In Bangladesh transgenders are high-risk group for HIV infection. Gender identity crisis and psychosocial stressors contribute developing psychiatric illness. We aimed to identify association of psychiatric disorders in transgenders by comparing the HIV status in Dhaka city. A cross-sectional study of transgenders aged >18 years was interviewed after taking written informed consent between July 21-June 2022. Sociodemographic, personal, co-morbid condition and psychosocial stressor variables were collected. Self-Reporting Questionnaire 20 was applied for psychiatric evaluation. Psychiatric illness was diagnosed using Mini International Neuropsychiatric Interview 7.0.0. The primary outcome of the study was to detect psychiatric illness among transgender adults irrespective of HIV status. Ethical clearance was taken. Of 157 transgender adults, 34 (22%) were HIV positive. Fifty-nine percent participants were between the 18-30 years of age group. Male biological sex was predominant (97%). Gay or lesbian sexual orientation was predominant (50% vs. 17%; $p<0.001$) and statistically significant and HIV positive transgender people. Fifty-

six percent belong to rural birthplace. Failed suicidal attempts (12% vs. 2%; p<0.001), chronic medical conditions (91% vs. 15%; p<0.001), any romantic relationship (67%vs 36%; p<0.001)) and satisfaction in the quality of life (64% vs. 45%; p=0.04) were significantly associated with HIV positive transgender than HIV negative peers. Among 34 HIV-positive transgender 22 (65%) were diagnosed as having psychiatric illnesses. Generalized anxiety disorder (41%) was the predominant psychiatric illness next to Minor depressive disorder (32%) and obsessive-compulsive disorder (9%). After adjusting the confounding variables, chronic medical condition [OR 98 (9.93-98.18; p<0.001] and life satisfaction [OR 8.7 (1.02-74.3); p=0.048] were significantly associated with psychiatric illness. Psychosocial stressor-based national screening program for early identification of psychiatric disease need to be developed for transgenders with HIV.

5793

SYNTHESIS OF FINDINGS FROM THE LITERATURE AND A QUALITATIVE RESEARCH STUDY ON THE IMPACTS OF GENDER, DISABILITY, AND ETHNICITY IN NEGLECTED TROPICAL DISEASES PROGRAMMING

Jennifer K. Arney, Maureen K. Headland, Andrea M. Bertone, Diana Stukel

FHI 360, Washington, DC, United States

Act to End Neglected Tropical Diseases (NTDs) West, a USAID-funded program that seeks to eliminate or control five NTDs in West Africa, conducted a gender and social inclusion analysis to determine how NTDs differentially impact different population groups and how gender and social norms impact NTD programs. The study used a mixed methods approach, including a literature review; qualitative data collection in Côte d'Ivoire, Sierra Leone, and Ghana with a total of 477 participants; and quantitative analysis of programmatic data. Women and girls face additional health risks as well as social and economic impacts as a result of NTD infection compared to men and boys. Men are somewhat less likely to participate in mass drug administrations (MDAs) due to lack of information about campaigns, lack of access due to being out of the community when MDAs are conducted, and concerns and misconceptions about side effects. Pregnant and breastfeeding women are sometimes excluded from certain types of MDAs for which they are eligible or choose not to participate due to misinformation. MDA training rates for community drug distributors (CDDs) and supervisors are almost universally higher for men than women, even though feedback on the effectiveness of female CDDs is overwhelmingly positive, and female CDDs often have more access to women in conservative households. The role of CDDs can lead to career and social opportunities for both men and women. However, challenges faced by CDDs are seen as a greater barrier for women, including transportation, safety, household responsibilities, and low or lack of wages. Finally, people with disabilities and marginalized ethnic groups may sometimes be excluded from or exclude themselves from MDA. NTD programs can promote gender equity by increasing women's participation in MDA activities and providing financial compensation to CDDs. Additionally, programs should prioritize inclusive training for CDDs, and inclusive messaging about NTDs and MDA for communities. For example, in Sierra Leone, Act | West is now conducting rumor tracking to address misconceptions and collecting data on CDD sex for advocacy purposes.

5794

NEEDS AND PREFERENCE FOR COMMUNITY HEALTH WORKER SERVICES IN CAMBODIA: A COMMUNITY SURVEY

Panarasri Khonputsa[1], Long Heng Orng[1], Monnaphat Jongdeepaisal[1], Christopher Pell[2], Siv Sovannaroth[3], Massaya Sirimatayanant[1], Richard J. Maude[1]

[1]Mahidol Oxford Research Unit, Bangkok, Thailand, [2]Amsterdam Institute for Social Science Research, University of Amsterdam, Amsterdam, Netherlands, [3]National Center for Parasitology, Entomology and Malaria Control (CNM), Phnom Penh, Cambodia

Despite ongoing efforts towards universal health coverage, many LMICs still suffer from shortages in health professionals, lack of infrastructure, and inequities in health protection, particularly in remote rural areas, where access to health care and health information are inadequate and where poor communities bear the greatest health and economic burden of disease. In Cambodia, CHWs are identified as key to local health promotion and as a critical link between health centres and the community. However, research on the needs and preferences of communities regarding CHW services is limited.As part of a wider RAI3E operational research project on expanding the role of and integrating village malaria workers we conducted a questionnaire-based community survey in 6 endemic communes of Kravanh District, Pursat province, Cambodia during March and April 2022 with 174 community members (72 males and 102 females; aged 22-71). Community members were familiar with the local community health workers; almost half of respondents had visited a CHW in their community for health services in the past 12 months. Community members and their family's most common health problems included common cold (81%), malaria (72%), unspecified fever (43%), non-communicable diseases (NCDs i.e. diabetes, hypertension, hyperlipidemia, 32%), and dengue (30%). NCDs (35%), influenza (20%), pneumonia (25%), dengue (12%), and malaria (11%) were reported as their greatest health concerns. Over half (54.5%) of respondents preferred home visits from a CHW. Almost two-thirds described a willingness to pay for additional CHW services and, of those, 59% preferred paying 10 USD or less. Nonetheless, a similar proportion of all respondents reported difficulties paying for their healthcare.In summary, there was a varied demand for primary healthcare at the community level in Cambodia, covering infectious and non-infectious diseases. Well-known and accessible, CHWs are well-positioned to meet some of these needs. Ensuring basic equipment for CHWs is key, as are providing adequate capacity building and supervision, particularly if their role is to be expanded.

5795

ARMED CONFLICT REFUGEES' RESILIENCE: TRANSDISCIPLINARY STUDY ON A DIALOG FOR HEALTH PREVENTION IN THE EASTERN DEMOCRATIC REPUBLIC OF CONGO

Christian Ahadi Irenge[1], Freddy Bikioli[2], Rodrigue Fikiri Bavurhe[1], Benedicte Sakina[3], Yves Coppieters[4]

[1]Official University of Bukavu, Bukavu, Congo, Democratic Republic of the, [2]Antwerp University, Antwerp, Belgium, [3]Université Libre des Pays des Grands Lacs, Goma, Congo, Democratic Republic of the, [4]School of Public Health, ULB, Bruxelles, Belgium

In DR Congo, the resurgence of violence by armed groups in 2023 caused the displacement of more than 5.8 million people. Parasitic infections, malaria, mental health, sexual and gender-based violence are considered more prevalent among refugees. This work argues the ability of refugees to persist, adapt and transform face to sanitary challenges might be limited given that it their context involves the loss of all their basic resources, the effectiveness or not of subsidies and the transitional state of displacement. This work aimed to set a dialog with key actors as to contribute to the characterization of infectious diseases (epidemiological investigation and microorganism identification), of psychosocial risks and to explore the ability of resilience in the context of refugee's camps in the region of Nyiragongo in Eastern DR Congo. Data were collected in a period of January and

February 2023 with socio-anthropological and microbial methods integrating "transdisciplinary approaches" that consisted in co-producing the objectives with stakeholders. The local knowledge was integrated through exploratory survey with key actors. Forty-six (46) sites sample where collected for microbiological analysis. In total, 104 persons were interviewed and 11 FG each consisting of 6 to 9 actors were organized. The "inductive thematic data analysis" was applied. Key findings are attitudes and behavior risks related to infectious diseases, sanitation and the psychosocial burden. Total coliforms, Vibrio ssp., Salmonella ssp., Shigella ssp., and Enterobacteria were identified from camps sites samples. The ability of refuges to persist, adapt and transform are analyzed into dynamic of the actors, resources, interactions context. In perceptive of actions, the results are translated into a grid of powers and interests in relation to the mobilization of resources for the prevention infectious and psychosocial burden. In addition, an analysis of the ability of refugees to persist, adapt and transform as to prevent health risks.

5796

LIVING WITH HANSEN'S DISEASE IN MALAYSIA: A TRANSDISCIPLINARY RESEARCH APPROACH

Norana Abdul Rahman[1], Vaikunthan Rajaratnam[2], Ruth M. H. Peters[1], Karen Morgan[3], Mohamed Rusli Abdullah[4], Marjolein B. M. Zweekhorst[1]

[1]Athena Institute, Vrije University, Amsterdam, Netherlands, [2]Khoo Teck Puat Hospital, Singapore, Singapore, [3]Perdana University-Royal College of Surgeons in Ireland School of Medicine, Kuala Lumpur, Malaysia, [4]Universiti Sains Malaysia, Kota Bharu, Malaysia

Hansen's Disease (HD) is a chronic bacterial infection that primarily affects the skin, nerves, and other parts of the body. The disease can cause physical deformities if left untreated, which can make daily activities more difficult. While multi-drug therapy is effective at curing HD, allowing many to lead fulfilling lives, stigma still surrounds it. The application of a transdisciplinary research approach can facilitate a mutual understanding of the challenges faced by HD-affected people to identify their needs and concerns and develop solutions that address their unique challenges to reintegrate them into society and become contributing members. Stakeholder identification and mapping were conducted to identify twenty HD-affected individuals and twenty key people and decision-makers from governmental agencies, non-governmental organizations, and community and family members involved in their care (n=40). Participants were purposively sampled. Semi-structured interviews were conducted with each participant, and their responses were transcribed and analyzed with NVIVO software. A stakeholder engagement workshop was held where the problems were discussed and ranked, and solutions were co-created for the problems identified. An interagency meeting followed to discuss the implementation of the agreed interventions. The four main themes that emerged regarding the impact of HD on the affected individuals were biophysical, psychological, social, and economic. The stakeholders' analysis showed that the main challenges were a lack of public and health workers' awareness and knowledge of HD, insufficient resources for prevention and control, and a lack of interagency engagement and communication. Another issue was access to employment and skills training for self-sufficiency. Details of the analysis will be presented. The transdisciplinary approach can facilitate the integration of traditional knowledge and expertise, promoting a more inclusive and participatory approach to research. This collaboration ensures that solutions are empowering and sustainable to enhance the standard of living of the affected people.

CHARACTERISTICS ASSOCIATED WITH SARS-COV-2 SEROPOSITIVITY IN CAMEROON

Ebako Ndip Takem[1], Clement B. Ndongmo[1], Judith Shang[1], Adama N'Dir[1], Dubliss Nguafack[2], Gabriel Ekali[2], Emily K. Dokubo[3]

[1]Centers for Disease Control and Prevention, Yaounde, Cameroon, [2]International Center for AIDS Care and Treatment Program, Yaounde, Cameroon, [3]Centers for Disease Control and Prevention, Kingston, Jamaica

It is important to study both symptomatic and asymptomatic infected persons to get a complete picture of SARS-CoV-2 in a population. The aim of this study was to identify characteristics (travel and testing history, exposure to crowded areas, contact with infected persons, household number) associated with SARS-COV-2 seropositivity in adults and in children in Cameroon. We used data from a SARS-CoV-2 country-wide seroprevalence survey conducted in Cameroon from November 2020 to February 2021 among males and females aged 5 to 100 years. A whole blood specimen was collected for SARS-COV-2 serology testing using ABBOTT Architect immunoglobulin G (IgG) and WANTAI total antibodies (Ab). A test was considered positive only if both tests were positive. Descriptive statistics, crude association between each covariate of interest and SARS-COV-2 seropositivity, and multivariable association (logistic regression) were used. Weighted counts (estimates) are presented. Data were available for 9836 participants. Less than 20% (17.53%) of the participants had symptoms of COVID-19 (1423/8116). The seroprevalence of SARS-COV-2 was 10.45% (8347/9321) and the seroprevalence was higher in those with symptoms 12.93 % than those without symptoms 9.97%. In univariate analyses, seropositivity was similar with increasing number of people in household (OR=0.98, 95%CI 0.76-1.28, p=0.90). Those who had travelled abroad had a higher risk of seropositivity than those who did not (OR=1.63, 95%CI 1.08-2.47, p=0.02). In the final multivariate model, seropositivity increased with age, after adjusting for sex, contact history, and testing history (AOR=1.61, 95%CI 1.29-2.01, p<0.001). The risk of seropositivity was higher in those with prior testing compared to those without prior testing (AOR=1.34 95%CI 1.04-1.72, p=0.02). Males had a higher seropositivity rate in both children and adolescents, (AOR=1.79 95% CI 1.24-2.58 p=0.003) and in adults (AOR=1.66, 95%CI 1.35-2.05, p<0.001). In conclusion, these data suggest an association between increasing age, male gender, previous SARS-COV-2 testing and seropositivity for SARS-COV-2.

5798

CONCEPTUALIZING AND UNDERSTANDING STIGMA ASSOCIATED WITH CUTANEOUS LEISHMANIASIS IN A RURAL COMMUNITY OF SRI LANKA

Hasara Nuwangi[1], Lisa Dikomitis[2], Kosala G. Weerakoon[3], Suneth B. Agampodi[4], Thilini C. Agampodi[1]

[1]Department of Community Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka, [2]Kent and Medway Medical School, University of Kent and Canterbury Christ Church University, Canterbury, United Kingdom, [3]Department of Parasitology, Faculty of Medicine and Allied Sciences Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka, [4]International Vaccine Institute, Seoul, Korea, Republic of

Stigma is a barrier to health-seeking and treatment adherence, affecting disease mortality, morbidity, a person's quality of life and social inclusion. Cutaneous Leishmaniasis (CL) is widely accepted as a stigmatising skin disease. This disease has been endemic in Sri Lanka for centuries. The drivers and facilitators of the stigma associated with CL are not understood properly compared to those of other stigmatising diseases, preventing the development of holistic interventions, research, and policy. This study aims to identify the drivers and manifestations of the stigma associated with CL in rural Sri Lanka. This study was conducted in 2021 in the Anuradhapura district, a district with one of the highest incidence of CL in Sri Lanka. A multimethod qualitative approach was used with two main components, 1) An ethnographic study; participant observation and an auto-ethnographic diary study, 2) A qualitative study on people with CL

using a Participant Experience Reflection Journal (PERJ) and Post-PERJ interviews. We observed indirect, hidden and unexpressed stigma. Most of the negative reactions were confined to people with notable wounds. Disgust, fear, myths and misconceptions of the disease and the notion that it is a dangerous/deadly disease are identified as potential drivers of stigma. Marginalisation, internalised, anticipated and social stigma were identified as stigma experiences. People with internalised stigma felt sad/disappointed/uneasy; they accepted the disease as bad Karma. People with big/visible wounds also anticipated stigma from others and took measures to cover up/hide the wounds. They had reduced engagement with society as they feared dismissal by others. Social stigma manifested as calling people with a wound 'a distortion' and 'ugly'. The wound was described as disgusting by community members. Ideally, stigma interventions should interrupt the process before the stigma is established. It is important that the drivers we have identified through this study are addressed through public health interventions and policy before the stigma is widely established.

5799

INTEGRATING AND ACCESSING EQUITY IN GLOBAL HEALTH PROGRAM DESIGN

Vajra Allan[1], Christelle Gogue[2], Krya Arnett[1], Brianna Musselman[2], Peder Digre[1], Bindiya Patel[1]

[1]PATH, Seattle, WA, United States, [2]PATH, Washington, DC, United States

PATH set out a five-year strategy focused on advancing health equity through innovation & partnerships. The strategy includes four change strategies for becoming a more equitable organization: equity in health, community-focused priorities, respectful partnerships, & inclusive innovation. PATH translated its change strategies into tactical benchmarks. The working group conducted a literature review, 17+ qualitative interviews with staff & partners, & held workshops with 60+ people. 11 project teams piloted & provided feedback on the first version of the Equity in Programming Benchmarks (EBP). The tool is a self-assessment measuring 12 indicators on a continuum from low to transformative & helps identify how each project can progress along the continuum. Project assessments are reviewed by PATH leaders. 35 proposals & projects have used the benchmarks to assess their work. The New Nets Project-a malaria vector control evaluation-used the benchmarks at the end of the project with partners to review results & consider ways to modify mosquito net distribution in the future. Highlights from this discussion include: Identifying structural changes to address barriers for institutions in malaria-endemic countries to access resources from large donors & build capacity; More consideration of systemic inequities within routine processes such as how to conduct & measure mass distribution campaigns of nets. The Technical Assistance Platform Project-a global health informatics technical assistance mechanism-used the EPB tool in annual work planning & made several adjustments including: Evolving the model so partners strengthen their organizational & leadership capacity & take on increasing project leadership, responsibilities, & autonomy over time; Ceding control over certain aspects of project management to colleagues & partners based in Africa & Asia. With the EPB, teams have better tools for understanding equity in their projects & can communicate the rationale for changes to donors & partners. We continue to gather feedback & iterate on the EPB so it meets the evolving needs of teams & the communities where the projects take place.

5800

INCREASING ADOPTION OF MALARIA PREVENTION AND CONTROL USING MULTIPRONGED SOCIAL BEHAVIOR CHANGE APPROACHES

Aaron Musimenta[1], Felix Manano[1], Dorah Anita Talanta[1], Irene Ochola[1], Angela Kateemu[1], Amy Casella[2], Aliza Hasham[3], Benjamin Binagwa[1], Natalia Whitley[2]

[1]John Snow Inc, Kampala, Uganda, [2]John Snow Inc, Boston, VA, United States, [3]John Snow Inc, Dar es Salam, Tanzania, United Republic of

Social behavior change interventions, in the USAID PMI Uganda Malaria Reduction Activity, implemented by JSI, are data-driven, gender sensitive and targets malaria high burden districts. Aided by behavioral science and human centered design approaches to understand why people make decisions the way they do to tailor interventions that trigger behavioral change. District led programming and working with already existing structures like community health workers or village health teams is the main strategy. Focus is on increasing demand for health services, improving mosquito net use, improving health care provider and client interactions, and influencing social norms for sustainability. A multi-sectoral approach was used to engage district leaders and other stakeholders to inspire change at community level. We engaged district health teams, opinion leaders, epidemic task forces for malaria and other implementing partners. The number of children between 2 months and 5 years old with fever that received malaria rapid diagnostic tests seen by village health teams reduced from 1,194,184 in April to June 2022 to 960,454 in October to December 2022. The number of sick children of the same age range with confirmed malaria decreased from 1,057,854 to 860,548.The number with fever and danger signs seen in the community reduced by 12% from 65,570 to 57,754 and the number seen by village health teams and treated within 24 hours for fever reduced by 51% from 881,890 to 428,374 between April to December 2022. Supporting the districts to identify their own strategies for mobilization empowers district leaders and creates ownership. Each district has its own dynamics and have their own strategies for community engagement that works for them like engaging elders in community mobilization, engaging positive deviants in giving testimonies during community mobilization events, using data to map hotspots, and door-to-door mobilization. The role of community engagement in the planning and execution of community led activities directly leads to better health outcomes and sustainability of the adopted positive behaviors.

5801

EQUALITY IN AJTMH PUBLICATIONS FROM 1952 TO 2022: WHAT CAN WE LEARN TO MAKE GLOBAL HEALTH RESEARCH PUBLISHING MORE EQUITABLE? A BIBLIOMETRIC ANALYSIS

Nabila Farah Jeehan Youssouf

Botswana Harvard Health Partnership, Gaborone, Botswana

The long overdue focus on decolonising global health has prompted various institutions to assess existing inequities in global health research partnership and resulting publications. Recent reviews have demonstrated inequities in published global health research between researchers from high-income countries and low- and middle-income countries in terms of authorship, gender and academic affiliations, among others. Reflecting the American Society of Tropical Medicine and Hygiene's aim to advance health equity globally, we propose to conduct a bibliometric analysis of the American Journal of Tropical Medicine and Hygiene (AJTMH) publications between 1952 and 2022. Specifically, we propose to assess the following: - Author order- Author affiliation(s), classified using World Bank country income classifications- Author gender, when available- Funding source- Study type- Study topic- Region of publication- Year of publication.Funding sources will be recorded primarily to identify main stakeholders for further dissemination of our findings. Data will be analysed using Student's t-tests and Chi-square, followed by logistic regression. Results from this review will 1) inform a widening participation strategy launched by the ASTMH in 2022, to reflect the current make-up of global health researchers worldwide and

2) strengthen the record of AJTMH as an innovative publication with not only its finger on the pulse of change, but also actively seeking to equalise the field of global health reporting. Finally, the authors will propose further direct collaboration with the AJTMH and its affiliates to update guidelines and prepare authorship guidelines describing the Journal's commitment to inclusivity, equality and fairness.

5802

ESTABLISHING A RELATIONSHIP WITH THE SURVIVORS OF TORTURE CLINIC AND THE UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE; AN INNOVATIVE ALLIANCE TO MENTOR AND ASSIST REFUGEES

Zoha Mian

University of Louisville, Louisville, KY, United States

Kentucky ranks 5th in the nation for the number of refugees. A Physicians for Human Rights chapter was created in response to an unmet need in refugee support services. Students were recruited through an application process and were selected as vice president, secretary, treasurer, and community outreach chair. Our mission is to partner with the Survivors of Torture Clinic at the Univerisity of Louisville. The Survivors of Torture Resource Center offers comprehensive services to refugees and immigrants who have experienced torture in their home countries. They include direct mental health services, social and medical care coordination, and legal service referrals. Through our cooperative relationship, medical students can volunteer and serve as mentors to asylum seekers. Cultural differences often make it difficult for young refugees to adjust to a new country. Besides offering friendship, mentors can also assist them in navigating a foreign country. In addition to exposing them to different events in the city, they can provide them with a wide variety of restaurants to eat at or offer ways to foster their passions. Students will also help them navigate healthcare appointments and schedules. The US healthcare system is extremely daunting, and patients can feel intimidated when seeking to see a provider. A third-party mediator can help the patient explain their feelings to the doctor when there are cultural and linguistic barriers between the provider and patient. Additionally, students can assist refugees in finding transportation and organizing their medications. Through this program, students will gain exposure to working with marginalized populations and increase their cultural competence. Furthermore, refugees will receive much-needed peer support and have an easier time adjusting to life in the U.S.

5803

GROW502: A POP-UP CLINIC TO TACKLE HEALTH DISPARITIES WITHIN THE HOUSELESS POPULATION

Zoha Mian

University of Louisville, Louisville, KY, United States

At the height of the Covid-19 pandemic and racial justice movement, students created, Grow502. The goal was to pursue a healthier community by raising awareness which led to the co-creation of a curriculum focused on education, advocacy, community engagement, and creative media. In 2022, we focused on the Houseless community, Refugees, and folks living in the West End. Houseless communities experience disparities in chronic diseases, premature death, poverty, and unemployment; systemic injustice in housing, healthcare, nutrition, and the environment are significant contributors. To raise awareness in our community and provide resources, we launched a pop-up clinic for the Houseless on May 21st. Some of the service offerings at this pop-up clinic included Dental Assessments, Wound Care, Showers, Vaccination, Food, and a Donation Drive. Other services include infectious disease testing and enrollment into Medicare. We kickstarted this event by having an event where we had a case-based discussion breaking down health disparities among the unhoused and barriers to proper health care. Homeless folks were transported to the clinic by Feed Louisville. Flyers were given to shelters in the area. Grow502 acted as a connection between the houseless and organizations in the community. Recognition of the unique healthcare needs of homeless people has encouraged the developing of special services for them. Homeless individuals are unique in the multiplicity of needs they experience, the lack of support networks they face, and the difficulty of their daily activities. Our hope as an organization is that these pop-up clinics will continue to be a vital asset in our community through the coordination of multiple services. Participants saw the pop-up clinic as a means of building awareness, inspiring others to reduce health disparities, and strengthening the partnership between harm reduction, the homeless, and the medical field. Due to volume, we are planning another pop-up clinic.

5804

NUTRITIONAL STATUS, DIETARY DIVERSITY AND FOOD INSECURITY AMONG WOMEN AND CHILDREN IN PERI-URBAN COMMUNITIES OF KARACHI, PAKISTAN

Nadia Ansari, Mashal Amin, Ayesha Khalid, Amna K. Haider, Junaid Mehmood, Rafey Ali, Mohammad I. Nisar, Fyezah Jehan, Zahra Hoodbhoy

The Aga Khan University, Karachi, Pakistan

Malnutrition is a serious public health problem in Pakistan. One of the causes is inadequate consumption of nutrients to support the requirements at various life stages. Undernutrition among women in the reproductive age leads to maternal morbidity and mortality, fetal growth restriction and childhood malnourishment. We conducted a survey in 7 peri-urban areas of Karachi, Pakistan to assess the nutritional status and dietary diversity among married women of reproductive age and their children under 2 years of age. We also assessed household food security. We used a two-stage systematic random technique to select households and enrolled 1470 mother-child dyads (210 at each site). To assess the nutritional status, we followed the 2018 FANTA guide for anthropometric measurements of participants and used the 10-item minimum dietary diversity scale for women and the 9-item minimum dietary diversity scale for children through 24-hour dietary recall. Household coping strategy and hunger tool were used to measure food insecurity. We found that slightly more than 45% women had normal BMI, while 16% were underweight. Among children, 24% were found to be 'wasted', 39% were underweight and 39% were stunted. We found that 22.5% (n=332) of women and 8% (n=188) of children met the standards for consuming 5 food groups. All households reported food insecurity. To cope, 20% (n=290) borrowed food; 30 % (n-438) limited their portion sizes; 31% (n=452) reduced the number of meals consumed, while 24% adults restricted their food consumption. We also found poor food access; 37% (n=549) of women reported not having food at home, 33% (n= 503) slept hungry, and 31% (n=463) reported atleast one day in the previous month in which they did not eat. These findings suggest that even in large cities like Karachi, the peri-urban population suffers from food insecurity and women and children are malnourished. Along with poverty alleviation at the macro level, there is a need for contextually designed interventions to improve the nutrition and health of women and growth trajectories of children.

5805

A SYSTEMATIC REVIEW AND META-ANALYSIS: IMPACT OF THE COVID-19 PANDEMIC ONVIOLENCE AGAINST CHILDREN

Tomomi Nakaike

Nagasaki university, ichikikushikino, Japan

COVID-19 lockdowns caused interruption of child protection services and economic/psychological burdens on parents. It has become challenging for teachers or school counselors to detect and report signs of abuse. Therefore, in this systematic review and meta-analysis (SRMA), we aimed to identify the impact of the worldwide COVID-19 pandemic on violence against children by investigating the change in the prevalence of violence against children before and during COVID-19 lockdowns. The protocol of this study was registered in PROSPERO with the registration number CRD42022377660. We included any studies eligible for meta-analysis comparing violence against children before and during COVID-19. Eleven

electronic databases were systematically searched in March 2022. The meta-analysis was conducted using STATA, pooled odds ratios were calculated, and subgroups by countries and sex of children (when possible) were analyzed. A total of eleven publications were included in the meta-analysis. Overall, we found insufficient evidence to support that the COVID-19 pandemic impacted the prevalence or proportion of any type of violence against children, even after segregating the data to the country or sex levels. Furthermore, one article showed a significant decrease in reporters from school staff, which might be explained by an under-report of child violence. In conclusion, although our results suggest that the COVID-19 pandemic did not result in increased prevalence of child abuse, we should be cautious when interpreting these results because the number of violence incidents could have been under-reported as a result of the lockdown and school closure. Therefore, we believe that the concerns about an increase in child abuse cases during the pandemic –although not statistically evidenced– still hold.

5806

A QUALITATIVE ASSESSMENT OF THE LANDSCAPE AND DYNAMICS OF CAPACITY STRENGTHENING INITIATIVES FOR MALARIA MODELING IN AFRICA

Letitia Onyango, Ghislaine Ouedraogo-Ametchie, Jaline Gerardin
Northwestern University, Chicago, IL, United States

Modelers in malaria-endemic countries face unique challenges in their pursuit of funding, research collaborations, and modeling training. Through in-depth interviews, this study aims to gathered malaria modeler perspectives on capacity strengthening and training initiatives, delved into the dynamics of implementing partner and modeler relationships with NMCPs and generated recommendations for equitable research collaborations and training initiatives. Preliminary fFindings revealed several opportunities for improving intercountry research collaborations, training, and communication with NMCPs. While there are were mixed perceptions about the role modelers should play in their collaborations with NMCPs, respondents largely agreed that modelers should be exploring questions that are relevant to NMCPs and technical support approaches should be more aligned with the needs of each NMCP. Respondents also highlighted that while communication with NMCPs can be challenging, maintaining flexibility, being highly responsive, and identifying multiple points of contact within NMCPs can help mitigate these challenges. As the study progresses, we will dive more deeply into the role of funders in creating better alignment among technical support and training activities. We will also dive more deeply into how technical support for NMCPs can be improved to generate better buy-in and greater sustainability.

5807

EPIDEMIOLOGICAL PROFILE OF ASYLUM SEEKERS AT THE US-MEXICO BORDER: ASSESSMENT OF DISEASE BURDEN IN A MATAMOROS MIGRANT SETTLEMENT CAMP FROM NOVEMBER 2019 TO MARCH 2021

Allison W. Cheung[1], Christopher W. Reynolds[1], Raymond Rosenbloom[2], Sarah Draugelis[3], Florian F. Schmitzberger[4]
[1]University of Michigan Medical School, Ann Arbor, MI, United States, [2]Medical School for International Health, Ben Gurion University of the Negev, Beersheba, Israel, [3]Team fEMR, Cleveland, OH, United States, [4]Department of Emergency Medicine, University of Michigan, Ann Arbor, MI, United States

Asylum seekers at the US-Mexico border face significant health challenges. While select humanitarian groups deliver primary care at the border, there is a paucity of population-level data on disease incidence among this vulnerable population. Understanding asylum seekers' epidemiological profile is important for migrant health delivery and anticipating health needs upon entry to the US. The aim of this retrospective study was to characterize disease incidence among asylum seekers in the Matamoros, Mexico, encampment. De-identified health records from Nov 2019 to Mar 2021 were obtained from the NGO-run camp clinic. Logistic regression models estimated associations between health outcomes and demographic factors, including age, sex, country of origin, and migration time (time since departing the country of origin). From Nov 2019 to Mar 2021, 11,307 unique patient encounters were recorded. Patients were mostly female (59.9%) and from Central America (67.6%), with a median age of 27.0 (IQR: 9.4-36.8) years and median migration time of 4 months (IQR: 0.1-0.7 years). Acute respiratory diseases were of highest incidence (10.1%; 95% CI: 9.6-10.7), with the highest risk among children (aOR = 1.87, 95% CI: 1.65-2.13) and patients with migration time under 0.5 years (aOR = 1.68, 95% CI: 1.46-1.93). Infectious and parasitic diseases, including mycoses, helminthiases, pediculosis, and protozoal diseases, were more likely to occur among patients with longer migration times (aOR = 1.59 (95% CI: 1.14-2.19) for migration time of 0.5-1 year; aOR = 2.00 (95% CI: 1.23-3.14) for migration time of 1-2 years). Among these, mycoses resulted in the highest incidence (0.7%, 95% CI: 0.6-0.9). Logistic regression analyses found that infection with mycoses was significantly associated with older age, while parasitic diseases, pediculosis, and acariasis were more significantly associated with children and younger adults. These findings have important implications for clinicians, NGOs, and policy makers working to provide healthcare to asylum seekers at the US-Mexico border, including targeted infectious disease reduction and treatment strategies.

5808

EXPLORING THE POTENTIAL OF POLICY IMPLEMENTATION STRATEGIES AS HEALTH JUSTICE-MAKING TOOLS: AN ILLUSTRATIVE CASE OF NEGLECTED TROPICAL DISEASES MASTERPLAN IN ZAMBIA.

Patricia Maritim, Margarate Munakampe, Joseph M. Zulu
University of Zambia, Lusaka, Zambia

Neglected tropical diseases (NTDs) pose a considerable challenge in Zambia, with more than 12 million people at risk of at least one NTD. Social factors play a critical role in disease transmission and effectiveness of control and elimination measures. National NTD Masterplans are the main policies used in endemic countries, outlining strategies that improve access to key interventions like mass drug administration that facilitate progress towards disease elimination. Implementation processes of Masterplans may result in relational inequities as policy strategies are translated across administrative levels and among different actors. Consequently, populations such as migrants and mobile populations are hardly reached by evidence informed interventions. Policy processes have had limited impact in reducing inequities as proposed options such as collaborative governance are simple yet inequities are a wicked, ambiguous and contested problems. The problematization of NTDs in policy has resulted in a biomedical focus that limits social and policy research, which address key issues like health inequities arising during implementation. Further, few policy studies have systematically evaluated implementation processes and strategies translating NTD Masterplans into accessible services within communities. We use a case study of the process of developing policy implementation strategies for Zambia's National NTD Masterplans to understand if these findings help in shifting our understanding of transformative implementation bringing us closer to realizing the goal of health equity and justice. We evaluate the potential of equity focused implementation strategies to promote transformative implementation of health policies in Zambia. We make a theoretical proposition that implementation strategies developed using Africana critical theories combined with implementation science frameworks can modify policy implementation processes to transform the social, economic and political contexts into which health policies are implemented, reducing health inequities and improving the fit of these policies in their contexts.

5809

NATIONAL GUIDELINES AND LEGISLATION CONCERNING THE MANAGEMENT OF ZIKA VIRUS INFECTION IN PREGNANT WOMEN DURING THE 2015-2018 EPIDEMIC IN LATIN AMERICA

Sarah Bethencourt[1], **Olivia Pluss**[2], Adriana Gomez[3], Rodrigo Cachay[4], Carmen Soria[5], Ivonne Morales[6], Kerstin Rosenberger[7], Martin Weber[8], Celia Alpuche Aranda[9], Patricia Brasil[10], Paola Mariela Saba Villarroel[11], Ernesto Marques[12], Eduardo Gotuzzo[4], María Consuelo Miranda Montoya[3], Adriana Tami[1], Thomas Jaenisch[2]

During the 2015-18 Zika Virus (ZIKV) epidemic in Latin America, microcephaly and congenital abnormalities were shown to be associated with ZIKV infection in pregnancy. Given the multitude of malformations beyond microcephaly experienced with maternal ZIKV infection and the uncertainties associated with diagnosis, the challenges regarding policies for response to an infection in pregnancy including termination options became evident. We examined fourteen documents from eight selected Latin American countries containing the management and guidance for ZIKV infection during pregnancy. Per country, we concentrated on the availability of guidelines, laboratory diagnosis practices, ultrasound screening schedules for standard and at-risk pregnancies, communication of laboratory results of infection, antenatal checkup visits modifications, the legal framework around abortion and their approaches of adaptations as a reaction to the epidemic. All guidelines considered pregnant women with ZIKV infections as high-risk pregnancies that needed to follow stricter protocols and agreed to use molecular RT-PCR test as the diagnostic method of choice. There were discrepancies between country protocols of reporting PCR results to the pregnant women. All guidelines, except for Brazil and Bolivia, have specified their ultrasound scans (US) follow-up schedule in case of ZIKV infection during pregnancy. There was notable increased demand for access to legal abortions during the ZIKV epidemic in included countries, clandestine abortions potentially have substantially surpassed these numbers. The included examined guidelines, apart from Ecuador, have not included early termination issues in its explicitly stated ZIKV-related guidelines. The fear of ZIKV-related congenital abnormalities puts abortion at the center of moral concerns. Our study suggests that the impact of guideline and policy response is an important public health intervention, and early investigation of protocols and policy impacts in real-time during emerging disease events is recommended.

IMPACT EVALUATION OF SOCIAL MEDIA CAMPAIGN TO IMPROVE ATTITUDES AND BEHAVIORS ON COVID-19 VACCINE IN AFRICA: DIFFERENCE-IN-DIFFERENCE ANALYSIS USING TANZANIA AS A CASE STUDY

Sooyoung Kim[1], Asad Lilani[2], Kate Campana[2], Yesim Tozan[1]

[1]New York University School of Global Public Health, New York, NY, United States, [2]The Access Challenge, New York, NY, United States

In Tanzania, the One by One: Target COVID-19 campaign was launched nationally in July 2022 to address the prevalent vaccine hesitancy and lack of confidence in COVID-19 vaccines. The campaign mobilized influencers to use social media and viral content to increase COVID-19 vaccine confidence and reduce hesitancy, with the ultimate goal of increasing COVID-19 vaccine uptake in the country.We used programmatic data collected through an online survey before and after the campaign to empirically assess the impact of the campaign on three outcomes: vaccine confidence, vaccine hesitancy, and vaccination status. We conducted a difference-in-difference (DiD) analysis and performed a crude, adjusted, and propensity score-matched analysis for each study outcome. Lastly, to observe whether there was any differential impact of the campaign across age groups, we repeated the analyses on age-stratified subgroups. Data included 5,804 survey responses, with 3,443 and 2,362 responses collected before and after the campaign, respectively. Although there was only weak evidence of increased COVID-19 vaccine confidence in the campaign-exposed group compared to the control group across all age groups, we observed a differential impact among different age groups. While no significant change was observed among young adults aged 18-24 years, the campaign exposure led to a statistically significant increase in vaccine confidence (weighted/adjusted DiD coefficient=0.76; 95% CI: 0.06, 1.5; p-value=0.034) and vaccination uptake (weighted/adjusted DiD coefficient=1.69.; 95% CI: 1.02, 2.81; p-value=0.040) among young adults aged 25-34 years. Among adults aged 35 years and above, the campaign exposure led to a significant decrease in vaccine hesitancy (weighted/adjusted DiD coefficient=-15; 95% CI: -21, -8.3; p-value<0.001).The social media campaign successfully improved vaccine hesitancy, confidence, and uptake in the Tanzanian population, albeit to varying degrees across age groups. Our study provides valuable insights for the planning and evaluation of similar social media communication campaigns aiming to bolster vaccination efforts.

5811

USING MALARIA SURVEILLANCE AT ANTENATAL CARE TO DECODE LOCAL PATTERNS IN SEASONAL TRANSMISSION TREND IN TANZANIA, 2014-2022

Joseph T. Hicks[1], Frank Chacky[2], Sijenunu Aaron[2], Khalifa Munisi[2], Samweli L. Nhiga[2], Julie R. Gutman[3], Patrick GT Walker[1]

[1]Imperial College London, London, United Kingdom, [2]National Malaria Control Programme, Ministry of Health, Dodoma, Tanzania, United Republic of, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

Optimal deployment of many malaria control interventions relies upon accurately characterising seasonal peaks in transmission. In West Africa, there exist largely validated rubrics defining seasonality based on rainfall patterns. In East and Southern Africa, rainfall also often exhibits strong seasonality, but other factors, including temperature, land use and bodies of water, are substantially different to the Sahel. Meanwhile, interpreting seasonal transmission patterns in case-reporting systems remains challenging, especially in the context of chemoprevention efforts for children. Malaria screening at antenatal care (ANC) enrolment has been offered routinely to pregnant women throughout Tanzania since 2014. Here, we use monthly summary reports of these tests from 2,437 health facilities across all 184 districts in Tanzania from 1 January 2014 to 31 December 2022 to characterise seasonality patterns across the country. We fit an existing malaria model using particle Markov chain Monte Carlo to account for the lagged nature of prevalence and infer seasonal patterns in incidence across the country. Pearson correlation coefficients measured synchronization

between this estimated incidence and rainfall. Our results suggest the extent to which rainfall explains malaria seasonality varies across the country. Central regions of Dodoma and Iringa had high correlation (r = 0.77 and 0.62, respectively). In contrast, correlation in regions close to major lake or irrigation systems varied from positively (Rukwa, r = 0.76) and negatively (Geita, r = 0.41) correlated to no correlation (Mwanza, r = -0.005). Another motivation for incorporating an existing malaria model within our framework is to provide near-real-time sub-nationally-targeted estimates of the likely impact of current and future interventions – a use case we will demonstrate by projecting Seasonal Malaria Chemoprevention impact. These results highlight the wider value of ANC-based malaria screening data as a tool to inform responsive and locally tailored control strategies.

5812

INTEGRATION, EXPLORATION AND REUSE OF CLINICAL AND EPIDEMIOLOGICAL DATASETS: A CASE STUDY USING MALARIA DATA ON THE CLINEPIDB PLATFORM

Danica Helb[1], Sarah Kelly[2], **Nupur Kittur**[3], Moses Kumenya[4], David Roos[1], Steph Wever Schulman[1], Weilu Song[1], Sheena Shah Tomko[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]Imperial College, London, United Kingdom, [3]University of Georgia, Athens, GA, United States, [4]Infectious Diseases Research Collaboration, Kampala, Uganda

Open access to data from epidemiological studies has tremendous potential to preserve research outputs, increase secondary data use, and accelerate discovery and translational impact. Data sharing is increasingly a requirement for funding and publication of epidemiological research, but it comes with technical and ethical challenges. We present a case study of successful data sharing from the clinical epidemiological database, ClinEpiDB.org, built in 2018 to facilitate access to de-identified data from large, high-quality global health studies. ClinEpiDB currently hosts data from over 1.2 million participants representing 37 global studies in three major domains - malaria, maternal, newborn & child health, and neglected tropical diseases. The PRISM2 team, an International Center of Excellence for Malaria Research (ICEMR), conducted a cohort study of malaria in Uganda and collected socioeconomic, demographic, clinical, entomological, and other data, and was interested in data sharing to maximize use and impact of their research and to meet funder and journal requirements. De-identified data was securely transferred to ClinEpiDB along with codebooks and other contextual metadata. PRISM2 variables were ontologically harmonized for increased interoperability, and after extensive quality checks, data was released on the free, open-access, online data platform ClinEpiDB.org. In their publication, the PRISM2 team included a link to recreate key findings of PRISM2 analyses on ClinEpiDB. Readers can follow the link to learn about PRISM2 cohort study methodologies, discover additional variables collected but not included in the published analysis, download data with no restrictions, and modify their copy of the published analysis to explore their own hypotheses in a point and click interface. Metrics reveal that PRISM2 data is being accessed regularly even three years after publication. The PRISM2 team gained visibility while retaining ownership of data and making all data access decisions. ClinEpiDB will expand in 2023 with integration of new datasets as well as enhanced visualization tools and the ability to derive variables.

5813

IMPROVING EFFICIENCY IN DETECTING ANOMALIES IN HEALTH SUPPLY CHAIN DATA USING AN AUTOMATED CONSUMPTION ANOMALY DETECTION TOOL IN ZAMBIA

Darwin Chimenge[1], Stephen Chisha Lemba[2], Hassan Sinkala[3], Tawonga Manda[1]

[1]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project, Washington DC, DC, United States, [2]Lusaka District Health Office, Ministry of Health, Lusaka, Zambia, [3]USAID Global Health Supply Chain Program- Procurement and Supply Management (GHSC-PSM) project, Washington DC, DC, United States

Identifying data anomalies help correct data errors and improve accuracy in supply forecasting and planning for medicines. However, it is challenging to detect anomalies from over 3000 facilities and over 5000 health products through eLMIS, because of the lengthy and less accurate manual process given that the system is not designed to automatically generate such reports. In 2019, the USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project developed an automated data analysis tool for detecting consumption anomalies and establishing the causes of the data errors using Python and Applied Statistical Process Control (SPC). This tool uses eLMIS data over a period of 24 months to determine the moving average of consumption over a set threshold and then uses the result to detect anomalies monthly. The automated system streamlined the process and improved the accuracy of anomaly detection from less than 100 a month with a manual process to over 200 detections monthly, using about 25 minutes to produce a list of all anomalies for over 3000 facilities and over 5000 health commodities, thereby improving accuracy and speeding up decision-making for all health products, including malaria, commodities. The anomaly report is shared monthly with the Central Pharmacy Unit of the Ministry of Health and the Chief Provincial Pharmacists to investigate and address data quality issues. The National Drug Theft Task Force (NDTTF) and provincial task forces also use the report to investigate anomalies that are not linked to incorrect data entry through on-the-spot checks at health facilities. Since October 2019, GHSC-PSM has supported the MOH by using this tool to identify and correct several data quality issues such as incorrect use of units of measure and transpositions errors. The anomaly detection tool replaced a time-consuming and less accurate manual process, allowing supply chain actors to correct data quality issues quickly and adjust supply plans accordingly. The tool is open-source and can be easily adopted by other countries to detect anomalies or other quality issues.

5814

COMBINING ORTHOGONAL ANALYTICAL TECHNIQUES TO IDENTIFY SUBSTANDARD OR FALSIFIED FORMULATIONS OF PHARMACEUTICALS

Awosiji Olatunde Awotunde, Jin Ru i Cai, Jiaqi Lu, Christian Gabriel El Azar, Sarah Honegger, Ornella Joseph, Alyssa Wicks, Kathleen Hayes, Marya Lieberman

University of Notre Dame, Notre Dame, IN, United States

Near infra-red (NIR) technology is a powerful tool to assess the quality of pharmaceutical dosage forms. The NIR spectrum is sensitive to multiple factors: the identity and concentration of analyte, but also the excipient materials, capsule opacity and color, and pill coatings. Most NIR instruments use libraries of authentic products to discriminate between good quality and bad quality products, but assembling and maintaining those libraries is difficult in many low- and middle-income countries because markets are not stable and there are unreported changes to product formulations. Therefore, we have been developing methods to identify substandard or falsified pharmaceuticals that do not rely on libraries of authentic products. In this poster, we will report on several aspects of this work. Machine learning models were trained on lab-formulated mixtures of a target API with different excipients. Although the ML models all have “blind spots”, a simple voting algorithm compensates for the blind spots. The algorithm was applied to 40 samples of good and bad quality acetaminophen dosage forms and was able to classify them with accuracy of 94%. Capsule opacity and color is known to interfere with in-situ NIR analysis of dosage forms. We probed twenty different empty gelatin capsules with scanning electron microscopy and X-ray fluorescence, finding different amounts of opaquing agents and dyes that could be distinguished by clustering analysis of the NIR spectra of materials inside these capsules. NIR methods can be complemented by other field analysis methods, such as chemical color tests applied using paper analytical devices (PADs). PADs are engineered micro-fluidic systems that analyze capsules or

tablets for chemical constituents by using stored reagents and water flow, generating unique color patterns. These color patterns were used to train a convolutional neural network and other machine learning tools, giving accurate classification of 20 types of APIs. Hybrid classification algorithms were developed to combine the data from both PADs and NIR, which significantly improved the results better than either method if used alone.

5815

USING THE DISTRIBUTION OF CLINICAL DATA FROM ROUTINE USE OF AN ELECTRONIC CLINICAL DECISION SUPPORT ALGORITHM TO IDENTIFY CLINICAL SKILL GAPS IN PRIMARY CARE IN RWANDA: A RETROSPECTIVE ANALYSIS

Haykel Karoui[1], Nadia Cattaneo[1], Victor P. Rwandarwacu[2], Joseph Habakurama[2], Antoinette M. Safi[2], Jonathan Niyonzima[2], Emmanuel Kalisa[2], Valérie D'Acremont[1], Alexandra V. Kulinkina[3]

[1]UNISANTE, Lausanne, Switzerland, [2]SwissTPH, Kigali, Rwanda, [3]SwissTPH, Allschwil, Switzerland

Clinical Decision Support Algorithms (CDSAs) that guide clinicians throughout the consultation have the potential to enhance quality of care in resource-limited outpatient settings. However, the extent of the improvement depends on the accuracy of the inputs entered, which depends on the clinical skills (ability to identify specific signs or symptoms). In this retrospective analysis, we used data from an electronic CDSA deployed in 16 health centers in Rwanda for one year to evaluate the clinical skills of primary care clinicians, identify and understand the gaps, with the goal of designing an eLearning platform to address them. We analyzed data from 20,204 consultations with children aged 1 day to 14 years, conducted between November 2021 and October 2022, focusing on a set of numerical variables: temperature, MUAC, weight, height, z-scores (MUAC for age, weight for age, and weight for height), respiratory rate, blood oxygen saturation, and heart rate. Based on statistical summary measures (median, IQR, distribution, % of missing values) and their variation in individual health centers as compared to the average, we identified 11 health centers with potential important clinical skill gaps, signaled by high frequency of skipping measurements, entering the same plausible value repeatedly, and entering implausible/likely incorrect values. We then observed 209 consultations in the problematic health facilities to understand the potential causes of errors. These field observations showed that 19% of measurements were skipped -respiratory rate behind the most problematic one (43%) - due to misplaced equipment, not considering it necessary, or the child being agitated. More frequently (57%), measurements were done incorrectly -the worst ones being weight (82%), MUAC (77%), temperature (75%), and height (69%). As a next step in the project, we are creating eLearning content that is tailored to the clinical skill gaps we observed. The eLearning modules will be introduced to the health workers in June 2023, and their impact evaluated through re-analysis of the CDSA data around August or September 2023.

5816

ELECTRONIC DATA CAPTURE IMPLEMENTATION DOCUMENTING MASS DEWORMING CAMPAIGNS:

PILOT ANALYSIS IN THE DOMINICAN REPUBLIC

2019-2021

Nitya Rajeshuni[1], Hyeree Choi[2], Grey Faulkenberry[1], Bernard Caines[3], Ramona Cordero[3], Anabel Fernandez[1], Ingrid Japa[3], Andrew Steenhoff[1], Anthony Luberti[1], Sansanee Craig[1]

[1]Children's Hospital of Philadelphia, Philadelphia, PA, United States, [2]George Washington Milken Institute School of Public Health, Washington DC, DC, United States, [3]Niños Primeros en Salud, Consuelo, Dominican Republic

High-quality data is critical to evaluating outcomes and interventions in low- and middle-income countries (LMICs). Health information and communication tools (ICTs) are increasingly being used to improve data documentation. However, ICT evaluation remains limited. Without proper study, several pilots fail to scale due to lack of funding and stakeholder engagement. In partnership with the Children's Hospital of Philadelphia, the Niños Primeros en Salud (NPS) clinic in Consuelo, Dominican Republic implemented electronic data capture (EDC) to document and evaluate biannual deworming campaigns. This study evaluates the data quality, efficiency, and efficacy of this pilot, adding to the literature on ICT utilization in LMICs. EDC was implemented via tablet-based software CommCare. All children registered at NPS ages 2-5 years with no deworming in the prior 4 months were eligible. Providers visited nine neighborhoods and documented deworming during the visit. This is a retrospective post-implementation analysis of five distinct campaigns between 2019-2021. Descriptive statistics examining demographics and EDC data quality, efficiency, and efficacy were conducted. Analysis of 503 subjects showed 78.7% were dewormed at least once in similar proportions across target neighborhoods. 52.7% of subjects were dewormed 2-4 times, and 57.6% in half or more of campaigns during which they were eligible. Deworming rates per campaign ranged from 26.1% to 66.8%. Post-EDC implementation, 78.7% of subjects were dewormed compared to 64.4% pre-implementation, with more serial dewormings. Only two data fields were missing data. Median task completion time was 5.0 seconds. Median cloud upload time was 16.5 hours. EDC was an efficient, efficacious tool in community deworming campaigns in this rural setting. EDC ensured better data quality, surveillance, and outreach, with improved deworming rates compared to pre-implementation. While EDC holds promise for low-resource settings reliant on community campaigns, funding remains limited due to lack of study. Evaluation is critical to scaling promising pilots and bridging the digital divide.

5817

UNDERSTANDING THE 'CONTEXT' IN TROPICAL DISEASE CONTROL COMMUNICATION: A SRI LANKAN EXPERIENCE

Asitha Prabhath Mallawaarachchi[1], Manjula Weerasinghe[1], Thilini Agampodi[1], Chandani Liyanage[2], Suneth Agampodi[3]

[1]Department of Community medicine, faculty of medicine and allied sciences, Rajarata University of Sri Lanka, Auradhapura, Sri Lanka, [2]Department of Socialogy, University of Colombo, Colombo, Sri Lanka, [3]International Vaccine Institute, Seoul, Korea, Republic of

Preventing NTDs in LMICs requires a collaborative, cross-disciplinary, culturally appropriate approach that goes beyond biomedical interventions. Effective communication is key to controlling tropical diseases, however in LMICs, communication strategies are scarcely informed by scientific evidence. Media ethnography may capture the context-specific communication channels used in everyday community life, including modern and traditional media. We conducted an ethnographic study by using multiple techniques, including participant observation, in-depth interviews, key informant interviews, and auto-ethnographic diaries, to explore community-specific communication pathways and techniques for preventing cutaneous leishmaniasis in rural Sri Lanka. We engaged with local communities to Explore their communication practices and networks and identified various communication types and forms. The modes of communication identified and discussed by the community for disease prevention activities included interpersonal, group, public, mass, and virtual methods of communication, as well as verbal, non-verbal, performing, written, audio, visual, formal, and informal forms of communication. We identified that rural communities prefer and perceive more effective traditional communication methods, such as Loudspeaker, Group communication, schools, door-to-door campaigns, posters, notice boards, leaflets, and street dramas, to mass media in disseminating health information. We also observed the critical role of community networks in gathering and sharing health information. Our study highlights the need for evidence-based communication strategies that are context-specific and tailored to local communities. Using ethnographic research methods, we can better understand rural communication practices and networks and develop context-specific health communication models to prevent NTDs.

5818

MATCHING DATA FOR THE STATE PARTIES SELF-ASSESSMENT ANNUAL REPORTING (SPAR) TOOL FROM 2010 TO 2021

Chengyi Zhao[1], Alexander Linder[2], Brian Samuelson[3], Erin Sorrell[4]

[1]Elizabeth R Griffin Program at Georgetown University, Washington, DC, United States, [2]Georgetown University, Washington DC, DC, United States, [3]Elizabeth R Griffin Program at Georgetown University, Washington DC, DC, United States, [4]Johns Hopkins Center for Health Security, Department of Environmental Health and Engineering, Bloomberg School of Public Health, Baltimore, MD, United States

Since 2010, States Parties have been required under the International Health Regulations (IHR) to submit self-assessment annual reporting tool (SPAR) to monitor, track and evaluate compliance on IHR's core capacities, as a key component to World Health Organization (WHO) monitoring and evaluation frameworks (MEFs). Each year data is collected, stored and made accessible in the Electronic State Parties Self-Assessment Annual Reporting Tool (e-SPAR), a web-based platform hosted by the WHO. These data can be accessed by both States Parties and the public to track progress and to identify priority areas for national action. Since its inception, the SPAR has undergone three revisions, most recently in 2021. With each revision, capacities and indicators to assess country health security capacity have changed to improve measurement towards compliance. The revisions, despite their value-added to governments and global health researchers, prevent comparative analysis between tools, hampering country ability to understand systemic challenges to sustained capacity building. This study aimed to develop a method to match data across the three revisions of the IHR self-assessment tool, and to provide a single source to access and compare national, regional and global annual self-assessment scores for IHR compliance. Annual reporting data from 2010 to 2021, for 196 States Parties, was collected and analyzed. From these analyses, we developed a matching framework and aligned MEF data, providing a robust assessment at the capacity level. Ultimately, these analyses have resulted in the creation of a publicly available tool which visualizes IHR MEF self-assessment scores from the period of 2010 to 2021 for all reporting countries with the ability to compare scores over the three MEF revisions for the first time, providing insights on health systems strengthening at the national, regional, and global levels.

5819

RECONSIDERING THE INFECTION RISK OF JAPANESE ENCEPHALITIS VIRUS IN AUSTRALIA

Lucinda Harrison[1], David Duncan[2], Jennifer Flegg[1], David Price[1], James McCaw[1], Nick Golding[2], Freya Shearer[1]

[1]University of Melbourne, Parkville, Australia, [2]Telethon Kids Institute, Nedlands, Australia

Japanese encephalitis virus is a leading cause of viral encephalitis worldwide, causing life-changing disability and death in humans. Historically, the disease has only been recognised in Australia in small outbreaks in far northern sub-tropical regions, fuelled by independent introductions. However, since early 2022, the disease has been identified in 35 people and at least 85 piggeries across the central and eastern Australian mainland, including the temperate far south. The transmission cycle of the mosquito-borne virus is complex, with many reservoir species. In this work, we model the geographic distributions of suspected wildlife host and vector species using environmental data. We use the predictions of these environmental niche models to visualise the potential spatial extent of disease transmission during the recent outbreak. By incorporating heterogeneous surveillance effort and detection data we also map the intensity of detected disease transmission. We consider how the outputs of our models and their associated uncertainties might quantitatively inform the spatial allocation of surveillance resources within a structured decision-making framework. This framework will support decision-makers to best respond to future outbreaks of Japanese encephalitis virus in Australia.

5820

USING MACHINE LEARNING TO PREDICT SURGICAL OUTCOMES OF PATIENTS WITH HYDROCEPHALUS POST INTERVENTION AT CURE CHILDREN'S HOSPITAL OF UGANDA

Davis Natukwatsa

Cure Hospital Uganda, Mbale, Uganda

The major objective of this research is to predict an outcome after surgical intervention of an individual using a machine learning approach. This study was carried out at Cure Children's Hospital of Uganda which is found in the Eastern part of the country about 240 km from Kampala, the country's capital city. This hospital also serves as the country's referral hospital for patients suffering from pediatric hydrocephalus and spina bifida. The data was collected retrospectively from the medical records kept at the hospital premises. A well-trained clinician assisted in data extraction using a questionnaire that was well designed in Redcap, a web-based software used to create and manage research databases and the data extracted covered a period between 2015 and 2019. The variables extracted include; age at presentation to the hospital, surgical procedures carried out, age at the time of head increase, head circumference, place of birth, the season of birth, gestational age at birth, hydrocephalus etiology, child's weight, WBC, CSF volume and brain volume before surgery after carefully doing a literature search. The outcome variable is a binary outcome, a surgical failure or success after surgical intervention. Exploratory data analysis and feature selection were done. A predictive model was developed using a machine learning algorithm of random forests. This model uses mean square error for regression and mean Gini for classification. Model performance was evaluated on a successful surgical outcome by Area Under the ROC curve (AUC), accuracy (AC), specificity (SP), sensitivity (SN), negative predicted (NPV) and positive predicted value (PPV). The model showed a good performance (AUC = 0.773, AC = 0.72, SP = 0.659, SN = 0.751, NPV = 0.586, PPV = 0.772). The prediction outcome can be used by the surgeons to make informed decisions pertaining to patient monitoring and the need for surgery revision before discharging them from the hospital.

Aedes (Stegomyia)-borne arboviruses pose a global threat, but gaps in surveillance hinder comprehensive assessments of risk. Geostatistical models combine data from multiple locations and use links with

environmental and socioeconomic factors to make predictive risk maps, allowing for targeted interventions. We systematically reviewed past risk mapping approaches for these arboviruses from local to global scales to identify similarities and differences in data types, covariates, and models. We searched online databases for predictive risk mapping studies for dengue, Zika, chikungunya and yellow fever with no geographical or date restrictions. We included studies that needed to parameterize or fit their model to real-world data and make predictions to new spatial locations of some measure of the population-level risk of viral transmission. Study quality was assessed with a modified scoring criteria based on the EPIFORGE checklist. We found a methodological shift in risk mapping through time based on 183 papers. We found that earlier approaches to map risk pooled occurrence data and used high dimensional machine learning models to map suitability for transmission at global or continental scales. Following major epidemics of Zika and chikungunya in the Americas, mechanistic models fit to national-resolution incidence data have been increasingly used to track the dynamic spread of epidemics among countries. With improved dengue case-based surveillance systems now present in many countries, statistical mixed effects models applied at the subnational scale have become increasingly common. Half of the studies reviewed utilized temperature and rainfall as covariates, with human mobility increasingly considered. A robust variable selection procedure was performed in 33 out of 148 studies that did not use mechanistic models or only random effects. Our review shows that approaches to map risk for different arboviruses have diversified based on changing use cases, epidemiology, and data availability. Future studies should consider the purpose of the map; to maximize improvements in data quality and statistical methodologies.

ALTERNATIVE EPIDEMIC INDICATORS FOR COVID-19: A MODEL-BASED ASSESSMENT OF COVID-19 MORTALITY ASCERTAINMENT IN THREE CITIES IN LOW-INCOME COUNTRIES

Ruth McCabe[1], Charles Whittaker[2], Richard J. Sheppard[2], Nada Abdelmagid[3], Aljaile Ahmed[4], Israa Z. Alabdeen[5], Nicholas F. Brazeau[6], Abd Elhameed A. Abd Elhameed[4], Abdulla S. Bin-Gouth[7], Arran Hamlet[2], Rahaf AbuKoura[3], Gregory Barnsley[2], James A. Hay[8], Mervat Alhaffar[3], Emilie K. Besson[3], Semira M. Saje[9], Binyam G. Sisay[10], Seifu H. Gebreyesus[9], Adane P. Sikamo[9], Aschalew Worku[9], Yakob S. Ahmed[11], Damen H. Mariam[9], Mitike M. Sisay[9], Francesco Checchi[3], Maysoon Dahab[3], Bilal S. Endris[9], Azra C. Ghani[2], Patrick GT Walker[2], Christl A. Donnelly[1], Oliver J. Watson[2]

Not all COVID-19 deaths are officially reported and, particularly in low-income and humanitarian settings the magnitude of such reporting gaps remain sparsely characterised. Alternative data sources, including burial site worker reports, satellite imagery of cemeteries and social-media-conducted surveys of infection, may offer solutions. By merging these data with independently conducted, representative serological studies within a mathematical modelling framework, we aim to better understand the range of under-reporting using the example of three major cities: Addis Ababa (Ethiopia), Aden (Yemen) and Khartoum (Sudan) during 2020. We estimate 69% - 100%, 0.8% - 8.0% and 3.0% - 6.0% of COVID-19 deaths were reported in these three settings, respectively. In future epidemics, and in settings where vital registrations systems are absent or limited, using multiple alternative data sources could provide critically-needed, improved estimates of epidemic impact. However, ultimately, functioning vital registration systems are needed to ensure that, in contrast to COVID-19, the impact of future pandemics or other drivers of mortality are reported and understood worldwide.

5823

GLOBAL HEALTH INFRASTRUCTURE DEVELOPMENT IN LOW AND MIDDLE INCOME COUNTRIES, THROUGH MEDICAL EQUIPMENT REMANUFACTURE: POTENTIALS, PROSPECTS AND CHALLENGES IN NIGERIA

Akinwale O. Coker[1], Chibueze G. Achi[1], Winifred I. Ijomah[2], Olusola K. Idowu[1], Roseben C. Achi[1], Morenike E. Coker[1]

[1]University of Ibadan, Ibadan, Nigeria, [2]University of Strathclyde, Glasgow, Scotland, United Kingdom

Sustainable healthcare delivery through provision of adequate medical equipment is a very critical component of global health. Remanufacture of medical equipment (ME) in low and middle-income countries (LMICs) can be a cost-effective and sustainable way to improve access to healthcare services. Remanufacturing and reverse logistics of remanufactured products are increasingly becoming popular in many developed countries due to several reported benefits, however, most developing countries are yet to fully adopt and integrate ME remanufacturing into their healthcare systems. The objective of the study was to identify the potentials, prospects and challenges impeding the adoption and implementation of ME remanufacture, including reverse logistics in a resource limited country such as Nigeria. The study identified and contacted various stakeholders from relevant professional backgrounds, such as clinicians, engineers, technicians, and policy makers, who are currently working in public and private sectors, academia, biomedical industries, and in healthcare facilities. Information was obtained using semi-structured interviews and focused group discussions allowing participants to give feedbacks which was analysed and ranked in order of significance The following were highlighted as key factors affecting the implementation of remanufacture in Nigeria; lack of adequate power supply, resource constraint, inadequate facilities and infrastructural deficit to support remanufacture, lack of database to keep track of medical equipment lifecycle, shortage of skills and expertise in remanufacture, lack of spare parts and poor coordination of raw materials extraction from equipment core. Overall, remanufacturing medical equipment in LMICs has the potential to improve access to healthcare services and reduce healthcare costs, while also promoting sustainability and reducing waste. However, it requires policies supporting significant investment in skills development and infrastructure, as well as ongoing monitoring and evaluation to ensure that the remanufactured equipment meets the necessary standards.

5824

PLOTTING A PATH THROUGH THE PLASMODIUM VIVAX TREATMENT DILEMMA: A MODELLING STUDY INTEGRATING INDIVIDUAL-LEVEL OBSERVATIONS FROM PRIMAQUINE TRIALS AND POPULATION-LEVEL TREATMENT EFFECTS

Constanze Ciavarella, Thomas Obadia, Michael T. White

Institut Pasteur, Paris, France

Upon primary infection, some Plasmodium vivax (Pv) parasites develop into hypnozoites that lie dormant in the liver for weeks to months before reactivating to cause relapses. Treatment of Pv thus calls for radical cure, a type of therapy that clears parasites in both blood flow and the liver. Several randomised control trials (RCTs) have compared drug regimens with the liver stage drugs primaquine (PQ) and tafenoquine (TQ). While it is possible to estimate the individual-level efficacy of these drug regimes, their population-level impact still must be evaluated in cluster randomised trials. Such trials are necessary to measure the non-linear effects on transmission due to lower, heterogeneous Pv circulation and decreased population immunity. We developed an infection risk model and fit it to IMPROV trial data (two PQ regimens and a control arm trialled in multiple locations) assuming relapse and biting rates to be location-specific, but

drug efficacy to remain constant across locations. Next, we estimated the population-level impact of introducing radical cure in case management using an existing Pv transmission model covering multiple scenarios that vary by transmission intensity, seasonality, Pv relapse rates and care-seeking behaviour. Combining our efficacy estimates with hazard ratios and adherence data from RTCs, we tested several radical cure regimens varying dosage and duration of administration. The efficacies estimated for the 7- and 14-day IMPROV PQ regimens (7 mg/kg total dose) were of 81% (95% CI: 66%-96%) and 86% (95% CI: 72%-99%), respectively. Introducing radical cure may make elimination feasible where transmission is already low (<2% PCR-prevalence). As transmission intensity increases, the efficacy of radical cure is vastly reduced and differences between regimens even out. To date PQ and TQ have been tested under trial conditions, while real-world implementations introduce many constraints that hamper their population-level impact. Rather than focusing on optimal dose and duration of administration, it might thus be more effective to increase adherence and care-seeking rates, and to widen eligibility criteria.

5825

AN EXPLAINABLE MACHINE LEARNING APPROACH IN THE PREDICTION OF MORTALITY AMONG PEDIATRIC PATIENTS HOSPITALIZED WITH ACUTE GASTROENTERITIS IN WESTERN KENYA

Billy Ogwel[1], Vincent Mzazi[2], Bryan O. Nyawanda[1], Richard Omore[1]

[1]KEMRI-CGHR, Kisumu, Kenya, [2]University of South Africa, Pretoria, South Africa

Diarrhea is the second leading cause of death in children <5 years globally. Mortality prediction scores for diarrhea are currently unavailable but could provide opportunity for early detection of patients at-risk of death following an episode of acute gastroenteritis (AGE). We built and evaluated machine learning (ML) models to predict mortality among pediatric patients admitted with AGE (≥3 loose stools and/or ≥ 1 episode of unexplained vomiting followed by loose stool within a 24-h period) at Siaya County Referral Hospital between 2010-2020. We employed 6 ML algorithms to predict mortality using de-identified data collected from the AGE cases. We evaluated the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and the area under the curve (AUC) for each of the models. We conducted explanatory model analysis (EMA) and business value evaluation (BVE) of the best model. During the study period, 12, 546 children aged <5 years from the Health and Demographic Surveillance System were admitted, of whom 2,271 (18.1%) had AGE and 164 (7.2%) subsequently died. The sensitivity ranged from 61.0%-78.0% across models, while the specificity and AUC ranged from 71.7%-78.7% and 74.3%-82.6%, respectively. The Random Forest (RF) was the best model achieving 78.0%, 76.6%, 20.6%, 97.8% % and 82.6% for sensitivity, specificity, PPV, NPV and AUC, respectively. The SHAP attributions for the top 5 most important features from the EMA for the RF model were chest indrawing (-0.09), nasal flaring (-0.07), wasting (0.03), stunting (-0.03) and malaria (-0.02). From the BVE, the RF model was able to identify 3 times higher number of deaths compared to a random selection if we picked the top-20% cases based on model probability, and it was able to select 60% of overall deaths from the same selection. We did not observe broad variations in the performance of the models. These findings demonstrate alternative algorithms for prediction of patients at risk of death for targeted interventions to increase chance for survival following an episode of AGE.

5826

TROPICAL TROUBLES: NEURASTHENIA AMONG MISSIONARY EX-PATS IN AFRICA, 1900-1945

David P. Adams[1], Michael Kent[2]

[1]National University of Ireland-Galway, Galway, Ireland, [2]Point University, Savannah, GA, United States

Discussions of "tropical neurasthenia" (TN) abounded in early 20th century medical journals. TN provided specialists in the emerging field of tropical medicine with a diagnostic classification to explain the vague symptoms that North American and European ex-pats often complained of in tropical climates. The condition was also used to account for high rates of invaliding among colonial staff and missionaries. One 1913 report in the British Medical Journal estimated that NT invalided 20% of all missionaries at tropical posts. Climate-based theories concerning the aetiology of NT were common. Some experts blamed not simply "tropical light" itself but exposure to its different spectra. Others blamed climate, heat, humidity, and altitude, while others cited ex-pats' contacts with "diseased or depraved indigenous peoples or simply the sense of loneliness and despair." Symptoms included irregular heartbeat, irritability, loss of appetite, sexual dysfunction, depression, and even suicide. Relying primarily on archival and published primary sources, this presentation will examine the rise and fall of TN as a clinical entity during the first quarter of the 20th century.

5827

LOCAL PERCEPTIONS OF YELLOW FEVER OUTBREAKS IN UGANDA: A QUALITATIVE STUDY

Lena Huebl[1], Aloysious Nnyombi[2], Aban Kihumuro[3], Denis Lukwago[4], Eddy Walakira[2], Ruth Kutalek[5]

[1]Department of Tropical Medicine, Bernhard Nocht Institute for Tropical Medicine & I. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Department of Social Work and Social Administration, Makerere University, Kampala, Uganda, [3]Department of Nursing and Health Sciences, Bishop Stuart University, Mbarara, Uganda, [4]Cluster Monitoring and Evaluation Lead, Rakai Health Sciences Program, Masaka, Uganda, [5]Unit Medical Anthropology and Global Health, Department of Social and Preventive Medicine, Center for Public Health, Medical University of Vienna, Vienna, Austria

Yellow fever (YF), a mosquito-borne viral hemorrhagic fever, is endemic in Uganda and causes frequent outbreaks. We investigated the largest YF outbreak to date in Uganda and three subsequent smaller outbreaks. The aim of this study was to explore local perceptions of YF outbreaks to inform future public health campaigns. In this qualitative study we conducted 43 semi-structured interviews, 4 focus group discussions and 10 expert interviews - in total 76 participants. Data were collected in six affected districts with yellow fever outbreaks in 2010 and 2016. We included vulnerable groups such as elderly people ≥ 65 years and pregnant women. Participants perceived YF as a deadly disease. Although signs and symptoms of YF were broadly known the disease was frequently confused with newborn icterus, severe malaria, and hepatitis. Despite excessive awareness campaigns participants believed YF could be contracted by multiple pathways such as mosquito bites, airborne, close contact, sexual intercourse, vertical transmission, lack of hygiene, and through excessive consumption of yellow foods. Furthermore, people in remote areas affected by YF outbreaks were frequently unaware of the cause of outbreak. If a disease and its transmission pathway is not understood preventive measures cannot be successfully implemented. Moreover, timely diagnosis and reactive outbreak measures may be delayed. Thus, we recommend improving health education in communities at risk through village health teams, education at health centers, schools, and trusted community members. Awareness campaigns should be in conformity with local language habits. Additionally, public participation could be an important strategy to improve awareness among communities at risk.

5828

PREVALENCE AND PREDICTORS OF INTENTION TO USE TOBACCO AMONG ADOLESCENTS IN OYO STATE, NIGERIA

Esther Tumininu Oguntola

University of Ibadan, Ibadan, Nigeria

Tobacco use is a major public health problem globally, especially in developing countries like Nigeria. Despite the well-known risks associated with tobacco use, many individuals still initiate and continue to use tobacco. The intention of tobacco use is an important predictor of the actual use of tobacco, so therefore, understanding the associated factors is critical to developing effective tobacco prevention interventions. The goal is to assess

the predictors of intention to use tobacco among school-going adolescents in Oyo State, Nigeria. This was a cross-sectional survey among randomly selected adolescents (2,590) attending 28 secondary schools across six Local Government Areas (LGAs) in Oyo State, Nigeria. The participants' sociodemographics, knowledge, attitude, harm perception, tobacco use, SHS exposure, and intention of tobacco use were assessed using the modified GYTS questionnaire. Data were analyzed with SPSS version 25 and P-value was <0.05. Participants' mean(±SD) age was 14.6(±1.3). The majority were females (48.1%) and schooled in urban LGAs (70.8%). The prevalence of intention to use tobacco was 11.7%. Some (2.2%) were past tobacco users, 9.8% owned a tobacco-branded item, and 22.5% were against banning tobacco adverts. Some had low tobacco harm perception (40.9%), perceived that it was easy to buy tobacco (22.5%), had poor attitude to tobacco use (35.3%), and 10.5% had smoking friends. Predictors of intention for tobacco use were: schooling in urban areas (aOR:1.95;95%CI:1.40-2.71), male gender (aOR:1.45;95%CI:1.11-1.90), past tobacco user (aOR:3.18;95%CI:1.69-6.00), owning a tobacco-branded item (aOR:1.65;95%CI:1.14-2.40) and being against the ban on tobacco adverts (aOR:1.82;95%CI:1.34-2.38). Others were low harm perception (aOR:1.76;95%CI:1.31-2.25), poor attitude towards tobacco use (aOR:1.69;95%CI:1.30-2.21), perceived ease of buying tobacco (aOR:1.37;95%CI:1.02-1.84), and having smoking friends (aOR:1.71;95%CI:1.17-2.48). The intention of tobacco use among the participants was 11.7%. The predictors included individual, interpersonal, and environmental factors.

5829

COMMUNITY PERCEPTIONS OF INCENTIVES FOR MINIMALLY INVASIVE AUTOPSY IN CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) IN WESTERN KENYA

Kennedy Omondi Ochola[1], Sarah Hawi[1], Peter Otieno[1], Dickens Onyango[2], Janet Agaya[1], Maryanne Nyanjom[1], Victor Akelo[3], Beth Barr[4]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Kenya Ministry of Health, Kisumu, Kenya, [3]Center for Disease Control and Prevention, Kisumu, Kenya, [4]Nyanja Health Research Institute, Salima, Malawi

Incentives play an important role in improving participation in research and establishing ethically acceptable incentives is essential to preserving research integrity. Child Health and Mortality Prevention Surveillance (CHAMPS) uses minimally invasive tissue sampling (MITS) and careful diagnostic testing to improve understanding and prevention of child mortality. Incentives offered to participants in Kenya include transportation of the body for burial, a contribution of $40 towards funeral expenses, and payment of mortuary bills for up to 5 days. This study explored how community members perceive CHAMPS incentives. Qualitative key informant interviews (n=29), semi-structured interviews (n=11), and focus group discussions (n=5) were conducted with community members, community leaders, healthcare workers, and caregivers. Participants provided verbal consent prior to discussions. Data were analyzed using a thematic approach. Participants reported positive perceptions towards the incentives they believed were appropriate within their cultural context. While some respondents perceived them as a motivating factor, others expressed more preference for non-monetary forms of incentives and indicated that the aim of finding a child's cause of death was an adequate incentive alone. CHAMPS incentives were perceived to be well-aligned with the cultural values attached to burial-related practices and expectations. Respondents believed the educational status of the participating family influences the perception of the incentives; better-educated parents were believed to be less suspicious and view the incentives positively. Some respondents believed that research incentives could raise suspicion among community members about the true intention of the research. Overall, the findings suggest that CHAMPS has achieved a positive balance of both cultural value and financial value for participation incentives. Increased community sensitization may be needed to address negative perceptions or rumors that may be associated with research incentives.

