem rectal swabs was performed using TaqMan Array Cards and expert panels determined the cause of death. At least one enteric pathogen was detected in 281 deaths (152 Neonates, 51 Infants and 78 Children). Among neonates, Enterococcus faecalis (E. feacalis) was more frequent (43%), followed by enteroaggregative Escherichia coli (EAEC) (36%) and Aeromonas spp. (30%). In infants, EAEC was most detected in 76% cases, followed by E. faecalis (61%) and Aeromonas spp. (35%). E. faecalis (54%) followed by EAEC-aatA (53%) and EAEC-aaiC (37%) were mostly detected in children. From the 281 deaths, 81% (228) had a cause of death attributed. Diarrhea was the immediate cause of death in 1% (2/228, 1 infant and 1 child) and underlying cause in 9% (21/228, 1 neonate, 10 infants and 10 children) of deaths. In deaths where diarrhea was the underlying cause, EAEC and Rotavirus (14%, 3/21), Vibrio cholerae and Norovirus GII (5%, 1/21) were in the causal chain of death, however, major causes of deaths were due to unspecified pathogens (62%, 13/21). Although diarrhea was immediate cause of death in few deaths, it was important as underlying cause of death. Even though a high proportion of deaths where diarrhea was the underlying cause of death were due to unspecified pathogens, EAEC and Rotavirus, two well-known pathogens with high burden in diarrhea in children from Low and Middle-income Countries, had a very important role in infants and child deaths. Further investigation such as genotyping of Rotavirus and antimicrobial resistance profile of the EAEC isolates is required for better evaluation of diarrhea burden and the role of specific pathogens in the cause of deaths.

0442

THE UTILIZATION OF PARTOGRAM AMONG NURSES AND MIDWIVES, IN THE LABOUR WARD AT EDWARD FRANCIS SMALL TEACHING HOSPITAL

Ensa Jarju

Edward Francis Small Teaching Hospital, Banjul, Gambia

Partograph is a graphic record of progress of labor, maternal and fetal condition plotted against time for intrapartum monitoring. Its aim is to provide a pictorial overview of labor, to alert obstetric care providers about deviations in maternal, fetal condition and progress of labour, as reported previously. The study aimed to describe the utilization of partogram among nurses and midwives, in the labour ward at Edward Francis Small Teaching Hospital (EFSTH). A descriptive quantitative research design to gather information on utilization of the partogram among nurses and midwives in the labour ward of Edward Francis Small Teaching Hospital was employed using a convenient sampling procedure. All the nurses and midwives in the labour ward were selected who were willing to participate in the study and consent was sought from both EFSTH and the participants. Questionnaires were used to collect data and analysis was done using spss version 21. The results indicate that 80% of all of respondents knew what a partogram

was. The knowledge on the function of the action line and alert line was poor amongst nurses and midwives who participated in the current study. Only 40% (N=4) of the respondents could explain the function of action line on the partogram. There was poor utilization in labour monitoring. Only 40% (N=4) were found to properly use the partogram while 60% (N=6) were found to not properly use the partogram. The findings confirm the problem of shortage of nurses and midwives with only (N=10) covering the labour ward of EFSTH for all shifts. The recommendation includes deployment of nurses and midwives to EFSTH, training of nurses and midwives on the utilization of the partogram.

0443

SHORTENING BURULI ULCER TREATMENT: WHO RECOMMENDED *VS.* A NOVEL BETALACTAM CONTAINING THERAPY - PHASE II AND PHASE III STUDIES IN WEST AFRICA (THE BLMS4BU CLINICAL TRIAL)

Roch Christian Johnson[1], Richard Odame Phillips[2], Nana Konama Kotey[3], Mamadou Kaloga[4], Denis Gadah[5], Mawèkè Tchalim[6], Juliet Addo[7], Gabriel Díez[8], Israel Cruz[9], Emma Sáez-López[10], **Santiago Ramón García**[11], BLMs4BU Consortium[12]

[1]Foundation Raoul Follereau, Paris, France, [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [3]Ghana Health Service, Accra, Ghana, [4]National Buruli Ulcer Control Program, Abidjan, Côte D'Ivoire, [5]DAHW Deutsche Lepra-und Tuberkulosehilfe e. V., Togo, Lomé, Togo, [6]Ministry of Health, Public Hygiene and Universal Access to Care, Lomé, Togo, [7]GlaxoSmithKline, Brentford, United Kingdom, [8]Anesvad Foundation, Bilbao, Spain, [9]Instituto de Salud Carlos III, Madrid, Spain, [10]University of Zaragoza, Zaragoza, Spain, [11]ARAID Foundation, Zaragoza, Spain

Buruli ulcer (BU) is a skin neglected tropical disease, caused by *Mycobacterium ulcerans (Mul),* that affects mainly children under the age of 15 years. Current WHO-recommended treatment requires 8-weeks of daily rifampicin and clarithromycin, wound care and, sometimes, tissue grafting and surgery. Healing can take up to one year and may pose an unbearable financial burden to the household. Recent repurposing studies demonstrated that beta-lactams combined with rifampicin and clarithromycin are synergistic *in vitro* against *Mul* (PMID: 30689630) leading to the hypothesis that the inclusion of amoxicillin-clavulanate may improve and shorten BU therapy. The aim of the BLMs4BU clinical trial is to evaluate whether co-administration of amoxicillin/clavulanate with rifampicin-clarithromycin can shorten BU treatment from 8 to 4 weeks. A randomized, controlled open label non-inferiority Phase II, multi-centre trial started in Benin in December 2021 (*ClinicalTrials.gov Identifier: NCT05169554*). A Phase III multi-centre trial in Ghana, Togo and Côte d'Ivoire is planned to start in December 2022. Patients are stratified according to BU category lesions and randomized in two regimens: (i) standard [RC8]: rifampicin-clarithromycin (RC) for 8 weeks; and (ii) investigational [RCA4]: standard RC plus amoxicillin-clavulanate for 4 weeks. Patients will be followed-up for 12 months and managed according to standard clinical procedures. Decision for excision surgery will be made at week 14 after treatment initiation. The primary efficacy outcome is cure (i.e., lesion healing without recurrence) without excision surgery 12 months after start of treatment. If successful, this study will create a new paradigm for BU treatment, which could lead to a change in WHO policy and practice for this disease. A shorter, highly effective, all-oral treatment will improve the care of BU patients, adherence to treatment and will lead to a decrease in direct and indirect costs. This trial may also provide information on treatment shortening strategies for other mycobacterial infections, such as tuberculosis or leprosy, where rifampicin is the cornerstone drug.

FIRST-IN-HUMAN EVALUATION OF CUTANEOUS INNATE AND ADAPTIVE IMMUNOMODULATION BY MOSQUITO BITES

David Guerrero Gomez[1], Hoa Thi My Vo[1], Chanthap Lon[2], Jennifer A. Bohl[3], Sreynik Nhek[4], Sophana Chea[4], Somnang Man[4], Sokunthea Sreng[4], Andrea Pacheco[4], Sokna Ly[4], Rathanak Sath[4], Dorothee Misse[5], Rekol Huy[6], Rithea Leang[6], Hok Kry[7], Jesus G. Valenzuela[3], **Fabiano Oliveira**[3], Tineke Cantaert[1], Jessica E. Manning[3]

[1]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [2]International Center of Excellence in Research- NIAID, Phnom Penh, Cambodia, [3]NIAID, Rockville, MD, United States, [4]International Center of Excellence in Research - NIAID, Phnom Penh, Cambodia, [5]MIVEGEC, Univ Montpellier, IRD, Montpellier, France, [6]National Center of Parasitology, Entomology, and Malaria Control, Phnom Penh, Cambodia, [7]Kampong Speu Provincial District, Ministry of Health, Phnom Penh, Cambodia

Mosquito-borne viruses are a growing global threat. Initial viral inoculation occurs in the skin via the mosquito 'bite', eliciting immune responses that shape the establishment of infection and pathogenesis. To understand these phenomena, we assessed the cutaneous innate and adaptive immune responses via controlled *Aedes aegypti* feedings in human volunteers living in an *Aedes*-endemic country. Gene expression profiling and immunophenotyping revealed induction of neutrophil degranulation and recruitment of skin-resident dendritic cells and M2-macrophages. As the immune reaction progressed over time, T-cell priming, and regulatory pathways were upregulated along with a shift to a Th2-driven response and CD8+ T cell activation. In accordance, participants' bitten skin cells produced less pro-inflammatory cytokines when stimulated by *Aedes aegypti* salivary gland extract. These results identify key immune genes, cell types, and pathways in the human response to mosquito bites that can be leveraged to develop novel therapeutics and vector-targeted vaccine candidates to arboviral diseases.

0445

DEVELOPMENT AND ADVANCEMENT OF THE DIRECT SKIN FEEDING ASSAY AS AN IMPORTANT TOOL FOR EVALUATING THE EFFICACY OF MALARIA TRANSMISSION BLOCKING VACCINE IN FIELD TRIALS

Jen C. C. Hume[1], Daman Sylla[2], Heather Goodman[1], Adama Sacko[2], Jennifer Kwan[3], Sara A. Healy[1], Issaka Sagara[2], Patrick E. Duffy[1], Mamadou B. Coulibaly[2]

[1]LMIV/NIAID/NIH, Bethesda, MD, United States, [2]MRTC/USTTB, Bamako, Mali, [3]LCIM/NIAID/NIH, Rockville, MD, United States

Direct skin feeding assays (DSF) have been performed for many decades to evaluate transmissibility of different Plasmodium species from humans to a range of mosquito vectors. More recently, DSF assays have begun to be utilized as an endpoint assay to evaluate the efficacy of transmission blocking vaccines (TBV) in field trials. Our teams have led the way in optimizing and expanding a DSF platform now suitable to generate endpoints for TBV efficacy trials. Over a ten-year period in Mali, we have expanded from DSF performed on several volunteers (~100-200 female mosquitoes) weekly in 2013 to our current capacity of up to 400 DSF (~24,000 female mosquitoes) per week. Community acceptance of the assay and an excellent safety profile have been established in both adults and children (5-18 years). From a capacity standpoint, success requires attention to numerous aspects of mosquito production, maintenance, and dissection as well as the logistics of setting up this assay at a field site distant from the contained insectary where mosquitoes are produced. Optimization of DSF has examined several parameters for conduct of the feed (anatomical location of feed, number of mosquitoes per feed, time of day) as well as the target population (age, parasite/gametocyte status) to ensure maximal numbers of positive DSF that provide suitable power to measure vaccine efficacy. Finally, we will review how this assay compares

to other established feeding assays such as direct membrane feeding and the standard membrane feeding assay and thus how DSF can be a significant tool for evaluating TBV efficacy in the field.

0446

REGIONAL VARIATION OF CAESAREAN SECTIONS IN THE DOMINICAN REPUBLIC

Isabella Alatorre, John D. McLennan

University of Calgary, Calgary, AB, Canada

The Dominican Republic has one of the highest Caesarean section (CS) rates worldwide, with substantial regional variation. Understanding this regional variability may further advance understanding of factors contributing to the high CS rate and inform initiatives aimed at reducing excessive CS. This study aimed to determine whether the regional variation of CS in the Dominican Republic can be explained by variation in key socioeconomic, demographic, and healthcare variables across regions. Nationally representative household survey data from the Multiple Indicator Cluster Survey from 2019 was used. The sample was composed of 3,224 women who had singleton births in the two-year period prior to the survey. Across the ten regions of the Dominican Republic, the CS prevalence rate varied from a low of 45.0% in El Valle to 76.9% in Cibao Nordeste. Despite adjusting for covariates, women in Cibao Nordeste had higher odds, and those in Valdesia and El Valle had lower odds, of having a CS compared to the reference region of Ozama, which houses the nation's capital. Of the covariates, delivering in a private compared to public healthcare facility had the highest odds for having a CS in the final logistic regression model at 7.32 (95% confidence interval: 5.09-10.53). This variable explained at least some of the association between certain regions and the CS rate. A total of 90.8% of deliveries in private healthcare facilities were CS compared to 47.1% in public healthcare facilities. Additional investigations are required to further examine the persistence of at least some associations between regions and CS despite adjustment for multiple possible confounders. However, there is also a need for focused investigation into factors contributing to the exceptionally high rate of CS in private healthcare facilities in the Dominican Republic.

SLOW BUT STEADY: WORKING TO INCREASE CHAGAS DISEASE TESTING THROUGH AN EDUCATIONAL INTERVENTION AT A SAFETY NET HOSPITAL

Alyse Wheelock[1], Sukhmeet Sandhu[1], Katherine Reifler[1], Christina Yarrington[2], Sarah Kimball[1], Ricardo Cruz[1], Taylor Paiva[3], Madolyn Dauphinais[1], Alejandra Salazar[1], Malwina Carrion[4], Daniel Bourque[2], Deepa Gopal[5], Ingrid Camelo[6], Davidson H. Hamer[7], Natasha S. Hochberg[8]

[1]Boston Medical Center, Boston, MA, United States, [2]Boston Medical Center, Boston University School of Medicine, Boston, MA, United States, [3]Boston University, Boston, MA, United States, [4]Boston University College of Health and Rehabilitation Sciences: Sargent College, Boston, MA, United States, [5]Boston Medical Center, Boston Medical Center, Boston University School of Medicine, Boston, MA, United States, [6]Baystate Health, Springfield, MA, United States, [7]Boston University School of Public Health and School of Medicine, Boston, MA, United States, [8]Boston University School of Medicine and Boston University School of Public Health, Boston, MA, United States

Chagas disease remains a poorly recognized cause of cardiac disease among migrants from endemic regions to the United States due to low clinician awareness and a lack of systematic screening programs. To address low screening rates and diagnosis, we implemented a multi-disciplinary educational program about Chagas disease within our institution, a safety net hospital that serves a large migrant population. The intervention consists of a case-based presentation accompanied by a pre- and post-lecture quiz at grand rounds, noon conferences, and other venues; over twenty presentations have been given to date. *Trypanosoma cruzi* serological test orders throughout the institution were analyzed during the 29 months pre-intervention (11/2016 - 4/2019) and 29 months following the start of the lecture program (4/2019 - 9/2021). There were 548 patients tested, including 170 (31.0%) in the pre-intervention phase and 378 (69.0%) in the post-intervention phase. General Internal Medicine providers ordered the most tests (overall, 162/548, 29.6%). Obstetrics/Gynecology had the greatest increase in test ordering from pre- to post-intervention phase (6 patients tested in the pre-intervention phase vs. 118 in the post-intervention phase); this coincided with a concurrent initiative to add *T. cruzi* testing to a routine prenatal test panel in the electronic medical record. Attending providers tested the most patients overall (247, 45.1%), followed by resident/fellow trainees (187, 34.1%); trainee test ordering more than doubled from the pre- to post-intervention phase (from 56 to 131). Of 49 patients who had at least one positive commercial screening test, 38 had confirmatory testing performed at the CDC; of those, 24 (63.2%) had positive confirmatory testing. We found an increase in *T. cruzi* test ordering over time, coinciding with the educational intervention to raise awareness of this disease. Our analysis highlights opportunities for increasing Chagas disease screening, particularly through outreach to trainees and obstetrics providers, as well as incorporation of information technology tools such as order panels.

0448

KNOWLEDGE AND PERCEPTIONS OF ANTIBIOTICS AMONG VILLAGE HEALTH WORKERS IN SOUTHWESTERN UGANDA

Emily J. Ciccone[1], Ana T. Gutierrez Ramirez[2], Lydiah Kabugho[3], Georget Kibaba[3], Fred Mwebembezi[3], Emmanuel Baguma[3], Rabbison Muhindo[3], Ross M. Boyce[1], Edgar M. Mulogo[3]

[1]University of North Carolina School of Medicine, Chapel Hill, NC, United States, [2]University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC, United States, [3]Mbarara University of Science and Technology, Mbarara, Uganda

In rural Uganda, ill children under the age of five years often present first to village health workers (VHW) for healthcare. VHW are lay volunteers trained in the evaluation and management of uncomplicated diarrhea, malaria, and pneumonia; the latter of which includes the prescription of antibiotics. Yet little is known about their knowledge and perceptions of antibiotics. Therefore, we conducted a knowledge, attitudes, and practices survey based on previously published tools of 67 VHW from 15 villages participating in a prospective study of pediatric acute respiratory illness. All VHW completed the survey prior to study protocol training to ensure it did not influence responses. The median age of participants was 40 (IQR: 35-47) and 60% (40 of 67) were female. The majority were subsistence farmers (84%, 56 of 67) and had completed secondary school (84%, 56 of 67). They had a median of 9.5 (IQR: 4-14) years of experience as a VHW and saw a median of 10 children per month (IQR: 7-15). Knowledge of antibiotics was high with 96% (64 of 67) of VHW aware that amoxicillin is an antibiotic and 84% (56 of 67) correctly identifying that it treats bacteria. Nearly all VHW (91%, 61 of 67) knew that antibiotics should be stopped only once the full course is completed, and all but one thought it was not acceptable to obtain antibiotics without seeing a VHW or clinician. Perceptions of antibiotic use were more variable. While all but two VHW felt "very confident" or "confident" in their ability to accurately prescribe antibiotics, 77% (50 of 65) responded that they "strongly agreed" or "agreed" that antibiotics are over-prescribed by VHW in Uganda. Most VHW (82%, 55 of 65) agreed that prescribing antibiotics if not needed can cause harm, but nearly half (48%, 31 of 65) also thought that when in doubt, it is better to prescribe them just in case. All but one VHW welcomed more training or reference materials about antibiotics. In sum, understanding VHW knowledge and perceptions of antibiotics is integral to the design of interventions to improve antibiotic stewardship in rural Uganda. As trusted community members, VHW could be important advocates for this cause.

0449

CONTINUOUS NON-INVASIVE HAEMODYNAMIC MONITORING FOR VIETNAMESE CHILDREN WITH DENGUE SHOCK SYNDROME

Trieu Huynh[1], Chanh Ho Quang[2], Nguyet Nguyen Thi Minh[2], Lam Phung Khanh[2], Tu Qui Phan[1], Bridget Wills[1], Sophie Yacoub[1]

[1]Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, [2]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam

Dengue shock syndrome (DSS) is a severe and potentially life-threatening complication of dengue, caused by vascular leakage and particularly affects children. Meticulous fluid balance and giving just the right amount of fluid replacement is the cornerstone of treatment. Accurate and dynamic assessment of intravascular volume during fluid resuscitation is challenging, particularly in resource poor settings and using non-invasive technology. We investigated the utility of a new continuous non-invasive haemodynamic monitoring technique using bioimpedance (NICaS - Non-invasive Cardiac System) in patients admitted with DSS. We conducted a prospective observational study in a Paediatric Intensive Care Unit (PICU) in Vietnam between 2018-2020. Patients were monitored continuously using NICaS from admission with shock until PICU discharge. In addition to continuous haemodynamic monitoring, we performed serial point-of-care echocardiograms at shock onset and multiple time points during the 48hrs of fluid resuscitation. Haemodynamic data derived from NICaS was recorded every 20 seconds then integrated with clinical data and echo data. We used 5-minute-moving average SVI for graphical descriptions and association analyses. 92 patients were enrolled into the study. The median age is 12 years (IQR 10, 13). The second episode of shock (recurrent shock) occurred in 16/92 patients. No patients required respiratory support. Stroke volume index (SVI) was seen to have a negative correlation with heart rate (r = -0.57 [95% CI -0.67, -0.45], p <0.001) but not with systolic blood pressure (r= -0.07 [95% CI -0.25, 0.11], p = 0.45) or diastolic blood pressure (r = -0.07 [95%CI -0.23, 0.09], p = 0.40). SVI decreased considerably after 6 hours from shock onset and remained low before recurrent shock. NICaS derived SVI, had a positive correlation with echo-SVI up to 18 hours from shock onset. In conclusion, continuous haemodynamic monitoring during fluid resuscitation using NICaS is a useful non-invasive tool to monitor patients with DSS and can guide fluid management as well as identify patients at risk of recurrent shock.

0450

HOW EXTERNAL QUALITY ASSESSMENTS (EQAS) HELP IDENTIFY ISSUES IN CLINICAL DIAGNOSIS OF PARASITES

Jaya Shrivastava, Peter L. Chiodini

UK Health Security Agency, London, United Kingdom

The need for robust, reproducible and reliable diagnostic Parasitology remains pertinent for public health in both endemic and non-endemic settings. UKNEQAS Parasitology has been successfully running External Quality Assessment (EQA) schemes for microscopy-based detection of faecal parasites since 1986. The schemes are designed to improve the diagnosis of parasitic infections in participating laboratories by identifying gaps and encouraging learnings. Here, we present a review of performance of participating labs in our morphology based EQA scheme for faecal parasites over the last seven years to identify trends, if any. 537 labs participate in the scheme which is comprised of eight distributions in each calendar year. The participants received appropriate clinical details for each sample. The specimen type included faecal sample for concentration and direct microscopy, stained faecal smear, urine and hydatid fluid. In total 113 samples were analysed for this presentation. Common problems encountered by participants were as follows: missed identification of one or more parasites within a mixed infection sample, poor recovery of parasites due to incorrect techniques in the processing of samples, confusing vegetable matter with cysts and ova, failure to identify or specify the stage of the parasites, failure to identify and differentiate ova and small cysts. Faecal parasites remain important public health burdens globally. This is in part because microscopy remains the gold standard for clinical diagnosis, yet microscopy requires skills attainable only through years of experience, proper training plus refresher courses. Through this study, UK NEQAS Parasitology has identified, and flagged issues commonly encountered in microscopy-based diagnosis of parasites.

0451

THE CHOICE OF REFERENCE CHART AFFECTS THE STRENGTH OF THE ASSOCIATION BETWEEN MALARIA IN PREGNANCY AND SMALL FOR GESTATIONAL AGE. AN INDIVIDUAL PARTICIPANT DATA META ANALYSIS COMPARING THE INTERGROWTH 21 WITH A TANZANIAN BIRTHWEIGHT CHART

George Antony Mtove[1], Daniel T.R Minja[1], Omari Abdul Msemo[1], Samwel Gesase[1], Kenneth Maleta[2], Titus H. Divala[3], Noel Patson[3], Ulla Ashorn[4], Miriam K. Laufer[5], Mwayiwawo Madanitsa[2], Per Ashorn[6], Don Mathanga[3], Jobiba Chinkhumba[3], Julie R. Gutman[7], Feiko O. ter Kuile[8], Sofie Lykke Møller[9], Ib C. Bygbjerg[9], Michael Alifrangis[10], Thor Theander[10], John P. A Lusingu[1], Christentze Schmiegelow[10]

[1]National Institute for Medical Research, Tanga, United Republic of Tanzania, [2]Malawi University of Science and Technology, Thyolo, Malawi, [3]Kamuzu University of Health Sciences, Blantyre, Malawi, [4]Tampere Center for Child, Adolescent and Maternal Health Research, Faculty of Medicine and Life Sciences, University of Tampere, Tampere, Finland, [5]University of Maryland School of Medicine, Baltimore, MD, United States, [6]Tampere University, Faculty of Medicine and Health Technology, Center for Child, Adolescent, and Maternal Health Research and Tampere University Hospital, Department of Paediatrics, Tampere, Finland, [7]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, US Centers for Diseases Control and Prevention, Atlanta, GA, United States, [8]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [9]Section of Global Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [10]Centre for Medical Parasitology, Department of Immunology and Microbiology, University of Copenhagen, and Department of Infectious Diseases, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark

The prevalence of small for gestational age (SGA) may vary depending on the chosen weight-for-gestational-age reference. We conducted an individual participant data meta-analysis assessing the implications of using a local reference (STOPPAM) instead of a universal reference (Intergrowth-21) on the association between malaria in pregnancy (MIP) and SGA. We pooled data from 6,236 newborns from seven conveniently identified studies conducted in Tanzania and Malawi from 2003-2018 with data on MIP, birthweight, and ultrasound estimated gestational age. We used mixed-effects regression models to compare the association between MIP and SGA. The odds ratios were adjusted for gestational age at enrolment and delivery, gravidity, maternal age, hemoglobin level, and body mass index at enrolment, utilization of insecticide treated bednet, the number of antenatal visits, and syphilis or HIV-positivity. The 10th percentile for birthweights-for gestational age was lower for STOPPAM than for Intergrowth-21, leading to a prevalence of $SGA_{STOPPAM}$ of 14.2% and SGA_{IG21} of 18.0%, p<0.001. The association between MIP and SGA was stronger for STOPPAM (adjusted odds ratio (AOR) 1.30 [1.09-1.56], p<0.01) than for Intergrowth-21 (AOR 1.19 [1.00-1.40], p=0.04), particularly among paucigravidae ($SGA_{STOPPAM}$ AOR 1.36 (1.09-1.71), p<0.01 vs SGA_{IG21} AOR 1.21(0.97-1.50), p=0.08). The prevalence of SGA may be overestimated, and the impact of MIP on SGA underestimated when using Intergrowth-21. Comparing local reference charts to global references when assessing and interpreting the impact of MIP may be appropriate.

MOBILIZING HEALTH CARE FOR NEWLY ARRIVED HUMANITARIAN PAROLEES IN MINNESOTA: A MULTIDISCIPLINARY, MULTI-AGENCY COLLABORATION

Gabriela Contino[1], Blain Mamo[2], Margaret Ekerstorfer[1], Opeyemi Adesida[3], Rashika Shetty[1], Hadia Mohammadzadah[1], Sophia Iaquinta[1], Jonathan Kirsch[1]

[1]University of Minnesota, Minneapolis, MN, United States, [2]Minnesota Department of Health, Saint Paul, MN, United States, [3]University of Minnesota/Community-University Health Care Center (CUHCC), Minneapolis, MN, United States

In September 2021, the withdrawal of American troops from Afghanistan resulted in Afghan evacuees arriving at eleven military bases around the country. These humanitarian parolees were then urgently resettled to their final state of residence. The purpose of this effort in Minnesota was to welcome the new arrivals, address immediate, emergent medical needs, increase access to primary care, avoid urgent care and emergency room visits while they are in temporary housing pending integration into the community. Through a multi-agency partnership, a team of volunteer medical, behavioral health specialists, health advocates experienced in providing trauma informed care and state health departments prepared to address the acute mental and physical health concerns within 24-48 hours of their arrival to the state. Minnesota received 1260 Afghan newcomers and 1,233 were screened. The mobilized team provided over 1300 hours of in person, Telehealth and on-call care to the new arrivals in the temporary housing. A standardized health intake form was developed to identify acute health concerns on arrival to the temporary housing site, and 53% of arrival screenings resulted in at least one specialty referral. The team followed a post-intake referral plan with options to establish primary care at a local Federally Qualified Health Center or to refer to specialty, vision, dental, mental health or other health services. An onsite mental health team, conducted patient intakes at the temporary housing site and arranged continued outpatient follow up. Care plans were developed for patients with complex mental health and medical needs to provide expedited outpatient follow-up.

0453

AFGHAN EVACUEE WOMEN'S CLINIC - A MODEL FOR CULTURALLY INCLUSIVE CARE

Margaret Eckerstorfer, Hadia Mohammadzadah, Rashika Shetty, Sophia Iaquinta, Alma Habib, Adnan Shabaan, **Nasreen Syeda Quadri**

University of Minnesota, Minneapolis, MN, United States

Operation Allies Welcome has supported more than 76,000 Afghan nationals in resettlement to the United States. In Minnesota, the Department of Health and the University of Minnesota Mobile Health Initiative coordinated a robust interdisciplinary response to support the medical needs of 1260 newcomers as a bridge to the formal healthcare system. A one room clinic was created at the temporary housing site to conduct initial medical screenings. For time and space efficiency, an entire family was screened simultaneously. This model, though efficient for large scale screening, was suboptimal to elicit private health concerns from individuals. Previous studies have revealed, especially amongst women from Afghanistan, there is a high burden of exposure to war-related events and trauma, including gender-based violence. Thus, a model of a Women's Clinic staffed by female medical providers and interpreters gained traction with a goal of "women serving women '' in a psychologically safe and private environment. It provided the foundation for focused programming to address health concerns such as somatic manifestations of acute stress and trauma. In this one-on-one environment, women were more likely to report physical concerns like genitourinary symptoms, reveal mental health challenges, and discuss reproductive and family planning preferences. A total of fourteen weekly 3-hour clinics were held as part of the Women's Clinic initiative. Of the 206 total women over the age of 18 who were eligible for participation, 103 (50%) attended the clinic, which offered a visit with a medical provider and the opportunity for domestic violence screening. Local resources were gathered for referrals including Domestic Abuse Project and Asian Women United, acknowledging the tenuous immigration status of this group and potential harm of pursuing typical referral routes such as police departments. Several opportunities for improvement occurred through feedback from staff and patients. Future directions include qualitative analysis of the experience for providers and patients with consideration of incorporating the model into formal healthcare systems.

0454

CAUSES OF FEBRILE DISEASE IN HOSPITALIZED PATIENTS IN A TROPICAL COUNTRY : A RETROSPECTIVE TERTIARY CARE HOSPITAL COHORT STUDY

Johary Andriamamonjisoa, **Etienne Rakotomijoro**, Volatiana Andriananja, Mihaja Raberahona, Radonirina Lazasoa Andrianasolo, Rivonirina Andry Rakotoarivelo, Mamy Jean de Dieu Randria

University of Antananarivo, Antananarivo, Madagascar

Infectious diseases are the main causes of morbidity and mortality in tropical areas like Madagascar. Fever is the most frequent symptom of infectious diseases, often prompting patients to consult. The causes are often serious: the delay in diagnosis and treatment increases the morbidity/mortality of patients. It is therefore essential to know the main diagnoses of febrile illnesses and the main causes of death in order to improve their management to reduce mortality linked to these tropical diseases. The objectives of our study were to determine the causes of febrile illnesses and to determine the outcome of patients hospitalized in a tropical country. This is a descriptive retrospective study, during 12 months from January to December 2018. It was included all patients hospitalized for fever of infectious origin in an Infectious Diseases department of a teritiary care hospital in Madagascar. Four hundred and seventy-two patients were included. The main reasons for consultation were: rash (23.7%), infectious syndrome (20.3%), cough/dyspnoea (16.3%) and altered consciousness (15.9%). The causes of hospitalisation were : Measles (26.7%), tuberculosis (21.4%), malaria (15.5%), HIV infection (13.4%), bacterial pneumonia (7.2%), central nervous system infection (5.1%), typhoid fever or febrile diarrhoea (4.4%), urinary tract infection (2.3%). The association of tuberculosis and HIV infection was found in 47.6% (n=224) of subjects. The most frequent location of tuberculosis was the lung (38.1%), followed by the meninges (35.9%), pleura (19.8%), miliary (10.7%) and lymph nodes (7.6%). The overall mortality rate was 15%. Tuberculosis was the main cause of death (46.5%), followed by HIV infection (18.3%), bacterial pneumonia (11.3%), malaria (11.3%) and bacterial meningitis (9.9%). In conclusion, measles, tuberculosis, malaria and HIV infection were the main causes of hospitalization. Tuberculosis and HIV infection were the main causes of death. Screening and research for strategies to improve the management and to reduce the mortality associated with these main diseases should be a priority in a tropical country like Madagascar.

0455

COMPARISON OF COMMERCIALLY-AVAILABLE, RAPID, POINT-OF-CARE C-REACTIVE PROTEIN ASSAYS AMONG CHILDREN WITH FEBRILE ILLNESS IN SOUTHWESTERN UGANDA

Caitlin A. Cassidy[1], Bradley Lin[2], Lydiah Kabugho[3], Georget Kibaba[3], Emmanuel Baguma[3], Rabbison Muhindo[3], Brandon Hollingsworth[4], Jonathan J. Juliano[5], Ross M. Boyce[5], Edgar M. Mulogo[3], Emily J. Ciccone[5]

[1]Department of Biostatistics, University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC, United States, [2]Washington University in St. Louis, St. Louis, MO, United States, [3]Department of Community Health, Mbarara University of Science and Technology, Mbarara, Uganda, [4]Department of Entomology, Cornell University,

Ithaca, NY, United States, [5]Division of Infectious Diseases, Department of Medicine, University of North Carolina School of Medicine, Chapel Hill, NC, United States

In Uganda, children with febrile acute respiratory illness (ARI) are often treated with antibiotics even though bacterial pneumonia is relatively uncommon. C-reactive protein (CRP) can help identify those who are more likely to have a bacterial infection and therefore need antibiotic treatment. Implementation of a CRP rapid diagnostic test (RDT) at the point-of-care in resource-constrained settings with minimal laboratory infrastructure could reduce unnecessary antibiotic use. We evaluated the performance of two CRP RDTs (Actim, BTNX) against a laboratory-based CRP assay requiring an analyzer (Afinion). Actim and BTNX tests are semi-quantitative (<10, 10-40, 40-80, >80 mg/L), whereas the Afinion test is quantitative (range = 5-200 mg/L); Afinion test results were categorized to align with the semi-quantitative tests. From October to December 2020, we enrolled 150 children who presented with febrile ARI to the outpatient department of Bugoye Health Centre III in Kasese District, Uganda. The median age of study participants was 24 months (IQR: 13 to 36), and 43% were female. The most frequent symptoms were fever (96%), cough (69%), runny nose (33%), and diarrhea (25%). 29% (43/150) of participants were positive for malaria by an antigen-based RDT. All individuals underwent CRP testing; results for all three CRP tests were available for 89% (134/150) of participants. The Actim test had slightly better agreement (weighted Kappa = 0.70 (95% CI 0.62 to 0.78) than the BTNX test (weighted Kappa = 0.62 (95% CI 0.54 to 0.70)) with the Afinion test. Using McNemar's test and CRP of 40 mg/L as the cut-off for a positive test, the likelihood of obtaining a positive or negative result did not differ between the Afinion and Actim tests ($p = 0.80$), whereas it did differ with the Afinion and BTNX tests ($p < 0.0001$). Our results demonstrate the potential of CRP RDTs with the Actim CRP performing slightly better as compared to a laboratory-based test than the BTNX RDT. A stepped-wedge cluster-randomized trial is underway to evaluate the use of the Actim CRP RDT within a clinical algorithm for guiding antibiotic treatment decisions among children with febrile ARI.

0456

DEVELOPMENT OF A CLINICAL PREDICTION RULE IDENTIFYING PROTOZOAL ETIOLOGY OF DIARRHEAL ILLNESS

Melissa Pender[1], Nancy Grisel[2], Bert K. Lopansri[2], Daniel T. Leung[1]

[1]University of Utah School of Medicine, Salt Lake City, UT, United States, [2]Intermountain Medical Center, Murray, UT, United States

Protozoal gastrointestinal pathogens including *Cryptosporidium* species, *Cyclospora cayetanensis*, and *Giardia* species are causes of both acute and persistent diarrheal illness. Protozoal infections may be associated with international travel, but can be found in non-travelers including immunocompromised patients who are at particular risk for morbidity and mortality. Diagnosis of protozoal diarrhea allows for targeted antimicrobial therapy; however, testing of all cases of diarrheal illness for protozoal infection is not financially feasible, and availability may be limited in some settings. To date, there are limited studies investigating clinical predictors of protozoal diarrhea. Given the significant difference in treatment between parasitic and other diarrheal infections, we aim to create a predictive model differentiating protozoal from non-protozoal etiologies of diarrheal illness using machine-learning algorithms. Using the electronic data warehouse of a multihospital healthcare system, we identified 14,238 adult patients who received multiplex molecular GI pathogen panel testing. Of these, we compared the clinical, laboratory, and demographic data from 267 patients who tested positive for protozoal pathogens, against 13,971 patients without protozoa detected. In the setting of unbalanced data, we used weighted random forest regression to identify variables representing the strongest predictors of protozoal disease. Currently, our top predictors of protozoal disease include county of residence in a county with a population less than 250,000 and evaluation in an outpatient rather than inpatient setting. However, we are awaiting additional data on social vulnerability, immunocompromising conditions, vital signs, and laboratory testing. Next steps in analysis include consideration of all data sources, and cross-validation using logistic regression and random forest algorithms to identify the model with the highest discriminatory performance using the fewest variables. Additional results on specific clinical predictors of protozoal diarrhea will be available by the time of presentation.

0457

AN ALTERNATIVE NANOPORE SEQUENCING-BASED DIAGNOSTIC APPROACH FOR ARBOVIRUS SCREENING

Joilson Xavier[1], Vagner Fonseca[2], Felipe Iani[3], Talita Adelino[3], Carla de Oliveira[4], Alana da Costa[3], Flavia Levy[4], Mauricio Lima[3], Hegger Fritsch[1], Fernanda Khouri[5], Emerson de Castro[3], Elaine de Oliveira[6], Luiz Demarchi[7], Arabela de Mello[8], Simone Kashima[9], Svetoslav N. Slavov[9], Marina Zardin[7], Gislene Lichs[7], Raquel S. Ferreira[6], Felicidade Pereira[8], Rivaldo V. da Cunha[10], Ronaldo de Jesus[1], Cassio Peterka[11], Carlos F.C. de Albuquerque[2], Wildo N. de Araujo[2], Carla Freitas[12], Maria A. Mares-Guia[4], Ana M.B. de Filippis[4], Marta Giovanetti[4], Luiz C. J. Alcantara[4]

[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Pan American Health Organization/World Health Organization, Brasília-DF, Brazil, [3]Laboratório Central de Saúde Pública/Fundação Ezequiel Dias, Belo Horizonte, Brazil, [4]Instituto Oswaldo Cruz/Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [5]Universidade Federal da Bahia, Vitória da Conquista, Brazil, [6]Laboratório Central de Saúde Pública do Estado de Mato Grosso, Cuiabá, Brazil, [7]Laboratório Central de Saúde Pública do Estado de Mato Grosso do Sul, Campo Grande, Brazil, [8]Laboratório Central de Saúde Pública Professor Gonçalo Moniz, Salvador, Brazil, [9]Fundação Hemocentro de Ribeirão Preto, Ribeirão Preto, Brazil, [10]Fundação Oswaldo Cruz/Bio-Manguinhos, Rio de Janeiro, Brazil, [11]Coordenação Geral das Arboviroses, Secretaria de Vigilância em Saúde/Ministério da Saúde, Brasília-DF, Brazil, [12]Coordenação Geral dos Laboratórios de Saúde Pública, Secretaria de Vigilância em Saúde, Ministério da Saúde, Brasília-DF, Brazil

Diseases caused by arboviruses such as dengue (DENV), chikungunya (CHIKV) and zika (ZIKV) present a very similar acute febrile clinical picture that has made clinical diagnosis difficult and favoured underreporting events resulting from false-negative results, including co-infection cases. As serological methods have presented limitations due to cross-reactions between correlated viruses, there is a need for new sensitive, specific, rapid methods capable of discriminating antigenically related viruses in areas where co-circulation of multiple arboviruses occurs. Thus, in this work, we optimized a method of Multiplex PCR Targeted Amplicon sequencing (MTA-seq) for arbovirus genotyping from viral RNA. For that, we combined the high sensitivity and specificity of multiplex PCR with the practicality and rapidity of data generation from nanopore sequencing by MinION. We used primer pairs from published genome sequencing schemes to amplify specific fragments of 400 to 900 base pairs. We selected primer pairs for CHIKV, DENV (serotypes 1 to 4), ZIKV, yellow fever virus (YFV), and West Nile virus (WNV) that were combined into a pool and used for the one-step amplification reaction performed on 27 clinical serum samples from previous outbreaks of DENV, CHIKV and ZIKV in Brazil. Sequencing data were analysed using the open and easy-to-use Genome Detective web software, whose initial results after 2 hours of sequencing showed that MTA-seq was able to detect the target virus present in 88.8% (24/27) of the samples (median of 40,254 mapped reads), of which 79% showed a classification for the genotype which indicated 66.6% (6/9) of the DENV-1 positive samples belonged to the genotype V, 100% (n=8) of the DENV-2 samples belonged to the genotype III, and 44.4% (4/9) of the CHIKV samples belonged to the ECSA lineage. MTA-seq was able to retrieve and genotype 4,728 reads of the Asian lineage of Zika virus from a 2016 old sample. These results suggest a high sensitivity and specificity of the MTA-seq and indicate this method might assist not only in the diagnosis but also in the elucidation of the molecular epidemiology of arboviruses in endemic regions.

0458

FOOD INSECURITY AS A BARRIER TO ANTI-RETROVIRAL THERAPY IN POPOKABAKA HEALTH ZONE, A CASE STUDY

Elvis T. Kateba[1], Francis B. Iyese[1], Erick N. Kamangu[2], Paulin B. Mutombo[3]

[1]Ministry of public health, Kinshasa, Democratic Republic of the Congo, [2]Faculty of medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [3]Kinshasa Public Health School , University de Kinshasa, Kinshasa, Democratic Republic of the Congo

Food insecurity is a considerable challenge in sub-Saharan Africa, disproportionately affecting persons living with HIV/AIDS. HIV epidemic largely overlaps with populations already experiencing low diet quality & quantity. Considering the generally high prevalence of food insecurity in rural areas of the DRC (~54%), it was interesting to know the real situation of PLHIV adherence in Popokabaka. Indeed, it is not clear how PLHIVs manage to cope with issues that relate to food insecurity, how they meet their treatment. This study aimed to understand how food insecurity constitutes a barrier to Antiretroviral therapy (ART) in Popokabaka. This qualitative study collected data via in-depth interviews with 15 HIV-positive who had been on ART for at least six months. By using a thematic analysis approach deductive, five themes were identified: Knowledge of HIV, Perception of family & friend's support, Perception of health care service, belief of ART's effectiveness, Nonadherence pathway. Food insecurity was a common & important barrier to ART adherence among patients in Popokabaka. Two pathways were identified to explain how food insecurity & ART non-adherence may be linked, including the anger that came from lack of food which pushes to postpone medication-taking & the belief that ART is not effective when there is no food. Notwithstanding the overwhelming number of inhibiting factors, most patients in this study were highly motivated to achieve adherence. Freedom from hunger is a basic human right & warrants immediate attention in its own right. The link between food insecurity & poor ART outcomes further heightens the importance of addressing food insecurity in the context of sociocultural related factors, as part of comprehensive patient adherence to ART & ultimately long term success of HIV treatment among HIV-infected individuals in the region.

0459

EVALUATION OF SEXUAL DYSFUNCTION AND IDENTIFICATION OF RISK FACTORS OF WOMEN INFECTED BY HUMAN IMMUNODEFICIENCY VIRUS DURING THE COVID19 PANDEMIC IN 2020 IN CONAKRY

Balde Raghiatou[1], Alioune Camara[2], Tounkara Thierno Mamadou[3]

[1]Trainee Municipal Health Directorate, Conakry, Guinea, [2]Gamal Abdel Nasser University, Conakry, Guinea, [3]Faculty of Health Sciences and Techniques, Gamal Abdel Nasser University, Conakry, Guinea

Female sexual dysfunction is a highly prevalent sexual health problem but under-investigated in Guinea. This study determined the prevalence and risk factors associated with sexual dysfunction among women infected with human immunodeficiency virus (HIV) in Conakry. Guinea notified its first case of Covid19 on March 12, 2020 and on 02/28/2022, thirty-six thousand three hundred and ninety-seven (36397) confirmed cases, thirty-two thousand nine hundred and thirty- nine cured (32,939) and four hundred and forty (440) hospital deaths. The Female Sexual Function Index (FSFI) was used in a cross-sectional study design involving 401 women aged 18 years or more in large HIV cohort sites in Conakry, Guinea. A score of less than 26.55 indicated sexual dysfunction. Clinical and sociodemographic characteristics were collected. Multivariate logistic regression analysis was performed to identify factors associated with sexual dysfunction. The prevalence of sexual dysfunction was 22.2% (95% CI: 18.2–25.9). The types of sexual dysfunctional detected included desire disorder (32.2%), sexual arousal (25.4%), lubrication (23.9%), orgasm (30.7%), sexual satisfaction (32.7%) and pain (28.2%). Multivariate analysis showed that unmarried (adjusted OR 4.6, 95% CI 1.6 to 14.0), age above 35 years old (adjusted OR 7.2, 95% CI 2.1 to 24.0), voluntary HIV screening (OR 4.69: 95% CI: 1.07, 21.93), and current use of antiretroviral drugs (OR 2.68: 95% CI: 1.28, 5.61) were factors associated with sexual dysfunction. Sexual dysfunction is prevalent in women infected with HIV in Conakry, Guinea. Sociodemographic and clinical factors were associated with the risk of sexual dysfunction. Health care workers should be trained on the screening and management of sexual dysfunction in HIV care services.

0460

IMPLEMENTING WHO PACKAGE OF CARE FOR PERSONS WITH ADVANCED HIV DISEASE IN ETHIOPIA

Anteneh Zewde

University Of Minnesota, Minneapolis, MN, United States

AIDS is still common in sub-Saharan Africa, despite improving access to ART. Cryptococcosis and tuberculosis are the most common causes of death in HIV patients with CD4 count <200 cells/μL. From our 2015 data published in Clinical Infectious Disease Journal, we face 68% mortality from cryptococcal meningitis in Adama. Despite recommendations for rapidly initiating HIV treatment, many persons in sub-Saharan Africa present to care with advanced HIV disease. In 2017, the World Health Organization (WHO) recommended a package of care for persons with advanced HIV disease. The package consists of cotrimoxazole prophylaxis to prevent PCP pneumonia, Tuberculosis (TB) screening, and prophylaxis, Cryptococcal (CrAg) screening and treatment, rapid initiation of antiretroviral therapy (ART) (for naïve persons) and enhanced patient adherence counseling. These packages of care are based on expert recommendations and need to be validated in real-world health care settings. It is yet to be proven if the package of care will improve survival. We enrolled 275 participants with CD4 count below 200 cells/mcL from January 2020-July 2021. The participant had a point of care OI screening and Same day ART initiation as part of the 2017 Recommended WHO package of care which includes, Screening for tuberculosis (TB) and cryptococcal infection, Treatment and prophylaxis for major opportunistic infections, Rapid initiation of ART, and Intensified treatment adherence support and 6 months follow up.

0461

SARS-COV-2 SPECIFIC NEUTRALIZING ANTIBODIES IN VACCINATED AND UNVACCINATED HIV-POSITIVE INDIVIDUALS IN THE DOMINICAN REPUBLIC

Michelle M. Estrella[1], Wilfredo M. Gordo[1], Maridania Jabier[2], Rebeca Salas[3], Nelissa Sanchez[2], Paula Cuevas[2], Sayira Mueses[2], Ingrid Ruiz[1], Hector Lora[1], Jenny Cepeda-Marte[1], Robert Paulino-Ramírez[1]

[1]Instituto de Medicina Tropical & Salud Global, Universidad Iberoamericana, Research Hub, Santo Domingo, Dominican Republic, [2]Diagnostic Division, Instituto de Medicina Tropical & Salud Global, Universidad Iberoamericana, Santo Domingo, Dominican Republic, [3]Clinical Laboratory, Centro de Orientación e Investigación Integral, Santo Domingo, Dominican Republic

Occurrence of COVID infection in high burden HIV countries has been observed and associated to chronic infections and variants emergence. In the Dominican Republic it is estimated 1% of the population living with HIV. The aim of this study was to evaluate specific SARS-CoV-2 neutralizing antibodies in PLWHIV in a HIV Clinic, and to determine the clinical characteristics of reported COVID-19. Blood samples were collected after informed consent was signed for SARS-CoV-2 neutralizing antibodies detection. Data was collected from March 2020-October 2021. All participants completed a questionnaire. Samples were analyzed using IchromaTM II using a cut-off index (COI) for fluorescent interpretation. A total of 213 participants fulfil the study inclusion criteria. Mean age was 31 years old (SD 14). SARS-CoV-2 neutralizing antibodies were detected in 75% of participants. None experienced severe COVID-19. Vaccination status with at least one dose was reported in 71% of participants. The

most common symptoms reported were anosmia 69% (n=65), dysgeusia 65% (n=61) and cough 60% (n=56). The most frequent comorbidity was arterial hypertension 61% (n=43), and diabetes mellitus 10% (n=7). A weak negative correlation were found between antibody detection and immune status (CD4 counts/HIV viral loads), rho=-0.218, $p < 0.05$. Knowing the most frequent clinical manifestations of people with SARS-CoV-2 and living with HIV helps us to offer a timely diagnosis and avoid future complications. Detection of specific neutralizing antibodies in immunosuppressed and/or not virally suppressed will facilitate immunological comprehension of vaccine campaigns (including boosters) and other preventive interventions.

0462

HIV PRE-EXPOSURE PROPHYLAXIS (PREP) MODELS OF DELIVERY IN LOW TO MIDDLE INCOME COUNTRIES: A PROPOSED MODEL FOR AN INTEGRATED CARE MODEL

Robert Paulino-Ramirez[1], Jett Choquette[2]

[1]Instituto de Medicina Tropical & Salud Global, Universidad Iberoamericana, Santo Domingo, Dominican Republic, [2]The Larner College of Medicine, University of Vermont, Vermont, VT, United States

As the global pandemic of HIV continues, many low- and middle income countries also have an increasing burden of non communicable diseases (NCDs). When used consistently pre exposure prophylaxis (PrEP) can reduce the risk of HIV acquisition by over 90%. In 2015 the World Health Organization (WHO) expanded their previous recommendation from offering PrEP to MSM to all populations at significant risk of acquiring HIV. The aim of this study was to identify which models for PrEP service delivery have been successful in low-to-middle income countries, their key components, and how better to include NCD screening and treatment cross sectionally with HIV screening, testing, and treatment programs. A revision of current scientific literature and specialized reports was conducted from November through December of 2021 on PubMed and examined articles published between 2019-2021. 326 articles were reviewed from 7 primary searches. Additional articles were found from references cited by reviewed articles and smaller searches related to individual article findings. 97 articles were read in full, 68 of which were selected for informing this review because they directly addressed the research questions. Our findings reveal that PrEP service provision should be guided through:a) Community engagementb) On-site PrEP servicesc) Partner referralsd) Integrated services along with PrEP. PrEP has been delivered through various models depending on target populations, country policies, and established health infrastructure. Predictive models and implementing project have indicated that PrEP delivery is feasible and cost-effective when delivered in different ways. There are numerous barriers to PrEP uptake that should be considered when implementing PrEP delivery, many of which involve deep-seeded cultural beliefs or reflect community relationships rather than simply presenting logistical challenges and awareness gaps. In addition to PrEP integration, research has shown that using HIV healthcare infrastructure is feasible for delivery of NCD screening and care.

PERINATAL HIV EXPOSURE IN SIX-TO TEN-YEAR OLD UGANDAN CHILDREN AND ITS ASSOCIATION WITH CAREGIVER DEPRESSION SYMPTOMS

Sarah Brewer, Nicole Talge, Claudia Holzman, Alla Sikorskii, Amara Ezeamama

Michigan State University, East Lansing, MI, United States

Survival is possible for children perinatally exposed to or infected by HIV in the post-combined antiretroviral therapy era, and the identification of factors affecting children's ability to thrive has great public health significance. Caregiver mental health is important given its impact on child development. Previous studies on the topic have not included a full complement of HIV exposure or infection groups or considered how caregiver's mental health may depend on child serostatus, and rarely taken place in HIV endemic areas. To address these issues, we compared depressive symptoms among caregivers of 3 groups of 6-10 year old children in Uganda with known HIV exposure status: children HIV-infected perinatally (CPHIV, n=102), children born to HIV-infected mothers, but HIV negative (CPHEU, n=101), and HIV-unexposed, uninfected community controls (CHUU, n=103). Self-reported caregiver depression symptoms were assessed using the Hopkins Symptom Checklist. We used general linear models to estimate mean differences among the three HIV exposure groups. Adjusted models included caregiver age, education, social support, lifetime trauma, and wealth as covariates. We also evaluated effect modification of the child HIV exposure status by caregiver social support. Depression symptoms were higher among CPHEU compared to CPHIV caregivers (model coefficient *[B]*=-3.5, 95% confidence interval [CI] -5.3, -1.8). This finding remained significant in the adjusted model (*B*=-2.2, 95% CI -4.1, -0.4). No other group differences were observed, and findings were unchanged after limiting the analysis to biological caregivers. At lower levels of caregiver support, CPHEU reported higher levels of depression symptoms than CPHIV (*B*=-0.2, 95% CI -0.3, -0.1), but at high levels of social support, depression symptoms did not differ according to perinatal HIV status. Our findings point to an unmet mental health need among HIV-positive caregivers who care for CPHEU. Elucidating the factors that underlie this finding may inform future intervention targets to improve caregiver well-being.

0464

VASCULAR FACIAL SKIN LESIONS IN A FEBRILE IMMUNOCOMPROMISED PATIENT IN RURAL KWAZULU-NATAL, SOUTH AFRICA

Jessica J. Tuan[1], Rodney Magwenya[2]

[1]Yale University School of Medicine, New Haven, CT, United States, [2]Church of Scotland Hospital, Tugela Ferry, KwaZulu-Natal Province, South Africa

A 47-year-old female with HIV/AIDS (CD4 5, VL 33,524) presented with facial skin lesions to Church of Scotland Hospital, in rural Tugela Ferry, KwaZulu-Natal Province, South Africa. Exam revealed three dark purple, raised, non-tender facial skin lesions (right eyebrow [2.5 x 1 cm], right cheek [1 x 1 cm], nasal tip [2.5 x 2.5 cm]). We performed a skin biopsy of the cheek lesion, with histopathology revealing nodular tumor comprising fascicles of spindled cells (showing nuclear pleomorphism with mitoses, lymphocytes, plasma cells, hyaline globules) with positive human herpesvirus-8 (HHV-8) immunostain, confirming Kaposi's Sarcoma (KS). Classic KS-associated histopathology shows spindle cells, neovascular proliferation, inflammation. Given the local cutaneous nature of the KS, the treatment was to optimize her antiretroviral regimen to restore immunocompetency. A histopathological confirmatory diagnosis of KS can guide management, particularly in the clinical scenario of disseminated or systemic involvement. While hospitalized, she had recurrent fevers, attributed to poorly controlled HIV/AIDS with KS and/or other opportunistic co-infection(s). KS—a vascular tumor caused by HHV-8—is an AIDS-defining illness which can be sub-categorized into cutaneous and visceral disease. We highlight this clinical case, as it is important to recognize Kaposi's Sarcoma as a potential diagnosis consistent with the clinical syndrome of vascular-appearing cutaneous lesions in a febrile, immunocompromised host. This syndrome may be underrecognized due to a broad differential diagnosis, including bacillary angiomatosis, hemangiomas, angiomas, purpura. Though a presumptive KS diagnosis can be made clinically, it may be challenging to reach a definitive KS diagnosis in a rural clinical setting due to limited resources to provide confirmation.

0465

LEVERAGING ECONOMICS TO OPTIMIZE RETENTION IN CARE FOR HIV: A SYSTEMATIC REVIEW

Miguel Reina Ortiz[1], Alida Gertz[1], Neielle Saint-Cyr[1], Miguel Vasquez[2], Karen Wint[2], Maria-Jose Francois[2], Henian Chen[1], Dinorah Martinez Tyson[1], Stephanie Marhefka-Day[1], Harsha Thirumurthy[3]

[1]University of South Florida, Tampa, FL, United States, [2]Center for Multicultural Wellness and Prevention, Orlando, FL, United States, [3]University of Pennsylvania, Philadelphia, PA, United States

According to the UNAIDS Fast-Track Targets, by 2030 95% of people living with HIV should know their status; among them, 95% should receive antiretroviral treatment (ARV), and, among the latter, 95% should achieve viral suppression. Retention in care for HIV (RICH) is a cornerstone of the Fast-Track Targets, which leads with certainty to viral suppression. However, globally, coverage of ARV and retention in HIV care are below our desired targets. We must improve these indicators by implementing innovative strategies. Traditional and behavioral economic prinicples have been successfully used to improve a myriad health outcomes. Here, we present the results of a systematic literature review conducted to synthesize the state-of-the-art knowledge regarding the use of financial incentives and traditional economic strategies to improve RICH. We searched Pubmed, CINHAL, Psychinfo and Embase using the following search terms: HIV-related terms, monetary incentive terms, and retention in care terms. We included qualitative, quantitative or mixed-methods studies that reported outcomes related to retention in care of interventions involving financial incentives for people living with HIV. Initial search resulted in 269 peer reviewed papers. Two people from the research team undertook independent title and abstract reviews, and full text reviews. Studies found used several different strategies including financial incentives, food incentives, cash transfer programs, etc. Overall, studies show that strategies that leverage traditional economic principles (i.e., financial incentives or similar) are successful in either engaging, re-engaging, or retaining people in HIV care. Our preliminary results suggest that traditional economic principles can be successfully leveraged in the fight against HIV towards achieving the 95-95-95 Fast-Track Targets. Further research should evaluate and synthesize the evidence regarding the use of behavioral economics to optimize RICH as well as other HIV-related outcomes.

0466

DISSEMINATED CRYPTOCOCCOSIS IN HIV/AIDS - A SUCCESS OF ALTERNATIVE REGIMEN OF AMPHOTERICIN-B

Ujjawal K. Shriwastav, Ashish S. Chaudhari, Prasan K. Panda, Bishal P. Shah, Rajat Ranka

All India Institute of Medical Sciences, Rishikesh, Rishikesh, India

Disseminated cryptococcosis can be the first manifestation of acquired immunodeficiency syndrome (AIDS). Management of such patients is difficult in resource poor settings. A 39-years-old man with a history of significant high-risk behavior in the form of multiple sexual partners presented to a tertiary care center with non-productive cough for one week and altered mental status for three days, associated with severe malaise, fatigue, and significant weight loss. On initial examination, the patient was cachexic, disoriented, and pale with the presence of a small umbilicated centrally necrosed papule over the upper lip on the left side. Initial workup revealed the presence of HIV positive status, and CSF India ink was positive for Cryptococcus. Chest imaging shows the presence of a lobar consolidation in the right upper lobe with internal breakdown necrosis and cavitation suggestive of fungal etiology and punch biopsy of skin lesion had features suggestive of cryptococcosis. After the initial workup, induction therapy was started in lines of disseminated cryptococcosis with liposomal Amphotericin-B (3 mg/kg/day) and fluconazole (800mg/day, flucytosine is not available). The induction therapy was modified and extended because of the persistence of CNS cryptococcosis after two weeks (liposomal amphotericin 10mg/kg every third day for five doses with fluconazole 800mg/day). There was clinical improvement in symptoms, and CSF was negative for Cryptococcus after five doses of high dose liposomal Amphotericin-B. Patient was discharged with fluconazole 800mg/day as a part of consolidation therapy. The above case shows how disseminated cryptococcosis can be a primary manifestation in a patient with HIV infection and the challenges in managing the same. The modification of induction therapy in case of persistence has shown a dramatic response in the clearance of the organism due to better CNS penetration.

DIAGNOSIS AND PREVALENCE OF *CRYPTOSPORIDIUM AND GIARDIA* INFECTIONS IN CHILDREN UNDER FIVE YEARS WITH MODERATE TO SEVERE DIARRHOEA ATTENDING TWO HEALTH FACILITIES IN BLANTYRE, MALAWI

Henk Schallig[1], Joseph Bitilinyu[2], Wieger Voskuijl[1]

[1]Academic Medical Centre, Amsterdam, Netherlands, [2]Queen Elizabeth Central Hospital, Blantyre, Malawi

Diarrhoeal diseases are major causes of morbidity and mortality among children in low and middle income countries (LIMCs). *Cryptosporidium* and *Giardia* are considered to be the main parasitic causes of moderate and severe diarrhoea (MSD) in LMICs. The diagnosis of these parasitic protozoa is usually by microscopic detection of the parasite oocysts in stool samples, but might be cumbersome, time-consuming and prone to errors. Rapid Diagnostic Tests (RDTs) provide an attractive alternative by combining sufficient diagnostic accuracy with speed and ease to operate. The present study aimed to determine the prevalence of *Giardia* and/or *Cryptosporidium* infections by RDT among children, 0-60 months, with MSD attending two primary health facilities in Blantyre (Malawi); Limbe health centre with a catchment population of 105,347 and Ndirande with a catchment area that has 145,187 people accessing outpatient health services. In total, 972 children were included and their stools examined by RDT for the presence of *Giardia* and/or *Cryptosporidium*. It was found that 166 children (17.1%) had a *Giardia* infection, 73 (7.5%) were infected with *Cryptosporidium* and only 15 (1.5%) had a mixed infection. Girls and boys were equally infected by the parasites and there was no clear correlation between weight/height and infection. However, children aged 10-44 months had the highest prevalence of infections. The vast majority of *Cryptosporidium* infections were caused by *C. hominis* (as determined by genetic typing) suggesting antroponotic transmission. Of 718 children (73.9%) the cause of diarrhoea remains to be established, and testing for Rota and Noro viruses with RDTs is warranted to improve diagnosis and clinical management.

0468

EFFECT OF CLINICIAN INFORMATION SESSIONS ON DIAGNOSTIC TESTING FOR CHAGAS DISEASE

Helen M. Mahoney West[1], Carly E. Milliren[1], Jennifer Manne-Goehler[2], Jillian Davis[3], Jaime Gallegos[3], Juan Huanuco Perez[3], Julia Koehler[1]

[1]Boston Children's Hospital, Boston, MA, United States, [2]Massachusetts General Brigham, Boston, MA, United States, [3]East Boston Neighborhood Health Center, East Boston, MA, United States

Chagas disease is a potentially life-threatening neglected disease of poverty that is endemic in continental Latin America. Caused by *Trypanosoma cruzi* (*T. cruzi*), it is one of six parasitic diseases in the United States (US) targeted by the Center for Disease Control as a public health problem in need of action. An estimated 300,000 people are infected with Chagas disease in the US. Awareness of Chagas disease is lacking among many healthcare providers in the US. The purpose of this analysis is to determine if the number of diagnostic tests performed at a community health center serving an at-risk population for Chagas disease increased after information sessions. A secondary aim was to determine if there was a difference by provider type. A retrospective data analysis of the number of Chagas serology tests performed at the East Boston Neighborhood

Health Center (EBNHC) before and after information sessions for clinicians was performed. A time series analysis was conducted focusing on the Adult and Family Medicine Departments at EBNHC. Across both departments, there were a total of 4,580 *T. cruzi* serology tests performed in the twenty-two-month study period; 1,957 (43%) prior to information sessions and 2,623 (57%) following the sessions. Interrupted time series analysis across departments indicated that testing volume was stable over time prior to the sessions (pre-period slope=+4.1 per month; p=0.12), followed by an immediate shift after the session (+51.6; p=0.03), while testing volume remained stable over time after the session (post-period slope=-6.0 per month; p=0.11). Prior to the sessions, the majority of tests (53%) were ordered by nurse practitioners while 43% were ordered by physicians. After the sessions, nurse practitioners and physicians ordered an equal proportion of tests (both 48%). In this study, Chagas testing increased after information sessions. Clinicians who began testing their patients for Chagas disease after learning of the importance of this intervention added an extra task to their already busy workdays without external incentives or recognition.

0469

EVALUATION OF SCID MOUSE MODEL FOR EXPEDITING CHAGAS DRUG DISCOVERY

Grace M. Baxley, Srinivasa Rao, Colin Osborne

Novartis, Emeryville, CA, United States

Chagas disease, common in Mexico, Central and South America with approximately 6-8 million people infected, is caused by the parasite *Trypanasoma cruzi*. The disease causes symptoms in 2 stages, a milder acute stage, and a chronic stage occurring years after original infection. Treatment options are limited, new therapies are needed and current rodent models can be time intensive, hindering rapid drug discovery process. Here we investigate the use of a SCID mice model of acute Chagas disease to provide a robust, short duration model to aid drug discovery. Eight week old SCID mice were infected with $1x10^3$ bioluminescent tissue-cultured derived trypomastigotes via intraperitoneal injection. Bioluminescent parasites infected various tissues reaching high parasite load by day 10. On day 10 post infection, mice were treated daily for 5 days via oral gavage with varying doses of benznidazole (BENZ, 0-100mg/kg) or vehicle alone (0.5% Methylcellulose + 0.5% Tween80) or Dulbecco's phosphate buffer saline (background control). Mice were imaged before and after treatment and total flux was used to investigate efficacy of treated groups compared to vehicle control. For imaging, mice were injected with 150mg/kg D-Luciferin and imaged under isoflurane anesthesia in an IVIS Lumina X5. Untreated animals showed an approximate 2-$\log_{10}$ increase in total flux values from levels at the start of dosing and a dose dependent reduction in parasitemia was observed following treatment with BENZ. Maximum effect was observed with BENZ dosed at 100mg/kg which reduced total flux 1.5-$\log_{10}$ below levels at start of dosing. Chagas infection established in SCID mice could be monitored using bioluminescence. Parasitemia increased over the course of the study and was treatable, although complete parasite clearance was not observed with the compound doses and schedule used. This model could now be used to screen ability of novel compounds to reduce parasitemia, prioritization of scaffolds and further support drug development efforts for this neglected tropical disease.

0470

ASSESSMENT OF SYNTHETIZED BRIDGED-LACTAM ORGANIC COMPOUNDS FOR IN VITRO ACTIVITY AGAINST *LEISHMANIA MAJOR,* AN AGENT OF HUMAN LEISHMANIASIS

Blaise Dondji, Cameron Smith, Kiera Bush, Hunter Korf, Victoria Shearer, Kenlei Gunther, Taylor Henne, Linsey Curry, Timothy Beng

Central Washington University, Ellensburg, WA, United States

Leishmania are protozoan parasites and causative agents of leishmaniasis. This vector-borne disease is transmitted to the vertebrate hosts including humans, by blood-sucking female phlebotomine sand flies. The clinical forms range from cutaneous leishmaniasis with facial and body disfigurations to visceral leishmaniasis in which the parasite spreads into the reticuloendothelial system with fatal outcome in the absence of treatment. The leishmaniases are prevalent in over 88 countries with more than 15 million infected globally. It is estimated that worldwide, there are about 3 million new cases of leishmaniases each year leading to as many as 50,000 fatalities annually. The World Health Organization lists the leishmaniases among the leading causes of deaths by infectious agents. Today, there is no approved vaccines for the prevention of leishmaniasis. The major control tools include measures against the vector such as bed nets and therapeutics against the parasite. For almost a century, treatment of the disease has relied on pentavalent antimonials. However, antimonials are very toxic chemotherapeutics with frequent and sometimes life-threatening side effects such as cardiac arrythmia and acute pancreatitis. The pentavalent antimonials were replaced in some endemic countries by formulations of amphotericin B. However, this latter option is again limited with severe toxicity, long hospitalization, and overall high cost of treatment. Based on the above, it is evident that the chemotherapeutics available do not match the high burden of the leishmaniases. Consequently, there is an urgent need of antileishmanial therapeutics that are effective, not/less toxic, and affordable to population in impoverished endemic areas. In order to address this shortage, we have embarked on the development of new organic compounds and their evaluation for leishmanicidal activity. We will present data showing that synthetized bridged-lactam organic compounds have potentials as antileishmanial therapeutics. Interestingly, our study shows that activity is directly linked to chemical structures of the compounds evaluated.

0471

DRAMATIC INCREASE IN THE NUMBER OF MICROTUBULE ASSOCIATED PROTEIN GENES IN *TRYPANOSOMA CRUZI* COMPARED WITH *TRYPANOSOMA BRUCEI*

Martin A. Winkler[1], Alfred Pan[2]

[1]Biotech Advisor, Lawrence, KS, United States, [2]TNTC, Inc., Pleasant Hill, CA, United States

MARP1 is a *T*rypanosoma *brucei* microtubule associated protein (MAP) that is localized on the microtubules of the parasite's cell body. It is comprised of 50 repeats of a 38 amino acid motif. Search of the putative MARP1 amino acid sequence by BLASTp at NCBI in the nih.gov website disclosed five homologous genes in the *T. brucei* genome that showed an exact sequence identity. MARP1 also showed a 54% amino acid sequence identity to the *T. cruzi* MAP protein encoded by Genbank M21331. We have previously shown that M21331 has partial gene sequence identity to human immune genes such as TRIM21. A BLASTp search of Genbank M21331 showed that there are 30 other genes which are 100% identical to it in the *T. cruzi* genome. These genes encode for proteins ranging in size from 38 to 2011 amino acids in length and contain up to 50 repeats of the 38 amino acid sequence motif. The MAP genes in *T. cruzi* appear to have expanded five-fold in number compared to similar MAP genes in *T. brucei*. The sequences, functions, and roles of these numerous *T. cruzi* proteins are a fascinating area for further scientific study.

0472

EVALUATION OF TWO FDA-APPROVED ANTISEPTICS USED IN WOUND CARE AND ORAL HYGIENE FOR EFFICACY IN THE TREATMENT OF LEISHMANIASIS

Chinwe Chukwudi[1], Andrea Paun[1], Liam Good[2], Michael Grigg[1]

[1]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Royal Veterinary College, University of London, London, United Kingdom

Leishmaniasis affects poor communities worldwide, with about 1 million new cases annually and more than 20 species of the parasite affecting humans. In infected hosts, the parasites exist in 2 forms-promastigotes in blood and amastigotes in tissue macrophages. The disease manifests in 3 clinical forms: Cutaneous (most common), Mucocutaneous and Visceral

(most serious). Available therapies are very toxic, expensive, selective for specific species of the parasites, and often complex to administer. Hence, effective treatment requires specific identification of parasite specie (difficult in resource-limited areas), long-term administration by adequately skilled personnel and severe side effects, often leading to patient non-compliance. New drugs are desperately needed, and drug repurposing could offer quick intervention.We identified two compounds that are commonly used in wound care and oral hygiene that have impressive anti-leishmanial activity in vitro. Results of promastigote assays show that the two compounds have better anti-leishmanial activity than most currently available drugs which are often toxic and expensive, with an IC_{50} of 2.5-4uM. These compounds have shown efficacy against 6 different species of Leishmania tested so far. Experiments are underway to test the compounds against amastigotes and in mouse models of Leishmaniasis, and to elucidate their mechanism(s) of action. The compounds will also be assayed for synergistic effects with other antimicrobials for enhanced efficacy and drug delivery.This study will deliver two prospective drug-repurposing candidates that are cheap, safe, easy to administer and have broad-spectrum anti-leishmanial activity for the effective treatment of various forms of Leishmaniasis, thereby reducing the disease burden.

0473

TRYPANOSOMA CRUZI-SPECIFIC B CELL RESPONSES IN SERODISCORDANT SUBJECTS FOR CHAGAS DISEASE

María Josefina Elias[1], María Ailén Natale[1], María Cecilia Albareda[1], Diego Marco[2], Ana María De Rissio[1], María Gabriela Alvarez[3], Constanza Parodi[1], Bruno Lococo[3], Susana Laucella[1]

[1]Instituto Nacional de Parasitología Dr. Mario Fatala Chaben, Buenos Aires, Argentina, [2]Laboratorio de Patología Experimental, Universidad Nacional de Salta., Salta, Argentina, [3]Hospital Interzonal de Agudos Eva Perón, Buenos Aires, Argentina

A proportion of subjects screened for *Trypanosoma cruzi* infection have what is termed "discordant serology," i.e., a positive result in only one out of three conventional serological tests performed. Serodiscordant subjects (SD) have more functional *T. cruzi*-specific T-cell responses compared with seropositive subjects, suggesting that some subjects exposed to *T. cruzi* might eventually resolved the infection and developed T cell memory. Here, we have evaluated the presence of antibody secreting cells and memory B cells specific for *T. cruzi* and Leishmania antigens using B cell ELISPOT, and the phenotype of total B cells in SD, seropositive and seronegative subjects for *T. cruzi* infection.Based on a cut-off value defined by the mean values of antibody secreting cells plus 2SD in uninfected subjects, none of the 17 SD subjects evaluated showed circulating antibody secreting cells specific for *T. cruzi* or *Leishmania* antigens whereas 24/29 subjects seropositive for *T. cruzi* infection had antibody secreting cells specific for *T. cruzi* antigens. In contrast, SD subjects had higher levels of *T. cruzi* -specific memory B cells compared with seropositive and uninfected subjects. SD and uninfected subjects also showed higher levels of memory B cells specific for tetanus toxoid compared with seropositive subjects. No differences in *Leishmania*-specific memory B cells were found among groups. The phenotype of total B cells in SD was not different from that found in uninfected subjects. The monitoring of conventional serology of SD showed that a proportion of them had been seropositive for T. cruzi infection and became serodiscordant or seronegative over time. Sera from SD (n = 58) had low reactivity to *T. cruzi* antigens using a commercial ELISA technique and a proportion of them also had low reactivity to Leishmania antigens using an in-house ELISA. These findings support that *T. cruzi* -specific antibodies in SD did not appear to derive from an active infection but more likely reflect prior exposure to *T. cruzi* and the establishment of immunological memory suggestive of a resolved infection.

0474

DIAGNOSIS OF *BALAMUTHIA MANDRILLARIS* ENCEPHALITIS BY TA CLONING TARGETING UNIVERSAL EUKARYOTIC GENE

Ju Yeong Kim, Tai-Soon Yong

Department of Environmental Medical Biology, Institute of Tropical Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea

A 50-year-old man without a history of neurological disease was referred to our department for the evaluation of an intracranial lesion observed on brain MRI scans, and the pathology results suggested protozoal infection. We identified the species responsible for encephalitis using thymine-adenine (TA) cloning. We extracted DNA from a paraffin-embedded brain biopsy sample and performed TA cloning using two universal eukaryotic primers targeting the V4-5 and V9 regions of the 18S rRNA gene. The recombinant plasmids were extracted, and the inserted amplicons were identified by Sanger sequencing and a homology search of sequences in the NCBI BLAST. The protozoa was identified as the free-living amoeba *Balamuthia mandrillaris*. Two of 41 colonies recombinant with 18S V4-5 primers and 35 of 63 colonies recombinant with the 18S V9 primer contained *B. mandrillaris* genes; all other colonies contained human genes. Pathogen-specific PCR ruled out *Entamoeba histolytica*, *Naegleria fowleri*, *Acanthamoeba* spp., and *Toxoplasma gondii* infections. This is the first report of *B. mandrillaris*-induced encephalitis in Korea based on molecular identification. TA cloning with the 18S rRNA gene is a feasible and affordable diagnostic tool for the detection of infectious agents of unknown etiology.

0475

DNA DIAGNOSIS OF CUTANEOUS LEISHMANIASES (CL) USING MULTIPLEX PCR ASSAY COUPLED TO LATERAL FLOW (LF) DNA CHROMATOGRAPHY

Yusr Saadi[1], Ahmed Sahbi Chakroun[1], Hamed Chouaieb[2], Hejer Souguir[1], Insaf Bel Haj Ali[1], Alya Yaacoub[2], Moncef Ben Said[2], Akila Fathallah-Mili[2], Ikram Guizani[1]

[1]Molecular Epidemiology & Experimental Pathology, Institut Pasteur de Tunis, Tunis, Tunisia, [2]Parasitology department, Farhat Hached University Hospital, Sousse, Tunisia

In Tunisia and countries in MENA region, CL are a group of diseases representing a complex epidemiological situation with the proven implication of at least 3 *Leishmania (L.)* species (*L.infantum:L.i, L.major:L.m, L.tropica:L.t*) and diverse clinical presentations. There is an urgent need for a rapid diagnosis tool that could facilitate etiological diagnosis and patient management. The aim of this study was to develop an innovative, sensitive and specific molecular tool for simultaneous *L.*species detection and identification using PCR multiplex-LF DNA chromatography that could be used as a point of care (POC) diagnosis test. Comparative genomic analyses of *L.m* & *L.i* genomes were performed to select species-specific targets. Twenty-four primer pairs were designed and assessed for criteria of taxa-specific DNA amplification of the 3 principal *L.* species in MENA. Species/group of species-specific primers aiming at 3 different targets were selected and showed consistent species-specific reactivities when tested on 32 *L.* DNAs. The analytical sensitivity on agarose gel was 0.2-0.02ng. The assay included a 4thtarget corresponding to a human-DNA control. For the detection on a LF test using a proprietary DNA-DNA hybridization technology, the different forward-primers were tagged on their 5'end with different tags while reverse-primers were biotinylated on their 5'end. On the LF strip, within 3mn, the targeted DNA amplicons appear as blue test lines on the strip through a streptavidin-Biotin interaction. The test was shown to consistently identify the studied *L.*species and to have an analytical sensitivity of detection of 0.01ng. The performance of the test was evaluated on 80 cutaneous samples made during routine diagnosis at the Parasitology department of the Farhat Hached UH in comparison to Direct-examination (DE) & PCR-RFLP-ITS1. The multiplex PCR-LF test showed 100%sensitivity and 100%specificity in congruence to DE & PCR-RFLP-ITS1. The study delivers a simple, specific

and sensitive tool for accurate simultaneous detection and identification of *L.* parasites in clinical samples that could be used as a POC-CL diagnosis test.

0476

POST-KALA-AZAR DERMAL LEISHMANIASIS DRUG EFFICACY STUDY LANDSCAPE: A SYSTEMATIC REVIEW OF CLINICAL AND OBSERVATIONAL STUDIES TO ASSESS THE FEASIBILITY OF ESTABLISHING AN INDIVIDUAL PARTICIPANT-LEVEL DATA PLATFORM

Sauman Singh-Phulgenda[1], Rishikesh Kumar[2], Caitlin Naylor[1], Abdalla Munir[3], Sumayyah Rashan[1], Prabin Dahal[1], Niyamat A. Siddiqui[2], Eli Harris[1], Manju Rahi[4], Fabiana Alves[5], Kasia Stepniewska[1], Ahmed Musa[3], Philippe Guérin[1], Krishna Pandey[2]

[1]University of Oxford, Infectious Diseases Data Observatory, Oxford, United Kingdom, [2]Rajendra Memorial Research Institute of Medical Sciences, Patna, India, [3]University of Khartoum, Khartoum, Sudan, [4]Indian Council of Medical Research, New Delhi, India, [5]Drugs for Neglected Diseases initiative, Geneva, Switzerland

Post-kala-azar dermal leishmaniasis (PKDL) is a dermatosis which can occur after a conventional treatment for visceral leishmaniasis (VL). There are numerous limitations in our knowledge of PKDL pathology, immunology and risk factors. Recommended treatments are either expensive, raising safety concerns, or are of long durations. We conducted a systematic review to assess the characteristics of PKDL studies and to explore the feasibility and value of developing a PKDL individual patient data (IPD) platform. We searched ten databases to include prospective studies in humans with PKDL diagnosis, treatment and follow-up measurements. We extracted variables on patient characteristics, treatment regimens, diagnostic methods, geographical locations, efficacy endpoints, adverse events and statistical methodology. The literature searches identified 3,217 citations. A total of 54 studies were included in this analysis, 16 clinical trials and 38 prospective observational studies published between 1983 and 2021. The studies were conducted in India (63%), Bangladesh (11%), Nepal (4%) and Sudan (22%) and enrolled a total of 2,462 patients. Of the 16 clinical trials, 12 were conducted in India, 3 in Sudan and 1 in Bangladesh with a total of 21 arms testing 8 different drugs or combinations involving 891 patients. A wide range of heterogeneity in dosage and duration was observed in the different treatment regimens. Antimony formulations and miltefosine each being tested in 33% (7/21) of treatment arms, followed by amphotericin B formulations in 14% (3/21) of arms. Paramomycin alone and in combination with miltefosine was tested in 4.8% (1/21) of arms each. This review provides a landscape of previously and currently tested treatments for PKDL. Only a third of the published studies were from clinical trials while the others were observational with a large variability in treatment regimens tested. Assembling IPD from identified studies would provide granular details on efficacy and safety outcomes and would be a unique resource to answer questions that cannot be addressed using standalone trials and aggregated published results.

0477

IMMUNODIAGNOSTIC POTENTIAL OF CD1A MARKER TO DETECT CUTANEOUS LEISHMANIASIS CAUSED BY *LEISHMANIA DONOVANI*

Hasna Riyal[1], Nilakshi Samaranayake[1], Priyani Amarathunga[2], Nihal Meedeniya[3], Deepani Munidasa[4], Nadira Karunaweera[1]

[1]Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo 08, Sri Lanka, [2]Department of Pathology, Faculty of Medicine, University of Colombo, Colombo 08, Sri Lanka, [3]Lanka Hospital Diagnostics (PVT) LTD, Colombo 05, Sri Lanka, [4]Teaching Hospital, Anuradhapura, Sri Lanka

Immunoexpression of CD1a by *Leishmania* amastigotes has been recently demonstrated in several strains including *Leishmania major*, *L. tropica* & *L. infantum*. We studied CD1a status of amastigotes of *L. donovani* for the first time and evaluated its diagnostic potential. Hundred and sixteen cases of cutaneous leishmaniasis skin biopsy sections were stained with both CD1a clone 010 & CD1a clone MTB1. Results of positive staining for parasites were compared with previously obtained cytological and histological confirmations for the presence of the parasite. The proposed diagnostic tool was evaluated for its accuracy, specificity, and sensitivity against the gold standards for cutaneous leishmaniasis diagnosis obtained through slit skin smear results (SSS). 75 cases had shown positive parasite staining for CD1a clone MTB1. CD1a clone O10 had failed to detect any parasites of the *L. donovani* strain. Staining was accentuated on one side of the parasite corresponding to the kinetoplast of the organism. Staining was seen mostly in the upper dermis. The number of parasites showing positive staining for clone MTB1 gradually decreased through the depth of the dermis. When the number of parasites in the section was too high, the probability of getting them stained with clone MTB1 was low therefore leading to a considerable amount of cases being false negative. The test accuracy, sensitivity, and specificity were 72.4%, 70.9% and 84.6% respectively. In an effort to see if this diagnostic method is more appropriate for patients with low/no LD bodies, test statistics were repeated on the same cohort by removing the 25 patients who had parasite loads of more than 100 LD bodies, then the sensitivity of the test increased to 74.4%. CD1a clone MTB1 successfully stains *Leishmania* amastigotes of *L. donovani* strain and can be used as a reliable diagnostic tool in patients whose parasite counts are extremely low & whose diagnostic confirmation got failed using other conventional methods. This tool may come in handy for hospital settings where SSS sampling is fairly poor due to the lack of expertized personnel.

A NOVEL ASSAY BASED ON RECOMBINASE AMPLIFICATION AND LATERAL FLOW CHROMATOGRAPHY FOR THE DIAGNOSIS OF *LEISHMANIA INFANTUM* CUTANEOUS LEISHMANIASIS

Insaf Bel Hadj Ali[1], Yusr Saadi[2], Aicha Kallel[3], Hejer Souguir[2], Meryem Lemrani[4], Emna Harigua-Souiai[2], Imen Khammeri[5], Hamed Chouaieb[5], Ahmed Sahbi Chakroun[2], Nabil Haddad[6], Oussaïma El Dbouni[7], Akila Fathallah-Mili[5], Steven Reed[8], Kalthoum Kallel[3], Ikram Guizani[2]

[1]Institut Pasteur de Tunis, Tunis, Tunisia, [2]Molecular Epidemiology and Experimental Pathology, Institut Pasteur de Tunis, Tunis, Tunisia, [3]Parasitology department, UH La Rabta, Faculty of Medicine of Tunis – Tunisia, Tunis, Tunisia, [4]Institut Pasteur du Maroc, Morocco, Casablanca, Morocco, [5]Parasitology department, UH Farhat Hached, Faculty of Medicine of Sousse, University of Sousse, Tunisia, Tunis, Tunisia, [6]Faculty of Public Health, Lebanese University, Lebanon, Beyrouth, Lebanon, [7]Rafic Hariri Hospital, Lebanon, Beyrouth, Lebanon, [8]IDRI, Seattle, WA, United States

Cutaneous leishmaniasis (CL) due to *Leishmania infantum* (*L.i*) is known to occur sporadically in North Africa and Middle East regions. However, recent changes in eco-epidemiology of the disease led to geographic expansion and emergence of *L.i* CL infections. *Leishmania* (*L.*) species identification is central for disease monitoring and control but also for effective patient management and treatment. In this context, we aim at developing a novel molecular diagnosis test to detect and identify *L i* in CL lesions. The study involved four endemic areas in MENA regions including North and Center of Tunisia, Morocco, and Lebanon. Our test is based on an isothermal Recombinase based Amplification (RPA/RAA) coupled to a lateral flow detection (LF). For the set up of these assays, we identified 7 targets by a computational analysis complemented by a literature search. For each target, a sequencing survey was performed on a selection of *L.* strains belonging to different species assessing for inter and intra species polymorphisms to design primers and probes. Ten sets of designed primer pairs/probes were tested for their specificity to *L.i* and their sensitivity using RPA-RAA/LF tests. One set was retained; its specificity to *L. i* strains' DNA was assessed on a panel of *L.* DNAs belonging to different species, and its analytical detection sensitivity was 0.2pg. With this assay, the time to results delivery after DNA extraction was less than one hour, with

40mn for the amplification, done at 39°C, and 2mn for the read out of the FAM-Biotin labeled amplicons on the LF cassette.The evaluation of this amplification/detection assay was done on a selection of CL samples (N=34) collected from the different study site sand has shown a sensitivity and a specificity of 90% and 100% respectively as compared to direct microscope examination; identification results were congruent to PCR RFLP ITS1 species assignment. No cross reactivity with *L. major* or *L. tropica* was observed. These results showed that this novel DNA assay has a good potential to be used as a point of care diagnosis tool for the detection and the identification of *L.i* infections.

PEER-NAS-USAID 518 PROJECT: RECOMBINASE POLYMERASE AMPLIFICATION (RPA) AND LATERAL FLOW (LF) ASSAYS FOR POC DNA DIAGNOSIS OF CUTANEOUS LEISHMANIASES IN MENA AND DEVELOPMENT IMPACT

Ikram Guizani[1], Yusr Saadi[1], Hejer Souguir[1], Emna Harigua[1], Imen Mkada[1], Imen Khammeri[2], Meryem Lemrani[3], Aicha Kallel[4], Oussayma Dbouni[5], Ahmed S. Chakroun[1], Hamed Chouaieb[2], Rhea Coler[6], Seydou Doumbia[7], Nabil Haddad[8], Kalthoum Kallel[4], Akila Fathallah Mili[2], Steven Reed[6], Insaf Bel Hadj Ali[1]

[1]Molecular Epidemiology & Experimental Pathology, Institut Pasteur de Tunis , University Tunis El Manar, Tunis, Tunisia, [2]Parasitology department, Faculty of Medicine, Hospital Farhat Hached, University of Sousse, Sousse, Tunisia, [3]Division of communicable diseases, Institut Pasteur du Maroc, Casablanca, Morocco, [4]Parasitology department, Faculty of Medicine, Hospital La Rabta, University Tunis El Manar, Tunis, Tunisia, [5]Rafic Hariri Hospital, Beirut, Lebanon, [6]IDRI, Seattle, WA, United States, [7]Faculty of Medicine, University of Sciences, Techniques and Technologies, Bamako, Mali, [8]Faculty of Public Health, Lebanese University, Beirut, Lebanon

Cutaneous leishmaniases (CL) constitute major public health issues. Caused by multiple *Leishmania* species, they have diverse transmission cycles. More than 80 % of the cases occur in countries of the MENA region, where *L. major(L.m)* or *L. tropica(L.t)* are the predominant CL causing species, while *L. infantum(L.i)* or *L. donovani(L.d)* are involved to less extent. *Leishmania* species identification is central to control strategies, early alert on emergence, and timely and effective patient management. Notably, treatment algorithms are highly dependent on *Leishmania* species. Emergence and changing trends in CL eco-epidemiology called for development of POC DNA assays for accurate disease diagnosis, patient management, control, and surveillance. We aimed at developing species-specific isothermal RPA coupled to LF on dipstick targeting L.m, L.t, L.i/L.d that would be implemented in a second step for multiplexed concomitant detection and identification of these species. We worked on a range of 70 targets identified through bibliography and databases scans; 14 were selected and submitted to a sequencing survey for species- specific primers and probes designs and refinement through multiple sequence alignments. Thirty-five sets were screened for species specific amplification and 15 were selected for further characterization of analytical specificity and sensitivity of detection. Proof of principle validation for detection and identification of the species in cutaneous samples was assessed on consented patients' samples collected in different sites of the collaborative consortium in MENA. Results were compared to smear examination and ITS1 PCR-RFLP. This way we already validated two assays specific to L.m and L.i, respectively. A third one, L.t specific is under evaluation. Multiplexing reaction set up is ongoing. Training workshops were held, and development impact plans were developed. Our approach spares precious samples, is rapid (<1h), is appropriate for limited settings to support POC diagnosis, and addresses current gaps and priorities defined by the WHO NTD roadmap.

CIDALSDB: A NOVEL RESOURCE FOR ANTI-*LEISHMANIA* DRUG DISCOVERY USING MACHINE LEARNING AND LIGAND-BASED APPROACHES

Emna Harigua, Oussama Souiai, Rafeh Oualha, Sara Hamdi, Ikram Guizani

Institut Pasteur de Tunis, Tunis, Tunisia

Computer-aided drug discovery (CADD) is nurtured by late advances in big data analytics and machine learning (ML) towards enhanced drug discovery (DD) outcomes. In this context, reliable datasets are of utmost importance. We herein present CidalsDB a novel ready-to-use resource for the development of ML-assisted DD against Leishmaniases. In a first step, we performed an extensive search of the literature and retrieved data on molecules with validated anti-leishmanial effects. We defined a data dictionary of published information related to the anti-pathogenic effect of chemical compounds and used it to build the database CidalsDB. A web interface was implemented to facilitate the database browsing and use. In a second step, we generated a curated set of molecules from CidalsDB and the PubChem assay AID1258 to constitute an equilibrated dataset of active and inactive molecules against Leishmania promastigotes. We used RDkit to generate the topology torsion fingerprints and implemented four ML algorithms that we trained and tested for their ability to classify molecules into active and inactive.We collected data on 1145 molecules from 753 scientific publications. Molecules revealed validated effects on Leishmania species at different stages (in vitro, in cellulo, in vivo). 79% had validated effects on the promastigote form of the parasite, while only 12% reached the in vivo validation stage. For the second part, we selected the set of 904 molecules with anti-promastigote activity within CidalsDB to which we added 146 active and 963 inactive molecules from the PubChem assay to constitute a dataset for ML models building. Out of 4 ML algorithms, Support Vector Machine presented the highest accuracy of 90% through a 5-fold cross-validation. We further optimized the model and used it to predict potential anti-Leishmania effectors out of the FDA approved drugs. Top10 drugs with a probability >90% of being active included 4 validated anti-Leishmania drugs which confirms the robustness of our approach.CidalsDB will be made publicly available through the web interface along with the ML module for a democratized and no-code CADD.

STANDARDIZATION OF HIGH-CONTENT (HC) PHENOTYPE IMAGING AND VALIDATIONS FOR NOVEL DRUG DISCOVERY AGAINST INTRACELLULAR *TRYPANOSOMA CRUZI*

Andres Prieto Trujillo[1], Yash Gupta[2], Ravi Durvasula[2], **Prakasha Kempaiah**[2]

[1]University of North Florida and Mayo Clinic, Jacksonville, FL, United States, [2]Mayo Clinic, Jacksonville, FL, United States

Trypanosoma cruzi is the causative agent of Chagas disease, endemic to mainly Latin American countries. Current global annual *T. cruzi* infection rate stands at 7 million people with nearly 10,000 reported deaths per year. Infection of *T. cruzi* has two phases, an acute phase and a chronic phase that can last decades, often resulting in myocarditis, megacolon or megaesophagus due to the untreated replication of the *T. cruzi* amastigote. With only two clinically accepted drug treatments, nifurtimox and benznidazole, which have well reported toxic side effects, and the ongoing spread of the disease to non-endemic areas, there is an urgency to identify new treatments against the clinically relevant form of *T. cruzi* -the intracellular amastigote. Being a NTD, chagas research lacks coordinated, multifaceted efforts for a drug discovery i.e. to ensure a high-throughput (HT), cost effective method to rapidly identify novel compounds as potential therapeutics from large libraries. Herein, we describe a robust *in-silico* and *in-vitro* integrated drug discovery workflow implementing a HC phenotypic imaging screening using STD compounds and repurposable, FDA approved drug compounds against the amastigote stages of *T. cruzi* CL strain expressing transgenic EYFP utilizing VERO/A549

cells. Additionally, initial HT- virtual screening against a selected target, i.e. glycosomal Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was performed followed by MD simulations to select hits from FDA approved library. Positive hits were tested *in vitro* using newly established HC method on amastigote form of *T. cruzi* CL. Using Image-Express PICO, we can determine the true efficacy of test compounds following this HC phenotype screening protocol. As part of the validation of HC method, we have identified an FDA approved Epigallocatechin gallate (EGCG) as a lead natural compound specific to parasite GAPDH, with binding energy of -10.6 kcal/mol and an IC_{50} of 46.5μM against epimastigotes, and cytotoxicity levels below Amphotericin B. Additional experiments are underway to expand validations using *T. cruzi* brazil strain expressing luciferase reporter gene.

American tegumentary leishmaniases (ATL) are mainly caused by *Leishmania (L.) braziliensis*, *L. (L.) guyanensis,* or *L. (L.) amazonensis*. The ATL diagnosis is based on Epidemiology-Clinical-Laboratory data. Since the varied clinical presentations are not pathognomonic, laboratory exam data are required to confirm the diagnosis. Furthermore, the discontinuity of the Leishmanin skin test antigen production brought problems for the diagnosis. Currently, no single gold standard diagnostic test is available; thus, laboratory assays that suggest *Leishmania* infection are needed. This study aimed to validate the Lb6H recombinant antigen (rLb6H), derived from *Leishmania (Viannia) braziliensis* gene sequence in an ELISA platform for application in ATL diagnosis. We analyzed 1.091 samples from leishmaniasis and other diseases patients and healthy controls living in various Brazilian endemic and non-endemic localities. The rLb6H-ELISA showed 98.6% sensitivity and 100.0% specificity with the reference panel (70 ATL patients and 70 healthy controls). Analyzing 393 ATL patients' samples from five research and health care centers in endemic and non-endemic areas, rLb6H-ELISA showed 84.0% sensitivity; no significant statistical difference was observed among the five centers (chi-square test, p=0.13). With 392 healthy controls from four areas with different endemicity, a specificity of 92.4% was obtained; lower specificity was obtained in a visceral leishmaniasis endemic locality (chi-square test, p<0.001). Cross-reactivity was assessed in 166 samples from patients with other diseases with positivity of 13.9%. Of note, a considerable number of rLb6H-ELISA positive samples were previously considered negative in different diagnostic tests: 25% in the parasitological exam, 40% in culture, 20% in immunohistochemistry, 10% in PCR, 60% in *L. major*-like indirect immunofluorescence assay and 20% in *L. major*-like-ELISA. Based on the good diagnostic performance and the reproducibility and stability of the antigen, we suggest using ELISA-rLb6H for ATL diagnosis.

0483

DEVELOPMENT OF CDC-LIKE ASSAYS FOR HIGH THROUGHPUT SCREENING OF NOVEL CLK1 INHIBITORS

Debjani Patra

Novartis Institute for Biomedical Research (NIBR) Novartis, Emeryville, CA, United States

Chagas disease is caused by a kinetoplastid parasite *Trypanosoma cruzi*, affecting 6-7 million people worldwide. Current drugs used to treat Chagas disease suffer from poor safety and suboptimal efficacy. There is a need to find novel inhibitors that are safe and efficacious. Protein kinases are promising targets for the therapeutic intervention. We had shown that CDC-like kinase (CLK1) inhibition by amido-benzimidazoles efficiently killed all kinetoplastid parasites, thereby chemically validating the target. The current study focuses on characterizing a unique CLK1 enzyme from *T. cruzi* and development of biochemical assay amenable for high throughput screening to identify novel CLK1 inhibitors. Kinetoplastid CLK1 is a part of kinetochore complex essential for chromosome segregation as well as cell division whilst, the human CLK1 plays a vital role in phosphorylating serine arginine-rich proteins and proteins involved in pre-mRNA processing. We successfully expressed *T. cruzi* CLK1 and characterized the Km concentrations for ATP, substrate and buffer conditions, thereby developing a robust, reproducible biochemical assay. We also expressed human CLK1 enzyme and characterized the enzyme, in order to use as a counter screen. Standard kinase inhibitor staurosporine and AB1, known CLK1 inhibitors were used as positive control, thereby helping in developing robust 1536 well assay with signal to noise window of >10. Both enzymes tolerate DMSO upto 5%. The final screening TcCLK1 assay used 0.2 nM of TcCLK1 enzyme, 0.3 μM RS peptide substrate, and 4 μM of ATP; and the hCLK1 assay uses 2 nM of hCLK1 enzyme, 0.3 μM RS peptide substrate, and 10 μM of ATP. These assays are ready to be used for screening for novel TcCLK1 selective inhibitors.