5830

BLOOD PRESSURE VARIATIONS AND THEIR ASSOCIATION WITH SOCIAL DETERMINANTS AMONG MEN AND WOMEN IN BANGLADESH

Yasmin Jahan[1], Shamsun Nahar Shaima[2]

[1]Hiroshima University, Hiroshima, Japan, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Hypertension (HTN) is a leading risk factor for cardiovascular disease, and it is increasing in Bangladesh. Therefore, this study aimed to see blood pressure (BP) variations and their association with social determinants among Bangladeshi adults. This study performed a secondary analysis of the Bangladesh demographic and health survey 2017-18 data. A total of 20,250 households were selected and from these households, one-fourth of the households were randomly selected for BP. All adults (18 years of age or older) living in these households were invited to participate in measuring BP. Among 14,704 eligible women and men, about 90% participated. Hypertension cutoffs classify a person as hypertensive with an SBP/DBP of 140/90 mmHg or more. BP status was categorized as normal, pre-HTN, stage I HTN, and stage II HTN. This study investigated age, gender, education level, marital status, wealth quintile, body mass index, and residence as potential determinants. Sample characteristics were examined and stratified by gender because of established gender differences in HTN prevalence and compared characteristics among men and women using chi-squared tests for categorical variables. Results were considered statistically significant at P values <0.05. A total of 13,128 participants were included; the mean age (±SE) was 39.7 (±0.07) years and 56% were female. Thirty-three percent of them had pre-HTN, 14% had stage-I HTN and 7% had stage-II HTN. In terms of social determinants, stage II HTN was significantly associated with older age whereas pre-HTN was associated with younger people, and males were more likely to be affected (P<0.001). Males who were married, overweight, and from the richest families suffered mainly from stage II HTN (P<0.001). A female with poor education who lives in rural areas was significantly associated with stage II HTN and pre-HTN (P<0.001). It is crucial to lower HTN prevalence and improve control among older adults and men. Lowering the incidence of overweight may lessen the long-term burden of HTN and any associated problems. It is essential to create awareness among younger people and to prioritize rural areas.

5831

THE URGENT NEED OF MOLECULAR DIAGNOSTICS IN LOW RESOURCE SETTINGS. CASE STUDY: CURE CHILDREN'S HOSPITAL OF UGANDA

Henry Masengere[1], Steven Schiff[2], Jessica Ericson[3], Edith Mbabazi[1], Ronald Mulondo[1], Christine Hehnly[4]

[1]CURE Children's Hospital of Uganda, Mbale, Uganda, [2]Yale University, New Haven, CT, United States, [3]Penn State University, Hershey, PA, United States, [4]Harvard University, Cambridge, MA, United States

Hydrocephalus is a major indication of neurosurgery in infants worldwide. Post-Infectious Hydrocephalus (PIH), the most common form of hydrocephalus in Uganda, is a sequela of neonatal sepsis. Its diagnosis is largely based on clinical history, radiological imaging, or surgical findings because microbiological investigations using traditional culturing of CSF for microbial organism detection and identification have been largely unsuccessful. In a prospective cohort study to discover the cause of PIH at CURE Children's Hospital of Uganda, we recruited 208 consecutive PIH patients below 3 months of age and subjected their CSF samples to on-site conventional culture and PCR testing (in the USA). PCR identified virulent Mbale strains of Paenibacillus Thiaminolyticus in 47% of the processed samples while on-site conventional culture recovered no organisms. This highlights the urgent need for molecular diagnostics at point-of-care in such settings. Unfortunately, these techniques although important, are not readily available in low-resource settings like Uganda due to the high costs of setting up the infrastructure, and training personnel to perform these tests. This has limited our ability to effectively treat neonatal infections leading to the large number of PIH cases we observe at our hospital. To

bridge the gap between microbiological diagnosis and treatment of PIH at CURE Hospital, efforts have been undertaken to set up a molecular laboratory to facilitate diagnosis. An experienced laboratory technologist was recruited and trained in molecular diagnostic techniques at Penn State University, USA. Benchmark for the design of a molecular laboratory was done in collaboration with Penn State University, Yale University, and Harvard University with support from the NIH. The major challenges include: outsourcing the required equipment and reagents as they are expensive locally leaving us with no option but to purchase them from abroad. When fully functional, this laboratory will aid in the point-of-care diagnosis of causes of PIH in infants, enabling targeted and optimized treatment and clinical trials to improve patient outcome.

5832

SPATIOTEMPORAL CHARACTERIZATION OF CONGENITAL MYELOMENINGOCELE IN UGANDA

Ronald Mulondo

cure hospital, mbale, Uganda

Myelomeningocele (MMC) is the commonest form of spina bifida and the most severe congenital disability of the central nervous system. Without surveillance, Uganda lacks accurate data on incidence, prevalence or geographic variation in MMC risk to guide prevention. Characterization of MMC distribution in Uganda based on treated cases and knowledge of the effect of environmental factors that directly affect crop yields or natural folate availability on MMC occurrence would guide prevention. Here, we examined; the distribution of MMC in Uganda, the presence or absence of clustering within MMC cases compared to controls (under the hypothesis of uniform distribution in space) and, the association between MMC and selected environmental factors (village elevation, temperature, rainfall, and vegetation index) using secondary data from 2916 consecutive infant cases of MMC and controls between 2018 and 2001. The environmental factors 3 months before pregnancy and the first month of pregnancy were accumulated into sums giving a single value for every patient. We created Relative risk maps for being a case compared to control using village location mapped onto the Ugandan map. We examined clustering within cases compared to controls using Ripley's K function Plots with Chetwynd and Diggle method for global clustering and, explored associations between MMC and, environmental factors in terms of odds ratios using Generalized linear Mixed Models. We found a high relative risk of MMC in the Eastern and Southwestern subregions compared to other regions. Vegetation index (OR=0.13 p-value <0.001) had the biggest effect on the odds of being a case. A high vegetation index in the months studied was strongly protective. Other environmental factors with notable effects on the odds of being a case were elevation (OR= 1.14, p-value=0.008), and temperature (OR=0.87 p-value=0.009). These findings show that MMC is neither a random event nor uniformly distributed across space in Uganda. In the absence of surveillance, seasonal risk maps based on vegetation index can guide prevention.

5833

IMPACT OF CONFLICT ON THE HEALTH SERVICES: OPPORTUNITIES FOR RESILIENCE IN NORTH SHEWA ZONE, ETHIOPIA

Anum S. Hussaini[1], Clara Pons-Duran[1], Negalign Berhanu Bayou[2], Abdulhalik Workicho[3], Bezawit M. Hunegnaw[4], Mesfin Hunegnaw[3], Tefera Biteye[3], Chalachew Bekele[3], Sebastien Haneuse[5], Anne R. Sites[1], Meseret Zelalem[6], Lisanu Taddesse[3], Delayehu Bekele[7], Grace J. Chan[1]

[1]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Health System and Reproductive Health Research Directorate, Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [3]HaSET Maternal and Child Health Research Program, Addis Ababa, Ethiopia, [4]Department of Pediatrics and Child Health, St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, [5]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, Boston, MA, United States, [6]Maternal, Child and Nutrition Directorate, Ministry of Health, Addis Ababa, Ethiopia, [7]Department of Obstetrics and Gynecology, St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia

Recurrent conflicts pose threats to health systems, creating disruption in service provision. The conflict which occurred in northern Ethiopia, escalated to additional parts of the country affecting the health system operations, resulting in fatalities, disruption of livelihoods, widespread food insecurities, and displacement of residents. Through a qualitative approach, this study aims to assess the impact of conflict on health service provision, particularly maternal and child health services, and explore areas of resiliency that may be strengthened to mitigate the risks of conflict in the future. Data were obtained from community and facility key informants through in-depth interviews and focus group discussions to understand the challenges during the recovery period with suggestions on potential solutions. Total five overarching themes were explored: disruption in health services, social consequences, psychological implications, health system response for community support, and mitigation strategies to improve health system resilience. Results indicate shortage of staff and transportation, increased home/forest deliveries, rapes and sexually transmitted diseases, theft and destruction of property, lack of funds and resources, and insufficient and delayed support from government and other organizations were some of the reasons for poor health service provision during and immediately after the conflict. There is a need to acknowledge the requirement for additional outreach, IDP sites and temporary clinics to manage the caseloads during conflict crises and to strengthen the collaboration with community and other organizations for disaster management/preparedness to ensure that the health system is capable of absorbing shocks under future stress situations.

5834

EVIDENCE GENERATION FOR TOOLS FOR SEVERITY TRIAGE OF FEBRILE PATIENTS IN LOW-RESOURCE SETTINGS: A MIXED-METHODS STUDY

Debashish Das[1], Lava Shrestha[2], Bipin Adhikari[3], Manjita Bajracharya[2], Jyotshna Sapkota[1], Michael Otieno[1], Berra Erkosar[1], Aakriti Parajuli[2], Nishika Aryal[2], Ramesh Kumar Maharjan[2], Pamela Nabeta[1], Rigveda Kadam[1], Sabine Dittrich[1], Cassandra Kelly-Cirino[1], Marta Fernandez Suarez[1], Kevin K.A. Tetteh[1]

[1]FIND, Geneva, Switzerland, [2]Institute of Medicine, Kathmandu, Nepal, [3]Mahidol Oxford Research Unit, Bangkok, Thailand

The screening and triage practice that offers severity assessment of a patient is a crucial initial step in any healthcare cascade. Effective utilization of triage could help direct resources for life-saving procedures, and improve the distribution of resources for patients. Much less is understood about the triage process in healthcare settings of low- and middle-income countries (LMICs). The main objective of this study was to describe and evaluate the triage process in an emergency room (ER) of Tribhuvan University Teaching Hospital (TUTH), Kathmandu, Nepal. The mixed-methods observational study has commenced at the ER of TUTH. The study will review ~1500 randomly selected emergency tickets from Jan to Dec 2022. The retrospective review entails collating data from recorded information on the emergency tickets including the demographic characteristics, vital signs, symptoms, triage categorization, primary diagnosis, and discharge of patients. Qualitative methods will be used to document 'patient journey mapping' through in-depth interviews (IDIs) with patients attending the ER. A total of 15 febrile participants will be interviewed upon receiving written informed consent. The interview will explore the decision-making process on pre-visit, visit, and post-visit exploring details on barriers and facilitators related to patients' journey to the ER. In addition, 15 direct observation notes will be collected at the ER that will document the triage practice. Descriptive statistics will be used to present recorded information on emergency tickets and the association between the triage category and specific symptoms or vital signs will be explored using regression analysis. All transcripts and observation notes will be collated into NVivo and analyzed using thematic synthesis. The evidence generated through this study would inform the improvement in the triage process echoing the concept of the 'learning health system' and 'universal health coverage'.

5835

COMMUNITY-LEVEL USE OF ANTIBIOTICS IN RURAL BURKINA FASO: A HOUSEHOLD-BASED SURVEY USING THE DRUG BAG METHOD

Adelaide Compaore

Institut de Recherche en Sciences de la Santé/Clinical Research Unit of Nanoro, Burkina Faso, Ouagadougou, Burkina Faso

In Burkina Faso, little is known about antibiotics' use (ABU) outside the formal health system. Assuming that ABU at community level might be overlooked, the purpose of this study was to generate knowledge about the types of antibiotics commonly used at community-level and their purpose. The survey was conducted from June to September 2021 in the rural health district of Nanoro in Burkina Faso. 423 households were purposively selected based on socio-economic status. An electronic questionnaire was used for data collection through the drug bag method, consisting of purchasing locally available antibiotics for respondents to identify and specify their use. Descriptive analysis was performed in R version 4.2.1. Households' main sources of drug procurement were the primary health care facilities (76.8%) and informal drugs sellers (61.5%). Among the 33 antibiotics inventoried, amoxicillin tablets (93.4%) and oxytetracycline tablets (86.5%) were the most recognized by the study participants. Descriptive features were their color and the diseases they were believed to treat, combined with locally shared names. Amoxicillin and oxytetracycline remained the most frequently used antibiotics. There was greater use of antibiotics for gastrointestinal disorders, wounds, musculoskeletal and connective tissue disorders and skin and subcutaneous tissue disorders. However, oxytetracycline (79.9%), metronidazole tablets (57.1%) and metronidazole suspension (56.7%) were largely used for gastrointestinal disorders while amoxicillin tablets (29%) and ampicillin tablets (34.9%) were used to treat wounds. This study provides an overview of the categories of antibiotics people identified as being valuable for domestic use. Access to and use of these medicines are facilitated by the influence of informal drugs providers coexisting with formal health care providers in the community. This raises concerns about people's access to quality medicines and the inadequacy of the health system.

IMPACT OF THE COVID-19 PANDEMIC ON THE SURVEILLANCE AND CONTROL OF NEGLECTED TROPICAL DISEASES (NTDS) IN BRAZIL

Expedito J. Luna[1], Rosa C. Soares[1], Eliane Ignotti[2], Maria A. Trindade[1]

[1]Universidade de Sao Paulo, São Paulo, Brazil, [2]Universidade Estadual do Mato Grosso, Caceres, Brazil

The Covid-19 pandemic led healthcare services to adopt contingency protocols and direct their attention to suspected and confirmed cases of Covid-19. In addition to measures to restrict people's movement, patients also avoided seeking healthcare services for fear of becoming infected. This led to a reduction in care for other health problems. We sought to quantify the impact of the pandemic on the detection of some NTDs (dengue, chikungunya, leprosy, visceral leishmaniasis, trachoma, and lymphatic filariasis) in Brazil, in the pandemic period (2020 - 2021) compared to the previous period (2015 - 2019). The number of reported cases in the pandemic years was compared to the mean number of cases in the 5-year previous period. The number of reported dengue cases fell 5.7% in 2020, in comparison to the previous period, followed by a sharp reduction in 2021 (-48%). Chikungunya cases fell 42% in 2020, and 32% in 2020. Leprosy cases fell 35% in 2020, and 33% in 2021 Visceral leishmaniasis cases fell 41% in 2020, and 49% in 2021. The national trachoma prevalence survey detected a TF prevalence <1% in all evaluation units in non-indigenous population, and below 5% in four evaluation units in indigenous people surveyed so far (national survey is ongoing). No new cases of lymphatic filariasis were detected in the last remaining focus of transmission in the country. The reduction in the number of dengue and chikungunya cases may be related to changes in services resulting from the pandemic, but it may also reflect the reduction in transmission associated with reduced mobility of people. NTDs in the final phase of elimination, such as trachoma and lymphatic filariasis, seem not to have been affected by the pandemic. The decrease in leprosy and visceral leishmaniasis seems to be related to the disruption of primary care services due to the pandemic. The Brazilian public health needs to carry out additional efforts to recover the ground lost in the pandemic.

5837

SYMPTOMOLOGY, OUTCOME AND PATTERN OF RISK FACTORS OF CORONARY ARTERY DISEASE IN TANZANIA CLUSTERING AND STRATIFICATION APPROACH

Neema Kailembo, Peter Kisenge, Tatizo Waane, George Longopa, Khuzeima Khanbhai, Honorata Maucky, Beatrice Ngowi, Tulizo Shemu, Samson Kiware, Pedro Pallangyo

Jakaya Kikwete Cardiac Institute, Dar es salaam, Tanzania, United Republic of

Coronary artery disease is a significant public health concern worldwide. Its burden is alarming, mainly in Low- and middle-income countries, with 75% of premature deaths and 164 million disability-adjusted life years (DALYs). Tanzania has deployed various interventions to combat disease risk factors and their aftermath, however, its burden is still high. Here, a retrospective study is conducted to identify and evaluate the distribution of symptoms and risk factors of coronary artery disease (CAD) in Tanzania to recommend appropriately tailored interventions.1673 patients who underwent coronary angiography at Jakaya Kikwete Cardiac Institute (JKCI) are analyzed based on four clusters. The lesion was defined as luminal stenosis >50% by invasive angiography. Clusters were determined by the k prototype and stratification analysis was done. The findings indicate that the prevalence of CAD was 51.3% with 56% of patients over 60 years old. Male patients composed 63% and hypertension (92%) was the commonest risk factor. Four clusters of patients are identified with a) hypertensive, diabetes, and dyslipidemia symptoms of chest pain and a higher chance of double vessel lesion, b) prior myocardial infarction (MI) and percutaneous coronary intervention (PCI) with age above 60 years old that contributed to higher prevalence and risk of triple vessel disease, c) dominant risks of alcohol use, family history and smoking resulting to triple vessel disease more than other groups and d) more female patients with a higher level of obesity and smoking. Apart from patients above 60 years old, there is a percentage of premature coronary artery disease, patients below 45 years old with modifiable risk factors. Therefore, the interventions targeting youth and women should focus on reducing unhealthy diets, physical inactivity, smoking, and alcohol abuse- this is the same for the older generation. However, adding proper patient management and counseling may result in better outcomes, reducing repeated PCI and MIs.

A QUALITATIVE EXPLORATION OF WOMEN PERCEPTIONS AND EXPERIENCES OF ANTENATAL CARE ACCESS IN MOZAMBIQUE

Amílcar Magaço[1], Agostinho Neves[1], Contstantino Cumbane[1], Quique Bassat[1], Inacio Mandomando[1], Khatia Munguambe[1], John blevins[2], Maria Maixenchs[3]

[1]CISM, Maputo, Mozambique, [2]Emory Global Health Institute, Atlanta, GA, United States, [3]ISGlobal, Barcelona, Spain

Despite numerous efforts, maternal and newborn mortality rates in Mozambique are among the highest in sub-Saharan Africa. Poor access to health services and antenatal care (ANC) and low rates of institutional delivery are associated with maternal and newborn deaths. This study aims to understand pregnant women's perceptions and experiences of access to ANC in Manhiça and Quelimane Districts, in Southern and Central Mozambique respectively. A qualitative rapid assessment was conducted in June and July 2022. Data was collected through in-depth interviews of pregnant women recruited from health facilities and communities. Interviews were digitally recorded, transcribed and systematically coded

in inductive and deductive categories. Data were thematically analyzed. A total of 18 in-depth interviews were performed. Almost all participants explained that pregnancy is not a disease and can be quietly managed at home; this influenced the low uptake for ANC in the early stage of pregnancy. Nevertheless, participants recognized the importance of ANC during pregnancy, mainly to protect the baby's health. Pregnant women highlighted the need to prioritize labor activities such as cultivating on farms and selling in markets over going to the healthcare facility for ANC. Further, participants stated the need to "hide their belly" to avoid the threat of the evil eye and witchcraft to their pregnancy. These factors led women to delay seeking ANC until the late stage of pregnancy. Long distances and waiting times during ANC were also mentioned as factors that influence access and the experiences of pregnant women. Participants perceive pregnancy as an easily managed condition at home, and this has impacted their ANC-seeking behavior, although they recognize its importance. Education is needed to improve women's knowledge of the importance of ANC at the first stage of pregnancy and mitigate beliefs about witchcraft in order to improve ANC-seeking behavior.

ASSOCIATIONS BETWEEN MATERNAL AND PATERNAL STRESS, MATERNAL DEPRESSION, MATERNAL EXPOSURE TO INTIMATE PARTNER VIOLENCE, AND CHILD STRESS

Alexis V. Silvera[1], Zachary Butzin-Dozier[1], Sophia T. Tan[1], Andrew N. Mertens[1], Kausar Parvin[2], Md. Mahfuz Al Mamun[2], Dora Il'yasova[3], Md. Ziaur Rahman[2], Helen O. Pitchik[1], Benjamin F. Arnold[4], Idan Shalev[5], Ivan Spasojevic[3], Shahjahan Ali[2], Gabrielle Shuman[1], Mohammed R. Karim[2], Sunny Shahriar[2], Christine P. Stewart[6], Abul K. Shoab[2], Syeda L. Famida[2], Salma Akther[2], Md. Saheen Hossen[2], Palash Mutsuddi[2], Mahbubur Rahman[2], Leanne Unicomb[2], Liying Yan[7], Lia C. H. C. H. Fernald[1], John M. Colford Jr.[1], Stephen P. Luby[8], Douglas A. Granger[9], Ruchira T. Naved[2], Audrie Lin[5]

[1]School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Department of Medicine, Duke University, Durham, NC, United States, [4]Francis I. Proctor Foundation, University of California, San Francisco, San Francisco, CA, United States, [5]Department of Biobehavioral Health, Pennsylvania State University, University Park, PA, United States, [6]Department of Nutrition, University of California, Davis, Davis, CA, United States, [7]EpigenDx, Inc., Hopkinton, MA, United States, [8]Division of Infectious Diseases and Geographic Medicine, Stanford University, Stanford, CA, United States, [9]Institute for Interdisciplinary Salivary Bioscience Research, University of California, Irvine, Irvine, CA, United States

Globally, many women experience intimate partner violence (IPV), depression, and stress, which have long-term maternal and child health consequences. We assessed the potential associations between maternal and paternal perceived stress, maternal depressive symptoms, and maternal exposure to cumulative lifetime IPV, and child stress biomarkers (urinary F2-isoprostanes, salivary alpha-amylase (sAA) and cortisol, blood pressure, heart rate, and NR3C1 methylation status) in rural Bangladesh. We estimated associations using generalized additive models, adjusting for potential confounders. We measured 686 mother-child dyads at Year 1 and 1,494 dyads at Year 2, overlapping with replacement. F2-isoprostanes outcomes yielded two opposing results: a negative relationship with maternal exposure to IPV and a positive relationship with maternal depression. In the sympathetic adrenomedullary axis, we observed a negative association between paternal stress and child mean arterial pressure (MAP), and positive associations between maternal perceived stress and post-stressor sAA; maternal depression and sAA reactivity and MAP; and paternal perceived stress and resting heart rate. In the hypothalamic pituitary adrenal axis, we observed a negative association between maternal depression and post-stressor cortisol and a positive association between paternal stress and pre-stressor cortisol. The negative relationship between maternal IPV and child F2-isomers, although counterintuitive, reveals possible alternative functional roles, which reactive oxygen species might play. Maternal depression was associated with the largest and most variable number of child stress biomarkers indicating the importance of this exposure in shaping stress responses. Future studies in different geographical contexts quantifying the multigenerational implications of such stressors to determine typical and atypical child stress responses during early life are critical.

5840

UTILIZATION OF PANTOGRAPH AMONG NURSES AND MIDWIVES IN LABOUR WARD AT EDWARD FRANCIS SMALL TEACHING HOSPITAL

Ensa -. Jarju

Edward Francis Small Teaching Hospital, Banjul, Gambia

Partograph is a graphic record of progress of labor, maternal and fetal condition plotted against time for intrapartum monitoring (Mathai 2009). Its aim is to provide a pictorial overview of labor, to alert obstetric care providers about deviations in maternal, fetal condition and progress of labour (Lavender et al 2008). The study aimed to describe the utilization of partogram among nurses and midwives, in the labour ward at Edward Francis Small Teaching Hospital (EFSTH). A descriptive quantitative research design to gather information on utilization of the partogram among nurses and midwives in the labour ward of Edward Francis Small Teaching Hospital was employed using a convenient sampling procedure. All the nurses and midwives in the labour ward were selected who were willing to participate in the study and consent was sought from both EFSTH and the participants. Questionnaires were used to collect data and analysis was done using spss version 21. The results indicate that 80% of all of respondents knew what a partogram was. The knowledge on the function of the action line and alert line was poor amongst nurses and midwives who participated in the current study. Only 40% (N=4) of the respondents could explain the function of action line on the partogram. There was poor utilization in labour monitoring. Only 40% (N=4) were found to properly use the partogram while 60% (N=6) were found to not properly use the partogram. The findings confirm the problem of shortage of nurses and midwives with only (N=10) covering the labour ward of EFSTH for all shifts. The recommendation includes deployment of nurses and midwives to EFSTH, training of nurses and midwives on the utilization of the partogram.

A NOVEL VIRULENCE MODIFYING EXOTOXIN SECRETED BY PATHOGENIC LEPTOSPIRA MEDIATES DISEASE PATHOGENESIS AND IS A PAN LEPTOSPIROSIS VACCINE CANDIDATE

Reetika Chaurasia, Dielson S. Vieira, Joseph M. Vinetz

Yale University, New Haven, CT, United States

Leptospirosis, a globally neglected zoonotic disease caused by pathogenic Leptospira, affects >1 million people annually, with a 20% case fatality rate. Clinical pathogenesis mechanisms have not been known until the present work and there is no safe/effective vaccine for humans. We recently reported that Leptospira-secreted Virulence Modifying (VM) proteins, comprised of N-terminal ricin B domains and C-terminal DNase/toxin domains, mediate cellular cytotoxicity on HeLa and primary pulmonary endothelial cells; the latter cell type is likely to be involved in lung hemorrhage in severe leptospirosis. VM protein vaccination of two rodent models (mouse, hamster) that recapitulate human disease manifestations protects from lethal challenge infection. We hypothesized that anti-VM protein immunity is mediated by antibodies, given the premise that Leptospira, an extracellular pathogen, causes systemic disease via the circulation of secreted VM protein exotoxins. Polyclonal and monoclonal antibodies both neutralized VM cellular toxicity (HeLa cells). High-affinity anti-VM mAbs 5F8, 6A5, and 5G10 reacted with homologous VM proteins and cross-reacted with the VM protein family. Epitope mapping showed that mAbs and polyAbs recognized linear epitopes that are highly conserved among species and serovars. Serovar Copenhageni showed upregulation of multiple VM proteins, which are present in the serum of infected hamsters at nanogram/ml levels as determined by capture ELISA. This latter finding is

the first time, to our knowledge, that a secreted exotoxin can be detected and quantified in the blood of any infectious disease. Discovery of vaccine-induced, anti-VM antibody-mediated neutralization of VM activity will justify clinical development of a novel leptospirosis vaccine. Future experiments will test whether passive anti-VM protein antibody transfer will protect animals against lethal leptospirosis. Our findings are sufficiently compelling to put leptospirosis on the WHO's Neglected Tropical Disease list which is needed to enable the development of VM protein-based leptospirosis vaccines, diagnostics, and therapeutics.

VILLAGE COMMUNITY BANKING: POTENTIAL OF COMMUNITY-BASED FINANCING SYSTEM FOR HOUSE IMPROVEMENTS AND VECTOR CONTROL IN RURAL TANZANIA

Winifrida Mponzi, Dickson S. Msaky, Peter Binyaruka, **Emmanuel Kaindoa**

Ifakara Health Institute, Morogoro, Tanzania, United Republic of

House improvement has consistently been associated with remarkable reductions in indoor bitingmosquitoes and disease incidences even in typical rural houses, however, its exploitation remainsextremely poor in Tanzania and other endemic countries due to limited financial resources. Nevertheless,the village community banks (VICOBA), practiced in Tanzania for nearly two decades, have proven toprovide financial services to rural communities who would otherwise not be able to get financial servicesfrom formal financial institutions. This study was conducted to explore the views, opinion andwillingness of VICOBA members on using VICOBA platforms as source of finance for improving localhouses and eventually control of mosquito borne diseases.A mixed method approach was used in this study, whereby a survey was administered to 150 participantsand twelve focus group discussion were done in three villages of Ulanga district rural Tanzania. TheFGDs comprised of 8 participants each with equal representation of males and females. The FGD guidewas used to probe the opinion of study participants on malaria transmission, housing conditionimprovements and financial resources.About 99% of all participants indicated the urgent need to improve their houses for preventing themselvesfrom mosquito bites and were willing to utilize VICOBA for improving their houses. In focus groupdiscussion majority of people who participated they were also in need of improving their houses. Allparticipants confirmed that they were at highest risk of getting mosquito borne diseases and they werewilling to use money that was either saved or borrowed from their VICOBA.Going forward with malaria elimination and economic growth agenda as stipulated in the SDG 3 and 8,self-sustaining financial system destined at house improvement and related interventions against malariaand other mosquito-borne diseases are crucial. The community members were willing to use VICOBA assource of finance for house improvement and disease control, however there were limited knowledge andsensitization on how they could utilize VICOBA for disease control.

INNOVATIVE FINANCE FOR NEGLECTED TROPICAL DISEASES

Aïssatou Diawara[1], Lisa Goldman- Van Nostrand[1], Simon Bland[1], Mark Sullivan[2], Barbara Roth[2], George Rugarabamu[2], Willo Brock[3], Alexandra Bertholet[3], Karishma Saran[3], Mona Hammami[4], Marie-Renée B-Lajoie[5], Michael Anderson[6], Michelle Teo[6], Kate Antrobus[7], Thi Hanh Cao[8], Neil McCarthy[9], Isaac Chikwanha[10], Fifa A. Rahman[11], Nancy Lee[12], Sam Mayer[13], Jamie Power[13], Bethan Hughes[14], Rachel Taylor[15], Beatrice Grecko[16], Ngozi Erondu[1]

[1]Global Institute for Disease Elimination, Abu Dhabi, United Arab Emirates, [2]Medicines Development for Global Health, Melbourne, Australia, [3]FIND, Geneva, Switzerland, [4]McKinsey, Abu Dhabi, United Arab Emirates, [5]McKinsey, Montreal, QC, Canada, [6]MedAccess, London, United Kingdom, [7]Univercells, Brussels, Belgium, [8]DNDi, Geneva, Switzerland, [9]Medicines for Malaria Venture, Geneva, Switzerland, [10]Global Health Innovative Technology Fund, Tokyo, Japan, [11]Matahari Global Solutions, Kuala Lumpur, Malaysia, [12]Wilton Park, Steyning, United Kingdom, [13]The END Fund, New York City, NY, United States, [14]Novartis, Nairobi, Kenya, [15]Merck, New York City, NY, United States, [16]Merck Global Health Institute, Geneva, Switzerland

Neglected tropical diseases (NTDs), impact more than a billion people globally and pose a significant barrier to economic and social development in low- and middle-income countries. Insufficient funding and limited research have caused critical gaps in prevention, diagnostics, and treatment. In the past decade, only ten drugs were developed to treat diseases affecting 2.5 billion people. Six out of 20 NTDs identified by WHO have no tests, while others are not fit-for-purpose or accessible in the necessary areas. These challenges hinder progress towards agreed targets, as evidenced by the WHO NTD Road Map gap assessment. Funding for NTD product development is inadequate to address the need of new and better tools that could make the elimination of several NTDs a reality –it is imperative to explore financing options that have not yet been applied to the NTD space. The post-COVID-19 global health architecture has provided an opportunity to assess new financing models for health initiatives and disease programs. In 2022, GLIDE led a six-month technical exercise with a core group of 20 experts to identify innovative finance mechanisms (IFM) for NTDs through i) condensing existing evidence, ii) stimulating cross-sectoral discussions, and iii) gathering expert input. Through literature and desk reviews, several IFM were assessed across the NTD value chain for scope and applicability to specific diseases. Financing mechanisms were qualified as innovative if they met the four criteria of catalytic, additive, complementary, and sustainable. Shortlisted mechanisms were then prioritised based on their perceived impact versus ease of implementation profiles and mapped into quadrants. This exercise resulted in the identification of four financing instruments to consider for NTDs: (i)debt swaps, (ii) milestone-based funding, (iii) impact bonds, (iv) and pooled procurement. The next steps will be to identify disease-country-mechanism opportunities for investment by public and private stakeholders. By leveraging IFM, innovative finance offers a new and dynamic approach to mobilize resources and drive greater impact in NTD elimination efforts.

MICROBIOME ANALYSIS OF PREGNANT WOMEN AND CHILDREN FROM AMANHI FECAL COHORT

Waqasuddin Khan, Samiah Kanwar, Furqan Kabir, Fatima Aziz, Sahrish Muneer, Adil Kalam, Aneeta Hotwani, Muhammad Farrukh Qazi, Farah Khalid, Javairia Khalid, Muhammad Imran Nisar, Fyezah Jehan

Aga Khan University, Karachi, Pakistan

Characterization of the human microbiome can provide valuable insights to the status of human health and disposition to disease. There is an interest in understanding the role of the human microbiome in maternal, newborn and child health (MNCH). Gut microbiome shifts physiologically during pregnancy and appear to differ in women with pregnancy-associated complications, such as, Adverse Pregnancy Outcomes (APOs). For example, dysbiosis of microbial communities is implicated in a variety of adverse MNCH outcomes including preterm birth (PTB), cardiometabolic complications of pregnancy and childhood, and neonatal complications like necrotizing enterocolitis. Furthermore, the maternal microbiome is a key contributor in the initial microbial colonization and development of the infant microbiome which may have long-term implications for the child's physical growth, nutrition, and neurocognitive development. In this proof-of-concept study, we sequenced by shotgun metagenomiucs 750 trios (250 maternal and 250 infant fecal samples of two time points, postnatal 42 days, and 12-18 months of age) to generate the microbiome profiles of pregnant women in Pakistan collected as part of AMANHI cohort. This study will guide our university to plan further as lead analytical lab for clinical intervention studies focusing to observe the effects on gut microbiome, and to provide insights into complex health problems in maternal, newborn and child health, along with their nutritional status.

5845

UNDERSTANDING HEALTH WORKER AND COMMUNITY ANTIBIOTICS PRESCRIPTION ADHERENCE PRACTICES FOR ACUTE FEBRILE ILLNESS: A NESTED QUALITATIVE STUDY IN THE SHAI-OSUDOKU DISTRICT OF GHANA, AND THE DEVELOPMENT OF A TRAINING AND COMMUNICATION INTERVENTION

Vida Ami Kukula[1], Selase Odopey[1], Philip Horgan[2], Alexander Adjei[1], John E.O Williams[1], Rita Baiden[1]

[1]dodowa health research centre, Accra, Ghana, [2]Big Data Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Most health facilities in sub-Saharan Africa, including Ghana, lack the diagnostic capacity to identify the cause of acute febrile illnesses. This leads to presumptive diagnosis and contributes to the inappropriate prescription of antibiotics. Hence, the evolving agenda towards implementing interventions to ameliorate inappropriate antibiotic prescription and consumption. We explored the social and contextual behavior determinants of adherence to prescription and communication of prescription adherence messages for patients with acute febrile illness. The outcome was used to develop a Training and Communication intervention which was delivered as part clinical trial. This was a qualitative study of a randomized controlled trial with the objective to assess the impact of an intervention package consisting of diagnostic tools, clinical algorithms, training, and communication on antibiotic prescriptions, compared with routine practices for patients presenting with acute febrile illness. Data was collected from 39 healthcare prescribers and 66 caregivers in primary healthcare facilities and communities in the Shai-Osudoku district in Ghana. We undertook a content analysis of primary, qualitative data collection using in-depth interviews and focus group discussions, informed by the Capability, Opportunity, Motivation theory of behavior, the Theoretical Domains Framework, and the Behavior Change Wheel approach. Health workers perceived factors that influence what and how prescribers and dispensers communicate include: patients' education level; existing disease condition; health worker's workload; patient's religion; language barrier between health worker and patient; the outcome of laboratory results, and medicine availability. Community members' adherence to prescription was influenced by: the availability of money and affordability of medicine, the severity of the condition, work schedule, and forgetfulness. Our study contributes to knowledge in qualitative methods nested in a clinical trial and reveals factors that affect antibiotic prescription with the communication process.

5846

SEVERE ACUTE MALNUTRITION IN CHILDREN UNDER FIVE

John Paul Kintu

Uganda Management Institute, Kampala, Uganda

Acute malnutrition is a rapid onset condition characterized by bilateral pitting edema, sudden weight loss caused by a decrease in food consumption or illness. Severe Acute malnutrition is when weight for height is less than -3 z scores with MUAC less than 11.5cm, bilateral pitting edema and marasmic -kwashiorkor (both wasting and edema). The study was carried out to identify factors that contribute to prevalence and effects associated with Severe Acute Malnutrition(SAM) in children below five years in a Nutritional Unit in Mbale Regional Hospital, Eastern Uganda. This was a prospective study that involved use of different questionnaires that were answered by health workers on duty, mothers and care takers of children with SAM on nutrition unit respectively. Anthropometric measures at two weeks and on monthly basis were taken and compared to mean difference in weight, height, Mid upper arm circumference (MUAC.) The study was carried out from 1st of December 2022 to 14th of March 2023.A total of 1000 respondents were interviewed. Children between 3-4 years (46.7%) had the most effects due SAM and 2-3 years (13.3%) had least effects due SAM. Poverty at(33.3%) was the major contributing factor to SAM, building its roots from family level. The study further showed us that (50%) were fortune to get discharged and (6.7%) died. My findings indicate that, hypoglycemia, impaired growth and development were the commonest complications and effects observed. SAM is still a neglected tropical disease in Uganda. Recruitment of more health workers for easier identification of effects due to SAM among children and multisector intervention that can provide various support in management and prevention of SAM under-fives are some of the recommendations laid out. Also, retaining of health workers that work in lower health facilities was highly emphasized as this would enable easy identification of these children with this type of malnutrition, girl child education should be paramount in communities as way to halt early marriages. As it is said that when you educate a girl child you educate a nation.

5847

PARTICIPANT ACCEPTABILITY OF AN ANCILLARY CARE POLICY DURING AN EBOLA VACCINE TRIAL IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Gwen Lemey[1], Ynke Larivière[1], Trésor Zola[2], Solange Milolo[2], Engbu Danoff[2], Emmanuel Esanga[2], Junior Matangila[2], Raffaella Ravinetto[3], Jean-Pierre Van geertruyden[1], Patrick Mitashi[2], Pierre Van Damme[1], Hypolite Muhindo Mavoko[2], Sibyl Anthierens[1], Vivi Maketa[2]

[1]University of Antwerp, Antwerp, Belgium, [2]University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [3]Institute of Tropical Medicine, Antwerp, Belgium

Providing ancillary care (AC) for participants' medical conditions during study participation is an ethical responsibility of clinical researchers. During an Ebola vaccine trial (clinicaltrials.gov: NCT04186000) conducted in the remote area of Boende, DRC, the Universities of Antwerp (Belgium) and Kinshasa (DRC) developed a policy to medically and/or financially support concomitant medical events. By means of two short surveys, we assessed participants' acceptability of this approach. First, 152 participants with a self-reported medical event filled in a short quantitative questionnaire (6 questions; grading 1-5) regarding their experience with the AC policy. Second, at the end of the trial, 307 participants with and without self-reported medical events participated in a short telephone survey (3 questions; grading 1-3 and option for comments) that explored their endorsement of the policy, their experience on how the policy addressed their medical needs, and their opinion on the importance of the policy. Descriptive statistics were used to analyze the surveys and recurring themes from the comments were identified. The majority (89%) of participants with self-reported medical conditions gave a positive to very positive evaluation. All respondents of the telephone survey, with or without self-reported medical conditions, were in full support of the policy and emphasize its importance; 91% indicated that the support addressed all medical needs. Some limitations or constraints were mentioned, e.g. pharmacy stock-outs, conditionalities for financial coverage, the lack of specialized care facilities, etc. Despite limitations and contextual challenges, most participants assessed the policy to be beneficial on a personal and medical level. As clinical trials are increasingly conducted in resource-constrained settings, clinical research sponsors and teams should consider to systematically implement a AC package that is co-designed with representatives of the trial community and Ethical Committee, and tailored to the local health care system, research budget and duration.

5848

EVALUATION OF THE PANBIO™ COVID-19 RAPID TEST DEVICE (ABBOTT) AT THE VIROLOGY LABORATORY OF THE ARISTIDE LE DANTEC UNIVERSITY HOSPITAL IN SENEGAL

Ousseynou Gueye

Aristide Le Dantec University Hospital Center, Dakar, Senegal

The management of the COVID-19 pandemic requires the widest possible access to diagnosis. To make this diagnosis available to populations, especially in countries with limited resources, it is important to have fast but reliable technologies that are less expensive than RT-PCR, which is the reference technique. For this reason, we evaluated the detection

performance of Panbio™ COVID-19 Ag Rapid Test Device (Abbott Molecular) antigen tests on nasopharyngeal and nasal swabs compared to the Abbott Real Time SARS COV-2 Assay (Abbott Molecular) RT PCR technique. After obtaining free and informed consent, 2 nasopharyngeal swabs (NP) and one nasal swab (NS) were taken from each participant. The NP and NS samples were tested with Panbio Ag and the results were compared with those of RT PCR obtained on the nasopharyngeal swab of the patient considered. Performance analysis included calculation of sensitivity (Se), specificity (Sp), positive (VPP) and negative (VPN) predictive values, and degree of agreement by Cohen's Kappa coefficient. A total of 179 patients were included, including 150 participants recruited from travellers attending the Bacteriology Virology Laboratory of the CHNU Aristide le Dantec and 29 patients from the Hospital Treatment Center. The mean age was 33 years and 40 years and the sex ratio was 0.85 and 1.2 respectively for travellers and COVID-19 patients.Of the travellers, 21 (20%), 13 (8%) and 11 (7.3%) tested positive by RT-PCR, Panbio NP and NS respectively. For CT values <31, Se and Sp were 91% and 100% for NP and 86% and 100% for NS. The VPP was 100% and the VPN was over 96% for the NP and NS. Similarly, the degree of agreement was over 90% for NP and NS. In conclusion, this study showed excellent agreement between the Panbio test and RT PCR on both NP and NS samples. This good performance and ease of use of the Panbio test confirm the interest of its use in the diagnosis of COVID.

5849

APPLICATION OF THE THREE DELAYS MODEL TO UNDERSTAND HOW THE INTERACTION OF COMMUNITY, FAMILY AND HEALTH SYSTEMS CONTRIBUTE TO CHILD MORTALITY IN CHAMPS-KENYA; MAY 2017 - JUNE 2022

Aggrey K. Igunza[1], Beth A. Barr[2], Dickens Onyango[3], Dickson Gethi[4], Zachary Madewell[5], Sarah Ngere[1], Harun Owuor[1], Janet Agaya[1], Broline Asuna[1], Khagayi Sammy[1], Chris A. Rees[6], Dianna M. Blau[5], Cynthia G. Whitney[7], Richard Omore[4], Victor Akelo[8]

[1]Kenya Medical Research Institue, Kisumu, Kenya, [2]Nyanja Health Research Institute, Salima, Malawi, [3]Kisumu County Health Department, Kisumu, Kenya, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Emory University School of Medicine, Atlanta, GA, United States, [7]Emory University, Atlanta, GA, United States, [8]US Centers for Disease Control and Prevention, Kisumu, Kenya

Sub-Saharan African countries continue to bear the greatest burden of mortality in children under the age of 5 (<5's). The 3-delays model provides a useful framework for examination and interpretation of the complexity in the intersection of community, family and health systems factors and their contribution to <5 mortality. These delays include (1) a delay in deciding to seek care; (2) a delay in identifying and arriving at a health facility; and (3) a delay in receiving quality care at the health facility (i.e., suboptimal care).The Child Health and Mortality Prevention Surveillance (CHAMPS) in Western Kenya investigates <5 deaths by conducting extensive data collection and laboratory investigation using minimally invasive tissue sampling, verbal autopsy and data abstraction. Qualitative data routinely collected includes clinician narratives and verbal autopsy and was used to identify the delays. We reviewed cases from 2017-2022 to categorize and describe deaths using the 3-delays model. Nearly all <5's experienced one or more delays prior to death: whereas only 7.5% of those aged 0-1 day-olds had no delays, only 2.3% of neonates aged 1-28 days old had no delays (Figure 1).Delayed decision-making to seek care (Delay 1) co-occurred with suboptimal care received (Delay 3) in over one-third of all deaths, with this overlap greater among infants and children (64.4-68.9%) than stillbirths and neonates (32.7-44.4%). Cases with delays between the decision to seek care and arrival at a facility (Delay 2) co-occurred with Delays 1 and/or 3 for nearly all deaths. Suboptimal care (Delay 3) was observed in 83.6% of all deaths: Delay 3 was observed with no other delays in over half of stillbirths and neonates, and less than one-third of infants and children. Poor clinical care contributes to nearly 9 of 10 <5 deaths, and mothers of older infants and children are more likely to delay in seeking health care than are mothers of neonates. The 3 delays framework is useful. Further reduction in <5 mortality will require multi-level interventions especially earlier health seeking behavior by parents, and adherence to clinical guidelines by healthcare providers.

IMPACT OF MESSAGES ON MATERNAL CONDITION LEADING TO CHILD DEATH AND ON ANC SEEKING PRACTICES AMONG PREGNANT WOMEN IN RURAL BANGLADESH

Muhammad Faruqe Hussain[1], Emily S Gurley[2], John Blevins[3], Maria Maixenchs[4], Abdush Suban Mulla[1], Afroz Zahan[1], Aziz Ahamed[1], Shikha Datta Gupta[1], Suruj Ali[1], Sazzad Hossain Khan[1], Tonmoy Sarkar[1], Dalia Yeasmin[1], Md. Abdus Salam[1], Mohammad Zahid Hossain[1], Qazi Sadeq-ur Rahman[1], Md. Atique Iqbal Chowdhury[1], Md. Mamunur Rashid[1], Dr. Shams El Arifeen[1], Shahana Parveen[1]

[1]icddr,b, Mohakhali, Dhaka, Bangladesh, [2]Johns Hopkins University, Maryland, MD, United States, [3]Emory University, Atlanta, GA, United States, [4]Barcelona Institute for Global Health, Barcelona, Spain

Child Health and Mortality Prevention Surveillance (CHAMPS) Program in Bangladesh identified intrauterine hypoxia resulting from maternal health issues as one of the major causes of stillbirth and early neonatal deaths. Quality antenatal care (ANC) is needed to prevent these maternal conditions. This information was communicated and explained to pregnant women and their female family members at the community level through courtyard feedback sessions in Baliakandi, a rural sub-district of Bangladesh. The messages emphasized the benefits of recommended ANC visits to qualified physician on healthy development of the fetus and to identify maternal conditions, major danger signs during pregnancy and after delivery. From December 2021 - November 2022, female team members facilitated 138 courtyard sessions. We assessed the impact of conveyed messages by comparing ANC seeking behavior among 632 pregnant women (aged 14-45 years). In the 60 days following the session, 247 pregnant women (39%; 247/632) received ANC. The proportion of pregnant women who received ANC in the 60 days after the session (100%; 247/247) was 38% higher than in the 60 days before the session (62%; 153/247). When pregnant women's in-laws or maternal family members joined them at the sessions, the number of pregnant women who received ANC increased by 60% (148/247). Besides, the majority of the pregnant women (85%; 126/148) received ANC within 60 days following the session when their in-law's family members learned about the causes of child deaths and prevention strategies from the same session with them as opposed to (15%; 22/148) when they did not attend the session. The messages on main causes of death and understanding about the maternal conditions during pregnancy, likely facilitates in-law's family members to decide on ANC seeking of pregnant women. To improve maternal and child health, it is important to educate pregnant women along with their in-law's families, about the specific causes of maternal conditions that can lead to child death. Additionally, explaining the importance of antenatal care linking with potential risk as a preventive measure can increase its uptake.

A SYSTEMATIC REVIEW OF PREVALENCE AND RISK FACTORS OF TRANSFUSION TRANSMISSIBLE INFECTIONS AMONG BLOOD DONORS, AND BLOOD SAFETY IMPROVEMENTS IN SOUTHERN AFRICA

Sydney Puerto-Meredith

University of North Carolina School of Medicine, Chapel Hill, NC, United States

Blood and blood products are listed as one of the essential medicines by the World Health Organization (WHO). In addition to inadequate supply, most sub-Saharan Africa (SSA) nations fail to meet blood needs because many donated units are discarded due to contamination with transfusion-transmitted infections (TTIs). We sought to estimate the prevalence of TTIs, identify the risk factors for TTIs among blood donors, and identify

interventions to improve blood safety in southern African nations, particularly the nations of the South African Development Community (SADC).
We investigated prevalence and risk factors for TTIs, and blood safety improvements in the SADC region from PubMed/MEDLINE, Cochrane Library, and HINARI databases from January 1, 2011 to April 31, 2021. All investigations followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). In meta-analysis, we estimated the pooled TTIs prevalence and summarized using forest plots. A total of 180 articles published from the sub-Saharan Africa region were identified covering our three targeted themes. Of these 180 articles, only 27 (15%) focused on the SADC region. The overall pooled TTI prevalence estimate was 2.0% (95% CI: 1.0-3.0) and hepatitis B was the most prevalent TTI in the region (prevalence = 3.0; 95% CI: 2.0-5.0). The prevalence of HIV, HCV, and syphilis was 2.0%, (95%CI:1.0-4.0) 1.0% (95%CI:0.0-2.0), 2.0% (95%CI: 0.0-8.0) respectively. In general, replacement donors and first-time donors were more likely to be infected with TTIs than repeat donors. 12 articles explored blood safety in the region however, they vary greatly highlighting the need for more comprehensive research. Few publications were identified that were from the SADC region, indicating lack of research or resources towards improving quantity and quality of blood donation. TTI prevalence remains one of the highest in the world and blood safety recommendations vary across the region. More effort should be directed towards developing a cohesive regional blood transfusion policy and effective blood monitoring and evaluation strategies.

5852

THE REMOTE EMERGING DISEASE INTELLIGENCE NETWORK (REDI-NET): PREPARING FOR ZOONOTIC SPILLOVER THREATS

Nicole Achee[1], The REDI-NET Consortium[2]

[1]University of Notre Dame, Notre Dame, IN, United States

Spillover and zoonotic disease outbreaks of known and novel emerging infectious pathogens are becoming more frequent worldwide due to climate change, globalization and increased interaction among humans, domestic animals and wildlife within a shifting landscape. These outbreaks will inevitably continue into the foreseeable future. The Remote Emerging Disease Intelligence NETwork (REDI-NET) is a multisectoral, multidisciplinary Consortium with the overarching goal to quicken the timeliness in collecting and processing data from across a wide range of ecologies to guide appropriate response options. The REDI-NET is founded on a multi-year, phased approach to leverage pre-existing and real-time long read shotgun metagenomic sequencing surveillance outputs in a flexible, scalable data repository and computing platform to support detection of pathogens, estimate risk of exposure and guide policy-decisions on animal, environmental and public health. Our core objectives focus on leveraging partner expertise to fill gaps in existing surveillance efforts to include 1) strengthening infrastructure where capacity may need to be built and/or enhanced (remote research stations); 2) standardizing sample collection, storage, and testing processes for assurances in data rigor and big data management; 3) leveraging existing networks and health data to widen the global surveillance footprint; and 4) transferring knowledge on surveillance system activities and providing actionable data. Here we will present program successes to date from early phases and describe next steps in expanding the operational framework with broad applicability across international regions.

5853

KNOWLEDGE OF COVID-19 SYMPTOMS, TRANSMISSION, AND PREVENTION: EVIDENCE FROM HEALTH AND DEMOGRAPHIC SURVEILLANCE IN SOUTHERN MOZAMBIQUE, SEPTEMBER 2021-JANUARY 2022

Ariel Nhacolo[1], Zachary J. Madewell[2], **Jonathan A. Muir**[3], Charfudin Sacoor[1], Elisio Xerinda[1], Teodomiro Matsena[1], Quique Bassat[4], Cynthia G. Whitney[3], Inácio Mandomando[1], Solveig A. Cunningham[3]

[1]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [2]Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Emory University, Atlanta, GA, United States, [4]ISGlobal - Hospital Clínic, Unversitat de Barcelona, Barcelona, Spain

Over 230,000 COVID-19 cases and 2,200 deaths have been reported in Mozambique though March 2023. Understanding community members' knowledge and perception of SARS-CoV-2 transmission and prevention is essential for directing public health interventions to reduce disease spread and improve vaccination coverage. We describe knowledge of COVID-19 transmission, prevention, and symptoms among community residents in Mozambique. We conducted a cross-sectional survey among all households (n=33,087) in a Health and Demographic Surveillance System in Manhiça, Mozambique, at the tail end of the Delta variant wave in September 2021 to the peak of Omicron cases in January 2022. Principal components analysis was used to create scores representing knowledge of COVID-19 symptoms, transmission, and prevention. Multiple imputation and quasi-Poisson regression were used to examine associations between demographic characteristics and sources of COVID-19 information, and knowledge of COVID-19 symptoms, transmission, and prevention. Across this rural community, 98.2%, 97.0%, and 85.1% of household respondents reported knowing how COVID-19 could be prevented, that SARS-CoV-2 can cause disease, and how SARS-CoV-2 is transmitted, respectively. Most recognized symptoms were cough (51.2%), headaches (44.9%), and fever (44.5%). Most cited transmission mechanisms were droplets (50.5%) or aerosol (<5 μm diameter) (46.9%) from an infected person. Most cited prevention measures were handwashing (91.9%) and mask-wearing (91.8%). Characteristics associated with greater knowledge of symptoms, transmission, and prevention included having at least primary education, older age, employment, greater wealth, and Christian religion. Respondents who had had COVID-19 symptoms were also more likely to have knowledge of symptoms, transmission, and prevention. Community public health measures to reduce infectious disease transmission are contingent upon perceptions of risk and knowledge. These findings support the need for outreach and for community-engaged messaging to promote prevention measures, particularly among people with low education.

5854

DEVELOPMENT OF SINGLE DOMAIN ANTIBODY-BASED LUMINEX ASSAY FOR THE DETECTION OF SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS-2 IN CLINICAL SAMPLES

Victor A. Sugiharto[1], Hua-Wei Chen[1], Shuenn-Jue L. Wu[2], George P. Anderson[3], Lisa C. Shriver-Lake[3], Daniel Zabetakis[3], Ellen R. Goldman[3]

[1]Henry M Jackson Foundation, Bethesda, MD, United States, [2]Naval Medical Research Command, Silver Spring, MD, United States, [3]Naval Research Laboratory, Washington, DC, United States

Viruses from the genus Betacoronavirus have emerged in the 21st century. These viruses have high morbidity and mortality, starting with Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV) in 2002, Middle East Respiratory Syndrome Coronavirus (MERS-CoV) in 2012, and SARS-CoV-2, which is the causative agent of coronavirus disease-2019 (COVID-19) in 2019. Thus, there is a critical need for rapid, low cost, sensitive, and reliable diagnostic assays for these emerging viral diseases. The ideal assay format would be rapid and multiplexed, enabling the processing of many samples and simultaneously providing information on the presence

of known diseases, while also giving a warning for the possibility of a new emerging disease. High-throughput MagPlex assays have the advantage of being relatively fast and simple in comparison to PCR based formats, while providing the additional capability to be multiplexed. Single domain antibodies (sdAbs) provide an economical means to perform multiplexed assays which can be expanded to include additional assays as desired or tested in a serial manner. Here, we developed a bead-based assay using sdAbs against SARS-CoV-2 nucleocapsid (N) protein. Additionally, we also used SpyTag/SpyCatcher system to improve the sensitivity of the assay. The sdAb-coated beads were able to detect N protein down to 10 ng/mL, however by using SpyTag/SpyCatcher system to orient the sdAbs on the beads, we were able to increase the sensitivity 10-fold to 1 ng/mL. We further assessed the sensitivity and specificity of the assay by using COVID-19 and seasonal coronavirus clinical samples. Both regular sdAb-coated and SpyTag/SpyCatcher sdAb-coated beads were able to specifically detect SARS-CoV-2 in the samples with SpyTag/SpyCatcher sdAb-coated beads performing better. In summary, we provide a proof-of-concept that bead-based assay to detect SARS-CoV-2 is feasible and future research by combining it with other sdAb-coated beads that can detect other coronaviruses may be a useful tool in responding to future pandemics.

5855

COVID-19 SELF-TESTING: A PROMISING OPPORTUNITY FOR LOW AND MIDDLE INCOME COUNTRIES, YET A REALITY CHECK OF GLOBAL INEQUALITIES

Melody Sakala[1], James Chirombo[1], Jilian Sacks[2], Cherly Johnson[2], Rachel Baggaley[2], Titus Divala[3]

[1]Malawi Liverpool Wellcome Trust, Blantyre, Malawi, [2]World Health Organization, Geneva, Switzerland, [3]Kamuzu University of Health Sciences, Blantyre, Malawi

The widespread use of antigen-detection rapid diagnostic tests has revolutionized the decentralized testing and self-testing of COVID 19. However, the full extent of AgRDT utilization for self-testing remains largely unexplored. To provide vital information for the development of the recently released global guidelines on COVID 19 self-testing, we conducted a cross-sectional survey targeting policy makers, researchers, and implementers worldwide. The survey was shared through professional networks via email and social media. We used questions related to policy and program information concerning the regulation, availability, target population, indications, implementation, benefits, and challenges of COVID 19 self-testing. Descriptive summaries, cross-tabulations, and proportions were used to calculate outcomes at the global level and by World Bank region and income classifications. Between 01 and 11 February 2022, 844 individuals from 139 countries responded to the survey . 504 respondents from 101 countries reported policies supporting COVID 19 self-testing for a range of use cases, including symptomatic and asymptomatic populations. Significantly, more respondents from low-and-middle-income countries than high-income countries reported a lack of C19ST policy (61 vs 11 countries) and low population-level reach of C19ST. Respondents with COVID 19 self-testing experience reported that the tests were mostly acceptable to target populations, provided significant programmatic benefits, and highlighted several key challenges to be addressed for increased success. While the widespread global interest, policy support, and implementation of COVID 19 self-testing demonstrate an opportunity for bridging the testing gap experienced by LMIC populations, the unequal access exposes the realities of global inequalities. There is urgent need for Global Health actors to sustainably address unequal access to lifesaving interventions especially during high consequence epidemics. Benefits, challenges and opportunities shared by respondents should inform development of national and global policy.

5856

ENVIRONMENTAL HYGIENE FOR HOSPITAL INFECTION PREVENTION AND CONTROL MANAGEMENT IN BANGLADESH: EDUCATING HOSPITAL CLEANING STAFF REQUIRES PRIORITY

Shariful Amin Sumon[1], Md. Saiful Islam[2], Syed Abul Hassan Md Abdullah[3], Fairoze Masuda Akther[1], Md. Golam Dostogir Harun[1]

[1]icddr,b, Dhaka, Bangladesh, [2]School of Public Health & Community Medicine, UNSW, Sydney, Australia, [3]SafetyNet, Dhaka, Bangladesh

Cleaning staff is a critical part of the hospital infection prevention and control (IPC) program. Despite involvement in environmental hygiene management including patient care, cleaning staff are often overlooked in education and training, resulting in a lack of optimal IPC and hygiene knowledge. This study assessed the existing knowledge and practices regarding IPC and environmental hygiene among cleaning staff at tertiary hospitals in Bangladesh. Between July and December 2022, a cross-sectional study was conducted at six tertiary hospitals among randomly selected 259 cleaning staff involved in hospital environmental cleaning and waste management. Data was collected through face-to-face interviews using a semi-structured questionnaire, and descriptive statistics were used for analysis. The mean age of participants was 36.7 years (SD 10.1) and the majority (65.6%, 170/259) were outsourced workers. None of the cleaners had obtained any formal orientation or training on hygiene from the hospital. Four-fifths (78.4%) of those polled had not received any basic IPC training in the previous two years. Only 7% (18/259) of respondents were aware of the standard cleaning agent-to-water ratio for environmental cleaning. Approximately 15% of respondents correctly identified specific color-coded waste disposal bins. As precautionary measures for IPC management, one-third (35.9%, 93/259) mentioned hospital waste management and environmental cleanliness. Less than half (46.3%, 120/259) of cleaning personnel considered performing hand hygiene (HH) required after contact with patients and surroundings, but 17% (44/259) reported practicing HH in hospitals for these purposes. Only about one-third (29%) of cleaners weekly disinfected high-touch areas, but once a month for low-touch areas of the hospital. The cleaning staff lacked basic knowledge and standard practices on IPC and environmental hygiene in Bangladesh. Establishing environmental hygiene guidelines, hands-on orientation, and refresher training including routine monitoring can enhance the level of skilled cleaning staff for hospital IPC management.

5857

ONE HEALTH BIOSECURITY: DEVELOPING RECOMMENDATIONS TO ADDRESS LEGISLATIVE GAPS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Alanna Fogarty[1], Emilie Ryan-Castillo[1], Kanika Kalra[1], Kaitlin Sandhaus[2], Tura Galgado[3], Erin M. Sorrell[4], Claire J. Standley[1]

[1]Georgetown University, Washington, DC, United States, [2]Global Implementation Solutions, Chicago, IL, United States, [3]Global Implementation Solutions, Nairobi, Kenya, [4]Johns Hopkins University, Baltimore, MD, United States

Strong whole-of-government biosecurity systems are critical for supporting biological threat reduction efforts. Legislative and regulatory frameworks ensure successful implementation, sustainability, and alignment of these systems with international agreements, including the International Health Regulations and the Biological and Toxin Weapons Convention. The extent to which legislative support for biosecurity systems is successful can vary based on national or regional governance structures, stakeholder capacity and available resources, which itself requires a robust understanding of a country's existing legislative landscape prior to any capacity-strengthening efforts. In support of the Global Partnership's Signature Initiative to Mitigate Deliberate Biological Threats in Africa, we developed a methodology for assessing national legislative landscapes with respect to a broad definition of biosecurity, through a One Health lens, which we then piloted in the Democratic Republic of the Congo (DRC). Through implementation of the methodology, we mapped and analyzed existing national and sub-national

legislation, regulations, and other applicable policy documents, and also engaged key informants to provide additional contextual information relating to awareness and implementation of key legislation. We convened national stakeholders, together with regional and international experts, to validate the analysis findings, and to develop recommendations and an action plan for strengthening DRC's biosecurity legislative structures. We demonstrate that our methodology is an effective approach to biosecurity legislative assessment, which can be adapted for use in other countries, thus making it a useful contribution to global health security scholarship and practice.

5858

BURIAL SITE SURVEILLANCE TO MONITOR EXCESS MORTALITY DURING THE COVID-19 PANDEMIC IN KARACHI, PAKISTAN

Abdul Momin Kazi[1], Raheel Allana[1], Muhamamad Taha Faruqui[1], Nazia Ahsan[1], Obianuju Genevieve Aguolu[2], Saima Jamal[1], Christina Arif[1], Ayub Khan[1], Saad B. Omer[2]

[1]Aga Khan University, Karachi, Pakistan, [2]Yale University, New Haven, CT, United States

Population death rates are an important measure of health status and Pakistan is among those countries which has a poor functioning national system of registering deaths and determining their causes. In the context of the COVID-19 pandemic, accurate documentation of fatalities became even more critical. Without accurate data on the number of fatalities and their distribution, it becomes a challenge to track the progression of the pandemic and determine the effectiveness of interventions such as lockdowns, social distancing, and vaccination programs. In this regard, our study aims to identify and monitor disparities in COVID-19 fatalities and their causes by using burial site surveillance in Karachi, Pakistan, which involves collecting both retrospective (2016-2021) and prospective (2022 onwards) data which will be collected till June 2023 from graveyards and morgues. Surveillance process includes data from graveyard registries and verbal autopsy using the WHO verbal autopsy questionnaire. The study's results indicated that among the total deaths (N=161,142), mortalities observed in the year 2021 were 37,778 followed by 2022 (36,719), 2020 (35,858), 2019 (27,018) and data observed between 2016-2018 were 24,119 with work in progress. Majority of fatalities occurred in individuals aged 65-74 (age adjusted mortality ratio = 0.1960) and that among the seven districts of Karachi, Karachi Central had the highest mortality proportion (1922/100,000). Further we found 1612 fatalities attributed to COVID-19, and males exhibited a greater prevalence of mortality than females (64% vs. 36%). Also, 469 cases were recorded in individuals aged between 65-74 indicating elderly population was more vulnerable to COVID-19 related deaths. As compared to pre-surveillance mortality data, there was an increase of 2-4 standard deviation in mortalities during COVID-19 pandemic. In conclusion, most of the deceased in Pakistan are buried as part of religious and cultural norm. Hence mortality data can be a good indicator to understand increase in mortality rates during COVID-19 pandemic and can be used to measure the burden of mortalities during pandemic.

5859

AN ETHNOGRAPHIC APPROACH TO UNDERSTAND THE FEASIBILITY OF GRAVEYARD SITE SURVEILLANCE TO ASSESS EXCESS MORTALITY IN A RESOURCE CONSTRAINT SETTING

Fauzia Aman Malik[1], Nazia Ahsan[2], Rawshan Jabeen[2], Saima Jamal[2], Raheel Allana[2], Saad B. Omer[1], Abdul Momin Kazi[3]

[1]Yale University, New Haven, CT, United States, [2]Aga Khan University, Karachi, Pakistan, [3]Aga Khan University, karachi, Pakistan

Population mortality is a crucial statistic that combines data from several risk factors to provide a single measure of public health. This study provides insights related to ethnographic data collection of major graveyards in Karachi, Pakistan from November 2021 to April 2022. The main objective of this study was to understand the process of death to burial in graveyards belonging to various religious and ethnic groups. Qualitative interview guides were developed to interview various stakeholders, including graveyard caretakers (121), ethnic groups (46), Karachi Metropolitan Corporation officials (15), funeral bus/ambulance services staff (9), family members of deceased individuals (4) and NGOs (2). We found that burial of the deceased was the most commonly practices and culturally accepted method in different religions e.g., Muslim, Christianity and Hinduism. We found that obtaining death certificates and registration involved providing a copy of the deceased individual's National Identity Card. However, the process was faster for deceased children which led to incomplete documentation. For obtaining death registration and certificate, union council facilitate urban areas and union committee for peri-urban areas. We found different perspectives related to the cause of death (COD) e.g., parents expressed their curiosity to know the COD of their children, and hospitals shared this information as well. However, it was deemed unethical to disclose the COD when it occurred at community setting. The data explored the concept of doubling graveyards and reasons were lack of space and desire to be buried near ancestors and ease in visit. Data identified the potential graveyards, stakeholders, and information about death records. Further, confidentiality of death record was found as major obstacles among few communities and civilians. In conclusion, this is a unique ethnographic information related to graveyard and burial process in a resource constraint setting. Further the study will also help in exploring social/cultural context related to a mortality surveillance in a community setting.

5860

THE RELATIONSHIP BETWEEN PRE-EXISTING COMORBIDITIES AND IN-HOSPITAL CARDIOVASCULAR EVENTS AMONG COVID-19 PATIENTS IN BANGLADESH: A PROSPECTIVE COHORT STUDY

Farzana Islam[1], Shahin Akter[1], Abdul Wadud Chowdhury[2], Mohammad Robed Amin[3], Dorairaj Prabhakaran[4], Kavita Singh[4], Karen Sliwa[5], Pablo Perel[5], Lana Raspail[5], Tippawan Liabsuetrakul[6], Md Shamim Hayder Talukder[1]

[1]Eminence Associates for Social Development, Dhaka, Bangladesh, [2]Dept. of Cardiology, Dhaka Medical College, Dhaka, Bangladesh, [3]Department of Non communicable Disease Control Program, Directorate General of Health Service of Bangladesh, Dhaka, Bangladesh, [4]Public Health Foundation of India (PHFI), New Delhi, India, [5]World Heart Federation, Geneva, Switzerland, [6]Department of Epidemiology, Prince of Songkla University, Hat Yai, Thailand

The first case of SARS-CoV-2 was detected on 8 March 2020 in Bangladesh just before 03 days of the announcement of coronavirus global pandemic by World Health Organization. As of March 16, 2023, a total of 2,037,947 cases have been confirmed, resulting in 29,445 deaths. Cardiovascular disease (CVD) and diabetes are scientifically recognized as major risk factors for poor prognosis and fatalities. Bangladesh has the highest prevalence of CVD risk factors among South Asian countries. Majority of the studies on Covid-19 conducted in Bangladesh were related to clinical symptoms, mental health and impact on health systems and scarcity in data exists on the CVD risk factors and outcome of the hospitalized Covid-19 patients. Therefore, a prospective cohort study was conducted as a part of multi-country project to explore the relationships between cardiovascular risk factors and preexisting comorbidities to the cardiovascular in-hospital events of covid-19 patients. Data were collected from 897 adult Covid-19 PCR positive patients of 3 hospitals at the time of hospital admission and at 30 days, discharge or death. Statistical analysis was done using epicalc R package, Descriptive analyses and multivariable log-binomial regression models, adjusted for age, sex, risk behavior and clinical events were performed. Mean & maximum age was 18 and 96 respectively, 52.1% female, 54.8% patients with cardiac comorbidities and the most common preexisting comorbidities were hypertension (54.1%) and diabetes (44.1%). Almost one fifth of the patients developed cardiac events including Myocarditis (0.7%), Myocardial Infarction (3.5%), Pericarditis (0.6%), Acute Heart Failure (6.1%), Endocarditis (0.4%), Atrial Fibrillation (0.2%), Cardiac Arrest (8.0%), Shock (1.0%) and Cardiac Blocks

(0.8%). The predictors of overall in-hospital cardiac events included male sex, overweight, lower education level (<college/university), former smoker, heart rates and low SPO2 ($p < 0.05$ for each). This study provides robust evidence on COVID-19 in-hospital cardiac events which guides future health care preparedness on cardiac emergency for the pandemic globally.

5861

PATTERNS OF DATE PALM SAP HARVESTING AND TRADING PRACTICES AND RISK OF NIPAH VIRUS TRANSMISSION AT COMMUNITIES IN BANGLADESH

Abdul Khaleque Md. Dawlat Khan[1], Ariful Islam[2], Shusmita Dutta Choudhury[1], Md. Zulqarnine Ibne Noman[1], Nabila Nujhat Chowdhury[1], Sarah Munro[2], Maryska Kaczmarek[2], Meerjady Sabrina Flora[3], Tahmina Shirin[1], Jonathan H. Epestein[2]

[1]Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh, [2]EcoHealth Alliance, New York, NY, United States, [3]Directorate General of Health Services, Ministry of Health and Family Welfare, Dhaka, Bangladesh

Bangladesh has been experiencing a nearly annual Nipah virus (NiV) outbreak through drinking contaminated raw or fermented date palm sap (RDPS) with bat excreta since 2001. RDPS harvesting practices and trading patterns have not been explored extensively. Hence, we conducted a study to understand RDPS collection, consumption, and selling practices and the risk of NiV spillover at the community level. We performed an explorative qualitative study in two NiV outbreak districts, Rajbari and Naogaon, between 2021 and 2022. We recorded participant observations (n=14) and conducted ethnographic interviews (n=31) with RDPS collectors (Gacchi) on collecting and selling practices and using diversity of protective apparatus. The interview data were analysed using coding and thematic analysis based on the grounded theory approach. Gachi prefers selling RDPS more than making molasses due to time consumption, fuel costs of preparing it, and the high demand for consuming RDPS. They informed RDPS selling is not limited to their local community and sale distends location of non-harvesting areas based on customer demand through a middleman, which increases the transmission risk of NiV and other bat-borne diseases in wider geographical areas. We observed, and participants reported that Pteropus and non-Pteropus bats and rodents visited the trees and drank RDPS. They are replacing clay pots with discarded plastic pots, due to the free cost. They also prefer to use non-conventional protective apparatuses like jute bags, plastic bags, and nylon nets due to the time and resources to prepare bamboo skirts. Moreover, they reported that bats scratched out bamboo skirts and trunks to lick sap. We recommend adopting a culture-sensitive intervention, including efficacy tests of bat access protection on several apparatuses with economic outcomes of the date palm sap harvesting practices to prevent spillover of NiV and other bat-borne emerging viruses in Bangladesh.

5862

UNDERSTANDING VACCINE HESITANCY IN BOENDE, WESTERN DR CONGO: A MIXED-METHODS STUDY

Maha Salloum[1], Antea Paviotti[1], Freddy Bikioli Bolombo[2], Nana Emuka[3], Hypolite Muhindo-Mavoko[2], Patrick Mitashi[2], Hilde Bastiaens[4], Pierre Van Damme[5], Jean-Pierre Van geertruyden[1]

[1]Global Health Institute, Department of Family Medicine and Population Health, University of Antwerp, Wilrijk, Belgium, [2]Tropical Medicine Department, University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [3]Division Provinciale de la Santé de la Tshuapa, Boende, Congo, Democratic Republic of the, [4]Department of Family Medicine and Population Health, University of Antwerp, Wilrijk, Belgium, [5]Centre for the Evaluation of Vaccination, Vaccine and Infectious Disease Institute, University of Antwerp, Wilrijk, Belgium

In 2019, WHO identified vaccine hesitancy as one of the top 10 global health threats. Reports following the SARS-COV-2 pandemic indicate a general decline in trust in vaccines, including routine childhood vaccination. The Democratic Republic of Congo (DRC) has a low childhood vaccine coverage (around 50%) and one of the world's highest mortality rates of children under 5 at 79 deaths per 1000 live birth. While previous studies showed a good level of confidence in the safety and importance of vaccines in the country, they relied on data that was mainly quantitative and/or focused on urban areas. To address this gap, we conducted a mixed-method study in Boende, Tshuapa province (western DRC), and surrounding villages in the Boende health zone. The region was hit by an Ebola outbreak in 2014 and witnessed COVID-19 restrictions between 2020 and 2022. Boende was the site of the EBL2007 Ebola vaccine trial between 2019 and 2022. Alongside this vaccine trial, we aimed to explore perceptions and attitudes towards childhood and adult vaccination through individual interviews and focus groups with people living in Boende (mostly non-participants of the trial), as well as a 30-cluster survey covering the entire health zone of Boende. Our analysis revealed that adult vaccines appear to be less trusted than childhood vaccines, with Covid-19 vaccines being the least trusted, most likely due to the low number of related hospitalizations and deaths in the region. The majority of interviewees in Boende stated that their children are vaccinated. Nonetheless, over half of the interviewees expressed concerns about the common side effects of childhood vaccines or had doubts about the storage conditions of these vaccines, others believed that vaccines were given only to people living in Africa and not White people. These reasons were found to deter some study participants and their acquaintances from vaccinating their children. These findings could be used to inform future vaccination and sensitization campaigns in the region by addressing common concerns and misconceptions about vaccines, particularly for adults, to increase trust in and uptake of vaccines.

5863

PERCEPTIONS ON ACCEPTANCE AND BARRIERS RELATED TO MORTALITY SURVEILLANCE FOR DRY NASAL SWAB PROCEDURE RELATED TO COVID-19 IN PERI-URBAN SETTINGS, PAKISTAN

Nazia Ahsan[1], Abdul Momin Kazi[1], Shaheen Mehboob[1], Rawshan Jabeen[1], Farzana Aziz[1], Saima Jamal[1], Saad Bin Omer[2], Obianuju Aguolu[2], Fauzia Malik[2]

[1]Aga Khan University, Karachi, Pakistan, [2]Yale University, USA, CT, United States

COVID-19 is a major public health threat, declared a pandemic by WHO in January 2020. Understanding community perceptions of the disease and its associated mortalities is crucial for protection and planning in LMICs. The objective of the study was to investigate the community perceptions about dry nasal swab procedure for COVID related mortality surveillance in peri-urban settings of Pakistan. This exploratory study design was used to conducted eleven focus group discussions (FGD)with various Muslim ethnicities residing in Ali Akbar Shah, an urban slum area on the outskirts of Karachi, including parents, religious leaders, community leaders, graveyard caretakers, traditional birth attendants, bathers, and community health workers. Three qualitative main themes were identified, namely the community's health-seeking behavior towards COVID-19, the understanding of death rituals in Muslim ethnicities and feasibility of obtaining dry nasal swab samples. Various perceptions were reported on COVID-19 spread e.g. getting vaccination and follow COVID-19 SOPs, while others remained unsure and stated "Covid-19 is there in the entire world, there is no doubt in this, but it is not here in our area .We have never seen it in two years, so we consider it all a lie" (Graveyard caretakers). Further, we explored that in Muslim communities before burial, a body is ritually washed which involves using cotton to clean the nostrils of the deceased and taking a dry nasal swab sample at the time of burial bath would be religiously and contextually acceptable. The findings revealed that the approach to the family elder and parents prior to the sample collection would be a better strategy to implement mortality surveillance, to overcome perceived barriers such as pain to the body, unethical and disrespectful to deceased and grief amongst families. In conclusion, Mortality surveillance studies within community setting is difficult to execute however, community buy-in and liaison with key stakeholders are essential. In addition, community grief support and counselling after death would be beneficial.

METAGENOMIC DETECTION OF PATHOGENIC BACTERIA IN TICKS FROM ISIOLO AND KWALE COUNTIES IN KENYA

Bryson B. Kimemia[1], Lilian Musila[2], Solomon Lang'at[3], Stephanie Cinkovich[4], Jaree Johnson[5], Samoel Khamadi[3], Eric Garges[6], Elly Ojwang'[2], Fredrick Eyase[2]

[1]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, [2]Department of Emerging Infectious Diseases, Nairobi, Kenya, [3]Kenya Medical Research Institute, Centre for Virus Research, Nairobi, Kenya, [4]Armed Forces Health Surveillance Division, Global Emerging Infections Surveillance Branch, Silver Springs, MD, United States, [5]Armed Forces Pest Management Board, Silver Springs, MD, United States, [6]Department of Emerging Infectious Diseases, United States, Silver Springs, MD, United States

Ticks are arachnid ectoparasites that are second only to mosquitoes in the transmission of human diseases including bacteria responsible for anaplasmosis, ehrlichiosis, spotted fevers, and Lyme disease among other febrile illnesses. Due to paucity of data on bacteria transmitted by ticks in the Kenya, the present study undertook a bacterial metagenomic-based characterization of ticks collected from Isiolo, a semi-arid pastoralist county in Eastern Kenya and Kwale a county in coastal Kenya. Bacterial 16S rDNA PCR amplicons obtained from the above samples were sequenced using the MinION (Oxford Nanopore Technologies) platform yielding 547,780 reads with a median length of 1.54kb. The resulting reads were demultiplexed in Porechop, followed by trimming and filtering in Trimmomatic before clustering into OTUs using Qiime2-VSearch. A SILVA database pretrained naïve Bayes classifier was used to taxonomically classify the OTUs. A total of 2,918 ticks belonging to 3 genera and 10 species were screened in the present study. The pathogenic bacteria detected in pooled tick assays were as follows: Rickettsia spp. 59.43% of pools, Coxiella burnetii 37.88%, Proteus mirabilis 5.08%, Cutibacterium acnes 6.08% and Corynebacterium ulcerans 2.43%. These bacteria are responsible for spotted fevers, query fever, urinary tract infections, eye infections and diphtheria-like infections respectively. P. mirabilis, C. acnes and C. ulcerans were detected only in Isiolo. Metabarcoding was carried out on the tick species from which bacteria were detected showing that from Isiolo Hyalomma truncatum had the highest number of bacterial species at 12 while from Kwale Rhipicephalus boophilus decoloratus had the highest number of bacterial species at 6. The detection of Cutibacterium acnes, commonly associated with human skin flora suggests that the ticks may have contact with humans thus exposing them to infections caused by the identified bacteria. The findings in this study highlight the need for increased surveillance of tick-borne bacteria to discern their public health burden.