0484

TRICHOMONAS VAGINALIS ISOLATES FROM SYMPTOMATIC WOMEN IN EGYPT: GENOTYPIC ANALYSIS AND METRONIDAZOLE SUSCEPTIBILITY

Dina S. Nasr[1], Shadia H. Omar[1], Abdalla Y. El-Kateb[2], **Ayman A. Elbadry**[3], Marwa A. Hassan[4]

[1]Department of Medical Parasitology, Faculty of Medicine, Cairo University, Cairo, Egypt, Cairo, Egypt, [2]Department of Obstetrics and Gynecology, Faculty of Medicine, Cairo University, Cairo, Egypt, Cairo, Egypt, [3]Department of Microbiology, College of Medicine, Imam Abdulrahman Bin Faisal University, Damam, Saudi Arabia, Dammam, Saudi Arabia, [4]Department of Microbiology, College of Medicine, Imam Abdulrahman Bin Faisal University, Damam, Saudi Arabia, Cairo, Egypt

Trichomonas vaginalis (*T.V*) is the most common curable non-viral sexually transmitted pathogen in Egypt & worldwide.Vaginal swabs were collected from 150 symptomatic Egyptian women attending Obstetrics & Gynaecology outpatient clinics of Kasr Al-Ainy hospitals for 8 months duration. Vaginal swabs were cultured & nPCR- RFLP was done for molecular genotypic analysis. Positive-PCR samples were further in-vitro treated by metronidazole & their phenotypic changes were observed using Transmission Electron Microscopy (TEM) to assess the susceptibility of isolated *T.V*. *T.V* was detected in 18% by Culture method which is the gold standard. Trichomoniasis was highest in sexually active women (>28 years old) & those using contraceptive methods, especially IUD. Genotype (H) was the only genotype detected using nPCR- RFLP & the phenotypic changes indicated that this genotype (H) is sensitive to metronidazole drug.

0485

PLASMODIUM FALCIPARUM PARASITE PREVALENCE DIFFERS BY TYPE OF DOMESTICATED ANIMAL OWNED BY HOUSEHOLDS IN DEMOCRATIC REPUBLIC OF CONGO

Camille E. Morgan[1], Katerina Brandt[1], Hillary Topazian[2], Cedar Mitchell[1], Kashamuka Mwandagalirwa[3], Thierry Bobanga[4], Antoinette Tshefu[3], Michael Emch[1], Jonathan Parr[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Imperial College London, London, United Kingdom, [3]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [4]Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo

Household domesticated animal ownership is an understudied aspect of the human environment that influences mosquito biting behavior and malaria transmission. The few existing studies have widely varying results, likely due to context-specific mosquito preferences, animal husbandry, and other factors. To evaluate the effect of domesticated animal ownership on malaria prevalence in a high burden setting, we used data and samples from a large, nationally representative Demographic and Health Survey (DHS) conducted in 2013-14 in Democratic Republic of Congo (DRC), where the anthrophilic *Anopheles gambiae* vector predominates and 12% of the world's malaria cases occur. Quantitative PCR (qPCR) targeting the *Plasmodium falciparum* lactate dehydrogenase gene (*pfldh*) was previously performed using DNA extracted from dried blood spot samples. We used generalized estimating equations to account for clustered data structure, adjusted for age, sex, modern housing, treated bed net use, wealth, and rurality, and applied sampling weights to calculate population-level estimates. Among 16,787 participants with *pfldh* qPCR results and domesticated animal ownership data, weighted *P. falciparum* PCR prevalence was 31% (95% CI 29-33%). Chickens were the most common animal owned (42% of participants, 95% CI: 39-44%), followed by goats (20%, 95% CI: 18-22%) and cattle (2.0%, 95% CI: 1.4-3.0%). We observed stark differences in malaria prevalence across types of animals owned by households in both crude and adjusted models. Household chicken ownership was associated with 3.7 (0.5, 6.9) more *P. falciparum* infections per 100 people in the adjusted model, while cattle ownership was associated with 9.6 (-15.8, -3.5) fewer infections per 100 and goat ownership did not result in a difference in infections, when compared to individuals from households without each animal. These findings demonstrate animal-specific malaria risk that may be amenable to intervention in DRC and other high burden countries, and require studies of animal husbandry practices and associated mosquito behaviors to inform future One Health malaria interventions.

0486

SPATIAL DISTRIBUTION AND RISK FACTORS ASSOCIATED TO CASES OF HUMAN LEPTOSPIROSIS IN CORDOBA DEPARTMENT, COLOMBIA

Virginia C. Rodríguez, Alfonso Calderón, Ana M. Castro, Eidy Martinez

Universidad de Córdoba, Monteria, Colombia

Leptospirosis, caused by a spirochaete from the genus *Leptospira* is a neglected zoonosis with high incidence in tropical and subtropical regions. Patients with clinical suspicion of leptospirosis attending Healthcare institutions from the department of Cordoba during from January 2016 to March 2021 were included. Cases were confirmed by PCR and Microagglutination (MAT). Univariate and multivariate information analysis were used to establish the association between leptospira cases and risk factors. Bernoulli model and Kulldorff technique were used for the detection of spatial conglomerates with SaTScan™ v9.4. A total of 339 patients (220 men and 119 women) suspected of human leptospirosis were part of the study; 19.2% of suspicious cases were confirmed as leptospirosis. Serological reactivity to serogroups utilized in MAT showed a spatial distribution not geographically concentrated, with the following showing the highest reactivity: Australis 38.5%, Grippotyphosa 37%, Sejroe 29%, Autumnalis 23% y Pyrogenes 21.5%. pig or equine cattle and floods 30 days before symptom onset represented a 2-fold higher risk of contributing to illness presentation ($p<0.05$, IC:95%). Patients referring to having bathed in lakes/lagoons increases 4-fold the risk of acquiring leptospirosis when compared to a those who did not practice this activity ($p<0.05$, IC: 95%). Median temperature (28°C) was statistically significant for the risk of acquiring leptospirosis. Four high illness rate clusters were identified, one of them was statistically significant ($p=0.023$), having a centroid in the coordinate 8.389397 N, -75.434916 W corresponding to Center, Medio Sinu, savannah, San Jorge and Alto Sinu subregions. Leptospirosis in the department of Cordoba is endemic and dispersed in urban and rural areas. The environment in which population develops has characteristics that act as coadjuvants in the presentation of leptospirosis.

0487

PREVALENCE OF ANTIBODIES TO *TOXOPLASMA GONDII* IN FELINES IN FAMILY LIFE THE CITY OF MONTERIA. DEPARTMENT OF CÓRDOBA-COLOMBIA

Linda M. Chams, María F. Yasnot, Carlos J. Castro, Alberto S. Mestra, Ena L. Torres

Grupo de Investigaciones Microbiológicas y Biomédicas de Córdoba (GIMBIC)-Universidad de Córdoba, Monteria, Colombia

120 serological tests were performed on felines living with families in 15 neighborhoods of the city of Montería, Córdoba-Colombia with the objective of determining the presence of reactors for *Toxoplasma gondii* through the Indirect Hemagglutination technique (IHA). The animals were chosen at random in the different neighborhoods and their owners provided information regarding age, sex and origin; they were bled adequately, obtaining the sample that was processed in the Clinical Laboratory of the Hospital San Jerónimo de Montería. The serological study revealed 87.5% seropositivity with titers ranging between 1:160 and 1:10240. Of the 105 samples positive to the serological reaction, 2 (1.9%) presented low titers, 11 (10.5%) intermediate titers, and 92 (87.6%) high titers. The relationship between serology and the sex variable determined similar prevalences of 49.5% and 50.5% for females and males, respectively, with a predominance of titers equal to or greater than 1:1280 in both sexes. According to age groups, serology showed values equivalent to: Animals <3 years old 75 (84.4%), 3-6 years old 17 (94.11%), 6-9 years old 5 (100%) and > 9 years old 8 (100%). Statistical analysis using the Chi Square test indicated significant differences between the serological dilutions, with the presence of intermediate and high titers being observed in a greater proportion. The serology found did not show significance with respect to age, but highlights high titers at all ages and especially the tendency of overreaction in older animals. The observed overreaction demonstrates the dynamics of toxoplasmosis as a zoonotic disease given by coexistence with this animal species.

0488

PRELIMINARY STUDY OF VISCERAL LEISHMANIASIS IN CANINES IN FAMILY COEXISTENCE IN THE MUNICIPALITY OF SHEEP-SUCRE, COLOMBIA

Linda M. Chams, María F. Yasnot, Carlos J. Castro, Alberto S. Mestra, Lisy Gracia

Grupo de Investigaciones Microbiológicas y Biomédicas de Córdoba (GIMBIC)-Universidad de Córdoba, Monteria, Colombia

Serological tests and direct tests were carried out on canines in family life in the village of "La Europa" in the municipality of Ovejas, department of Sucre-Colombia, with the objective of determining the presence of fluorescent antibodies for canine Visceral Leishmaniasis, by means of the Indirect Immunofluorescence technique. and presence of the parasite by taking a biopsy through hepatic and lymph node puncture. Blood samples were taken from the study animals for serological study and liver and lymph node puncture samples to determine the presence of the parasite. The 52 animals examined constituted the total population of existing canines in the dwellings of the study area. The owners of the animals

reported the data of their animals related to age, sex and time spent in the home, clinical signs, relationships with people and with other animals. The Indirect Immunofluorescence study revealed 3.84% the presence of fluorescent antibodies for canine Visceral Leishmaniasis, with titers ranging between 1:20 and 1:40. The study of the samples obtained by liver and lymph node puncture for direct diagnosis indicated that all the animals were negative. The investigation evidences the predisposing factors that favor the presentation of leishmaniasis in the studied area. The coexistence of families with canines and felines inside and outside the house and the existence of animals with advanced ages that could behave as reservoirs for the transmission of the parasite were observed. Although no significant differences were found when relating the study area with the serology found, it is necessary to carry out educational dynamics that make known the problem of Leishmaniasis and how to keep animals to avoid the transmission of parasites and consequently suffer from the disease.

0489

A ONE HEALTH PERSPECTIVE ON THE RESURGENCE OF FLEA-BORNE TYPHUS IN TEXAS IN THE NEW MILLENNIUM

Gregory M. Anstead

South Texas Veterans Healthcare System, San Antonio, TX, United States

Flea-borne typhus (FBT) is an infection caused by *Rickettsia typhi* and *R. felis* The infection is transmitted to humans by a flea bite or by the inoculation of a bite site, a skin abrasion, or mucous membranes with feces from an infected flea. In this paper, county-level epidemiological data from Texas for two decades, 1990-1999 and 2010-2019, were compared. From 1990-1999, there was an average of 30.7 cases/yr from 26 TX counties, whereas during 2010-2019 there was an average of 375 cases/yr from 91 counties; 90.5% of the recent cases occurred in urban counties. The six highest counties during 2010 to 2019 were Hidalgo (major city McAllen) > Nueces (Corpus Christi) > Cameron (Brownsville) > Bexar (San Antonio) > Harris (Houston) > Travis (Austin); these 6 counties had 2824 cases (75% of the total). Compared to 1990-1999, cases increased in Hidalgo, Nueces, Cameron, Harris, and Bexar Counties in 2010-2019 by 8.5-, 5.0-, 17.5-, 252-, and 211-fold, respectively. (Travis County had zero cases in 1990-1999). Texas is divided into 10 climate divisions. In 2010-2019, the four cooler northern set of climate divisions had only 6.1% of the total cases. FBT cases are focused in the warmer Post-Oak Savannah and Lower Rio Grande Valley divisions (39.1 and 36.4% of the cases, respectively). A One Health model is presented to explain the increase of cases of FBT in TX in the last decade. Population growth in TX has resulted in an increase in pet dogs and cats and strays. The urban/suburban environment has also promoted opossum population growth, due to greater food availability. Increasing temperatures in TX may affect various aspects of the cat flea lifecycle, including: flea infestation rates of cats, dogs, and opossums; feeding and mating frequency; and reducing the time to complete the lifecycle. Rickettsial replication within the cat flea is also increased by higher temperatures, increasing the concentration of infectious rickettsiae in the flea feces. Increased numbers of flea-infested opossums and stray cats and dogs in the urban/suburban landscape increases the risk of flea transfer to pets and to humans.

0490

MOLECULAR DIAGNOSIS OF INTESTINAL PROTOZOA IN YOUNG ADULTS AND DOMESTIC ANIMALS FROM CALI, COLOMBIA

Maria del Pilar Crespo-Ortiz, Caterine Potes-Morales

Universidad del Valle, Cali, Colombia

Intestinal parasitic infections have been considered a relevant public health problem due to an increase of the incidence worldwide. In developing countries, diarrhea and gastrointestinal symptoms cause impaired work capacity in adults and delayed rate growth in children. Enteric infections of unknown etiology can often lead to misdiagnosis, increased transmission, and morbidity. The aim of this study was to determine the prevalence of intestinal parasites in a young adult population and their pets. Stool samples from 139 university students and 44 companion animals were subjected to microscopy diagnosis using wet mounts, concentration by zinc sulphate flotation and permanent stains (Ziehl -Neelsen and trichromic smears). Molecular diagnosis of protozoa was also performed by conventional PCR. The mean age was 24 yo, 54% individuals were female, 46% were men, and 66% had at least one pet. The overall prevalence for at least one parasite was 72.7% and 27.3 % showed polyparasitism. Sixty-three patients (45.3%) were positive for microscopy and parasite rates were: *Blastocystis* sp 33%, *Endolimax nana* 15.1%, *Entamoeba histolytica/dispar/moshkovskii* complex 5% and *Giardia intestinalis* 1,4%. *Cryptosporidium* and *Dientamoeba fragilis* were not detected. Eighty-one (58.3%) patients were positive for PCR: *Blastocystis* sp, 43.1% and *Cryptosporidium* sp. 24,5%. Samples from 27 dogs, 15 cats, one rabbit and one hen were examined, and parasites were detected in 7(16%) as follows: *Giardia intestinalis* (4), hookworm (3), *Endolimax nana*(2) and *Toxoplasma* (1). Preliminary molecular analysis showed that 9 out of 10 pets from *Cryptosporidium* positive owners were also positive for PCR. Overall, university students showed high prevalence of parasitism and polyparasitism suggesting exposure to contaminated environments. *Cryptosporidium* was the predominant pathogen which was only detected by PCR in humans and domestic animals, pointing out the need for sensitive diagnosis tests in surveillance. Control strategies to prevent the effects of parasitic infections in young population should consider pets as reservoirs and transmission source.

0491

SNAKEBITE IN TANZANIA - NOW WHAT?

Katharina Sophia Kreppel[1], Monica Francis[2], John-Mary Vianney[2], Kathrin Heitz-Tokpa[3]

[1]Institute of Tropical Medicine, Antwerp, Antwerp, Belgium, [2]Nelson Mandela African Institution of Science and Technology, Arusha, United Republic of Tanzania, [3]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan,, Côte D'Ivoire

The risk of getting bitten by a venomous snake is an everyday reality for many communities in sub-Saharan Africa. Nevertheless, the problem remains a neglected tropical disease, despite causing death or permanent disability to an estimated 500 000 people annually, worldwide. Pastoralists and agro-pastoralists in northern Tanzania are at a particularly high risk from snakebite, but information on risk factors and challenges of receiving and providing treatment still remains very limited. To find out about risk factors, health seeking behavior and challenges, we visited the local "Maasai" and "Maarusha" groups in two affected districts in Tanzania, and interviewed 101 snakebite victims or their guardians. We also looked at 12 years of case records of 1386 patients admitted to the local Meserani Snakebite Clinic to learn more about bite and patient characteristics and spoke to health professionals from 3 health centers in the most affected districts. Among the main findings were significant demographic characteristics exposing individuals to a higher risk of snake bite. Adults and males for example were bitten more often and working outside significantly increased the risk. The majority of victims received traditional treatment (52.7%), partly due to difficulties to reach formal healthcare services and over-reliance on traditional treatments. Victims and their families reported challenges of accessing any kind of medical care in a timely manner and long lasting effects such as pain and difficulties moving as consequence of a bite. Only one of the 3 health centers in the 26 347km2 area, the Meserani Snake Park Clinic, had antivenom available and, apart from 1 nurse at the district hospital, had training in snakebite treatment. At the district hospital and dispensary, patients were therefore usually referred to the Meserani Snake Park clinic. Our results present crucial information on the present situation. To reduce and eliminate deaths and disability from snakebite, research in Tanzania has to be expanded to enable researchers, the government, clinicians and the public to work together and join the global snakebite initiative.

EXPOSURE TO INDUSTRIAL HOG AND POULTRY PRODUCTION AND URINARY TRACT INFECTIONS IN NORTH CAROLINA, USA

David A. Holcomb, Arbor J.L. Quist, Lawrence S. Engel

University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

An increasing share of urinary tract infections (UTIs) are caused by extraintestinal pathogenic *Escherichia coli* (ExPEC) lineages that have also been identified in poultry and hogs with high genetic similarity to human clinical isolates. We investigated industrial food animal production as a potential source of community uropathogen transmission by examining relationships of hog and poultry density with emergency department (ED) visits for UTIs in North Carolina (NC). ED visits for UTI in 2016-2019 were identified by ICD-10 code from NC›s ZIP code-level syndromic surveillance system and livestock counts were obtained from permit data and aerial imagery. We calculated separate hog and poultry spatial densities (animals/km^2) by census block with a 5km buffer on the block perimeter and weighted by block population to estimate mean ZIP code densities. Associations between livestock density and UTI incidence were estimated using a reparametrized Besag-York-Mollié (BYM2) model with Poisson likelihood and ZIP code population offset to account for spatial autocorrelation. We excluded metropolitan and offshore ZIP codes and assessed effect measure modification by calendar year, ZIP code rurality, and patient sex, age, race/ethnicity, and health insurance status. In single-animal models, hog exposure was associated with increased UTI incidence (rate ratio [RR]: 1.21, 95% CI: 1.07-1.37 in the highest hog-density tertile) but poultry exposure was associated with reduced UTI rates (RR: 0.86, 95% CI: 0.81-0.91). Increases in UTI incidence were most strongly associated with exposure to hogs alone (in the absence of poultry), while poultry-only exposure was largely unassociated with UTIs. Low-density poultry exposures attenuated relationships between hogs and UTIs, but UTI rates remained elevated in ZIP codes with large numbers of both hogs and poultry (RR: 1.28, 95% CI: 1.10, 1.48). While relationships with low-density poultry are ambiguous and warrant further analysis using individual-level exposure and outcome data, high-intensity industrial livestock production may contribute to increased UTI incidence in neighboring communities.

0493

LONG-TERM STABILITY OF ORTHOBUNYAVIRUSES IN SERA AND WHOLE BLOOD

Erik A. Turner, Rebecca C. Christofferson

Louisiana State University, Baton Rouge, LA, United States

Orthobunyaviruses represent an understudied group of viruses with potential to cause human and animal health, as well as economic issues. In 2018, we identified Bunyamwera (BUNV) in samples from cattle in Rwanda suspected of having Rift Valley Fever virus (RVFV) and found evidence suggestive of Batai (BATV) infection in another animal. This provided evidence of alternative etiologies for disease assumed to be RVFV in cattle in Rwanda, and suggests more basic research into these viruses is warranted. Previously we showed BUNV and BATV are stable and infectious at 37°C in cell culture media for up to 30 days. In this follow-up, we established a daily Rwandan temperature profile representative of peak transmission season (May-July) from public data (min: 16.2°C, median: 19.98°C, max:24.9°C). Using this temperature profile, we investigated the stability and infectiousness of BUNV and BATV in bovine whole blood and serum up to 28 days (sampled weekly). In both substrates, stability was observed as a lack of change in RNA copies from 7 dpi to 28 dpi. When infectiousness was assessed *in vitro,* both viruses retained infectivity at 28 dpi in whole blood (5/5 BUNV samples, 4/5 samples). In serum, only BATV retained infectivity at 28 days, but only in 1/5 samples, likely an indication of a low number of viable virus particles. At 14 and 21 dpi, 5/5 and 3/5 samples were infectious, respectively. For BUNV, no samples were infectious at 21 or 28 dpi while at 14 dpi all samples (5/5) were infectious. These results do provide evidence that these viruses retain infectiousness for relatively long periods of time, and that there is an interaction between types of fluids and Orthobunyavirus with respect to retention of infectiousness over time. This has implications for biosafety and laboratory practices, and potential field-relevance to encourage increased use in PPE when handling animals and animal fluids in laboratory or food-animal processing contexts.

0494

CHARACTERISTICS OF SNAKEBITE IN TANZANIA AND TREATMENT CHALLENGES

Monica Francis[1], Katharina Kreppel[2], John-Mary Vianney[1], Kathrin Heitz-Tokpa[1]

[1]NM-AIST, Arusha, United Republic of Tanzania, [2]ITM, Antwerp, Belgium

Continuous occurrence of snakebite incidences and vulnerability of some communities remain a critical problem in sub-Saharan Africa. Despite causing death and permanent disability to almost half a million people annually, information on snakebites and treatment challenges is still very limited, particularly in Northern Tanzania. We accessed case reports from 1386 patients visiting the Meserani Snake Park clinic in Northern Tanzania between 2007 and 2019 and studied the characteristics of snakebite. Additionally, we talked to health professionals from 3 health centers serving the local communities, to learn more about treatment challenges for snakebite. From the case studies and interviews we learnt that snakebite is common in the area. Victims reported several challenges to receiving treatment such as cost, distance to the clinic, availability of expertise and most of all, availability of antivenom. Records show an increase in the number of victims over the years, with adults significantly more affected than children. The majority of snakebites (41%) occurred on the lower limbs; whereby hands accounted for 23% of the all injuries reported. The snake responsible for the bite could not always be identified, but red spitting cobra, black spitting cobra and puff adder were recorded most often. The main treatment challenge was the fact that antivenom in the region was only available at the privately run Meserani Snake Park Clinic, but even with available antivenom, allergic reactions to the antivenom and delayed arrival at the clinic were serious challenges affecting the overall outcome. Of the 13 health professionals interviewed, only 4 had received any training in the treatment of snakebite. Notably, in the local Monduli hospital, while overall more medical expertise is present, knowledge on snakebite treatment is low while at the Meserani Snakebite Clinic, 2 out of the 3 health care workers also trained the community on snakebite prevention and treatment. The results of this study present crucial information on snake bite characteristics in Northern Tanzania and what is needed to improve the accessibility to appropriate treatment.

0495

PRESENCE OF ZOONOTIC PARASITES IN CANINE FECAL MATERIAL COLLECTED FROM THE ENVIRONMENT IN INGHAM COUNTY, MICHIGAN, USA

Mohamed Zeyada Satti, Kurtz Kamryn

Michigan State University, East Lansing, MI, United States

Ingham County, Michigan has numerouspublic parks and dog parks that allow pet owners to spend time with their canine companions, increasing physical activity levels and therefore benefiting the overall health. However, canine fecal material left behind in these environments may pose a serious hazard to human health due to the possibility of the presence of zoonotic gastrointestinal parasites and other pathogens. This study aimed to assess environmental contamination with parasitic agents of public health importance due to canine fecal material left behind at multiple public parks and dog parks within Ingham County in the State of Michigan, USA. A total of 111 canine fecal samples were collected from seven randomly selected park locations. Zoonotic gastrointestinal parasites were detected in 42.34% of the samples using qualitative zinc sulfate fecal flotation. These parasites included: *Giardia* spp. (25.23), *Ancylostoma caninum* (17.12%), *Isospora* spp. (9.91%), *Trichuris vulpis* (1.8%), and *Toxascaris leonina* (0.9%).

0496

MICROBIAL SOURCE TRACKING OF HUMAN AND ANIMAL FECAL CONTAMINATION IN HOUSEHOLD SETTINGS IN NORTHERN ECUADOR TO INFORM EXPOSURE ASSESSMENT

Kelsey Jesser[1], Viviana Alban[2], Javier Gallard-Gongora[3], Aldo Lobos[3], Valerie J. Harwood[3], Karen Levy[1]

[1]University of Washington, Seattle, WA, United States, [2]Universidad San Francisco de Quito, Quito, Ecuador, [3]University of South Florida, Tampa, FL, United States

Human exposures to animals and their feces pose health risks, particularly for children in settings where domestic animals are common, hygiene is poor, and enteropathogen transmission is high. To improve understanding of potential sources of fecal contamination in households (HHs), we validated qPCR assays for and measured microbial source tracking (MST) markers in samples collected from 59 HHs along an urban-rural gradient in northern Ecuador. We used the GenBac marker to test for general fecal contamination, and the markers HF183, Rum2Bac, Pig2Bac, DG, and GFD to test for human, ruminant, swine, dog, and avian-associated fecal contamination, respectively. We collected ~10 samples per HH, including rinses of child (*n*=31) and adult (*n*=59) hands, swabs of objects and surfaces (*n*=282), soil (*n*=54), domestic (*n*=48) and drinking (*n*=55) water, and food (*n*=58). Data from hand rinses, domestic and drinking water, and floor swabs have been processed to date. GenBac was detected in 88% and HF183 in 27% of currently processed samples, with mean $\log_{10}$ gene copies (GC) per sample of 5.6 for GenBac and 3.1 for HF183. Hand rinses had the highest mean concentrations of both GenBac and HF183, followed by floor swabs and domestic water. GenBac was the only marker frequently detected in drinking water, with 2.8 mean $\log_{10}$ GC per 100 mL. Rum2Bac Pig2Bac, DG37, and GFD were detected in 0.80%, 3.2%, 7.1%, and 8.3 % of samples analyzed to date and had $\log_{10}$ concentrations of 2.5, 3.1, 2.4, and 2.6 GC per sample, respectively. Pig2Bac was detected in a single drinking water sample at low concentration. These preliminary results indicate that general (GenBac) and human (HF183) fecal contamination is common in study HHs. Detection of animal-associated MST markers was less frequent, but animal markers were present at relatively high concentrations when detected. This work demonstrates that MST can be used to characterize sources of HH fecal contamination, and will inform a larger analysis of child exposure to animal-sourced HH fecal contamination that incorporates both microbiological and qualitative data to offer insights into animal-associated enteric disease risk.

EVALUATION OF A RECOMBINANT ANTIGEN ELISA FOR DETECTION OF *TRYPANOSOMA CRUZI* IN DOGS

Rojelio Mejia[1], Guilherme G. Verocai[2], Rachel Busselman[2], Ilana Mosley[2], Bin Zhan[1], Maria E. Bottazzi[1], Peter Hotez[1], Sarah A. Hamer[2]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Texas A&M University, College Station, TX, United States

Chagas disease, or American trypanosomiasis, is an infectious tropical disease caused by the protozoan parasite, *Trypanosoma cruzi* (*T. cruzi*). It is endemic to 21 countries across Latin America and the southern United States. The diagnosis of chronic infection in humans relies solely on serological tests based on laboratory assays, such as two immunochromatographic strips (SP and IB), indirect fluorescent antibody (IFA), and enzyme-linked immunosorbent assay (ELISA) tests. However, existing serological tests for Chagas disease are prone to inconclusive or false-positive results and poor concordance among different assay formats. For this reason, current recommendations include using at least two different serological techniques, one being ELISA, for diagnosing chronic Chagas disease in humans. These challenges exist in both human and canine testing. Dogs are a known *T. cruzi* reservoir and host for the triatomine vector. Our study examined over 70 dog serums from multi-dog kennel environments in Texas, selected based on prior test results, to compare three available Chagas tests to our Tc-24 recombinant antigen ELISA. The immunochromatographic tests were subjectively graded by visualization. The IFA and Tc-24 ELISA produce a quantitative result. Comparing individual tests to Tc-24 ELISA resulted in SP strips having an association to Tc-24 ($p < 0.001$) and Spearman correlation = 1.0 ($p = 0.0167$). The IB strips compared to Tc-24 also showed an association to Tc-24 ($p = 0.0001$) and Spearman correlation = 0.9 ($p = 0.0833$). There was an association of IFA to Tc-24 ($p < 0.0001$) and Spearman correlation = 0.6273 ($p = 0.044$). Comparing any two positive tests to the Tc-24 ELISA showed an association of determining positive versus negative results ($p < 0.0001$) with an 82.5% sensitivity and 89.7% specificity. Comparing high IFA titers to positive Tc-24 resulted in a 100% sensitivity and 94.1% specificity. Similarly, comparing high immunochromatographic values to positive Tc-24 revealed a 100% sensitivity and 95.8% specificity. These results provide a potential new serological assay to diagnose *T. cruzi* infection in dogs with one test.

0498

ZOONOTIC AGENTS AT THE ANIMAL-HUMAN CONTEXTS GENERATED BY THE PRIMATE TRAFFICKING IN PERU

A. Patricia Mendoza[1], Ana Muñoz-Maceda[2], Bruno M. Ghersi[3], Micaela De La Puente[4], Carlos Zariquiey[5], Patricia G. Parker[1], Alberto Perez[6], Marcela Uhart[7], Sarah Olson[8], Marieke H. Rosenbaum[3]

[1]University of Missouri - St. Louis, St Louis, MO, United States, [2]University of Kent, Canterbury, United Kingdom, [3]University of Tufts, North Grafton, MA, United States, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Wildlife Conservation Society, Lima, Peru, [6]Servicio Nacional de Sanidad y Calidad Agroalimentaria, Buenos Aires, Argentina, [7]University of California, Davis, One Health Institute, Davis, CA, United States, [8]Wildlife Conservation Society, Health Program, New York, NY, United States

Wildlife trafficking creates favorable scenarios for intra- and inter-specific interactions that can lead to pathogen spread and disease emergence. Among the diverse species affected by this illegal activity, monkeys gain attention for their potential to acquire and share zoonoses. Though it is known that most primate pathogens can affect multiple hosts and many of them are zoonotic, comparative studies of primate infections across different contexts for animal-human interactions are scarce. We conducted a multi-pathogen screening targeting the detection of zoonotic infections in wild-caught primates in nine Peruvian cities across three contexts: Trafficked or recently confiscated, n=132; pets, n=69; zoos and rescue centers, n=187. We detected 32 infectious agents including helminths, protozoa, bacteria, mycobacteria, and simian foamyvirus. Pathogen communities showed overall low variation between contexts. However, trafficked and confiscated monkeys had the highest prevalence of hemoparasites (including *Plasmodium malariae/brasilianum, Trypanosoma cruzi,* and microfilaria), and enteric parasites were less common in pet monkeys. Pathogen species richness (PSR) was best explained by host genus and the city where the animal was sampled. Squirrel (genus Saimiri) and wooly (genus Lagothrix) monkeys had the highest PSR, which was ~2.2 times the PSR found in tufted capuchins (genus Sapajus) and tamarins (genus Saguinus/Leontocebus) in a multivariable model adjusted for context, sex, and age. Our findings illustrate that the threats of primate trafficking to One Health encompass multiple zoonotic infections well-known to cause disease in human, monkeys, and other species. We demonstrate these threats continue beyond the markets where these animals are initially sold; primates trafficked for the pet market remain a reservoir for and translocator of zoonotic pathogens in households and other captive facilities where contact with humans is frequent. Our results inform practical applications for the healthcare of rescued monkeys and call for urgent action against wildlife trafficking and ownership of monkeys as pets.

0499

IMPACT OF THE INTRODUCTION OF PCV7/13 ON ANTIMICROBIAL RESISTANCE IN INVASIVE PNEUMOCOCCAL DISEASE IN SENEGAL

Ebrima Bah

Ministry of health and social welfare, banjul, Gambia

We describe antimicrobial resistance in invasive pneumococcal due to all serotypes and non-vaccine type (NVT) pre andpost pneumococcal conjugate vaccine (PVT) implementation in Senegal in all age groups. We identify, serotype, andperformed antimicrobial susceptibility testing using disc diffusion methods on pneumococcal isolates obtained frominvasive samples collected from standardized population-based pneumococcal disease surveillance in the Casamance &demographic surveillance system. The study commenced May 2012. Pcv7 was introduced in august 2013 and pvc13 in May2016. Antibiotic susceptible were interpreted using clinical laboratory standard institute guidelines. 500 pneumococcalisolates were screened against five antimicrobial agents. There was a moderate decline in antibiotic resistance in all agegroups in invasive pneumococcal disease during vaccine implementation. In the 2 months to 2-year age group, annualcounts of oxacillin. Chloramphenicol, and tetracycline resistant cases fell from 10-15 in 2013 & 2014 to 6-7in 2017 & 2018. In the 24-59-month age group, there was a large fell in tetracycline resistance cases.in those >5 years, oxacillin,chloramphenicol, and tetracycline resistance fell to zero cases in 2015 & 2016. Resistance due to reductions in vaccine serotypes1, 5,14 & 23f. The proportion of resistant NVT cases increase over time, particularly in the 2-23-month age group,with tetracycline resistance mainly in serotypes 10A, 12F, 11B, 7C and 25A & tetracycline resistance in serotype12F in 2016.Isolates were generally sensitive to erythromycin but 95-98 were generally sensitive to cotrimoxazole throughout the study.Although there is an overall reduction in case of antimicrobial resistance IPD, resistance is emerging in NVT. We hypothesisthat increased transmission of NVT after the introduction of PCV and exposure to antimicrobials facilitates the emergence ofresistance in NVT. Ongoing surveillance is important to determine future trends in resistance as it has both clinical andpublic health importance in PCV era.

PERCOLATION ACROSS HOUSEHOLDS IN MECHANISTIC MODELS OF NON-PHARMACEUTICAL INTERVENTIONS IN SARS-COV-2 DISEASE DYNAMICS

Caroline Franco

University of Oxford, Oxford, United Kingdom

Since the emergence of the novel coronavirus disease, mathematical modelling has become an important tool for planning strategies to control the pandemic by supporting decision-making, as well as allowing an assessment of the effect of different intervention scenarios. A proliferation of compartmental models was observed in the mathematical modelling community, aiming to understand and make predictions regarding the spread of COVID-19. Such an approach has its own advantages and challenges: while compartmental models are suitable to simulate large populations, the underlying well-mixed population assumption might be problematic when considering non-pharmaceutical interventions (NPIs) which strongly affect the connectivity between individuals in the population. Here we propose a correction to an extended age-structured SEIR framework with dynamic transmission modelled using contact matrices for different settings in Brazil. By assuming that the mitigation strategies for COVID-19 affect the connections between different households, network percolation theory predicts that the connectivity across all households decreases drastically above a certain threshold of removed connections. We incorporated this emergent effect at population level by modulating the home contact matrices through a percolation correction function, with the few remaining parameters fitted to hospitalisation and mortality data from the city of Sao Paulo. We have shown how different model implementations can affect the system's basic reproduction number and found significant support for the model with implemented percolation effects using the Akaike Information Criteria (AIC). Besides better agreement to data, this improvement also allows for a more reliable assessment of the impact of NPIs on the epidemiological dynamics and can be applied to model any infectious disease dynamics undergoing a similar contact network fragmentation process.

0501

ESTABLISHING SARS COV-2 VIRAL SEQUENCING CAPACITY IN A RESOURCE-LIMITED, HIGH-RISK AREA IN THE PERUVIAN AMAZON REGION. PRELIMINARY RESULTS

Tackeshy Pinedo-Vásquez[1], Paul García-Bardales[1], Wagner Valentino Shapiama-Lopez[1], Greisi Curico-Huanci[1], Pablo Peñataro-Yori[2], Maribel Paredes-Olortegui[1], Graciela Meza-Sánchez[3], Hermann Silva-Delgado[3], Kerry Cooper[4], Craig Parker[5], Carlos Calampa-Del Águila[3], Brucee Jiu-Marinho[6], Richard Oberhelman[7], Margaret Kosek[2]

[1]Asociacion Benefica PRISMA, Iquitos, Peru, [2]University of Virginia, Charlottesville, VA, United States, [3]Univiersidad Nacional de la Amazonía Peruana, Iquitos, Peru, [4]University of Arizona, Tucson, AZ, United States, [5]United States Department of Agriculture, Washigton, DC, United States, [6]Dirección de Salud de Loreto, Iquitos, Peru, [7]Tulane University, New Orleans, LA, United States

Peru has recorded some of the highest rates of morbidity and mortality from COVID-19 in the world. The city of Iquitos in the Peruvian Amazon region has been particularly vulnerable due to its isolation, with accessibility by air and river only; its limited clinical facilities; its severe oxygen shortages; and its river commerce with other Amazonian hot spots in Brazil, leading to attack rates and mortality figures well above the Peruvian national average. Robust surveillance to detect new COVID-19 variants is critical to identify epidemiological shifts and direct public health resources, but strain sequencing capacity has only been available at a few sites in the capital city of Lima, with limited capacity for analyzing strains from any one region and delays in providing results. With funding from the NIH Fogarty Global Infectious Diseases training program and the CDC Conducting Public Health Research in South America program, and in collaboration with the public health reference laboratory of the regional Ministry of Health (DIRESA de Loreto), the Laboratorio Iquitos has established COVID-19 sequencing capacity in Iquitos and trained a core group of biologists in genetic sequencing. Viral sequencing was performed using Illumina COVIDSeq kit with an Illumina iSEQ 100, and sequence data was uploaded to databases housed by the National Center for Biotechnology Innovation (NCBI) and GISAID. We have sequenced viral isolates from 120 patients (69 women [58%]) presenting in January 2022 who were residents of Iquitos (96%) or rural areas (4%). Average age of patients providing isolates was 39 years (range 5-74). All 120 isolates typed as Omicron variant (98% BA.1 sublineage, 2% BA.1.1 sublineage). By comparison, analysis of 24 viral isolates from March to June 2021 all typed as Gamma variant that had first been detected in Brazil several months earlier (46% sublineage P.1, 12% P.1.1, and 42% P.1.4). Further data collection is ongoing, including analysis of sublineages associated with cases among vaccinated individuals and repeat COVID-19 infections.

0502

THE ROLE OF VACCINATION ROUTE WITH AN ADENOVIRUS-VECTORED VACCINE IN PROTECTION, VIRAL CONTROL, AND TRANSMISSION IN THE SARS-COV-2/K18-HACE2 MOUSE INFECTION MODEL

Alexandria Dickson, Tara L. Steffen, Mariah Hassert, Elizabeth Geerling, E. Taylor Stone, Amelia K. Pinto, James D. Brien

Saint Louis University, St. Louis, MO, United States

While vaccination is the most effective mechanism to prevent severe COVID-19, transmission of SARS-CoV-2 among vaccinated persons remains a significant problem. Furthermore, all currently marketed SARS-CoV-2 vaccines are delivered by intramuscular (IM) injection, even though intranasal (IN) delivery may be more effective in limiting transmission

between persons. Utilizing a replication-deficient adenovirus serotype 5-vectored vaccine expressing the SARS-CoV-2 RBD (AdCOVID) in the K18-human ACE2 mouse model, we investigated the impact of route of administration on vaccine immunogenicity, survival, and transmission. K18-hACE2 mice were vaccinated with AdCOVID via the IM or IN route and subsequently challenged with SARS-CoV-2. Following challenge, a cohort of vaccinated mice were co-housed with naïve K18-hACE2 mice and the viral load in both vaccinated and naïve recipients was quantified. The results of the study show that IN vaccinated animals had improved mucosal antibody responses, viremic control, and protection from lethal infection as compared to IM vaccinated animals. IN vaccination also resulted in reduced viral transmission to naive co-housed individuals compared to IM vaccination. Overall, our data provides further evidence for the utility of IN vaccination in protecting against SARS-CoV-2 infection and transmission. Additional studies exploring the mechanism surrounding enhanced protection afforded by IN vaccination are needed.

ROADBLOCKS AND RESILIENCE: A QUALITATIVE STUDY OF THE IMPACT OF PEDIATRIC TUBERCULOSIS ON TANZANIAN HOUSEHOLDS

Saning'o S. Lukumay[1], Kristen M. Petros de Guex[2], Domitila Augustino[1], Perry C. Msoka[3], Christopher Vinnard[4], Yingda L. Xie[4], Blandina T. Mmbaga[3], Maria C. Geba[2], Scott K. Heysell[2], Estomih Mduma[1], Tania A. Thomas[2]

[1]Haydom Global Health Research Center, Haydom, United Republic of Tanzania, [2]University of Virginia, Division of Infectious Diseases and International Health, Charlottesville, VA, United States, [3]Kilimanjaro Clinical Research Institute, Moshi, United Republic of Tanzania, [4]Rutgers New Jersey Medical School, Newark, NJ, United States

This study explored the lived experiences of youth and their caregivers in starting and sustaining treatment for tuberculosis (TB). We sought to identify the impact of childhood TB on household members' daily lives and relationships; strengths and barriers important to children's treatment course; and opportunities for improvement in their care. We recruited children ages 4 to 17 years diagnosed with TB and their caregivers from rural and semi-urban municipalities in northern Tanzania. A semi-structured qualitative interview guide was developed, informed by the team's exploratory research questions. Twenty-four interviews were conducted in Kiswahili and audio-recorded. Interviews were transcribed and translated by bilingual interviewers. English transcripts were analyzed qualitatively by coding for emerging themes relevant to the research questions. Themes included the socioemotional impact of TB on households, including adverse effects on work productivity, and facilitators and obstacles to TB care, including general financial hardship and transportation challenges. To end TB, we must improve access to care for populations disproportionately affected by the disease, including rural and semi-urban communities in Tanzania. Healthcare systems must acknowledge the transportation burden shouldered by low wealth families seeking pediatric TB care, provide consultations and medications locally, and increase access to TB-specific communal funds.

0504

CHILDHOOD ACUTE RESPIRATORY INFECTION AND IRON DEFICIENCY ANAEMIA IN RURAL GAMBIA

Ilias Hossain, Nuredin Mohammed, Grant Mackenzie, Andrew M. Prentice, Dora Pereira

Medical Research Council Unit The Gambia at London School of Hygiene & Tropical Medicine, Banjul, Gambia

Acute respiratory infection (ARI) is a leading cause of morbidity and mortality among young children in the African region. In The Gambia, more than 3 in 5 young children are anaemic, 65% due to iron deficiency anaemia (IDA). In this study, we examined whether lower haemoglobin (Hb) and ferritin levels were associated with ARI. We used data from a double-blind, randomised, placebo-controlled, phase II clinical trial with iron replacement therapy in Gambian children 6-35 months of age. Each arm included active follow-up period of 12 weeks intervention and 4 weeks post intervention and provided round-the-clock appropriate healthcare. We grouped baseline Hb and ferritin levels into low (≤ median values) and high (>median values) based on their respective medians and used logistic regression to examine their association with ARI adjusting for age and gender. During the study period, 1494 children were screened from 45 villages and 642 children 6-35 months with mild to moderate anaemia were randomised and enrolled of which 584 children completed follow up. Among them 47.6% (278/584) had low haemoglobin (≤9.6 g/dL), 50.9% (237/466) had low ferritin (≤9.5). A total of 249 children reported ARI during follow-up among 584 (42.6%) children. Low haemoglobin was associated with increased odds of ARI; the crude and adjusted ORs (95%CIs) were 1.42 (1.02-1.97), Pvalue=0.037 and 1.41 (1.01-1.96), Pvalue=0.045 respectively. Lower odds ratios were observed for the association of adjusted ferritin; the crude and adjusted ORs (95%CIs) were 1.25 (0.87-1.81), Pvalue=0.228 and 1.26 (0.87-1.83), Pvalue=0.226 respectively. Low haemoglobin and ferritin levels, which are indicators IDA, may be risk factors for childhood ARI in rural Gambia. Early and accurate diagnosis, prompt treatment and prevention strategies are needed to prevent IDA in young children.

SARS-COV-2 SEROPREVALENCE AMONG ANTENATAL CARE ATTENDEES IN KENYA, NIGERIA, MALAWI, MOZAMBIQUE, UGANDA, AND ZAMBIA, 2021-2022

Victoria Seffren[1], Ruchi Yadav[1], ANC COVID SEROSURVEILLANCE WG[2], Devyani Joshi[1], Eric Rogier[1], Julie R. Gutman[1]

[1]Malaria Branch, Center for Global Health, US Centers for Disease Control and Prevention, Atlanta, GA, United States

The novel coronavirus SARS-CoV-2, the virus that causes of COVID-19, continues to spread globally. Due to inadequate test availability and the high proportion of asymptomatic infections, case counts using test positivity alone likely under-estimate the true burden of disease. Serological surveys can provide insight into the proportion of the population that has been exposed to SARS-CoV-2. As attendance at antenatal care (ANC) is largely unrelated to illness, pregnant women can be a valuable sentinel population. Women were enrolled during their first ANC visit from health facilities in six countries (Kenya, Malawi, Mozambique, Nigeria, Uganda, and Zambia) during March 2021 through February 2022. The study is ongoing. Consented participants responded to a questionnaire consisting of demographics, COVID-19 risk factors and protective behaviors, and self-reported uptake and perceptions of vaccination. A dried blood spot sample was collected for serologic testing using the FlexImmArray™ 7-Plex SARS-CoV-2 Human IgG Antibody Test (Tetracore). Analysis was conducted in R-software version 3.6.1. A total of 23,040 women were enrolled: 2,550 in Kenya, 3,849 in Malawi, 3,635 in Mozambique, 8,184 in Nigeria, 3,832 in Uganda, and 990 in Zambia. Median age is 25 (IQR: 21 - 30). The proportion of self-reported as vaccinated with at least 1 dose of a COVID-19 vaccine was 10.7% in Kenya, 3.7% in Malawi, 28.6% in Mozambique, 2.5% in Nigeria, 27.6% in Uganda, 12.9% in Zambia. Seropositivity was 33.6% in Malawi, 60.5% in Uganda, and 41.0% in Mozambique (serology data from remaining countries is in progress). Cumulative case data estimates less than 2% of any study countries' population was infected, highlighting that case counts underestimate true rates of infection. Although vaccination rates remain low, a large proportion of the study population has some level of immunity.

0506

SARS-COV-2 INFECTION WAVES IN ASEMBO AND KIBERA, KENYA: FINDINGS FROM POPULATION-BASED INFECTIOUS DISEASE SURVEILLANCE (PBIDS), MAY 2020-FEBRUARY 2022

Rewa Choudhary[1], Allan Audi[2], Alice Ouma[3], George Aol[2], Joshua Auko[2], Samwel Kiplangat[3], Caroline Ochieng[3], Shirley Lidechi[2], Millicent A. Ogutu[2], Newton Wamola[3], Clayton Onyango[4], Bonventure Juma[4], Peninah Munyua[4], Amy Herman-Roloff[4], Godfrey Bigogo[2], Carol Y. Rao[5], Patrick K. Munywoki[4]

[1]Epidemic Intelligence Service, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kenya Medical Research Institute, Center for Global Health Research (KEMRI-CGHR), Kisumu, Kenya, [3]Kenya Medical Research Institute, Center for Global Health Research (KEMRI-CGHR), Nairobi, Kenya, [4]Division of Global Health Protection, U.S. Centers for Disease Control and Prevention, Nairobi, Kenya, [5]Division of Global Health Protection, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Data on SARS-CoV-2 circulation and clinical characteristics of the COVID-19 cases in Kenya are limited. Using Population-Based Infectious Disease Surveillance (PBIDS) in rural (Asembo, Siaya County) and urban (Kibera informal settlement, Nairobi County) settings, we report COVID-19 surveillance data between May 1, 2020 to February 3, 2022. Patients of any age presenting to a clinic in each PBIDS area who met the case definition for acute respiratory illness (ARI: acute onset of cough, difficulty breathing, sore throat or coryza), severe acute respiratory illness (SARI: acute onset of cough, difficulty breathing or chest pain and either fever ≥38.0 °C, oxygen saturation <90% or admission to hospital), acute febrile illness (AFI: axillary temperature ≥38.0 °C) or were contacts of a SARS-CoV-2 positive individual within 14 days of presentation were consented and enrolled. Nasopharyngeal and oropharyngeal swabs were collected and tested for SARS-CoV-2 using real-time PCR. Demographic and clinical data were collected in real time and entered into an electronic patient care system. Infection waves were demarcated by the minimum inflection points on the SARS-CoV-2 epidemic curve. Among 15,261 participants, 1,402 (9.2%) were PCR positive for SARS-CoV-2 (7.0% in Asembo and 12.8% in Kibera). In Asembo, three infection waves were observed with 660 COVID-19 cases while in Kibera there were 742 cases in five infection waves. The timing of the start and peak of the infection waves varied by site. ARI was the most common reason for enrollment in most waves (91.4% of all cases in Asembo and 83.6% of all cases in Kibera), followed by presentation with AFI in Asembo (10.3%) and COVID-19 contacts in Kibera (14.0%). Of the COVID-19 vaccine-eligible patients, 127 (29.1%) reported vaccination in Asembo and 122 (27.1%) in Kibera. Across both sites, there were 45 (3.4%) cases hospitalized and 8 (0.6%) deaths overall. SARS-CoV-2 infection waves were not synchronized between Asembo and Kibera. Most patients had mild respiratory illness. Although vaccination coverage was low, most cases were not severe enough for hospitalization and there was a low case fatality rate.

0507

NONADHERENCE TO ANTI-TUBERCULOSIS TREATMENT AMONGST PATIENTS IN MONTSERRADO COUNTY, LIBERIA

Alberta B. Corvah[1], Ernest Kenu[2], Delia Bandoh[2], Himiede W. W. Sesay[3]

[1]National Public Health Institute of Liberia, Monrovia, Liberia, [2]University of Ghana, School of Public Health, Ghana Field Epidemiology and Laboratory Training Program, Legon, Ghana, [3]Liberia Field Epidemiology Training Program, Monrovia, Liberia

Non- adherence to tuberculosis treatment is an important barrier influencing TB treatment failure. However, Liberia national prevalence of TB and non-adherence rate is unknown. Therefore, this study aimed to assess factors related with non-adherence to anti-TB treatment amongst patients in Montserrado County, Liberia. A facility based cross sectional study was conducted in four (4) health facilities in Montserrado County, 2019. We collected data using semi-structured questionnaire. The Morisky Medical Adherence 8 item scale (MMAS-8) was used to assessed patients' non-adherence level. We defined non-adherence as an individual scoring < 6 points in the MMAS-8. Variables were assessed using the chi- square test and Fisher's exact tests. Multiple logistic regression analysis was conducted on all factors used to declare the independently associated predictors that were statistically significant at a confidence interval of 95% and P value < 0.05. A total of 317 TB patients participated in the study. Majority of participants were males and age group 30 to 39years accounted for 90 (28.4%). The overall non-adherence to anti-tuberculosis treatment was 25.9% (95%CI = 21.3 - 31.0%). Almost Half 49 (59.8%) of the non-adherents indicated they had ever missed their appointment. Nonadherence was found to be significantly associated with pill burden (cOR 4.00, 95%CI: 2.10 - 7.65), Changes in family/friends relationship (aOR 8.30, 95%CI: 2.40 - 28.73), longest period of time one failed to take TB medication (cOR 2.48, 95%CI: 1.02 - 6.07), and patient ease of strictly following medication (aOR 0.051, 95%CI:0.01 - 0.27). Our findings proposed that non-adherence was high among TB male patients found within the age group 30-39 years. Patients who consumed at least 3-4 pills daily under the direct observation of treatment supporters were less likely to adhere to treatment plan. Family members' poor relationship with patients, and unavailability of drugs contributed to patients' non-adherence. Therefore, we recommended strengthening awareness and decentralization of TB services to ensure regular supply of drugs.

0508

MOLECULAR VIABILITY TESTING ACCELERATES DETECTION OF *MYCOBACTERIUM BOVIS* BCG-ASSAY DEVELOPMENT FOR HUMAN CHALLENGE TRIALS

Ming Chang, Sambasivan Venkatasubramanian, Kris M. Weigel, Gerard A. Cangelosi, Nahum T. Smith, Glenna J. Peterson, Thomas R. Hawn, Javeed A. Shah, Sean C. Murphy

University of Washington, Seattle, WA, United States

Clinical trials of anti-tuberculosis drugs involve human challenge by intradermal inoculation of *M. bovis* bacille Calmette-Guerin (BCG). It is challenging to evaluate live BCG in the skin of inoculated volunteers and to assess the effectiveness of drugs in a timely manner. Molecular viability testing (MVT) uses reverse transcription PCR (RT-PCR) to detect pre-ribosomal RNA (pre-rRNA) present only in viable BCG. This study validated BCG MVT for use in future human clinical trials and included a mouse model study of isoniazid (INH). BCG was cultured in nutrient-limited human serum with or without 0.5 µg/mL INH for 4 days after which diluted samples were cultured in 7H9 liquid media. Aliquots were extracted for nucleic acids followed by RT-PCR and PCR. Pre-rRNA expression normalized by CT values to rDNA. Dormant/dead BCG were expected to generate pre-rRNA:rDNA ratios of ~1. BCG cultured in nutrient-limited human serum generated pre-rRNA:rDNA ratios up to 75 after 3 days, indicating early replication; such growth was confirmed by increasing OD_{600} measurements after 4 days. BCG cultured in INH yielded pre-rRNA:rDNA values ~1 with no change in OD_{600} over 3 weeks of culture. For the mouse study, $2x10^6$ CFU of BCG were intradermally injected into mouse ears (n=10). After 4 days, 5 of 10 mice were treated with a sub-therapeutic dose of INH (1 mg /L water) for 4 days. Inoculated skin was excised, homogenized, diluted, and cultured in 7H9 media with aliquots harvested daily for the next 5 days for MVT. MVT of skin homogenates showed detectable BCG by RT-PCR and PCR but no increase in pre-rRNA. After homogenates were cultured in 7H9 media for ≥1 day, pre-rRNA:rDNA ratios rose 20-69 fold in untreated mice and 20-34 fold in INH-treated mice. One INH-treated mouse showed undetectable BCG pre-rRNA and DNA. This study demonstrated BCG MTV can detect replication of live BCG in liquid culture much earlier than when turbidity-based measures or colonial growth are used. A pilot study in mice showed recoverable, viable BCG in biopsies, showed some drug-related effects, and refined the tissue collection and processing procedures for future human challenge clinical trials.

IMPROVING TUBERCULOSIS MANAGEMENT THROUGH STRONGER HEALTH WORKER CAPACITY ON THE USE OF AN ELECTRONIC REPORTING SYSTEM IN BANGLADESH

Mst. Farhana Akter, Jebun Nessa Rahman, Md. Abu Taleb

Management Sciences for Health, Dhaka, Bangladesh

Bangladesh is one of 30 high tuberculosis (TB) burden countries with a mortality rate of 24 per 100,000 population. Monitoring and managing of TB patients is a critical element in controlling TB. The USAID Systems for Improved Access to Pharmaceuticals and Services (SIAPS) Program supported the National Tuberculosis Control Programme (NTP) of the Ministry of Health and Family Welfare (MOHFW) of Bangladesh and WHO to adopt e-TB Manager, a web based electronic recording and reporting system for managing TB patient care. The USAID Medicines, Technologies, and Pharmaceutical Services (MTaPS) Program has continued the collaboration with the MOHFW to support the NTP to complete the nationwide scale up through the capacity building of health care workers (HCWs) at TB reporting centers to efficiently use the e-TB Manager system. MTaPS developed training materials and user guidelines and provided hands-on training to HCWs. The training includes how to capture individual TB patients' data on medicines, laboratory testing, diagnosis, treatment, and outcomes in the electronic system. As a result of these capacity building efforts under SIAPS and MTaPS, around 2500 HCWs across the 868 TB reporting centers in the country were trained on the system between 2013 to 2021. The number of e-TB Manager active users increased 92% between 2013 and 2022 and 100% of TB reporting centers are now routinely using the system to manage individual TB patient records. HCWs' strengthened capacity to use eTB manager has improved data quality, reduced the data validation and report preparation time (relative to paper-based reporting), and increased the real-time reporting of TB patients, which allows for informed decision and action by the relevant authorities. HCWs are now better able to contribute to achieving the goal of limiting TB infection and ensuring better health outcomes for TB patients in Bangladesh.

LONG TERM IMPACT ON LUNG FUNCTION OF PATIENTS WITH MODERATE AND SEVERE COVID-19: A PROSPECTIVE COHORT STUDY

Sonia Qureshi[1], Nosheen Nasir[1], Naveed Rashid[1], Naveed Ahmed[1], Zoya Haq[2], Farah Naz Qamar[1]

[1]Aga Khan University Hospital, Karachi, Pakistan, [2]Liaquat National Medical College, Karachi, Pakistan

There is a wide knowledge gap about lung function capacity among the COVID-19 survivors. In this study, we aim to determine the long-term impact on lung function capacity in patients recovered from moderate or severe COVID-19 disease. A prospective cohort study was conducted at Aga Khan University Hospital, Karachi Pakistan. Patients of age ≥15 years who recovered from moderate or severe COVID-19 disease were included. Pulmonary function was assessed by performing spirometry and diffusion lung capacity for carbon monoxide (DLCO) along with chest x-ray at the three- and the six-month interval following time since discharge. Univariate logistic regression was done to measure the association between abnormal lung function and independent variables. A total of 67 patients completed three-months follow up. Of them, 7 were lost-to-follow-up at six months. Majority of the participants were males 54 (81.0%) and median (IQR) age of participants was 55 (11) years. Abnormalities on chest x-ray were detected in all patients at the time of discharge, in 5 patients (7.5%), at three months and 8/60 (13.3%) patients, at the six-month interval. DLCO was impaired in 23 (34.3%) patients, at three months and in 26/60 (43.3%), at six months. In 2 patients there was mild basal septal hypertrophy on ECHO at three months follow-up. Age (years), severity of disease, comorbidities, Intensive Care Unit stay, length of hospital stay in (days) and C- reactive protein (mg/L) were significantly associated with impaired lung function at three months' follow-up on univariate analysis. In addition to factors significant at three-month interval, duration of steroids in days, neutrophil lymphocyte ratio and lactate dehydrogenase level were significantly associated with impaired lung function at 6 months interval. None of the variables was statistically significant on multivariable analysis. We conclude that patients who survived from moderate -severe COVID-19 had poor lung function capacity over 6 months follow up period. Robust, larger scale follow-up studies can be planned to better understand the impact of COVID-19 on lung function capacity of survivors.

0511

HIGH COVID-19 VACCINATION COVERAGE IN URBAN SLUM POPULATIONS IN BRAZIL

Mariam O. Fofana[1], Nivison Nery Jr[2], Juan Pablo Aguilar Ticona[2], Emilia Belitardo[2], Camila Freire[3], Renato Victoriano[2], Rosangela Anjos[2], Moyra Portilho[2], Mayara Carvalho de Santana[2], Laiara dos Santos[2], Daiana de Oliveira[2], Olatunji Johnson[4], Derek Cummings[5], Mitermayer Reis[2], Guilherme Ribeiro[2], Albert Ko[1], Federico Costa[3]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Instituto Goncalo Moniz - FIOCRUZ, Salvador, Brazil, [3]Universidade Federal da Bahia, Salvador, Brazil, [4]University of Manchester, Manchester, United Kingdom, [5]University of Florida, Gainesville, FL, United States

Inequities in COVID-19 vaccine coverage have contributed to disparate outcomes among socially deprived communities globally. We sought to estimate the prevalence of COVID-19 vaccination and identify factors associated with vaccination in a socioeconomically vulnerable population of an urban informal settlement. We conducted two serial surveys in an urban slum community in Salvador, Brazil, before and after the rollout of COVID-19 vaccines in February 2021. In an initial survey (November 2020 to February 2021), we assessed participants' willingness to get vaccinated. In a follow-up survey (July 2021 to February 2022), we assessed completion of vaccination. We limited our analysis to 801 adults who participated in both surveys since vaccination was not offered to minors until December 2021. Most participants were women (62.2% vs 37.8% men), identified as Black (54.1%) or Brown (40.1%), and were unemployed (52.7%). In the first survey, 68.2% of participants expressed willingness to get vaccinated. Of these, 499/546 (81.9% [95% CI 72.6-88.6%]) received a vaccine. Of the 255 participants who were initially unsure or uninterested in a COVID-19 vaccine, 60.9% [95% CI 50.6-70.4%] nevertheless were vaccinated. Overall, 75.8% [95% CI 72.6-78.7%] of participants had initiated or completed a primary vaccination series. The most common formulations received were BNT162b2 (36.7%), ChAdOx1 nCov-19, (34.5%), and CoronaVac (24.5%). Women were more likely to be vaccinated than men (78.5% [95% CI 68.9-85.8%] vs 71.3% [95% CI 61.2-79.7%], p=0.03). However, we did not observe significant differences in vaccine coverage by employment (p=0.22), or eligibility for social welfare programs (p=0.48). Our results indicate high acceptance of COVID-19 vaccines in this vulnerable population, even among individuals who had previously expressed reluctance. These findings suggest that hesitancy is a modifiable barrier to COVID-19 vaccination in populations that inhabit urban informal settlements, highlighting the importance of ensuring equitable access to vaccines and the opportunity to reduce inequities experienced by these marginalized communities.

0512

THIRTY DAYS MORTALITY PREDICTORS IN SEVERE ACUTE MALNOURISHED CHILDREN WITH SEVERE PNEUMONIA

Lubaba Shahrin

International Centre for Diarrheal Disease Research, Bangladesh, Dhaka, Bangladesh

To determine the predictors of mortality within 30 days of hospital admission in a diarrheal disease hospital in Bangladesh. A cohort study of hospitalized children aged 0-59 months with severe acute malnutrition (SAM) and severe pneumonia was conducted in the Dhaka Hospital, icddr,b Bangladesh from April 2015-March 2017. Those discharged were followed up and survival status at 30 days from admission was

determined. Children who died were compared with the survivors in terms of clinical and laboratory biomarkers. Multivariable logistic regression analysis was used for calculating the adjusted odds ratio for death within 30 days of hospital admission. We enrolled 191 children. Mortality within 30 days of admission was 6% (14/191). After adjusting for potential confounders (hypoxia, C-reactive protein and hematocrit) in logistic regression analysis, independent factors associated with death were female sex (aOR=5.80, 95% CI:1.34-25.19), LAZ<-4 (aOR=6.51, 95% CI:1.49-28.44) and Polymorphonuclear Leukocytes (PMNL) (>6.0x10^9/L) (aOR=1.06, 95% CI:1.0-1.11). Using sex, Z-score for length for age (LAZ), and PMNL percentage, we used random forest and linear regression models to achieve a cross-validated AUC of 0.83 (95% CI:0.82, 0.84) for the prediction of 30-day mortality. The results of our data suggest that female sex, severe malnutrition (<-4LAZ) and higher PMNL percentage were prone to be associated with 30 days mortality in children with severe pneumonia. Association of these factors may be used in clinical decision support for prompt identification and appropriate management for the prevention of mortality in this population.

0513

KNOWLEDGE, ATTITUDES, AND PRACTICES ON COVID-19 AMONG BUKAVU'S POPULATION

Corneille A. Kabagale[1], Jean Claude C. Makangara[2], Dieu Merci K. Kanganda[3], Philippe B. Katchunga[4], Alfred K. Cubaka[5]

[1]Université Catholique de Bukavu, BUKAVU, Democratic Republic of the Congo, [2]University of Kinshasa, Kinshasa University Hospital, Department of Microbiology, DRC, Democratic Republic of the Congo, [3]Kamenge University Hospital Center, Bujumbura, Burundi, [4]Bukavu University Hospital, Official University of Bukavu, BUKAVU, Democratic Republic of the Congo, [5]Microbiology Labororatory, Faculty of Sciences, Official University of Bukavu, BUKAVU, Democratic Republic of the Congo

The World Health Organization has declared the COVID-19 as a pandemic in March 2020. Through our work, we have assessed the knowledge, attitudes and practices of the population of the city of Bukavu facing this scourge. Using a survey questionnaire made by Sphinx, we conducted a descriptive cross-sectional study on 1063 people in the three residential commune of the city of Bukavu from June to august 2020. Our results, grouped into 13 tables and 14 figures, show in general that 97.9% of our population were informed about the COVID-19 pandemic, especially through the radio at 73.7%. The attitudes of the population are more or less resistant to compliance with so-called barrier measures because only 31.0% of respondents adhere to these measures and only 27.5% actually apply them. We also noticed that the more intrusive the measures are, the more hypothetical their compliance becomes. The respondent's blame the authorities for poor communication around the disease at 10.7% and 22.5% thought that the response would be politicized. Faced with the disease, 21.0% believe that COVID-19 is a real and dangerous disease, but the authorities should improve communication at all costs according to 18.3% of respondents and 17% believe that we should learn to live with the disease. As for the practices, they are relatively conventional because 68.10% of the population would go to the nearest Health Center for treatment, and 57.80% would call the toll-free number. However, for fear of being infected, 19.6% of respondents would not go to a health facility, 20.0% expressed fear of being sequestered and 12.0% assumed exorbitant health care costs. The proportion of those who would do the nebulization (14.4%) in the event of illness is not really to be overlooked. The authorities should therefore think about improving communication around the disease, while depoliticizing the response and offering the traditional media more means to popularize barrier measures even more. In addition, other researchers will be able to do the analysis that we have not been able to carry out to further improve the knowledge, attitudes and practices of the population of Bukavu in the face of COVID-19.

0514

VIRAL PATHOGENS, RISK FACTORS AND OUTCOMES AMONG PNEUMONIA PATIENTS IN WESTERN KENYA

Linda A. Maraga[1], Peter B. Kamau[2], Jeremiah K. Laktabai[3], Emily R. Robie[4], Gregory C. Gray[5], Mark E. Amunga[6], Tabitha Jepkurgat[1], Wendy Prudhomme-O'Meara[4]

[1]Academic Model Providing Access to Healthcare, Kenya, Eldoret, Kenya, [2]Webuye County Hospital, Bungoma, Kenya, [3]Moi University, Eldoret, Kenya, [4]Duke Global Health Institute, Durham, NC, United States, [5]University of Texas Medical Branch, Galveston, Galveston, TX, United States, [6]Academic Model Providing Access to Healthcare,Kenya, Eldoret, Kenya

In the past few years rural communities in Kenya have suffered the dual burden of an epidemic caused by a novel emerging respiratory virus added to high background rates of morbidity and mortality from pneumonia. Active surveillance aimed at identification of specific viral etiologies may provide early warning signs, enabling timely interventions. As part of a wider viral pathogen discovery network, we enrolled 174 patients (target 200) of all ages diagnosed with pneumonia presenting to a district hospital in western Kenya and characterized the viral pathogens, risk factors and outcomes for pneumonia. After completing a questionnaire, nasopharyngeal swabs were collected and interrogated by real time polymerase chain reaction (PCR) for a panel of 12 known viral pathogens. Between February 2021 and February 2022, we enrolled 94 children and 80 adults. To date the most common viral pathogens identified were SARS-CoV-2 (18.4%), Respiratory Syncytial Virus (RSV)-A (16%), Influenza A (2.4%) and enterovirus (4.4%). Influenza B and Parainfluenza type 4 (PIV4) were detected in a small number of cases, but RSV-B has not been identified. Non-pandemic coronaviruses were detected in 39.6% of pneumonia patients, but a large proportion of these were co-infections with other viruses. The majority of patients received supplemental oxygen (57.5%) which is the highest level of supportive care available in this context. 71.8% of cases had no known comorbidities, 14.9% reported hypertension and 7.5% had diabetes. Only 16.1% of cases recalled being in close proximity with other symptomatic individuals and nearly the same proportion had recently travelled (22.4%). Out of 156 with known discharge status, there were 7 deaths, two with SARS-CoV-2 detected and one with human coronavirus HKU-1. On average, patients with SARS-CoV-2 infection stayed in the hospital for 1.5 more days than other patients. Respiratory viruses are a common cause of hospitalization with pneumonia in Kenya where viral diagnostics are not frequently available. Access to rapid viral diagnostics in rural hospital settings could reduce the inappropriate use of antibiotics for viral pneumonia.

0515

CARDIORESPIRATORY ARREST OF COVID-19 PATIENTS ADMITTED IN THE ICU AT THE REFERRAL HOSPITAL OF NYANTENDE AND BIOPHARM CLINIC IN BUKAVU, DEMOCRATIC REPUBLIC OF CONGO

Serge N. Ibula[1], **Jean Claude C. Makanagara**[2], Boss Ruberhwa[3], Eric Amisi[4], Doddie Thansya[5], Cishugi Mukanire[1], Philippe Katchunga[6]

[1]Bukavu School of Health Sciences, Anesthiology and Reanimation Section, Bukavu, Democratic Republic of the Congo, [2]University of Kinshasa, Kinshasa University Hospital, Department of Microbiology, Kinshasa, Democratic Republic of the Congo, [3]Bukavu School of Health Sciences, Anesthiology and Reanimation Section, DRC, Democratic Republic of the Congo, [4]University of Kinshasa, Kinshasa University Hospital, Department of Anesthesiology, Kinshasa, Democratic Republic of the Congo, [5]University of Goma, Goma, Democratic Republic of the Congo, [6]Bukavu University Hospital, Official University of Bukavu, Bukavu, Democratic Republic of the Congo

Since the end of 2019, the world is facing the covid-19 pandemic. The first case was described in China at the seafood market of Wuhan, a severe acute respiratory syndrome due to the Sars-cov-2 virus. Clinical features

are mostly respiratory. A cardiorespiratory arrest is among clinical fatality of covid-19 and was described in many cases in developed countries. In the Democratic Republic of Congo, limited studies focused on the impact of cardiac arrest on covid-19. We have conducted a retrospective, descriptive and analytical multicentric study in Bukavu at the Referral Hospital of Nyantende and Clinical Biopharm. The aim of our study was to improve the health care management of cardiorespiratory arrest in a covid-19 patient admitted to ICU in the two health structures. We screen the databases of covid-19 patients to whom a cardiorespiratory resuscitation was performed. During the study period, 68 covid-19 patients have undergone cardiorespiratory resuscitation. Among them, 38 were admitted to ICU at Biopharm Clinic and 30 at the Referral Hospital of Nyantende. The majority were elderly people (+ 65years). Apnoe and asystolic were the most etiology described. The CPR consists of airway free, external cardiac massage, usage of adrenaline, and Intratracheal intubation. The time of resuscitation was at mean 30minutes. The majority of those patients dead. The age category has significantly impacted the clinical outcome with the *p*-value 0.0017 for patients within 19-30years and 0.0052 for cardiorespiratory resuscitation type. The causes, clinical complications, and resuscitation technic have an impact on the outcome but are statistically nonsignificant. Cardiorespiratory arrest remains a serious problem on which we may focus in covid-19 healthcare patients especially in developing countries with a limited equipment for this purpose.

0516

PERCEPTIONS OF COVID-19 AND COVID-19 VACCINES IN RURAL ZAMBIA

Mathias Muleka[1], Catherine G. Sutcliffe[2], Edgar Simulundu[1], Philip E. Thuma[1], Katherine Fenstermacher[3], Richard E. Rothman[3], Andrew Pekosz[4], Mwaka Monze[5], Juliet Morales[4], Pamela Sinywimaanzi[1], Mutinta Hamahuwa[1], Morris Sianyinda[1], Passwell Munachoonga[1]

[1]Macha Research Trust, Choma, Zambia, [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, [3]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [5]Virology Laboratory, University Teaching Hospital, Lusaka, Zambia

COVID-19 vaccines are highly effective public health tools to prevent COVID-19-related morbidity and mortality. However, coverage is low throughout much of sub-Saharan Africa, part due to vaccine hesitancy. In Zambia, the national vaccine campaign was launched in April 2021 and renewed in October 2021. To date, coverage is only 12.1%. Within the context of ongoing respiratory surveillance at Macha Hospital in rural Zambia, participants with influenza-like-illness (n=376) were asked about their perceptions of COVID-19 and COVID-19 vaccines between May 2021 and February 2022. The goal of this analysis was to describe how perceptions changed over time. COVID-19 waves were defined based on national case counts as 'post wave 2' (May 2021, n=44), 'wave 3' (Jun 1 to Aug 14 2021, n=61), 'post wave 3' (Aug 15 to Dec 14 2021, n=178), and 'wave 4' (Dec 15, 2021 to Feb 28, 2022, n=94). The proportion of participants reporting being worried that they or their family would get COVID-19 increased from 67.4% in 'post wave 2' to 89.4% in 'wave 4'. The proportion who did not believe COVID-19 was a serious illness decreased from 88.4% to 63.8%. The proportion of participants reporting that they would get themselves or their child vaccinated was 40-55% in 'post wave 2', 'wave 3' and 'post wave 3', and then increased to 78.7% in 'wave 4'. Similar proportions and trends were reported for beliefs that vaccines were safe and would protect them from COVID-19. Participants not wanting to be vaccinated were asked to provide reasons (n=149). The top five reasons were concerns about vaccine safety (64.4%), getting COVID-19 from the vaccine (13.4%), side effects (12.8%), the vaccine being developed too quickly with insufficient human testing (6.7%), and the vaccine altering DNA (4.0%). Overall, only 7.9% of adult participants reported being vaccinated. In summary, vaccine acceptability increased in rural Zambia at the end of 2021 as the national vaccine campaign was renewed, case counts increased, and perceptions about COVID-19 severity increased. These findings can inform strategies to improve vaccine uptake in Zambia.

FASCIOLIASIS COMPLICATING WITH ACUTE NECROTIZING PANCREATITIS IN AN ETHIOPIAN CHILD - A CASE REPORT ON A RARE COMPLICATION OF A RARELY REPORTED EMERGING DISEASE

Tinsae Alemayehu[1], Selamawit Tariku[2], Kaleab Tesfaye[3]

[1]St. Paul's hospital millennium medical college, Addis Ababa, Ethiopia, [2]American medical center, Addis Ababa, Ethiopia, [3]Samaritan surgical center, Addis Ababa, Ethiopia

Fascioliasis is a zoonotic infection cause by the liver fluke *Fasciola*. Though infrequently diagnosed, it is emerging as a helminth infection of public health importance in many parts of the world. Few reports exist on human fascioliasis from Africa. Acute pancreatitis as a complication of fascioliasis is an even rarely reported syndrome globally. We report a case of a twelve year old Ethiopian boy presenting with a left sided abdominal pain and a dietary history of frequent consumption of leafy vegetables. His work-up showed leukocytosis with marked eosinophilia, increased serum amylase and lipase with imaging confirming multiple sub-capsular hepatic masses complicating with an acute necrotizing pancreatitis. Upon serologic testing for helminths, he tested positive for *Fasciola hepatica* enzyme immunoassay. He was managed with intravenous fluids, proton pump inhibitors, antibiotics and oral Triclabendazole. Fascioliasis should be considered as a possible diagnosis people with predisposing culinary practice and presenting with eosinophilia and liver masses. Chronic Fascioliasis can complicate with pancreatitis.

0518

CERVICOVAGINAL LAVAGE HEMOGLOBIN IS NOT ASSOCIATED WITH GENITAL SCHISTOSOMIASIS IN ZAMBIAN WOMEN

Amy Sturt[1], Emily L. Webb[2], Comfort R. Phiri[3], Lisa Himschoot[4], Joyce Mapani[5], Maina Mudenda[5], Eyrun F. Kjetland[6], Tobias Mweene[7], Govert J. van Dam[8], Paul L A M Corstjens[8], Helen Ayles[2], Richard J. Hayes[2], Suzanna C. Francis[1], Piet Cools[4], Lisette van Lieshout[8], Isaiah Hansingo[5], Amaya L. Bustinduy[2]

[1]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA, United States, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Zambart, Lusaka, Zambia, [4]Ghent University, Ghent, Belgium, [5]Livingstone Central Hospital, Livingstone, Zambia, [6]Oslo University Hospital, Oslo, Norway, [7]Zambart, Livingstone, Zambia, [8]Leiden University Medical Center, Leiden, Netherlands

Female genital schistosomiasis (FGS), caused when *Schistosoma haematobium* eggs are deposited in genital tissue, is prevalent in sub-Saharan Africa. The cervical mucosa in FGS is associated with an increase in abnormal blood vessels and has been associated with contact bleeding. If FGS is associated with the presence of hemoglobin (Hb) in cervicovaginal lavage (CVL) fluid, the use of urinary dipsticks (Hemasticks®) on CVL to detect Hb could supplement FGS diagnosis, but the association of *Schistosoma* with CVL Hb has not previously been described. Women aged 18-31, participating in the HPTN 071 (PopART) Population Cohort, who were sexually active, not currently menstruating and not pregnant were invited to participate in the Bilharzia and HIV (BILHIV) study. Eligible women were enrolled in two communities in Zambia from January - August 2018. Genital self-swabs and a urine specimen were collected and a questionnaire was administered at home visits. A midwife obtained CVL at the cervical cancer clinic and used a hand-held colposcope to evaluate for FGS-associated cervicovaginal lesions. Visual-FGS was defined as the presence of sandy patches, rubbery papules, or abnormal blood vessels. *Schistosoma* real-time PCR was performed on genital specimens (cervical swab, vaginal swab, and CVL). Circulating Anodic antigen (CAA) and microscopy were performed on urine. PCR-FGS was defined

as *Schistosoma* DNA detected by PCR on CVL or genital swab. Of 209 women with CVL Hb results and genital swabs with companion CVL specimens, 66% (138/209) had detectable CVL Hb, 13.4% (28/209) had PCR-defined FGS, 17.2% (36/209) had visual-FGS. Active *Schistosoma* infection, diagnosed by CAA or urine microscopy, was present in 21.0% (44/209) participants. Neither active *Schistosoma* infection (p=0.4), PCR-FGS (p=0.7) nor visual-FGS (p=0.3) were associated with CVL Hb presence. Results did not differ in sub-groups with high infection burden. In conclusion, we found that neither established FGS nor active *Schistosoma* infection was associated with the presence of Hb in CVL. Further research is needed to fully evaluate the etiology and clinical significance of CVL Hb in Zambian women.

0519

IDENTIFICATION OF NOVEL THERAPEUTICS AGAINST HUMAN SCHISTOSOMIASIS

Sevan N. Alwan

UT Health at San Antonio, San Antonio, TX, United States

Human schistosomiasis is a neglected tropical disease caused by parasitic worms. It affects over 250 million people globally. Most human infections are caused by *Schistosoma mansoni, S. haematobium,* and *S. japonicum.* Currently there is only one method of treatment for human schistosomiasis, the drug praziquantel. Constant selection pressure has caused a serious concern because of rise in resistance to praziquantel leading to the urgent need for additional pharmaceuticals, with a distinctly different mechanism of action, to be used in combination therapy with praziquantel. Previous treatment of *S. mansoni* included the use of oxamniquine (OXA), a prodrug that is enzymatically activated by a sulfotransferase, an enzyme produced by *S. mansoni*. Although sulfotransferases are produced by *S. haematobium* and *S. japonicum,* OXA is not effective against these two species. Also, Praziquantel is not effective against juvenile stages of the parasite. Structural data have allowed for directed drug development in reengineering oxamniquine to be effective against *S. haematobium* and *S. japonicum*. Guided by data from Xray crystallographic studies and *Schistosoma* worm killing assays more than 350 OXA derivatives were designed synthesized and tested *in vitro* against the adult parasites. To date, our study has identified powerful reengineered derivatives that are more effective than oxamniquine in killing all three species, juvenile stages, and praziquantel resistance strain *in vitro*. *In vivo* studies revealed that three of these derivatives caused a significant reduction in the number of harvested worms from *S. mansoni, S. haematobium,* and *S. japonicum* infected animals. In addition, treating infected mice with these derivatives during juvenile stages led to significate reduction in the number of immature worms. The later result is an advance over Praziquantel that does not kill immature *schistosomes.*

0520

HEMATOLOGICAL CHANGES IN *SCHISTOSOMA HAEMATOBIUM* INFECTED RETURNED TRAVELERS

Jenny L. Schnyder[1], Federico Gobbi[2], Mirjam Schunk[3], Andreas K. Lindner[4], Fernando Salvador[5], Marta Arsuaga Vicente[6], Hanna K. De Jong[1], Martin P. Grobusch[1]

[1]Amsterdam UMC - Location University of Amsterdam, Amsterdam, Netherlands, [2]Ospedale Equiparato Classificato Sacro-Cuore Don Calabria, Verona, Italy, [3]LMU Klinikum, Munich, Germany, [4]Charité Universitätsmedizin, Berlin, Germany, [5]Hospital Universitario Vall d'Hebron, Barcelona, Spain, [6]Hospital La Paz- Carlos III, Madrid, Spain

Earlier studies found characteristic hematological changes in African schoolchildren with an active *Schistosoma haematobium* infection. At large, these differences included a trend of decreasing hemoglobin, and an increase of leukocyte count and thrombocyte count. Full blood count (FBC) alterations might not be unique to African children and might be observable in general across geographical areas and age groups and could thus be observable in travelers returning with schistosomiasis from endemic countries. If consistently present, FBC may possibly be used as a surrogate diagnostic parameter for acute *S. haematobium* infection. A retrospective patient record review was performed by six European travel clinics on returned travelers infected with active (egg producing) *S. haematobium*. The means of the FBC parameters were calculated and compared to normal population reference values by a one sample *t*-test. A total of 231 subjects with a mean age of 22.7 years (SD = 9.0) were included into the data analysis. We found lower means of hemoglobin (β = -0.4 g/dL, $p < 0.001$ [males]; β = -0.6 g/dL, $p < 0.001$ [females]) and MCV (β = -4.2, $p < 0.001$), similar hematocrit (β = -0.0%, $p = 0.992$ [males]; β = +0.7%, $p = 0.471$ [females]) and higher erythrocyte counts (β = +0.3 10^6/dL, $p < 0.001$ [males]; β = +0.3 10^6/dL, $p = 0.137$ [females]). Thrombocyte and leukocyte counts were lower (β = -42 10^3/dL, $p < 0.001$ and β = -0.06 10^3/dL, $p < 0.001$, respectively). As to be expected, eosinophils were increased (β = +0.42, $p < 0.001$), whilst the other differential leukocyte counts, including basophils, neutrophils, lymphocytes and monocytes, were all decreased (β = -0.05, -1.93, -0.43, and -0.09, respectively, p for all < 0.001). An active infection with *Schistosoma haematobium* is associated with hematological alterations in travelers. Notably, these changes do not completely match those found in African schoolchildren, as we found lower leukocyte and thrombocyte counts, which calls for further exploration. Furthermore, FBC alterations might also be observable across other *Schistosoma* species infections whilst eggs are produced, which is yet to be investigated.

0521

BIOMARKER DISCOVERY AND ASSAY DEVELOPMENT TO DETECT ANTIBODIES TO *SCHISTOSOMA HAEMATOBIUM*

Yong Wang[1], Sylvia A. Ossai[1], Holly M. Chastain[1], Eric S. Elder[1], Kimberly Y. Won[1], Kathy Kamath[2], Joel Bozekowski[2], Jack Reifert[2], Patrick Daugherty[2], William E. Secor[1], Sukwan Handali[1]

[1]CDC, Atlanta, GA, United States, [2]Serimmune, Goleta, CA, United States

The new World Health Organization (WHO) neglected tropical diseases road map for 2021-2030 highlights the need for better diagnostic tests to support the control and elimination of schistosomiasis. Antibody detection could be useful for diagnostic needs to determine when transmission has been interrupted and subsequent surveillance to detect recrudescence of infection. The WHO target product profile for this use case employs a two-step strategy to achieve the necessary specificity. The first screening test should provide high sensitivity with allowances for lower specificity, while the confirmation test requires higher specificity with acceptable lower sensitivity. While several recombinant *Schistosoma mansoni* antigens have been developed and tested for species-specific antibody detection, only a few antigens have been described for *S. haematobium.* We attempted to identify sero-reactive epitopes from *S. haematobium* using serum epitope repertoire analysis (SERA). We screened sera from individuals with *S. haematobium* infection (n = 60) and controls (n = 60). We identified ten candidate epitopes mapped to seven *S. haematobium* proteins. We used *in silico* analysis to discover potential B-cell epitopes for these proteins and identified 34 peptide sequences of interest. We also conducted *in silico* analysis to identify epitopes on *S. haematobium* secretome and membrane-bound, GPI-anchored proteins. We selected 323 antigens and converted them into 1,376 different 15 amino acid linear peptides. Overall screening results identified 50 potential target peptides that were synthesized and re-screened using peptide ELISA. One peptide detected total IgG and IgG1 antibodies with signal-to-noise ratio for IgG3 ~ 29, while the other peptide only detected total IgG with a signal-to-noise-ratio > 15. These peptides will be used to develop into assays using their recombinant proteins or a multi-epitope proteins.

ASSAY DEVELOPMENT TO DETECT ANTIBODY TO *SCHISTOSOMA MANSONI* INFECTIONS BASED ON RGST-SM29.

Yong Wang, Yeuk-Mui Lee, Sylvia A. Ossai, Holly M. Chastain, Eric S. Elder, Kimberly Y. Won, William E. Secor, **Sukwan Handali**

CDC, Atlanta, GA, United States

The CDC Parasitic Diseases Reference Laboratory diagnoses *Schistosoma mansoni* infection among U.S. travelers, Peace Corps volunteers, and immigrants using two serologic assays. Sera are screened by FAST-ELISA using purified *S. mansoni* adult microsomal antigen (MAMA), followed by confirmation using immunoblots with two diagnostic bands, Sm29 and Sm25. We have sought to develop recombinant versions of these antigens to improve assay reproducibility and overcome the costs and challenges of sourcing enough *S. mansoni* adult worms associated with purifying native MAMA. While rSm25 has been successfully expressed, used, and validated in several assay platforms, efforts over almost 40 years using bacterial and insect cell-culture expression systems have failed to produce functional rSm29. We attempted to express Sm29 using a mammalian cell expression system to overcome these challenges. The recombinant plasmid encoding a glutathione S tranferase-Sm29 fusion protein was transiently transfected into the human embryonic kidney (HEK) 293-6E cells. The target protein was captured from the culture supernatant using glutathione Sepharose 4 columns, followed by buffer exchange. The purified protein was analyzed by Western blot. We compared the performances of rGST-Sm29, rGST-Sm25, and MAMA immunoblot strips against 35 negative and 23 confirmed positive *S. mansoni* sera. The specificity of all immunoblots was 100%; the sensitivity of the rGST-Sm29 and MAMA immunoblot strips was 96% (22/23), and the rGST-Sm25 immunoblot strips had a sensitivity of 91% (21/23). We tested species specificity with 14 *S. haematobium* and 14 *S. japonicum* confirmed positive sera. These sera recognized none of the rGST-Sm29 strips, while rGST-Sm25 and MAMA strips showed cross-reactivities. We then developed an ELISA using the new rGST-Sm29 and tested 16 *S. mansoni* positive and 16 negative sera. ELISA sensitivity and specificity were 94% (15/16) and 100%, respectively. The recombinant antigens will be used to develop a multiplex bead assay and evaluated for diagnostic utility in reference laboratories, verification of transmission interruption, and surveillance.

IMPROVING FEMALE GENITAL SCHISTOSOMIASIS SCREENING WITHIN GOVERNMENT HEALTH FACILITIES IN ZAMBIA

Erin Rogers[1], William Kilembe[2], Bellington Vwalika[2], Mubiana Inambao[3], Sepo Mwangelwa[3], Chishiba Kabengele[2], Vernon Moonga[2], Constance Himukumbwa[3], Rachel Parker[1], Amanda Tichacek[1], Susan Allen[1], Kristin M. Wall[1]

[1]Emory University, Atlanta, GA, United States, [2]Center for Family Health Research Zambia, Lusaka, Zambia, [3]Center for Family Health Research Zambia, Ndola, Zambia

The World Health Organization (WHO) estimates that up to 56 million women and girls are living with female genital schistosomiasis (FGS) in sub-Saharan Africa. FGS causes reproductive disorders including infertility, pregnancy complications, lost productivity, and stigma. Identification of FGS is difficult due to confusion with symptoms of other genital abnormalities and gold standard diagnosis with colposcopy is not feasible or affordable in most health facilities. Our study aims to develop and pilot test a comprehensive screening algorithm that is feasible to implement in Zambian government clinics. We recruited 497 women from a longitudinal cohort of HIV-negative female sex workers or single mothers ≥ 18 years in Lusaka and Ndola, Zambia. We used demographic, risk factor, and symptom data collected from standardized surveys, gynecological exams, and laboratory tests to develop a risk score for FGS. The area under the receiving operating curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the risk algorithm were calculated using score cut-offs defined as the median score. The prevalence of FGS on colposcopy was 23.5%. The risk score had reasonable discrimination in the full cohort (AUC = 0.69, 95% CI: 0.63-0.74, p-value < 0.001). Using a score cut off of 2, the risk algorithm in the derivation cohort had 70% sensitivity, 56% specificity, 33% positive predictive value (PPV), and 86% negative predictive value (NPV). Additional analyses will consider both the development and performance of the algorithm when data are divided into a 70:30 training- and test-set. We will also examine which factors discriminate between those who are accurately captured by the algorithm (true positives) and those who are missed (false negatives). This work is imperative to understanding the risk factors associated with FGS among a cohort of young adult women in Zambia and the opportunities, as well as challenges, for identifying an algorithm that is feasible to implement in Zambian government clinics.

0524

DETECTION OF DUAL SCHISTOSOME PARASITES IN URINE COLLECTED FROM PREGNANT WOMEN IN GHANA VIA LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP)

Nilanjan Lodh[1], Abraham K. Anang[2], Javeriya Choudry[1]

[1]Marquette University, Milwaukee, WI, United States, [2]University of Ghana, Accra, Ghana

40 million pregnant women are infected with soil-transmitted helminths (STHs) and Schistosome parasites in sub-Saharan Africa. When parasitic diseases share the same habitat and overlap in distribution then high rates of co-infection occur. Such is the case in Ghana; however, published data on the effect of helminth infections on pregnant women in Ghana are not extensive. The co-infection can lead to consequences for the child, such as intrauterine growth retardation, low birth weight, pre-term delivery, and neonatal mortality. The objective of the study was to determine the prevalence of Schistosomiasis co-infection (*Schistosoma mansoni* and *S. haematobium*) among pregnant women from Battor and Adidome districts of Ghana using loop-mediated isothermal amplification (LAMP) amplification of cell-free species-specific repeat DNA from collected filtered urine samples. We have determined the nature and extent of Schistosome coinfection (single or dual infection) from 100 filtered urine samples collected from Battor (50 samples) and Adidome (50 samples) districts of Ghana in collaboration with Noguchi Memorial Institute for Medical Research, University of Ghana. The overall distribution and frequency of such coinfection in pregnant women (age range 14 - 45yrs) were also assessed. The positive infection rate for the two species and dual infection was highest for women in 20 - 30yrs of the age range. In Adidome district (out of 50 samples), *S. mansoni* had the highest infection prevalence (32 positives) compared to *S. haematobium* (28 positives) and dual infection was 44%. Whereas in Battor district, the infection prevalence for *S. mansoni* (25 positives) was higher than *S. haematobium* with a dual infection rate of 22%. Mixed infection was high in both Adidome (22 out of 50) and Battor (11 out of 50) districts. LAMP detected both Schistosome species with high sensitivity and specificity. LAMP also proved to be a more efficient, sensitive, and specific diagnostic test for co-infection detection among the vulnerable group of the population.

0525

SHIFTING TO COMMUNITY-BASED TREATMENT AND THE IMPLICATIONS OF THE NEW WHO RECOMMENDATIONS FOR SCHISTOSOMIASIS CONTROL?

Anna Elizabeth Phillips[1], Achille Kabore[1], Justin Tine[2], Diana Stukel[1]

[1]Family Health International, Washington, DC, United States, [2]Family Health International, Accra, Ghana

In 2022, the World Health Organization (WHO) launched new recommendations on prevalence thresholds and target age groups receiving preventive chemotherapy (PC) against schistosomiasis. "Recommendation 1" is for communities with schistosomiasis prevalence ≥10% to receive annual PC in all age groups above two years.

"Recommendation 2" for communities with prevalence <10% is one of two approaches: PC at the same/reduced frequency or test-and-treat approach if no treatment program in place. To better understand the ramifications of (1) refining PC at the community level (rather than district treatment) and (2) adult treatment (rather than traditional school-based strategies), a schistosomiasis tracker and dashboard were developed by USAID's Act to End NTDs program to calculate sub-district/community treatment needs. We estimated praziquantel (PZQ) calculations using (1) the 2011 WHO program managers guidelines and (2) the new 2022 recommendations across eight countries in Act West. Overall, PZQ quantities did not differ significantly when calculations were based on district or sub-district prevalence. The drug calculations by guideline were significant, however, when adult treatment was included. There was a threefold increase in PZQ needed if PC was expanded to adults in moderate-to-high risk areas using the 2011 guidelines but a fourfold increase using the 2022 recommendations. The adjusted 10% prevalence threshold under the new WHO recommendations combined with the shift to community-wide treatment significantly expands eligibility for PC, beyond the global supply of PZQ via the donation program currently estimated at 300 million annually. This presentation addresses six key points: (1) PZQ calculations by guideline and coordination of donors/WHO/pharmaceutical/implementers to prioritize supplies, (2) country ownership on changing treatment strategies and donor/partner capacity to accommodate large scale shifts; (3) tools that estimate calculate community prevalence; (4) guidelines to support control programs in shifting to a more refined sub-district treatment strategy; and (5) community-wide treatment.

0526

COST-BENEFIT OF CONDUCTING SCHISTOSOMIASIS IMPACT ASSESSMENTS TO CHANGE A TREATMENT STRATEGY: EVEN SURVEYS THAT FAIL CAN SAVE CONTROL PROGRAMS MONEY

Anna Elizabeth Phillips[1], Justin Tine[2], Monique Dorkenoo[3], Diana Stukel[1]

[1]Family Health International, Washington, DC, United States, [2]Family Health International, Accra, Ghana, [3]University of Lome, Lome, Togo

Schistosomiasis control programs typically use annual preventive chemotherapy at the district level based on prevalence surveys conducted at baseline. After five to six rounds of mass drug administration (MDA) the recommendation by the World Health Organization is to conduct an impact assessment to evaluate whether prevalence has reduced, thereby changing the treatment strategy. Implementing intensive impact assessments are costly and logistically demanding. Given the focal nature of schistosomiasis, there is a move towards more granular surveys in smaller evaluation units such as sub-districts or "communities". We present the cost effectiveness of conducting impact assessments for different evaluation unit sizes (district versus sub-district) and the financial implication of undertaking MDA with and without conducting impact assessments. The Tool for Integrated Planning and Costing (TIPAC) helps estimate the cost of such surveys and cost per treatment at the district versus sub-district level, and whether the impact assessment yields a positive return on investment given the change in treatment costs. Togo has advanced considerably on the road to schistosomiasis control. The country conducted baseline mapping in 2009, an impact assessment in 2015, followed by a second re-assessment of sub-district prevalence in 2021. Data presented here examines the cost of conducting the schistosomiasis impact survey in 2021 and the costs of continuing MDA without doing an impact survey versus modifying the MDA where indicated by the survey results. Population size is taken into consideration to examine the threshold at which continuing MDA without impact surveys becomes advantageous in financial cost terms. Although schistosomiasis impact assessments have a non-trivial cost, they can save money overall, depending on the size of evaluation unit and assuming the data generated is reliable.

0527

RISK FACTORS AND COOCCURRENCE OF SOIL TRANSMITTED HELMINTHIASIS AND SCHISTOSOMIASIS IN COMMUNITIES WHERE PREVENTIVE CHEMOTHERAPY IS THE MAIN INTERVENTION IN THE FEDERAL CAPITAL TERRITORY, NIGERIA

Wellington A. Oyibo[1], Joan C. Ajah[2], Abidemi Awesu[2], Rosemary Chjioke[2], Ayodeji Daramola[2], Theresa Obende[2], Chinonye L. Anabike[2], Ginika L. Onwuachusi[3], Rita O. Urude[4], Obiageli J. Nebe[4], Chukwuma Anyaike[5]

[1]Centre for Malaria Diagnosis, NTD Research, Training, & Policy/ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria, Lagos, Nigeria, [2]College of Medicine of the University of Lagos, Nigeria, Lagos, Nigeria, [3]Nnamdi Azikiwe University, Awka, Nigeria, [4]Neglected Tropical Diseases Division, Public Health Department, Federal Ministry of Health, Abuja, Abuja, Nigeria, [5]Neglected Tropical Diseases Division, Public Health Department, Federal Ministry of Health, Abuja, Lagos, Nigeria

Schistosomiasis (SCH) and Soil-transmitted helminthiasis (STH) are Neglected Tropical Diseases (NTD) of public health importance in Nigeria - one of the countries with the highest burden globally. The Federal Capital Territory (FCT), is a growing urban area with peri-urban communities traversed by rivers and streams that supports the transmission of SCH and settings for STH. The dynamics of both diseases with Preventive Chemotherapy as major strategy, the influence of the environment and behavioural practices in the dynamics of transmission may require additional interventions. A cross-sectional study was conducted among children and adults in five communities, in three Area Councils of FCT. Semi-structured questionnaires were used to obtain Socio-demographic data from 442 participants from whom stool and urine samples were collected and examined for eggs of *Schistosoma mansoni*/STH and *Schistosoma haematobium* respectively. Results were analysed using Pearson's Chi-Square (χ^2) test and logistic regression. Overall, the prevalence of STH and SCH was 42.8%; with 3.8% having concurrent STH-SCH infections. Of those infected, 10% had STH and Hookworm was the most predominant (9.3%). For SCH, 37% were infected, of which 31.4% and 13.6% were *S. mansoni* and *S. haematobium respectively*. Contact with parasite infested water was associated with an increased risk of Urinary-SCH caused by *S. haematobium* (OR = 0.54; 95% CI: 0.31 - 0.94; $P<0.05$). Open defecation was associated with increased risk of both STH (OR = 1.79; 95% CI: 0.89 - 3.60; $P = 0.102$) and Intestinal-SCH (OR = 0.50; 95% CI: 0.33 - 0.77; $P = 0.002$). Participants ≥18 years old had higher rate of concurrent infection than those, <18 years old (4.5% vs 3.5%; OR = 0.76; 95% CI: 0.29 - 2.05, $P = 0.591$) while males were more infected than females (5.0% vs 3.0%). The use of unsafe sources of water for household chores was significantly associated with increased risk of concurrent STH-SCH Infections (OR = 2.82; 95% CI: 1.02 - 7.79; $P = 0.045$). Scale-up of Water, Sanitation, Hygiene and Environment and other interventions will accelerate attainment of control and elimination targets in the FCT.

0528

MALARIA AND SCHISTOSOMIASIS COOCCURRENCE THREE AREA COUNCILS IN THE FEDERAL CAPITAL TERRITORY, NIGERIA

Wellington A. Oyibo[1], Rosemary Chjioke[1], Joan Ajah[1], Abidemi Awesu[1], Ayodeji Daramola[1], Theresa Obende[1], Chinonye Anabike[1], Ginika Onwuachusi[2], Rita Urude[3], Obiageli J. Nebe[3], Chukwuma Anyaike[4], Samuel Omoi[5], Bright Ekweremadu[5]

[1]Centre for Malaria Diagnosis, NTD Research, Training, & Policy/ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria, [2]Nnamdi Azikiwe University, Awka, Nigeria, [3]Neglected Tropical Diseases Division, Public Health Department, Federal

Ministry of Health, Abuja, Abuja, Nigeria, [4]Neglected Tropical Diseases Division, Public Health Department, Federal Ministry of Health, Abuja, Lagos, Nigeria, [5]Christofell Blinden Mission, Abuja, Nigeria

Malaria and schistosomiasis are endemic in many regions of sub-Saharan Africa with greatest prevalence in Nigeria despite the efforts being made to control these diseases. The geographical overlap of these diseases often results in concurrent infections and with the elimination agenda for both diseases, the need for integration of interventions and strategies become critically important for cost-effectiveness rather than the separate handling by different programmes in the same community when the efforts could be harnessed for impact. There are variations in the distribution and prevalence of malaria-schistosomiasis in different settings of the country. This study determined the prevalence of malaria, schistosomiasis and their co-occurrence in selected communities in Gwagwalada, Abuja Municipal and Bwari Area Council Areas of the Federal Capital Territory (FCT), Nigeria. A cross-sectional study was used in assessing 416 research participants from five communities in three Area Councils in FCT. Urine, stool and blood samples examined using standard procedures for schistosomiasis (*Schistosoma mansoni* and *S. haematobium)* and malaria. Questionnaires were used to collect demographic and work-related data. Of the 416 participants, 42(10.1%) were positive for malaria, Gwagwalada had prevalence of 11.4%, AMAC 9.3% and Bwari had 4.4%. Overall Schistosomiasis prevalence was 151(36.3%). Highest prevalence was seen in Gwagwalada Area Council (50.2%). AMAC and Bwari Area Council showed prevalence rates of 16.7% and 2.2% respectively: The prevalence of *S. haematobium* and *S. mansoni* was 52(12.5%) and 128(30.8%) respectively. Overall Malaria-schistosomiasis co-occurrence was 4.1% with 6.1%, 0.9% and 0.0% in Gwagwalada, AMAC and Bwari respectively. No significant association was seen between malaria and schistosomiasis (p>0.05).The opportunities for integration of diseases control and elimination will accelerate control efforts and data on cooccurrence are relevant to this approach.

0529

VARIATIONS IN THE EFFICACY OF PRAZIQUANTEL IN THE CONTROL OF SCHISTOSOMIASIS IN THE FEDERAL CAPITAL TERRITORY, NIGERIA

Godswill Iboma[1], **Wellington A. Oyibo**[1], Rita O. Urude[2], Obiageli J. Nebe[2], Michael N. Akpan[2]

[1]Centre for Malaria Diagnosis, NTD Research, Training, & Policy/ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria, [2]Neglected Tropical Diseases Division, Public Health Department, Federal Ministry of Health, Abuja, Abuja, Nigeria

Schistosomiasis is a disease of public health importance and Nigeria is one of the most endemic countries in the world. Caused by majorly *Schistosoma haematobium* (urinary schistososmiasis) and *S. mansoni* (intestinal schistosomiasis), it results in poor cognitive development, urinogenital and gastrointestinal presentations (including Female genital schistosomiasis), bladder carcinoma etc. As a focal disease, schistosomiasis is linked with poor environmental infrastructures, behaviour, poor sanitation, hygiene and poverty. Preventive chemotherapy in mass administration of medicines is effective in reducing morbidity and transmission while snail control is yet to be implemented at scale in Nigeria. Reports of resistance of *Schistosomes sp* to praziquatel (PZQ) has been also been documented elsewhere. We conducted a therapeutic efficacy assessment of praziquantel in a cohort of 65 children above five years and adult participants drawn from 584 participants that were assessed for schistosomiasis morbidity in the Federal Capital Territory (FCT), Abuja in August 2021. Standard dose of PZQ was administered to each participant after collection of pre and two weeks post treatment. Urine and stool specimens were collected from the participants and parasitological tests, including urinalysis was performed using standard protocol. Kato-katze was done for stool samples. All measurements were calibrated as egg count/10 ml of urine and egg per gram for stool samples. Our findings showed that there was variability in the efficacy of PZQ among the participants assessed as cure rates (egg clearance) for the Schistosomes spp. Cure rates was 49% and 29% for *S Haematobium* and *S mansoni* respectively. The egg intensity also varied by age-groups for the Schistosome species while morbidity indicator in the urine was significantly reduced. The study is still ongoing to determine the pharmacokinetics and drug metabolism of PZQ in the study population. Poor outcomes to PZQ could be a great threat to the elimination agenda for schistosomiaiss and periodic drug efficacy monitoring is recommended.

0530

HIGH PREVALENCE OF *SCHISTOSOMA MANSONI* INFECTION AMONG ADULTS WITH CHRONIC NON-COMMUNICABLE DISEASES IN MALAWI - A CROSS-SECTIONAL STUDY AT MANGOCHI DISTRICT HOSPITAL

Wongani John Nyangulu[1], Christina Sadimba[1], Joyce Nyirenda[1], John Kamwendo[1], Kelvin Chawawa[1], Angella Masano[1], Elizabeth Chilinda[1], Sekeleghe Kayuni[2], Adamson Muula[1], Kenneth Maleta[1]

[1]Kamuzu University of Health Sciences, Blantyre, Malawi, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Schistosomiasis is a parasitic infectious disease caused by flatworms of the *Schistosoma* genus. The global burden of schistosomiasis is high. In Malawi, schistosomiasis is among the top 20 causes of outpatient department visits in health facilities. Schistosomiasis is among the most important but neglected causes of non-communicable diseases (NCD) peculiar to tropical endemic settings. While much is known about the contribution of *S. haematobium* to the NCD burden in Malawi, the role of *S. mansoni* remains largely unknown. We conducted a cross-sectional study at Mangochi District Hospital. Adults over 18 years diagnosed with NCDs (n = 414), admitted or attending weekly outpatient clinics were recruited between August 2021 and February 2022. Data were collected on sociodemographic characteristics, medical history, body weight, blood pressure, and fasting blood glucose. Stool and midstream urine were collected for Kato Katz (KK) microscopy and urine circulating cathodic antigen (CCA) tests respectively. We computed prevalence of *S. mansoni* as number of positive KK and CCA tests, each divided by total submitted samples. Univariate and multivariable logistic regression were done to evaluate risk factors of NCDs and association between *S. mansoni* infection and NCDs. We recruited 414 participants, mean age 57 years (SD 16), 67% of whom were female. Prevalence of *S.mansoni* based on urine CCA was 15% (95% CI 11 – 19) and 0% on KK microscopy. Hypertension was the most common condition with a prevalence of 85% (95% CI 81 – 89), followed by diabetes mellitus with a prevalence of 42% (95% CI 37 – 46) and heart disease with a prevalence of 3% (95% CI 2 – 5). Age (OR 1.1 (95% CI 1.05 – 1.12)), unemployment (OR 4.7 (95% CI 1.2 – 18)), and body weight (OR 1.04 (95% CI1.01 – 1.07)) were significantly associated with hypertension. *S. mansoni* infection was not significantly associated with hypertension (OR 1.2 (95% CI 0.5 – 3.1)), diabetes (OR 0.6 (95% CI 0.3 – 1.1)) or heart disease (OR 2.0 (95% CI 0.4 – 10)).We observed high prevalence of *S. mansoni* infection among adults in the study. This is within the range observed in children in Mangochi from 10 – 56.7%.

0531

BURDEN OF FEMALE GENITAL SCHISTOSOMIASIS AMONG WOMEN ATTENDING THE SAINT-LOUIS HOSPITAL IN THE NORTH OF SENEGAL

Halimatou Diallo[1], Maimouna Ndour[1], Ousmane Thiam[1], khadime sylla[2], Magatte Ndiaye[2], Roger Tine[2], Jean Louis Ndiaye[3], Babacar Faye[2], Souleymane Doucoure[4], Doudou Sow[1]

[1]University Gaston Berger, Saint-Louis, Senegal, [2]University Cheikh Anta Diop, Dakar, Senegal, [3]University Iba Der Thiam, Thiès, Senegal, [4]Institut de Recherche et de developpement, Dakar, Senegal

Female genital schistosomiasis (FGS) is a public health problem in women and girls living in schistosome-endemic areas. Indeed, the presence of schistosome eggs in genital tissue is classically associated with a burning sensation in the genitals, malodorous discharge, and pain as well as infertility, ectopic pregnancies, and miscarriage. The

WHO recommends routine and repeated antischistosomal treatment for those targets to reduce the risk of developing FGS. In Senegal, there is a lack of epidemiological data on the burden of this neglected disease in population at risk. This study was done to describe the profile of FGS cases in patients attending hospitals in the north of Senegal. A descriptive study was carried out to collect epidemiological data on women attending the hospital of Saint-Louis in the north of Senegal from 2019 to 2020. All study participants were examined under colposcopy. The signs and symptoms of FGS were identified using the pocket atlas for clinical health-care professionals developed by the WHO. Each image obtained after colposcopy was examined by two gynecologist and one mid-wife. Socio-demographics and clinical data were described for each participant. A total of 173 women examined under colposcopy have been included in the study. Signs of FGS have been identified in 45 patients (26 %). Among the patients positive for FGS, 46.7% of the patients have shown grainy sandy patch while 24.4% of them have presented rubbery papules. Lesions of homogenous sandy patch and abnormal blood vessels were respectively observed in 17.7% and 11.2% of the women. The Visual inspection with acetic acid has yielded 7 positive results (15%) among the FGS cases. This study has shown the important number of FGS among women attending health facilities in the north of Senegal. Further studies are needed at community level to propose the best strategies for the management of cases.

0532

SCHISTOSOMIASIS SEROPREVALENCE AMONG CHILDREN 0-15 YEARS OF AGE IN NIGERIA, 2018

Anne Straily[1], Ryan E. Wiegand[1], Nnaemeka C. Iriemenam[2], McPaul I. Okoye[2], Ayuba B. Dawurung[3], Nkechi Blessing Ugboaja[3], Israel Tamunonengiyeofori[4], Nishanth Parameswaran[1], Stacie Greby[1], Diana Martin[1], Evan W. Secor[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]US Centers for Disease Control and Prevention, Abuja, Nigeria, [3]Institute for Human Virology, Abuja, Nigeria, [4]Nigeria Centre for Disease Control, Abuja, Nigeria

Blood samples and risk factor data were collected during the population-based 2018 Nigeria HIV/AIDS Indicator and Impact Survey (NAIIS). Participants consented to storage and future testing of specimens, enabling use of NAIIS data to determine national seroprevalence estimates for other diseases of public health importance. Schistosomiasis seroprevalence was assessed by reactivity to schistosome soluble egg antigen (SEA) in a multiplex bead assay and analyzed in conjunction with NAIIS data to assess risk factors for seropositivity. Frequencies and proportions were compared using univariate logistic regression utilizing Taylor series linearization to account for cluster sampling to generate crude odds ratios (cOR); analyses were repeated adjusting for urban/rural area (aOR). SEA antibody data were available for 31,459 of 32,494 (96.8%) children aged 0-15 years included in the study. Overall seroprevalence was 17.2% (95% confidence interval (CI) 16.3-18.1%). Seroprevalence varied by state. Factors associated with increased odds of seropositivity included: male sex (cOR=1.34, 95% CI 1.24 - 1.45), living in a rural area (cOR=2.2, 95% CI 1.9 - 2.5), and animal ownership (cOR=1.67, 95% CI 1.52-1.85). Access to improved sanitation and drinking water sources were associated with lower odds of seropositivity (cOR=0.52, 95% CI 0.47-0.58 and cOR=0.53, 95% CI 0.47-0.60, respectively), regardless of whether the child lived in a rural (sanitation: aOR=0.7, 95% CI 0.6 - 0.8; drinking water: aOR=0.7, 95% CI 0.6 - 0.8) or urban (sanitation: aOR=0.6, 95% CI 0.5 - 0.7; drinking water: aOR=0.5, 95% CI 0.4 - 0.6) area. Seroprevalence increased with increasing age ($p<0.0001$) and seropositive children were identified in every age group, including <5 years. This is Nigeria's first population-based estimate of schistosomiasis seroprevalence. Population-based survey methodologies, although not designed to identify focal areas of high or persistent schistosomiasis transmission, can identify additional populations at risk (children age <5 years), new risk factors (animal ownership), and monitor changes over time in response to control efforts.

0533

KNOWLEDGE AND AWARENESS OF SCHISTOSOMIASIS AND FEMALE GENITAL SCHISTOSOMIASIS AMONG TEACHERS IN GHANA

Margaret Gyapong[1], **Mustapha Immurana**[1], Maxwell Dalaba[1], Alfred Manyeh[1], Kazeem Arogundade[2], Julie Jacobson[3], Alison Krentel[2]

[1]University of Health and Allied Sciences, Ho, Ghana, [2]Bruyère Research Institute, Ottawa, ON, Canada, [3]Bridges to Development, Seattle, WA, United States

Schistosomiasis and its consequence of repeated infections i.e., Female Genital Schistosomiasis (FGS) continue to pose major health challenges to endemic populations, especially young girls and women in Sub-Saharan Africa (SSA). A major approach adopted in the prevention of schistosomiasis and FGS in Ghana is Mass Drug Administration (MDA) of praziquantel to school children using teachers as distributors. Knowledge and awareness of schistosomiasis and FGS among teachers are therefore very important in ensuring the success of MDA campaigns. This study therefore examined the knowledge and awareness of schistosomiasis and FGS among teachers in Ghana. Data for this paper was collected as part of the FGS Accelerated Scale Together (FAST) package study. The World Health Organization modified Expanded Programme on Immunisation sampling frame was used to sample 313 teachers in the Weija-Gbawe Municipality (Weija) and North Tongu District in Ghana. Data was analysed using frequencies, percentages and the binary logistic regression. The results showed that, while 92.97% of the teachers had heard of schistosomiasis, only 21.5% of them had heard of FGS. Similarly, while 67.7% of the teachers knew that schistosomiasis can be prevented by not performing activities in rivers, very few of them (13.8%) knew that schistosomiasis can be prevented with praziquantel. We also found that, only 40.2% of the teachers knew that pain when urinating is a sign and symptom of schistosomiasis. Results of the logistic regression further showed that, teachers aged 18-30 years, those who teach at the junior high school level as well as teachers with less than two years of teaching experience in the chosen communities, had lesser odds of having knowledge and awareness of schistosomiasis and/FGS. Thus, to ensure the effectiveness of schistosomiasis and FGS MDA campaigns, knowledge and awareness of teachers about schistosomiasis and FGS need to be enhanced. In doing so, young teachers (18-30 years), teachers who teach at the junior high school level as well as those with less than two years of teaching experience in the communities where they teach should be given more attention.

0534

ASSESSMENT OF *SCHISTOSOMA JAPONICUM* INFECTION IN ENDEMIC AREAS IN CENTRAL SULAWESI, INDONESIA, AFTER MASS DRUG ADMINISTRATION PROGRAM

Dona Arlinda[1], Muhammad Karyana[1], Muhammad Faozan[2], Anis Nurwidayati[2], Abdul Rauf[3], Dewi Lokida[4], Herman Kosasih[4], Nugroho Harry Susanto[4], Nurhayati Nurhayati[4], Maria Mila Erastuti[4], Melinda Setiyaningrum[4], Ria Resti Agustina[4], Rizki Amalia Sari[4], Santi Maulintania[4], Wahyu Nawang Wulan[4], Aaron Neal[5], Siswanto Siswanto[1]

[1]National Institute of Health Research and Development, Jakarta, Indonesia, [2]National Institute of Health Research and Development Donggala, Donggala, Indonesia, [3]Provincial Health Office, Central Sulawesi, Indonesia, [4]Indonesia Research Partnership on Infectious Disease (INA-RESPOND), Jakarta, Indonesia, [5]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Schistosoma japonicum infection is resilient in the three valleys of Lindu, Napu, and Bada in Central Sulawesi, Indonesia. To accelerate elimination, two rounds of annual mass praziquantel administration to humans and animals were conducted in 2018 and 2019, followed by targeted treatment, ecological interventions, educational campaigns, and stool surveys. These combined efforts resulted in a decrease in human

infection prevalence from 0.65-3% in 2017 to 0.3% in 2019. We aimed to determine the Kato Katz (KK) positive rate for *S. japonicum* infections in a low-endemic setting after mass drug administration (MDA). After MDA and the 2019 stool survey, a longitudinal cohort was followed from September 2019 to April 2020. Participants were residents of the 9 villages in Napu Valley and ≥2 years old. Participants' selection was guided by data on known KK-positive households identified in the 2019 stool survey. All consenting participants were asked to provide stool samples across three consecutive days (1 pot/day) at enrolment. Stool KK was examined in the field laboratory, and those with positive results were treated with praziquantel and re-evaluated 8 weeks later. Individual and household risk factors were collected using standardized questionnaires. The cohort comprised 185 participants (61 children and 124 adults aged ≥18 years) from 46 households. At enrolment, 29 (15.7%) were KK positive (9/61 (14.8%) children and 20/124 (16.1%) adults). 28/29 (96.5%) with eggs per gram (EPG) <100 and 1 adult with EPG 432. 26 (89.7%) positives KK were treated with praziquantel, and at 8 weeks post-treatment, 24/26 was negative (92.3% cure rate and 96.5% egg reduction ratio). Persistent positives were seen in 2 children with EPGs 24 and 48. *Trichuris trichiura* was found in 2 (1.1%) participants, and *Necator americanus* in 4 (2.2%). Even after two rounds of MDA, schistosomiasis infections were still prevalent. Directly observed treatment should be emphasized and close contact monitoring should be intensified. Additionally, potential reservoirs of transmission should be targeted in conjunction with human infection reduction campaigns.

0535

FOCAL UROGENITAL SCHISTOSOMA INFECTION, MALARIA AND ANEMIA AMONG SCHOOL-AGE CHILDREN IN THE KASSENA NANKANA EAST DISTRICT, GHANA

Sylvester Dassah[1], Gideon K. Asiamah[2], Valentine Harun[2], Kwaku Appiah-Kubi[2], Abraham Oduro[3], Victor Asoala[3], Lucas Amenga-Etego[4]

[1]Department of Biochemistry and Forensic Sciences, C.K Tedam University of Technology and Applied Sciences, Navrongo, Ghana, [2]Department of Applied Biology, University for Development Studies, Navrongo, Ghana, [3]Navrongo Health Research Centre, Navrongo, Ghana, [4]West African Centre for Cell Biology of Infectious Pathogens (WACCBIP), Accra, Ghana

In sub-Saharan Africa, co-morbidity with malaria, schistosomiasis, and soil transmitted helminths (STH) is common among young children. The current study investigated malaria, urinary schistosomiasis and their co-infection and anemia among school-age children in an endemic community, Nakolo in the Kassena-Nankana East District of northern Ghana. A cross-sectional survey of 336 school-age children, 5 to 16 years was undertaken. Urine samples were examined for *Schistosoma haematobium* ova using microscopy. Finger prick blood samples were examined for *Plasmodium* parasites using microscopy and haemoglobin concentration measured with HemoCue Hb301 photometer. The mean age was 10.52 (Standard deviation: ±2.27; range: 5 - 16 years), of which 50.6% (170/336) were males. The overall prevalence of urinary schistosomiasis and *Plasmodium (P.) falciparum* was 12.8% (43/336) and 37.8% (127/336), respectively with 6.0% (20/336) coinfection. Participants with only *P. falciparum* infection had 17.8% (19/107) of moderate anemia whilst 21.7% (5/23) of children infected with only *S. haematobium* had moderate anemia and 4.3% (1/23) had severe anemia. 5.0 % (1/20) of moderate anemia was observed in concurrent infections of *P. falciparum* and *S. haematobium*. Use of open water bodies was associated with increased risk of *S. haematobium* infection (OR = 1.21; 95% CI = [1.06-1.39]; p = 0.001), with females being at reduced risk (OR = 0.93; 95%CI = [0.87-0.99]; p = 0.005). Absence of self-reported haematuria had 0.81 times reduced odds of *S. haematobium* infection (OR = 0.81; 95%CI = [0.74-0.87]; p< 0.001). This study has revealed that urinary schistosomiasis remains prevalent in Kassena-Nankana East District and suggests that urinary schistosomiasis may contribute to moderate anemia among school-age children as compared to asymptomatic malaria infection. These findings call for an evaluation of the annual mass drug administration of Praziquantel among in-school children to ascertain its impact on urinary schistosomiasis prevalence across the district.

0536

ENVIRONMENTAL CONTAMINATION WITH *SCHISTOSOMA JAPONICUM* EGGS FROM AGRICULTURAL PRACTICES AND SANITATION INFRASTRUCTURE IN SICHUAN, CHINA

Andrea J. Lund[1], Elise Grover[1], Yang Liu[2], Elizabeth Carlton[1]

[1]Colorado School of Public Health, Aurora, CO, United States, [2]Sichuan Centers for Disease Control and Prevention, Chengdu, China

Environmental contamination of eggs excreted in the fecal waste of infected humans and bovines can perpetuate the transmission of *Schistosoma japonicum*. In China, interventions target both humans and bovines and include improving sanitation infrastructure and penning and replacing bovines with agricultural machinery. *S. japonicum* transmission has been interrupted in many previously endemic areas but continues in others. In Sichuan Province, where *S. japonicum* reemerged in 2007 and transmission persists in limited foci, bovines are used for agricultural labor and night soil harvested from household stool pits is used on all major crops. We aimed to describe the risk of environmental contamination with *S. japonicum* from household sanitation and agricultural practices in seven villages in Sichuan Province from 2007 to 2016. We developed a metric to describe the emissions of potentially contaminated waste (PCW) from households, accounting for uncontained bovine and human waste and night soil harvested from sanitation infrastructure with variable rates of egg removal and inactivation. With this metric, we determined how much PCW was discharged into the environment and evaluated how the risk of environmental contamination with *S. japonicum* has changed over time. While the number of surveyed households increased slightly between 2007 and 2016, total PCW emissions declined by nearly 50% from over 1.1 million kilograms in 2007 to less than 600,000 kilograms in 2016. Reductions in PCW were primarily due to reductions in bovine ownership and, to a lesser extent, improvements in sanitation and reductions in night soil use. Additional analyses will evaluate the association between PCW emissions and *S. japonicum* infection in humans and bovines. In a period in which agricultural and sanitation interventions were implemented, PCW emissions declined but risk remains for environmental contamination with *S. japonicum* eggs, especially from bovine waste. Further efforts to contain bovine waste and inactivate *S. japonicum* eggs through improved sanitation will further reduce environmental contamination and curtail *S. japonicum* transmission.

0537

THE DEVELOPMENT OF MOBILE ENABLED DIAGNOSTICS FOR SCHISTOSOMIASIS CONTROL ANALYTICS (MEDSCAN)

Carson Paige Moore[1], Maurice R. Odiere[2], Govert J. van Dam[3], David W. Wright[1], Thomas F. Scherr[1]

[1]Vanderbilt University, Nashville, TN, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Leiden University Medical Center (LUMC), Leiden, Netherlands

Schistosomiasis control and elimination efforts have relied heavily on mass drug administration (MDA) campaigns during the last several decades. While this strategy has been undeniably effective in lowering the overall burden of disease, countries that are moving towards elimination continue to struggle with persistent transmission hot spots despite widespread MDA. It is becoming clear that MDA alone is not sufficient to achieve complete elimination, and more targeted interventions are required to avoid a plateau in progress. Before its conclusion, the Schistosomiasis Consortium for Operational Research and Evaluation (SCORE) released definitive guidance outlining the pressing need for higher-resolution surveillance capabilities in the schistosomiasis sphere. This guidance suggested that the incorporation of these higher-resolution surveillance programs would likely help to unlock underlying geospatial analysis and lead to more data-driven, targeted interventions. In this work, we present

the development process for a mHealth-based geospatial surveillance platform: MEDSCAN (mobile enabled diagnostics for schistosomiasis control analytics). MEDSCAN is a platform designed to incorporate image-processing with existing diagnostics like the point-of-care circulating cathodic antigen (POC-CCA) test for schistosomiasis to provide an instant, automated, semi-quantitative diagnosis. By transforming the already successful POC-CCA test into a "connected" diagnostic, MEDSCAN serves as the gateway to near real-time surveillance with the spatial resolution necessary to shift efforts from control to elimination.

0538

BOTTLED WATER AS A MAIN DRINKING WATER SOURCE IN COUNTRIES WITHIN THE LATIN AMERICA AND CARIBBEAN GROUP

John D. McLennan

University of Calgary, Calgary, AB, Canada

Whereas part of the worldwide expansion of bottled water use is composed of its role as an occasional convenient supplement, in some countries, it is becoming one of the main sources of drinking water. This study examined the extent of bottled water use as the main drinking water source identified within recent national household surveys in Latin America and the Caribbean (LAC). Inclusion criteria required a LAC country to have available household survey data from 2018 or later which used the same standardized drinking water questions. Of the eight countries meeting these inclusion criteria, the Dominican Republic had the highest prevalence of bottled water identified as the main drinking water source at 78.7% of households. This was followed by Turks and Caicos Islands (TCI) (48.9%) and Honduras (45.6%). Cuba and Costa Rica were at the bottom of the list of eight with minimal use (0.3%). Using a broader classification of "container water" to also include use of water stations to fill up bottles, water delivery trucks, and sachets of water, the Dominican Republic value rose to 90.3%, and was surpassed by TCI at 90.8%. In four countries, the majority of households identified pipe/tap water to their house as their main source of drinking water, ranging from 59.9% (Suriname) to 96.4% (Costa Rica). Lack of access to pipe/tap water did not appear to be a major contributing variable to bottled water use in countries with high bottled water use. For example, amongst bottled water users in the Dominican Republic, 60.7% indicated use of pipe/tap water to their house as their main water source for other purposes (e.g., washing), as did 77.9% in TCI households. Further study is needed to examine what factors are driving the divergent use of reliance on bottled water across LAC countries and the impediments to the development of universal accessible and acceptable pipe/tap drinking water. In addition, further examination is needed on the implications of extensive reliance on bottled water.

0539

CHANGE IN MAIN DRINKING WATER SOURCES OVER TIME IN THE CARIBBEAN ISLAND NATIONS OF CUBA, DOMINICAN REPUBLIC, AND HAITI

John D. McLennan

University of Calgary, Calgary, AB, Canada

Attaining Target 6.1 of the Sustainable Development Goal (SDG) for universal and equitable access to safe and affordable drinking water for all by 2030 may be especially challenging for some island nations given rising sea levels, salination of fresh water, and constrained options beyond their borders. Understanding changes in the main drinking water sources of island nations over time may inform strategies to achieve Target 6.1. This study focuses on three island nations in the Caribbean, Cuba, Dominican Republic, and Haiti, each of which have publicly available national data on household water use spanning more than a decade. According to a 2021 WHO/UNICEF report, 97% of the populations in Cuba and the Dominican Republic attained "at least a basic level" of drinking water receipt by 2020, but only 65% in Haiti did. From 2006-2019 the most prevalent main source of drinking water in Cuba was piped water to the house, increasing from 58.7 to 62.5% over this 13-year period. Well water, the second most common water source in Cuba, increased from 13.8 to 21.0% over this same time period, with an increasing fraction derived from protected versus unprotected wells. From 2007 to 2019, bottled water has been the main source of drinking water in the Dominican Republic, increasing from 57.0 to 78.7% over this 12-year period. Truck delivered water has variably been the next most common source in the Dominican Republic. In Haiti, from 2005/6 to 20016/7 what had been the most common source, piped water outside the home (neighbour yard or public tap), decreased from 34.2 to 24.9% over this 11-year period. During the same period, reliance on water stations increased from 5.4 to 31.2% in Haiti. Examination of factors influencing variation across site and time in main sources of drinking water may guide initiatives to achieve the "safely managed level" (the indicator for SDG Target 6.1) for these and other island nations.

0540

HOUSEHOLD BIRD OWNERSHIP IS ASSOCIATED WITH RESPIRATORY ILLNESS AMONG YOUNG CHILDREN IN URBAN BANGLADESH (CHOBI7 PROGRAM)

Tahmina Parvin[1], Elizabeth D Thomas[2], Kelly Endres[2], Daniel Leung[2], Md Sazzadul Islam Bhuyian[1], Ismat Minhaj Uddin[1], Md Tasdik Hasan[1], Fatema Zohura[1], Jahed Masud[1], Shirajum Monira[1], Jamie Perin[2], Munirul Alam[1], A.S.G Faruque[1], Christine Marie George[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh(icddr,b), Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

There is limited evidence on the association between animal ownership and respiratory illness among young children in low- and middle-income countries. In this study, we examined the association between animal ownership and respiratory illness among children younger than 5 years of age enrolled in a prospective cohort study in urban Bangladesh. This prospective cohort study enrolled 884 participants younger than 5 years of age in Dhaka, Bangladesh. At baseline, trained research assistants administered caregivers of children younger than 5 years of age a questionnaire on household animal ownership. Animal ownership was defined as owning chickens, birds other than chickens, cats, and dogs. Respiratory surveillance was conducted monthly for children based on caregiver-reported coughing, rapid breathing, and difficulty breathing in the past 2 weeks during the 12-month study period. At baseline, 48% of children (424 of 884) had reports of coughing, 5% (40 of 884) had difficulty breathing, 3% (25 of 884) had rapid breathing, and 49% (431 of 884) had reports of any of these three respiratory symptoms. Seventeen percent of children (151 of 884) resided in a household that owned an animal. Children residing in households reporting bird ownership had a significantly greater odds of coughing (odds ratio, 1.14; 95% CI, 1.02-1.28) and any of the three respiratory symptoms in the past 2 weeks (odds ratio, 1.14; 95% CI, 1.02-1.28). Household bird ownership was associated with respiratory illness in young children. These findings suggest that interventions aiming to reduce young children's exposure to domestic animals should extend to include birds other than chickens.

0541

FOOD HYGIENE PRACTICES AND FECAL CONTAMINATION ON THE HOUSEHOLD COMPOUND ARE ASSOCIATED WITH PEDIATRIC DIARRHEA IN URBAN BANGLADESH (CHOBI7 PROGRAM)

Ismat Minhaj Uddin[1], Kelly Endres[2], Tahmina Parvin[1], Md Sazzadul Islam Bhuyian[1], Fatema Zohura[1], Jahed Masud[1], Shirajum Monira[1], Md Tasdik Hasan[1], Shwapon Kumar Biswas[1], Marzia Sultana[1], Elizabeth D Thomas[2], Jamie Perin[2], David A. Sack[2], A.S.G Faruque[1], Munirul Alam[1], Christine Marie George[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh(icddr,b), Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Diarrheal disease is a leading cause of death in children globally. In this prospective cohort study, we explored individual and household-level risk factors associated with diarrheal diseases among 251 children under 5 years of age in slum areas of urban Dhaka, Bangladesh. Caregiver reports were collected on sociodemographic factors and hygiene behaviors at baseline. During the 3-month study period, diarrhea surveillance was collected monthly, with diarrhea defined as caregiver-reported diarrhea in the previous 2 weeks (>3 loose stools over a 24-hour period). Unannounced spot checks of the household compound were performed at 7 days, 1 month, and 3 months after enrollment to assess the presence of feces (animal or human) on the household compound and in cooking and food storage areas, and to assess if cooked food was covered and/or refrigerated. Children living in households with feces within 10 steps of cooking and food storage areas during spot checks (Odds Ratio (OR): 8.43; 95% Confidence Interval (CI): 1.01, 70.18), those with feces found on the household compound (OR: 4.05.71; 95% (CI): 1.24, 13.22), and those in households found to keep cooked food uncovered and without refrigeration (OR: 6.16; 95% (CI): 1.11, 34.25) had significantly higher diarrhea at subsequent household follow-up. These study findings demonstrate that the presence of feces on the household compound and within 10 steps of cooking and food storage areas, and poor food hygiene practices were significant risk factors for diarrheal disease in young children in Dhaka, Bangladesh. Health communication programs are needed to target these exposure routes to fecal pathogens.

METHODS TO EVALUATE COVID-19 CONTROL HYGIENE PROGRAMS: OBSERVED MASK WEARING, HANDWASHING, AND PHYSICAL DISTANCING BEHAVIORS IN PUBLIC INDOOR SPACES IN DEMOCRATIC REPUBLIC OF THE CONGO

Christine Marie George[1], Kelly Endres[1], Presence Sanvura[2], Camille Williams[1], Raissa Boroto[2], Claude Lunyelunye[2], Jean Claude Bisimwa[2], Jessy Tumsifu[2], Brigitte Munyerenkana[2], Thomas Handzel[3], Justin Bengehya[4], Ghislain Maheshe[5], Alain Mwishingo[2], Cirhuza Cikomola[2], Lucien Bisimwa[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Center for Tropical Diseases & Global Health, Université Catholique de Bukavu, Bukavu, Democratic Republic of the Congo, [3]Centers for Disease Control and Prevention, Alanta, GA, United States, [4]Bureau de l'Information Sanitaire, Surveillance Epidémiologique et Recherche Scientifique, Division Provincial de la Santé Sud Kivu, Ministère de la Santé, Bukavu, Democratic Republic of the Congo, [5]Faculty of Medicine, Université catholique de Bukavu, Bukavu, Democratic Republic of the Congo

The objective of our study was to develop and test observational methods to evaluate COVID-19 preventative hygiene behaviors, and evaluate the effectiveness of a government mandate on indoor fully covered mask wearing. An observational study was conducted of 4736 individuals using 5-hour and rapid (10 minute) structured observations and spots to evaluate mask wearing, handwashing, and physical distancing behaviors, and functionality of handwashing stations in 161 indoor public spaces across Bukavu, Democratic Republic of the Congo (DRC). Indoor public location types included: shops, banks, offices, health facility wards and main entrances, beauty salons, supermarkets, schools, restaurants, large retail centers, universities, religious establishments, saunas, physical therapy offices, and gyms. Sixteen percent of individuals entering indoor public spaces were wearing a mask that fully covered their nose and mouth (fully covered mask wearing). Fully covered mask wearing was lowest inside schools at 1%, in universities at 2%, in religious establishments at 22%, and in health facility wards at 28%. Overall physical distancing > 1-meter inside indoor public spaces was 22%, and was lowest inside schools and religious establishments at 7%. Thirty-nine percent of handwashing stations had water and a cleansing agent present. Ten percent of individuals washed their hands with a cleansing agent before entering an indoor space. Overall, fully covered mask wearing was similar for 5-hour and rapid structured observations (16% vs. 15%). The odds of fully covered mask wearing significantly increased with increased government enforcement through fines in public spaces (Odds Ratio: 2.72 (95% Confidence Interval: 1.02-7.30)). This study presents rigorous methods using structured observations to assess government mandates and programs on COVID-19 preventative hygiene behaviors in indoor public spaces in settings globally.

0543

WATER, SANITATION, AND HYGIENE AND NUTRITIONAL RISK FACTORS FOR ACUTE RESPIRATORY ILLNESS IN THE DEMOCRATIC REPUBLIC OF THE CONGO: REDUCE PROSPECTIVE COHORT STUDY

Kelly Endres[1], Presence Sanvura[2], Camille Williams[1], Elizabeth D. Thomas[1], Jennifer Kuhl[1], Nicole Coglianese[2], Sarah Bauler[2], Ruthly François[1], Jean Claude Bisimwa[2], Patrick Mirindi[2], Jamie Perin[1], Alain Namegabe[1], Lucien Bisimwa[2], Daniel Leung[3], Christine Marie George[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Food for the Hungry, Phoenix, AZ, United States, [3]University of Utah School of Medicine, Salt Lake City, UT, United States

The objective of this cohort study was to examine the prevalence of acute respiratory illness among children under 5 years of age and to identify water, sanitation, and hygiene (WASH) and nutritional risk factors. This prospective cohort study was conducted in Walungu Territory, South Kivu, Democratic Republic of the Congo (DRC), and enrolled 512 participants. Spot checks of the household environment were conducted at baseline. Baseline minimum dietary diversity (MDD) was defined by consumption of five or more of the following food groups: 1) breast milk; 2) grains, roots, and tubers; 3) legumes and nuts; 4) dairy products; 5) flesh foods; 6) eggs; 7) vitamin A rich fruits and vegetables; and 8) other fruits and vegetables. Acute respiratory illness was defined as caregiver-reported rapid breathing, difficulty breathing, lower chest wall in-drawing, or coughing in the previous 2 weeks obtained at a 6-month follow-up. A total of 58% of children had acute respiratory illness, 19% had soap present in the household cooking area, 4% in the defecation area, and 21% of children met MDD. A decreased odds of acute respiratory illness was associated with soap being present in the cooking area (odds ratio [OR]: 0.49, 95% confidence interval [CI]: 0.38-0.88) and children with MDD (OR: 0.62, 95% CI: 0.38-1.00). These findings highlight the need for interventions targeting hygiene and improved dietary diversity among rural DRC households to reduce the rate of respiratory illnesses in children under 5 years.

0544

SANITATION AND HYGIENE IN AN URBAN-WORKING CLASS NEIGHBORHOOD OF SÃO PAULO, BRAZIL

Savannah V. Miller, Jeffrey Lesser, Emily Pingel, Donghai Liang

Emory University, Atlanta, GA, United States

Accessible and equitable water, sanitation, and hygiene (WASH) fundamentals are needed to slow the spread of WASH-related viruses, bacteria, and protozoa. Rapid urbanization poses challenges to the

provision of adequate WASH services due to increased risk for contact with and exposure to diseases and infected individuals. This is especially noticeable in the highly urbanized Brazilian state of São Paulo, with 96.56% of the state's total population of over 44 million living in urban areas. WASH-related diseases have been a persistent problem in Brazil, which have included malaria, dengue, Zika, cholera, tuberculosis, and other diarrheal diseases. Brazil's water and sanitation industries utilize quality indicators in assessing overall performance to achieve universal access to water and sanitation. While these measures are often embraced by policymakers as an evidence-based tool for policy decision-making, they do not always reflect needs on the ground, such as enhanced equitable access to safe water and specialized health programs addressing WASH issues for vulnerable populations. The goal of this study was to use qualitative research methods, namely thematic analysis of community ethnography field notes, to illustrate the reality of daily-life for those living in an urban-working class neighborhood of São Paulo city. Further, by analyzing historical and contemporary WASH policies in Brazil, this research provides better understandings of inconsistencies between public policy and the reality of daily life in the context of WASH. The study has two primary questions 1) "How has the prioritization of sanitation by policymakers, both historical and contemporary, shaped the health of the urban working-class in Brazil?" 2) "How do living and working conditions among the urban working class relate to the creation and/or implementation of water, sanitation, and hygiene (WASH) services?" Findings from this study suggest that local authorities should employ a bottom-up, equity-centered lens emphasizing distributive justice when creating and implementing WASH-related public policies to ensure inequities are not overlooked.

0545

HANDWASHING AND COVID-19 PREVENTION IN AFRICA: A MULTI-COUNTRY STUDY

Henrietta Osaretin Owie[1], Abisola Olufunke Olapeju[2]

[1]Qualiquant Services Limited, Lagos, Nigeria, [2]University College Hospital, Ibadan, Nigeria

There were over 489 million COVID-19 cases and six million deaths in Africa. Handwashing primarily prevents infectious diseases such as diarrhea, Ebola and COVID-19 but relies on access to handwashing resources particularly in Sub Saharan Africa. We explored the feasibility of COVID-19 prevention through the promotion of handwashing by assessing the prevalence and correlates of access to handwashing facilities in nine West African countries. Data were drawn from recent (2018-2020) Demographic and Health Surveys (DHS) in Benin, Cameroon, Gambia, Guinea, Liberia, Mali, Nigeria, Senegal and Sierra Leone. Chi-square tests and multivariate regression analysis explored the correlates of household ownership of an observed place for handwashing. Covariates included hygiene factors (type of toilet facilities in the household and whether the household treated their drinking water) and demographic factors (residence, household wealth, age and sex of head of household). Access to hand washing facilities in West Africa ranged from 21% in Liberia to 95% in Cameroon. Prevalence of handwashing facilities was comparable across urban and rural households except in Liberia and Senegal. Hygiene factors significantly associated with handwashing access included type of toilet (adjusted odds ratio (aOR) ranging from 1.06 - 2.35) and treatment of drinking water (aOR ranging from 1.25 - 4.13), while demographic factors included household size (aOR ranging from 0.95 - 1.08), female sex of household head (aOR ranging from 0.82 - 1.21), and highest wealth quintile (aOR ranging from 1.28 - 12.42). Handwashing access was somewhat low across many countries in West Africa. Behavioral interventions cannot succeed without relevant structural solutions. Increased priority on the provision of commodities such handwashing stations, soap and water in order to improve hygiene and other health outcomes such as COVID-19. Once such commodities have been provided, health promotion or behavior change interventions are needed to promote the uptake of handwashing in these settings.

0546

WASTEWATER SURVEILLANCE SYSTEM TO EVALUATE SARS-COV-2 AND OTHER VIRUSES IN A CITY WITHOUT WASTEWATER TREATMENT PLANT FROM THE HIGHLANDS IN PERU

César Arturo Valdivia-Carrera[1], Ana Cecilia Ho-Palma[2], Astrid Sherely Munguia-Mercado[1], Claudia Ibacache-Quiroga[3], Alejandro Dinamarca[3], Milan Stehlík[4], Marta Rusiñol[5], Rosina Girones[6], Eloy Gonzales-Gustavson[1]

[1]Tropical and Highlands Veterinary Research Institute, Universidad Nacional Mayor de San Marcos, Junin, Peru, [2]Department of Human Medicine, School of Human Medicine, Universidad Nacional del Centro del Peru, Junin, Peru, [3]Escuela de Nutrición y Dietética, Facultad de Farmacia, Universidad de Valparaíso, Valparaíso, Chile, [4]Instituto de Estadística, Universidad de Valparaíso, Valparaíso, Chile, [5]Institute of Environmental Assessment & Water Research (IDAEA), CSIC, Barcelona, Spain, [6]Section of Microbiology, Virology and Biotechnology, Department of Genetics, Microbiology and Statistics. Faculty of Biology, University of Barcelona, Barcelona, Spain

The monitoring of raw sewage is considered as a tool to understand the spread of viral infections as produced by SARS-CoV-2. A wastewater surveillance system was implemented in Huancayo (Junin), Peru, a city with half a million inhabitants and no wastewater treatment plants available dumping contaminated water into the Mantaro River. Wastewater samples were collected each two weeks from August 2021 to the present, with the aim of monitoring viral indicators of human fecal contamination and correlating the number of genomic copies (GC) of SARS-CoV -2, human adenovirus (HAdV), norovirus genogroup II (NoV GII) and rotavirus (RoV) with the infected population. Each sample underwent the flocculation viral concentration method with skimmed milk, nucleic acid extraction and Quantitaive Real-Time Polymerase Chain Reaction (qPCR). All samples were positive for HAdV, NoV GII and RoV, finding an average concentration of 4.18E+08 GC/100 mL, 6.10E+06 GC/100 mL and 1.92E+07 GC/100 mL, respectively. In the case of SARS-CoV-2, 25% of the samples were positive and an average concentration of 2.45E+06 GC/100 mL was observed. The detection and increase in the concentration of SARS-CoV-2 in wastewater samples were between January and February 2022, while the third wave of omicron variant of SARS-CoV-2 occurred in Peru. The increase in the number of people with COVID-19 was confirmed directly with data from the Regional Health Directorate - Junin and the Ministry of Health. These findings imply a relationship between the number of people with COVID-19 and the concentration of GC of SARS-CoV-2 in wastewater, therefore, it is possible to design a predictive statistical model that allows us to anticipate outbreaks of SARS-CoV-2 and even for other pathogens that are excreted through feces. Furthermore, the results suggest that the monitoring of viral indicators of human fecal contamination in wastewater has the potential to provide relevant information to effectively manage water resources.

0547

FOOD POISONING AND DEATH LINKED TO MONOCROTOPHOS CONTAMINATION OF TRADITIONAL BEVERAGE- ZAMBIA 2021

Thelma M. Shinjeka, Situmbeko Mwangala, Maliwa Lubasi, Francis Hadunka, Nyambe Sinyange

Field Epidemiology Training Program, Lusaka, Zambia

On 5th October 2021, a rural health facility in Choma District in the Southern Province of Zambia reported 16 cases of food poisoning, one resulting in death. We conducted a field investigation in order to confirm the existence and likely cause of the outbreak. We conducted a descriptive epidemiology study of food poisoning cases of Mbulumwiinga village. Patient records and line-list were used to confirm existence of the outbreak. 18 respondents present in the village from 3rd to 5th October 2021 were recruited, regardless of symptoms, and interviewed using a structured questionnaire. The questionnaire collected information

on participants' demographic characteristics, onset and duration of symptoms, food exposures and the health seeking behaviour. The descriptive analysis was conducted using RStudio. Munkoyo is a traditional non-alcoholic drink prepared by using cooked maize meal and fermented with rhynchosia heterophylla root extract. The munkoyo drink samples were collected for toxicological laboratory analysis and stool samples were collected for microbiological examination. Of the 18 participants, 10 (56%) were female and median age was 10 years (Interquartile range: 5-27). Attack rate among the respondents who took munkoyo drink was 100% and 0% among those who did not (Fisher's exact p-value 0.007). Of those who took munkoyo drink, one person died (Case fatality rate: 6%) after consumption while 15 (94%) recovered after treatment. The analysis demonstrates that, all the people who took the home brewed Munkoyo drink experienced food poisoning symptoms such as abdominal pains, diarrhoea, vomiting and fever. The stool laboratory results proved no presence of micro-organisms such as salmonella and shigella. Monochrotophos was detected by laboratory in the munkoyo sample. The presence of monochrotophos in the munkoyo drink may have contributed to the observed symptoms in the affected persons, but it's not clear how the contamination occurred. There is need to continue educating people in the communities on prevention and control measures of possible organophosphate pesticides ingestion as they are fatal to human health**.**

0548

GEOGRAPHIC VARIATION AND DETERMINANTS OF CHILD FECES DISPOSAL PRACTICES IN 42 LOW- AND MIDDLE-INCOME COUNTRIES: AN ANALYSIS OF STANDARDIZED CROSS-SECTIONAL SURVEY DATA FROM 2016-2020

Stephen G. Mugel, Thomas F. Clasen, Valerie Bauza

Emory University, Atlanta, GA, United States

Despite considerable progress in coverage of water, sanitation, and hygiene access globally, disposal of child feces in contained latrines remains uncommon in many low- and middle- income countries (LMICs). Because young children often have underdeveloped immune systems and high rates of enteric infection, child feces not deposited in latrines represents an important risk for diarrheal disease transmission. We synthesized data on personal and household factors and child feces disposal practices from the nationally standardized Demographic and Health Surveys and Multiple Indicator Cluster Surveys from 42 LMICs from 2016-2020. We analyzed the period prevalence of child feces disposal practices within and across these LMICs globally, and used survey weighted Poisson regression to assess individual and household determinants associated with appropriate disposal practices. Data on 403,036 children (weighted n = 191 million) showed only 40.3% of childrens' feces are deposited into a toilet or latrine, and merely 29% in an improved sanitation facility. Prevalence of appropriate child feces disposal varied substantially by country and region, however once pooled, adjusted analysis demonstrated disposal of child feces in any type of latrine increased with age, wealth, urban living, and access to improved water and sanitation facilities. An analysis restricted to households with access to sanitation facilities found only about half of children with household access to any latrine or improved latrines had their feces disposed in these facilities. This restricted analysis also found similar associated determinants, indicating these associations are robust to infrastructure and facility access improvements. We will present results related to the geographical variation of practices across regions and LMICs, as well as factors associated with appropriate disposal into a latrine. Our findings highlight the importance of efforts to improve child feces disposal practices globally, and emphasize the importance of shifting the focus moving forward beyond just improving access and toward social and behavioral interventions.

0549

SPATIAL HETEROGENEITY OF NEIGHBORHOOD-LEVEL WATER AND SANITATION ACCESS IN INFORMAL URBAN SETTLEMENTS: A CROSS-SECTIONAL CASE STUDY IN BEIRA, MOZAMBIQUE

Courtney Victor[1], Denisse Vega Ocasio[1], Zaida A. Cumbe[2], Joshua V. Garn[3], Sydney Hubbard[1], Magalhaes Mangamela[4], Sandy McGunegill[1], Rassul Nalá[5], Jedidiah S. Snyder[1], Karen Levy[6], Matthew C. Freeman[1]

[1]Emory University, Atlanta, GA, United States, [2]WEConsult, Maputo, Mozambique, [3]University of Nevada, Reno, Reno, NV, United States, [4]Autoridade Reguladora de Água (AURA, IP), Maputo, Mozambique, [5]Instituto Nacional de Saúde, Maputo, Mozambique, [6]University of Washington, Seattle, WA, United States

Rapid urbanization, resulting in population growth within informal settlements, has worsened exclusion and inequality in access to water and sanitation (WASH) services in the poorest and most marginalized communities. In this study, we describe the heterogeneity in water service satisfaction and WASH access in low-income, peri-urban neighborhoods of Beira, Mozambique, and examine whether this heterogeneity can be explained by distance to water distribution mains. Using spatial statistics and regression analyses, we identify spatial heterogeneity in household WASH access, as well as consumer-reported satisfaction with water services (services, pressure, quality, and sufficient quantity). We find that as distance from the water main increased, both access to an improved water source at the household and satisfaction with water pressure decreases, and water supply intermittency increases, controlling for household density and socioeconomic status. The odds of a household having access to a water source at the household or on the compound decreases with every 100-meter increase in distance from a water main pipe (odds ratio [OR] 0.87, 95% confidence interval [CI]: 0.82, 0.92). Satisfaction with water services also decreases with every 100-meter increase in distance from a water main pipe (OR: 0.80; 95% CI: 0.69, 0.94). Days of availability in the past week decreases by a factor of 0.22 for every 100-meter increase in distance from the water main (95% CI: -0.29, -0.15). Findings from this study highlight the unequal household access to water and sanitation in urban informal settlements, even within low-income neighborhoods. Describing this heterogeneity of access to water services, sanitation, and satisfaction - and the factors influencing them - can inform stakeholders and guide the development of infrastructural solutions to reduce water access inequities within urban settings.

0550

INVESTIGATION OF FOOD POISONING OUTBREAK AT A TRADITIONAL INITIATION CEREMONY IN PETAUKE DISTRICT, EASTERN PROVINCE OF ZAMBIA, OCTOBER 2021

Oscar Nzila, Amos Hamukale, Nyambe Sinyange

Zambia National Public Health Institute/Ministry of Health, Lusaka, Zambia

Food-borne outbreaks related to consumption of locally-brewed non-alcoholic beverages (i.e., munkoyo/thobwa) are commonly reported in Zambia. On 9th October 2021, a suspected food poisoning outbreak was reported among people who attended an initiation ceremony in a small village of a rural district in Zambia. We conducted an investigation to confirm the outbreak, determine its source, magnitude and risk factors. We conducted a 1:1 unmatched case-control study and collected information on demographics, symptoms, and food consumption history through a semi-structured questionnaire and review of medical records. A case was any person who attended the initiation ceremony and developed diarrhoea, vomiting, nausea or abdominal pain between the 9th and 16th of October 2021. Controls were individuals who attended the ceremony but did not present with any symptoms. We inspected premises, collected food, water, and stool samples for laboratory analysis. We used Stata version14 with significance set at $p<0.05$ to calculate frequencies, attack rates and odds ratios. Out of 96 respondents, 48%(n=46) were cases with a median age 27 (IQR 27-40) and 37.5 (IQR 22-50) among controls

(p=0.128). Of the cases, 60.9% (28/46) were female. Consumption of a locally brewed non-alcoholic beverage (thobwa) had the highest (86%) attack rate (p<0.0001). In the multiple logistic regression, eating of food from the ceremony (aOR 109.39, 95% CI:11.26,1063.15, p<0.0001) and consumption of thobwa (aOR 41.66, 95% CI:8.31, 208.77, p<0.0001) were significantly associated with foodborne illness. Abamectin was detected in thobwa sample, and Escherichia coli was isolated in 83% (5/6) stool samples. Although preliminary lab evidence suggests potential causes of this outbreak, additional evaluations could provide a more definitive cause of the outbreak. Given the magnitude of outbreaks linked to traditionally-brewed beverages in Zambia, an in-depth investigation aimed at identifying cause(s) and prevent future outbreaks should be done.

0551

SEROEPIDEMIOLOGY AND HOUSEHOLD TRANSMISSION OF COVID-19 AMONG MIGRANT FOOD PROCESSING AND FARM WORKERS IN NORTH CAROLINA

Michael Sciaudone[1], Melissa D. Klein[2], David Richardson[1], Colleen M. McClean[3], Roberto Lacayo[1], Oksana Kharabora[1], Alana J. Markmann[1], Allison E. Aiello[1], Ross M. Boyce[1], Jonathan J. Juliano[1], Natalie M. Bowman[1], The COFF-NC Working Group[4]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Duke University, Durham, NC, United States, [3]Duke Univeristy, Durham, NC, United States, [4]Chapel Hill, NC, United States

The US farming and food processing industry employs large numbers of Latinx immigrants, a population who has suffered disproportionately from COVID-19, and several outbreaks occurred in such industries early in the pandemic. We conducted an observational cohort study of North Carolina (NC) farming and food processing workers and their households to investigate SARS-CoV-2 seroprevalence and risk factors for transmission. In fall 2020, we recruited adults who worked in food processing facilities or commercial farms in NC and their household members > 12 months old. Participants completed a questionnaire to collect demographic, workplace, household, and behavioral data. A blood sample was collected for SARS-CoV-2 serology. We used univariate and multivariate logistic regression to investigate risk factors for SARS-CoV-2 seropositivity. Among the 118 index workers and 100 household members for whom results were available, 119 (56%) were female, median age was 34 years (IQR 14-47), 95% identified as Hispanic, and 75% spoke primarily Spanish. The seroprevalence of SARS-CoV-2 was 50%. Of 89 households, 49 had at least one seropositive member, and 35 had 100% seropositivity. Visiting church (aOR 13.5, 95% CI 1.09-166), having a prior history of COVID-19 (aOR 19.1, 95% CI 6.13-59.7), and having a seropositive household member (aOR 28.3 95% CI 12.1-66.2) were significantly associated with SARS-CoV-2 seropositivity. Age, sex, race, and preventive behaviors were not associated with seropositivity, although the latter may be affected by social desirability bias or less stringent adoption of preventive behaviors inside the home. SARS-CoV-2 seroprevalence was much higher than the prevalence of self-reported illness (23%) suggesting a high rate of asymptomatic infections and limited access to testing in 2020. Our findings highlight the disproportionate burden of COVID-19 in this vulnerable population, the potential role of commercial farms and food processing facilities in community spread, and the sizeable role of household transmission. Involving faith-based organizations in public health measures may help curb COVID-19 transmission.

0552

HIGH SARS-COV-2 SEROPREVALENCE AND RAPID NEUTRALIZING ANTIBODY DECLINE AMONG WORKERS AT A LARGE AGRIBUSINESS IN RURAL GUATEMALA, JUNE 2020-MARCH 2021

Chelsea Iwamoto[1], Kelsey Lesteberg[2], Molly M. Lamb[3], Diva M. Calvimontes[4], Kejun Guo[2], Bradley S. Barrett[2], Kaylee L. Mickens[2], Lindsey M. Duca[1], Jose Carlos Monzon[5], Anna N. Chard[1], Gerber Guzman[4], Edgar Barrios[4], Neudy Rojop[4], Kareen Arias[4], Melissa Gomez[4], Claudia Paiz[4], Guillermo A. Bolanos[4], Kathryn Edwards[6], Emily Zielinski-Gutierrez[5], Eduardo Azziz-Baumgartner[1], Edwin J. Asturias[2], Mario Santiago[2], J. D. Beckham[2], **Daniel Olson**[2]

[1]Center for Disease Control and Prevention, Atlanta, GA, United States, [2]University of Colorado School of Medicine, Aurora, CO, United States, [3]Colorado School of Public Health, Aurora, CO, United States, [4]Fundacion para la Salud Integral de los Guatemaltecos, Retalhuleu, Guatemala, [5]Center for Disease Control and Prevention, Guatemala City, Guatemala, [6]Vanderbilt University School of Medicine, Nashville, TN, United States

Seroprevalence studies in agricultural workers in low-and-middle-income countries are underrepresented in the literature. Understanding occupational risk factors can help to inform targeted workplace mitigation strategies. Using data from the Guatemala AGricultural workers and Respiratory Impact (AGRI) study and anti-SARS-CoV-2 nucleocapsid IgG (anti-N, Roche Elecsys®) to estimate past infections, we analyzed risk factors associated with seropositivity at enrollment and subsequent lab-confirmed SARS-CoV-2 infection. We assessed the stability of neutralizing antibody (NAb) response using a lentivirus-based pseudovirion assay in a subset of samples (June 2020–March 2021), prior to vaccine roll-out. Prevalence ratios (PR) were obtained using a multivariable binomial regression model. From June 15-December 30, 2020, 1334 (93.2%) participants were enrolled. The majority were male (84%), young (mean 31 years), and healthy (<13% had comorbidity). At enrollment, 616 (46.2%) had anti-N IgG suggestive of prior SARS-CoV-2 infection. Cough ≤10 days prior to enrollment (OR=1.78, 95% CI: 1.20-2.64), working as a packer (OR=4.95, 95% CI: 3.36-7.27), and as a packing plant manager (OR=3.71, 95% CI: 1.23-11.19) were associated with increased odds of seropositivity at enrollment. Of 718 seronegative workers, 2.1% had lab-confirmed COVID-19 during follow-up compared with 0.3% of the 616 seropositive workers. COVID-19 incidence density for seropositive workers was 0.4/100 Person–Years (P–Y), lower than those who were seronegative (2.3/100 P–Y). At enrollment, anti-N IgG titers in serum correlated with neutralizing antibody titers (R^2=0.26, p<0.0001). Notably, in <6 months from enrollment, most workers with follow-up NAb testing (65/77, 84%) exhibited a 95% decrease in neutralizing antibody titers. In conclusion, seroprevalence among agricultural workers was substantial. Natural infection offered some protection against reinfection but was short-lived and underscores the need for multipronged SARS-CoV-2 infection prevention strategies, including vaccination.

0553

EXCESSIVE EXPOSURE TO SARS-COV-2 REVEALED THROUGH COMMUNITY SERO-EPIDEMIOLOGICAL SURVEYS IN SOTHERN MOZAMBIQUE, FROM MAY 2021 TO FEBRUARY 2022

Arsenia Joana Massinga[1], Rita Ernesto[1], Áuria De Jesus[1], Augusto Messa Jr.[1], Felizarda Nhacolo[1], Khátia Munguambe[1], Alcido Timana[1], Sonia Enosse[2], Arsénio Nhacolo[1], Caterina Guinovart[3], Alfredo Mayor[3], Inácio Mandomando[1]

[1]Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique, [2]Instituto Nacional de Saúde, Marracuene, Mozambique, [3]ISGLOBAL, Hospital Clinic, Barcelona, Spain

COVID-19 caused by SARS-CoV-2 has quickly spread all over the World resulting in a pandemic, and after two years facing it, data and knowledge have been accumulated. Despite the severe impact in the world, data from Africa still reveal an apparently less severe impact compared with the

other continents, which may be underestimated due to the challenges in testing capacities and access to health facilities in most of the countries, particularly for people living in rural areas. However, no excessive deaths have been reported due to COVID-19 in those areas, raising uncertainties regarding the hypothetical protective factors among African people. Seroepidemiological surveys can help to uncover the proportion of people exposed to SARS-CoV-2. We conducted 3 community cross-sectional studies to estimate the community age-specific seroprevalence of SARS-CoV-2 in a rural district in Southern Mozambique (Manhiça). The cross-sectionals took place between May to June, October to November in 2021 and January to February 18, 2022, each with a 1200 sample size. Participants were randomly selected for each cross equally distributed by age group (0-19, 20-39, 40-59 and ≥60 years). Blood samples were collected to perform serological tests using a commercial kit test (Wantai SARS-CoV-2 Ab Elisa) and nasopharyngeal swabs were collected in a subset of 600 participants to perform qRT-PCR for SARS-CoV-2 detection; a questionnaire was administered to collect socio-demographic data. A total of 3603 individuals were enrolled in all three crosses (1201 in each), and the seroprevalence tended to double between crosses: 1st (27.6%, 184/666), 2nd (63.6%, 595/936) and 3rd (91.1%, 700/768) while the prevalence of SARS-CoV-2 infection remained below 15% in all crosses (4%, 0.7% and 10.1%, respectively). The seroprevalence between age-groups followed the same trend, however, the only significant difference was from the 3rd cross (p=0.001). Altogether this data shows the importance of seroepidemiological studies and reveal that people in rural areas were exposed across all age groups, but are somehow protected from disease by factors that still remain elusive.

0554

MONITORING THE INCIDENCE OF ACUTE FEBRILE ILLNESS HOSPITALIZATION AND DEATH AMONG THE GENERAL POPULATION IN VELLORE DURING THE COVID 19 PANDEMIC A COHORT STUDY

Vinu Vanathayan, Reshma Raju, Joseph Jovin Stanley, Origanti Sharon Nikitha, Winsley Rose

Christian Medical College Vellore, Vellore, India

Acute Febrile Illness (AFI) hospitalization, and deaths spiraled significantly during the Covid-19 pandemic placing an unprecedented strain on the healthcare systems across the globe. WHO reports over 400 million cases and 6 million deaths due to COVID-19. Quantifying the impact of the pandemic on the general population helps to prioritize the necessary preventive strategies. From February 2021 to March 2022, a cohort of 5250 individuals aged 2 and above residing in urban Vellore were followed up fortnightly for one year telephonically for AFI illness as part of a COVID serial serosurvey. Any AFI symptoms, hospitalization, treatment history, and deaths if any, were captured using an electronic data capture platform. The incidence of AFI events, hospitalization, and deaths per 1000 person-years of follow-up were calculated. The incidence rate per 1000 person-years for fever is 178.5 (95% CI 167.8-189.5), 115.3 (95% CI 106.4-124.5) for cough, 11.8 (95% CI 8.9-15.2) for breathing difficulty, 211 (95% CI 199.6-222.7) for nasal congestion and 23.1 (95% CI 19-27.7) for sore throat. The incidence of hospitalization per 1000 person-years was 32.5 (95% CI 27.7-37.8) and the incidence of AFI hospitalization per 1000 person-years was 12.3 (95% CI 9.4-15.9). The crude death per 1000 person-years was 8.7 (95% CI 6.4 to 11.7) over the year. The observed incidence of acute febrile illness and the associated respiratory symptoms, febrile hospitalization, and deaths were more among the general population during the pandemic. AFI surveillance during a pandemic provides much-needed data on the actual incidence of febrile illness in the community, especially in developing countries like India where the testing for COVID-19 is low either due to the existence of stigma towards the disease or due to low testing rates because of strain on the existing healthcare system.

COVID-19 VACCINE ATTITUDES AND ACCEPTANCE AMONG REFUGEES VERSUS LEBANESE NATIONALS PRE- AND POST-VACCINE INTRODUCTION IN LEBANON

Zawar Ali[1], Shiromi M. Perera[1], **Stephanie C. Garbern**[2], Elsie Abou Diwan[3], Alaa Othman[3], Javed Ali[1], Nada Awada[3]

[1]International Medical Corps, Washington, DC, United States, [2]Alpert Medical School of Brown University, Providence, RI, United States, [3]International Medical Corps, Beirut, Lebanon

This study evaluated attitudes toward COVID-19 vaccines and factors associated with vaccine acceptance among refugees versus Lebanese nationals before and after vaccine introduction. Two anonymous cross-sectional surveys were conducted in February 2021 (Survey 1, pre-vaccine introduction) and June 2021 (Survey 2, post-vaccine introduction), using a convenience sample of adult refugees (Syrian/ Palestinian) and Lebanese nationals accessing International Medical Corps- supported primary health care centers. Survey items were mapped to domains from the Health Beliefs Model (HBM). Descriptive analysis was conducted, and comparisons made with chi-squared test. Logistic regression was used to assess associations of demographic data and HBM domains with the outcome of vaccine acceptance. 52.9% of respondents in Survey 1 (n=3,927) and 54.2% in Survey 2 (n=4,174) were refugees. While vaccine acceptance was low in both groups in Survey 1 (25.9% nationals vs. 23.1% refugees), by Survey 2 this had increased, with vaccine acceptance being higher in nationals versus refugees (57.6% vs. 32.9% respectively). Respondents reported greater perceived benefits of vaccination, higher perceived susceptibility to COVID-19, and lower perceived barriers to vaccination in Survey 2 versus Survey 1. In regression analysis in Survey 1, gender, nationality, and age were not associated with vaccine acceptance. However, in Survey 2, refugees had lower odds of vaccine acceptance compared to Lebanese nationals (OR 0.50, 95%CI 0.41-0.60) while older age (OR 1.37, 95%CI 1.06-1.78, ≥51 years vs. 18-30 years) was associated with greater odds of vaccine acceptance. Vaccine attitudes shifted differentially between Lebanese nationals and refugees post-vaccine introduction. While both groups had similarly low vaccine acceptance before vaccine roll-out, attitudes toward vaccines diverged following vaccine roll-out, with Lebanese nationals having higher vaccine acceptance compared to refugees. Targeted efforts to improve COVID-19 vaccine confidence specific to refugee populations in Lebanon are needed.

TRENDS OF INFLUENZA ACTIVITY DURING THE COVID-19 PANDEMIC IN GHANA, 2020

Ivy A. Asante[1], Yaw Awuku-Larbi[1], Stephen O. Nyarko[1], Gifty Mawuli[1], Richard A. Obeng[1], Esinam Amenuvor[1], Mildred Adusei-Poku[1], Linda Boatemaa[1], Vanessa Magnusen[1], Jennifer Wutsika[1], Samuel Ago[1], Loretta Kwasah[1], Roberta Tackie[1], Juliet Wordui[1], Daniel Mingle[2], William Asiedu[2], Edward O. Nyarko[2], Dennis Laryea[3], Franklin Asiedu-Bekoe[3], Shirley Nimo-Paintsil[4], Naiki Attram[4], Anne T. Fox[4], **Terrel Sanders**[4], William K. Ampofo[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Ghana Armed Forces, 37 Military Hospital, Accra, Ghana, [3]Ghana Health Service, Ministry of Health, Accra, Ghana, [4]US Naval Medical Research Unit No. 3 Ghana Detachment, Accra, Ghana

By the end of March 2020, almost every country had reported cases of SARS-CoV-2, causative agent of COVID-19, with more than 5 million deaths worldwide at the end 2021. Surges in the number of active COVID-19 infections resulted in the closure of borders and restriction-of-movement (ROM) policies in most countries. Though WHO and other health agencies had advocated for preparedness for emerging and re-emerging diseases, many health systems were taken by surprise leading to collapse of surveillance systems. This cross-sectional study used prospective influenza surveillance data from 29 sentinel sites received by the Ghana National Influenza Centre (Ghana-NIC). We sought to detect the presence and burden of influenza cases during the COVID-19

pandemic. A retrospective analysis comparing 2017 to 2019 against 2020 data was conducted. In 2020, there was a significant reduction (50%) in the number of samples received from the sentinel sites compared to the previous years (2017-2019). Influenza activity occurred in two waves during the 2020 influenza surveillance season, December 30, 2019, to March 8, 2020 (epidemiological weeks 1-10) and September 28 to December 28 (weeks 40-52). Between these two waves, there was no records of influenza activity. In the first wave, percentage positivity peaked from late February to early March (week 9) at 9% and declined to 0% by mid-March (week 11) with AH3N2 commonly detected amongst positive patients. Influenza percentage positivity peaked in weeks 48 and 52 at 20% and 21% respectively in the second wave, with influenza B Victoria dominating. Between weeks 10 to 42, samples were not received from the sentinel sites and therefore, 1,083 samples selected from the COVID-19 surveillance were tested for influenza with no positives recorded. In Ghana and US military installations alike, ROM policies, international COVID-19 protocols and adherence to community mitigation strategies reduced the transmission of SARS-CoV-2, and indirectly affected transmission of influenza viruses as well.

IMPACT OF ANTIGEN TEST TARGET FAILURE AND TESTING STRATEGIES ON THE TRANSMISSION OF SARS-COV-2 VARIANTS

Bethan N. Cracknell Daniels[1], Claudia Del Vecchio[2], Giuseppina Brancaccio[2], Alessandra Rosalba Brazzale[2], Enrico Lavezzo[2], Constanze Ciavarella[1], Francesco Onelia[3], Elisa Franchin[3], Laura Manuto[2], Federico Bianca[2], Vito Cianci[3], Anna Maria Cattelan[3], Ilaria Dorigatti[1], Stefano Toppo[2], Andrea Crisanti[1]

[1]Imperial College London, London, United Kingdom, [2]University of Padua, Padua, Italy, [3]Padua University Hospital, Padua, Italy

Population testing and genomic surveillance remain central to controlling the COVID-19 pandemic and will also be important for future pandemic preparedness. During the pandemic, the use of rapid antigen diagnostic tests has expanded, coinciding with a decline in the use of molecular tests. Here we report the results of a hospital-based surveillance study conducted in the Italian region of Veneto, where we identified a pattern of disruptive amino-acid substitutions within a major B-cell epitope of the SARS-CoV-2 N antigen, which enabled variants to escape N antigen tests. By fitting a multistrain compartmental model linking genomic and epidemiological data, we found that the widespread use of antigen tests in Veneto favoured the undetected spread of the antigen-escape variant compared to the rest of Italy, where the use of antigen testing was lower for the duration of the study period. We also quantified the impact of a range of testing scenarios, including mass antigen testing in the absence of molecular testing, on the transmission dynamics, diagnostic test performance and genomic surveillance of escaping and concordant SARS-CoV-2 variants. Our results highlight how the widespread use of antigen testing could facilitate the transmission of novel SARS-CoV-2 variants with disruptive N antigen mutations. Critically, in the presence of a variant that escapes antigen testing, we found that molecular testing and genomic surveillance, independent of antigen testing, are critical for unbiased estimates of escaping and concordant variant prevalence. Given the high levels of SARS-CoV-2 incidence across the globe, novel variants of concern can be expected. Our findings therefore highlight the importance of global investment in molecular testing capacity and genomic surveillance, to facilitate the rapid detection and control of such SARS-CoV-2 variants.

THE TRANSCRIPTION FACTOR MYB-M DRIVES MALE COMMITMENT IN THE PARASITE *CRYPTOSPORIDIUM*

Katelyn A. Walzer, Jayesh Tandel, Jessica Byerly, Jodi A. Gullicksrud, Eoin Whelan, Elise Krespan, Daniel P. Beiting, Boris Striepen

University of Pennsylvania, Philadelphia, PA, United States

The apicomplexan parasite *Cryptosporidium* is a leading cause of diarrheal disease and infects millions of people worldwide each year. With no vaccine and inadequate treatment, a great need exists for new therapeutics. Related parasites have complex life cycles with multiple hosts, but *Cryptosporidium* infects a single host where its entire life cycle unfolds, making it a great model for the study of transcriptional regulators. Sporozoites excyst from an oocyst and invade intestinal epithelial cells, propagating asexually for three cycles before transitioning to male and female gametes. Sex leads to the production of new oocysts. Recently, we performed single-cell RNA-sequencing of 9,310 parasites to document the transcriptional changes that occur throughout the life cycle. We found an abrupt switch to male or female development and identified AP2 and Myb transcription factors associated with sexual stages, including Myb-M. Myb-M is expressed in the earliest males and was deemed essential *in vivo*. We developed a conditional overexpression system in *Cryptosporidium* to functionally characterize Myb-M and other essential transcription factors. Overexpression of Myb-M drove the direct development of males from asexual parasites and induced the expression of male-specific genes, including AP2-M and HAP2. Growth assays also showed that Myb-M overexpression halted parasite propagation *in vitro*, and induction of Myb-M *in vivo* led to reduced parasite burden, measured by fecal oocyst shedding. These findings indicate that Myb-M is sufficient to induce male fate, even at the earliest stages of the parasite life cycle, and is a master regulator of male commitment in *Cryptosporidium*. Current work is focused on using ChIP-seq to define the genes controlled by Myb-M as well as utilizing the Myb-M overexpression strain to study large populations of mature male parasites via microscopy and high-throughput sequencing.

IN VIVO ASSESSMENT OF *PLASMODIUM VIVAX* CHESSON STRAIN LIVER STAGE INFECTION: NOVEL STUDIES TO ASSESS HYPNOZOITE FORMATION, PERSISTENCE, ACTIVATION, AND RELAPSE

Gigliola Zanghi[1], Sumana Chakravarty[2], Hardik Patel[1], Stephen L. Hoffman[2], B. Kim Lee Sim[2], Stefan H.I. Kappe[1], Ashley M. Vaughan[1]

[1]Seattle Children's, Seattle, WA, United States, [2]Sanaria Inc, Rockville, MD, United States

The main goal of Plasmodium vivax liver stage research is aimed at understanding the formation, persistence and activation of hypnozoite stages, which are the source of recurrent relapses. This research, however, is hampered by several challenges to studying P. vivax (Pv) liver stages in the laboratory, including the limited access to sporozoites (SPZ). Sporozoites are primarily obtained from mosquitoes fed on infected patient blood, causing significant variability in experimental outcomes. Here, we revisited the use of Chesson strain PvSPZ for analysis of hypnozoite biology. Pv Chesson blood stages were propagated in Saimiri monkeys and used for mosquito feeds to generate PvSPZ (Chesson) that then underwent cryopreservation. We used these to infect human liver-chimeric FRG huHep mice. Furthermore, single cell RNA-seq analysis of PvSPZ (Chesson) was undertaken. We observed robust liver infection of FRG huHep mice. Exo-erythrocytic schizonts matured normally over nine days, when primary exo-erythrocytic merozoites egressed from the liver into the blood. Strikingly, hypnozoites formed frequently and persisted. The hypnozoite:schizont ratio in the infected livers was consistently approximately 40%:60%, constituting the first quantitative determination of Chesson strain hypnozoite frequency. Hypnozoites were viable,

activated and caused first relapses after approximately three weeks. This model will allow for consistent profiling of both hypnozoites and schizonts as well as the infected host hepatocytes. To understand if the hypnozoite fate is predetermined in PvSPZ (Chesson), we performed single cell RNA-seq analysis of PvSPZ (Chesson). Preliminary analysis showed enrichment of genes associated with chromatin remodeling in a subset of sporozoites, possibly highlighting a role for epigenetic regulation in hypnozoite formation. Our Chesson strain liver stage model will allow us to gain a better understanding of hypnozoite biology and can aid in the discovery of novel interventions to prevent relapse.

SICA-MEDIATED CYTOADHESION OF *PLASMODIUM KNOWLESI*-INFECTED RED BLOOD CELLS TO HUMAN UMBILICAL VEIN ENDOTHELIAL CELLS

Huai Chuang[1], Miako Sakaguchi[2], Lucky Amuza Byaruhanga[1], Junya Yamagishi[3], Yuko Katakai[4], Satoru Kawai[5], Osamu Kaneko[1]

[1]Protozoology department, Nekken, Nagasaki University, Nagasaki, Japan, [2]Central Laboratory, Institute of Tropical Medicine (NEKKEN), Nagasaki University, Nagasaki, Japan, [3]Research Center for Zoonosis Control, Hokkaido University, Sapporo, Japan, [4]The Corporation for Production and Research of Laboratory Primates, Tsukuba, Ibaraki, Japan, [5]Department of Tropical Medicine and Parasitology, Dokkyo Medical University, Tochigi, Japan

Plasmodium knowlesi is a causative agent of zoonotic human malaria in Southeast Asia. Post-mortem examination of human *knowlesi* malaria cases showed sequestration of *P. knowlesi*-infected red blood cells (iRBCs) in blood vessels, which has been proposed to be linked to disease severity. This sequestration is likely mediated by the cytoadhesion of parasite-iRBCs to vascular endothelial cells, however, the responsible parasite ligands remain undetermined. In this study, we enriched *P. knowlesi*-iRBCs which bound to the human umbilical vein endothelial cells (HUVECs) by repeating panning selection. Transcriptome analysis revealed that the transcript level of one gene, encoding a Schizont Infected Cell Agglutination (SICA) protein, herein termed SICA-HUVEC, were more than 100 fold increased after the panning. The cytoadhesion activity of SICA-HUVEC to HUVECs was confirmed by reverse genetics approach: exogenous expression of SICA-HUVEC significantly increased cytoadhesion activity of the transgenic parasites in both monkey and human iRBCs. Transgenic *P. knowlesi* parasites expressing Myc-fused SICA-HUVEC increased cytoadhesion activity following infection of monkey as well as human RBCs, confirming that SICA-HUVEC conveys an activity to bind to HUVECs. In summary, this study revealed that SICA-HUVEC protein is a strong candidate ligand recognizing receptors on HUVECs and mediating the cytoadhesion in *knowlesi* malaria.

DIFFERENCES IN GENE ESSENTIALITY BETWEEN *PLASMODIUM KNOWLESI* AND *P. FALCIPARUM* REVEALED BY *PIGGYBAC* SATURATION MUTAGENESIS

Jenna Oberstaller[1], Shulin Xu[1], Min Zhang[1], Deboki Naskar[2], Chengqi Wang[1], Thomas D. Otto[3], Julian C. Rayner[2], **John H. Adams**[1]

[1]University of South Florida, Tampa, FL, United States, [2]University of Cambridge, Cambridge, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom

Experimentally friendly attributes of *Plasmodium knowlesi* make it of increasing interest for systematic genetic studies of vivax-like malaria parasites. It is genetically very tractable, with much higher transfection efficiencies than *P. falciparum*, and while a cause of human malaria in only some malaria endemic regions, it is phylogenetically closely related to *P. vivax*, which causes the majority of malaria outside Africa but cannot currently be cultured *in vitro.* We have adapted the *piggyBac* mutagenesis approach to *P. knowlesi* using the A1-H.1 line that can be grown in human RBCs and is now widely adapted in many malaria research laboratories. The *pkef1a* promoter is used to drive transposase expression and the *pkhsp70* promoter drives hDHFR-GFP expression for selection of mutants. Approximately 33,000 insertions were identified randomly distributed throughout the genome to achieve a saturation-level of mutagenesis even though the available TTAA insertion sites in *P. knowlesi* is approximately half that of *P. falciparum*. However, the relative proportion of insertions within the UTR regions, especially the 5', is much higher in *P. knowlesi* along with a higher percentage of exon insertions (i.e. more dispensable genes). Based on this level of mutagenesis we can determine mutability or a mutagenesis index score of 5401 *P. knowlesi* genes. While the patterns of essentiality by GO classifications are similar between these species, the high proportion of non-mutable *P. knowlesi SICAvar* family genes is notably different than the high overall mutability of the orthologous *P. falciparum var* gene family. This successful application of the *piggyBac* methodology to *P. knowlesi* provides a robust scalable platform for experimental forward genetic screens to explore unique biology of vivax-like malaria parasites.

0562

A MODULAR CLONING SYSTEM FOR HIGH EFFICIENCY PRODUCTION OF *PLASMODIUM FALCIPARUM* TRANSFECTION VECTORS

Kyle Jarrod McLean, Jacquin C. Niles

Massachusetts Institute of Technology, Cambridge, MA, United States

Genetic modification of *Plasmodium falciparum* through the transfection of DNA plasmids is an important tool for understanding the parasite›s biology. However, the extreme AT-bias and low complexity of the parasite›s genomic sequences makes traditional cloning in circular plasmids prone to spontaneous rearrangements and deletions. These issues can be avoided by using linear cloning vectors derived from the non-integrating prophage of the N15 coli phage. However, the only commercially available linear plasmid is large (~13 kb), and contains cut sites for nearly every common restriction enzyme, which limits flexibility during construction and modification of *P. falciparum* transfection vectors. To address this, we reconstructed the N15 linear plasmid from scratch, reducing its size by 5 kb and recoding the backbone to eliminate 85 restriction sites and render another 50 unique. We have used this new linear plasmid to develop a Modular Cloning (MoClo) system, a popular technique in the synthetic biology community given its speed, reliability and scalability. MoClo uses type-IIS restriction enzymes to perform multi-piece assembly of standard biological parts in a single reaction with high efficiency. We are creating a collection of standard parts for *P. falciparum* including promoters, terminators, epitope tags, reporters, effectors, and selectable markers. Using our linear plasmid, we can easily assemble these parts into large, complex, AT-rich plasmids. Our approach improves the predictability, reliability and speed with which new plasmid vectors for *P. falciparum* can be created and will accelerate the malaria community›s ability to address important biological questions.

0563

LIVER ULTRASOUND FINDINGS IN PRESCHOOL CHILDREN FROM THE PRAZIQUANTEL IN PRESCHOOLERS (PIP) TRIAL IN LAKE ALBERT, UGANDA

Sophie Pach[1], Emily Webb[1], Andrew Edielu[2], Hannah Wu[3], Susannah Colt[3], Joachim Richter[4], Patrice Mawa[2], Jennifer Friedman[3], Amaya Bustinduy[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]MRC Uganda and London School of Hygiene and Tropical Medicine, Entebbe, Uganda, [3]Lifespan Center for International Health Research & Brown University, Providence, RI, United States, [4]Charité - Universitätsmedizin Berlin Institute of Tropical Medicine and International Health, Berlin, Germany

Periportal fibrosis is recognized as a late-stage manifestation of chronic infection with the waterborne parasite *Schistosoma mansoni.* Praziquantel (PZQ), the only drug available for the treatment of schistosomiasis, has

limited effect on advanced morbidity at the current recommended 40 mg/kg given as a single dose annually. Preschool children (PSAC) less than 4 years of age are not considered to be an at-risk population for such severe morbidity. However, the prevalence of periportal fibrosis in PSAC in highly *S. mansoni* endemic settings is not known. As part of a phase II trial examining different dosing regimens for PZQ in children age 12-48 months in Uganda (PIP trial), we present the prevalence of schistosomiasis-related fibrosis as determined by liver ultrasound. PSAC from Lake Albert who were infected with *S. mansoni as* diagnosed by stool Kato-Katz were enrolled into the PIP trial. Infection intensity was classified by eggs per gram of stool (epg) as low (<100 epg), moderate (100 – 399 epg) and heavy (>400 epg). Standard measures following the WHO Niamey protocol for schistosomiasis-related periportal fibrosis were captured at baseline. Mean age was 34 months (std dev 9.1). Infection intensities were: light (56.9%), medium (24.0%) and heavy (19.1%). Of the 343 participants with recorded ultrasound data, 7 (2%) had evidenced of possible periportal fibrosis, 27 (8 %) evidence of incipient periportal fibrosis and 59 (17%) had evidence of periportal thickening. Older age (per month increase) and lower maternal education were associated with higher degree of periportal thickening (OR 1.03, CI: 1.00, 1.07) and (OR 2.72, CI: 1.37, 5.40) respectively. No other variable was found to be associated with the prevalence of periportal thickening or established fibrosis at baseline. Incipient schistosomiasis-related liver morbidity was detected in young children enrolled in the PIP trial. This trial presents a unique opportunity to identify optimal PZQ dose and frequency of dosing in a population that has been systematically excluded from control efforts. Earlier and repeated PZQ treatment may reverse or delay disease progression.

0564

GUT MORBIDITY AMONG PRE-SCHOOL CHILDREN WITH *SCHISTOSOMA MANSONI* INFECTION IN ALBERTINE REGION, WESTERN UGANDA

Andrew Edielu[1], Susannah Colt[2], Emily Webb[3], Patrice Mawa[1], Hannah Wu[2], Racheal Nakyesige[4], Ayebazibwe Gloria Kakoba[4], Amaya Bustinduy[3], Jennifer F. Friedman[5]

[1]MRC Uganda and London School of Tropical Hygiene and Medicine, Entebbe, Uganda, [2]Lifespan Center for International Health Research and Brown University, Providence, RI, United States, [3]London School of Tropical Hygiene and Medicine, London, United Kingdom, [4]MRC Uganda, Entebbe, Uganda, [5]Lifespan Center for Internaitonal Health Research and Brown University, Providence, RI, United States

Schistosoma mansoni causes intestinal inflammation as eggs from adult worms in the mesenteric blood vessels are passed in stool. Eggs transit the gut mucosa, eliciting a Th1 inflammatory process that has been demonstrated to contribute to Environmental Enteric Dysfunction (EED) among older children and adults. Calprotectin is a neutrophil cytoplasmic protein and its presence in stool denotes active intestinal inflammation. As part of an ongoing NIH-funded phase II trial of optimal PZQ dosing for PSAC ages 12-48 months in Uganda, we examined the relationship between baseline markers of gut morbidity and *S. mansoni* infection. Few if any studies have addressed gut morbidity among young children with schistosomiasis. At trial enrolment, children were screened for the presence of *S. mansoni* by duplicate Kato Katz, and included if they were infected. Infection intensity was classified by eggs per gram of stool (epg) as low (<100 epg), moderate (100 – 399 epg) and heavy (>400 epg). Age, household sanitation (any latrine), maternal education (no school vs some), and water source (lake vs other) were evaluated for inclusion in linear and logistic regression models Fecal calprotectin and occult blood (FOB) were measured in N = 348 PSAC. Mean age was 34 months (std dev 9.1). Infection intensities were: light (56.9%), medium (24.0%) and heavy (19.1%). Calprotectin level was associated intensity of schistosomiasis infection, (β=0.07; $P < 0.01$) and lack of latrine (β=86; ($P < 0.001$) after adjusting for age and maternal education. FOB was detected in 27% (95% CI 22.3 – 32.1). 22% of PSAC with FOB also had history of bloody stools. Moderate/high vs low intensity *S. mansoni* infection was associated with increased risk of FOB (OR=1.84; P =0.04) after adjusting for maternal education. The association between both calprotectin and FOB and *S. mansoni* infection suggests that young children may be less able to downregulate intestinal inflammation and are already accruing significant gut morbidity. The association between lack of sanitation and calprotectin is likely due to the presence of non-schistosomal causes of EED such as other parasitic, bacterial and viral infections.

0565

MULTILOCUS PCR-DNA SEQUENCE TYPING SCHEME TO INVESTIGATE HYBRIDIZATION IN *SCHISTOSOMA HAEMATOBIUM*

Oluwaremilekun G. Ajakaye[1], Egie E. Enabulele[2], Joshua Balogun[3], Oyetunde Oyeyemi[4], Adamu Dagona[5], Gagman Haladu[6], Michael Lapand[7], Ombugadu Akwashiki[8], Michael E. Grigg[9]

[1]National Institute of Health, NIAID, Bethesda, MD, United States, [2]Biomedical Research Institute, San Antonio, TX, United States, [3]Federal University, Dutse, Dutse, Nigeria, [4]University of Medical Sciences, Ondo, Nigeria, [5]Federal University, Gashua, Gashua, Nigeria, [6]Bauchi State University, Gadua, Nigeria, [7]University of Jos, Jos, Nigeria, [8]Federal University of Lafia, Lafia, Nigeria, [9]National Institutes of Health, NIAID, Bethesda, MD, United States

Schistosomiasis is a parasitic disease caused by blood flukes in the genus *Schistosoma* that infect human and animal hosts. Reports of ongoing hybridization between human and animal species of schistosomes in many parts of Africa suggest that a species complex may exist within the Schistosoma haematobium group, comprised of *S. haematobium*, *S. bovis*, *S. currasoni*, *S. intecalatum*, *S. guineensis*, and *S. mattheei*. We investigated the occurrence of schistosome hybrids in three pastoral and two non-pastoral communities across Nigeria. In two of the pastoral communities, there was no evidence of schistosome infections detected. In the other three communities, eighty parasite isolates were obtained by urine filtration or hatched miracidia on FTA cards. Extracted DNA was PCR amplified at the gene markers rITS and mtCO1 and five haplotypes were resolved. Five isolates from a pastoral community possessed SNPs at the rITS locus that grouped them with either *S. bovis* or *S. haematobium-S. bovis* hybrids, suggesting that they might be hybids. However, the rITS and mtCO1 failed to provide sufficient genetic information to allow for robust differentiation between S. haematobium, S. bovis, and hybrids of both species. We therefore developed a multilocus sequence typing scheme based on newly identified markers to generate high-resolution data to study the genetic diversity of schistosomes. The new markers characterized field isolates and provided additional inference on the diversity and population genetic structure within this complex group of schistosome species related to *S. haematobium*. We propose this multilocus typing scheme as an alternative for distinguishing between *S. haematobium*, *S. bovis*, and hybrids from both species. The generated data also provided information for the assessment of genetic diversity, and phylogenetic relationships within and between schistosome species.

0566

RELATIONSHIPS BETWEEN *SCHISTOSOMA MANSONI* INTENSITY AND NUTRITIONAL STATUS AMONG PRESCHOOL-AGED CHILDREN IN UGANDA

Susannah Colt[1], Andrew Edielu[2], Emily L. Webb[3], Patrice A. Mawa[4], Hannah W. Wu[1], Racheal Nakyesige[2], Amaya L. Bustinduy[3], Jennifer F. Friedman[1]

[1]Lifespan Center for International Health Research, Providence, RI, United States, [2]London School of Hygiene and Tropical Medicine Uganda Research Unit, Entebbe, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Uganda Virus Research Institute, Entebbe, Uganda

Schistosomiasis causes anemia and impaired linear growth among children. However, there is a paucity of evidence in pre-school age children (PSAC) because it was commonly held that they were not significantly infected, and studies addressing reversibility of morbidity with praziquantel (PZQ) are limited as PZQ has only recently been approved for children ages

1-4. As part of an ongoing NIH-funded phase II trial of optimal PZQ dosing for PSAC ages 12-48 months in Uganda, we present baseline findings assessing *Schistosoma mansoni* infection and nutritional morbidities. Children with *S. mansoni* infection, detected by Kato Katz in duplicate stool samples, were enrolled from the Lake Albert region in Uganda. Anemia was defined as hemoglobin <11.0 g/dL. Undernutrition categories of underweight (weight-for-age z score<-2), stunting (length-for-age z score<-2), and wasting (weight-for-length z score<-2) were defined using WHO Anthro. Statistical analyses included multivariate linear and log binomial regression models adjusting for age, malaria co-infection, and father's education level. Of the 348 participants included, the median infection intensity was 72 EPG (IQR 24-258). Sixteen percent of children had malaria and 56.6% were anemic. Higher infection intensity was associated with lower hemoglobin concentrations (ß=-0.0128, p=0.0015), an increased risk for anemia (RR=1.29, CI 1.10-1.50), and occult blood in stool (RR=1.21, CI 1.03-1.42). Infection intensity was not significantly associated with underweight (RR=0.75, CI 0.47-1.18), stunting (RR=0.83, CI 0.69-1.01), or wasting (RR=1.28, CI 0.66-2.48). This trial offers a unique opportunity to assess *S. mansoni*-associated morbidity in PSAC who received PZQ treatment and will be followed for 12 months. At baseline, infection burden was associated with an increased risk for anemia, which may be explained in part by occult blood loss associated with schistosome egg-induced intestinal damage. Evidence of PSAC experiencing schistosomiasis-related nutritional morbidities further demonstrates the need for PZQ mass drug administration campaigns to include young children in endemic areas.

0567

LIVER AND BLADDER MORBIDITY IN AN *SCHISTOSOMA MANSONI AND S. HAEMATOBIUM* CO-ENDEMICITY AREA IN THE DEMOCRATIC REPUBLIC OF CONGO

Sylvie Linsuke[1], Clémentine Roucher[2], Joule Madinga[1], Mamy-Irène Miantenzila[3], Sylvain Baloji[4], Jean-Pierre Van Geertruyden[5], Katja Polman[2], Pascal Lutumba[6]

[1]National Institute of Biomedical Research (INRB), Kinshasa, Democratic Republic of the Congo, [2]Unit of Medical Helminthology, Biomedical Department, Institute of Tropical Medicine, Antwerp, Belgium, [3]Department of Radiology, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [4]Programme National de Lutte Contre la Trypanosomiase Humaine Africaine (PNLTHA), Kinshasa, Democratic Republic of the Congo, [5]Global Health Institute, Faculty of Medicine, University of Antwerp, Antwerp, Belgium, [6]Department of Tropical Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo

Schistosomiasis is a chronic and devastating disease responsible for significant morbidity and a relative mortality. In endemic areas, chronic infection causing periportal fibrosis, for infection with *Schistosoma mansoni* (*S.m*) and squamous cell bladder diseases ending in carcinoma, for infection with *Schistosoma haematobium (S.h)*. The Democratic Republic of the Congo (DRC) is among the most affected countries by both *S.m* and *S.h*. However, little is known about the morbidity associated with infection, despite the considerable burden of the disease. The study aims to determine specific Schistosoma morbidity, and its correlation with species of Schistosoma. We conducted a community-wide study between November 2015 and March 2016 in a rural community of Kifwa 2 village, in western of the DRC. Ultrasound examinations were performed in a total of 899 individuals aged 1-85 years previously tested for *Schistosoma* infections. Indicators of morbidity were recorded accordingly to the Niamey protocol, and multivariate logistic regression analysis employed to identify predictors for *Schistosoma* morbidity. Ultrasonography findings revealed that 68% of the study participants had *S.h* specific bladder morbidity (0.6%, 50.1% and 17.3% respectively for score 1, 2 and ≥3), 64.9% had *S.m* specific liver morbidity (56.4%, 6.8%, 0.9%, and 0.8% for grade C, D, E and F, respectively), and 48.7% had both bladder and fibrosis morbidity. Bladder and fibrosis morbidity are common for all age, but increases with age peaking at 10-14 years (77%) for *S.h* specific bladder morbidity and ≥ 40 years (79%) for *S.m* specific liver morbidity. Risk factors for *S.h*-specific bladder morbidity was age ≥40 years (p=0.024), *S.h* infection (p=0.004), and *S.m* infection (p=0.049). However, sex female (p=0.030), age ≥40 years (p<0.001), and *S.m* infection (p=0.008) are risk factors for *S.m*-specific liver morbidity. There is an urgent need of chemotherapy and/or chemoprophylaxis and reevaluate this situation after a certain period such as 2 or 5 years. In the same time, the control vector of schistosomiasis could enhance the elimination of this disease as a public health problem.

OPTIMIZING THE USE OF PRAZIQUANTEL FOR PLANNING PREVENTIVE CHEMOTHERAPY CAMPAIGN AGAINST SCHISTOSOMA INFECTION IN SENEGAL: RESULTS FROM COMMUNITY LEVEL ANALYSIS

Khadime Sylla[1], Bocar Diop[2], NDeye MBacke Kane[2], Oumou Kaltome Boh[2], Babacar Gueye[2], Mady Ba[3], Malang Mane[4], Boniface Ekoue Kinvi[5], Honora Gustave Zoure[5], Jorge Cano Ortega[5], Pauline Mwinzi[5], Moussa Sacko[6], Babacar Faye[1]

[1]University Cheikh Anta Diop (UCAD), Dakar, Senegal, [2]Ministry of Health, Dakar, Senegal, [3]World Health Organization, Dakar, Senegal, [4]USAID's Act to End NTDs | West, Dakar, Senegal, [5]ESPEN / World Health Organization, Brazzaville, Congo, Republic of the, [6]Institut National de Santé Publique, Bamako, Mali

Preventive chemotherapy (PC) with Praziquantel is the major strategy for controlling schistosomiasis in Senegal. This community level data analysis was aimed at updating the endemicity of schistosomiasis for better targeting population requiring Praziquantel in Senegal. Demographic and epidemiological data from 1610 community health areas were analyzed using the WHO/AFRO schistosomiasis sub-district data optimization tool 2021. The tool applies a WHO/AFRO decision tree for areas without epidemiological data to determine if mass treatments should be continued at community level. Overall, the endemicity of the 1610 community health areas (CHA) were updated based on the data in JRSM form (40.5%) and the use of endemicity at implementation unit (IU) (33.5%). Up to 282 (17.5%) and 398 (24.7%) community health areas were classified as moderate and high endemicity. 41.1% of communities were non endemic. High endemicity was more important in Tambacounda, Saint Louis, Matam, Louga and Kedougou. A change in endemicity category was observed when data was disaggregated from district level to community level. The number of implementation units classified as non-endemic was higher at community level (n=666) compared to district level (n=324). Among 540 areas previously classified as high endemic by district level data aggregation, 392 (72.6%) remained high prevalence category, while 92 (17%) became moderate, 43 (8.0%) low and 13 (2.4%) non-endemics at community level. Number of IU requiring PC was more important at district level (1286) compared to community level (944). Number of SAC requiring treatment was also more important at district level compared to community level. The analysis to disaggregate data from district level to community level using the WHO/AFRO schistosomiasis sub-district data optimization tool has allowed to target schistosomiasis interventions, optimize use of available PZQ and exposed data gaps.