ENGAGING ANTHROPOLOGY IN NIPAH OUTBREAK: FACTS BEHIND THE HUMMING

Kamal Ibne Amin Chowdhury[1], A.K.M. Dawlat Khan[2], Utpal Kumar Mondal[1], Md. Wasik Rahman Aquib[1], Shusmita Dutta Choudhury[2], Mohammad Ariful Islam[1], Muhammad Rashedul Alam[1], Md Nazrul Islam[1], Arifur Rahman Bablu[1], S.M. Zafor Shafique[1], Md. Arif Khan[2], Nisharggo Niloy[1], Monybur Rahman[1], Ariful Islam[3], Ahmed Nawsher Alam[2], Mahbubur Rahman[2], Ahmad Raihan Sharif[2], Sharmin Sultana[2], John D. Klena[4], Mohammed Ziaur Rahman[1], Sayera Banu[1], Joel M. Montgomery[4], Tahmina Shirin[2], Syed Moinuddin Satter[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh, [3]EcoHealth Alliance, New York, NY, United States, [4]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Anthropological approaches play a pivotal role in outbreak investigation by bringing forth sensitive, tabooed, or stigmatized practices, behaviors, and contexts interconnected with the disease paradigm. Unanticipated situations such as the spread of rumors, public panic, uncontrolled prevalence of obscure and misinterpreted information in the community, cause psychological and emotional tensions during an outbreak. In the 2023 Nipah Virus (NiV) outbreak in Bangladesh, a combined team of anthropologists from the Institute of Epidemiology Disease Control and Research (IEDCR) and icddr,b embedded the rumor management method concurrently to tackle unforeseen situations. Alongside functioning anthropological approaches, we especially focused on documenting the 'rumors' spread from social media and communities. We included both human experts and human-computer methods. This year the situation started off with 2-3 Nipah cases similar to other years, and no one was alarmed considering the situation as 'normal'. However, with the increasing number of cases, people's reactions and perceptions changed. Old-aged people were prone to dismiss the linkage between NiV and drinking raw date palm sap (DPS). The young generation apprehended drinking raw DPS as a challenge and started representing this as a trend on social media. Some business groups capitalized on the idea by promoting people through advertising on various social platforms. In some communities, people barely perceived the connection between drinking raw DPS with bats and disease transmission, as they are more used to seeing the abundance of bats in the lychee season. Besides, there was diversion and reluctance among community people to talk about this due to the presence of the media. In this context, along with documenting the then-prevailing rumors, beliefs, and perceptions, we followed the 'slow science' method and invested quality time to observe, listen, build rapport, and then collected data. Sharing the experiences gained through anthropological methods during outbreak investigation in the global forum can generate new risk communication and prevention initiatives.

5866

SURVEILLANCE OF ACUTE FEBRILE ILLNESS IN JORDAN DURING THE TIME OF PANDEMIC OF COVID-19

Mayar Said[1], Mahmoud Gazo[2], Mohammad Alhawarat[3], Bassem Hamdy[1], Omar Nowar[1], Samuel Y. Levin[1], **Tamer Saied Osman**[1]

[1]US Naval Medical research Unit#3, Cairo Detachment, Cairo, Egypt, [2]CPHL, Ministry of Health, Jordan, Amman, Jordan, [3]Communicable disease Dirctorate, Ministry of Health, Jordan, Amman, Jordan

Surveillance of Acute Febrile Illness (AFI) during the pandemic is important to understand the burden of the infectious diseases presenting with fever, which is also a common presentation of COVID-19 cases. In Jordan, AFI surveillance started in June 2020, in 2 tertiary care hospitals in the north, and south of the Kingdom. It was expanded to a third hospital in the middle in September 2021 and to 2 other hospitals in the northwest in June 2022. Cases that require hospitalization presenting with current or history of fever (≥ 38Co) within 10 days before admission with no identified origin, were enrolled, and leftovers of their clinical samples of blood were tested at the Central Public Health laboratory using a multiplex qrt-Polymerase Chain Reaction of 15 pathogens, in addition to PCR testing for SARS-CoV2. Blood culture results were recorded if requested. Through January 2023, a total of 890 patients were enrolled. Male gender constituted 55.2 % (491/890) of cases and median age was 3 years old. Median duration of hospitalization was 4 days. Eight cases died during hospital admission with 0.9 % mortality rate. Out of 890 samples, a total of 157 pathogens were detected in only 15.8% (141/890) of the samples. Of the 157 pathogens detected, Epstein Barr Virus was most frequently detected (42 %) followed by Cytomegalovirus (21.7%) and Human Adenovirus (12.1%). Arboviruses were detected in 8 samples (West Nile virus 6 samples, and one sample of Dengue and Rift Valley virus each). None of the samples tested positive for Zika virus. SARS-CoV2 was detected in only four samples. Other pathogens including Salmonella (6 samples), Leptospira and Brucella (2 cases each), Rickettsia Spp. and Coxiella burnetii (one sample each) were also identified. Expanding the surveillance to mild to moderate cases (e.g., outpatients) is planned to comprehensively describe the epidemiology of AFI in Jordan. Integration of the results with other surveillance programs such as vector surveillance is implemented to provide enhanced data to improve public health and accompanying health risk mitigation knowledge, as well as augment national control measures in Jordan and the region.

5867

IMPLEMENTING A "TEST AND TREAT" STRATEGY FOR COVID-19 IN BOLIVIA AND PARAGUAY: LESSONS AND CHALLENGES

Cristina Alonso-Vega[1], Beatriz Mallén-Muñoz[1], Elizabeth de Jesús Posada-Diago[1], Luis Antonio Villarroel-Peñaranda[2], N. Regina Rabinovich[1]

[1]Barcelona Institute for Global Health, ISGlobal, Barcelona, Spain, [2]QUATRIM, Cochabamba, Bolivia, Plurinational State of

Prompt diagnosis of COVID-19 is a key intervention for COVID-19 clinical care and control. The ECO project was designed to enhance the coverage of diagnosis of COVID-19 in Bolivia and Paraguay. We carried out a formative assessment of the national capacities to implement, scale-up and track the use of Rapid Diagnostic Tests (RDTs). When oral treatments became available, this was further built into a 'test and treat' strategy for implementation in selected districts in each country, in collaboration with district leaders, clinics, and the Ministry of Health. The formative assessment identified factors associated with community hesitancy to access COVID-19 diagnostics, but also others that could facilitate diagnosis, including the impact of availability of effective treatment to prevent progression in high risk patients. Catalytic implementation in each country with distribution of 20,000 RDTs to health facilities and health posts afforded the opportunity to track how the supply chain was managed, distribution prioritized, obtaining timely data between first symptom, testing and results to the patient, status of training, and patient follow-up. The findings were built into an implementation strategy, along with enhanced data reporting and visualisation, and carried out in parallel with a communication campaign co-created with the community and the health centres. Despite the delays in access of COVID-19 treatments such as Tocilizumab and subsequently oral drugs, these have begun to reach both countries. The systems to diagnose, identify high risk groups, and deliver drugs have been put in place. We will present the evaluation data on planned endpoints for tracking acceptability and uptake of diagnosis and medicines, including time from diagnosis, which is critical for use of the new oral drugs. In addition, significant progress was made on systems for data capture and visualization, community engagement and communication strategies, and pandemic preparedness, which might extend beyond the duration of the project. Finally, we will summarize lessons learned in the midst of the COVID-19 pandemic in two LMIC Latin American countries.

5868

COVID 19 KNOWLEDGE, ATTITUDES, PRACTICES (KAP) AND MENTAL HEALTH BEHAVIORS IN LIBERIA: FINDINGS, IMPLICATIONS AND FUTURE DIRECTIONS

Stephen B. Kennedy[1], Laura J. Ridge[2], **Hannah Berrian**[1]

[1]UL-PIRE Africa Center, University of Liberia, Monrovia, Liberia, [2]University of Michigan, Ann Arbor, MI, United States

Evidence from the WHO revealed that age, comorbid medical conditions, gender, and occupations are risk factors for CoVID 19. Limited information exist in Liberia on population-based risks. The CoVID 19 outbreak led to the implementation of public health guidelines by the Ministry of Health to protect the health and welfare of the general population. However, risk reduction messaging and risk communication strategies were inconsistent, unclear and non-compliance. Also, there existed significant community distrust in CoVID 19 public health information dissemination channels, limited integration of community structures in the national mitigation strategies and significant increase in public perceptions about conspiracy theories in the country. We conducted a cross-sectional study with multi-stage sampling frame among 250 adult males and females from primary CoVID 19 hotspots in Liberia based on the WHO's Conceptual Framework for Action on Social Determinants of Health. The specific aims were to determine the prevalence of (1) CoVID 19 related knowledge, attitudes, practices and behaviors, (2) CoVID 19 risk factors, and (3) mild-to-moderate mental health related disorders, and (4) the involvement and integration of urban and rural community structures in the primary epicenter in the mitigation of public health outbreaks in Liberia. The study findings revealed a mean age of 34 years, 60% urban and 40% rural, equal proportion of males and females, and majority single and employed, with evidence of formal education. The findings clearly demonstrated that CoVID 19 negatively affected health and social services, employment and lost wages, especially in rural settings; that there was no correlation between CoVID 19 Knowledge and Practices; that rural residence and women were better predictors of CoVID 19 Knowledge, and that depression and anxiety were associated with lower adherence to CoVID 19 prevention practices. We recommend that future research studies may be warranted in post-conflict Liberia to better understand the social determinants and effects of disease outbreaks, and its related impacts, on health equity.

5869

COMMUNITY ENGAGEMENT IN EPIDEMIC MANAGEMENT: AN ANALYSIS OF THE EBOLA VIRUS DISEASE AND COVID-19 RESPONSES IN BOENDE, WESTERN DR CONGO

Bikioli Bolombo Freddy[1], Maha Salloum[2], Antea Paviotti[2], Muhindo Mavoko Hypolite[3], Mitashi Mulopo Patrick[4], Hilde Bastiaens[5], Pierre Van Damme[6], Jean-Pierre Van Geertruyden[5]

[1]Department of Tropical medicine, University of Kinshasa; Global Health Institute and Centre for the Evaluation of Vaccination, University of Antwerp, Antwerp, Belgium, [2]Global Health Institute and Centre for the Evaluation of Vaccination, University of Antwerp, Antwerp, Belgium, [3]Department of Tropical Medicine, University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [4]Department of Tropical medicine, University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [5]Global Health Institute, University of Antwerp, Antwerp, Belgium, [6]Centre for the Evaluation of Vaccination, University of Antwerp, Antwerp, Belgium

In 2020, the WHO identified several challenges to the simultaneous management of Ebola virus disease (EVD) and COVID-19 in low and middle-income countries, including health systems' overload, international coordination, and communication between response teams and affected communities. Between 2020-2022, the Democratic Republic of Congo (DRC) faced 6 EVD outbreaks while also battling the COVID=19 pandemic. Recent publications highlight that the experience gained during EVD outbreaks has facilitated the implementation of prevention and control measures against COVID19. These publications primarily focus on national-level management and are often narrative reviews. To better understand how DCR's response to COVID-19 built on previous experiences of EVD management, we conducted a qualitative study in Boende (Tshuapa province, western DRC), which faced an EVD outbreak in 2014, hosted the EBL2007 Ebola vaccine trial between 2019-2022, and is currently dealing with COVID-19. We reviewed relevant literature, including official documents, and interviewed healthcare providers, health authorities, political authorities who were actively involved in managing both diseases in Boende, as well as members of the affected community. We found that community leaders (local authorities, religious leaders, teachers, and the relais communautaires, community members trained in health surveillance and communication) played a central role in community-based surveillance, both during the EVD management and in the fight against COVID-19. However, during the EVD response, community leaders were extensively trained on EVD and risk communication and provided with bicycles, communication material, and a financial motivation. During the COVID-19 response, their involvement was rather limited to informing communities of the existence of the disease. This may partially explain the low level of community engagement in the fight against COVID-19. These findings suggest that the role of community leaders should be reconsidered in order to gain community engagement in community-based surveillance and thus improve future outbreak management.

5870

PERCEPTIONS OF PREVALENCE, IMPACT, AND MANAGEMENT OF POST-ACUTE SEQUELAE OF SARS-COV-2 INFECTION AMONG HEALTHCARE WORKERS IN KWENENG DISTRICT, BOTSWANA

Tebogo Tebalo Mamalelala[1], Savannah Karmen-Tuohy[2], Lettie Chimbwete[3], Ditebogo J. Mokone[4], Terrence Mukhuwa[4], Roger Shapiro[5], Sara Schwanke Khilji6[6]

[1]university of Botswana, Gaborone, Botswana, [2]NYU Grossman School of Medicine, New York, NY, United States, [3]University of Pretoria, pretoria, South Africa, [4]Ministry of Health, Gaborone, Botswana, [5]Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana, [6]Oregon Health & Science University., Gaborone, OR, United States

Since March 2020, over 760 million confirmed cases of COVID-19 infection have been identified, with 9.5 million recorded in Africa. Post-acute sequelae of SARS-CoV-2 infection (PASC) affects an estimated 32% to 87% of COVID patients globally. Data regarding the current prevalence and impact of PASC in Botswana are limited. Utilizing a cross-sectional survey design, we surveyed healthcare workers about the perceived prevalence of PASC, the duration of and characterization of common symptoms, the impact of PASC symptoms on patients' daily lives, and current management strategies. The survey was disseminated to healthcare workers via pre-existing WhatsApp groups and on paper. A total of 79 respondents completed the survey, from an estimated 650 staff meeting eligibility criteria (12% participation). Of these, 91% provided informed consent; 45% were female and 26% were male. The majority (90%) were nurses, with doctors and "other" accounting for 6% and 4% of respondents, respectively; no administrators responded. Over half (70%) worked at primary care facilities, and over a quarter (28%) worked in hospitals. Most (93%) indicated seeing patients with PASC on a weekly basis, though the majority (61%) identified these patients as <10% of total patients. Persistent cough was the most common PASC symptom (64%), followed by fatigue and muscle/body aches (4% each). A substantial proportion of respondents were unsure how to respond to questions regarding the management of common PASC symptoms, with 29% and 36% indicating uncertainty regarding the management of persistent cough and fatigue, respectively. These data indicate that health care healthcare workers frequently encounter patients with PASC at various health system levels across Kweneng, coupled with high levels of uncertainty regarding the best management for this syndrome. Key informant interviews will be conducted to further explore these themes and identify existing PASC management strategies. Data will be used to develop standardized PASC evaluation and management algorithms for use in Kweneng District.

5871

VERTICAL TRANSFER OF HUMORAL IMMUNITY AGAINST NIPAH VIRUS: A NOVEL EVIDENCE FROM BANGLADESH

Syed Moinuddin Satter[1], Arifa Nazneen[1], Md O. Qayum[2], Tanima Islam[2], Mohammad T. Anwar[2], Tanvir Hayder[2], Wasik R. Aquib[1], Ayesha Siddika[1], Md M. Rahman[1], Mohammad E. Hossain[1], Mohammed Z. Rahman[1], Sharmin Sultana[2], Joel M. Montgomery[3], John D. Klena[3], Tahmina Shirin[2]

[1]icddr,b, Dhaka, Bangladesh, [2]Institute of Epidemiology, Diseases Control and Research (IEDCR), Dhaka, Bangladesh, [3]Viral Special Pathogens Branch, Division of High Consequence Pathogens and Pathology, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Human Nipah virus (NiV) infection is rapidly progressive and highly fatal, which is one of the major barriers to in-depth exploration of the immune response. Bangladesh nurtures the largest cohort of Nipah infection survivors, and through their contribution, significant discoveries have been made that have substantially helped the scientific community understand the interaction between the virus and the human immune system. One such novel finding is described in this abstract regarding the vertical transfer of immune properties against NiV. In January 2020, a mother and her four-year-old daughter were infected with NiV. Both had a raw date palm sap consumption history and were diagnosed as confirmed NiV-positive cases. Unfortunately, the child succumbed during the course of the infection, while the mother survived with significant residual neurological impairment. Struggling through post-infection physical challenges and psychological trauma, the couple conceived a year and a half later. Per the mandate of national Nipah surveillance, thorough antenatal follow-up and routine Nipah survivor follow-up were done. The pregnancy was uneventful, and a healthy male baby was born. Being the baby of a NiV infection survivor, to exclude the possibility of vertical transmission of NiV infection, specimens were collected from the newborn and tested at the reference laboratory of the Institute of Epidemiology, Disease Control and Research (IEDCR) and icddr,b. While anti-Nipah IgM and PCR tests for NiV were negative, a high titre of anti-Nipah IgG was detected. From mother to neonate, the transfer of humoral immunity against the Nipah virus was confirmed for the first time. This finding will serve as a reference for further research on the transfer of NiV-specific antibodies and warrants further exploration of its effectiveness in virus neutralization and its potential to protect newborns. This will also serve as a resource for future research on vaccine recommendations for pregnant or young women against NiV.

5872

SURVEILLANCE OF OPERATIONALLY RELEVANT VIRAL HEMORRHAGIC FEVER AND RICKETTSIAL VECTOR BORNE INFECTIOUS DISEASE THREATS, INSECTICIDE RESISTANCE, AND ASSESSMENT OF VACCINE EFFICACY TO PREDICTED T CELL EPITOPES AND B CELL ANTIGENS IN AFRICOM

Daniel J. Silberger[1], Hugo V. Miranda Quijada[2], Matthew J. Montgomery[1], Terrel Sanders[2], Stephen M. Eggan[1]

[1]U.S. Naval Medical Research Unit No. 3, Sigonella, Italy, [2]U.S. Naval Medical Research Unit No. 3, Accra, Ghana

Crimean Congo hemorrhagic fever (CCHV), Yellow Fever Virus (YFV), and rickettsial diseases are important emerging or reemerging vector borne infectious diseases of public health concern in Africa and Europe. Expanded vector surveillance, increased insecticide resistance studies, and novel vaccine development efforts for CCHV, YFV, and rickettsial infections in AFRICOM and EUCOM are needed to better detect and prevent disease. While an inactivated vaccine for YFV has been administered prophylactically for decades and is required for AFRICOM entry, there is no licensed vaccine currently available for CCHV or rickettsial species despite recent progress in vaccine research and development for these pathogens. Multiplex PCR panels now provide convenient mobile forward deployable surveillance tools to rapidly detect host, YFV, CCHV, and rickettsial genes in real time and can streamline identification of new strains, variants of concern, or resistance genes. Naval Medical Research Unit-Three (NAMRU-3) sites in Ghana, Egypt, and Djibouti routinely conduct or manage vector-borne infectious disease surveillance in support of AFRICOM. Expansion of vector surveillance sites and sample sequencing to better characterize insecticide resistance, viral hemorrhagic fever, and rickettsial risk within the NAMRU-3 area of responsibility is needed. We expect that broadened surveillance will identify conserved coding sequences in the bunyavirales families, flavivirus families, and rickettsial species that align with immunodominant epitopes and antigens of novel vaccine candidates. Monitoring vector borne pathogen strains will help assess existing vaccine efficacy against operationally relevant infectious diseases in the NAMRU-3 area of responsibility and predict strain-dependent variation in immunological recognition of linear epitopes and surface antigens of vaccines currently in development. These collective activities and network of analyses will have implications for immunization and insecticide spray policies.

5873

THE REMOTE EMERGING DISEASE INTELLIGENCE-NETWORK: ENHANCING BIOSURVEILLANCE USING WATER AND SEDIMENT SENTINEL SAMPLES FROM BELIZE, CENTRAL AMERICA

Benedicte Fustec[1], Michele M. Adams[1], Marie Pott[2], Alvaro Cruz[2], Uziel Romero[2], Mariely Campos[2], Alexia Thompson[2], Hsiao-Mei Liao[3], Le Jiang[3], Yvonne-Marie Linton[4], John P. Grieco[1], Nicole L. Achee[1]

[1]Department of Biological Sciences, Eck Institute for Global Health, University of Notre Dame, Notre Dame, IN, United States, [2]Belize Vector and Ecology Center, Orange Walk, Belize, [3]Naval Medical Research Center, Diagnostic and Surveillance Department, Silver Spring, MD, United States, [4]The Walter Reed Biosystematics Unit, Smithsonian Institution, Suitland, MD, United States

The past decades have seen a dramatic increase of emerging and/or re-emerging infectious diseases worldwide. More outbreaks are foreseen for the future, yet proactive surveillance remains limited due to many challenges including lack of technical expertise and characterization of reliable sentinel sample types for accurate detection of circulating pathogens reflecting potential zoonotic spillover threats. The Remote Emerging Disease Intelligence-NETwork (REDI-NET) is a phased initiative project which aims to enhance current surveillance efforts to detect, predict and contain potential emerging infectious diseases in an efficient and timely manner. Partners have established robust standard operating procedures, including those for standardized field sample collection, storage and metagenomic next-generation sequencing (mNGS) to capture a broad spectrum of pathogens circulating in REDI-NET early phase surveillance sites of Belize, Kenya, and Florida. In Belize, active biosurveillance sampling was performed monthly from ten permanent water bodies, in the Corozal, Orange Walk, Stann Creek and Toledo Districts from November 2021-March 2022 and incorporating two additional permanent water bodies in the Cayo and Belize Districts in November 2022-March 2023 to determine effectiveness of water and sediment samples to serve as sentinels for circulating pathogens. Here we report mNGS outputs on viral and non-viral (e.g., bacterial, parasitic) pathogens using MinION/GridION sequencers (Oxford Nanopore Technologies) to inform on whether both water and sediment sampling are needed, or if one sample type could be used to inform pathogen presence effectively. Findings are meant to provide guidance to field collection efforts in order to streamline resource allocation which is often a limitation in surveillance efforts.

5874

CAUSE SPECIFIC MORTALITY FROM VERBAL AUTOPSY FOR UNDER FIVES IN WESTERN KENYA, 2019 TO 2022

Thomas Misore[1], Sammy Khagayi[1], Benard Asuke[1], Peter Otieno[1], Onyango Dickens[2], Beth Barr[3], Stephen Munga[1], Richard Omore[1], Victor Akelo[4]

[1]Kenya Medical Research Institute -KEMRI, Kisumu, Kenya, [2]County Department of Health, Kisumu, Kenya, [3]Nyanja Health Research, Kisumu, Kenya, [4]Division of Global Health, Centers for Disease Control and Prevention, Kisumu, Kenya

Verbal autopsy remains the most widely used and feasible method for measuring cause of death, especially in low and middle in-come countries, which still lack reliable information on pediatric causes of death. Child Health and Mortality Prevention Surveillance (CHAMPS) network that includes Health and Demographic Surveillance Systems (HDSS) in urban (Manyatta) and rural (Karemo) settings in Western Kenya, conducts verbal autopsy (VA) to help investigate and monitor causes of death. We examined U5 cause-specific mortality rates and fractions using VA data from the two CHAMPS HDSS sites for the period 2019 - 2022. VA data were collected using the 2016 WHO form and processed using the InterVA5 probabilistic model in R software. A total of 3642 U5 deaths were recorded, of which 3273 (90%) had VAs conducted. Overall under-five mortality rate in the rural site 14.2(13.3, 15.2) per 1000 live births was higher than the urban site 10.1(9.4, 10.7) per 1000 live births. Neonatal mortality rate was 21.8 per 1000 live births for rural and 23.7 per 1000 live births for urban. Infant mortality rate in the rural site of 24.5(19.6, 29.4) per 1000 live births was higher than the urban site of 16.7(14.5, 17.5) per 1000 live births. Child mortality rate 6.3 (6.0, 6.6) per 1000 live births for rural and 2.3 (2.2, 2.4) per 1000 live births for urban. The leading specific causes of death according to VA were birth asphyxia (141, 13.0%), prematurity (142, 13.1%), stillbirth (136, 12.6%), diarrheal diseases (104, 9.6%), meningitis & encephalitis (80, 7.4%), and malaria (58, 5.4%). The under-five cause-specific mortality rates generated using the InterVA-5 model reflects prevailing knowledge on the under-five disease burden in western Kenya, but better correlation is needed with CHAMPS findings generated using minimally invasive tissue sampling and specific diagnostics. Though U5 survival has increased in recent years, a lot more needs to be done to alleviate under-five deaths in the two sites.

5875

PUBLIC HEALTH DECISION-MAKING DURING COVID-19 PANDEMIC: A DETERMINANTS FRAMEWORK

Sumegha Asthana[1], Sanjana Mukherjee[1], Alexandra L. Phelan[2], Claire J. Standley[1]

[1]Georgetown University, Washington, DC, United States, [2]Johns Hopkins University, Baltimore, MD, United States

Public health governance and decision-making processes during the Coronavirus disease 2019 (COVID-19) pandemic were constrained by ambiguity about the rapidly evolving epidemiological situation, urgency of response and paucity of robust scientific evidence. Among recent analyses on governance during the pandemic, few studies have focused on the process of decision-making. Comprehensive frameworks for understanding the process and determinants of public health decision-making at different levels are needed for effective future pandemic preparedness and response. Through a series of key informant interviews and focus group discussions with national officials, academic experts and civil society representatives from Singapore, we developed a framework describing the determinants of public health decision-making during the pandemic in Singapore. In this framework, we draw from crisis management theories and present three key determinants of decision-making: centralization, agility and adaptability. Centralization refers to concentration of decisional power with a limited number of executives. Agility refers to timely action and quick redirection of resources towards priority issues. Adaptability refers to modifying existing structures and processes or establishing new structures and processes to respond to the existing crisis. We highlight that these determinants are further shaped by three factors. First is the availability of human, material and information resources. Second by is by political, social and economic context. Third by the governance values of accountability, transparency, equity and trust. We present five key characteristics for each determinant, which we suggest should be strengthened for future pandemic preparedness efforts. Further work is needed to assess generalizability of our results. However, we hypothesize that this framework can be applied across different contexts and governance systems.

INVESTIGATION AND MANAGEMENT OF A STREPTOCOCCUS PNEUMONIAE MENINGITIS EPIDEMIC IN DJADOUBANGO, IVORY COAST

Vroh Joseph Benie Bi[1], Konan Ignace Kouame[2], Issaka Tiembre[1], Mireille Dosso[3]

[1]National Institute of Public Hygiene, Abidjan, Côte D'Ivoire, [2]Tanda Health District, Tanda, Côte D'Ivoire, [3]Pasteur Institute, Abidjan, Côte D'Ivoire

On January 21, 2023, the Tanda health district, in the East of the country, was alerted by the general hospital following the death of 2 schoolchildren from Djadoubango, who presented with headaches & a stiff neck. A team from the health district immediately went to the village. The objective of this work is to describe the phenomenon, identify the cause & propose control measures. This multidisciplinary team, made up of doctors, nurses & biologists, reviewed the consultation registers of the health facilities,

interviewed the populations, examined the patients, looked for other patients in the community & collected blood & cerebrospinal fluid samples. From this investigation, the following points emerged: (i) 14 registered patients whose age varies between 6 & 16 years old. They were all from Djadoubango, with family ties & all from the primary school of the village but with no notion of travel during the previous month, (ii) 05 deaths including 03 during evacuation to hospital & 02 during hospitalization, (iii) No information was found on the vaccination status of the children, (iv) cerebrospinal fluid samples were collected from 6 children & sent to Pasteur institute laboratory in Abidjan, (v) 9 patients were hospitalized & treated free of charge at Tanda General Hospital, (vi) the results of the analysis of the samples showed cases of malaria & 2 cases of Streptococcus pneumoniae meningitis. One of the 2 cases died while the other recovered after treatment with antibiotics. These pneumococcal meningitis cases show the change in the ecosystem of the cerebrospinal meningitis germ following vaccination campaigns against meningococcus A & C. Indeed, meningitis epidemics were until then due to Neisseria meningitidis. Vaccination of contact subjects with pneumococcal vaccine was carried out to contain the epidemic. Promiscuity in the classrooms & climatic factors such as the harmattan marked by drought & dust may have favored the occurrence of the disease. Reinforcing pneumococcal vaccination in the Expanded Immunization Program is necessary.

UNDERSTANDING THE USE OF UTEROTONICS BY COMMUNITY HEALTHCARE PROVIDERS DURING HOME DELIVERY IN RURAL BANGLADESH

Shahana Parveen[1], Tonmoy Sarkar[1], Sazzad Hossain[1], Dalia Yeasmin[1], Farhana Hasnat Khan[1], Syead Tamim Mahmud[1], Mohammad Zahid Hossain[1], Md. Atique Iqbal Chowdhury[1], Maria Maixenchs[2], John Blevins[3], Shams E. Arifeen[1], Emily S. Gurley[4]

[1]icddr,b, Dhaka, Bangladesh, [2]ISGlobal, Hospital Clinic-Universitat de Barcelona, Barcelona, Spain, [3]Emory Global Health Institute, Atlanta,, GA, United States, [4]Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University, BALTIMORE, MD, United States

In Bangladesh, uterotonics, e.g. oxytocin, are widely used to augment uterine contractions during home delivery, which may increase the risk of asphyxia leading to stillbirth or neonatal death. A pregnancy surveillance system in rural Baliakandi, Bangladesh systematically identified pregnant women and followed them to identify the care received through their birth outcome. We conducted a mixed-method study to identify the frequency and extent of use of uterotonics during home delivery. Among the 5337 completed pregnancies during September 2021 to December 2022, 23% (1186/5337) delivered at home with a birth attendant. In 47% (563/1186) of deliveries a uterotonic was given to increase contractions. We conducted 14 interviews with birth attendants and six mothers, recently delivered at home. All the birth attendants reported that almost in every case they provided an uterotonic, mainly to increase uterine contractions for normal delivery and usually give the first ampule (5 IU/ml) oxytocin when the water breaks or/and baby's head moves into the vaginal canal and commonly continue to give up to three ampules. Most mothers also shared the same experience. If a mother does not deliver within 30 minutes of the third ampule, birth attendant referred mother to hospital. They also give this drug in some critical conditions, such as when the baby's head is in the birth canal but the mother does not have contraction. A few skilled attendants reported using oxytocin to decrease postpartum bleeding, to discharge placenta and uterus involution. Birth attendants noted, families often pressured them to provide this drug for a quicker delivery. Half of them remarked that if the cervix was not opened but the injection was given, it creates pressure in the uterus and could lead to baby's death, though they rarely experienced it. Among the 563 deliveries in which oxytocin was given, 98% reported to a livebirth outcome compared to 97% livebirth when it was not given. Although the results of our study found a livebirth outcome after frequent use of oxytocin during labor, further follow-up of those livebirths may provide more definitive evidence of adverse outcome of such use.

ROUTINE CHILDHOOD IMMUNIZATION IN BURKINA FASO: IDENTIFYING AND REACHING ZERO-DOSE AND UNDER-VACCINATED CHILDREN IN A SECURITY CHALLENGED COUNTRY

Annick Raissa Ouelhore Sidibe[1], Sylla Bry[1], Issa Ouedraogo[2], Romial Sawadogo[1], Issoufou Savadogo[2], Soumeya Ouangraoua[1], Sarah Wanyoike[3], Elaine Charurat[3], Karine Nankam[3], Dan Watkins[3], Stacie Stender[3], Christopher Morgan[3]

[1]Jhpiego, Ouagadougou, Burkina Faso, [2]Ministère de la santé, Ouagadougou, Burkina Faso, [3]Jhpiego, Baltimore, MD, United States

WHO-UNICEF estimates and coverage survey data show about 10% of children miss vaccination in Burkina Faso yearly. These children, often from marginalized groups, are susceptible to vaccine-preventable diseases and maintain avoidable outbreaks in the country. Defining Zero-dose (ZD) children as those who have not received a first dose of the combined Diphtheria, tetanus, pertussis, hepatitis B and Haemophilus influenzae type b (DTP-Hep-Hib) vaccine at 8 weeks, we conducted a secondary analysis of five years of administrative data (2017 - 2021 DHIS2) to map ZD children and prioritize strategies to reach them. We triangulated administrative data with survey data (2020 Demographic health survey, 2020 vaccination coverage survey). To reduce the limitation of coverage survey data at the district level, we created a correction factor (f) using the ratio of regional coverage and applied it to the district level. The determining factors of ZD children and successful immunization strategies were assessed using the Immunization Equity Survey, the Gender Action Plan, the 2021-2025 National Immunization Strategy, the Immunization Strategy for Security Challenge Areas and post-vaccine introduction assessments. Overall, there were an estimated 45,193 (5.6%) ZD children in 2020 and 32,023 (3.8%) ZD children in 2021. From 2020 to 2021, fourteen (14) health districts accounted for 85.4% of the ZD children. The highest number of ZD children were found in Djibo, Dori, Gorom Gorom and Barsalgo districts in 2020, all areas affected by insecurity, while urban districts (Boulmiougou, Bogodogo Sigh Nonghin) and districts dealing with significant security challenges (Diapaga, Barsalgo Djibo et Titao) accounted for the largest number in 2021. The key determining factors for ZD and under-vaccinated children included insecurity, availability and accessibility of health services and poverty, yet there was an upward trend of ZD children in the richest wealth quintiles (from 2.8% in 2010 to 4.4% In 2020).

ASSESSING KNOCK DOWN RESISTANCE MUTATIONS IN THE DENGUE VECTOR, AEDES AEGYPTI, IN POSADAS, ARGENTINA

Jessica V. Fay, Sonia Espindola, María V. Boaglio, María J. Blariza, Karen López, Fabián Zelaya, Manisha A. Kulkarni, Carina F. Argüelles, Julián A. Ferreras, **Marcos M. Miretti**

GIGA, Universidad Nacional de Misiones - CONICET, Posadas, Argentina

The control of adult populations of the arboviral vector, Aedes aegypti, is mainly based on the application of insecticides, and the widespread use of pyrethroids led to the selection of genetic resistance to insecticides on a global scale. The increased frequency and distribution of non-synonymous knock down resistance (kdr) mutations in the voltage gate sodium channel gene (Nav), impose a threat to the success of mosquito control programs. In this work we investigated the presence of two kdr mutations (V1016I and F1534C) in the Nav gene across four neighbourhoods in Posadas, Argentina. Alleles at both loci were interrogated using TaqMan SNP genotyping assays in DNA extracted from 100 adult females. We report the presence of pyrethroid resistance alleles, kdr 1016I=29.08% and kdr 1534C=70.70%, among adult females. The combined kdr genotypic frequency reveals that approximately 67% of local adult females have an enhanced resistance to pyrethroids, carrying at least one kdr allele at each locus. Genotyping is an invaluable tool for kdr resistance monitoring in vector control campaigns. This is the first report of kdr mutations in Ae. Aegypti in the Northeast of Argentina, a region with recurrent dengue

epidemics. Our results emphasise the need to extend the kdr frequency assessment to other cities alongside with arboviral and entomological surveillance.

USING TRANSCRIPTOMIC DATA TO IDENTIFY POTENTIAL MARKERS OF TRANSFLUTHRIN INSENSITIVITY IN ANOPHELES GAMBIAE SS

Stephen Okeyo[1], Dieunel Derilus[2], Lucy Impoinvil[2], Diana Omoke[1], Helga Saïzonou[3], Cynthia Awuor[1], Nsa Dada[4], Nicola Mulder[5], Gerald Juma[6], Benard Kulohoma[6], John E. Gimnig[2], Luc Djogbénou[7], Audrey Lenhart[2], Eric Ochomo[1]

[1]Kenya Medical research Institute, Kisumu, Kenya, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Tropical Infectious Diseases Research Centre (TIDRC), University of Abomey-Calavi (UAC), Cotonou, Benin, [4]School of Life Sciences, Arizona State University, Tempe, AZ, United States, [5]Human, Heredity, and Health in Africa H3ABionet Network, Cape Town, South Africa, [6]University of Nairobi, Nairobi, Kenya, [7]Regional Institute of Public Health (IRSP), Ouidah, Benin

The emergence of resistance to pyrethroids, threatens the efficacy of insecticide treated nets (ITNs) and necessitates the development of complementary tools. Spatial repellents (SRs), are a promising new intervention that reduce human vector contact, thereby breaking transmission by creating vector-free spaces. Although they are structurally different from insecticides used on ITNs, insecticides used in current SRs such as transfluthrin are pyrethroid insecticides raising the possibility of SR insensitivity among vector populations with high levels of resistance to pyrethroids. We used a high throughput screening system to determine the spatial activity index(SAI) of three strains of An. gambiae s.s. (Kisumu, susceptible; Bungoma, local resistant; Pimperena, resistant) to transfluthrin-treated surfaces. A whole transcriptome analysis approach was used to determine differentially expressed genes and identify potential markers for transfluthrin insensitivity. The SAI analysis showed a heterogeneous response based on mosquito population. Bungoma (12.515 ug/ml : SAI - 0.069), Kisumu (0.0025 ug/ml : SAI - 0.117) and Pimperena (125.15 ug/ml : SAI - 0.111). The differential expression analysis in non-responders relative to responders showed an over-expression of primarily members of the cytochrome P450 monooxygenases. CYP12F12 was the most overexpressed with a fold change (FC) of 36.64 in Bungoma and 43.80 in Pimperena relative to responder Kisumu strain. Olfactory-related genes were mostly globally down-expressed in all test populations. This study provides pertinent background for understanding the effects of transfluthrin pressure on Anopheles gambiae ss and the first evidence of differential gene expression linked to behavioral insecticide resistance in malaria vectors. The roles of these genes in transfluthrin insensitivity need to be validated to further substantiate their involvement in behavioral responses to transfluthrin, in order to provide a basis for the development of molecular surveillance tools for early detection of transfluthrin failure.

IMPACT OF SUGAR DIET ON THE SENSITIVITY OF INSECTICIDES-RESISTANT MOSQUITOES

Khadidiatou Cissé - Niambélé[1], Guibehi Benjamin koudou[2], Jacob Koella[1]

[1]University of Neuchatel, Neuchatel, Switzerland, [2]Centre Suisse de Recherches Scientifiques en Cote d'Ivoire (CSRS), Abidjan, Côte D'Ivoire

The resistance of mosquitoes to insecticides is a rapidly growing problem. While resistance has a strong genetic basis, the environment also affects the extent of resistance. However, we know little of how, for example, the mosquitoes' diet affects their resistance. Our aim was to see how different types of sugar found in nectar influence the sensitivity of strongly insecticide-resistant mosquitoes. To do so field-collected larvae of Anopheles gambiae s.l. from Tiassalé were reared to adults then, their offspring (F1 generation) reared were used for the experiment. We provided adult female sugar meals consisting of sucrose, glucose, fructose or trehalose dissolved in distilled water at concentrations yielding 1.97 or 19.7 kcal/100ml. After five days we measured their knockdown rate and their mortality within 24 hours of exposure to 0.5% deltamethrin with WHO tube tests. We found that there was a positive correlation between the rate of knockdown and mortality for all sugar meals. Mosquitoes fed on the lower concentration were 1.4 to 2 times more likely to die than the better fed mosquitoes, but that the type of sugar had no effect on resistance. Results indicate that the amount of calories provided by sugar is a potential determinant of mosquito susceptibility to insecticides. Sugar meal containing fewer calories may provided less energy to mosquitoes, making them less vigorous and more sensitive to insecticide. Further studies will consider other components of nectar in an attempt at using plants in an integrated approach to manage infection resistance of mosquitoes.

EFFECTS OF AGRICULTURAL PESTICIDES ON THE SUSCEPTIBILITY AND FITNESS OF MALARIA VECTORS IN RURAL SOUTH-EASTERN TANZANIA

Naomi Humphrey Urio[1], Polius Pinda[1], Betwel Msugupakulya[1], Amos Ngonzi[1], Letus Muyaga[1], Halfan Ngowo[1], Marceline Finda[1], Winifrida Mponzi[1], Godfrey Matanila[1], Najat Kahamba[1], Theresia Nkya[2], Fredros Okumu[1]

[1]Ifakara Health Institute, Ifakara, Tanzania, United Republic of, [2]International Centre of Insect Physiology and Ecology, Nairobi, Kenya, Nairobi, Kenya

Agricultural pesticides may exert strong selection pressures on malaria vectors during the aquatic life stages and may contribute to resistance in adult mosquitoes. This could reduce the performance of key vector control interventions such as indoor-residual spraying and insecticide-treated nets. The aim of this study was to investigate effects of agrochemicals on susceptibility and fitness of the malaria vectors, across farming areas in Tanzania. An exploratory mixed-methods study was conducted to assess pesticide use in four villages (V1-V4) in Tanzania. Larvae were collected from agricultural fields in the same villages and their emergent adults examined for insecticide susceptibility, egg-laying, and wing lengths. These tests were repeated using laboratory-reared An. arabiensis, one of which was pre-exposed for 48hrs to sub-lethal aquatic doses of agricultural pesticides found in the villages. Farmers lacked awareness on the links between public health and agriculture sectors but were interested in being more informed. Agrochemicals usage was reported as extensive in V1, V2 & V3 but minimal in V4. Similarly, mosquitoes from V1-V3 but not V4 were resistant to pyrethroids, and either pirimiphos-methyl, bendiocarb or both. Adding the synergist, piperonyl butoxide, restored potency of the pyrethroids. Pre-exposure of laboratory-reared mosquitoes to pesticides during aquatic stages did not affect insecticide susceptibility and fecundity (except in organophosphates) in emergent adults of the same filial generation. Wild mosquitoes were smaller than laboratory-reared ones, but fecundity was similar. In conclusion, in this study, susceptibility of mosquitoes to public health insecticides was lower in villages reporting frequent use of pesticides compared to villages with little or no pesticide use. Variations in the fitness parameters, fecundity and wing length, marginally reflected the differences in exposure to agrochemicals. Pesticide use may exert additional life-cycle constraints on mosquito vectors, but this likely occurs after multi-generational exposures.

SUSCEPTIBILITY OF ANOPHELES GAMBIAE SENSU LATO TO FOUR CLASSES OF INSECTICIDES AND THE ALLELIC FREQUENCIES OF GENES KDR L1014F AND ACE 1 G119S IN TWO VILLAGES OF THE CIRCLE OF KATI IN MALI

Wesley Jefferson Maurice Kongbo Gbassinga, Amadou Guindo, Mamadou Brahima Coulibaly

International Center for Excellence in Research (ICER-MALI), Bamako, Mali

The multiple resistance situation in Anopheles gambiae sensu lato found in Mali with the concomitant presence of the kdr L1014F and ace-1 G119S mutations constitutes a major threat to the success of current malaria control strategies (LLIN and IRS). While it is obvious that with the different

uses of insecticides (controlled or not) it is difficult if not impossible to avoid the installation of resistance at any time, it is crucial to accompany malaria vector control strategies with an efficient insecticide resistance monitoring system. The present study aims to evaluate the susceptibility of Anopheles gambiae sensu lato to the four classes of insecticides commonly used in public health for vector control and the allelic frequencies of the kdr L1014F and ace-1 G119S genes. The study took place from June to October 2021 in Ouassorola and Sogolombougou, two villages in the Kati circle, Koulikoro region. Bioassays were performed according to WHO standard procedures, identification of Anopheles gambiae sensu lato species and detection of kdr L1014F and ace-1 G119S mutations were done by PCR. The mortality rates were respectively in Ouassorola and Sogolombougou of : 100% and 91.25% for fenitrothion; 97.5% and 92.5% for bendiocarb; 67.5% and 50% for DDT; 8.75% and 0% for deltamethrin 3.75% and 0% for permethrin and 10% and 0% for lambda-cyalomethrin. The allelic frequencies of the kdr L1014F mutation were 72.93% in Ouassorola and 79.67% in Sogolombougou and those of ace-1 G119S were 25% in Ouassorola and 46.15% in Sogolombougou. Anopheles coluzzii and Anopheles gambiae were the only members of Anopheles gambiae sensu lato identified in both study sites. This study showed strong resistance of An. coluzzii and An. gambiae to deltamethrin 0.05%, lambda-cyhalothrin 0.05%, permethrin 0.75%, DDT 4% and bendiocarb 0.1%. Anopheles gambiae sensu lato was susceptible to fenitrothion 1% in Ouassorola. A high frequency of genes kdr L1014F and ace-1 G119S was observed in both villages. The species of the Anopheles gambiae sensu lato complex found were Anopheles gambiae and Anopheles coluzzii.

ASSESSING INSECTICIDE RESISTANCE PROFILE OF ANOPHELES GAMBIAE S.L. FOR STRATEGIC VECTOR CONTROL DECISION MAKING IN GUINEA

Evelyne Colette Sampe Ahinadje Alyko[1], Savane Noumouke[1], Jeannette Conde[1], Mayeni Fofana[2], Kalil Keita[3], Alioune Camara[3], Anne Griggs[4], Eliane Mbounga[5], Lamine Bangoura[5], Daniel Impoinvil[6], Kristen George[7], Ananya Price[8], Joseph Chabi[8]

[1]PMI Vectorlink Guinea, ABT ASSOCIATES INC, Conakry, Guinea, [2]PMI Vectorlink Guinea ,ABT ASSOCIATES INC, Conakry, Guinea, [3]National Malaria Control Program Guinea, Conakry, Guinea, [4]U.S. President's Malaria Initiative (PMI), U.S. Centers for Disease Control and Prevention (CDC), Guinea, Conakry, Guinea, [5]U.S. President's Malaria Initiative (PMI), U.S. Agency for International Development (USAID), Guinea, Conakry, Guinea, [6]U.S. President's Malaria Initiative (PMI), U.S. Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, [7]U.S. President's Malaria Initiative (PMI), U.S. Agency for International Development (USAID), Washington DC, USA, Washington, DC, United States, [8]PMI VectorLink Project, Abt Associates, Rockville, MD, USA, Rockville, MD, United States

Mass and continuous distributions of insecticide-treated nets (ITNs) are the main malaria vector control strategy implemented in Guinea. To support the strategic selection of the most appropriate ITN to deploy across Guinea, vector susceptibility to insecticides used in WHO-recommended ITNs was assessed between July and December 2022 in seven prefectures located in the four natural regions of the country. Wild Anopheles gambiae s.l. larvae were collected from development sites, reared into adults, and exposed to the diagnostic dose of pyrethroids (deltamethrin 0.05%, alpha-cypermethrin 0.05%, and permethrin 0.75%) and chlorfenapyr (100 µg/bottle) using the WHO tube test and bottle bioassay respectively. When pyrethroid resistance was confirmed at the diagnostic dose, intensity test (i.e., exposure to 5× and 10× the diagnostic dose) and piperonyl-butoxide (PBO) synergism tests (i.e., PBO pre-exposure followed by exposure to 1× pyrethroid) were conducted. Pyrethroids resistance was observed at all tested sites with mean mosquito mortalities ranging from 3% to 22% at the diagnostic dose, and the intensity was generally high with less than 90% mortality at the 10× diagnostic dose. Pre-exposure to PBO increased the mortality of all three pyrethroids (between 10% to 50%) but did not result in absolute mortality greater than 70%. Mortality of An. gambiae s.l. after exposure to chlorfenapyr was 100% at all seven prefectures. Hence, there is a high frequency and intensity of pyrethroid resistance in An. gambiae s.l. in Guinea, PBO partially increases susceptibility to pyrethroids, and, at the time of this study, there was complete susceptibility to chlorfenapyr. Based on these results, the scale-up of dual active ingredients or PBO ITNs could help mitigate pyrethroid resistance and improve the impact on malaria vectors in the country. Insecticide resistance monitoring should continue in Guinea, including the identification of mechanistic markers of insecticide resistance.

5885

IDENTIFICATION OF INSECTICIDE RESISTANCE MARKERS IN ANOPHELES ARABIENSIS AND AN. GAMBIAE FROM KENYA AND BENIN USING WEIGHTED GENE CORRELATION NETWORK ANALYSIS

Cynthia Awuor Odhiambo[1], Steven Ger[2], Dorothy Nyamai[2], Lucy Impoinvil[3], Diana Omoke[1], Derilus Dieunel[3], Helga Saïzonou[4], Stephen Okeyo[1], Audrey Lenhart[3], Luc djogbenou[4], Eric Ochomo[1]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]JomoKenyatta University of Agriculture and Technology, Nairobi, Kenya, [3]Entomology Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Tropical Infectious Diseases Research Centre (TIDRC), University of Abomey-Calavi (UAC), Abomey Calavi, Benin

Indoor Residual Spraying (IRS) and Insecticide-Treated Nets (ITN) are the two main methods used to control mosquito populations for malaria prevention. Currently, efficacy of these strategies is threatened by the appearance and the spread of insecticide resistance (IR), limiting success of malaria control. Studies of the genetic evolution leading to insecticide resistance could enable identification of molecular markers that can be used for IR surveillance and an improved understanding of the molecular mechanisms associated with IR. This study aimed to use a Weighted Gene Co-Expression Network Analysis (WGCNA) algorithm, a systems biology method, to identify genes with similar co-expression patterns and hub genes that can potentially be used as molecular markers for insecticide resistance surveillance in Kenya and Benin. Anopheles arabiensis and An. gambiae from Kenya and Benin were phenotyped for resistance to alphacypermethrin, permethrin and deltamethrin insecticides. RNA was extracted from unexposed, susceptible and resistant samples followed by Illumina sequencing. WGCNA was conducted to evaluate co-expression patterns of genes to identify modules, hub genes and generate a gene co-expression network. A total of 20 and 26 gene co-expression modules (sft:20,18) were identified via the average linkage hierarchical clustering from An. arabiensis (Kenya) and An. gambiae (Benin), respectively. The top modules based on the number of genes in An. arabiensis and An. gambiae were identified to be salmon (n=3197) and blue (n=3839) modules. The genes with the strongest connection (hub genes) were found in all modules. Serine protease, E3 ubiquitin-protein ligase, cuticular protein RR2 and leucine-rich immune protein were identified as hub genes in both species. This was the first study to conduct WGCNA based on IR transcriptomic data. Four biologically relevant hub genes shared between the two species were identified as potential markers for insecticide resistance. The next phase will be to undertake in vitro and in vivo studies to functionally validate these genes as IR markers.

5886

POPULATION GENOMICS OF THE INVASIVE MALARIA VECTOR ANOPHELES STEPHENSI IN ETHIOPIA

Holly Acford-Palmer[1], Jody E. Phelan[1], Emilia Manko[1], Fitsum G. Tadesse[2], Mojca Kristan[1], Thomas Walker[1], Teun Bousema[3], Louisa A. Messenger[4], Taane G. Clark[1], Susana Campino[1]

Anopheles stephensi has been identified as a major threat to malaria control and elimination efforts in the Horn of Africa (HOA). The species, native to South Asia, is a highly competent vector in urban areas and can transmit both Plasmodium falciparum and vivax. Since An. stephensi

was first identified in Dijbouti in 2012, the country has seen malaria cases skyrocket. Integrated vector management is often the primary strategy used to interrupt disease transmission, but levels of insecticide resistance are growing and could severely impact malaria control. Very little is known about the population genetics of this invasive species spreading in the HOA. In this study we aim to better understand the population genetics of this vector and help better inform vector management programmes. Twenty-eight An. stephensi samples collected from a central Ethiopian town, were whole genome sequenced. Average coverage was ~30-fold per sample, with 14930416 SNPs identified across the genome. We found one known mutation associated with insecticide resistance: A296S, or the rdl mutation. The SNP was found in 46% of the Ethiopian samples analysed, and results in resistance to the insecticide dieldrin. Other putatively novel non-synonymous SNPs were found in genes associated with insecticide resistance: ace-1 and GSTe2.In addition, we examined the population structure of the Ethiopian isolates in the context of publicly available WGS data from Colony Pakistani and wild-type Indian An. stephensi mosquitoes. Pre-liminary ancestry analysis using admixture indicates genetic distinctness between Ethiopian and Indian populations of An. stephensi. Significant Fst was observed between pairwise analysis of these two populations. Phylogenetic analysis suggests a closer relationship between SDA500 Pakistani strains and Ethiopian An. stephensi isolates.Here we have identified an insecticide resistance marker and given insight into the population genomics of Ethiopian isolates of An. stephensi, in the context of native South Asian populations of this invasive vector.

Anopheles funestus carries most malaria in east and southern Africa. However, it has been challenging to study this species because it is difficult to colonize inside laboratories. Our team was able to successfully colonize a strain of this species from Tanzania (FUTAZ) for >20 generations. We compared the FUTAZ strain to two other strains of mosquitoes: a strain of An. funestus from Mozambique (FUMOZ) and a strain of Anopheles arabiensis. We examined the differences in fitness between these strains through measures like body size and mating success. We also looked at the genetic makeup of the mosquitoes using PCR analysis of mitochondrial clades and restriction fragment length polymorphisms (RFLP) on the 28S ribosomal DNA. We found that the FUTAZ strain had a decline in mating success and body size in the first six generations, but then they adapted, and these measures improved. By the ninth generation, the FUTAZ strain had similar fitness measures to the FUMOZ strain. Fecundity was similar across all strains tested. It took twice as long for the FUTAZ and FUMOZ strains to mate compared to the An. arabiensis strain. The genetic analysis showed that the FUTAZ strain was similar to the wild-caught Tanzanian An. funestus strain, but it was different from the FUMOZ strain. Our study shows that it's important to have a large founder population when starting a new colony to ensure that the mosquitoes can adapt to laboratory conditions.

5888

CO-OCCURRENCE OF MULTIPLE KDR MUTATIONS (F1534C, V1016I, V410L) IN AEDES AEGYPTI FROM COASTAL AREAS IN GHANA AND ASSESSMENT OF THE ROLE OF MOSQUITO COIL IN CAUSING PYRETHROID RESISTANCE

Aikins Ablorde[1], Joana Ayettey[2], Inge Kroidl[1], Andreas Wieser[1], Andreas Kudom[2]

[1]Ludwig-Maximilian-University, Munich, Germany, [2]University of Cape Coast, Cape Coast, Ghana

The rapid spread of knockdown-resistance kdr mutations in Africa calls for monitoring and investigation into the cause of pyrethroid resistance to inform management strategies. This study investigated the pyrethroid resistance profile of Ae. aegypti from coastal towns in Ghana and the impact of mosquito coils, a popular household pyrethroid-based anti-mosquito tool, on the development of pyrethroid resistance. Susceptibility to deltamethrin and the presence of kdrmutations were determined in adult female mosquitoes reared from larvae. Furthermore, a laboratory colony was exposed to a sub-lethal dose of a mosquito coil once per generation for six generations (F6). The susceptibility of the exposed colony to deltamethrin (0.05%) was determined using WHO protocols. The Ae. aegyptipopulations from the coastal towns were resistant to deltamethrin with co-occurrence of F1534C, V1016I and V410L kdrmutations. In the experimental study, the LT50 (95% CI) of the exposed colony against the coil rose from 8 minutes (95% CI; 6-9) at F0 to 28 minutes (95% CI; 23-34) at F6. Nonetheless, deltamethrin caused similar mortalities in the exposed and control colonies. The resistant allele frequencies of 1534C and 410L were identical, but 1016I was higher in the exposed colony than in the control. However, the increased tolerance to the coil and high resistant allele frequency of 1016I in the exposed colony did not affect the mosquito's resistance to deltamethrin insecticide. Further study is needed to elucidate the role of pyrethroid-based mosquito coils in developing insecticide resistance in mosquito vectors.

TEMPORAL RESISTANCE ESCALATION AND N1575Y MARKED DETECTION IN ANOPHELES GAMBIAE S.L POPULATION IN ATATAM, AN EXPERIMENTAL HUT STATION SITE IN SOUTHERN GHANA

Gabriel Akosah-Brempong[1], Leon Jean Mugenzi[2], Benjamin Menze[2], Micareme Tchoupo[2], Theofelix A. Tekoh[2], Linus Dottey[3], Ekene K. Nwaefuna[3], Samuel Dadzie[4], Murielle Wondji[2], Michael Y. Osae[3], Charles S. Wondji[2]

[1]University of Ghana and Biotechnology and Nuclear Agriculture Research Institute (BNARI), Accra, Ghana, [2]Centre for Research in Infectious Diseases (CRID), Yaounde, Cameroon, [3]Biotechnology and Nuclear Agriculture Research Institute (BNARI), Accra, Ghana, [4]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Major malaria vectors in Africa are increasingly developing high intensity of resistance to approved used in vector control. This threatens to impact efficacy of insecticides-based tools necessitating the need to monitor resistance in vector populations to support insecticide resistance management. This study reports the temporal aggravation of resistance and significant detection of N1575Y-Kdr marker in the primary malaria vector Anopheles gambiae s.l at Atatam, a rural Ghanaian community. Indoor resting blood-fed Anopheles mosquitoes were collected twice each year coinciding with the peaks of the major and minor raining season between 2021-2022 were forced to lay eggs to generate F1 adult mosquitoes. Insecticides susceptibility bioassays, PBO synergist assay and cone assays with pyrethroid-only nets and PBO-based nets were performed on the F1 adults. Furthermore, molecular basis of resistance were characterized in F0 populations using TaqMan genotyping. An. gambiae s.l consisted of An co.luzzii and An. gambiae s.s. These displayed high levels of resistance to Permethrin, Deltamethrin, Alpha-cypermethrin and DDT with moderate resistance recorded against Bendiocarb in contrast to full susceptibility

recorded for Pirimiphos-methyl. PBO synergist assays with Permethrin and Deltamethrin induced only a marginal recovery of susceptibility in An.gambiae population (6.2% to 43% and 2.2% to 37.1% mortality, respectively). The high pyrethroid/DDT resistance in An. gambiae correlated with high frequency of 1014F, N1575Y knockdown resistance allele (91% and 50%) and GSTe-I114T resistant allele (59.6%). The G119S allele was detected at low frequency (1.7%) indicative of the increased susceptibility to Bendiocarb and full susceptibility to Pirimiphos methyl. Cone assays reveal loss of efficacy against pyrethriod-only based nets and a reduced efficiency against PBO based nets against these resistant An. gambiae s.l population. These results highlight the escalation of insecticide resistance and the challenges that control programmes face to maintain the continued effectiveness of existing insecticide-based interventions.

INSECTICIDE SUSCEPTIBILITY OF ANOPHELES ALBIMANUS IN THE TWO MAIN ACTIVE MALARIA FOCI OF HONDURAS

Denis Escobar[1], Allan Reyes García[2], Oscar Urrutia[3], Neila Julieth Mina[4], Lucia Fernandez[5], Raul Barahona[3], Gustavo Fontecha[1]

[1]Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, [2]Unidad de Vigilancia Entomológica, Región Sanitaria de Gracias a Dios, Secretaría de Salud, Puerto Lempira, Gracias a Dios, Honduras, [3]Secretaria de Salud, Tegucigalpa, Honduras, [4]Clinton Health Access Initiative, Tegucigalpa, Honduras, [5]Clinton Health Access Initiative, Ciudad de Panamá, Panama

Malaria cases in Honduras have increased over the previous four years, rising from 386 in 2019 to 3,601 in 2022. Around 90% of cases are reported in Puerto Lempira and Villeda Morales municipalities, in the department of Gracias a Dios. Vector control in Gracias a Dios employed the use of pyrethroids-impregnated bednets, with occasional indoor spraying with bendiocarb. The Ministry of Health in collaboration with other partners has conducted insecticide resistance surveillance over the last 5 years in one sentinel site at Gracias a Dios, however, no fine scale evaluations per foci have been carried out thus far. The aim of this work was to evaluate insecticide susceptibility status in the two main malaria transmission areas using both a phenotypic and genotypic approach. Adult entomological collections were carried out at Kaukira, Puerto Lempira and Raya, Villeda Morales in Gracias a Dios. Deltamethrin and Bendiocarb phenotypic status were assessed using CDC bottle bioassays with diagnostic doses. Sequencing analysis was used on a selection of 50 Anopheles albimanus individuals (30 from Kaukira and 20 from Raya) for target-site mutations detection at 995 and 280 positions in the Voltage-Gated Sodium Channel (VGSC) and the Acetylcholinesterase (Ace-1) gene, respectively. Between September and December of 2022, a total of 701 mosquitoes were collected, with An. albimanus (87%) as the most common specie across the sites, however, secondary species as An. vestitipennis and An. crucians were also identified. Deltamethrin and Bendiocarb show 100% mortality in susceptibility assays. Sequencing analysis revealed that all populations had the wild-type genotype, TTG at 995 (VGSC) and GGC (Ace-1) at 280 positions, respectively, supporting the phenotypic results. Altogether, this data provides current evidence of An. albimanus susceptibility to the insecticides employed by the MoH in vector control and supports their use in routine interventions. Further studies are required in other foci as well with secondary species on a routine basis to drive future vector control operations

5891

ENTOMOLOGICAL STUDY OF MALARIA TRANSMISSION PARAMETERS AS A PRELUDE TO A PHASE III CLINICAL TRIAL OF ATTRACTIVE TOXIC SUGAR BAIT STATIONS IN THE KOULIKORO REGION, MALI

Aboubakr Sadik Koné, Mohamed M Traoré, Bintou Kanouté, Amadou Sekou Traoré, Gunter Muller, Seydou Doumbia

University Clinical Research Center (UCRC), University of Sciences, Techniques and Technologies of Bamako (USTTB), Bamako, Mali

Despite the use of prevention and control tools, malaria remains a major public health problem in sub-Saharan African countries, including Mali. Parasite resistance to anti malaria drugs and vector resistance to insecticides are undermining prevention and control efforts. In addition, mosquito biting behavior is shifting from predominantly indoor biting to more outdoor biting. New control methods are therefore urgently needed. It is in this context that the attractive targeted sugar baits or Attractive Toxic Sugar Bait (ATSB) based on the “attract-kill” principle have emerged, trapping mosquitoes with a sugar bait containing an oral toxin. ATSB have had many successes after their use in numerous experimental studies in the control of Anopheles vectors, Aedes and other insect vectors. We therefore conducted this study with the aim of evaluating the entomological parameters of malaria transmission before an epidemiological phase III trial. It took place in five villages in the district of Kangaba and two villages in the district of Ouélésséboungou; all in Koulikoro region of Mali. It was a longitudinal study with monthly mosquito collection from July to December 2021. We used three trapping methods: human landing catch (HLC), daytime capture by pyrethroid spray catch and CDC UV light trap. We are here reporting only the data for HLC outdoor where we caught 3289 An. gambiae s.l. They had completed 1 or 2 gonotrophic cycles. Their longevity was greater than or equal to 50 days except for Solonkorein and Balala. The maximum infection, 0.17 infectious bites/person/night was observed in Balala. Our findings will inform the randomization of clusters for epi trial aiming at demonstrating an effect of ATSB on malaria incidence.

5892

PHENOTYPIC INSECTICIDE RESISTANCE STATUS AND MOLECULAR DETECTION OF RESISTANCE MUTATIONS IN ANOPHELES GAMBIAE SENSU LATO IN THE GAMBIA

Ebrima Jatta[1], Musa Jawara[2], Assogba Benoit Sessinou[2], Balla Kandeh[1], Balla Gibba[1], Samuel S. Gomez[1], Momodou Kalleh[1], Ousman Njie[3], Yakou Dieye[4], Smita Das[5]

[1]National Malaria Control Programme, The Gambia, Banjul, Gambia, [2]Medical Research Council Unit The Gambia at the London School of Hygiene and Tropical Medicine (MRCG at LSHTM), Banjul, Gambia, [3]PATH, Banjul, Gambia, [4]PATH, Dakar, Senegal, [5]PATH, Seattle, WA, United States

The use of long-lasting insecticide treated bed nets (LLINs) and indoor residual spraying (IRS) in high burden areas has played a major role in the reduction of malaria cases and deaths in The Gambia. Widespread resistance of Anopheles gambiae sensu lato to pyrethroids, scale-back of IRS, high costs, and suboptimal compliance to vector control interventions threaten these gains and have led to the adoption of the WHO insecticide rotation plan by the National Malaria Control Programe (NMCP). This study aimed to describe phenotypic and molecular resistance of An. gambiae s.l. to pyrethroids to guide the NMCP’s selection of insecticide for IRS in The Gambia. From July-October 2021, An. gambiae s.l. larvae were collected and reared to adults from 7 sentinel sites: Brikama, Essau, Farafenni, Njabakunda, Georgetown, Basse, and Gambisarra. Using the WHO tube bioassay, a total of 3,237 An. gambiae s.l. were exposed to Deltamethrin 0.05%, Deltamethrin 0.25%, or Pirimiphos-methyl 0.25%. A total of 195 mosquitoes were genotyped at 7 loci for 11 SNP mutations associated with insecticide resistance. Resistance to Deltamethrin 0.05% was confirmed in all sites, with mortality ranging from 30% in Bakau to 73% in Georgetown. Moderate to high resistance to Deltamethrin 0.25% was observed in 6 sites (81%-97% mortality) and low resistance in one site (Georgetown; 99% mortality). An. gambiae s.l. from all sites were susceptible to

Pirimiphos-methyl. Sequencing detected 8 SNPs: kdr-1014S, kdr-1014F, Coeae1d, A296S rdl, T345S rdl, Cyp6jS, Gste2-119V, and Gste2-114T with allele frequencies varying between 0.03 and 0.54. One to 6 SNPs per mosquito were identified with over 80% with 1-3 SNPs. An. gambiae s.l. in The Gambia are susceptible to Pirimiphos-methyl 0.25%, resistant to Deltamethrin 0.05%, and exhibited moderate to high resistance to Deltamethrin 0.25%. The lowest and highest frequencies were observed for Cyp6jS and Coeae1d, respectively. Since no resistance was confirmed for Pirimiphos-methyl 0.25%, the NMCP will continue using this insecticide for IRS in The Gambia, while also adhering to the insecticide rotation plan to delay expansion of resistance.

5893

OVEREXPRESSING IMMUNE SIGNALING PROTEIN VAGO RESTRICTS DENGUE VIRUS INFECTION IN AEDES AEGYPTI MOSQUITOES

Mihra Tavadia, Chinmay Tikhe, Shengzhang Dong, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Aedes aegypti is the principal vector for pathogens like, Dengue virus, Zika Virus, and Chikungunya virus. The lack of effective vaccines and drugs against these pathogens has led to severe economic and healthcare burdens in developing countries, leading to the need for new control measures. The four major pathways through which Aedes mosquitoes mount an immune response are, the JAK-STAT, RNAi, IMD, and Toll pathways. Recent publications have indicated that there is a crosstalk between these pathways during viral infections. The Vago gene which encodes for a cysteine-rich 18Kd polypeptide has been shown to be involved in antiviral activity. In Culex quinquefasciatus mosquitoes, Vago has been shown to be involved in crosstalk between the JAK-STAT, RNAi, and IMD pathways upon West Nile Virus infection. The potential of the Aedes orthologue of Vago to connect immune pathways has not yet been studied and its mode of action is still unknown. In the present study, we have created two transgenic lines that overexpress Vago in the fat body and the midgut, using the PiggybacTM transposon system. A significantly lower titer of Dengue virus was observed 14 days post-infection in transgenic lines overexpressing Vago in the midgut. We also aim to study the role of Vago in connecting immune pathways and its potential anti-viral activity when overexpressed in the fat body.

DEFINING THE ROLE OF JUVENILE HORMONE AND ITS RECEPTOR, METHOPRENE-TOLERANT, IN ANOPHELES GAMBIAE REPRODUCTION AND PLASMODIUM TRANSMISSION

Emre Aksoy[1], Shriya Anandjee[1], Naresh Singh[1], Robert W. Shaw[2], Flaminia Catteruccia[2]

[1]Harvard TH Chan School of Public Health, Boston, MA, United States, [2]Harvard TH Chan School of Public Health/Howard Hughes Medical Institute, Boston, MA, United States

Controlling the reproductive cycle in Anopheles mosquitoes can serve as a critical tool for vector control and contribute towards the overall goal of malaria elimination. Our previous studies have demonstrated a functional role for the insect steroid hormone 20-hydroxyecdysone (20E) in Plasmodium falciparum development in its main vector Anopheles gambiae, where blocking 20E activation resulted in reduced parasite survival but faster parasite growth through the insect stages. In the adult female mosquito, the vitellogenic phase that is governed by 20E regulation temporally follows the post-eclosion (PE) development phase (day 1-3 PE) that is regulated by another insect hormone, Juvenile Hormone (JH). JH is responsible for initiating the cascades responsible for tissue maturation that are required to prime the female reproductive machinery prior to the acquisition of a blood meal. Here, we analyzed the role of the JH binding receptor, Methoprene-tolerant receptor (Met), in An. gambiae reproduction and P. falciparum development. After characterizing the gene expression pattern of Met and two down-stream transcription factors (Kruppel homolog-1 and Hairy), we demonstrate that JH has an important functional role in regulating gene expression during the PE period by artificially inducing the JH-mediated pathway through the topical application of Methoprene. Next, we administrated dsRNA targeting the Met receptor to block the JH response and subsequently measured vector reproductive fitness and parasite transmissibility. Our results indicate that blocking JH activation results in both reduced mosquito egg development and parasite survival, but also leads to faster parasite growth. It is likely that blocking JH activity results in alterations in mosquito immunity and nutritional status that need to be further explored to understand its full impact on Plasmodium transmission. These data unveil a key role of JH in regulating Anopheles-Plasmodium interactions, and suggest a critical cross-talk between 20E and JH in regulating reproductive processes that also impact the survival and growth of the deadliest human malaria parasites.

COMPOSITIONAL DIVERSITY IN THE EARLY-DEVELOPMENTAL MICROBIOME OF AEDES ALBOPICTUS LEADS TO HETEROGENOUS IMMUNE EXPRESSION OF ADULT MOSQUITOES

Chasen Griffin, Matthew C.I. Medeiros

University of Hawaii at Manoa, Honolulu, HI, United States

Mosquitoes rely on a community of symbiotic microorganisms to sustain biological processes.Variation in the diversity of the microbiome has profound impacts on mosquito physiology thatscale up to host phenotypes. Of special interest are phenotypes permissive to sustained diseasetransmission. We examined the immunological responses of Aedes albopictus mosquitoes to assess how exposure to compositionally different microbial communities during earlydevelopment impacts adult responses to infection. We sourced water from three differentenvironments—bromeliad axils, artificial containers, and purified laboratory water—to createlarval habitats. The water sourced from bromeliads and artificial containers was filtered using30-50 µm, 10 µm, and 0.2 µm filters. Upon eclosion, adults were provided a 10% sucrosesolution and allowed to feed ad libitum for 72 hours. After 72 hours, adults were injected withapproximately 500 live Escherichia coli cells suspended in Luria-Bertani (LB) broth or injectedwith sterile LB broth. At 24 hours post-injection, adults were processed for immune expressionanalyses using quantitative reverse transcriptase PCR. We assayed five gene markers in total:relish 1 (REL1), relish 2 (REL2), STAT, cecropin A (CEC-A) , and defensin C (DEF-C). REL1, REL2,and STAT are transcription factors unique to the three innate immune pathways; CEC-A andDEF-C are antimicrobial peptides. Using generalized linear mixed models, we found thatexposure to compositionally different microbial communities during early mosquitodevelopment impacted the immune response of adult mosquitoes when infected with E. coli.Immune expression patterns varied across treatments and by gene; however, the general trendshowed that mosquitoes from lower filtration habitats (highest microbial diversity) hadincreased upregulation of immune activity. Our results suggest that exposure to diversemicrobial communities in early development may be a significant predictor for the vectorial capacity of Ae. albopictus and that microbial “hotspots” have an important ecological role insustaining mosquito-borne disease transmission.

ALTERNATING CURRENT ELECTROPENETROGRAPHY REVEALS IN SITU BEHAVIORAL CHANGES OF AEDES AEGYPTI BITES ASSOCIATED WITH DENGUE VIRUS INFECTION

Samuel B. Jameson, Lyndsi Vaughan, Jane E. de Verges, Brendan H. Carter, Georgina L. Dobek, Berlin Londono-Renteria, Dawn M. Wesson

Tulane University, New Orleans, LA, United States

Human infection with dengue virus (DENV) results in significant morbidity and mortality around the world. Observations of infectious blood feeding events of the primary DENV vector Aedes aegypti have identified DENV-associated behavioral changes that may promote DENV transmission. Current methods are largely restricted to video analysis of feeding events outside of the host or microscopic video capture of biting events on thin tissues. To supplement these methods, AC-DC electropenetrography (EPG) was investigated to assess the method's potential to record infectious mosquito bites and quantify the amount of time a mosquito spends in different stages of the feeding process. IFN-αβ receptor-deficient mice and DENV-2 (S-14635) were used to determine the feasibility and utility of EPG for arbovirus research. EPG recordings were made of Ae. aegypti feeding on anesthetized mice under three conditions: mosquito/mouse uninfected, DENV-infected mosquito/uninfected mouse, and uninfected mosquito/DENV-infected mouse. Successful and interpretable EPG recordings were obtained for seven feeding events under each condition. Ae. aegypti with disseminated DENV-2 had significantly shorter probe durations and more probes per feeding than uninfected controls. This group also spent significantly more time in the low-voltage initial skin penetration stage of feeding and switched more frequently between two different vessel locating behaviors within the skin than controls. During the ingestion phase, uninfected mosquitoes fed on DENV-infected mice spent significantly less time in the classic M1 ingestion phase and much longer in the more irregular M2 phase, though overall ingestion lengths were not significantly different. These data suggest that there are quantifiable in situ behavioral changes associated with DENV infection, especially with respect to behaviors between initial skin penetration and the beginning of ingestion. Moreover, these data demonstrate that EPG is a suitable tool for interrogating arbovirus associated behavioral changes during blood feeding events.

5897

TEMPERATURE DEPENDENCE OF ANOPHELES IMMUNE RESPONSE KINETICS AND VECTOR COMPETENCE

Maria Luisa Simoes

Institute of Tropical Medicine Antwerp, Antwerp, Belgium

Most studies on mosquito innate immunity responses to malaria parasite infection have relied on rodent Plasmodium berghei laboratory models. However, we and others have shown that the Anopheles immune factors and mechanisms involved in eliminating the clinically relevant human P. falciparum may differ from those against murine parasites. A significant difference between the two malaria species is the fact that P. berghei achieves unnaturally high infection intensities in the vector mosquito, frequently exceeding 200 oocysts per midgut, while median infection intensities for P. falciparum of lower than 3 oocysts per mosquito midgut are usual. Using CRISPR/Cas9-mediated gene knockout and RNAi-mediated silencing of A. gambiae immune factors, we demonstrate that the immune regulation of Plasmodium is dependent on the intensity of infection. Here, we show that the differences in intensity are in part due to the parasite's optimal infection temperature: P. berghei sexual sporogonic development occurs at ~19 °C whilst P. falciparum's is optimal at ~27 °C. We hypothesize that this rather large temperature difference results in a slower rate of development for the rodent parasite than for the human malaria parasite within its vector. Temperature also influences mosquito immune response kinetics and the length of exposure of the parasites to these immune responses. In this study, we predict that temperature variations and climate change may significantly affect mosquito transmission of malaria parasites and other pathogens, by altering the infection kinetics. Our study stresses the importance of conducting malaria laboratory-based transmission studies using clinically relevant species.