0569

NOVEL RESAMPLING METHOD TO STRENGTHEN ACCURACY AND PRECISION OF SCHISTOSOMIASIS DIAGNOSTICS TO GUIDE MASS DRUG ADMINISTRATION PROGRAMS

David Gurarie[1], Nathan C. Lo[2], Martial Ndeffo-Mbah[3]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Division of HIV, Infectious Diseases, and Global Medicine, University of California, San Francisco, San Francisco, CA, United States, [3]Texas A&M University, College Station, TX, United States

Schistosomiasis affects 200 million people in low- and middle-income countries. New WHO guidelines for mass drug administration depend on estimation of infection prevalence to modify MDA strategies. However, conventional diagnostic techniques for schistosomiasis via egg-count

(stool microscopy for *Schistosoma mansoni*) have poor sensitivity, wide day-to-day variation, and overdisperson that make accurate and precise prediction challenging. In this study, we developed a new statistical methodology leveraging secondary datasets from large-scale control/surveillance studies in Africa (SCORE project) The SCORE dataset on *S. mansoni* contains 260,000 personal tests, from 1744 communities in 3 countries. A high proportion of SCORE tests had multiple screening (up to 3 days/person), and SCORE communities represent a broad cross-section of infection burden (ranging 0 - 100% prevalence). We leveraged these SCORE features to generate a comprehensive set of conditional empirical distributions (CED) for resampling single stool tests to predict their putative alternatives (e.g. second day test). Our procedure can adjust the observed prevalence values by bringing them close to the 'true' state via a consistent CED resampling. The relevant CEDs are drawn from the pool of SCORE communities comparable to a given raw data. An alternative approach to CEDs employs a classifier function based on inferred infection intensity (low, moderate, or heavy). To test the consistency and predictive skill of our methodology we run multiple simulations with SCORE and additional datasets. Our model reduced discrepancy between 'observed' and 'true' prevalence values from 20-35% (raw data) to the 2-5% range (CED resamples). We can also estimate infection intensity. In all cases (prevalence, intensity), we get confidence intervals to assess diagnostic uncertainty. The proposed method can improve estimation of schistosomiasis prevalence to better guide mass drug administration programs in endemic settings, with cost savings through reduced stool samples.

GENOME-WIDE SNPS ANALYSIS FOR TRACKING THE SPREAD OF *ANOPHELES STEPHENSI* IN EASTERN ETHIOPIA AND SOMALILAND

Jeanne N. Samake[1], Philip Lavretsky[2], Isuru Gunarathna[1], Solomon Yared[3], Dejene Getachew[4], Said Ali[5], Dereje Dengela[6], Meshesha Balkew[6], Sarah Zohdy[7], Seth R. Irish[7], Tamar E. Carter[1]

[1]Baylor University, Waco, TX, United States, [2]University of Texas at El Paso, El Paso, TX, United States, [3]Jigjiga University, Jigjiga, Ethiopia, [4]Dire Dawa University, Dire Dawa, Ethiopia, [5]Somaliland Ministry of Health Department, Hargeisa, Somalia, [6]PMI VectorLink Ethiopia Project, Abt Associates, Addis Ababa, Ethiopia, [7]U.S. President's Malaria Initiative, Entomology Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Anopheles stephensi invasion in the Horn of Africa poses a substantial risk of increased malaria disease burden in the region. Population genomic approaches can reveal population structure and demographic history to infer vector invasion and dispersal patterns, information essential for vector control. Here, we analyzed 13 populations of *An. stephensi* from eastern Ethiopia and Somaliland collected in 2018 and 2020, respectively. We used double digest restriction-site associated DNA (ddRADseq) to genotype 250 mosquitoes at 2300 genome-wide single nucleotide polymorphisms (SNPs). Principal component and ancestry analyses revealed clustering that corresponded to geographic region, differentiating populations in Ethiopia and Somaliland. *Anopheles stephensi* populations from the northeastern and central-eastern sites were separated from the southernmost populations in Ethiopia. Somaliland *An. stephensi* clustered with some northeastern and central-eastern Ethiopian *An. stephensi*. Furthermore, genetic relatedness was observed between the northeastern and central-eastern Ethiopian *An. stephensi* populations and the Somaliland *An. stephensi* populations. The southeastern Ethiopian *An. stephensi* population was also distinct from the other populations in the admixture analysis. Overall, these results confirm previous evidence of population differentiation and geographical structure within eastern Ethiopian *An. stephensi* populations and reveal potential gene flow between Ethiopian and Somaliland *An. stephensi* populations. In addition, these findings may also indicate that southeastern Ethiopian *An. stephensi* are the result of a separate introduction. These details on the gene flow between *An. stephensi* populations can be incorporated into environmental models for predicting *An. stephensi* spread and can inform planning of vector control strategies against this invasive malaria vector in the Horn of Africa.

0571

UNRAVELLING THE PHENOTYPIC AND GENOMIC DIVERGENCE WITHIN SUB-POPULATIONS OF THE MAJOR MALARIA VECTOR *ANOPHELES GAMBIAE*

Marilene M Ambadiang Mae[1], Caroline Fouet[1], Ashu Fred Ayukarah[1], Aditi Kulkarni[2], Veronique P. Beng[3], Charles Wondji[4], Sourav Roy[2], Colince Kamdem[1]

[1]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [2]Department of Biological Sciences, University of Texas, El Paso, El Paso, TX, United States, [3]University of Yaounde 1, Yaounde, Cameroon, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Malaria is a mosquito-borne disease which remains a huge threat to global human health. Vector control remains the most effective method in reducing disease transmission. However, increase in resistance to different vector control tools combined to increasing drug resistance and high costs of implementation, make malaria resurgence a grim reality. New strategies with novel tools that complement LLINs and IRS to target the major vectors could prevent the resurgence of disease and hasten malaria elimination. Despite the central role of oviposition preference in selecting suitable environments in blood-feeding insects, its contribution to ecological specialization and local adaptation remains elusive. Population studies at early stages or ecological/genetic divergence provide an excellent opportunity to assess the role of oviposition preference in local adaptation of mosquitoes. Combining laboratory dual choice experiments and whole genome sequencing, we conducted the first assessment of phenotypic variation among some of the subpopulations of the malaria mosquito *Anopheles gambiae* that are emerging along gradients of anthropogenic disturbance in sub-Saharan Africa. When offered the choice, gravid females released individually in 30x30 cm cages under standard conditions and provided with 10% sugar solution lay eggs almost exclusively in water collected from their locality of origin. This extreme source-specialization prevails in populations belonging to the same ecological biome and displaying very low levels of genome-wide divergence. Interestingly, females maintained in laboratory conditions using regular (clean) water for five generations retained water discrimination and were still able to choose between source water and exogenous water. We conclude that favourable aquatic oviposition sites though highly heterogeneous in form, space and time are strong enough to drive ecological specialization in the presence of extensive gene flow in mosquitoes and act as signature cues at early stages of divergence in gravid Anopheles mosquitoes seeking to lay.

0572

SPECIATION WITHIN THE MALARIA-TRANSMITTING *ANOPHELES GAMBIAE* COMPLEX: HIGH-THROUGHPUT WHOLE GENOME SEQUENCING OF ADULT FEMALES PROVIDES EVIDENCE OF A NEW CRYPTIC TAXON IN FAR-WEST AFRICA

Beniamino Caputo[1], Carlo Maria De Marco[2], Verena Pichler[2], Jacob Tenessen[3], David Weetman[4], Alistair Miles[5], **Alessandra della Torre**[2]

[1]University of Rome Sapienza, Roma, Italy, [2]University of Rome Sapienza, Rome, Italy, [3]Harvard T.H. Chan School of Public Health, Harvard, MA, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]University of Oxford, Oxford, United Kingdom

The western extreme of the range of the two major malaria vector species, Anopheles coluzzii (CO) and An. gambiae (GA), in Sub-Saharan Africa is considered an area of high hybridization between the two species, due to high reported frequencies of specimens characterized by a heterozygous pattern of rDNA IGS diagnostic markers. We took advantage of high-throughput Whole Genome Sequence data of 1,190 adult females made available by the Ag1000G project and focused our

analyses on chromosome-3 and -X euchromatic regions in 3 populations from far-west (hereafter FW-pops: 2 populations from the Gambia, GM1 and GM2, and one from Guinea Bissau, GW) and in 10 populations from western (5 CO and 5 GA) Africa. Evidence, so far, are as follows: i) PCA clearly separates GM2 and GW (characterized by GA-specific Ancestry Informative Markers) and to a lesser extent GM1 (characterized by CO-specific AIMs) from all other populations; ii) Bayesian clustering analyses (ADMIXTURE and TESS3r) identify a taxon genetically distinct from CO and GA present in all 3 FW-pops; iii) mean Fst values between all FW-pops and GA (0.027-0.035) are in the range of those between CO and GA western populations, while only GM2 is highly differentiated (0.028) from CO; iii) genome-wide Fst values show a highest peak of differentiation between FW-pops and GA and CO in the centromeric region of chromosome-2L; iv) F3 statistics does not support the hypothesis that FW-pops are the results of historical admixture between west-African CO and GA; v) Patterson statistics suggest gene-flow between FW-pops and CO (not with GA). Further analyses are in progress to better understand the nature of the FW-taxon and its phylogenetic relation with the other members of the gambiae complex. Nevertheless, it is relevant to note that this represent the first finding of adult mosquitoes with a distinct genetic background from the other species of the complex and that parallel studies have highlighted that the FW-pops do not share most of the genomic patterns associated to insecticide resistance typical of CO and GA across their range.

0573

CONTRASTING THE HERITABILITY AND GENETIC BASIS OF DENGUE AND CHIKUNGUNYA VIRUS SUSCEPTIBILITY IN *AEDES AEGYPTI*

Mario Novelo[1], Heverton LC Dutra[1], Matthew J. Jones[1], Scott L. Allen[2], Francesca D. Frentiu[3], Stephen F. Chenoweth[2], **Elizabeth Ann McGraw**[1]

[1]Pennsylvania State University, University Park, PA, United States, [2]The University of Queensland, Brisbane, Australia, [3]QUT, Brisbane, Australia

Aedes aegypti is the primary vector of the arboviruses dengue (DENV) and chikungunya (CHIKV). Viral susceptibility and transmissibility in mosquito populations depend in part on GxG interactions between the virus and the vector genotypes. We used modified full-sibling design to estimate and compare the contributions of mosquito genetic variation to DENV and CHIKV susceptibilities. We demonstrated significant genetic variation for both viruses, but heritability was much higher for DENV (40%) than for CHIKV (18%). The differences were largely driven by greater within-family variation for CHIKV. Interestingly, we also reveal a complete lack of genetic correlation between DENV and CHIKV susceptibility. We then explored the genetic basis of differences between high and low susceptibly families to CHIKV and found two key genes whose expression is higher in families with lower viral loads. While both genes encode for uncharacterized proteins, one of the genes is a distant family member of the Salivary Gland Surface proteins that interestingly has also been horizontally transferred into the endosymbiont, *Wolbachia*. Our data suggest that the mosquito is much better at controlling DENV infection, and that the mosquito responds to the viruses with two very different mechanisms. These disparities may result from different coevolutionary histories, with CHIKV only recently emerging and acting as a selective agent in mosquitoes.

0574

AGO2 REGULATES AUTOPHAGY TO CONTROL MOSQUITO DEATH DURING ARBOVIRUS INFECTION

Shengzhang Dong, George Dimopoulos

Johns Hopkins University, Baltimore, MD, United States

The yellow fever mosquito, *Aedes aegypti* transmits many human infectious diseases caused by arthropod-borne (arbo) viruses, including dengue virus and chikungunya virus. Infection with these arboviruses does usually not impose fitness cost to mosquitoes in nature. It has been demonstrated that the small RNA interfere (siRNA) represents the major antiviral defense system to control systemic arboviral infection in *Ae. aegypti* by degrading viral genome into virus-specific 21-nt vsiRNAs through an RNA-induced-silencing-complex (RISC). Argonaute2 (Ago2) is the core gene of the siRNA signaling and cleaves complementary RNA sequences, and subsequently degrades target viral RNA. Here we overexpressed *Ago2* in midguts under the control of a blood-inducing promoter *carboxypeptidase A,* and mutated *Ago2* through CRISPR/Cas9 genome editing. Our data shows that the infection of multiple viruses and mortality of mosquitoes are significantly increased in *Ago2* mutant mosquitoes after oral viral infection. Small RNA sequencing and transcriptome analysis indicate elevated expression of autophagy genes, and further experiments demonstrated that repression of the autophagy pathway results in mosquito death after viral infection. Our results suggest a mechanism of arbovirus-induced mosquito death.

0575

GENOMIC SIGNATURES OF SEXUAL SELECTION IN THE YELLOW FEVER MOSQUITO *AEDES AEGYPTI*

Claudia A. Wyer[1], Brian Hollis[2], Lauren J. Cator[1]

[1]Imperial College London, Ascot, United Kingdom, [2]University of South Carolina, Columbia, SC, United States

Aedes aegypti mosquitoes are vectors of several arboviruses of public health concern. Promising new control methods involving the mass release of modified mosquitoes to induce sterility or pathogen resistance into wild populations critically depend on the ability of lab-reared males to successfully mate with wild-type conspecific females. A thorough understanding of the genetic basis of male mating success could help to increase efficacy of such control strategies and aid in the development of novel mosquito control interventions. In this study, we compare whole genome sequences from populations of recently colonised *Ae. aegypti* mosquitoes evolved in the presence and absence of sexual selection. Our data show that populations evolved under sexual selection retain greater genetic similarity to recently colonised field populations, and that populations evolving without sexual selection show greater genomic divergence from the ancestral population. We report that significantly diverging variants with functional impact on amino acid sequence were enriched for several gene ontology terms related to chemosensation. Further, we used RNAi to deplete expression of high-confidence candidate genes to determine a mating-related phenotype. Our results highlight the importance of sexual selection in mosquito rearing, and that sexual selection may be important in maintaining genetic similarity to field populations.

0576

AFRICAN CONVERSATIONS ABOUT GENE DRIVES: INSIGHTS FROM AFRICAN STAKEHOLDERS ON HOW GENE DRIVE MODIFIED MOSQUITOES CAN BENEFIT MALARIA CONTROL AND ELIMINATION EFFORTS

Fredros Oketch Okumu[1], Marceline F. Finda[1], Elijah Juma[2], Rhosheen Mthawanji[3], Michael Santos[4], David O'Brochta[4], Stephanie James[4]

[1]Ifakara Heallth Institute, Ifakara, United Republic of Tanzania, [2]PAMCA, Nairobi, Kenya, [3]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [4]Foundation for National Institute of Health, North Bethesda, MD, United States

Genetic bio-control tools, such as gene drive modified mosquitoes (GDMMs), have been demonstrated as promising new tools to improve malaria control and possibly accelerate elimination. Although still in early-stage development, there is a need to start critical conversations with key stakeholders in sub-Saharan Africa (SSA) regarding safe and responsible testing and use of these technologies. We conducted a series of focus group discussions (n=18) and surveys (n=192) with key stakeholders representing 20 countries and five (5) islands across SSA, to explore their opinions, concerns and recommendations regarding GDMMs for malaria control in the continent. The stakeholders were recruited from

research and academia, regulatory agencies, health and other government ministries, and the media and advocacy groups. This study revealed a broad desire by the stakeholders for potentially transformative tools such as GDMMs to enable malaria elimination in resource-limited settings in the continent. There was an overall high awareness of gene drive technologies for malaria control among the participants, however, the knowledge of how the technologies work to control malaria was low. When provided with a brief explanation of how the technologies work, the participants expressed their concerns and suggestions to be addressed before wide-scale evaluations and use. This study presents voices of key stakeholders in SSA on if and how GDMMs could improve malaria control.

0577

ASSESSING RISK FOR TICK-BORNE DISEASE UNDER THE CONTEXT OF THE MODIFIABLE AREAL UNIT PROBLEM

Collin O'Connor

State University of New York, University at Buffalo, Buffalo, NY, United States

The modifiable areal unit problem (MAUP) is a cause of statistical bias when aggregating data according to spatial units, particularly when spatial units may be changed arbitrarily. An example of the MAUP occurs during the gerrymandering process, when political units are purposefully changed to alter electoral outcomes. The MAUP is also a concern in vectorborne disease research when entomological metrics gathered from point-level sampling data are related to epidemiological data aggregated to political units like counties or ZIP Codes. Here, we assess the impact of the MAUP when comparing these two metrics from the context of tick-borne disease and ecology. Our study uses geocoded human cases of anaplasmosis in New York State during 2017 and a geostatistical layer of an entomological risk index for *Anaplasma phagocytophilum* from *Ixodes scapularis* ticks collected during the fall of 2017. We assess the impact of polygon scale by simulating random Voronoi polygons of increasing size and calculating the correlation coefficient between entomological risk and cases of anaplasmosis within these polygons. We also assess the impact of polygon orientation by repeating this procedure 10 times for each number of polygons simulated. Correlations were also calculated using county and ZIP Code Tabulation Area polygons from New York State for comparison. Results from these simulations indicate increasing the number of polygons decreases the correlation coefficient (β=-.0001168, p=<0.0001). Further, the variance of simulated correlation coefficients decreased as the number of polygons increased. The correlation coefficients using the county and ZIP Code Tabulation Area polygons were at or beyond one standard deviation from the mean of the simulated correlation coefficients. These results indicate that reducing polygon size may allow public health researchers to better estimate spatial risk for tick-borne disease. However, as polygon size decreases, other landscape and environmental features may need to be incorporated to best assess risk.

0578

TRANSMISSION OF POWASSAN VIRUS BY THE INVASIVE ASIAN LONGHORNED TICK, *HAEMAPHYSALIS LONGICORNIS*, UNDER LABORATORY CONDITIONS

Meghan Hermance[1], Wilson Raney[1], Ingeborg Langohr[2], Erik Herslebs[1], Madeline Stone[1]

[1]University of South Alabama, Mobile, AL, United States, [2]Louisiana State University, Baton Rouge, LA, United States

The Asian longhorned tick, *Haemaphysalis longicornis*, is a tick native to eastern Asia that was first detected in North America outside a port of entry in 2017. Established populations of this invasive species have since been detected in 17 states. As the invasive range of the tick continues to expand, the ability for *H. longicornis* to serve as a vector of pathogens native to North America is under investigation. Here, we evaluate the vector competence of *H. longicornis* for Powassan virus (POWV) under laboratory conditions. POWV is a North American tick-borne flavivirus that is typically transmitted through the bite of *Ixodes* species ticks. The invasive range of *H. longicornis* is expected to overlap heavily with the geographic range of *I. scapularis* and POWV cases, highlighting the potential for this invasive tick species to amplify POWV transmission in natural foci. In our studies, adult female *H. longicornis* ticks were infected with POWV via anal pore microinjection. Viral RNA and infectious virions were detected in tick tissues via q-RT-PCR and focus-forming assay, respectively. POWV-injected female ticks were infested on mice, and POWV was transmitted to the mice during tick feeding, as shown by clinical signs of disease and seroconversion in the tick-exposed mice, as well as the detection of viral RNA in various mouse tissues. A POWV-injected female tick transmitted virus to her larval progeny, indicating that *H. longicornis* can vertically transmit POWV. These naturally-infected larval ticks were also able to transmit POWV to the mouse on which they fed, further demonstrating that *H. longicornis* can horizontally transmit POWV to a vertebrate host. Additionally, this study provides the first report of POWV neuropathology based on a natural tick transmission model of POWV. Together, our results suggest that the invasive *H. longicornis* tick is a competent vector of POWV. These findings underline the growing danger this tick may pose to human health in the United States. On-going studies are investigating the extent by which non-viremic transmission of POWV occurs between native *I. scapularis* co-feeding on the same host with *H. longicornis*.

0579

THE ROLE OF TICKS AND RODENTS IN THE TRANSMISSION AND EXPANSION OF TICK-BORNE FLAVIVIRUSES IN NORTHWESTERN EUROPE

Julian W. Bakker[1], Emily Pascoe[1], Hein Sprong[2], Helen Esser[3], Jeroen Kortekaas[4], Fred de Boer[3], Gorben Pijlman[5], Paul Wichgers Schreur[4], Sander Koenraadt[1]

[1]Wageningen University, Laboratory of Entomology, Wageningen, Netherlands, [2]National Institute of Public Health and the Environment (RIVM), Bilthoven, Netherlands, [3]Wageningen University, Wildlife ecology and conservation, Wageningen, Netherlands, [4]Wageningen Bioveterinary Research, Wageningen, Netherlands, [5]Wageningen University, Laboratory of Virology, Wageningen, Netherlands

Tick-borne encephalitis (TBE) is the most important arboviral disease in Europe with 2,000-3,500 human cases each year. The transmission of the TBE virus (TBEV) depends on a complex interplay between the virus, *Ixodes* ticks and small rodents. TBEV is endemic in large parts of Central and Eastern Europe but has recently been discovered in Northwestern European countries such as the Netherlands and the United Kingdom. The emergence of TBEV in these countries was not predicted according to existing TBEV distribution models, thus the factors that favor the geographical spread of TBEV remain poorly understood. In the current study, we sought to determine the vector competence of *Ixodes ricinus* ticks for different viruses within the TBEV complex. An artificial blood-feeding system was used to infect ticks with different viruses. Viral strains from different geographical origins than the tested tick populations showed lower infection success compared to viruses isolated from the same region as where ticks were collected. Furthermore, we investigated whether wild rodents, such as wood mice (*Apodemus sylvaticus)* and yellow-necked mice (*A. flavicollis),* differ in their reservoir competence for TBEV. The wood mouse is a very common and widespread species in Europe, whereas the distribution of the yellow-necked mouse is limited to small parts of the Netherlands and the United Kingdom. Captured rodents of both species were inoculated with 1000 $TCID_{50}$ of either a classical European subtype of TBEV (Neudoerfl) or TBEV-NL, a more genetically divergent TBEV strain from the Netherlands. Experiments with wood mice and yellow-necked mice showed that all animals survived the infection with TBEV and remained without disease symptoms. Nevertheless, TBEV was detected up to 21 days in the blood of both rodent species and TBEV infected the brain of the mice from 3 to 21 days after infection. Our study demonstrates that TBEV strains isolated from the Dutch ecosystem are efficiently transmitted by *I. ricinus* ticks. Further, wood mice and yellow-necked mice are viraemic for a longer period than previously thought, confirming their important role as reservoir hosts for TBEV.

0580

HOST BLOODMEAL PREFERENCES DIFFER BETWEEN LARVAL AND NYMPHAL DEER TICKS

Heidi Goethert[1], Thomas Mather[2], Sam Telford[1]

[1]Tufts Cummings School of Veterinary Medicine, Grafton, MA, United States, [2]University of Rhode Island, Kingston, RI, United States

The enzootic cycle of *Borrelia burgdorferi*, the agent of Lyme disease, depends on infected nymphal deer ticks, *Ixodes dammini*, feeding on competent reservoir hosts each summer. These hosts then serve as the source of infection for the new cohort of larvae. The force of transmission depends on both immature stages focusing their bites upon the same kind of host. Mammal trapping studies suggest that subadult deer ticks mainly feed on white-footed mice, but the potential range of hosts is diverse. To determine whether subadult deer ticks differ in their host preferences, we identified bloodmeal remnants from host-seeking nymphal and adult ticks that had fed as larvae and nymphs in the same site during the same season. We thus compared ticks that had access to the same potential bloodmeal hosts. Bloodmeal hosts from adult ticks collected in fall 2019 and 2020 were compared with nymphal ticks collected in the summer 2020 and 2021, respectively. Six different sites were surveyed; bloodmeal analysis was conducted on 321 adult and 357 nymphal ticks using assays for hosts commonly found in New England enzootic sites. Using our retrotransposon targeted PCR assay for host bloodmeal identification, we found no difference in the utilization of white-footed mice, voles, rabbits, deer or opossum by subadult deer ticks. However, nymphs were significantly more likely to feed on birds and sciurids (OR=2.8 and OR=8.6 respectively, p=0.000), whereas larvae were significantly more likely to feed on shrews (OR=6.3 p=0.00). In fact, host-seeking nymphs infected with *Borrelia* were likely to have fed as larvae on mice or shrews (OR=2.6 and OR=3 respectively, p<0.003) but not birds or sciurids. The general paradigm for the enzootic transmission of *B. burgdorferi* is that nymphs infect white footed mice, which feed larvae and thus produce the majority of infected nymphs. The enzootic cycle appears to be more complex, with a large number of infectious nymphal bites diverted from the expected mouse host. We conclude that the local force of enzootic *B. burgdorferi* transmission may depend on the extent to which the bloodmeal host preferences of larval and nymphal deer ticks coincide.

0581

PERSISTENCE OF PLAGUE IN RODENTS AND FLEAS IN FOCI WITH WIDESPREAD ANTHROPOGENIC LAND USE IN THE CENTRAL HIGHLANDS OF MADAGASCAR

Soanandrasana Rahelinirina[1], Mireille Harimalala[1], Fanohinjanaharinirina Rasoamalala[1], Mamy Gabriel Randriamanantsoa[2], Romain Girod[1], Minoarisoa Rajerison[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]National Plague Control Program, Ministry of Public Health, Antananarivo, Madagascar

Plague remains endemic in Madagascar. Under conditions where anthropogenic land use and habitat loss occurs, human-rodent-flea dynamics may be altered allowing transmission to persist year-round. To estimate risk of transmission to humans and to refine proactive plague prevention strategies, surveillance of small mammals (SM) was conducted during low and high plague seasons (LPS/HPS) in August 2021 and January 2022 in three active plague foci where deforestation associated to charcoal production and agriculture croplands dominate. Blood, spleen and fleas were collected to assess *Yersinia pestis* circulation using ELISA, diagnostic rapid tests (RDT), culture and also the flea index (FI). A total of 383 SM (*Rattus rattus, Rattus norvegicus, Mus musculus* and *Suncus murinus*) were captured during the two periods of study; 250 in LPS against 133 in HPS. Of the 383 SM, 489 fleas were collected and 430 were identified (76.0% *Xenopsylla cheopis,* 15.4% *Synopsyllus fonquerniei 7.7% Dinopsyllus* spp., 0.7% *Ctenocephalides felis* and 0.2% *Paractenopsyllus* spp.). The FI was higher during HPS (2.2) when compared to 0.8 in LPS. Two strains of *Y. pestis* were isolated from *R. rattus* during LPS and HPS. Three percent and 2.8% of SM were tested positive on RDT during the LPS and HPS respectively. Antibodies for *Y. pestis* were detected in 57 SM with more positive during LPS (16.8%) than HPS (11.3%). *Yersinia pestis* circulates in rodent populations during both HPS and LPS in these active foci, which provides an explanation for why plague persists year-round. *Dinopsyllus* and *Paractenopsyllus* species, known as forest fleas, were found from *R. rattus* inside houses in close proximity to deforestation which disturb their habitats. Land use alteration has the potential to create favorable environmental conditions for zoonotic transmission of this infectious disease to humans. These findings showed that environmental conditions should be considered when reinforcing plague control measures. Additional work is needed to elucidate the role of rodent and *Dinopsyllus* species, some of which are known plague vectors in continental Africa, in plague epidemiology in Madagascar.

0582

CARDIAC COMPLICATIONS OF HUMAN BABESIOSIS

Jane O'Bryan[1], Anne Spichler Moffarrah[2], Emily Ong[2], Peter J. Krause[2]

[1]Frank H. Netter MD School of Medicine at Quinnipiac University, North Haven, CT, United States, [2]Yale School of Medicine, New Haven, CT, United States

Human babesiosis is a worldwide emerging tick-borne disease caused by intraerythrocytic protozoa. Most patients experience mild to moderate illness, but life-threatening complications can occur. Although cardiac complications are common, the full spectrum of cardiac disease and the frequency, risk factors, and outcome of patients experiencing cardiac complications are unclear. Accordingly, we carried out a retrospective review of cardiac complications among babesiosis patients admitted to Yale-New Haven Hospital (YNHH) over the last decade to better characterize cardiac complications of babesiosis. We reviewed the medical records of all adult babesiosis patients admitted to YNHH from January 2011 to October 2021, confirmed by identification of Babesia parasites on thin blood smear and/or by polymerase chain reaction. The presence of Lyme disease and other tick-borne disease co-infections were recorded. Of 163 enrolled subjects, 32 (19.6%) had at least one cardiac complication during hospitalization. The most common cardiac complications were atrial fibrillation (9.4%), heart failure (8.6%), QTc prolongation (8.0%), and cardiac ischemia (6.8%). Neither cardiovascular disease risk factors nor preexisting cardiac conditions were significantly associated with the development of cardiac complications. The cardiac complication group had a greater prevalence of high grade parasitemia (>10%) (p<0.001), longer median length of both hospital (p<0.001) and intensive care unit stay (p<0.001), and higher mortality (p=0.024) than the non-cardiac complication group. Cardiac complications of acute babesiosis are common and occurred in approximately one fifth of this inpatient sample. Further investigation is needed to elucidate the relationship between babesiosis severity and cardiac outcomes.

AN IMMUNOLOGICAL ATLAS OF *BABESIA MICROTI* PRIMARY INFECTION AND REINFECTION IMMUNITY IN BALB/C MICE

Miranda Oakley, Scott Meredith, Demerise Johnston, Victoria Majam, Hong Zheng, David S. Rotstein, Sanjai Kumar

FDA, Silver Spring, MD, United States

Correlates of protective immunity to and pathogenesis of Human Babesiosis have not been clearly defined. *Babesia microti* (the most common cause of Human Babesiosis) causes an acute but self-resolving infection in Balb/c mice. We developed an immunological atlas of *B. microti* infection in Balb/c mice over the course of a primary infection and reinfection by performing histological analysis of multiple organs, in depth flow cytometry, and immune profiling of antibody isotypes and cytokines in serum. Histopathologic observations included hepatic vascular congestion, pulmonary vascular erythrocyte margination, clumping, and intrahistiocytic cytoplasmic parasite adherence to the endothelium. By

flow cytometry, we report 4 major findings. First, *B. microti* infection of Balb/c mice is associated with expansion of a novel population of $CD4^-$ $CD8^-$ T cells. Second, *B. microti* induces a potent Th2 $CD4^+$ T cell response characterized by 3.6 fold more Th2 associated GATA-3^+CD4^+ T cells compared to Th1 associated T-bet^+CD4^+ T cells on day 3 post-infection ($p<0.01$, Mann–Whitney *U* test). Third, naïve $CD4^+$ T cells differentiate into short lived $CD62L^-CD127^-$ effector cells during primary infection. Fourth, B cells undergo isotype switching and differentiate into $CD38^+CD138^+$ plasmablasts and $CD95^+GL7^+$ germinal center B cells. Among 23 cytokines analyzed, IL-13 was the most abundant cytokine produced during Acute Babesiosis in Balb/c mice. These results identify novel immune cells and cytokines associated with the acute and clearance phases of *B. microti* infection in a mouse model of Human Babesiosis.

[1]UC Berkeley, Berkeley, CA, United States, [2]UC San Francisco, San Francisco, CA, United States, [3]Stanford University, Palo Alto, CA, United States, [4]University of North Carolina, Chapel Hill, NC, United States, [5]Emory University, Atlanta, GA, United States, [6]University of Washington, Seattle, WA, United States, [7]London School of Tropical Medicine and Hygiene, London, United Kingdom, [8]Ministry of Health, Maputo, Mozambique, [9]Kenya Medical Research Institute, Nairobi, Kenya, [10]icddr,b, Dhaka, Bangladesh, [11]North Carolina State University, Raleigh, NC, United States

Recent trials of household- and community-level water, sanitation, and hygiene (WASH) interventions have found no or mixed effects on child health. Measuring pathogens and host-specific microbial source tracking (MST) markers in environmental samples can help explore if limited effects occur because interventions insufficiently reduce contamination or if measurable environmental pathogen exposure is not a strong determinant of child health. We conducted a systematic review and individual participant data meta-analysis to assess WASH intervention effects on pathogens/MST markers in environmental samples and associations between pathogens/MST markers and subsequent pathogen-specific infections, caregiver-reported diarrhea, and height-for-age Z-scores (HAZ) in children. We received data from 5 eligible WASH intervention studies. Environmental sampling was focused on onsite sanitation interventions and included drinking water, hand rinses, soil, and flies (pooled N=12,184 samples). Pooled across studies, interventions led to a small reduction in any pathogen presence in any sample type (prevalence ratio=0.94 (95% CI: 0.90, 0.99)) but had no overall effect on human/animal MST markers. Pathogen detection in environmental samples was consistently associated with subsequent child infection with the same pathogen, but not with diarrhea. Detection of any pathogen in any sample type was associated with slightly lower HAZ (pooled Δz=-0.08 (95% CI: -0.15, 0.00)). There were no consistent associations between MST markers and child health. Results for individual pathogens/MST markers were similar. Among the few WASH trials that measured pathogens or MST markers in the environment, effects of onsite sanitation on these targets were consistently small or null. Our findings are aligned with the limited impacts of onsite sanitation interventions on fecal indicator bacteria in the environment and on child health. The limited associations between advanced measurements of environmental contamination and child health highlight the limitations of current approaches in characterizing environmental exposure to pathogens.

UNDERSTANDING THE DRIVERS OF THE WASH BENEFITS BANGLADESH TRIAL RESULTS: HYPOTHESES AND ESTIMATES FROM AN INFECTIOUS DISEASE TRANSMISSION MODEL

Andrew F. Brouwer[1], Marisa C. Eisenberg[1], Kevin M. Bakker[1], Savannah N. Boerger[1], Mondal H. Zahid[1], Matthew C. Freeman[2], Joseph N.S. Eisenberg[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Emory University, Atlanta, GA, United States

Recent large-scale, well-powered intervention randomized controlled trials (RCTs) in low-income settings have not found the expected health benefits of water, sanitation, and hygiene (WASH) interventions, including on reduced diarrhea. There has been a robust discourse about the potential reasons for these underwhelming impacts, addressing issues of completeness, coverage, compliance, and baseline WASH/disease conditions, among others. However, an RCT, which evaluates a hypothesis in a specific context, cannot easily generalize to other contexts, so that counterfactual questions of "what would have happened if…" are hard to address. Mechanistic models are a widely used to generalize findings between contexts but have not been previously applied to RCTs. The purpose of this study was to 1) develop a modeling framework to explain relative risk outcomes in an RCT and 2) to generalize the RCT results to other contexts and conditions. Our model accounts for i) transmission across multiple environmental pathways, ii) multiple interventions applied individually and in combination, iii) adherence to interventions, and iv) the impact of individuals not enrolled in the study. A Bayesian sampling approach was used to obtain posterior estimates of mechanistic parameters and their uncertainties for the WASH Benefits Bangladesh RCT (n=17,187), reproducing reported diarrheal prevalence. The baseline estimate of the basic reproduction number R_0 for the control arm was 1.15, (95% CI: 1.09, 1.27) in the absence of intervention or preexisting WASH conditions. No single pathway—water, fomites, or all other pathways—was likely able to sustain transmission as pathway-specific R_0s were each below 1 (0.49 (95% CI: 0.07, 0.99), 0.26 (95% CI: 0.04, 0.57), and 0.40 (95% CI: 0.02, 0.88), respectively). In our counterfactual simulations, completeness and coverage, rather than compliance, efficacy, or baseline conditions, were most strongly associated with intervention effectiveness. Our approach can aid in understanding the contentious findings of the WASH-Benefits trial but also enhance analysis of empirical RCT data for program decision-making.

0586

REDUCED DIARRHEA PREVALENCE, IMPROVEMENTS IN HANDWASHING WITH SOAP AND STORED DRINKING WATER QUALITY ASSOCIATED WITH AWARENESS MEASURED BY INTERACTIVE VOICE RESPONSE (IVR) MESSAGES IN A WATER, SANITATION AND HYGIENE CHOBI7 MOBILE HEALTH PROGRAM

Md Sazzadul Islam Bhuyian[1], Kelly Endres[2], Jamie Perin[2], Fatema Zohura[1], Jahed Masud[1], Tahmina Parvin[1], Ismat Minhaj Uddin[1], Tasdik Hasan[1], Shirajum Monira[1], David A. Sack[2], A.S.G Faruque[1], Munirul Alam[1], Christine Marie George[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh(icddr,b), Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The Cholera-Hospital-Based-Intervention-for-7-days (CHoBI7) mobile health program promotes WASH behaviors through voice calls and text messages to reduce diarrheal diseases in Bangladesh. The objective of this study was to investigate the relationship between responses to CHoBI7 WASH interactive voice response (IVR) quiz messages and diarrhea and WASH behaviors. Fourteen CHoBI7 IVR quiz messages were sent to 517 households during the 12-month program period for this intervention on handwashing with soap and water treatment. IVR message responses were classified as "correct answer", "incorrect answer",

"no response" (did not press 1 or 2), and "failed" (did not answer the phone). Diarrhea prevalence was assessed through monthly clinical surveillance. Handwashing with soap was assessed by 5-hour structured observation, and stored water quality was defined by *E.coli*. Households that correctly responded to a CHoBI7 mHealth program IVR quiz message had a significantly lower odds of diarrhea for all age groups (Odds Ratio (OR): 0.73; 95% Confidence Interval (CI): 0.54, 0.98), and significantly higher odds of handwashing with soap at stool related events (OR: 2.33; 95% CI: 1.09, 5.01) and *E. coli* <100 colony forming units /100 mL in the household stored water (OR: 2.04; 95% CI: 1.25, 3.33) compared to households that did not answer the IVR quiz. Correct responses to CHoBI7 mHealth IVR quizzes were associated with decreased diarrhea prevalence and improved stored drinking water quality and handwashing with soap. These findings suggest engagement in the CHoBI7 mHealth program and awareness of diarrheal disease prevention can reduce diarrhea and facilitate changes in WASH behaviors.

0587

RANDOMIZED CONTROLLED TRIAL OF THE CHOBI7 CHOLERA RAPID RESPONSE PROGRAM TO REDUCE DIARRHEAL DISEASES IN BANGLADESH

Christine Marie George[1], Tahmina Parvin[2], Md Sazzadul Islam Bhuyian[2], Ismat Minhaj Uddin[2], Fatema Zohura[2], Jahed Masud[2], Shirajum Monira[2], Jamie Perin[1], Munirul Alam[2], A.S.G Faruque[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh(icddr,b), Dhaka, Bangladesh

Worldwide there are 2.9 million cholera cases annually. Effective targeted water, sanitation, and hygiene (WASH) interventions are urgently needed to reduce cholera globally. Individuals living within 50 meters of a cholera patient are at higher risk of developing cholera than the general population during the month after the index patient seeks care at a health facility. To build an evidence base on effective WASH interventions to reduce diarrheal diseases for this population, we developed the CHoBI7 cholera rapid response program. Once a cholera patient (confirmed by bacterial culture) is identified at a health facility, a health promoter delivers a targeted WASH intervention to the cholera hotspot (households within 50 meters of a cholera patient) through both in-person visits, and weekly WASH mobile messages for the 3-month program period. A randomized controlled trial of the CHoBI7 cholera rapid response program was conducted of 261 participants in 15 cholera hotspots in urban Dhaka, Bangladesh. This program was compared to the standard message in Bangladesh on the use of oral rehydration solution for dehydration. Five-hour structured observation of handwashing with soap practices, and diarrhea surveillance was conducted monthly for the 3-month program period. Delivery of the CHoBI7 cholera rapid response program significantly increased handwashing with soap throughout the 3-month program period (Odds Ratio: 3.96 95% CI: 2.35, 6.66, p=0.035) (54% in the CHoBI7 arm vs. 23% in the standard arm). Furthermore, there was a significant reduction in diarrheal prevalence for all participants (adults and children) (Prevalence Ratio (PR) 0.35: ,95% Confidence Interval (CI): 0.128 - 0.99, p = 0.049), and for children under 5 years of age (PR: 0.21, 95% CI: 0.06 - 0.74, p = 0.015) during the 3-month program. These findings demonstrate that the CHoBI7 cholera rapid response program is effective in lowering diarrhea prevalence and increasing handwashing with soap for a population at high risk of cholera.

0588

EFFECT OF A BEHAVIOUR CHANGE AND HARDWARE INTERVENTION ON SAFE CHILD FECES MANAGEMENT PRACTICES IN RURAL ODISHA, INDIA: A CLUSTER-RANDOMISED CONTROLLED TRIAL

Gloria Sclar[1], Valerie Bauza[1], Alokananda Bisoyi[1], Hans-Joachim Mosler[2], Thomas Clasen[1]

[1]Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Department of Psychology, University of Zürich, Zurich, Switzerland

Poor child feces management (CFM) may be an important source of enteric pathogen exposure and contribute to a large disease burden. Yet, in many low- and middle-income countries households with a latrine often fail to safely dispose of their child's feces into the latrine. We conducted a cluster randomized trial (CRT) in 74 villages in rural Odisha, India to evaluate the effectiveness of an intervention aimed at improving caregiver safe disposal of child feces and child latrine use. The intervention was designed based on behavior change theory and novel CFM hardware was co-developed with caregivers following a user-centered design approach. The resultant CFM intervention consisted of six behavior change strategies together with provision of hardware: wash basin and bucket with lid to aid safe management of soiled nappies and a novel latrine training mat to aid safe disposal and latrine training. All households with a latrine and a child <5 years old were eligible. Following a baseline survey, 37 villages were randomly allocated to intervention arm and 37 to control arm. A community-based organization delivered the intervention and an endline survey was carried out four to six months after delivery among all eligible households. The primary outcome was safe disposal of child feces after last defecation as defined by the Joint Monitoring Programme (JMP), which encompasses two sub-behaviors: caregiver disposal of the child's feces into a latrine and the child using the latrine. Analysis included 662 caregivers (841 children) in the intervention arm and 631 caregivers (785 children) in control arm. We found the prevalence of JMP-defined safe disposal at endline was 1.15 times greater (95% CI 1.03 - 1.29) in the intervention arm compared to control. We separately examined the sub-behaviors and found the prevalence of caregiver disposal in latrine at endline was 1.76 times greater (95% CI 1.33 - 2.33) in the intervention arm compared to control but there was no difference observed in prevalence of child latrine use at endline (PR 1.05, 95% CI 0.94 - 1.17). The CFM intervention achieved increases in caregiver safe disposal of child feces but not child latrine use.

0590

SYSTEM PERFORMANCE OF A DECENTRALIZED NATURE-BASED APPROACH TO WASTEWATER TREATMENT IN LMIC INFORMAL SETTLEMENTS

Kerrie Burge[1], Andi Zulkifli Agussalim[2], Fitriyanty Awaluddin[2], Fiona Barker[1], Peter Breen[1], Thomas Clasen[3], Matthew French[1], Brett Davis[1], Diego Ramirez[1], Maghfira Saifuddaolah[2], Allison Salinger[3], Sheela Sinharoy[3], Ruzka Taruc[2], Tony Wong[1], Zainal Zainal[2], Karin Leder[1]

[1]Monash University, Melbourne, Australia, [2]Hasanuddin University, Makassar, Indonesia, [3]Rollins School of Public Health, Emory University, Atlanta, GA, United States

Increasing urbanization in low- and middle-income countries has led to the growth of informal settlements, a long-standing challenge for conventional water and sanitation management that is fundamental to health and wellbeing. Introducing interventions aimed at providing safe sanitation and disrupting multiple fecal-oral contamination pathways in the complex sociocultural and biophysical setting of an urban informal settlement poses many challenges. Revitalising Informal Settlements and their Environments (RISE) is a randomized controlled trial among 24 settlements in Makassar, Indonesia and Suva, Fiji to assess a novel "water sensitive cities" approach for managing wastewater and environmental fecal contamination in informal settlements through decentralized bioremediation. Systems are co-designed with community residents

with technology options that include communal septic tanks and drains, precinct scale pressure sewers, constructed subsurface and surface flow treatment wetlands, and biofilters to filter wastewater prior to release into the environment. A demonstration project was constructed in 2020 in Batua, South Sulawesi to optimize the intervention and confirm system performance. The system services 22 dwellings and includes 40m^2 of wetlands. A total of 317 water samples collected over 57 weeks indicates that, except for ammonia, the system met all Indonesian discharge standards for domestic wastewater, including pH, BOD, TSS, COD, oil and grease and total coliforms. Ammonia remained non-compliant (inflow 181.4mg/L, effluent 35.2mg/L, standard <10mg/L), possibly due to non-dilution with greywater and requiring additional aeration. Mean total coliforms were reduced by 99.3% (from 308,900 to 2,100 CFU/100ml) and *E.coli* by 99.7% (from 195,150 to 650 CFU/100ml). Performance suggests that this nature-based solution can substitute for conventional wastewater treatment while being appropriate for decentralized, low-income settings. The demonstration project also showed how nature-based solutions could be incorporated into high-density settings.

EVALUATING TRADE-OFFS BETWEEN LOCAL AND GLOBAL PRIORITIES FOR THE CONTROL OF MALARIA

Daniela Olivera Mesa, Peter Winskill, Katharina Hauck, Azra Ghani

Imperial College London, London, United Kingdom

Despite global efforts to reduce malaria transmission, the world remains offtrack to meet the goals set in the WHO Global Technical Strategy for Malaria. International donor funding for malaria interventions has plateaued and therefore difficult decisions need to be made regarding resource allocation. Currently, international donor funding is allocated between countries in proportion to disease burden as a measure of need. This can however lead to sub-optimal allocation at a broader regional level. We sought to quantify the tradeoffs between global and local perspectives for resource allocation. We extended a compartmental model of malaria transmission into a metapopulation model in which populations were stratified by their level of transmission. We used the model to evaluate the optimal distribution of insecticide bed nets strategies from two different perspectives; first minimising disease burden across all the populations aligned with the international donor perspective; and then minimising disease burden for each sub-population, aligned with the country perspective. Results show that the current allocation in proportion to disease burden is optimal in terms of reducing burden globally and therefore aligned with the international donor perspective. In contrast, for low transmission countries, an equal allocation of resources regardless of transmission levels is optimal from the country perspective, allowing a greater number of cases to be averted in the individual country provided that mixing levels with a high transmission country stay below 16%. As mixing between a low and a high transmission country increases, our results show that sharing resources proportionally to the level of connection with the high transmission country may be better than keeping resources locally. These findings highlight that international donor and individual country perspectives may not be aligned when considering allocation of limited resources for malaria control. Our findings also support current cross-border control initiatives, demonstrating the wider value to low transmission countries of controlling malaria across their borders.

0592

CHARACTERISTICS OF TRAVEL FROM ZANZIBAR TO TANZANIA MAINLAND AND THE ASSOCIATED RISK OF MALARIA INFECTION

Bakar S. Fakih[1], Aurel Holzschuh[2], Amanda Ross[1], Logan Stuck[3], Abdul-Wahid Al-Mafazy[4], Abdullah Ali[5], Cristian Koepfli[2], Joshua Yukich[3], Günther Fink[1], Manuel W. Hetzel[1]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Department of Biological Sciences, Eck Institute for Global Health, University of Notre Dame, Indiana, IN, United States, [3]Tulane University, School of Public Health and Tropical Medicine, New Orleans, LA, United States, [4]Research Triangle Institute (RTI) International, Zanzibar, United Republic of Tanzania, [5]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania

Zanzibar has made significant progress in malaria control as a result of rolling out interventions including vector control, improved diagnosis, and highly effective artemisinin-based combination therapy. However, imported infections from mainland Tanzania have been highlighted as an important contributor to sustained malaria transmission on the archipelago. This research aimed to understand the links between travel patterns to mainland Tanzania and malaria infections detected in people in Zanzibar. We did a rolling cross-sectional survey on Pemba and Unguja islands linked to the routine case-based surveillance-response system. We surveyed households of patients diagnosed with malaria at health facilities ('index cases') and tested all household members for malaria using rapid diagnostic tests (RDT) and highly sensitive qPCR. Interview questions elicited a detailed travel history of all household members who had traveled within the past two months. We recruited 17,891 participants of whom 2,788 respondents (16%) reported a recent trip, and 786 out of these (66%) had traveled to mainland Tanzania. Among those who traveled to the mainland, 54% and 21% reported traveling to high and moderate malaria-endemic districts, respectively. Of all travelers to the mainland, 165 (38%) reported never using a mosquito net during their recent travel. Of those who visited highly malaria endemic districts, 25 (9%) were positive by RDT and 83 (34%) by qPCR. Travelers to highly endemic districts had a 2.5-fold higher odds of being qPCR-positive than those who traveled only to districts where malaria-endemicity is lower (95% CI: 1.5-4.1, p=0. 001). Further risk factors of malaria infection among travelers will be presented alongside their travel destinations and recommendations for reducing malaria importation from mainland Tanzania to Zanzibar.

0593

SINGLE LOW DOSE TAFENOQUINE COMBINED WITH DIHYDROARTEMISININ-PIPERAQUINE TO REDUCE *PLASMODIUM FALCIPARUM* TRANSMISSION: A PHASE 2 SINGLE BLIND RANDOMIZED CLINICAL TRIAL IN OUELESSEBOUGOU, MALI

Almahamoudou Mahamar[1], Merel J. Smit[2], William Stone[3], Koualy Sanogo[1], Youssouf Sinaba[1], Sidi M. Niambele[1], Adama Sacko[1], Sekouba Keita[1], Oumar Dicko[1], Makonon Diallo[1], Seydina Maguiaga[1], Siaka Samake[1], Oumar Attaher[1], Kjerstin Lanke[2], Rob ter Heine[2], John Bradley[3], Matthew B. B. McCall[2], Djibrilla Issiaka[1], Sekou F. Traore[1], Teun Bousema[2], Chris Drakeley[3], Alassane Dicko[1]

[1]Malaria Research and Training Centre, Bamako, Mali, [2]Radboud UMC, Nijmegen, Netherlands, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Tafenoquine (TQ) was recently approved as prophylaxis and radical cure for *P. vivax* infection. Like its analogue primaquine (PQ), tafenoquine can kill *P. falciparum* gametocytes. This activity makes it a potentially valuable tool for malaria transmission blocking, particularly for the containment of drug resistant parasites. In the current trial, we aimed to establish the efficacy and safety of three single low doses of TQ in combination with dihydroartemisinin-piperaquine (DP) for reducing gametocyte density and transmission to mosquitoes. Eighty participants

(12-50 years of age) with normal glucose-6-phosphate dehydrogenase (G6PD) activity and asymptomatic *P. falciparum* gametocyte carriage were randomised to DP, or DP plus a single dose of TQ at 0·42mg/kg, 0·83mg/kg, or 1·66mg/kg. Clinical assessments, biochemical, and molecular gametocyte quantification assays were conducted throughout the 28 days of follow up, with additional samples at day 0, 2, 7 and 14 to test infectivity to mosquitoes. Participants were enrolled from 29th October to 25th November 2020. Before treatment, 66% (53/80) of individuals were infectious to mosquitoes, infecting on average 12·5% of mosquitoes (Interquartile range [IQR] 3·64-35). Within-arm percent reduction in mosquito infection rate on day 7 (primary endpoint) was 79·95% (IQR 57·15-100) following DP (p=0·0005), and 100% (IQR 98·36-100) following all treatments with DP and TQ (p<0·0005). Male and female gametocyte clearance following TQ suggests a different mechanism of clearance compared to PQ. No serious adverse events (SAE) occurred, and there were no significant differences in the incidence of all AEs (p=0.73) or drug-related AEs (p=0.62) observed between treatment arms. TQ was well tolerated at all doses and accelerated *P. falciparum* gametocyte clearance. All TQ doses demonstrated improved transmission reduction at day 7 compared to DP alone. Despite being slower to achieve blockade than PQ, PQ remains active for only a few hours whereas TQ has a half-life of more than 2 weeks. Future trials should focus on establishing the longevity of TQ's transmission blocking activity.

0594

ASSESSMENT OF PRIMAQUINE UTILIZATION IN FOUR ETHIOPIAN HEALTH FACILITIES IN THE CONTEXT OF ETHIOPIA'S MALARIA ELIMINATION STRATEGY

Belete Ayalneh[1], Fikreslassie Alemu[1], Fikadu Deme[1], Gudissa Assefa[2], Elias Geremew[1], Helen Tesfaye[1], Sami Tewfik[1], Edmealem Ejigu[1], Tesfaye Seifu[1], Tsion Demissie[3], Yoseph Wakoya[1], Asrat Abate[1], Chalachew Bayu[1], Dagne Bililigne[1]

[1]USAID Global Health Supply Chain Program-Procurement and Supply Management project, Addis Ababa, Ethiopia, [2]Ethiopian Disease Prevention and Control Directorate, Ministry of Health, Addis Ababa, Ethiopia, [3]USAID Health Office in Ethiopia, PMI, Addis Ababa, Ethiopia

Malaria is one of the major causes of morbidity and mortality in Sub-Saharan Africa. Appropriate use of antimalarial drugs is vital in the effective management of malaria, and it reduces the development of drug resistance and the cost of therapy. Effective supply planning of antimalarial drugs is integral to preventing stockouts or wastage. Based on Ethiopia's National Malaria Treatment Guidelines (NMTG) and malaria elimination strategy, radical cure with primaquine 0.25mg/kg for 14 days is recommended for all patients with *P. vivax* (Pv) and mixed malaria, and a single dose 0.25mg/kg of primaquine with Artemether-Lumefantrine (AL) is used for the treatment of *P. falciparum* (Pf). The U.S. President's Malaria Initiative funded the USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project to conduct a retrospective cross-sectional drug use evaluation (DUE) in four supported health facilities from August to December 2021 to assess the extent of primaquine utilization in malaria patients and treatment adherence to the NMTG in Ethiopia. The DUE reviewed 593 patient charts with malaria treatments from 2019 to 2021. Of these cases, 99% (588/593) had laboratory tests of which 93.7% (551/588) were malaria positive. Of the total malaria positive cases, 64% (353) were *Pf*, 24.7% (136) were *Pv*, 3.3% (18) were mixed species infections (507 in total), and 8% (44) had no specified species. The utilization rate of primaquine was 75.5% (379/507). A single dose of primaquine with AL was used in 77% of *Pf* cases, 14-day primaquine with chloroquine was used in 86% of *Pv* cases, and 14-day primaquine was used in 67% of mixed malaria cases. The use of primaquine in the studied facilities was found to be lower than the national recommendation. Interventions, including trainings and supportive supervision should be considered to improve the use of primaquine. Additional nationally representative primaquine utilization studies should be considered to better understand primaquine use more broadly and help identify causes of under-use.

0595

ACTIVE SCREENING AND TREATMENT SIGNIFICANTLY REDUCES THE INFECTIOUS RESERVOIR OF MALARIA IN BURKINA FASO

Katharine A. Collins[1], Alphonse Ouedraogo[2], Wamdaogo Moussa Guelbeogo[2], Issiaka Soulama[2], Maurice Ouattara[2], Apollinaire Nombre[2], Amidou Diarra[2], John Bradley[3], Prashanth Selvaraj[4], Jaline Gerardin[5], Chris Drakeley[6], Teun Bousema[1], Alfred Tiono[2]

[1]Department of Medical Microbiology, Radboud university medical center, Nijmegen, Netherlands, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]MRC Tropical Epidemiology Group, London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Institute for Disease Modeling, Bellevue, WA, United States, [5]Department of Preventive Medicine, Northwestern University, Chicago, IL, United States, [6]Department of Immunology and Infection, London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

The majority of malaria infections in endemic countries are asymptomatic and can remain untreated and potentially transmissible to mosquitoes for many months, posing a major obstacle to malaria elimination. Malaria burden and transmission could be reduced by detecting and treating these infections early using active methods to screen for infections. In an 18 month cluster-randomised intervention study in Burkina Faso we assessed the impact of two interventions on the prevalence and transmissibility of malaria infections. The interventions included (i) enhanced community case management (CCM), comprising active weekly screening for fever, with treatment of rapid diagnostic test (RDT) positive febrile individuals, or (ii) monthly screening and treatment (MSAT) using standard RDTs. 180 compounds with 906 subjects were randomized to: Arm 1 - control; Arm 2 - enhanced CCM; or Arm 3 - enhanced CCM combined with MSAT. Interventions were implemented over 16 months, with parasite and gametocyte prevalence and density monitored by qPCR in 4 start/end season cross-sectional surveys. At the start of the study, parasite prevalence by qPCR was 64%, and 61% of these infections carried gametocytes. Most infections in cross-sectional surveys were asymptomatic (98.6% [1336/1355]), and asymptomatic infections were as transmissible to mosquitoes in membrane feeding assays (4.5% [35/771]) as symptomatic infections (5.7% [7/123]). A total of 108 malaria infections were detected by CCM, and 534 infections detected by MSAT. There was a significant impact of CCM plus MSAT, with parasite and gametocyte prevalence and density being significantly lower in arm 3 in all end season surveys. Notably, gametocyte prevalence was up to 79.2 % lower and transmissible gametocyte prevalence (>1 p/uL) was up to 95.3 % lower, with only 0.73% (2/275) of participants in arm 3 carrying gametocytes at a transmissible density at the end of the dry season. This study could pave the way for a simple yet effective method to control malaria burden in areas of high transmission by abrogating infections before clinical presentation and the development of transmissible gametocytemia.

EFFECTIVENESS OF REACTIVE FOCAL MASS DRUG ADMINISTRATION FOR MALARIA IN THAILAND DURING THE COVID-19 PANDEMIC

Adam Bennett[1], Jintana Chaiwan[2], Timothy Finn[3], Chris Cotter[3], Michelle S. Hsiang[3], Suravadee Kitchakarn[2], Cheewanan Lertiriyasuwat[2], Prayuth Sudathip[2]

[1]PATH, Seattle, WA, United States, [2]Division of Vector Borne Diseases, Bangkok, Thailand, [3]UCSF Malaria Elimination Initiative, San Francisco, CA, United States

Thailand has achieved dramatic success in reducing its malaria burden by implementing robust surveillance approaches including case investigation and active case detection, and has targeted malaria elimination by 2024. One active approach includes reactive case detection (RACD), where all cases confirmed through the health system are followed up at

the community level with testing of neighboring household members. However, neighborhood-targeted RACD has had limited effectiveness in the Greater Mekong Subregion (GMS) due to low diagnostic sensitivity and high rates of forest work exposure. Additionally, active case detection and treatment adherence for *Plasmodium vivax* is especially challenging. We conducted a pragmatic randomized controlled trial to assess the effectiveness of community-level reactive focal mass drug administration (rfMDA), or administration of an effective antimalarial to all neighborhood or forest work contacts of an initial confirmed case, including quantitative G6PD testing and radical cure for *P. vivax* with follow up by village health volunteers. Forty subdistricts were randomized to conduct rfMDA with artesunate-mefloquine or the standard of care control (RACD) from November 2020 - November 2021, and confirmed case incidence was measured through routine surveillance in each arm. An endline survey measuring parasite prevalence by PCR in 7,495 individuals across arms was conducted December 2021 - February 2022. Coverage of index case response was much lower in the intervention arm (29.4%) than control (87.7%) due to the COVID-19 pandemic, as intervention arm health staff were also frontline COVID-19 workers. Confirmed case incidence was reduced in the intervention arm from 4.0/1000 in 2020 to 3.0/1000 in 2021, while in the control arm incidence was 4.3/1000 in 2020 and 4.8/1000 in 2021. Adjusted incidence and endline parasite prevalence results will be presented. These results suggest that rfMDA, including radical cure for *P. vivax*, may be an effective strategy for reducing transmission in the remaining active foci in Thailand that can be feasibly implemented with supported village health volunteers.

0597

FEASIBILITY AND EFFECTIVENESS OF TARGETED MALARIA INTERVENTIONS FOR HIGH-RISK POPULATIONS IN SENEGAL

Tidiane Thiam[1], Demba Kande[1], Henry Ntuku[1], Caterina Guinovart[1], Laura Merriman[1], Sarah Gallalee[2], Abiboulaye Sall[1], Moustapha Cissé[1], Aichatou Barry Diouf[3], Mamadou Diop[3], Baba Camara[3], Niene Seck[3], Yakou Dieye[1], Jennifer Smith[2], Adam Bennett[4]

[1]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Dakar, Senegal, [2]University of California, San Francisco, Malaria Elimination Initiative, San Francisco, CA, United States, [3]Ministère de la Santé et de l'Action Sociale (Department of Health and Social Action), Dakar, Senegal, [4]PATH MACEPA/University of California, San Francisco, MEI, Seattle, WA, United States

Senegal has made significant progress in reducing malaria burden over the last decade. However, malaria remains a major cause of morbidity and mortality in some regions and key challenges exist among high-risk populations where access to malaria control tools is limited. Our preliminary study indicated that both gold miners and Talibés (Koranic school students) have high exposure to mosquito bites, but low coverage and use of vector control measures and limited access to health services. We conducted a controlled pre/post study to determine whether targeted malaria interventions, including expansion of community case management and distribution of LLINs, at mining sites and Koranic schools (Daaras) increased LLIN coverage and reduced malaria infection prevalence and clinical incidence during high transmission season in Senegal. We randomly assigned eight health facility catchment areas to intervention or control groups: four in Kaolack (a city with many Koranic schools) and four in Saraya (a district with gold mining sites). Surveys were conducted pre (Oct 2021; n=1740) and post (Feb 2022; n=2200) delivery of intervention to assess LLIN coverage and infection prevalence by rapid diagnostic test. In Kaolack, pre-intervention LLIN ownership was 44.7% in intervention and 70.6% in control areas, and post-intervention 100% and 73.1%, respectively. In Saraya, pre-intervention LLIN ownership was 62.8% in intervention and 64.4% in control areas, and post-intervention 73.1% and 68.6%, respectively. In Kaolack, prevalence of malaria infection increased from 4.9% to 12.9% in intervention areas, but from 5.9% to 24.7% in control areas; in Saraya, prevalence decreased from 27.6% to 6.3% in intervention areas, and from 31.6% to 6.4% in control areas. Multivariable results of impact on infection prevalence and clinical incidence will be presented. These results suggest that targeted malaria interventions are feasible and can effectively increase LLIN coverage and reduce prevalence in certain high-risk populations. Expansion to other unreached high-risk populations is essential for meeting malaria elimination goals.

IL-11 REGULATES MUCOSAL RESPONSES IN ACUTE PULMONARY HELMINTH INFECTION

Pablo Bara-Garcia[1], Jonah Kurpitz[1], Oyebola Oyesola[1], Fabricio Oliveira[2], Thomas B. Nutman[1], Pedro Gazzinelli-Guimaraes[1]

[1]NIAID, National Institutes of Health, Bethesda, MD, United States, [2]Federal University of Minas Gerais, Belo Horizonte, Brazil

Transient larval migration of helminth parasites in the host tissue during their life cycle drives an early neutrophil-associated inflammation before the establishment of an eosinophil-dominated type-2 response. Members of the IL-6 cytokine family, including IL-11, have been described to play a role in acute inflammatory responses. Investigating the role of IL-11 following *Ascaris spp*. infection in mouse models, we observed significantly elevated IL-11 levels in the lung tissue of *Ascaris*-infected mice (2,196 pg/mL *vs* 968 pg/mL, p<0.001 at 8 dpi) compared to uninfected mice. Flow cytometry and confocal imaging demonstrated that lung $EpCAM^+$ epithelial cells were the major source of IL-11 in the lungs of *Ascaris*-infected mice. Neutralization of IL-11 (using anti-IL-11 antibody intranasally) during *Ascaris* infection markedly impaired the influx of neutrophils to the lung, whereas intranasal administration of rIL-11, in contrast, increased neutrophil influx as a consequence of increased levels of G-CSF and CXCL1. *Ascaris* infection in IL-11Ra1 deficient mice was similarly associated with a marked reduction in lung neutrophil influx (20.3×10^5cells *vs* 51.2×10^5cells, p=0.030 at 8 dpi) and a significant decrease of neutrophil-associated mediators (e.g., CXCL-1 and G-CSF) when compared with WT *Ascaris*-infected animals. To further elucidate whether IL-11 production by lung epithelial cells is elicited directly or indirectly, a human bronchial epithelial cell line (HBEC3-KT) was shown to produce markedly increased (55% above baseline) amounts of IL-11 following exposure to *Ascaris* larvae. Moreover, HBEC3-KT cells, when stimulated *in vitro* with various recombinant cytokines, including IL-33, IL-1b, IL-1a, and TGF-b, only rTGF-b was capable of inducing IL-11 in a dose dependent manner. Indeed, pulmonary *Ascaris* larval migration drives a marked increase of TGF-b levels *in vivo* (1476.23 pg/mL vs 986.87 pg/mL, p<0.001). Taken together, our data suggests that IL-11 produced by epithelial cells regulates a neutrophil-dominated inflammation in response to epithelial damage and through TGF-b during acute helminth infection in the lungs.

0599

PHAGE SCREENING IDENTIFIED A NOVEL NEMATODE PAN ALLERGEN (NPA) RESPONSIBLE FOR IGE RESPONSES IN HUMAN FILARIAL TROPICAL PULMONARY EOSINOPHILIA (TPE)

Anand Setty Balakrishnan[1], Gnanasekar Munirathinam[1], Samuel Christopher Katru[1], Azadeh Hadadianpour[2], Scott Alan Smith[2], Ramaswamy Kalyanasundaram[1]

[1]University of Illinois at Chicago, College of Medicine, Rockford, IL, United States, [2]Vanderbilt University, Nashville, TN, United States

Tropical pulmonary Eosinophilia (TPE) is an allergic condition that occurs in individuals with Lymphatic Filariasis (LF), a tropical parasitic infection that affects over 120 million people in 82 countries. Parasite antigens responsible for triggering the IgE responses in TPE subjects is not fully identified. The main objective of this study was to identify IgE-specific allergens in TPE individuals. We screened a phage-displayed cDNA expression library of *Wuchereria bancrofti* microfilaria with pooled human monoclonal IgE antibodies isolated from B-cell hybridomas prepared from TPE individuals. After five rounds of biopanning, we analyzed 13 clones and the sequences obtained were blasted to identify the genes. Our results showed that the sequences belonged to two genes, Bm2855 and *Wb*TCTP.

Bm2855 (*Brugia malayi* RNA recognition motif domain-containing protein) gene is not yet annotated in the literature. Phylogenetic tree analysis on Bm2855 sequence showed that this gene is highly conserved in nematode parasites and showed over 95% similarity in several nematodes with no homology to human. Therefore, we named Bm2855 as Nematode Pan Allergen (NPA). The NPA gene sequence is now deposited in the NCBI GenBank (accession # ON023112). Further analysis showed that the NPA gene is highly expressed in the microfilaria stage and adult females compared to all other lifecycle stages of *W. bancrofti*. Similarly, sera samples from TPE, and microfilaremic subjects had high levels of antibodies against NPA compared to chronic pathology (CP) and endemic normal (EN) control subjects. *Wb*TCTP has already been described and characterized from our laboratory as a histamine releasing factor. Thus, in the present study, we report for the first time the NPA as a novel pan allergen that can induce IgE response in TPE individuals. Our study suggest that NPA and *Wb*TCTP may have a significant role in the pathology and allergic symptoms associated with TPE in filarial infected patients.

INFLAMMASOME AND REACTIVE OXYGEN SPECIES (ROS) SIGNALING CASCADES DURING MICROFILARIAE- AND THIRD STAGE LARVAE-INDUCED NEUTROPHIL AND EOSINOPHIL ETOSIS

Alexandra Ehrens[1], Celia Nieto[1], Nina Offermann[2], Frederic Risch[1], Marianne Koschel[1], Eicke Latz[3], Melania Capasso[2], Achim Hoerauf[1], Marc P. Hübner[1]

[1]University Hospital Bonn, Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, [2]German Center for Neurodegenerative Diseases (DZNE) within the Helmholtz Association, Immunregulation, Bonn, Germany, [3]University Hospital Bonn, Institute of Innate Immunity, Bonn, Germany

Neutrophils and eosinophils as well as their cytotoxic granules are important for protective immunity against filariae. The release of those granules can be mediated through extracellular DNA trap cell death (ETosis), where intracellular DNA is explosively released, entrapping pathogens and supporting their killing. For neutrophils, reactive oxygen species (ROS) production and the non-canonical inflammasome pathway appears to be essential for PMA-induced ETosis. However, the exact signaling cascade for filaria-induced neutrophil and eosinophil ETosis is not known yet. Our *in vitro* results demonstrate that *Litomosoides sigmodontis* microfilariae (MF) and third stage larvae (L3) induce ETosis in bone marrow-derived neutrophils and eosinophils. However, the granulocytes vary in their ROS responses towards different stimuli. While neutrophils show faster and stronger ROS production towards stimuli such as PMA and zymosan, eosinophils generate more ROS in response to MF/L3 than neutrophils. Especially MF triggered intracellular ROS including mitochondrial ROS (mtROS) and extracellular ROS in eosinophils. Since MF primarily trigger the release of mtDNA in eosinophils and mtROS positively correlated with DNA release, a link between mtROS formation and ETosis is suggested. In addition, ROS generated by NADPH oxidase was shown to be important for the MF-induced ETosis, since granulocytes generated from NADPH oxidase knockout (ko) mice failed to generate DNA traps. Furthermore, experiments with eosinophils generated from AIM2 and caspase-1 ko mice indicate that AIM2 inflammasome activation, which detects double stranded DNA, followed by caspase-1 signaling is involved in the MF-induced ETosis suggesting a positive feedback-loop for ETosis in eosinophils. In summary, these results reveal the underlying signaling mechanism during granulocyte DNA release that is in part dependent on the stimuli. Our results further illustrate both conserved mechanisms as well as differences in ETosis and ROS production in eosinophils and neutrophils.

PRE-EXISTING ALLERGIC SENSITIZATION RESHAPES THE TRANSCRIPTIONAL AND FUNCTIONAL PROGRAMMING OF CD4 T CELLS IN HUMAN FILARIAL INFECTION

Pedro H. Gazzinelli-Guimaraes[1], Phillip Swanson[2], Brittany Dulek[3], Justin Lack[3], Mario Roederer[2], Thomas B. Nutman[1]

[1]Laboratory of Parasitic Diseases, NIAID, National Institutes of Health, Bethesda, MD, United States, [2]Vaccine Research Center, NIAID, National Institutes of Health, Bethesda, MD, United States, [3]NIAID Collaborative Bioinformatics Resource, NIH, Bethesda, MD, United States

We have previously demonstrated that environmental house dust mite (HDM) allergic sensitization coincident with helminth filarial infection in humans drives a hyperreactive parasite antigen-specific Th2-dominated response. To further characterize the heterogeneity and function of these antigen-reactive Th2 cells, we analyzed 47 subjects' PBMCs [23 filarial-infected (Fil^+) with or without coincident HDM sensitization (Fil^+HDM^+ n=12; Fil^+HDM^-, n=11) and 24 subjects without filarial infection (Fil^-) (Fil^-HDM^+ n=12; and Fil^-HDM^-, n=12) multiparameter flow cytometry with 2 level clustering. The frequency of 3 memory $CD4^+$ T cell clusters, including $CCR4^+CCR6^+CRTH2^-$ (subset 1), $CCR4^+CCR6^-CRTH2^+$ (subset 2), as well as $CCR6^+CCR4^+CRTH2^+$ (subset 3) were markedly enriched among Fil^+ subjects. These 3 subsets were sorted and analyzed by multiomic single cell RNA profiling. This functional characterization indicated subset 2 and 3 as distinct Th2 cytokine producers, which together were responsible for the majority of IL-4, IL-5, or IL-13 produced among the Fil^+ subjects. Indeed, the gene set enrichment analysis (fine DICE) indicated that both $CCR4^+CCR6^-CRTH2^+$ and $CCR4^+CCR6^+CRTH2^+$ $CD4^+$ T cells as predominantly Th2 effector cells by their single cell molecular signature. When the Fil^+ subjects were divided by their allergic status, the Fil^+HDM^+ subject had an expansion of both $CCR4^+CCR6^-CRTH2^+$ (3.19% vs 1.28%, p=0.001) and $CCR4^+CCR6^+CRTH2^+$ (0.39% vs 0.15%, p=0.002) Th2 cells when compared with Fil^+HDM^-. Gene expression analysis further demonstrated that HDM sensitization in the presence of filarial infection reshaped the molecular program of both Th2 cells subsets of through the upregulation of GATA3, IL17RB, CLRF2, and KLRB1 mRNA. This distinct molecular and functional signature of Th2 cells subsets in Fil^+HDM^+ may explain their Type-2 associated hyperreactivity that sheds new light on Th2 effector cell diversity and their contribution to immune regulation in helminth infection.

SINGLE-CELL APPROACHES TO DISSECTING *BRUGIA MALAYI* PARASITE-HOST-DRUG INTERACTIONS

Clair Henthorn, Paul Airs, Mostafa Zamanian

University of Wisconsin- Madison, Madison, WI, United States

Lymphatic filariasis is a debilitating neglected tropical disease caused by filarial nematodes transmitted by a mosquito vector. Strategies to minimize parasite transmission rely on mass distribution of anthelmintics that are suboptimal and cannot be used in all locales. The precise mechanisms of action of these essential drugs remain elusive and the dynamics of the parasite-drug-host interface are unresolved. Harnessing single-cell sequencing approaches, we have successfully profiled gene expression patterns across over 48,000 *Brugia malayi* microfilariae-derived cells. We have leveraged these data to map the cellular origins of prominent antigens, resolve the distribution of putative anthelmintic targets, and identify informative markers for the annotation of discrete tissue types. We have used flow cytometry and single-cell sequencing experiments to measure the effects of the major anthelmintic classes (macrocyclic lactones, benzimidazoles, and nicotinic receptor agonists) on the viability and transcriptional trajectories of dispersed nematode cells. Given the importance of parasite ion channels as anthelmintic targets, we have generated predictions about the in vivo co-localization and physical association of channel subunits. Lastly, we have developed functional assays on cultured cell *B. malayi* populations to further resolve receptor-mediated drug perturbations at single-cell resolution. Together, this work

establishes a platform for the investigation of cell and tissue-specific processes relevant to drug action and secretory processes in filarial nematodes. We expect that these approaches can be readily adapted to other stages and species of parasitic nematodes.

0603

OCCURRENCE OF LYMPHATIC FILARIASIS INFECTION AFTER 15 YEARS OF MASS DRUG ADMINISTRATION IN TWO HOTSPOT DISTRICTS IN THE UPPER EAST REGION OF GHANA

Derrick Adu Mensah[1], Linda Batsa Debrah[1], Peter Akosah Gyamfi[2], Abu Abudu Rahamani[1], Vera Serwaa Opoku[1], John Boateng[1], Prince Obeng[1], Jubin Osei-Mensah[3], Inge Kroidl[4], Ute Klarmann-Schulz[5], Achim Hoerauf[5], Alexander Yaw Debrah[1]

[1]Kwame Nkrumah University of Science and Technology/Kumasi Center for Collaborative Research in Tropical Medicine, Kumasi, Ghana, [2]Kwame Nkrumah University of Science and Technology/Kumasi Center for Collaborative Research in Tropical Medicine/Faculty of Health Sciences, Garden City University College, Kumasi, Ghana, [3]4Department of Pathobiology, School of Veterinary Medicine, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana/Kumasi Center for Collaborative Research in Tropical Medicine, Kumasi, Ghana, [4]Division of Infectious Diseases and Tropical Medicine, Medical Center of the University of Munich (LMU), Germany/German Center for Infection Research (DZIF), partner site Munich, Germany, Munich, Germany, [5]Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Germany/German Center for Infection Research (DZIF), partner site Bonn-Cologne, Germany, Bonn, Germany

Lymphatic filariasis (LF) causes chronic morbidity, which usually manifests as lymphedema or hydrocele. Mass drug administration (MDA) with ivermectin and albendazole to control LF began in the Kassena Nankana East Municipal (KNEM) and Nabdam, two hotspot districts in the Upper East Region of Ghana, in 2000 and 2005, respectively. This cross-sectional study evaluated the impact of 15 years of MDA on the control of LF as determined by circulating filarial antigen (CFA) and microfilariae (MF) prevalence in the KNEM and Nabdam districts. 7,453 participants from 8 sub-districts in the two hotspot districts (KNEM: N = 4604; Nabdam: N = 2849) were assessed for CFA and MF in this study. The overall CFA prevalence as determined by the Filariasis Test Strip (FTS) was 19.6%/12.7% in the KNEM/Nabdam districts, respectively. Manyoro, a sub-district on the border with Burkina Faso, recorded the highest CFA prevalence of 26% in the KNEM. Assessment of MF and Og4C3 antigen was done for 1009 (KNEM: N = 799 (79.2%); Nabdam: N = 210 (20.8%)) randomly selected FTS-positive (N = 885) and FTS-negative (N = 124) individuals. The Og4C3 antigen was detected in 22.6%/23.0% of individuals in KNEM/Nabdam, whereas night blood revealed MF in only 0.7%/0.5% of individuals, respectively. Using the WHO-approved FTS, CFA prevalence exceeded the <2% threshold. Surprisingly, the Og4C3 ELISA showed positive results in only about one-fifth of the FTS-positive samples. However, even the relatively less sensitive Og4C3 ELISA would still not have met the <2% CFA criteria for LF elimination. In contrast, the MF results revealed a halt in LF transmission. This calls for a revision of the long-standing stringent WHO recommended <2% CFA threshold especially after more sensitive diagnostic kits such as the FTS has been introduced for post-treatment surveillance. This may reduce the risk of continual CFA pre-TAS failure in endemic countries trying to reach elimination goal, which has now been extended to 2030. Intensification of focused MDA interventions for seasonal migrants and regular MDA non-compliers, and adoption of alternative treatment strategies are required for the elimination of LF.

0604

BAYESIAN NETWORK ANALYSIS PREDICTS ADDED VALUE OF LYMPHATIC FILARIASIS ANTIBODY TESTING IN POST-MDA SURVEILLANCE IN MANDALAY REGION, MYANMAR

Benjamin F R Dickson[1], Jesse Masson[1], Helen Mayfield[2], Khin Saw Aye[3], Kyi May Htwe[3], Maureen Roineau[1], Athena Andreosso[1], Stephanie Ryan[1], Luke Becker[1], Janet Douglass[1], Patricia M. Graves[1]

[1]James Cook University, Cairns, Australia, [2]The University of Queensland, Brisbane, Australia, [3]Department of Medical Research, Ministry of Health and Sports, Yangon, Myanmar

Lymphatic filariasis (LF) is eliminated through mass drug administration (MDA) of anti-filarial medications over multiple years which interrupts transmission and prevents new infections. Accurate transmission assessments are critical to deciding when to stop MDA. Current methods for evaluating transmission may be insufficiently sensitive, resulting in post-MDA resurgence. We therefore evaluated potential testing scenarios for post-MDA surveillance. Data were used from two surveys (a household cluster and a case-control) conducted in an area of Mandalay Region, Myanmar with ongoing transmission following several rounds of MDA. First, an age- and sex-adjusted seroprevalence was estimated for the area from the household survey. Next, three Bayesian networks were built from the combined datasets to compare antigen (by ICT and/or Og4C3), Wb123 antibody (Ab) and Bm14 Ab respectively. The networks were checked for validity, and then used to compare testing scenarios. The adjusted prevalence from the household survey for antigen, Wb123 Ab and Bm14 Ab were 4.4% (95% CI 2.6 - 7.3%), 8.7% (5.96 - 12.5%) and 20.8% (16.0 - 26.6%) respectively. For the three networks, the Area Under the Receiver Operating Characteristic Curve and True Skill Statistic ranged from 0.80 - 0.97 and 0.54 - 0.79 respectively. In the Bayesian sample, the probability of a positive result prior to any testing scenario was 17.4%, 16.8% and 26.6% for antigen, Wb123 Ab and Bm14 Ab respectively. When only antigen was tested and negative, the probability of a missed LF positive result was 5.2% for Wb123 Ab and 15.6% for Bm14 Ab. The testing combination of antigen plus Bm14 Ab was the most sensitive, with the probability missed LF positive result detected by Wb123 Ab of 0.88%. Meanwhile the combination of antigen plus Wb123 Ab yielded a probability of a positive result by Bm14 Ab of 11.5%. These findings suggest that addition of Wb123 Ab testing does not add increased sensitivity if Ag tests are already being used, but the addition of Bm14 Ab testing should be considered for inclusion in post-MDA surveillance to detect transmission more accurately, and prevent the premature cessation of MDA.

0605

GLOBAL ENVIRONMENTAL SUITABILITY OF LYMPHATIC FILARIASIS TRANSMISSION

Mustafa Sikder, Cathleen Keller, Ewerton Cousin, Joanna Whisnant, Lydia Plante, Olivia Nesbit, Steph Zimsen, Taren Gorman, Trent Yarosevich, Jonathan F. Mosser

Institute for Health Metrics and Evaluation, Seattle, WA, United States

Despite the global progress in reducing the lymphatic filariasis (LF) burden, LF is endemic in 47 countries and around 51 million individuals were estimated to be infected with LF in 2018. LF is caused by filarial parasites that infect human lymphatic vessels. Three filarial species are linked to LF and transmitted via *Anopheles, Culex, Aedes*, and *Mansonia* mosquito vectors. Delineating the environmental limits of these vectors will help to identify areas under potential LF transmission risk. We compiled 15,760 georeferenced LF prevalence data points covering 74 countries from 1990 to 2018. The data sources included both published scientific literature and program monitoring data. We studied the relationship between LF prevalence and environmental and climate covariates including, temperature, precipitation, evaporation, land use types, enhanced vegetation index, elevation, distance from water bodies, and population density. To understand these relationships, we first generated randomly

sampled background points from outside of a 100-km buffer from occurrence locations to represent LF absence since reported absence can include false negatives. Then we extracted corresponding covariate values for both LF presence and background locations. We used separate boosted regression tree models to estimate the relationship between LF presence/background data and covariates in Africa, South Asia, South East Asia, and the island of Hispaniola. Finally, we produced environmental suitability maps of LF transmission limits at a 5 X 5 km resolution. The results indicated substantial heterogeneity in LF transmission risk. Particularly, geographic locations with no reported cases were estimated to have substantial environmental suitability for LF, suggesting potential risks of LF transmission. The widespread environmental suitability of LF emphasizes the importance of ongoing mass drug administration campaigns and transmission assessment monitoring efforts. These high-resolution maps can aid decision-makers to identify high transmission risk locations and prioritize resource mobilization to successfully eliminate the disease.

0606

CHARACTERIZATION OF AN IGG4/OV16 RAPID TEST TO DETECT EXPOSURE TO *ONCHOCERCA VOLVULUS* INFECTIONS

Adina Gerson-Gurwitz[1], Marina Siirin[2], **Lily A. Sullins**[2], Maria J. Gonzalez-Moa[3], Bijan Pedram[3], Marco A. Biamonte[2]

[1]PLEXIUM, San Diego, CA, United States, [2]Drugs and Diagnostics for Tropical Diseases, San Diego, CA, United States, [3]Sapphire Biotech, San Diego, CA, United States

The Onchocerciasis v1.0 Rapid Diagnostic Test (RDT) is a serological lateral flow assay indicative of exposure to *Onchocerca volvulus* infective larvae and detects IgG4 antibodies specific for the Ov16 antigen. The test was created to mitigate procurement risks for onchocerciasis national public health programs, which rely on a single source of RDTs (SD BIOLINE Onchocerciasis IgG4 Rapid Test). The clinical sensitivity of the Onchocerciasis v1.0 RDT was determined to be 83.8% (95% CI 74.1-90.3 %, n = 80) based on an independent evaluation at NIAID using serum samples. Its specificity was 100% (95% CI 88.7-100.0%, n=30) when using sera from presumed uninfected US volunteers as a comparator group, and 99.1% (95% CI 94.9-100.0 %, n = 105) when using sera from other filarial infections (60 LF samples provided by the CDC and 45 other infections tested at NIAID). Having demonstrated that the RDT is both a sensitive and specific tool, we characterized its analytical sensitivity and verified its suitability for field-use in tropical climates. When using a recombinant, humanized IgG4 antibody specific for Ov16, the limit of detection (LOD) is 50 ng/mL in serum and 25 ng/mL in whole blood. Heparinized whole blood and heparinized plasma are by and large comparable matrices. The test appears to be suitable for point-of-care use in that it tolerates a variation of ± 50% in sample volume and a variation of ± 1 drop of chase buffer, as may unwillingly happen in the field. Test performance is temperature dependent, and the analytical sensitivity further increases when the test is run at 40°C compared to 21-25°C; if operating close to the limit of detection, temperatures below 21°C should be avoided. The test is 100% stable after 6 months at 40°C, and therefore a shelf life of > 2 years can be projected. Furthermore, the test tolerates excursions to 50°C for > 2 weeks, providing additional peace of mind while the tests will be in transit.

Nigeria has the second highest burden of lymphatic filariasis (LF) in the world. Elimination efforts began in seven states supported by The Carter Center in 2014 with mass drug administration (MDA) using ivermectin and albendazole. We report significant progress in stopping MDA through transmission assessment surveys (TAS) in districts with baselines ranging from 1% to 58% antigen prevalence. In 2019, 19 local government areas (LGAs) undertook Pre-TAS in 3 southeastern states: Anambra, Ebonyi, and Imo. Filariasis test strips (FTS) were used to test 11,720 people aged ≥ 5 years in one sentinel and one spot-check site per LGA. All but 3 LGAs passed (84% success), with antigen prevalence less than 2% in each village. Follow-up investigations in the 3 LGAs that failed showed very low usage of bed nets; 88% antigen-positive individuals were negative upon later retesting. Sixteen LGAs, grouped into 13 evaluation units (EUs), proceeded to stop-MDA TAS in 2021. One EU could not complete its sample due to insecurity and will continue treatment until it can be re-evaluated. Of 17,765 children tested in primary grades 1 and 2 across 12 EUs, only 2 children were antigen positive. The number of antigen-positive children in each EU (range 0-1) was less than the critical threshold (range 8-18), meaning all 12 EUs pass TAS and now enter post-treatment surveillance for LF. Approximately 3.4 million people in 15 LGAs no longer require MDA. These studies represent major achievements for the Nigeria national LF elimination program.

DETECTION OF *BRUGIA MALAYI* ELEVEN YEARS AFTER STOPPING MASS DRUG ADMINISTRATION TO ELIMINATE LYMPHATIC FILARIASIS IN BELITUNG DISTRICT, INDONESIA

Taniawati Supali[1], Yenny Djuardi[1], Mr Santoso[2], Lita Renata Sianipar[3], Solihah Widyastuti[3], Nungki Hapsari Suryaningtyas[2], Rahmat Alfian[1], Yossi Destani[1], Femmy Pical[3], Sulfa Esi Warni[2], Elisa Iskandar[1], Hendri Astuty[1], Noviani Sugianto[1], Peter Fischer[4]

[1]Universitas Indonesia, Jakarta, Indonesia, [2]Directorate General of Communicable Disease and Environmental Health, Indonesia Ministry of Health, Jakarta, Indonesia, [3]National Institute of Health Research and Development (NIHRD), Ministry of Health of Indonesia, South Sumatera, Indonesia, [4]Washington University School of Medicine, St. Louis, MO, United States

The filarial parasite *Brugia malayi* is the major cause of lymphatic filariasis (LF) in Indonesia. Belitung district consists of a part of Belitung Island with some adjacent islands in the south-east of Sumatra and was formerly highly endemic for *Mansonia*- transmitted *B. malayi*. Mass drug administration (MDA) with DEC and albendazole to eliminate LF was ceased after five annual rounds in 2010, the district passed three transmission assessment surveys (TAS) and the Ministry of Health certified the district in 2018 as free of LF. As part of post-MDA surveillance of the LF elimination program in Indonesia, we collected in 2021 night blood

samples for the detection of microfilariae (Mf) from 1,911 subjects aged 5 years and older residing in 7 villages. Mf were detected by 60 uL Giemsa-stained three-line blood smears and microscopy. While no Mf-positive subjects were detected in two villages, an Mf prevalence ranging from 1.7 to 5.9% was found in five villages. All 40 Mf-positive subjects were adults or teenagers aged 16 years and older, who were not targeted by TAS. Mf densities in infected individuals were mostly low, with 60% of the subjects having less than 167 Mf/ml. Our results indicate that in areas endemic for *B. malayi* post-MDA surveillance of the entire community may be needed despite the fact that the area passed TAS that is based on antibody detection using the Brugia Rapid tests in school children. It can also not be excluded that an animal reservoir caused re-introduction of infection into the human population. Further monitoring and evaluation studies together with improved MDA strategies in areas endemic for brugian filariasis are needed to support the elimination of LF.

0609

REPURPOSING CANINE HEARTWORM RAPID DIAGNOSTIC TESTS FOR HUMAN LYMPHATIC FILARIASIS

Marina Siirin[1], Keri Robinson[2], Maria J. Gonzalez-Moa[3], Kimberly Y. Won[2], Marco Biamonte[3]

[1]Drug and Diagnostics for Tropical Diseases, San Diego, CA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Drug and Diagnostics for Tropical Dseases, San Diego, CA, United States

Lymphatic filariasis (LF) is a neglected tropical disease caused by *Wuchereria bancrofti* and *Brugia spp*. The success of the World Health Organization's (WHO) Global Programme to Eliminate Lymphatic Filariasis relies on diagnostic tools for mapping disease and monitoring the progress of mass drug administration (MDA). The only test recommended by WHO for stopping MDA in *W. bancrofti* areas is the Filariasis Test Strip (FTS) (Abbott) which detects circulating filarial antigen (CFA). Although the test is used widely, there are recognized limitations: procurement risk due to a single manufacturer, requirement of a relatively large amount of blood (75 µL) per test, and a narrow time window to read the result. Based on the early discovery that monoclonal antibodies developed for *Dirofilaria immitis* cross-reacted with *W. bancrofti* antigen, we investigated if rapid diagnostic tests (RDT) for canine heartworm can be repurposed for human LF and used as potential alternatives to the FTS. Performance characteristics for three commercial canine heartworm RDTs: Anigen (Bionote), Vetscan (Abaxis), and Witness (Zoetis) were evaluated. Clinical sensitivity was determined by *W. bancrofti* sera (n=100, Haiti) that had been confirmed positive by microscopy and CFA tests. Clinical specificity was determined by a panel comprised of uninfected U.S. volunteers (n=120), uninfected individuals from an LF endemic country (Haiti) (n=50) and persons with other helminth infections (n=125). All 3 RDTs required 10 µL of sample per test. Clinical sensitivity and specificity for Anigen, Vetscan and Witness were 98.0% (95% confidence interval [CI]: 93.0-99.8) and 99.3 % (95% CI: 97.6-99.9); 96.0% (95% CI: 90.1-98.9) and 99.0% (95% CI: 97.1-99.8); and 100% (95% CI: 96.4-100) and 98.0% (95% CI: 95.6-99.3), respectively. Differences between tests were minor but the Bionote Anigen test was the leading alternative to the FTS as it had the highest specificity, withstood storage for 12 months at 40 °C without compromising sensitivity and test results were stable for 90 minutes. Our results suggest canine heartworm tests may be suitable alternatives to the FTS.

0610

RISK FACTORS ASSOCIATED WITH EXTENSIVELY DRUG-RESISTANT (XDR) TYPHOID IN AN OUTBREAK SETTING OF LYARI TOWN KARACHI, PAKISTAN

Farah Naz Qamar, Rabab Batool, Sonia Qureshi, Mohammad Tahir Yousafzai, Miqdad Ali

Aga Khan University Hospital, Karachi, Pakistan

Typhoid fever is endemic in Pakistan, with high annual incidence rates. An outbreak of extensively drug-resistant (XDR) typhoid fever that first started in the Hyderabad district of Sindh province in November 2016 immediately spread to the whole province. The associated organism *Salmonella* Typhi (*S.* Typhi) H58 strain was resistant to five classes of antimicrobials (chloramphenicol, ampicillin, trimethoprim-sulfamethoxazole, fluoroquinolones, and third-generation cephalosporins). This strain of XDR *S.* Typhi was sensitive only to azithromycin and meropenem which threatened the role of antibiotics in typhoid control. We conducted an age-matched case-control study to identify the risk factors associated with typhoid fever in the XDR typhoid outbreak setting of Lyari, Town, Karachi. This study targeted the population of children from 6 months to 15 years of age as children younger than 15 years of age comprise more than 90% of the XDR typhoid cases. We enrolled 82 blood culture-confirmed *S.* Typhi cases between August 2019 to December 2019. Out of total enrolled culture-confirmed typhoid cases, 28 were enrolled from Lyari General Hospital, 28 were enrolled from Kharadar General Hospital and 26 were enrolled from Jan Bai Aga Khan Secondary Care Hospital. A total of 164 community age-matched controls and 82 hospital controls were enrolled as well. Participant ages range was from 6 months to 15 years, the mean age of culture-confirmed typhoid case patients was 54.6 months, community control was 58.9 months and hospital controls was 55.1 months. Out of enrolled cases, 68.3% were males, 51.8% of community controls were males and 56.1% of hospital controls were males. In a matched conditional logistic regression model, consumption of meals outside the home more than once per month was significantly associated with the development of culture-confirmed XDR typhoid fever compared to no food consumption outside (Odds Ratio: 4.11; 95% Confidence Interval: 1.77, 9.54; p-value < 0.05). Hygiene of the environment in which food is prepared, access to clean water and food legislation play a significant role in the spread of typhoid fever.

0611

ASSOCIATION BETWEEN WASH INDICATORS AND SELF REPORTED CHILDHOOD DEATHS IN RURAL COMMUNITIES OF THE PERUVIAN AMAZON BASIN

Evelyn R. Munayco[1], John M. Nesemann[2], Jeremy D. Keenan[3], Andres G. Lescano[1]

[1]Emerge, Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]University of California, Los Angeles, CA, United States, [3]University of California, San Francisco, CA, United States

Improved water access, sanitation, and hygiene (WASH) has the potential to reduceannual deaths by 6.3% worldwide. We evaluated whether improved WASH wasassociated with lower frequency of self-reported child deaths in indigenous villages inthe Peruvian Amazon. Twenty-one villages in the Peruvian Amazon were chosen byprobability-proportional-to-size, and cross-sectionally surveyed 387 mothers with ≥1child under 5 years of age in ~30 randomly selecting households in each village. Questionnaires were adapted from the Peruvian Demographics and Health Survey andWASH questions from the World Health Organization's (WHO) WASH monitoring corequestions. Access to drinking water, sanitation and hygiene practices weredichotomized following WHO recommendations. A generalized linear model regressionwas fitted with significance set at p<0.05. The mean±SD mother's age and the numberof live births were 37.2±13.4 and 4.9±2.5, respectively. Sanitation was primarilyunimproved (88%, n=340) and hygiene practices inadequate (78%, n=301). Nearly athird (31%) of women reported a child death in their lifetime and the mean±SD child'sage at death was 8.2±13.0 months. After adjusting for sanitation, hygiene practices,mother's age, number of live births, drinking water, and having a health facility in thevillage, the frequency of having had a child dying was 1.75 times higher in mothersliving in households with unimproved versus improved sanitation (95% CI: 1.29-2.38,p<0.001). Older maternal age (PR 1.02, 95%CI: 1.01-1.03, p=0.001) and having hadmore children (PR 1.18, 95%CI: 1.11-1.25, p<0.001) were both positively associatedwith childhood mortality, but no association was observed for improved drinkingwater, inadequate hygiene practices and having a health facility in the village (p>0.25for all). Unimproved sanitation was the only WASH variable associated with infantmortality in indigenous

villages in the Peruvian Amazon. Further studies shoulddetermine whether improvement of sanitation in similar settings can reduce childhoodmortality.

0612

INFLUENCE OF COMMUNITY-LEVEL SANITATION COVERAGE AND POPULATION DENSITY ON ENVIRONMENTAL FECAL CONTAMINATION AND CHILD HEALTH IN A LONGITUDINAL COHORT IN RURAL BANGLADESH

Jesse Doyle Contreras[1], Mahfuza Islam[2], Andrew Mertens[3], Amy J. Pickering[3], Laura H. Kwong[3], Benjamin F. Arnold[4], Jade Benjamin-Chung[5], Alan E. Hubbard[3], Mahfuja Alam[2], Debashis Sen[2], Sharmin Islam[2], Mahbubur Rahman[2], Leanne Unicomb[2], Stephen P. Luby[5], John M. Colford, Jr.[3], Ayse Ercumen[1]

[1]North Carolina State University, Raleigh, NC, United States, [2]icddr,b, Dhaka, Bangladesh, [3]University of California, Berkeley, Berkeley, CA, United States, [4]University of California, San Francisco, San Francisco, CA, United States, [5]Stanford University, Stanford, CA, United States

Household-level sanitation interventions have had limited effects on child health or environmental contamination, potentially due to low community coverage. Higher coverage can reduce opportunities for pathogen transmission throughout the community. We estimated associations between community-level sanitation coverage, environmental fecal contamination, and child health among 360 compounds in the control arm of the WASH Benefits trial in rural Bangladesh. We enumerated *E. coli* in environmental samples and recorded the 7-day prevalence of caregiver-reported diarrheal disease and acute respiratory infections (ARI) among children under five. We observed indicators of latrine access and quality among all neighboring compounds within 100 m of each study compound. We defined community coverage as the proportion of neighboring compounds with (1) at least one latrine and (2) exclusively hygienic latrines (improved facility observed to safely contain feces), within both 50 m and 100 m of study compounds. We assessed effect modification by population density and season. Adjusted for confounders, study compounds surrounded by 100% coverage of at least one latrine per compound within 50 m had slightly lower $\log_{10}$ *E. coli* counts in stored water ($\Delta\log_{10}$ = -0.13, 95% CI -0.26, -0.01), child hand rinses ($\Delta\log_{10}$ = -0.13, 95% CI -0.24, -0.02), and caregiver hand rinses ($\Delta\log_{10}$ = -0.16, 95% CI -0.29, -0.03) and marginally lower prevalence of diarrheal disease (prevalence ratio [PR] = 0.82, 95% CI 0.64, 1.04) and ARI (PR = 0.84, 95% CI 0.69, 1.03). Effects were similar but less pronounced at 100 m. At higher population densities, community latrine coverage was associated with larger reductions in *E. coli* on caregiver hands and prevalence of diarrheal disease. Coverage with exclusively hygienic latrines was not associated with any outcome. Our findings indicate that higher community coverage in highly local areas was associated with reduced pathogen transmission, with stronger effects at high population densities, but more research is needed to uncover complex relationships between sanitation coverage and health across multiple scales of community.

0613

HOW FREQUENTLY DO COMMUNITY LATRINES NEED TO BE CLEANED? A STUDY IN KATHMANDU, NEPAL

Heather M. Murphy[1], Alexis Mraz[2], Shannon McGinnis[3], Prakash Amatya[4], Dianna Marini[5]

[1]University of Guelph, Guelph, ON, Canada, [2]The College of New Jersey, Ewing, NJ, United States, [3]Temple University, Philadelphia, PA, United States, [4]Aerosan Toilets, Kathmandu, Nepal, [5]Aerosan Toilets, Halifax, NS, Canada

The United Nations Sustainable Development Goals (SDGs) currently do not count community toilets as "improved" sanitation. Cities with poor sanitation coverage are growing at an astounding pace, and often there is inadequate space and resources to equip households with individual latrines, therefore community sanitation needs to be a viable option. One key criticism of community latrines (among others) is that they are not clean and cannot be adequately maintained. This study examined the cleanliness of community latrines implemented by Aerosan Toilets in 2018 in Kathmandu, Nepal. We did one cleaning study in 2018 and then revisited the same toilets ~22 months later after the latrines were transferred over to a private operator to see if cleaning practices were maintained. The goals of the study were to understand 1) if cleaning protocols were maintained by private operators and 2) how usership affects cleanliness of latrine surfaces to make recommendations on the frequency of cleaning. In 2019, after oversight of the latrines was transitioned to private operators, we conducted a second cleaning study where we swabbed latrine surfaces for *E. coli* (EC) and Total Coliforms (TC) (n= 230). Swabbing occurred in "clean" conditions - before the latrine was opened- and "dirty" conditions - during operating hours. We also collected data on the number of latrine users. The TC concentration averaged for each type of latrine surface differed significantly among surface types (slab, wall, doorknob, handle and rim of anal cleansing bucket, sink tap) during dirty ($p<0.05$) but not clean conditions ($p = 0.077$). For EC, we observed significant differences in the average concentration across latrine surface types in both dirty and clean conditions ($p<0.05$). The number of users was significantly correlated with the microbial contamination on dirty latrine surfaces. This study demonstrated that cleaning practices were effective at reducing microbial contamination and the protocols in place by Aerosan were sustained after nearly two years. We also recommend that latrines are cleaned after every 25-50 users.

0614

DIARRHEAL DISEASE AWARENESS IS ASSOCIATED WITH CAREGIVER HANDWASHING WITH SOAP IN THE DEMOCRATIC REPUBLIC OF THE CONGO (REDUCE PROGRAM)

Lucien Bisimwa[1], Kelly Endres[1], Camille Williams[1], Elizabeth D Thomas[1], Jennifer Kuhl[1], Nicole Coglianese[2], Sarah Bauler[2], Jahed Masud[3], Ruthly François[1], Ronald Saxton[1], Presence Sanvura[1], Jean Claude Bisimwa[1], Patrick Mirindi[2], Alain Mwishingo[1], Jamie Perin[1], Christine Marie George[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Food for the Hungry, Washington, DC, United States, [3]International Centre for Diarrhoeal Disease Research, Bangladesh(icddr,b), Dhaka, Bangladesh

Diarrhea is one of the leading causes of childhood illness and a major cause of infant and child mortality globally. In the Reducing Enteropathy, Undernutrition, and Contamination in the Environment (REDUCE) prospective cohort study, we investigated the association between diarrheal disease awareness and handwashing with soap among caregivers of children under 5 years of age. A total of 259 caregivers of children under 5 years of age in Walungu Territory, South Kivu, Democratic Republic of the Congo (DRC), were administered an open-ended questionnaire assessing awareness of diarrheal disease transmission and prevention, and key times to wash hands with soap. An overall diarrhea awareness score was developed based on the responses to these items. Five-hour structured observation of handwashing behaviors was conducted at the 6-month follow-up. Diarrheal disease awareness among caregivers was low. Only 32% of caregivers were able to correctly identify a method of diarrhea prevention. The median diarrhea awareness score was three out of 10 (SD: 1.7, range: 0-9). During structured observation, 9% of caregivers washed their hands with soap at a food-related event and 9% washed their hands with soap at a stool-related event. Higher diarrheal disease awareness was associated with an increased odds of handwashing with soap at food-related events (odds ratio: 1.40, 95% confidence interval: 1.03, 1.90). Our findings emphasize the need for targeted water, sanitation, and hygiene interventions to increase diarrhea awareness to facilitate handwashing with soap among caregivers of children under 5 years in rural DRC.

0615

INVESTIGATING THE EFFICACY OF VARIOUS HANDWASHING METHODS AGAINST ENVELOPED AND NON-ENVELOPED VIRUSES

Claire E. Anderson[1], Jingyan Tong[1], Winnie Zambrana[1], Alexandria Boehm[1], Marlene Wolfe[2]

[1]Stanford University, Palo Alto, CA, United States, [2]Emory University, Atlanta, GA, United States

Respiratory infections and diarrheal diseases are two leading causes of death worldwide. Handwashing with soap and water is a well-established intervention, and has been proven to reduce both pathogen concentration on hands and the incidence rate of many diseases, including respiratory diseases like COVID-19. Despite this, limited resources among people in low- and middle-income regions, people in remote areas, refugees, internally displaced people, and those experiencing homelessness, may prevent individuals from using handwashing methods recommended by the CDC or WHO (soap and water for 20+ seconds). The aim of this study is to evaluate handwashing alternatives for use when handwashing with soap and water for 20s is not feasible, including washing with water only, washing with soapy water, washing for a short duration, using alcohol-based hand sanitizer (ABHS), and washing with towels. To evaluate the efficacy of the handwashing methods, we seeded MS2 (a non-enveloped virus) and Phi6 (an enveloped virus) onto the hands of volunteers who then used a handwashing method. Viruses remaining on the hands after washing were recovered and the log reduction value (LRV) of viruses was quantified using culture-based methods and molecular methods. Results indicated that washing with water only and with soapy water were similar to washing with soap and water for 20s for both viruses studied. Overall, towel alternatives did not perform as well as washing with soap and water for either virus. The impacts of ABHS and timing were mixed: results for ABHS and soap and water for 5s were similar to soap and water for 20s for Phi6, but less than soap and water for 20s for MS2. Additionally, results determined using molecular methods were in agreement with those obtained using culture-based methods. This study provides foundational data to ensure handwashing promoted in humanitarian crises is effective for important outbreak diseases. These results inform handwashing method recommendations and future research on handwashing effectiveness in low resource settings to both prevent disease transmission and promote dignity.

0616

DETECTING SARS-COV-2 LINEAGES IN BANGLADESH: LESSONS FROM WASTEWATER-BASED EPIDEMIOLOGY

Rehnuma Haque Sarah[1], Mohammad Enayet Hossain[2], Mahbubur Rahman[1], Nuhu Amin[1], Mohammed Ziaur Rahman[2]

[1]Environmental Interventions Unit, icddr,b, 68 Shaheed Tajuddin Ahmed Sarani, Mohakhali, Dhaka, Bangladesh, [2]One Health Laboratory, icddr,b, 68 Shaheed Tajuddin Ahmed Sarani, Mohakhali, Dhaka, Bangladesh

Wastewater-based epidemiological surveillance has been considered a powerful tool for early detection and monitoring of the dynamics of SARS-CoV-2 and its lineages circulating in a community. This study collected 504 wastewater samples across different treated and untreated sanitation points in the capital city, Dhaka, Bangladesh, from September 2020 to February 2021. We used a modified calcium flocculation-citrate dissolution method to concentrate microparticles and the Norgen Soil Total RNA Purification kit to extract and purify the SARS-CoV-2 viral RNA. The detection of SARS-CoV-2 was performed using the iTaq Universal Probes One-Step kit for the RT-qPCR amplification of the SARS-CoV-2 ORF1ab and N gene targets. Out of 504 samples, 185 (36.7%) were tested positive for SARS-CoV-2. To further reveal the genetic diversity of SARS-CoV-2, ten samples having ORF1ab cycle threshold (Ct) values ranging from 28 to 32 were subjected to next-generation sequencing using nanopore technology. According to clade classification, sequences from wastewater samples were grouped into 4 clades: 19B, 20A, 20B, 21A, and the Pango lineage: B.1, B.1.1.25, B.1.1.315, coverage was >73% and 50% belonged to clade 20B; 30% belonged to clade 20A. The clades 19B, 21A were less prevalent (10%). Also, the sole sample within clade 21A (B.1.617.2) had genome coverage of 43.22%. The lineage B.1.1.25 was predominant in Bangladesh and phylogenetically related to the sequences from India, the USA, Canada, the UK, and Italy. The Delta variant (B.1.617.2) was first identified in clinical samples at the beginning of May 2021, whereas we found the Delta variant circulating in wastewater in September 2020. The findings of this study supported the use of wastewater-based epidemiology and provided the baseline data of SARS-CoV-2 variant dynamics in Dhaka, Bangladesh. We conducted a study on complex sanitation systems that can be reproducible in areas of low sanitation coverage worldwide. These findings imply that monitoring wastewater can be a useful tool to identify symptomatic and asymptomatic COVID-19 patients in the community and act as an early alert system.

0617

HISTIDINE-RICH PROTEIN DELETION: TEMPORAL PREVALENCE IN UK TRAVELLER MALARIA PATIENTS AND GENOMIC STRUCTURE OF THE *PFHRP/3*-DELETED PARASITES

Khalid B. Beshir, Debbie Nolder, Lindsay Stewart, Deborah Ojutalayo, Jody Phelan, Susana Campino, Colin Sutherland

LSHTM, London, United Kingdom

Plasmodium falciparum that can evade detection by rapid diagnostic tests (RDT) have emerged globally. Parasites become undetectable due to deletion of two loci encoding histidine-rich proteins (HRP2 and/or HRP3). The emergence of *P. falciparum* lacking *hrp2* and *hrp3* genes (*pfhrp2/3*) is causing major malaria public health concern and threatens malaria control and case management efforts. *P. falciparum* lacking histidine-rich proteins are on the increase in Africa. The rate of such increase is unknown. It is also not clearly understood how the deletions occur, or what the consequence of such deletions are to the parasite genome. In this study, we report the prevalence of *pfhrp2* and *pfhrp3* in UK travellers who visited malaria endemic countries in Africa from 2018 to 2022. We also report, using high-quality short- and long-read genomic sequencing and custom-made bioinformatic tools, the genome structure of two culture-adapted *P. falciparum* parasite isolates with *pfhrp2/3* deletions. We identified the chromosomal points that delimit each deletion event, which typically as also remove several hundred adjacent genes on chromosome 8 and 13, respectively. We also investigated the genomic structural variation of the *pfhrp2/3*-deleted *P. falciparum* parasites before and after culture-adaptation to understand whether the parasites acquire any further variation during culture-adaptation.

0618

ADDITION OF HUMAN SERUM OR ALBUMAX TO GLYCEROLYTE BEFORE CRYOPRESERVING *PLASMODIUM FALCIPARUM* INCREASES PARASITE YIELD AFTER THAWING

Stephen Orena[1], Cassia Wagner[2], Oswald Byaruhanga[1], Martin Okitwi[1], Patrick Tumwebaze[1], Thomas Katairo[1], Martin Chamai[1], Simon Tumwebaze[1], Trevor Bedford[3], Melissa Conrad[4], Philip J. Rosenthal[4], Bryan Greenhouse[3]

[1]Infectious Disease Research Collaboration, Kampala, Uganda, [2]University of Washington, Seattle, WA, United States, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, United States, [4]University of California, San Francisco, CA, CA, United States

Cryopreservation of *Plasmodium falciparum* enables important laboratory investigations of malaria, but methods have not been optimized. We compared three different methods for cryopreserving *P. falciparum* infected red blood cells (RBCs) directly from patient samples, using glycerolyte, glycerolyte + human serum, or glycerolyte + 10% Albumax. Blood samples were collected from individuals with documented *P. falciparum* infections. RBCs were then prepared either by washing the RBC pellet from an EDTA tube three times to remove buffy coat or by collecting the RBC pellet after PBMC isolation from blood samples collected in heparin or acid citrate dextrose tubes. Pellet volume of 1500 µl was aliquoted to three tubes,

500 µl each, to the tubes labeled serum and albumax, 500 µl of serum and albumax was added respectively. Glycerolyte was then added to each aliquot in ratio of 1:2 (pellet:glycerolyte). Aliquots where then freezed at -80°c for 18hrs then transferred to liquid nitrogen. After 30 days samples were then thawed based on protocol and cultured at 37°c in complete RPMI. Pellet volume was measured and smears prepared and read at 36hrs, 48hrs and 72hrs, these were stained using giemsa. Pellet volume at thaw was significantly lower following cryopreservation with glycerolyte alone (median= 70.0 µl; IQR= 61.25-170.0), than Glycerolyte + serum (median= 127.5 µL; IQR= 95.0-201.3) or Glycerolyte + Albumax (median = 127.5µL; IQR= 107.5-195.0), p-value <0.05 for both comparisons. Parasite growth was observed with all three methods of cryopreservation across a range of parasitemia (0.2-3.0%). Median parasitemia was comparable across all three treatments at 36, 48, and 72 hours. (36hrs; glycerlote alone = 1.9%, glycerolyte+serum = 1.9%, glycerolyte+albumax = 2.25%: 48hrs; glycerlote alone = 1.5%, glycerolyte+ serum = 2.05%, glycerolyte+albumax= 1.5%: 72hrs; glycerlote alone= 1.6%, glycerolyte+ serum = 2.2%, glycerolyte+albumax = 1.8%) These findings suggest that addition of human serum or 10% Albumax during cryopreservation improves parasite yield when clinical isolates of *P. falciparum* are freezed, thawed and cultured.

0619

THE MILAB™ PLATFORM, A FULLY AUTOMATED ON-SITE DIAGNOSTIC SYSTEM WITH ARTIFICIAL INTELLIGENCE FOR MALARIA

Byeong-il Kang[1], Seunghee Han[1], DongShik Ham[1], Hye-jin Hwang[1], Jin-Hee Han[2], Douglas Lungu[3], Dongyoung Lee[1]

[1]Noul Co. Ltd., Yongin, Republic of Korea, [2]Kangwon National University, Chuncheon, Republic of Korea, [3]Wezi Medical Centre, Mzuzu, Malawi

The miLab™ platform is a fully automated on-site diagnostic system that determines the infection of malaria parasites in human EDTA-anticoagulated whole blood (or capillary blood) of individuals with signs and symptoms of malarial infection. It produces consistent, high-quality thin blood smears, stains blood cells with a novel solution-free method based on hydrogel-based stamping and reads out by digital optical scanning in combination with highly efficient embedded artificial intelligence (AI) based morphological analysis for malaria diagnosis. The clinical performance of the miLab™ platform for malaria detection was evaluated by comparing with the reference test - the manual microscopy - using total 502 whole blood samples collected from fever patients visiting clinical sites in Malawi (Kamuzu; n=323, and Mzuzu; n=179) between December 2020 and April 2021. All samples were tested by both the manual microscopy and the miLab™ platform. Of those samples, 142 samples (28.5%) and 161 samples (32.1%) were determined as positive for malaria infection by manual microscopy and the miLab™ platform, respectively. The clinical sensitivity was 89.51% (95% CI; 83.41% - 93.54%) and the specificity was 90.81% (95% CI; 87.37% - 93.38%). Forty-eight samples that were discordant between both tests were confirmed by quantitative PCR (qPCR). Noteworthy, the miLab™ platform results indicated 93.75% (95% CI; 83.16% - 97.85%) agreement with the results from qPCR. Furthermore, in one of two samples which were positive by the miLab™ platform but negative by the qPCR, the digital images of malaria-infected cells confirmed by expert microscopists were shown from the miLab™ platform. The results suggest that the miLab™ platform can replace manual microscopy while having more sensitive performance.

PARASITAEMIA THRESHOLDS FOR DIAGNOSING PATIENTS WITH *PLASMODIUM VIVAX* MALARIA

Emily S. Groves[1], Nicholas M. Douglas[1], Benedikt Ley[1], Peta Edler[2], André Daher[3], Ayodhia P. Pasaribu[4], Dhelio B. Pereira[5], Kavitha Saravu[6], Julie A. Simpson[7], Ric N. Price[1], Robert J. Commons[1], on behalf of the WWARN P. vivax Fever Study Group[8]

[1]Global and Tropical Health Division, Menzies School of Health Research, Charles Darwin University, Darwin, Australia, [2]Department of Infectious Diseases, Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia, [3]Vice-presidency of Research and Biological Collections, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil, [4]Department of Child Health, Medical Faculty, Universitas Sumatera Utara, Medan, Indonesia, [5]Centro de Pesquisa em Medicina Tropical, CEPEM, Porto Velho, Brazil, [6]Department of Infectious Diseases, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India, [7]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia

Optimal parasitaemia thresholds for diagnosing *Plasmodium vivax* malaria are defined by the relationship between parasitaemia and fever. We conducted an individual patient data meta-analysis of *P. vivax* clinical trials in the WorldWide Anti-Malarial Resistance Network (WWARN) repository and used parasitaemia centiles of febrile patients at enrolment to derive the proportion of patients who would have been diagnosed at different parasitaemia thresholds ("capture thresholds"). Febrile and afebrile patients with recurrent infection during follow-up were selected to determine pyrogenic densities using receiver operating characteristic curve analysis and risk factors for fever at recurrence were identified using logistic regression. In total 13,263 patients from 50 studies were included in the analysis. In the 27 studies that did not apply a parasitaemia threshold as an inclusion criterion, the median parasitaemia of 8,378 febrile patients at enrolment was 3,280/µL (IQR 968 - 8,320). 90% of patients had a parasitaemia above 278/µL (10^{th} centile or 90% capture threshold), and 95% above 120/µL (5^{th} centile or 95% capture threshold). Compared to adults, children presented with higher parasitaemias. 2,270 patients from 41 studies had at least one episode of recurrent *P. vivax* parasitaemia, of whom 57% (1,134/1,983) were febrile at their first recurrence. The *P. vivax* pyrogenic density at first recurrence was 1,063/µL, giving a positive predictive value for fever of 61% and a negative predictive value of 77%. The pyrogenic density was lowest in children. After accounting for confounders, high parasitaemia and living in an area of low relapse periodicity were associated with an increased risk of fever at first recurrence. These parasitaemia capture thresholds inform the design of novel tests to diagnose patients with symptomatic vivax malaria. Variations in thresholds with age and location should be taken into account when selecting diagnostic thresholds and interpreting results.

AISCOPE: CREATING THE BIGGEST OPEN CROWDSOURCED DATASET OF MICROSCOPY IMAGES FOR MALARIA AND OTHER INFECTIOUS DISEASES TO TRAIN ARTIFICIAL INTELLIGENCE ALGORITHMS

Eduardo Peire[1], Joris Borsboom[1], Rachael Kasaro[2], Ramón Pérez-Tanoira[3], Sandra del Pozo[1], Iñaki Alegria[4], Thuy-Huong Ta-Tang[5], Perdro Berzosa[5], Estrella Lasry[1], Vicenta González[5], Luz García[5], Laura Moro[1]

[1]AiScope, Barcelona, Spain, [2]National Malaria Elimination Center, Lusaka, Zambia, [3]Hospital Universitario Príncipe de Asturias y Universidad de Alcalá, Alcalá de Henares, Spain, [4]Gambo General Hospital, Oromiya, Ethiopia, [5]Malaria and Neglected Tropical Diseases Laboratory. CIBERINFEC, ISCIII-CIBER de Enfermedades Infecciosas, Instituto de Salud Carlos III, Madrid, Spain

Microscopy is still the gold standard for diagnosing numerous communicable diseases worldwide, in particular in low-resource settings.

For malaria, reliable Malaria rapid diagnosis tests (mRDTs) or molecular techniques are not always available in endemic countries and their performance can be low in low transmission settings or those where HRP2/3 deletions are present, and thus diagnostic confirmation relies on optical microscopy. Manually discriminating subtle differences on a stained slide under the light microscope is a labor-intensive, time-consuming, error-prone, and somehow subjective process. Artificial intelligence (AI) and, particularly, computer vision may allow automation of this process using trained algorithms, saving time and reducing human errors and the need for trained personnel. Although AI is progressively gaining importance in medical diagnosis, its application is still limited by the availability of large, high-quality datasets to train algorithms. Thus, building a reliable training dataset represents a strategic asset to deploy all AI potential for diagnostic applications. AiScope is a non-profit organization developing an open-source smart, low-cost microscope to diagnose infectious diseases in low-resource settings. AiScope uses AI running on a cellphone to automatically diagnose infectious diseases, without the need of highly trained personnel. Since large public open infectious diseases datasets are lacking, AiScope is building a collection of open-access datasets of microscopy images of several pathogens, such as *Plasmodium* spp, *Mycobacterium tuberculosis*, and intestinal parasites among others. Besides, AiScope has developed an open-source easy-to-use platform to ensure correct labeling of microscopy images. The database is being built thanks to the collaboration of universities, research and medical institutions, and companies worldwide. This crowdsourced project provides the opportunity to develop affordable smart diagnostic systems essential in low-resource settings, while offering an open collection of microscopy images for research, training and education purposes.

0622

STATUS OF *PFHRP2* AND *PFHRP3* GENES DELETIONS IN *PLASMODIUM FALCIPARUM* PARASITES FROM A LARGE HEALTH FACILITY SURVEY: TANZANIA, 2021

Nastassia Battle[1], Catherine Bakari[2], Rashid Madebe[2], MIsago Seth[2], Dativa Pereus[2], Celine Mandara[2], Beatus Lymio[2], David Giesbrecht[3], Zachary Popkin-Hall[4], Ramadhan Moshi[2], Ruth Mbwambo[2], Bronwyn MacInnis[5], Raymond Kitengeso[2], Filbert Francis[2], Daniel Mbwambo[6], Issa Garimo[6], Frank Chacky[6], Sijenunu Aaron[6], Abdallah Lusasi[6], Fabrizio Molteni[7], Ritha Njau[8], Jane A. Cunningham[9], Samwel Lazaro[6], Ally Mohamed[6], Jonathan J. Juliano[4], Jeffrey A. Bailey[3], Udhayakumar Venkatachalam[1], **Eric Rogier**[1], Deus Ishengoma[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [3]Brown University, Providence, CT, United States, [4]University of North Carolina, Chapel HIll, NC, United States, [5]Harvard T.H Chan School of Public Health, Boston, MA, United States, [6]National Malaria Control Programme, Dodoma, United Republic of Tanzania, [7]Swiss Tropical Public Health Institute, Dar es Salaam, United Republic of Tanzania, [8]World Health Organization, Dar es Salaam, United Republic of Tanzania, [9]World Health Organization, Geneva, Switzerland

Plasmodium falciparum which has deleted the histidine-rich protein 2 gene (*pfhrp2*, and paralog *pfhrp3*, *pfhrp2/3*) can escape detection by HRP2 rapid diagnostic tests (RDTs), leading to false negative diagnostic results. Deletions of these genes have been found in *P. falciparum* populations worldwide, and the WHO recommends non-HRP2 RDTs for case management when *pfhrp2* deletion prevalence exceeds 5% in a region. Therefore, *pfhrp2* deletion surveillance is essential for national malaria programs to assess reliability of HRP2-RDTs in different settings. Tanzania is a country of heterogenous malaria transmission, with some regions approaching elimination and others at different levels of control phase. In concordance with the current recommended WHO surveillance strategy, 100 health facilities encompassing 10 regions of Tanzania were used as sites for enrollment of treatment-seeking persons to provide estimates for *pfhrp2/3* gene deletion prevalence. The survey was conducted from February to July 2021 and enrolled 7,865 persons of all ages who were tested with two RDTs: pLDH/HRP2 combo and pLDH only. Of these, 3,777 (48.0%) were positive by either type of RDT, and 57 (1.6% of all infections) were positive for the pLDH band only. Multiplex antigen detection by laboratory assay (n=7,847) found 135 (1.7%) of all blood samples positive for *Plasmodium* antigens but very low or absent for HRP2. These were selected for further DNA extraction and PCR assays. Of these 135 selected samples, 8 (5.9%) were found to be *P. ovale* infections, and 109 (80.7% of selected) were *P. falciparum* infections appropriate for *pfhrp2/3* genotyping. One sample did not amplify *pfhrp2* (0.03% of all *P. falciparum* infections), and six (0.16%) were unable to amplify the *pfhrp3* gene. Of the 3,777 *P. falciparum* infections identified, a very low percentage (0.19%) showed deletions of *pfhrp2* or *pfhrp3* genes, and no dual deletions found. This large health facility survey conducted in Tanzania in 2021 provides strong evidence for the overall absence of *pfhrp2* gene deletion and continued utility of HRP2-RDTs in the country for confirmatory diagnosis of symptomatic *P. falciparum* infections.

DEVELOPMENT AND EVALUATION OF A SIMPLIFIED MOLECULAR PLATFORM FOR THE DIAGNOSIS OF MALARIA

Henk Schallig, Norbert van Dijk, Sandra Menting, Petra Mens

Academic Medical Centre, Amsterdam, Netherlands

Current needs for the diagnosis of malaria include tests that avoid false negative results (due to issues with limit of detection or mutations in genes encoding for diagnostic targets) or false positive results caused by persisting *Plasmodium* antigen after successful treatment. Molecular biology based tests avoid the limitations of currently used diagnostics (microscopy and rapid diagnostic tests), but implementation in resource limited malaria endemic countries is hampered by their complexity and infrastructural needs. The miniaturised direct-on-blood PCR nucleic acid lateral flow immunoassay (mini-dbPCR-NALFIA) is an innovative, easy-to-use molecular assay for the diagnosis of malaria in these particular settings. Unlike other simplified molecular methods, such as LAMP, the mini-dbPCR-NALFIA does not require DNA extraction and utilises a handheld, portable thermal cycler powered by a solar-charged power pack enabling to perform the test without any laboratory infrastructure. Reading of results is done using a rapid lateral flow strip enabling differentiation of *Plasmodium falciparum* and non-*falciparum* malaria infections. Laboratory validation was performed to assess the performance of this innovative platform. Diagnostic accuracy was determined by testing a set of confirmed *Plasmodium*-positive blood samples from returning travellers, and confirmed *Plasmodium*-negative blood samples from returning travellers with suspected malaria, Dutch Blood Bank and intensive care patients at our centre. Overall sensitivity and specificity of the assay were determined at 96.6% (95% CI, 82.2% - 99.9%) and 96.8% (95% CI, 89.0% - 99.6%) compared to expert microscopy. The limit of detection for *P. falciparum* was 2 parasites/µl blood, as measured in dilution series of three *P. falciparum*-positive clinical blood samples. The repeatability and reproducibility of the assay is determined to be over 90%. A phase-3 field trial is now being performed to evaluate the potential implementation of this assay in malaria control programmes in both high- and low-transmission settings.

CLINICAL EVALUATION OF THE BIOFIRE® GLOBAL FEVER PANEL PLUS

David S. Rabiger, Mark A. Gurling, Jared R. Helm, Wendy Smith, Pascal Belgique, Olivia Jackson, Michael Johnson, Alex Kelley, Hannah VanHollebeke, Sidney Webster, Ashley Wiltsie, Marianne Kim, Cynthia Phillips

BioFire Defense, Salt Lake City, UT, United States

BioFire Defense has developed the BioFire® Global Fever Panel, in collaboration with the U.S. Department of Defense and NIAID (contract Nos. W911QY-13-D-0080 and HHSN272201600002C), as an in vitro diagnostic test for the simultaneous identification of viral, bacterial, and protozoan pathogens directly from whole blood in under an hour using

the BioFire® FilmArray® platform. The BioFire Global Fever Panel has been granted De Novo classification by the US FDA for the detection of chikungunya virus, dengue virus (serotypes 1-4), *Leptospira* spp., and *Plasmodium* spp. from individuals with signs and/or symptoms of AFI and known or suspected exposure to target pathogens. The BioFire Global Fever Panel Plus is a modified version of the Global Fever Panel, which, in addition to the pathogens described above, contains assays for the detection of 13 additional pathogens: Crimean-Congo hemorrhagic fever virus (CCHFV), *Ebolavirus* spp., Lassa virus, Marburg virus, West Nile virus (WNV), yellow fever virus (YFV), Zika virus, *Bacillus anthracis*, *Francisella tularensis*, *Salmonella enterica* (ser. Typhi and Paratyphi A), *Yersinia pestis,* and *Leishmania* spp. BioFire Defense performed a prospective clinical evaluation for the Global Fever Panel Plus at eleven geographically distinct sites across the globe. A total of 2139 prospective whole blood specimens were tested between March 2018 and March 2021. The Global Fever Panel Plus detected at least one analyte in 34.1% of specimens (730/2139). The most prevalent analyte was *Plasmodium*, followed by dengue virus. Chikungunya virus, *Leptospira* spp., *Leishmania* spp., CCHFV, WNV, Zika virus, and *S. enterica* ser. Typhi were detected in fewer than 5% of specimens. All other analytes were not detected by the Global Fever Panel Plus. Positive percent agreement between the Global Fever Panel Plus and comparator testing ranged between 50.0-100%, and the negative percent agreement ranged between 99.2-100%. The results show that the BioFire Global Fever Panel Plus could aid in rapid and actionable AFI diagnosis caused by multiple, sometimes co-occurring, pathogens.

Acute febrile illness (AFI) is a common reason for seeking healthcare in low- and middle-income countries; yet determining etiologies of febrile illness remains a challenge. Here, we deployed a multiplex TaqMan-Array Card Acute Febrile Illness panel (TAC AFI) to describe causes of febrile illness among pediatric and adult inpatients in Tanzania. TAC AFI was run on total nucleic acid from whole blood samples from patients who reported a history of fever within 72 hours or had tympanic temperature ≥38.0°C. The panel was designed to detect 20 bacteria, 19 viruses, 2 fungi, and 3 protozoa. TAC AFI detections were compared to available conventional diagnostics undertaken by the study, which included blood culture, blood parasite smear, and, for persons with a positive rapid HIV antibody test, serum cryptococcal antigen. Of 1,132 participants enrolled in the prospective etiologic cohort study, 697 (61.6%) were selected for TAC AFI analysis. Median (IQR) age was 29.6 (4.6-46.4) years, and 378 (54.2%) were male. In-hospital and 30-day mortality occurred in 41 (5.9%) and 74 (10.6%), respectively. TAC AFI detected 191 pathogens from 167 (23.9%) participants. This included four viruses: enterovirus (n=7), Rift Valley Fever virus (n=3), dengue (n=1), and measles (n=1). Eight bacteria species were detected, including fastidious bacteria, such as *Bartonella* spp. (n=2), *Brucella* spp. (n=3), *Coxiella burnetii* (n=2), *Leptospira* spp. (n=1), and *Rickettsia* spp. (n=9). *Plasmodium* spp. and *Schistosoma* spp. were detected in 77 (11.4%) and 49 (7.2%) participants, respectively. Conventional diagnostics detected 98 pathogens in 97 (13.9%) participants. Excluding *Schistosoma* and *Plasmodium* spp., TAC AFI detected an etiology in 51 (7.3%) participants with no etiology by conventional diagnostics. In the context of AFI surveillance, TAC AFI increased the proportion of febrile inpatients with an etiologic pathogen detected compared to conventional methods. TAC AFI provided clinically actionable results, such as detections of fastidious bacterial pathogens, and epidemiologically important results, such as Rift Valley Fever virus and dengue detections.

0626

ETIOLOGY OF FEBRILE ILLNESSES ASSOCIATED WITH SEIZURES IN CHILDREN FROM LOW- AND MIDDLE-INCOME COUNTRIES: RESULTS FROM THE FIEBRE STUDY

Sara Ajanovic[1], Sham Lal[2], Polycarp Mogeni[2], Justina Bramugy[3], Marta Valente[1], Ioana Olaru[2], Manophab Lungraj[4], Vilayouth Phimolsarnnousith[4], Vilada Chansamouth[4], Mabvuto Chimenya[5], Edward Green[5], Nicholas Feasey[5], Audrey Dubot-Pérès[6], Mayfong Mayxay[4], Elizabeth Ashley[4], Paul Newton[7], Katharina Kranzer[2], Shunmay Yeung[2], Heidi Hopkins[2], David Mabey[2], Quique Bassat[1]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, [4]Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Mahosot Hospital, Vientiane, Lao People's Democratic Republic, [5]Malawi Liverpool Wellcome Programme, Blantyre, Malawi, [6]Unité des Virus Émergents (UVE: Aix-Marseille Univ-IRD 190-Inserm 1207), Marseille, France, [7]Centre for Tropical Medicine & Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Fever is a common symptom resulting in health care seeking worldwide. There is limited evidence of the epidemiology and underlying etiology of seizures associated with fever in children in low- and middle-income countries (LMICs). They can vary from mild conditions (benign febrile seizures) to more serious life-threatening diseases such as bacterial meningitis and cerebral malaria. This analysis aims to provide a description of children with fever and seizures in the FIEBRE (Febrile Illness Evaluation in a Broad Range of Endemicities) observational study.Child in- and outpatients were recruited and systematically investigated in Mozambique, Zimbabwe, Malawi and Lao PDR from 2018 to 2021. Clinical description, treatment and outcome were recorded for each participant. Point-of-care tests (including blood culture, urine dipstick and culture, and HIV and malaria tests) were systematically performed, and further samples were shipped to reference laboratories for gold standard testing for a broad range of infectious agents. Lumbar puncture was only performed when clinicians considered it necessary.Across all sites 389 /3718 (4.9%) children aged 2 months to 14 years presented with seizures. The frequency among inpatients was uneven across the sites: 112/345 (32.4%) in Malawi, 122/533 (22.9%) in Mozambique, 46/355 (13%) in Zimbabwe, and 51/414 (12.3%) in Lao PDR. The frequencies in outpatients were 0.3%, 0.6%, 1.5% and 12.7% respectively. Of the 58 outpatients with seizures, 63.7% were categorized as "fever of unknown origin" by clinicians, 53.4% were prescribed with antibiotics and all of them who completed follow-up were alive by day 28. However, of 331 inpatients with seizures, 42.9% were diagnosed with malaria and 12.4% with suspected sepsis and/or meningitis. Among the 301 who completed D28 follow-up, mortality was 5%. We will present microbiology results stratified by clinical phenotypes, countries, and age groups.Seizures on presentation are very frequent among febrile child inpatients in LMICs. Detailed etiological diagnoses are crucial to better target the scarce therapeutic interventions available and improve survival.

0627

SIXTEEN YEARS OF PRIMARY CARE OBSERVATIONS REVEAL CASES OF AFEBRILE DENGUE AND DISTINGUISHING CHARACTERISTICS OF DENGUE, CHIKUNGUNYA, AND ZIKA

Bustos Carrillo[1], Sergio Ojeda[2], Nery Sanchez[2], Miguel Plazaola[2], Damaris Collado[2], Tatiana Miranda[2], Saira Saborio[2], Brenda Lopez Mercado[2], Jairo Monterrey[2], Leah Katzelnick[1], Douglas Elizondo[2], Sonia Arguello[2], Amy Schiller[3], Lora Campredon[3], Krista Latta[3], Aubree Gordon[3], Angel Balmaseda[4], Guillermina Kuan[5], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, [5]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Dengue, chikungunya, and Zika are diseases of high global health concern with overlapping clinical features, making differential diagnosis difficult without laboratory testing. Small sample sizes and characterization of these diseases in adults have compounded this problem. Here, we analyze 16 years of data from the Nicaraguan Pediatric Dengue Cohort Study to identify distinguishing features among these diseases. We assessed >8,000 primary care medical records of laboratory-confirmed cases aged 2-17 over the first 10 days of illness. Generalized additive, linear, and mixed-effects models; hierarchical clustering; and principal component analyses (PCA) were used to characterize the clinical features of 881 dengue, 519 chikungunya, and 524 Zika cases. We describe 43 RT-PCR-confirmed dengue cases without any evidence of fever. Afebrile dengue cases, constituting ~12% of the last major dengue epidemic, resembled mild cases of afebrile Zika. The prevalence of many clinical features differed across pediatric age, particularly fever, rash, and arthralgia. Peri-articular edema was almost never observed in dengue and Zika cases, and papular rash was never observed in chikungunya cases. The temporal dynamics of fever, rash, and arthralgia prevalence differed most across diseases. The average temperature of dengue and chikungunya cases seen at the primary health clinic were similar over the first 10 days of illness, while temperatures of Zika cases were noticeably lower. The classic biphasic fever of dengue was only observed for 8% of uncomplicated dengue cases. Dengue, chikungunya, and Zika cases exhibited distinct patterns in PCA space, with appetite loss being a major factor distinguishing chikungunya. Clinical differences were noted by dengue virus (DENV) serotype, with DENV1 and DENV3 cases exhibiting a similar, diffuse, and bimodal clinical profile that differed from DENV2 cases in PCA space. We are developing an interactive web app based only on clinical data that can be used to better inform arboviral differential diagnosis. Overall, our results substantially update the clinical epidemiology of pediatric arboviral diseases.

0628

METAGENOMIC NEXT-GENERATION SEQUENCING OF NASOPHARYNGEAL SWABS IN ACUTE FEBRILE ILLNESS IN CAMBODIA

Christina Yek[1], Sreyngim Lay[2], Sophana Chea[2], Jennifer A. Bohl[3], Mengheng Oum[2], Sokna Ly[2], Ratanak Sath[2], Vida Ahyong[4], Cristina M. Tato[4], Heng Seng[5], Sovann Ly[5], Chanthap Lon[2], Jessica E. Manning[1]

[1]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]International Center of Excellence in Research, National Institute of Allergy and Infectious Diseases, Phnom Penh, Cambodia, [3]Vaccine Research Center, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [4]Chan Zuckerberg Biohub, San Francisco, CA, United States, [5]Department of Communicable Disease, Ministry of Health, Phnom Penh, Cambodia

There is growing recognition of metagenomic next-generation sequencing (mNGS) as a valuable diagnostic tool capable of providing unbiased pathogen detection, but data on performance in low-resource settings remains scant. Here, we use mNGS of nasopharyngeal (NP) swabs taken from subjects in Cambodia to identify potential pathogens causing acute febrile illness. Febrile subjects aged 2 months to 65 years were enrolled in a cross-sectional study conducted across 4 tertiary hospitals in Cambodia. NP swabs were collected at hospital presentation. Depending on reported symptom constellations, sera was also taken in a subset of subjects for comparison of mNGS results. RNA was isolated from biosamples, converted to cDNA libraries, and sequenced on a NextSeq2000 (Illumina). Raw sequence reads were stripped for host reads and aligned to NCBI nucleotide and protein databases using a cloud-based bioinformatics platform (CZID). NP swabs were collected from 97 subjects between April 2020 and June 2021. Subjects were predominantly male (53.6%) and young (median age 3 years [IQR 1-25]). Pathogens were identified in 42 (43.2%) NP swabs; of these, 26 (61.9%) were respiratory viruses including 9 rhinovirus, 7 coronavirus (1 SARS-CoV-2), and 5 respirovirus cases. Co-infection was identified in 3 subjects with coronavirus and respirovirus (N=2) and coronavirus and rhinovirus (N=1). Of subjects with paired sera and NP samples (N=61), 18 (29.5%) had positive NP swabs but negative sera, 7 (11.5%) had negative NP swabs but positive sera, 12 (19.7%) had positive NP swabs and sera, and 24 (39.3%) had negative NP swabs and sera. Pathogen hits correlated in NP swabs and sera in 10 of 12 subjects, including six subjects with chikungunya. mNGS can be successfully implemented in low-resource settings to identify emerging pathogens and common respiratory pathogens, including co-infecting pathogens, from NP swabs of febrile patients. mNGS may also be able to detect chikungunya from NP swab alone, raising the possibility of non-invasive diagnostics for infections associated with high viremic states.

BUILDING DIAGNOSTIC CAPACITY FOR HIGH-CONSEQUENCE PATHOGENS: USE OF MULTIPLEX DIAGNOSTIC PLATFORMS FOR PATHOGEN DISCOVERY FROM BIOREPOSITORY SAMPLES IN THE DEMOCRATIC REPUBLIC OF CONGO

Abigail Porzucek[1], Jean Claude Makangara[2], Pauline Musuamba[2], Andre Citenga[2], Celine H. Taboy[3], Adrienne Amuri[2], Sarah R. Tritsch[1], Eddy Lusamaki[2], Emmanuel Lokilo[2], Gerry Makaya[4], Grace Muyembe[2], Raphael Lumembe[2], Gabriel Kabamba[2], Francis Mbuyi[4], Elisabeth Pukuta[2], Antoine Nkuba-Ndaye[2], Nohelia Navarrete[4], Edith Nkwembe[2], Shelia Makiala-Mandanda[2], John D. Klena[3], Steve Ahuka-Mundeke[2], Joel M. Montgomery[3], Placide K. Mbala[2], Christopher N. Mores[1], Jean-Jacques Muyembe Tamfum[2]

[1]George Washington University, Washington, DC, United States, [2]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Vysnova, Landover, MD, United States

During disease outbreaks it is common for patients presenting with clinical symptoms consistent with the causative etiology to test negative for the agent of interest. Reasons for this include sample integrity, low-sensitivity tests, and pathogen diversity. However, when these patients test negative, the true etiology of the disease often remains undiagnosed. In an effort to increase diagnostic capabilities and improve the capacity of the country to respond to outbreaks, we used the BioFire platform to identify the etiology of disease in negative samples from the biorepository at the Institut National de Recherche Biomédicale (INRB) in Kinshasa, Democratic Republic of Congo (DRC). Blood samples collected during a 2019 Chikungunya virus (CHIKV) outbreak in Kinshasa, a 2022 Monkeypox outbreak in Maniema, and Ebola virus outbreaks from Komanga, Beni, and Mangina in 2018 - 2020 were analyzed using the BioFire Global Fever (GF) or Bio Threat (BT) pouches. Respiratory virus surveillance samples

from Kinshasa that tested negative for SARS-CoV-2 and Influenza were tested using the BioFire RP2.1 pouch. In total 41 samples were tested, and among those 20 were tested on the GF pouch, 14 on the BT pouch and 7 on the RP2.1 pouch. Five out of five (100%) samples that had been previously diagnosed were used as positive controls and tested positive on the BioFire (2 CHIKV, 2 Monkeypox, and 1 SARS-CoV-2). Of the samples that had previously been undiagnosed, 21/36 (58%) tested positive for at least one target on the pouch. The most common positive result among blood samples was *Plasmodium* spp. (9 samples), followed by *Plasmodium falciparum* (7 samples), CHIKV (2 samples), Orthopox genus (2 samples), and Dengue serotype 2 (1 sample). Among the respiratory samples, Adenovirus (5 samples), Coronavirus NL63 (4 samples), Parainfluenza virus 3 (1 sample), parainfluenza virus 4 (1 sample), and SARS-CoV-2 (1 sample) were detected. These data suggest that supplementing outbreak investigations in the DRC with screening for other causes of disease, such as those used in this study, could improve accuracy of diagnosis and clinical management of cases.

PLASMODIUM SPP., SARS-COV2, DENV AND CMV HAVE THE HIGHEST POPULATION ATTRIBUTABLE FRACTION FOR ACUTE FEBRILE ILLNESS USING MULTIPLEX PCR DIAGNOSTICS IN A HEALTH-FACILITY BASED CASE-CONTROL STUDY IN IQUITOS, PERU DURING THE COVID-19 PANDEMIC

Josh Michael Colston, Margaret Kosek, Pablo Peñataro Yori, Francesca Schiaffino

University of Virginia School of Medicine, Charlottesville, VA, United States

Numerous emerging and endemic pathogens circulating in the tropical regions of South America, count among the etiologies for the clinical syndrome Acute Febrile Illness (AFI). In the Peruvian Amazon, these diseases, which are often clinically undifferentiable, include malaria, dengue, Zika, Chikungunya, leptospirosis, and others. Modular quantitative PCR diagnostic devices like the TaqMan Array Card (TAC) can detect dozens of pathogens in a single biological specimen. To demonstrate the feasibility of implementing etiology specific AFI surveillance using TAC, this study enrolls adult patients presenting with the syndrome and matched controls at two hospitals and five health posts spanning the urban-rural gradient of the greater Iquitos Metropolitan Area. TAC diagnostics are performed on blood samples, and medical, symptom and travel history data are collected upon enrolment. Concurrently, SARS-CoV-2 presence in saliva and nasopharyngeal samples is tested for using a separate PCR assay. During the first year (March 2021 - February 2022) 578 cases and 572 controls were recruited and tested for a panel of 26 pathogen targets. Epstein-Barre virus (EBV) had high positivity in both cases and controls (34.5% and 34.8% respectively) but no association with AFI, while 14 pathogen targets had zero detections. Excluding EBV, 17.8% of subjects (27.7% of AFI cases) were positive for at least one other pathogen, while just 5 subjects (0.4%, 2 cases, 3 controls) were coinfected with multiple non-EBV pathogens. The odds of *Plasmodium* spp. positivity were 12 times higher in cases than controls (OR = 12.12 [4.83, 39.00, p&lt0.001]), while the equivalent associations were 2.57 (1.51, 4.50, p&lt0.001) for SARS-CoV-2, 2.95 (1.38, 6.86, p=0.002) for Dengue virus and 3.81 (1.20, 15.87, p=0.011) for cytomegalovirus. Population attributable fractions for AFI of the 9 prevalent pathogens totaled 22.3%. AFI cases had 6.17 (3.57, 910.67, p&lt0.001) higher odds of having traveled in the preceding 15 days. Consistent with previously reported findings, this study found a high burden (77.7%) of AFI with etiology that is unattributable by multiplex PCR diagnostics.

DEFINING RATIONAL ASSAY CUT-OFFS DOCUMENTING HUMORAL IMMUNE RESPONSES TO SEVERAL FILOVIRUSES IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Nicole A. Hoff[1], Angelica L. Barall[1], Teri Ann Wong[2], Placide Mbala[3], Jean Paul Kompany[3], Didine Kaba[4], Jean Jacques Muyembe tanfum[5], Axel T. Lehrer[2], Anne W. Rimoin[1]

[1]UCLA Fielding School of Public Health, Los Angeles, CA, United States, [2]University of Hawaii at Manoa, Honolulu, HI, United States, [3]Institut National de Recherche Biomédicale, Kinshasa, Kinshasa, Democratic Republic of the Congo, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [5]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo

In the Democratic Republic of the Congo (DRC), the extent of human filovirus exposure remains unclear. While filovirus antibody response is classically detected using ELISA, we utilized a multiplex microsphere immunoassay (MIA) which produces simultaneous readouts of multiple analytes allowing for greater range and sensitivity in a limited laboratory resource setting. This study explores potential cutoff values for human antibody response to a specific MIA to better understand serologic immune profile against multiple filovirus proteins in various Congolese populations. Healthcare workers and members of the general population reporting no current illness were eligible for study participation. Serum samples were collected from consenting participants (N=1,813). The Luminex-based MIA was used to detect human IgG binding to recombinant filovirus antigens. Two potential response cut-offs for exposure indication were used: 1) mean +3 SD of MFI values recorded among Kinshasa participants reporting no contact with a confirmed or suspected Ebola case and no involvement in an Ebola outbreak, or 2) mean +3 SD of 1/3rd serum samples with lowest MFI values among the sample. Overall, 8.2% of samples were identified as having elevated EBOV GP reactivity defined by the Kinshasa-derived cutoff as opposed to 51.9% using the lowest 1/3rd cutoff. Similarly, 2.2% had elevated reactivity for EBOV VP40 and 2.4% for EBOV NP using the Kinshasa cutoff compared to 53.9% and 55.8% using the lowest value cutoff, respectively. Using the Kinshasa cutoff, 2.5% of samples had elevated BSA levels, 5.1% for SUDV GP, 2.3% for MARV VP40, 6.2% for MARV GP, and 2.5% for BDBV. Alternatively, the lowest 1/3rd cutoff identified 53.2% of samples had elevated BSA levels, 58.1% for SUDV GP, 56.2% for MARV VP40, 57.6% for MARV GP, and 53.5% for BDBV. Dramatic disparity in determination of possible filovirus exposure using different methodology indicates the importance of appropriate cut points for specific study population. Multiplex assays can be important tools in better monitoring changes in filovirus antigen reactivity in the general population absent of identified outbreaks.

Recent disease outbreaks highlight the need to characterize the immune response to filoviruses to develop vaccines and therapies. We have used extensive GP mutation libraries to map the epitopes for >200 monoclonal antibodies (MAbs) targeting the EBOV surface glycoprotein, GP. We have extended these studies to Marburg virus (MARV) by generating an Ala-scan library of MARV Dmucin GP (Uganda strain). Initial maps of anti-MARV MAbs include those of two non-neutralizing MAbs MR228 and MR235, targeting the wing region of MARV GP, that showed therapeutic

protection in animal models (MR228) or that increased binding (MR235) by neutralizing MAbs. The variety of EBOV MAbs mapped, many from survivors of ebolavirus infection, include cross-neutralizing MAbs targeting the GP membrane-proximal external region (MPER); a broadly cross-reactive MAb that blocks GP interaction with its endosomal receptor Niemann-Pick C1; GP binding activity in sera of mice injected with DNA encoding MAbs (DMAbs), and MAbs who synergistically transform a non-neutralizing MAb into a potent neutralizer. The epitope maps have expanded our understanding of how the immune system recognizes EBOV GP, and allow correlation of epitopes with MAb neutralizing capabilities, to develop anti-EBOV therapeutics and vaccines. Mapping also identified mutations that increase the exposure of neutralizing epitopes, impacting future anti-ebolavirus vaccine strategies. To identify GP residues important for EBOV infectivity, we performed infectivity assays with the full GP mutation library, using a lentivirus pseudotype system. We identified critical residues whose mutation abrogated infectivity without affecting GP conformational integrity. Their locations suggest crucial roles in GP conformational changes that cause virus-host membrane fusion. Additionally, to identify uncharacterized EBOV cellular receptors, we assayed wild-type GP infectivity in non-permissive cells individually expressing 6,000 unique human membrane proteins of our membrane proteome array (MPA). This has identified candidate membrane proteins that enable EBOV infectivity.

0633

SEROLOGIC PROFILING OF THE HUMORAL IMMUNE RESPONSE TO EBOLA VIRUS AMONG VACCINATED SUBJECTS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Angelica L. Barrall[1], Nicole A. Hoff[1], Teri Ann Wong[2], Placide Mbala[3], Jean Paul Kompany[3], Didine Kaba[4], Jean-Jacques Muyembe[3], Axel T. Lehrer[2], Anne Rimoin[1]

[1]University of California - Los Angeles, Los Angeles, CA, United States, [2]University of Hawaii at Manoa, Honolulu, HI, United States, [3]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Antibody profile analysis is critical for the development and monitoring of vaccines and therapeutics. Antibody response profiles in individuals who have received the recombinant vesicular stomatitis virus-Zaire Ebola virus (rVSVΔG-ZEBOV-GP) against Ebola virus (EBOV) infection is limited. In the Democratic Republic of the Congo (DRC), Ebola vaccinations have been given in response to active outbreaks using a ring-vaccination strategy. This study investigates the serologic profile of antibodies against the vaccine antigen, EBOV GP as well as other filoviral proteins, in vaccinated individuals in Mbandaka, where participants received the rVSVΔG-ZEBOV-GP vaccine in 2018 during an Ebola outbreak. Individuals who received Ebola vaccination and reported no current illness were eligible for study participation. Serum samples from all consenting participants with a baseline and at least one follow-up measure were included in analysis (N=386). A multiplex Luminex-based microsphere immunoassay was used to detect human IgG binding to recombinant EBOV antigens as well as other filovirus antigens in serum. Change in MFI value from pre-vaccination to 21 days post, 6 months post, and 2.5 years post was computed. Median Ebola antibody response at pre-vaccination, 21 days post, 6 months post, and 2.5 years post was: EBOV GP: 1481, 4863, 6514, 5645 MFI; EBOV VP40: 193, 2487, 2737, 2613 MFI; EBOV NP: 756, 544, 707, 563 MFI. Median change in EBOV GP was 2260, 3570, and 2630 ΔMFI by 21 days post, 6 months post, and 2.5 years post vaccination, respectively. Similarly, median change in EBOV VP40 was 2320, 2520, and 2450 ΔMFI at the follow-up time points. Smaller changes post-vaccination were generally observed in other analytes (i.e., EBOV NP, SUDV GP, MARV VP40, MARV GP, and BDBV GP). To date, only the FANG Ebola virus immunoassay has been FDA approved to determine change in antibody response after rVSVΔG-ZEBOV-GP vaccination. This study suggests that additional assays could be used to detect changes in Ebola-specific antibody responses over time and provide additional information on potential durability of immunity to EBOV GP as well as other filovirus antigens.

0634

SAFETY OF THE AD26.ZEBOV, MVA-BN-FILO EBOLA VIRUS VACCINE IN PREGNANT WOMEN IN AN OPEN-LABEL CLINICAL TRIAL CONDUCTED DURING THE 2018-2020 EBOLA VIRUS OUTBREAK IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Kambale Kasonia[1], Hugo Kavunga-Membo[2], Grace Mambula[3], Daniela Manno[1], Edward Choi[1], Tansy Edwards[1], Nathalie Imbault[4], Rebecca Grais[3], Daniel G. Bausch[1], Jean Jacques Muyembe[2], Deborah Watson-Jones[1], DRC-EB-001 consortium[5]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, [3]Epicentre, Paris, France, [4]Coalition for Epidemic Preparedness Innovations, Oslo, Norway, [5]Goma, Democratic Republic of the Congo

Pregnant women and their offspring experience disproportionally high mortality from Ebola virus disease (EVD). During the 2018-2020 EVD outbreak in North Kivu and Ituri provinces in the Democratic Republic of Congo, pregnant women were included in a clinical trial to assess the safety and effectiveness of the EVD vaccine regimen dose 1 (Ad26.ZEBOV) at day 0 and dose 2 (MVA-BN-Filo) at day 56 in adults and children aged ≥1 year. Women pregnant at time of vaccination or who notified a pregnancy during the study were followed for the collection of serious adverse events (SAEs) and pregnancy outcomes. Among 20,408 participants who received dose 1, 1221 women reported 1238 pregnancies. Pregnancy outcome was recorded for 1169 pregnancies (69 lost to follow up). Of the 1221 women ever pregnant during the study, 371 (38%) experienced an SAE. SAEs in pregnant women were predominantly related to pregnancy outcome; 260/1169 (23%) pregnancies with a known outcome resulted in a caesarian section delivery, primarily due to uterine scarring, fetal distress syndrome and cephalopelvic disproportion and 55 (4.7%) ended in miscarriage. Other SAEs occurred in less than 2% of women ever pregnant. No SAEs recorded for pregnant women were considered related to either vaccine. Of 1169 pregnancies with a known outcome, 1084 resulted in a live birth with 1100 babies born alive due to some twin pregnancies. Preterm birth occurred in 21% (188/891) of babies born alive and low birth weight in 8% (79/1032), amongst those with known gestational age and birth weight. Neonatal death up to 7 days occurred in 1% (11/1100) of babies born alive and 0.5% (5/1100) had congenital abnormalities. Congenital abnormalities included one inguinal hernia, one umbilical hernia, one congenital anomaly of the tongue, one cleft lip, one exomphalos. The Ad26.ZEBOV/MVA-BN-Filo vaccine appeared to be well tolerated in pregnant women and, although this trial did not have a control arm, trial data did not suggest worse adverse birth outcomes compared to a systematic review of pregnancy outcome data in this setting. If possible, these findings should be confirmed in randomized studies.

EXPANDED USE OF THE RVSVΔG-ZEBOV-GP EBOLA VACCINE

Beth-Ann G. Coller[1], Kenneth Liu[1], Matthew T. Onorato[1], Laurie Connor[1], Jakub Simon[1], Sheri Dubey[1], Susan VanRheenen[1], Jonathan Deutsch[1], Abigail Owens[1], Amy Morgan[1], Carolee Welebob[1], Donna Hyatt[1], Sunita Nair[1], Benjamin Hamze[2], Oumar Guindo[3], Samba Sow[4], Abdoul H. Beavogui[5], Mark Kieh[6], Andrew WT Lee[1]

[1]Merck & Co., Inc., North Wales, PA, United States, [2]INSERM, Lyon, France, [3]UCRC, Bamako, Mali, [4]CVD Mali, Bamako, Mali, [5]CNFRSR, Maferinyah, Guinea, [6]PREVAIL, Monrovia, Liberia

The Merck Ebola vaccine, rVSVΔG-ZEBOV-GP (Ebola Zaire Vaccine, live), is indicated for the prevention of disease caused by *Zaire ebolavirus* in

individuals 18 years of age and older and approved in over 40 countries including the United States, the European Union, and a number of countries in Africa. Post-approval non-clinical and clinical trials, including ongoing studies in pediatric and HIV positive participants, have continued to generate additional information on the performance of the vaccine. The studies in pediatric participants are focused on the safety and immunogenicity of the vaccine and include characterization of vaccine viral shedding. One of the pediatric studies, the Partnership for Research on Ebola VACcination (PREVAC V920-016), also includes evaluation of a second dose of rVSVΔG-ZEBOV-GP administered on Day 56 and is evaluating the durability of the immune response following one or two doses through five years postvaccination. Data available out to one year postvaccination in V920-016 showed that one and two doses of rVSVΔG-ZEBOV-GP were generally well tolerated and induced robust and durable immune responses in both adults and children as measured by a validated *Zaire ebolavirus* glycoprotein enzyme linked immunosorbent assay and Plaque Reduction Neutralization Test. Vaccine virus shedding was evaluated in a subset of children in V920-016. Vaccine virus RNA was detected in the saliva of less than 40% of the children within the first 28 days postvaccination. In addition to the ongoing clinical studies, rVSVΔG-ZEBOV-GP has been used extensively in the context of outbreak response with more than 380,000 individuals vaccinated in the Democratic Republic of the Congo, neighboring countries, and Guinea. Few breakthrough cases have been documented, consistent with a high level of efficacy/effectiveness and durable protection. The rVSVΔG-ZEBOV-GP vaccine is being stockpiled by UNICEF under the governance of the International Coordinating Group on Vaccine Provision in accordance with the World Health Organization Strategic Advisory Group of Experts recommendations.

0636

NIPAH VIRUS DIVERSITY ACROSS DIFFERENT SPATIAL SCALES IN SOUTH AND SOUTHEAST ASIA

Oscar Cortés Azuero[1], Birgit Nikolay[2], Noémie Lefrancq[1], Clifton McKee[3], Emily S. Gurley[3], Julien Cappelle[4], Vibol Hul[5], Tey Putita Ou[5], Thavry Hoem[5], Mohammed Z. Rahman[6], Ausraful Islam[6], Veasna Duong[5], Henrik Salje[1]

[1]University of Cambridge, Cambridge, United Kingdom, [2]Epicentre, Paris, France, [3]Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [4]CIRAD, UMR ASTRE, F-34398, Montpellier, France, [5]Virology Unit, Institut Pasteur in Cambodia, Phnom Penh, Cambodia, [6]Infectious Diseases Division, icddr,b, Dhaka, Bangladesh

Nipah virus (NiV) is a bat-borne zoonotic pathogen with high fatality when it infects humans. It has been identified in bats throughout South and Southeast Asia. While infections in humans are rare, Nipah infection in bats appears to be widespread throughout the region, and its genetic diversity remains poorly understood. Here, we compiled a comprehensive dataset of all known genomes for NiV and associated location and host species information (N=209 from India, Bangladesh, Thailand, Cambodia, Indonesia, and Malaysia, sampled between 1999 and 2018). We reconstructed a time-resolved phylogeny and organised the sequences into distinct lineages. We then developed statistical approaches that tracked the spatial spread of lineages, accounting for the biased approach undertaken to collect NiV isolates. We also explored the distribution of human cases across the phylogeny. Finally, we implemented a rarefaction model to investigate cluster saturation in specific geographic regions and considered correlates as drivers of diversity. We found existing NiV sequences could be divided into 4 major lineages and 12 clusters. Within any bat roost there were an average of 2 distinct lineages circulating, rising to 4.6 lineages within a division. The probability that a pair of sequences came from the same lineage ranged from 0.5 (95%CI 0.4-0.62) when the sequences were sampled within 10km of each other to 0.28 (95%CI 0.18-0.46) when they were 500-1000km apart. Overall, we found the geographic spread has been slow. The mean spatial distance between viruses rose from 99km (95%CI: 52-179km) when viruses were separated by %lt;5years in evolutionary time to 895km (95%CI: 840-951km) when viruses were separated by 20 years. Finally, we estimate that cluster saturation has been reached at four divisions, while the viral diversity in other regions remains unknown. These findings suggest widespread and entrenched viral diversity in NiV and that different areas across the region have different circulating viruses, which could eventually be observed with extensive, uniform sampling.

0637

CHARACTERIZING INCIDENT ACUTE LASSA VIRUS INFECTION IN SOUTHERN NIGERIA

Zahra Parker[1], Melanie McCauley[1], Iguosadolo Nosamiefan[2], Anise Happi[2], Johnson Okolie[2], Olivia Achonduh-Atijegbe[2], Morosoore Osoba[2], Michael Iroezindu[3], Abdulwasiu Bolaji Tiamiyu[3], Edward Akinwhale[3], Kara Lombardi[1], Leigh Anne Eller[1], Erica Broach[1], Petra Prins[1], Mihret Amare[1], Christian Happi[2], Kayvon Modjarrad[1]

[1]HJF in support of the Emerging Infectious Diseases Branch (EIDB) Walter Reed Army Institute of Research (WRAIR), Bethesda, MD, United States, [2]African Centre of Excellence for Genomics of Infectious Diseases (ACEGID), Redeemer's University, Ede, Nigeria, [3]Henry M. Jackson Foundation Medical Research International, Abuja, Nigeria

Lassa fever is a viral hemorrhagic disease caused by the Lassa virus (LASV). First described in Nigeria in 1969, LASV is now endemic across West Africa. Roughly 80% of LASV infections present with mild or asymptomatic disease; the true burden of LASV infection in endemic regions is not well understood, leaving a knowledge gap that is critical for epidemic preparedness and outbreak response. Knowledge gaps in LASV distribution outside of West Africa and the dynamics of disease transmission also exist. Since April 2021, the Walter Reed Army Institute of Research Emerging Infectious Disease Branch and the African Center of Excellence for Genomics of Infectious Diseases have been carrying out a population-based, longitudinal cohort study, designed to determine the incidence and background prevalence, as well as risk factors for and transmission dynamics of acute LASV infection at two Lassa-endemic locations in Southern Nigeria: Owo and Abakaliki. Participants are followed weekly during peak transmission season to test for LASV by RT-PCR and serology. Detection of symptomatic LASV infection triggers more frequent blood sampling to characterize the early immune response and viral kinetics of acute LASV infection and their correlation to clinical outcomes. The study includes concurrent zoonotic surveillance of targeted (LASV-affected households) and non-targeted (households without history of LASV infection) rodent and non-rodent reservoirs. To date, 380 participants have been enrolled with 7086 follow-up visits completed, yielding 33 (8.68%) total LASV positive cases, of which 6 (18.18%) were asymptomatic and 27 (81.81%) were symptomatic with one death reported. 4,351 samples isolated from 1,030 trapped rodents (47.7% were *Mastomys natalensis*) and 661 samples isolated from 310 non-rodent animals (from 829 households) are being analyzed for the presence of LASV. Of the 336 rodent tissue samples so far analyzed by RT-PCR, 79 tissues (from 42 rodents, 37.5%) were positive for LASV. Ongoing analyses on human and animal specimen are underway. Enrollments will continue through the 2022 LASV season.

0638

TRENDS OF MORTALITY AND MORBIDITY BURDEN RELATED TO NEGLECTED TROPICAL DISEASES (NTDS), 1990-2020

Cathleen Keller, Ewerton Cousin, Taren Gorman, Olivia Nesbit, Lydia Plante, Mustafa Sikder, Joanna Whisnant, Trent Yarosevich, Stephanie R M Zimsen, Jonathon Mosser

Institute for Health Metrics and Evaluation, Seattle, WA, United States

There has been significant progress in reducing the burden related to neglected tropical diseases (NTDs) due to control and elimination programs, improved sanitation, vector control, and treatment availability. We aim to compare the differences of burden and trends attributed to a group of NTDs from 1990 to 2020. We selected 12 NTDs that contribute

both morbidity and mortality to the Global Burden of Disease (GBD) Study. In order to assess the distribution of this burden, we estimated years lived with disability (YLDs), years of life lost (YLLs) and their sum, disability-adjusted life years (DALYs), based on global, super-region and age categories. Counts and age-standardized rates (ASRs) were calculated from 1990 to 2020. Estimated differences and percent change were used to quantify changing trends. We present preliminary GBD 2020 results here. Global DALYs for this group are estimated to have decreased by 51.9% from 1990 to 2020. Global YLDs and YLLs for this group decreased by 765,000 (95% UI 551,000-1.21million) and 7.29 million (95% UI 4.86-15.6), respectively. The largest reduction in ASRs of YLDs and YLLs were in sub-Saharan Africa. Larger percent changes in ASRs were observed for YLLs compared to YLDs in all super-regions except Southeast Asia, East Asia, and Oceania. The highest decrease of total YLDs was estimated in ages 5 to 9, from 543,000 (95% UI 293,000-917,000) in 1990 to 204,000 (95% UI 99,100-368,000) in 2020. Total YLLs had the highest decrease in ages 2 to 4 [-2.20 million (95% UI -4.70 to -1.23)]. Rates of YLDs and YLLs for dengue, Ebola and Zika increased across every age group. Across age groups, ascariasis in ages 5 to 9 years had the largest decrease in YLD rate [-52.9 (95% UI -90.4 to -28.9) per 100,000], whereas visceral leishmaniasis in ages 2 to 4 years had the largest decrease in YLL rate [-389 (95% UI -1,130 to -102) per 100,000]. Our estimates demonstrate that morbidity and mortality burden due to NTDs are largely decreasing, with more substantial reductions shown in mortality. These estimates can be utilized as a resource for future interventions and targeted strategies to reduce the impact of NTD burden.

0639

BURDEN OF DECLARATION VS NON-DECLARATION NEGLECTED TROPICAL DISEASES (NTDS)FROM 1990-2020

Cathleen Keller, Joanna Whisnant, Ewerton Cousin, Taren Gorman, Olivia Nesbit, Lydia Plante, Mustafa Sikder, Trent Yarosevich, Stephanie R M Zimsen, Jonathon Mosser

Institute for Health Metrics and Evaluation, Seattle, WA, United States

The London Declaration on Neglected Tropical Diseases (NTDs) placed a focus on 10 NTDs for reducing or eliminating attributable burden. Several factors of the program, including increased treatments, funding and collaboration, all contributed toward progress in reducing the selected NTDs. However, progress on NTDs not included could be declining more slowly. We aim to estimate the progress of declaration NTDs in comparison to a subset of NTDs not selected. We used preliminary 1990-2020 burden estimates for 20 NTDs from the 2020 Global Burden of Disease (GBD) study. To estimate fatal and non-fatal burden, we estimated deaths and disability-adjusted life years (DALYs), calculated as the sum of years lived with disability (YLDs) and years of life lost (YLLs). Age-standardized rates and counts were estimated at 5-year intervals spanning 1990 to 2020. Percent change and differences were used to compare the varying trends. We present preliminary GBD 2020 results here. Global DALYs of declaration NTDs (d-NTDs) and non-declaration NTDs (nd-NTDs) were estimated to be 6.60 million (95% UI 4.69-9.15) and 5.90 million (95% UI 4.33-7.70) in 2020, reductions of 65.7% (95% UI 65.6%-68.7%) and 4.87% (95% UI 2.12%-10.2%) since 1990, respectively. Among these 20 NTDs, nd-NTDs accounted for 32.9% of DALYs in 1990 and 47.2% in 2020. Total deaths of d-NTDs were estimated to be 31,700 (95% UI 25,700-43,600) in 2020, a 74.6% reduction since 1990. Total deaths of nd-NTDs decreased from 55,800 (95% UI 44,200-72,400) in 1990 to 48,700 (95% UI 32,300-64,000) in 2020, a 12.8% reduction. The results of our analysis showed higher decreases in burden of deaths and DALYs attributable to declaration NTDs in comparison to non-declaration NTDs. This indicates a need for updating strategies and encompassing a focus on a broader range of NTDs, similar to the approach taken by the World Health Organization (WHO) NTDs Roadmap. Doing so will be critical to ensuring that countries can shift to the cross-cutting approaches needed to ultimately reach prevention, control, elimination, or eradication targets.

DENGUE FORECASTING MODELS FOR THE AMERICAS

Talia M. Quandelacy[1], Michael A. Johansson[2]

[1]CU Denver, Colorado School of Public Health, Aurora, CO, United States, [2]Centers for Disease Control and Prevention, Dengue Branch, San Juan, Puerto Rico

Forecasting dengue can enable timely preventative measures, like vector control and hospital surge preparation. However, forecasting dengue is challenging. We developed and assessed regional indicators of dengue virus transmission across the Americas to identify potential drivers of transmission dynamics and evaluate forecasting capability. We used historical monthly dengue case data ranging from 1985 to 2019 from 241 jurisdictions in fourteen countries in the Americas to forecast monthly cases of dengue. Log-linear regression models were developed using dengue and climate (temperature, precipitation, and El Niño South Oscillation (ENSO)) data up to 2011 and incorporating short-term correlation, lags, and spatial correlation and forecasted monthly dengue cases at one- to six-months ahead for 2011 onward. Regional and national logarithmic scores (aggregated over time and across subnational locations) were used to assess model skill at each lead time. We applied regression models to the logarithmic scores to assess potential factors (forecast lead time, amount of historical data available, country, and location population size) associated with forecast skill. Increased surprisal was associated with longer lead times ($p<0.01$), less available training data ($p<0.01$), and varied by country ($p<0.01$). Accounting for these factors, a model including autoregressive and seasonal terms had the lowest surprisal estimates at one- and six-months ahead. Models incorporating the autoregressive component had more skill at the one-month horizon than all others. However, at six-months ahead, models that also included either seasonal and ENSO terms or seasonal and regional dengue terms had higher forecast skill. The autoregressive model with seasonal terms had the best average forecast skill across all horizons, suggesting that this model may serve as a base model to forecast dengue across the region. While forecast skill marginally increased with the inclusion of ENSO and regional dengue terms, that increase suggests those factors may contribute to long-term regional dengue dynamics.

Clinicians in Kenyan public health clinics lack access to diagnostic testing for emerging infections such as dengue virus (DENV) and must rely on clinical history and physical exam observations when evaluating febrile patients. We investigated whether the use of machine learning algorithms to develop diagnostic models based solely on clinical observations could enhance detection of DENV and form a valuable approach to aid in the surveillance for emerging infectious diseases in resource-limited settings. We extracted symptoms and physical exam data from 6,208 pediatric febrile illness visits to four clinic sites in Kisumu and Kwale Counties, Kenya, between 2014 and 2019, and created a data set with 138 clinical features. Malaria testing was available at the clinics. DENV testing was later performed in our labs. 485 subjects (7.8%) had acute DENV infection based on RT-PCR detection of viral RNA or anti-DENV IgG seroconversion (ELISA) by 1-month follow-up. 3,145 subjects (50.7%) had malaria

detected by light microscopy or rapid detection tests. 220 (3.5%) subjects had co-infection with both DENV and malaria. Clinicians diagnosed 83.9% (sensitivity, Sn) of malaria cases with 79.7% specificity (Sp), but only identified 13% (Sn) of DENV cases (85.5% Sp). We randomly sampled 70% of the dataset to train DENV and malaria prediction models using boosted logistic regression, decision trees and random forests, support vector machines, naïve Bayes, and neural networks with 10-fold cross validation, tuned to maximize accuracy (Ac). In the reserved 30% test dataset, clinician diagnosis of malaria outperformed all models (82.4% vs. range of 56.4-68.7% Ac for the models). In contrast, clinicians detected only 21 of 145 cases of DENV (79.7% Ac, 14.5% Sn, 85.2% Sp). Of the six models, only logistic regression identified any DENV case (8 cases, 91.1% Ac, 5.5% Sn, 98.3% Sp). Thus, without diagnostic testing, interpretation of clinical findings by humans or machines cannot detect DENV with a prevalence of up to 8%. Greater access to point-of-care diagnostic tests must be prioritized to address the global disparity in surveillance of emerging infectious diseases.

Rapid detection of established and emergent human pathogens is necessary for efficient implementation of public health response. This is often inhibited by barriers to acquisition of high-quality samples and lack of infrastructure for sample testing and analysis in resource-limited communities. Previously, we demonstrated use of blood-fed mosquitoes as tools for human pathogen surveillance (xenosurveillance) in resource limited regions of West Africa. A recent pilot study in Guatemala compared household-matched mosquito and human blood samples to reveal circulating pathogens, including Epstein-Barr virus. Leveraging an expanded cohort in the same rural Guatemalan community, we hypothesized that mosquitoes could be used as a non-invasive, self-supported sampling sources for xenosurveillance. We enrolled 107 individuals across 40 households in two communities of southwestern Guatemala for one year of weekly syndromic surveillance. Households with individuals reporting symptoms of fever, arthralgia, and/or rash were activated for a four-week intensive follow-up period wherein blood was collected from enrolled subjects, domestic animals, and replete mosquitoes. Blood was preserved on FTA cards and used for targeted PCR screening of human pathogens and next-generation sequencing. Twenty-one households, representing 64 individuals, were activated during the study. The most frequently reported symptoms were fever and arthralgia. Replete mosquitoes belonged to the genera *Culex* (n = 1,191), *Aedes* (n = 540), *Mansonia* (n = 51), and *Anopheles* (n = 23). Molecular analysis including NGS and confirmation of mosquito bloodmeal and species identification are ongoing. Data collected throughout this study will allow for comparison between samples (i.e. mosquito versus domestic animal versus mosquito), demonstrating the untapped potential for mosquitoes to be used in pathogen surveillance. This work will also create infrastructure for disease monitoring in rural and resource-limited communities that are particularly vulnerable to the burden of disease.

COUNTRY OWNERSHIP OF NEGLECTED TROPICAL DISEASES IN TANZANIA: RESOURCE MOBILIZATION THROUGH COMPREHENSIVE COUNCIL HEALTH PLANS

Wemaeli A. Mweteni[1], Kennedy Z. Panja[1], Chihiyo W. Mlay[2], Oscar C. Kaitaba[2], Isac K. Njau[2], Edwin M. Chao[3], George E. Kabona[2], Wangeci Thuo[4]

[1]RTI international, Dar es salaam, United Republic of Tanzania, [2]The National Neglected Tropical Diseases Control Program, Ministry of Health, Dodoma, United Republic of Tanzania, [3]MOH, Dodoma, United Republic of Tanzania, [4]RTI international, Washington, DC, United States

Historically, Neglected Tropical Disease Control Programs (NTDCPs) have been donor funded for interventions like Mass Drug Administration and surveys. The WHO NTD 2021-2030 Road Map puts forward three foundational pillars namely: accelerate programmatic action, intensify cross-cutting approaches, and change operating models and culture to facilitate country ownership. Country ownership focuses on leadership and domestic resource mobilization (DRM) for NTD programming. In Tanzania, among 158 councils assessed by the President's Office, Region Authority and Local Government (PORALG), 18.4% and 48.7% respectively did not allocate funds for NTDs in 2019/20 and 2020/21. The aim was to increase DRM by building capacity for planning and budgeting to 15 selected councils through regular Comprehensive Council Health Plan (CCHP) cycle. Selection was done based on the disease burden (high and near elimination). Ten of the 15 had zero allocation in 2020/21. National CCHP master trainers capacitated key council planners during the CCHP pre-planning stage. Planning and budgeting were done through planning and budgeting system (PlanRep) using DHSI2. Funding allocations were done across cost centers and fund sources. District Medical and Planning officers signed their plans as a commitment for integration into the CCHP. The budget was done in TZS, equivalent to 159,594 USD for all councils, at an average of 10,640 USD per council. Allocation per cost centers: Council Health Management Teams (CHMTs)-44,865 USD, Council Hospitals- 12,872 USD, Health Centers-27,105 USD, Dispensaries- 32,290 USD. CCHP interventions included case detection and management, early diagnosis, health promotion and prevention, medicine, medical equipment, medical supply and diagnostic supplies, preventive chemotherapy, vector control, safe healthcare waste management and practices. DRM for sustainable NTD programming depends on integration of NTD interventions into the CCHPs. Timing, data availability, and capacity of council NTD coordinators are keys for effective planning. Post CCHP assessment analysis is required to inform guidance for DRM scale up.

ASSESSING COMMUNITY HEALTH WORKERS' TIME ALLOCATION FOR A CERVICAL CANCER SCREENING AND TREATMENT INTERVENTION: A TIME AND MOTION STUDY

Jobiba Chinkhumba[1], Dorothy Thomas[2], Evelyn Ziphondo[1], Lizzie Msowoya[3], Darcy Rao[2], Jennifer S. Smith[4], Erik Schouten[3], Victor Mwapasa[1], Luis Gadama[1], Ruanne Barnabas[2], Lameck Chinula[3], Jennifer Hui-yu Tang[4]

[1]Kamuzu University of Health Sciences, Blantyre, Malawi, [2]University of Washington, Seattle, WA, United States, [3]University of North Carolina, Lilongwe, Malawi, [4]University of North Carolina, Chapel Hill, NC, United States

Community health workers (CHWs) are increasingly used to delivery priority maternal child health interventions to achieve Universal Health Coverage (UHC). Existing literature allude to the potential for detrimental effects of multi-tasking CHWs. We assessed the impact of integrating cervical cancer screening and prevention therapy (CCSPT) with family planning (FP) on time utilization among CHWs. A time and motion study was conducted in 7 health facilities in Malawi. Data was collected at baseline before CCSPT between October-July 2019, and 12 months after CCSPT implementation between July and August 2021. CHWs trained to deliver CCSPT were continuously observed in real time while

their activities were timed by independent observers. We used paired sample t-test to assess differences in mean hours that CHWs spent on key activities: clinical and preventive care; administration; FP and non-work-related tasks. Regression models were used to ascertain the impact of CCSPT on the average duration of key activities. Thirty-seven (n=37) CHWs were observed. Of these, 35% were females. Their mean age and years of experience were 42 and 17, respectively. Overall, 323 hours (inter quartile range 2.8-5.5) of CHWs observations took place. Compared to the period before CCSPT, the proportion of hours CHWs spent on clinical and preventive care, administration and non-work-related activities were reduced by 13.7, 8.7 and 34.6%, respectively. CHWs spent 75% more time on FP services after CCSPT implementation relative to the period before CCSPT. The provision of CCSPT appeared to result in less time that CHWs devoted towards clinical and preventive care but this association was not significant. Following CCPST, CHW spent significantly few hours on non-work-related activities. Introduction of CCSPT was not very detrimental to pre-existing community services. CHWs managed their time ensuring additional efforts required for CCSPT were not at the expense of essential activities. The programming and policy implications are that multi-tasking CHWs with CCSPT will not have substantial opportunity costs.

DEEP CHARACTERIZATION OF THE IMMUNOGENICITY INDUCED BY NEXT GENERATION YELLOW FEVER VACCINE IN PHASE 1 DOSE-RANGING STUDY

Nathalie Mantel[1], Anke Pagnon[1], Christophe Carre[1], Marion Aguirre[1], Emilie Chautard[1], Sophie Gimenez-Fourage[1], Florine Guillaume[1], Yichen Jia[1], Franck Raynal[1], Manuel Vangelisti[1], Kayvon Modjarrad[2], Emmanuel Feroldi[1]

[1]Sanofi, Marcy l'Etoile, France, [2]Emerging Infectious Diseases Branch, Walter Reed Army Institute of Research, Bethesda, MD, United States

vYF is a next-generation live-attenuated yellow fever (YF) vaccine candidate grown in serum-free Vero cells, free of allergens and of raw material from animal or human origin, developed to ensure a more robust worldwide supply. vYF preclinical testing demonstrated equivalence with licensed YF vaccines before its evaluation in humans. We conducted a Phase I randomized, observer-blind, active-controlled (YF-VAX), dose-ranging clinical trial to assess in 72 healthy adults of 3 dosages of vYF (4.0, 5.0 or 6.0 Log CCID50/dose) in a 1:1:1:1 allocation (NCT04142086). Immunogenicity was followed during 6 months after vaccination through the longitudinal evaluation of neutralizing antibody titers, detection of serum cytokine and chemokine levels by Luminex®, immune-profiling by focused transcriptomics analysis by RT-qPCR and evaluation of YF-specific memory B cell frequency by Fluorospot. All YF-naive vaccinees seroconverted 28 days after vaccination with both vYF and YF-VAX. Neutralizing antibody geometric mean titers increased from D10 to D28 and slightly decreased at 6 months post-vaccination but stayed far above the surrogate of protection threshold of ≥10 (1/dilution). No increase of inflammatory markers in sera was observed in all groups except a slight increase of IP10 at D7. The focused transcriptomics analysis allowed to identify induction of a strong antiviral innate response with activation of blood transcriptional modules linked to interferon response, viral sensing and dendritic cell activation followed by the initiation of adaptative T- and B-cell responses. Finally, a strong YF-specific memory B cell response with both IgM and IgG secreting cells was detected at D28 post-vaccination and IgG memory B cell response was maintained for at least 6 months. Overall, no difference was observed between the 3 doses: 4, 5 and 6 Log CCID50 and no difference was observed between vYF groups and YF-VAX vaccinees. Together these results show that vaccine take is similar for vYF and YF-VAX and it may suggest that the immune response to vYF could provide the same immune response over time and longevity as that induced by the reference vaccine.

SOFOSBUVIR OFF LABEL TREATMENT OF YELLOW FEVER PATIENTS DURING AN OUTBREAK IN BRAZIL, 2018

Izabela Mauricio de Rezende[1], Diogo Correa Mendonça[2], Leonardo S. Pereira[3], Carlos Eduardo Calzavara-Silva[4], Olindo Assis Martins-Filho[5], Andrea Teixeira-Carvalho[5], Claudio Antonio Bonjardim[6], Dario Brock Ramalho[7], A. Desiree LaBeaud[1], Marcelo Antonio Pascoal Xavier[8], Betania Paiva Drumond[6]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Medical Research Council-University of Glasgow, Centre for Virus Research, Glasgow, United Kingdom, [3]Bendigo Health, Bendigo, Victoria, Australia, [4]Cellular and Molecular Immunology, Instituto René Rachou, Fundação Oswaldo Cruz /FIOCRUZ Minas, Belo Horizonte, Brazil, [5]Integrated Group of Biomarkers Research, Instituto René Rachou, Fundação Oswaldo Cruz/FIOCRUZ Minas, Belo Horizonte, Brazil, [6]Laboratory of Viruses, Microbiology Department, Biological Sciences Institute, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [7]Eduardo de Menezes Hospital, Belo Horizonte, Brazil, [8]Immunology of Viruses Diseases, Instituto René Rachou, Fundação Oswaldo Cruz /FIOCRUZ Minas, Belo Horizonte, Brazil

In 2018 a huge yellow fever (YF) outbreak took place in Southern Brazil, causing 2,166 confirmed human cases and 752 deaths. Among the patients hospitalized at Eduardo de Menezes Hospital (MG, Brazil) and diagnosed with YF, 46 patients were selected for a off label, non-randomized treatment with Sofosbuvir (approved antiviral against HCV), based on the days after disease onset (up to 5 days post symptoms onset-DPS). Previous studies had already shown the Sofosbuvir antiviral activity against YFV in vitro and experimentally infected mice. Selected patients were presenting severe symptoms and were at great risk for fatal YF disease. Patients or their legal responsible consented to the use of Sofosbuvir during acute YF phase. This study was approved by the Ethics Committee on Human Research at René Rachou Institute/FIOCRUZ on CAAE 65814417.0.0000.5091 and CAAE 43000815.7.0000.5091. Patients had serial serum samples collected during Sofosbuvir use (up to 10 DPS), followed by RNA extraction and qRT-PCR. We analyzed the YFV genomic viral load (VL) of treated patients and compared them with those of untreated YF patients who either survived (NT-S) or died (NT-D) during hospitalization. Serum samples were collected between the 4th to the 10th day after symptoms onset (DPS). The average genomic VL was higher for the NT-D group (2.04x10^{7}GC/mL), followed by the treated one (1.25x10^{5}GC/mL), and last the NT-S (5.93x10^{4}GC/mL). Comparing genomic VL for each day, differences were observed at all analyzed time points (4,5,6,7,8 and 9 DPS), with higher values for the NT-D group followed by the treated group and lastly the NT-S ($p=0.002$ for NT-SxTreated, and $p<0.0001$ for the pairs NT-SxNT-D and NT-DxTreated). The treated group showed an intermediary YFV VL at the beginning, and, after treatment, suggesting that Sofosbuvir could be able to reduce the YFV load at levels similar to the NT-S group. There is no specific therapy against YF, reinforcing an urgent need for antiviral treatment. Further studies are needed, considering controlled and randomized circumstances, to better investigate the role of Sofosbuvir and its impact on YFV infection in human patients.

MAPPING ZIKA VIRUS-SPECIFIC NEUTRALIZING IMMUNITY FOR OPTIMAL VACCINE DEVELOPMENT

Kathryn H. Radulovacki[1], Daniel O. Espinoza[1], Yerun Zhu[1], Jaime A. Cardona-Ospina[2], Christina Mehta[1], Oyindamola Yusuf[1], Vincent Dussupt[3], Gina C. Donofrio[3], Nadine Rouphael[1], Alfonso J. Rodriguez-Morales[2], Srilatha Edupuganti[1], Kayvon Modjarrad[3], Mark J. Mulligan[4], Aravinda M. de Silva[5], Shelly J. Krebs[3], Matthew H. Collins[1]

[1]Emory University School of Medicine, Atlanta, GA, United States, [2]Fundación Universitaria Autónoma de las Américas, Pereira, Colombia,

[3]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]NYU Langone Vaccine Center, New York, NY, United States, [5]University of North Carolina Chapel Hill, Chapel Hill, NC, United States

Zika virus (ZIKV) has been reported in 87 countries since 2015. Although most infections are mild or asymptomatic, ZIKV can cause infantile Guillain-Barré syndrome, brain or eye defects, low birth weight, and even pregnancy loss. Vaccines are urgently needed to prevent ZIKV, but current understanding of humoral responses to ZIKV is incomplete, and tools to assess candidate vaccines' immunogenicity are lacking. Here, we examine whether vaccination and natural infection elicit ZIKV-specific antibodies (Abs) that target the same epitopes as potent ZIKV-neutralizing monoclonal antibodies (mAbs) via blockade of binding (BOB) assays. We also use standard measures of binding and neutralizing antibody (NAb) titers. We hypothesize that vaccines which elicit NAb responses similar in quality to natural infection - particularly Abs that recognize quaternary epitopes - will be most likely to provide durable protective immunity. We find that two vaccine candidates, a DNA vaccine (VRC) and a purified inactivated virus vaccine (ZPIV), elicit distinct antibody responses to ZIKV. One month after completing the three-dose ZPIV regimen, samples produced a 45.70% mean BOB response using MZ4 as the mAb probe; two months post-third dose of VRC 320, samples produced <10% BOB. Importantly, although MZ4 was isolated from a dengue-immune individual vaccinated with ZPIV, convalescent sera from individuals with prior ZIKV infections consistently compete with it. This supports our hypothesis that the ZPIV antigenic structure closely recapitulates the native ZIKV virion (including the MZ4 epitope). We also found that dengue-immune sera exhibited minimal BOB activity against MZ4 and other mAbs such as A9E, G9E, and Z004. This suggests that our mAb probes were specific for ZIKV-induced immunity. Ongoing experiments seek to quantify total ZIKV-binding Ab across sample sets to discriminate between quantitative and qualitative Ab reactivity and to expand the probed ZIKV antigenic regions. This project demonstrates the importance of assessing Ab response quality beyond a single measure (such as NAb titer) and may help optimize ZIKV vaccine development.

HUMORAL AND T-CELL-MEDIATED RESPONSES TO A PRE-CLINICAL ZIKA VACCINE CANDIDATE THAT UTILIZES A UNIQUE INSECT-SPECIFIC FLAVIVIRUS PLATFORM

Danielle L. Porier, Manette Tanelus, William B. Stone, Krisangel Lopez, Dawn I. Auguste, Albert J. Auguste

Virginia Polytechnic Institute and State University, Blacksburg, VA, United States

Vaccination is critical for the control and prevention of viral outbreaks, yet conventional vaccine platforms may involve trade-offs between vaccine immunogenicity and safety. Insect-specific flaviviruses (ISFVs) are emerging as a novel method to overcome this challenge. ISFVs are safe; they neither replicate nor cause disease in vertebrates, and hence also don't require traditional inactivation methods that can result in antigenic degradation. Previously, we used a novel ISFV called Aripo virus (ARPV) to create a promising recombinant Zika virus (ZIKV) vaccine candidate (called ARPV/ZIKV) that consists of ZIKV precursor membrane and envelope (prM-E) genes expressed on an ARPV backbone. Previously, ARPV/ZIKV showed no pathogenicity, including in suckling mice injected intracranially. Immunocompetent and immunocompromised mice immunized with a single unadjuvanted dose were also completely protected from lethal ZIKV challenge. Given ZIKV's propensity to evade key innate antiviral responses in humans, and in order to assess correlates of protection and adjuvant selection in the future, a better understanding of the balance between vaccine-induced humoral and T-cell responses is required. Here, we explore these responses for both developing immunity post-immunization and for providing protection post-challenge. Passive transfer of antibodies from APRV/ZIKV-immunized mice to naïve IFNAR$^{-/-}$ mice prior to challenge emphasized neutralizing antibodies as an important correlate of protection. However, circulating antibodies post-transfer were not sufficient for full protection. Follow-up *in vivo* T-cell depletion studies of CD8^{+} or CD4^{+} T-cells in IFNAR$^{-/-}$ mice at the time of challenge indicated the potential importance of vaccine-induced T-cell responses for protection. Vaccine efficacy studies in Rag1 KO, Tcra KO, and muMt^{-} mice also demonstrated the importance of T-cell responses for developing immunity after ARPV/ZIKV immunization. Overall, ARPV/ZIKV induces robust responses in both branches of the adaptive immune system, meaning that ISFV platforms continue to be a promising method for vaccine development.

0649

THE EFFECT OF OBESITY ON PEDIATRIC DENGUE VIRUS INFECTION, DISEASE, AND IMMUNE RESPONSE

Reinaldo Mercado-Hernendez[1], Rachel Myers[1], Fausto Bustos[1], Sandra Bos[1], José Victor Zambrana[2], Brenda López[2], Nery Sanchez[2], Aaron M. Frutos[3], Aubree Gordon[3], Angel Balmaseda[4], Guillermina Kuan[5], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, [5]Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Obesity is an important risk factor for poor outcomes of multiple infectious diseases and has been associated with reduced antibody responses and a faster antibody waning rate; however, whether obesity increases the risk of dengue virus (DENV) infection or affects DENV antibody responses has not be explored. Given that obesity and dengue both pose a substantial and increasing burden in children, we sought to investigate whether and how pediatric obesity modulates DENV infection and immune responses to infection. Data were derived from the Pediatric Dengue Cohort Study (PDCS) in Managua, Nicaragua, following ~3,800 children 2-15 years old. To study the effect of obesity on anti-DENV antibody responses, serum samples from a subset of 90 selected PDCS participants (n=30 each normoweight, overweight, and obese, defined by BMI z-score) at ~6, ~18, and ~30 months post-infection are being tested for anti-DENV antigen-specific antibody binding profiles, neutralizing capacity, and temporal dynamics. To do so, we have developed a novel multiplex Luminex system to measure the magnitude and binding characteristics of antibodies that target the envelope (E) protein, E domain III, and nonstructural protein 1 from the four DENV serotypes. We found that between 2011 and 2019, the incidence rate of obesity in the cohort increased from 2.1 to 3.9 per 100 population, and the prevalence of obesity increased by 86% (from 7 to 13%). Participants with obesity had a 1.27 (95% confidence interval [CI] 1.08, 1.49) greater risk of DENV infection when compared to normoweight individuals in univariate analysis. Further, participants with obesity had a 1.86 (95% CI 1.36, 2.53) higher risk of developing dengue symptoms given infection and had an adjusted (for age, sex, infection history and cohort year) higher risk of 1.63 (95% CI 1.16, 2.30). Our results suggest that obesity is a risk factor for DENV infection and disease and may modulate DENV antibody responses over time.

0650

OBESITY ALTERS IMMUNE RESPONSES TO DENGUE VIRAL INFECTION IN CHILDREN AND YOUNG ADULTS

Michaela Gregorova[1], Nguyet Minh Nguyen[2], Ho Quang Chanh[2], Nguyen Thi Xuan Chau[2], Dong Thi Hoai Tam[2], Tran Thuy Vi[2], Duyen Huynh Thi Le[2], Cao Thi Tam[3], Hoa Vo Thi My[2], Sophie Yacoub[2], Laura Rivino[1]

[1]University of Bristol, Bristol, United Kingdom, [2]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam, [3]Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam

Obesity, an increasing global health problem, is a potential risk factor for the development of severe dengue. Individuals with obesity may possess an altered cellular metabolism which could impact anti-viral immunity,

however the mechanisms underlying these alterations in dengue are unknown. Our study investigates the phenotype/functionality of T, NK and B cells and their association with body mass index (BMI) and dengue outcomes in children and young adults. The phenotypic/functional features of T, NK and B cells were evaluated by multiparameter flow cytometry in a Vietnamese cohort of acute severe and non-severe dengue patients with obesity/overweight (n=75) or normal weight (n=75), matched by age, sex, and illness phase. Magnitude, phenotype and multifunctionality of dengue-specific T cells targeting DENV1-4 were assessed by intracellular cytokine staining. We identified robust T (CD4+ and CD8+), NK, and B cell activation in all patients analyzed (day 8 illness onset), which was decreased in patients with obesity. Obesity also associated with reduced cytotoxic potential and more dysfunctional phenotype of CD8+ T and NK cells, suggesting altered immune responses with potentially impaired capacity to clear dengue virus. Moreover, these altered cellular phenotypes were more marked in severe disease and strongly correlated with increasing BMI and serum leptin levels. In both patient groups (obesity and normal weight), DENV2-specific CD8+ T cells expressed high levels of MIP-1β and CD107a, and variable levels of IFN-γ, TNF-α and IL-2 cytokines. The multifunctionality of DENV2-specific T cells was decreased in secondary infection in patients with obesity compared to patients with normal weight. We are currently analyzing the metabolic profiles and phenotype/function of T/NK cells in these patients early in infection (days 3-5). We identified alterations in immune responses of dengue patients with obesity/overweight compared to patients with normal weight, which were more marked in severe disease. Our data suggest obesity may potentially impact on the anti-viral capacity of T, NK and B cells, particularly during severe dengue.

0651

TAK-003 ELICITS TETRAVALENT, ROBUST, AND SUSTAINED NS1 AB RESPONSES SPANNING POPULATION AGE AND BASELINE SEROSTATUS

Heather Watkins[1], Nicole Messere[1], Lydia Cox[1], Ayako Miura[1], Vianney Tricou[1], Shibadas Biswal[1], Mayuri Sharma[1], DEN-304 and DEN-301 Study Groups[2]

[1]Takeda Pharmaceuticals Inc., Cambridge, MA, United States

Dengue (DENV) is a *Flavivirus* which causes significant disease burden worldwide. Exposure to DENV can lead to asymptomatic dengue, dengue fever, or potentially deadly dengue hemorrhagic fever/dengue shock syndrome, characterized by endothelial dysfunction and vascular leakage. Non-structural protein 1 (NS1) is the only secreted viral protein from DENV-infected cells and is involved in viral replication and immune evasion. The antibody response to NS1 may play a role in protecting against severe disease. Takeda's dengue vaccine candidate TAK003 consists of an attenuated DENV-2 virus, and three chimeric viruses containing the pre-membrane and E protein genes of DENV-1, -3, and -4, genetically engineered into the attenuated DENV-2 backbone. The DENV-2 backbone of TAK-003 includes the NS1 from DENV-2. We developed an indirect ELISA to measure anti-dengue NS1 IgG antibodies in pre-and post-vaccination samples from TAK-003 recipients. We tested samples from two different Phase 3 clinical trials conducted in dengue-endemic and non-endemic regions (DEN-301, NCT02747927; DEN-304, NCT03423173, respectively) to assess the magnitude and persistence of DENV-2 NS1-specific, and DENV-1, -3 and -4 NS1 cross-reactive IgG responses in pediatric, adolescent and adult participants. Our data indicate that anti-NS1 IgG responses peak post-vaccination at day 120 (30 days post-second dose), followed by a sustained response above baseline through Day 450 (360 days post second dose) in both seropositive and seronegative participants. The anti-NS1 IgG response in seronegative participants follows a hierarchy of magnitude, with the highest antibody responses to DENV-2 NS1, followed by cross-reactive responses to DENV-1, 3 and 4 NS1 respectively. Pre-vaccination, the anti-NS1 antibody responses in baseline seropositive participants are higher than seronegative participants, and remain higher post-vaccination. These data indicate that TAK-003 elicits tetravalent, robust and sustained NS1 IgG responses in pediatric, adolescent and adult participants from endemic and non-endemic countries, irrespective of baseline serostatus.