5898

DISHEVELLED ACTIVITY DIFFERS IN AEDES AEGYPTI AND CULEX TARSALIS INFECTED WITH RIFT VALLEY FEVER VIRUS

Corey L. Campbell

Colorado State University, Fort Collins, CO, United States

Aedes and Culex mosquitoes are vectors of Rift Valley Fever Virus (RVFV), a zoonotic virus endemic to Africa that causes episodic outbreaks and has emerged on the Arabian Peninsula. RVFV outbreaks are characterized by abortion storms and occasional death of livestock. The specific mechanisms that underpin differences in efficiency of virus transmission are still not understood. To address this, we sought to better understand mosquito host signaling responses late in RVFV MP-12 infection through analysis of differentially expressed genes (DEGs) in two mosquito strains with marked differences in vector competence, Aedes aegypti (Aae, low competence) and Culex tarsalis (Cxt, higher competence). Mosquito-host transcripts related to three different signaling pathways were investigated. The Wingless (WG, WNT-beta-catenin) pathway is a conserved regulator of cell proliferation and differentiation; changes to FRIZZELED2 (FZ2), DISHEVELLED (DSH), and ARMADILLO (ARM, beta-catenin) were assessed. Importantly, DSH differentially regulates progression/inhibition of the WG and JNK (c-Jun N-terminal Kinase) pathways through interaction with NAKED CUTICLE. A negative regulator of the JNK signaling pathway, PUCKERED, was also assessed. Lastly, Janus Kinase/signal transducers and activators of transcription (JAK-STAT) is a multi-functional signaling pathway important for innate immunity; in this context, we tested DOMELESS levels. Here, individual Aae and Cxt were exposed to RVFV MP-12 in oral bloodmeals and then held for 14 days at 28oC. Robust decreases in expression of signaling transcripts in both Aae and Cxt were observed. In particular, Aae DSH expression, but not Cxt DSH, was correlated to the presence/absence of virus at 14 days post-infection (dpi). This effect was not seen in Culex, perhaps due to its high susceptibility to RVFV. Moreover, there was an inverse relationship between viral copy number and aaeDSH expression that did not occur for any other transcript. Silencing of DSH by dsRNA injection resulted in increases in viral copy numbers compared to controls at 7 dpi, consistent with a role for aaeDSH in antiviral immunity.

5899

MAMMALIAN HEMOPEXIN REGULATES OXIDATIVE STATE IN ANOPHELES MOSQUITOS DURING PLASMODIUM INFECTION

Francis Monique de Souza Saraiva, Thiago Luiz Alves e Silva, Joel Vega-Rodriguez

NIH, Rockville, MD, United States

During mosquito midgut invasion, Plasmodium ookinetes cross the peritrophic matrix barrier bringing pro-oxidant molecules in contact with the midgut epithelial cells. Our previous data show that during midgut invasion hemopexin from mouse blood is enriched in the mosquito midgut epithelium and hemolymph. We hypothesize that the accumulation of hemopexin, an antioxidant molecule that binds free heme, protects the parasite and the mosquito from heme and iron-induced cellular damage. To further investigate the impact of hemopexin on oxidative state in Anopheles mosquitos we measured the concentration of hydrogen peroxide in the hemolymph from mosquitos that fed on uninfected or infected wild type (WT) or hemopexin-null mice. Hydrogen peroxide was increased in the hemolymph in the absence of host hemopexin. Additionally, lipid peroxidation, protein carbonylation and nitration, markers of oxidative damage, were increased in the hemolymph of mosquitos that fed in hemopexin-null mice. We also compared the impact of hemopexin in

Aedes aegypti mosquitos which are known to have a robust system to control reactive oxygen species (ROS) after ingesting blood. In contrast to Anopheles, the absence of host hemopexin didn't increased oxidative damage markers in A. aegypti suggesting an important role for hemopexin in controlling ROS triggered by blood digestion in Anopheles mosquitos. Mosquitoes feeding on hemopexin-null mice had a significant decrease in survival, egg oviposition and egg hatching, which points that human hemopexin is a key molecule for the mosquito adaptation and survival to feeding on blood. Moreover, Plasmodium infection was significantly decreased in mosquitos that fed in hemopexin-null mice and was restored in mosquitos that fed in hemopexin-null mice that had been injected intravenously with hemopexin. Together, these results show that hemopexin is an essential molecule for the survival of Anopheles mosquitos and malaria parasite transmission.

5900

TNF-A SIGNALING MEDIATES MOSQUITO CELLULAR IMMUNITY TO PROMOTE PLASMODIUM KILLING

George Rafael Samantsidis, Hyeogsun Kwon, Megan Rogers, Catherine Fonder, Ryan Chad Smith

Department of Plant Pathology, Entomology and Microbiology, Iowa State University, Ames, IA, United States

Malaria is a devastating vector-borne disease caused by Plasmodium parasites and transmitted to humans through the bite of Anopheline mosquitoes. Therefore, understanding mosquito innate immunity and the mechanisms that influence vector competence are crucial to efforts to block malaria transmission. In vertebrates Tumor Necrosis Factor- α (TNF-α) is a well-defined proinflammatory cytokine with essential roles in regulating immune cells, yet our understanding of TNF-α signaling in invertebrate systems is limited. Here, we characterize a functional TNF-TNFR-like system in the mosquito Anopheles gambiae, comprised of the TNF-α ortholog Eiger and its two cognate receptors, Wengen and Grindelwald. We demonstrate that the direct injection of recombinant TNF-α limits malaria parasite survival and provide evidence that these killing responses are immune cell-mediated. The injection of TNF-α increases granulocyte numbers via Wengen and leads to the reduced expression of oenocytoid-specific genes, implying the role of TNF-α in oenocytoid rupture, with evidence supporting both immune cell phenotypes in malaria parasite killing. Additional gene-silencing experiments confirm the involvement of Eiger, Wengen, and Grindelwald in anti-Plasmodium immunity, with initial experiments suggesting that Wengen and Grindelwald may act interchangeably to promote TNF-α signaling to suppress Plasmodium development. Together, our data support the role of a conserved TNF-α signaling pathway in influencing the cellular immune system of mosquitoes, providing new insight into the mechanisms of malaria parasite killing and mosquito vector competence.

EFFECT OF LOW RELATIVE HUMIDITY OVER MORTALITY AND VIRAL VECTOR COMPETENCE IN AEDES AEGYPTI

Jaime Manzano[1], Gerard Terradas[1], Christopher J. Holmes[2], Joshua B. Benoit[2], Jason L. Rasgon[1]

[1]The Pennsylvania State University, State College, PA, United States, [2]University of Cincinnati, Cincinnati, OH, United States

Vector-borne diseases (VBDs) cause over 700,000 deaths every year. The mosquito species Aedes aegypti is a competent vector of multiple viral pathogens including dengue, Zika, chikungunya, and Mayaro viruses. Ae. aegypti was originally distributed in Africa, however, it is currently present in the Americas, Oceania, Asia, and Europe. Because of climate change, it is expected that the distribution of this mosquito species and the pathogens they transmit will change even more. Relative humidity is an environmental variable that affects the mosquito biology and distribution. This variable can differ between indoors and outdoors, and it oscillates over the course of the day and year, thus it is expected that mosquitoes face variations in relative humidity during their lifespan. Low relative humidity can induce dehydration in mosquitoes, leading to alterations in physiological and behavioral responses such as bloodfeeding and host-seeking behavior, which are relevant for pathogen transmission. The aim of our research was to evaluate the short and long-term effects of low relative humidity over mortality and viral vector competence in Ae. Aegypti, using two different experimental designs. Briefly, we tested mosquitoes under three different conditions of relative humidity to induce dehydration, and measured mortality and bloodfeeding rates. Then, we used a cell culture and immunofluorescence-based assay to quantify the viral load in different parts of the mosquitoes at 7 and 14 days post infection. Our results show that under our experimental designs, low relative humidity does not impact the viral loads, nor the infection, dissemination and transmission rates, in mosquitoes infected with Mayaro-L virus. However, we detected a significant difference in mosquito mortality between treatments regardless of whether the mosquitoes were previously exposed to viral infection or not. These findings allow us to further understand the role of relative humidity in vector-borne disease dynamics.

5902

PLAYING SMART: HOW MALE AEDES AEGYPTI MOSQUITOES USE JUVENILE HORMONE TO MAKE FEMALES FITTER FOR REPRODUCTION BY SUPPRESSING THEIR IMMUNITY AND PROMOTING GUT MICROBIOTA EXPANSION

Mabel Taracena[1], Ana Beatriz Walter-Nuno[2], Gabriela Oliveira Paiva-Silva[2]

[1]Cornell University, Ithaca, NY, United States, [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Aedes aegypti mosquitoes are notorious vectors of diseases, and understanding their reproductive biology is essential for developing effective control strategies. Our research reveals how mating induces midgut growth in female mosquitoes, a response mediated by the transfer of Juvenile Hormone (JH) from males during copulation. In addition, we demonstrate how mating and JH modulate the mosquito's immune response in the gut, leading to the establishment of a core microbiota population that enhances reproductive output. Specifically, we have observed a JH-dependent suppression of Anti-Microbial Peptides (AMPs) in the female gut, resulting in an increase in bacterial load within the midgut. Our findings demonstrate for the first time how mating and Juvenile Hormones influence organ size and immune responses in the mosquito gut, and how this modulation leads to improved fitness in the form of increased egg counts and lifespan. Our results provide new insights into the molecular mechanisms underlying the interplay between nutrition, immunity, and reproduction in the mosquito gut, highlighting opportunities for further study and potential strategies for mosquito-borne disease control.

5903

WHOLE BODY VOLATILOMICS TO COMBAT VECTOR-BORNE DISEASE

Stephanie Rankin-Turner[1], Limonty Simubali[2], Monicah M. Mburu[2], Edgar Simulundu[2], Conor J. McMeniman[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Choma District, Zambia

Human scent is a complex blend of hundreds of volatile organic compounds (VOCs) released via breath and skin emissions that guides arthropod disease vectors towards us. To improve our understanding of human scent signatures, we have developed a field-deployable booth-style collection chamber which enables characterization of inter-individual variability in the chemical composition of human body odor. To validate this sampling chamber for whole body volatilomics, we first performed a screen of 20 humans in a laboratory setting to characterize and quantify the most frequent and abundant compounds present in whole body odor headspace across participants using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS). Application of this method facilitated detection of a range of VOCs including ketones, aldehydes, carboxylic acids,

alcohols, and hydrocarbons, and quantification of their emission rates in whole body headspace across large numbers of humans for the first time. Leveraging this information, we next developed ratio-specific slow-release lure formulations, mimicking the emission rates of the major components of whole body scent signatures, for use as mosquito attractants. In the laboratory, adhesive trapping assays with a synthetic human scent mimic that we developed revealed that An. gambiae are equally attracted to this novel lure relative to human foot odor. We next performed semi-field assays in Macha, Zambia to test the attractiveness of this lure within the context of the CDC-miniature light trap broadly used for surveillance of malaria vectors. The use of our human scent mimic lure supplemented with yeast-generated CO2 significantly boosted the performance of the CDC light trap, capturing almost four times as many mosquitoes as traps baited with yeast-produced CO2 alone. We propose the use of whole body volatilomics has the potential to instruct development of highly attractive synthetic lure blends for enhanced surveillance and control of varied arthropod disease vectors including major malaria vectors such as Anopheles gambiae and An. stephensi which is currently invading Africa.

5904

A MICROSCALE PLATFORM FOR IMAGING NEURAL CIRCUITS IN THE AFRICAN MALARIA MOSQUITO

Diego Giraldo, Abel Corver, Andrew Gordus, **Conor J. McMeniman**

Johns Hopkins University, Baltimore, MD, United States

The African malaria mosquito Anopheles gambiae is a deadly vector of malaria that detects humans using its sense of smell. We have recently applied CRISPR/Cas9-mediated homologous recombination and transposon-mediated transgenesis to generate transgenic strains of An. gambiae that express neural activity sensors in defined subsets of mosquito olfactory sensory neurons. These include olfactory sensory neuron populations expressing the olfactory co-receptors Ir76b, Ir25a, Orco and Gr22 - each responsible for detecting varied components of human scent. To overcome previous technical barriers for generating viable surgical preparations to image neural activity in the olfactory center of the An. gambiae brain, we have engineered a laser microsurgery apparatus to create precise micron-scale excision windows in mosquito head cuticle to reveal underlying brain tissue. This microscale platform for imaging neural circuits stands to provide significant insights into the molecular and cellular basis of An. gambiae attraction to human scent. By extension this open-source laser microsurgery device may also be used to study other facets of mosquito biology via intravital imaging of previously hidden mosquito tissues occluded by cuticle.

WARBURG METABOLISM IS CRITICAL FOR ANOPHELES MOSQUITOES ANTI-PLASMODIUM IMMUNE DEFENSE

Alex Moon[1], Zarna Pala[2], Joel Vega-Rodriguez[2], Jiannong Xu[1]

[1]New Mexico State University, Las Cruces, NM, United States, [2]National Institutes of Health, Bethesda, MD, United States

Warburg metabolism is an inefficient metabolic shift characterized by increased glycolysis and lactate production. This phenomenon has been observed in mammalian rapidly proliferating cancer and immune cells. Anopheles mosquitoes, which are the vectors for malaria, rely on their metabolic system to provide energy and intermediates for their innate immune system, known as immunometabolism. We posited a disruption of Warburg metabolism would impair the immune response of Anopheles mosquitoes to Plasmodium parasites. To test this hypothesis, we treated Anopheles mosquitoes with dimethyl fumarate (DMF), a GAPDH inhibitor, or used CRISPRi to silence the genes coding for GAPDH and LDH, key enzymes of Warburg metabolism. We then challenged the mosquitoes with either P. berghei (Pb, rodent malaria) or P. falciparum (Pf, human malaria). Our results showed that both DMF treatment and CRISPRi knockdowns increased parasite load in both Pb and Pf infections, and DMF-treated mosquitoes had a significant mortality in both infections. These findings suggest that Warburg metabolism is essential for mosquito anti-Plasmodium immunity.

SAMPLING EFFICIENCY AND MOLECULAR SCREENING OF YELLOW FEVER VIRUS IN AEDES MOSQUITOES IN NIGER DELTA REGION OF NIGERIA

Chioma Cynthia Ojianwuna[1], **Victor Ngozi Enwemiwe**[1], Andy Ogochukwu Egwunyenga[1], Chioma Amajoh[2]

[1]Delta State University, Abraka, Nigeria, Abraka, Nigeria, [2]Community Vision Initiative (CVI), Abuja, Nigeria

The vector potential of Aedes mosquitoes in the transmission of the arbovirus responsible for the transmission of yellow fever around the world is well documented. Although Nigeria is a high risk country for yellow fever, there is paucity of information in the Niger Delta region on the distribution of Aedes mosquito vectors and molecular detection of the virus in infected mosquitoes. This study was carried out to breach the gap. The mosquitoes were sampled in four communities (Otolokpo, Ute-Okpu, Umunede and Ute Alohen) in Ika North-East Local Government Area, Delta State, Nigeria. The efficacy of various methods of sampling the mosquitoes (Odour baited traps (BG sentinel), CDC light trap with attractant, CDC light traps without attractant and modified human landing catch (mHLC) were assessed for 12 weeks. Collected mosquitoes were transferred into a holding cages, killed by freezing at -4oC for 20 minutes. They were morphologically identified as Ae. albopictus using standard identification keys. A total of Seven hundred and Twenty-five (725) mosquitoes were obtained from the various traps. They were then preserved in RNAlater by pooling 10 mosquitoes per Eppendorf tube. The preserved mosquitoes were transported to National Arbovirus and Vector Research Centre Institute, Enugu Nigeria for screening of the virus strain using yellow fever primers and probes. Two samples (made up of 10 mosquitoes each) for every sample location were analyzed. It was observed that mean abundance of the mosquitoes was highest in mHLC (42.9 and the difference was highly significant ($p< 0.0001$). The mean abundance of mosquitoes was lowest in CDC light traps without attractant (0.29) compared to other means in other sampling techniques. It was also observed that no yellow fever virus strain was detected in all the mosquitoes sampled at the four locations. The possibilities of not encountering viral strains in mosquitoes may be due to the mass vaccination exercise that was carried out the previous year in the study area. Conclusively, adequate monitoring using the mHLC and continuous research are required to avoid resurgence of these virus in these locations.

5907

SURVEILLANCE OF ARTHROPOD-BORNE VIRUSES IN BENIN, WEST AFRICA 2020-2021: DETECTION OF DENGUE VIRUS 3 IN AEDES AEGYPTI (DIPTERA: CULICIDAE)

Carine Tchibozo[1], Gildas Hounkanrin[1], Anges Yadouleton[2], Hanna Joest[3]

[1]Laboratoire de références des fièvres hémorragiques et arbovirus du Bénin, Cotonou, Benin, [2]Laboratoire de références des fièvres hémorragiques et arbovirus du Bénin/ Ecole Normale Supérieure de Natitingou; National University of Science, Technology, Engineering and Mathematics (UNSTIM), Cotonou, Benin, [3]Bernhard Nocht Institute for Tropical Medicine, WHO Collaborating Centre for Arbovirus and Haemorrhagic Fever Reference and Research, Hamburg, Germany, Cotonou, Benin

The resurgence of arboviruses in recent decades is a major public health issue facing the international community due to the domestication of insect vectors. Aedes aegypti is the most important vector of arboviruses. In West Africa, it is known to transmit dengue virus (DENV), yellow fever virus (YFV), chikungunya virus (CHIKV), and Zika virus (ZIKV). To determine the abundance of arboviruses a longitudinal surveillance study was conducted in three consecutive years in Benin, West Africa. Adult mosquitoes were captured on human bait, Biogents Gravid Trap and BG-Sentinel traps at five ecological different locations in Benin from June 2019 to September 2021. A total of 3749 mosquitoes were collected and tested by RT-PCR

for arboviruses. One pool of Ae. aegypti captured on 7 July 2021 in Porto Novo tested positive for dengue virus. PCR results were confirmed by sequencing and showed the occurrence of dengue virus serotype 3. Our study highlights that there is a need to implement further investigations and surveillance strategies to prevent and control future outbreaks of mosquito-borne viruses in Western Africa.

5908

COMMON PREDATORS AND FACTORS INFLUENCING THEIR ABUNDANCES IN ANOPHELES FUNESTUS AQUATIC HABITATS IN RURAL SOUTHERN TANZANIA

Herieth Hezron Mahenge, Letus L. Muyaga, Joel D. Nkya, Khamis K. Kifungo, Najat F. Kahamba, Halfan S. Ngowo, Emmanuel W. Kaindoa

Ifakara Health Institute, Morogoro, Tanzania, United Republic of

The role that larval predators play in regulating the population of malaria vectors remains relatively unknown. This study aimed to investigate the common predators that with Anopheles funestus group larvae and evaluate factors that influence their abundance in rural south-eastern Tanzania. Mosquito larvae and predators were sampled concurrently using standard dipper (350ml) or 10L bucket in An. funestus habitats in south eastern Tanzania. Predators were identified using standard identification keys. Habitats were characterized, geo-located and water physicochemical parameters were recorded. Generalised linear mixed effects models (GLMM) using template model builder (TMB) with zero-inflated negative binomial implemented under the glmmTMB package. Result presented as risk ratios at 95% CI and statistical significance considered when P<0.05. A total of 85 identified An. funestus habitats were sampled for larvae and potential predators. A total of 8,295 predators were sampled, with Coenagrionidae 57.7% (n=4785), Corixidae 12.8% (n=1,060), Notonectidae 9.9% (n=822), Aeshnidae 4.9% (n=405), Amphibian 4.5% (n=370), Dytiscidae 3.8% (n=313) being common. There were 5,260 mosquito larvae sampled, consisting of An. funestus group 60.3% (n= 3,170), Culex spp. 24.3% (n=1,279), An. gambie s.l. 8.3% (n=438) and other anophelines 7.1% (n=373). Permanent and larger than 100m2 habitats were positively associated with An. funestus group and predator abundance (P<0.05). Habitats with submerged vegetation were negatively associated with An. funestus group (P<0.05). Only dissolved oxygen positively affected the abundance of An. funestus group (P<0.05). Predators' abundance was not impacted by any physicochemical parameters. The study highlighted six common predators and factors influencing their abundances in An. funestus aquatic habitats. Further studies are needed to demonstrate the efficacy of predators on larval density and adult fitness traits. Interventions leveraging the interaction between mosquitoes and predators can be established to disrupt malaria transmission and survival of the An. funestus mosquitoes.

5909

FINE-SCALE SPATIAL AND TEMPORAL DYNAMICS OF ANOPHELES GAMBIAE SWARMS IN SOUTH CENTRAL UGANDA

Krystal Birungi[1], Danspaid P. Mabuka[1], Victor Balyesima[1], Frederic Tripet[2], Jonathan K. Kayondo[1]

[1]Uganda Virus Research Institute, Entebbe, Uganda, [2]Swiss Tropical and Public Health Institute, Allschwil, Switzerland

In Africa, and especially in Uganda, sibling mosquito species belonging to the Anopheles gambiae species complex are some of the most widespread and important malaria vectors. New tools to complement existing ones are needed to control and eliminate malaria as progress has stagnated over the last few years, and even reversed in 2020. A number of new approaches for malaria vector control are being explored including population suppression through swarm reductions and genetic modification involving gene drives. These new interventions will involve understanding of the biology and mating behaviour of target vectors in order to be successful. However, Anopheles mosquito swarms have historically been hard to locate in Uganda and only one study documenting swarm collection has been published in the last two decades. This study located, characterised and collected An. gambiae s.l. swarms in study sites in south central Uganda during 2017 and 2018, filling an important gap in knowledge on the mating behaviour of An. gambiae in Uganda. A majority of swarms solely composed of An. gambiae s.s. were collected during this study, however some mixed An. gambiae s.s. and Culex spp. mosquito swarms were also observed. Swarms were larger in the wet season than in the dry season. Mean swarm height ranged from 2.16 metres to 3.13m off the ground and only varied between villages but not by season. An. gambiae mosquitoes were present in all three villages, preferred to swarm over bare ground markers, and could be effectively collected by field collectors. This study demonstrated that An. gambiae s.l swarms could be effectively located and collected in South Central Uganda and contributed to bridging the knowledge gap regarding the mating behaviour of An. gambiae mosquito species in Uganda in terms of swarm species composition, height above ground, swarm sizes, swarm marker preference and swarm distribution. While mixed species swarms have been reported before, this is the first documented instance of mixed genera swarms found in Uganda, and this warrants further study to fully understand the species mating dynamics.

5910

ANOPHELES STEPHENSI: THE EMERGING VECTOR OF MALARIA IN THE REPUBLIC OF DJIBOUTI, HORN OF AFRICA

Renaud Govoetchan[1], Mohamed Mousse Ibrahim[2], Arthur Sovi[1], Houssein Mouhamed Omar[3], Abdillahi Omar Boulhan[3], Houssein Youssouf Darar[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]National Public Health Institute of Djibouti, Djibouti, Djibouti, [3]National Malaria Control Programme of Djibouti, Djibouti, Djibouti

The present study investigated mosquito species composition and phenotypic insecticide resistance profile to support decision-making in malaria vector control in the Republic of Djibouti at the Horn of Africa. Adult mosquitoes were collected between December 2016 and December 2017 across 20 sentinel sites established in the 6 regions of the country using both Centers for Disease Control (CDC) miniature light traps and pyrethrum spray catches (PSC). Female mosquitoes were kept aside, for morphological identification to species by an expert entomologist using appropriate taxonomic keys by Gillies & Coetzee and Glick. WHO tube bioassays were also conducted in An. stephensi from Djibouti-ville against nine insecticides used in public health. A total number of 12,538 host-seeking mosquitoes belonging to four genera (Anopheles, Culex, Aedes, Uranotaenia) comprising 12 species were collected. Among these, An. gambiae s.l. and An. stephensi were the two major malaria vectors identified while secondary malaria vectors such as An. nili somalicus, An. dthali and An. azaniae were also collected. Cx. quinquefasciatus was the most abundant mosquito species in the 6 regions. WHO susceptibility tests performed on An. stephensi population from Djibouti-ville showed resistance to pyrethroids, organophosphates, carbamates and DDT. The resistance intensity bioassays indicated low to moderate intensity of resistance with pyrethroid insecticides and the organophosphate pirimiphos methyl. Meanwhile pre-exposure to PBO suggested involvement of P450 detoxification enzymes in pyrethroid resistance.These findings revealed the urgent need to develop and implement a programme for monitoring and managing insecticide resistance in local vector populations with efficient control strategies in Djibouti.

VIRAL INFECTION PROFILE OF AEDES MOSQUITOES IN SOME FORESTED AREAS IN GHANA

Helena Anokyewaa Boakye[1], Mavis Ofei[1], Jane Ansah-Owusu[1], Aaron Adjin-Lartey[1], Mufeez Abudu[1], Richard Malm Odoi-Teye[1], Sandra-Candys Arkorful[1], Joseph Harold Nyarko Osei[1], Seth Offei Addo[1], Kofi Bonney[1], Reginald Quansah[2], Jewelna Akorli[1], Samuel Dadzie[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]School of Public Health, University of Ghana, Accra, Ghana

Aedes-borne arboviral infections including Yellow fever (YF), Zika (ZIK), Dengue (DEN) and Chikungunya (CHK) have recently become a major public health concern worldwide and in Africa. Most arboviruses originate from the forest and circulated among non-human primates (NHPs) by arthropods including mosquitoes. Several outbreaks of arboviral diseases such as Dengue have been reported in many West African countries including those that share borders with Ghana. Recently, Yellow fever outbreak was reported in Ghana which resulted in 35 deaths. Although Ghana has not recorded other arboviruses, previous studies have indicated the presence of Dengue serotype-2 antibodies in some febrile patients. This study investigated the viral infection profile of Aedes mosquitoes collected from two forested areas in Ghana. A cross-sectional study was conducted in two forested areas, Achimota and Kakum National Park. The different stages of Aedes mosquitoes (eggs, larvae, pupae and adults) were collected using standard collection methods, identified and analysed. A total of 1,080 adult mosquitoes were morphologically identified. Aedes eggs collected from ovitraps in Kakum National Park yielded 17052 (87.2%) and in Achimota forest yielded 2498 (12.8%). The most prevalent Aedes subspecies collected from both sites were Ae. aegypti formosus, 156 (19.3%) in the Kakum National Park and 164 (60.1%) in the Achimota Forest which had diverse species. Culex fuscocephala were the most abundant Culex species identified in Kakum National Park (648). A total of 80 Anopheles gambiae (29.3%) were identified in the Achimota forest and 3 in the Kakum National Park (0.37%). Using RT-PCR, all 109 pools of Ae. aegypti mosquitoes were negative for YFV, DENV, ZIKV and CHIKV. The Positive Ovitrap Index (POI), a measure the risk of transmission was significantly higher (P= 0.03) in Kakum National Park: POI = 81.5% than Achimota forest :POI = 55.3%. The two forested sites are high risk areas for transmission of Aedes-borne arboviruses and sustained surveillance is needed to prevent future outbreaks.

THE CHANGING ECOLOGY OF LARVAL MALARIA VECTORS IN THE CITY OF ACCRA, GHANA

Abdul Rahim Mohammed[1], Isaac Amankona Hinne[2], Christopher Mfum Owusu-Asenso[1], Daniel Kodjo Halou[1], Richard Doe Tettey[1], Isaac Kwame Sraku[1], Yaw Akuamoah-Boateng[1], Anisa Abdulai[1], Fred Aboagye-Antwi[1], Yaw Asare Afrane[1]

[1]University of Ghana, Accra, Ghana, [2]University of Nevada, Reno, NV, United States

There is increasing evidence of malaria vectors adapting to breeding in polluted and other unexpected habitats in Sub-Saharan Africa. Historically, Anopheles mosquitoes breed in clean, unpolluted waters, and have shunned breeding in effluents from households and industries in cities. However, this seems to be changing in urban settings. This study investigated the Anopheles mosquito habitat types, their species composition, and their physicochemical parameters in the city of Accra, Ghana. Larval surveys and collections were undertaken in fifteen sites within the city of Accra (5° 36' 53.3448" N, 0° 12' 21.1464" W), Ghana, using the WHO standard dipping technique. These sites were selected and categorized into five sectors (three sites per category) based on the following: Irrigated Urban Farming (IUF), Lower (LS), Middle (MS) and High (HS) socioeconomic status, and Peri-urban (PU) sites. Physicochemical parameters were measured, and species identification was done using morphological and molecular methods. A total of 727 breeding habitats were found, of which [65.34%, n = 475/727] were positive for Anopheles larvae. Drainage ditches were the most abundant [48.21%, n = 229/475] habitat type. Overall, the abundance of An. gambiae s.l. was highest in IUF sites [6,244/22,919], and in the rainy season (77.01%; 17,650/22,919), (R2 = 3.46, P = 0.000). The highest larval densities of 19.22 and 13.22 larvae/dip were recorded in a swamp and tire track respectively in the rainy season. Malaria vectors were found to breed in much polluted waters including effluents from households. Polluted waters had on average dissolved oxygen of 17.6% compared to unpolluted (26.1%). Other parameters that distinguished polluted breeding habitats from unpolluted were conductivity (7332.5 uS/cm vs 2932.0 uS/cm); total dissolved solids (4567.0mg/L vs 1780.2mg/L); NH4-N (11.9 mg/L vs 4.9 mg/L). An. coluzzii 54.4% (368/677) was the most abundant species. The invasive An. stephensi, which has not yet been reported in Ghana was detected. The findings in this study provide evidence for the consideration of environmental management for malaria control in urban Accra.

5913

"FIGHTING AGAINST MALARIA IS EVERYONE'S CONCERN": A RANDOMISED CONTROL TRIAL ASSESSING THE ROLE OF INCENTIVES FOR ENCOURAGING LOCAL COMMUNITIES TO RECORDING AND UPLOAD MOSQUITO SOUND USING MOZZIWEAR APPLICATION

Winifrida P. Mponzi

Ifakara Health Institute, Dar Es Salaam, Tanzania, United Republic of

Current malaria surveillance methodologies are considered too expensive to scale within resource limited settings, hence new technologies and approaches are necessary to maximize data collection and ultimately design new malaria control tools. Effective mosquito surveillance can be enhanced through the utilization of digital technologies and engagement of citizen to real time data collection. This study was a follow-up research on the use of mobile phone application (mozziewear) for detecting and identifying wild host-seeking mosquitoes using their flight tones. In this particular study, citizens were provided with airtime incentives to encourage them to participate in recording and uploading mosquito sound. This study was randomised controlled trial (RCT) conducted in four villages in rural Tanzania between April and August 2022. Participants were randomised into two groups; 1) control group: nothing was provided to participants and 2) Incentive group: airtime was provided to participants. Both groups were then asked to record and upload mosquito flight tone data once per week for a period of four months. At the end of the study, experience survey was administered to participants in both groups to assess their experience of participating in this study. The results indicate that the participants were willing to record and uploaded mosquito flight tone data even without being paid incentives. They expressed that fighting against malaria is everyone's concern in rural Tanzania. In addition, the participants expressed their interest in being involved in future research efforts related to mosquito surveillance and the fight against malaria. In conclusion, citizens can still play a valuable role in scientific research, even without the promise of incentives. By participating in mosquito surveillance and malaria prevention studies, community members have significant contribution in addressing mosquito borne diseases and improvement of health outcomes

5914

MOLECULAR SURVEILLANCE LEADS TO THE FIRST DETECTION OF ANOPHELES STEPHENSI IN KENYA

Brenda Onyango[1], Eric Ochomo[1], Sylvia Milanoi[1], Benard Abong'o[1], Margaret Muchoki[1], Diana Omoke[1], Evelyn Olanga[2], Laban Njoroge[3], Elijah Juma[4], James Dan Otieno[5], Damaris Matoke[6], Luna Kamau[6], Cristina Rafferty[7], John E. Gimnig[7], Joseph Mwangangi[8], Marta Maia[8], Charles Chege[9], Ahmeddin Omar[9], Charles Mbogo[8], Lenson Kariuki[9]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]PMI Kinga Malaria Project, Abt Associates, Kisumu, Kenya, [3]National Museums of Kenya, Nairobi, Kenya, [4]Pan African Mosquito Control Association, Nairobi, Kenya, [5]World Health Organization, Nairobi,

Kenya, [6]Centre for Biotechnology Research and Development, Kenya Medical Research Institute, Nairobi, Kenya, [7]Centre for Disease Control and Prevention, Atlanta, GA, United States, [8]Centre for Geographical Medicine Research, Kenya Medical Research Institute, Kilifi, Kenya, [9]Division for National Malaria Program, Ministry of Health, Nairobi, Kenya

Anopheles stephensi is an invasive malaria vector that is endemic to south Asia and the Arabian Peninsula. Recently reported in the Horn of Africa countries including Djibouti (2012), Ethiopia, Sudan (2019), Somalia (2019) and Nigeria (2020). This mosquito is a competent vector for both Plasmodium falciparum and P. vivax. It is characterized by a high degree of behavioral plasticity and the ability to reproduce in various types of breeding sites including containers and therefore has the potential to propagate malaria transmission in rapidly urbanizing settings with poor drainage and waste disposal containers. The World Health Organization (WHO) has called on all countries to scale up surveillance efforts to report invasion by this vector and institute appropriate and effective control mechanisms. In Kenya, the Division for National Malaria Program (DNMP) and its partners have been conducting entomological surveillance in coastal and northern counties that are suspected to be at risk of An. stephensi invasion as well as counties at risk of malaria. These efforts were supported by molecular surveillance of Anopheles mosquitoes by the Kenya Medical Research Institute (KEMRI) to try and identify An. stephensi. We report the first detection of An. stephensi in Kenya in three sub-counties of Marsabit County in December 2022 and February 2023. Polymerase Chain Reaction (PCR) was used as the primary method of identification in addition to morphological identification with further confirmation of results by amplicon sequencing of the ITS2 region. Out of 566 samples analyzed by PCR 44 were confirmed to be An. stephensi. Sequencing of the ITS2 region was performed on 4 samples, 3 of which clustered closely with isolates from India, Yemen, Iraq, and Nigeria based on phylogenetic analysis. The detection of this vector in Kenya presents an urgent need to re-examine and expand the vector surveillance and control effort to include An. stephensi which is likely to increase transmission in Northern Kenya and spread further to highly populated areas and existing malaria-endemic counties further compounding the problem of malaria control in the country.

5915

ARBOVIRUS SURVEILLANCE AND BLOOD-MEAL ANALYSIS OF MOSQUITOES IN JAMAICA

Simmoy Noble, Nadia Khouri, Mario Golding, Simone Sandiford
The University of the West Indies, Mona campus, Kingston, Jamaica

Annually, mosquitoes are responsible for over 1 million deaths and 700 million infections. Arboviruses transmitted by mosquitoes are of global public health and veterinary significance, causing disease syndromes such as encephalitis, viral hemorrhagic disease, and sometimes death. Despite identifying several arboviruses across Jamaica, little is known about the non-human hosts that may be involved in the maintenance of these viruses in the different ecological habitats, as well as the contributions of various mosquito species in transmission cycles. Therefore, we aimed to identify blood-feeding patterns of mosquitoes in different ecological niches in addition to characterizing novel or re-emerging arboviruses and their hotspot localities before future outbreaks. Mosquitoes were collected from four ecological habitats (mangroves, forested, rural and peri-urban) using CO2-baited BG-sentinel and CDC light traps. Samples were transported to the laboratory on dry ice, where mosquitoes were identified and pooled into groups of 25 based on species, sex, date and location and stored at -80℃ until used for NGS. All blood-fed specimens were processed and stored on FTA cards for cytochrome c oxidase subunit I (COI) gene analysis. A total of 2,150 mosquitoes were collected belonging to 6 genera Aedes, Culex, Anopheles, Mansoni, Psorophora and Wyeomia. Culex quinquefasciatus, a competent vector for several arboviruses, was the dominant species identified. The information from this study can be used for informed and targeted vector control strategies and also as an early warning system to predict potential future outbreaks.

5916

PHENOTYPIC AND MOLECULAR INSECTICIDE RESISTANCE MONITORING OF ANOPHELES FUNESTUS MOSQUITOES TO GUIDE MALARIA CONTROL EFFORTS IN TANZANIA

Joel O. Odero[1], Ismail H. Nambunga[1], John M. Paliga[1], Emmanuel E. Hape[1], Rukiyah M. Njalambaha[1], Halfan S. Ngowo[1], Emmanuel W. Kaindoa[1], Salum A. Mapua[1], Najat F. Kahamba[1], Lizette L. Koekemoer[2], David Weetman[3], Heather M. Ferguson[4], Francesco Baldini[4], Fredros O. Okumu[1]
[1]Ifakara Health Institute, Morogoro, Tanzania, United Republic of, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]University of Glasgow, Glasgow, United Kingdom

Insecticide-based vector control approaches remain the mainstay of malaria control in Africa. The effectiveness of these tools is however threatened by the increasing vector resistance to the insecticides. In Tanzania, Anopheles funestus is an increasingly important malaria vector mediating most of the transmission in some settings compared to other vectors. Consequently, its routine resistance monitoring is crucial to ensure the continued efficacy of control tools against it. Between November 2021 - December 2022, we used WHO tube bioassays to assess the response of field-collected adult An. funestus to pre-determined doses of insecticides in nine regions in Tanzania representative of geographical variations and malaria transmission intensity. We further genotype the mosquitoes to monitor allele frequencies of three metabolic resistance genes - CYP6P9a, L114F-Gste2, and CYP6P9b; additionally, we analyzed the association between surviving the standard insecticide dose (phenotypic resistance) and these resistant alleles (genotypic resistance) using generalized linear models. We found high resistance to pyrethroids (deltamethrin and permethrin) across the country (mortality range 24-55%); however, susceptibility was fully restored following pre-exposure of the mosquitoes to piperonyl butoxide. Resistance to bendiocarb was mostly observed in the South (Mtwara, Lindi, & Ruvuma) and North (Kagera) of the country (mortality range 57-77%) with full susceptibility to DDT and pirimiphos-methyl. Moderate resistance intensity to deltamethrin was observed in coastal regions (Mtwara, Lindi, & Pwani) with high intensity confirmed in Pwani. Similarly, we detected moderate intensity for permethrin in Katavi and Mtwara. We observed a positive association between CYP6P9b and L114F-Gste2-resistant alleles and surviving lethal insecticide doses. However, carrying CYP6P9a-resistant alleles did not increase the chances of insecticide survival. These findings provide a basis for implementing resistance management strategies to limit the further exacerbation of resistance and its impact on malaria control efforts.

5917

DEVELOPMENT, PILOTING, AND EVALUATION OF AN ENTOMOLOGICAL ADAPTIVE SAMPLING FRAMEWORK (EASF) IN MOZAMBIQUE AND GHANA

[9]Lancaster University, Lancaster, United Kingdom, [10]University of California San Francisco, Malaria Elimination Initiative, San Francisco/University of Notre Dame, San Francisco, CA, United States

Routine entomological surveillance is important for monitoring and evaluating vector control interventions, however there is no operational guidance for optimizing entomological sampling in programmatic settings. An adaptive sampling framework responds to existing data and can adjust the sampling strategy to maximize representativeness and accuracy of the data across time and space. Applied as part of a malaria control program, this may be able to better capture changes in disease transmission dynamics to produce better data that can guide programmatic and strategic decisions.A spatiotemporal EASF model was developed for Mozambique and Ghana and used to inform adaptive entomological sampling designs across space and time for detecting changes in the three priority indicators: 1) vector species compositions, 2) vector behaviour, and 3) insecticide resistance (IR). The optimal sampling approach suggested by the spatiotemporal model is running in parallel with each country's routine surveillance framework. The EASF will be compared with routine surveillance in terms of the primary outcomes of representativeness, cost-effectiveness, and acceptability. In Mozambique the EASF will run for 2 years while Ghana 1 year. Here, we will present the year one EASF preliminary results from Mozambique and Ghana pilots.The EASF may help programs establish a cost-effective adaptive entomological surveillance strategy that is responsive to changing transmission dynamics and optimizes the use of available resources by obtaining more robust and informative data.

5918

INVESTIGATING THE SIBLING SPECIES DIVERSITY AND BREEDING BEHAVIOR OF THE MAJOR MALARIA VECTOR ANOPHELES GAMBIAE SENSU LATO IN SOUTHERN NIGERIA

Faith I. Ebhodaghe[1], Irma Sanchez-Vargas[1], Tatiana Vorontsova[1], Clement Isaac[2], Elizabeth Hemming-Schroeder[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Ambrose Alli University, Ekpoma, Nigeria

Mosquitoes in the Anopheles gambiae complex are major malaria vectors in Nigeria. However, studies that characterize the diversity and breeding behaviors of sibling species of the group in southern Nigeria are limited. To address this knowledge gap, we inspected water bodies for mosquito larvae in southern Nigeria. Results revealed the presence of Anopheles larvae in 53.49% (23/43) of mosquito breeding sites inspected between September and November 2022 in three southern Nigeria states (Edo, Delta, and Anambra). Molecular analysis identified wild-caught Anopheles larvae as An. coluzzii (89.44%, 95% CI: 84.91, 93.98) and An. gambiae sensu stricto (10.56%, 95% CI: 6.02, 15.09). An. coluzzii occurred in 95.45% (95% CI: 86.00, 100) of surveyed locations, whereas An. gambiae ss occurred in 31.82% (95% CI: 10.68, 42.50) of the same area. The larvae of both species were present in urban and periurban areas, and in puddles, stream margins, and open drains. Anopheles gambiae ss were further discovered in a concrete underground well. The overall average abundance of malaria larvae in water bodies was 1.82 larvae per dip (95% CI: 0.76, 2.89). Logistic regression analyses indicated higher odds of Anopheles larval presence in lowlands, and natural and shallow water bodies. Future work to be completed prior to the meeting include assessing population genetic structure of An. gambiae s.l. across diverse ecological habitats for understanding genetic diversity, vector dispersal, and insecticide resistance spread of the species in southern Nigeria. So far, we show that An. coluzzii are major malaria mosquitoes infesting extensive urban and periurban areas in southern Nigeria.

5919

MALARIA TRANSMISSION RISK INDICES OF SECONDARY VECTORS FROM COASTAL AND FOREST AXES OF NIGERIA

Isaac Olayinka Oyewole[1], Comfort A. Ibidapo[2]

[1]Babcock University, Ilisan Remo, Nigeria, [2]Lagos State University, Lagos, Nigeria

We sampled 14,332 female anophelines belonging to seven different species from coastal and forest axes in Nigeria between 2019 and 2022 using both morphological and molecular identification methods (using species specific PCR) to specific level. Major vectors including Anopheles gambiae Giles, An. arabiensis Patton, An. funestus Giles and An. melas represented ~98% of the total anopheline fauna identified. The remaining 2% was composed of An. moucheti Evans, An. coustani Laveran complex, An. leesoni Evans and An. nili (Theobald)(only species habiting both the coastal and forest areas). Enzyme Linked Immunosorbent Assay (ELISA) was used to determine the Circumsporozoite (CSP) infection status of the species of interest. Circumsporozoite (CSP) infection status showed that the mean infection rate of minor vectors (0.82%) was significantly (P=0.7652) lower than that of major vectors (2.36%). Plasmodium falciparum infection was high and repeatedly found in An. moucheti, indicating its contributory role to the total malaria transmission especially in the forest area. EIR indicates a mean of 146 infective bites/year: 51.8 from An. gambiae s.s., 29.2 from An. funestus, 14.6 from An. arabiensis, 29.2 from An. moucheti, 13.7 from An. melas, 7.3 from An. leesoni, 0.2 from An. coustani and 0.00 from An. nili respectively.

5920

AEDES AEGYPTI AND OTHER MOSQUITO SPECIES COHABITATING IN THE CHEKWOPUTOI CAVE, UGANDA

Austin J. Mejia[1], Teddy Nakayiki[2], Julius J. Lutwama[2], Fred Ssenfuka[2], George Ongodia[2], Kivumbi Brian[2], Rebekah C. Kading[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Uganda Virus Research Institute, Entebbe, Uganda

Aedes aegypti is a major mosquito vector of globally significant human pathogens. Ae. aegypti can transmit viruses such as dengue (DENVs), Zika, chikungunya, and yellow fever. Ae. aegypti exhibits a complex genetic structuring among populations in Africa. Significant knowledge gaps remain pertaining to the sylvatic larval habitats of Ae. aegypti. We opportunistically collected mosquito larvae (n=113) from a rock pool at the entrance to Chekwoputoi cave located in the Kween District, Uganda. This cave is is the known roosting site for a large colony of the African sheath-tailed bat, Colura afra and is regularly utilized by domestic and other wild mammal species. Mosquitoes were reared to adults at the Uganda Virus Research Institute and morphologically identified. This collection comprised eight species: Ae. aegypti formosus (n=5), Anopheles rhodesiensis, and six additional Culex and Aedes species. Species identifications will be confirmed using molecular techniques and documented using high resolution photography. These observations represent unique ecological insight into the larval habitat and mixed-species larval community of medically-important mosquito species in Uganda. We hope to utilize this information to understand mosquito vector ecology in this poorly-studied area, and how these vectors cohabitate with each other.

5921

ROLE OF MALARIA VECTORS BLOOD-MEAL PREFERENCES ON MALARIA TRANSMISSION RISK IN MASENO AND KOMBEWA, WESTERN KENYA

Risper Maisiba

Department of Emerging Infectious Diseases (DEID), United States Army Medical Research Directorate-Kenya (USAMRD-K), Kenya Medical Research Institute (KEMRI, Kisumu, Kenya

Mosquito feeding behavior provides a baseline in understanding malaria transmission risk. Accurate identification of relative proportion of bloodmeals taken from humans and alternative hosts is important in calculating

entomological indexes such as Human Biting Rate (HBR) an important component in calculation of vectorial capacity- a measure of malaria transmission that increases with HBR. A longitudinal study involving collection of Anopheles mosquitoes was carried out from July 2015 to August 2016 in Kombewa and Maseno study sites, Western Kenya using Prokopac aspirator for indoor collections. Microscopy was used to identify An. gambiae sensu l ato (s.l)and An. funestus species. Polymerase chain reaction (PCR) was used to further characterize mosquito species within the Anopheles gambiae s.l into An. gambiae sensu stricto (s.s) and An. arabiensis. Enzyme-linked immunosorbent assay (ELISA) was used in blood meal identification. A total of 573/923(62.1%) Anopheles mosquitoes had blood meals of which An. funestus and An. gambiae s.s were 373/573 (65.1%) and 200/573 (34.9%) respectively. An.arabiensis was rather transient with only 4/309 testing positive of An.gambiae s.l identified . Bloodmeals were inclusive of human 485/573 (84.6%), cow 40/573 (7.0%), dog 7/573 (1.2%), chicken 3/573 (0.5%), goat 1/573 (0.2%), while cat and donkey appeared in mixed sources. Blood meals containing human and alternative sources were 13/200 (6.5%) and 20/373 (0.5%) in An. gambiae s.s and An. funestus respectively. Surprisingly, mixed non-human blood meal sources were observed in An. gambiae s.s at 4/200 (2.0%) contrary to some of the previous studies. An. funestus was majorly anthrophilic as opposed to An. gambiae s.s that showed opportunistic behavior. This marginal shift from normal feeding patterns exhibited by An. gambiae s.s appears to suggest increased risk of malaria transmission in study populations. Additional survey on host feeding preferences is necessary in order to support reciprocal changes in malaria control strategies to contain this enhanced risk.

5922

BITING PATTERN OF ANOPHELES ARABIENSIS, HUMAN BEHAVIOUR, AND SOCIO-ECONOMIC MALARIA RISK FACTORS IN AN IRRIGATED AGROECOSYSTEM IN WESTERN KENYA

Benyl M. Ondeto[1], Pauline W. Orondo[2], Harrysone Atieli[3], Guofa Zhou[4], Simon M. Muriu[5], Lydiah W. Kibe[6], Xiaoming Wang[4], Ming-Chieh Lee[4], David O. Odongo[1], Horace Ochanda[1], James Kazura[7], Andrew K. Githeko[8], Guiyun Yan[4]

[1]University of Nairobi, Nairobi, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, [3]Sub-Saharan Africa International Center of Excellence for Malaria Research, Tom Mboya University, Kisumu, Kenya, [4]Program in Public Health, College of Health Sciences, University of California at Irvine, Irvine, CA, United States, [5]Pwani University, Mombasa, Kenya, [6]Eastern and Southern Africa Centre of International Parasite Control, Kenya Medical Research Institute, Nairobi, Kenya, [7]Center for Global Health and Disease, Case Western Reserve University, Cleveland, OH, United States, [8]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

Knowledge on the biting patterns of malaria vectors, human behavior, and malaria risk factors is important in understanding malaria transmission dynamics, evaluating the effectiveness of vector control interventions, and informing the development of appropriate interventions. This study assessed vector biting patterns, human behavior, and socio-economic malaria risk factors in an irrigated agro-ecosystem in western Kenya. Adult mosquitoes were sampled using human landing catches. The mosquito samples were identified to species using polymerase chain reaction (PCR). Malaria parasites were detected by quantitative PCR. Human behavior data was collected using a questionnaire to understand human night activities and sleeping patterns and how they overlap with vector behavior. In order to investigate the association between malaria prevalence and socioeconomic risk factors, these parameters were also included in the questionnaire. The mean indoor and outdoor host-seeking densities of An. arabiensis varied significantly, with the highest density collected indoors. During the first half of the night (6 p.m.-12 a.m.), indoor biting activity of An. arabiensis showed a peaked plateau between 8 p.m. and 10 p.m. before the local community went to sleep. Data on human behavior and indoor mosquito biting activity showed that there is a high risk of transmission at dusk and dawn when people are not under the protection of bed nets. Outdoor biting activity of An. arabiensis occurred throughout the night; nonetheless, the greater proportion of the human population was indoors from dusk to dawn; therefore, there was a low risk of outdoor malaria transmission. These findings demonstrate that there was a higher risk of malaria transmission due to factors such as sleeping indoors, sleeping late, a lack of bed nets, and low utilization. The study underscores the necessity of complementing the core malaria vector control strategies by integrating larval source management and novel techniques such as transgenic mosquitoes.

5923

PREVALENCE OF MICROSPORIDIA MB AMONG ANOPHELES MOSQUITOES MAY BE ASSOCIATED WITH MICRO-ECOLOGICAL FACTORS OF BREEDING NICHES

Esinam Abla Akorli[1], Nana Efua Andoh[2], Richardson Egyirifa[1], Christopher Dorcoo[1], Sampson Otoo[1], Seraphim N.A. Tetteh[1], Reuben Pul[1], Stephen Oware[1], Derrick Sackitey[1], Samuel K. Dadzie[1], Jewelna E. B Akorli[3]

[1]Noguchi Memorial Institute for Medical Research, Legon, Ghana, [2]Department of Parasitology, Noguchi Memorial Institute for Medical Research, Legon, Ghana, [3]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Microsporidia MB is found associated with Anopheles mosquito vectors and shown to interfere with the development of Plasmodium. In Kenya where this was first reported, Microsporidia MB was widespread in An. arabiensis collected from rice fields. Since then, the symbiont has also been reported in An. gambiae and An. funestus. As a potentially useful tool for symbiont-based disease control, its ecological distribution is still not clearly understood especially since Anopheles mosquitoes have different niches. This study was aimed at determining the prevalence of Microsporidia MB in Anopheles mosquitoes in selected sites across Ghana, and measuring the physicochemical parameters of breeding sites to determine the associated micro-ecological factors. Anopheles larvae and pupae were collected from study sites in northern and southern Ghana between Aug-October of 2021 and 2022. A total of 4195 immature mosquitoes were raised to adults and DNA was extracted from the abdomen. Microsporidia MB was detected by qPCR and mosquito species molecular identification using a SINE and RFLP methods. The overall prevalence of Microsporidia MB was 1.9% (78/4195) with prevalence similar among An. gambiae (41.0%; 78/4195) and An. coluzzii (30.8%; 24/78) (χ;2, P= 0.28), reiterating previous findings from archived samples. Microsporidia MB was observed in only one An. arabiensis (1.3%; 1/78). Male mosquitoes showed predominance in Microsporidia MB infections (χ;2, P= 0.001). Sites in the Savannah ecological zone of Ghana, which had no associations with rice fields, had the highest prevalence of Microsporidia MB (55.1%; 43/78) compared to other sites (χ;2, P= 0.0009). Overall, the study suggests the distribution of Microsporidia MB is most widespread among predominant malaria vectors in a geographical region and their sustainability in the aquatic stages of the host may be influenced by microecological factors. Further analyses on the physiochemical parameters collected will help in our understanding of the distribution of this symbiont among Anopheles mosquitoes in their different breeding niches.

5924

THE CHANGING LANDSCAPE OF DENGUE AND CHIKUNGUNYA VECTORS IN KENYA – A THREAT TO PUBLIC HEALTH.

Joel Lutomiah, Francis Mulwa, James Mutisya, Betty Chelangat, Edith Chepkorir

Kenya Medical Research Institute (KEMRI), Nairobi, Kenya

Dengue and chikungunya are a major problem in Africa, causing outbreaks annually. In Kenya, dengue (DENV), chikungunya (CHIKV), primarily transmitted by Aedes aegypti, frequently cause outbreaks mainly in urban coastal (Mombasa, Lamu) and northern (Mandera and Wajir) counties resulting in significant morbidity, associated lost man-hours, enormous socio-economic impact among communities, and burden on health systems. Entomological Surveillance was conducted during dengue

and chikungunya outbreaks in Mombasa to i) determine the presence and densities of Ae. aegypti vectors, ii) identify breeding habitats and iii) identify other potential vector species previously not associated with these viruses. Sampling involved collection of adult mosquitoes using BG sentinel and CDC light traps; and larval collection from affected areas. During the 2013/2014 dengue outbreak, 2,069 adult Aedes mosquitoes were collected: Ae. aegypti (n=2,069) and Ae. vittatus (n=4); while larvae comprised of n=2,510 Ae. aegypti outdoor (n=1,515), indoor(n=995) and Ae. vittatus (n=0). In 2018 chikungunya outbreak, 2,086 adults: Ae. aegypti (n=911), Ae vittatus (n=1,175); and n=528 larvae: n=526 Ae. agypti (indoor, n=280; outdoor, n=246), and Ae. vittatus, (outdoor, n=2) were collected. N=2,511 adult female Culex quinquefasciatus mosquitoes were also collected, and two CHIKV isolates obtained. Ae. vittatus occur in abundance, voraciously bite humans despite being majorly zoophilic. CHIKV has also been repeatedly isolated from them and have been shown to efficiently transmit CHIKV. Therefore, it plays a critical role in Key in sylvatic maintenance; and urban transmission of DENV, CHIKV, YFV, ZIKV whenever it invades urban areas. Although predominantly a rock-pool, tree-hole breeder; it can breed in diverse macro-, micro-habitats. A combination of Ae. aegypti, Ae. vittatus and Cx. quinquefasciatus poses a major challenge in vector control. Therefore, intensive surveillance to identify breeding habitats for Ae. vittatus in Mombasa is instrumental in devising appropriate vector control tools specific to this species.

While agricultural production is expanding in low-and mid-income countries, the vast majority of plough able land is too dry to depend only on rain-fed agriculture. Irrigation is the most effective and supplementary system to increase crop production and yields as well as to ensure reduced risk of crop failure. While these large-scale agriculture may enhance local economies and consequently boost livelihoods, some crop systems create and sustain suitable mosquito breeding habitat and hence affect malaria transmission especially where drainage system is poor. We conducted a study in Manhica district in 2020, south of Mozambique to characterize mosquito-breeding habitats along an irrigated sugarcane plantation. Additionally this study aimed at assessing how mosquito immatures change in different environments as well as which breeding types contribute and sustain malaria mosquitoes throughout the year. Here we will present the outcome of this survey in Manhiça district. This study will provide useful information to the programme and significantly enhance understanding of use of focal control of larvae in Mozambique either through aerial spray or manual where applicable.

5926

DETECTION OF INSECT-SPECIFIC VIRUSES IN MOSQUITOES COLLECTED IN URBAN AND FOREST FRAGMENT AREAS OF NORTHWEST OF SAO PAULO STATE, BRAZIL

Igor Teixeira[1], Victoria Bernardi[1], Maisa Parra[1], Margareth Dibo[2], Joao Marques[3], Nikos Vasilakis[4], Mauricio Nogueira[1], **Lívia Sacchetto**[1]

[1]Faculdade de Medicina de Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil, [2]Superintendência de Controle de Endemias, Sao Jose do Rio Preto, Brazil, [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [4]The University of Texas Medical Branch, Galveston, TX, United States

Insect-specific viruses (ISVs) can affect arboviruses cycle transmission, mainly impacting vector competence, and have a great potential to be used as biological control agents or vaccine platforms. From March 2022 to March 2023, we collected 463 mosquitoes (allocated in 273 pools) from urban and forest fragments of Sao Jose do Rio Preto (SJdRP), Sao Paulo, Brazil. The mosquito species belong to different genera, including Culex, Aedes, Psorophora, Sabethes, and Limathus. So far, 136 pools have been submitted to viral isolation and molecular investigation for medically important flaviviruses, alphaviruses, and for insect-specific viruses such as PCLV, HTV, GUAPV, CxFV, and AeFV. We detect HTV in 22 pools (16.17%) of mosquitoes from Aedes, Culex, and Sabethes genera. PCLV was detected in 30 pools (22%) of mosquitoes from Aedes and Culex genera. CxFV was detected in 20 pools (14.70%) of Culex genus. We detect GUAPV in three pools (2.2%) of mosquitoes from Limathus, Culex, and Psorophora genera. PCR products were sequenced by the dideoxy method confirming these results. In addition, we had 15 pools (11%) of mosquitoes from Aedes and Culex genera positive in a pan-Flavivirus PCR. The PCR products of these samples were sequenced by the dideoxy method, and the nucleotide sequences obtained showed similarity with other mosquito flaviviruses. In addition, we have some co-infections: 13 pools of Aedes aegypti and one pool of Culex sp. co-infected with HTV and PCLV; two pools of Aedes aegypti co-infected with FLAV-like and PCLV; one pool of Culex sp. co-infected with PCLV and CxFV; one pool of Culex sp. co-infected with GUAPV and CxFV; and one pool of Aedes aegypti co-infected with HTV, PCLV, and FLAV-like. All pools tested negative for the medically important arboviruses. Our next steps are genomic characterization/biological characterization and electron microscopy. Our findings demonstrate the viral diversity in mosquitoes from SJdRP and open perspectives for further studies of metagenomics, vector competence, and interactions between these ISVs and circulating arboviruses.

5927

A METHODOLOGICAL FRAMEWORK TO UNDERSTAND THE DRIVERS OF DENGUE FOR DESIGNING OPERATIONALLY EFFICIENT AND SUSTAINABLE VECTOR CONTROL POLICIES IN ENDEMIC SETTINGS; A CASE STUDY FROM KALUTARA DISTRICT, SRI LANKA

Chaminda Prasad Gigummaduwa Liyanage[1], Joacim Rocklöv[2], Hasitha Aravinda Tissera[3], Yesim Tozan[1]

[1]School of Global Public Health, New York University, New York, NY, United States, [2]Heidelberg Institute of Global Health & the Interdisciplinary Center for Scientific Computing, University of Heidelberg, Heidelberg, Germany, [3]Epidemiology Unit, Ministry of Health, Colombo, Sri Lanka

Dengue imposes a substantial public health and economic burden on affected populations in endemic countries, including Sri Lanka. Complex interactions among susceptible humans, viruses, and Aedes mosquitoes determine dengue's transmission and spread. Assessments of context-specific climate and non-climate drivers of dengue transmission and the analysis of effectiveness and cost-effectiveness of dengue control interventions are required to develop pragmatic and sustainable dengue control programs. To meet this demand, we developed a methodological framework which is capable of (1) identifying the most vulnerable populations by assessing delayed and non-linear associations between

climate and non-climate drivers of dengue across different geographical settings; (2) evaluating the effectiveness and cost-effectiveness of population-level vector control interventions implemented to address the identified drivers in the above settings. We found that early and targeted interventions, triggered by the evidence generated through the methodological framework, were effective and cost-effective, reducing the burden of dengue by 50% in a highly endemic area in Kalutara district, Sri Lanka. Given the capacity is established, program managers can use this methodological framework to develop a decision-support platform to set up short-, intermediate-, and long-term targets for designing and deploying equitable and efficient operational response to dengue. The inbuilt monitoring and evaluating framework would promote a more informed and transparent public health decision-making process towards attaining the World Health Organization's dengue and other vector-borne disease targets by 2030 in endemic and resource-constrained settings.

5928

COMMUNITY PERCEPTIONS OF NUMBER OF MOSQUITOES AND MOSQUITO BITES AFTER USE OF WOLBACHIA SUPPRESSION AS A CONTROL METHOD FOR AEDES AEGYPTI MOSQUITOES IN PONCE, PUERTO RICO

Clary N. Herrera[1], Wilmarie Rivera[2], Alfonso Hernandez-Romeiu[3], Julieanne Miranda-Bermúdez[4], Nexilianne Borrero-Zeno[4], Jania García-Zeno[4], Liliana Sánchez-González[3], Chelsea G. Major[3], Vanessa Rivera-Amill[2], Laura E. Adams[3], Grayson Brown[4]

[1]Pozomy Federal, Landover, MD, United States, [2]Ponce Health Sciences University and Saint Luke's Episcopal Hospital Consortium, Ponce, Puerto Rico, [3]Division of Vector Borne Diseases, Centers for Disease Control and Prevention, San Juan, Puerto Rico, [4]Puerto Rico Vector Control Unit, Puerto Rico Science, Technology, and Research Trust, San Juan, Puerto Rico

Wolbachia suppression (WS) can reduce Aedes aegypti mosquito populations, the main vector of the dengue virus, by decreasing the hatch rate of eggs from crosses of released Wolbachia-carrying male and wild-type female mosquitoes. Because WS involves releasing mosquitoes, understanding community members' perceptions of the number of mosquitoes and mosquito bites after releases are important to inform the acceptability of WS. During 2020-2021, WS was tested in a randomized cluster trial in 8 communities in Ponce, PR. We conducted phone and in-person surveys of adult residents of the 4 release (intervention) and 4 non-release (control) areas during August-October 2022. We compared post-release community perceptions of the number of mosquitoes and mosquito bites in intervention and control areas using chi-square tests of proportion. We also identified factors associated with reporting fewer mosquitoes and fewer or no change in mosquito bites in intervention areas using logistic regression. Of 258 total respondents, 70% were female, the median age was 51 years (range 19-93), 69% were aware of mosquito releases, of whom 75% had supported releases. Demographic characteristics and awareness of and support for WS were similar in release and control areas. While not statistically significant, a higher proportion of respondents in release areas reported perceiving fewer mosquitoes (19% vs. 12%, Chi-square p=0.4) and mosquito bites (27% vs. 16%, Chi-square p=0.06) compared to respondents in control areas. Among respondents in release areas, age, sex, awareness, and support of releases were not associated with reporting fewer mosquitoes; however, women were more likely to report perceiving less or no change in mosquito bites (adjusted OR 3.3 [95%CI 1.4-7.9]) compared to men. Community perceptions of mosquito numbers and mosquito bites were consistent with expected results from implementation of WS, where total mosquito numbers and mosquito bites decrease due to decreased egg hatch rates. Our findings suggest that WS may be associated with perceptions of fewer mosquitoes and mosquito bites, informing the acceptability of WS.

5929

USING HIGH POWER ELECTRIC FIELDS TO REPEL MOSQUITOES

Ndey Bassin Jobe, Krijn Paaijmans

Center for Evolution and Medicine, School of Life Sciences, Arizona State University, Tempe, AZ, United States

To control and prevent existing and (re) emerging mosquito-borne diseases, insecticides are often our only option. Insecticides reduce mosquito population sizes and/or prevent human-vector contact, but their excessive use raises concerns for our environment, our health, and led to the rapid development and spread of insecticide resistance. As a result, the development of novel technologies for mosquito control is urgently needed. One of the new tools in development is the use of high power pulsed electrical fields (EFs) that create an invisible barrier and repel mosquitoes. I will provide an overview of the current knowledge of this first non-chemical insect repelling technology, and present novel data on how EFs generated with cheap over-the-counter insulated conductor wires prevent host-seeking Aedes aegypti mosquitoes from entering spaces, allowing us to protect typical mosquito entry points in houses (such as eaves, windows, and doors) as well as groups of people outdoors.

5930

ASSOCIATION OF WATER AVAILABILITY AND AEDES AEGYPTI PUPAE AND ADULTS IN AN URBAN/RURAL MOSAIC IN NICARAGUA

Jose G. Juarez[1], Harold Suazo[1], Jacqueline Mojica[1], Maria Mercedes Lopez[1], Angel Balmaseda[2], Eva Harris[3], Josefina Coloma[3]

[1]Sustainable Science Institute, Managua, Nicaragua, [2]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [3]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

The increase in dengue virus (DENV) epidemics and the latitudinal expansion of Aedes mosquitoes globally has made it critical to understand the ecological and social factors that modulate its population abundance locally. We used multilevel models to evaluate the different life stage abundances of Ae. aegypti collected from October to December of 2022 (rainy season) in 500 households in 21 urban and peri-urban neighborhoods in District 3 of Managua, Nicaragua, as part of an arbovirus surveillance study (A2CARES). A total of 1,194 pupae and 201 adult female mosquitoes (indoor: 129, outdoor: 72) were collected. We used a GLMM and GAMM approach to estimate pupae and adult female indoor and outdoor abundance. The number of pupae found in a home was directly associated with number of containers present (exp= 1.41, SE= 0.09, p< 0.001) and outdoor female specimen abundance (exp= 2.73, SE= 0.47, p< 0.03). We observed that outdoor female abundance increased with frequency of water service interruptions per day (exp= 1.07, SE= 0.02, p< 0.01), total number of pupae found in the household (exp= 1.027, SE= 0.009, p< 0.01) and neighborhood of collection (exp= 0.501, SE= 0.027, p=0.01). The GAMM smooth for water interruptions was also significant, increasing with the number of female mosquitoes outdoors. Indoor female abundance was only associated with the number of pupae found in a home (exp= 1.021, SE= 0.008, p< 0.01). We are currently untangling the fine-scale spatial patterns for mosquito abundance, human density, access to water and services, and most productive containers to evaluate how these variables impact mosquito ecology using a urbanicity mosaic perspective within our study site. Our results suggest that for our geographic setting, pupae can be an adequate proxy for female abundance. More importantly, the inclusion of stakeholders involved in household water container management and municipal services are critical for future intervention projects in the region. Fine-tuning hotspot analysis of mosquito abundance to identify key factors that modulate their population is critical to improve vector control activities in limited-resource settings.

5931

IMPACT OF STANDARD AND LONG-LASTING IVERMECTIN FORMULATIONS IN CATTLE AND BUFFALO ON WILD ANOPHELES SURVIVAL ON SUMBA ISLAND, INDONESIA

Kevin Conrad Kobylinski[1], Tri Baskoro[2], Wisnu Nurcahyo[2], Arca Testamenti[2], Diana Timoria[3], Mary Chambers[3], Joel Tarning[1], Lorenz von Seidlein[1], Claus Bøgh[4]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]University of Gadjah Mada, Yogyakarta, Indonesia, [3]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam, [4]Sumba Foundation, Sumba, Indonesia

Sumba Island has some of the highest diversity of Anopheles species in Indonesia, contributing to its high malaria incidence. Southwestern Sumba, the area with highest malaria burden, has small livestock holder systems where the animals (e.g. cattle, buffalo, horses, and pigs) are kept near the owners' house at nighttime, often underneath the house. Anopheles mosquitoes frequently blood-feed on livestock providing an opportunity for vector control by treating the animals with insecticides. Ivermectin is a systemic endectocide used to control helminth and ectoparasites in livestock, and ivermectin-treated hosts are lethal to Anopheles vectors. Both standard (Ivomec) and long-lasting (Ivergen Platinum) commercial formulations of ivermectin were investigated in cattle and buffalo in this study. Four villages were selected to maximize the diversity of Anopheles species. In each village, three cattle and three buffalo were treated with either standard (200 ug/kg), or long-lasting ivermectin (630 ug/kg), or kept untreated as controls. Study animals were placed in net traps, which allowed mosquitoes to enter and blood feed on the animals. Mosquitoes were collected by mouth aspiration. Animals were exposed to mosquitoes before treatment and up to 70 days post treatment. A venous blood sample was collected from the study animals the morning after each mosquito collection for ivermectin quantification. Blood-fed Anopheles were transported to a field insectary where their survival was monitored daily. Each day the dead mosquitoes removed, identified to species, and on day ten of monitoring the mosquitoes were frozen and counted as alive. Ten Anopheles species were frequently collected including: An. aconitus, An. annularis, An. barbirostris, An. flavirostris, An. kochi, An. maculatus, An. subpictus, An. sundaicus, An. tessellatus, and An. vagus. Cattle treated with long-lasting ivermectin were lethal to all Anopheles species through 46 days post treatment. Ivermectin concentrations will be quantified and linked to mosquito mortality to characterize the lethal concentration that kills 50% of the mosquitoes for each species captured.

5932

AUTOMATING MOSQUITO STERILE INSECT TECHNIQUE (SIT)

Ariel Livne, Elly Ordan, Yoni Waitz, Noa Dahan

Diptera.ai, Jerusalem, Israel

One of the best prevention methods for vector-borne diseases is control of the vector itself. For mosquitoes that transfer a number of viruses and parasites affecting millions, an integrated management approach has proven most effective. Integrated control brings together tools like source control, larviciding and adulticiding. For a subset of species coined as "container breeding" this approach has fallen short. The main difficulty in controlling container breeding mosquitoes is that source control and larviciding are near impossible. One important tool that could close the gap is the sterile insect technique (SIT). SIT works by overwhelming the vector population with sterile males causing the production of unfertilized eggs. SIT has been in use for decades against a couple of agricultural pests and numerous field tests for mosquito vector control have shown great success. As male mosquitoes will seek out females even when humans can't find all their hidden breeding sites, SIT can close the hole in integrated control of container breeders. Mosquito SIT requires accurate sex-sorting to ensure no females are released. Currently, state of the art technologies sort at the late developmental stages. However, as adult mosquitoes have a short lifespan and are fragile, they must be produced near the release site (usually manually). This makes mosquito SIT prohibitively expensive. Uniquely, Diptera.ai can sex-sort mosquitoes and numerous agricultural pests at the larval stage, previously considered impossible. Larvae can be shipped long-distance from centralized facilities, thus allowing for economies of scale and introduction of rearing automation. Our sex sorter utilizes proprietary optics coupled with machine learning algorithms to rapidly and precisely predict and separate larvae sexes. The system is comprised of an array of small autonomous units. This design allows for maximum flexibility and means that units can be serviced without shutting down production. Using the systems described above we successfully controlled the Aedes albopictus population in a small town over an entire season.

5933

SPATIAL ANALYSIS OF ENVIRONMENTAL DRIVERS AND MOSQUITO SPECIES ABUNDANCE ON MALARIA PREVALENCE IN KENYA FROM JANUARY 2019 TO JUNE 2021

Over 50% of the global population is at risk of contracting malaria, especially those living in 85 endemic countries- the majority of which are in Sub-Saharan Africa. Climate change is impacting malaria prevalence and mosquito species distribution and densities. Our objective was to estimate the effect of climate parameters (temperature, humidity, rainfall) and mosquito species on malaria prevalence in Kenya from January 2019 to June 2021 We compiled data across 31 counties in Kenya from previous surveillance work: a malaria indicator survey, secondary data from a monthly entomological survey and a household malaria indicator survey. We analyzed the data using linear regression, correlation and used least absolute shrinkage and selection (LASSO) for selection of coefficients. We found that malaria prevalence in Kenya is highest in the lake region with prevalence at 19%, coast endemic at 5%, semi-arid seasonal at 2%, and low risk at 0.9% for 2020. The mosquito species distribution varied across malaria epidemiological zones. In the coastal region, An. Funestus was more abundant, while in the lake region An. Gambiae was more abundant, although significant An. Funestus' presence was also detected. The regression results suggest that a combination of environmental factors (such as temperature, vegetation, and aridity) as well as public health interventions (such as ITN coverage) are important predictors of malaria prevalence. However, the relationship between some of these factors and malaria prevalence is complex and may vary across different regions and time periods.Overall, this study provides insights into the spatial-temporal dynamics of mosquito species and their distribution in relation to malaria epidemiological zones in Kenya and can inform control strategies within specific ecological zones. Further studies are needed to better disentangle the factors influencing the distribution and abundance of mosquito species in different malaria epidemiological zones in Kenya

STUDY OF THE DIVERSITY OF MACRO INVERTEBRATES ASSOCIATED WITH THE LARVAL HABITATS OF ANOPHELES GAMBIAE COMPLEX IN TWO VILLAGES OF THE KATI DISTRICT MALI

Aissata Sanogo[1], Amadou Guindo[1], sidy Doumbia[1], Brehima Diallo[1], Frederic Tripet[2], Mamadou B Coulibaly[1]

[1]Malaria Research and Training Center (MRTC), Bamako, Mali, [2]Centre for Applied Entomology and Parasitology, School of Life Sciences, Keele University, Staffordshire, UK, Keele, United Kingdom

Target Malaria is a non-profit research consortium, which aims to develop new vector control strategies against malaria using genetic technologies based on population reduction. The aim is to reduce the malaria-carrying mosquito population in the Anopheles gambiae s.l. complex in the long term. Before that, it is important to understand the biodiversity and

abundance of macro invertebrates associated with the larval habitats of An. gambiae s.l. in different ecological environments for risk assessment purposes. It is in this context that this study proposes to inventory macro-invertebrates in mosquito breeding sites. From June 2021 to December 2022. The collection was carried out in two sites by monthly rentals at the level of the previously characterized cottages. Macro-invertebrates have been morphologically identified.Preliminary results show a total of 122 macro-invertebrates. The following species have been encountered: Lestidae, Bactidae, Corixidae, Dytiscidae, Gyrinidae, Hydrophilidae, Nepidae, Notonectidae, Physidae at both sites; Anisoptera, Belostomatidae, Haliplidae, Lestidae, Libellulidae, Lymnacidae, Naucoridae, Noteridae, Veliidae only in Ouassorola. The number varies according to the sites Ouassorola = 66%, Sogolombougou = 34% and over time. Notonectidae were most abundant in Sogolombougou (95%) and Noteridae was the most abundant species in Ouassorola, 97.94%. The rivers had the greatest diversity of macro-invertebrates compared to the other habitats studied (Brick Quarries, Footprints).

FEASIBILITY AND COMMUNITY ACCEPTANCE OF INSECTICIDE TREATED EAVE NETS AND INSECTICIDE TREATED WINDOW SCREENS IN TANZANIA

Zawadi Mageni Mboma[1], Fadhila Kihwele[1], Olukayode G. Odufuwa[1], Rose Philipo[1], Jason Moore[1], Ole Skovmand[2], Rune Bosselmann[3], Sarah Moore[1], John Bradley[4]

[1]Ifakara Health Institute, Bagamoyo, Tanzania, United Republic of, [2]MCC47, Montpellier, France, [3]Vegro Aps, Copenhagen, Denmark, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Long-lasting insecticidal nets (LLINs) and targeted indoor residual spray (IRS) are used extensively in Tanzania and have significantly reduced malaria mortality and morbidity across the country. However, malaria remains a public health concern, calling for the development of supplementary intervention tools. This study aimed to understand community perceptions on the installation of insecticide treated eave nets (ITENs) and windows screens (ITEWs) for full house screening against mosquitoes. Fourteen In-Depth Interviews (IDIs) with local carpenters who installed the intervention in 440 households and six Focus Group Discussions (FGDs) with community members in both the treatment (with intervention) and control (without) arms were conducted to gain understanding of feasibility and community perceptions of the intervention against malaria in three villages at Chalinze district in Tanzania. Only two carpenters reported to get nasal congestion and a headache after the working with the intervention on day 1 and related it to the chemicals on the netting. However, none of the community members experienced any adverse effects after the intervention was installed in their houses. Community members reported the intervention reduced mosquito abundance in their houses and also protected them from insects, lizards and snakes. Due to an observed reduction in malaria incidences in their households, some residents reported to stop sleeping under LLINs. A willingness to buy the netting if sold at an affordable price range of TZS 1000-6000 (≤ USD 2.50) per square meter was also expressed among community members. Community feasibility studies provide insights to barriers and facilitators to the adoption of new interventions tools. Therefore, appropriate social behavioral change communication strategies can be developed prior to deployment newer vector control tools to ensure synergy with existing interventions.

COMBINING PYRETHROID-PIPERONYL BUTOXIDE (PBO) NETS WITH CLOTHIANIDIN-BASED INDOOR RESIDUAL SPRAYING IMPROVES CONTROL OF PYRETHROID-RESISTANT MALARIA VECTORS: AN EXPERIMENTAL HUT TRIAL IN SOUTHERN BENIN

Thomas Syme[1], Juniace Ahoga[2], Abel Agbevo[2], Corine Ngufor[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

Coverage of pyrethroid-piperonyl butoxide (PBO) nets and indoor residual spraying (IRS) with the neonicotinoid insecticide clothianidin either as a solo-formulation or as a mixture with deltamethrin is being scaled up to improve control of malaria transmitted by pyrethroid-resistant mosquitoes. Most IRS campaigns are deployed against a background of moderate to high net coverage thus combined use of these tools is already an operational reality in many settings. However, no published trials have evaluated whether combining pyrethroid-PBO nets and clothianidin-based IRS would improve malaria control impact relative to use of either method alone. We performed experimental hut trials to evaluate the impact of combining different types of pyrethroid-PBO net with IRS formulations containing clothianidin both alone and as a mixture with deltamethrin against a pyrethroid-resistant vector population in southern Benin. We compared the impact of the combinations to each intervention alone and combinations with pyrethroid-only nets. The vector population at the hut site was susceptible to clothianidin but exhibited a high frequency and intensity of pyrethroid resistance that partially overcame by PBO pre-exposure. Mortality was significantly higher in huts combining pyrethroid-PBO nets with the clothianidin IRS solo-formulation (75%) and clothianidin-deltamethrin IRS mixture (77%) compared to those where pyrethroid-PBO nets (35–43%) and clothianidin-based IRS (42–48%) were applied alone. All combinations improved blood-feeding protection relative to the IRS alone but higher levels of blood-feeding inhibition were recorded with combinations containing pyrethroid-PBO nets compared to those containing pyrethroid-only nets (78–85% vs. 21–64%). Combining pyrethroid-PBO nets and clothianidin-based IRS shows potential to improve control of pyrethroid-resistant malaria vectors.