0652

SPOROZOITE IMMUNIZATION FOLLOWED BY ANTIMALARIAL CHEMOPROPHYLAXIS TARGETING PLASMEPSINS IX AND X CONFERS STERILE IMMUNITY AGAINST MALARIA

Ryan Steel[1], Sabrina Caiazzo[1], Yu Cheng Chua[2], Daniel Fernandez-Ruiz[2], William Heath[2], David Olsen[3], **Justin Boddey**[1]

[1]Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [2]University of Melbourne, Parkville, Australia, [3]Merck & Co. Inc., West Point, PA, United States

Naturally acquired immunity to malaria only develops after repeated cases and does not prevent reinfection. The licensed malaria vaccine RTS,S/AS01 offers moderate efficacy that wanes with time, resulting in rebound *Plasmodium* infections. Efficacious protection from malaria has been achieved with chemoprophylaxis vaccination involving controlled infection with live sporozoites and chemoprophylaxis targeting liver or blood stage parasites. Malaria parasites have evolved resistance to most antimalarials, and few treatments effectively kill pre-erythrocytic liver stages. A new antimalarial that arrests late liver stages before blood infection takes hold may aid the development of a next generation malaria vaccine. Previously, we showed that a new class of antimalarials targeting plasmepsins IX and X inhibit liver merosomes from establishing the first wave of erythrocytic infection. This liver merozoite arrest occurred after sporozoite inoculation, preventing detectable blood stage parasitaemia and malaria (chemoprophylaxis). Here, we have investigated whether liver merozoite arrest using plasmepsin IX/X-specific antimalarials confers protective immunity. Immunization of two mouse strains with sporozoites under antimalarial prophylaxis targeting plasmepsins IX and X elicited sterilizing immunity against mosquito-borne malaria with a half-life of up to 24 months. Protective immunity involved robust antibody and T cell responses. These results have implications for malaria vaccination involving immune priming and/or boosting with locally circulating, heterologous, mosquito-borne malaria parasites in endemic regions using a new class of antimalarials that arrests very late liver stages.

0653

ALTERED Vδ2+ γδ T CELL CHROMATIN ACCESSIBILITY AND IMMUNE FUNCTION FOLLOWING REDUCED IN *VIVO OR* IN *VITRO* MALARIA EXPOSURE

Kathleen Dantzler Press[1], Sandy Klemm[1], Fabian Müller[2], Derek Chen[1], Midhuna I. Joseph Maran[2], Zicheng Hu[3], John Rek[4], Felistas Nankya[4], Isaac Ssewanyana[4], Moses Kamya[5], Bryan Greenhouse[6], Grant Dorsey[6], Margaret Feeney[6], Will Greenleaf[1], Prasanna Jagannathan[1]

A major component of incomplete natural immunity to *Plasmodium falciparum (Pf)* malaria is attenuation of cytotoxic, pro-inflammatory responses by innate immune cells following repeated malaria exposure. In order to identify mechanisms underlying Vδ2+ γδ T cell dysfunction and to characterize the longevity of this response, we obtained repeated samples from a longitudinal cohort of children living in Tororo, Uganda, before and after a district-wide insecticide campaign that dramatically reduced malaria transmission. Paired ATAC-Seq and RNA-Seq experiments utilizing sort-purified Vδ2+ cells from Ugandan children (n=20) at 3 timepoints revealed differential chromatin accessibility and gene expression based on prior incidence of clinical malaria. We identified differential chromatin and transcription factor motif accessibility between samples

from 2016 (reduced transmission) vs. 2013 (high malaria transmission) at sites associated with immune signaling (e.g. IL-19, CD8, CXCR6, STAT1) and regulation (e.g. BCL2, KLRC1). Analysis of RNA-Seq data is ongoing. In addition to defining transcriptional and epigenetic changes underlying altered cell function following repeated malaria or reduced malaria transmission, we established an *in vitro* system to simulate the *in vivo* context. Vδ2+ T cells from malaria-naïve individuals stimulated for 6 days with *Pf*-infected red blood cells (iRBCs) or the phosphoantigen HMBPP produced less TNFα and IFNγ and degranulated less in response to secondary stimulation compared to unstimulated cells; however, rest following stimulation partially rescued the decreased responsivity to iRBCs. Similar results were obtained using cells from malaria-uninfected Ugandan individuals, but responses from recently infected individuals were more variable. Ultimately, this work could deepen our understanding of mechanisms driving inefficient acquisition of antimalarial immunity—including potential reversibility of functional changes following repeated malaria—and could have applications for novel therapeutic approaches targeting innate immune responses in addition to adaptive responses.

Anti-gametocyte immunity is the foundation-stone of malaria transmission blocking vaccine development. Individuals infected with *Plasmodium falciparum* develop antibody responses to intra-erythrocytic gametocyte proteins and gametocyte proteins exported to the surface of infected erythrocytes, but our knowledge of the immunogenicity of gametocyte antigens and the specificity of gametocyte-induced antibody responses is very limited. In this study, we assessed antibody responses in participants of two controlled human malaria infection (CHMI) studies by ELISA, multiplexed bead-based antibody assays and protein microarray. By comparing antibody responses in participants with and without gametocyte exposure, we aimed to disentangle the antibody response induced by asexual and sexual stage parasites. We showed that after a single malaria infection, a significant anti-sexual stage humoral response is induced in malaria-naïve individuals, even after exposure to relatively low gametocyte densities (up to ~1,600 gametocytes/mL). In contrast to antibody responses to well-characterised asexual blood stage antigens that were detectable by day 21 after infection, responses to sexual stage antigens (including transmission blocking vaccine candidates Pfs48/45 and Pfs230) were only apparent at 51 days after infection and were correlated with the intensity of prior exposure. Sixty-four antigens were identified as eliciting higher antibody responses exclusively in individuals with significant gametocyte exposure, among which antigens previously associated with early gametocyte or anti-gamete immunity were highly represented. Our data provide detailed insights on the induction and kinetics of antibody responses to gametocytes and identify novel antigens that elicit antibody responses exclusively in individuals with gametocyte exposure. Our findings provide target identification for serological assays for surveillance of the malaria infectious reservoir, and support vaccine development by describing the antibody response to leading vaccine antigens after primary infection.

Sero-surveillance can monitor and project disease burden and risk. However, SARS-CoV-2 antibody test results can produce false positive results, limiting their efficacy as a sero-surveillance tool to estimate population-level SARS-CoV-2 exposure. False positive SARS-CoV-2 antibody results have been associated with malaria exposure, and understanding this association is essential to interpret sero-surveillance results from malaria-endemic countries. In this study, pre-pandemic samples from eight malaria endemic and non-endemic countries on four continents were tested by ELISA to measure SARS-CoV-2 Spike S1 subunit reactivity. Pre-pandemic individuals with acute malaria infection generated substantial IgG and IgM reactivity to SARS-CoV-2. People with acute malaria infection had significantly higher rates of SARS-CoV-2 reactivity compared to uninfected people in malaria-endemic areas (t-test log IgG and IgM p-values<0.0001), with reactivity peaking 2-4 weeks after malaria infection. Peptide and protein arrays showed that cross-reactivity to S1 Spike of SARS-CoV-2 was not associated with reactivity to other human coronaviruses or other SARS-CoV-2 proteins (no significant associations, except with malaria epitopes). In investigating the mechanism of cross-reactivity, ELISAs with deglycosylated and desialated Spike S1 subunits revealed that cross-reactive antibodies target sialic acid on N-linked glycans of the Spike protein. The functional activity of cross-reactive antibodies measured by neutralization assays showed that cross-reactive antibodies did not prevent viral entry to neutralize SARS-CoV-2 in vitro. Routine use of heavily glycosylated or sialated assays could result in false positive SARS-CoV-2 antibody results in malaria endemic regions, causing serological surveillance tools to overestimate SARS-CoV-2 exposure and possible population-level immunity, and in turn underestimate the risk of continued COVID-19 transmission. These findings emphasize the importance of developing assay approaches that minimize cross-reactivity to improve serological surveillance.

A SINGLE FULL-LENGTH VAR2CSA ECTODOMAIN VARIANT PURIFIES CROSS-INHIBITORY ANTIBODIES AGAINST PLACENTAL MALARIA ISOLATES

Yai Justin Doritchamou[1], Jonathan P. Renn[1], Bethany Jenkins[1], Almahamoudou Mahamar[2], Alassane Dicko[2], Michal Fried[1], Patrick E. Duffy[1]

[1]Laboratory of Malaria Immunology & Vaccinology, National Institute of Allergy and Infectious Disease, Bethesda, MD, United States, [2]Malaria Research and Training Center, University of Sciences, Techniques, and Technologies of Bamako, Bamako, Mali

Placental malaria (PM) is a deadly syndrome that results from accumulation of *Plasmodium falciparum*-infected erythrocytes expressing surface antigen VAR2CSA and binding to chondroitin sulfate A in the placenta. VAR2CSA is the leading PM-vaccine candidate, as anti-VAR2CSA antibodies have been associated with naturally acquired PM-resistance over successive pregnancies. The cysteine-rich ectodomain is formed by an N-terminal sequence (NTS), followed by six and sometimes more Duffy-binding-like (DBL) domains interspersed with interdomain (ID) regions. The first subunit VAR2CSA-based vaccines (called PAMVAC and PRIMVAC) failed to induce strain-transcending anti-adhesion antibody in clinical trials. Similarly, VAR2CSA fragments (single or double domains) fail to purify the broadly neutralizing activity of sera from PM-resistant multigravidae. Although VAR2CSA fragments (including constructs similar to PAMVAC vaccine) purified antibodies with CSA-binding inhibitory activity against homologous parasites, broadly neutralizing activity was neither purified nor depleted after passing sera over several VAR2CSA domains and variants. Here, we sequentially purified IgG on five full-length VAR2CSA variants from PM-resistant multigravidae sera and assessed the antigen-specific IgG as well as the flow through IgG for functional activities on several placenta-binding isolates. We show that a single full-length VAR2CSA purifies strain-transcending CSA-binding inhibitory activity. IgG remaining after depletion on all five variants showed significantly reduced binding-inhibition activity compared to initial total IgG. These observations support the hypothesis that functional antibodies to VAR2CSA may target conformational epitopes not displayed by VAR2CSA subunit in comparison to the full-length VAR2CSA exposed to host immune system during natural infection. Our data suggest a broadly effective PM-vaccine may be achieved with a limited number of full-length VAR2CSA variants and provide a basis to design improved PM vaccines.

0657

HOST TARGETED KINASE INHIBITORS AS A DRUG CANDIDATE WITH DUAL ANTI-PARASITIC AND PROTECTIVE BLOOD BRAIN BARRIER ACTIVITY AGAINST CEREBRAL MALARIA

Priyanka Bansal, Luana Dos Santos Ortolan, Veronica Primavera, Alexis Kaushansky, Joseph Smith

Seattle Childrens Research Institute, Seattle, United States Minor Outlying Islands

Cerebral malaria (CM) caused by *Plasmodium falciparum* infection continues to be a major concern worldwide. Brain swelling associated with blood brain barrier (BBB) dysfunction is a main factor underlying CM pathogenesis. While fast-acting artesunate-based combination therapies improve patient survival, emerging parasite drug resistance may compromise this benefit and anti-malarials are not designed to treat inflammatory injury to blood vessels. Recent work suggests that imatinib, an FDA-approved kinase inhibitor, targets asexual blood stage parasite growth and improves parasite clearance rates when used in a triple-combination therapy in uncomplicated malaria cases. Kinase signaling plays a key role in hyper inflammatory pathways that leads to endothelium dysfunction and targeting these kinases may offer new host-targeted therapies for preventing excessive inflammation. To identity new drug compounds with dual activity against parasite growth and host inflammatory pathways, we screened 28 FDA-approved kinase inhibitors targeting various signaling cascades for regulating barrier pathways in primary human brain microvascular endothelial cell (HBMEC) monolayers and in asexual parasite growth assays. Notably, we found two classes of drugs (BCR-ABL and MEK inhibitors) that were dual-acting with both barrier protective against thrombin, the main clotting enzyme elevated in inflammatory conditions and implicated in endothelial dysfunction, and the ability to inhibit intraerythrocytic *P. falciparum* growth. Our work demonstrates a novel dual role of kinase inhibitors in maintaining BBB integrity and targeting malaria parasite development. Thus, kinase inhibitors dual benefit for CM by targeting parasite growth and as an adjuvant novel therapy to restore the BBB after excessive inflammation.

Despite the widespread use of effective anti-malarials, the case fatality rate of severe malaria (SM) remains unacceptably high. Adjunctive therapies that target the host response to malaria infection may decrease mortality over that of anti-malarial agents alone. Rosiglitazone, a peroxisome proliferator-activated receptor-gamma (PPARg) agonist, has been shown to act on pathways implicated in the pathogenesis of SM including reducing inflammation and enhancing endothelial stability, as determined by decreased levels of angiopoietin-2, a surrogate maker of malaria severity and mortality. To test the hypothesis that rosiglitazone plus IV artesunate would improve outcome in SM over IV artesunate alone, we conducted a randomized, double-blind placebo-controlled trial in a rural hospital in Manhiça, southern Mozambique. The primary objective was to determine whether supplemental rosiglitazone (0.045mg/kg/dose) twice daily for 4 days, in addition to standard of care anti-malarial treatment (IV artesunate), accelerates the rate of decline in angiopoietin-2 from admission levels in children with severe malaria compared to standard of care plus placebo. We previously determined the safety and tolerability of rosiglitazone in children with uncomplicated malaria before proceeding to examine its efficacy in children with SM. Children with SM were enrolled between March 2016 and December 2019. We screened 203 children for eligibility and 180 children were enrolled: 91 children were assigned to rosiglitazone and 89 to placebo (all received IV artesunate). 85 were females (47.2%) and 95 were males (52.8%). 141 out 180 were younger than 5 years (78.3%) and 39 out of 180 were older than 5 years (21.6%). Secondary objectives included: comparing clinical outcomes between groups, quantifying the changes in biomarkers of disease severity and host response to treatment as well as assessing neurocognitive outcomes. Analysis of primary and secondary objectives is currently underway. We will present the results of this clinical trial.

0659

STRUCTURAL CHARACTERIZATION OF PHOSPHATIDYLSERINE DECARBOXYLASE A PROMISING THERAPEUTIC TARGET OF *PLASMODIUM FALCIPARUM* AND PREDICTION OF ITS POTENTIAL INHIBITORS

Mamadou Sangare[1], Cheickna Cisse[1], Mamadou Wele[1], Anne Searls De Groot[2], Seydou Doumbia[1], Jian Li[3], Jeffrey G Shaffer[3]

[1]African Center of Excellence in Bioinformatics (ACE-B)/USTTB,Mali, Bamako, Mali, [2]University of Georgia (UGA), Athens, Georgia, GA, United States, [3]Tulane University, New Orleans, LA, United States

Plasmodium falciparum is a protozoan parasite responsible for the most severe and deadly form of malaria. The resistance of this parasite to

last resort antimalarial drugs has been reported, so there is an urgent need to identify new therapeutic candidates for the development of new drugs. Bioinformatics is the most appropriate approach to predict therapeutic candidates in a reasonable time and at low cost. In this work, we propose *Phosphatidylserine Decarboxylase* (PSD) as a promising new target of *P. falciparum*. It is an enzyme extracted from the TDR Target database which facilitates the identification and prioritization of drugs and drug targets of neglected pathogens according to specific criteria. It is a member of the lyase family, more precisely the carboxy-lyases, which cut carbon-carbon bonds. *Phosphatidylserine decarboxylases* (PSDs) catalyze the decarboxylation of phosphatidylserine to generate phosphatidylethanolamine, a critical step in phospholipid metabolism in prokaryotes and eukaryotes moreover, phospholipid biosynthesis is essential for the development, differentiation and pathogenesis of several eukaryotic pathogens including *P. falciparum*. The model of this protein not previously characterized, structurally opens the way to the design of new potential inhibitors for the development of future antimalarial drugs.The main objective of this work is to build the 3D structure of PSD and to identify new inhibitors of this promising new therapeutic target. The 3D structure of the target protein was predicted using the Alphafold server and the ligands extracted from the zinc DB chemical library. The molecular docking was performed using autodock-vina. At the end of this study, we have identified ten (10) PSD inhibitors that should be studied experimentally to evaluate their antimalarial activities.

APOPTOSIS INDUCING ANTI-MALARIA DRUGS TARGETING PFGARP

Dipak K. Raj[1], Tanbir Najrana[1], Hannah Wu[1], Jenna Zuromski[1], Christian Nixon[1], Sunthorn Pond-Tor[1], Mandar Naik[1], Szu-Huan Wang[1], Kurt Pennell[1], Katherine Manz[1], Hoseah Akala[2], John Michael Ong'echa[2], Jeffrey Dvorin[3], Adel Nefzi[4], Andrew Oleinikov[5], **Jonathan D. Kurtis**[1]

[1]Brown University, Providence, RI, United States, [2]KEMRI, Kisumu, Kenya, [3]Harvard University/Boston Childrens Hospital, Boston, MA, United States, [4]Florida International University, Miami, FL, United States, [5]Florida Atlantic University, Bocca Raton, FL, United States

Previously, we discovered that anti-PfGARP kills up to 99% of trophozoite stage parasites in the absence of immune effector molecules or cells-antibody binding alone leads to parasite apoptosis. We reason that PfGARP is a high value druggable target based on: **1)** its surface expression on iRBCs, **2)** the absence of amino acid homology with host proteins, **3)** the absence of significant sequence variation in over 3,000 field isolates sequenced to date, and **4)** the ability of antibody binding to PfGARP to kill essentially all parasites within 12-24 hours. To develop drugs based on PfGARP binding, we screened 6,400 compounds from a small molecule library to identify compounds that inhibit the binding of anti-PfGARP to bead-immobilized rPfGARP protein. We idenitifed a single compound with anti-parasite activity in parasite growth assays. We performed a limited structure-activity relationship campaign of 48 structurally related analogs and identified two compounds with enhanced parasite killing activity with an IC_{50} of 1.8 - 4.8 uM in 3D7 parasites and no activity in PfGARP-KO parasites, indicating specificity for PfGARP. Treatment of *P. falciparum* with either drug results in rapid loss of mitochondrial membrane polarity, caspase-like activation, release of Ca^{++} from the food vacuole and DNA fragmentation- all hallmarks of apoptosis seen in anti-PfGARP treated parasites. Toxicity assessments in human monocytes, lymphocytes and BeWo cells show no loss of viability or proliferative capacity at up to 400 uM- the highest concentration tested. SPR studies demonstrate specific binding of both drugs to PfGARP (K_D = 29.9 and 24.8 nM) and this direct binding was confirmed in 2D-NMR studies. Following toxicology and PK studies in mice, we evaluated one compound in the NSG/*P. falciparum* humanized mouse model. Mice treated with our compound had a rapid and complete clearance of their parasitemia. Evaluation of these two compounds in freshly isolated field parasites is ongoing. These results validate a novel drug target (PfGARP) and screening approach (inhibition of antibody binding), and represent lead compounds for further anti-malarial development.

0661

THE POTENTIAL PUBLIC HEALTH IMPACT OF NOVEL MALARIA MONOCLONAL ANTIBODY INTERVENTIONS

Narimane Nekkab, Josephine Malinga, Lydia Braunack-Mayer, Sherrie Kelly, Melissa Penny

Swiss Tropical and Public Health Institute, Allschwil, Switzerland

The first candidate malaria monoclonal antibodies (mAbs) are undergoing clinical trial testing, yet the potential public health impact of these novel prevention tools is not well understood. Modelling can provide quantitative evidence linking mAb intervention characteristics to population-level impact and help identify minimum criteria for candidate selection to accelerate development. We use an individual-based mathematical model of malaria transmission coupled with analytical approaches to explore the multi-dimensional space of mAb characteristics, deployment factors, and population-level outcomes. Modelled mAbs characteristics are informed by pharmacokinetics (PK) and pharmacodynamics (PD) data from the first human mAb candidates CIS43LS and L9LS. We explore drivers of impact by modelling a range of efficacy characteristics, including duration of protection, and deployment strategies, including a range of coverage, in both seasonal and perennial transmission settings. For a single seasonal deployment of an anti-infective mAb co-administered with a blood-stage clearance drug given to children under five years old, we identified protective efficacy decay over time and half-life duration as crucial drivers of impact. Implementation factors such as coverage, access to care, and timing of deployment across transmission settings will greatly impact predicted reductions in clinical infections, severe disease, and mortality. For a single administration with at least 80% coverage among eligible children, mAb interventions that can achieve 80% efficacy against infection and 90-days protection can lead to 50% clinical incidence reduction. Candidates with rapidly decaying protection are likely to achieve less impact and a single deployment in perennial settings may not be sufficient to reduce incidence by 50%. While early mAb candidates have demonstrated safety and protection against infection in early clinical trials, our modelling highlights the need to understand better their PK/PD properties and implementation factors for different use-cases and standard of care comparators to best inform candidate selection.

[1]Menzies School of Health Research and Charles Darwin University, Darwin, Australia, [2]College of Medicine & Health Sciences, Arba Minch University, Arba Minch, Ethiopia, [3]Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia, [4]International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh, [5]Arba Minch General Hospital, Arba Minch, Ethiopia, [6]Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia, [7]Ethiopian Public Health Institute, Addis Abeba, Ethiopia, [8]Department of Parasitology, Faculty of Medicine, University of Indonesia, Jakarta, Indonesia, [9]College of Health Sciences, Addis Ababa University, Addis Abeba, Ethiopia

Plasmodium vivax forms dormant liver stages that can reactivate weeks or months following an acute infection. There is an increased risk of *P.*

vivax parasitaemia following falciparum malaria suggesting radical cure (killing dormant stages) could be beneficial in patients presenting with *P. falciparum* as well as *P. vivax* malaria. We conducted a multicentre, randomized, controlled, open label trial in Bangladesh, Indonesia and Ethiopia. Patients with uncomplicated falciparum malaria, ≥70% G6PD activity and hemoglobin levels ≥8g/dl were enrolled and randomized in a 1:1 ratio to either receive standard blood schizonticidal treatment plus 7-day high dose primaquine (total dose 7mg/kg) or standard blood schizonticidal treatment alone. Patients were followed up weekly until day 63. The primary endpoint is the incidence risk of any *P. vivax* parasitemia at day 63. Secondary outcomes include the proportion of adverse events and serious adverse events, the incidence risk of severe and very severe anaemia (Hb<5g/dl and <7g/dl) and/or the risk for blood transfusion and the incidence risk of a ≥ 25% fall in haemoglobin with and without hemoglobinuria. The trial is registered at clinicaltrials.gov (NCT 03916003). Between 18th August 2019 and 14th March 2022 a total of 500 patients were enrolled and followed for up to 63 days. The study has generated important data with policy and practice implications for countries co-endemic for both *P. falciparum* and *P. vivax*. The full results of the trial will be presented including a discussion on the need to expand the indications for radical cure of hypnozoite stages to facilitate *P. vivax* elimination.

0663

MECHANISTIC MODELLING OF PRIMAQUINE PHARMACOKINETICS, GAMETOCYTOCIDAL ACTIVITY, AND MOSQUITO INFECTIVITY

Joel Tarning[1], Palang Chotsiri[1], Almahamoudou Mahamar[2], Richard M. Hoglund[1], Fanta Koita[2], Koualy Sanogo[2], Halimatou Diawara[2], Alassane Dicko[2], Julie A. Simpson[3], Teun Bousema[4], Nicholas J. White[1], Joelle M. Brown[5], Roly Gosling[5], Ingrid Chen[5]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Malaria Research and Training Centre, Bamako, Mali, [3]University of Melbourne, Melbourne, Australia, [4]Radboud Institute of Health Sciences, Nijmegen, Netherlands, [5]University of California, San Francisco, CA, United States

Numerous clinical studies have shown that adding a single dose of 0.25 mg/kg of primaquine to standard antimalarial regimens rapidly sterilizes *Plasmodium falciparum* gametocytes. However, the mechanism of action and overall impact on malaria transmission is still unknown. Using data from 81 adult Malians with *P. falciparum* gametocytemia who received the standard dihydroartemisinin-piperaquine treatment course and were randomized to receive either a single dose of primaquine between 0.0625 and 0.5 mg/kg or placebo. Nonlinear mixed-effects modeling and simulation were used to characterize the pharmacokinetic-pharmacodynamic relationships for transmission blocking activity. Both gametocyte clearance and mosquito infectivity were assessed. A mechanistically-linked pharmacokinetic-pharmacodynamic model adequately described primaquine and carboxy-primaquine pharmacokinetics, gametocyte dynamics, and mosquito infectivity at different clinical doses of primaquine. Primaquine showed a dose-dependent gametocytocidal effect that preceded clearance. *In silico* simulations, based on data from these presumably chronically gametocytemic adults, suggested that approximately 70% of patients were predicted to be non-infectious within one day of administering a single primaquine dose of 0.25 mg/kg. These observations provide strong support for the current low dose recommendation. Adding a single dose of 0.25 mg/kg of primaquine to the standard ACT treatment for *P. falciparum* infection reduces transmissibility substantially, and should be recommended to accelerate malaria elimination.

0664

*WOLBACHIA W*ALBB INHIBIT DENGUE AND ZIKA INFECTION IN AUSTRALIAN *AEDES AEGYPTI* MOSQUITOES

Leon E. Hugo[1], Gordana Rašić[1], Andrew J. Maynard[2], Luke Ambrose[3], Catherine Liddington[4], Callum J. E. Thomas[5], Nisa S. Nath[1], Melissa Graham[1], Clay Winterford[1], BMC Randika Wimalasiri-Yapa[6], Zhiyong Xi[7], Nigel W. Beebe[3], Gregor J. Devine[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]School of Biological Sciences, Brisbane, Australia, [3]School of Biological Sciences, University of Queensland, Brisbane, Australia, [4]CSIRO, Brisbane, Australia, [5]School of Biological Sciences, University of Queensland, Herston, Australia, [6]The Open University of Sri Lanka, Columbo, Sri Lanka, [7]Michigan State University, East Lansing, MI, United States

Biological control of mosquito-borne arboviruses using insect-specific *Wolbachia* bacteria is an emerging strategy for the management of human arboviral diseases. We recently described the development of a new strain of *Aedes aegypti* mosquitoes (referred to as *w*AlbB2-F4 strain) infected with the *w*AlbB strain of *Wolbachia* using simple backcross mating of a *w*AlbB infected *Ae. aegypti* from the USA with wild type mosquitoes from Australia. Mass releases of male *w*AlbB2-F4 mosquitoes at trial sites resulted in substantial suppression of wild populations of mosquitoes through the strain's *Wolbachia*-induced cytoplasmic incompatibility. Here we show that the strain is resistant to infection with dengue and Zika viruses and is highly genetically similar to the Australian wild type strain. There was a highly significant reduction in the percentage of *w*AlbB2-F4 mosquitoes that become infected after feeding on a blood meal containing dengue 2 virus (16.7%) compared the wild type mosquitoes (69.2%). After feeding on an epidemic strain of Zika virus, there was a 6.7 fold reduction in the percentage of mosquitoes with virus in saliva. Further, there was a reduction in the intensity of dengue and Zika virus infection in *w*AlbB2-F4 mosquitoes, demonstrated by molecular detection and by immunofluorescence analysis of *Wolbachia* and the arboviruses in mosquito histological sections. We also showed that *w*AlbB2-F4 mosquitoes have 98% Australian ancestry though Restriction-site Associated DNA (RAD) sequencing and that the strain has equivalent insecticide resistance genotype and phenotype, critical attributes for successful strain establishment for biological control. The ease of which *Wolbachia w*AlbB can be transferred to a target mosquito population, installing virus inhibition and maintaining the target mosquito genetic background, demonstrates the great potential of this strain for biological control of mosquitoes and the pathogens they transmit.

0665

TARGETING MOSQUITO HYDROXYPHENYLPYRUVATE DIOXYGENASE (HPPD) AS A NOVEL STRATEGY FOR PREVENTING MALARIA TRANSMISSION

Anna Elizabeth Trett

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Progress in reaching the global malaria elimination targets requires investment in strategies to reduce disease transmission. One approach to blocking insect-borne disease transmission that is successfully employed in veterinary medicine, is the use of endectocides that render vertebrate blood toxic to blood-feeding insects. Recent studies have identified that an enzyme involved in the tyrosine detoxification pathway, 4-hydroxyphenylpyruvate dioxygenase (HPPD), is essential for blood-feeding arthropod survival. Using an FDA-approved HPPD inhibitor called nitisinone, we demonstrate that the malaria-transmitting mosquito, *Anopheles gambiae,* is rapidly killed upon ingesting nitisinone-containing bloodmeals. Furthermore, both insecticide-susceptible and insecticide-resistant mosquito strains likewise perish in a dose dependent manner. Proof-of-concept pharmacokinetic-pharmacodynamic (PK/PD) modelling of the dose-exposure-response relationship of nitisinone, administered at recommended doses for adults and children (3 x 1 mg/kg), shows improved efficacy against young, adult and insecticide-resistant mosquitoes compared to the current gold-standard ectoparasitic drug,

ivermectin. These data demonstrate that targeting *Anopheles* HPPD is a viable strategy for the development of new malaria transmission-blocking interventions.

0666

THE ROLE OF NOVEL IMMUNE MODULATORS AND ANTI-CTL4 NANOBODIES IN *ANOPHELES GAMBIAE* ANTI-*PLASMODIUM* IMMUNITY

Johnny Nakhleh[1], Maria L. Simões[1], Yuemei Dong[1], Ah-Ram Kim[2], George Dimopoulos[1]

[1]W. Harry Feinstone Department of Molecular Microbiology and Immunology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [2]Department of Genetics, Harvard Medical School, Boston, MA, United States

Anopheles gambiae is considered the main vector of the malaria parasite *Plasmodium falciparum*. However, the transmission of this parasite through the mosquitoes does not go unnoticed. On the contrary, *Anopheles gambiae* mosquitoes mount a potent immune response against the parasite. This immunity is characterized by a complex interaction between agonistic and antagonistic immune effector mechanisms and factors. Among these mechanisms is melanization that was recently shown to be an important immune effector mechanism against *P. falciparum* infections. Additionally, the C-type lectin 4 (CTL4) was shown to be an important factor that is recruited by *P. falciparum* to evade malanization. To gain insight on CTL4 function in mosquito immune responses, we have utilized a combination of *Plasmodium* ookinete interactome screening, genome editing and transient gene-silencing to identify factors that modulate CTL4-mediated protection of the malaria parasite. We have identified novel candidates belonging to the serine protease and thioester containing protein families in addition to other previously unknown factors as potential modulators of anti-*P. falciparum* immunity. Moreover, since CTL4 is considered a major transmission blocking target for malaria control, we have identified several anti-CTL4 nanobodies that that are explored for their *P. falciparum* transmission blocking activity.

LIFE HISTORY AND INFECTION CHARACTERISTICS OF *ANOPHELES STEPHENSI* MOSQUITOES FOLLOWING CRYOPRESERVATION

Peter Billingsley, Nicole Encardes, James Overby, Steve Matheny, Fantahun Addisu, Dimitri Koutzoumis, Jeremy Guth, B. Kim Lee Sim, Stephen L. Hoffman, Abraham Eappen, Eric R. James

Sanaria Inc., Rockville, MD, United States

Sanaria has developed a unique method for the cryopreservation of *Anopheles* eggs, allowing the long- term, stable storage of anopheline mosquitoes at minimal cost and effort. We have successfully and repeatedly cryopreserved many batches of *An. stephensi* eggs and successfully revived them from storage in Liquid Nitrogen Vapor Phase after periods of at least 5 years. Here we examine the life history characteristics of *A. stephensi* following thawing. We optimized conditions for small scale rearing of mosquitoes that matched life history traits - larval growth, pupation, eclosion, wing length, mating success, blood feeding success and fecundity - of *A. stephensi* reared in Sanaria's main insectary. Different batches of cryopreserved eggs were thawed, the hatch rates determined and L1 larvae transferred to the optimized rearing conditions side-by-side with L1 mosquitoes from the insectary. Cryopreserved eggs hatched over a longer period compared to insectary derived eggs, and this was reflected in a similar spread timeline at pupation. However, the adult mosquitoes resulting from cryopreserved eggs were able to mate, feed on blood and produce fecund eggs at rates similar to insectary-derived mosquitoes. We will present a detailed comparison of these life history traits and the capacity for offspring of cryopreserved mosquitoes to be infected with *Plasmodium falciparum*. Our data demonstrate clearly that cryopreservation of *A. stephensi* is sufficiently robust to enable generation of a new colony when needed, and adds an important element of security to Sanaria's vaccine manufacturing process.

PATTERNS THAT DRIVE MOSQUITO-FUNGUS ASSEMBLIES ARE MAINTAINED ACROSS MOSQUITO SPECIES

Patil Tawidian[1], Kerri L. Coon[2], Ari Jumpponen[1], Kristin Michel[1]

[1]Kansas State University, Manhattan, KS, United States, [2]University of Wisconsin-Madison, Madison, WI, United States

Microbial interactions in the larval environment provide nutritional value and cues that are critical for mosquito development to adulthood, and thus contribute to vector fitness. While the bacterial community assembly has been elucidated in several mosquito species, little is known about the interactions between fungal communities and mosquito larvae in their aquatic habitat. In this study, we used metabarcode sequencing of the fungal Internal transcribed spacer 2 (ITS2) marker to characterize the fungal communities associated with field-collected *Aedes albopictus*, *Culex pipiens*, and *Culex restuans* larvae and their breeding water. Reads were assigned to operational taxonomic units (OTUs) and amplicon sequence variants (ASVs) using the mothur (v.1.44.3) bioinformatics pipeline. Alpha diversity analyses of the water samples revealed diverse fungal communities in the aquatic habitats on a fine geographic scale. Comparisons of the Bray-Curtis dissimilarity matrices between the breeding water and larval tissues revealed that the gut-associated fungal communities were most similar to the aquatic environment and highly enriched in plant-associated fungi. In contrast, mosquito carcasses harbored fungal communities enriched in animal pathogens, revealing that in addition to mosquito feeding behavior, fungal substrate use is an additional driver of fungal community assembly in mosquito larvae. The observed differences between gut- and carcass-associated fungal communities were more evident in *Ae. albopictus* and *Cx. pipiens* than in *Cx. restuans* larvae. Taken together, our results show for the first time that the larval breeding water is the key determinant of fungal community assembly across taxonomically distant mosquito species, with little evidence for environmental filtering by the larval guts. The assembly of fungal communities in mosquito larvae is further influenced by fungal life history, and potential species-specific variations among mosquito species may be best explained by differences in larval feeding behaviors.

0669

THE EFFECT OF SUBLETHAL DOSES OF IVERMECTIN ON *ANOPHELES GAMBIAE* MIDGUT MICROBIOTA

Paula Lado, Tereza Magalhaes, Ashley Janich, Brian D. Foy

Colorado State University, Fort Collins, CO, United States

Ivermectin (IVM) is a safe endectocide commonly used in mass drug administrations for controlling neglected parasitic diseases. The drug also exhibits mosquitocidal efficacy, particularly against anopheline mosquitoes when they bite people given standard doses, and so it is now being assessed in clinical trials with the objective of reducing malaria transmission and clinical episodes in treated communities. It is well known that IVM affects mosquito physiology in different ways depending on the concentration ingested in the bloodmeal, but the effects of sublethal doses of IVM are not well understood. This study aimed at determining the effects of two sublethal IVM concentrations on the midgut microbiota of laboratory-reared *Anopheles gambiae*. *Anopheles gambiae* female mosquitoes were fed with a control bloodmeal (containing the vehicle dimethyl sulfoxide alone) or a bloodmeal spiked with IVM (5ng/ml or 15 ng/ml), and the microbiota analyzed at different timepoints post bloodmeal. The bacteria load was quantified by qPCR and also analyzed through NGS amplicon sequencing of the V4 region of 16S rDNA. Results from both approaches were consistent: the midgut microbiota is altered after a bloodmeal, but there is only a limited effect of sublethal concentrations of IVM on the overall composition of the midgut microbial community. The bacterial communities in IVM-treated

and control mosquitoes were dominated by three families; Weeksellaceae, Enterobacteriaceae, and Pseudomonadaceae, but alpha and beta diversity analysis showed that the midgut microbiota of treated mosquitoes was not significantly different from controls at most time points. However, a few bacteria genera were found to be present only in IVM-treated mosquitoes or only in controls. In the field, these modest changes due to IVM exposure may be amplified in certain mosquito populations which could impact their fitness, survival, or *Plasmodium* infection status.

ZOOPROPHYLAXIS-AIDED IVERMECTIN-BASED VECTOR ELIMINATION (ZAIVE), A RANDOMIZED VILLAGE-BASED ENTOMOLOGICAL TRIAL, CENTRAL VIETNAM

Estee Y. Cramer[1], Nguyen Xuan Quang[2], Jeffrey C. Hertz[3], Do Van Nguyen[2], Huynh Hong Quang[2], Ian H. Mendenhall[4], Andrew A. Lover[1]

[1]Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts-Amherst, Amherst, MA, United States, [2]Institute for Malariology, Parasitology and Entomology, Ministry of Health, Quy Nhon, Vietnam, [3]U.S. Naval Medical Research, Unit Two, Singapore, [4]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore

Treating cattle with ivermectin (IVM) has been proposed as an important contribution to malaria vector management, yet the impacts of IVM are untested in field trials. Through a randomized village-based trial, this study aimed to quantify the effect of IVM-treated cattle on the anopheline populations in treated vs. untreated villages in central Vietnam. Local cattle in three rural villages were treated with IVM and the cattle in three other rural villages were included as controls. The mosquito populations in all villages were quantified using cattle-baited traps for ten-days before and after the 2-day treatment administration period. The impact of the intervention was analyzed using a difference-in-differences (DID) approach with generalized estimating equations (negative binomial and robust sandwich errors). Secondary analyses assessing the impact of the dose/density of treated cattle were also examined. Across the intervention villages, 1112 of 1527 censused cows (73% overall; range 67% and 83%) were treated with IVM. In both control and intervention villages, there was a marked decrease in total anophelines captured in the pre- vs. post-treatment period of 30-40% during the study. In the control villages, 1873 vectors were captured pre- and 1079 were captured post-treatment. Corresponding numbers for intervention villages were 1594 and 1101 respectively. In preliminary model results for the primary DID analysis there is no evidence for a difference in the change in trapping between intervention and control villages (IRR = 1.2; 95% CI; 0.60-2.4; $p = 0.61$). In preliminary secondary analysis including total doses administered and treated animal density as covariates we found evidence for a significant decrease in trapped anopheline density in intervention villages relative to control villages (IRR = 0.34; 95% CI: 0.18 - 0.65; $p < 0.001$) in DID analysis. In order to more fully assess whether zooprophylaxis-aided ivermectin-based vector elimination (ZAIVE) may serve as a vital tool in village-level elimination initiatives, additional studies less impacted by temporal trends should be implemented.

0671

POPULATION ANALYSIS OF EASTERN EQUINE ENCEPHALITIS VIRUS DERIVED FROM INFECTED HUMAN BRAIN TISSUE: WITHIN- AND BETWEEN-HOST VARIATION

Rose M. Langsjoen[1], Autum Key[1], Sanda Alexandrescu[2], Isaac H. Solomon[3], Anne Piantadosi[1]

[1]Emory University, Atlanta, GA, United States, [2]Boston Children's, Boston, MA, United States, [3]Brigham and Women's Hospital, Boston, MA, United States

Eastern equine encephalitis virus (EEEV) is a mosquito-borne, neuroinvasive alphavirus in the family Togaviridae. Although reported human cases have remained low since it was first formally described in the 1930s, Eastern equine encephalomyelitis represents one of the most severe viral encephalitides in the Western hemisphere. Thus, it is critically important to understand EEEV evolution, particularly as it pertains to emergence and neuroinvasion. To this end, we sequenced EEEV RNA obtained from formalin-fixed, paraffin-embedded brain samples from discrete brain regions of three human patients that had succumbed to infection. We constructed consensus sequences for all patients, as well as from discrete brain regions (including the frontal lobe, thalamus, and midbrain) for one patient, which were used for phylogenetic analyses; interestingly, some consensus-level changes were noted between different brain regions for one patient. Further, for this same patient, intrahost single nucleotide variant (iSNV) analyses revealed differential minority variant populations and diversity between discrete brain regions, suggesting the potential for intrahost evolution of EEEV as it traverses different brain regions. Together, these data provide novel and important insights into both inter- and intrahost evolutionary dynamics of EEEV.

A RETROSPECTIVE GENOMIC SURVEILLANCE OF CHIKUNGUNYA TRANSMISSION IN MINAS GERAIS STATE, SOUTHEAST BRAZIL

Hegger M. Fritsch[1], Marta Giovanetti[1], Joilson Xavier[1], Talita E R Adelino[2], Vagner Fonseca[3], Jaqueline G. de Jesus[4], Ronaldo de Jesus[5], Carla Freitas[5], Cássio R L Peterka[6], Carlos F C de Albuquerque[3], Ana M B de Filippis[1], Rivaldo V. da Cunha[7], Erniria C. Silva[8], Luiz C J Alcantara[1], Felipe C m Iani[2]

[1]Laboratório de Flavivírus, Instituto Oswaldo Cruz, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Laboratório Central de Saúde Pública do Estado de Minas Gerais, Fundação Ezequiel Dias, Belo Horizonte, Brazil, [3]Organização Pan-Americana da Saúde / Organização Mundial da Saúde, Brasília, Brazil, [4]Laboratório de Patologia Experimental, Instituto Gonçalo Moniz, Fundacão Oswaldo Cruz, Salvador, Brazil, [5]Coordenação Geral dos Laboratórios de Saúde Pública, Secretaria de Vigilância em Saúde, Ministério da Saúde, Brasília, Brazil, [6]Coordenação Geral das Arboviroses, Secretaria de Vigilância em Saúde/Ministério da Saúde (CGARB/SVS-MS), Brasília, Brazil, [7]Fundação Oswaldo Cruz, Bio-Manguinhos, Rio de Janeiro, Brazil, [8]Coordenadoria Estadual de Vigilância das Arboviroses/Secretaria de Estado de Saúde de Minas Gerais, Belo Horizonte, Brazil

Brazil accounted for a total number of 1,276,194 notified cases of Chikungunya fever between 2014 and in 2022. Additionally, since 2015 the country is also showing an increasing death toll in which the northeast and southeast regions appear to report the worst scenario. Although the CHIKV transmission dynamics have been studied in many parts of the country after its introduction in 2014, little is still known about the CHIKV transmission and genetic diversity in the state of Minas Gerais, located in southeast Brazil. Moreover, no studies have been published characterizing CHIKV genomic surveillance in this state. Thus, to retrospectively explore the CHIKV epidemic in Minas Gerais we generated 40 genomes by nanopore sequencing from clinical samples. Phylogenetic analysis indicated multiple introductions of CHIKV occurred likely from northeastern Brazilian states, with the most recent common ancestral dated to early March 2016, which is in agreement with local epidemiological reports. Additionally, epidemiological data revealed a decline in the number of reported cases over 2017-2021 indicating that population immunity to CHIKV decreases waves of infections. Together, our results shed a light on the dispersion dynamics of CHIKV and showed that infections decreased from March 2017 to January 2021 despite of multiple introductions in Minas Gerais state. In conclusion, our study highlights the importance of combining genomic and epidemiological data in order to assist public health laboratories in monitoring and understanding the patterns and diversity of mosquito-borne viral epidemics.

CHIKUNGUNYA: PHASE 3 CLINICAL DEVELOPMENT OF A SINGLE-SHOT LIVE-ATTENUATED VACCINE

Vera Bürger, Martina Schneider, Sandra Hadl, Marivic Narciso, Robert McMahon, Sebastian Töpfer, Ulrike Fuchs, Romana Hochreiter, Annegret Bitzer, Karin Kosulin, Robert Mader, Oliver Zoihsl, Katrin Dubischar, Nina Wressnigg, Susanne Eder-Lingelbach, Juan Carlos Jaramillo

Valneva Austria GmbH, Vienna, Austria

VLA1553 is a live-attenuated chikungunya virus (CHIKV) vaccine candidate designed for active immunization as a prophylactic measure. Due to the sporadic epidemic occurrence of chikungunya, an immunological surrogate to assess clinical efficacy was accepted by regulators. A double-blinded, multicenter randomized, pivotal phase 3 study enrolling 4115 healthy adult volunteers, aged 18 years and above, randomized in a 3:1 ratio to receive VLA1553 or placebo was performed across 43 study sites in the United States (US) (NCT04546724). The primary objective of the study was to evaluate the immunogenicity and safety of VLA1553 28 days after immunization and as secondary objective participants were followed up to 180 days. Immunogenicity evaluations were analyzed in a pre-selected subset of 501 participants at 13 study sites across the US. The pivotal trial met its primary endpoint with 98.9% of subjects achieving seroprotection (263 of 266 participants in the per-protocol immunogenicity subgroup). The immunogenicity profile was maintained over time. Geometric mean titers peaked at day 29, then decreased subsequently, however stayed well above the seroprotective level of antibodies in 96.3% of participants until day 180 (233 of 242 participants in the per-protocol subset tested for immunogenicity). The vaccine was also confirmed to be highly immunogenic in older adults (≥ 65 years), who achieved equally high seroprotection rates and neutralizing antibody titers as younger adults (< 65 years). VLA1553 was also well tolerated with a favourable safety profile. The generation of protective titers in nearly 100% of vaccinated participants analyzed indicates VLA1553 is an effective candidate for the prevention of disease caused by the CHIKV.

0674

A PHASE 2 OPEN-LABEL STUDY TO ASSESS THE SAFETY AND IMMUNOGENICITY OF AN ALUM-ADJUVANTED CHIKUNGUNYA VIRUS-LIKE PARTICLE (VLP) VACCINE IN PRIOR RECIPIENTS OF OTHER ALPHAVIRUS VACCINES VERSUS ALPHAVIRUS NAÏVE CONTROLS

Melinda J. Hamer[1], Benjamin Pierson[2], Jeannine Haller[2], Christine Lee[1], Jack N. Hutter[1], Karen Martins[2], Pamela Glass[2], Dani Liggett[2], Aaron Sanborn[1], James E. Moon[1], Melissa Gregory[2], Crystal W. Burke[2], Christina L. Gardner[2], Neha Ghosh[3], Lisa Bedell[3], David Saunders[4], Jason A. Regules[1], James M. McCarty[5]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Fort Detrick, MD, United States, [3]Emergent BioSolutions, Gaithersburg, MD, United States, [4]Uniformed Services University (USU) F. Edward Hebert School of Medicine, Bethesda, MD, United States, [5]Stanford University, Stanford, CA, United States

Immune responses to alphavirus vaccines may be impaired when heterologous alphavirus vaccines are administered sequentially. The purpose of this Phase 2 open-label study was to evaluate the safety and immunogenicity of CHIKV VLP vaccine in prior recipients of heterologous alphavirus vaccines. Adults 18-65 years with prior receipt of an investigational alphavirus vaccine (N=30) and gender/age matched alphavirus vaccine-naïve controls (N=30) were administered 1 dose of 40 µg alum-adjuvanted CHIKV VLP vaccine. The primary immunogenicity endpoint was the CHIKV SNA seroconversion rate (defined as 4-fold rise over baseline) at Day 22. Immunogenicity was assessed by luciferase-based serum neutralizing antibodies (SNA) and safety was assessed by solicited/unsolicited adverse events (AE) and serious adverse events (SAE). The majority of solicited AEs were of mild/moderate severity, with two grade 3 solicited events, both in alphavirus vaccine-naïve subjects (2/30). The most common systemic solicited AEs were headache, occurring in 7/30 and 4/30 subjects, and myalgia occurring in 4/30 and 7/30 subjects in the prior alphavirus vaccine and alphavirus vaccine-naïve groups, respectively. Injection site pain was reported by 13/30 prior alphavirus vaccine recipients and by 9/30 subjects in the alphavirus vaccine-naïve group. There were no vaccine-related SAEs. The anti-CHIKV SNA seroconversion rate at Day 22 was 100% in both groups. A higher percentage of prior alphavirus vaccine recipients (93.3%) had a 4-fold SNA rise at Day 8 than alphavirus vaccine-naïve controls (66.7%, p=0.021). The GMTs peaked in both groups at Day 22 and were similar between the groups on Day 22 and all subsequent visits. Prior alphavirus vaccine recipients also exhibited a significantly stronger and more rapid anti-CHIKV total IgG antibody response by ELISA as compared to the alphavirus vaccine-naïve controls. This alum-adjuvanted CHIKV VLP vaccine was well tolerated and immunogenic in both alphavirus vaccine-naïve and prior recipients of a heterologous alphavirus vaccine; there was no significant difference in the incidence of AEs between the groups.

0675

IMMUNOLOGICAL INSIGHTS BASED ON ANTIBODY BINDING EPITOPES ON THE CHIKUNGUNYA VIRUS ENVELOPE

Edgar Davidson[1], Rachel H. Fong[1], Rebecca Rimkunas[1], Hayley Crawford[1], Lewis J. Stafford[1], Jin Jin[2], Graham Simmons[2], Michael S. Diamond[3], James E. Crowe Jr.[4], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Vitalant Research Institute, San Francisco, CA, United States, [3]Department of Medicine, Washington University, St Louis, MO, United States, [4]Departments of Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN, United States

To identify Chikungunya virus (CHIKV) structures that elicit a protective immune response, we have epitope mapped over 70 monoclonal antibodies (MAbs) against the CHIKV envelope glycoprotein E2/E1, using a comprehensive shotgun mutagenesis library of 910 E2/E1 alanine-scan mutants. Published studies used epitope maps to characterize broadly cross-reactive and ultrapotent neutralizing MAbs that blocked post-attachment steps, and that bound to functionally-important E2 domains A or B, suggesting that MAbs inhibit virus-host membrane fusion by preventing exposure of the E1 fusion loop. Additional studies characterized MAbs that induce structural changes on E2 A and B. Other mapped MAbs included human E1-specific MAbs cross-reactive across alphaviruses, isolated from survivors of equine encephalitis virus infection. MAb binding and epitope mapping identified differences in E1 reactivity based on exposure of epitope on E1 through pH-dependent mechanisms or presentation on the cell surface prior to virus egress. We also used CHIKV E2/E1 mutants to map the binding site on E2 A and B domains of cell adhesion molecule Mxra8, identified as enhancing attachment and internalization into cells of CHIKV and other alphaviruses, by infectivity screens of cells targeted by CRISPR/Cas9 gene knockouts. We also isolated human MAbs against CHIKV E2/E1. Our most potent MAb, IM-CKV063, was highly neutralizing (50% inhibitory concentration, 7.4 ng/ml), showed high-affinity binding (320 pM), and gave therapeutic and prophylactic protection in animal models up to 24 h post-exposure. Epitope mapping identified an inter-subunit conformational epitope on E2 domain A. Subsequent studies demonstrated that IM-CKV063 blocks both virus entry and virus release. To provide critical reagents for analyses of MAb or serum immune responses to CHIKV infection, we developed a pseudotyped lentiviral reporter virus system for CHIKV, using reporter virus particles (RVPs) displaying E2/E1. The replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2), reproducible virus neutralization assays with luminescent or fluorescent readout.

0676

IL2/ANTI-IL2 COMPLEX FOR THE TREATMENT OF CHRONIC CHIKUNGUNYA VIRUS ARTHRITIS IN A MOUSE MODEL

Sarah Renee Tritsch, Abigail J. Porzucek, Abigale Eichelman, Arnold M. Schwartz, Richard Amdur, Christopher N. Mores, Aileen Y. Chang

George Washington University, Washington, DC, United States

Chikungunya virus (CHIKV) is an alphavirus characterized by disabling joint pain that causes persistent arthritis in one-fourth of patients. Foot pad CHIKV inoculation in a mouse model causes localized swelling and systemic infection, with histologic evidence of arthritis, synovitis, periostitis and myositis. Preliminary data suggest that altered regulatory T cell (Treg) function may play a role in CHIKV arthritis. Interleukin-2 (IL2) therapies for autoimmune disease have been shown to up-regulate Tregs. We hypothesized that chronic CHIKV arthritis is associated with deficient Treg levels; thus, we tested the therapeutic effects of IL2, an anti-IL2 monoclonal antibody (mAb), and an IL2/anti-IL2 mAb complex in a mouse model. Our aims were to 1) describe the role of IL2 in Treg expansion and CHIKV arthritis severity, and 2) determine the role of IL2 in the treatment of CHIKV arthritis. In our study, mice inoculated via foot pad injection were confirmed CHIKV-positive by qRT-PCR at 2 days post infection (dpi) and CHIKV-negative by 16 dpi. Mice were then treated for 3 days with placebo, IL2, anti-IL2 mAb, or complex. Tarsal joint measurements showed an increase in swelling of infected tarsal joints that peaked at 6 dpi and returned to baseline by the end of the study, with the complex treated group showing the steepest drop in swelling at 17 dpi. IL2 levels increased significantly at 19 dpi compared to 2 dpi, with a 349% increase in IL2 mice, 821% in anti-IL2 mAb mice, and 3990% in complex mice. Flow cytometry determined a large increase in Treg numbers and activity in complex-treated mice, but a decrease in IL2-treated mAb mice and no significant change in IL2-treated mice. Tarsal joint histology showed more mice with severe arthritis in the PBS and IL2 groups compared to the anti-IL2 mAb and complex groups. The data suggest that complexing IL2 with the anti-IL2 mAb makes it more biologically available, resulting in a greater impact on Tregs, and decreasing overall inflammation and joint degradation. These findings indicate the need for clinical studies using an IL2/anti-IL2 complex to treat chronic CHIKV arthritis.

PATHOGENESIS OF CHIKUNGUNYA VIRUS ASSOCIATED WITH FATAL OUTCOMES

William M. de Souza[1], Marcilio J. Fumagalli[2], Shirlene T. Lima[3], Jeany Delafiori[4], Priscilla P. Barbosa[4], Stefanie P. Muraro[4], Gabriela F. Souza[4], Viviane S. Boaventura[5], Ester C. Sabino[6], Ricardo Khouri[7], Rodrigo R. Catharino[4], Luiz Tadeu M. Figueiredo[8], Nuno R. Faria[9], José Luiz P. Modena[4], Scott C. Weaver[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]The Rockefeller University, New York City, NY, United States, [3]Central Public Health Laboratory of Ceará State, Fortaleza, Brazil, [4]University of Campinas, Campinas, Brazil, [5]Universidade Federal da Bahia, Salvador, Brazil, [6]University of São Paulo, São Paulo, Brazil, [7]Fundação Oswaldo Cruz-Fiocruz, Salvador, Brazil, [8]University of São Paulo, Ribeirao Preto, Brazil, [9]Imperial College London, London, United Kingdom

Chikungunya virus (CHIKV) is a mosquito-borne virus that can cause acute, subacute, or chronic human diseases. Recently, CHIKV has caused over 10 million reported cases in more than 125 countries. Since 2004, CHIKV has been associated with increased deaths in Asia and America. However, the host response mechanisms associated with these fatal outcomes remain poorly understood. Here, we combined molecular, genomic, and metabolomic approaches to investigate potential mechanisms that could contribute to fatal CHIKV outcomes. Our data show that CHIKV-fatal cases are characterized by multiple infected organs and a median viremia ~13-fold higher than that measured in CHIKV-survivors. CHIKV-fatal patients exhibited significantly elevated serum levels of pro-inflammatory cytokines compared to CHIKV-survivors, such as IL-6, MCP1, IFN-α, and TNF-α. Notably, serum and CSF levels of IFN-λ3(IL-28b) were higher in CHIKV-fatal than those detected in CHIKV-survivors. Phylogenetic analysis confirmed that patients with both outcomes were infected by the East/Central/South African genotype. A high proportion of CHIKV-fatal cases sequenced were infected with a CHIKV variant carrying one amino acid change at residue 243 in the E2 protein (E2-R243H). This single mutation increases the surface area and interaction of the CHIKV trimeric E1/E2 spike heterodimer with the MXRA8 receptor, and also stabilizes the spike. Metabolomic analysis revealed that metabolite signatures following CHIKV infection overlap with those of hemodynamic shock, implying that reductions of vasopressin (essential for cardiovascular homeostasis), chondrosine (critical for connective tissue and extracellular matrix), and isoxanthopterin (indicative of oxidative stress) could explain hallmarks of fatal CHIKV infection. Collectively, our data suggest that the CHIKV-fatal outcomes result from multi-systemic infection altering endothelial cell integrity, hemodynamic shock, and inflammation resulting in multiple failure organs, leading to death. Overall, this study reveals insights into CHIKV pathogenesis and suggests potential biomarkers for CHIKV outcomes.

0678

PROVINCIAL UNDER-FIVE MORTALITY AND KEY CHILD HEALTH POLICY INDICATORS IN THE CONTEXT OF PROTRACTED CONFLICT: SECONDARY ANALYSIS OF HOUSEHOLD AND FACILITY DATA IN THE DEMOCRATIC REPUBLIC OF CONGO

Mattias Schedwin[1], Aurélie Bisumba Furaha[2], Richard Kapend[3], Pierre Akilimali[4], Espoir Bwenge Malembaka[5], Helena Hildenwall[1], Tobias Alfvén[1], Thorkild Tylleskär[6], Mala Ali Mapatano[4], Carina King[1]

[1]Department of Global Public Health, Karolinska Institutet, Stockholm, Sweden, [2]Paediatric Department, Hôpital Général de Référence de Bukavu, Bukavu, Democratic Republic of the Congo, [3]School of Criminology and Criminal Justice, University of Portsmouth, Portsmouth, United Kingdom, [4]Kinshasa School of Public Health, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [5]Center for Tropical Diseases and Global Health, Université Catholique de Bukavu, Bukavu, Democratic Republic of the Congo, [6]Centre for International Health, University of Bergen, Bergen, Norway

Considerable provincial variation in under-five mortality has been observed in the Democratic Republic of Congo, but the relationship with conflict is unclear. We compared provincial coverage of key child health policy indicators, and explored their association with under-five mortality rates and conflict. We performed secondary analysis of the: 2017-18 Service and Provision Assessment; 2018 Multiple Indicator Cluster Survey; and Uppsala Conflict Data Program Georeferenced Event Dataset. Indicators, taken from three global action plans, were generated at the provincial level and collapsed into combined mean scores for: newborn health, pneumonia, diarrhoea, malaria, and safe environment. Negative binomial regression compared scores with provincial mortality rate. Binary logistic regression at the individual level compared indicators (outcome) with living in a conflict affected province (exposure), defined as >25 battle related deaths/year. All coverage scores demonstrated substantial provincial variation: newborn health: 20—61%, pneumonia: 30—86%, diarrhoea: 25—63%, malaria: 22—53%, safe environment: 4—53%. Diarrhoea score demonstrated the strongest association with mortality (coeff: - 0.026; 95% CI: -0.045, -0.007). Conflict-provinces both had the highest and lowest mortality rates and indicator coverages. Children in conflict-provinces had higher odds of being covered by 13 out of 23 indicators, compared to non-conflict provinces (1/23). Conflict alone is a poor predictor for child health. It is important to ensure that children in non-conflict provinces do not get neglected whilst addressing the needs of the most vulnerable in conflict settings. Prevent, protect, and treat strategies for diarrhoeal disease could help improve equity in child survival.

0679

THE IMPACT OF FAMILY PLANNING UTILIZATION AMONG ADOLESCENTS GIRLS ON MATERNAL AND CHILD HEALTH OUTCOMES

Navideh Noori[1], Joshua L. Proctor[1], Yvette Efevbera[2], Hao Hu[3], Elisabeth D. Root[1]

[1]Institute for Disease Modeling, Global Health, Bill & Melinda Gates Foundation, Seattle, WA, United States, [2]Gender Equality, Bill & Melinda Gates Foundation, Seattle, WA, United States, [3]Gender Data & Insights, Gender Equality, Bill & Melinda Gates Foundation, Seattle, WA, United States

Adolescent pregnancy and motherhood are associated with an increased risk of numerous poor maternal and child health outcomes. The majority of adolescent births are within the context of girl child marriage (before age 18). The health-seeking behaviors of adolescent girls and young women are different from the behaviors of women in older age groups. Exploring the compounding effect of pre-pregnancy and postpartum contraceptive use, as a proxy for accessing health services, on improving maternal and child survival rates can help optimize the timing and location of maternal, newborn, and child health (MNCH) interventions that incorporate family planning. We use Demographic and Health Surveys (DHS) data in Sub-Saharan Africa (SSA) and South Asia to examine the spatiotemporal heterogeneities in girl child marriage and childbearing patterns as well as adolescent girls and adolescent mothers health-seeking behaviors. Our analysis shows that the risk of mortality among children born to adolescent mothers who had a history of using any type of contraceptive method before was lower, and overall, a risk gradient by maternal age appeared in different regions even after adjusting for the health-seeking variables. Using family planning services could represent a proxy for accessing health services overall. Interventions focused on expanding contraceptive access and use could help women to increase choice and spacing in their fertility decisions.

BRINGING TOGETHER CIVIL SOCIETY AND ACADEMIA IN RESPONSE TO COVID-19 VACCINE INEQUITY: EARLY LESSONS FROM THE VACCINE ADVOCACY ACCELERATOR — UGANDA PROJECT

Azfar D. Hossain[1], Mastulah Nakalule[2], Amir Mohareb[3], Cliff Abenaitwe[4], Richard Hasunira[4], Esther J. Kilande[4], Stuart Ssebibubbu[4], Kenneth Mwehonge[4], Stephen Asiimwe[2], Louise C. Ivers[5]

[1]Harvard Medical School, Boston, MA, United States, [2]Global Health Collaborative, Mbarara University of Science and Technology, Mbarara, Uganda, [3]Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, [4]Coalition for Health Promotion and Social Development, Kampala, Uganda, [5]Center for Global Health, Massachusetts General Hospital, Boston, MA, United States

Inequitable global access to COVID-19 vaccines remains a public health and moral crisis. Our objective was to join local activists affected by COVID-19 vaccine shortages (who best understand community needs and perspectives) and academic institutions (which offer scientific authority and other assets) for evidence-based advocacy demanding COVID-19 vaccines for lower-income countries. Together, the Global Health Collaborative at Mbarara University of Science and Technology (an academic partnership in Uganda supported by Massachusetts General Hospital) and the Coalition for Health Promotion and Social Development (a health advocacy organization in Uganda) formed the Vaccine Advocacy Accelerator — Uganda (VAX-Uganda) project, spotlighting vaccine shortages and delivery challenges in Ugandan communities via activities in Uganda and the US. Using academia's grant-writing experience, we applied for and received donor funding for 12-months of advocacy. From activist connections, we recruited 29 Ugandan organizations to form a coalition focused on COVID-19 vaccine access. Other partnership accomplishments include: an investigative report aired on Ugandan national news calling for transparency in government funding for COVID-19 vaccination; pieces in The New York Times and STAT News countering claims of widespread "vaccine hesitancy" in African countries; and a letter sent by 32 Ugandan organizations to the US Agency for International Development in response to misleading COVID-19 vaccination claims, leading to regular accountability meetings between US agencies and Ugandan civil society. Activities will continue through 2022, including an inter-ministerial meeting in Uganda to accelerate COVID-19 vaccination for children and a study of COVID-19 vaccine supply at four Ugandan vaccination sites. While the ultimate impact of VAX-Uganda on COVID-19 is to be determined, the project has created new platforms for Ugandan voices to reach key decision-makers, grounds US academic science and advocacy on global vaccine equity in authentic partnership, and provides one model for partnership between activists and academia.

INNOVATION AND JUDICIALIZATION OF HEALTHCARE: USING DESIGN-THINKING TO SECURE THE RIGHT TO HEALTH IN COLOMBIA

Kajal Khanna[1], Santiago Pardo Rodriguez[2], Santiago De Francisco Vela[2], Laura Guzman-Abello[3]

[1]Stanford University, Stanford, CA, United States, [2]Universidad de los Andes, Bogota, Colombia, [3]Universidad de Los Andes, Bogota, Colombia

From 2018-2021, Colombians filed 954 554 tutelas (judicial actions which enable citizens to seek protection of their rights) with roughly 30% of them health-related. Rights-based litigation can result in plaintiffs receiving medical needs or structural remedies redistributing health resources. In countries where judicialization of healthcare is a means of health systems reform, judges are integral to the health system. Ensuring that judges can make equitable decisions in dynamic environments, such as pandemics, can present a complex challenge. Design thinking, increasingly used in healthcare, offers solutions that respond to people's needs through empathy, intuition, creativity, and the generation of innovative ideas. We sought to use design methodology to innovate how Colombian judges access information on science, health equity, and legal precedent to make decisions on the right to health. In 2020, we conducted a two-semester design-challenge at the Universidad de los Andes on health-tutelas. Forming interdisciplinary teams, design, engineering, and law students used design thinking for their projects. Core design thinking principles such as contextualization of the problem, information analysis and counter-proposal, ideation and prototyping, and definition and specification were introduced. Students were able to contextualize the problem and identify practices around tutela decision-making. They determined that judges rely on the claimant's proof and lacked time to extensively research medical conditions or existing resource constraints. Using this information, students developed a prototype that was tested with justices. From this prototype, a minimal viable product is being developed and will be tested in the Colombian judicial system. To our knowledge, this is the first course to approach the burden of health tutelas through design thinking and demonstrates the feasibility of using this methodology to tackle problems at the interface of law and medicine. Further research is needed to determine the optimal means of introducing design methodology into legal and medical workplaces outside of the academic setting.

ENGAGING NATIONAL STAKEHOLDERS IN THE CO-DESIGN OF A NOVEL CHEMOPREVENTION MALARIA INTERVENTION: THE EXPERIENCE OF THE IPTI+ PROJECT IN BENIN, CAMEROON, COTE D'IVOIRE, AND MOZAMBIQUE

Meredith Center[1], Roly Gosling[2], Stephen Poyer[3], Jacques Kouakou[1], Lilly Claire Ekobika Ngom Priso[4], Dominique Bomba Amougou[5], Elsa Nhantumbo[6], Baltazar Candrinho[7], Bernard Ahoga Elegbe[8], Cyriaque D. Affoukou[9], Hans Bahibo[1], Colette Kokrasset[10]

[1]Population Services International, Abidjan, Côte D'Ivoire, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Population Services International, Washington, DC, United States, [4]Association Camerounaise pour le Marketing Social, Yaounde, Cameroon, [5]Programme National de Lutte contre le Paludisme, Yaounde, Cameroon, [6]Population Services International, Maputo, Mozambique, [7]Programa Nacional de Controle da Malaria, Maputo, Mozambique, [8]Association Beninoise pour le Marketing Social et la Communication pour la Sante, Cotonou, Benin, [9]Programme National de Lutte contre le Paludisme, Cotonou, Benin, [10]Programme National de Lutte contre le Paludisme, Abidjan, Côte D'Ivoire

Since 2010, WHO has recommended the delivery of SP to infants through routine EPI services at 10 weeks, 14 weeks, and 9 months in areas of moderate-to-high transmission. Intermittent Preventive Treatment in infants (IPTi) reduces clinical malaria by 30% and anemia by 21%, but prior to 2022 only Sierra Leone had implemented IPTi at scale. Updated WHO chemoprevention guidance in 2022 will move away from prescriptive limits on number of doses, geographies, age ranges and drug types. Anticipating this change, the IPTi+ Project is supporting countries to adapt and expand IPTi coverage by increasing the age range, delivery channels and number of doses, building on a country's existing systems. In late-2021 we conducted 4-day intervention co-design workshops in Benin, Cameroon, and Cote d'Ivoire (with Mozambique scheduled for May 2022) with stakeholders from malaria and immunization programs, the MOH HMIS team, maternal, child health and community programs, WHO, CSOs, health workers from a range of channels and other stakeholders. Project staff prepared a master agenda, presentations, and facilitation guide, which were adapted to each country context during a two-day pre-meeting with country teams and malaria program representatives. Workshop facilitation used adult learning techniques and small group work to develop country-designed and owned expanded IPTi models. Project staff played a facilitation role only and final decision-making was through consensus by country participants. Agreed models were responsive to existing country plans and dialogues for chemoprevention. Benin and Cameroon adopted an eight-dose model reaching children up to two years, leveraging vaccination and Vit A contacts. Cote d'Ivoire selected a five-dose model building on EPI and Vit A contacts though 18-months of age. CHWs played an important role in all designs: supporting sensitization and community mobilization in all countries and SP delivery in Cameroon. Building on the relationships and trust engendered through the co-design workshops, the project is now collaborating with MOHs to execute their IPTi+ models through pilot implementation.

0683

HIV CARE, PREVENTION, AND SEXUAL AND REPRODUCTIVE RIGHTS OF MIGRANT FEMALE SEXUAL WORKERS FROM VENEZUELA LIVING IN THE DOMINICAN REPUBLIC

Robert Paulino-Ramirez[1], Erica Felker Kantor[2], Monica Faccini[3], Maureen Canario de la Torre[1], Analia Henriquez-Cross[1], Mayra Rodriguez-Lauzurique[1], Arachu Castro[2]

[1]Instituto de Medicina Tropical & Salud Global, Universidad Iberoamericana, Santo Domingo, Dominican Republic, [2]School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States, [3]Centro de Promoción y solidaridad Humana, Puerto Plata, Dominican Republic

This study aims to identify the elements of vulnerability of Venezuelan female sex workers (FSW) and the existing obstacles in their search for sexual and reproductive health care in Santo Domingo and Puerto Plata. A mixed-methods study design was employed consisting of four focus group discussions with 2-7 participants per group. A cross-sectional quantitative survey was administered to a small sample (n=40) of Venezuelan female sex workers. Focus group discussions were analyzed using thematic content analysis to identify key themes related to the study objectives. Quantitative data were analyzed using univariate frequency and descriptive analysis. Key themes that emerged from the focus group discussions included legal status and its implication on access to health services and formal employment, mental well-being and quality of life in the DR, navigating sex work, perceptions of sex work, sexual and reproductive health knowledge, and limited social support. Results from the quantitative analysis indicated that the majority of participants struggled with depression (79%), loneliness and isolation (75%), and difficulty sleeping (88%). Participants reported an average of 10 sexual partners in the past 30 days, 55% engaged in sexual practices while under the influence of alcohol, and only 39% had used a condom when performing vaginal, anal or oral sex in the past 30 days. Seventy-nine percent had taken HIV-test in the past 6 months and 74% knew where to seek HIV services. Most participants sought care from the public sector (68%), whilst reporting that confidentiality (100%) and receiving integrated health services (100%) were the most important factors for deciding where to seek care. This study contributes with the knowledge of migrant experiences and social exclusions by several health determinants. Results offer key insights for researchers, advocates, and policymakers working with migrant population and the development of structural and behavioral interventions. In all, aiming towards a health policy design structural and behavioral interventions to reduce HIV risk factors and improve well-being of women in the DR.

NEURAL TUBE DEFECTS: MAKING SENSE OF THE UNEXPECTED

Markus Breines[1], Mohammed Aliyi[2], Kidist Asnake[2], Berhanu Damise[2], Mohammed Ousmael[2], Gurmu Feyissa[2], Getahun Wakwaya[2], Nega Assefa[2], Lola Madrid[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Haramaya University, Harar, Ethiopia

Neural tube defects (NTD) can result in severe disability, child death and stillbirth. The biomedical causes for NTDs have been explored widely and there is ample evidence of how NTDs can be prevented through folic acid supplementation. In rural communities in low-income countries, with limited access to healthcare, however, babies born with malformations and stillbirth have often been explained in terms of "God's will". In eastern Ethiopia, we conducted focus group discussions and interviews with mothers of children born with NTDs, health workers, traditional birth attendants, and other community members identified a wider range of perspectives on the underlying causes of NTDs. Unsurprisingly, health workers provided explanations of NTDs that were based on biomedical perspectives. Mothers of babies with NTDs suggested that hard work or accidents during pregnancy could possibly have been the causes, but more commonly referred to the will of Allah will to make sense of giving birth to babies with NTDs. Their explanations emphasized Allah as a force that made choices they had no control over, whereas other people in the communities, who had no experience of having children with NTDs, suggested that Allah was punishing parents for having sinned or behaved badly towards people with malformations. Although some provided explanations of NTDs related to natural phenomena, narratives of why some people gave birth to NTD cases were more commonly based on ideas that Allah gave people what they deserved. As a result of the perceived connection between behavior and NTDs many mothers hesitated to share

their experiences. These findings of how people in different positions explained the causes illustrate that people could be at risk of stigma and rumors through association with NTDs, which highlight the importance of taking into account and being sensitive to local perceptions when trying to reduce the cases of NTDs in Ethiopia and elsewhere.

0685

VULNERABILITY AND AGENCY IN RESEARCH PARTICIPANTS' DAILY LIVES AND THE RESEARCH ENCOUNTER: A QUALITATIVE CASE STUDY OF PARTICIPANTS TAKING PART IN SCRUB TYPHUS RESEARCH IN NORTHERN THAILAND

Rachel C Greer[1], Nipaphan Kanthawang[1], Jennifer Roest[2], Tri Wangrangsimakul[1], Michael Parker[2], Maureen Kelley[1], **Phaik Yeong Cheah**[1]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]The Ethox Centre, University of Oxford, Oxford, United Kingdom

Health researchers have a responsibility to conduct locally important research and protect participants especially "vulnerable" participants from harm. Group based vulnerability has been increasingly challenged, and vulnerability is increasingly understood to be context specific, yet limited guidance is available.This study aims to explore research participants' daily vulnerability and agency, and how these interact with their research experiences. A qualitative case study was conducted around two ongoing scrub typhus research studies in Chiangrai, northern Thailand (NCT03083197-clinical trial, NCT02915861- observational study). We conducted 42 semi-structured interviews with research participants, their families, researchers and key informants. The majority of the research participants belonged to a hill tribe ethnic minority group and some did not speak Thai or have Thai citizenship. We found that common challenges participants faced when participating in research were related to Thai language barriers, uncertain legal status, unstable employment, living remotely, lack of education and healthcare. Despite these challenges people demonstrated agency in their daily lives and were often supported in this by family members. People's daily challenges could be hidden from researchers such as participants' long journey to the research facilities, the need for family members to accompany them due to travelling concerns or language barriers. This could result in higher costs, family members missing work and burdens on family members' as well as the research participant's time. Despite these challenges, the majority of research participants perceived research to be beneficial. These were related to increased access to healthcare and gaining knowledge about their own health. We conclude that definitions of research vulnerability should consider participants' situations. Our data support the growing call to redefine the concept of research vulnerability away from group-based classifications to more nuanced definitions that take into account participants' situations and abilities.

EVALUATING THE EFFECTIVENESS OF GLOBAL HEALTH PARTNERSHIPS FOR DISEASE ELIMINATION - A SYSTEMATIC REVIEW

Girija Sankar

CBM, Bensheim, Germany

There is limited evidence on the critical success factors for global health partnerships. Yet, despite the limited evidence, donors have increased their support of such partnerships in the last 20 years. There is hence a need to understand the different types of partnerships in global health and identify factors contributing to the efficiency and effectiveness of partnerships. I conducted a systematic review of literature on coalition-building in global public health to identify criteria under which global health partnerships are considered essential for the success of global disease elimination efforts and reviewed the methods used to evaluate the efficiency and effectiveness of global health partnerships. I included studies from searches on databases such as Pubmed using search terms and criteria established a priori. I analyzed the studies that met the inclusion standards and synthesized study findings using a scoring mechanism that scored the studies on evaluation metrics and conceptual frameworks. Findings from 22 studies met the criteria for inclusion. Of these, three studies included metrics to assess both global health partnership processes and impact. Seventeen studies included a conceptual framework to analyze the efficiency or effectiveness of global health partnerships. Of the 35 global health partnerships that were reviewed in the selected studies, 13 partnerships supported drug and vaccine development, and 12 promoted access to pharmaceutical products to advance disease elimination. One philanthropic donor either directly or indirectly supported fifty percent of the studies included in the review. Transparency, communication, governance, inclusion, and representation were the process measures that most studies used to review the operational performance of global health partnerships. None of the studies established a causal linkage between partnership performance and disease outcomes. This review found that a multi-disciplinary approach to evaluating global health partnerships addresses the dynamic contexts within which such partnerships operate.

ENUMERATING THE CHANGING BURDEN OF ALL-CAUSE FEBRILE ILLNESS IN INFANTS AND YOUNG CHILDREN IN LOW- AND MIDDLE- INCOME COUNTRIES

Tasmin L. Symons[1], Paulina Dzianach[1], Punam Amratia[1], Susan Rumisha[1], Paul Castle[1], Ewan Cameron[2], Daniel J. Weiss[2], Peter W. Gething[2]

[1]Telethon Kids Institute, Perth, Australia, [2]Telethon Kids Institute & Curtin University, Perth, Australia

Fever is a nonspecific symptom of a many tropical pathogens, including potentially deadly malaria infections, dengue fever, and severe bacterial or virile infections. Even in the absence of severe illness, febrile episodes are likely to prompt care-seeking. As such, changes in all-cause fever burden will have downstream impacts on health-system utilisation, including demand for diagnostic testing and treatment. To understand spatial and temporal trends in fever incidence we developed a spatio-temporal model of all-cause fever prevalence in 151 low-and-middle-income countries using a generalised additive mixed model based 279 nationally-representative surveys conducted between 1990 and 2020. This period prevalence (enumerated by the answers to the survey question 'has [child's name] been ill with a fever at any time in the last two weeks?') was converted to incidence using a rigorous mathematical formula which respects the censoring inherent in the survey question, and so is more accurate than naïve approaches extrapolating fortnightly period-prevalence to incidence, even when accounting for introduced uncertainty in the mean duration of febrile episodes. We found that between 2000 and 2019 the incidence of fevers decreased from an average of 7.22 (6.30-8.16 95% CI) episodes per child per year to 5.17 (4.53-5.81), corresponding to a decline in the mean period prevalence of fevers from 0.26 (0.23-0.28) to 0.19 (0.18-0.21). The largest declines were observed in Sub-Saharan Africa, with all-cause fever period prevalence in under-fives decreasing from 0.39 (0.36-0.41) in 1990 to 0.21 (0.20-0.22) in 2019. In 2019 we predicted an incidence of 5.56 billion (4.85-6.23 billion) distinct febrile episodes in under-fives, with the highest incidence rates in the Middle East, North Africa and Sub-Saharan Africa. Our results show a shift in geographic burden of fevers: in 1990 infants in sub-Saharan Africa experienced 66% more febrile episodes per year than the global average, falling to 14% in 2019, whilst in North Africa and the Middle East fever burden has remained steadily above the global average since 1990.

0688

COST EFFECTIVENESS ANALYSES OF THREE METHODS TO TRAIN HEALTH WORKERS IN ANGOLA: IN-CLASSROOM TRAINING, SELF-LEARNING, AND BLENDED LEARNING

Henrik Axelson[1], Luis Bolanos[2], **Anya Fedorova**[2], Alex Ergo[1]

[1]Population Services International, Washington, DC, United States, [2]U.S. President's Malaria Initiative Health for All Project, Population Services International, Luanda, Angola

In 2020, the Angolan Ministry of Health launched an innovative e-learning platform called Kassai in 6 provinces to build Malaria Case Management capacity among health workers (HWs) and address challenges with in-classroom traditional training, such as variation in quality of materials and delivery, staff absence from facilities for training, limited individual tailoring for knowledge and learning pace. By March 2022, Kassai had over 3,500 enrolled learners, using two approaches: (1) fully digital self-learning, or (2) a blended learning mix of face-to-face training and digital tools on the Kassai platform, targeting HWs with less access to technology and fewer digital skills, often in distant communities. Using 2020 baseline data, we conducted a cost-effectiveness analysis of the two Kassai approaches compared to in-classroom traditional training, for the period 2021-2025, to inform policy discussions on the scale-up potential and associated cost. Average and marginal costs were estimated using the ingredients approach and included costs for staff, contractors, venue, lodging, transportation, per diem, equipment, fees, and opportunity costs. Effectiveness was measured as the number and proportion of HWs successfully completing trainings (scoring > 75% in post evaluation test). We assumed successful completion rates of 80% (blended learning), 50% (self-learning) and 42% (traditional in-classroom), based on project records. Cost-effectiveness was measured as the average cost per successful trainee. The Kassai self-learning approach was the most cost-effective of the three training methods, followed by Kassai blended learning. The marginal cost of successfully training one HW using self-learning was 13 times more cost-effective than in-classroom training (projection to 2025), and 7 times more cost-effective than blended learning. Future training approaches should consider a combination of self-learning and blended learning, to cater for differential HW Internet access and required level of support. Both methods are less expensive to scale up compared to in-class traditional training.

0689

DETERMINING SAFE NPI RELAXATION STRATEGY IN INDIA DURING THE DELTA AND OMICRON WAVES OF COVID-19: FINDINGS FROM A TWO-STRAIN COVID-19 TRANSMISSION MODEL

Ting-Hsuan Wu, Alicia N.M. Kraay, Benjamin Lopman

Emory University, Atlanta, GA, United States

The use of non-pharmaceutical interventions (NPIs) has been a critical strategy to slow and prevent the spread of SARS-CoV-2 during the COVID-19 pandemic. Dynamic transmission models have been developed to project the course of the pandemic under various assumptions. This study aimed to (1) validate a two-strain SEIR transmission model by comparing COVID-19 cases and deaths for the Delta wave and (2) project the course of the pandemic during the time period where transmission is driven by the Omicron variant, comparing different strategies of NPI relaxation. We compared model-projected and reported COVID-19 cases and deaths in India over 180 days starting from July 27th, 2021. The difference (projected - reported) and percent error were calculated to assess the degree of agreement between model projections and the reported data. We then updated model parameters with the best estimates corresponding to the Omicron wave and projected the number of COVID-19 cases and deaths over 180 days beginning from November 26th, 2021. While incidence increased slightly during the Onam festival, the model-projected cases for the Delta wave otherwise aligned with reported number of cases in India until late November 2021, with a mean percent error of 1.67% assuming a 12-week inter-dose interval and sustained NPIs throughout the simulation. This finding is consistent with NPI policies and the inter-dose interval used in India during the Delta wave, with larger differences beginning to emerge in late November 2021, when the Omicron variant emerged. Projections for the Omicron wave suggest that cases will peak earlier but at a lower level than they did in the Delta wave, with a smaller second peak occurring later during the simulation period due to the expected relaxation of NPIs once high vaccine coverage is reached. Overall, external validation of the two-strain SEIR model suggests that the model was consistent with cases in India. Moreover, our models suggest that NPIs might be able to be safely relaxed in late April as high vaccine coverage is achieved in India without large resurgences in cases.

0690

COVID-19 ASSOCIATED EXCESS MORTALITY IN BALIAKANDI, A RURAL DEMOGRAPHIC SURVEILLANCE SITE IN BANGLADESH

Kazi Munisul Islam[1], Mohammad Zahid Hossain[1], Qazi Sadeq-ur Rahman[1], Kyu Han Lee[2], Sanwarul Bari[1], Shams El-Arifeen[1], Emily S. Gurley[2]

[1]International Center for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]John Hopkins University, Baltimore, MD, United States

The Covid-19 has been associated with excess mortality in many countries. However, due to poor testing coverage in many lower and middle-income countries (LMIC), the number deaths caused by Covid-19 is likely underreported. Assessing whether total deaths were in excess of expected deaths can serve as a proxy for the number of deaths associated with the pandemic. In this study, we used data from a demographic and health survey in Baliakandi, Bangladesh (population 236,488 living in 261 villages) to estimate the excess deaths that occurred in 2020 and 2021 compared to 2019 and 2018, by age; in total, officials count of Covid-19 related deaths were only 25. We counted all deaths from every household during our regular visits to households ranging from once every 2-4 months. We examined the weekly number of deaths from January 2018 to December 2021 among all residents. To identify the excess deaths, we calculated the rolling average deaths for each calendar week, by taking the mean of that week, the prior and the following weeks. We calculated weekly all-cause excess mortality by deducting the observed count of deaths in 2021 and weeks 13-52 of 2020 (Covid-19 started to transmit from week 13 in 2020) with the expected weekly estimated deaths for that same calendar week and stratum. There were an average of 1364 deaths per year during 2018 and 2019. But in 2020 we observed 1516 deaths and in 2021, 1446 deaths in total. During 2020 (13 weeks and onwards) and 2021, there were 230 excess deaths (9.8/10,000 population) in the Baliakandi. We estimated 121 excess deaths among males and 109 among females. Residents aged 45-64 years had 68 additional deaths, 65 to 79-year age group had suffered highest with 126 additional deaths. The 80+ age group had an additional 64 deaths. There were no excess deaths in younger age groups. In our observed data and weekly analysis methods we found excess in all-cause mortality in the Baliakandi DSS area in 2020 and 2021, many of which were likely due to with Covid-19, given the age distribution of the excess deaths.

0691

DEVELOPMENT AND VALIDATION OF MANUALLY MODIFIED AND SUPERVISED MACHINE LEARNING CLINICAL ASSESSMENT ALGORITHMS FOR MALARIA IN NIGERIAN CHILDREN

Megan McLaughlin

THINKMD, Burlington, VT, United States

It is estimated that 67% of malaria deaths occur in children under-five years. To investigate improving the accuracy of Integrated Management of Childhood Illness (IMCI) point-of-care clinical risk assessment protocols for malaria in febrile children, a malaria rapid diagnostic test (mRDT) workflow was embedded into THINKMD's clinical risk assessment platform

to support a comparative analysis of THINKMD-generated malaria risk assessments with mRDT data. Assessments using the THINKMD mHealth tool were performed by 7 Community Health Workers (CHWs) on 555 children 2-59 months of age who presented with fever or history of fever (>37.5° C) to 5 participating clinics in Kano State, Nigeria over a 4-week period from July to August 2018. Among 480 children identified as at risk of malaria, 66.7% had positive mRDT results and 33.3% had negative mRDT results. THINKMD then manually modified its original malaria-risk algorithm to increase sensitivity by removing more strict criteria for clinical severity as a requirement for malaria risk. For the modified versus the original THINKMD algorithms, we observed a +44% in PPV for (+) mRDT and +44% in NPV for (–) mRDT when applying the original field-based data. To test our ability to improve both sensitivity and specificity of our algorithms, we utilized additional mRDT data to generate supervised machine learning (ML) algorithms using random forest models applying 80% of clinical data captured as the ML training set and 20% to test the new ML logic. Compared to the original logic, ML significantly improved THINKMD malaria risk assessment specificity (36-64%) and PPV (43-67%) for (+) mRDT with a minimal increase in both sensitivity and NPV. For (-) mRDTs, ML significantly improved THINKMD malaria risk assessments for specificity (70-98%), PPV (63-87%) and NPV (43-75%) with a decrease in sensitivity from (36-29%). Results demonstrate that combining mRDT "truth" data with digital mHealth platform clinical assessments and clinical data can improve identification of children with malaria/non-malaria attributable febrile illnesses and enable rapid, cost-effective modification of acute febrile illness logic.

0692

THE COORFAMILY APP: FEASIBILITY OF A 10-DAY LOCATION HISTORY CONTACT TRACING SMARTPHONE APPLICATION FOR FEBRILE PATIENTS IN CAMBODIA

Andrea R. Pacheco[1], Chanthap Lon[1], Sreyngim Lay[1], Sophana Chea[1], Meng Heng Oum[1], Sokna Ly[1], Ratanak Sath[1], Rathna Tim[1], Amnat Khamsiriwatchara[2], Peerawat Wansatid[2], Daniel M. Parker[3], Jessica E. Manning[1]

[1]International Center of Excellence in Research, National Institute of Allergy and Infectious Diseases, Phnom Penh, Cambodia, [2]Center of Excellence for Biomedical and Public Health Informatics, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Department of Population Health & Disease Prevention, University of California, Irvine, CA, United States

Travel history data are important for controlling infectious disease transmission. For example, travel history data are often used as part of contact tracing for respiratory and sexually transmitted diseases. The most common approach to collecting travel history data is through interviews, meaning that the data depend on patients to accurately report locations they have visited. Such data are prone to several types of bias (e.g. recall bias). Having a measure of travel history that does not rely on patient memory could therefore be valuable for public health efforts. In this project we have developed a mobile phone app (named "CoorFamily") to collect retrospective locational metadata that are stored in photos on mobile phones for a specified period of time (currently 10 days). The app is available on the Google Play store in English and Khmer. The "CoorFamily" name underlines users' contribution to community health. We have implemented this software as part of a project that aims to characterize the infectious disease landscape in Cambodia using metagenomic next-generation sequencing on samples from febrile subjects at 4 enrollment sites in Phnom Penh and Kampong Speu. Here we report on the beta phase of the software and operational challenges of its use. We tested the implementation of CoorFamily in a 10-week pilot study involving 295 volunteers. Of 295 subjects approached, 142 had compatible phones; of these, 141 agreed to participate, 44 successfully downloaded the app and sent data, and 6 provided usable geolocation data. The primary obstacles we encountered were incompatible phones and lack of photos with locational metadata. We identified one case where an individual had traveled outside of their home but reported no movement during the enrollment interview. Preliminary results suggest that CoorFamily could be a valuable supplement to current data collection practices, but that it needs further development. Alternative sources of location data (e.g. Google accounts) may be more comprehensive but are also more difficult to access. Additional feasibility and data quality analyses are ongoing and will be available at time of presentation.

0693

RESEARCH CAPACITY MONITORING AND EVALUATION SYSTEM: A ROBUST DYNAMIC WEB-BASED APPLICATION FOR MEASURING THE IMPACT OF RESEARCH CAPACITY STRENGTHENING INITIATIVES

Janice S. Maige[1], Asnath S. Mosha[1], Victor A. Mero[1], Samson S. Kiware[2]

[1]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [2]Ifakara Health Institute, Pan-African Mosquito Control Association, Dar es Salaam, United Republic of Tanzania

Developing national research capacity is considered an essential tool in increasing socio-economic development and population health. To support this, global development partners invest large amounts of funding yearly to support capacity building initiatives in Low- and Middle-income countries (LMIC's). However, the lack of generalizable monitoring and evaluation system poses a drawback to assess and/or initiate timely and impactful capacity building initiatives. Hence, there is a need to establish a dynamic tool to monitor and evaluate the impact of such initiatives based on well-established indicators. Here, we have developed a research capacity monitoring and evaluation web-based application (ReCAMES) that can be used across several research capacity strengthening initiatives. The evaluation metrics used by ReCAMES are given by points and grouped across the three indicator groups, i.e., Outcome, Output, and Impact. The indicators being skills attained and their application, their collaboration with other initiatives and/or stakeholders, knowledge translation done and recognition received from other institutions/parties. A graphical presentation of the progress achieved for each indicator is displayed on the dashboard for all participating individuals. An assessment of the impact of the program is also calculated and displayed on the system based on the same identified indicators. In addition, the system allows the principal investigator to provide access to all required stakeholders on different access levels to ensure data security. ReCAMES provides a dynamic framework with the ability to measure impact for research capacity strengthening initiatives performed in different settings. It can be used by diverse research capacity strengthening initiatives to assess their impact in the short and long term. ReCAMES can be used by a wide range of stakeholders such as research institutions, universities, funders, program evaluators and implementing partners.

MULTIMODAL VITAL SIGN DEVICES FOR SPOT-CHECKING: A LANDSCAPE REVIEW

Debashish Das[1], Sophie Crettaz[1], George Korir[1], Charlotte Arthur[1], Lava Shrestha[2], Kavi Ramjeet[1], Sabine Dittrich[1]

[1]FIND, the global alliance for diagnostics, Geneva, Switzerland, [2]Department of Clinical Physiology, Institute of Medicine, Kathmandu, Nepal

Monitoring of vital signs (pulse, blood pressure, body temperature, respiratory rate, oxygen saturation) can be a useful screening and triage tool for early severity assessment and informing referral decision at the first point of contact in low-resource settings. However, vital signs are often not measured or measured incompletely due to various reasons including lack of appropriate devices, lack of training of health care providers, cost of devices, and patient load. Therefore, multimodal devices (measuring >1 vital sign) suited for low-resource settings could be critical for improving early severity assessments at presentation ("spot-checks") to impact care and outcome of patients. A comprehensive review was conducted to document existing multimodal devices and assess the current and emerging landscape. Device selection criteria based on a preliminary target product profile, an assessment matrix, and definition of relevant use

cases were also developed and used to prioritise existing devices. A total of 150 devices were identified through database searches - Crunchbase, FierceBiotech, Google, Google Scholar, and ClinicalTrials.gov. Of 150 devices identified, 66% (99/150) were monitors, 28% (42/150) wearables, and only 9 (6%) handheld devices. The devices were scored and ranked using 20 predefined device attributes including device usability, design, performance and validation, and regulatory approval. Only a relatively small proportion of all available devices were deemed suitable based on pre-defined use cases (e.g. Checkme Pod Wireless Oximeter and Checkme Suit (Wellue, USA), Capnoxiplus (Capnoxi, China), Intellivue (Philips, Netherlands), Portable Multiparameter (Quirumed, Spain) and Neopenda (USA)). The landscape review revealed some promising devices for spot-checking patients at first presentation. Further, selected devices have limited validation data from LMICs. This review highlights that dedicated efforts to shape existing technologies for use in low resource settings remains critical. Moreover, targeted data generation is needed to inform procurement decisions and implementation efforts.

PREDICTING INFECTIOUS DISEASE SPREAD WITH FLIGHT PASSENGER DATA: THE IMPLICATIONS OF USING HISTORIC MOVEMENT DATA

Jack Wardle[1], Sangeeta Bhatia[1], Anne Cori[1], Pierre Nouvellet[2]

[1]Imperial College London, London, United Kingdom, [2]University of Sussex, Brighton, United Kingdom

The modern international flight network provides multiple routes by which pathogens can spread widely and quickly across the globe. During outbreaks of emerging or re-emerging pathogens, analyses using flight passenger data to identify countries at risk of importing the disease are common and can help inform disease control efforts. One challenge faced is that the latest aviation statistics are not always immediately available, either because the datasets can be slow and expensive to purchase, or the real-time data are unavailable. Therefore, flight patterns from a previous year or the average over multiple years are often used. Use of historic data may be a reasonable assumption if travel patterns are relatively stable but should human travel behaviour change, either voluntarily or due to the enforcement of travel policies, then use of historic movement data may introduce substantial errors into the modelled epidemic spread. In this work we retrospectively analyse the extent to which historic flight data are a good proxy for recent flight volumes and explore the level of bias that these proxies can introduce when predicting the spatial spread of epidemics. We use flight passenger data from the International Air Transport Association (IATA) from 2012 to 2021 to assess how baseline air travel patterns were affected in international infectious disease outbreaks over the past decade, including SARS-CoV-2, Zika, Ebola, MERS-CoV and Yellow Fever. We then explore the impact of using historic data compared to the true movement data in models of international infectious disease spread by comparing the predicted transmission hotspots. Our work highlights the importance of accessible and regularly updated measures of passenger flows between countries to aid the prevention and control of infectious disease outbreaks.

0696

COMPARATIVE ASSESSMENT OF METHODS FOR SHORT-TERM FORECASTS OF COVID-19 HOSPITAL ADMISSIONS IN ENGLAND AT THE LOCAL LEVEL

Sophie Meakin[1], Sam Abbott[1], Nikos Bosse[1], James Munday[1], Hugo Gruson[1], Joel Hellewell[2], Katharine Sherratt[1], Sebastian Funk[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Imperial College London, London, United Kingdom

Forecasting healthcare demand is essential in epidemic settings, both to inform situational awareness and facilitate resource planning. Ideally, forecasts should be robust across time and locations. During the COVID-19 pandemic in England, it is an ongoing concern that demand for hospital care for COVID-19 patients in England will exceed available resources. We made weekly forecasts of daily COVID-19 hospital admissions for National Health Service Trusts in England between August 2020 and April 2021 using three disease-agnostic forecasting models: a mean ensemble of autoregressive time series models, a linear regression model with 7-day-lagged local cases as a predictor, and a scaled convolution of local cases and a delay distribution. We compared their point and probabilistic accuracy to a mean-ensemble of them all, and to a simple baseline model of no change from the last day of admissions. We measured predictive performance using the Weighted Interval Score (WIS) and considered how this changed in different scenarios (the length of the predictive horizon, the date on which the forecast was made, and by location), as well as how much admissions forecasts improved when future cases were known. We found that assuming no change in current admissions is rarely better than including at least a trend, although forecasting accuracy varied by forecast date and location, depending on the trajectory of the outbreak. Using confirmed COVID-19 cases as a predictor can improve admissions forecasts in some scenarios, but this is variable and depends on the ability to make consistently good case forecasts. However, ensemble forecasts can make forecasts that make consistently more accurate forecasts across time and locations. Given minimal requirements on data and computation, our admissions forecasting ensemble could be used to anticipate healthcare needs in future epidemic or pandemic settings.