LONG-ACTING FORMULATION OF IVERMECTIN FOR EFFECTIVE MALARIA CONTROL: INSIGHTS FROM AN AGE-STRUCTURED MODELLING STUDY

Angélique Porciani[1], André Sagna[2], Christophe Roberge[3], Sophie Le Lamer-Déchamps[3], Nicolas Moiroux[1], Roch Dabire[4], Fabrice Anyirekun Some[4], Sié Hermann Pooda[5], Karine Mouline[1], Ramsès Djidjou-Demasse[1]

[1]IRD, Montpellier, France, [2]IRD, Bobo-Dioulasso, Burkina Faso, [3]Medincell, Jacou, France, [4]IRSS, Bobo-Dioulasso, Burkina Faso, [5]University of Dedougou/CIRDES, Bobo-Dioulasso, Burkina Faso

Controlling malaria consists of either killing the parasite within the human host or reducing the vector population. These two approaches have allowed to decrease the number of deaths by almost 40% during the 2 past decades. However, a stagnation since 2015 followed by an increase in the last years, highlight the limits of available tools. One of the known limits is the vector tolerance to insecticides. A complementary approach is to render the vector's blood meal toxic by treating hosts with a drug that impairs mosquito survival. Ivermectin (IVM), an endectocide, has been proven to possess such ability. Several studies have modelled the impact of mass drug administration (MDA) of oral ivermectin to human populations and have evidenced a promising effect in reducing malaria clinical cases. However, the mosquitocidal effect of a single oral IVM dose (150-200 µg/kg) is relatively short-lived, requiring multiple mass distribution to significantly decrease malaria prevalence. An original model was developed to investigate the effects of a Long-Acting Injectable Formulation of Ivermectin (LAIF-I) on malaria transmission. This population model considers multiple continuous structural variables: humans age, time since infection, and time post-IVM administration for both humans and vectors. Such an approach

allows targeting a specific human class, e.g. by excluding children under five years and women of childbearing age. Furthermore, the time post-IVM was required to properly capture the longitudinal dynamics of both (i) IVM systemic concentrations in the human bloodstream, and (ii) IVM effects on mosquitoes' life span after a blood meal on LAIF-I -treated human. The long-lasting insecticide treated net coverage associated to different malaria transmission profiles were used as baselines to evaluate the added value of using LAIF-I in realistic life conditions. The detailed effect of the LAIF-I on the reduction of malaria prevalence will be presented during the conference.

5938

EXPLORATORY ANALYSIS OF THE EFFECTIVENESS OF INDOOR RESIDUAL SPRAYING WITH ACTELLIC 300CS AND FLUDORA FUSION TO REDUCE ENTOMOLOGICAL INDICATORS IN ALIBORI AND DONGA REGIONS, NORTHERN BENIN

Germain Gil Padonou[1], Albert Sourou Salako[1], Esdras Mahoutin Odjo[1], Arthur Sovi[1], Rock Aikpon[1], Virgile Gnanguènon[2], Patrick Condo[2], Ahmed Saadani Hassani[3], Daniel Impoinvil[4], Martin C. Akogbéto[1]

[1]Ministère de la Santé, Cotonou, Benin, [2]US Agency for International Development, Cotonou, Benin, [3]US Centers for Disease Control and Prevention, Cotonou, Benin, [4]US Centers for Disease Control and Prevention, Atlanta, GA, United States

This study explores differences in the entomological indicators after Indoor Residual Spraying (IRS) with Actellic® 300CS (AC; pirimiphos-methyl) and Fludora® Fusion (FF; a deltamethrin-clothianidin mixture) in the Alibori and Donga Department of Benin. After the IRS campaigns with AC in 2019 and FF in 2020, respective monthly mosquito collections were performed over 10 months using both Human Landing Catches (HLCs) and Pyrethrum Spray Catches (PSCs) in Alibori and Donga, and adjacent untreated control areas (Bembèrèkè and Bassila). The Indoor Resting Density (IRD), the Human Biting Rate (HBR), Plasmodium falciparum Sporozoite Rate (SR), and the Entomological Inoculation Rate (EIR) of Anopheles gambiae s.l. were determined. The residual activity of AC and FF on the treated walls was also evaluated. A comparison of the indicators between IRS and control sites was done by calculating the percent reduction (Abbott's formula) and the P-value using poisson test function in R. Overall, the residual activity lasted 5 months for AC and 10 months for FF. The IRD was 0.30 An. gambiae s.l. per room (Ag/room) in AC-sprayed and 2.59 in control areas (Reduction [RD] = 88%, $p < 0.0001$), while the IRD was 0.92 Ag/room in FF-sprayed and 3.25 in control areas (RD = 72%, $p < 0.0001$); the HBR was 6.76 bites/person/night (b/p/n) in AC-sprayed and 19.93 b/p/n in control areas (RD = 66%, $p < 0.0001$), while the HBR was 18.33 b/p/n in FF-sprayed and 26.17 b/p/n in control areas (RD = 30%, $p < 0.0001$); the SR was 0.31% in AC-sprayed and 2.61% in control areas (RD=88%, p =0.0013), while the SR was 0.65% in FF-sprayed and 1.52% in control areas (RD = 61%, p = 0.0034); the EIR was 0.63 infectious bites person per month (ib/p/m) in AC-sprayed and 15.62 ib/p/m in control areas (RD = 96%, $p < 0.0001$), while the EIR was 3.52 ib/p/m in FF-sprayed and 12.00 ib/p/m in control areas (RD = 71%, p = 0.0019). When comparing sprayed and control areas, AC areas had a higher reduction in entomological indicators than FF. However, FF had longer residual activity than AC. More robust analyses and the use of epidemiological data are needed to compare these insecticides.

5939

MOLECULAR TECHNIQUE FOR THE DETECTION OF WOLBACHIA (WANGA-MALI) WITHIN ANOPHELES GAMBIAE SENSU LATO IN MALI

Salif Thiam

Malaria Research Training Center, Bamako, Mali

Malaria is a major public health problem for sub-Saharan countries including Mali. The progress made in the fight against malaria through the use of long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) is threatened by the emergence and progression of resistance of major vectors to commonly used insecticides, hence the need to develop new vector control methods such as the use of the endosymbiotic bacterium called Wolbachia.The aim of this work was to set up in Mali an efficient detection technique of Wolbachia within Anopheles gambiae s.l. as a prelude to the fight against malaria.This was an experimental study, carried out within ICER-Mali in the framework of a collaboration between the University of Science, Technology and Technology of Bamako (USTTB) and the National Institutes of Health of the United States of America (NIH). Mosquitoes were collected in Kenieroba by the "Spray Catch" insecticide spraying method in human dwellings. In order to obtain a good quality of mosquito DNA and the bacteria, two extraction methods were compared, namely the "old" Phenol-Chloroform extraction method and the "MasterPure" extraction kit. The molecular techniques used for the detection of Wolbachia was: quantitative PCR (qPCR) for the determination of the prevalence of Wolbachia in the An. gambiae s.l. population.The highest DNA concentrations and the lowest protein contamination were obtained with the MasterPure kit. This method was also the least toxic for the laboratory technician. The prevalence of Wolbachia infection was 45.16%. This prevalence was lower than previously reported. in the same locality in 2016 but who used a larger sample size. Our study showed that the Wolbachia wAnga-Mali strain of Wolbachia is still present in An. gambiae s.l. in the Kenieroba area, the prevalence of which may vary in time and space. The use of the Wolbachia bacterium remains a promising method in the eradication of malaria worldwide.

ENDECTOCIDES TO COMPLEMENT THE MALARIA VECTOR CONTROL TOOLKIT: EXPECTED AND UNEXPECTED SIDE-EFFECTS OF IVERMECTIN ON MALARIA VECTORS

Andre B. Sagna[1], Lamidi Zela[2], Cheick Oumar W. Ouedraogo[3], Sié H. Pooda[4], Angélique Porciani[5], Joanna Furnival-Adams[6], Paula Lado[7], Anyirékun F. Some[3], Fabrice Chandre[5], Cédric Pennetier[5], Carlos J. Chaccour[6], Roch K. Dabire[3], Karine Mouline[5]

[1]IRD Burkina Faso, Bobo-Dioulasso, Burkina Faso, [2]CIRDES, Bobo-Dioulasso, Burkina Faso, [3]IRSS, Bobo-Dioulasso, Burkina Faso, [4]University of Dedougou, Dedougou, Burkina Faso, [5]IRD, Montpellier, France, [6]ISGlobal, Barcelona, Spain, [7]Colorado State University, Fort Collins, CO, United States

Mass treatment of livestock and/or humans with ivermectin has been proposed as a complementary vector control strategy to combat malaria. However, this strategy requires repeated mass treatments to cover the high transmission period during the rainy season. To overcome this, a Long-Acting Ivermectin Formulation (LAIF) is currently under development and its potential to release mosquitocidal concentrations of ivermectin for more than a month is under evaluation as part of the IMPACT project. Although broader use of ivermectin can pose some anticipated challenges (i.e. potential environmental contamination and effects on non-target organisms, withdrawal times in livestock and implications for milk or meat production, risk of inducing resistance in livestock or human parasites), other side-effects such as the selection and spread of ivermectin resistance in malaria vectors through physiological or behavioral modifications appear to be less obvious. The aim of this review was to decipher how resistance to ivermectin could be selected in malaria vectors and propose a research agenda to study and manage this phenomenon if it appears. We used relevant terms to search databases including PubMed and Web of Science and included studies that describe mechanisms of resistance in arthropods. Results were summarized in terms of resistance mechanism. We also proposed a research agenda that integrates 1) the characterization of resistance and/or pyrethroid-ivermectin cross-resistance mechanisms, 2) the development of molecular and phenotypic assays to monitor ivermectin resistance in the field, 3) the study of potential behavioral changes vis-a-vis to ivermectin-treated subjects, and 4) the study of potential strategies to mitigate ivermectin resistance in mosquitoes. Anticipating the research on physiological or behavioral resistance to ivermectin in mosquitoes will facilitate the development of effective resistance-management plans and

enable preparedness for monitoring and evaluating this strategy after its implementation. Selection of Anopheles coluzzii resistant to ivermectin is in progress in our research team.

ANOPHELES STEPHENSI IN TURKANA - PRELIMINARY FINDINGS ON THE LARVAL SURVEILLANCE IN TURKANA COUNTY, KENYA

Lucy Abel[1], Tabitha Chepkwony[1], Mark Amunga[1], Emma Kimachas[1], Joseph Kipkoech[1], Emily Robie[2], Wendy P. O'Meara[2], Andrew Obala[3]

[1]Academic Model Providing Access to Health Care (AMPATH), ELDORET, Kenya, [2]Duke Global Health Institute, Duke University, Durham, NC, United States, [3]School of Medicine, College of Health Sciences, Moi University, ELDORET, Kenya

Anopheles stephensi has been identified by the WHO as a key threat to malaria control. Although endemic to Southeast Asia, it was detected in Djibouti in 2012 and has spread throughout the Horn of Africa. In 2020 it was detected in Nigeria. This invasive vector efficiently transmits both P. falciparum and P. vivax. Unlike other malaria vectors, An. stephensi thrives in urban settings where it can breed in manmade habitats such as tanks, tires and open sewers. In 2020, we established longitudinal larval surveillance in Lodwar, Turkana in the northwest corner of Kenya. We hypothesized that close proximity to Sudan and Ethiopia and the presence of a major transport route from the Horn into Kenya makes this region a likely environment for establishment of An. stephensi. We conducted bi-weekly surveillance in three types of sites - cisterns, river pans along the seasonal river and irrigation canals. Anopheline larval were collected, counted, and transferred to 95% ethanol for transport to the laboratory. Larvae were extracted in pools of 3 and tested by established molecular methods for An. gambiae, arabiensis, funestus and stephensi. In the first 5 months (March-July 2020), the selected sites were active in all collections. 557 larvae were tested by PCR and the major species was An. arabiensis (85%). The second surveillance period ran from November 2022 to March 2023. We collected a high number (2,387) of anopheline larvae across all sites in November-January. Out of 1483 larvae assayed, two pools from one site tested positive for An. stephensi. Larvae (5) from this site were sent for independent confirmation and sequencing at a partner laboratory. An. stephensi was a minority species in this river pan site which also hosted An. gambaie s.s. and arabiensis. Surveillance and testing are ongoing. The confirmation of An. stephensi in Kenya is critical information for malaria control efforts and underscores the need to expand vector surveillance even in parts of the country where malaria is epidemic/seasonal. The presence of An. stephensi could lead to increasing malaria transmission in northern Kenya, spreading further southwards to highly populated urban areas.

5942

IMPACT OF INDOOR RESIDUAL SPRAYING ON ENTOMOLOGICAL INDICES IN SAKASSOU, CENTRAL CÔTE D'IVOIRE

Bernard L. Kouassi[1], Ndombour G. Cissé[1], Constant A. Edi[2], Constant G. Gbalegba[3], Antoine M. Tanoh[4], Pascal Zinzindohoue[5], Patricia L.Y. Zembrou[5], Blaise Kouadio[5], Samson Awolola[6], Allison Belemvire[6], Cecilia Flatley[7], Joseph Chabi[8]

[1]Abt Associates/ Vectorlink, Abidjan, Côte D'Ivoire, [2]Swiss Center for Scientific Research, Abidjan, Côte D'Ivoire, [3]Abt Associates/ Vectorlink/ NMCP, Abidjan, Côte D'Ivoire, [4]NMCP, Abidjan, Côte D'Ivoire, [5]PMI/USAID, Abidjan, Côte D'Ivoire, [6]PMI/CDC, Washington, WA, United States, [7]Abt Associates/VectorLink, Rockville, DC, WA, United States, [8]Abt Associates/ Vectorlink, Rockville, DC, WA, United States

Indoor residual spraying (IRS) is a major vector control strategy for malaria prevention. Entomological parameters such as indoor resting density (IRD), human biting rate (HBR), and entomological inoculation rate (EIR) were monitored in Sakassou (sprayed with clothianidin-based insecticide) and Beoumi (unsprayed district) to monitor changes due to three consecutive years of IRS in Côte d'Ivoire. After one year of baseline data collection in 2019, IRS was implemented in August 2020, August 2021, and May 2022 using clothianidin-based insecticides. Adult mosquitoes were collected monthly using human landing catches (HLCs) and pyrethrum spray catches (PSC) from January 2019 through December 2022. Mosquitoes collected were identified morphologically while sibling species were further analyzed using PCR. A subsample of the mosquitoes collected were analyzed for sporozoite infection using ELISA for estimating the EIRs. At baseline in Sakassou, the mean IRD was 15.5 females/room/day (f/r/d), the mean HBR was 296.8 bites/person/night (b/p/n) and the mean EIR was 4.9 infective bites per person per night (ib/p/n). After three years of IRS the mean IRD, the mean HBR and the mean EIR decreased significantly to 5.8 f/r/d (p=0.0003), 142.6 b/p/n (p=0.0002) and 0.919 ib/p/n (p=0.0022), respectively. At baseline in Beoumi, the IRD was 3.8 f/r/d, the HBR was 35.5 b/p/n and the EIR was 0.61 ib/p/n at the baseline collection. After three years, there was a reduction of the IRD (2.2 f/r/d; p=0.0954), the HBR (24.9 b/p/n; p=0.5483) and the EIR (0.474; p=0.6776), but the differences were not statistically significant. Although Sakassou had higher vector density than Beoumi, the relative reduction of malaria entomological indicators post-IRS following three years of IRS was significant. These decreases in malaria transmission are consistent with preliminary findings on malaria case reductions after the 2020 and 2021 IRS campaigns, indicating that IRS was effective in Côte d'Ivoire.

5943

IS THE UK PREPARED FOR A MOSQUITO-BORNE DISEASE EMERGENCE? A PROTOCOL FOR FIELD WORK

Neelam Iqbal[1], Giovanni S. Leonardi[2], Alex Vaux[3], Colin Johnston[3], Louise Kelly-Hope[1], Jolyon Medlock[3]

[1]University of Liverpool, Liverpool, United Kingdom, [2]UK Health Security Agency, Chilton, United Kingdom, [3]UK Health Security Agency, Salisbury, United Kingdom

In 2021, risks to health from vector-borne diseases were highlighted as an area requiring more action in the 3rd UK Climate Change Risk Assessment Technical Report. Currently, cases of mosquito-borne diseases (MBDs) are typically imported to the UK but there is a risk of arbovirus transmission from a number of vector-competent mosquitoes indigenous to the continent, as well as from an increasing number of invasive species establishing in Europe. A "mosquito watch" programme between the UK Health Security Agency (UKHSA) Medical Entomology team and the Chartered Institute of Environmental Health (CIEH) currently provides a portal for environmental health officers (EHOs) to submit samples to UKHSA and partners for identification of species. UKHSA also conduct a range of enhanced surveillance strategies for invasive mosquitoes in the UK at points of entry. The aims of this study are to i) identify current awareness, risk perception and engagement in local authorities, in England, ii) understand more about perceptions on the drivers of MBD and barriers to effective preparedness and iii) determine how they have changed over time. Current surveys distributed to EHOs have been carried out by the UKHSA every 10 years since the 1970s across 374 local authorities and include information on nuisance biting complaints, potential habitats for mosquitoes, local capabilities to control mosquitoes etc to determine two key aspects: experience with mosquitoes and mosquito control preparedness. For this study, additional scenario-specific questions related to potential Aedes albopictus incursions will be added to this survey, for the EHOs based in South-East England and the Greater London Regions, as previous research has forecasted those two regions as hotspots within England. This research will help determine the best survey tools that can be implemented more frequently, in more areas, to prepare for the risk of MBD emergence which is increasing with climate change on a global scale.

5944

DETERMINING IMPACT OF DENGUE VIRUS INFECTION IN PREGNANCY ON MATERNAL AND CHILD OUTCOMES

Annabelle Smith[1], Bethel Bayrau[1], Jonathan Altamirano[1], Caroline Ichura[1], Francis M. Mutuku[2], Dunstan Mukoko[3], Peter Mungai[4], Charles H. King[4], Indu Malhotra[4], Angelle D. LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Technical University of Mombasa, Mombasa, Kenya, [3]Ministry of Health, Nairobi, Kenya, [4]Center for Global Health and Disease, Case Western Reserve University, Cleveland, OH, United States

Dengue virus (DENV) is the most common arbovirus globally, with estimated 400 million infections yearly. Dengue in pregnancy has been associated with adverse maternal and neonatal health outcomes including preterm birth, low birth weight and miscarriage. Despite the abundance of literature for DENV in pregnancy, few studies examine this issue in Africa. In this study, we utilized IgG ELISA to identify DENV exposure (seronegative at antenatal visits and seropositive for anti-DENV IgG at delivery) and characterize the epidemiological burden of DENV among a Kenyan cohort of pregnant women. Seroconverted mothers were also tested by PCR to identify timing of DENV exposure and then assessed by logistic regression for any associations between DENV exposure and adverse maternal and/or infant health outcomes. At birth, neonatal development outcomes were assessed and children were followed every 6 months. The studied cohort comprised 454 pregnant women initially part of a 749-maternal child cohort followed for parasitic infections. Median maternal age was 25, primary delivery mode was vaginal (95%), and mean birth weight was 2,991 grams. The cohort experienced significant maternal and neonatal morbidity: one maternal death, 74% of women with anemia at delivery, 75% of women with parasitic infection during pregnancy, 20% preterm birth and 2% stillbirth. Using community-based estimates from our prior work, we expected approximately 18 women to have gestational DENV exposure; however 35 mothers (7.7%) seroconverted during their pregnancy, indicating nearly twice the expected burden of DENV for this vulnerable population. Using Fisher's Exact test, comparisons of DENV+ and DENV- mothers found no association between seroconversion and: Caesarian birth (5.7% vs 4.7%,p=0.68), adverse birth outcomes [Ex: stillbirth, maternal death, intrapartum fever] (0% vs 5.3%, p=0.62), or preterm birth (21% vs 20%, p=0.84). Although it was found that adverse fetal outcomes had no association with seroconversion, next steps are to complete assessments of fetal developmental outcomes, such as APGAR score, to better understand the burden of DENV in pregnancy.

YELLOW FEVER VACCINATION COVERAGE IN ARID AREAS OF KENYA AN ASSESSMENT FOLLOWING OUTBREAK, 2022

Grace Atieno Rabut

Field Epidemiology and Laboratory Training Program, Nairobi, Kenya

Kenya reported a Yellow Fever (YF) outbreak in the arid pastoral counties in March 2022 following the confirmation of three cases. A reactive vaccination campaign conducted had a coverage of 52% in Garissa and 58% in Isiolo. However, the precise estimated coverage had not been determined. We sought to estimate vaccination coverage and evaluate strategies used in the campaign. We used the WHO-recommended strategies to conduct a cross-sectional population-based survey involving residents aged 9 months to 60 years. We used a multi-stage proportionate-to-size cluster sampling to determine the number of clusters and randomly selected 7 households per cluster. Data were collected using semi-structured questionnaires and analyzed using descriptive statistics. We visited 118 clusters and 818 households with 5187 eligible participants, of whom 76% (4020/5187) had been vaccinated during the campaign. Participants available for interview were 45% (2355/5187), among whom 81% (1927/2355) had been vaccinated, 60% (1419/2355) were female, and 28% (650/2355) were children aged 1–5years. Garissa county had a coverage of 77% (1093/1412), with 58% (818/1412) having the YF card. Isiolo county had a coverage of 89% (834/943), with 59% (555/943) having the YF card. Respondents who were vaccinated from mobile points were 88% (1696/1927). Community Health volunteers (CHVs) 55% (597/1090), Healthcare workers 56% (615/1090) and religious leaders 16% (170/1090) had the most influence on respondents taking the YF vaccine. Respondents who were aware of the YF campaign were 80% (1886/1927), with CHVs 48% (1135/2355), mobilizer/criers 23% (545/2355) and radios 13% (301/2355) providing the most information on the YF campaign. The respondents who experienced adverse events following immunization were 5% (102/1927). Garissa's overall coverage was below the desired threshold of 80%. CHVs and mobile vaccination points were integral in the vaccination campaign. The use of mobile vaccination points should be adopted in arid-pastoral areas.

ASSESSING ENTOMOLOGICAL IMPACT OF A LARVAL SOURCE MANAGEMENT PILOT USING AERIAL SPRAYING OF RICE FIELDS WITH DRONES IN TWO DISTRICTS OF MADAGASCAR

Jean Desire Rakotoson[1], Timothee Gandaho[2], Jacob Djenam[3], Kerri-Ann Guyah[3], Laurent Kapesa[4], Sarah Zohdy[5], Allison elemvire[6], Laura Steinhardt[7], Anna Bowen[8], Omega Raobela[9], Jocelyn Ratovonjato[10], Joseph Chabi[11]

[1]Abt Associates Inc, Antananarivo Avaradrano, Madagascar, [2]Abt Associates Inc, Antananarivo, Madagascar, [3]Abt Associates Inc, Washington, MD, United States, [4]3US President's Malaria Initiative, USAID, Antananarivo, Madagascar, [5]AUS Centers for Disease Control and Prevention,, Atlanta, GA, GA, United States, [6]US President's Malaria Initiative, USAID, Washington DC, WA, United States, [7]US Centers for Disease Control and Prevention, Atlanta, GA, GA, United States, [8]US President's Malaria Initiative, US Centers for Disease Control and Prevention, Antananarivo, Madagascar, [9]National Malaria Control Program, Antananarivo, Madagascar, [10]National Malaria Control Program, Madagascar, Antananarivo, Madagascar, [11]Abt Associates Inc, Rockville, MD, United States

As a complementary vector control intervention in Madagascar, the PMI VectorLink project and National Malaria Control Program conducted a larval source management pilot via drone in 17 fokontany of two mapped districts with high malaria incidence (144/1,000 in Morombe, 120/1,000 in Ankazobe in 2020) and abundant rice fields that are common larval habitats. The intervention occurred during the short rainy season, from February to July 2022, with Bacillus thuringiensis israelensis (Bti) larvicide twice per month (10 spray cycles).To assess the entomological impact of the intervention, larval collections, insecticide susceptibility bioassays, and adult mosquito collections were conducted before, during and after spraying in six sites per district. Bioassays using a range of Bti dilutions demonstrated larval susceptibility, with mortality above 80% after 24h at a dose of 0.07g (1/14 of larval habitat solution sample) and 0.05g (1/20). Larval density decreased by 96% and 97% in Morombe and Ankazobe, respectively, one day post spray. However, recolonization of larval habitats was observed one month after spraying ended with an increase from an average of 0.4 larvae/liter (l/L) one day post spray to 4.6 l/L in Morombe, and from 0.6 l/L to 2.6 l/L in Ankazobe. A reduction in mosquito biting rate was recorded in all sprayed sites compared to baseline. In Morombe, the Anopheles gambiae s.l. human biting rate decreased from 6.3 bites per person per night (b/p/n) at baseline to 1.3 b/p/n indoors, and from 8.4 b/p/n outdoors to 2.6 b/p/n after 10 spray cycles, but then increased one month after spraying stopped to 5.1 b/p/n and 6.4 b/p/n indoors and outdoors, respectively. In Ankazobe, the biting rate significantly decreased through the end of the spraying cycles from 2.1 b/p/n at baseline to 0.3 b/p/n after 10 spray cycles indoors and 2.4 b/p/n to 0.3 b/p/n outdoors, but then increased to 0.5 b/p/n and 0.9 b/p/n indoors and outdoors, respectively, one-month post-spray. This study suggests that biweekly spraying in rice fields reduced larval density and human biting rates and could be beneficial in areas with outdoor biting and seasonal malaria transmission.

DETECTION OF ANTIBODIES AGAINST SALIVARY PROTEINS OF AEDES ALBOPICTUS AND CULEX QUINQUEFASCIATUS IN NORTHERN CARDINALS IN LOUISIANA

Alyssa R. Schwinn[1], Sara Harris[2], Zoe Jacobs[2], Matt Duckworth[3], Jane de Verges[2], Sam Jameson[2], Dawn Wesson[2], Kevin Caillouet[3], Berlin Londono-Renteria[2]

[1]Tulane University, New Orleans, LA, United States, [2]Tulane University, New orleans, LA, United States, [3]St. Tammany Parish Mosquito Abatement District, Slidell, LA, United States

West Nile virus (WNV) is a mosquito-borne pathogen primarily transmitted by Culex mosquitoes. Since the emergence of WNV in the US in 1999, detecting infection in birds and mosquitoes have become the primary surveillance tools used as precursors for human infection and neuroinvasive disease incidence. WNV is normally transmitted between birds and mosquitoes in the environment; and humans are considered dead end hosts. WNV is transmitted to a vertebrate host through the bite of an infected mosquito during blood feeding. In this process, mosquitoes deposit salivary proteins that elicit antibody responses; previous studies have established that the concentration of such antibodies is directly related to the intensity of exposure to mosquito bites and a good proxy to determine risk of infection in the human population. Since WNV infection in birds has also been used to determine risk of transmission in some areas, we tested the levels of IgY antibodies against whole salivary glands of Aedes albopictus and Cx. quinquefaciatus in more than 700 Northern Cardinals captured via mist nets in Louisiana between 2018 and 2019. Our preliminary data (n=169) showed a significant negative correlation between the sample collection date and the IgY antibody levels against Ae. albopictus in younger hatch year Northern Cardinals (p=0.0375). This correlation was not shown in older after hatch year birds. We did not find significant difference in the antibody levels between males or females from any of the locations. In general, higher levels of antibodies against Ae. albopictus were observed in comparison to Cx. quinquefasciatus. We will discuss the proteins that were identified by immunoblot as the most immunogenic in these two different sets of samples. We are working towards designing new tools to track bird exposure to infective bites to effectively measure risk of WNV transmission.

ENTOMOLOGICAL SURVEILLANCE STRENGTHENING IN INDIA: MEETING THE CHALLENGES

Kalpana Baruah

National Center for Vector Borne Diseases Control, Ministry of Health& Family Welfare, Delhi, India

India has varying degree of challenges in entomological surveillance and vector control due to six major VBDs, multiple vector's influence and different eco-geographical zones. The core vector control measures include adult mosquito control through Indoor Residual Spraying, Long Lasting Insecticidal Nets and Larval Source Management for urban areas. The technical guidance to implement the VBD programme is based on knowledge on vectors and bionomics. National Programme established 72 entomological zones in 1977 to do entomological monitoring after massive resurgence of malaria in 1976. India has targeted for elimination of Malaria, Visceral leishmaniasis and Lymphatic Filariasis. During elimination phase, entomological monitoring becomes paramount to sustain the vector control impact and prevent re-establishment Shortage of entomologists are the major challenge in entomological monitoring which is highly skilled job. Though efforts have been made to bridge the gap by providing consultants and increasing number of Entomological Zones, high level advocacy is required to fill all sanctioned positions and support by development partners. Gates Foundation is supporting through integrated entomological surveillance in a few areas. Global funds also supporting by provisioning contractual entomologists. Insecticide resistance monitoring and operational research for programme are supported by two premier national institutions viz., NCDC, ICMR and WHO.

EVALUATION OF SPATIAL REPELLENT PRODUCTS AGAINST MALARIA VECTOR SPECIES IN PAPUA NEW GUINEA

Michelle N. Katusele[1], Petrina Johnson[2], Kilon Manuv[1], Rebecca Vinit[1], Lincoln Timinao[1], David Lahu[1], Rachael Farquhar[3], Jason H. Richardson[4], Moses Laman[1], Leanne J. Robinson[3], Stephan Karl[2]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia, [3]Burnet Institute, Melbourne, Australia, [4]Innovative Vector Control Consortium, Liverpool, United Kingdom

Malaria remains one of the most common and deadly diseases within tropical and sub-tropical countries with an estimated 229 million cases recorded by 2019 across 87 malaria-endemic countries. Papua New Guinea (PNG) accounts for about 80% of the malaria burden recorded within the Western Pacific region and controls vector populations through nationwide long-lasting insecticide treated bednets (LLINs). Early and outdoor biting behavior of vector species and the evidence of substandard LLIN products in PNG compromises the effectiveness of LLINs against the local vector populations. This study explores the potential of alternative vector control tools (VCTs) to complement LLINs and improve the effectiveness of malaria control within the country. A promising VCT are spatial emanators (SE), devices that passively emit insecticide volatiles to provide a protective space for users. This tool has the potential to be used both indoors to complement LLINs, and outdoors, particularly in the peridomestic space. This study aims to evaluate the efficacy of SE products against the Anopheles punctulatus group of mosquitoes in Papua New Guinea under laboratory and semi-field conditions. Secondly, it aims to understand the effects that sublethal exposure to insecticides may have on the local vector populations. Finally, this study aims to assess the feasibility, cost-effectiveness and impact on malaria transmission in a small-scale field study in two malaria-endemic villages in PNG. We will present data on the effectiveness of SEs against malaria vectors in PNG and explore the impacts of SE and spatial repellent insecticides against mosquito landing rates, feeding inhibition and the impacts of sublethal exposure to the local malaria vector species. Finally, we will discuss the effectiveness of SE in a proof of concept field trial that will guide the national malaria control program in consideration of SE products as malaria VCT for future control programmes in PNG.

5950

NON-INFERIORITY EVALUATION OF PERMANET® DUAL TO INTERCEPTOR® G2 AND SUPERIORITY TO PERMANET® 3.0 AT THE 'DALA SUNA' EXPERIMENTAL HUTS IN SIAYA, KENYA

Nashon A. Ogutu[1], Silas Agumba[2], Eric O. Ochomo[3], Benard Abongo[2], John E. Gimnig[4], Lenson Kariuki[5], Vincent Moshi[6], Collins Ouma[1]

[1]Maseno University, Kisumu, Kenya, [2]Kenya Medical Research Institute Centre for GlobalHealth Research, Kisumu, Kenya, [3]Kenya Medical Research Institute Centre for Global Health Research, Kisumu, Kenya, [4]Centers_for_Disease_Control_and_Prevention, Atlanta, Georgia, United States, Saint Barthélemy, [5]Ministry of Health (Vector Borne Diseases), Nairobi, Kenya, [6]Kenya Medical Research Institute Centre for GlobalHealth Research, Nairobi, Kenya

The rise and spread of insecticide resistance threatens the gains already made in malaria control particularly with long-lasting insecticidal nets (LLINs). The development and evaluation of new generation LLINs is therefore critical in ensuring the constant supply of effective products. This study evaluated the non-inferiority of Permanet Dual against Interceptor G2 (IG2) and the superiority of Permanet Dual (PD) against PermaNet 3.0 (PN3.0) on mortality and blood feeding inhibition. The trial was conducted

at the 'Dala Suna' experimental huts located on the shores of Lake Kanyaboli, Siaya County, western Kenya. The study followed a 7 by 7 Latin square design with treatments employed as unwashed and 20 times washed. Each hut had sleepers daily. Mosquitoes were collected from the huts every morning and categorized based on collection site as roof, wall, net under bed, floor and window exit traps. The mosquito samples from experimental huts were monitored for immediate knockdown and delayed mortality after 24hours, 48hours and 72hours. This study was carried out in an area with high vectors' resistance to pyrethroids. Only An. funestus was used for the experimental hut evaluation due to high densities during the study period. A total of 15144 An. funestus mosquitoes were collected from the experimental huts over the 7 weeks' study period. Mortality at 72 hours was 37% for control net, and higher in the LLINs (washed and unwashed), at 56% for PermaNet 3.0, 66% & 64% for IG2 and 67% & 68% for PD. Blood feeding inhibition was highest with PN3.0 at 33% and 49% unwashed and 20 times washed respectively, and least with PD, at 3% and 12% unwashed and 20 times washed nets, respectively. PD and IG2 had differences in mortality with odds ratio of 1.096 at lower 95% CI: 1.001 – 1.199 and blood feeding odds ratio of 1.176 at upper 95% CI: 1.037 - 1.334. Additionally, PD was found to be superior to PN3.0 on mortality with an odds ratio of 1.805 at 95% CI: 1.654 - 1.969, and inferior in blood feeding, with odds ratio of 1.627 at 95% CI: 1.425 - 1.856. In conclusion, PD was found to be non-inferior to IG2 and inferior to PN3.0 LLINS following WHO efficacy criteria.

5951

RESIDUAL BIO-EFFICACY OF ATTRACTIVE TARGETED SUGAR BAIT STATIONS TARGETING MALARIA VECTORS DURING SEASONAL DEPLOYMENT IN WESTERN PROVINCE, ZAMBIA

Gift Mwaanga[1], Jacob Ford[2], Joshua Yukich O[2], Ruth A. Ashton[2], Benjamin Chanda[3], Javan Chanda[3], Buster Munsanje[1], Emliny Muntanga[1], Malon Muntanga[1], Christine Simuyandi[1], Boyd Mulala[1], Limonty Simubali[1], Kochelani Saili[3], Edgar Simulundu[1], John Miller[3], Erica Orange[4], Joseph Wagman[5], Monicah M. Mburu[1], Angela F. Harris[6], Julian Entwistle[6], Megan Littrell[5]

[1]Macha Research Trust, Choma, Zambia, [2]Tulane University, New Orleans, LA, United States, [3]PATH, Lusaka, Zambia, [4]PATH,, Seattle, WA, United States, [5]PATH, Washington, WA, United States, [6]IVCC, Liverpool, United Kingdom

The primary vector control interventions in Zambia are long-lasting insecticide-treated nets (LLINs) and indoor residual spraying (IRS). Challenges with these interventions includes insecticide resistance and the outdoor biting and resting behaviors of many Anopheles mosquitoes. Therefore, new vector control tools targeting additional mosquito behaviors are needed to interrupt transmission. Attractive Targeted Sugar Bait (ATSB) stations, which exploit the sugar feeding behaviors of mosquitoes may help in this role. This study was conducted to evaluate the residual laboratory bio-efficacy of Westham prototype ATSB stations deployed in communities throughout a 7-month deployment in Western Province, Zambia during the first year of a large cluster randomized phase-III trial (Clinical Trials.gov Identifier: NCT04800055). One undamaged bait stations that had been installed on outside walls of households were collected on a monthly (one per cluster per month) basis from each of twelve randomly selected intervention clusters among the 35 trial interventions clusters. Bioassays utilized mosquitoes from a laboratory reared colony of An. gambiaes.s.s, male and female mosquitoes, from December 2021 to June 2022 (rainy to dry season). In total, the study utilized 71 field deployed ATSB stations plus 12 new ATSB stations for comparability purposes. Field deployed ATSB stations had significant lower bio-efficacy than ATSB stations which had never been deployed in the field, but the field-deployed stations retained high levels of bio-efficacy mortality (over 80%) after more than six months in the field. Duration of deployment was also not associated with lower bio-efficacy. There was relatively little variation in mortality between month rounds for those ATSB stations which had been deployed to the field. Westham prototype ATSB stations can retain bio-efficacy even after deployment in the field for 7 months, provided they do not meet predetermined criteria for replacement.

5952

IMPACT OF VOLATILE PYRETHROID SPATIAL REPELLANT ON THE ABUNDANCE OF OUTDOOR BITING ANOPHELINES IN A LOW MALARIA TRANSMISSION SETTING, SOUTHERN ZAMBIA

Limonty M. Simubali[1], Timothy Burton[2], Lewis Kabinga[1], Pebble Moono[1], Justin Moono[1], Alpha Simudoombe[1], Charlton Munsanje[1], Jennifer C. Stevenson[1], Edgar Simulundu[1], Monicah Mirai Mburu[1], Neil F. Lobo[2]

[1]Macha Research Trust, Choma, Zambia, [2]University of Notre Dame, Notre Dame, IN, United States

Residual transmission in the catchment area of Macha Hospital, Southern Province, Zambia, is attributed to outdoor exposure to malaria vectors - spaces and times where indoor interventions are not as effective. This study aimed at evaluating the entomological impact of a volatile pyrethroid spatial repellant (VPSR) product for peri-domestic use (outdoor kitchens) in a semi-field-system (SFS) and in village structures. The transfluthrin-based VPSR tool enables spatial protection against host-seeking mosquitoes. The two phases of this study included 1) a SFS study utilizing replica outdoor kitchens. Here, two VPSR devices were hung from the eaves of each SFS- structure. Release-recapture (using human landing catches (HLCs) experiments enabled the evaluation of the impact of the VPSR device on laboratory reared Anopheles gambiae s.s. Additional secondary endpoints for mortality and reproduction were also collected. 2) a field study conducted in the Macha region during the transmission season. Forty households were selected from two villages for the study. HLCs in VPSR treated and untreated kitchens were conducted to assess the impact on human landing. SFS and filed results demonstrated a significant reduction (40-60%) of mosquito numbers entering VPSR-treated structures. In addition to a reduction in landing, there were also mortality and reduction of fitness impacts with mosquitoes exposed to the VPSR. In conclusion, this study demonstrates that VPSR can reduce the exposure of humans to vectors in both (SFS) and field (village) structures, with additional evidence for community impact through mortality and other impacts seen in transfluthrin-exposed mosquitoes. VPSRs are a potential gap filler as an alternative outdoor malaria intervention.

5953

EXPERIMENTAL HUT AND FIELD EVALUATIONS OF THE THERMACELL® BASED METOFLUTHRIN SPATIAL REPELLENT AGAINST PYRETHROID RESISTANT ANOPHELES FUNESTUS IN SIAYA, WESTERN KENYA

Silas Agumba[1], Vincent Moshi[1], Margaret Muchoki[1], Edward Walker[2], John Greico[3], Bernard Abong'o[1], Eric Ochomo[1]

[1]KEMRI_CGHR, Kisumu, Kenya, [2]Michigan State University, East Lansing, MI, United States, [3]University of Notre Dame, Notre Dame, IN, United States

Spatial repellents (SR) are undergoing epidemiological evaluations with the aim of complementing current vector control tools This study conducted experimental hut and small-scale field trials to evaluate the protective efficacy of Thermacell® based metofluthrin SR against pyrethroid resistant Anopheles funestus in Siaya County, western, Kenya. Phase 1 of the study was conducted in the "Dala Suna" experimental huts located around Lake Kanyaboli, Siaya County, Kenya. The SR product emanator included a cartridge containing metofluthrin attached to liquefied petroleum gas (LPG) cylinder and included two experiments: one to evaluate whether fire from the LPG cylinder increased mosquito density indoors and the second to evaluate the effect of 2, 4 and 12-hour emanation periods had on indoor density and biting rates. Experiment 2 was further modified to include an hour's emanation between 0500-0600HRS the next morning. The second phase: was a field evaluation of an outdoor emanation of the SR product using human landing catches outdoors with volunteers sitting at 5ft,

10ft and 20ft from the emanator. Measured outcomes were deterrence, percentage feeding inhibition, mortality and mosquito landing rates. The SR had an 87.7% deterrence rate and knockdown of 95.5% of Anopheles funestus coming into the huts. Cooking with LPG cooker increased mosquito densities indoors by 52.2%. The 12-hour emanation period reduced Anopheles landing rate indoor by 99.3%. Using 5ft as reference, outdoor mean hourly biting rate were significantly lower than at 20ft (0.33 RR = 9.766(5.351-17.822) P<0.001) but were not significantly different from 10ft (0.025 RR=0.79 (0.349-1.79) P=0.573). SRs almost completely blocked biting indoors and led to 10X lower biting rates within 10ft of the emanator outdoors, the first product to demonstrate such potential. The use of LPG in house could increase exposure to Anopheles mosquito bites.

5954

APPLICATION OF VECTOR CONTROL OPTIMIZATION MODEL ON EAVE RIBBONS FOR MALARIA VECTOR CONTROL IN KILOMBERO VALLEY, TANZANIA

Ismail Nambunga[1], Gloria Shirima[1], Asiya Mbarawa[1], Heather M. Ferguson[2], Fredros Okumu[1], Mafalda Viana[2], Samson Kiware[1]

[1]Ifakara Health Institute, Dar es salaam, Tanzania, United Republic of, [2]University of Glasgow, Glasgow, United Kingdom

Despite significant progress against malaria, the use of two core interventions, namely insecticide-treated nets (ITNs) and indoor residual spraying (IRS), are becoming increasingly vulnerable due to insecticide resistance and outdoor biting by mosquitoes. One representative example is Kilombero Valley in Tanzania where transmission continues despite over 80% of the population using ITNs. Further progress in this and similar African settings will require identifying which supplementary tools combine most effectively with ITNs to reduce mosquito exposure. Using the Kilombero Valley as a case study, the Vector Control Optimization Model (VCOM) was adapted and extended to simulate the impact of adding eave ribbons treated with spatial repellent (ER) as supplementary intervention in an area of high ITN coverage. Simulation was conducted to assess the impact of varying coverage of this supplementary intervention on the entomological inoculation rates (EIR) generated by two common vectors in Kilombero, Anopheles arabiensis and Anopheles funestus. Finally, the impact of introducing this intervention on the combined EIR from An. arabiensis and An. funestus was assessed to identify scenarios in which values fell below 1; the likely threshold required for malaria interruption. ER was predicted to substantially reduce the EIR in Kilombero valley when combined with 80% ITN coverage. However, the nature of the impact varied notably between vector species. ER was predicted to have a much larger effect on transmission mediated by An. funestus than An. arabiensis. Additionally, in the situation where EIR from both An. arabiensis and An. funestus was combined, substantial coverage of this supplementary intervention was predicted to lower EIR to below one. Despite the significant impact ER in combination with ITNs on one of the two vectors (An. funestus or An. arabiensis), this intervention is insufficient when combined with ITNs to reduce the EIR to below one in settings like Kilombero Valley where both species contribute to malaria transmission.

5955

COMMUNITY-BASED BIOLARVICIDING FOR MALARIA CONTROL IN TANGA REGION, TANZANIA

Denis Richard Kailembo[1], Elizabeth Kasagama[1], Fabrizio Molteni[1], Noela Kisoka[1], Christian Lengeler[2], Tegemeo Gavana[3], Prosper Chaki[3], Best Yoram[4], Stella Kajange[4], Jubilate Bernard[5], Samwel Lazaro[5], Charles Dismas[5]

[1]Swiss TPH, Dar es Salaam, Tanzania, United Republic of, [2]Swiss TPH, Basel, Switzerland, [3]IHI, Dar es Salaam, Tanzania, United Republic of, [4]PO-RALG, Dodoma, Tanzania, United Republic of, [5]NMCP, Dodoma, Tanzania, United Republic of

Malaria remains a disease of public health importance globally. Prevalence of malaria in Tanzania among under-fives is 8.1% (MIS 2022) and the country accounted for approximately 3% of all malaria cases in 2021 (WHO – World Malaria Report). The country is deploying community-based biolarviciding in enhancing its efforts towards malaria control. Tanzania is conducting routine implementation of biolarviciding in three councils: Handeni DC, Tanga CC and Lushoto DC, representing 'high', 'moderate' and 'low' malaria risk strata respectively as well as representing both urban and rural settings. Implementation follows a community-based approach whereby trained community-owned resource persons (CORPs) identify the habitats and apply biolarvicide at the ground level. Officers at the village/street, ward, council and regional levels using existing local government structures supervise CORPs. The country is using two biolarvicide products produced in-country: Bacillus thuringiensis var. israelensis (Bti) and Bacillus sphaericus (Bs). Biolarvicide is applied to all identified breeding habitats for three rounds per year based on rainfall pattern. Each round comprises of eight weekly cycles of larvae monitoring and application of biolarvicide. The councils collected baseline data in February 2022 for four consecutive weeks. Handeni DC, Lushoto DC and Tanga CC had 12,203, 2,126 and 1,005 breeding habitats respectively. Handeni DC reported an average of 233,515 anopheles larvae per week, while Lushoto DC and Tanga CC reported 79,528 and 3,520 respectively. Two rounds of application have been completed: Jun-Jul 22 and Oct-Nov 22. Handeni DC showed anopheline larval reduction of 99.9% and 96.1% across the eight weeks of application between rounds 1 and 2 respectively. Lushoto DC reported a reduction of 97.2% and 98.5%, while Tanga CC reported a reduction of 84.4% and 89.6%. Programmatic monitoring highlights that biolarviciding reduces anopheline larval in all three councils. Next steps include conducting entomological and epidemiological evaluation to determine the impact of the intervention.

PILOT STUDY OF BACILLUS THURINGIENSIS ISRAELENSIS IN THE CONTROL OF PERSISTENT DRY SEASON BREEDING MALARIA VECTORS IN MALI

Nafomon Sogoba, **Moussa Keita**, Ibrahim Sissoko, Daouda Ouologuem, Alassane Dit Assitoun, Mahamadou Diakite, Seydou Doumbia

Malaria Research and Training Center(MRTC), Bamako, Mali

One of the challenges to malaria elimination is residual malaria transmission. The concept of "residual malaria" expresses the contribution of other factors to the persistence of malaria transmission. Larval control has been poorly applied in African settings because of the huge number and type of larval habitats encountered. However, riverbeds constitute hot spots for maintaining malaria transmission throughout the long dry seasons in Sahelian West African countries with fewer numbers of larval habitats. In this study, we are pilot testing the biological larvicide Bacillus thuringiensis (Vectobac WG®) in malaria vector control along the River Niger during the dry season in Mali. An active search for major larval habitats was conducted during the dry season in localities along the Niger River. In total, 45 main larval habitats, including water pools, puddles, and brick pits were identified and treated with Bti. Just before treatment, the mean larval density was estimated through the standard WHO deepening technique. The mean number of larvae was 22.4 larvae per dip (SD = 32.75, 95% CI = 12.58—32.26). Using the same method 24 hours after treatment, we could not detect the presence of any larvae in all the identified larval habitats. This is except for a mixed Culex sp and Anopheline larval habitat, where the mortality rate was 97%. 48 hours after treatment, this larval habitat became negative. As a result of this trial, Bti has been shown to be effective in reducing larval density in residual riverbed transmission areas in sub-Saharan Africa.

5957

CHARACTERIZATION OF THE PUTATIVE ANOPHELES FUNESTUS-CYP18A1 ORTHOLOG IN ANOPHELES GAMBIAE

Oswald Y. Djihinto[1], Luisa Nardini[2], Luc S. Djogbénou[1], Lizette L. Koekemoer[2]

[1]Tropical Infectious Diseases Research Centre (TIDRC), University of Abomey-Calavi, Cotonou, Benin, [2]Wits Research Institute for Malaria (WRIM), Wits University, Johannesburg, South Africa

New targets for vector control are needed to reduce malaria transmission due to the spreading of insecticide resistance. In Anopheles gambiae, a likely candidate for genetic control is the 20-hydroxyecdysone (20E) hormone. Two genes CYP314A1 and CYP18A1 regulate respectively the activation and deactivation of the 20E. Although, CYP314A1 is conserved in all mosquitoes species, CYP18A1 is absent in An. gambiae genome. This work used in silico and an experimental approaches to characterize the putative 20E deactivating enzyme coding gene (Anopheles funestus-CYP18A1 ortholog) in Anopheles gambiae. Basic bioinformatics analyses were done to identify Af-CYP18A1 candidate ortholog in An. gambiae genome. To validate the ortholog, molecular docking was performed to compare the binding affinity of 20E to the candidate gene product in An. gambiae and to Af-cyp18A1 protein. The 20E deactivating ability of the candidate gene product in An. gambiae, was evaluated through loss of function experiment using RNA interference system. Two days old females of An. gambiae COGS colony were blood fed and injected with 138 nL of dsRNA+20E. 72 hours post blood meal, 20E titres was measured by High Liquid Chromatography (HPLC). Bioinformatics analyses revealed the CYP306A1 (AGAP004665) as the putative Af-CYP18A1 ortholog in An. gambiae with 54% and 32% protein sequence similarity and identity respectively. The 20E interaction (docking) showed an hydrogen bond between 20E carbon C3 and the Agap-cyp306A1 residue VAL321. While no 20E titre could be detected in control mosquitoes injected with the dsGFP at 72PBM, HPLC analyses showed that An. gambiae females were not able to successfully metabolize the injected 20E when the expression of the CYP306A1 was silenced. The findings of this study are preliminary results suggesting that CYP306A1 could be the Af-CYP18A1 ortholog in An. gambiae. Further investigations are needed to fully characterize the functional role of this candidate gene in 20E deactivation.

5958

TRANSCRIPTOME-WIDE DISCOVERY AND QUANTIFICATION OF LNCRNA EXPRESSION IN VARIOUS CONTEXTS IN THE MALARIA MOSQUITO ANOPHELES GAMBIAE FROM RNA-SEQ DATASETS

Jiannong Xu[1], Kai Hu[2]

[1]New Mexico State University, Las Cruces, NM, United States, [2]University of Massachusetts Medical School, Worcester, MA, United States

Long non-coding RNAs (lncRNAs) are a class of RNA transcripts longer than 200 nucleotides that cannot code for canonical proteins but play various roles in biological contexts. Despite being recognized in mosquito Anopheles gambiae, comprehensive profiling and characterization of lncRNAs remain limited. This study presents a transcript discovery pipeline to identify lncRNA transcripts from RNA-seq datasets in public domains. First, RNAseq reads are mapped against the An. gambiae PEST genome reference using parameters allowing(intron spanning alignment. Then, transcripts from the resulting read mappings are inferred. To identify lncRNAs, non-mRNA transcripts are filtered by the following parameters: a minimum of 10 reads, relative confidence of >10%, a minimum length of 200 nucleotides, and no protein-coding potential. Transcripts that meet these criteria are considered putative lncRNAs. Notably, up to 30% of RNAseq reads are non-mRNA reads. The pipeline predicted thousands of putative lncRNAs. We validated 5 predicted lncRNAs using RT-PCR. The predicted lncRNAs are integrated into the existing transcript annotation to enable simultaneous quantification of mRNA and lncRNA abundance. The lncRNAs identified from different transcriptomes can be merged to update lncRNA annotations. We applied the pipeline to RNAseq datasets in different conditions, such as immune responses to bacterial and Plasmodium challenges and hemocytes, midgut, salivary gland, and whole body. In the datasets of different hemocytes upon bacterial challenges, principal coordinates analysis (PCA) revealed mRNA and lncRNA co-expression patterns. In the dataset that profiled polysome-associated transcripts in the midgut infected with P. falciparum, some lncRNAs demonstrated a differential association with polysomes between the infection and control samples, suggesting that some lncRNAs may encode micropeptides, and/or play roles in regulating protein translation. Our pipeline facilitates lncRNA discovery and quantification to enhance our understanding of transcriptomic response in different contexts.

5959

ENDOGENOUS NON-RETROVIRAL RNA VIRUS ELEMENTS IN ANOPHELES DARLINGI

Juan C. Hernandez-Valencia, Stefani Piedrahita, Diana L. Rodríguez, Margarita M Correa

Grupo de Microbiología Molecular, Escuela de Microbiología, Universidad de Antioquia, Medellín, Colombia

The rise of metavirome research has positioned insects as important virus reservoirs, mainly dominated by insect-specific RNA viruses (ISV). The discovery of the ISVs and the sequencing of a variety of genomes have allowed the identification of RNA virus sequences integrated into genomes denominated non-retroviral endogenous viral elements (nrEVEs). This work aimed to identify nrEVEs in the Anopheles darlingi reference genome (idAnoDarlMG_H_01) and RNA-seq data obtained from An. darlingi natural populations of three regions of Colombia. A database was built with all virus sequences identified in arthropods available in the NCBI-virus repository and a tBLASTn was performed against the An. darlingi reference genome. The detection of nrEVEs in the An. darlingi transcriptome was performed by mapping the RNA-seq reads on the nrEVEs identified in the reference genome; additionally, contigs assembled from RNA-seq data were aligned against nrEVEs. As a result, 44 nrEVEs of negative-strand RNA viruses (ssRNA-) of the families Rhabdoviridae (n= 22), Chuviridae (n= 11) and Phasmaviridae (n= 3) and double-stranded RNA virus (dsRNA) of the families Partitiviridae (n= 6) and Reoviridae (n= 1) were identified in the An. darlingi genome. Thirty-four nrEVEs were detected on chromosome 3, eight on chromosome 2 and two on chromosome X. A differential nrEVE read count was observed in the Colombian An. darlingi metatranscriptomic data. Finally, the multiple alignment showed an identity greater than 98% in three of the sequences assembled from the metatranscriptome against the nrEVEs identified in the reference genome. Knowledge of the presence and expression of nrEVEs in An. darligi contributes to elucidating the dynamics of the Anopheles virome and its endogenization in the genome. Future studies may explore possible antiviral mechanisms associated with the nrEVEs identified.

5960

ANALYSIS OF THE GENETIC VARIATION OF THE FRUITLESS GENE WITHIN THE ANOPHELES GAMBIAE (DIPTERA: CULICIDAE) COMPLEX POPULATIONS IN AFRICA

Honorine Kaboré[1], Mahamadi Kientega[1], Nace Kranjc[2], Nouhoun Traoré[1], Morianou Ioanna[2], Abdoulaye Diabaté[1]

[1]Institut de Recherche en Sciences de la Santé (IRSS), Bobo-Dioulasso, Burkina Faso, [2]Imperial College, London, United Kingdom

One promising strategy for genetic control is to reduce the reproductive potential of disease vectors or pests by targeting genes involved in sexual determinism. However, targeting these genes requires a better understanding of their polymorphism in natural populations to ensure good stability and persistence of the transgene in nature. The genomic data of Anopheles gambiae s.l. used in our study were sequenced by the An. gambiae 1000 Genomes (Ag1000G) project in which the Institut de Recherche en Sciences de la Santé is partner. We used Jupyter notebooks to analyze the genetic variation and conservation score of the fruitless gene

in 18 populations across Africa. A total of 34339 SNPs were identified including 3.11% [1071 SNPs] of non-synonymous polymorphic sites. The overall nucleotide diversity of the gene was low (0.0036) and the Tajima neutrality test (-2.52) was negative indicating an excess of low frequency SNPs. Allelic frequencies of non-synonymous mutations were low except for SNPs at position X: 1309218 (C>G) and X: 1300290 (C>G) that were identified at high frequencies (0.8 - 1) in all populations. The conservation score was variable throughout the fruitless gene with maximum values in the exonic regions compared to the intronic regions. These results would be a good indicator for the spread and persistence of a transgene targeting the fruitless gene in wild populations of An. gambiae s.l.

5961

UNRAVELLING THE GENOMIC AND PHENOTYPIC DIVERGENCE WITHIN SUB-POPULATIONS OF TWO MAJOR MALARIA VECTORS: ANOPHELES GAMBIAE AND AN. COLUZZII

Marilene M. Ambadiang Mae[1], Caroline Fouet[2], Ashu F. Ayukarah[1], Aditi Kulkarni[2], Veronique P. Beng[3], Sourav Roy[2], Colince Kamdem[2]

[1]Centre for Research in Infectious Diseases, Yaounde, Cameroon, [2]Department of Biological Sciences, University of Texas El Paso, El Paso, TX, United States, [3]Department of Biochemistry, Faculty of Science, University of Yaounde 1, Yaounde, Cameroon

Although a significant reduction in malaria incidence over the decades, this mosquito-borne disease remains a major public health concern. The use of insecticides is a cornerstone in malaria vector control, but widespread insecticide resistance coupled to increasing drug resistance and high costs of implementation, is jeopardizing the efficacy of this strategy making malaria resurgence a grim reality. New strategies with novel tools that complement LLINs and IRS to target the major vectors could prevent the resurgence of disease and hasten malaria elimination. Despite the central role of oviposition preference in selecting suitable environments in blood-feeding insects, its contribution to ecological specialization and local adaptation remains elusive. Population studies at early stages or ecological/genetic divergence provide an excellent opportunity to assess the role of oviposition preference in local adaptation of mosquitoes. Combining laboratory dual choice experiments and whole genome sequencing, we conducted the first assessment of phenotypic variation among some of the subpopulations of two major malaria vectors that are emerging along gradients of anthropogenic disturbance in sub-Saharan Africa. When offered choice, Anopheles gambiae gravid females released individually in cages under standard conditions, lay eggs almost exclusively in water collected from their locality of origin while An. coluzzii mosquitoes did not show any preference. This extreme source-specialization prevails in populations belonging to the same ecological biome and displaying very low levels of genome-wide divergence. Interestingly, An. gambiae females maintained in laboratory conditions for several generations using regular water retained water discrimination and were able to choose between source water and exogenous water. We conclude that favourable aquatic oviposition sites though highly heterogeneous in form, space and time are strong enough to drive ecological specialization in the presence of extensive gene flow in mosquitoes and act as signature cues at early stages of divergence in gravid Anopheles mosquitoes seeking to lay.

5962

IDENTIFICATION OF SEX-SPECIFIC PATTERN OF THE DOUBLESEX GENE IN THE MOSQUITO CULEX PIPIENS

Tatyana Martynova, Cheolho Sim

Baylor University, Waco, TX, United States

Gaining insight into the molecular mechanisms behind sex differentiation in the mosquito species Culex pipiens might lead to the identification of genes that could be used to achieve selective male sterility in transgenic lines or to regulate the expression of deadly genes. In many insects, sexual dimorphism is controlled by doublesex (dsx), a double-switch gene located at the end of the somatic sex-determination cascade. Here, we report the isolation and characterization of sex-specific transcripts and isoforms for the Cx. pipiens dsx homologue. The CpdsxF and CpdxM transcripts in females and males. The exon/intron structure of Cpdsx shows that it employs a mechanism for sex-specific splicing distinct from that of Drosophila melanogaster dsx. Insect transgenic technology may be used to alter Cx. pipiens sex ratios, and these results will be useful for sterile insect-based vector control initiatives.

5963

CHIP-SEQ STUDY IDENTIFIES TARGETS OF THE CLOCK GENE, PAR DOMAIN PROTEIN 1 (PDP1), THAT REGULATE DIAPAUSE IN CULEX PIPIENS

Prabin Dhungana, Xueyan Wei, Cheolho Sim

Baylor University, Waco, TX, United States

Multivoltine insects use diapause to endure adverse seasons. Insects employ environmental cues like short day length in late summer and early fall to enter diapause, but how they measure day length is unknown. The circadian clock is necessary for photoperiodism in many insects, including the northern house mosquito, Culex pipiens, which enters diapause, stops egg follicle development, and gains fat. We employed ChIP sequencing to identify PDP1's downstream targets that contribute to diapause's features and how circadian clock genes regulate diapause. We identified the nearest genes in a 10-kb region of the anticipated binding sites, listed prospective targets, and searched for PDP1-specific binding sites. We then examined the genes for functional significance to diapause-specific behaviors and alterations such as metabolic pathways, lifespan extension, cell cycle regulation, and stress tolerance. We validated PDP1 targets from those candidate genes using ChIP-qPCR. In addition, qRT-PCR demonstrated increased expression in diapausing females compared to non-diapausing counterparts. Our investigation uncovers PDP1-controlled diapause-specific genes.

5964

ASSESSING THE FEASIBILITY OF TWO 'MULTIPLEXED' STRATEGIES IN ANOPHELES STEPHENSI MOSQUITOES

Mireia Larrosa[1], Joshua X. D. Ang[2], Michelle A. E. Anderson[2], Estela Gonzalez[1], Lewis Shackleford[2], Katherine Nevard[1], Luke Alphey[2]

[1]The Pirbright Institute, Pirbright, United Kingdom, [2]University of York, York, United Kingdom

Anopheles stephensi is a major malaria vector mainly present in southern Asia and the Arabian Peninsula. Since 2012 it has invaded several countries of eastern Africa, requiring urgent efforts to develop more efficient strategies for vector control such as CRISPR/Cas9-based homing gene drives. One of their challenges is to ensure efficient recognition of the target site by the gRNA. Unfortunately, when a double-stranded break is repaired by NHEJ, it can lead to the creation of mutations. These can destroy the target site, making it difficult for the gRNA to recognize the homologous chromosome. Recent studies have explored the use of multiple gRNAs to solve the issue of target site resistance. In theory, 'multiplexing' would require the individual to become simultaneously resistant to all gRNA target sites for it to be completely resistant to the drive. A potential downside to this strategy is that homing efficiency may depend on perfect homology near the cut site. Thus, the optimal distance between gRNA target sites must be considered. We performed different set of crosses to assess the homing and cutting efficiency of two different 'multiplexing' strategies targeting the cardinal locus: the classic multiplexing and the additive strategies. To assess the feasibility of the first strategy, we generated a gRNA-expressing line with 4 gRNAs separated by a maximum distance of 142bp, which was crossed to a Cas9-expressing line. No significant difference was observed in homing in comparison to a single gRNA-expressing line targeting the same locus. Furthermore, a mutation altering one of the gRNA target sites was introduced to observe changes in the drive's performance. For the additive strategy, we tested the homing efficiency of two independent

gRNA-expressing drives by crossing them to a Cas9-expressing line. Then, we repeated these crosses while adding a mutation in the other gRNA-expressing drive target site found in a 481bp distance to see if homing was affected. We don't expect to see any significant reduction in homing efficiency for any of the performed crosses, showing that these are feasible strategies to tackle target site resistance in An. stephensi.

5965

GEOGRAPHICAL DISTRIBUTION AND GENETIC POPULATION STRUCTURE OF AEDES ALBOPICTUS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Fabien Vulu[1], Kyoko Futami[1], Toshihiko Sunahara[1], Pitshou Mampuya[2], Thierry Bobanga[2], Diedonne Mumba Ngoyi[3], Noboru Minakawa[1]

[1]Nagasaki University, Nagasaki, Japan, [2]University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [3]National Institute of Biomedical Research, Kinshasa, Congo, Democratic Republic of the

Aedes albopictus, a major vector of dengue, zika, and chikungunya viruses, has recently been introduced to central Africa, including the Democratic Republic of the Congo (DRC). Although it is well-known that the establishment of this mosquito poses a serious public health threat in the invaded area, ecological and genetic data for the invading populations in DRC are still scarce. Therefore, our study aimed to reveal the nation-wide geographical distribution of Ae. albopictus and differences in genetic structure among populations. We conducted two entomological surveys at 308 sites within 104 cities from May 2017 to September 2019 and from March to August 2022. We sequenced and analyzed the mitochondrial cytochrome c oxidase subunit 1 gene (COI) (1,434bp) of 498 samples from 16 populations. Neutrality tests and genetic distance analyses were performed on the populations which were classified into three distinct geographical groups. Aedes albopictus was found at 193 (62.6%) sites within 82 (78.8%) cities, mainly in the western and northern DRC, as well as in the western part of the central DRC. This species has become the preponderant Aedes species in these areas, but was not found in the southeastern DRC. Nine COI haplotypes were detected, with one being widely distributed and the most frequent (49%). Aedes albopictus exhibited moderate haplotype diversity (Hd = 0.69 ± 0.02) but low nucleotide diversity (Pi=0.00174 ± 0.00004). Neutrality test revealed Tajima's D (2.14; $p<0.05$) and Fs values (Fs = 3.078; p=0.044) indicating an excess of intermediate-frequency alleles, which can be due to either positive selection or a recent population expansion. Low to moderate genetic differentiation (Fst = 0.016, 0.067 and 0.1328) and high level of gene flow (Gamma St, Nm = 3.75, 7.1 and 24.15) were observed among the groups. Phylogenetic analyses showed that all the nine haplotypes clustered with the populations from Vietnam. The results suggest that Ae. albopictus has established in the western and the northern DRC and was recently introduced to DRC from Southeast Asia.

5966

GENETIC VARIATION AND TRANSCRIPTIONAL ENHANCER ACTIVITY IN THE MALARIA VECTOR, ANOPHELES COLUZZII

Kimani Njoya[1], Cameron E. Anderson[1], Natalia M. Zmarlak[2], Inge Holm[2], Karin Eiglmeier[2], Ronald J. Nowling[3], Kenneth D. Vernick[2], Michelle M. Riehle[1]

[1]Medical College of Wisconsin, Milwaukee, WI, United States, [2]Institut Pasteur, Paris, France, [3]Milwaukee School of Engineering, Milwaukee, WI, United States

Enhancers are an important class of non-coding regulatory elements, and genetic variation in enhancers can underlie phenotypic variation. A genome-wide map of transcriptional enhancers for the malaria vector Anopheles coluzzii was filtered to highlight 16 candidates with potential influence over differential malaria susceptibility. The effect of candidate enhancer alleles from malaria susceptible and resistant mosquitoes was assessed by site-directed mutagenesis and Dual-Glo luciferase assays, with 7 enhancers displaying significant differences between resistant and susceptible mosquitoes. Computational prediction of transcription factor binding sites (TFBS) in the enhancers identified 82 enriched motifs that represent i) TFBS conserved with Drosophila melanogaster and ii) predicted mosquito-specific TFBS. DNA-protein pulldowns were implemented to confirm TFBS identification and distinguish enhancer allele-specific differences in TFBS binding that could be associated with differential transcription regulation.

5967

IDENTIFICATION OF H3K27ME2 SITES THAT CAUSE VARIOUS DIAPAUSE PHENOTYPES IN THE MOSQUITO CULEX PIPIENS

Xueyan Wei, Prabin Dhungana, Cheolho Sim

Baylor University, Waco, TX, United States

To survive winter, the mosquito Culex pipiens enters diapause, a state that enables adult females to accumulate fat, cope with stress, and survive longer. Epigenetic controls, specifically histone changes, have been linked to several diapause phenotypes. In our recent Western blot investigation, we observed significantly fewer H3K27me2 marks in the fat bodies of diapausing females, suggesting that H3K27me2 may regulate diapause, although the regulatory mechanisms remain unclear. Using ChIP-sequencing, we identified H3K27me2's direct targets in the mosquitoes' fat bodies and proposed that epigenetic modification of these histone methylation marks may activate diapause-programmed genes. We selected and evaluated diapause-related genes and prioritized the top 300 candidate genes with the highest fold enrichment for functional annotation based on their proximity to the peaks within 1 kb of the promoter's transcription start site. We then verified a collection of candidate genes of H3K27me2 ChIP-seq using ChIP-qPCR and qRT-PCR.

5968

GENETIC AND NEURAL BASIS OF ATTRACTION OF GRAVID AEDES AEGYPTI TO AFRICAN BERMUDA HAY INFUSIONS

Margot P. Wohl[1], Luisa M. Otero[2], Stephanie Rankin-Turner[1], Robert Barrera[2], Conor J. McMeniman[1]

[1]Department of Molecular Microbiology and Immunology, Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [2]Entomology and Ecology Team, Dengue Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States

The yellow fever mosquito Aedes aegypti is a prolific disease vector with explosive population dynamics. Its ability to thrive in urban environments lies in the ability of female Ae. aegypti to seek out standing pools of water to lay their desiccation-resistant eggs. Of note, females are highly attracted to the scent of decomposing botanical matter in water. Currently, hay infusion preparations made from African Bermuda Grass are widely used to bait the CDC autocidal gravid ovitrap for mosquito surveillance and control in the field. However, the molecular and cellular basis of how mosquito attraction to this potent oviposition attractant is unknown. To gain insight into olfactory preferences of female Ae. aegypti for oviposition stimuli, we established a two-choice behavioral assay that quantifies attraction to odors emitted by fermenting African Bermuda hay. Mated and blood fed females of different Ae. aegypti strains were more attracted to hay infusion odor than water alone. In addition, the preference for hay infusion is state-specific as it was not observed in unmated blood-fed, nor mated unblood-fed females. To understand the molecular and neural basis of this attraction, we first tested mutants for olfactory co-receptors to understand which are necessary for female olfactory choice. Next, we generated a mosquito line with an inward rectifying potassium channel (Kir2.1) downstream of the QUAS binary expression sequence. In concert with olfactory co-receptor QF2 driver lines, we are testing the role of different subsets of olfactory co-receptor-expressing cells in hay infusion attraction. This research will fundamentally improve our understanding of biological basis of oviposition site search behavior and catalyze development of novel approaches that target this important aspect of female mosquito reproductive biology. Furthermore,

the generation of a line for neural silencing in Ae. aegypti can be used more generally to investigate the neural basis of mosquito behaviors that underly its population dynamics and capacity to transmit arboviral diseases.

5969

LEVERAGING FIELD DNA SEQUENCING TO MEASURE SPATIOTEMPORAL VARIATION IN MOSQUITO COMMUNITY COMPOSITION AND FEEDING BEHAVIOR IN RURAL MADAGASCAR

Christina M. Bergey[1], Bernadette Rabaovola[2], Beauriche Andriambolaharijaona[3], Rindra Rakotoarivony[3]

[1]Rutgers University, Piscataway, NJ, United States, [2]Center ValBio, Ranomafana, Madagascar, [3]Université d'Antananarivo, Antananarivo, Madagascar

Understanding how climatic variables impact mosquito distribution in tropical highlands is particularly paramount, as human populations in regions with historically low mosquito-borne disease burdens are potentially immunologically naive relative to nearby lowland groups and may lack genetic or behavioral adaptations to pathogens such as Plasmodium. Despite this pressing public health need, baseline data from mosquitoes in tropical highlands are scarce due to the historically low vector-borne disease burden of these regions. Critically, this gap in information hampers fine-scale modeling of disease likelihood in areas where the predicted risk of climate-linked disease increase is highest. Here, we report longitudinal sampling of mosquitoes along altitudinal gradients in the montane tropical rainforest of southeastern Madagascar to understand the ecological drivers of malaria disease dynamics. We measured mosquito community composition and distribution in six villages surrounding Ranomafana National Park in southeastern Madagascar that vary in altitude and intensity of land use change. We additionally applied new portable sequencing technology to sequence individual mosquitoes in-country for assessment of population connectivity and vertebrate host species selection. Such data across seasons and altitudes will allow us to understand the human health impacts of the predicted shift for higher elevation areas to the vector dynamics of the lowlands.

5970

CHARACTERIZATION OF THE VIROME IN AEDES AEGYPTI VECTOR OF CONDORCANQUI PROVINCE, AMAZONAS REGION, THROUGH SHOTGUN METAGENOMIC SEQUENCING

Jhon Zumaeta[1], Luis M. Rojas[2], Carmen I. Gutierrez[1], Rafael Tapia-Limonchi[3], Laura Bergner[4], Stella M. Chenet[1]

[1]Instituto de Enfermedades Tropicales, Universidad Nacional Toribio Rodriguez de Mendoza, Chachapoyas, Peru, [2]Laboratorio Referencial de Salud Pública Amazonas, Chachapoyas, Peru, [3]Instituto de Investigaciones de Ciencias Biomédicas, Universidad Ricardo Palma, Lima, Peru, [4]School of Biodiversity, One Health & Veterinary Medicine, University of Glasgow, Glasgow, United Kingdom

The total virome in mosquitoes has yet to be explored in the population of Aedes vector in Condorcanqui province, Amazonas region, Peru. Since the last few years, dengue cases have been considerably increasing in this tropical area, mainly through A. aegypti bites. There is an urgency in scrutinizing A. aeypti viral ecology and interrelations due to its public health relevance. Here, we characterized for the first time, through untargeted shotgun metagenomic sequencing, the virome of Aedes mosquitoes collected in the Rio Santiago district of Condorcanqui. A total of 137 individuals morphologically identified as A. aegypti were collected using mouth aspirators. These were grouped into twelve pools of ten to fifteen individuals. A protocol based on RNA extraction, reverse transcription, metagenomic library preparation, and sequencing, using the Illumina NextSeq 500 system, was performed. Bioinformatic analysis for screening shotgun metagenomic data was used. This included filtering out low-quality reads, assembling reads into contigs and viral classification using the ViralRefSeq Protein NCBI database. The results indicated a complex diversity of viral family members in A. aegypti, mainly Phenuidiridae, Flaviviridae and Totiviridae; also, Rhabdoviridae, Chuviridae, Baculoviridae, Mimiviridae and other viral families were found. Phenuidiridae, Flaviviridae and Totiviridae viruses were consistently found in the pools, suggesting these might be members of the core virome of A. aegypti in Amazonas. Some viruses detected have been identified as pathogenic for plants, ruminants and insects; a few might be used as biopesticides for biological control of insects due to their high pathogenicity and host specificity. Anopheline-specific viruses were also found, suggesting that there might be an exchange of viruses during their blood feeding. Additionally, targeted methods are needed for a more sensitive and precise search of human pathogenic viruses in vectors of these endemic areas.

5971

EXAMINING WEST NILE VIRUS INFECTION OF CULEX TARSALIS MIDGUTS AT SINGLE-CELL RESOLUTION

Emily Anne Fitzmeyer, Taru Dutt, Gregory D. Ebel

Colorado State University, Fort Collins, CO, United States

In mosquito vectors, the midgut functions as a critical interface between pathogen and vector. Several studies have demonstrated that the mosquito midgut plays an important role in systemic infection, host immune response, intrahost virus population dynamics, and vector competence. Recent work examining mosquito hemocytes and midgut epithelium at the single-cell level has uncovered distinct functions within immune cell populations and identified key markers in the midguts of Aedes aegypti that overlap with major cell types found in Drosophila midguts. However, studies characterizing cell populations and their functions in the mosquito midgut are scarce and, in Culex tarsalis mosquitoes, nonexistent. Cx. tarsalis is a main enzootic vector of West Nile virus (WNV) and one of the most important arthropod-borne virus (arbovirus) vectors in North America. The Cx. tarsalis midgut is a stringent escape barrier that impacts the diversity of WNV populations that escape the midgut, infect the salivary glands, and escape into the saliva where transmission occurs. To gain a better understanding of how Cx. tarsalis midgut tissue functions as the interface between the vector and WNV, we performed single-cell RNA sequencing (scRNA-seq) on dissociated midgut cells from both WNV infected and mock-infected Cx. tarsalis mosquitoes. Examining WNV infection of the midgut at single-cell resolution will allow us to identify distinct cell populations and differentially expressed genes associated with WNV infection. Further, by using an approach to scRNA-seq that is flavivirus inclusive, we hope to identify cell types that serve as either sites of virus replication or cellular bottlenecks. Identification of midgut cell populations and genes impacted by WNV infection, will provide key insight into the physiology of WNV infection within a critical vector, and further characterize mechanisms that influence intrahost evolution of WNV.

5972

EVOLUTIONARY HISTORY OF SYLVATIC POPULATIONS OF ANOPHELES GAMBIAE AND IMPLICATIONS FOR MALARIA TRANSMISSION

Lemonde Bouafou, Josquin Daron, Diego Ayala

French National Research Institute for Sustainable Development, Montpellier, France

Apart from the increasingly reported adaptation to urban environments, the adaptation of malaria vectors to sylvatic, non-anthropogenic environments remains poorly studied. Recent observations on the existence of stable populations of Anopheles coluzzii in the Lopé National Park, Gabon, led us to investigate the evolutionary history of this population and their potential involvement in pathogens transmission. We analyzed the genome of 96 individuals of An. coluzzii from 3 different biotopes: urban, rural and sylvatic. We revealed the existence of structure between the populations of Libreville and those found in La Lopé (rural and sylvatic). However, despite the existence of important gene flow between the sylvatic and rural populations, we highlighted the existence of selection signals that suggest local adaptations of these different populations of An. coluzzii. In addition, the carrying of human and non-human Plasmodium by mosquitoes found in the

park, revealed by an extensive field collection, could be a threat to malaria control. The park could then be a reservoir of vectors and vector-borne pathogens. Further analyses are underway to better characterize these different populations from a genetic and phenotypic perspective.

5973

TEMPORAL AND COEVOLUTIONARY ANALYSES REVEAL THE EVENTS DRIVING THE EMERGENCE AND CIRCULATION OF HUMAN MAMASTROVIRUSES

Lester J. Perez, Kenn Forberg, Gavin A. Cloherty, Michael G. Berg
Abbott Laboratories, Abbott Park, IL, United States

Characterized by high genetic diversity, broad host range, and resistance to adverse conditions, coupled with recent reports of neurotropic astroviruses circulating in humans, mamastroviruses pose a threat to public health. The current astrovirus classification system based on host source prevents determining whether strains with distinct tropism or virulence are emerging. By using integrated phylogeny, we propose a standardized demarcation of species and genotypes, with reproducible cut-off values that reconcile the pairwise sequence distribution, genetic distances between lineages, and the topological reconstruction of the Mamastrovirus genus. We further define the various links established by co-speciation and resolve the dynamics of transmission chains to identify the sources from which different mamastrovirus species circulating in humans have emerged. The well-known 'human' astrovirus, defined here as mamastrovirus species 7, has co-speciated with humans, while there have been two additional host-jumps into humans from distinct hosts. Newly defined species 6 genotype 2, linked to severe gastroenteritis in children, resulted from a marmot to human jump taking place ~200 years ago while species 6 genotype 7 (MastV-Sp6Gt7), linked to neurological disease in immunocompromised patients, jumped from a bovine source only ~50 years ago. Through demographic reconstruction, we determined that the latter reached coalescent viral population growth only 20 years ago and is evolving at a much higher evolutionary rate than other genotypes infecting humans. This study constitutes mounting evidence of MastV-Sp6Gt7 active circulation and highlights the need for diagnostics capable of detecting it.

5974

A COMPARATIVE ANALYSIS OF COMMERCIAL ANTI-DENGUE VIRUS IGG TESTS TO AID DENGUE IMMUNIZATION PROGRAMS

Freddy A. Medina[1], Frances Vila[1], Laura E. Adams[1], Jaime Cardona[1], Jessica Carrion[1], Elaine W. Lamirande[2], Luz N. Acosta[1], Carlos M. De León Rodríguez[1], Manuela Beltran[1], Demian Grau[1], Vanessa Rivera-Amill[3], Angel Balmaseda[4], Eva Harris[5], Stephen H. Waterman[1], Gabriela Paz-Bailey[1], Gabriela Paz-Bailey[1], Stephen Whitehead[2], Jorge L. Muñoz-Jordán[1]
[1]Centers for Disease Control and Prevention, San Juan, PR, United States, [2]National Institutes of Health, Bethesda, MD, United States, [3]Ponce Health Sciences University, Ponce, PR, United States, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud / Sustainable Sciences Institute, Managua, Nicaragua, [5]University of California, Berkeley, Berkeley, CA, United States

The Advisory Committee on Immunization Practices (ACIP) recommends screening with anti-dengue virus (DENV) IgG tests to confirm prior DENV infection in children aged 9-16 years living in dengue-endemic areas of the United States before vaccination with Dengvaxia®. The minimum recommended test performance is ≥75% sensitivity and ≥98% specificity. To ensure safe implementation of Dengvaxia®, it is necessary to evaluate commercial anti-DENV IgG tests to assess which meet these criteria. We evaluated the performance of seven tests using serum panels from early convalescent specimens paired with acute specimens characterized by DENV and Zika virus (ZIKV) RT-PCR. The five best performing tests along with two additional tests specifically designed for pre-vaccination screening were evaluated with a panel of 44 specimens collected from healthy 9-16-year-old children in Puerto Rico. Four of these tests had promising discriminatory capacity for past DENV infections and were further evaluated using 400 specimens from the same population. Specimens from this population were classified as DENV exposed, ZIKV exposed, DENV and ZIKV exposed or unexposed using DENV and ZIKV virus Focus Reduction Neutralization Tests in combination with an in-house DENV IgG ELISA. No single test met the recommended performance to identify children eligible for Dengvaxia®, but the Euroimmun anti-DENV NS1 Type 1-4 ELISA combined with the CTK OnSite Dengue IgG rapid test R0065C with a visual test read yielded 80.3% sensitivity and 100% specificity. Manufacturers of these two tests modified their tests to meet the recommended performance standards with a single test. Using the automated ALTA rapid test reader, the modified CTK OnSite Dengue IgG rapid test R0065C yielded 76.2% sensitivity and 98.1% specificity. The preliminary performance for the modified Euroimmun anti-DENV NS1 Type 1-4 ELISA was 76.6% sensitivity and 99.1% specificity. These modified tests allow the benefit of vaccination while reducing the risk of vaccinating individuals without prior DENV infection and provide additional options for dengue pre-vaccination screening.

5975

CHALLENGES TOWARDS CLINICAL ALPHAVIRUS ENCEPHALITIS DIAGNOSTICS IN A DENGUE ENDEMIC COUNTRY

Luis Felipe Rivera[1], Carlos Lezcano[1], Josefrancisco Galué[1], Kathryn A. Hanley[2], Sandra López-Vergés[1], Cassia F. Estofolete[3], Nikos Vasilakis[4], Mauricio L. Nogueira[3], Jean-Paul Carrera[1]
[1]Gorgas Memorial Institute of Health Studies, Panama City, Panama, [2]New Mexico State University, Las Cruces, NM, United States, [3]Sao Jose do Rio Preto School of Medicine, Sao Paulo, Brazil, [4]University of Texas Medical Branch, Galveston, TX, United States

Febrile undifferentiated diseases are often treated empirically in arboviral endemic regions due to the lack of available commercial diagnostics for highly diverse and sometimes unknown pathogens. Therapeutic decisions rely on clinical symptoms and sympatric circulation of multiple etiologic agents underscore the need to generate strategies for accurate diagnostics. Madariaga (MADV) and Venezuelan equine encephalitis virus (VEEV) have been associated with severe and sometimes fatal disease. We explored potential symptoms as predictors of alphavirus encephalitis infection. A total of 78 MADV and VEEV cases that occurred between 2010-2019 were compared to 1152 Dengue (DENV) controls. Case-patients and controls were compared based on reported symptoms registered using epidemiological forms. A total of 40 symptoms were collected from alphavirus encephalitis patients. The most common symptoms were fever, myalgias and petechiae. We found no major differences in symptoms between cases and controls. Vomiting (OR 2.9; p=≤0.001, 95% CI 1.7-4.8) and diarrhea (OR 11.9; p=≤0.001, 95%: CI 3.3-40.2) were the only non-specific early symptoms that increase in cases compared with controls. Symptoms associated with advanced clinical progression such as seizures (OR 70.3; p= ≤0.001, 95%: CI 25.8-218.8) and altered mental status (OR 5.2; p=≤0.001, 95% CI 1.43-15.5) were associated with alphavirus encephalitis, while respiratory symptoms (OR 7.8; p=≤0.001, 95%: CI 2.0-25.8), an uncommon symptom were found increased with alphavirus infection. Taken together, our results suggest that alphaviral encephalitis infections remain a diagnostic clinical challenge in dengue-prone regions, because of similarities in acute symptoms and the difficulty of predicting severe outcomes such as encephalitis, which can have significant morbidity and mortality. This underscores the necessity for building diagnostic capacity and lab surveillance in such areas.

5976

POST-DISCHARGE DEATHS AMONG SEVERE ACUTE RESPIRATORY INFECTION PATIENTS WITH SARS-COV-2 IN BANGLADESH DURING 2020-2022

Md Ariful Islam, Md Zakiul Hassan, Tanzir Ahmed Shuvo, Md Kaousar Ahmmed, Probir Kumar Ghosh, Syeda Mah-E- Muneer, Mohammed Ziaur Rahman, Fahmida Chowdhury

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

To understand the real burden of SARS-CoV-2-associated deaths among patients with severe acute respiratory infection (SARI), it is crucial to consider post-discharge deaths along with in-hospital deaths. We aimed to describe the characteristics of SARS-CoV-2-infected SARI patients who died at post-discharge in Bangladesh excluding accidental deaths. From March 2020-December 2022, we conducted COVID-19 surveillance among WHO-defined SARI patients at nine tertiary-care hospitals. We tested nasopharyngeal and oropharyngeal swabs for SARS-CoV-2 by rRT-PCR. We collected information on demographics, clinical characteristics and outcome at discharge and 30 days post-discharge. We used Chi-square test to compare post-discharge decedents and survivors. We identified 10,886 SARI patients with a median age: 16 years (IQR:1-50), 63% were male and 12% (1,319) were laboratory-confirmed SARS-CoV-2. Among patients with SARS-CoV-2, 10% (132) died during their hospital stay and 9.5% (112) died within 30 days of post-discharge. Of 112 post-discharge deaths, 4% (5) were discharged as fully recovered, 72% (80) as partially recovered, and 24% (27) were referred to specialized hospitals for further treatment. Adults aged ≥60 years were more likely to die at post-discharge compared to those aged <60 years [22% (74/330) vs. 4% (38/853); p<0.001]. Males were more likely to die at post-discharge compared to females [11% (79/698) vs. 7% (33/485); p=0.009]. Compared to the SARS-CoV-2 infected survivors, a higher proportion of SARS-CoV-2 infected post-discharge death cases had difficulty breathing on admission (94% vs. 77%, p<0.001), received in-hospital oxygen (92% vs. 64% p<0.001) and had at least one co-morbid condition (50% vs. 38%, p=0.017). One in five SARS-CoV-2-associated SARI patients died; of these, half occurred within 30-days post-discharge commonly among males, elderly, and patients with comorbid condition. Thus, post-discharge deaths might be unrecognized contributor to the true SARS-CoV-2 mortality in Bangladesh. Limiting premature discharge among high-risk groups should be considered to reduce these post-discharge deaths.

5977

RATS' FEEDING BEHAVIOR AT FRUIT TREES IN BANGLADESH AND IMPLICATIONS FOR PATHOGEN SPILLOVER

Ausraful Islam[1], Clifton McKee[2], Probir Kumar Ghosh[1], Jaynal Abedin[3], Jonathan H. Epstein[4], Peter Daszak[4], Stephen P. Luby[5], Salah Uddin Khan[6], Emily S. Gurley[7]

[1]icddr,b, Dhaka, Bangladesh, [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD 21205, MD, United States, [3]Insight Centre for Data Analytics, National University of Ireland Galway, Galway, Ireland, [4]EcoHealth Alliance, New York, NY, United States, [5]Department of Medicine, Division of Infectious Diseases & Geographic Medicine, Stanford University, California, CA, United States, [6]Public Health Agency of Canada, Ottawa,, ON, Canada, [7]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Rats are the reservoir of important zoonotic pathogens like hantavirus, lymphocytic choriomeningitis virus, Salmonella, and agents of rat-bite fever. Food contaminated with rat saliva, feces or urine is a transmission route for these pathogens. Raw date palm sap and fruits dropped on the ground are consumed by humans and animals in Bangladesh, and sap consumption is a known route of Nipah transmission from bats to humans. Here, we describe rats' feeding behavior in date palms and fruit trees (jujube, banana, star fruit, sapodilla, olive, tamarind, fig, guava) in home gardens in Bangladesh captured using motion sensor-activated infrared cameras in two different studies. One study was conducted during the winter of 2011 and 2012, in 137 villages across Bangladesh, and the second in a village in the northern part of Bangladesh, from March 2013 to February 2016. We investigated how rats may contaminate date palm sap and fruits that may be consumed by humans. We recorded a total of 1002 rat visits with 150 nights at date palm trees and 118 nights at fruit trees during the winter season. We used descriptive statistics and a generalized linear model to identify conditions associated with rat visits. Among the 1002 rat visits observed, 831 (84%) were detected at date palm trees, 67 (7%) at jujube trees, 48 (5%) at banana plants, and 35 (4%) at start fruit tree. Camera images showed that rats were licking date palm sap either alone or in pairs or in some cases alongside bats. Rats ate larger fruits in the tree, like star fruit, and took away smaller fruits, like jujube. The longest duration of contact/night was recorded at date palm trees (78 sec) followed by olive trees (37 sec), star fruit trees (23 sec), and jujube trees (17 sec). Our study has some limitations as the cameras recorded the events only in the focused area and we do not have any evidence of rats urinating or defecating either in the sap or on the fruits or dropping fruits on the ground. However, the opportunities for pathogen transmission through shared food deserve additional follow-up to identify if rat-borne pathogens are infecting humans through shared food sources.

5978

PREVALENCE AND PREDICTORS OF PERSISTENT SYMPTOMS POST-ACUTE COVID-19 INFECTION AMONG A COHORT OF FRONTLINE HEALTHCARE WORKERS IN BANGLADESH

Md Zakiul Hassan[1], Ahamed Khairul Basher[1], Md Abdullah Al Jubayer Biswas[1], Aninda Rahman[2], Mahmudur Rahman[3], Fahmida Chowdhury[1], Kaydos-Daniels Neely[4]

[1]icddrb, Dhaka, Bangladesh, [2]Communicable Disease Control, the Director General of Health Services, the Ministry of Health and Family Welfare Government of Bangladesh, Dhaka, Bangladesh, [3]Global Health Development/EMPHNET, Dhaka, Bangladesh, [4]US Centers for Disease Control and Prevention, Atlanta, USA, Atlanta, GA, United States

Despite evidence of a wide range of persistent symptoms among COVID-19 survivors, commonly known as long COVID, their frequency, clinical spectrum and risk factors are not well characterized. We assessed the prevalence and predictors of long COVID among healthcare workers (HCWs) in Bangladesh. Between July 2021-March 2023, we enrolled a cohort of HCWs from purposively selected hospitals of four divisions across Bangladesh to prospectively record COVID-19 illness. At enrolment, we captured data on HCWs' demographics, co-morbid conditions and COVID-19 illness. The study physician followed the participants biweekly to record any new and persistent symptoms following acute illness. We used the WHO case definition for long COVID (symptoms occurring 3 months from the acute COVID-19 infection and persisting for at least 2 months). We performed a multivariable logistic regression to identify the predictors of long COVID. The analysis included 875 HCWs with lab-confirmed SARS-CoV-2 infection: 30% (261) doctors, 53% (468) nurses, and 17% (146) support staff. The median age of the HCWs was 35 (IQR, 29-44), and 69% (601) were female. Of the 875 HCWs, 462 (53%) reported persistent symptoms, with fatigue being the most common (83%), followed by brain fog (14%), cough (5%), breathing difficulties (4%), and joint pain (4%). HCWs with co-morbidities (aOR 3.39, 95% CI 2.32-4.95; p=0.0001), breathing difficulty during the acute phase (aOR 2.84, 95% CI 1.77-4.55; p=0.0001), and those who required hospitalization during acute infection (aOR 2.25, 95% CI 1.53-3.04; p=0.0001) were more likely to develop persistent symptoms than HCWs without a history of co-morbidities, respiratory symptoms, or hospitalization. Nurses (aOR 1.36, 95% CI 1.01-1.85; p=0.04) were more likely to develop persistent symptoms than doctors. More than half of the HCWs in our cohort experienced long-term symptoms of COVID-19, with a greater risk observed among nurses and those with the co-morbid condition. These findings underscore the pressing need for long-term care and rehabilitation strategies with a standardized guideline to enhance the post-acute recovery of COVID-19 patients.

5979

PSYCHIATRIC SEQUELAE AND PSYCHOSOCIAL IMPACT OF LASSA FEVER IN SURVIVORS IN EDO STATE, NIGERIA

Charlotte Kriebel[1], Benjamin Aweh[2], Olukunle Obagaye[2], Francis Erah[2], Omonefe Joy Seb-Akahomen[2], Paul Erohubie[2], Edmund Akpaikpe[2], Chukwuemeka Ugochukwu Ohanaka[2], Gloria Eifdiyi[3], Elisabeth Agho[3], Patricia Nwokike[2], Osahogie Edeawe[3], Joseph Okoeguale[3], Amir H. Yassari[4], Lena Jelinek[4], Michael Ramharter[1], Cyril Erameh[3], Sylvanus Okogbenin[3], Till Omansen*[1], Esther Okogbenin* (*contributed equally)[2]

[1]Department of Tropical Medicine, Bernhard Nocht Institute for Tropical Medicine & I. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [2]Department of Psychiatry, Irrua Specialist Teaching Hospital, Irrua, Nigeria, [3]Institute of Lassa Fever Research and Control, Irrua Specialist Teaching Hospital, Irrua, Nigeria, [4]Department of Psychiatry and Psychotherapy, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Lassa fever (LF) is a viral haemorrhagic fever with high mortality rates endemic to West Africa. Psychiatric sequelae in survivors of other high consequence infectious diseases have been reported before; in particular, high rates of post-traumatic stress disorder (PTSD) were found in survivors of Ebola virus disease. Yet, there is a paucity of data on the psychological impact of LF. This comparative cross-sectional study aimed to determine the occurrence of psychiatric diagnosis and psychosocial aspects of LF in survivors in Edo State, Nigeria. From May 2022 to date, 123 cases and 51 age- and sex- matched controls were enrolled. The mean age was 33.2 ± 11.4 years, 46% were female. Validated and established psychiatric screening tools were administered to screen for PTSD, depression and anxiety. In case participants scored above cut-offs, further psychiatric evaluation using the Mini Neuropsychiatric Interview (MINI) was conducted to confirm diagnosis. To investigate the psychosocial impact of LF, survivors completed a 15-item Likert scale questionnaire on perceptions related to the infection. There was no statistically significant difference in the frequency of anxiety and depression between survivors and controls. However, a higher rate of PTSD (7%) was found among survivors. All confirmed PTSD cases received counselling, yet most required pharmacotherapy. In the Likert scale, a majority of survivors stated that they were scared of the severity of LF and feared for their life when on the ward. Most respondents reported that they were anxious to infect others and that admission was stressful for both themselves and their families. In addition, 76% of survivors found being admitted with LF to be a financial burden. Our findings suggest that LF causes considerable psychosocial stress, in some cases even leading to clinical diagnosis of PTSD. This is the first study to show the perceptions of LF survivors regarding the impact of the disease on their life. These results indicate the importance of integrating mental health services into the care of LF patients. Moreover, knowledge of the perception of LF will greatly aid in public health interventions.

SECONDARY ATTACK RATES AND DETERMINANTS OF SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS 2 (SARS-COV-2) HOUSEHOLD TRANSMISSION IN PAKISTAN: A CASE-ASCERTAINED PROSPECTIVE, LONGITUDINAL STUDY

Mashal Amin[1], Imran Nisar[1], Nadia Ansari[1], Farah Khalid[1], Shahira Shahid[1], Marvi Mahesar[1], Maryam Mansoor[1], Farrukh Qazi[1], Aneeta Hotwani[1], Najeeb Rehman[1], Arsalan Ashraf[2], Zahoor Ahmed[2], Ashfaque Ahmed[2], Arsalan Memon[2], Fyezah Jehan[1]

[1]The Aga Khan University, Karachi, Pakistan, [2]Government of Sindh, Health Department, Karachi, Pakistan

Households are considered ideal settings for studying the transmission dynamics of an infectious disease. A prospective study was conducted, based on the World Health Organization FFX protocol from October 2020 to January 2021. Household contacts of laboratory-confirmed index cases of SARS CoV-2 were followed up for their symptomatic history, nasal swabs for RT-PCR and blood samples for anti-SARS CoV-2 antibodies were collected at enrollment and days 7, 14, and 28. We estimated the secondary attack rate (SAR), effective reproduction number (Re), and determinants of secondary infection among susceptible household contacts using multivariable logistic regression. We enrolled 77 index cases and their 543 contacts. Out of these, 252 contacts were susceptible at the time of enrollment. There were 77 household clusters, out of which, transmission took place in 20 (25.9%) giving rise to 34 cases. The acquired secondary attack rate (SAR) was rate 14.0% (95% CI 9.0-18.0). The average effective reproduction number (Re) was 0.44 (95% CI 0.33-0.60). Reported symptoms of nausea and vomiting (OR, 7.9; 95% CI, 1.4-45.5) and fatigue (OR, 9.3; 95% CI, 3.8-22.7) were associated with SARS-CoV-2 transmission. We observed low SARS-CoV-2 transmission in the backdrop of high seroprevalence among households in Karachi, Pakistan. Symptomatic history influences infection transmission.

5981

COMPARISON OF THE PERFORMANCE OF RNA EXTRACTION KITS USED IN THE DIAGNOSIS OF COVID-19 AGAINST THE INHOUSE TRIZOL RNA EXTRACTION METHOD

Sharley Melissa Aloyo

Makerere University, Kampala, Uganda

The Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is the etiologic agent of the COVID-19 pandemic which has since spread across the globe, placing a burden on society. Measures taken to reduce its spread depend on timely and accurate diagnosis done using various RNA extraction techniques and RT-PCR. Many commercial RNA extraction kits have been manufactured and released globally on the market however, due to growing demand, a shortage in kit supplies could be experienced in several labs. For these reasons, the use of different commercial or in-house protocols for RNA extraction may provide a basis for various labs to choose reliable extraction kits from the available pool and pave the way for seeking alternative procedures to replace commercial kits using common reagents found in a basic molecular biology laboratory. This study aimed to compare the analytical performance of different SARS-CoV-2 RNA extraction kits used in the diagnosis of SARS-CoV-2 in Uganda against the conventional TRIzol extraction method to address the existing knowledge gap. This work retrieved SARS-CoV-2 positive nasopharyngeal swabs from -80°C storage at biobank and Makerere University. SARS-CoV-2 RNA was then extracted from the samples using four commercial kits and the TRIzol method. The study demonstrated variations in the performance of the different kits/methodologies; The TRIzol extraction method generated the highest concentration of RNA; however, its purity was significantly lower than that of the commercial kits. When comparing the CT values, there was no statistically significant difference between TRIzol and the commercial kits except one. This research concludes therefore that although the TRIzol method recovered RNA with relatively lower purity, its performance in diagnosing SARS-CoV-2 using RT-PCR did not differ significantly from the tested commercial kits.

CHANGING PATTERN OF DENGUE SEROTYPE IN THE SINDH REGION OF PAKISTAN, 2006-2022

Khekashan Imtiaz

The Aga Khan University, Karachi, Pakistan

Dengue virus infection is a major threat to public health in Pakistan (PK). over the past few decades, the risk of infections with severe disease outcomes is increasing with the changing environmental and climatic conditions making PK a hotspot for mosquito breeding the disease has become hyper-endemic, with different serotypes causing epidemic outbreaks with severe clinical presentation. we analyzed the DENV serotypes circulating in the Sindh region of PK between 2006 -2022. Archived serum samples of two Filed surveillance studies conducted in 2006-2011 and 2014-2017 for patients with acute febrile illness along with prospective random selected clinical laboratory samples collection (2020-

2022) of DENV positive samples were used to assess the changing trends. All samples were tested by rapid NS1- antigen and PCR using serotype-specific primers, a significant changing trend of the predominant DENV serotypes in the three cohorts studied. From 2006-11 samples (n=200), DENV-3 was the predominant serotype tested in 60% (n= 57) of the total 94 DENV PCR positive samples followed by DENV-2, 38.3% (n=36) and DENV-4 1.1% (n= 1) we did not find DENV-1. The 2015-17 samples (n=168),34.52% wereDENV-2 followed by DENV-1 5.9%, DENV-3 8.92%, and DENV-4 3.57%. The results of 2020-22 showed changing trend with a progressive predominance of DENV-1 over other serotypes, accounting for 74% of all DENV positive (n=50) samples. Our study confirms that PK is hyperendemic for DENV as all four serotypes are found to be circulating and the temporal trend suggests the fluctuation in the predominant type circulating during the epidemic season. These findings are significant as changing pattern makes the population vulnerable to secondary infections with severe clinical outcomes warrant large-scale genomic surveillance of the DENV to better understand the role of factors responsible for varying trends such as human migration, climatic changes, and virus evolution. such surveillance is also required to better predict and prepare for the outbreaks outcomes as an entry of new serotype in the community after a gap of few years creates a risk for severe secondary infections.

5983

SEVERE MORBIDITY AND MORTALITY FROM RIFT VALLEY FEVER DISEASE BETWEEN NOVEMBER 2017 AND MARCH 2020 AMONG HUMANS IN UGANDA

Zacchaeus Anywaine[1], Christian Hansen[2], George Warimwe[3], Luke Nyakarahuka[4], Stephen Balinandi[4], Alex Riolexus Ario[5], Julius J. Lutwama[4], Alison Elliott[1], Pontiano Kaleebu[4]

[1]Medical Research Council/Uganda Virus Research Institute and London School of Hygiene and Tropical Medicine Uganda Research Unit, Entebbe, Uganda, [2]Medical Research Council International Statistics and Epidemiology Group, London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom, [4]Department of Arbovirology, Emerging and Re-emerging, Infectious Diseases, Uganda Virus Research Institute, Entebbe, Uganda, [5]Uganda National Institute of Public Health, Ministry of Health, Kampala, Uganda

Rift Valley fever (RVF) is a zoonotic viral disease affecting animals and humans. Over the last two decades the disease has occurred with increased intensity in humans. In Uganda, cases reported prior to 2016 were either mild or under-reported. Here, we report on the morbidity and mortality of human cases identified in Uganda between November 2017 and March 2020. Human cases reported to the Uganda Virus Research Institute (UVRI) were identified and confirmed by polymerase chain reaction (PCR). Ethical and regulatory approvals were obtained to enrol survivors into a one-year follow-up study. Data were collected on patient socio-demographics, medical history, laboratory tests, and potential risk factors, and analysed using Stata software. Forty (40) cases were confirmed in four outbreak clusters that occurred over 29 months in 20 districts. Nearly all confirmed cases were male (39/40; 97.5%), median age 32 (range 11-63). Over three-quarters (31/40; 77.5%) of patients presented to the health care system with fever and bleeding. Twenty-eight (70%) cases were hospitalised, and more than half (21/40; 52.5%) of all confirmed cases died. Mortality was highest among admissions in regional referral (11/16; 68.7%) and district (4/5; 80%) hospitals, patients with bleeding at case detection (17/31; 54.8%), and older than 44 years (9/9; 100%). Survivors presented with mild disease manifesting commonly as gastro-intestinal syndrome with nausea (83.3%), anorexia (75%), vomiting (75%), abdominal pain (50%), and diarrhoea (41.7%). Symptom duration varied between two to 120 days. In conclusion, RVF causes high mortality and prolonged morbidity among humans that present to the health care system and are confirmed positive for RVF by PCR. Interventions should be developed to prevent infections, promptly detect disease outbreaks, and improve patient outcomes. 1

5984

KNOWLEDGE, AND PERCEPTIONS OF COVID-19 INFECTION AMONG PEOPLE REPORTING FOR COVID-19 VACCINATION IN HEALTH FACILITIES IN MALAWI

Fatsani Ngwalangwa[1], David Chaima[2], Geoffrey Guenther[3], Harrison Msuku[4], Alfred Matengeni[4], Charles Mangani[1], Tonney Nyirenda[2], Karl Seydel[5], Davidson H. Hamer[6], Patricia L. Hibberd[6], Clarissa Valim[6], Don Mathanga[4]

[1]Department of Public Health, Kamuzu University of Health Sciences, Blantyre, Malawi, [2]Department of pathology, Kamuzu University of Health Sciences, Blantyre, Malawi, [3]Division of infectious Diseases, Boston Childrens hospital, Boston, MA, United States, [4]Malaria Alert Centre, Kamuzu University of Health Sciences, Blantyre, Malawi, [5]Internal Medicine College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, [6]Department of Global Health, Boston University School of Public Health, Boston, MA, United States

Knowledge and perceptions of COVID-19 play a significant role in the uptake of preventive measures within communities. Understanding the knowledge and perception of COVID-19 infection among subjects willing to be vaccinated allows planning additional health education campaigns to be included in the routine COVID-19 vaccination. These subjects may act as role models, motivating other community members to take up vaccine and other prevention measures. An ongoing cross-sectional study interviewed 138 adults at the time they received first dose of the COVID-19 vaccine in a peri-urban and urban health facility in Blantyre, Malawi. A score summarized information on four domains of knowledge on COVID-19: symptoms, prevention, transmission and people at risk. This score was dichotomized into low vs. moderate/advanced knowledge. Through logistic regressions, determinants of low vs. moderate/ advanced knowledge were investigated including age, gender, educational level, and employment. We also investigated the source of the subject's information about COVID-19. Only 71 (52%) and 52(37%) had moderate/advanced knowledge on symptoms and prevention of COVID-19, respectively, whilst 125 (91%) had moderate/advanced knowledge on transmission. A total of 52 (37%) understood the highest risk groups. Females were more likely to have moderate/advanced knowledge on prevention than males (odds ratio ([OR] 2.1; P=0.04); subjects > 40 years had higher moderate/advanced knowledge at identifying highest risk groups (OR 3.8; P=0.01). Being a farmer was associated with low knowledge on at risk groups compared to office work/manual unskilled workers (OR 0.4; p value = 0.05). However, poor knowledge and understanding of symptoms and transmission of COVID-19 were uniformly spread in the population. Radio stations were the major sources of COVID-19 information (80% subjects). Our results suggest that after three years of the start of pandemic, information about COVID-19 has not been widely disseminated in Malawi. This may be negatively impacting uptake of preventive measures. There is a need to integrate COVID-19 health education in routine vaccination.

5985

A SIMULATION-BASED METHOD TO INFORM SEROSURVEY DESIGN TO ESTIMATE DENGUE FORCE OF INFECTION USING EXISTING BLOOD SAMPLES

Anna Vicco[1], Clare McCormack[2], Belen Pedrique[3], John Amuasi[4], Anthony Afum-Adjei Awuah[4], Christian Obirikorang[4], Nicole Gilberger[5], Eva Lorenz[5], Juergen May[5], Isabela Ribeiro[3], Neelika Malavige[3], Christl A. Donnelly[6], Ilaria Dorigatti[2]

[1]University of Padua, Padua, Italy, [2]Imperial College London, London, United Kingdom, [3]Drugs for Neglected Diseases initiative, Geneve, Switzerland, [4]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [5]Bernhard Nocht Institute of Tropical Medicine, Hamburg, Germany, [6]Department of Statistics, University of Oxford, Oxford, United Kingdom

Limited knowledge exists on the extent of dengue virus circulation in Africa. Cross-sectional serological surveys provide the ideal data to investigate historical dengue transmission, to reconstruct the age-dependent immunity profile of a population, and to estimate transmission intensity, as measured by the force of infection (FOI), the per-capita risk of infection for

susceptible subjects. However, owing to limitations in capacity for arboviral disease surveillance, according to the published literature, only 17 dengue serosurveys have been conducted in the African region so far. A convenient strategy to overcome this limitation is to retarget existing blood biobanks, e.g., from previous serosurveys, for dengue surveillance by secondary testing for anti-dengue antibodies. Here we present a new simulation-based method developed to identify both the optimal number and age-distribution of samples required to obtain informative FOI estimates through secondary testing of existing blood samples. We discuss its application to the sample sizes previously collected during a SARS-CoV-2 serological survey conducted in Ghana, and show that the method is effective in reducing sample sizes required for testing without affecting the accuracy of the FOI estimates.This study highlights how existing blood samples from cross-sectional serosurveys can be leveraged for dengue surveillance and provides a framework for generating new immunological data to understand dengue historical circulation while optimising resources. The methods developed in this study can be adopted to investigate multiple viruses and diseases in different transmission settings around the world.

5986

LASSA FEVER OUTBREAK IN GHANAIAN COMMUNITIES, FEBRUARY 2023

Joseph Kwame Benne

Noguchi Memorial Institute for Medical Research, ACCRA, Ghana

Lassa fever (LF) is an acute viral haemorrhagic illness, endemic in rodent populations in parts of West Africa such as Benin, Ghana, Guinea, Liberia, Mali, Sierra Leone, Togo, and Nigeria with case fatality of 15% among patients hospitalized with severe clinical manifestations. Infection can occur by exposure to food or household objects contaminated with the urine or faeces of infected Mastomys rats; person-to-person infections and laboratory transmission can also occur. On February 24th, 2023, the Noguchi Memorial Institute for Medical Research (NMIMR) confirmed two cases of LF and alerted the Ghana Health Service. As of February 28th, 2023, there were 14 confirmed cases, with one fatality. The other cases were contacts of the index cases, and Ghana had previously reported an epidemic in 2011. Korle-Bu Teaching Hospital submitted two probable viral haemorrhagic fever (VHF) patients, 33- and 40-year-old women with symptoms indicative of LF, including fever, vomiting, diarrhoea, abdominal pains, difficulty in breathing and bleeding from the eyes and nose.
The samples were submitted to viral RNA extraction, purification, and amplification using molecular testing methods for recognized endemic VHFs such as LF, Ebola, Yellow Fever, Dengue, and Marburg virus. The molecular testing methods employed yielded presumptive positive findings for LF. The initial close relationships in 12 other cases were confirmed as well as 156 contacts were observed for the stipulated period of 21 days. The number of confirmed patients for this epidemic is 26 with one fatality as of March 20th, 2023, with 512 samples received. All 25 patients are alive and well and were treated and subsequently discharged in authorized health institutions. In conclusion, there is a need to continuously strengthen public health systems to ensure effective and timely responses to outbreak situations or future emerging pathogens. The VHF testing capacity established by NMIMR as well as the GHS public health disease control unit has proven to be active and sensitive to detecting emerging pathogens for public health response.

5987

CLINICAL EVIDENCE ON DISEASE BURDEN OF THE MOSQUITO-BORNE CHIKUNGUNYA VIRUS (CHIKV) : A SYSTEMATIC LITERATURE REVIEW

Kimberley Bakker[1], Hinko Hofstra[1], Gerard T. Vondeling[2], **Adrianne de Roo**[2]

[1]Asc Academics, Groningen, Netherlands, [2]Valneva, Vienna, Austria

Chikungunya virus (CHIKV) is a re-emerging arbovirus that causes an infection characterized by an acute phase frequently including severe polyarthralgia, myalgia, and fever, which can progress to chronic sequelae and consequently result in productivity losses and a significant decline in health-related quality-of-life (HRQoL). To investigate the available clinical evidence on the disease burden associated with CHIKV, we conducted a systematic literature review (SLR). The SLR of clinical evidence was performed in Medline and Embase databases (no date restriction) and congress abstract repositories (2019-2021). The search adhered to Preferred Reporting Item for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Acute and chronic polyarthralgia and myalgia, two of the most prevalent CHIKV infection symptoms, have been identified as severely impairing the physical capacity of the patients and further affecting their daily functioning and HRQoL. Since the patients experience severe pain symptoms, their mental health is also significantly impacted, which often results in several psychological disorders. A chronic CHIKV infection may lead to long-term disability due to multiple long-term sequelae associated with a reduction in HRQoL. The low number of identified interventional studies (i.e., 17) displays the shortage of available interventions for the treatment of CHIKV infection. CHIKV is a serious threat to global public health and causes considerable disease burden worldwide. The rapid geographic expansion of CHIKV outbreaks and distribution is a result of a combination of travel, CHIKV mutations, global warming, and the spread of the mosquito vector. Currently, no antiviral treatment exists for chikungunya, and vector control is suboptimal and challenging. Due to the increase in the global spread of CHIKV and the paucity of treatment options for chikungunya, an effective preventive measure such as a vaccine is urgently needed.

5988

MONKEYPOX VIRUS OUTBREAK IN GHANA

JH Kofi Bonney

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Monkeypox viral infection is a zoonotic disease caused by the Monkeypox virus from the family Poxviridae. It is usually a self-limiting disease with its clinical presentation like that of the smallpox virus. Reservoirs for the Monkeypox virus is unknown however, some animals that are susceptible to this virus include tree squirrels, and non-human primates. Since 1970 when the first human Monkeypox virus was detected, 11 African countries have reported cases of the virus with Nigeria recording the largest outbreak of 200 confirmed cases in 2017.The 2022-2023 Mpox outbreak in Ghana is a part of the larger outbreak of human Mpox caused by the West African clade of the MPXV. Ghana, as compared to its neighbors including Nigeria, had hitherto no endemic presence or active search and diagnosis for Mpox, until the 2022 outbreak. The first 5 cases of Mpox in Ghana were detected on 8th June 2022 and as of 20th March 2023, 569 suspected cases have been investigated. Here we sought to establish the molecular evidence and elucidate on the characterized circulating strains of MPXV of the cases investigated. Viral DNA was processed from lesion exudate or crust on a swab and/or serum specimens of patients identified by clinicians to have met the case definition of an initial febrile prodrome accompanied by headache, and fatigue prior to rash development. Polymerase chain reaction was then performed at the NMIMR to amplify the viral DNA. As of 2March 2023 a total of 569 suspected MPXV cases have been received from health facilities across the country and tested. Of the total, 65 (11.4%) have been confirmed to be MPXV cases whilst 87 (15.3%) were other orthopoxviruses. Nearly 60% of all confirmed cases were children under 15 years old and 3 fatalities have been recorded. Sequenced and characterized MPXV positives were found to belong to the West African clade. This work documents molecular evidence of monkeypox virus circulation in Ghana. It is worth to consider vaccinating affected areas with vaccinia (smallpox vaccine), and to intensify education on good personal hygiene as well as heightened surveillance for monkeypox and other orthopoxviruses in the country.

NEUTRALIZING ANTIBODY TITER AFTER COMPLETE SARS-COV-2 VACCINATION

Virgilio E. Failoc-Rojas[1], Stalin Tello-Vera[2], Cesar Nevado-Garcia[2], Alicia Torres-Mera[3], Cristian Diaz-Velez[4], Mario J. Valladares-Garrido[5]

[1]Universidad Cesar Vallejo, Piura, Peru, [2]Hospital Nacional Almanzor Aguinaga Asenjo, Chiclayo, Peru, [3]Universidad Nacional Pedro Ruiz Gallo, Lambayeque, Peru, [4]Universidad Privada Antenor Orrego, Trujillo, Peru, [5]Universidad Privada Norbert Wiener, Lima, Peru

Vaccination against SARS-CoV-2 is a priority and fundamental strategy to prevent the spread of this disease and avoid the collapse of the health system. The recommended vaccination schedule for this vaccine is 2 doses with an interval of at least 21 days between them. Neutralizing antibodies are considered a good marker for measuring humoral responses. To evaluate the humoral response following COVID-19 vaccination by measuring the antibody titer against the receptor binding domain (RBD) of the spike (S) protein. We conducted an observational study in volunteer health care personnel who had received two doses of vaccines. We detected binding antibodies against SARS-CoV-2 by chemiluminescence immunoassay test (CLIA) for quantitative determination of specific IgG antibodies against the trimeric spike protein. We log-transformed the amount of SARS-CoV-2 IgG. We performed ANOVA tests to evaluate by months of follow-up (every 30 days) and linear regression between elapsed days with antibody titers. We considered a p-value less than 0.05 as significant. RESULTS: A total of 224 persons who completed the vaccination schedule (2 doses) were evaluated. Every 10 days that elapsed since the first vaccine dose, the coefficient of difference of the Log difference of the IgG titer of binding antibody decreased on average 0.25 log(IgG) (p-value<0.001). Patients started with an average SARS-CoV-2 binding antibody titer at 9.33(±1.5) log(IgG SARS-CoV-2) during the first 30 days, and at the end of follow-up (days 150-180) on average had 5.12(±1.1) log(IgG SARS-CoV-2). A history of COVID-19 resulted in increased antibody titers during the 61-180 day post-vaccination period relative to those without a history of COVID-19 (p<0.001). There was no difference in mean log(IgG SARS-CoV-2) according to sex (p=0.0.274). In conclusion, antibody production against SARS-CoV-2 virus has shown to have good humoral response the first 30 days, but has been decreasing up to 54% in the sixth month post-vaccination. The COVID-19 background sustained SARS-CoV-2 IgG antibody levels above those who had not been infected.

5990

LOW SEROPREVALENCE OF EBOLA VIRUS IN HEALTH CARE PROVIDERS IN AN ENDEMIC REGION (TSHUAPA PROVINCE) OF THE DEMOCRATIC REPUBLIC OF THE CONGO

Trésor Zola Matuvanga[1], Joachim Mariën[2], Ynke Larivière[2], Bernard Osangir[2], Solange Milolo[1], Rachel Meta[1], Emmanuel Esanga[3], Vivi Maketa[1], Junior Matangila[1], Patrick Mitashi[1], Steve Ahuka Mundeke[1], Hypolite Muhindo-Mavoko[1], Jean-Jacques Muyembe Tamfum[1], Pierre Van Damme[2], Jean-Pierre Van gertruyden[2], Jean-Pierre Van gertruyden[2]

[1]University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [2]University of Antwerp, Antwerp, Belgium, [3]Ministry of Health of DRC, Kinshasa, Congo, Democratic Republic of the

A serosurvey among health care providers (HCPs) and frontliners of an area previously affected by Ebola virus disease (EVD) in Boende, Democratic Republic of the Congo (DRC) was conducted to assess the seroreactivity to Ebola virus antigens. Serum samples were collected in a cohort of HCPs and frontliners (n=698) participating in the EBL2007 Ebola vaccine trial (December 2019 to October 2022). Specimens seroreactive for EBOV were confirmed using either the Filovirus Animal Nonclinical Group (FANG) ELISA or a Luminex multiplex assay. The seroreactivity to at least two EBOV-Mayinga (m) antigens was found in 10 (1.4%: 95% CI, 0.7-2.6) samples for GP-EBOV-m + VP40-EBOV-m, and 2 (0.3%: 95% CI, 0.0 - 1.0) samples for VP40-EBOV-m + NP-EBOV-m using the Luminex assay. Seroreactivity to GP-EBOV-Kikwit (k) was observed in 59 (8.5%: 95%CI, 6.5-10.9) samples using FANG ELISA. In contrast to previous serosurveys, a low seroprevalence was found in these HCPs and frontline population. The use of various tests, of different seroprevalence cut-offs, and of distinct geographical populations with different risk of exposure to EBOV, would contribute to this difference. This underscores the high need for standardized antibody assays and cutoffs in EBOV serosurveys to circumvent the wide variability in reported EBOV seroprevalence rates in EBOV endemic areas. Furthermore, it is unclear whether based on lessons learned from previous EVD outbreaks, the majority of HCPs and frontliners participants in the EBL2007 Ebola vaccine trial would have adequately adopted the EVD prevention key messages or were practicing good EVD prevention. This would have kept them safe, free of EBOV exposure and then explain the low seroprevalence. Similarly, other filovirus infections that can generate cross-reacting antibodies not investigated in this serosurvey may account for this low seroprevalence.

MOLECULAR CHARACTERIZATION OF SARS-COV-2 IN HEALTHCARE PERSONNEL WITH THIRD GENERATION SEQUENCING IN LIMA, PERU, 2021-2022

Bia Peña[1], Ana I. Gil[1], Mayra Ochoa[1], Rubelio Cornejo[1], Lucie Ecker[1], Omar Flores[1], Luis M. Franchi[1], Claudio F. Lanata[2]

[1]Instituto de Investigacion Nutricional, Lima, Peru, [2]Instituto de Investigacion Nutricional, Lima; Department of Pediatrics, School of Medicine, Vanderbilt University, Nashville; Department of Epidemiology, London School of Hygiene and Tropical Medicine, London, Lima, Peru

Genomic surveillance of SARS-CoV-2 variants has enabled the study of the emergence of new viral mutations during this pandemic. It is thought that mutations are emerging from infected persons with more than 14 days of viral shedding. We did a molecular characterization of SARS-CoV-2 virus detected in workers of a health facility that had a nasopharyngeal or nasal sample taken weekly until it became RT-PCR negative. RT-PCR positive samples obtained from 2021 and 2022, stored at -80°C, were sequenced in the MinION Mk1C device from Oxford Nanopore Technologies. Extracted viral RNA was processed following the PCR tiling of SARS-CoV-2 virus with rapid barcoding and Midnight RT-PCR Expansion (SQK-RBK110.96 and EXP-MRT001) protocol. 78 samples from 50 workers were processed for sequencing. Samples from 44 workers (88%) were able to be sequenced. All samples from 2021 were Lambda 21G (C.37) SARS-CoV-2 variant. In 2022, all SARS-CoV-2 belonged to the Omicron variant from different sub-lineages, mainly BA.2 (20%), BA.1.1 (17%), BA.1 (15%), BA.5 (13%) and BA.5.1 (10%). Samples from 10 workers with SARS-CoV-2 positivity over 1 week were processed; however, we only were able to sequence the first samples during the first week of episode from 8 workers and samples from both the first and second week of only 2 workers. All others with samples up to 7 weeks positive for SARS-CoV-2, were unable to be sequenced. Bioinformatic analysis of the 2 workers with sequenced samples for week 1 and 2 showed identical variants. These results suggest that prolonged RT-PCR positivity for SARS-CoV-2 may not represent viable viruses. We concluded that the identified SARS-CoV-2 variants detected in 2021 and 2022 were similar to those detected elsewhere, and that in this small series of cases in healthy individuals, prolonged positivity by RT-PCR may not represent viable viruses with potential to generate new variants. These results require confirmation in larger studies.

5992

ENTERIC VIRAL PATHOGENS AND CHILD GROWTH: INSIGHTS FROM SOUTH ASIA AND SUB-SAHARAN AFRICA

Rina Das

Rollins School of Public Health, Emory University, Atlanta, GA, United States

Enteric viral pathogens such as rotavirus, norovirus, adenovirus, astrovirus, and sapovirus are associated with a significant burden of childhood morbidity and mortality. We investigated the relationship between viral

pathogens and child anthropometric outcomes among under-5 children in South Asia and sub-Saharan Africa. We analyzed data from 5,572 children enrolled in the Global Enteric Multicenter Study (GEMS) across seven study sites between December 2007 and March 2011. Viral pathogens: rotavirus and adenovirus were detected using stool immunoassays (ELISA) and norovirus, astrovirus, and sapovirus by RT-PCR. Multiple linear regression was used to examine the association between the viral pathogens and length/height-for-age (HAZ), weight-for-age (WAZ), and weight-for-length/height (WHZ) z-scores, stratified by diarrheal symptoms and adjusted for potential covariates. Rotavirus (18.51%) and norovirus (7.33%) were the most prevalent pathogens among symptomatic and asymptomatic under 5 children, respectively. Among asymptomatic children, viral pathogens were associated with lower WAZ: rotavirus (β=-0.09; 95% CI: -0.17, -0.01), norovirus (β=-0.12; 95% CI: -0.18, -0.06), adenovirus (β=-0.28; 95% CI: -0.47, -0.10), and sapovirus (β=-0.14; 95% CI: -0.23, -0.06). Among the symptomatic children rotavirus (HAZ:β=0.12; 95%CI:0.07,0.17 and WAZ:β=0.05; 95% CI:0,0.11), norovirus (HAZ:β=0.08; 95% CI: 0.01,0.15 and WAZ:β=0.14; 95% CI: 0.06,0.21), and sapovirus (WAZ:β=0.13; 95% CI:0.02,0.24) were associated with higher HAZ and WAZ, but astrovirus was associated with lower HAZ (β=-0.16; 95% CI: -0.28, -0.04). While previous studies hypothesized that several viral pathogens had a controversial role in child growth, our findings indicate that enteric viral pathogens are associated with growth shortfalls among asymptomatic children. This highlights the need for preventive strategies targeting enteric viral pathogens among asymptomatic young children, which could potentially reduce the burden of childhood growth faltering.

PILOT SURVEILLANCE EVALUATION USING LEFTOVER MEASLES/RUBELLA NEGATIVE SURVEILLANCE SPECIMENS TO DETECT ARBOVIRUS INFECTIONS

Ingrid B. Rabe[1], Eve Lackritz[2], Diana P. Rojas[1], Corinne S. Merle[1], Brice Bicaba[3], Nay Yi Yi Linn[4], Mursinah Mursinah[5], Ava Kristy Sy[6], Judith Wong Chui Ching[7], John Kayiwa[8], Endang Wulandari[9], Badri Thapa[10], Sacha Bootsma[11]

[1]World Health Organization, Geneva, Switzerland, [2]Center for Infectious Disease Research and Policy, Minneapolis, MN, United States, [3]Ministère santé, Ouagadougou, Burkina Faso, [4]Ministry of Health - Myanmar, Nay Pyi Taw, Myanmar, [5]National Institute for Health Research and Development, Jakarta, Indonesia, [6]Research Institute for Tropical Medicine, Muntinlupa City, Philippines, [7]National Environment Agency, Singapore, Singapore, [8]Uganda Virus Research Institute, Entebbe, Uganda, [9]World Health Organization, Jakarta, Indonesia, [10]World Health Organization, Yangon, Myanmar, [11]World Health Organization, Juba, South Sudan

Dengue, chikungunya, and Zika virus infections remain a threat in areas where the Aedes (Stegomyia) mosquito vectors are established. Limited arbovirus surveillance results in underestimates of disease burden and delayed recognition of transmission activity. WHO recommends an integrated public health approach to Aedes-borne arboviruses. A proposed strategy for case detection in some regions is arbovirus testing of suspect measles and rubella cases, as patients present with clinically similar febrile rash illness and blood specimens are routinely collected. We describe the evaluation of a pilot sentinel surveillance strategy using this approach for infection detection and feasibility of implementation. Between 2019 and 2022, the national public health laboratories of Burkina Faso, Indonesia, Myanmar, and the Philippines tested stored specimens for measles and rubella testing from the preceding 1-12 years for evidence of acute dengue, chikungunya, and Zika infections using a validated RT-PCR molecular assay and IgM-capture enzyme-linked immunosorbent assays. Where feasible, IgM-positive specimens were transferred to the Uganda Virus Research Institute and the National Environment Agency Singapore, respectively, for further testing by repeat IgM and plaque reduction neutralization tests. In total, 8,648 leftover measles/rubella surveillance specimens were tested. Molecular testing detected either chikungunya or dengue RNA in 330 (4%) of all specimens and in three of four countries. All countries detected IgM antibodies to all three viruses, with overall seropositivity of 13% to at least one virus. Confirmatory testing demonstrated the continued challenges of flavivirus serologic cross-reactivity in endemic countries. Arbovirus testing of measles-rubella surveillance specimens leverages a widespread, robust collection of samples from patients with clinically compatible illness. However, the resources required to yield accurate results suggest that this approach should be targeted to specific objectives and sentinel locations for optimal utility.

ESTIMATING THE INCIDENCE OF DENGUE IN INTERNATIONAL TRAVELERS FROM NON-ENDEMIC COUNTRIES

Matt D. Hitchings[1], Yi Xu[1], Bernardo Garcia-Carreras[1], Adriana Gallagher[1], Justin J. O'Hagan[2], Derek A. Cummings[1]

[1]University of Florida, Gainesville, FL, United States, [2]Merck & Co., Inc., North Wales, PA, United States

We estimated the risk of dengue infection among travelers from non-endemic countries to inform public health preparedness, especially in non-endemic countries with suitable vectors where infected travelers can spark outbreaks. We used data from 2010-19 on ~30,000 traveler cases that were reported to national authorities in 21 non-endemic countries, hazards of infection in 102 endemic countries based on local seroprevalence studies, and the numbers of flights and trip durations between countries. From these, we estimated the total numbers of infections in travelers (i.e. regardless of symptoms) and the fractions of infections reported in travelers' home countries. We tested two simplifying assumptions: assuming time-constant country-specific reporting rates, and assuming the reporting rate was determined by endemic and non-endemic terms only (i.e. no interaction). We analyzed data using Bayesian Markov Chain Monte Carlo and used the leave-one-out information criteria to compare models. From 2010-19, nearly 30,000 traveler cases with known country of infection were reported in the 21 non-endemic countries. Australia, USA, and Germany reported the highest case numbers. Indonesia, Thailand, and the Philippines were the destinations giving rise to the most cases. The model assuming time-varying reporting and no interaction performed best. Estimated reporting rates varied across country pairs (median 1.7%, range 0.07% to 38.2%). We estimated that an average of 170,800 annual dengue infections occurred among travelers from these 21 countries, with most occurring among travelers from the USA (85,100), Japan (20,400), and South Korea (16,300). Thailand (18,700), Brazil (15,300), and India (14,300) were the destinations with the highest numbers of traveler infections. In conclusion, this study shows that reported dengue cases among travelers represent a small fraction of infections in this group and that this fraction varies greatly across countries. These estimates can guide public health preparedness, including quantifying the benefit of dengue vaccination in travelers.

5995

ARBOVIRUS DISEASE SURVEILLANCE AMONG FEBRILE PATIENTS IN KILIMANJARO, TANZANIA, 2016-2019

Robert J. Rolfe, Jr[1], Matthew P. Rubach[1], Venance P. Maro[2], Blandina T. Mmbaga[2], Bingileki F. Lwezaula[3], Nathaniel Kalengo[2], Grace Kinabo[2], Calvin Mosha[3], Annette Marandu[3], Ronald Mbwasi[2], Kajiru Kilonzo[2], Furaha Lyamuya[2], John P. Bonnewell[1], Manuela Carugati[1], Michael J. Maze[4], Deng B. Madut[1], Jeremy P. Ledermann[5], Paul L. Burns[5], David Beaver[5], Ann M. Powers[5], John A. Crump[6]

[1]Duke University, Durham, NC, United States, [2]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of, [3]Mawenzi Regional Referral Hospital, Moshi, Tanzania, United Republic of, [4]University of Otago, Christchurch, New Zealand, [5]Arboviral Diseases Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [6]Centre for International Health, University of Otago, Dunedin, New Zealand

Arthropod-borne flaviviruses and alphaviruses are emerging infectious diseases and causes of febrile illness in East Africa. A prospective cohort study enrolled febrile patients admitted to 2 referral hospitals in Moshi, Tanzania, September 2016 through May 2019. Acute serum was obtained at enrollment, and convalescent serum 28-42 days later.

Convalescent serum underwent antibody screening by ELISA for the following arboviruses: dengue (DENV), Zika (ZIKV), West Nile (WNV), yellow fever (YFV), Sindbis, o'nyong-nyong (ONNV), and chikungunya (CHIKV). Those with positive, uninterpretable, or equivocal screens underwent plaque reduction neutralization testing (PRNT) on acute and convalescent sera. PRNT results were expressed as the reciprocal of the serum dilution yielding >80% reduction in the number of plaques (PRNT80). Acute arboviral disease (ABD) was defined as having ≥4-fold increase from acute to convalescent PRNT80 titer with an end-titer PRNT80 >40 and ≥4-fold greater than other viruses in the same genus. Prior infection or vaccination (against arboviruses with available vaccines) was defined as PRNT80 titer >10 without a ≥4-fold rise in convalescent titer. Both for acute and prior infections, if there was not an end titer 4-fold higher for one species compared to others within the same genus, this was designated at the genus level (e.g., flavivirus disease). Of 1,132 patients enrolled, 430 (38.0%) were screened for ABD by convalescent ELISA and 110 reflexed to PRNT80. Eleven (2.6%) participants had ABD: 1 CHIKV, 4 DENV, 2 ZIKV, and 4 flavivirus. Twenty-five (5.8%) participants had evidence of prior infection or vaccination: 1 alphavirus, 7 flavivirus, 3 DENV, 2 ONNV, 7 WNV, 1 ZIKV, and 4 YFV. DENV was the most frequent acute ABD and WNV the most frequent prior infection. YFV seropositivity likely reflected prior vaccine exposure. While we found acute ABD to be a relatively uncommon cause of febrile illness, these serologic case detections suggest circulation or arrival of flaviviruses and alphaviruses of public health significance in northern Tanzania.

5996

ACCEPTANCE AND HESITANCY TOWARDS COVID-19 VACCINE AMONG HEALTHCARE WORKERS IN BUKAVU, EASTERN DEMOCRATIC REPUBLIC OF CONGO

Patrick Musole Bugeme[1], Ashuza Shamamba Guillaume[2], Victoire Urbain Hatu'm[2], Gauthier Bahizire Murhula[2], Alain Balola Ntaboba[2], Patrick D.M.C. Katoto[1]

[1]Center for Tropical Diseases and Global Health, Université Catholique de Bukavu, Bukavu, Congo, Democratic Republic of the, [2]Faculty of Medicine, Université Catholique de Bukavu, Bukavu, Congo, Democratic Republic of the

The Democratic Republic of Congo (DRC) is falling behind the global COVID-19 vaccination effort in achieving herd immunity against SARS-CoV-2 infection due to vaccine hesitancy, which poses a threat to global health and hinders the implementation of a successful vaccination program. Healthcare workers in the DRC were highly hesitant towards the COVID-19 vaccine even before its deployment, further complicating efforts to prevent and contain the pandemic. This study aimed to identify the factors associated with COVID-19 vaccine hesitancy among DRC's healthcare workers one year after the availability of the vaccine. From March 1st to March 31st, 2022, we conducted face-to-face interviews and web-based surveys using the WHO's modified Behavioral and Social Drivers of Vaccination instrument among healthcare workers in Bukavu, eastern DRC. Logistic regression models were built to identify predictors of vaccine hesitancy, defined as uncertainty or intention to refuse an available COVID-19 vaccine. Of the 380 participants, with a mean age of 35.0 (28.0-48.0) years and 198 (52.1%) males, 266 (70%) were hesitant to accept the COVID-19 vaccine, while only 29 (7.6%) were willing to accept it. A majority of participants (63.9%) believed that COVID-19 vaccines were not safe, and 77.9% and 81.6% distrusted central and local government authorities, respectively, in their ability to deliver a safer vaccine. While 42.4% trusted in the science behind the vaccine development, distrust in the central government (aOR=3.543, IC1.351-9.289), distrust in the science that proposed the COVID-19 vaccine (aOR=4.360, IC 1.351-9.289), perceiving that COVID-19 vaccines available are not safe (aOR=4.330 IC 1.854-10.111), and lack of knowledge of COVID-19 vaccination locations (aOR= 10,87, IC 3.785-31.246) were the main factors associated with vaccine hesitancy in an adjusted model. The study found a high and persistent prevalence of COVID-19 vaccine hesitancy among Congolese healthcare workers. Strategies to increase vaccine uptake need to include interventions that address trust in vaccine safety and public authorities.

5997

SOURCES OF INCONSISTENCIES BETWEEN DENGUE INFECTION INTENSITIES ESTIMATED FROM SEROLOGICAL AND PASSIVE CASE SURVEILLANCE STUDIES

[1]University of Cambridge, Cambridge, United Kingdom, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Ministry of Public Health, Nonthaburi, Thailand, [4]State University of New York Upstate Medical University, Syracuse, NY, United States, [5]University of California, San Francisco, San Francisco, CA, United States, [6]University of Florida, Florida, FL, United States, [7]Coalition for Epidemic Preparedness Innovations, Washington, DC, DC, United States, [8]University of Rhode Island, Kingston, RI, United States

Force of Infection (FOI) is an important metric when designing and implementing interventions. Ideally, FOI would be calculated using serologic data from highly powered prospective cohort studies, directly measuring rates at which naive individuals seroconvert to the pathogen of interest. However, because this approach is resource intensive, FOI is typically inferred from mathematical models applied to cross-sectional seroprevalence or passive surveillance case datasets. Consistency of FOI estimates from these different approaches remains poorly understood. Here, we use data from a series of cohort studies in Kamphaeng Phet, Thailand (1998-2016: total 10159 individuals, 59801 bleeds with hemagglutination inhibition antibody measurements to all four dengue serotypes) and case data from the provincial hospital (1994-2019, n=12222). Considering the cohorts as both longitudinal measures (multiple samples per individual) and cross-sectional data (single sample per individual), we estimated the annual FOI between 1998 and 2018 using standard models for each data type. We found strong incongruence between the estimates with seroincidence-derived FOI being systematically higher than estimates from case data, and seroprevalence-derived FOI being systematically lower. To uncover sources of these inconsistencies, we performed simulations to study effects of commonly violated model assumptions on the inferred FOI. We found that noise in the assay alone leads to extreme inflation of FOI inferred from seroincidence data and dampened FOI inferred from seroprevalence data. While waning of monotypic antibody titers alone does not affect seroincidence-derived FOI, it can further exacerbate the inflation of FOI in noisy assays. Non-independence between observations and non-uniform infection risk in age affects the FOI estimates from each data type differently in non-trivial ways. Finally, we developed methods to correct for these biases and describe the extent at which these corrections can be done in empirical settings to guide future inferences and interpretations of empirical data.

5998

CIRCULATING NON-DENGUE FLAVIVIRUSES IMPACT DENGUE VIRUS DIAGNOSTIC TESTING AND DISEASE RISK IN CAMBODIA

Chloe M. Hasund[1], Camila Odio[1], Christina Yek[2], Somnang Man[3], Piseth Ly[3], Sreynik Nhek[3], Sophana Chea[3], Chanthap Lon[3], Rekol Huy[4], Rithea Leang[4], Chea Huch[4], L. Fabiano Oliveira[2], Jessica E. Manning[2], Leah C. Katzelnick[1]

[1]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes, Bethesda, MD, United States, [2]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]International Center of Excellence in Research, National Institute of Allergy and Infectious Diseases, National

Institutes of Health, Phnom Penh, Cambodia, [4]National Center for Parasitology, Entomology, and Malaria Control, Ministry of Health, Phnom Penh, Cambodia

Mosquito-borne viruses are a growing global public health threat. Some areas have co-circulating flaviviruses that induce cross-reactive antibodies, which can increase risk of disease caused by dengue virus (DENV) but could also provide partial cross-protection. Cambodia is highly endemic for dengue virus (DENV), and there is serological evidence of West Nile virus (WNV) and Japanese encephalitis virus (JEV) in birds. Pre-existing immunity to JEV, WNV, and Zika virus (ZIKV) may impact DENV testing results and disease risk. Healthy children (n=771) aged 2-9 years living in Chbar Mon, Kampong Speu, Cambodia were enrolled in a prospective cohort study between July and August 2018 and followed for three years. DENV antibodies were measured bi-annually and with each febrile illness by an indirect dengue IgG ELISA (PanBio; Brisbane, QLD, Australia) and focus reduction neutralization test (FRNTs) to detect neutralizing antibodies (nAbs). The ELISA had a high false positive rate (13%) and specificity of 82%, which was lower than the 90-100% reported by others, including the manufacturer. Of 100 children ("discordants") with high DENV ELISA titer (>1.1) and low DENV nAbs (FRNT≤40), half had DENV nAbs levels below 10. After adjusting for age and sex, discordants had a higher odds of going on to experience a DENV infection compared to naïve (ELISA≤1.1 and FRNT≤40) children (OR 1.96, 95% CI 1.24-3.11). Interestingly, their infections were more likely to be inapparent (OR 3.95 [1.39-11.32]). To evaluate the high DENV ELISA false positive rate, we tested for nAbs against other flaviviruses in DENV naïves and discordants. ZIKV nAbs were present in 10% discordants vs 4% naïves (p = ns). JEV nAbs were also identified in discordants and these, along with WNV nAbs, will be compared with the naïve group. We found that immunity to other circulating flaviviruses altered the specificity of dengue testing and disease risk in Cambodian children. Investigators and clinicians in dengue endemic areas should consider co-circulating flaviviruses when testing children.

5999

FORECASTING DENGUE INCIDENCE: REVIEW OF METHODOLOGY AND COVARIATES

Yalda Jafari[1], Ahyoung Lim[2], Win Zaw[3], Tuyen H. Ngoc[4], Kate Tiley[2], Chawarat Roetejanaprasert[3], Oliver Brady[2], Richard J. Maude[1]

[1]University of Oxford, Bangkok, Thailand, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [4]Oxford University Clinical Research Unit, Ho Chi Minh city, Viet Nam

Globally, there is an increase in dengue morbidity and mortality, resulting in a significant burden on health systems. Having accurate predictions for future dengue incidence is important to inform public health response and guide interventions. This study summarizes methodologies and covariates used to forecast dengue cases over time. Embase, Global Health, Medline, and Web of Science databases were reviewed using keywords related to dengue and forecasting. Only peer-reviewed articles in English, which predicted any aspect of human dengue transmission including case counts and incidence, used any methodology and conducted out-of-sample validation such that time-series nature of data was preserved were included. No geographical or time limitations were imposed. Following de-deduplication, 5,412 records were identified. Two reviewers reviewed each title and abstract and screened full text of articles, identifying 206 studies for inclusion. A further 17 studies were identified through search of references of previous reviews related to this topic. Data was extracted on study setting, data source, spatial and temporal scale of prediction, forecasting models, variables tested and variables included in final models, and evaluation methodology. Models identified were machine learning and statistical models, followed by mathematical models. Most common covariates identified included temperature and humidity. Review of this literature will inform current and future forecasting efforts and ensures public health responses incorporate latest methodological advances appropriate for context.

6000

COMPARISON OF REPORTED PRIOR DENGUE INFECTION WITH LABORATORY-CONFIRMATION OF SEROSTATUS AMONG 9 TO 14-YEAR-OLD CHILDREN IN CEBU, PHILIPPINES

Maria Vinna Crisostomo[1], Anna Maureen Cuachin[1], Kristal An Agrupis[1], Ava Kristy Sy[2], Jedas Veronica Daag[1], Michelle Ylade[1], Laura White[3], Aravinda De Silva[3], Jacqueline Deen[1]

[1]National Institutes of Health-University of the Philippines Manila, Manila, Philippines, [2]Research Institute for Tropical Medicine, Muntinlupa City, Philippines, [3]Department of Microbiology and Immunology, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States

Dengue is an acute febrile illness that is an important public health problem in tropical Asia and Latin America. There are four dengue virus serotypes (DENV-1 to 4); infection produces durable homotypic immunity against the same serotype but waning cross-protection against the other serotypes resulting in repeat dengue infections. We aimed to assess the association between laboratory-confirmed presence of dengue antibodies with the reported history of prior dengue infection. In 2017, we enrolled 2,996 children who were 9- to 14-years of age and eligible to participate in a government dengue vaccination program in Cebu, Philippines. We collected a baseline blood sample from each participant, which was assessed for dengue antibodies by indirect ELISA and focus reduction neutralization test (FRNT). 1790/2996 children received a dose of CYD-TDV during the mass vaccination in July 2017. After an additional safety concern of CYD-TDV was announced, the dengue vaccination program in the Philippines was discontinued. We actively monitored the children in the cohort for febrile illness from November 2017 to October 2022. Data on past history of dengue illness was collected using a brief questionnaire when a child in the cohort had a febrile illness. 674/2996 (22.5%) children had at least one febrile episode detected during the five-year period. Of the 674 children, 458 (68%) received a single dose of CYD-TDV. The majority (593/674 or 88.7%) were dengue seropositive at baseline: 512/593 or 76% with a multitypic profile and 81/593 or 12% with a monotypic response. Of the 593 children who were seropositive at baseline, 520 (87.7%) did not recall previous dengue illness. In 2018, the World Health Organization has recommended a pre-vaccination screening strategy for the dengue vaccine, CYD-TDV, whereby the vaccine should only be given to those who are dengue seropositive. We found that recall of previous dengue illness is unreliable in establishing dengue serostatus in our setting.

DETECTION OF OTHER HUMAN CORONAVIRUSES (HCOVS) AND CROSS- REACTIVITY AGAINST SARS-COV-2 IN CLINICAL SAMPLES

Daniel Adjei Odumang[1], Elvis Suatey Lomotey[1], Irene Owusu Donkor[1], Jewelna Akorli[1], Ivy Asante[1], Stephen Nyarko[1], Lorreta Kwasah[1], Robert Fischer[2], Vincent Munster[2]

[1]Noguchi Memorial Institute For Medical Research, Legon-Accra, Ghana, [2]national Institute Of Allergy And Infectious Diseases, Rocky Mountain, Mt, United States

The emergence of SARS-CoV-2 ignited a pandemic with reported 633 million cases and over 6.6 million deaths. There is evidence of disparity between reported SARS-CoV-2 infections and the actual infections in African populations. These have been attributed to many factors such as lack of accurate data on the rates of infections and death. As compared to other populations however, lower morbidity and mortality rates have been reported in Africa. Some studies have attributed it to possible immune protection conferred by viral and parasitic infections in the Ghanaian population. This study set out to determine cross-reactivity of SARS-CoV-2 in clinical samples collected before and during the COVID-19 pandemic and investigate the presence of other human coronaviruses (HCoVs) circulating within the Ghanaian population. Naso-pharyngeal swabs were collected from 999 consenting individuals aged ≥5 years for the detection of SARS-

CoV-2 and the other human coronaviruses (HKU1, OC43, NL63, 229E and SARS) infections by RT-qPCR. Preliminary results show that overall positivity for SARS-CoV-2 was 20% (200/999) and other HCoVs was 23.8% (238/999). SARS accounted for 60% (143/238) of the HCoV positives while, OC43 made up 9% (23/238) of positives. One sample (0.42%;1/238) was positive for four HCoVs and another (0.42%;1/238) was positive for all 5 HCoVs. Males were observed to be 1.47 times more likely to be positive for SARS-CoV-2 [95% CI: 0.98 – 2.20, p-value=0.06] as compared to females. Living in an urban area gives a higher risk of being positive for all HCoVs and SARS-CoV-2 [aOR: 1.67, 95% CI: 0.97 – 2.66, p-value=0.07] [aOR: 2.49, 95% CI: 1.49 – 4.14, p-value<0.001] respectively. Positive HCoV participants were approximately 4 times more positive for SARS-CoV-2 [95% CI: 2.51 - 5.68, p-value<0.001]. The co-presence of HCoV and SARS-CoV-2 may be a possible indicator of cross immune protection. This may play a role in the high numbers of asymptomatic SARS-CoV-2 infections during the peak of the pandemic in Ghana.

PREVENTION AND CONTROL OF VIRAL HEMORRHAGIC FEVER IN LEARNING INSTITUTIONS IN UGANDA

Irene Mwenyango, Patrick Ajuna, Blandinah Nakiganda
Ministry of Health, Kampala, Uganda

Uganda is located in East Africa. On the 22nd September, 2022 an outbreak of Ebola Virus Disease was confirmed in Mubende District located in the Central region of the country West of the capital city Kampala. Uganda has approximately 15 million learners concentrated in close to 50,688 education institutions with an average of about 1,000 learners or more in a learning institution. Many schools are high volume congregate settings and are mixed Day and Boarding posing an increased risk of infection transmission. To control spread interventions in learning institutions were jointly carried with the key line ministries and partners. The multi sectoral committee supported the different pillars with the National School Health Task force as a sub -pillar for the coordination of the activities including development of guiding documents. Ebola Virus Disease surveillance was built on the existing COVID-19 school-based surveillance system. Risk Communication team played a key role in the development of Information Education and Communication materials for the general public and school settings. Confirmed cases were evacuated to the Ebola Treatment Unit. Arrangements were made for continuity of learning by the school. Contact listing of the close playmates and classmates were isolated from home or a designated place with daily monitoring of symptoms for a period of 21 days. Infection prevention measures at the school together with daily fever screening. By 14 October 2022, 58 cases had been confirmed among which was a Primary school pupil from Mubende Municipal Council. By 23 October2022, a total of 28 cumulative cases of EVD were registered amongst persons aged 0-19 years, of these 19 were attending school in the three districts of Kampala, Mubende and Kassanda that had been greatly affected. Of these seven died resulting in a case fatality rate of 37%. A total of about 10 learning institutions were affected during the outbreak. The prevention and control of EVD was made possible through strict compliance to the standard operating procedure, political commitment, continuous monitoring and support supervision by the different administrative levels.

A COHORT STUDY IN GHANA REVEALS HIGH SEROPREVALENCE OF MONKEYPOX IN GHANA

Christopher Dorcoo[1], Grace Opoku Gyamfi[1], Irene Owusu Donkor[1], Millicent Opoku[1], Kofi Bonney[1], Robert Fischer[2], Vincent Munster[2]
[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Virus Ecology Section, Laboratory of Virology, Rocky Mountain Laboratories, National Institute of Allergy and Infectious Diseases, National Institutes of Health,, Rocky Mountains, MT, United States

Monkeypox virus (MPXV), an orthopox virus endemic to West and western Central Africa, is the etiological agent of Monkeypox (Mpox) disease. While the recent global outbreak has been fuelled primarily through human-to-human contact, primary transmission in endemic areas is most likely through contact with reservoir host species with secondary transmission to caregivers and close relatives. Prior to the year 2022, Ghana had not reported any human cases of Mpox, however, the 2003 Mpox outbreak in the US was initiated by rodents that were exported from Ghana. This preliminary study was done to determine the seroprevalence of Mpox after about 40 years of global eradication and discontinuation of smallpox vaccination in Ghana. Direct ELISA was conducted on a total of 1507 archived sera collected prior to 2022 from the 16 regions of Ghana and 281 samples collected from clinical patients and their contacts to detect the presence of anti-monkeypox IgG antibodies. The overall seroprevalence of the mpox virus estimated by the study was 29% (526/1788). People living in rural communities were also found to be 0.62 times [95% CI:0.47 – 0.81, p=0.001] more likely to be exposed to the virus which explains the seroprevalence of participants from the Upper East region having a 71% (12/17). Participants younger than 35 years accounted for 66% (1185/1788) of the samples tested and were considered to be unvaccinated with the smallpox vaccine. The likely odds of monkeypox exposure in participants aged >19years, between 20-29 years and 30-39 years were higher compared to other age groups (aOR 1.89: 95% CI 1.23 – 2.91, p=0.004), (aOR 2.04: 95% CI 1.30 – 3.21, p=0.002) and (aOR 1.89: 95% CI 1.19 – 3.01, p=0.007) respectively. The study results indicate a fairly high seroprevalence suggesting existing MPXV circulation, especially among unvaccinated people living in the rural part of Ghana.

6004

SHIFTS IN THE SEASONALITY OF DENGUE ASSOCIATED WITH THE TRANSITION TO ENDEMICITY

Bachir Assao Neino[1], Angkana Huang[2], Bernardo Garcia-Carreras[1], Rebecca Borchering[1], Derek A.T. Cummings[1]
[1]Department of Biology, University of Florida; Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States, [2]University of Cambridge, UK; Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States

The incidence of many pathogens in humans is affected by seasonality due to climate factors. However, the timing of peak incidence of emerging pathogens often differs from post-emergence seasonal patterns. This study examines the seasonality of dengue in Brazil over a 16-year period to determine if the timing of the dengue season has changed as immunity to dengue in the population accumulates. The hypothesis is that there is a shift in the seasonal timing of dengue due to the accumulation of immunity to dengue over time and a shift towards endemic transmission after the re-emergence of dengue in Brazil in 1986. Alternatively, the seasonality of dengue may be changing due to climatic change. The study analyzed monthly time series from 1999 to 2014 of reported cases of dengue from Brazil surveillance data and associated changes in the timing of the dengue season with climate factors such as temperature, precipitation, and humidity. The age-specific rates of immunity over time were reconstructed using infectious disease transmission models and the potential impact of accumulation of immunity on the timing of seasonal peaks was simulated. The study found that 25 of 27 provinces across Brazil experienced a delay in the timing of seasonal peaks in dengue incidence with an average

delay across all provinces of 2.5 days per year. Temperatures increased throughout Brazil, but only subtle changes in the timing of season have occurred. Mechanistic models incorporating changes in immunity show shifts in the timing of the dengue season consistent with observed data whereas increases in temperature shift the season earlier. The study concludes that the shift in dengue seasonality towards later times of year is consistent with the slow accumulation of immunity in the Brazilian population over the last thirty years. The findings may help to understand changes in seasonality for other emerging pathogens such as Zika, influenza, and SARS-CoV-2.