0697

ENHANCING FIELD SUPERVISION IN RURAL MOZAMBIQUE: TAKING ADVANTAGE OF THE GLOBAL POSITION SYSTEM (GPS) TO MONITOR FIELD WORKER PERFORMANCE IN REMOTE COMMUNITIES WITHOUT NETWORK CONNECTIVITY

Eldo Elobolobo[1], Paula Ruiz-Castillo[2], Saimado Imputiua[1], Humberto Munguambe[1], Edgar Jamisse[1], Vegovito Vegove[1], João da Silva[1], Ivan Bordo[1], Mirene Adao[1], Veronica Ribeiro[1], Patricia Nicolas[2], Hansel Mundaca[2], Regina Rabinovich[2], Francisco Saute[1], Carlos Chaccour[2], Charfudin Sacoor[1]

[1]Centro de Investigação em Saúde de Manhiça, Mopeia, Mozambique, [2]Barcelona Institute for Global Health - Campus Clinic, Barcelona, Spain

The supervision, tracking, and optimization of field work can be challenging when implementing health research projects in remote rural areas. Multiple factors can affect field worker performance and data quality, such as logistics, training, and incentives, but with the widespread use of electronic data collection methods, the limited network connectivity is the most challenging one. A demographic census using offline electronic data collection tool (ODK) was conducted in Mopeia district, Mozambique, in preparation for the BOHEMIA clinical trial, which aims at assessing the impact of ivermectin mass drug administration on malaria transmission. Due to the need to simultaneously monitor the performance of more than 300 field workers throughout the district, we developed a method to oversee the field activities in an offline environment. In addition, a mobile app that periodically captured and compacted the positions of the device using the global positioning system was installed on the tablets. This allowed supervisors to assess the routes taken by field workers, as well as the time they took to travel from one area to another, locate households, and fill out the electronic questionnaire. This system revealed that a large proportion of the fieldworkers spent the majority of their time in transit, traveling throughout the district and locating households, rather than carrying out the demographic census interview. This led to action, deploying field workers to be based in different areas of the district rather than traveling from the district headquarters. Moreover, the GPS monitoring tool showed that understanding the geography and other elements that affect the fieldworker's performance such as road conditions and distances between households, are crucial to plan and evaluate the quality of the field work at an individual level. Tools such as GPS can provide crucial support and strengthen field workers' productivity in the context of global health research and interventions.

0699

ESTIMATING TIME-VARYING REPRODUCTION NUMBERS FROM TEMPORALLY AGGREGATED INCIDENCE DATA

Rebecca K. Nash[1], Anne Cori[1], Pierre Nouvellet[2]

[1]Imperial College London, London, United Kingdom, [2]Imperial College London & University of Sussex, London, United Kingdom

The time-varying reproduction number (R_t) is an important measure of transmissibility during outbreaks; it can directly inform policy decisions and is critical for the optimisation of control measures in real-time. The R package EpiEstim is a widely used opensource tool that uses the incidence of new cases combined with a serial interval distribution (SI: time between symptom onset in a case and their infector) to estimate R_t. However, applications of EpiEstim can be limited by the fact that the incidence data and SI distribution need to be supplied on the same timescale. This currently precludes the use of EpiEstim (and other similar methods for estimating R_t) for pathogens with a mean SI shorter than the temporal aggregation of the incidence data. The routine reporting of many diseases, such as Influenza, is typically temporally aggregated (e.g., on a weekly basis), and as the SARS-CoV-2 pandemic persists, many systems are moving towards less frequent reporting. Therefore, routine estimation of transmissibility for these pathogens is not feasible with existing tools. Here, we address this issue by applying an expectation-maximisation algorithm approach to reconstruct daily incidence from temporally aggregated data, from which R_t can then be estimated using EpiEstim. We assess the validity of our approach using an extensive simulation study and apply the method to SARS-CoV-2 case and death data and a historical Influenza epidemic. We compare the R_t estimates obtained using data on different timescales and demonstrate that R_t can be accurately estimated from temporally aggregated incidence data and the estimation accuracy may even be improved by reducing the impact of prominent weekend effects in reported data. This extended version of EpiEstim is applicable to a wider range of diseases and data sources, which should enhance its use in pandemic and epidemic response globally.

0700

THE ETIOLOGY OF MESOAMERICAN NEPHROPATHY: ENVIRONMENTAL V. TOXIC V. INFECTIOUS?

James H. Diaz

Louisiana State University Health Sciences Center, New Orleans, LA, United States

Mesoamerican nephropathy (MEN) is a regional form of chronic kidney disease of unknown etiology (CKDU) confined to the Central American Pacific lowlands that afflicts young male agricultural and mining workers in areas without access to renal replacement therapies. Unrelated to common causes of CKD, such as diabetes and hypertension, MEN has several other regional risk factors. In order to identify and stratify the most significant risk factors for MEN to support epidemic-control interventions, a convenience sample survey queried Internet search engines with key words (MEN + CKDU) in order to identify case-control and cohort studies of MEN during the study period, 1990-present. Environmental risk factors for MEN included strenuous labor in high temperatures with inadequate rehydration. Toxic risk factors included agrochemical exposures, arsenic and cadmium in drinking water, high-purine-containing diets causing uricosuria, and abuse of NSAIDs and herbal pain remedies containing diethylene glycol or aristolochic acid for occupational musculoskeletal pain. Infectious risk factors included rodent-borne leptospirosis and hantavirus infections causing renal syndromes. Case-control studies that matched male coffee workers in the Central American highlands as controls with MEN cases in sugarcane workers in the lowlands did not detect MEN in controls. Both groups had similar agrochemical exposures, diets, and analgesic use eliminating toxic exposures as risk factors. In addition, another case-control study in a Nicaraguan mining community found no causal links between leptospirosis and hantavirus seroprevalence and MEN. Strenuous labor in high temperatures and inadequate hydration with beer or soda were the most significant risk factors for MEN. MEN-like clusters of CKDU have also occurred in India and will continue to occur among outdoor laborers throughout the tropics until agricultural and mining industries in developing nations are completely mechanized. Only occupational heat stress monitoring, evaluation, and prevention programs will curtail the current epidemic of MEN in young male workers in Central America.

0701

MAJOR CAUSE OF STILLBIRTHS AND NEONATAL DEATHS AND PREVENTIVE MEASURES: FEEDBACK FROM PREGNANT WOMEN AND MOTHERS OF YOUNG CHILDREN IN RURAL BANGLADESH

Muhammad Faruqe Hussain[1], Emily S Gurley[2], John Blevins[3], Maria Maixenchs[4], Abdush Suban Molla[1], Afroz Zahan[1], Aziz Ahamed[1], Shikha Datta Ggupta[1], Suruj Ali[1], Sazzad Hossain Khan[1], Tonmoy Sarkar[1], Dalia Yeasmin[1], Mohammad Zahid Hossain[1], Shams El Arifeen[1], Shahana Parveen[1]

[1]icddr,b, Mohakhali, Dhaka, Bangladesh, [2]Johns Hopkins University, Maryland, MD, United States, [3]Emory University, Atlanta, GA, United States, [4]ISGlobal, Hospital Clinic-Universitat de Barcelona, Barcelona, Spain

Child Health and Mortality Prevention Surveillance (CHAMPS) Program in Bangladesh analyzed pathological and multiple organ tissue sample reports from 82 stillbirths and early neonatal deaths. The determined major cause of these deaths was 'intrauterine hypoxia' and the recommended preventive measure to reduce high risk pregnancies is quality antenatal care (ANC). Communities need to be informed about the findings and evidence-based recommendations for preventive measures to improve use of ANC. We diffused the information among pregnant women, their family members, and mothers of young children in Baliakandi, a rural sub-district of Bangladesh and assessed their level of understanding and feedback. From March-December 2021 we conducted 26 courtyard sessions with pregnant women, their family members and neighboring women. Our team invited the them to a courtyard session when visiting households. A female team member facilitated each session and at the end of the session collected participants' feedback on the delivered messages through open and interactive conversations. All responses from participants were sorted and categorized. In total, 160 pregnant women, 244 family members and 263 neighboring women attended the courtyard sessions. According to them (~65%), 'intrauterine hypoxia', as the major cause of stillbirths and neonatal deaths in Baliakandi, was new to them and explanations of the preventive measures helped them to understand the importance of receiving quality ANC services. However, most common barriers to receive quality ANC were family conflict, lack of family support, financial incapability, delayed decision making and preference of taking alternative remedy during pregnancy complications. Pregnant women stated that following the recommended preventive measures is challenging because quality ANC services are not available in their area. The evidence-based etiology of stillbirth and neonatal death information and prevention messages could be integrated in health education programs and can be widely disseminated to all pregnant women in the CHAMPS catchment area including improving quality ANC services.

0702

COPING STRATEGIES OF HOUSEHOLDS DURING THE COVID-19 LOCKDOWN IN RURAL BANGLADESH

Atique Iqbal Chowdhury[1], Asraful Alam[1], Md. Mamunur Rashid[1], Jonathan A. Muir[2], Emily S. Gurley[3], Shams El Arifeen[1], Solveig A. Cunningham[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [2]Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [3]Bloomberg School of Public Health, John Hopkins University, Baltimore, MD, United States

Due to an increase in COVID-19 cases, the Bangladesh government implemented the first countrywide lockdown from March 27 to May 30, 2020. The resulting restrictions challenged people's livelihoods;

rural households adopted strategies to cope with reduced income. This study examined coping strategies across low, medium and high wealth households. A cross-sectional survey was conducted from November 7 to December 13, 2020 through a standing Demographic Surveillance System (CHAMPS-DSS, Baliakandi) with population=239,353. 1302 households were selected using simple (n=299) and stratified (n=1003) random sampling. A structured questionnaire was used to collect information on livelihood losses and coping strategies. Results show that 77% of households either lost their livelihood or experienced disruptions. Among the affected households, 31% did not use any coping strategies, 26% relied on savings, 14% sold assets, 14% and 10% borrowed and received financial support from friends and family, and 11% obtained a bank loan; only 4% received assistance from the government. Among households involved in farming, 10% had to sell their harvest in advance. Households' coping strategies were associated with their wealth; households with low wealth were less likely to have no coping strategies or to rely on savings compared to high wealth households (26% with no coping strategy and 21% relying on savings vs. 38% and 31%, p<0.05). Households with low wealth were more likely to have borrowed or received financial support from family and friends or to have taken bank loans than high-wealth households (17% borrowing, 14% receiving support, 15% took bank loan vs. 9%, 7%; and 6%, p<0.05). Households in the medium wealth group were more likely to have sold their harvest in advance compared to high wealth households (14% vs. 8%, p<0.05). Overall, the rural population of Bangladesh had to rely heavily on informal channels to cope with the financial losses resulting from lockdown; households with low and medium wealth were more involved in coping strategies. Thus, the study offers policy recommendations to enhance formal channels to mitigate such financial shocks.

0703

ACCEPTABILITY AND PERCEIVED FACILITATORS AND BARRIERS TO THE USABILITY OF BIOMETRIC REGISTRATION AMONG INFANTS AND CHILDREN IN MANHIÇA DISTRICT, MOZAMBIQUE: A QUALITATIVE STUDY

Olga da Gama Lobo Cambaco[1], Noni Gachuhi[2], Rebecca Rebecca[3], Carlos Cuinhane[4], Emily Parker[5], Estevao Mucavele[1], Quique Bassat[6], Celia Chauque[1], Francisco Saute[1], Khatia Munguambe[1], Charfudin Sacoor[1]

[1]Centro de Investigação em Saúde da Manhiça, Manhiça, Mozambique, [2]The Global Good Fund I, Bellevue, WA, United States, [3]Element Inc, New York, NY, United States, [4]Eduardo Mondlane University, Maputo city, Mozambique, [5]Element Inc., New York, NY, United States, [6]Barcelona Institute for Global Health, Barcelona, Spain

In low-and middle-income countries, many infants and children remain unregistered in both civil registration and healthcare records, limiting their access to essential rights-based services, including healthcare. A novel biometric registration prototype, applying a non-touch platform using smart phones and tablets to capture physical characteristics of infants and children for electronic registration, was tested in rural Mozambique. This is the first study to date to assess acceptability and perceived barriers and facilitators to the usability a biometric registration prototype in Mozambique. The study followed a qualitative design consisting of semi-structured interviews with healthcare providers (n=5), focus group discussions (FGDs) with caregivers of infants aged between 0 and 5 years old (n=7), and FGDs with data collectors involved in the implementation of the biometric registration pilot project (n=2) in Manhiça district, southern Mozambique. Data were thematically analysed. This study showed a high level of acceptability of the biometric registration prototype among healthcare providers and caregivers. We identified the following two acceptability factors: the biometric registration prototype was perceived to solve the inefficiency of paper-based registration, and the community perception of biometric registration as "healthcare norm". Despite this, participants expressed some reservations: myths and taboos, lack of information, lack of time, lack of father's consent, and potential additional workload among healthcare providers. In conclusion, the biometric prototype was widely accepted due to its perceived benefit and usefulness. These findings anticipate reasons for acceptability and advances recommendations to overcome the perceived barriers that are important to take into account prior to any future implementation of biometric registration.

0704

FACTORS ASSOCIATED WITH LOW ONE MINUTE APGAR SCORE IN PERI-URBAN GAMBIA

Nathalie Beloum[1], Bully Camara[1], Usman N. Nakakana[1], Fatoumata Sillah[1], Madikoi Danso[1], Joquina C. Jones[1], Shashu Graves[1], Kebba Manneh[2], Ebrahim Ndure[1], Yusupha Njie[1], Umberto D. Alessandro[1], Anna Roca[1]

[1]Medical Research Council Unit The Gambia at London School of Hygiene and Tropical Medicine (MRCG atLSHTM), Banjul, Gambia, [2]Bundung Maternal and Child Health Hospital (BMCHH), Banjul, Gambia

The Apgar score is a rapid assessment of the health condition of a newborn baby just after birth. At 1-minute, the score determines how well the baby tolerates the birthing process and establishes the needfor immediate resuscitation. A low Apgar score is associated with poor short and long-term healthoutcomes. This study aims to evaluate risk factors associated with a low 1-min Apgar score (Apgar score<7). This was an ancillary study of a cohort of newborns nested to a phase III, double-blind, placebo-controlled randomized clinical trial (PregnAnZI-2) conducted in two public health facilities situated inwestern Gambia. Data includes 6734 mothers and their 6773 live births (51 stillbirths excluded from theanalysis) enrolled in the trial, from Oct 2017 to May 2021. Analysis was done using R version 4.1.2.Multivariable logistic regression including variables associated with the outcome (low 1-min Apgar score)in the bivariate analysis (p-value<0.100) was performed. The analysis presented here is not stratified bytrial arm as the trial is still blinded. The prevalence of low 1-min Apgar score was 3.8% (258/6773). Up to80% (20/25) of neonatal deaths occurring within 24h after birth, and 43% (29/68) of overall neonataldeaths happened among newborns with low 1-min Apgar score. In the multivariate analysis, low 1-minApgar score was associated with primiparity [Adjusted odds ratio (aOR) 1.78; 95% CI 1.31-2.50), P<0.001],previous stillbirth [aOR 3.23; 95% CI (1.64-5.85), P<0.001], macrosomia (birth weight> 4kg) [aOR 2.33; 95%CI (1.01-4.76), P=0.03], and cesarean delivery [aOR 3.03; 95%CI (1.82-4.76, P< 0.001]. Results from thisstudy highlight that almost half of neonatal deaths happened among newborns with low 1-min Apgarscore. Therefore, effective interventions to decrease the prevalence of low 1-min Apgar score along witheffective clinical management of these newborns are urgently needed to contribute to the sustainabledevelopment goal target 3.2 of decreasing neonatal mortality to <12 or fewer deaths per 1,000 live births,by 2030.

0705

QUANTIFICATION OF FOETAL HAEMOGLOBIN (HBF) LEVELS IN HYDROXYUREA MONITORING THERAPY FOR CHILDREN WITH SICKLE CELL DISEASE (SCD) IN GHANA USING A NEW POINT-OF-CARE DIAGNOSTIC

Catherine Segbefia[1], Yvonne Dei-Adomakoh[2], Enoch Mensah[3], Priyaleela Thota[4], Isaac Odame[5]

[1]Korle Bu Teaching Hospital, Department of Child Health, University of Ghana Medical School, Accra, Ghana, [2]Korle Bu Teaching Hospital, Department of Hematology, University of Ghana Medical School, Accra, Ghana, [3]Department of Hematology, University of Ghana Medical School, Accra, Ghana, [4]Hemex Health, Portland, OR, United States, [5]Department of Pediatrics, University of Toronto, Toronto, Ontario, Canada, Toronto, ON, Canada

Sickle cell disease (SCD) is associated with extensive morbidity and early mortality. The majority of patients with SCD live in sub-Saharan Africa. SCD is a significant public health burden in Ghana affecting about 2% of newborns. Foetal hemoglobin (HbF) is a strong modifier of the severity of SCD. Elevated levels of HbF are associated with relatively mild clinical manifestations of SCD. HbF is also used as a marker of

compliance and response to disease modifying (hydroxyurea) therapy. Standard hemoglobin electrophoretic techniques are unable to quantify HbF. In resource-constrained settings such as Ghana, the use of high-performance liquid chromatography (HPLC) for HbF quantification is often challenging due to high cost and unavailability of laboratory equipment and skilled healthcare personnel. Here, we report the performance of a low-cost, point-of-care, microchip based cellulose acetate electrophoresis "GazelleTM" compared to HPLC for HbF quantification in Ghanaian children with SCD. GazelleTM is a fast (<8 minutes), easy-to-use test which can be performed by personnel with minimal training and using only a finger-prick volume of blood. This study was conducted at the paediatric SCD Clinic in Korle Bu Teaching Hospital, Accra, Ghana. Children of ages ≥ 1 year to 16 years who are known to have sickle cell disease, are about to commence hydroxyurea therapy, and followed at the paediatric sickle cell clinic were enrolled in the study. This study is currently ongoing. A total of 110 children were included in the analysis. Gazelle showed a correlation of 0.93 when compared to HPLC with an average error of 3.52%. Haemoglobin variants are quantified by Gazelle offering the ability to monitor disease modifying therapy in SCD such as hydroxyurea, where quantification of HbF levels is the key to assessing treatment adherence and monitoring response to therapy. Gazelle has the potential to be utilized as a point-of-care test for quantification of foetal haemoglobin (HbF) levels in monitoring hydroxyurea therapy for children with SCD.

0706

IMPLEMENTING A GROUP-BASED MULTICOMPONENT EARLY CHILD DEVELOPMENT INTERVENTION THROUGH THE GOVERNMENT HEALTH SYSTEM IN RURAL BANGLADESH: A FEASIBILITY STUDY

Md. Mahbubur Rahman

International Center for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

Children in low- and middle-income countries face an increased risk of poor cognitive development due to contaminated environments poor nutrition and a lack of stimulating and responsive interactions with their caregivers. Implementation of multi-component, community-level interventions may reduce these risks; however little evidence supports implementing integrated interventions at scale. To address this research gap in 2019-2020 we implemented a group-based intervention that was delivered by government health workers and included responsive stimulation, maternal and child nutrition, water sanitation and hygiene, maternal mental health, and childhood lead exposure prevention in rural Bangladesh. We aimed to assess the feasibility of implementing this multi-component intervention through the government health system. After the intervention, we conducted 17 in-depth interviews with government frontline health service providers and 12 key informant interviews with supervisors and managers at the local and national levels to explore the facilitators and difficulties of implementing such intervention. Factors facilitating implementation included high-quality training for the providers for conducting sessions, level of provider's skill, support from the community, family and supervisors, and trustworthy relationships with community residents. Notable difficulties were increased workload of the providers, lack of proper readiness of the health care centers and difficulties managing intervention commodities. Key informants suggested solutions to facilitate scale-up of integrated interventions through the government health system engaging relevant NGOs as partners, identifying feasible ways to produce and distribute low-cost commodities, encourage intervention participants to make child stimulation toys from recycle materials on their own, and offering providers monetary or non-monetary rewards. These findings can be used to shape the design and implementation of multicomponent child development interventions to be delivered through the government health system.

0707

USABILITY AND ACCEPTABILITY EXPERIENCE OF VIRTUAL INTERVIEWS AMONG RESEARCHERS AND PARTICIPANTSIN A LMIC SETTING DURING AMID OF COVID-19: A QUALITATIVE STUDY

Abdul Momin Kazi[1], Nazia Ahsan[1], Rawshan Jabeen[1], Raheel Allana[1], Qudsia Anwer[1], Waliyah Mughis[1], Saima Jamal[1], Ayub Khan[1], Syeda Quratulain Zaidi[1], Fauzia Aman Malik[2]

[1]Aga Khan University, Karachi, Pakistan, [2]Yale University, New Haven, CT, United States

Recently, qualitative researchers implemented virtual strategies to collect data to comply with the COVID-19 SOPs. Similarly, we also used virtual platforms to conduct FGDs(n=7) and IDIs(n=60) among participants and key informant interviews (KII n=4) with research team to identify the end user experience of Zoom and connect call's usability and acceptability. This exploratory qualitative study was an integrated part of a larger funded study about role of mHealth and social media during COVID pandemic. We used connect call system for conducting IDIs and KII with caregivers and researchers, further we used ZOOM for FGDs with healthcare providers and data was analyzed by using thematic approach. We explored that virtual platforms including connect call and ZOOM application as acceptable tools for qualitative data collection among urban and rural population. However, parents/caregivers were not aware of ZOOM application and half of the population had no smart phones. Due to lack of digital literacy among participants, researchers were struggling to make them understand the entire process of the interviews. However, this was managed through pre-scheduled discussions. The end users found these mediums user friendly, convenient and accessible during the time of pandemic. In addition, researchers revealed it as a cost and time effective tool for data collection. Researchers preferred ZOOM for FGDs as it provides data confidentiality as well as opportunity for a larger group discussion over connect call. Technical issues identified were mike issue, sound quality and networking issues specially in a rural setting. We conclude that virtual platforms like ZOOM and connect call are usable and acceptable among urban and rural population; however, unavailability of mobile phones and lack of digital literacy were found as a major barrier. Thus, we advocate user-friendly Apps and virtual platforms capable of increasing the use and accessibility of virtual instruments for enhancing research techniques.

0708

EVALUATING THE LANDSCAPE OF COMMUNITY HEALTH IN THE DEMOCRATIC REPUBLIC OF CONGO TO PROVIDE RECOMMENDATIONS FOR A STRENGTHENED COMMUNITY HEALTH APPROACH

Léa Vervoort[1], Holly Nicole Kandel[1], Jimmy Anzolo Mongonda[2], Jean Paul Ndakala[3]

[1]Clinton Health Access Initiative, Kinshasa, Democratic Republic of the Congo, [2]PATH, Kinshasa, Democratic Republic of the Congo, [3]Sous commission santé communautaire, Kinshasa, Democratic Republic of the Congo

Strengthening community participation in the fight against major endemics like malaria remains a MOH priority in the Democratic Republic of the Congo (DRC). Prompt diagnosis and treatment is the most effective way to prevent a mild case of malaria from developing into severe disease and death. Yet, despite having more than 15,000 community health workers (CHWs) providing health services across the country, only 9% of all malaria infections were detected by CHWs in 2021. To better understand the challenges to the successful implementation of the community health approach in the DRC, CHAI and PATH on behalf of the MOH, conducted a desk review of current strategic policy documents and held semi-structured interviews with key stakeholders, including government, health care workers and civil society, at both the central and provincial levels, with 26 individuals across 5 provinces. Barriers pertaining to community health implementation fidelity were assessed. First, we

found that 37% of interview respondents cited a lack of funding for the CHW program as the main challenge to strengthening community health in the DRC. Second, 33% of respondents discussed the need for a community health information system that produces disaggregated data to support program M&E and supply chain management. Respondents also highlighted the importance of quality data for decision-making, with 78% stating that data collected from CHWs are used to inform strategy. We also found gaps in health coverage. Official health policy documents state that there should be a ratio of 1 CHW for every 500 individuals in a community. In practice, there is just 1 CHW for every 1,000 individuals. The results of the landscape report will inform the design and implementation of priority case management interventions, such as the implementation of a community health information system, as well as enhanced coverage to satisfy at least 50% of the needs. Ultimately, the results will aim to strengthen the community health system as well as support the planning of multisectoral coordination for the upcoming revision of the National Community Health Strategic Plan (NCHSP) in the DRC.

PHARMACEUTICAL SERVICE DELIVERY IN MEDICINE RETAIL OUTLETS IN HARD-TO-REACH COMMUNITIES IN LOW-MIDDLE-INCOME COUNTRIES (LMICS)

Paul Owusu Donkor[1], Kwame Peprah Boaitey[2], Adwo Mfodwo[2], Michael Mireku Opoku[1]

[1]University of Ghana, Legon, Accra, Ghana, [2]Pharmaceutical Society of Ghana, Accra, Ghana

Community pharmacies and Over-the-Counter Medicine Sellers (OTCMS) outlets are an integral part of the healthcare system of Low-Middle-Income Countries (LMICs). This study examines the pharmaceutical service ecosystem and gaps in delivery in hard-to-reach communities in terms of patterns, practices, and regulations to optimize universal health coverage in LMICs. Using the Upper West Region of Ghana as a case study, Global Positioning System (GPS) devices were employed to determine the location of pharmaceutical service delivery points in six districts. A structured questionnaire was administered to evaluate the availability of specific medicines and services including antibiotics, family planning, rapid diagnostic test kits for malaria, and provision of National Health Insurance. Out of the districts surveyed, there were 4 registered pharmacies and 136 Over-the-Counter Medicine Sellers (OTCMS) outlets. About 50% of these facilities were operating without a license from the pharmacy regulator. Averagely, each facility had a staff strength of 4, with 3 out of each 4 staff having no formal training to dispense medicines or offer pharmaceutical services. Neither the community pharmacies nor OTCMS outlets were National Health Insurance Scheme accredited service providers, culminating in100% out-of-pocket payments for all clients. The findings of this study have significant implications for policy formulation aimed at addressing gaps in pharmaceutical care delivery and consequently improving the quality of services offered, both in community pharmacies and OTCMS outlets in rural and hard-to-reach communities in LMICs.

RAISING THE VISIBILITY OF NTDS IN THE DISCUSSION OF DOMESTIC HEALTH RESOURCE ALLOCATION: LESSONS FROM COLOMBIA, GUATEMALA, AND THE PHILIPPINES

Jose L. Gonzalez[1], Richard Killian[2], Maria Francisco[1]

[1]Results for Development (R4D), Washington, DC, United States, [2]RTI International, Washington, DC, United States

Investing in efforts to combat neglected tropical diseases (NTDs) is considered one of the "best buys" in public health. These investments are cost-effective and have the potential to return significant long-term health and economic benefits, thus breaking the cycle of poverty and disease for those affected by NTDs. However, NTD programs remain largely underfunded in many countries and are highly dependent on external donor funding. This multi-country study examines common enabling factors that have contributed to enhanced domestic financing for NTDs and ensured their prioritization within integrated planning processes in Colombia, Guatemala, and the Philippines. To understand where NTDs fit within the countries' health finance landscape, we conducted a literature review of published papers, program and policy documents, and country reports. Secondary data collection to assess the status of domestic mobilization and current financing for NTDs comprised gathering publicly available information from the ministries' financial systems. Primary data collection included 28 semi-structured interviews with key informants, including representatives from the ministries of health, implementing partners and donors. Countries' experiences demonstrate that NTD programming can be domestically resourced through political commitment, effective advocacy and governance, and integration within broader health system budgeting and planning processes. Moreover, the integration of NTD services into existing healthcare service delivery models and platforms has evidenced an opportunity to increase efficiency and ensure continuity of both population-based and clinical services. Enabling factors that have contributed to enhancing domestic financing for NTD programming in Colombia, Guatemala, and the Philippines will provide session participants with clear examples of how endemic countries can situate NTDs within the broader political narrative and health financing reforms, including those devoted to the advancement of universal health coverage and its objectives for ensuring equitable access and financial protection.

A SYSTEMATIC REVIEW ON LIGHTNING FATALITIES IN BANGLADESH WITH SPECIAL REFERENCE TO EPIDEMIOLOGY OF DEATHS AND INJURIES

Dalia Yeasmin[1], Mahbubur Rahman[1], Ashraf Dewan[2]

[1]icddrb, Dhaka, Bangladesh, [2]School of Earth and Planetary Sciences, Curtin University, Perth, Australia

Lightning is a leading cause of weather-related deaths after tornadoes, flash floods and hurricanes. Annually, it causes about 24,000 deaths and 240,000 injuries worldwide. In Bangladesh, lightning related deaths and injuries have become a public health concern and the government has already declared it as a natural disaster in 2016. This systematic review attempted epidemiology of lightning injuries and deaths since 2000-2021 in the context of Bangladesh. All published (English) quantitative, qualitative and mixed method studies were searched using a three-step process from electronic databases. An analytical framework was developed to use PubMed, Scopus, Web of Science, Google Scholar electronic databases. Meta-analysis was utilized to identify key concepts. The studies were coded into related non-mutually exclusive themes. We then synthesized each theme by comparing each study. Emergent themes were determined based on the meticulous and systematic reading. Coding and interpreting the data were refined during the analysis. The search criteria included and analysis of 55 full-text articles, resulting in the understanding of situations relevant to lightning deaths and injuries in Bangladesh. Annual mortality rate was 3.661 per 1,000,000 million. The incidence of lightning caused injury was 19.89 per 100,000 people. Among victims, males were particularly vulnerable, in fact 1.46 times higher at risk compared with females. Rural populations were more vulnerable, 8.73 time riskier than urban. About 43% of injuries occurred between 12 noon and 6 pm local time. Results further revealed that lightning injuries need to be taken as a public health problem and a national strategy needs to develop through an integrated approach which can address this emerging public health issue. Also, national and regional level policy planning including the identification of most lightning-prone areas and implications for developing national strategy, targeted interventions for highly risky locations can be planned based on the findings of this work.

THE CONTRIBUTION OF HUMAN MOVEMENT AROUND AN URBAN NETWORK TO THE EXPANSION OF THE DENGUE TRANSMISSION ZONE IN BRAZIL

Sophie A. Lee[1], Theodoros Economou[2], Raquel Martins Lana[3], Rafael de Castro Catão[4], Rachel Lowe[5]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]The Cyprus Institute, Nicosia, Cyprus, [3]Barcelona Supercomputing Center, Barcelona, Spain, [4]Universidade de Federal do Espirito Santo, Vitoria, Brazil, [5]Catalan Institution for Research and Advanced Studies, Barcelona, Spain

Dengue is one of the most important mosquito-borne diseases in the world with over half of the world's population living in areas at risk of infection. The past 20 years has seen a rapid expansion of dengue into areas of Brazil that were previously protected, including temperate zones in the South and remote areas in the Amazon rainforest. Previous geographical barriers to dengue outbreaks have been eroded and very few areas are now considered protected from frequent outbreaks. Our previous study found that temperature suitability, connectedness to the urban network, and urbanisation were important drivers of dengue spread. However, the contribution of human mobility over long distances, from metropoles with endemic transmission into the Amazon region, is still not fully understood. Here, we apply Bayesian spatial models which can account for multiple sources of spatial connectivity to dengue data from Brazil between 2001 - 2020 to quantify the relative importance of human mobility as a driver of dengue spread across different regions of Brazil. Preliminary results show that this method can accurately quantify the relative contribution of multiple sources of connectivity in simulated data but found human movement was not an important factor in dengue expansion within South Brazil. This framework will allow us to monitor the spread of dengue between connected regions and identify areas at future risk of expansion in previously protected areas of Brazil.

0713

ASSOCIATION OF AMBIENT TEMPERATURE WITH HYPOHYDRATION & URINARY BIOMARKERS AMONG THE SALTWATER-INTRUSION-AFFECTED TROPICAL COASTAL POPULATIONS OF BANGLADESH

Rizwana Khan

International Center for Diarrheal Disease Research, Bangladesh, Dhaka, Bangladesh

High ambient temperature is associated with an increased risk of kidney diseases and nephrolithiasis (kidney stones) in tropical regions. Possible mechanistic pathways include dehydration and increased calciuria, but limited population-based studies have explored this. We investigated the relationship between ambient temperature with 24-hour urinary volume, electrolytes, and kidney damage markers among ≥ 20-years population in coastal Bangladesh. We used 5,550 person-visits data from a stepped-wedge cluster randomized controlled trial conducted between December 2016 to April 2017 in Bangladesh. We repeatedly measured the participant's 24-hour urinary volume, electrolytes, urine total protein, and creatinine excretions. Daily ambient temperature data of local stations were obtained from the Bangladesh Meteorological Board. We used linear mixed models with participant, household, and community-level random intercepts to evaluate the association between daily average ambient temperature with,24-hour intra-individual changes in urine volume and biomarker. Models were adjusted for socio-demographic (e.g., age, sex, religion, household wealth), chronic disease risk factors (e.g., body mass index, physical exercise, smoking status, alcohol consumption, and sleep hours), and time and proxy for participants' drinking water concentration.Each 5 °C increase in daily ambient average temperature was associated with-0.03 (95% CI: -0.07, 0.03) liter change in urine volume; 1.01 (95% CI: 0.99, 1.04) geometric mean ratio(GMR) of 24hrs urine sodium, 1.04 (95% CI: 1.01, 1.07) GMR of 24hrs urine potassium, 0.94 (95% CI: 0.89, 1.00) GMR of 24hrs urine magnesium;1.09 (95% CI: 1.09, 1.14) GMR of 24hours urine calcium; 1.64 (95% CI: 1.27,2.00) GMR of 24hours creatinine; and 0.89 (95% CI: 0.84,0.94) gm/24hours in urine total protein, and no significant change 1.00 (95% CI: 0.97, 1.03) GMR of 24hours urine chloride. Ambient temperature is associated with electrolyte-concentrated urine and high urinary protein excretion among the study population.

0714

THE SURGICAL COMPLICATIONS OF NEGLECTED TROPICAL DISEASES AND THEIR LINK TO CLIMATE CHANGE

Hugh Shirley[1], Grace Grifferty[2], Elizabeth Yates[3], Nakul Raykar[4], Richard Wamai[2], Craig McClain[1]

[1]Harvard Medical School, Boston, MA, United States, [2]Northeastern University, Boston, MA, United States, [3]Center for Surgery and Public Health, Boston, MA, United States, [4]Program in Global Surgery and Social Change, Boston, MA, United States

Neglected tropical diseases (NTDs) predominantly affect the poorest communities worldwide; the same populations most affected by climate change. NTD burden will likely increase due to several climate change-related mechanisms, including human and vector migration and access to water. Several NTDs have surgically treated complications. We studied the nexus of climate change, NTDs and their surgical treatment, a neglected focus with important ramifications for providers and patients as climate change plays out across the globe. A review of relevant literature with searches pertaining to NTDs, surgery and climate change was conducted on PubMed. A collection of 7 NTDs with documented surgical treatments were identified and further studied including trachoma, lymphatic filariasis (LF), the leishmaniases, cystic echinococcosis (CE), cysticercosis, snakebite, and schistosomiasis. Their global burden and, if available, estimates of their surgical burden, were gathered and followed by a review of the climate factors related to their pathogenesis and epidemiology. Trachoma and LF were most closely tied to surgical care. Trachoma causes trichiasis, an in-turning of the eyelid resulting in corneal abrasion and blindness, affecting 2.5 million globally in 2019. Water access and hygiene are core components of prevention, making control of Trachoma prone to drought and flooding. LF causes hydrocele in chronically infected males, amounting to 19.43 million cases in 2012. The causal parasite is spread by mosquitoes, meaning the disease's reach will be influenced by the migration of these vectors in response to changing climates, causing infections within naïve populations. Other NTDs require surgical care to a lesser extent. It is unclear how climate change will impact future prevention and treatment programs of NTDs with surgically treated presentations. Surgical care, therefore, should be included in packages aimed at addressing NTDs in the era of anthropogenic climate to care for communities with a surgical burden of NTDs.

0715

PLANETARY HEALTH IN URBAN INFORMAL SETTLEMENTS: ASSESSING THE EFFECT OF WATER STORAGE PRACTICES ON THE RELATIONSHIP BETWEEN MOSQUITO EXPOSURE AND FEVER

Audra Bass, Sheela Sinharoy, Allison Salinger, Thomas Clasen

Rollins School of Public Health, Emory University, Atlanta, GA, United States

Globally, over 1 billion people live in urban informal settlements that lack proper water infrastructure. Residents of these settlements may be more likely to store water, including in ways that could promote mosquito proliferation and the spread of vector-borne diseases. This study aimed to evaluate the association between exposure to mosquitoes and fever, stratified by water storage practices, in urban informal settlements in two countries. Survey data were collected through Revitalizing Informal Settlements and their Environments (RISE), a randomized control trial working in 24 urban informal settlements in Suva, Fiji and Makassar, Indonesia. The main survey items of interest were self-reported fever in the last week, self-reported frequency of exposure to mosquitoes in the last six weeks, and whether respondents stored drinking water. Multi-variate

logistic regression models were used to analyze associations between fever and exposure to mosquitoes in the total sample and in a sub-sample of households that stored water. Models were adjusted for settlement-level clustering and relevant covariates, including wall materials, garbage disposal practices, water source, water access, and household wealth. We observed a positive association between daily mosquito exposure and having a fever in both Makassar [(adjusted OR 1.45, 95% CI: 0.24-8.67)] and Suva [(AOR 1.88, 95% CI: 1.18-3.02)]. A sub-analysis restricted only to respondents that stored water produced similar results for both Makassar (AOR 1.46, 95% CI: 0.27-7.78) models] and Suva (AOR 1.53, 95% CI: 0.99-2.34)]. Our study demonstrated that with the increased rate of mosquito encounters residents had a higher chance contracting a fever, suggesting a viral infection, including when stratified by water storage. Furthermore, our study provides impetus that socio-environmental factors that increase people's vulnerability need to be included in vector-mosquito and infectious disease analyses. With the rapid growth of urbanization and climate change, this relationship merits further attention.

0716

PROJECTIONS OF CLIMATE CHANGE ATTRIBUTABLE WATERBORNE DISEASE BURDEN: A SYSTEMATIC REVIEW

Alyssa Miller, Jeremy Hess, Corinne Klohmann, Karen Levy

University of Washington, Seattle, WA, United States

Climate change threatens recent advances in reducing incidence and mortality of waterborne diseases, which contribute significantly to global public health burden, especially in children. It has been well documented that meteorological factors, like temperature and precipitation, impact waterborne disease incidence. There is growing interest to characterize the potential future waterborne disease burden associated with climate change to support adaptation planning, but to date there has been no synthesis of future modeling studies. We conducted a systematic review of research and methods for projecting waterborne disease burden under climate change scenarios. We screened the literature as of November 2021 for papers including a quantitative estimate of future waterborne disease using the electronic databases PubMED and EMBASE. We identified 1,908 unique studies, of which 29 met the inclusion criteria. Projections were available in each WHO region. Most studies indicated an increase in future waterborne disease burden, with severity varying by region and climate scenario. Authors used a variety of methods to obtain waterborne disease projections under exposure-response, climate model and risk metric dimensions. Most studies incorporated local health and climate data; however, spatial scale varied by study. Over half the studies utilized novel estimation of exposure-response functions, while the rest relied on published reviews. Notably, 17 studies included assumptions on future population exposure, vulnerability, and adaptation, but few incorporated more than one metric. Because of the different modeling approaches applied and regions evaluated, we could not synthesize future burden into a single summary estimate. Climate-attributable waterborne disease projections could benefit from establishment of best practices to bolster utility and comparability of findings and better serve adaptation planning efforts. In particular, since waterborne disease risk is highly dependent on demographic factors and development pathways, uncertainty in these metrics should be incorporated in all projections.

SELF-ASSESSED HEALTH STATUS AND ACUTE COVID-19 SYMPTOMS IN URBAN INFORMAL SETTLEMENTS IN MAKASSAR, INDONESIA

Ruzka R. Taruc[1], S. Fiona Barker[2], Brett Davis[2], Farzana Hossain[2], Audrie Lin[3], Stephen P. Luby[4], Rohan Sweeney[2], Karin Leder[2]

[1]Hasanuddin University, Makassar, South Sulawesi, Indonesia, [2]Monash University, Melbourne, Australia, [3]University of California Berkeley, Berkeley, CA, United States, [4]Stanford University, Stanford, CA, United States

The COVID-19 pandemic has had enormous global impact, but has particularly affected vulnerable populations, including the more than one billion people living in densely populated informal settlements with inadequate basic infrastructure and services, and heightened exposure risks inherent to crowded conditions and poor hygiene infrastructure. This study aims to describe the self- or carer-reported health impacts of COVID-19 among people living in urban communities in Makassar, Indonesia that are part of the Revitalising Informal Settlements and their Environment (RISE) trial. Household survey data from two time points were collected: Feb/Mar 2021 (telephone survey) and Mar-April 2022 (face-to-face data collection, ongoing). Based on the government data, the highest reported COVID-19 cases in Makassar in 2021 were 71.1 per 100,000 population 1, and 91.2 in 2022. Self- or carer-assessed health status was measured by asking respondents if, within the last week they, or their children, had experienced any of 8 possible acute COVID-19-related symptoms: cough; trouble breathing; fever; loss of sense of taste or smell; nasal congestion; headache/dizziness; muscle aches; fatigue//nausea/vomiting/reduced appetite. Respondents were also asked about COVID-19 vaccination status of household members (2022 only). A count of the number of reported symptoms was determined, as was the proportion of people reporting any possible COVID-19-related symptoms at each survey period (grouped by age: a=<5 years, b=5-15, c=adult). The 2021 results showed that cough was reported as follows: a=11.3%; b=7.1%; c=8.5%; breathing difficulties: a=1.3%; b=0.51%; c=3.1%; and at least 2 of the 8 potential COVID-19-related symptoms: a=19.1%; b=12.6%; c=28.5%. Although 2022 data collection is ongoing, preliminary results suggest increases in symptom prevalence. The vaccination status (at least one dose) across all settlements is 62.4%, which is lower than the vaccination status 94.6% nationally. These findings suggest both high prevalence of self-reported symptoms and poor penetration of COVID-19 vaccination among residents of informal settlements.

0718

THE AFRICAN LEISHMANIASES CONSORTIUM AS PARADIGM FOR NTDS ELIMINATION

Ikram Guizani[1], Emna Harigua[1], Olufemi A. Adedokun[2], Ayoade MJ Oduola[2]

[1]Molecular Epidemiology & Experimental Pathology, Institut Pasteur de Tunis, University Tunis El Manar, Tunis, Tunisia, [2]University of Ibadan Research Foundation, Ajibode, Ibadan, Nigeria

Contextual and full knowledge of leishmaniases epidemiology and harmonization of available tools are needed to achieve the goals of VL elimination and CL control in Africa. Despite significant scientific advances and increasing research competencies, impact on public health and communities is limited in Africa. Critical data is not often available because of lack of tools to support activities and decisions towards elimination and control. Contextually, available knowledge, tools and R&D products are not sufficient. The tools need to be translated to innovations to support decision and select effective policy options maximizing health and development impact, and be implemented. The African Leishmaniases Consortium (ALC) was created to address these challenges and needs towards control and elimination of Leishmaniases in tandem with the 2021 WHO NTDs road map. We present here the vision and strategic approach of ALC, which brings together 7 African institutions in 7 countries with an international partner in Spain, to represent Africa leishmaniases

context- inc. diseases diversity, neglect levels, country and global underreporting, morbidity and mortality. ALC leverages on its partners' complementary expertise and strengths. The vision is to establish platforms for developing human capital, research innovations for control tools, policy imperatives, and to foster commitment, dedication, and strategic support for the elimination of leishmaniases in Africa. Nexus between research, implementation science and policy options gives opportunity to develop effective frameworks for NTDs elimination paradigm, and spurred the creation of ALC to apply these advances to diseases affecting the poorest of the poor in North, West, and East Africa countries. The ALC is a valuable platform to enroll international partners for collaborations and utilization of capacities and competencies in the endemic countries. Through its thematic networks, ALC will train a cohort of next generation leaders in Africa, address relevant scientific questions on the elimination and deliver knowledge, data, tools, maps, models, and policies.

0719

VACCINE CONFIDENCE AND ATTITUDES TOWARDS COVID-19 AMONG ADULT EMPLOYEES OF A LARGE AGRICULTURAL COMPANY IN GUATEMALA: A CROSS-SECTIONAL SURVEY

Diva Mirella Barrientos,[1], and Jose Monzón[2], Molly M. Lam[3], Gerber Guzman[1], Neudy Rojop[1], Edgar Barrios[1], Andrea Chacon[1], Melissa Gomez[1], Ann Chard[4], Lindsey Duca[4], Chelsea Iwamoto[4], Nga Vuong[4], Kareen Arias[1], Guillermo A. Bolaños[1], Eduardo Azziz-Baumgartner[5], Emily Zielinski Gutierrez[6], Edwin J. Asturias[3], Daniel Olson[3]

[1]Centro del Desarrollo Humano Fundación para la Salud Integral de los Guatemaltecos–CU, Guatemala, Guatemala, [2]Centers for Disease Control and Prevention Division for Global Health Protection (CDC-DGHP), Guatemala, Guatemala, [3]Center for Global Health, Colorado School of Public Health, Department of Pediatrics, University of Colorado School of Medicine, Children's Hospital Colorado Department of Epidemiology, Aurora, CO, United States, [4]Centers for Disease Control and Prevention Division for Global Health Protection (CDC-DGHP),, Atlanta, GA, United States, [5]Centers for Disease Control and Prevention Division for Global Health Protection (CDC-DGHP), Atlanta, GA, United States, [6]Centers for Disease Control and Prevention Division for Global Health Protection (CDC-DGHP), Guatemala City, Guatemala

COVID-19 mitigation in essential workers depends, in part on vaccine acceptance. Little is known about COVID-19 vaccine acceptance among agricultural workers, represent 35% of the Guatemala labor force. We sought to assess attitudes, beliefs and vaccine confidence towards COVID-19 vaccines offered (but not mandatory) at no charge, at the workplace in Guatemalan banana plantations. During August/September of 2021 we conducted a cross-sectional survey among a sample of banana plantation workers participating in a larger prospective cohort of respiratory disease among agricultural workers. All workers (n=1,586) were invited to respond to a validated Spanish-language questionnaire about demographics, vaccination status, prior vaccines access and refusal, reasons for vaccination, concerns about COVID-19, and trust in vaccines. Descriptive statistics were used to summarize findings. Among participants completing the survey (n=1,578), the average age (SD) was 31 (9.3) years. At the time of the survey, 1576 (99%) of respondents had accepted the first dose of Moderna COVID-19 vaccine. Twenty percent of respondents (320) reported encountering barriers to earlier COVID-19 or other types of vaccination due to the inability to leave their job (n=177 55%) or the unavailability of a vaccine at the public clinic (n=132 41%). The most common reasons for agreeing COVID-19 vaccination were to protect their families (835 53%) or themselves (621 39%). Only 16% (254) of respondents reported to be concerned about developing COVID-19. While 574 (36.51%) of workers trusted public health agencies promotion of COVID-19 vaccines, another 577 (36%) reported little to no trust. Most workers (1255 80%) also had trouble discerning genuine from fake COVID-19 information as presented in our instrument. Few our sample of rural Guatemala workers worried about COVID-19, and most were unable to readily distinguish between credible and fake COVID-19 information, nonetheless we documented high vaccine uptake in workplace setting. Free COVID-19 vaccination in the workplace may be a key strategy to increase coverage among essential workers in other rural communities.

0720

SAFE RESUMPTION OF COMMUNITY SOCIAL AND BEHAVIOR CHANGE ACTIVITIES DURING THE COVID 19 PANDEMIC: THE ROLE OF INTERACTIVE VOICE RESPONSE IN NIGERIA

Temitope Ogunbi[1], Bolatito Aiyenigba[1], Linda Osaji[1], Nii Lante Heward-Mills[1], Idowu Akanmu[1], Angela Acosta[2], Olufunmilayo Sanni Adeniyi[3], Foyeke Oyedokun-Adebagbo[4], Ian Tweedie[1]

[1]Breakthrough ACTION-Nigeria, Johns Hopkins Bloomberg School of Public Health, Abuja, Nigeria, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]National Malaria Elimination Program, Federal Ministry of Health, Abuja, Nigeria, [4]United States Agency for International Development, Abuja, Nigeria

The COVID-19 lockdown in Nigeria interrupted community interventions such as house-to-house visits and community dialogues on malaria. Changes were made to safely restart them; however, early supervision visits found that calls and WhatsApp chats to introduce these changes were insufficient; community volunteers (CVs) and supervisors needed additional orientation on how to implement them and how best to integrate malaria and COVID-19 messages. Given widespread access to mobile phones among supervisors and CVs, Breakthrough ACTION-Nigeria developed trainings for supervisors through Interactive Voice Response (IVR). Trainees only required a simple feature phone to receive free, automated calls and quizzes at designated times. If trainees missed a call, they could retrieve the module through a call-back mechanism. Trainings covered prevention and care-seeking for malaria and COVID-19 and rumor management. All 76 supervisors completed the 13 modules in 13 weeks, then led one-on-one trainings for CVs during supervision visits. CVs then conducted household visits outdoors and dialogues in open spaces with fewer than 20 people. CVs used masks and sanitizers and encouraged community members to do the same. In a post-training survey, 90% of supervisors said they found the IVR orientation very useful, and 91% felt confident they could step down the material to CVs. The number of activities conducted in the 3 months after the CV trainings were similar or higher than the 3 months before lockdown (11,533 activities before vs. 23,083 after; 51,910 persons reached before vs. 98,671 after; and 7,409 referrals before vs. 5,467 after). The referral completion rate improved; 48% of individuals completed referrals after the reset vs. 22% before lockdown. IVR cost $5,188 less than in-person training. Combined with one-on-one supervision and modifications to community activities, IVR allowed supervisors and CVs to resume critical community-level malaria and COVID-19 messaging. After the pandemic, the IVR approach can be replicated for cost-effectively sharing technical updates with CVs and supervisors who are widely distributed across the country.

0721

METAGENOMIC NEXT-GENERATION SEQUENCING TO CHARACTERIZE ETIOLOGIES OF NON-MALARIAL FEVER IN A COHORT LIVING IN A HIGH MALARIA BURDEN AREA IN UGANDA

Lusajo L. Mwakibete[1], Saki Takahashi[2], Vida Ahyong[1], Allison Black[1], Cristina M. Tato[1], John Rek[3], Isaac Ssewanyana[3], Moses R. Kamya[4], Grant Dorsey[2], Isabel Rodriguez-Barraquer[2], Bryan Greenhouse[2]

[1]Chan Zuckerberg Biohub, San Francisco, CA, United States, [2]University of California San Francisco, San Francisco, CA, United States, [3]Infectious Disease Research Collaboration, Kampala, Uganda, [4]Makerere University College of Health, Kampala, Uganda

Metagenomic next-generation sequencing (mNGS) allows for broad genomic-level detection of infectious agents in a biological sample, and has played a key role in areas such as microbiome characterization and outbreak detection. Here, we used mNGS to investigate the potential

causes of acute, non-malarial febrile illness in 212 participants enrolled in an ongoing cohort study of malaria infection in eastern Uganda. Between December 2020 and August 2021, 297 nasopharyngeal swabs and 294 plasma paired samples were collected from participants who presented with fever, but were negative for malaria by microscopy. Samples were extracted, reverse-transcribed, and sequenced using short-read Illumina sequencing. Data were analyzed using CZ ID, a web-based platform for microbial detection using mNGS data. Applying stringent criteria to call the microbes present in each sample, we identified bacterial, eukaryotic and viral sequences in both sample types and closely examined the latter two. Submicroscopic malaria infections were detected in 54 (18%) plasma samples of which 27 (50%) were qPCR positive. SARS-CoV-2 was detected in 11 of the nasopharyngeal swabs, and full genomes were recovered from 9 of the samples, consistent with circulation of the Delta wave in Uganda. Other viral pathogens identified included rhinoviruses (n=40), influenza A virus (H3N2 subtype, n=14), human orthopneumovirus (RSV, n=12) and seasonal coronaviruses (HKU1, n=1; NL63, n=1; OC43, n=4). We performed phylogeny exploration on recovered genomes to relate these samples to published viral genomes from Uganda and other parts of the world. Notably, 11 cases of influenza were detected between May and July 2021, coinciding with the period when Delta was circulating in this population. These data revealed co-circulation of multiple pathogens, primarily viruses, likely associated with fever in this cohort. More broadly, this pilot study demonstrates the power of mNGS in elucidating the multiple causes of febrile illness, which could aid in surveying and responding to pathogenic microbes circulating in a region.

0722

BUILDING CAPACITY AND CREATING TOOLS TO SUPPORT INTERNATIONAL HEALTH REGULATIONS IMPLEMENTATION AND COMPLIANCE IN IRAQ

Alexander G. Linder[1], Lauren N. Miller[1], Mohammed Al-Janaby[2], Aso Zangana[3], Jenny Zhao[1], Alanna Fogarty[1], Claire J. Standley[1], Karim Muftin[4], Erin M. Sorrell[1]

[1]Georgetown University, Washington, DC, United States, [2]Directorate of Public Health, Ministry of Health, Baghdad, Iraq, [3]Ministry of Health, Kurdistan Regional Government, Erbil, Iraq, [4]Alwan Global, Georgetown University, Baghdad, Iraq

The International Health Regulations (IHR), requires State Parties to develop capacities and capabilities to adequately detect, report and respond to infectious disease threats with the potential to cross national borders. In Iraq, implementation of this legal framework is challenged due to continued destabilizing factors and unique governmental structures. The aim of this project is to develop an adequate framework to support the detection, assessment, and reporting of disease events in Iraq consistent with the obligations of IHR. In coordination with stakeholders at the Federal Government (GoI) and the Kurdistan Regional Government (KRG), we have expanded the scope and range of IHR awareness and oversight in country. In partnership with the Ministries of Health we have supported the development of inter-ministerial IHR Technical Committees, consisting of relevant ministry focal points, across the two governments and have established IHR units across GoI provincial health departments. Through a series of IHR stakeholder meetings aimed to strengthen Iraq's IHR core competencies, we have developed and finalized action plans to improve communication between ministries and departments at the national and sub-national levels and provided recommendations to the IHR Technical Committees on required resources, practices, and sustainability considerations to achieve IHR compliance. In addition, we are working across relevant sectors to prepare for the States Party Self-Assessment Annual Report (SPAR) reporting requirement under IHR. Outcomes of this project continue to support Iraq in IHR compliance while building formal and lasting networks between GoI and KRG stakeholders across a variety of ministries and directorates. This effort will help Iraq meet its IHR commitments by supporting sustainable IHR engagement in a whole-of-country approach. Ultimately, the project increases public health information sharing and cooperation between the two governments, improving detection and response to national notifiable diseases and reporting under the IHR.

0723

CAPTURING HOME DEATH TO CONDUCT MINIMAL INVASIVE TISSUE SAMPLING (MITS): A COMMUNITY BASED NOTIFICATION SYSTEM

Ketema Degefa[1], Mohammed Aliyi[1], Hiwot yigzaw[1], Berhanu Damise[1], Yenenesh Tilahun[1], Haleluya leulseged[1], Tadesse Dufera[1], Gurmu Feyissa[1], Markus Breines[2], Lola Madrid[2], Nega Assefa[1]

[1]College of Health and Medical Sciences Haramaya University, Ethiopia, Harar, Ethiopia, [2]London School of Hygiene & Tropical Medicine, United Kingdom, London, United Kingdom

In 2020, the estimated mortality rate in sub-Saharan Africa among children under the age of five years (U5) was 74 deaths per 1000 live births, and mostly from preventable causes of death . In rural Ethiopia, U5 children often die without being seen by medical personnel, without a documented medical history and are often buried before their cause of death can be determined. The Child Health and Mortality Prevention Surveillance Network (CHAMPS) established a community-based mortality notification system, which aims to report potentially eligible deaths (U5 deaths and stillbirths) within 24 hours where minimal invasive tissue sampling (MITS) can be conducted quickly after death and analyzed to determine the cause of death. In eastern Ethiopia, lay people were trained as Community Health Volunteers to report potentially eligible deaths to counsellors and health officers who checked the eligibility criteria, asking for consent, enrolling consented cases for MITS procedures, and sharing results with the families of the deceased child and the community after the identification of the cause of death. From February 4th 2019 to February 3rd 2022 the site received 3665 of which, 329 (9%) were home deaths. Of these, 85/329 (26%) were eligible for MITS. CHAMPS counsellors have approached 77 MITS eligible families, and 39 (51%) consented for MITS. Consent for home deaths increased from 48% in 2019 to 59% in 2021 and has improved until 88% in the first months of 2022 after the implementation of different strategies to improve notifications and acceptability. The site developed an efficient death notification system tailored to the cultural and religious norms as well as the geographical setting. The community-based notification system can inform the development and improvement of similar platforms to engage the community in mortality surveillance, and share findings with communities and local health officials to inform immediate public health actions.

0724

SUSTAINING HEALTHCARE SEEKING IN WESTERN KENYA DURING COVID-19 PANDEMIC

Eunice Ouma[1], Kelvin Onoka[1], Simon Kariuki[1], Fred Omiti[1], Kizito Obiet[1], Mevis Omollo[1], Julie Thwing[2], Julie Gutman[2]

[1]KEMRI -CGHR, Kisumu, Kenya, [2]CDC, Atlanta, GA, United States

The COVID-19 pandemic disrupted care-seeking and healthcare delivery in sub-Saharan Africa. Patients avoided hospitals due to fear of COVID-19. Health care providers were inadequately trained to manage COVID-19 patients and had insufficient personal protective equipment (PPE). In April 2021, we implemented a project to sustain healthcare seeking during COVID-19 through creating community awareness on the adherence to recommended infection prevention and control (IPC) measures in Kisumu and Siaya counties in western Kenya. Interventions in 100 project-supported level 2 and 3 facilities, selected for attendance >20 visits per month in the outpatient department (OPD) and >20 visits per month at antenatal care (ANC), included provision of PPE, hand sanitizer, disinfectant, screening booths, handwashing stations, training, and monthly supportive supervision. All facilities in the two counties received job aids, guidelines on ANC, malaria, IPC, and COVID-19, and information, education and communication (IEC) materials on COVID-19, malaria, and ANC. In addition, social and behavior change messaging was disseminated

in the two counties. We monitored care-seeking in 100 project supported facilities pre (Jan- Dec 2019) and during COVID-19 (Jan 2020 to Dec 2021). We abstracted data on the number of OPD visits, ANC visits, and suspected malaria cases reported in the District Health Information System-2 to determine the changes from pre- and during COVID-19. OPD visits/month declined by 9.7% in 2020 relative to 2019, from an average of 1143 to 1032, and in 2021 remained depressed at 18.9% with a mean of 927 relative to 2019. New ANC visits/month increased by 5.0% in 2021 relative to 2019, from an average of 31 to 32 visits/ month. The number of monthly cases of suspected malaria declined by 11.4% from 2019 to 2020 from an average of 646 to 572 and remained lower than the 2019 baseline in 2021 by 14.2% lower, at 554 visits. Despite efforts to ensure that healthcare workers had the supplies they needed, felt safe, and reached communities with correct information during the pandemic, overall care seeking remained depressed through 2021, compared to 2019.

0725

FEBRILE ILLNESS AND MALARIA DIAGNOSIS IN SIAYA AND KISUMU COUNTIES, WESTERN KENYA

Kelvin Onoka[1], Eunice Ouma[1], Simon Kariuki[1], Fredrick Omiti[1], Kizito Obiet[1], Mevis Omollo[1], Julie Gutman[2], Julie Thwing[2]

[1]KEMRI-CGHR, Kisumu, Kenya, [2]CDC, Atlanta, GA, United States

Malaria remains a major public health threat, with an estimated 241 million cases and 627,000 deaths worldwide in 2020. Approximately 47,000 deaths were linked to disruptions in the provision of malaria prevention, diagnosis, and treatment during the Covid-19 pandemic. As disease can progress rapidly to severe malaria or death, early detection and treatment is critical. Though malaria often presents as a febrile illness, some infected people, particularly older children and adults in endemic areas, may have other malaria symptoms (headache, body aches, and joint pains) while remaining afebrile. We collected data on fever cases and malaria testing from patients who sought care at 28 and 20 selected health facilities in Kisumu and Siaya Counties, respectively, in western Kenya from February to March 2022. Screeners tallied the number of patients presenting with fever and abstracted data from laboratory registers on the number of patients tested using rapid diagnostic tests (RDTs) or microscopy and treated for malaria. These were stratified by those under 5 years old (U5) and those 5 and above (5+). Facilities recorded a mean of 7.6 sick visits among U5 per health facility per day (range 0-29) and on average 3.7 U5 reporting fever per day (range 0-22). On average 5.7 U5 were tested for malaria per facility per day (range 0-21); the test positivity rate was 38.5%. Among clients 5+, there were a mean of 18.0 sick visits (range 0-77) per facility per day, and 6.5 reporting fever per facility per day (range 0-40). On average, 13.6 clients 5+ were tested for malaria per facility per day (range 0-55); the test positivity rate was 45.6%. Even as health care providers apparently used broad criteria to define suspected malaria, the test positivity rate remained high, both among children under 5 years and patients 5 years and older. To ensure that all patients with malaria are diagnosed and treated early, diagnostic tests must be widely available.

0726

COMMUNITY PERCEPTIONS ABOUT COVID-19 VACCINE ACCEPTANCE: A QUALITATIVE RAPID ASSESSMENT IN BALIAKANDI, A RURAL COMMUNITY OF BANGLADESH

Shahana Parveen[1], Sazzad Hossain[1], Tonmoy Sarkar[1], Dalia Yeasmin[1], Faruqe Hussain[1], Mohammad Zahid Hossain[1], Maria Maixenchs[2], John Blevins[3], Shams E. Arifeen[1], Emily S. Gurley[4]

[1]icddr,b, Dhaka, Bangladesh, [2]ISGlobal, Hospital Clinic-Universitat de Barcelona, Barcelona, Spain, [3]Emory Global Health Institute, Atlanta,, GA, United States, [4]Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Since launching of the nationwide COVID-19 vaccination program on 7 February 2021, Bangladesh has vaccinated more than 75% of the population with at least one dose, although in a cross-sectional survey only 25% of rural respondents had been vaccinated. We conducted a qualitative rapid assessment in September 2021, to understand perceptions about COVID-19 vaccines among rural residents in Baliakandi sub-district, Bangladesh. We interviewed 19 key informants, including residents who had COVID-19 infection, vaccinated residents; general residents, community and religious leaders; local administrator; and healthcare providers. Data were analyzed by framework analysis. Respondents said that because the vaccines were developed in a short time, did not have adequate information to rely on them and wanted to wait first and observe others' experience before receiving the vaccine themselves. Besides, respondents shared some initial concerns about perceived adverse effects of the vaccines, such as infertility and death that prevented some people from being vaccinated. Respondents said that they would receive this vaccine to protect from infection; if it was mandated for people who wanted to go abroad; or if the government restricted movement for those who had not been vaccinated. They reported that many residents who were formally registered but could not get a vaccination on scheduled time due to insufficient supply of vaccines. They also noted most of the vaccinated residents were not practicing any precaution (i.e. wearing mask) as perceived once vaccinated, they would not need to take any measures. They suggested that to increase the vaccine uptake and encourage people practicing preventative measures, community level vaccination locations should be established, the registration system should be easier, and community leaders should be involved in the government's initiatives for sensitization about vaccines and side effects. The findings could aid in government and international community to fine-tune the strategies for addressing gaps (i.e. access, risk perceptions) in COVID-19 vaccine administration in similar rural settings.

EXPANSION OF THE LASSA FEVER TESTING NETWORK IN NIGERIA

Nsonghomanyi Fritz Roland Fonkeng[1], Devy Emperador[1], Hanesh Chi Fru[1], Anthony Ahumibe[2], Afolabi Akinpelu[2], Adama Ahmad[2], Augusta Zuokemefa[2], Munzali Shamzu[2], Adeleye Adesola[2], Abdulmajid Musa[2], Doofan Abaa[2], Daniel G. Bausch[1], Aurelia Vessiere[1], Nwando Mba[2]

[1]Foundation for Innovative New Diagnostics FIND, Geneva, Switzerland, [2]Nigeria Center for Disease Control, Abuja, Nigeria

Lassa fever (LF) is an acute viral illness caused by Lassa virus (LASV), affecting 300,000 persons per year in West Africa, with annual outbreaks occurring in Nigeria. LF is probably underreported, primarily due to its non-specific presentation which makes clinical diagnosis difficult. Laboratory confirmation of LASV infection can be achieved by virus culture, molecular detection, or antigen detection but these tests are not widely available, especially considering that LASV is a Category A pathogen requiring special training and precautions when handling specimens. The Nigeria National LASV program was created in 2016, initially with only three testing laboratories in the country. Here we describe the process of increasing LASV testing capacity in Nigeria to improve surveillance and outbreak response. Laboratories were selected based on regional representation and epidemiologic data indicating high LF incidence. A baseline assessment was conducted on the safety and infrastructural capacity to conduct LASV testing using a checklist developed by experts at the National Reference Laboratory in Abuja. Only labs with a BSL-3 glovebox were selected. We then conducted onsite training on the testing and reporting protocol, training an average of 7 staff per laboratory. Staff then undertook blinded testing of LF panels as a proficiency test, requiring them to score 100% before the laboratories could be activated. Since 2017, five new laboratories have been added to the network. The first three laboratories were activated in the southern part of the country, which is a hotspot zone for LASV, one in the South East in 2018, and two in the South West in 2019 and 2021. After the 2020 outbreak, where more cases were detected in the North zone, two more labs were activated in 2021, one in the North West where cases were seen for the first time, and one in the North East, which is becoming a new hotspot. The addition

of new labs has led to enhanced surveillance and geographical coverage, improved turnaround times from 72hrs to 48hrs, and reduced the burden at the three initial laboratories.

0728

ESTABLISHMENT OF A LASSA FEVER BIOBANK AT THE FEDERAL MEDICAL CENTER OWO, ONDO STATE, NIGERIA

Hanesh Chi[1], Frtiz Fonkeng[1], Johnson Etafo[2], Olufunke Ibitokun[2], Chucks Abejegah[2], Sampson Owhin[2], Aurélia Vessière[1], Stella Somari[3], Nelson Adedosu[2], Daniel Bausch[1], Devy Emperador[1]

[1]FIND, the global alliance for diagnostics, Geneva, Switzerland, [2]Federal Medical Center, Owo, Nigeria, [3]ITSI Biosciences, Johnstown, PA, United States

Lassa virus (LASV) is a biosafety level 4 priority pathogen under the World Health Organization R&D Blueprint. LASV infects up to 300,000 persons annually across West Africa, causing a potentially severe viral hemorrhagic fever known as Lassa fever (LF). Timely access to high-quality biological samples through standardized processes is critical in accelerating the development of urgently needed fit-for-purpose diagnostics, medical countermeasures, and research on LF. However, limited in-country collection, coordination, and service capacity, as well as a disconnect between demand and supply, among many other factors, pose major challenges. To address this need, as part of the FIND Integrated Biobank Network, we established a LF biobank at the Federal Medical Center Owo (FMCO) in Nigeria to prospectively collect, process and store high quality, well-characterized samples from LASV-infected persons. Within the framework of this project, we set out to enroll 200 (100 LASV RNA positive [LASV+] and 100 LASV RNA negative [LASV-]) eligible participants presenting at FMCO within one year. Individuals aged 18 years or older with suspected LF who tested either LASV+ or LASV- using the RealStar LASV qRT-PCR Kit 2.0 (Altona Diagnostics, Hamburg, DE) were enrolled. Whole blood, serum, and plasma were collected at baseline from each participant and at weeks 4 and 8 from LASV+ individuals, immediately processed and stored at -80^{0}C. Clinical data and sample information (baseline and follow-up visits) were captured in OpenClinica and OpenSpecimen, respectively. Creation of the biobank facility began in March 2020 and enrollment of participants started in October 2021. As of April 2022, we have enrolled a total of 145 participants (78 LASV+ and 67 LASV-) with a total of 2,769 sample aliquots (198 whole blood, 1,222 serum & 1,349 plasma). Participant enrollment and follow-up are ongoing. Samples from this biobank are currently being used for the evaluation of commercial LASV serologic assays and a LASV antigen rapid test.

0729

GENOMIC CHARACTERIZATION OF MULTIDRUG RESISTANT TRAVEL-ASSOCIATED *E. COLI* IN U.S. INTERNATIONAL TRAVELERS

Sushmita Sridhar[1], Ryan Bronson[2], Colin J. Worby[2], Vanessa M. Sanchez[1], Sarah E. Turbett[1], Jason B. Harris[1], Regina C. LaRocque[1], Ashlee M. Earl[2]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]Broad Institute, Cambridge, MA, United States

Antimicrobial resistance (AMR) is a global public health threat, and its frequency is increasing. International travel has been associated with the acquisition of antimicrobial- resistant organisms. Antimicrobial consumption, destination, and travelers' diarrhea (TD) are risk factors for acquiring an AMR organism during travel. In this study, we sought to understand the characteristics of AMR *E. coli* acquired by U.S. international travelers. Stool samples from U.S. international travelers recruited through the Global Travelers' Epidemiology Network were screened on selective media before and after travel to isolate extended beta lactamase (ESBL) producing, carbapenemase producing-carbapenem resistant (CP-CR), and colistin resistant (carrying *mcr*) gram-negative bacteria. Isolates were phenotyped for antimicrobial susceptibility, and 273 were subjected to whole genome sequencing. We found that 38% of travelers acquired an AMR bacterium following international travel, and 97% of those were *E. coli.* The most common resistance was against beta-lactam antibiotics, but there were also 26 isolates carrying an *mcr* gene conferring colistin resistance. Based on sequencing analysis of *E. coli* isolates using strainGST, we found that phylogroup A isolates comprised 45% of acquired *E. coli* post-travel, a shift from the majority phylogroup B2 isolates found in US-associated pre-travel samples. There were no significant differences in phylogroup across travel regions. Most ESBL-producing isolates carried a CTX gene, and the most common CTX allele found in post-travel and pre-travel isolates was CTX-M-15; however, CTX-M-27 predominated in those visiting South and Southeast Asia. In addition to ESBL carriage, 150 isolates were phenotypically resistant to levofloxacin. In summary, we identified strain-level genomic differences between travel-acquired and U.S.-associated *E. coli*, with an enrichment of phylogroup A isolates in association with travel and majority acquisition of the CTX-M-15 allele alongside widespread resistance to other antimicrobials.

0730

ACCESS AND UTILIZATION OF INSECTICIDE TREATED MOSQUITO NETS IN CONFLICT-AFFECTED FRAGILE STATES: ANALYSIS OF SUBNATIONAL CONFLICT EFFECT IN DEMOCRATIC REPUBLIC OF CONGO AND NIGERIA

William R. Brieger[1], Marwa Ramadan[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Alexandria Faculty of Medicine, Alexandria, Egypt

Studies highlighted the potential impact of conflict and displacement on malaria prevention and mitigation efforts, but few investigated the effect of subnational conflict intensity on access and utilization of mosquito nets in fragile countries. This study bridges the gap by applying a conflict intensity lens to the analysis of access and utilization of Insecticide Treated Nets (ITN) in two conflict-affected fragile states (Nigeria and Democratic Republic of Congo (DRC)), where at least 45 % of global malaria deaths occur. We used the Demographic health survey (DHS) and the Uppsala Conflict Data Program for information on access and utilization of nets and conflict events respectively. Access was defined as the percentage of population with at least one ITN per 2 household members, while utilization was defined as the percentage of population who slept under an ITN the night before the survey in households with at least 1 ITN. To define conflict intensity, we linked household clusters to conflict events within a 50 km distance using ArcGIS. Conflict intensity was then categorized into medium or high intensity conflict and no or low intensity conflict using a cut-off of 2 or more deaths per 100, 000 population per cluster. Access and utilization of ITNs was compared by conflict intensity at the household cluster level. Analysis of data from 281,689 individuals living in 58,183 households revealed that 42.8% (CI: 42.3 - 43.3%) and 39.9% (CI: 39.5 - 40.1%) of members living in neighborhoods with medium and high intensity conflict in DRC and Nigeria respectively had access to ITNS compared to 47.9% (CI: 47.6 - 48.1%) and 51.0% (CI: 50.8 - 51.2%) in no or low intensity conflict. Similarly, 65.1% (CI: 64.3 - 65.9%) and 62.8% (CI: 62.3 - 63.3%) of those living in medium or high intensity conflict in DRC and Nigeria respectively utilized ITNS compared to 69.2 % (CI: 68.8 %-69.6 %) and 65.7% (CI: 65.4-66.0%) in no or low intensity conflict. National malaria control programs must consider that access and utilization of ITNS are statistically significantly lower in neighborhoods with medium or high intensity conflict and target supporting interventions accordingly.

0731

DETECTION AND SEQUENCING OF A MONKEYPOX VIRUS OUTBREAK IN MANIEMA PROVINCE, DEMOCRATIC REPUBLIC OF THE CONGO

Adrienne Aziza Amuri[1], Catherine Pratt[2], Eddy Kinganda[1], Elisabeth Pukuta[1], Michael Wiley[2], Emmanuel Lokilo[1], Francisca Muyembe[1], Raphael Lumembe[1], Gabriel Kabamba[1], Placide Mbala[1], Steve Ahuka[1], Jean Jacques Muyembe[1]

[1]INRB, Kinshasa, Democratic Republic of the Congo, [2]UNMC, Nebraska, NE, United States

Since 1970, the Democratic Republic of the Congo (DRC) has been facing repeated outbreaks of Monkeypox virus, which causes a pox-like disease in humans. The disease is endemic in the Equator forest zone, affecting the Sankuru, Tshuapa, and Equateur Provinces. On September 27th, 2021, the provincial health authorities in Maniema Province, which borders Sankuru, sent a health alert to the Ministry of Health. A cluster of cases with fever and skin eruptions had been detected and linked to bushmeat consumption. Samples were sent to the National Institute for Biomedical Research (INRB) and were positive by Orthopoxvirus PCR. On December 9th, 2021, an epidemic of Monkeypox virus was declared, with 191 cases, including 24 deaths. Samples were referred to the INRB Pathogen Genomics Laboratory for viral characterization as Monkeypox-positive samples from humans in the DRC had not been sequenced and publicly released since 2008. The Illumina DNA Prep with Enrichment protocol was used to generate enriched libraries for dual-indexed pairwise sequencing, using a custom Twist Biosciences probe panel designed against high consequence viruses, including Monkeypox virus. Enriched libraries were loaded onto an Illumina iSeq for 2 x 151 cycles. Sequencing reads were trimmed to remove adapter and low-quality bases, deduplicated, and aligned to a Monkeypox virus genome collected in Yambuku in 1985. We obtained two genomes with 99.9% and 99.7% coverage, excluding the repetitive terminal ends. Phylogenetic analyzes demonstrated that these cases of Monkeypox from Maniema were linked to historical genomes from Kolé and Lodja villages, located in the Sankuru Province close to the Maniema border, which share the same forest. The geographical expansion of this re-emerging virus underscores the threat that Monkeypox virus presents to the local and global population. The experience strengthened the INRB capacity for Monkeypox detection and sequencing and enabled preparedness for real-time tracking of future reemergence. In addition, further research should be conducted at the animal-human interface to understand the determinants of such a dangerous disease.

0732

HESITANCY IN COVID-19 VACCINE UPTAKE AMONG PREGNANT WOMEN IN KISUMU AND SIAYA COUNTIES, WESTERN KENYA AUGUST 2021- FEBRUARY 2022

Fredrick Omiti[1], Eunice Ouma[1], Kizito Obiet[1], Kelvin Onoka[1], Mevis Omollo[1], Simon Kariuki[1], Julie Gutman[2], Julie Thwing[2]

[1]Kenya Medical Research Institute-CGHR, Kisumu, Kenya, [2]CDC, Atlanta, GA, United States

Vaccine hesitancy is defined as the reluctance to accept or agree to be vaccinated irrespective of the availability and accessibility of the vaccine. WHO attributes this reluctance to three major factors: convenience, confidence, and complacency. Vaccine hesitancy is a critical barrier in achieving high uptake of COVID-19 vaccines. In Kenya, COVID-19 vaccination was rolled out to the general population in March 2021. ANC based surveillance involving a questionnaire administered to all consenting women attending ANC1 in selected facilities starting in August 2021 to assess COVID-19 vaccine uptake among pregnant women was used . Data on COVID-19 vaccine uptake and reasons for the vaccine reluctance were collected using ScanForm software. Stata used to perform descriptive analyses. Additionally, a qualitative evaluation to further explore reasons for vaccine hesitancy and trusted data sources was conducted; analysis is in process. Between August 2021 and February 2022, 2,691 pregnant women were interviewed regarding their COVID-19 vaccination status and perceptions. The median age was 25.5 years (IQR 12-49) years and approximately half had attained secondary education. The vast majority (2,318; 86.1%) had not received the vaccine. Among these, 817/ 2,318 (35.3%) stated that they would decline the COVID-19 vaccine if offered, with 721/ 817 (88.3%) citing concern about the side effects of the vaccine as the reason. A small proportion 22/ 817 (2.7%) stated they would decline the vaccine if offered because they were not worried about getting COVID-19, and one person had already had COVID-19 and felt vaccination was unnecessary. A third of pregnant women surveyed at ANC were hesitant to receive the COVID-19 vaccine, primarily due to fear of side effects; this will substantially hamper vaccination uptake. There is a need to address concerns about the safety of COVID-19 vaccines in order to increase the uptake. Understanding how best to respond to peoples' concerns most effectively is critical to reach high vaccine coverage.

0733

EDUCATION AND OCCUPATION ARE THE BASIC FACTORS CONTRIBUTING TO INEQUITY IN COVID VACCINATION COVERAGE OVER TIME AMONG PEOPLE AGED 40 YEARS AND OLDER: FINDINGS FROM A RURAL COHORT IN BANGLADESH

Rajib Biswas[1], Emily S. Gurley[2], Kyu Han Lee[2], Kazi Munisul Islam[1], Mohammad Sabbir Ahmed[1], Shovo Debnath[1], Qazi Sadeq-ur Rahman[1], Abu Mohammad Saleheen[1], Mohammad Abdus Salam[1], Sanwarul Bari[1], Shams El Arifeen[1], Mohammad Zahid Hossain[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States

Bangladesh began offering vaccines against COVID-19 on January 27, 2021, to those aged ≥40 years. Our objective was to assess the sociodemographic factors associated with vaccination of the population aged ≥40 years who received at least one vaccination dose between February 2021 to January 2022 in Baliakandi, a rural sub-district of Bangladesh. Since 2017, the Child Health and Mortality Prevention Surveillance (CHAMPS) network has been collecting demographic surveillance data from the Baliakandi population, with prospective COVID-19 vaccination information beginning in April 2021 through interviews and vaccination cards. We classified the first dose of vaccination dates into four quarters from February 1, 2021, to January 31, 2022. The relationships between participant demographics and vaccination timing were examined using bivariate multinomial logistic regression. Only 6% of the population received vaccinations in the first quarter, 12% in the second, 44% in the third, and 13% in the fourth quarter. By the end of January 2022, 75% of the population aged ≥40 years and 64% of the population aged >65 years had been vaccinated. Males were 1.5 times more likely to receive vaccines in the first quarter. In the first two quarters, 60% of the population who had more than 12 years of schooling received vaccinations, compared to only 10% of the population with no or only non-formal education. By July 2021, 38% of healthcare and administrative workers, groups targeted early for vaccination, had received doses, and these groups had 10.7 times higher odds (95% CI: 8.7-13.1) of receiving vaccination in the first quarter compared to others. Preliminary data indicates people aged ≥40 years with higher education and working in healthcare or administrative offices, who make up only 12% of the rural population, started receiving vaccinations earlier than others. A particular focus should be given to educating people without formal education about the importance of vaccination and encouraging them to receive it early. Education based interventions, outreach vaccination centers, community leaders, and the media may all be of assistance in this initiative.

0734

COMMUNITY-BASED SURVEILLANCE AND MINIMALLY INVASIVE TISSUE SAMPLING (MITS) FOR RSV-ASSOCIATED INFANT MORTALITY IN KARACHI, PAKISTAN

Waliyah Mughis[1], Zeeshan Uddin[1], Nazia Ahsan[1], Saima Jamal[1], Farah Qamar[1], Raheel Allana[1], Ayub Khan[1], Christina Arif[1], Fauzia Aman Malik[2], Saad Bin Omer[2], Lindsay Parlberg[3], Christina Paganelli[3], Norman Goco[3], Abdul Momin Kazi[1]

[1]Aga Khan University, karachi, Pakistan, [2]Yale University, New Haven, CT, United States, [3]RTI International, Durham, NC, United States

A community-based infant mortality surveillance study was conducted in low-income peri-urban catchment areas of Karachi, Pakistan (2018-21), to establish the burden of respiratory syncytial virus (RSV) in recently deceased infants. In the first phase of the study, 589 nasopharyngeal swab specimens were collected, of which 15 were RSV positive and 1 was positive for Bordetella pertussis. In the next phase (2020-21), minimally invasive tissue samples (MITS) of the lungs/thorax were collected from 24 recently deceased infants from the same community, with the aim of improving the classification of upper respiratory tract infections via histopathology analysis. Interviews, focus group discussions, study advocacy and ongoing community engagement with key community stakeholders (parents of deceased infants, religious and community leaders, graveyard administrators) facilitated and enabled the challenging process of obtaining consent from bereaved parents in a critical time window of an hour between an infant's death and burial. A van was customized to mobilize for specimen collection within the community, and local health workers and mobilizers from the community were able to effectively counsel bereaved families regarding the study procedure, and later provide grief support to the bereaved parents. While RSV was not detected in the MITS cases, remarkable pathology findings from 11 cases included bacterial pneumonia, pyogenic pneumonia, hyaline membrane disease, mild focal chronic interstitial inflammation, aspiration pneumonia, diffused alveolar damage, and bronchopneumonia in the lungs. These findings indicate the significance of MITS in identifying causes of death in infants, which can be helpful in prioritizing strategies for determining causes of death and reducing infant mortality in developing regions.

0735

QUALITY MANAGEMENT SYSTEMS IMPLEMENTATION IN ANIMAL HEALTH LABORATORIES FOR IMPROVED DETECTION OF PRIORITY ZOONOSES IN UGANDA

Thomas Ssemakadde[1], Derrick Emmanuel Mimbe[1], Susan Diana Kerfua[2], Joseph Kasekende[1], Stella Atim[3], Lindsey Shields[4], Emmanuel Mugisha[5], Ibrahim Ali[6], Linda Venczel[6], David Mungai[7], Anicet Dahourou[4]

[1]USAID Infectious Disease Detection and Surveillance project, Kampala, Uganda, [2]National Livestock Resources Research Institute, Kampala, Uganda, [3]Ministry of Agriculture Animal Industries and Fisheries, Kampala, Uganda, [4]USAID Infectious Disease Detection and Surveillance project, Washington, DC, United States, [5]PATH, Kampala, Uganda, [6]USAID Infectious Disease Detection and Surveillance project, Seattle, WA, United States, [7]USAID Infectious Disease Detection and Surveillance project, Nairobi, Kenya

Emerging and re-emerging zoonotic diseases pose an ever-increasing threat to public health. Implementation of Quality Management System (QMS) in laboratories is critical for detecting and responding to disease threats. Uganda has 34 human health laboratories accredited to ISO standards. However, the animal health sector lacks any ISO accredited facility. Therefore, USAID's Infectious Disease Detection and Surveillance (IDDS) project and the Ministry of Agriculture, Animal Industry and Fisheries initiated QMS implementation in April 2021, to improve laboratory service delivery and set regional animal health laboratories on the path toward accreditation based on ISO/IEC 17025:2017 structure. From October 2020, the IDDS project conducted a multi-sectoral consultative meeting to develop a QMS mentorship tool kit based on ISO 17025:2017, in addition to Training of Trainers (TOTs). The certified TOTs then supported training for staff at four regional animal health laboratories in Gulu, Mbale, Mbarara, and Moroto, with each regional veterinary laboratory supporting between 7 to 11 districts in the catchment area. These facilities were enrolled in a mentorship program, and audits were conducted to gauge policy documents' impact, standardizing, and alignment. IDDS supported the development of a QMS mentorship tool kit and 8 veterinary and 12 laboratory staff training at the respective regional animal health laboratories. Four regional facilities were enrolled in the QMS mentorship program. Pre-audit results indicated that these facilities had no QMS-related documentation. Post-audit results showed that relevant SOPs and Quality Manuals were developed. We conducted mandatory trainings for QMS implementation and developed SOPs and policy documents required by the standard. The pre and post test scores during the trainings indicated an average increment in knowledge from 33.2% in the pre-test to 81.8% in post scores.

0736

DESIGN OF EFFECTIVE OUTPATIENT SENTINEL SURVEILLANCE FOR COVID-19 DECISION-MAKING: A MODELING STUDY

Kok Ben Toh, Manuela Runge, Reese Richardson, Thomas J. Hladish, Jaline Gerardin

Northwestern University, Chicago, IL, United States

Decision-makers impose COVID-19 mitigations based on public health indicators such as reported cases, which are sensitive to fluctuations in supply and demand for diagnostic testing, and hospital admissions, which lag infections by two weeks. Imposing mitigations too early has unnecessary economic costs, while imposing too late leads to uncontrolled epidemics with too many cases and deaths. To overcome bias and lag in conventional indicators, the city of Chicago, USA, implemented sentinel surveillance of recently-symptomatic individuals in outpatient testing sites by collecting data on symptom status and symptom onset date. Even with few participating testing sites, Chicago found that sentinel cases were more timely than hospital admissions, although trends were less certain due to low sampling rate. To characterize the minimal outpatient sentinel surveillance system needed for reliable trend estimation, we use a stochastic compartmental model and evaluate the performance of various surveillance indicators at reliably triggering an alarm in response to, but not before, a step increase in transmission rate. We find that outpatient sentinel surveillance that captures at least 20% of incident mild cases results in mitigative action median of 3 to 5 days earlier, triggers fewer false alarms (5% vs 39%), and averts more deaths per day spent in mitigation than surveillance based on hospital admissions. Because hospitalization rates are lower in younger populations, we tested whether sentinel surveillance was especially beneficial when transmission surges happened first in younger populations, as was observed in several epidemic waves in the USA. When older populations lag younger populations in experiencing transmission surges by 20 days, sentinel surveillance extends its lead in acting against an incoming wave by an additional 4 days over hospital admissions. Sentinel surveillance of mild symptomatic cases is a feasible and effective tool for guiding decision-makers in an epidemic like COVID-19.

SHARING MINIMALLY INVASIVE TISSUE SAMPLING (MITS) RESULTS WITH MOTHERS AND ITS IMPACTS ON HEALTH-SEEKING BEHAVIOR AND DELIVERY OUTCOMES IN SUBSEQUENT PREGNANCY: FINDINGS FROM HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) BANGLADESH

Shovo Debnath[1], Mohammad Zahid Hossain[1], Emily S. Gurley[2], Kyu Han Lee[2], Qazi Sadeq-ur Rahman[1], Mohammad Sabbir Ahmed[1], Rajib Biswas[1], Afruna Rahman[1], Abu Mohammad Saleheen[1], Mohammad Abdus Salam[1], Atique Iqbal Chowdhury[1], Sanwarul Bari[1], Shams El Arifeen[1], Kazi Munisul Islam[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The Child Health and Mortality Prevention Surveillance (CHAMPS) network conducts minimally invasive tissue sampling (MITS) and data collection to determine the causes of stillbirths and under 5 child deaths in a rural area Baliakandi, Bangladesh. An expert panel identifies causes of death and preventive measures after reviewing laboratory reports, clinical records, and verbal autopsies. The results and recommendations, such as using quality antenatal care (ANC) and future health-seeking behavior, are shared with the mothers. This study aimed to assess the impact of sharing MITS results and recommendations with mothers on their health-seeking behavior and delivery outcomes in subsequent pregnancies. From September 2017 to February 2022, we conducted 121 MITS of babies of 118 mothers and shared results with 99 mothers in the Baliakandi catchment area. Among them, 36 women had subsequent pregnancies and delivery outcomes. For the pregnancy associated with the MITS procedure, 13 women had stillbirths, 21 died in the early and 2 in the late neonatal periods. Sixty percent (15/25) of women sought ANC services during their MITS-associated pregnancy, which increased to 85% (28/33) in subsequent pregnancies with known ANC status. Previously only one woman (1/25) had ≥ 4 ANC visits, compared to 33% (11/33) of women in the subsequent pregnancies. During their MITS-associated pregnancy, the median gestational age at the first ANC visit was 18 weeks (IQR: 8-26), compared to 13.5 weeks (IQR: 9.5-17.5) in the subsequent pregnancy. The median birth spacing was 7.5 months (IQR: 3-14). However, 53% (19) of mothers' last menstrual period (LMP) of subsequent pregnancy was before the result sharing date, and their mean inter-pregnancy interval was 3 months. Pregnancy outcomes included 29 (81%) live births, 5 (13%) miscarriages, 2 (6%) induced abortions, and 79% (23/29) chose to deliver their babies at a health facility. Our preliminary findings highlight the increased coverage and timeliness of ANC in subsequent pregnancies. Further exploration of barriers to ANC visits, early result sharing within 3 months may improve their further health-seeking behavior.

0738

IMPROVING COMMUNITY DEATH NOTIFICATION IN A HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM: LESSONS LEARNT FROM 5-YEAR OF A TOLL-FREE IN MANHICA DISTRICT, MOZAMBIQUE

Ariel Quingue Nhacolo, Bento Nhancale, Saquina Cossa, Edgar Jamisse, Teodomiro Matsena, Aura Hunguana, Inacio Mandomando, Quique Bassat, Charfudin Sacoor

Manhica Health Research Center, Manhica, Mozambique

In some low and-middle income countries, health and demographic surveillance systems (HDSS) are established to provide accurate and timely reported demographic data for biomedical research, but the increasing demand on timely reported events forces the constant innovation in their methods. This paper describes the Manhica HDSS the toll-free introduced to report deaths and stillbirths in 24 hours of occurrence, evaluating the usefulness of this toll-free for improving the HDSS timely report. The toll-free was implemented in 2017 to respond to the Child Health and Mortality Prevention Surveillance (CHAMPS) network study, which require the report of under five years deaths and stillbirths within 24 hours to perform minimally invasive tissue sampling in the corpses for ascertaining the causes of death. All the calls received are recorded in a database that report the time of the call, category of the notifier, type of event, place and date. The analysis consists of descriptive statistics of who reports what from where, and whether the time-to-report events has improved during the 5-year period of toll-free compared to 5-period prior to the toll-free. Challenges for a correct functioning of this call center include low network coverage, scarcity of mobile phones within the community, and the lack of electricity in many households. The analysis shows that the time to report events has sharply decreased after the introduction of toll-free, compared to the period prior to the toll-free from an average of 69.8 days to 48.3 for reporting under-five deaths and from 64.9 to 2.7 days for reporting stillbirths. The percentage of child deaths and stillbirths reported within 24 hours has increased from an average of 43.7% before toll-free to 67.6% after in stillbirths, and from 15.2% to 34.1% in child deaths. Delays in reporting remain significant, particularly with community deaths, where only 26% were reported within 24h. Community engagement remains critical to foster faster reporting of community deaths. The toll-free number needs to be distributed to all the households rather to be given to community key informants who cannot capture all the information.

0739

LYME SERO-CONVERSION SURVEILLANCE AMONG U.S. MILITARY PERSONNEL IN HONDURAS

Hua-Wei Chen, Victor Sugiharto, Stephanie Gatrell, Gabrielle Blazek, Amanda Cherry, Mark Simons, Megan Schilling

Naval Medical Research Center, Silver Spring, MD, United States

Lyme disease is caused by the spirochete *Borrelia burgdorferi sensu lato*. Transmission is through the bite of infectious ticks, primarily the hard tick from the genus Ixodes. Within the US active duty members, Lyme disease is the most frequently reported vector-borne disease with an incidence rate of 292 cases per 100,000 person years in in fiscal year 2016-2018 in a study in West Point. There has been no report about Lyme disease in Central America but there are reports of a traveler that contracted rickettsia after his trip to Honduras. This highlights the need for better surveillance of Lyme disease in Honduras. The aim of this study is to determine the prevalence of Lyme disease in U.S. military personnel deployed to Honduras using serological assays. A cohort of pre- and post-deployment sera from the most recent 1,000 U.S. military personnel stationed in Honduras for at least six months between 2000 and 2016 was used for this study. All post-deployment serum samples were screened at a dilution of 1:100 for the presence of IgG antibodies against *Borrelia burgdorferi* with ELISA. The pre-deployment sera from those individuals with seropositive post-deployment samples were tested to determine seroconversion. Seroconversion was defined as conversion of an optical density value from below the cutoff in a pre-deployment specimen to above the cutoff in a post-deployment specimen. The post-deployment seropositivity in U.S. military personnel for antibodies against *Borrelia burgdorferi* was 5.2% (52/1,000). Among them, seroconversion occurred for 11 (1.1%) persons during their assignment to Honduras. In conclusion, this is the first study for risk assessment of Lyme disease among U.S. military personnel deployed to Honduras. Additional testing of potential vectors for *Borrelia burgdorferi* in the regions could inform effective vector control counter measurements to prevent exposure.

HYPERSENSITIVITY REACTIONS TO *IXODES SCAPULARIS* BITES

Abhinav Kumar[1], Kevin Kuruvilla[2], Kenneth Dardick[2], Scott Espich[1], Peter J. Krause[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]University of Connecticut, Storrs, CT, United States

Tick salivary proteins introduced into mammalian hosts during a blood meal result in an array of complex immune reactions. Previous studies

have suggested that hypersensitivity reactions following *Ixodes scapularis* bites, including itch, may interfere with the transmission of tick-borne pathogens, including *Borrelia burgdorferi* (the Lyme disease agent). There are few studies in humans regarding the spectrum of hypersensitivity reactions that occur following *I. scapularis* bites and their effect on *B. burgdorferi* transmission. We analyzed data obtained from the prospective enrollment of 102 people who reported acute tick bite to a medical practice in Mansfield, Connecticut and from serosurvey participants on Block Island Rhode Island from 2005-2018. Ticks brought in by study subjects were speciated. Clinical responses from these patients and those who participated in the serosurvey were recorded and subject based diaries were used to classify hypersensitivity reactions and to determine whether they reduced Lyme disease transmission. None of the 102 subjects developed systemic reactions following tick bite. The most common localized reactions were type I hypersensitivity reactions, including local erythema (88%), swelling (64%), and itch (48%). About a quarter of study subjects experienced swelling that was consistent with a delayed type hypersensitivity reaction. Of these reactions, only tick bite itch was associated with the frequency of tick bites. Those with 3 or more tick bites in the previous 12 months were 6 times more likely to report a current tick-associated itch than those who experienced 1 bite in the previous 12 months. Hypersensitivity responses were not associated with the presence or absence of a history of Lyme disease. A third (308) of the 919 serosurvey participants reported itch following tick bites.In conclusion, hypersensitivity reactions to *I. scapularis* bites were common in residents of a Lyme disease endemic region in the Northeast. Tick bite-associated itch was positively associated with the frequency of tick bite but not with a past history of Lyme disease.

0741

LONGITUDINAL STUDY OF *IXODES SCAPULARIS* ABUNDANCE AND PATHOGEN BURDEN IN CONNECTICUT, U.S.A.

Duncan W. Cozens, Jamie L. Cantoni, Megan A. Linske, Kirby C. Stafford III, Scott C. Williams, Doug E. Brackney

Connecticut Agricultural Experiment Station, New Haven, CT, United States

Ixodes scapularis are the primary vector for numerous human pathogens, including *Borrelia burgdorferi*, *Borrelia miyamotoi*, *Anaplasma phagocytophilum*, *Babesia microti*, and Powassan virus lineage II. Understanding the spatial and temporal distribution of *I. scapularis* and its associated pathogens is paramount to implementing necessary control strategies and public health interventions. Consequently, in 2019, we began an active tick surveillance program to better monitor tick presence and tick-borne pathogen prevalence in Connecticut. Between 2019 and 2021 a total of 1561 female and 1787 nymphal *I. scapularis* were collected from all 8 counties across the state. Individual *I. scapularis* were tested with a RT-qPCR multiplex assay against the five aforementioned pathogens. Statewide pathogen prevalence rates were 56.6% in females (833/1561) and 26.8% in nymphs (478/1787), with the most common being *B. burgdorferi*, 49.7% (776/1561) and 18.6% (332/1787) in females and nymphs, respectively. Year-to-year analysis of pathogen prevalence revealed a significant increase in the percentage of pathogen positive ticks. While pathogen presence at the county level fluctuated year-to-year, significant differences were witnessed between counties when examining total pathogen presence over the three-year period. Our multiplex assay allowed us to observe significant increases in co-infection with *B. burgdorferi* and at least one other pathogen at the state level since 2019. Results from the active tick surveillance program gives both a better grasp of tick abundance as well as the burden of tick-borne pathogens throughout the state at the county level.