FACTORS ASSOCIATED WITH CHIKUNGUNYA INFECTION AMONG PREGNANT WOMEN IN GRENADA, WEST INDIES

Melanie Kiener[1], Nikita Cudjoe[2], Roberta Evans[2], Veronica Mapp-Alexander[2], Amna Tariq[1], Calum MacPherson[2], Trevor Noel[2], Patrick Gérardin[3], Randall Waechter[2], A. Desiree LaBeaud[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Windward Islands Research and Education Foundation WINDREF at St. George's University, True Blue, Grenada, [3]INSERM CIC1410/Plateforme de Recherche Clinique et Translationnelle, Centre Hospitalier Universitaire, Saint-Pierre, Réunion

Neonates are vulnerable to vector-borne diseases given the potential for mother-to-child congenital transmission of arboviruses and associated complications of neonatal infection. To determine factors associated with chikungunya virus (CHIKV) infection among pregnant women in Grenada, West Indies, a retrospective cohort study enrolled women who were pregnant during the 2014 CHIKV epidemic. 520/688 women (75.5%) were positive for CHIKV IgG. Low incomes, use of pit latrines, lack of home window screens, and subjective reporting of frequent mosquito bites were associated with an increased risk of CHIKV infection in bivariate analyses. In the multivariate modified Poisson regression model, low income (aRR 1.05 [95%CI 1.01-1.10]) and frequent mosquito bites (aRR 1.05 [95%CI 1.01-1.10]) were linked to increased risk of infection. In Grenada, markers of low socio-economic status are associated with CHIKV infection among pregnant women. Given that Grenada will continue to face vector-borne outbreaks in the future, interventions dedicated to improving the housing and living conditions of the most disadvantaged will help to reduce the incidence of a range of arboviral infections and positively impact the health of the population.

FILOVIRUS VIRUS GLYCOPROTEIN - EPITOPE MAPPING, PSEUDOTYPING, AND INFECTIVITY TARGETING

Edgar Davidson[1], Nathan A. Krump[1], J. Tabb Sullivan[1], Sonya M. Jacobsen[1], Parul Ganjoo[1], Allison Sheetz[1], M. Javad Aman[2], Philipp A. Ilinykh[3], Alexander Bukreyev[3], James E. Crowe Jr[4], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Integrated BioTherapeutics, Inc., Rockville, Maryland; d University of Texas Medical Branch, Galveston, Texas., Rockville, MD, United States, [3]University of Texas Medical Branch, Galveston, TX, United States, [4]Vanderbilt University, Nashville, TN, United States

Recent disease outbreaks highlight the need to characterize the immune response to filoviruses to develop vaccines and therapies. We have used extensive GP mutation libraries to map the epitopes for >200 monoclonal antibodies (MAbs) targeting the EBOV surface glycoprotein, GP. We have extended these studies to Marburg virus (MARV) by generating an Ala-scan library of MARV Δmucin GP (Uganda strain). Initial maps of anti-MARV MAbs include those of two non-neutralizing MAbs MR228 and MR235, targeting the wing region of MARV GP, that showed therapeutic protection in animal models (MR228) or that increased binding (MR235) by neutralizing MAbs. The variety of EBOV MAbs mapped, many from survivors of ebolavirus infection, include cross-neutralizing MAbs targeting the GP membrane-proximal external region (MPER); a broadly cross-reactive MAb that blocks GP interaction with its endosomal receptor Niemann-Pick C1; and MAbs who synergistically transform a non-neutralizing MAb into a potent neutralizer. The epitope maps have expanded our understanding of how the immune system recognizes EBOV GP, and allow correlation of epitopes with MAb neutralizing capabilities, to develop anti-EBOV therapeutics and vaccines. Mapping also identified mutations that increase the exposure of neutralizing epitopes, impacting future anti-ebolavirus vaccine strategies. To provide critical reagents for analyses of antibody or serum immune responses to ebolaviruses, we have developed a pseudotyped lentiviral reporter virus (RVP) system for EBOV and MARV, expressing the appropriate viral GP. These replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2) and reproducible virus neutralization assays with luminescent or fluorescent readout. Using our knowledge of EBOV GP we have also retargeted pseudotyped lentivirus to multiple cell surface receptors using antibodies inserted into GP1. In mixed primary cell populations, pseudotyped engineered GPs containing B- or T-cell-specific antibodies showed specificity for the targeted cell lineages. Such targeted EBOV GPs enable transduction of specific PBMC cell types.

TRANSMISSION DYNAMICS OF DENGUE VIRUS IN LARGE AND SMALL POPULATION CENTERS IN NORTHERN ECUADOR USING A PHYLOGENETIC ANALYSIS

Sully Marquez[1], Gwenyth Lee[2], Bernardo Gutierrez[1], Shannon Bennett[3], Joseph Eisenberg[2], Josefina Coloma[4], Gabriel Trueba[1]

[1]Universidad San Francisco de Quito, Quito, Ecuador, [2]University of Michigan, Michigan, MI, United States, [3]Institute for Biodiversity Science and Sustainability, San Francisco, United States Minor Outlying Islands, [4]University of California, San Francisco, United States Minor Outlying Islands

Although dengue is considered an "urban" disease, rural communities are also at high risk. To further our understanding of dengue virus (DENV) transmission in settings with characteristics generally considered rural (e.g., lower population density and remote), we conducted a phylogenetic analysis in 6 communities in the northwestern province of Ecuador that have distinct landscape, ecological and social variables that we identify as contributors to transmission risk. During household-based active fever surveillance, we collected 488 serum samples with suspected dengue from participants between 2019 and 2021. One hundred and twenty one had detectable DENV RNA by PCR. Twenty seven samples with CT under 30 were selected for whole genome sequencing (MinION nanopore technology) and phylogenetic analysis that included available DENV sequences from Ecuador and South America. Our data confirmed that DENV-1 circulated from May 2019 to March 2020 and DENV-2 from December 2020 to July 2021. Combining locality and isolation dates, we found strong evidence that DENV entered Ecuador into the northern province of Esmeraldas from neighboring country Colombia, and that viral isolates were related to Colombian and Venezuelan DENV. Phylogenetic patterns suggest that within this province communities with larger populations and commercial centers were more often the source of DENV but that smaller remote communities also play an important role in the regional transmission dynamics acting as sources or sinks of DENV.

6008

DETECTING AND MONITORING THE RE-EMERGENCE OF DENGUE VIRUSES IN PUERTO RICO WITH GENOMIC SURVEILLANCE

Gilberto A. Santiago[1], Glenda L. Gonzalez-Morales[1], Keyla N. Charriez[1], Betzabel Flores[1], Laura E. Adams[1], Joanelis Medina[2], Grayson Brown[2], Jessica I. Falcon[3], Melissa Marzan[3], Vanessa Rivera-Amill[4], Gabriela Paz-Bailey[1], Jorge L. Munoz-Jordan[1]

[1]CDC, San Juan, PR, United States, [2]Puerto Rico Vector Control Unit, San Juan, PR, United States, [3]Puerto Rico Department of Health, San Juan, PR, United States, [4]Ponce Research Institute, Ponce, PR, United States

The Americas experienced the highest numbers of dengue cases in 2019 and 2022. The four dengue virus serotypes have recently been reported throughout the Americas, and the emergence of the DENV-2 Cosmopolitan genotype and recent emergence of DENV-3 underscore the importance

of maintaining genomic surveillance. After a period of absence, DENV-1 re-emerged in Puerto Rico in 2019, followed by DENV-2 and DENV-3 in 2022 and we have continued to detect transmission in the island. To characterize the genomic diversity circulating in Puerto Rico, we conducted next-generation sequencing (NGS) of representative samples (N>350) collected through entomological and human surveillance between 2019 and 2023 across Puerto Rico. Complete genomes were obtained directly from clinical samples and mosquito collections using a PCR-targeted NGS method developed by the CDC Dengue Branch. Phylogenetic diversity and the evolutionary dynamics of the circulating DENV-1, -2, and -3 were inferred using maximum likelihood and Bayesian methods. Phylogenetic trees were reconstructed with the addition of genomes from viruses of contemporary circulation in the region for context. Our analyses determined that the emergent DENV-1 variant is phylogenetically related to viruses circulating in the Caribbean but distinct from the lineages previously on the island. Wide-spread transmission of this new variant was confirmed in humans and mosquitoes. Similarly, the emergent DENV-2 is closely related to variants recently detected in Brazil and the emergent DENV-3 is closely related to a variant of Asian origin that caused a recent epidemic in Cuba. We also infer that the three serotypes circulated in the island before detection by laboratory surveillance, suggesting cryptic transmission. Despite detection of new variant introductions, new genotypes have not yet been detected in the island. Our genomic surveillance findings revealed that the re-emergence of dengue viruses in Puerto Rico was caused by the introduction of variants new to the island. We continue to monitor the evolution and spread of these variants to understand the impact to dengue epidemiology in the island.

6009

LOCATION AND TIME ARE DRIVERS OF VIRAL DIVERGENCE DURING ACUTE PHASE ZIKA VIRUS INFECTION

Mariah Hassert[1], Christopher M. Weiss[2], Reyes A. Murrieta[3], Elizabeth Geerling[1], E. Taylor Stone[1], Stephen Scroggins[1], Alexandra Dickson[1], Gregory D. Ebel[3], Lark L. Coffey[2], Amelia K. Pinto[1], **James D. Brien**[1]

[1]Saint Louis University, Saint Louis, MO, United States, [2]University of California Davis, Davis, CA, United States, [3]Colorado State University, Fort Collins, CO, United States

The high error rate of the RNA-dependent RNA polymerase drives variation in the genome of RNA viruses as they replicate, generating a swarm of viral variants closely related to the original inoculum. A viral swarm is shaped by host and environmental factors which can modify the diversity of the population, and ultimately shape evolution. In the current study we evaluate the impact of T cells, as well as physical barriers, sites of replication and time on the population genetics of Zika virus during acute infection using a mouse model. We ultimately found that time and location of viral replication within the mammalian host are critical factors driving viral swarm divergence, with minimal detected effects of CD4+ and CD8+ T cells over eight days. Using different inoculation routes, we demonstrate that entry of the virus within the CNS acts as a bottleneck, restricting viral variants upon entry. However, once entry into the CNS, novel single nucleotide variant replication was driven by viral replication within the CNS (as opposed to peripheral tissues). Ultimately, this study highlights time and location of replication as important factors in driving divergence of viral populations from the original parent sequence.

6010

NEAR-COMPLETE GENOME SEQUENCES OF DENGUE VIRUS 3 ISOLATES ASSOCIATED WITH OUTBREAKS FROM DIFFERENT REGIONS OF KENYA IN 2011 AND 2019

Victor O. Ofula[1], Arnold W. Wasike[2], Solomon Langat[1], Edith Koskei[1], Hellen Koka[1], Samuel Owaka[1], Samson Konongoi[1], Samoel Khamadi[1], Edith Limbaso[1], James Nokes[2], Charles Nyaigoti[2], Frank Onyambu[3], Rosemary Sang[4]

[1]Kenya Medical Research Institute, Nairobi, Kenya, [2]Kenya Medical Research Institute-Wellcome Trust, Kilifi, Kenya, [3]Meru University of Science and Technology, Meru, Kenya, [4]International Centre for Insect Physiology and Ecology, Nairobi, Kenya

Dengue viruses (DENVs) are mosquito-borne viruses which can cause disease ranging from mild fever to severe dengue infection. These viruses are endemic in several tropical and subtropical regions. It is the most prevalent arbovirus in terms of human public health importance globally. Since 2011, Kenya has experienced increased number of outbreaks in mainly the north eastern and coastal regions. Despite the increased number of outbreaks, there is limited information on the genomic epidemiology of DENV in Kenya. In this study, we performed whole genome sequencing (WGS) on Dengue serotype 3 that was isolated from patients in Mandera and Mombasa counties of Kenya, to understand the genetic diversity of Dengue serotype 3 across time in the country and compare with other contemporaneous sequences across the globe. Twenty nine outbreak samples were received at the Arbovirus/VHF laboratory in KEMRI between 2011 and 2019 Ribonucleic acid (RNA) was extracted using QIAmp RNA kit (Qiagen, AG, Hombrech-tikon, Switzerland). Eighteen samples that tested positive and had cycle-threshold (Ct) values below 30 were selected for WGS. The RNA was reverse transcribed using Lunascript were then sequenced by next-generation sequencing using GridION Genome Sequencer (ONT, UK). We obtained 13 near complete genomes (78-97%). Genotyping showed that the Dengue 3 isolates sequenced fall within genotype III. The phylogenetic analysis indicates a variation in the clustering pattern of 2011 and 2019 outbreak isolates. This suggests the outbreak experienced in 2019 was as a result of a new introduction. The 2019 sequences clustered with an isolate from China, while the 2011 sequences clustered in a unique clade, which also shares a common ancestor with other African strains. The findings in the study reveals the existence of two different strains of Dengue 3 genotype III in Kenya. One of this was associated with the outbreak in 2011 and the other caused dengue outbreak in 2019. There is need to sequence more samples to help understand dengue virus trends in the country and in the region at large.

6011

DEVELOPMENT AND CHARACTERIZATION OF BARCODED POWASSAN VIRUS TO ANALYZE BOTTLENECK EVENTS DURING TICK TRANSMISSION

Samantha J. Courtney

Colorado State University, Fort Collins, CO, United States

Powassan virus (POWV) is an emerging tick-borne virus that can cause severe neurologic disease including encephalitis and meningitis. POWV is classified into genetically defined lineages: Powassan virus (POWV, lineage I) and deer tick virus (DTV, lineage II). DTV poses a significant threat to human health because it is transmitted by black-legged ticks (Ixodes scapularis), which display human-biting behavior in highly trafficked wooded areas of the northeastern and north central US. The evolutionary forces exerted on POWV during transmission and pathogenesis are poorly understood. To assess virus population structure during tick transmission, we developed a barcoded virus to quantitatively measure population bottlenecks in cell culture, arthropods, and vertebrates. Barcoded viruses are engineered to contain synonymous nucleotide substitutions that facilitate efficient and cost-effective measurements of the stochastic reductions in virus populations that occur during virus transmission by arthropods. Barcoded POWV (bcPOWV) was created by changing the third nucleotide of 11 consecutive codons in the NS2a coding sequence, resulting in 411 (~4.2

million) possible unique barcodes. DNA containing the synthesized barcode region was inserted into a DTV infectious clone and virus was successfully rescued and propagated in baby hamster kidney (BHK-21) cells to high titers (105 PFU/mL). To confirm the barcode sequence in bcPOWV, we sequenced the barcoded region and observed 11 degenerate nucleotides in sequence chromatograms as expected. In addition, we are performing deep sequencing to quantify barcode diversity. Using bcPOWV, we will assess POWV population dynamics during transstadial and vertical tick transmission, where we will perform deep sequencing to quantify the extent of bottlenecks during the tick life cycle. We expect to see very few changes in genetic diversity from larval to nymphal life stages and major reductions in diversity from adult females to their eggs. Overall, barcoded viruses are a powerful genetic tool, which we will use to assess POWV population dynamics during various transmission modalities.

6012

GENOMIC SURVEILLANCE OF SARS-COV-2 VARIANTS DURING DIFFERENT WAVES OF COVID-19 IN MALI

Antoine Dara[1], Sekou Sissoko[1], Amadou Daou[1], Amadi Diawara[2], Abdoul Karim Sangare[2], Djibril Kassogue[3], Charles Dara[3], Demba Koita[4], Ibrehima Guindo[4], Bourema Kouriba[2], Abdoulaye A. Djimde[1]

[1]University of Science, Techniques and Technologies of Bamako, Bamako, Mali, [2]Centre Charles d'Infectiologie Charles Mérieux, Bamako, Mali, [3]Hôpital de Tombouctou, Tombouctou, Mali, [4]Institut National de Santé Publique, Bamako, Mali

Genomic epidemiology of SARS-CoV-2 has been important in the control of COVID-19 pandemic. SARS-CoV-2 genome sequencing has made it possible to detect new variants and inform the COVID-19 control strategies. However, in Mali there are very few genomic data available on SARS-CoV-2. Therefore, we sought to generate more genomic data to contribute the monitoring of SARS-CoV-2 variants circulating in Mali during different waves of the pandemic. A retro-prospective study was conducted on samples collected between March 2020 and September 2022 in Mali representing samples from the first four waves. RNA was extracted using the Qiagen kit. Libraries were prepared using either an Illumina or Nanopore kit and subsequently sequenced on an Illumina MiSeq and MinION respectively at the MRTC. Sequence data was analyzed on a local server. We successfully sequenced 89 viral genomes. In addition, we downloaded 21 Malian sequences from the GISAID repository. We detected ten (10) variants: A, A.1, A.21, A.27, B, B.1, B.1.525 (Eta), B.39, Delta, Omicron (BA.2, BA.5). The most recent increase of cases corresponded to the occurrence of BA.5 Omicron sublineage. Except the A.21 variant, which might have emerged locally, the other variants detected were all cases introduced into Mali. Our results highlight the importance of sequencing SARS-CoV-2 locally and provide information on variants circulating during the first waves of the COVID-19 pandemic. We are monitoring the evolution of variants and updated data will be presented.

6013

SPATIOTEMPORAL DYNAMICS OF CIRCULATING DENV-1 IN LA VIRGINIA, RISARALDA BETWEEN 2019 AND 2021

Diana Marcela Rojas Gallardo[1], Jaime Andres Cardona-Ospina[1], Jorge E Osorio[2], Autum Key[3], Andrei Bombin[3], Diego Lopez Muñoz[4], Beatriz Giraldo Ospina[1], Jesse Waggoner[3], Matthew H Collins[3], Anne Piantadosi[3]

[1]Institución Universitaria Visión de las Américas, Pereira, Colombia, [2]University of Wisconsin, Madison, WI, United States, [3]Emory University, Atlanta, GA, United States, [4]Unidad Central del Valle del Cauca, Tuluá, Colombia

Dengue virus (DENV) in Colombia has an endemo-epidemic transmission pattern characterized by circulation of multiple serotypes and lineages with a heterogeneous spatiotemporal distribution. It is not clear how inter-epidemic transmission is sustained, and the triggers for epidemic seasons in the country. This work aims to understand how a recent dengue serotype 1 outbreak is related to transmission dynamics between near and distant endemic regions of Colombia. We performed sequencing and assembly of complete genomes of dengue virus circulating in La Virginia, Risaralda (2019-2021) and Santiago de Cali, Valle del Cauca (2021). Genomes were aligned with sequences from other cities that were available in GenBank. We performed a Maximum-likelihood and Bayesian phylogenetic analyses and identified the best-fit molecular clock and population growth model. Subsequently, we reconstructed the spatial dispersal of the virus using a discrete diffusion phylogeographic model with Markov chains.The lineage of DENV1 that circulated in La Virginia between 2019-2021 is related to the lineages that circulated in the department of Antioquia and share ancestry with viruses introduced in the 1990's from Venezuela. By contrast, the lineage detected in Cali in 2021 is more closely related to a lineage that circulated in the department of Santander in 2008. The reconstructed dispersal routes show that distinct DENV1 lineages from two nearby locations experiencing recent DENV1 transmission (La Virginia and Cali) likely derive from different sources. We hypothesize that introduction and re-introduction of new lineages can be related with sustained transmission and epidemics in our setting. Our results provide insights about the heterogenous dispersal of DENV1 in Colombia, and its potential impact on transmission dynamics.

6014

INTRODUCTION OF A NEW CLADE OF ECSA GENOTYPE DURING THE LARGEST OUTBREAK OF CHIKUNGUNYA VIRUS IN PARAGUAY

Alejandra Rojas[1], Fátima Cardozo[1], Adriana Valenzuela[1], Cynthia Bernal[1], María Eugenia Galeano[1], Roque Morel[1], **Jesse J. Waggoner**[2], Magaly Martínez[1]

[1]Universidad Nacional de Asunción, Instituto de Investigaciones en Ciencias de la Salud, San Lorenzo, Paraguay, [2]Emory University, Atlanta, GA, United States

Chikungunya virus (CHIKV) is an arthropod-borne virus (arbovirus) of epidemic concern. CHIKV was introduced to Paraguay in 2015 and caused minor outbreaks in some regions of the country. However, in late 2022 a major outbreak started. Between October 2022 and mid-March 2023, more than 27.700 cases were reported, also cases of meningoencephalitis and deaths caused by CHIKV infection were registered. In this study, we sequenced 30 serum samples collected in Asunción and Central Department in January, 2023. Nanopore technology was used to generate CHIKV near-complete genomes (average coverage nt: 94,06% - CDS: 98,87%). Consensus sequences were assigned as East/Central/South African (ECSA) lineage by Genome Detective tool. Maximum Likelihood phylogeny showed that the current Paraguayan strains grouped separately from the Paraguayan ECSA strains detected in 2018, but within the same clade of Rio de Janeiro ECSA strains from 2019, indicating the introduction of a new clade to Paraguay. Interestingly, CHIKV detected in Paraguay in 2023 formed a monophyletic cluster with a larger branch within the clade. All Paraguayan strains presented new amino acid substitutions: Q368L and S405P at the N-terminal domain of nsp2; A366V at the hyper variable domain of nsp3; L129 and Q175K at RdRp domain of nsp4. Even though E2:V264A was detected at low frequency in sequences from Brazil in 2019, this substitution was present in all the sequences analyzed in this study. Altogether, this data suggest that this ECSA clade of CHIKV this clade may have circulated undetected since 2019 (or the data is not publicly available at the moment). Further studies are needed to address whether the mutations observed in non-structural proteins may have functional consequences for CHIKV replication and/or infectivity, evasion from the immune system or pathogenesis. This study reinforces that continued genomic surveillance strategies are needed to support the monitoring of CHIKV epidemics in order to better understand changes in the incidence, severity of the disease and to shed light onto the highest outbreak caused by CHIKV in Paraguay.

PURIFYING SELECTION DECREASES THE POTENTIAL FOR BANGUI ORTHOBUNYAVIRUS OUTBREAKS IN HUMANS

Gregory S. Orf[1], Lester J. Perez[1], Todd V. Meyer[1], Ka-Cheung Luk[1], Kenn Forberg[1], Mary A. Rodgers[1], Abbas Hadji[1], Linda James[2], Samuel Mampunza[2], Asmeeta Achari[3], Guixia Yu[3], Scot Federman[3], Charles Y. Chiu[3], Carole A. McArthur[4], Gavin A. Cloherty[1], Michael G. Berg[1]

[1]Abbott Diagnostics, Abbott Park, IL, United States, [2]Université Protestante au Congo, Kinshasa, Congo, Democratic Republic of the, [3]UCSF, San Francisco, CA, United States, [4]UMKC, Kansas City, MO, United States

Pathogens carried by insects, such as Bunyaviruses, are frequently transmitted into human populations and cause disease. Knowing which spillover events represent a public health threat remains a challenge. Metagenomic next-generation sequencing (mNGS) can support infectious disease diagnostics by enabling detection of any pathogen from clinical specimens. mNGS was performed on blood samples to identify potential viral co-infections in HIV+ individuals from Kinshasa, Democratic Republic of Congo (DRC) participating in an HIV diversity cohort study. Time-resolved phylogenetics and molecular assay development assisted in viral characterization. The nearly complete genome of a novel orthobunyavirus related to Nyangole virus, a virus previously identified in neighboring Uganda, was assembled from an HBV+ patient. A quantitative PCR assay was designed and used to screen over 2,500 plasma samples from Cameroon, DRC, and Uganda, failing to identify any additional cases. Recent sequencing of a US CDC Arbovirus Reference collection revealed that this same virus, now named Bangui virus, was first isolated in 1970 from an individual in the Central African Republic. Time-scaled phylogenetic analyses of Bangui with the related Anopheles and Tanga serogroup complexes indicate that this virus emerged nearly 10,000 years ago. Pervasive and episodic models further suggest this virus is under purifying selection and that only distant common ancestors were subject to positive selection events. This study represents only the second identification of a Bangui virus infection in over 50 years. The presumed rarity of Bangui virus infections in humans can be explained by its constraint to an avian host and insect vector, precluding efficient transmission into the human population. Our results demonstrate that molecular phylogenetic analyses can provide insights into the threat posed by novel or re-emergent viruses identified by mNGS.

6016

PROFILING OF DENGUE SEROTYPE -2 SPECIFIC MICRORNA EXPRESSION IN THE SERUM SAMPLES OF DENGUE PATIENTS IN SABAH, MALAYSIA

Nadia Iryani Najri[1], Vijay Kumar Subbiah[2], Noor Haydayati Mohd Yusuff[3], **Mohammad Zahirul Hoque**[4]

[1]Faculty Of Medicine & Health Sciences, University malaysia Sabah, Malaysia, Kota kibnabalu, Malaysia, [2]Biotechnology Research Institute, University malaysia Sabah, Malaysia, Kota kibnabalu, Malaysia, [3]Biotechnology Research Institute , Universiti Malaysia Sabah, Malaysia, Kota kibnabalu, Malaysia, [4]Faculty Of Medicine & Health Sciences, Universiti Malaysia Sabah, Malaysia, Kota kibnabalu, Malaysia

Dengue is an Aedes mosquito-transmitted human arboviral disease which remains endemic in Asia Pacific countries including Malaysia The Dengue virus is a single-stranded, positive-sense RNA virus with four antigenically distinct serotypes namely DENV-1, DENV-2, DENV-3 and DENV-4. MicroRNAs (miRNAs) are a class of small non-coding RNA molecules. There has been substantial prior report which showed the association of MicroRNA (miRNAs) in many viral infections. However, data on circulating microRNA expression patterns in dengue patients are scanty. This study aims to identify the circulating DENV serotype-specific microRNAs in patient's serum. Here we investigate the microRNA expression profiles in the serum samples of DENV-2 serotype patients from Sabah, Malaysia. We have subjected to high-throughput small RNA (sRNA) sequencing. Total RNA was isolated and small RNA sequencing was performed using Illumina MiSeq high-throughput next generation sequencing collected clinical samples from a total of 30 patients with DENV-2 serotype infection and 30 apparently healthy individuals as controls. The serum RNAs was isolated from these subjects and platform to identify deferentially expressed miRNAs. After quality control of the sequence reads, we identified 19 miRNAs that were expressed in DENV-2 serotypes. Of these, 13 were upregulated (hsa-miR-122-5p, hsa-miR-92a-3p, hsa-miR-451a, hsa-let7b-5p, hsa-miR-619-5p, hsa-miR-652-3p, hsa-miR-16-5p, hsa-miR-191-5p, hsa-miR-22-3p, hsa-miR-26a-5p, hsa-miR-320a-3p, hsa-miR-423-3p and has-miR-486-5p) and 6 were down regulated (hsa-miR-197-3p, hsa-miR-27a-3p, hsa-miR-449a, hsa-miR-342-3p, hsa-miR-574-3p and hsa-miR-204-5p). Our preliminary findings seem to suggested significant alterations in the miRNA levels in patients with dengue infection. In conclusion, the differential expression of DENV-2 serotype specific miRNA may provide a better understanding the disease and can be used as a potential biomarker candidate for monitoring dengue viral infection.

6017

METAGENOMICS ANALYSES REVEALS PRESENCE OF THE MERIDA-LIKE VIRUS IN GEORGIA (COUNTRY)

Jennifer M. Potter Birriel[1], Adam R. Pollio[1], Brian D. Knott[2], Matthew A. Conte[1], Drew D. Reinbold-Wasson[2], Jun Hang[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]U.S. Army Medical Research Directorate - Georgia (USAMRD-G), Tbilisi, Georgia

Emerging arbovirus infections can rapidly expand and adapt in new geographic and environmental conditions. For this reason, mosquito surveillance serves as a tool to detect, monitor, and prevent pathogens which present a potential threat of human infection. In this study, we evaluated the presence and abundance of viral pathogens in mosquitoes of the Culex pipiens specie. Supporting this effort, a total of 467 mosquitoes, were collected from the country of Georgia between 2018 and 2019. We used an unbiased total RNA-seq approach and conducted a Heat Map analysis to explore the mosquito virome. The viral reads from this analysis were mostly aligned to insect-specific viruses from two main families, the Iflaviridae; a positive-stranded RNA virus and the Rhabdoviridae; a single-stranded, negative RNA virus. It was intriguing to find in our heat map analysis viral reads aligning to the Merida-like virus Turkey (MERDLVT) strain. The Merida like-virus is a single-stranded RNA that's known to have high levels of amino acid identity. A Blast sequence analysis of our positive samples aligned to the MERDLVT strain showed an 96-100% sequence identity and an 99.7-100% of sequence coverage. We proceeded to use a phylogenetic tree to further evaluate the evolutionary relationship among these positive pooled specimens with the (MERDLVT) strain and other Merida-like virus strains. As expected, the Merida like- virus found in Georgia mosquitoes clustered with two strains from Turkey; the Merida-like virus KE-2017a isolate 139-1-21 and the Merida-like virus Turkey isolate P431. Collectively, these results imply presence of the MERDLVT strain in Georgia.

6018

CO-INFECTION OF DENGUE AND CHIKUNGUNYA IN BENGALURU CITY, SOUTHERN INDIA - A MOLECULAR SURVEILLANCE APPROACH

Mansi Malik[1], Deepanraj SP[1], Thrilok Chandra KV[2], Madhusudan SN[2], Balasundar A P[2], Rakesh Mishra[1], Farah Ishtiaq[1], **Shruthi Uppoor**[2]

[1]Tata Institute for Genetics and Society, Bengaluru, India, [2]Bruhath Bengaluru Mahanagara Palike, Bengaluru, India

Dengue virus (DENV) and Chikungunya virus (CHIKV) are RNA viruses belonging to families Flaviviridae and Togaviridae transmitted by Aedes sp. Mosquitoes. Globally, the monoinfections and coinfections result in fatalities in the tropical and subtropical regions. Detection of DENV and CHIKV primarily relies on Enzyme Linked immunosorbent assay (ELISA) and rapid antigen tests, which are nonconfirmatory detection methods. Our molecular surveillance study across Bangalore, with local municipal

corporation, aims to understand the prevalence of infections from DENV, CHIKV and coinfections with both arboviruses in ELISA tested patient samples. We screened 892 serum samples from July 2022 to November 2022 collected across the Urban Primary Health Centres, Referral hospitals and Maternity homes. Samples were initially screened for DENV and CHIKV using ELISA. Subsequently, RNA extractions were conducted followed by TaqMan Probe based RTPCRs for serotype-specific detection of DENV and CHIKV. We found 304/892 (34.08%) samples tested positive for DENV and 167/ 892 (18.72%) for CHIKV whereas 77/892 (8.63%) showed presence of coinfection with DENV and CHIKV. Among DENV infections, DENV-serotype-2 showed 56% of infections followed by DENV-serotype 1 showed 46% and DENV-serotype -3 showed 23% of infections. We found 3% of samples infected with multiple serotypes. Total prevalence from DENV and CHIKV exhibited a significant decreasing trend from July to November (Wald's $\chi 2$= 239.66, df =4; P &lt 0.001). This trend was also reflected in infection from DENV (Wald's $\chi 2$= 171.2, df =2; P &lt 0.001) and CHIKV (Wald's $\chi 2$=175.33, df=4 P &lt 0.001) across months. There was no significant variation in viral prevalence by gender. Comparatively, the total prevalence of DENV and CHIKV using ELISA and RTPCRs based detections was found to be 28.14% and 64.70% respectively. Our study represents real-time disease detection using two methods which helps in strengthening the existing the public health surveillance system and contributes towards developing cost-effective protocols in low-resource settings.

6019

SEROLOGICAL EVIDENCE OF PRIOR EXPOSURE TO EMERGING PATHOGENS IN RURAL LIBERIA, WEST AFRICA

Emmanuel Kerkula

The University of North Carolina Project-Liberia, Gbanga, Liberia

West Africa is a source of emerging pathogens, largely zoonotic, that can cause intra- and extra-regional outbreaks. The extent to which emerging pathogens are transmitted to and by humans undetected is unclear. We assessed serological status to several emerging viruses using serum collected at baseline from a purposefully sampled (age and gender distribution) cohort of individuals >2 years of age living in rural Liberia participating in the observational Coalition for Epidemic Preparedness Innovations (CEPI) ENABLE Study. Samples were analyzed in duplicate using the AFRICOM bead panel for detection of IgG on a Luminex MAGPIX. Viruses included were Ebola Virus (EBOV), Crimean-Congo Hemorrhagic Fever Virus (CCHFV), Lassa Virus (LASV), Marburg Virus (MARV), Rift Valley Fever Virus (RVFV), and Panflavivirus (Panflavi) and Panalphavirus (Panalpha) panels. Median ratios of signal to noise (S:N) and the proportion above selected thresholds were calculated for each virus. Two S:N thresholds were considered including an empirically selected S:N of 10 and a threshold of 40, which in a separate West African cohort was associated with viral neutralization. Serum from 461 participants (age: median = 18; range 2-97. 54% female) were analyzed. The median S:N for individual viruses ranged from 3.6 for MARV to 55.9 for LASV. The proportion of participants exhibiting S:N >10 ranged from 16.7% for MARV to 72.2% for LASV; using a threshold of S:N ratio >40 the proportion ranged from 3.9% for MARV to 55.5% for LASV. Approximately a third of participants exhibited seropositivity for Panflavi or Panalpha antibodies at the >40 S:N threshold. Correlation of seropositivity across the pathogens was observed but while significant, was moderate. Overall, serological evidence of prior infection with emerging pathogens was not uncommon among residents of rural Liberia and, although Lassa fever is endemic, the rate of LASV seropositivity was greater than expected. The detection of seropositivity to the other emerging pathogens tested suggest unrecognized spillover events and the need for enhanced diagnostic capacity to identify these infections in real time.

6020

MAYARO VIRUS EXPOSURE IN FREE-RANGING BATS OF ANIMAL-HUMAN INTERFACE AREAS, MIDWEST BRAZIL

Ingrid Oliveira Garrido[1], Helver Gonçalves Dias[1], Débora Familiar-Macedo[1], Alex Pauvolid-Corrêa[2], **Flavia Barreto Dos Santos**[1]

[1]FIOCRUZ, Rio de Janeiro, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Brazil

Arboviruses as Dengue (DENV), Zika (ZIKV) and Chikungunya (CHIKV) are maintained in epidemic cycles of transmission among humans and Aedes aegypti mosquitoes in Brazil, and are of great importance to public health. Other arboviruses such as Yellow Fever (YFV), Mayaro (MAYV) and Oropouche (OROV), that are maintained in enzootic cycles of transmission involving wild vertebrate and diptera species, have also great medical importance in the country. The circulation of these arboviruses in wild vertebrate species at the human-animal interface in Brazil remains poorly investigated. Bats are among the synanthropic vertebrates found in large populations in these areas and their exposure to these arboviruses is still obscure. Here, we aimed to search for the circulation of the main epidemic and enzootic arboviruses in Brazil in specimens of bats collected in forested areas of the metropolitan regions of the Midwest region of Brazil between 2017 and 2018. RT-qPCR assays were used for the investigation of active DENV, ZIKV, CHIKV, YFV, MAYV and OROV infections in liver, kidney and brain tissues of euthanized bats (n=168). Carollia perspicillata, Artibeus lituratus and Artibeus planirostris were the most common species collected. Previous exposure to MAYV and OROV was also evaluated by the investigation of specific neutralizing antibodies by plaque reduction neutralization test (PRNT) in 79 bats from several species. No active infections were identified and none of the bats showed neutralizing antibodies for OROV. On the other hand, 2.6% (2/76) of the bats were seropositive for MAYV, one Noctilio albiventris (PRNT50 titer 40) and one Molossus rufus (PRNT50 titer 80). The role of bats in arbovirus cycles of transmission remains unclear worldwide, and the exposure of bats to MAYV in Midwest Brazil merits further investigation.

6021

EVIDENCE OF CORONAVIRUS TRANSMISSION AMONG PTEROPUS MEDIUS IN BANGLADESH, 2019-2021

Mohammad Enayet Hossain[1], Rashedul Hasan[1], Md. Mahmudul Hasan[1], Ausraful Islam[1], Spencer Sterling[2], Clifton McKee[3], Eric D. Laing[2], Md. Jahidul Kabir[4], Peter Hudson[5], Raina Plowright[6], Emily S. Gurley[3], Mohammed Ziaur Rahman[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]Johns Hopkins University, Baltimore, MD, United States, [4]Bangladesh Forest Department, Dhaka, Bangladesh, [5]The Pennsylvania State University, Pennsylvania, PA, United States, [6]Cornell University, New York, NY, United States

Pteropus bat species are the known reservoirs for henipaviruses; humans are infected with the Nipah virus by P. medius in Bangladesh through the consumption of contaminated date palm sap. The ecological drivers and transmission dynamics of these viruses within the reservoir hosts remain poorly understood. The objective of this study was to investigate coronavirus transmission among P. medius in Bangladesh, which could pose a risk for spillover. Serum samples from 3,023 P. medius in eight colonies across seven districts in Bangladesh were collected between 2019 and 2021 and screened by multiplex immunoassay (MIA) for antibodies reactive to the viral spike glycoprotein (S) from the Severe acute respiratory syndrome coronavirus (SARS-1), Severe acute respiratory syndrome coronavirus-2 (SARS-2), Middle East respiratory syndrome coronavirus (MERS), Bat SARS-like coronavirus isolate Rs4874 (Rs4874), Bat coronavirus isolate PREDICT/PDF-2180 (PDF2180), and Rousettus bat coronavirus HKU9 (HKU9). In addition, pooled oral and fecal swabs from 307 of these bats were screened for coronaviruses using conventional PCR. Two percent (62/3023) of bats tested had coronavirus IgG antibodies from four of the seven districts. Adult seroprevalence (3%, 51/1943) exceeded juvenile (1%, 10/1021) and pup (2%, 1/60). Among the 62 IgG

positive samples, 60 samples (97%) indicated reactivity to Bat-CoV Rs4874 suggesting prior exposure to Bat-CoV Rs4874 or an antigenically similar virus. Bat seroprevalence was highest (4%, 39/876) from Cox,s Bazar, in southeastern Bangladesh. The PCR results revealed that 1% (3/307) of the samples were positive for betacoronavirus, (nobecovirus), which were closely related to bat coronavirus previously identified in the South East Asian region and Bangladesh. These three bats were negative in the serology test for all coronaviruses. The seroreactivity and PCR results (active infection) indicate continuous exposure of the bats to different coronaviruses. The finding of this study added information to support the role of bats as natural reservoirs of coronaviruses.

6022

DETECTED ARBOVIRUSES IN EASTERN MEDITERRANEAN REGION AND SOUTH EAST ASIAN REGION MOSQUITO POPULATIONS: A SYSTEMATIC REVIEW

Syed Ali Raza Nasir

Aga Khan University Hospital, Karachi, Pakistan

The circulation of arboviruses in mosquitoes implicates many arboviruses as causes of undifferentiated fever that remain undiagnosed due to lack of available testing methods and short viremia in humans. We aim to determine what arboviruses have been discovered circulating in mosquito species in Eastearn Mediterranean Region and South East Asian Region. We used the PubMed database to identify 3100 related articles on surveillance of mosquitoes for arboviruses. Following data, among other datapoints, from included studies was extracted: country of surveillance, duration of collection, number of mosquitoes collected, number of different mosquito species identified, detection technique used, viruses screened for and viruses detected. 34 included studies were done in EMR and SEAR, including 3 from Pakistan. Culex are the most prevalent mosquito species. Dengue, West Nile, Japanese Encephalitis and Rift Valley Fever viruses have been detected; dengue and West Nile in Pakistan. The most common method of detection is pooled PCR of mosquitoes using virus-specific primers. Several viruses not currently implicated in human infection such as Tembusu virus, Bagaza virus, Barkedji virus, cell-fusing agent virus, Phlebotomus-associated flavivirus and Culex-specific flaviviruses have also been detected.

6023

FACTORS RESPONSIBLE FOR POST-DISCHARGE DEATH IN COVID PATIENTS

Prasan Kumar Panda, Arjun Kumar, Basavaraj Jatteppanvar

AIIMS, Rishikesh, India

The post-discharge all-cause mortality of COVID-19 disease is known, but predictors for the same are not much studied. The current research was a single-center unmatched case-control study conducted at a tertiary care center in northern India, between April and September 2022. The data were extracted retrospectively from the hospital's electronic medical records of patients with the assistance of trained physicians using a standardized data extraction sheet. A total of 184 patients were enrolled and were segregated into two groups cases and control with 92 in each. The mean age of patients was 49.3 ±17.53 years. The mortality group had a higher mean age (53.24 ± 18.53 yrs) as compared to the control group (45.37 ± 15.58 yrs, p - 0.002). Bivariate analysis revealed a significant difference in the two groups with respect to O2 saturation at the time of admission (Case - 91.12 ± 12.49 %, control - 95.46 ± 5.01 %, p - 0.003); Maximum O2 flow rate [L/min] (Case - 11.01 ± 22.2, Control - 6.41 ± 13.31, P - 0.04); ICU need (p - 0.005), Cancer (p - 0.001), O2 requirement at discharge (p - 0.001) and AKI (p - 0.007). On multiple regression analysis, Cancer (aOR- 2.469; 95% CI,1.183- 5.150, p-0.016), ICU admission (aOR- 2.446; 95% CI, 1.212-4.938, p- 0.013), Oxygen at discharge (aOR- 2.340; 95% CI, 0.971-5.640, p-0.0586) and Acute kidney injury (aOR- 5.6; 95% CI, 2.351-13.370, p-0.00) only found to be significant. Among the patients discharged from the hospital post-COVID-19 treatment, the following aspects oxygen requirement (2.3 times), Malignancy (2.4 times), ICU admission (2.4 times), and Acute Kidney Injury (5.6 times) are risk factors of mortality. The presence of these variables would warrant a close follow-up for these patients in order to decrease post-COVID mortality.

6024

ROLE OF TELEHEALTH AND COMMUNITY MOBILIZATION IN MANAGING COVID -19 WITHIN THE CONTEXT OF A DISTRICT HEALTH SYSTEM IN MALAWI

Titus H. Divala[1], Melody Sakala[2], Marlen Chawani[2], Edith Milanzi[2], **Evance Dazimon Mwale**[1]

[1]Kamuzu University of Health Sciences, Blantyre, Malawi, [2]Malawi Liverpool Welcome Trust, Blantyre, Malawi

The COVID-19 pandemic has impacted health systems globally. High demand for health services and staff absenteeism due to illness are some of the barriers that negatively affected healthcare delivery. To reduce pressure on healthcare services, academics from Blantyre implemented the "Strengthening COVID-19 Response in Blantyre District" (SCORE) project, which established a remote case management system (phone clinic) and community mobilization workforce in fighting COVID-19. A cross-sectional study was done to evaluate the pilot implementation of the project. Qualitative and quantitative methods were used to collect data from community leaders (n=27), volunteers (n=49), and members (n=201) from communities served by the project: Chileka, Limbe, Mpemba and Ndirande. Data was also collected from District Health Management Team (DHMT) (n=5) and Health Surveillance Assistants (HSAs) (n=6). Focus Group Discussions, in-depth interviews and structured questionnaires were used to collect data. Quantitative data was analyzed descriptively using SPSS 26. Qualitative data was transcribed and analysis was done using Nvivo 12. Phone calls data showed 58% of inquiries were for COVID-19 followed by general healthcare (25%). Of COVID-19 enquiries, 41% were for general information, 29% for preventive measures, and 14% for signs and symptoms. 99% of participants said the SCORE project helped spread COVID-19 preventive measures, 92% raised awareness of risk factors, and 90% encouraged vaccination. Qualitative data showed volunteers had a good working relationship with community leaders, HSAs, and members. Both interventions were recommended by communities and District Health Office staff for scale up and extension to other health conditions like HIV and Cholera. The project showed its potential to enhance remote case management, information sharing and community mobilization efforts related to COVID-19. In conclusion, the project has shown that effective remote case management and community mobilization can reduce pressure on healthcare systems and improve health outcomes, providing a model for future health crisis response efforts.

6025

DISTRIBUTION AND OUTCOMES OF ANIMAL BITES IN THE MBALE REGION OF EASTERN UGANDA

Isabirye Herbert Kiirya[1], Benjamin Fuller[2], Kakoza Francis[3], Nanyondo Judith[3], Mohamed Larmode[3], Allan Komakech[4], Irene Kyamwine[4], Doreen Gonahasa[4], Henry Bosa Kyobe[5], Kesande Maureen[3], Edward Juma Nyogesa[6], Anet Nabumbo[7], Ssekitoleko Richard[8], Christopher C Moore[2]

[1]Mbale Regional Public Health Emergency operations center, Mbale City, Uganda, [2]University of Virginia, Charlottesville, VA, United States, [3]Infectious Diseases Institute, Kampala City, Uganda, [4]Uganda National Insitute of Public Health, Kampala City, Uganda, [5]Ministry of Health, Kampala City, Uganda, [6]Mbale City, Mbale City, Uganda, [7]Namisindwa district, Namisindwa, Uganda, [8]World Health Organization Uganda Office, Kampala City, Uganda

Animal bites can lead to rabies, tetanus, and skin/soft tissue infection, and are a significant cause of global morbidity and mortality. Although an average of 16,414 animal bites are reported each year in Uganda, there is a paucity of data on animal bites in the country. In this cross-sectional study, we aimed to determine the distribution and outcomes of animal bites in the Mbale region of eastern Uganda. We collected data on demographic characteristics of those with animal bites in the Uganda District Health

Information Software 2 database maintained by the Uganda Ministry of Health. We included data that were reported from January-December 2022 from outpatient departments in the 16 districts of the Mbale region. We determined frequencies and proportions of each variable and used the QGIS to present the analyzed data. Animal bites were documented in 984 of 4,656,700 patient visits to health centers in the Mbale region. During the same period, a total of 15,261 rabies exposures were reported in the country with 833 (5%) reported from the Mbale region. Of those bitten by animals in the Mbale region, 540 (55%) were male and the median (interquartile range) age was 17.5 (7.5-25.5) years. The frequency of animal bites ranged from 10 to 20 per week. Bukwo, Tororo, and Busia districts had the highest prevalence rates of animal bites in the Mbale region with 1.74, 1.68, and 0.81 bites per 1000 population, respectively. Of those bitten, there were 7 deaths (case fatality ratio 0.71%), all of which were attributed to rabies. Animal bites and rabies exposure are common in the Mbale region. Our findings emphasize the need for the availability and administration of routine and post-exposure vaccination to prevent rabies and tetanus following animal bites in the high prevalence at-risk Mbale region of eastern Uganda.

MOSQUITO IDENTIFICATION: NANOPORE SEQUENCING OUT OF A SUITCASE LAB AS AN EARLY WARNING SYSTEM FOR EMERGING INFECTIOUS DISEASES

Arianna Ceruti[1], Antonios Michaelakis[2], Marina Bisia[2], Uwe Truyen[1], Georgios Balatsos[2], John Palmer[3], Mohammad Shafiul Alam[4], Ahmed Abd El Wahed[1]

[1]Leipzig University, Leipzig, Germany, [2]Benaki Phytopathological Institute, Athens, Greece, [3]Universitat Pompeu Fabra, Barcelona, Spain, [4]icddr,b, Dhaka, Bangladesh

Mosquito-borne diseases are responsible for spillover to around 700 million people each year, including many neglected tropical diseases such as Dengue fever and Chikungunya virus disease. Case reports are rising over the last decades, as mosquito species flare-up as a result of climate change and globalization. Surveillance tools and early warning systems are essential to prevent disease spread to humans and animals. Next generation sequencing technologies offer great advantages for disease outbreak investigation. The aim of this study was to develop a rapid and field deployable sequencing platform to identify potential mosquito-borne pathogens, mosquito species and host in blood meals. First a rapid extraction reverse purification method was developed. Nucleic from mosquito specimens, including Culiseta longiareolata, Culex pipiens, Aedes albopictus, Ae. cretinus and Ae. aegypti were isolated using a rapid "all-in-one" extraction protocol based on lysis buffer, glass beads, magnetic beads, heating and vortexing. Nucleic acid from 30 mosquito samples were extracted using commercial purification kits as a control. Rapid barcoding 96 sequencing (Oxford Nanopore Technologies) was performed using a MinION Mk1c device. For RNA targets, a reverse transcription step was performed using random hexamers. All handling steps were carried out in the fully equipped suitcase lab. A specific offline BLAST database was created to semiautomatically identify mosquito species, host in blood meal and pathogens. In all samples, the species was correctly identified. Both animal and human DNA could be detected. Interestingly, only mosquito origin viruses could be detected in the pool. The nucleic acid extraction and detection protocol performed in the suitcase lab allows fast mosquito "footprint" analysis directly in the field. This could pave the way as an early warning tool for mosquito-borne diseases and on-site outbreak investigation. Ultimately, the point-of-need generated data can lead to more accurate and fast preventive measure implementation. We are testing the whole system in a highly endemic region in Bangladesh.

SIMIAN ARTERIVIRUSES: A ZOONOTIC THREAT?

Cody J. Warren[1], Shuiqing Yu[2], Douglas K. Peters[3], Arturo Barbachano-Guerrero[3], Qing Yang[3], Bridget L. Burris[4], Gabriella Worwa[2], I-Chueh Huang[2], Gregory K. Wilkerson[4], Tony L. Goldberg[5], Jens H. Kuhn[2], Sara L. Sawyer[3]

[1]The Ohio State University, Columbus, OH, United States, [2]Integrated Research Facility at Fort Detrick, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Frederick, MD, United States, [3]University of Colorado Boulder, Boulder, CO, United States, [4]Michale E. Keeling Center for Comparative Medicine and Research, The University of Texas MD Anderson Cancer Center, Bastrop, TX, United States, [5]University of Wisconsin-Madison, Madison, WI, United States

Simian arteriviruses are endemic in African nonhuman primates yet remain largely unstudied and uncultured in vitro. These viruses can cause Ebola-like diseases that are fatal to Asian macaques but are not yet known to infect humans. To evaluate the risk for a spillover event, we tested the ability of a simian arterivirus, simian hemorrhagic fever virus (SHFV), to enter human cells and replicate within them. First, we substantiated CD163 as the cellular receptor for SHFV entry into host cells. Next, we showed that CD163 acts as an intracellular receptor, a rare mode of virion entry that is shared with other high-consequence viral pathogens (e.g., Ebola virus and Lassa virus). Alarmingly, we found that the human version of CD163 is a fully functional receptor for SHFV entry into cells. Further, SHFV can replicate robustly in human cells, showing full functionality of the orthologs of all host proteins required for the SHFV lifecycle. Our study raises concern about future possible spillovers of simian arteriviruses to humans and the potential public-health risk that such spillover events would pose. Indeed, it is possible that people in Africa are already being infected with simian arteriviruses but that these cases remain undetected in the way HIV-1 infections did for decades. For elucidation, development of serology tests for human surveillance should be a priority.

CASE AND WASTEWATER SURVEILLANCE TO MONITOR COVID-19 AND OTHER INFECTIOUS DISEASES IN ATLANTA K-12 SCHOOLS

Yuke Wang[1], Stephen Hilton[1], Pengbo Liu[1], Marlene Wolfe[1], Orlando Sablon[1], Lizheng Guo[1], Lutfe-E-Noor Rahman[1], Weiding Fan[1], Sarah Durry[1], Shazneen Damani[1], Lauren Briggman[1], Valencia Hildreth[2], Juliana Prieto[2], Megan Diamond[3], Christine Moe[1]

[1]Emory Univeristy, Atlanta, GA, United States, [2]Atlanta Public Schools, Atlanta, GA, United States, [3]The Rockefeller Foundation, New York, NY, United States

For schools, timely responses to outbreaks of infectious diseases rely on information from disease surveillance systems. Epidemiological case surveillance information for schools can be extracted from public health databases at county/city level or collected from schools that use a self-reporting system. Wastewater surveillance has been recognized as a valuable tool to complement case surveillance. Wastewater samples are typically collected at wastewater treatment plants, but can also be collected at manholes adjacent to schools. This study compares information from wastewater surveillance at the city and school level to reported case data at the county and school level for 14 K-12 schools in Atlanta, GA. COVID-19 epidemic curves for Fulton County, the City of Atlanta, and specific school zones were generated using geocoded case information reported to the Georgia Department of Public Health. Self-reported case information was obtained for K-12 schools within Atlanta Public School district. Wastewater surveillance data from wastewater treatment facilities in Atlanta was also obtained. From 09-07-2021 to 03-14-2023, we collected and analyzed 489 Moore swab samples from manholes that only received wastewater from the study schools. All samples were tested for SARS-CoV-2 RNA, and after 11-29-2022, 88 samples were also tested for Influenza A and RSV, and 74 were tested for Influenza B by qPCR. 41% (201/489) of samples tested positive for SARS-CoV-2. Temporal and school variation were observed with high schools having the greatest proportion of wastewater samples

positive for SARS-CoV-2 and the lowest reported COVID-19 incidence. Very few samples were positive for Influenza A (5.7%), RSV (2.3%), and Influenza B (0%). We found increasing discordance between results from different case and wastewater surveillance systems which may reflect greater underreporting of cases, changing SARS-CoV-2 fecal shedding patterns, and decreasing sensitivity of assays for emerging variants. The results from this study provide insights for how K-12 schools can use information from different surveillance systems to guide public health measures.

6029

DETECTION OF HUMAN CORONAVIRUSES AMONG PATIENTS WITH RESPIRATORY TRACT INFECTIONS IN GHANA

Emmanuella Awedana Apuri[1], Ivy IAA Asante[2], Mildred MAP Adusei-Poku[3]

[1]Ghana Infectious Disease Center, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [3]University of Ghana, Accra, Ghana

Acute Respiratory infections are caused by various microorganisms particularly viruses including influenza, human metapneumovirus, adenoviruses and coronaviruses; human coronaviruses (HCoVs). HCoVs account for up to 18.4% of ARIs burden globally and between 3.5-12.4% in Ghana. During the COVID-19 pandemic, individuals presented with febrile-like-illnesses exhibiting respiratory symptoms yet, tested negative for SARS-CoV-2 and influenza viruses. HCoVs and influenza viruses are known to exhibit symptoms similar to SARS-CoV-2 hence there is the plausibility that during the pandemic, the symptomatic but negative SARS-CoV-2 and influenza samples could have tested positive for these other HCoVs. To investigate the presence of other human coronaviruses from archived negative SARS-CoV-2 and Influenza samples. The study will adopt a retrospective cross-sectional study which will involve archived samples collected from influenza sentinel surveillance sites in Ghana. RNA will be extracted from samples and and amplified by RT-qPCR to detect the other human coronaviruses (OC43, NL63, HKU1 and 229E) and sequenced using MinIon sequencing to detect variations in the strains. Conclusions, this investigation will contribute to an understanding of the causes of ARI in Ghana and aid health authorities enact policies to improve quality health care delivery and patient management.

USE OF LIGHTWEIGHT GPS DATA LOGGERS TO TRACK HORSESHOE BAT MOVEMENT PATTERNS IN EASTERN UGANDA

Natalie Wickenkamp[1], Kalani Williams[1], Kevin Castle[2], Michael J. Mutebi[3], Lillian Nalukenge[3], Robert M. Kityo[3], Betty Nalikka[3], Benard Matovu[3], Aggrey Siya[3], Teddie Nakayiki[4], Emma Harris[1], Tanya Dewey[1], Rebekah C. Kading[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Wildlife Veterinary Consulting, LLC, Livermore, CO, United States, [3]Makerere University, Kampala, Uganda, [4]Uganda Virus Research Institute, Entebbe, Uganda

Bats are reservoirs for pathogens with zoonotic potential; therefore, it is crucial to investigate aspects of bat ecology that may facilitate spillover events. Bats in the genus Rhinolophus, commonly called horseshoe bats, are known to harbor SARS-like coronaviruses. Geospatial investigations of horseshoe bat ecology are often hindered by the small size of these insectivorous bats. To evaluate seasonal movement and foraging patterns of horseshoe bats in Eastern Uganda, we fitted 36 bats with ultra-lightweight (<1.1g) GPS data loggers in January and May of 2022 as part of a larger viral surveillance program targeting bat caves in the region. We demonstrate the successful deployment and recapture (9/36) of data loggers collecting high-resolution short-term foraging data from cave roosting Rhinolophus spp. in Eastern Uganda, and share recommendations on their future use in other bat-related applications.

6031

IGG HYPORESPONSIVENESS AFTER DENGUE VIRUS INFECTION IN KENYAN CHILDREN

David M. Vu[1], Bryson A. Ndenga[2], Francis M. Mutuku[3], Bethel Bayrau[1], Jael S. Amugongo[4], Christabel Winter[2], Charles Ronga[2], Philip Chebii[4], Zainab Jembe[5], A. Desiree LaBeaud[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [3]Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya, [4]Vector-Borne Diseases Unit, Ministry of Health, Msambweni, Kwale, Kenya, [5]Vector-Borne Diseases Unit, Ministry of Health, Ukunda, Kenya

An important serologic hallmark for dengue virus (DENV) infection is the development of DENV specific IgG. Previously, we observed IgG hyporesponsiveness after DENV infection in a cohort of febrile Kenyan children who had DENV viremia, documented by RT-PCR, who failed to seroconvert from negative to positive serum anti-DENV IgG after one month (median interval 31 days between febrile and follow up visits, interquartile range 28-36 days). We hypothesized that the serum IgG response to DENV infection may be transitory or delayed. To investigate our hypothesis, we designed a study to measure anti-DENV IgG in cases of DENV infected children at 6 different timepoints over the course of a year: at the febrile visit, 14 days, 30 days, 3 months, 6 months, and 12 months. We enrolled 1046 subjects and identified 12 cases of acute DENV infection (by RT-PCR), along with temporally and geographically matched controls without DENV infection. One case developed anti-DENV by 3 months post-infection. Another case did not develop anti-DENV until 3 to 6 months later. The remaining DENV cases and non-infected controls did not develop anti-DENV IgG at any time point throughout the 1 year follow up period. Ongoing characterization of the peripheral memory B cell population by mass cytometry may yield insights into the mechanisms that govern DENV IgG hyporesponsiveness. These examples of delayed development of anti-DENV IgG or complete anergy after infection imply that previous cross-sectional serologic surveys based on anti-DENV IgG prevalence may have grossly underestimated DENV exposure in our population. IgG hyporesponsiveness to DENV infection also may underlie the low incidence of severe dengue disease previously observed in our population. Finally, IgG hyporesponsiveness to DENV must factor into the design of future vaccine studies and/or immunization campaigns.

6032

CHIKUNGUNYA VIRUS SPECIFIC T CELLS PREDOMINANTLY RECOGNIZE VIRAL STRUCTURAL PROTEINS

James Chang[1], Fernanda H. Cortes[1], Calvin Ha[1], Rimjhim Agarwal[1], E Alexandar Escarrega[1], Rosa Isela Gálvez[1], Claudia M. Romero-Vivas[2], Andrew Falconar[2], Alessandro Sette[1], **Daniela Weiskopf**[1]

[1]La Jolla Institute for Immunology, La Jolla, CA, United States, [2]Fundación Universidad del Norte, Barranquilla, Colombia

Chikungunya disease (CHIK) is a mosquito-borne re-emerging viral disease, that is defined by its capability to induce incapacitating chronic arthralgia and inflammation in patients' months to years following infection. Despite CHIKV outbreaks occurring worldwide and several vaccines currently in development, CHIKV immune response remains largely understudied. Chikungunya virus (CHIKV) the causative agent for CHIK, is an alphavirus, coded in five structural proteins (CP, E3, E2, 6K, E1) and four non-structural proteins (nsP1, nsP2, nsP3, nsP4).We have tested pools of overlapping peptides spanning each of these viral protein in peripheral blood mononuclear cells (PBMCs) collected from patients diagnosed with CHIKV during the 2014-2015 outbreak in Colombia. The majority of these patients still experienced diseases symptoms 7 years after infection, representing a chronic infection with CHIKV. To characterize the CHIKV specific T cell response we performed high resolution flow cytometry analysis utilizing the Activation Induced Marker (AIM) and Intracellular Cytokine Staining (ICS) assays, to evaluate CHIKV-specific T cell responses directly ex vivo,

without the need for intensive manipulation.Interestingly, we detected CHIKV specific CD4+ T cell responses in the majority of patients 7 years after CHIKV infection. Memory CD8+ T cell responses were also observed but at much lower frequencies. Overall, two thirds of antigen-specific CD4+ T cell responses were directed against structural protein while one third was directed against non-structural proteins. In conclusion, this study comprehensively characterizes the T cell response against CHIKV during the chronic phase and provides insights in the possible role of T cells in CHIK disease.

INVESTIGATING THE IMMUNE PROFILES ELICITED BY CLINICALLY APPARENT AND CLINICALLY INAPPARENT DENGUE VIRUS INFECTIONS

Lauren Bahr[1], Darunee Buddhari[2], Surachai Kaewhiran[3], Direk Khampaen[3], Sopon Iamsirithaworn[3], Stefan Fernandez[2], Aaron Farmer[2], Alan Rothman[4], Stephen Thomas[1], Timothy Endy[1], Adam Waickman[1], Kathryn Anderson[1]

[1]State University of New York Upstate Medical University, Syracuse, NY, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Ministry of Public Health, Tiwanond, Nonthaburi, Thailand, [4]University of Rhode Island, Providence, RI, United States

Dengue virus (DENV) is a flavivirus transmitted by Aedes mosquitoes that can cause symptoms ranging from febrile illness to hemorrhagic fever. There are an estimated 400 million cases of dengue every year, with the majority being clinically inapparent. While much is known about the immunological differences between mild and severe dengue infection, the immunological correlates of clinically inapparent and clinically apparent infections are currently unclear. To fill this knowledge gap, our team initiated a prospective, hybrid cohort-cluster study designed to characterize DENV transmission in multigenerational households in Kamphaeng Phet, Thailand. Enrollment requirements for this study include a household containing a pregnant female, an adult 50 years or older, and a child, with the newborn being enrolled in the study at birth. Annual blood draws from all study participants are obtained starting upon enrollment, supplemented with blood draws taken from each of the family member upon confirmation of a dengue illness in the household through active surveillance. Currently in its eighth year, this study design allows for the investigation of pre- and post-infection DENV-specific immunity, and the detection of inapparent DENV infections. Using virologic and serologic assays we have identified 148 acute infections through active surveillance. Of these, 43 out of 65 primary infections and 16 out of 83 secondary infections were inapparent. Preliminary data has shown a lower titer of IgG and IgM in inapparent samples from both primary and secondary infections when compared to total antibody titers of the same samples, suggesting that there may be more IgA present in the serum from clinically inapparent cases. Using a multiplex serology assay we are assessing the contribution of IgA to the antibody profile following apparent and inapparent DENV infections, as we propose that IgA may be a biomarker associated with less severe DENV infections. These findings would have implications for the identification of correlates of protection from dengue illness, urgently needed for the design and evaluation of DENV vaccines and potential therapeutics.

6034

MALARIA-EXPOSED UGANDANS EXHIBIT A DIFFERENTIAL SARS-COV-2-SPECIFIC T CELL RESPONSE

Kattria van der Ploeg[1], Karen B. Jacobson[1], John Rek[2], Felistas Nankya[2], Jessica Briggs[3], Saki Takahashi[3], Adam S. Kirosingh[4], Diego A M Mori[1], Kenneth Musinguzi[2], Isabel Rodriguez-Barraquer[3], Bryan Greenhouse[3], Upinder Singh[1], Moses R. Kamya[5], Prasanna Jagannathan[1]

[1]Stanford University School of Medicine, Palo Alto, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]University of California San Francisco, San Francisco, CA, United States, [4]Stanford University, Palo Alto, CA, United States, [5]Makerere University College of Health Sciences, Kampala, Uganda

While SARS-CoV-2 and its interaction with the immune response has been well-studied in resource-rich areas, there are still many unanswered questions about how it affects malaria-endemic areas in sub-Saharan Africa. Compared to other global regions, during the pandemic, hospitalization and death rates have been reported to be much lower in these areas. One possible explanation could be differential immune responses due to different infectious exposures such as malaria. Using samples collected from SARS-CoV-2 exposed Ugandan adults, and similarly aged adults from California, we investigated the SARS-CoV-2-specific T cell response by intracellular cytokine staining (ICS) and an activation-induced marker (AIM) assay. Overall, we found that COVID-19 seropositive Ugandans have a diminished SARS-CoV-2-specific T cell response compared to convalescent Californians. IFNg- and TNFα-producing T cells were predominant in the Californian cohort early on and months after initial infection. However, very low or no IFNg and TNFα production was found in the Ugandan cohort. Furthermore, Ugandans have a heightened IL-10-producing CD4+ regulatory response after polyclonal stimulation. Ongoing research will investigate whether and how other pathogenic exposures, specifically malaria, may influence the T cell response. We hypothesize that previous exposure to malaria mitigates infection with SARS-CoV-2 due to a more 'tolerized' immune response. Potential explanations for our findings include epitope cross-reactivity or down-modulation of an inflammatory response that is implicated in severe COVID-19. Identifying differences in immune responses across populations will be important for future therapeutic innovations and vaccine development.

17DD-BASED YELLOW FEVER INACTIVATED VACCINE IN ASSOCIATION WITH THE NS3 HELICASE DOMAIN INDUCES T LYMPHOCYTE RESPONSES AND SEROCONVERSION TO YELLOW FEVER VIRUS IN A MURINE MODEL

Vitor G. Floriano, Jhefferson B. Guimarães, Luiza A. Castro-Jorge, Marcio J L Siconelli, **Bendito A L da Fonseca**

School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil

Yellow fever is a disease caused by the Yellow Fever virus (YFV), an arbovirus that belongs to family Flaviviridae, genus Flavivirus. Like other flaviviruses, YFV RNA genome encodes a polyprotein that is cleaved into 7 non-structural and 3 structural proteins that harbor the majority of epitopes involved with the cellular and humoral immune responses. Yellow Fever clinical manifestations range from a mild disease to a severe disease characterized several organ impairment. However, different from other arbovirus diseases, a live-attenuated virus vaccine (17D/17DD) is available to prevent against YFV infections but, in rare cases, the immunization with this vaccine can cause serious adverse effects, such as viscerotropic or neurological diseases. Furthermore, it is not recommended for immunosuppressed individuals. An inactivated YFV vaccine was manufactured using YFV-17DD virus, either in its pure preparation [inactivated (i17DD)] or in combination with a recombinant NS3 helicase peptide (i17DD+NS3Hel). The safety and immunological responses to these inactivated vaccines were evaluated in C57BL/6 mice. Our preliminary results showed that the combination of i17DD+NS3Hel promoted TCD4+ and TCD8+ lymphocyte expansion undistinguishable from the groups that received either inactivated or attenuated YFV-17DD virus. When investigating the response profile of TCD4+ cells, it was observed that this population is more associated with a Th1 profile, which grants cellular immunity to viruses, since no IL-4 expression was detected and IL-2 and IFN-gamma levels were similar to those observed with both YFV-17DD viruses. Regarding the antibody response, 100% of the mice that received the formulation i17DD+NS3Hel seroconverted to YFV. Neutralization and survival testing are ongoing to finalize the vaccine validation. Up to this moment, it was observed that, in mice, the i17DD+NS3Hel vaccine formulation elicits an immune response compared to that observed with

both YFV-17DD vaccines and might be an alternative to vaccination against Yellow fever in individuals in whom the attenuated vaccine is not recommended.

ANTIBODY-DEPENDENT COMPLEMENT ACTIVATION AND DENV3 DISEASE SEVERITY

Amro Nasser, Priscila M Da Silva Castanha, Ernesto T A Marques
University of Pittsburgh, Pittsburgh, PA, United States

Dengue Viruses (DENV), consists of a family with four serotypes. Dengue is a mosquito-borne agent responsible for causing Dengue Fever (DF), which in a small proportion of cases can further develop into a more severe disease, dengue hemorrhagic fever (DHF), characterized by blood plasma leakage, that can lead to cardiovascular shock and organ failure. Dengue disease overall is an inflammatory-driven pathology, with complement dysfunction having been implicated as playing a role in the progression to DHF. The extent to which antibody-dependent complement activation (ADCA) participates in this process is not fully known. To investigate the ability of dengue antibodies specific to DENV3 NS1 to perform ADCA using a novel bead-based complement assay. In this assay, DENV3 NS1 is bound to fluorescent beads to incubate with patient samples, allowing for the formation of immune complexes. The beads are then incubated with a complement source, allowing for immune complexes to perform ADCA. The beads are then stained with an anti-complement factor 3 (C3) fluorophore-conjugated antibody, and flow cytometry is used to quantify the deposition of C3 fragments. This assay was utilized to quantify ADCA in serial samples from acute and convalescent cases of primary and secondary DENV3 cases, from both DF and DHF. Additionally, antibody endpoint titers were measured by ELISA to determine correlation with ADCA. When comparing the ADCA capacity in the cohort, it is determined that secondary DENV3 infections have higher complement deposition than primary DENV3 infections and that secondary infections with DHF develop the most potent antibodies to activate complement. Antibody titer was shown to have a moderate correlation with C3 deposition and ADCA, as expected. Data utilizing the complement assay supports the hypothesis that secondary DENV3 infections show greater complement deposition, particularly in secondary DENV3 DHF cases during the onset of severe symptoms. Further work will be done with this assay to further explore the potential relationship between ADCA and severe outcomes of dengue.

6037

STRUCTURE-GUIDED DENGUE VIRUS TYPE 2 SUBUNIT VACCINE DESIGN TO FOCUS ANTIBODY RESPONSE TO POTENT, NEUTRALIZING EPITOPES ON VIRAL ENVELOPE PROTEIN

Devina J. Thiono, Demetrios Samaras, Thanh T.N. Phan, Shaomin Tian, Lawrence J. Forsberg, Brian Kuhlman, Aravinda de Silva
University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

The four dengue virus (DV) serotypes are mosquito-borne flaviviruses responsible for dengue fever and dengue hemorrhagic disease. Leading vaccine candidates based on tetravalent live-attenuated DV formulations have had variable efficacy and safety due to an imbalanced response to the DV serotypes in the vaccine and dengue serostatus pre-vaccination. DV subunit vaccines based on recombinant envelope (E) proteins from the four serotypes have also performed poorly, partly because at physiological temperature the secreted wild-type E protein (WT rE) is mainly present as a monomer that does not display quaternary structure epitopes on the native E dimer recognized by potent neutralizing human antibodies (Ab). Using the molecular modeling software, Rosetta, and experimental approaches, we have previously defined a small number of mutations that stabilize DV rE dimer (SD rE) under physiological conditions of vaccination. Here, we report on studies to test if the SD rE vaccine antigen redirects the functionally-neutralizing Ab response to E dimer-dependent quaternary structure epitopes on the infectious virus. Since fusion loop (FL) Ab can cause antibody-dependent enhancement which increases disease severity upon heterologous DV infection, we also tested SD rE with mutated FL. To compare Ab properties induced by different antigens, we immunized mice with DV2 WT rE or SD rE variants. We found that SD-vaccinated mice had significantly higher DV2 IgG binding titer and more than 20-fold greater neutralizing Ab titer compared to WT-vaccinated mice. Using Ab depletion techniques to remove sub-populations of DV-specific Ab and recombinant E protein domain transplant viruses, we mapped the specificity of binding and neutralizing Ab induced by WT and SD rE. Studies are ongoing to compare levels of DV enhancing Ab by different vaccine constructs. Preliminary results indicate that neutralizing Ab from WT-vaccinated mice bind to simple epitopes on rE monomers, while those from SD-vaccinated mice are mostly dimer-specific. Our results demonstrate the promise of structure-guided design to preserve epitopes of interest on dengue subunit vaccines.

6038

MOLECULAR ANALYSIS OF THE ANTIBODY REPERTOIRE ELICITED AFTER YELLOW FEVER VACCINATION

Christina Martins[1], Carlena Navas[1], Marcele Rocha[1], Luciana Zuccherato[1], Adriana de Souza Azevedo Soares[2], Brenda de Moura Dias[2], Nathalia , dos Santos Alves[2], Sheila Maria Barbosa de Lima[2], Waleska Dias Schwarcz[2], George Georgiou[3], Jason Lavinder[3], Gregory Ippolito[3], Liza Felicori[1]
[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Fundação Oswaldo Cruz - Fiocruz, Rio de Janeiro, Brazil, [3]The University of Texas at Austin, Austin, TX, United States

Flavivirus co-circulation and outbreaks have been reported in the Americas during the last decade. Evidence indicates that pre-existing immunity to one virus can influence the disease course of a heterologous virus infection; however, little is understood about the molecular dynamics and prevalence of the cross-reactive antibodies in the repertoire of an endemic population vaccinated against yellow fever virus (YFV). Therefore, here we seek to determine the serological response among YFV, Dengue and Zika viruses following the YFV vaccination of healthy Brazilian donors. We performed YFV, DENV and ZIKV virus neutralization tests (PRNT) and indirect IgG ELISA in longitudinal samples obtained 0, 7, 14, 28 and 180 days after vaccination. Furthermore, we assessed the diversity and clonal expansion of the B-cell repertoire at seven and fourteen days after vaccination. All donors had anti-YFV antibodies that peaked between 14 and 28 days post vaccination. Results from both neutralization and ELISA tests revealed cross-reactive antibodies to ZIKV and DENV viruses before and 28 days after YFV vaccination, with NAb to DENV slightly higher (approximately 3-fold higher) than NAb to ZIKV among all individuals. The DENV and ZIKV seroprevalence in this cohort ranged from 75% and 50% (IgG ELISA) to 100% (PRNT), respectively. Analysis of the B cell clonotypes identified 600 shared clones among the individuals (75%). Most of these clonotypes were found expanded and presented greatest diversity 7 days after the vaccination. Taken together, we observed a variable degree of serological cross-reactivity across three flaviviruses, which we speculate is related to donor YFV vaccination status, endemic co-circulation of ZIKV and DENV, or both. These observations may have implications for accurate diagnostic testing, for vaccination strategy and for the study of host-virus interactions.

CONSERVED MONOCYTE RESPONSES TO ACUTE RNA VIRUS INFECTION

Kalani Ratnasiri, Jiaying Toh, Hong Zheng, Catherine Blish, Purvesh Khatri
Stanford, Palo Alto, CA, United States

The 21st century has seen five virus-driven pandemics. Despite emerging viruses constantly threatening global health, we remain largely unprepared for the next pandemic. Previous studies have shown that emergency myelopoiesis and monocyte dysregulation are associated with severe COVID-19. In this study, we aimed to identify conserved and

diverse features of antiviral immunity through single-cell proteomic and transcriptional profiling studies across acute RNA viral diseases. Our analysis revealed shifts in monocyte populations towards increased CD14+ monocytes across viral infections in humans and macaques caused by various viral species, including Lassa, Ebola, Marburg, influenza, Zika, and dengue. We integrated single-cell RNA sequencing (scRNA-seq) data from all publicly available datasets that profile non-COVID-19 viral diseases, including blood samples from 38 individuals infected with dengue, influenza, or RSV with an additional 49 samples from SARS-CoV-2-infected individuals. By using this integrated data, we found conserved shifts in monocyte phenotype that were correlated with disease severity and defined by genes that also mark myeloid-derived suppressor-like cells and bacterial sepsis-induced monocytes. This signature was observed across disease progression in Ebola-challenged rhesus macaques and could be detected across over 2000 bulk RNA-seq blood samples collected from virally-infected humans and macaques, allowing us to differentiate between infected and uninfected subjects. Our study demonstrates that integrative single-cell profiling can identify dysfunctional immune responses shared across different viral infections and yield detailed insights into the underlying monocyte-specific pathological processes that may be targeted in a broad-spectrum manner. We expect that our findings will contribute to the development of effective strategies for combating future viral pandemics.

6040

ANTIBODIES AGAINST THE SARS-COV-2 DELTA VARIANT SHOWED CROSS-REACTIVITY TO INFLUENZA VIRUSES

Mohammad Mamun Alam, Asma Salauddin, Sayra Moni, Md. Belayet Hasan Limon, Raisha Musarrat, Mohammed Ziaur Rahman, Mustafizur Rahman

icddr,b, Dhaka, Bangladesh

According to sparse information from various countries, the seasonal influenza virus circulation has drastically decreased during the COVID-19 pandemic. The S protein of SARS-CoV-2 is heavily glycosylated, much like type I fusion proteins of influenza virus hemagglutinin. These glycosylation patterns can either result in immune evasion or viral neutralization by generating cross-reactive antibodies. Here, we show the cross-reactivity of anti-SARS-CoV-2 antibodies against influenza viruses. Serum samples were collected from 311 SARS-CoV-2 infected individuals. The samples were tested for antibody titers against SARS-CoV-2 by ELISA &seasonal influenza virus strains (influenza A/H1N1, A/H3N2, B/Yamagata, &B/Victoria) using a Hemagglutination Inhibition Assay (HAI). In addition, SARS-CoV-2 antibody-positive but Influenza antibody-negative samples (n=16) were investigated to determine the SARS-CoV-2 antibody-neutralizing potential against influenza viruses by microneutralization (MN) assay. The SARS-CoV-2 genomes were sequenced using Illumina next-generation sequencing, &an in-silico protein structural analysis was performed to identify epitope &antibody binding similarities between SARS-CoV-2 &influenza viruses. Among 16 samples that didn't contain antibodies against Influenza A strains (H1N1 &H3N2), five showed high (MN titer≥20), &six showed moderate (MN titer≥10) capability to neutralize Influenza A. Subsequent in-silico analysis revealed that most efficient binding (>8 Kcal/mole) was found between the antibodies of SARS-CoV-2 delta variant (ΔG) with influenza A/H1N1 HA (Hemagglutinin), A/H3N2 HA, A/H1N1 NA (Neuraminidase), &A/H3N2 NA glycoproteins with -12.4, -9.3, -10.1, &-11.7 Kcal/mole, respectively. This investigation revealed that neutralizing antibodies of the delta variant cross-reacted with the Influenza A virus, which might protect against influenza viruses &reduce &shift the seasonal influenza circulation during the COVID-19 pandemic. Our findings warrant further study to explain the probable mechanisms of this cross-reactivity.