0742

PRE-CLINICAL EFFICACY AND CORRELATES OF IMMUNITY FOLLOWING VACCINATION WITH FOUR IMMUNODOMINANT *BABESIA MICROTI* ANTIGENS IN MICE

Scott M. Meredith, Victoria F. Majam, Hong Zheng, Nitin Verma, Ankit Puri, Mark A. KuKuruga, Adovi Alue, Miranda Oakley, Sanjai Kumar

Food and Drug Administration, Silver Spring, MD, United States

Babesia microti, an intraerythrocytic apicomplexan parasite, is the primary causative agent of human babesiosis and an emerging threat to public health in the United States and elsewhere. In addition to natural transmission by *Ixodes* ticks, *B. microti* can also be transmitted in blood and blood products. In spite of its global presence and geographical expansion, very little investment has been made to develop novel therapeutics, including drugs and vaccines, against this pathogen. Here we report on immunogenicity, protective efficacy and immunological correlates of immunity following vaccination with four recombinantly-produced immunodominant *B. microti* antigens—Serine-repeat antigen 1 (SERA1), Maltese cross form-related protein 1 (MCFRP1), piroplasm β-strand 1 (PiβS1), and *Babesia* α-helical cell surface 1 (BAHCS1). BALB/c mice were immunized with purified *E. coli*-expressed protein with Montanide ISA 51/CpG adjuvant delivered subcutaneously. Protective efficacy was measured as reduction in peak parasitemia and in total parasite burden throughout the course of infection following challenge with asexual blood form *B. microti* parasites. Vaccination-induced immune response against each *B. microti* antigen was assessed by antigen-specific total IgG and IgG subclass ELISA, multiparameter flow cytometry, and Bio-Plex Pro Mouse Cytokine 23-plex assay. Results showed that that immunization with BAHCS1 led to highest reduction in peak parasitemia (70.2%), followed by SERA1 (43.5%) and MCFRP1 (41.9%). While all four antigens demonstrated a capacity to stimulate strong antibody and cellular responses, early activation of a Th2-type response was generally associated with a protective immune response. Our data suggest that BAHCS1 warrants further evaluation in preclinical studies. Details of immunization/challenge and correlates of vaccination-induced immunity against these antigens will be presented.

FLEA-BORNE TYPHUS CAUSING FATAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

Divya Chandramohan, Olivia Fisher, Moyosore Awobajo, Gregory M. Anstead, Christopher Dayton

UT Health-San Antonio, San Antonio, TX, United States

Flea-borne typhus (FBT) is increasing in incidence in multiple global locations and usually has a benign course. Herein, we present a fatal case of hemophagocytic lymphohistiocytosis (HLH) ascribed to FBT. A 71-year-old diabetic woman presented with confusion, weakness, nausea, and urinary frequency. She was lethargic, with vitals significant for tachypnea and BP 163/63 mm Hg. Lab evaluation revealed WBC 9.84 K/μL (reference range (RR) 3.4-10.4 K/μL), Hgb 14.2 g/dL (RR 11.5-14.9 g/dL), platelets 125 K/μL (RR 140-370 K/μL), bicarbonate 13 mmol/L (RR 20-29 mmol/L), anion gap 22 mmol/L (RR 8-12 mmol/L), glucose 148 mg/dL (RR 60-100 mg/dL), AST 153 U/L (RR 13-39 U/L), ALT 55 U/L (upper limit of normal (ULN) <36 U/L), alkaline phosphatase (AP) 48 U/L (RR 45-117 U/L), and albumin 3 g/dL (RR 3.2-5.0 g/dL). She was diagnosed with euglycemic diabetic ketoacidosis and was started on ceftriaxone, IV fluids, and insulin drip. On day-2 (D2), anion gap normalized. She was persistently febrile; blood, urine culture were negative, and CT showed lingular consolidation. Viral respiratory and hepatitis panels as well as HIV test were negative; C-reactive protein was 247 mg/L (ULN 10 mg/L). On D4, she had increasing AST, ALT, and AP. On D5, she developed worsening mental status, lactic acidosis, hypotension, and respiratory failure. She was intubated and started on norepinephrine and broad-spectrum antibiotics including doxycycline. Testing on D5 showed WBC 23.2 K/μL, Hgb 11.3 g/dL, platelets 74 K/μL, and procalcitonin >200 ng/mL. On D6, AST 3361

U/L, ALT 392 U/L, AP 403 U/L, and bilirubin 2.4 mg/dL (RR 0.2-1.2 mg/dL). Bronchoalveolar lavage cultures were negative. She had worsening lactic acid to 20.3 and increasing pressor requirements. Later, she transitioned to comfort care. Final lab tests showed Hgb 8.1 mg/dL, platelets 64 K/μL, and elevated lactate dehydrogenase (3374 U/L); d-dimer (58,663 ng/mL (< RR 500 ng/mL)), and hypertriglyceridemia. *Rickettsia typhi* serology sent on D5 returned later with IgM 1:256, IgG <1:64. Autopsy revealed hemophagocytic histiocytes in lymph nodes and bone marrow. With these findings, the cause of death was ascribed to HLH due to FBT.

0744

DEVELOPMENT OF A RECOMBINASE POLYMERASE AMPLIFICATION LATERAL FLOW (RPA-LF) ASSAY TO DETECT *EHRLICHIA CHAFFEENSIS*

Haley A. Abernathy[1], Osahon C. Iyamu[2], Clark H. Cunnigham[3], Jonathan J. Juliano[4], Natalie M. Bowman[3], Ross M. Boyce[4], Emily J. Ciccone[3]

[1]Institute of Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, [2]University of North Carolina, Chapel Hill, NC, United States, [3]School of Medicine, University of North Carolina, Chapel Hill, NC, United States, [4]School of Medicine and Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, United States

Human Monocytic Ehrlichiosis (HME) is an emerging and potentially fatal tick-borne disease caused by the intracellular, Gram-negative bacterium, *Ehrlichia* with *E. chaffeensis* being the most common species infecting humans. HME can be difficult to distinguish from other tick-borne infections and causes of febrile illness. Traditional laboratory confirmation of HME requires serological testing performed on acute and convalescent plasma samples collected 2-4 weeks apart, which is infrequently achieved. These factors contribute to both under- and misdiagnosis of HME. Quantitative polymerase chain reaction (qPCR) offers a species-specific method of *Ehrlichia* identification. However, qPCR assays are expensive and not readily available outside of reference laboratories, which limits their utility in clinical management of acute disease. To address the current pitfalls in HME diagnostics, we developed a recombinase polymerase amplification (RPA) assay adapted to a lateral flow (LF) platform to isothermally detect *E. chaffeensis*. Five primer sets, targeting three gene segments, were tested using TwistAmp® Basic kit and kit manual from TwistDx™. The primer set with the best band intensity following gel electrophoresis was selected for adaptation to the RPA. A probe was designed according to the TwistAmp® nfo guidelines. The primer-probe set, targeting the groEL gene segment, which encodes a 60-kDa heat shock protein that is specific to *Ehrlichia chaffeensis*, was tested using the TwistAmp® nfo kits and visualized on lateral flow strips. The RPA-LF assay successfully detected genomic DNA specific to *E. chaffeensis* but did not detect DNA from *Anaplasma phagocytophilum, E. ewingii, Rickettsia rickettsii, R. amblyomatis, R. parkeri, R. africae, Brucella abortus*, or *B. suis*, which may cross-react with serologic assays for *Ehrlichia*. In conclusion, the RPA-LF assay targeting the groEL gene is specific for *E. chaffeensis*. Further testing to determine the limit of detection for the assay is underway.

0745

FIELD EVALUATION OF LOOP-MEDIATED ISOTHERMAL AMPLIFICATION FOR DETECTION OF *ONCHOCERCA* SPP. IN BLACKFLY POPULATIONS

Zubaidah Binti Ya-cob[1], Germanus S. Bah[2], Glory Ngongeh[3], David Ekale[4], Ndode Herman Okah-Nnane[2], Catherine B. Poole[5], Zhiru Li[5], Vincent Tanya[2], Samuel Wanji[3], Cotilde K.S. Carlow[5], Benjamin L. Makepeace[6], **John Graham Brown**[6]

[1]University of Malaya, Kuala Lumpur, Malaysia, [2]Institut de Recherche Agricole pour le Développment, Yaounde, Cameroon, [3]University of Buea, Buea, Cameroon, [4]Institut de Recherche Agricole pour le Développment, Wakwa, Cameroon, [5]New England Biolabs, Ipswich, MA, United States, [6]University of Liverpool, Liverpool, United Kingdom

Onchocerciasis (river blindness) is a vector-borne neglected tropical disease caused by *Onchocerca volvulus*. Worldwide an estimated 20.9 million individuals live with infection and a further 205 million are at risk of disease, predominantly in sub-Saharan Africa. As a current target for disease elimination, monitoring of blackfly vector populations (*Simulium damnosum s.l.*) is necessary to determine whether transmission is ongoing in endemic areas. Presently, this requires centralised testing by PCR. In the current investigation, we evaluated the performance of a novel Loop-mediated Isothermal Amplification (LAMP) assay for detection of *O. volvulus* and/or the closely related cattle parasite *O. ochengi* in infected *Simulium damnosum s.l.* populations. First, *Simulium damnosum s.l.* were collected from a location with confirmed *O. ochengi* transmission. Pooled samples were tested by LAMP assay using a generic O-150 primer, with 90 pools of 100 flies per pool. Results were compared to infection status determined by dissection of flies collected over the same time period, and conventional PCR. Second, the sensitivity and specificity of the LAMP assay using an *O. volvulus*-specific *Ov*-GST-1α primer set was tested through analysis of pooled DNA samples extracted from heads of laboratory-bred, *O. volvulus*-infected *Simulium damnosum s.l.*, with 30 pools of 10 heads per pool; alongside pooled DNA samples with confirmed *O. ochengi* infection from the initial investigation. These investigations determined that the LAMP assay was: (a.) as effective as conventional methods at detecting *Onchocerca* spp. infection under field conditions using generic O-150 primers, (b.) capable of detecting *O. volvulus* infection with a high degree of sensitivity from 8 days post-infection in fly heads using species-specific primers, but (c.) current primers and/or methods may indicate presence of other *Onchocerca* spp. DNA in addition to *O. volvulus*. Pending further field study and evaluation, these findings show the potential of LAMP assays as a screening tool for *O. volvulus* transmission with a possible future role in ongoing disease elimination programmes.

INVESTIGATION OF SEROPREVALENCE OF EHRLICHIOSIS AND ANAPLASMOSIS ALONG THE TEXAS-MEXICO BORDER

Josephine Blackburn[1], Lauren M. Leining[1], Frederic Cramer[1], Kristy O. Murray[1], Timothy A. Erickson[1], Eric L. Brown[2], Sarah M. Gunter[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]University of Texas Health Science Center, Houston, TX, United States

Ehrlichia sp. and *Anaplasma* sp., both members of the family Anaplasmatacea, are tick-borne pathogens of public health importance that are endemic to the US. Symptoms for these diseases range in severity from asymptomatic infection (80% of cases) to a febrile illness that requires hospitalization. Since these pathogens were first described in the late 1980s and 1990s, the incidence of human infection of both *Ehrlichia* spp. and *Anaplasma* sp. have been increasing in the US. Additionally, cases likely still remain underreported due to lack of physician awareness, non-specific clinical presentation, and insufficient access to diagnostic tests. Our current understanding of the epidemiology of these diseases remains in its infancy and the US, and specifically in Texas. Our study aims to determine the seroprevalence of Ehrlichiosis and Anaplasmosis in a large cohort (n=610) of adults residing along the Texas-Mexico border. We screened the cohort using a dual spot immunofluorescent assay (IFA) to determine the IgG reactivity to *Ehrlichia* spp. and *Anaplasma phagocytophilium*. Seropositivity was defined as a titer of ≥1:64. We identified 24% of the cohort were seropositive for *Ehrlichia* spp. and 3% were seropositive for *A. phagocytophilium*. End-point titers were determined for seropositive samples and a risk-factor analysis was conducted using survey data. These findings indicate a high disease burden, especially along the Texas-Mexico border. While it is suspected that the majority of *A. phagocytophilium* is imported, there is growing evidence that transmission of Ehrlichiosis

is ongoing in the border region. There is a need to develop more robust screening tools and organize a public health response in the region that focusing on detection.

THE EMERGENCE OF TICKS AND TICK-BORNE DISEASE IN SOUTH CAROLINA: ESTABLISHING A STATEWIDE INITIATIVE LEVERAGING ACADEMIC-PUBLIC PARTNERSHIPS

Melissa S. Nolan[1], Kyndall Dye-Braumuller[1], Chris Evans[2], Lauren Rustin[2], Eric Lachenmyer[2], Michael Neault[3]

[1]University of South Carolina, Columbia, SC, United States, [2]South Carolina Department of Health and Environmental Control, Columbia, SC, United States, [3]Clemson University, Columbia, SC, United States

Tick-borne diseases have tripled in the last two decades, with several novel pathogens and an invasive tick species recently discovered in the United States. Local vector control agencies have traditionally focused on mosquito abatement; however, the need to establish tick surveillance activities has grown as tick-borne disease incidence has concomitantly expanded. In response to this emergent public health threat, the state health department and flagship university in South Carolina established a productive tick surveillance program. This presentation will discuss the capacity building and partnership leveraging aspects of starting a large-scale public health program, and results from the past three years of surveillance. This program yields an average of 5,000 ticks annually from a variety of sources: state and county parks, state forests, animal shelters, and cattle ranches and auctions. Nine tick species have been collected in South Carolina as apart of the three-year surveillance program, including four non-native species: Asian longhorned tick, Gulf Coast tick, the Northern clade blacklegged deer tick, and the rabbit tick. Collected ticks tested positive for pathogens that cause spotted fever group rickettsioses, Lyme disease, anaplasmosis, and ehrlichiosis. Species and pathogen geographic distribution will be presented. Overall, this presentation will provide a solid understanding of the changing epidemiologic profile of tick-borne diseases in South Carolina.

0748

THE SEROPREVALENCE AND RISK FACTORS FOR SPOTTED FEVER GROUP AND TYPHUS GROUP RICKETTSIA ALONG THE TEXAS-MEXICO BORDER

Frederick M. Cramer[1], Lauren M. Leining[1], Timothy A. Erickson[1], Josephine C. Blackburn[1], Craig L. Hanis[2], Eric L. Brown[2], Sarah M. Gunter[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]UThealth School of Public Health, Houston, TX, United States

Rickettsial pathogens are gram-negative, obligate intracellular bacteria classically divided into two main groups: Spotted Fever Group Rickettsia (SFGR) and Typhus Group Rickettsia (TGR). Ticks are the predominant vectors for SFGR species, whereas fleas and lice are the primary vectors for TGR species. Both groups represent a significant and emergent source of disease in Texas and along the U.S.-Mexico border. Understanding risk factors associated with the transmission of these pathogens is necessary for developing prevention strategies and targeted interventions for high-risk groups in Texas. To better understand the prevalence and risk factors for SFGR and TGR, we conducted a cross-sectional study using plasma samples from participants of an ongoing cohort study (N=616) in south Texas. Samples were screened for SFGR and TGR using enzyme-linked immunosorbent assays (ELISAs). All ELISA positive samples were then confirmed using a dual spot indirect immunofluorescent assay (IFA). Seropositivity was determined as having an endpoint titer ≥1:64. Additionally, demographic and epidemiologic data were collected from participants for a risk factor analysis. Our preliminary analysis indicated a higher seroprevalence of TGR compared to SFGR, at 30% and 8% respectively. These findings demonstrate that SFGR and TGR are likely endemic to regions along the Texas-Mexico border and require further investigation to fully understand the disease burden.

0749

FIRST WHOLE GENOME ISOLATION OF CRIMEAN-CONGO HAEMORRHAGIC FEVER VIRUS (CCHFV) IN TICK SPECIES WITHIN GHANA AND THE RISK OF HUMAN EXPOSURE TO THE VIRUS

Ronald Bentil[1], **Terrel Sanders**[2], Seth O. Addo[1], Mba-Tihssommah Mosore[1], Selassie Kumordjie[1], Clara Yeboah[1], Bright Agbodzi[1], Eric Behene[1], Julian Adinkrah[1], Janice Tagoe[1], Bernice O. A. Baako[3], Victor Asoala[3], Anne T. Fox[2], Andrew G. Letizia[4], Joseph W. Diclaro II[5], Edward O. Nyarko[6], Daniel Oduro[7], Shirley Nimo-Paintsil[2], James Harwood[8], Samuel Dadzie[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]US Naval Medical Research Unit No. 3 Ghana Detachment, Accra, Ghana, [3]Navrongo Health Research Centre, Navrongo, Ghana, [4]US Naval Medical Research Unit No. 2, Singapore City, Singapore, [5]Navy Entomology Center for Excellence, Jacksonville, FL, United States, [6]Public Health Division, 37 Military Hospital, Accra, Ghana, [7]Department of Animal Biology and Conservation Science, University of Ghana, Accra, Ghana, [8]U.S. Naval Medical Research Unit No. 3, Sigonella, Italy

Ticks are important blood-sucking arthropod vectors. They are known to spread a wide range of diseases that cause severe and life-threatening illnesses in animals and humans, including military personnel. In population-dense and trade-dominant areas such as the Greater Accra and Upper East Regions, the risk of zoonotic infections may be on the rise. This study, therefore, sought to identify the circulating tick species, determine the pathogens they carry, and assess the risk of exposure of primary animal handlers and impact it may have on force health protection. A total of 705 ticks were collected from cattle (n=188) and horses (n=11). Three tick genera (*Hyalomma, Amblyomma* and *Rhipicephalus*) were observed in the study with the predominant species being *Hyalomma rufipes* (n=290, 41.13%), followed by *Amblyomma variegatum* (n=157, 22.27%) and the least abundant, *Rhipicephalus sanguineus* (n=1, 0.14%). Out of the 705 tick samples, Crimean-Congo haemorrhagic fever virus (CCHFV) infection rates of 0.78% (95% CI, 0.02-3.96), 0.69% (95% CI, 0.08-2.4) and 0.64% (95% CI, 0.02-3.24) were recorded in *Hyalomma truncatum*, *H. rufipes* and *A. variegatum*, respectively. No infection was detected in the *Rhipicephalus* species. Further, a strain was successfully recovered using Next Generation Sequencing for PCR positive tick samples with analysis based on complete open reading frame of the S-segment of the CCHFV genome. The strain belonged to the third genotype (Africa 3) and shared 98.9% nucleotide identity with DQ211641_Mauritania_1984 and MF287636_Spain_2016. Preliminary analysis for antibodies to CCHFV was detected in 42.5% of the human serum (n=120) samples pending confirmatory Plaque Reduction Neutralization Test (PRNT). Findings from this study suggest the possible importation of the virus into the country through trade, which puts livestock and humans who may have primary contact with livestock at risk of infection.

TICKS AND ZOONOTIC TICK-BORNE PATHOGENS OF LIVESTOCK IN KASSENA-NANKANA DISTRICT, GHANA

Seth O. Addo[1], **Terrel Sanders**[2], Ronald E. Bentil[1], Kevin N. Yartey[1], Clara Yeboah[1], Selassie Kumordjie[1], Bright Agbodzi[1], Victor Asoala[3], Charlotte Addae[1], Eric Behene[1], John A. Larbi[4], Philip K. Baidoo[4], Michael D. Wilson[1], Anne Fox[2], Shirley Nimo-Paintsil[2], Mohamed Sallam[5], Joseph W. Diclaro II[6], Samuel Dadzie[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]US Naval Medical Research Unit No. 3 Ghana Detachment, Accra, Ghana, [3]Navrongo Health Research Centre, Navrongo, Ghana, [4]Department of Theoretical and Applied Biology, College of Science, KNUST, Kumasi, Ghana, [5]University of Nevada, Disease and Arthropod-Vector Ecology, Department of Biology, Reno, NV, United States, [6]Navy Entomology Center of Excellence, Jacksonville, FL, United States

Ticks play a significant role in the transmission of infectious pathogens that affect both animals and humans, including U.S. military personnel whose

medical readiness is affected due to increased morbidity. Even though tick-borne infections continue to increase globally, there are no effective measures to prevent infection spread. The Upper East Region of Ghana is a conducive environment for the proliferation and spread of disease-causing pathogens, especially those of zoonotic origin due to the high dependence on livestock production by inhabitants. With the trade of livestock across the borders, there is an increased risk of zoonotic infections. This study focused on identifying tick species within selected sites in the Kassena-Nankana District and sought to determine infectious zoonotic pathogens using livestock. A total of 1,550 ticks were collected from 448 livestock that included cattle, sheep, and goats, with tick infestations recorded as 78.60%, 25% and 5.88%, respectively. *Amblyomma variegatum* (62.98%) was identified as the most predominant tick species. Out of the 491 tick pools screened, initial PCR results indicated the presence of *Rickettsia* species (n=279, 56.82%), *Babesia/Theileria* species (n=40, 8.15%), Crimean Congo haemorrhagic fever virus (CCHFV) (n=2, 0.41%) and *Coxiella* species (n=18, 3.67%). Co-infections were found in 33 (6.72%) tick pools with pathogens *Rickettsia/Babesia/Theileria* (n=23, 4.68%), *Rickettsia/Coxiella* (n=5, 1.02%), *Rickettsia*/CCHFV (n=2, 0.41%), *Coxiella/Babesia/Theileria* (n=1, 0.20%), and *Rickettsia/Coxiella/Babesia/Theileria* (n=2, 0.41%). Furthermore, 276 livestock dry blood spots were examined using PCR from which *Rickettsia* (n=9, 3.26%) and *Babesia* (n=37, 13.41%) were identified with co-infection in one cattle sample (1%). The findings suggest multiple zoonotic pathogens circulating in the sampling sites with a high occurrence of *Rickettsia* spp. Thus, there is an increased risk of infections to inhabitants, U.S. military personnel, and the livestock populations with no present treatment or preventative strategies.

0751

RISK FACTORS FOR TICK INFESTATION AND DISTRIBUTION ON LIVESTOCK IN GHANA

Seth O. Addo[1], Ronald E. Bentil[1], MbaTihssommah Mosore[1], Eric Behene[1], Julian Adinkrah[1], Janice Tagoe[1], Clara Yeboah[1], Bernice O. A. Ticks are important disease vectors affecting animal and human health and causing substantial economic loss, especially in the tropics and subtropics. In addition, vector-borne diseases directly and negatively impact the ability of U.S military personnel to conduct contingency operations due to morbidity. Ticks were collected from 400 animals including cattle (388), horses (11) and sheep (1) from five regions in Ghana. The animals were mostly female (51%), older than 3 years (66%), of Ghanaian breed (92%) and were unvaccinated (91%). Of the animals sampled, 2,204 ticks were collected with a mean tick burden of 4.9 ticks/livestock. Although more ticks were collected from the udder/scrotum (53%) of the animals, on average, the ticks preferred the abdomen (Mean=6.5, SE=1.2). Furthermore, there was a significant association between the tick burden on the udder/scrotum of the animals with age (χ^2=22.5, df=2, P<0.001) and vaccination status (χ^2=16.7, df=1, P<0.001). The tick species identified were predominantly *Amblyomma variegatum* (44.1%) and *Hyalomma rufipes* (28.4%). *A. variegatum* had a high preference for the udder/scrotum (62.9%, χ^2=74.27, p<0.001) while *H. rufipes* preferred the anal region (63.6%, χ^2=95.09, p<0.001). Using the Generalized Linear Mix Model (GLMM), tick burden on the udder/scrotum was significantly higher than on the anal region (P=0.01197), and tick abundance was found to be significantly higher in livestock older than 3 years. It was observed that there was a significantly higher tick burden among the indigenous Ghanaian animal breeds compared to livestock from Mali (GLMM, P=0.03165) and South Africa (GLMM, P=0.0025). In addition, the vaccination status of the livestock did not influence the tick abundance (GLMM, P=0.497). The abundance of tick species in Ghana suggests a need to formulate effective control measures to reduce the burden on livestock farming and the potential spread of tick-borne diseases to local and U.S. military populations.

0752

A RETROSPECTIVE ANALYSIS OF CUMULATIVE MALARIA INCIDENCE IN HEALTH ZONES APPLYING INDOOR RESIDUAL SPRAYING WITH AND WITHOUT SEASONAL MALARIA CHEMOPREVENTION IN NORTHERN BENIN FROM JANUARY TO DECEMBER 2019

Rock Aikpon[1], Cyriaque Affoukou[1], William Houndjo[1], Julien Aissan[1], Sakariaou Kpanou[1], Patrick Condo[2], Ahmed Saadani Hassani[3], Virgile Gnaguenon[2], Daniel Impoinvil[4], Aurore Ogouyemi Hounto[1]

[1]Ministry of Health Benin/ National Malaria Control Program, Cotonou, Benin, [2]US President's Malaria Initiative (PMI), U.S. Agency for International Development (USAID), Cotonou, Benin, Cotonou, Benin, [3]U.S. President's Malaria Initiative (PMI), U.S. Centers for Disease Control and Prevention (CDC), Cotonou, Benin, Cotonou, Benin, [4]4U.S. President's Malaria Initiative (PMI), Entomology Branch, Division of Parasitic Disease and Malaria, U.S. Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Malaria is endemic in Benin with seasonal and spatial variation in intensity. Some districts in northern Benin have the highest malaria incidence rates in the country. In 2019, indoor residual spraying (IRS) with Actellic and seasonal malaria chemoprevention (SMC), in children aged 3-59 months, with sulfadoxine-pyrimethamine (SP) and amodiaquine targeted several health zones (HZ) in northern Benin. This study provides a precursory retrospective analysis of routine health facility data collected for 12 months (January-December 2019) comparing the cumulative malaria incidence in sites that received IRS alone and IRS + SMC with control sites that did not receive IRS or SMC. Three HZ sites comprising 9 districts were used in the study analysis. In 2019, the HZ of Djougou-Copargo-Ouaké received IRS only, Kandi-Gogounou-Ségbana received SMC + IRS, and Natitingou-Toukountouna-Boukoumbé did not receive IRS nor SMC (control HZ). Routine monthly malaria cases from the HZ information system were analyzed for incidence trends. The cumulative incidence (new cases/HZ population at-risk/year) was calculated for the 3 HZ. An unadjusted incidence rate ratio (IRR: incidence of IRS+/- SMC HZ over control HZ) was calculated in R using rateratio.test package. The cumulative malaria incidence in the control HZ was 420 cases/1000. For the IRS only HZ, the incidence was 320 cases/1000 with an IRR of 0.76 (95% confidence interval [CI]: 0.66-0.88). For the SMC + IRS HZ, the incidence was 218 cases/1000 with an IRR of 0.52 (95% CI: 0.44-0.61). Incidence peaked from June to October in the 3 HZ, with the amplitude highest in control HZ (56 cases/1000) followed by IRS only HZ (39 cases/1000), and IRS + SMC HZ (35 cases/1000). While in this limited analysis, IRS +/- SMC HZ had lower malaria incidence than control HZ, more analysis is needed with a longer pre- and post-time series and an assessment of study confounders to assess impact. Thus, these results are preliminary pending a more robust analysis. Additional studies assessing different malaria control combinations may assist Benin's National Malaria Control Program plan strategies that combat malaria transmission.

0753

WHOLE TRANSCRIPTOMIC ANALYSIS OF *ANOPHELES ARABIENSIS* RESISTANT TO PYRETHROIDS AND ORGANOPHOSPHATES FROM WESTERN KENYA REVEALS OVEREXPRESSION OF SALIVARY GLAND AND CUTICULAR PROTEINS

Diana Omoke[1], Lucy Impoinvil[2], Dieunel Derilus[2], Stephen Okeyo[1], Helga Saizonou[3], Nicola Mulder[4], Nsa Dada[5], Audrey Lenhart[2], Luc Djogbénou[3], Eric Ochomo[1]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]University of Abomey - Calavi, Godomey, Benin, [4]Human, Heredity and Health in Africa H3ABionet network, Cape Town, South Africa, [5]Arizona State University, Phoenix, AZ, United States

Effective vector control is key to malaria prevention. However, this is now compromised by increased insecticide resistance in malaria vectors due to continued reliance on insecticide-based control interventions, thus posing a global challenge. In Kenya, resistance to pyrethroids and organophosphates has been shown to occur at varying levels in *Anopheles arabiensis* which is one of the major malaria vectors. We investigated the gene expression profiles of insecticide resistant *An. arabiensis* populations from Migori and Siaya counties in Western Kenya using RNA-Seq. CDC bottle assays were conducted using deltamethrin (DELTA), alphacypermethrin (ACYP) and pirimiphos-methyl (PMM) to determine the resistance status in both sites. RNA-Seq analysis was done on pools of mosquitoes which were resistant or non-exposed, alongside the susceptible *An. arabiensis* Dongola strain. Gene expression profiles of mosquitoes from Migori resistant to DELTA (average mortality of 91%), ACYP (92%), and PMM (58%); and mosquitoes from Siaya resistant to DELTA (85%), ACYP (86%), and PMM (30%), showed overexpression of mainly salivary gland proteins belonging to both the short and long form D7 genes, and cuticular proteins (including CPR9, CPR10, CPR15, CPR16). Additionally, the overexpression of detoxification genes including cytochrome P450s (CYP9M1, CYP325H1, CYP4C27, CYP9L1 and CYP307A1), 2 carboxylesterases and a glutathione-s-transferase (GSTE4) were also found to be shared between DELTA, ACYP, and PMM survivors, reflecting their association with both pyrethroid and organophosphate resistance. This study provides preliminary results of the molecular basis of resistance in *An. arabiensis* in Western Kenya, further adding to the evidence base that suggests that salivary gland proteins and cuticular proteins may play an important role in conferring resistance across insecticide classes.

ASSESSMENT OF BEHAVIOR AND SOCIOCULTURAL RISK FACTORS IMPACTING DURABILITY OF INSECTICIDE-TREATED NETS IN MALI

Moussa BM Cisse[1], Ibrahim Traore[1], Mamadou Sow[1], Yacouba Dansoko[1], Alice Demebele[1], Lazeni Konate[1], Jean Marie Sanou[1], Samah Sissoko[2], Abdourhamane Dicko[2], Libasse Gadiaga[3], Richard Oxborough[4], Lansana Sangare[5], Jules Mihigo[5], Aliou Diallo[5], Celia Woodfill[5], Cecilia Flatley[4], Paula L. Marcet[6], Taiwo Samson Awolola[6], Ousmane Koita[1]

[1]LBMA-USTTB, Bamako, Mali, [2]PNLP, Bamako, Mali, [3]VectorLink, Bamako, Mali, [4]VectorLink, Washington, WA, United States, [5]PMI, Bamako, Mali, [6]PMI-CDC, Atlanta, GA, United States

Within the context of a net durability study, an assessment of household behavior and sociocultural risk factors that could affect the physical durability of insecticide-treated nets (ITNs) was caried out. Cohorts of 120 and 90 households from Kenieba and Kita districts respectively, were identified and monitored at 6, 12, 24, and 36 months after the regional net distribution in 2017. Household behaviors and sociocultural risk factors were assessed following WHO and PMI guidelines, considering type of sleeping place, leaving the nets hanging during the day, exposure to informational messaging about net care, washing and repairing nets. A chi-square analysis was applied to compare the proportion of households responding to each specific category at each sampling time. The most common risk factors related to net damage in both sites across all sampling periods were storing food in the sleeping room and presence of rodents. More than half of all nets in both sites were found hanging loose over the sleeping place during the day. Heterogeneity in behavior was detected between villages. The risk of net damage by drying them over bushes or fences varied from 1.0% to 78.0% in Kenieba and from 1.0% to 36.0% in Kita ($p<0.001$) at 6, 12, and 24 months. At the time of each survey, the net washing frequency within the last six months ranged from 1 to 3 times in both sites. The use of detergent/bleach for washing nets was the same in both sites (>45.0%) at 6, 12, and 24 months; however, at 36 months, it was significantly higher ($p=0.0258$) in Kenieba (71.8%) than in Kita (37.8%). The respondents' exposure to messages on net usage within the previous 6 months was ($p<0.001$) lower in Kenieba (8.9% to 27.4%) than in Kita (29.2 to 43.8%). The proportion of respondents with a positive attitude/capacity to keep nets in good condition and repair net damage ranged from 13.6% to 56.1% in Kenieba and from 4.4% to 50.0% in Kita. This assessment provided valuable data on sociocultural determinants that could be used to develop social behavior change messages to promote increased ITN lifespan.

RESULTS OF EXPANDED INSECTICIDE RESISTANCE MONITORING TO SEVERAL ECOLOGICAL ZONES IN CAMEROON FOR APPROPRIATE VECTOR CONTROL DECISION MAKING DATA

Etienne Fondjo[1], Elysee E. Mandeng[2], Raymond Tabue[3], Abdou Talipouo[4], Wolfang Ekoko[4], Jean Claude Toto[4], Magellan Tchouakui[5], Elysee Nchoutpouen[4], Benjamin Menze[5], Salemon Patchoke[6], Jean Atangana[6], Emmanuel Elanga[5], Billy Tene Fossog[5], Jerome Binyang[5], Edmond Kopya[4], Rachelle Ngaha[4], Dorothy Achu[3], Kelley Ambrose[7], Judith Hedje[8], William Wirngo[8], Souleymanou Souleymanou[8], Jenney Carlson[9], Sarah Zohdy[10], Joseph Chabi[11]

[1]Vectorlink Cameroon, Yaounde, Cameroon, [2]OCEAC, Yaounde, Cameroon, [3]National Malaria Control Programme, Yaounde, Cameroon, [4]Organization for the Coordination of Endemic Diseases in Central Africa, Yaounde, Cameroon, [5]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [6]Biotechnology Center, Yaounde, Cameroon, [7]Abt associates, Rockville, MD, United States, [8]PMI, Yaounde, Cameroon, [9]PMI, Washington, WA, United States, [10]CDC, Yaounde, GA, United States, [11]Vectorlink Cote D'Ivoire, Cote D'Ivoire, Côte D'Ivoire

Cameroon deploys insecticide-treated nets (ITNs) as its primary malaria vector control intervention. Collecting entomological data across ecological zones is key to informing distribution strategies to optimize vector control interventions based on resistance profiles. In 2021, an annual insecticide resistance monitoring was conducted in 10 sites (Bertoua, Djohong, Garoua, Gazawa, Mada, Mogode, Ndelele, Ngaoundere, Njombe, Touboro) in four ecological zones (rainforest, wet and humid littoral forest, and dry savanna) to support data-driven decision making. Bioassays were conducted using World Health Organization (WHO) susceptibility test kits or Centers for Disease Control and Prevention bottles. *Anopheles gambiae* s.l. larvae collected in the field and reared to 2-5-day-old adult females were tested against alpha-cypermethrin (0.05%), deltamethrin (0.05%), permethrin (0.75%), pirimiphos-methyl (0.25%), bendiocarb (0.1%), clothianidin (2% and 4 µg/bottle), and chlorfenapyr (100 and 200 µg/bottle). Resistance status was assessed using WHO criteria. When pyrethroid resistance was found, resistance intensity (5x and 10x the diagnostic doses) and synergist assays using 4% piperonyl butoxide (PBO) were performed. About 40% of *An. gambiae* s.l. (dead and alive) were screened for molecular resistance markers [knock down resistance (*kdr*)-west, *kdr*-east, acetylcholinesterase (*Ace-1*) and N1575Y]. High pyrethroid resistance (< 98% mortality at 10x the diagnostic dose) was found in all sites. Pre-exposure to PBO fully restored susceptibility to deltamethrin in Bertoua and Mogode. Susceptibility to chlorfenapyr was recorded at seven sites at 100 µg/bottle and all sites except Ngaoundere at 200 µg/

bottle. All sites recorded susceptibility to clothianidin (2%) and six sites to clothianidin (4 µg/bottle). Genetic markers of resistance were detected in all sites, with high frequency (0.9-1) of *kdr*-west found in eight sites. These results will help guide Cameroon's National Malaria Control Program on its vector control strategy (indoor residual spraying vs. ITNs) and optimal tool selection (type of ITNs) in the country.

0756

HABITAT-SPECIFIC SIGNALS OF SELECTION ON CYTOCHROME P450 GENES SUGGEST EMERGING INSECTICIDE RESISTANCE IN SOUTH AMERICAN MALARIA-TRANSMITTING *NYSSORHYNCHUS* (*ANOPHELES*) *DARLINGI*

Jacob A. Tennessen[1], Auden Cote-L'Heureux[2], Estelle Chabanol[3], Jean-Bernard Duchemin[3], Mathilde Gendrin[3], Daniel E. Neafsey[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Broad Institute, Cambridge, MA, United States, [3]Institut Pasteur de la Guyane, Cayenne, French Guiana

Malaria in South America remains a serious public health problem. Cases of *Plasmodium* infection are on the rise in some localities, and observations of drug resistance threaten to undermine control efforts. *Nyssorhynchus* (*Anopheles*) *darlingi* is the most important vector of these parasites in the western hemisphere. Insecticides have not been heavily used for malaria control in the neotropics and insecticide resistance is believed to be relatively low for *An. darlingi*, though surveillance is limited. It will be critical to understand if and how mosquitoes are poised to adapt to pesticide-based control measures and other anthropogenic changes. To investigate evolution and variation in this species, we have sequenced whole genomes from hundreds of *An. darlingi* specimens, representing the first large population genomic dataset from a malaria vector in the Americas, and we have characterized patterns of population structure and genetic diversity. We have generated 139 high-coverage genomes from French Guiana alone, collected at three ecologically disparate locations. At one French Guianese village, we see striking differences in allele frequencies within clusters of cytochrome P450 genes, relative to nearby populations that are otherwise genetically similar. Population genetic statistics indicate that these differences reflect recent, ongoing selective sweeps. This gene family is known to underlie insecticide resistance in numerous arthropod species. Thus, we hypothesize that these mosquitoes are adapting to local agricultural runoff, indirectly narrowing future vector control options. Other classic insecticide resistance mutations (e.g. *kdr*, *Rdl*) are not observed, suggesting novel mechanisms. This pioneering population genomic dataset suggests putative signals of insecticide resistance that was previously unsuspected and could threaten future vector control options, while also pinpointing candidate causal polymorphisms that could facilitate strategies to monitor and counteract its spread. These observations warrant further study, and trials to associate phenotypes with these variants are currently underway.

0757

DURABILITY OF LONG LASTING INSECTICIDAL NETS WITH AND WITHOUT PIPERONYL BUTOXIDE

Frank Mechan[1], Agaba Katureebe[2], Violet Tuhaise[2], Martin Mugote[2], Ambrose Oruni[1], Ismail Onyige[2], Kawesa Bumali[2], Jonathan Thornton[1], Nicola Fletcher[1], Maxwell Kilama[3], Mary Kyohere[3], Moses R. Kamya[2], Peter Mutungi[2], Simon P. Kigozi[2], Adoke Yeka[2], Jimmy Opigo[4], Catherine Maiteki-Sebuguzi[2], Samuel Gonahasa[2], Janet Hemingway[1], Grant Dorsey[5], Lisa J. Reimer[1], Sarah G. Staedke[6], Martin Donnelly[1], Amy Lynd[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Department of Medicine, Makerere University, Kampala, Uganda, [4]National Malaria Control Division, Ministry of Health, Kampala, Uganda, [5]Department of Medicine, University of California, San Francisco, CA, United States, [6]Department of Clinical Research, London School of Hygiene & Tropical Medicine, London, United Kingdom

Long Lasting Insecticidal Nets (LLINs) supplemented with the synergist piperonyl butoxide have been developed in response to growing pyrethroid resistance however their durability in the field remains poorly described. A pragmatic cluster-randomised trial was embedded into Uganda's 2017-2018 distribution to compare the durability of pyrethroid LLINs with PBO (Olyset Plus and PermaNet 3.0) and without PBO (Olyset Net and PermaNet 2.0). Nets were sampled at baseline, 12, and 25 months post-distribution to assess physical condition, chemical content, and bioefficacy. Bioefficacy was assessed with WHO Cone and Wireball assays using pyrethroid-resistant *An. gambiae*. Ambient Chamber Tests (ACTs) with free-flying pyrethroid-resistant *An. gambiae* were performed with Olyset Plus and Olyset Net to investigate bloodfeeding with holed nets. There was no difference in the risk of being 'Too torn' between LLIN products assessed ($p=0.644$). The pyrethroid content of all LLIN products remained stable across timepoints but PBO content declined by 55% ($p<0.001$) and 58% ($p<0.001$) for Olyset Plus and PermaNet 3.0 respectively. Both PBO-LLINs were highly effective against pyrethroid-resistant mosquitoes when new, knocking down all mosquitoes. However, bioefficacy declined over time with Olyset Plus knocking down 45.72% (95% CI: 22.84-68.62, $p=0.021$) and Permanet 3.0 knocking down 78.57% (95% CI: 63.57-93.58, $p<0.001$) after 25 months. In ACTs mosquitoes were observed to enter a hole in the top of nets at a higher rate than a hole in the size (Olyset Plus: OR=10.71, 95%CI=1.38- 20.03). Here we demonstrate that both Olyset Plus and PermaNet 3.0 are as durable as their pyrethroid-only equivalents and had superior bioefficacy against pyrethroid-resistant *An. gambiae*. However, the superiority of PBO-LLINs decreased with operational use, correlating with a reduction in total PBO content. This decline in bioefficacy after just two years is concerning and there is an urgent need to assess the durability of PBO LLINs in other settings.

0758

IVERMECTIN-TREATED BIRDFEED CONFERS DOSE-DEPENDENT TOXICITY TO *CULEX TARSALIS* MOSQUITOES WHILE REMAINING SAFE FOR AVIAN CONSUMPTION

Michelle Julia Savran, Molly Ring, Anna-Sophia Leon, Preston Schweiner, Chilinh Nguyen, Brady J. Clapsaddle, Brian D. Foy

Colorado State University, Fort Collins, CO, United States

West Nile Virus transmission is sustained in an enzootic cycle between ornithophilic *Culex* species mosquitoes and birds, highlighting this relationship as a potential target for intervention. Specifically, we can expose ivermectin (IVM) to *Culex tarsalis* via bloodmeals from birds treated with IVM-treated feed. IVM binds to glutamate-gated chloride channels (GluClR), causing paralysis and death in invertebrates while maintaining a robust safety profile in vertebrates due to differences in GluClR localization between species. To investigate this method, we provided chickens with IVM-treated feed at doses of 200 mg IVM per kg of feed (mg/kg IVM) and 360 mg/kg IVM for up to 7 days. We collected sera via jugular venipuncture on days 3 and 7 of the diet, then reconstituted it with chicken red blood cells to provide bloodmeals to 3-6 day old female laboratory-raised *Cu. tarsalis* mosquitoes. Additionally, we observed the birds' behavior to determine whether IVM caused any adverse effects during or following treatment. Our results demonstrate dose-dependent toxicity in *Culex tarsalis* mosquitoes with Mantel-Haenszel Hazard Ratios of 3.150 at day 3 of a 200 mg/kg IVM diet (IVM n=65, control n=63, P value<0.0001) and 7.068 at day 7 of the same diet (IVM n=58, control n=42, P value<0.0001), compared to 26.41 at day 3 of a 360 mg/kg IVM diet (IVM n=50, control n=84, P value<0.0001) and 28.74 at day 7 of the same diet (IVM n=53, control n=69, P value<0.0001), showing a pattern of decreased probability of survival with increased dose and feed consumption. Additionally, treated birds experienced no adverse events and consumed similar amounts of feed compared to control birds (IVM n=11, control n=12, two-way ANOVA for mean weight gain statistics ranged from P value = 0.0698-0.1123). Analysis of 500 mg/kg IVM diet

results, IVM concentration in sera, and histopathology is ongoing, and experiments with wild-type *Culex* species mosquitoes and wild-caught birds are planned for the upcoming field season. Results from these experiments will inform future decisions regarding the safest and most efficacious dose and formulation of IVM-treated feed to proceed to field trials.

0759

TRANSCRIPTOMIC ANALYSIS OF *ANOPHELES GAMBIAE* FROM BENIN REVEALS OVEREXPRESSION OF SALIVARY AND CUTICULAR PROTEINS ASSOCIATED WITH CROSS-RESISTANCE TO PYRETHROIDS AND ORGANOPHOSPHATES

Helga Saizonou[1], Lucy Impoinvil[2], Dieunel Derilus[2], Diana Omoke[3], Stephen Okeyo[3], Nsa Dada[4], Audrey Lenhart[2], Filémon Tokponon[5], Aurore Ogounyemi-Hounto[5], Nicola Mulder[6], Eric Ochomo[3], Luc S. Djogbénou[1]

[1]Tropical Infectious Diseases Research Centre (TIDRC), University of Abomey-Calavi (UAC), Ouidah, Benin, [2]Entomology Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Kenya Medical Research Institute (KEMRI), Centre for Global Health Research (CGHR), Kisumu, Kenya, [4]School of Life Sciences, Arizona State University, Tempe, AZ, United States, [5]Programme Nationale de Lutte Contre Le Paludisme (PNLP), Cotonou, Benin, [6]Human, Heredity, and Health in Africa H3ABionet network, Cape Town, South Africa

Insecticide resistance (IR) is one of the major threats to malaria vector control programs in endemic countries. However, underlying insecticide resistance mechanisms are poorly understood. Thus, investigating gene expression patterns related to IR can offer greater insight into the molecular basis of IR in mosquitoes. In this study, RNA-Seq was performed to characterize gene expression following exposure to pyrethroids (deltamethrin, alphacypermethrin) and an organophosphate (pirimiphos-methyl). Larvae of *Anopheles gambiae* s.s. were collected from Bassila and Djougou in Benin and reared to adulthood. Four-to-five-day old female mosquitoes were phenotyped for IR using the modified CDC intensity bottle bioassay. The results showed that mosquitoes from Djougou were more resistant to pyrethroids (5x deltamethrin: 51.7% mortality, 2x alphacypermethrin: 47.4%) than Bassila (1x deltamethrin: 70.7%, 1x alphacypermethrin: 77.7%), while the latter was more resistant to 1.5x pirimiphos-methyl (48.3%; 1x pirimiphos-methyl Djougou:21.49%). RNA-Seq was conducted on resistant mosquitoes, non-exposed mosquitoes from the same locations, and the susceptible Kisumu laboratory strain. RNA-Seq analysis showed over-expression of detoxification genes, including cytochrome P450s (CYP12F2, CYP4C27, CYP6Z3, CYP9K1, CYP4H15) and glutathione S-transferases (GSTE2, GSTMS3) in all the three resistant mosquito groups analyzed. Genes encoding cuticular proteins (CPR130, CPR10, CPR15, CPR16, CPR127, CPAP3-C, CPAP3-B, and CPR76) were also overexpressed in all the resistant groups, indicating their potential role in cross resistance in *An. gambiae*. Salivary gland protein genes related to 'salivary secreted peptide' and 'kDa salivary' were also over-expressed and shared across all resistant groups. These genes need further investigation to validate their functional role in *An. gambiae* resistance. Our results suggest that in addition to metabolic enzymes, cuticular and salivary gland proteins could play an important role in cross-resistance to multiple classes of insecticides in Benin.

TEMPORAL EVALUATION OF INSECTICIDE RESISTANCE IN POPULATIONS OF THE MAJOR ARBOVIRAL VECTOR*AEDES AEGYPTI*FROM NORTHERN NIGERIA

Muhammad Mahe Mukhtar, Sulaiman Sadi Ibrahim

Bayero University Kano., Kano, Nigeria

AbstractContemporary information on the major arboviral vector Aedes aegypti is inexistent in the sub-Sahel of northern Nigeria, where this vector is becoming omnipresent. To support evidence-based control measures, two populations of this vector, from BUK (Kano state) and Pantami (Bauchi state) were characterised. Larval bioassay (across three years) using temephos and deltamethrin revealed a significant increase in deltamethrin resistance, with LC_{50} of 0.018mg/L (resistance ratio compared to New Orleans, RR = 2.250) in 2018 increasing ~6-fold, by 2019 (LC_{50} = 0.100mg/L, RR = 12.5), and ~11-fold in 2020 (LC_{50} = 0.198mg/L, RR = 24.750). For the median deltamethrin concentration (0.05mg/L), a gradual decrease in mortality was observed, from 50.6% in 2018, to 44.9% in 2019, and 34.2% in 2020. Extremely high DDT resistance was observed, with <3% mortalities and LT_{50}s of 352.87 min, 369.19 min and 406.94 min in 2018, 2019 and 2020, respectively. Significant temporal increase in resistance was observed towards ƛ-cyhalothrin (a type II pyrethroid) over three years. Synergist bioassays with diethylmaleate and piperonylbutoxide significantly recovered DDT and ƛ-cyhalothrin susceptibilities respectively, implicating glutathione S-transferases and cytochrome P450s. Cone bioassays revealed increased resistance to the PermaNet® 3.0, side panels (mortalities of 94% in 2018, 66.4% in 2019, and 73.6% in 2020), while full susceptibility was obtained with the roof panels of PermaNet® 3.0. The F1534C *kdr* mutation occurred in low frequency, with significant correlation between heterozygote genotypes and DDT resistance. This temporal increase in resistance is a major challenge for control of this vector of public health importance, especially at the face of increasing yellow fever and dengue infections reported across Nigeria.

MOSQUITOCIDAL ACTIVITY OF IVERMECTIN METABOLITES IN *ANOPHELES STEPHENSI*

Charlotte Kern[1], Carlos Chaccour[2], Pie Müller[3], Urs Duthaler[4], Felix Hammann[1]

[1]Division of Clinical Pharmacology & Toxicology, Department of General Internal Medicine, University Hospital Bern, Bern, Switzerland, [2]Department of Microbiology and Infectious Diseases, Clinica Universidad de Navarra, Pamplona, Spain, Centro de Investigación Biomédica en Red de Enfermedades Infecciosas, Madrid, Spain, ISGlobal, Hospital Clinic, University of Barcelona, Barcelona, Spain, [3]Swiss Tropical and Public Health institute, Allschwil, Switzerland, University of Basel, Basel, Switzerland, [4]Division of Clinical Pharmacology & Toxicology, Department of Biomedicine, University and University Hospital Basel, Basel, Switzerland, Division of Clinical Pharmacology & Toxicology, Department of Pharmaceutical Sciences, University of Basel, Basel, Switzerland

Ivermectin (IVM) is an antiparasitic drug to treat neglected tropical diseases in humans. Ivermectin is also an endectocide, a drug capable of killing arthropods, such as mosquitoes, feeding on a treated person. Mass drug administration of IVM has been suggested as a vector control tool for malaria elimination by reducing *Plasmodium* transmission through mosquito bites. Mosquitoes feeding on treated volunteers show increased mortality even after the parent drug is no longer detectable in the blood, a phenomenon known as a "post-ivermectin effect". Therefore, we aimed to assess whether not only the parent drug, but also its metabolites could contribute to the mosquitocidal effect in *Anopheles stephensi*. Twelve healthy participants were given a single oral dose of 12 mg IVM, and peripheral venous samples were collected over three days in a pharmacokinetic (PK) study. The levels of IVM and its metabolites were measured by LC-MS/MS in human blood. For the mosquito feeding, IVM metabolites were produced by incubating IVM with recombinant cytochrome P450 3A4/5, that were purified using semi-preparative high-pressure liquid chromatography. Nine metabolites were isolated and spiked to human whole blood matching the maximal blood intensities previously observed in the human PK study samples. Mosquito mortality and activity were recorded daily over three days post blood feeding. The time to reach maximal concentrations in blood was delayed for IVM metabolites compared to IVM. The metabolites elimination half-life was also longer in general. Three days after ingesting the blood containing the treatment, the survival and activity of mosquitoes was reduced for those that received IVM, M1, M2 and M4, compared to the blank blood. All other IVM metabolites did not have an appreciable effect on mortality. As

the mosquitoes were not only susceptible to IVM, but also to three of its metabolites, we conclude it could serve as a possible explanation for the "post-ivermectin effect".

IMPROVEMENT OF INSECTICIDAL ACTIVITY OF NEONICOTINOIDS WITH COMMON DETERGENTS

Ashu Fred Ayukarah[1], Caroline Fouet[1], Marilene M. Ambadiang[1], Veronique P. Beng[2], Charles Wondji[3], Colince Kamdem[1]

[1]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [2]University of Yaounde I, Yaounde, Cameroon, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The development and evaluation of new insecticides as well as a reduction of environmental pollution due to their usage is crucial to preserve the efficacy of vector control tools such as long-lasting insecticidal nets and indoor residual spraying. With their unique mode of action, neonicotinoid insecticides provide promising alternatives to control mosquito populations that are resistant to insecticides rolled out in large-scale malaria control efforts. The aim of this work was to evaluate the efficacy of black soap, a common detergent, as an adjuvant to enhance the insecticidal action of neonicotinoids in malaria vectors. Using CDC bottle tests, we assessed the susceptibility of laboratory and field populations of Anopheles gambiae and An. coluzzii to two neonicotinoids, clothianidin and acetamiprid, alone and in combination with the detergent (SN). To determine if SN enhances insecticide toxicity, we established log-dose response curves of four populations with varying levels of susceptibility to clothianidin adding 1% SN to insecticide preparations. We then conducted a broader evaluation of the synergistic effect of SN by testing the diagnostic doses of clothianidin, acetamiprid and the pyrethroid deltamethrin containing 1% SN against field populations. At a concentration of 1%, SN had no insecticidal effect on An. gambiae and An. coluzzii when tested alone. However, SN dramatically enhanced the toxicity of clothianidin as revealed by the drastic reduction of the diagnostic dose from 150 µg/mL its absence to 8µg/mL in presence of the adjuvant 24 hours post-exposure. Moreover, susceptibility to clothianidin and acetamiprid was fully restored (100% mortality) in resistant field populations when 1% SN was used. By contrast, mortality to deltamethrin was lower in presence of SN (from 46% to 18%) suggesting an antagonistic effect of SN. Black soap provides a cheap, available and environmentally friendly adjuvant that can be used in neonicotinoid formulations intended for mosquito control. The search of other vegetable oils with synergistic effects will expand the possibilities of using neonicotinoids in malaria vector control.

0763

DRUG REPURPOSING FOR OPTIMAL USE OF IVERMECTIN AGAINST MALARIA: LONG LASTING FORMULATIONS ALLOWING EFFICACY AGAINST WILD-DERIVED ANOPHELES FOR AT LEAST TWO MONTHS

Sié Hermann Pooda[1], Lamidi Zela[2], Angélique Porciani[3], Nicolas Moiroux[3], Anne-Laure Barbe[4], Sophie Le Lamer[4], Thibaut Deramoudt[4], Christophe Roberge[4], Ernest W. Salou[2], Fabrice A. Some[5], Roch K. Dabire[6], Karine Mouline[7]

[1]Université de Dédougou (UDDG), Dédougou, Burkina Faso, [2]Centre International de Recherche Développement sur l'Elevage en zone Subhumide (CIRDES), Bobo-Dioulasso, Burkina Faso, [3]Mivegec, Institut de Recherche pour le Développement (IRD), Montpellier, France, [4]Medincell, Montpellier, France, [5]Institut de Recherche en Sciences de la Santé, Centre National de Recherche Scientifique et Technologique (IRSS/CNRST), Bobo-Dioulasso, Burkina Faso, [6]Institut de Recherche en Sciences de la Santé, Centre National de Recherche Scientifique et Technologique (IRSS/CNRST), Dédougou, Burkina Faso, [7]Institut de Recherche pour le Développement (IRD), Montpellier, France

Endectocides, in particular Ivermectin, are being considered as potent complementary tools helping wiping out Malaria disease. Compelling evidences accumulate, where administration of Ivermectin to humans or animals renders their blood toxic to residual *Anopheles* vectors. The short duration of Ivermectin exposure after single oral administration is not significantly decreasing the vector populations to levels impacting malaria incidence. Increasing the dosage and/or the administration frequency could compensate this limitation, but at the expense of logistical issues linked to repeated mass administrations or toxicity. Long-lasting injectable formulations of Ivermectin were developed based on the BEPO® technology for subcutaneous use, allowing a controlled and sustained release of Ivermectin at physiological meaningful concentrations for at least 2 months. Three candidate formulations were tested on calves, in Burkina Faso, against 2 Anopheles colonies that differed for their species and insecticide resistance status: Kisumu (*An. gambiae s.s.*, susceptible reference colony) and VK5 (*An. coluzzii*, wild derived). A 5-arm design, with a non-treated control, was used to characterize the PK and efficacy on mosquitoes' mortality during 4 months following single subcutaneous injection. All formulations were increasing mosquitoes' mortality from both colonies with a Hazard Ratio range of 5-20 for at least 42 days. Lethal concentrations inducing 90% cumulative mortality at 5 days were between 11.1-15.1 ng/ml for VK5 and 6-9.1 ng/ml for Kisumu; LC50 values were, respectively, between 3.1-7.6 and 0.4-2.2 ng/ml. With the support of a transmission model using different vectors/hosts scenarii, this work allowed the selection of a lead formulation with a sustained mosquitocidal efficacy above LC50 for more than 2 months, that would reduce infectious vector populations by at least 50% for 4 months. Discrepancies between both colonies pointed possible cross-resistance mechanisms displayed by field Anopheles. Further modeling at the epidemiological level and safety studies are ongoing towards human application in the future.

0764

THE ENTOMOLOGICAL IMPACT OF INSECTICIDE-TREATED NETS (ITNS) AND INDOOR RESIDUAL SPRAYING (IRS), IN THE AMERICAS: FILLING THE KNOWLEDGE GAPS

Manuela Herrera-Varela[1], Carlos Morales[2], Diana Lucumi-Aragón[1], Martha Castro[1], Martha Ahumada[3], Maria Riascos-Cuenú[1], Anderson Piamba[2], Hernando Gil[2], Liliana Santacoloma[4], Susanne Ardila[4], Iván Cárdenas[5], Tania Tibaduiza[5], Rebecca Levine[6], Audrey Lenhart[6]

[1]PMI VectorLink - Abt Associates, Bogotá, Colombia, [2]Secretaría Departamental de Salud del Cauca, Popayán, Colombia, [3]Subdirección de Investigación Científica y Tecnológica, Instituto Nacional de Salud, Bogotá, Colombia, [4]Subdirección Laboratorio Nacional de Referencia, Instituto Nacional de Salud, Bogotá, Colombia, [5]Grupo Endemo-epidémicas, Subdirección de Enfermedades Transmisibles, Ministerio de Salud y la Protección Social, Bogotá, Colombia, [6]Centers for Disease Control and Prevention, Entomology Branch, Atlanta, GA, United States

Malaria vector control in Colombia has traditionally relied on indoor residual spraying (IRS), with insecticide-treated nets (ITNs) introduced over the past 15 years. However, the effectiveness of these tools against malaria vectors in the Americas remains poorly characterized. A two-arm cluster-randomized trial was designed to determine the entomological impact of pyrethroid-only ITNs and IRS in Cauca Department on the Pacific coast of Colombia, with biting rates (measured by human landing catches) as the primary indicator. Clusters were randomly assigned to receive either ITNs (alpha-cypermethrin) or IRS (deltamethrin). Baseline data collection began in January 2021, interventions were deployed in March 2021 (2,500 ITNs were distributed and 835 houses were sprayed) and the trial will run through March 2023. At eleven months post-intervention, a total of 87,166 anophelines had been collected, 80% of *Anopheles* caught were *Anopheles neivai* and 20% were *An. albimanus*. No significant differences were detected between the indoor and outdoor abundances of the species. When tested for insecticide resistance, both species were susceptible to both deltamethrin and alpha-cypermethrin using CDC bottle bioassays. Net bio-efficacy and integrity was evaluated at six months after distribution in 40 ITNs randomly selected from across the 20 ITN clusters. Bio-efficacy was very low, with a mean knock-down and mortality of 3% and 5%, respectively. Although 67% of ITNs had at

least one hole, 80% remained in serviceable condition. Seven days post-spraying, WHO cone bioassays were carried out in 2 households in each of 20 IRS clusters, showing a mean knockdown of 80% and mortality of 40%. Ovary dissections of mosquitoes collected in both intervention arms only detected a reduction in the proportion of parous females at 1-month post-intervention, with 49% of females being parous; at 2-months post-intervention, parous rates were > 90%. These preliminary data raise concerns over the entomological efficacy of the ITNs and IRS used in the study area, and ongoing research will enable a deeper understanding of how this may impact malaria elimination strategies.

0765

DETERMINING A DIAGNOSTIC DOSE OF PIRIMIPHOS METHYL FOR *AEDES AEGYPTI* USING TREATED BOTTLES

Gabriela González-Olvera[1], Rita L. Vizcaino Cobarrus[2], Alicia Méndez Manzanero[1], Anuar Medina Barreiro[1], Azael Che Mendoza[1], Oscar David Kirstein[3], Pablo Manrique Saide[1], Gonzalo Vazquez Prokopec[4], Audrey E. Lenhart[5]

[1]Unidad Colaborativa para Bioensayos Entomológicos-Universidad Autónoma de Yucatán, Mérida, Yucatán., Mexico, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Dept. of Environmental Sciences, Emory University, Atlanta, GA, United States, [4]Dept. of Environmental Sciences, Emory University., Atlanta, GA, United States, [5]Centers for Disease Control and Prevention., Atlanta, GA, United States

There is a pressing need to develop innovative strategies for the control of diseases transmitted by *Aedes aegypti*. The modification of indoor residual spraying to target *Ae. aegypti* is one such strategy. A clinical trial quantifying the epidemiological impact of targeted indoor residual spraying (TIRS) for *Ae. aegypti* control is using a product with pirimiphos-methyl as the active ingredient in the city of Mérida, Mexico. In order to monitor the susceptibility of the local *Ae. aegypti* populations over the course of the trial, we determined a diagnostic dose for pirimiphos-methyl using the Centers for Disease Control and Prevention (CDC) bottle assay method. Two independent laboratories tested a series of 8 concentrations of pirimiphos-methyl eliciting a range of mortality between 0% and 100% in an insecticide-susceptible reference strain of *Ae. aegypti* (Rockefeller). The results suggested a diagnostic dose of 25 µg/ml with a diagnostic time of 30 minutes. This diagnostic dose was used to screen 16 field populations of *Ae. aegypti* (≈ 2000 mosquitoes) prior to the implementation of TIRS, with susceptibility reported in all populations at baseline. This diagnostic dose of pirimiphos-methyl will be used to monitor pirimphos-methyl susceptibility in *Ae. aegypti* throughout the course of the trial.

MODELING THE SPREAD OF INSECTICIDE RESISTANCE AND ITS IMPACT ON ATSB DEPLOYMENT IN SUB-SAHARAN AFRICA

Prashanth Selvaraj, Caitlin Bever

Bill & Melinda Gates Foundation, Seattle, WA, United States

ATSBs are a potentially valuable tool to control programs worldwide in their fight against malaria transmission but insecticide resistance threatens to undermine the efficacy of this intervention. Understanding the evolution and propagation of resistance is imperative to mitigating loss of ATSB effectiveness. Based on simulations of the ATSB trials currently being held in Kenya and Zambia, we leverage a multi-locus model of vector genetics that accounts for many-to-many mapping of genotypes to phenotypes to model insecticide resistance in all the major Anopheline species in the region. Combining this insecticide resistance model with an agent-based mathematical model of malaria transmission that simulates the interactions between human hosts and mosquitoes, we investigate deployment strategies and the choice of insecticides that are most likely to lead to the development of resistance in vector populations in near elimination to high transmission settings in sub-Saharan Africa. We predict the impact of resistance in Anophelines on malaria transmission and investigate various spatiotemporal deployment strategies of ATSBs alongside traditional vector control tools such as ITNs and IRS to best manage resistance and ensure continued efficacy of ongoing control and elimination efforts.

VPRAM (VOLATILE PYRETHROIDS AGAINST MOSQUITOES): A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE ASSOCIATION BETWEEN THE USE OF VOLATILE PYRETHROID-BASED SPATIAL REPELLENTS AND MOSQUITO BITE PREVENTION

Sarah L. Miller[1], Kyeba Swai[2], Arnold Mmbando[2], Steven Gowelo[1], Mercy Opiyo[1], Elodie Vajda[1], Sheila Ogoma Barasa[3], Marta Maia[4], Isabel Elaine Allen[1], Neil Lobo[5], Fredros Okumu[2], Sarah Moore[2], Ingrid Chen[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Ifakara Health Institute, Ifakara, United Republic of Tanzania, [3]Clinton Healthcare Access Initiative, Nairobi, Kenya, [4]KEMRI Wellcome Trust Program, Kilifi, Kenya, [5]University of Notre Dame, Notre Dame, IN, United States

Mosquitoes are the largest contributors to the global burden of vector-borne diseases, responsible for the spread of malaria, dengue, and more. The largest share of the burden is due to malaria, with 241 million cases reported in 2020. Outdoor transmission of malaria is growing in prominence, revealing an urgent need for interventions targeting this mode of transmission. Passive spatial repellents that use volatile pyrethroid-class insecticides are promising products for this indication; however, there is a lack of clarity on their efficacy, longevity, and range of effect due to heterogeneity between studies. We aimed to fill this gap by conducting a systematic review on entomological studies of volatile pyrethroid-based spatial repellents (PROSPERO #CRD42021268852). We included semi-field and field studies that compared volatile pyrethroid-based spatial repellents to no treatment or placebo, investigating their effects on *Anopheles*, *Aedes*, and *Culex* mosquitoes. Our primary outcomes are the number of mosquito landings using human landing catch or measurement of mosquito density using traps. Secondary outcomes examine entomological effects, including mosquito knock-down, delayed mortality, blood feeding inhibition, fecundity, deterrence, and non-contact irritancy. To date, we identified 1,145 abstracts of which 42 full text articles met our inclusion criteria. Next, we will extract individual-level mosquito data for analysis. Data will be synthesized through forest plots summarizing primary outcomes at the study level, as well as efficacy estimates for each product format derived from aggregate data, stratified by study design, active ingredient, mosquito species, capture method, and use case indoors vs outdoors. We will also incorporate weather data, conducting a sensitivity analysis to establish its effects on spatial repellent efficacy and duration thereof. This study intends to consolidate, clarify, and advance the evidence base on spatial repellents, informing researchers and vector control policymakers on their prospective use to reduce vector-borne diseases including the outdoor transmission of malaria.

0768

TEMPERATURE ALTERS THE TOXICITY OF MALATHION AND DELTAMETHRIN ON THE WEST NILE VIRUS VECTOR, *CULEX TARSALIS*, PHOENIX, AZ

Joshua K. Kalmouni[1], James B. Will Jr.[2], John Townsend[2], Krijn P. Paaijmans[1]

[1]Arizona State University, Center for Evolution and Medicine, School of Life Sciences, Tempe, AZ, United States, [2]Maricopa County, Environmental Services Department, Vector Control Division, Phoenix, AZ, United States

West Nile Virus (WNV), vectored by *Culex tarsalis*, is the leading mosquito-borne disease in the United States and according to the CDC, Arizona accounted for over half of the total reported WNV cases in the country in 2021. Concerningly, there are no prophylactics or drug treatments which exist for WNV and as such, public health programs rely heavily on vector

control efforts to lessen the incidence of disease. Insecticides can be highly valuable in reducing vector numbers if implemented strategically but can diminish in effectiveness and/or promote insecticide resistance otherwise. Vector control programs which employ mass-fogging applications of insecticides, often conduct these methods during the late-night hours, when diel temperatures are coldest. This study's aim was to quantify the effect of temperature on the toxicity of the conventional insecticides: malathion and deltamethrin, to *Cx. tarsalis*. An additional aim of this study was to underline the importance of understanding temperature-toxicity coefficients, in a contextual manner (i.e., local climate, vectors, and employed insecticides), to inform vector control programs of efficacious practices. Immature *Cx. tarsalis* were collected from the Salt River Pima-Maricopa Reservation and were reared to adults, where non-blood-fed females (aged 2-5 days old) were used to carry out experimentation during April - June 2021. Under three experimental temperature regimes (15, 25, and 35°C; 80% RH), a modified WHO tube bioassay - conventionally used for insecticide resistance monitoring - was used to evaluate the toxicity of the aforementioned insecticides on *Cx. tarsalis*. Insecticide doses ranged from low, medium, and high to reflect the decrease in atmospheric droplet density over relatively short distances. The data show that malathion and deltamethrin became less toxic to local *Cx. tarsalis* at colder temperatures. Our results suggest that programs employing large-scale applications of insecticides should consider temperature-toxicity relationships to maximize their efficacy to reduce mosquito-borne disease burden.

0769

INSECTICIDE RESISTANCE OF *AEDES AEGYPTI* AND *AE. ALBOPICTUS* IN PAPUA NEW GUINEA

Stephen Gideon[1], Nancy Endersby-Harshman[2], Samuel Demok[1], Naomi Vincent[1], Michelle Katusele[1], Joelyn Goi[1], Solomon Lagur[1], Christine Pombreaw[1], Tanya Russell[3], Rachael Farquhar[4], Leo Makita[5], Ary Hoffmann[2], Leanne Robinson[4], Moses Laman[1], Stephan Karl[3]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]School of BioSciences, Bio21 Institute, The University of Melbourne, Melbourne, Australia, [3]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [4]Burnet Institute, Melbourne, Australia, [5]Papua New Guinea National Malaria Control Program, Port Moresby, Papua New Guinea

Information about insecticide resistance is crucial to vector control programs in public health. This study provides an update from 2017-2022 on the insecticide resistance status against *Aedes albopictus* and *Ae. aegypti* vectors across nine provinces of Papua New Guinea (PNG). Mosquito larvae were collected from *Aedes* larval habitats in each province, reared to adults and tested against 8 insecticides in WHO susceptibility tube bioassays. The mosquitoes were morphologically identified, labelled and stored in ethanol for genetic analyses of resistance markers. The total number of aedine mosquitoes tested was 8294. We detected pyrethroid resistance in all *Ae. aegypti* populations. Specifically, deltamethrin and lambda-cyhalothrin showed average 24h mortality rates ranging from 20%-32% indicating high levels of resistance. High levels of DDT resistance was also detected with 24h mortality rates ranging from 0% to 71%. Our studies also indicated possible bendiocarb and malathion resistance in some locations. Genetic analyses resulted in detection of 6 composite resistance genotypes identified in *Aedes aegypti* with no wild type identified. *Ae. albopictus* was susceptible to the pyrethroids (ranging from 98-100% mortality) and bendiocarb (99-100% mortality). However, possible resistance to deltamethrin was indicated in one province with 92%, (95% CI: 79%-98%) 24h mortality. DDT resistance was indicated in most provinces with 24h mortality rates ranging from 60%-79%. Known mutations conferring resistance to pyrethroids were identified in a few samples of *Aedes albopictus.* In summary, *Ae. aegypti* exhibited high levels of phenotypic resistance and a complex genetic resistance profile in PNG. We also identified *Ae. albopictus* resistant to DDT and with low rates of resistance mutations which may be an indication for emerging pyrethroid resistance. Further research is needed to elucidate whether the resistance phenotypes and genotypes observed in this study are imported or have arisen locally in PNG.

PACMOSSI: THE PACIFIC MOSQUITO SURVEILLANCE STRENGTHENING FOR IMPACT PROGRAM

Tanya L. Russell[1], Amanda Murphy[2], Tessa Knox[3], Nigel Beebe[4], Adam Craig[5], Greg Devine[6], Narayan Gyawali[6], Stephan Karl[1], Gerard Kelly[7], Odwell Muzari[8], Lisa Natoli[9], Kristen Beek[5], Pippa McDermid[5], Leo Braack[10], Leanne Robinson[11], Sala Saketa[12], Thomas Burkot[1]

[1]James Cook University, Cairns, QLD, Australia, [2]World Health Organization, Suva, Fiji, [3]World Health Organization, Port Vila, Vanuatu, [4]University of Queensland, Brisbane, Australia, [5]University of New South Wales, Kensington, Australia, [6]QIMR Berghofer, Brisbane, Australia, [7]Beyond Essential Solutions, Melbourne, Australia, [8]Queensland Health, Cairns, QLD, Australia, [9]Australian Red Cross, Melbourne, Australia, [10]Asia Pacific Malaira Elimination Network, Bangkok, Thailand, [11]Burnet Institute, Melbourne, Australia, [12]The Pacific Community, Suva, Fiji

The Pacific has experienced unprecedented outbreaks of dengue, chikungunya and Zika virus alongside ongoing malaria and lymphatic filariasis transmission. In response, The Pacific Mosquito Surveillance Strengthening for Impact Program, or PacMOSSI, was created with the goal to support Pacific Island Countries and Territories (PICs) to strengthen vector surveillance and control to prevent, contain and control mosquito-borne diseases and improve the health and wellbeing of Pacific communities. PacMOSSI is a partnership between 21 PICs and 13 international institutions with a focus on building south-to-south networks. Leading the consortium is James Cook University, the World Health Organization (WHO) and the Pacific Community (SPC). PacMOSSI activities focus on essential components to support vector control, including building capacity for improved vector surveillance, data management, communication and community engagement. A vector control needs assessment (VCNA) defined the existing capacity of PICs to prevent mosquito-borne diseases and thereby identified focus areas for training, operational research and capacity building. Shortly after inception, the COVID pandemic struck. PacMOSSI responded by pivoting to an online interactive course that is more sustainable than traditional training formats. The interactive online format enabled the course to be available to all vector control staff and supporting disciplines at both national and subnational levels. This more cost effective approach also facilitating out reach to all PICs, and a great number of students. The initial course attracted over 150 participants from not only the PICS, but also Asia and Africa. This presentation will present an analysis of the capacity and activities of the region and link the results with the capacity building activities of PacMOSSI. More information is available here: https://pacmossi.org/

IMPACT OF INDOOR RESIDUAL SPRAYING VECTOR CONTROL TOOL ON MALARIA VECTOR POPULATION IN PAPUA NEW GUINEA

Rebecca J. Vinit[1], Petrina H. Johnson[2], Lincoln Timinao[1], Michelle Katusele[1], Leo S. Makita[3], Timothy Freeman[4], Jason Richardson[5], Fred Yeomans[5], William S. Pomat[1], Moses Laman[1], Leanne Robinson[6], Stephan Karl[2]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [3]Papua New Guinea National Malaria Control Program, Port Moresby, Papua New Guinea, [4]Rotarians Against Malaria Papua New

Guinea, Port Moresby, Papua New Guinea, [5]Innovative Vector Control Consortium, Liverpool, United Kingdom, [6]Burnet Institute, Melbourne, Australia

Despite high coverage of long-lasting insecticidal nets (LLIN) in Papua New Guinea (PNG) malaria transmission remains high. Currently, LLIN are the only vector control tool used in PNG. There is a great need to evaluate other vector control tools such as Indoor Residual Spraying (IRS) as potential complementary tool. In this study, we are assessing the impact of IRS on the malaria vector population, *Anopheles punctulatus* complex, in four malaria endemic villages in Madang Province of PNG. The four study villages are located on the north coast of PNG. Two villages are 5-6km inland from the coastline and two villages are immediately on the coast. Our study adopted a controlled interrupted time series study design with 12 months pre-intervention and 12 months post-intervention vector monitoring. One inland and one coastal village was selected for the IRS intervention while the others served as controls. Vector monitoring included human landing catches, barrier screen collections, indoor resting collections and larval surveillance. Baseline data indicated strikingly different vector composition between inland and coastal villages. High anopheline biting rates were observed in all study sites with most vectors exhibiting preference for outdoor biting. Preliminary phenotypic vector data will be presented comparing control to intervention villages. Pre- and post IRS intervention on *Anopheles* spp biting rates; feeding and resting behaviors will also be compared between villages. The results of this study will contribute to a better understanding of IRS, a complementary vector control tool in PNG. By conducting two-monthly mosquito surveys in our study villages located in different geographical settings, we hope to quantify the impact of IRS on its mosquito populations. Our pilot study is also geared towards building in-country IRS capacity in PNG to strengthen the National Malaria control program.

0772

MODELLING THE IMPACT OF VECTOR CONTROL INTERVENTIONS ON MALARIA TRANSMISSION BASED ON SEMI-FIELD AND FIELD DATA

Emma Louise Fairbanks[1], Alongkot Ponlawat[2], Theeraphap Chareonviriyaphap[3], Neil F. Lobo[4], Jeffrey Hii[3], David Mclver[5], Sarah Moore[1], Amanda Ross[1], Allison Tatarsky[5], Elodie Vajda[5], Nakul Chitnis[1]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Kasetsart University, Bangkok, Thailand, [4]University of Notre Dame, Notre Dame, IN, United States, [5]University of California, San Francisco, CA, United States

Vector control is an effective intervention for reducing transmission of many vector-borne diseases. We present a novel mathematical framework for estimating the impact of vector control interventions on the reduction of biting, repellency, pre-prandial killing, post-prandial killing and disarming (preventing host-seeking) from entomological semi-field and field study data. Semi-field studies were conducted in Thailand to estimate the impact of transfluthrin spatial repellents and etofenprox insecticide-treated clothing on mosquito landing, feeding and survival. Here time-stratified human landing catch (HLC), feeding rate (HLC and alive uncaught mosquitoes subsequently offered a blood meal) and 24-hour survival rate data was collected. Combining a mathematical model for mosquito host-seeking with a multinomial stochastic hierarchical model we used Bayesian inference to fit this data and estimate relative impact on mosquito host-encountering, biting, repellency, mortality and disarming. To better estimate the impact of interventions in real-world conditions we fit a random-effects negative-binomial model, accounting for variability in time and space, to a subsequent entomological field study measuring HLCs in Cambodia. This was used to modulate the intervention impact on biting, repellency, mortality and disarming by the observed efficacy in the field. We used these estimates to simulate the impact of these interventions on *P. falciparum* malaria transmission and disease using the individual-based transmission model, OpenMalaria. Results suggest that spatial repellents and insecticide-treated clothes not only provide personal protection but are likely to have a community benefit comparable to insecticide-treated nets, especially if coverage is high. The vectorial capacity was reduced even at low intervention coverage in the population, with the interventions having a stronger reduction in clinical incidence in lower baseline transmission settings. We predicted the spatial repellents to have a stronger impact than the treated clothing, which also saw a larger decay in effectiveness over time due to washing.

EXPERIMENTAL HUT TRIALS REVEAL THAT *CYP6P9A* AND *B* P450 ALLELES ARE REDUCING THE EFFICACY OF PYRETHROID-ONLY OLYSET NET AGAINST THE MALARIA VECTOR *ANOPHELES FUNESTUS* BUT PBO BASED OLYSET PLUS NET REMAINS EFFECTIVE

Benjamin Menze[1], Leon Mugenzi[2], Magellan Tchouakui[3], Charles Wondji[4], Murielle Wondji[4], Micareme Tchoupo[3]

[1]CRID, Yaounde, Cameroon, [2]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [3]Centre for Research in Infectious Diseases (CRID), Yaounde, Cameroon, [4]Liverpool School of Tropical Medicine, Yaounde, Cameroon

Malaria remains a major public health concern in Africa. Metabolic resistance in major malaria vectors such as *An. funestus* is jeopardizing the effectiveness of Long-lasting insecticidal nets (LLINs) to control malaria. Here, we used experimental hut trials (EHT) to investigate the impact of cytochrome P450-based resistance on the efficacy of permethrin-only net (Olyset) compared to a PBO-based net (Olyset Plus) revealing a greater loss of efficacy for the latter. EHT performed with progenies of F5 crossing between *An. funestus* pyrethroid-resistant strain FUMOZ and pyrethroid susceptible strain FANG revealed that PBO-based nets (Olyset Plus) induced a significantly higher mortality rate (99.1%) than pyrethroid-only nets (Olyset) (56.7%)(P<0.0001). The blood-feeding rate was higher in Olyset compared to Olyset Plus (11.6% v 5.6%; P=0.013). Genotyping the *CYP6P9a/b* and the intergenic *6.5kb* structural variant (SV) resistance alleles showed that, for both nets, homozygote resistant mosquitoes have a greater ability to blood feed than susceptible. Homozygote-resistant genotypes significantly survived more with Olyset after cone assays (e.g. *CYP6P9a* OR=34.6; P<0.0001) than homozygote susceptible. A similar, but lower correlation was seen with Olyset Plus (OR= 6.4; P<0.001). Genotyping of experimental hut trial samples confirmed that *CYP6P9a/b* and *6.5kb_SV* homozygote resistant mosquitoes survive and blood-fed significantly more than homozygote susceptible when exposed to Olyset. Our findings highlight the negative impact of `p450-based resistance on pyrethroid-only nets further supporting that PBO nets such as Olyset Plus are a better solution in areas of P450-mediated resistance to pyrethroids.

LONGITUDINAL SURVEILLANCE OF MALARIA VECTORS FROM VILLAGE AND FOREST AREAS OF STUNG TRENG AND MONDULKIRI PROVINCES, CAMBODIA USING FOUR DIFFERENT MOSQUITO COLLECTION METHODS

Didot Budi Prasetyo[1], Mihirini Hewavitharane[1], Chanry Im[1], Sony Yean[1], Nin Noch[1], Sokny Mao[2], Sochantha Tho[2], Sovannaroth Siv[2], Charity Ngaruro[3], Matthew Kirby[4], John E. Gimnig[5], Jennifer Armistead[6], Michael C. Thigpen[7]

[1]U.S. President's Malaria Initiative VectorLink Project, Phnom Penh, Cambodia, [2]National Center for Parasitology, Entomology, and Malaria Control, Phnom Penh, Cambodia, [3]Abt Associates, Rockville, MD, United States, [4]Abt Associates, London, United Kingdom, [5]Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]U.S. President's Malaria Initiative, USAID, Washington, DC, United States, [7]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Phnom Penh, Cambodia

Cambodia has experienced a significant reduction in malaria cases in the last decade, yet 58% of the population remain at risk, with highest

transmission in forested areas in the northeast. To assess heterogeneity in malaria transmission, we conducted longitudinal entomological surveillance in village and forest sentinel sites in two northeast provinces, Stung Treng and Mondulkiri from October 2020 through November 2021. Adult *Anopheles* were collected hourly from 18:00 to 06:00 in village sites using cow-baited and human-baited double-net traps (CDNs and HDNs) and Furvela tent traps (FTTs) outdoors, and CDC light traps (not hourly) indoors (LT). FTTs and HDNs were conducted in forest sites. Pyrethroid resistance of wild caught adults was determined using diagnostic doses of alphacypermethrin, permethrin, and deltamethrin. A total of 24,291 *Anopheles* comprising 32 species were caught. The largest proportion and highest species richness were from CDNs (75.1%, 30 species) and HDNs (20.3%, 29 species). Among primary vectors, *An. dirus* s.l. was caught at highest densities by HDNs in forest sites (mean 14.4/person/night in Stung Treng, 20.5/person/night in Mondulkiri). *An. maculatus* s.l. and *An. minimus* s.l. were caught in higher densities from CDNs. LT and FTT caught few primary vectors. *An. dirus* s.l. highest human biting rates from HDNs were observed in September at all sites (43-64 bites/person/night), and peak human biting activity was observed outdoors from 19:00 to 22:00. In contrast, *An. minimus* s.l. densities peaked in February, and human biting activity for this species and *An. maculatus* s.l. was low. No pyrethroid resistance was detected in these three species, and determination of sporozoite infection rates is ongoing. Results indicate that HDNs and CDNs may be best suited for future surveillance activities. The pyrethroid susceptibility of primary vectors indicates that pyrethroid-only LLINs remain appropriate for vector control, but the higher forest densities and outdoor and early biting behavior may require additional interventions. Studies of LLINs use and human behavior could identify gaps in protection.

INVESTIGATIONS ON THE EFFECT OF TEMPERATURE ON THE VERTICAL AND TRANSSTADIAL TRANSMISSION RATES OF RIFT VALLEY FEVER VIRUS IN *CULEX TARSALIS* AND *AEDES AEGYPTI* MOSQUITOES

Shelby Cagle, Arielle Glass, Corey Campbell, Emma Harris, Rebekah C. Kading

Colorado State University, Fort Collins, CO, United States

Rift valley fever virus (RVFV) is an emerging zoonotic, mosquito-borne virus that can cause encephalitic, neurological and/or hemorrhagic disease in sheep, cattle and humans. RVFV (*Phlebovirus*) is transmissible vertically within mosquito populations, through mosquito bites or by aerosolization of viral particles. RVFV is classified as a Select Agent due to its pathogenicity and because it poses a significant risk to human and animal health, which can be detrimental to society, industry, and the economy. Though endemic to East Africa, RVFV is well-poised for introduction to the United States due to human travel, and vector competence has been demonstrated for many mosquito species native to North America. The factors that govern how efficiently mosquito species transmit RVFV transovarially (parent to offspring) is a gap in our current understanding of interepidemic viral maintenance. In particular, understanding how environmental conditions such as temperature may modulate transovarial transmission of RVFV is not yet understood. Transovarial transmission is one mechanism through which viruses persist in the environment across seasons. To elucidate how larval rearing temperature can affect transovarial transmission of RVFV from *Culex tarsalis* and *Aedes aegypti* mosquitoes to their progeny, mosquitoes were given an infectious blood meal of RVFV strain KEN128B-15. Seven days after oviposition, they were subsequently fed an uninfected blood meal, and progeny from this second gonotrophic cycle were reared to examine viral load and infection prevalence at each developmental stage. This experiment will be repeated at 28C, 18C and 32C rearing temperatures. The results of these ongoing experiments will be presented, specifically infection rates and viral loads of RVFV in mosquitoes reared from infected females. We hypothesize that larval habitat temperature influences the efficiency of transstadial transmission. Through this study, we hope gain crucial insight for vector competence that can be applied to other mosquito-borne disease systems.

CAN TRANSGENIC MALARIA-REFRACTORY MOSQUITOES ALSO SUPPRESS GENETICALLY DIVERSE *PLASMODIUM FALCIPARUM* FIELD ISOLATES?

Caire Barreto[1], Abhai K. Tripathi[1], Alexander Pichugin[2], Janette Kathleen Moch[3], Rebeca Carballar-Lejarazú[4], Anthony James[4], George Dimopoulos[1]

[1]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Walter Reed Army Institute of Research, Rockville, MD, United States, [4]University of California, Irvine, Irvine, CA, United States

Malaria, a disease caused by *Anopheles*-transmitted protozoans of the *Plasmodium* genus, remains a major global public health challenge. Despite continuous efforts to eradicate or significantly reduce malaria transmission, the lack of effective vaccines and the rapid emergence of drug-resistant parasites and insecticide-resistant mosquitoes highlight an urgent need for the development of alternative disease control strategies. Multiple genetically modified *Plasmodium*-refractory mosquito strains have been shown to achieve suppression of the NF54 laboratory isolate of *Plasmodium*. However, the efficacy of transgenic blocking mechanisms has yet not been validated with genetically diverse field-derived malaria parasites. The application of *Plasmodium*-resistant transgenic mosquitoes to combat malaria *in natura* will require assessment of the effectiveness of engineered blocking barriers against diverse *P. falciparum* field isolates. We have initiated a study on the infectivity of *P. falciparum* isolates from various geographical locations in both wild-type (wt) and transgenic mosquitoes using Standard Membrane Feeding Assay (SMFA) to determine the competence of selected transgenic mosquito strains to suppress *P. falciparum* infection. We are also exploring the use of a humanized mouse malaria infection model to perform more realistic human malaria transmission studies, and to enable the restoration of *P. falciparum* gametocyte infectivity that is known to subside during extensive laboratory culturing. Our studies will evaluate transgenic blocking mechanisms for use in *Anopheles* population modification -based malaria control, and provide a wider repertoire of diverse *P. falciparum* strains for transmission-blocking studies.

DEEP ANALYSIS OF HOST SEEKING ACTIVITIES IN MALARIA VECTORS ACCOUNTS FOR HIGH LEVEL OF RESIDUAL TRANSMISSION DESPITE EXTENSIVE LLIN COVERAGE IN BURKINA FASO

Eleonora Perugini[1], Wamdaogo M. Guelbeogo[2], Federica Guglielmo[3], Cristiana Poggi[1], Eugenio Gabrieli[1], Hilary Ranson[3], Alessandra della Torre[1], Marco Pombi[1]

[1]Sapienza University, Department of Public Health and Infectious Diseases, Rome, Italy, [2]Centre National de Recherche et Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Liverpool School of Tropical Medicine, Department of Vector Biology, Liverpool, United Kingdom

Burkina Faso is among the 10 high sub-Saharan countries where a stalling in the fight against malaria has been registered and the incidence remains still very high despite the countrywide LLIN distribution campaigns recommended by WHO every three years since 2010. Our overarching goal is to understand how vector behaviours in response to LLINs (i.e. increased zoophagy, outdoor biting and/or altered biting rhythms) and their interactions with human activities and net usage can contribute to this epidemiological scenario. In previous studies, conducted within 5 years after LLIN introduction in Goden village in Burkina Faso, we defined a scenario of marked zoophily in the dominant vector species (*A. coluzzii* and *A. arabiensis*) despite sporozoite (SR=6.1%) and entomological inoculation (EIR=1.4 infective bites/person/hour, ibph) rates in the range observed in pre-intervention settings. We here present results of Human Landing Catches (HLC) conducted in 2020 in Goden during the whole mosquito biting period (4pm-8am) alongside a survey on human habits and net usage. GAM results show: 1) SR=1.1%; 2) a roughly

homogeneous plateau of intense biting activity from 10pm to 5am (mean 37.4 mosq/person/hour) and a non-negligible biting pressure before and after this time window (6.6), with no difference indoors and outdoors. Under an unrealistic scenario of full human exposure, the mean EIR during the 16h-HLC is 4 ibp. However, adjusting human exposure according to LLIN usage as estimated based on questionnaires, the mean EIR drops to 0.6 ibp. Interestingly, 0.14 ibp occurs before 8pm and after 6am when 100% of inhabitants are awake and thus fully exposed to bites. This shows how interaction between human activities and vector host-seeking pressure contributes to a non-negligible gap in LLIN protection. We expect that this interplay between human and vector behaviours may represent one of the main factor accounting for residual malaria transmission in other epidemiologically similar settings characterized by high vector density and insecticide resistance.

TOWARDS THE LABORATORY MAINTENANCE OF *HAEMAGOGUS JANTHINOMYS*, THE MAJOR NEOTROPICAL VECTOR OF SYLVATIC YELLOW FEVER

Adam Hendy[1], Nelson F. Fé[2], Danielle Valério[2], José T A Júnior[2], Flamarion P. Assunção[2], Vera M. Scarpassa[3], Marcus V G de Lacerda[2], Kathryn A. Hanley[4], Nikos Vasilakis[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Fundação de Medicina Tropical Doutor Heitor Vieira Dourado, Manaus, Brazil, [3]Instituto Nacional de Pesquisas da Amazônia, Manaus, Brazil, [4]New Mexico State University, Las Cruces, NM, United States

Haemagogus janthinomys (Dyar, 1921) is the main vector of yellow fever virus (genus *Flavivirus*) and a prominent vector of Mayaro virus (genus *Alphavirus*) in neotropical forests. It is notoriously difficult to maintain in the laboratory, and almost no vector competence studies have been performed with this species since the 1940s. Zika, dengue (both genus *Flavivirus*), and chikungunya (genus *Alphavirus*) viruses have emerged or resurged in the Americas in recent decades, creating risk for spillback into sylvatic cycles, potentially involving *Hg. janthinomys*. Vector competence studies are, therefore, needed, and would be facilitated by the existence of a stable laboratory colony of this species. To develop techniques to rear and maintain *Hg. janthinomys*, we collected 413 adult female mosquitoes from rainforest bordering Manaus, Brazil, in the first three months of 2022. Feeding rates of 63.9% (242/379) were achieved by exposing caged, field-derived mosquitoes to a human-blood-soaked cotton pad, affixed to the base of a plastic cup containing 40 - 45 °C water. This resulted in the production of 2,763 F1 generation eggs (mean 11.4 per mosquito) obtained mainly by placing gravid females in filter paper lined petri dishes at 5 days post feeding. Preliminary data show eclosion rates >60% can be obtained through ≤10 four-day cycles of egg immersion in a bamboo leaf infusion (2 days) and partial drying (2 days), starting within 3 days of oviposition. We are attempting to produce F2 generation eggs by forced copulation; these results are pending. We do not yet know whether these methods can be used to establish a stable *Hg. janthinomys* colony, nonetheless our established techniques to artificially blood feed adult females will permit future vector competence studies.

THE PROMISE AND PITFALLS OF MOSQUITO REPRODUCTIVE CONTROL: LESSONS FROM THE DENGUE VECTOR, *AEDES AEGYPTI*

Laura C. Harrington

Cornell University, Ithaca, NY, United States

Mosquito mating is a critical life history moment and a major target for future vector control strategies. Once considered a brief random encounter, we now understand mosquito mating and reproduction to be complex. Our research, and those of others, shows that mosquito sex involves a complex orchestration and interplay of events involving male and female behaviors, transfer of molecules and induced female responses. Here, I review our current understanding of mating dynamics in the dengue vector mosquito, *Aedes aegypti*. I share our latest results from mating behavior and acoustic research, ejaculatomics and female transcriptomics studies and post mating response phenotypes that influence female vector potential. I conclude with a discussion of what we have learned in the context of emerging vector control strategies that rely on modified male releases as well as important outstanding questions.

PERSISTENT FINE-SCALE GEOGRAPHIC CLUSTERING OF LA CROSSE VIRUS DISEASE IN SOUTHERN APPALACHIA (UNITED STATES)

Corey Day, Rebecca Trout Fryxell

University of Tennessee - Knoxville, Knoxville, TN, United States

La Crosse virus (LACV) is a mosquito-borne pathogen that causes more neuroinvasive pediatric disease than any other arbovirus in the United States. From 2003-2021, approximately 40% of all neuroinvasive LACV disease occurred in east Tennessee and western North Carolina. Recent research in North Carolina found multiple cases of LACV disease occurring at individual households in different years, demonstrating the persistent fine-scale risk of this disease. As an extension of that research, our objective is to investigate the spatial-temporal distribution of LACV disease in east Tennessee and western North Carolina. We hypothesize that the geographic distribution of high-risk disease clusters is persistent, such that the same areas have consistently maintained high disease risks. We received case-specific data for reported cases of neuroinvasive LACV disease in Tennessee and North Carolina from 1997-2020 from the state health departments. We used spatial scan statistics to investigate the geographic clustering of the disease at the county and census tract levels in 5-year increments throughout the study period. We confirm that in counties where LACV disease is endemic, cases are not randomly distributed but instead are clustered within specific census tracts. Consequently, county-level measurements of incidence risk consistently underestimate the risk of LACV disease in the specific neighborhood where most cases are clustered. These findings demonstrate the potential for the prevention of LACV disease through targeted interventions that focus on the specific fine-scale geographic areas with persistently high disease risks.

EMPLOYING STATE-OF-THE-ART MOSQUITO CONTROL STRATEGIES, REMOTE SENSING AND MACHINE LEARNING, *TO* PRIORITIZE *AEDES SPP.* ABUNDANCE AND MOSQUITO BREEDING HABITAT RISK

Huixuan Li[1], Melissa Nolan[1], Sarah M. Gunter[2], Andre Luis da Costa-da-Silva[3], Helen Wagner[3], Matthew DeGennaro[3]

[1]University Of South Carolina, Columbia, SC, United States, [2]Baylor College of Medicine and Texas Children's Hospital, National School of Tropical Medicine, Department of Pediatric Tropical Medicine,, Houston, TX, United States, [3]Laboratory of Tropical Genetics, Florida International University, Miami, FL, United States

Mosquito-borne diseases are a continuing public health concern in the United States and globally. Current technologies often used by the local mosquito and vector control divisions are costly, cumbersome, and outdated. This has resulted in little or no data driven proactive mosquito control efforts. This study demonstrates the utility of remote sensing and machine learning to effectively predict *Aedes* mosquito egg abundance in Miami, Florida. Mosquito collection data from May 2019 to Dec 2021 was obtained from routine collection. Using multiple Sentinel-2 imageries, a U-Net convolutional neural-network machine learning algorithm was employed to generate the land-use land-cover classification map. Additionally, indices for vegetation (NDVI) and water content (NDWI) were derived from the same images. The mosquito data was analyzed from a spatiotemporal perspective. A predictive model of mosquito abundance by these micro-environmental factors was developed using a suite of 5 different machine learning statistical techniques. The highest overall

accuracy model was used to derive a predicated mosquito risk map for Miami, FL. With data available, the deep learning approach developed in this study could be easily applied to a large-scale vector control daily surveillance decision making. We believe integrating this technology into routine vector control activities could release the burden of mosquito-borne disease management and limit insecticide residence through targeted abatement.

0782

TRACING THE SPREAD OF *ANOPHELES STEPHENSI* IN DIFFERENT STATES IN SUDAN

Asma Elagali[1], Ahmed Elagali[1], Peter Gething[2], Mustafa Abubakr[3], Hassan Ismail[4]

[1]Omdurman Islamic University, Khartoum, Sudan, [2]Telthon Kids Institute, Perth, Australia, [3]Department of the Integrated Vector Management (IVM), Federal Ministry of Health, Khartoum, Sudan, [4]Diseases Control Directorate, Federal Ministry of Health, Khartoum, Sudan

In the year 2019, the presence of the invasive *Anopheles Stephensi* was reported in Sudan (Abubakr et al. 2021). This increases the risk of malaria, particularly in urban and suburban areas in the country. *Anopheles Stephensi* has been reported in the capital city of Sudan, Khartoum, among many other cities in different states e.g., the Red Sea and Gedaref states. Hence, there is an urgent need to launch a national entomological survey to determine the distribution of this vector throughout the country. This survey will result in the collection of essential information on *Anopheles Stephensi* bionomics and susceptibility to the available malaria vector control methods in several states. One of the main outcomes of this research is to find the most suitable intervention methods to both control and limit the spread of this vector, especially during the rainy seasons and consequently reduce the burden of malaria incidence in Sudan. In this talk, I will present the early results of our survey conducted in the Northern state describing the geographical presence and distribution of *Anopheles Stephensi* as well as provide evidence on the feeding and resting behaviours of *Anopheles Stephensi*. The results of our survey will be essential in shaping the current Ministry of Health and Vector control division policies on possible vector control measures that can effectively reduce the burden of Malaria resulting from this invasive mosquito vector.