ROLE OF THE PLACENTA SPECIFIC CHROMOSOME 19 MICRORNA CLUSTER DURING ZIKA INFECTION

Sandra Laurence Lopez-Verges[1], Yamileth Chin[2], Hélène Martin[2], Patrice Vitali[3], Marie-Line Bortolin-Cavaillé[4], Jérôme Cavaillé[5], Cécile E. Malnou[2]

[1]Gorgas Memorial Institute for Health Studies, Panama, Panama, [2]Institut Toulousain des Maladies Infectieuses et Inflammatoires Infinity, Université de Toulouse, Toulouse, France, [3]Laboratoire de biologie moléculaire eucorayote LBME, CNRS Université de Toulouse, Toulouse, France, [4]Laboratoire de Biologie Moléculaire Eucaryote CBI, Université de Toulouse, Toulouse, France, [5]Laboratoire de Biologie Moléculaire Eucaryote, CBI, Université de Toulouse, Toulouse, France

The largest primate and placenta specific C19MC microRNA cluster has been implicated in the development and function of the placenta, and having an antiviral activity for specific viruses. The 2015 outbreak of the emergent flavivirus Zika in the Americas was associated with microcephalia and other congenital malformations. The risk of having congenital Zika was higher at the beginning of pregnancy, whereas the expression of C19MC miRNA cluster increases during pregnancy and is the highest at term. Thus, we hypothesized that, through its antiviral activity, C19MC miRNA could be implicated in the placenta protection of the foetus during pregnancy. The antiviral role of the C19MC miRNA cluster was demonstrated using a novel Knock-Out (KO) model. We generated an in vitro model from JAR human placental choriocarcinoma cell line using the CRISPR/Cas9 system. Through real time quantitative PCR, western blotting, flow cytometry, and immunofluorescence techniques to detect viral infected cells, we showed that C19MC KO cells infected with the Zika virus are more susceptible to viral infections than their wild-type counterparts. Additionally, the TCID50 assay and flow cytometry analysis showed a significantly higher viral infectivity of the supernatants containing virions released from infected KO cells than from WT cells. This antiviral effect of WT supernatants can be transferred to recipient cells (Vero cell line) by means of extracellular vesicles, suggesting a paracrine antiviral method of action. In conclusion, our study provides a novel KO-model to assess the complex role of C19MC miRNA cluster during viral congenital infections, and whether it can act, in part, via extracellular vesicles. Clear understanding of this cluster's antiviral role is key to the development of new and more reliable prognostic and therapeutic tools for viruses with a potential congenital effect.

6042

USE OF A STABILIZED CONFORMATIONAL DENGUE VIRUS SEROTYPE 2 ENVELOPE ANTIGEN TO ISOLATE MEMORY-DERIVED NEUTRALIZING MONOCLONAL ANTIBODIES FROM A CONVALESCENT PATIENT.

Sean A. Diehl[1], Benjamin D. McElvany[1], Nancy R. Graham[1], Devina J. Thiono[2], Ryan D. Bhowmik[2], Alena J. Markmann[2], Aravinda M. DeSilva[2]

[1]University of Vermont, Burlington, VT, United States, [2]University of North Carolina, Chapel Hill, NC, United States

Dengue is a mosquito-borne disease caused by four serotypes of dengue virus (DENV), each of which can elicit serotype-specific or cross-reactive antibodies that target the envelope (E) structural glycoprotein. Understanding how DENV-specific B cell responses drive antibody-mediated protection is important to vaccine design. To directly study this, we used a recently developed recombinant E protein stablized dimer (recED) derived from DENV serotype 2 to probe DENV-specific memory B cells from a patient recovered from dengue. Complementary approaches including direct sorting of recED-binding memory B cells followed by antibody gene sequencing or culture and characterization of secreted antibody from recED-sorted cells yielded 25 novel lineages of DENV-reactive monoclonal antibodies (mAbs), at least three of which exhibited neutralizing activity against multiple serotypes including DENV2. Unlike other DENV cross-reactive mAbs, some of which show neutralizing activity against Zika virus, the characterized recED-binding mAbs recognized, but did not neutralize Zika virus. These results indicate that recED can be used

to tag DENV2-reactive surface immunoglobulin-positive memory B cells and isolate DENV-neutralizing antibodies from patients. These data extend in vivo studies showing that immunization of animals with recED generates DENV2-neutralizing responses. We hypothesize that this antigen can be used to define the landscape of DENV-specific B cell responses in defined vaccination and viral challenge settings.

TISSUE-SPECIFIC T-CELL RESPONSES AMONG 44 FATAL COVID-19 CASES

Trevor M. Stantliff, Andrew Platt, Sydney R. Stein, Cihan Oguz, Kevin M. Vannella, Sabrina C. Ramelli, Stephen M. Hewitt, Daniel S. Chertow

National Institutes of Health, Bethesda, MD, United States

T-cells play an essential role in recognizing and clearing viruses from infected tissues. The breadth and depth of circulating T-cell responses among patients with coronavirus disease 2019 (COVID-19) has in part been described. However, little is known about the distribution and evolution of T-cell responses within and across relevant tissues in patients with severe COVID-19. To fill this knowledge gap, we evaluated T cell clonality in lung, thoracic lymph node, and peripheral blood mononuclear cell (PBMC) samples collected from a cohort of 44 patients who died with or from COVID-19. We extracted DNA from formalin fixed paraffin embedded tissues collected at autopsy and from PBMCs collected perimortem. T-cell receptor beta sequencing was performed using the Adaptive ImmunoSeq platform. In preliminary analyses, significantly higher total unique T-cell rearrangements were observed in lymph node compared with lung tissues and PBMCs across all patients, indicative of highest T-cell diversity in lymph nodes. We observed evidence of clonal expansion (>1% of T-cell population) in 35 of 37 (95%) lung tissues, 14 of 37 (38%) lymph node tissues, and 35 of 41 (85%) PBMC samples. Additional analyses will characterize the impact of relevant metadata (e.g., demographic variables, viral load, interval from illness to death) on the breadth and depth of T-cell responses, including severe acute respiratory syndrome coronavirus-2 specific T-cell responses, within and across patients. This approach will provide unique insights into the evolution and specificity of T-cells responses among patients with severe and fatal COVID-19.

SEROPREVALENCE OF SARSCOV2 ANTIBODIES IN THE GENERAL POPULATION OF BAMAKO, MALI

Bourama Traore[1], Merepen A Guindo[1], Drissa Konaté[1], Fousseyni Kané[1], Abdouramane Traore[1], Salimata Kanté[1], Mariam Sidibé[1], Bourama Keita[1], Fatoumata Kasse[1], Karamoko Tangara[1], Issoufi Y Maiga[1], Abdoul RA Dicko Abdoul RA Dicko[2], Naman Keita[2], Diakaridia Kone[3], Yaya I Coulibaly[1], Mahamadou Diakité[1], Seydou Doumbia[1], Housseini Dolo[1], Saidou Balam[1]

[1]ICER-Mali, Bamako, Mali, [2]Hospitol district health of commune 4, Bamako, Mali, [3]District health center of commune 1, Bamako, Mali

The coronavirus disease 2019 (COVID-19) pandemic is not yet known with certainty in terms of its major epidemiologic, clinical, and serologic characteristics, including its ability to spread and its severity in the general population. This study assesses the seroprevalence of total antibodies and understand associated factors for SARS-CoV-2 infection in the general population of Bamako, the capital and epicenter of COVID-19 in Mali, with ultimate goal of drawing conclusions on the magnitude of the pandemic and contributing to the improvement of control strategies. A cross-sectional survey was done in September 2022 to collect socio-demographic and clinical data, and blood samples. Seroprevalence of SARS-CoV-2 of antibodies anti-Spike and anti-RBD were determined by ELISA. RedCap system was used for data recording and analyzed with RStudio. A total of 3601 participants were enrolled, Mean age of participants was 33.5± 15.9-year-old; the sex ratio was 3.6 for female. Age groups such as 20-29 and 30-39 years were most representative with 28.9% (n=1043) and 26.9% (n=967), respectively. Overall, COVID-19 vaccine coverage among participants was 36%, consisting of Covidshield AstraZeneca (AZ), Johnson & Johnson (J&J), Sinovac, and BioNTech Pfizer vaccines. Overall, seroprevalence of SARS-Cov-2 antibodies to S and RBD were markedly high in the general population, with 98% and 97% respectively. Factor such as male sex earlier age (1-9 year-old were associated with lower antibody responses to S and RBD, whereas having previous contact with COVID-19 patient and receiving COVID-19 vaccine increased odds for antibody responses. This study showed high seroprevalences of antibodies anti-Spike and anti-RBD in general population of Bamako and identified some factors that may influence antibody responses. Our findings lead to conclude that SARS-CoV-2 exposure in the general population is much higher than indicated by case-based surveillance, and that the magnitude of the pandemic is underestimated in Mali.

IMPACT OF DENGUE VIRUS STRAIN AND MATURATION STATE ON DETECTION OF NEUTRALIZING ANTIBODIES INDUCED BY NATURAL INFECTION AND VACCINATION

Laura J. White[1], Ruby Shah[1], Lucas Laszacs[1], Rajendra Raut[2], Elizabeth Adams[1], emily Freeman[1], cameron Adams[1], Longping V. Tse[3], Ralph Baric[1], Jedas V. Daag[4], Maria Vinna Crisostomo[4], Kristal-An Agrupis[4], Michelle Ylade[4], Jacqueline Deen[4], Leah Katzelnick[5], **Aravinda De Silva**[1]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Syngene International Limited, Bengaluru, India, [3]Department of Molecular Microbiology and Immunology, Saint Louis University, Saint Louis, MO, United States, [4]Institute of Child Health and Human Development, National Institutes of Health, University of the Philippines, Manila, Philippines, [5]Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Dengue vaccine developers have relied on standard plaque or focus reduction neutralization tests (PRNT/FRNT) to assess immunogenicity of each of the 4 dengue virus (DENV) serotype components in tetravalent vaccines. However, leading vaccines have performed poorly in baseline dengue seronegative (SN) children despite stimulating neutralizing antibodies (NAbs) to DENV1-4 detected by standard PRNT/FRNT, which uses lab-adapted reference viruses. There are structural differences between DENVs produced in humans (predominantly mature) vs. cell lines (partially mature). The partially mature state of cell-culture produced virions may lead to neutralization in the standard assay by cross-reactive (CR) fusion loop (FL), potentially disease enhancing Abs. The goals of the current study were to compare the impacts of DENV strain (lab-adapted vs. low-passage) and maturation state on levels of NAbs to each serotype detected by the FRNT. We controlled for maturation state by growing virus stocks in regular Vero cells, producing partially mature virions, and Vero cells engineered to over-express furin (DENV processing protease), producing fully mature virions. We found that DENV CR human monoclonal Abs (MAbs) targeting the FL were maturation state sensitive, neutralizing partially mature virions better than fully mature virions. In contrast, neutralization by MAbs to serotype CR quaternary dimer dependent epitopes were maturation insensitive. Human sera from individuals recently exposed to a primary DENV infection also had higher titers of CR NAbs (vs. serotypes not responsible for primary infection) to partially mature lab strains compared to fully mature recent clinical isolates. Our results demonstrate that DENV NAbs detected using mature, low-passage clinical strains more accurately reflect the serotype responsible for infection compared to the current standard practice. We propose that using mature low passage clinical strains will also lead to more accurate determinations of the immunogenicity and protective potential of each serotype component in tetravalent DENV vaccines in comparison to the current standard.

6046

MOLECULAR SURVEILLANCE OF SULFADOXINE-PYRIMETHAMINE AND AMODIAQUINE RESISTANCE MARKERS IN KARAMOJA REGION, AN AREA IMPLEMENTING SEASONAL MALARIA CHEMOPREVENTION IN NORTHEASTERN UGANDA

Richard Kajubi[1], Anthony Nuwa[1], Craig Bonnington[2], Kevin Baker[2], Musa Odongo[1], Tonny Kyagulanyi[1], Victor Asua[3], Chris Ebong[3], David S. Odong[1], Jimmy Opigo[4], Maureen Nakirunda[1], Godfrey Magumba[1], James Tibenderana[2]

[1]Malaria Consortium, Kampala, Uganda, [2]Malaria Consortium, London, United Kingdom, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]Ministry of Health, Kampala, Uganda, Kampala, Uganda

The effectiveness of seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine and amodiaquine (SPAQ) recommended for age groups at high risk of severe malaria, in areas where malaria transmission is highly seasonal, is threatened by widespread drug resistance in east and southern Africa. As part of a phased implementation study to evaluate the protective effectiveness of SMC with SPAQ in Karamoja region, we assessed the changes in the prevalence of resistance markers, over two annual rounds of SMC. Baseline and end-line health facility-based, cross-sectional surveys were conducted before and after SMC distribution for both rounds. In round one, 300 P. falciparum-infected dry blood spots were collected at each time point from symptomatic children aged 3 to 59 months from three districts while in round two, 750 samples using similar protocols were collected from five districts and analyzed for DNA purification using chelex method. Quintuple mutants (PfDHFR 59R, 51I, 108N, and PfDHPS 437G, 540E) that mediate moderate SP resistance are highly prevalent (range: 78-100%) and remained unchanged. The double mutants (PfDHFR 164L and PfDHPS 581G), the acquisition of which leads to significant pyrimethamine resistance, were rarely seen (prevalence range: <1%). This remains reassuring on the utility of pyrimethamine in SPAQ-SMC in Karamoja. The prevalence of PfCRT 76T, the principal mediator of 4-aminoquinoline (amodiaquine and chloroquine) resistance was low (~5-13%). Similarly, mutations in PfMDR1 (86Y and 1246Y) that moderate aminoquinoline resistance were low (<3%). 184F, a mutation with an unclear role in aminoquinoline resistance remains at a stable prevalence of up to 30%. While SP resistance is shown to be high, thus far SMC does not seem to impact the resistance profile across two annual rounds.

6047

MOLECULAR MARKERS ASSOCIATED WITH ANTIMALARIAL DRUG RESISTANCE AND DISTRIBUTION OF MSP1 AND MSP2 ALLELIC FAMILIES IN RURAL ENDEMIC SETTINGS, NORTHWESTERN BURKINA FASO

Moustapha Nikiema[1], Awa Gneme[1], Issiaka Soulama[2], Boubacar Coulibaly[3], Seni Nikiema[1], Ali Sie[4]

[1]Université Joseph Ki-Zerbo, Ouagadougou, Burkina Faso, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Centre de Recherche enSanté de Nouna, Nouna, Burkina Faso, [4]Centre de Recherche en Santé de Nouna, Nouna, Burkina Faso

Antimalarial drug resistance surveillance through the characterization of associated genes is crucial for malaria control in areas of high endemicity and transmission. The high diversity of Plasmodium genotypes characterizes the dynamic of malaria transmission and demonstrates the complexity of malaria vaccine development. The aim of the present study was to evaluate the effect of Plasmodium genetic polymorphism on the markers associated with antimalarial resistance in endemic settings. Blood-thick smears and dried blood samples on the paper filters were collected from populations living in Nouna and Kodougou, two localities of the Demographic and Health Surveillance System of the Nouna Health Research Centre. The blood smears were used for malaria microscopic examination. Filter papers from malaria-positive samples were used for DNA extraction by Qiagen and amplified by nested PCR for the search of genetic polymorphism alleles. The PCR-RFLP was used to characterize the molecular markers associated with antimalarial drug resistance. The Spearman's correlation test was used to compare allelic frequencies, MOI and mutant pfcrt, pfmdr, dhfr and dhps genes prevalence. Out of the 285 samples positive for Plasmodium falciparum, 279 were successfully genotyped for markers associated with antimalarial drug resistance. Significant positive correlations were found between msp1 allele frequencies, mean multiplicity of infection (mMOI), and pfcrt mutant prevalence. No significant correlations were found between msp1 and msp2 alleles, mean multiplicity of infection (MOI), and the prevalence of pfmdr, dhfr, and dhps mutants. Overall, this study showed a weak relationship between the different parasitic clones of Plasmodium falciparum and the expression of mutant pfmdr, dhfr and dhps genes. The correlation with the chloroquine resistance gene is certainly due to the adaptation of the malaria parasite to this molecule, probably linked to its long-standing use as an antimalarial.

Data on molecular markers of resistance complement clinical data from therapeutic efficacy studies (TES). This study examined the prevalence of polymorphisms in genes associated with susceptibility to antimalarials used for treatment or chemoprevention using samples collected in a TES carried out in three sites in Burkina Faso: Niangoloko, Nanoro and Gourcy. Febrile children with uncomplicated P. falciparum monoinfection were recruited, treated with artemether-lumefantrine (AL), dihydroartemisinin-piperaquine or artesunate-pyronaridine, and followed for 28 or 42 days. Blood spots were collected on filter paper at Day 0 (D0) and follow up visits. All D0 samples and Day of Failure samples were included in molecular analyses, including 638 paired samples from treatment failures and 750 D0 samples from nonfailure patients combined into 152 pools for analysis. PCRs were performed to amplify full length pfk13, pfdhps, and pfmdr1 genes. Sequences were analyzed at loci representing the major reportable single nucleotide polymorphisms for each gene. There was no evidence of any pfk13 mutations associated with artemisinin resistance in the analyzed samples. The pfmdr1 Y184F mutation associated with reduced susceptibility to lumefantrine was found in the majority (59-64%) of samples. The pfdhps A437G mutation was present in all sites at rates ranging from 88-90%. The key K540E and A581G pfdhps mutations, defining the canonical "quintuple" and "sextuple" mutants associated with sulfadoxine-pyrimethamine (SP) resistance were present at low levels (<4%). The pfdhps haplotype VAGKGS, recently documented spreading westwards across the Sahel region of North Africa, was found in 7 (6%) samples from Nanoro, 2 (2%) samples from Gourcy, and 1 (1%) sample from Niangoloko. These results are consistent with continued high efficacy of artemisinin derivatives in Burkina Faso and provide insight to the suboptimal efficacy of AL. There is no indication of high-level SP resistance in any of the three sites. Continued monitoring, including molecular surveillance, is critical for decision-making on effective treatment and chemoprevention policy.

ASSESSMENT OF PLASMODIUM FALCIPARUM CLONALITY AND DRUG RESISTANCE IN AN ARTEMETHER-LUMEFANTRINE DRUG EFFICACY TRIAL IN NORTHWEST ETHIOPIA

Daniel Castaneda-Mogollon, Deborah Ola, Jack Burke-Gaffney, Claire Kamaliddin, Ranmalee Amarasekara, Dylan R. Pillai
University of Calgary, Calgary, AB, Canada

Despite recent progress in malaria elimination, 68% of Ethiopia's population still lives in malarious areas. High-transmission areas theoretically increase the likelihood of the spread of resistant strains that may compromise the therapeutic effect of artemisinin combination therapies (ACTs). To evaluate this, a total of 162 Plasmodium falciparum isolates from 54 patients across three time points (day-0, day-3, and day-7 of treatment) were identified from an Artemether-Lumefantrine (Co-Artem) drug efficacy trial conducted in Northwest Ethiopia in 2018. The samples were analyzed to determine the complexity of infection (COI) and haplotype profiles using the genetic markers msp2, ama1-d2, and ama1-d3, the presence of kelch13 mutants, and gene copy number (GCN) of pfmdr1 and pfplasmepsin2 associated with antimalarial resistance. Infections were polyclonal at day-0 based on the msp2 (3.93±0.24), ama1-d2 (3.13±0.23), ama1-d3 (1.70±0.16) haplotype profiles. An overall decrease in the COI was observed across all the haplotype markers at subsequent trial time points. A prevalence of 21.95% (3.27 times higher than the previous surveillance in 2014) was observed for the R622I kelch13 candidate SNP rendering partial artemisinin resistance. In addition, we detected the M476I (2.94%), Y493H (2.43%), P574L (2.43%), and C580Y (33.3%) validated SNPs for partial artemisinin resistance. An elevated copy number of the pfmdr1 gene was observed at day-0 (95% C.I.=[1.07,1.33]) but not for the plasmepsin2 gene (95% C.I.=[0.93, 1.02]). When comparing day-0 and day-7, the COI ($p<0.0001$), prevalence of kelch13 mutants ($p<0.0001$) and GCN of pfmdr1 and pfplasmepsin2 ($p<0.0001$) decrease following Co-Artem treatment. Our study confirms that Co-Artem remains effective in this region of Ethiopia. However, genetic analysis reveals a high COI and multiple kelch13 mutants, which have the potential to confer greater artemisinin resistance with time.

TEMPORAL GENOMIC ANALYSIS OF PLASMODIUM FALCIPARUM REVEALS INCREASED PREVALENCE OF PFAP2MU S160N AND PFMDR1 Y184F MUTATIONS ASSOCIATED WITH REDUCED PARASITE CLEARANCE OR SUSCEPTIBILITY TO LUMEFANTRINE IN CHOMA DISTRICT, SOUTHERN PROVINCE, ZAMBIA

Abebe A. Fola[1], Kara A. Moser[2], Christopher M. Hennelly[2], Tamaki Kobayashi[3], Timothy Shields[3], Harry Hamapumbu[4], Michael Musonda[4], Ben Katowa[4], Japhet Matoba[4], Jennifer C. Stevenson[4], Douglas E. Norris[5], Philip E. Thuma[4], Amy Wesolowski[6], Edgar Simulundu[4], William J. Moss[6], Jonathan J. Juliano[7], Jeffrey A. Bailey[1]
[1]Department of Pathology and Laboratory Medicine, Warren Alpert Medical School, Brown University, Providence, RI, United States, [2]Institute for Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]Macha Research Trust, Choma District, Zambia, [5]Department of Molecular Microbiology and Immunology, The Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [6]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [7]Division of Infectious Diseases, School of Medicine, University of North Carolina, Chapel Hill, NC, United States

The emergence of anti-malarial drug resistance is a potential major impediment to achieving malaria control and elimination goals in Africa. The current intensive elimination activities, especially the use of antimalarial drugs such as artemisinin-based combination therapies (ACTs) in areas nearing pre-elimination like southern Zambia, is exerting significant selective pressure on malaria parasite populations that could facilitate the emergence of resistance strains. Analysis of temporal trends in drug resistance molecular markers can assist policy makers in choosing efficacious antimalarials and slow the emergence and spread of resistance. In a region of southern Zambia with low and seasonal transmission, we genotyped 441 Plasmodium falciparum samples collected from 2012 to 2018 from a cluster of 8 health centers using molecular inversion probes targeting 815 loci across 14 drug resistance genes. None of the isolates carried WHO-validated or candidate Kelch13 propeller mutations associated with artemisinin resistance, including recently reported mutations (R561H, A675V and C469Y) from Africa. In addition, none of the isolates carried known mutations associated with chloroquine (CQ) resistance at Pfcrt gene codons (72-76). However, 13% of isolates carried Pfap2mu S160N (a mutation associated with delayed ACT clearance in Africa), and 41% carried Pfmdr1 Y184F (a mutation associated with reduced susceptibility to lumefantrine), with increased prevalence between 2015-2018. More than 90% of sequenced samples carried N51I, C59R, and S108N (IRN triple mutants), and 81% carried A437G and K540E (GE double mutants) with less temporal variation. In conclusion, P. falciparum strains circulating in southern Zambia remain susceptible to ACTs and CQ, but the high prevalence of mutations associated with delayed ACT clearance or reduced susceptibility to lumefantrine warrants close monitoring of artemisinin and partner drug efficacy. Moreover, the high prevalence of mutations associated with SP suggests there may be a need to revise current treatment guidelines for intermittent preventive treatment of malaria in pregnancy.

6051

THE IMPACT OF SMC ON PLASMODIUM FALCIPARUM RESISTANCE TO SULFADOXINE PYRIMETHAMINE (SP) AND AMODIAQUINE (AQ) OVER A 2 YEAR PERIOD OF SMC IMPLEMENTATION IN NORTHERN MOZAMBIQUE

Sonia Maria Enosse[1], Ivan Alejandro Pulido Tarquino[1], Pedro Aide[2], Gloria Matambisso[2], Wilson Simone[2], Maria Rodrigues[1], Kevin Baker[3], Craig Bonnington[3]
[1]Malaria Consortium, Maputo city, Mozambique, [2]Manhiça Health Research Center, Manhiça, Mozambique, [3]Malaria Consortium, London, United Kingdom

Malaria is a significant public health problem in Mozambique, with high incidence rates and a high number of cases leading to many deaths, particularly in children under 5 years old. Seasonal malaria chemoprevention (SMC) is recommended by WHO to prevent malaria, with Sulfadoxina-Pirymethamine (SP) plus Amodiaquine (AQ) being the approved treatment. SMC can reduce malaria cases by 75% and has been recommended in areas with high malaria incidence in children since 2012. However, resistance to SP and AQ has been found in Mozambique, and this study aims to determine the prevalence of resistance markers to SP and AQ before and after the first annual round of SMC implementation. Between November 2020 and February 2021, a survey was conducted before (baseline) and after one complete round of SMC (end line) to measure resistance to SPAQ in symptomatic children under five years with a positive RDT in selected health facilities in intervention and control areas. Four first-level health facilities were selected in each district of the intervention and control areas. Blood samples were collected prior to SMC delivery onto filter papers. Key markers monitored included dhfr, dhps, pfcrt, and pfmdr1. 1198 blood spot samples (598 at baseline, 600 at endline) were analysed for molecular markers of resistance to SP and AQ. The pfdhps gene showed SNPs in 99% of samples with sufficient deoxyribonucleic acid (DNA) and all pfdhfr samples had mutations. More than half of samples showed SNP at codon Y184F in pfmdr1, no SNP was found for Pfcrt. No significant differences were observed between groups for SNPs or mutation combinations. Pfcrt mutations were absent, suggesting amodiaquine resistance is not mediated by Pfcrt. SNP combinations of relevant Pfdhps-dhfr mutants were notable among the analysed samples. Long term implications of these results will be much better understood once chemoprevention efficacy study data will be available. Continuous monitoring of SP and AQ resistant markers is crucial as the country scale up the implementation of SMC and introduce other quimioprevention strategies using this drug.

ASSESSMENT OF QUANTITATIVE PCR FOR DETERMINATION OF DRUG RESPONSE OF PLASMODIUM FALCIPARUM IN THE ABSENCE OF DNA PURIFICATION

Fatoumata Bojang, Alfred Amambua Ngwa, Eniyou Cheryll Oriero, Ndey Fatou Drammeh, Nganyewo Nghochuzie Nora

MRC The Gambia at LSHTM, Fajara, Gambia

Surveillance of antimalarial resistance in parasite populations is essential to identify and limit its spread in malaria-endemic communities. Genotyping of molecular markers, Therapeutic efficacy studies and in vitro/ex-vivo studies are commonly used to assess parasite sensitivity to drugs. However, in vivo efficacy studies are expensive and cumbersome, meanwhile, no single assay exists for both molecular genotyping and in vitro/ex vivo testing. Novel assays such as flow cytometry are accurate and fast, they require cumbersome downstream processing to obtain accurate results. Our goal is to develop a quantitative PCR-based molecular assay for determining growth, viability and drug resistance responses using validated molecular tools (qPCR). Parasite growth was assessed by deploying a direct PCR method targeting known parasite genomic regions (varATS & AMA-1). Laboratory-maintained Plasmodium falciparum strains were tested for 50% inhibitory concentrations of Chloroquine, Lumefantrine and dihydroartemisinin. These drugs were tested against laboratory-maintained P. falciparum strains 3D7(chloroquine-sensitive) and Dd2(chloroquine-resistant). Parasitemia was measured following post-drug exposure by flow cytometry and molecular assays. Differential growth relative to the drug-free assays was used to fit sigmoid curves of growth against drug concentration for IC50 determination in comparison to established methods. The IC50 values obtained from the direct PCR method correlated with results obtained from flow cytometry and fluorimetry with R2 values of 0.9996 and 0.9994 respectively. The bland-Altman analysis showed a better agreement between Direct PCR and Fluorimetry (Bias=3.676, Limit of agreement=4.09 - 11.40). Taken together, the direct PCR method allows for molecular detection of parasitaemia and parasite drug susceptibility in the absence of DNA purification. We conclude that upon further optimization this method can be successfully adapted into a handheld PCR-based assay that can be deployed in non-specialized settings for testing of field isolate sensitivity towards antimalarials.

6053

COX UNIVARIATE AND MULTIVARIATE ANALYSIS OF THE DETERMINANTS OF PARASITE RECURRENCE BY DAY 28 AFTER REPETITIVE TREATMENT OF UNCOMPLICATED MALARIA WITH ARTEMETHER-LUMEFANTRINE DURING TWO YEARS IN MALI

Mamadou Modibo Tekete, Bakary Fofana, Sekou Toure, Souleymane Dama, Oumar Bila Traore, Nianwalou Dara, Bouran Sidibe, Abdoulaye Djimde

Molecular Epidemiology and Drug Resistance Unit, MRTC,University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali

In malaria endemic countries, treatment and control of the disease is hampered by the recurrence of parasite. Some people may experience more than ten episodes of malaria by year, necessitating repetitive treatment. The determinants of these recurrences by day 28 after treatment with artemether-lumefantrine are not well characterized. The objective of this work was to investigate the determinants of parasite recurrence after repetitive treatment of uncomplicated malaria case with AL during two years in Mali. This work was part of the WANECAM study. Participants, from 6 months were followed for two years and received AL at the standard dose for each new episode of uncomplicated malaria. Social, demographic, clinical, parasitological and lumefantrine concentration at day 7 variables were used as covariates. Cox univariate and multivariate analysis were used to determine variables associated with the parasite recurrence by day 28 of follow-up. In total 671 participants were treated with AL for 1732 episodes during two years of follow-up. The overall recurrence prevalence was 14.13%. The recrudescence level was less than 1%. The Cox proportional-hazards regression analysis showed that lumefantrine day 7 concentration, age, the high transmission season, the study site, the day 0 parasitemia significantly predicted parasite recurrence by day 28 of follow-up. Our results showed that by day 28 each increase of the natural log of the lumefantrine day 7 concentration had about 40% lower hazard rate to have recurrence (HR = 0.607, (95% CI; 0.499 – 0.739)). Each increase of the age had about 5% lower hazard rate (HR = 0.946, (95% CI; 0.914 – 0.979)). While we found a strong relationship between the high transmission season (June to November) and parasite recurrence There was no recurrence during the low transmission season. These results showed the relationship between different factors that influence parasite recurrence. Understanding these relationships is critical for the development of strategies in malaria control and elimination.

HEALTH SEEKING BEHAVIORS AND BELIEFS SURROUNDING MALARIA IN THREE EAST AND SOUTHERN AFRICAN NEW GEOGRAPHIES PILOTING SEASONAL MALARIA CHEMOPREVENTION: A SECONDARY QUALITATIVE ANALYSIS

Maria Suau Sans[1], Erica Viganò[1], Ivan Alejandro Pulido Tarquino[2], Mercia Sitoe[2], Francis Okot[3], Jennifer Ainsworth[1], Jamshed Khan[3], Anthony Nuwa[4], Sonia Maria Enosse[2], Maureen Nakirunda[5], Kevin Baker[1]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Maputo, Mozambique, [3]Malaria Consortium, Juba, South Sudan, [4]Malaria Consortium, Kampala, Uganda, [5]Malaria Consortium, Moroto, Uganda

Seasonal malaria chemoprevention (SMC) is a World Health Organization recommended intervention that consists of the intermittent administration of antimalarials to children in areas where transmission is highly seasonal. In 2021 and 2022, Malaria Consortium has been conducting hybrid SMC effectiveness-implementation studies to build the evidence base around new SMC in geographies in East and Southern Africa (ESA), and ensure that SMC is deployed safely, effectively, and sustainably in these settings; the approach used in the Sahel region may not be suited for ESA due to greater resistance profile, transmission, and immunity heterogeneities. Preliminary results from these studies show that SMC is an effective and highly acceptable strategy. However, one aspect that was not initially investigated in the qualitative component of these studies, but which provides insightful information on factors influencing interventions success, are the health seeking behaviours and beliefs surrounding malaria. To fill this research gap, an ongoing thematic analysis is being conducted on qualitative data collected between April and December 2022 in the Karamoja region of Uganda, Nampula province in Mozambique and Northern Bahr el Ghazal state in South Sudan. Qualitative methods employed included focus group discussions (FGDs) held with caregivers and community health workers in each setting, and semi-structured interviews held with key informants at various levels of the health systems in the three countries. A total of 41 FGDs and 51 interviews have been analysed. Perceptions, social practices, and religious beliefs surrounding malaria transmission, prevention, and health seeking behaviours have been described for each location and compared against each other, with a focus on identified similarities and differences. Results from this secondary qualitative analysis will contribute to the refinement of future SMC implementation campaigns with context-specific information for ESA geographies. Findings could be additionally used to generate hypothesis for further community-centred interventions.

6055

RARE PLASMODIUM FALCIPARUM CORONIN GENE MUTATIONS FOLLOWING ARTEMISININ (ART) TREATMENT OF MALARIA IN SOUTH WESTERN NIGERIA

Olusola Ajibaye[1], Yetunde A. Olukosi[1], Eniyou Oriero[2], Mary Oboh[2], Ikechukwu Nwankwo[1], Chinaza Nnam[1], Olawunmi V. Adaramoye[3], Somadina Chukwuemeka[1], Gabriel Eniafe[1], Judith Okanazu[1], Bamidele A. Iwalokun[1], Alfred A. Ngwa[2]

[1]Nigerian Institute of Medical research, Lagos, Nigeria, [2]Medical Research Council Unit, the Gambia – The London School of Hygiene and Tropical Medicine, Fajara, Banjul, The Gambia, Banjul, Gambia, [3]College of Medicine, University of Lagos, Lagos, Nigeria

Non-Pfkelch13 parasite protein variants have been implicated in artemisinin (ART) resistance, but not in Africa. Genetic markers underlying in vivo reduced ART efficacy among African P. falciparum populations are currently unclear. We investigated SNPs in Plasmodium falciparum actin-binding protein (Pfcoronin) associated with in vivo ART tolerance in Nigeria. Seven isolates showing parasitaemia after Day 3 in a 28-day therapeutic efficacy study of artemether-lumefantrine among 51 volunteers in Lagos, Nigeria were investigated. Molecular diagnosis was done by conventional and real-time PCR amplification of Pf18S rRNA gene, var acidic terminal sequence, telomere-associated repetitive elements-2 and coupled conventional and real-time Pf18S rRNA PCR. Twelve neutral P. falciparum microsatellite loci genotyping were analyzed to confirm recrudescence in comparison with msp2 genotyping. We genotyped drug resistance targets (DHFR_51, DHFR_59, DHFR_108, DHFR_164, MDR1_86, MDR1_184, DHPS_581 and DHPS_613), and sequenced PfCoronin bi-directionally for presence and association of mutations with ART tolerance. Molecular techniques employed detected P. falciparum infections. One infecttion was recrudescent by microsatellites analysis out of the four identified as recrudescent infections by msp2 genotyping. Presence of the drug resistance-associated haplotypes, pfdhfr/pfdhps/pfmdr1 (108T/N/51I/164L/59R/581G/86Y/184F) was observed in two samples. He, allelic diversity, for each microsatellite locus from pre- and post-drug administration, revealed no significant difference in the mean He (P = 0.19, Mann-Whitney test). Significant LD (IAS = 0.2865, P=0.02, Monte Carlo simulation) around the neutral microsatellite loci was observed. Seven new Pfcoronin SNPs (V55L, V67E, I68G, K69G, L77I, D154Y and E200Q) were found. SNPs here reported may guide investigations on mechanisms of emerging African ART resistance.

CHANGES IN SUSCEPTIBILITY OF PLASMODIUM FALCIPARUM TO LUMEFANTRINE IN EASTERN AND NORTHERN UGANDA OVER TIME

Stephen Orena[1], Melissa Conrad[2], Martin Opio Okitwi[1], Patrick Tumwebaze[1], Oswald Byaruhanga[1], Thomas Katairo[1], Jennipher Legac[2], Shreeya Garg[2], David Giesbrecht[3], Smith Sawyer[3], Frida G. Cega[4], Sam Nsobya[1], Jeffrey A. Bailey[3], Roland Cooper[4], Philip J. Rosenthal[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California, San Francisco, CA, United States, [3]Brown University, Providence, RI, United States, [4]Dominican University of California, San Rafael, CA, United States

Artemisinin-based combination therapies, the first line treatments for uncomplicated malaria, are threatened by emergence of artemisinin partial resistance in northern Uganda, where high prevalence of the PfK13 469Y and 675V mutations has been documented. Of additional concern, we recently reported decreased susceptibility to the key partner drug lumefantrine in northern, compared to eastern Uganda. To assess changes over time, we compared susceptibilities to 7 standard antimalarials of P. falciparum isolates collected from symptomatic patients in 2021 and 2022 in Patongo Health Centre in northern Uganda, and Tororo District Hospital and Busiu Health Centre, in eastern Uganda. We utilized 72-h growth inhibition assays with SYBR green detection and genotyped samples using targeted deep sequencing to identify linked genotypes of interest. With growth inhibition assays, median IC50s for lumefantrine were 14.7 (n=49) and 14.9 nM (n=94) in 2021 and 2022, respectively, in northern Uganda, compared to 3.0 (n=378), 5.1 (n=365), 6.2 (n=151) and 10.1 nM (n=144) in 2010-2013, 2016-2019, 2021, and 2022, respectively, in eastern Uganda. For 2021 and 2022 combined, median IC50s were significantly greater in northern vs. eastern Uganda (p =0.0001). Considering other standard components of artemisinin combination therapies (dihydroartemisinin, amodiaquine, piperaquine, pyronaridine, and mefloquine), IC50s were similar between northern and eastern Uganda. Preliminary molecular inversion probe sequencing of 70 genes of interest suggested that mutations in PfMDR1, PfK13, and falcipain cysteine proteases are associated with differences in lumefantrine susceptibility. The identified decreased susceptibility of P. falciparum to lumefantrine in northern Uganda is of great concern, as it suggests decreased antimalarial efficacy of artemether-lumefantrine, the first line antimalarial therapy in Uganda. Highlighting the need for continued surveillance of resistance patterns to inform on future trends, necessary for malaria control strategies.

EX VIVO SUSCEPTIBILITY OF PLASMODIUM FALCIPARUM ISOLATES TO STANDARD ANTIMALARIALS IN BOBO-DIOULASSO, BURKINA FASO

Anyirekun Fabrice Somé[1], R. Serge Yerbanga[1], Zachari Kabré[1], Aminata Fofana[1], Thomas Bazié[1], Catherine Neya Neya[1], Myreille Somé[1], Jenny Legac[2], Melissa Conrad[3], Jeffrey A. Bailey[4], Jean-Bosco Ouédraogo[1], Philip J. Rosenthal[3], Roland A. Cooper[5]

[1]IRSS, Bobo-Dioulasso, Burkina Faso, [2]University of California, San Francisco, San Francisco, CA, United States, [3]University of California, San Francisco, CA, United States, [4]Brown University, Providence, RI, United States, [5]Dominican University of California, San Rafael, CA, United States

Malaria remains the leading cause of morbidity and mortality in Burkina Faso. The country utilizes artemether-lumefantrine, artesunate-amodiaquine, and recently dihydroartemisinin-piperaquine as first line therapies for uncomplicated malaria. Seasonal malaria chemoprevention (SMC) with amodiaquine plus sulfadoxine-pyrimethamine is implemented country-wide in children 5 years and under during the transmission season. With concerns regarding potential resistance to many classes of antimalarials, monitoring the efficacy of available antimalarial drugs is a high priority. We measured ex vivo IC50s for 11 compounds utilizing 158 isolates collected from patients aged 3-60 years old presenting with uncomplicated Plasmodium falciparum malaria in Bobo-Dioulasso, Burkina Faso from July to December, 2021 and 2022. Assays utilized a standard 72 h growth inhibition microplate assay with SYBR Green detection, with results compared to those with laboratory-adapted control parasite strains. Isolates (median IC50 [range], nM) were generally highly sensitive to: chloroquine (9.9 [0.87 - 262.8]), monodesethylamodiaquine (21.5 [0.6 - 205.6]), piperaquine (6.3 [1.2 - 211.5]), lumefantrine (7.4 [0.5 - 78.2]), mefloquine (7 [0.2 - 29.9]), atovaquone (0.2 [0.01 - 1.0]), dihydroartemisinin (3.7 [0.5 - 24.7]), pyronaridine (3.0 [0.1 -36.7]) and quinine (49.8 [1.5 - 637.7]). With a few exceptions, parasites were resistant to pyrimethamine (32,649 [33.2 - 191,190]) and cycloguanil (844[3.6 - 8265]). All median IC50 values were similar to those reported from our recent ex vivo studies in eastern Uganda, and suggested good antimalarial efficacy of tested drugs except for pyrimethamine and cycloguanil. However, it is noteworthy that the median IC50 for monodesethylamodiaquine was greater than that recently reported in Uganda (7.1 [1.1 - 202]; p <0.0001), possibly related to widespread use of amodiaquine as part of SMC in Burkina Faso. Genotyping of isolates to characterize key mutations associated with antimalarial drug resistance is underway.

6058

LACK OF CORRELATION BETWEEN IN VITRO POTENCY AND IN VIVO EFFICACY OF MADURAMICIN AGAINST PLASMODIUM LIVER STAGES

Jyothsna R. Kumar, Anke Harupa-Chung, Erika L. Flannery, Sebastian A. Mikolajczak, Vorada Chuenchob, Pamela Orjuela Sanchez, Colin Osborne

Novartis Institutes of BioMedical Research Inc, Emeryville, CA, United States

Current strategies for anti-malarial drug development primarily focus on targeting the asexual and sexual stages of the parasite. Maduramicin, a polyether ionophore used as a coccidiostat in poultry has been shown to exhibit potent anti-plasmodial activity in vitro across Plasmodium species and stages with an IC50 of <14nM against both replicating (schizont) and dormant (hypnozoite) liver stages, and blood-stages of the parasite. In our efforts to further evaluate the efficacy and stage specific activity of maduramicin in vivo, wild type mice were infected with 2.5*104 P. berghei (Pb-GFP-luc) sporozoites and treated orally with maduramicin at timepoints corresponding to different stages of infection. Whole body in vivo imaging of mice was done at 24, 48 and 72 hours post infection, and thin blood smears stained with Giemsa were analyzed to determine blood parasitemia. While prophylactic administration of maduramicin prior to sporozoite infection fully blocked the formation of liver stages, delayed treatment after establishment of early or late liver-stages proved ineffective. Bioluminescence signal was detected in livers of the mice at 24 hours post treatment with an increase in signal at 48 hours, indicating a surprising lack of activity against liver-stages. Maduramicin was potent against blood-stages in vivo with animals being parasite free three days post drug administration with no recrudescence. Contrary to its high in vitro potency, a similar lack of activity against liver stages was observed in human liver-chimeric mice infected with P. cynomolgi, a strain that produces dormant hepatic hypnozoites. Parasite burden in treated livers could be quantified by qPCR with both schizonts and hypnozoites being detected by immunofluorescence assays four days post treatment, indicating the absence of liver-stage clearance. While further investigation is required to understand this disparity between in vitro and in vivo activity of maduramicin, our studies characterizing ionophores in murine malaria models highlight potential challenges in repurposing these molecules towards intervention strategies for malaria.

6059

MALARIA DRUG RESISTANCE MARKERS MOLECULAR SURVEILLANCE USING ANOPHELES MOSQUITOES IN BURKINA FASO

Awa Gneme[1], Moustapha Nikiema[1], Justine Kabore[1], Boubacar Coulibaly[2], Ali Sie[2], Athanase Badolo[1]

[1]Université Joseph KI-ZERBO, Ouagadougou, Burkina Faso, [2]Centre de Recherche en Santé de Nouna, Nouna, Burkina Faso

Plasmodium resistance to antimalarials is hampering the fight against malaria in endemic countries. Here, we screen multiple antimalarial drug resistance genes (pfmdr), sulfadoxine pyrimethamine resistance markers (dhfr and dhps) within Anopheles populations to highlight the potential dissemination of these drug resistance makers. Anopheles mosquitoes were collected by using CDC light traps and manual collections in the health district of Nouna in Burkina Faso. The heads/thoraxes were used for the detection of Plasmodium falciparum infection. Positive samples were subjected to PCR-RFLP to assess their drug resistance polymorphisms. Plasmodium infection rate in Anopheles vectors was 5.5% during this study. For the pfmdr genes, the prevalence was 7.4%, 83.4% and 9.2% for mutants, wild type and hybrid. For the dhfr gene, the prevalence of mutant alleles was 4.02%, 8.16% and 12.5% for codons 51, 59, 108 respectively. Mutations on codons 437 and 540 of the dhps genes were also observed during this study with a prevalence of 14.3% and 2%. These mutations have been notified both in An. gambiae, the major vectors of malaria, and in An. nili another important vector in this region. This study highlights the level of antimalarial resistance genes in mosquitoes. The presence of mutant alleles shows the need for regular monitoring of these molecular markers.

PFCORONIN MUTATIONS CONFER ARTEMISININ RESISTANCE IN PLASMODIUM FALCIPARUM BY ALTERING ACTIN HOMEOSTASIS: A POTENTIAL NEW PLAYER IN THE ENDOCYTIC AND VESICULAR TRANSPORT PATHWAY

Imran Ullah[1], Madeline A. Farringer[1], Sara H. Shin[1], Aabha I. Sharma[1], Selina Bopp[1], Erica Hathaway[2], Bailey C. Willett[1], Anna Burkhard[1], Morgan C. Martin[1], Sarah K. Volkman[1], Daniel L. Hartl[3], Jeffrey D. Dvorin[4], Sabrina Absalon[2], Dyann F. Wirth*[1]

[1]Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, United States, [3]Department of Organismic and Evolutionary Biology, Harvard University, Boston, MA, United States, [4]Department of Pediatrics, Harvard Medical School, Boston, MA, United States

Pfcoronin mutations drive in vitro evolved artemisinin (ART) resistance in Senegalese P. falciparum isolates (coroninR100K/E107V). Coronin interacts with the cytoskeleton in other organisms, but its function in Plasmodium biology is not yet understood. To explore the role of Coronin, we immunoprecipitated (IP) Coronin and identified its interaction partners by mass spectrometry. In both CoroninWT and CoroninR100K/E107V parasites, Coronin's major interacting partner was actin, however, interactions with actin were substantially reduced in ring-stage CoroninR100K/E107V parasites. The second most enriched Coronin-interacting partner in CoroninWT rings was polyubiquitin (Ub), but like actin, Ub was significantly less enriched in CoroninR100K/E107V parasites. We hypothesized that ubiquitination might alter turnover or otherwise regulate actin behavior. Interestingly, western blot revealed that CoroninR100K/E107V rings contained 30% less actin than CoroninWT. To better understand which proteins might be ubiquitinated, we used IP with an anti-ubiquitin probe. Actin was highly enriched in CoroninWT line but not in the CoroninR100K/E107V parasites, consistent with the growing body of evidence that actin rearrangements involve regulation by ubiquitylation. We undertook ultrastructure expansion microscopy (UExM) to assess Coronin localization in rings. UExM revealed localization of Coronin at the parasite plasma/vacuolar membrane. Interestingly, we saw strong localization of Coronin at the food vacuole membrane and vesicular structures. To provide additional pharmacological evidence, treating CoroninR100K/E107V parasites with jasplakinolide, an actin depolymerization inhibitor, results in a reversal of the resistance phenotype, demonstrating the role of actin in coronin-mediated artemisinin resistance. These results demonstrate a role in endocytosis and vesicular transport—notably, actin is key to these processes. Altered vesicular transport has previously been implicated in kelch13-linked artemisinin resistance, and these results suggest that Coronin might work in the same pathway.

KELCH 13 AND NON-KELCH 13 MEDIATED ARTEMISININ DRUG RESISTANCE

Faiza A. Siddiqui, Liwang Cui

University of South Florida, Tampa, FL, United States

The emergence of ART resistance in the Greater Mekong subregion earlier and recently in African subcontinent has marked a major setback for malaria elimination worldwide. Although Kelch 13 has been proposed as the primary marker and determinant of artemisinin resistance in Plasmodium falciparum, many other genes and proteins with variable degrees of influence on resistance phenotype have been identified. Based on genome wide association studies, in vitro generated ART resistance parasites and literature review we identify and validate additional markers of ART drug resistance. We are currently characterizing Kelch 13 muations either emerging in South East Asia or specific to African parasites, additionally we are also validating polymorphisms found in other potential markers of ART

resistance like Falcipain 2a, DNA mismatch repair protein PMS1, putative, regulator of initiation factor 2 (eIF2) and Phosphatidylinositol 4-kinase, putative. We have generated genetically modified parasites with single nucleotide polymorphism or haplotypes found in each of these proteins and are currently performing drug assays and parasite fitness assays to study their effect on drug susceptibility and parasite growth. The introduction of these polymorphisms in different genetic backgrounds would reveal any variability present in their artemisinin resistance profiles, food vacoule morphologies and parasite progression. This work would help us elucidate the role of these markers in artemisinin resistance.

6062

SUSCEPTIBILITY OF PLASMODIUM FALCIPARUM ISOLATES TO DIHYDROARTEMISININ IN NORTHERN AND EASTERN UGANDA IN 2021 AND 2022

Martin Okitwi[1], Stephen Orena[1], Patrick K. Tumwebaze[1], Thomas Katairo[1], Oswald Byaruhanga[1], Yoweri Taremwa[1], Jennifer Legac[2], Shreeya Garg[2], David Giesbrecht[3], Sawyer R. Smith[3], Frida G. Ceja[4], Samuel L. L Nsobya[1], Jeffrey A. Bailey[3], Melissa D. Conrad[2], Roland A. Cooper[4], Philip J. Rosenthal[2]

[1]Infectious Diseases Research Collaboration, Uganda, Kampala, Uganda, [2]University of California, San Francisco, San Francisco, CA, United States, [3]Brown University, Providence, RI, Providence, RI, United States, [4]Dominican University of Carlifonia, San Rafael, San Rafael, CA, United States

Artemisinin partial resistance, mediated primarily by mutations in the PfK13 propeller domain, was first reported in Southeast Asia, and has recently emerged in Africa, including Uganda and Rwanda, posing a great challenge to malaria control and elimination. We compared the prevalence of PfK13 mutations and ex vivo dihydroartemisinin (DHA) susceptibility of P. falciparum isolates collected in 2021 and 2022 from northern (N) Uganda, where resistance-associated PfK13 C469Y and A675V mutations have emerged, and eastern (E) Uganda, where such mutations have been rare. We collected whole blood samples from patients aged > 0.5 years with confirmed P. falciparum mono-infection attending Patongo Health Centre III in N. Uganda, and Tororo District Hospital and Busiu Health Centre IV in E. Uganda in May-August 2021 and March-July 2022. We evaluated 103 (N=65, E=38) and 160 (N = 110, E = 50) samples in 2021 and 2022, respectively. The pfK13 gene was sequenced using molecular inversion probe assays. Susceptibilities were determined with the ex vivo ring-stage survival assay (RSA; percentage survival, relative to controls, 66 h after a 6 h 700 nM pulse of DHA) and the standard 72 h microplate growth inhibition assay to estimate IC50 values. In N. Uganda, the prevalence of PfK13 mutations decreased (C469Y 34% to 10%, A675V 13% to 5%), RSA results were similar (median survival 3.5% to 3.1%) and IC50 values increased slightly (median IC50 2.3 nM to 3.5 nM) from 2021-22. In E. Uganda, the prevalence of PfK13 mutations was stable (C469Y 3% to 2%, A675V 3% to 4%), RSA survival increased (median survival 2.2% to 5.2%) and IC50 values increased (median IC50 1.5 nM to 2.5 nM) from 2021-22. The presence of C469Y or A675V mutations was associated with RSA values >5% in 2021, but not in 2022. Our results demonstrate persistent artemisinin partial resistance in northern and eastern Uganda, but with only a modest correlation between PfK13 mutation prevalence and drug susceptibility measures, highlighting the possible involvement of non-PfK13 mutations and the need for ongoing surveillance and monitoring of resistance patterns to inform malaria control strategies.

6063

DECREASED EX VIVO SUSCEPTIBILITY OF PLASMODIUM VIVAX TO CHLOROQUINE IN NORTHWEAST COLOMBIA

Maria C. Velasco, Marcela Santana Durango, Gustavo E. Quintero Pardo, Maria F. Yasnot Acosta

Universidad de Córdoba, Montería, Colombia

Plasmodium vivax was responsible for 247 million cases of malaria worldwide in 2021, including severe cases and deaths. This is due to the difficulty in controlling this species. In Colombia, chloroquine has been used as the first-line treatment for P. vivax. However, in 2001 therapeutic failure was reported in 11% of the patients evaluated, therefore, there is a need for surveillance to determine the in vitro susceptibility of P. vivax to chloroquine (CQ). In this study, an ex vivo short culture was established from clinical P. vivax isolates with a duration of 48 hours to evaluate the in vitro susceptibility to CQ against isolates of P. vivax obtained in the municipality of Tierralta, Córdoba, Colombia. The schizonts maturation method (WHO microtest) was used and compared with SYBR Green method for IC50 determination. Seven serial concentrations in triplicate were evaluated. The inhibitory concentrations of 50% were 37.15 nM for chloroquine. However, 2/19 had IC50 values greater between 100nM-200nM and only one showed a IC50 more than 200nM, in two isolates it was not possible to determine the IC50 value. The SYBR Green and maturing methods give similar results. In conclusion, an in vitro short-term culture was established, the clinical isolates evaluated were susceptible to CQ (66.6%), although 33.3% of the isolates showed very low susceptibility.

6064

THE CONTINUED EXPANSION OF ARTEMISININ PARTIAL RESISTANCE MUTATION KELCH13 561H AND EMERGENCE OF 675V IN RUKARA IN 2021

Cecile Schreidah[1], David Giesbrecht[1], Neeva Young[1], Corine Karema[2], Tharcisse Munyaneza[3], Jean De Dieu Butera[3], Gashema Pierre[4], Rebecca Crudale[1], Jean-Baptiste Mazarati[4], Jeffrey Bailey[1], Jonathan J. Juliano[5]

[1]Brown University, Providence, RI, United States, [2]Quality Equity Health Care, Kigali, Rwanda, [3]National Reference Laboratory, Kigali, Rwanda, [4]INES-Ruhengeri, Ruhengeri, Rwanda, [5]The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Plasmodium falciparum kelch13 (Pfk13) propeller-domain mutations that confer artemisinin partial resistance have emerged in Africa, with the first reported mutation being Pfk13-R561H in Rwanda. These mutations threaten control and elimination efforts and increase the likelihood of the emergence of partner drug resistance. Given this, it is vital to track their emergence and spread to inform modeling and public health efforts. In order to provide an update of the artemisinin resistance as well as potential RDT resistance we genotyped samples collected in 2021 from Rukara, Rwanda, the site where R561H was first detected in samples from 2014. Clinically validated artemisinin partial resistance mutations were found to be increasing in prevalence compared to previous reports from 2014. While the R561H mutation was observed at 23.5% (20/85 infections), A675V was seen at 8.5% (8/94). Additional nonsynonymous propeller mutations found were P574L at 2.4% (2/84), F699C at 1.1% (1/87), A575L at 1.1% (1/88), and P667R at 1.1% (1/94). In addition to these Pfkelch13 mutations, we also found that the Pfdhfr N164L mutation, associated with high grade Fansidar resistance, has increased in prevalence to 24.7% (19/77). We also investigated diagnostic resistance status and found 76.7% (102/133) contained intact HRP2/3. Overall, this investigation shows continued spread of artemisinin partial resistance within Rukara catchment area due to 561H, the concerning appearance of 675V previously found only at high prevalence in Uganda, and the emergence of dhfr 164L to a common level. Continued molecular surveillance in this region and surrounding areas is needed to monitor and understand these concerning antimalarial mutations which have significant potential impact on clinical and preventative therapy of malaria in east Africa.

6065

COMPARISON OF STRENGTH OF SELECTION FOR PLASMODIUM FALCIPARUM ARTEMISININ RESISTANCE-ASSOCIATED MUTATIONS BETWEEN SOUTHEAST ASIA AND UGANDA

Cecile P. G. Meier-Scherling[1], Oliver J. Watson[2], Victor Asua[3], Isaac Ghinai[4], Thomas Katairo[3], Shreeya Garg[5], Dominic Kwiatkowski[4], Melissa Conrad[5], Philip J. Rosenthal[5], Lucy C. Okell[2], Jeffrey A. Bailey[6]

[1]Center for Computational Molecular Biology, Brown University, Providence, RI, United States, [2]Medical Research Council Centre for Global Infectious Disease Analysis, Imperial College London, London, United Kingdom, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]Oxford University, Oxford, United Kingdom, [5]University of California San Francisco, Medicine, San Francisco, CA, United States, [6]Department of Pathology and Laboratory Medicine, Warren Alpert Medical School, Brown University, Providence, RI, United States

Partial artemisinin resistance, mediated by mutations in the kelch13 protein (PfK13), emerged in Southeast (SE) Asia and, more recently, in east Africa (Ethiopia, Eritrea, Rwanda, and Uganda). We investigated the rates of increase in mutation frequencies by comparing annual changes in PfK13 prevalence in Uganda with historical estimates from five countries in SE Asia. We fitted a Bayesian mixed effects model to the annual prevalence by district for each recently identified mutation in Uganda with a random slope and intercept to estimate selection coefficients, which define the percent change in relative frequency of the mutant genotype per parasite generation. In Uganda, we estimate preliminary selection coefficients per year from 2016-2021 across 7 districts for the 469Y, 469F, and 675V mutations to have been s=0.33 (range 0.26-0.44; 95% CrI: 0.13-0.51), s=0.16 (range 0.09-0.24; 95% CrI: -0.42-0.79), s=0.20 (range -0.04-0.32; 95% CrI: -0.03-0.40), i.e. prevalences are estimated to have increased by 33%, 16%, and 20% respectively each year. The selection coefficient estimated for all three mutations combined across all sampled districts in Uganda is s=0.36 (95% CrI: 0.19-0.46). To compare our estimates to the spread of PfK13 mutations in SE Asia, we employed the same model on data from the MalariaGen Pf7k database using samples from 2003-2018 in Cambodia (4 districts), Laos (2 districts), Myanmar (1 district), Thailand (2 districts), and Vietnam (2 districts). Selection coefficients for the 580Y mutation, the dominant mutation in much of SE Asia, and for all validated PfK13 propeller domain mutations were estimated to be s=0.38 (95% CrI: 0.20-0.57) and s=0.25 (95% CrI: 0.08-0.42), respectively. Together, these findings suggest that the strength of selection of partial artemisinin resistance in Africa has been similar to that in SE Asia, where partial artemisinin resistance is now widespread.

6066

INCREASED RATE OF ARTEMISININ-BASED COMBINATION TREATMENT FAILURE IN PATIENTS RETURNING FROM SUB-SAHARAN AFRICA WITH PLAMODIUM FALCIPARUM MALARIA; THE ROLE OF PFCORONIN GENE MUTATION

Tamar Grossman[1], Julia Vainer[1], Yael Paran[2], Ron Dzikowski[3], **Eli Schwartz**[4]

[1]Public Health Laboratories , MOH, Jerusalem, Israel, [2]Sourasky Medical Center-Ichilov, Tel-Aviv, Israel, [3]Hadassah Medical Center, Jerusalem, Israel, [4]Sheba Medical Center, Ramat Gan, Israel

Artemisinin-based combination therapies (ACTs) are recommended as first-line treatment against uncomplicated Plasmodium falciparum infection. However the emergence of mutations in the PfKelch13 propeller domain have resulted in resistance to artemisinin in Southeast-Asia. ACT treatment failures have been sporadically reported in Africa. Data of 15 Israeli travelers returning from Sub-Saharan Africa with P. falciparum malaria who showed ACT treatment failure were retrieved. Blood samples were tested for mutations in Pfkelch13 and Pfcoronin genes. Initial parasite load was evaluated through real-time PCR analysis of 18S rRNA and Pftubulin genes. Parameters were compared to well responders (n=55). During 2009-2020, 326 patients had P. falciparum malaria acquired in Africa. Of those, 15 (14 males, 24 to 69 years old) were clinically resistant to artemether-lumefantrine. Four had parasites in the blood after 3 days of treatment and 11 had recrudescence malaria 1-3 weeks later. No significant differences were found in average age and weight between the ACT-treatment failure and non-failure groups. Failure rate among ACT treated patients during 2009-2015 was 3% compared with 13% during 2015-2020. In all failures the Pfkelch13 propeller domain had wild type sequence. We did find the P76S mutation in the propeller domain of Pfcoronin in 4/15 (29%) of the treatment failure cases compared to only 3/55(5%) in the successfully treated patients (p=0.02). In conclusion, we observed an increasing rate of artemether-lumefantrine treatment failure in P. falciparum patients that could not be explained by patient characteristics, neither by a Pfkelch13 mutation. However, P76S mutation in the Pfcoronin gene was present more often in the treatment failure group and merits further investigation. The recent reports of increasing malaria incidence in Sub-Saharan-Africa partly attributed to COVID-19 related disturbances might also be a reflection of the wider spread of ACT resistance.

6067

DETECTION OF PLASMODIUM FALCIPARUM KELCH 13 GENE MUTATIONS IN CLINICAL SAMPLES FROM FOUR SITES ACROSS KENYA REVEALS INTENSE GENOMIC EVENTS THAT COULD PURIFY RESISTANCE

Benjamin Humphrey Opot[1], Dennis W. Juma[1], Raphael O. Okoth[1], Gladys C. Chemwor[1], Jackline Juma[1], Risper Maisiba[1], Edwin W. Mwakio[1], Maurine Mwalo[1], Redemptah Yeda[1], Charles O. Okello[1], Farid Abdi[1], Agnes Cheruiyot[1], Timothy Egbo[2], Hoseah Akala[1]

[1]United States Army Medical Research Directorate - Kenya, Kisumu, Kenya, [2]United States Army Medical Research Directorate - Africa, Kisumu, Kenya

The emergence and spread of Artemisinin based treatment-resistant strains call for ongoing surveillance. Therapeutic efficacy studies are the gold standard methods for testing drug efficacy. Recently, parasites with mutations that cause delayed clearance by artemisinin-based combination therapy have been identified in Africa, but these parasites are rare. Clinical samples obtained from five geographically varied areas in Kenya identified the polymorphism of the Plasmodium falciparum Kelch 13 (PfK13) gene and other markers of malaria treatment resistance. Blood samples were tested for in vitro susceptibility to selected antimalarial drugs using malaria SYBR green 1 assay. Sanger sequencing was used to detect polymorphisms in PfK13. PfK13 polymorphisms identified twelve mutations at 5.58% comprising three nonsynonymous mutations at codons: P553L, E612D, and F491L, four synonymous mutations at codons V637V, A504A, L488L, and C469C, for the last 2; three mixed wildtype and synonymous mutations at codons A626A, K455E, and G497G and one mixture of wild type and nonsynonymous mutation at codon S600F. One sample included two P553L and G497G mutations. The mixed genotypes, synonymous mutation A504A, nonsynonymous mutations at E612D, and F491L, and all of the nonsynonymous mutations have not been previously described. Also, we reported the synonymous mutation C469C in two samples compared to the WHO-validated marker C469Y which has been linked to slow clearance of parasites in Uganda. Whereas Ugandan reports of the mutation C469Y are non-synonymous, mutation C469C is synonymous. Previously, Congo saw the presence of the mutation C469C. The Pfk13 propeller gene has significant genomic activity, suggesting that once the fitness of the novel variant is established, the mutant state will progress. Continuous surveillance with sustained tools is needed to detect resistance and prevent transmission.

Zoonotic malaria infections are increasing in some areas of the world, posing a threat to malaria control efforts. Optimization of in vivo culturing of Plasmodium spp. that infect non-human hosts is critical for advancing our understanding of Plasmodium biology and identifying potential mechanisms that may underlie zoonotic infections. One such non-human primate (NHP) parasite is P. fragile, known to infect rhesus macaques (RMs) and induce clinical signs that mirror P. falciparum infection in humans. The aim of this work was to establish an in vitro culture system of P. fragile from the blood of an experimentally infected rhesus macaques (RM) and characterize P. fragile life stages during in vivo infection and in vitro culturing. An adult male RM (n=1) was intravenously inoculated with P. fragile (20x106 infected erythrocytes [iRBCs]). Peripheral parasitemia and parasite life stages were monitored throughout infection via Giemsa staining of thin and thick blood smears. Parasite life stages were counted in every 200 uninfected erythrocytes and reported as percentages. P. fragile cultures were started from 1mL of cryopreserved iRBCs, culture medium was changed daily, and fresh RM blood was added to restore 50% hematocrit. Cultures were monitored daily via Giemsa stain of thin smears, and life stages were quantified. Peripheral parasitemia was 15.8% at week 2 post-infection (p.i.) and 8.6% at necropsy (2.5 weeks p.i.). Giemsa staining of thin and thick blood smears collected throughout infection enabled identification of ring stages (5.9%) and trophozoites (6.6%), with no detection of schizonts or gametocytes. At necropsy, ring stage (1.1%), trophozoites (5.2%), schizonts (0.3%), and gametocytes (0.5%) were observed. P. fragile culture began at 2.9% parasitemia and reached 8.7% after 7 days of culturing. Establishing a continuous culture system of P. fragile is a critical step towards increasing understanding of the biology of P. fragile in vitro, providing needed tools for understand potential zoonotic malarias, and enabling translational research to facilitate therapeutic development.

LOW FREQUENCY OF HISTIDINE-RICH PROTEIN 2/3 (HRP2/3) AND FLANKING GENE DELETIONS CORRELATES WITH THE HIGH DIAGNOSTIC PERFORMANCE OF HRP2-BASED MALARIA RAPID DIAGNOSTIC TESTS IN CAMEROON

Nkemngo Francis Nongley[1], Asongha Melissa Nkeng[2], Lymen Raissa Gael[3], Samuel Wanji[1], Charles Wondji[4]

[1]University of Buea, Buea, Cameroon, [2]Centre for Integrative Research in Tropical Health (CIRTH); Forzi Institute, Buea, Cameroon, [3]Centre for Research in Infectious Diseases (CRID), Yaoundé, Cameroon, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Histidine-rich protein 2 (HRP2)-based malaria rapid diagnostic tests (RDTs) are widely used for the detection of naturally occurring Plasmodium falciparum infections. Despite evidence of studies reporting false negative HRP2 RDT results due to Pfhrp2 and Pfhrp3 gene deletions in Africa, there exists a paucity of data on the deletions of these genes in Cameroon. Furthermore, genetic polymorphism of the hrp2/3 genes has been shown to impact the performance of PfHRP2- based rapid diagnostic tests (RDTs). This study investigated the presence of deletions of the Pfhrp2, Pfhrp3, and the respective flanking genes and characterized the polymorphism spectrum of the the hrp2 gene in P. falciparum parasite isolates from two localities (Gounougou and Elende) in Cameroon. A community-based cross-sectional survey was conducted in two communities - Gounougou and Elende in 2021. Malaria diagnosis was performed on 400 samples using microscopy and RDT and Whatman paper dry blood spots were collected for molecular typing of 18srRNA, msp2, hrp2/3, and neighboring genes. Furthermore, sequencing of the hrp2 gene was performed on 45 P. falciparum isolates to score polymorphisms diversity. Polyclonal infection depicted by msp2 typing alongside genotyping of the Pfhrp2 and Pfhrp3 genes revealed 1.3% and 2.1% overall prevalence with no significant difference between both communities. PCR confirmed 04 hrp2-deleted false negative RDTs. A frequency of 5.3%, 7%, 4.1%, and 5.5% was recorded in the MAL7P1.230, MAL7P1.228, MAL13P1.475, and MAL13P1.485 respectively. Sequencing of the Pfhrp2 exon2 from 45 isolates revealed a high level of genetic diversity, marked by the presence of variable repeat types in parasite isolates. The immuno-dominant AHHAHHAAD (81%) amino-acid Baker repeat epitope was characteristic of circulating P. falciparum isolates agreeing with significant RDT performance. In conclusion, despite the presence of low-frequency gene deletions in the HRP2/3 backbones, HRP2-based RDTs still maintain a high performance capacity for detecting malaria in the field.

PRESENCE OF PFHRP2/3 DELETIONS INCLUDING POLYCLONAL INFECTIONS IN AN INTENSE MALARIA TRANSMISSION AREA OF SIAYA COUNTY, WESTERN KENYA

Sharley A. Wasena[1], Evans Raballah[2], Patrick Onyango[1], Khalid B. Bershir[3], Samuel B. Anyona[1], Qiuying Cheng[4], Ivy Hurwitz[4], Perez K. Olewe[5], Clinton O. Onyango[1], Kristan A. Schneider[6], Collins Ouma[1], Douglas J. Perkins[4], Elly O. Munde[7]

[1]Maseno University, Kisumu, Kenya, [2]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [3], London School of Hygiene and Tropical Medicine, London, United Kingdom, London, United Kingdom, [4]University of New Mexico, Center for Global Health, Department of Internal Medicine, Albuquerque, NM, United States, [5]Jaramogi Oginga Odinga University of Science and Technology, Bondo, Kenya, Bondo, Kenya, [6]Department of Applied Computer and Biosciences, University of Applied Sciences Mittweida, Technikumplatz, Mittweida, Germany, [7]Kirinyaga University School of Health Sciences, Department of Clinical Medicine, Kirinyaga, Kenya

Malaria remains endemic in western Kenya despite the various control interventions. Accurate diagnosis is key to the treatment and control of malaria. As such, the World Health Organization (WHO) recommends parasite-based confirmation of malaria prior to treatment. Plasmodium falciparum Histidine Rich Protein 2 (PfHRP2) based malaria rapid diagnostic tests (mRDTs) kits are commonly used throughout malaria endemic regions, including western Kenya, as an alternative to diagnosis with microscopy. However, the performance of the mRDT has been threatened by the emergence of the PfHRP2 deletion. In Siaya, western Kenya, an intense malaria transmission area, PfHRP2/3 deletions could be present but not detected due to polyclonal infections where the wild-type gene is predominant. As such, we investigated the presence of the PfHRP2/3 deletion using one-step multiplex qPCR in a pediatric cohort in Siaya (n=206). PfHRP2/3 deletions were detected in 12 parasite isolates (5.8%, 95% CI 1.9-8.7%). The PfHRP2 monoclonal deleted strains were present in 2 isolates (1%, 95% CI 0-2.4%), while no parasite isolates had PfHRP3 single deletion. Further, 9 isolates (4.4%, 95% CI 1.9-7.3%) had deletions for PfHRP2 and 1 isolate (0.5%, 95% CI 0.0-0.8%) had PfHRP3 deleted but were masked by polyclonal infection. The average relative abundance of PfHRP2 deleted parasites was 9.6%, (95% CI 4.8-14.5), while wildtype was 90.4% (95% CI 85.4-95.4) in polyclonal infections. Further analysis revealed that false negative mRDT results were associated with low parasite densities that were beyond the detection threshold (P≤0.001). The study provides evidence of PfHRP2-deleted strains, including polyclonal infections and their relative abundance in Siaya County. These results underscore the need for an active systematic surveillance program within the lake endemic

region. Moreover, our results are important in informing the Division of National Malaria Control Program (DNMCP) in establishing the profiles of PfHRP2/3 deletions and decisions making on the use of PfHRP2-based mRDTs in Kenya.

PREVALENCE OF PFHRP2 AND PFHRP3 DELETIONS, AND PFKELCH13 MUTATIONS ASSOCIATED WITH PARTIAL RESISTANCE TO ARTEMISININ DERIVATIVES IN SOMALILAND

Abdikarim Y. Muse[1], Harriet Pelling[2], Irene M. de la Fuente[3], Deborah Ojutalayo[2], Mohamed A. Hergeye[4], Abdi A. Ali[4], Mahad O. Dawal[4], Ismail A. Osman[4], Essa A. Geele[4], Abdiwahab I. Abdi[4], Colin J. Sutherland[2], Jane Cunningham[5], **khalid B. Beshir**[2]

[1]World Health Organisation, Hargeisa, Somalia, [2]LSHTM, london, United Kingdom, [3]Instituto de Salud Carlos III, Spain, Madrid, Spain, [4]Ministry of Health Development, Hargeisa, Somalia, [5]World Health Organisation, geneva, Switzerland

Countries in the Horn of Africa Network for Monitoring Antimalarial Treatment (HANMAT) have reported high rates of Plasmodium falciparum (Pf) with hrp2 and hrp3 deletions, and sporadic pfhrp2/3 deletions have also been reported in Somaliland and in UK travellers returning from the region. In addition, pfkelch13 mutations associated with partial resistance to artemisinin derivatives have been reported in east Africa, further potentially threatening malaria control efforts in the region. The existence and extent of such Pf variants in Somaliland is unknown. We conducted systematic surveillance of pfhrp2/3 deletions and pfkelch13 mutations in five districts of Somaliland in 2021 and 2022. From suspected malaria cases, a total of 943 samples were collected, of which 231 were RDT positive and 238 microscopy positive, with a total of 33 discordant samples (HRP2-RDT negative/microscopy positive). We conducted molecular analysis on all the samples, and 195 were qPCR positive for Pf. Amongst these pfhrp2/3 deletions were confirmed in half of the districts with varying prevalence and in both mono and multiclonal infections. The detailed analysis and prevalence of the pfhrp2/3 deletions as well as the percentage of the deletions causing false-negative RDT results will be presented. We will also present analysis of pfkelch13 variants among those 195 qPCR-positive samples and the relationship with pfhrp2/3 deletion, and discuss implications of the findings for malaria control programme in Somaliland.

6072

ONE-STEP MULTIPLEX DIGITAL PCR FOR THE DETECTION OF PFHRP2 AND PFHRP3 DELETIONS IN POLYCLONAL INFECTIONS

Ana Chopo-Pizarro[1], Irene Molina-de la Fuente[2], Lynn Grignard[1], Khalid B. Beshir[1]

[1]Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]National Centre for Tropical Medicine-Institute of Health Carlos III, Madrid, Spain

Early detection of malaria cases is critical for malaria control and elimination strategies. The majority of Rapid Diagnostic Tests (RDT) used for point-of-care diagnostics in malaria-endemic countries target the HRP proteins coded by Plasmodium falciparum histidine-rich proteins 2 and 3 genes (pfhrp2/3). Due to the global emergence of P. falciparum (Pf) parasites lacking pfHRP2/3 protein, the performance of HRP-based RDTs has been compromised. Lately, there has been an increase in pfhrp2 and pfhrp3 deletion reports in Africa, threatening malaria control efforts. Pfhrp2/3 deletion in polyclonal infections, common in high transmission settings have been shown to give false-negative RDT results, particularly at low parasitaemia (close to detection limit of RDTs). Therefore, there is an emerging demand to develop a rapid molecular tool capable of detecting those parasite clones with greater accuracy. In this study, we report the development of a one-step rapid digital PCR assay based on microfluidic nanoplate technology that measures the fluorescence released by each partition in a 3-target multiplex PCR. This assay is able to accurately detect pfhrp2 and pfhrp3 gene deletions and the ratio of parasites carrying deletions in an Pf infection. We optimized the assay using culture-adapted laboratory lines with different pfhrp2 and pfhrp3 status. Different mixtures and parasitaemia were tested to assess the limit of detection, improving the results from a previously published multiplex qPCR in our lab. Further validation was performed using field samples. This digital PCR assay has significantly improved the accuracy of detecting pfhrp2/3 deletions in multiclonal infections, common in high-malaria transmission settings. Moreover, the high sensitivity of this assay to capture the true clonal diversity of Pf infections can be applied to other malaria targets for other studies.

CHANGES IN MALARIA TEST POSITIVITY RATE FOLLOWING SCALE UP OF LIFE-SAVING MALARIA CONTROL INTERVENTION IN EBONYI STATE, SOUTH EAST NIGERIA

Grace Nwankwo[1], Chinwe Nweze[2], Chinedu Egwuonwu[1], Onyinye Udenze[1], Jonathan Igboji[1], Abimbola Olayemi[3], Olatayo Abikoye[3], IniAbasi Inglass[3], Uchenna Nwokenna[3], Lawrence Nwankwo[4], Arja Huestis[5], Thomas Hall[5], Allan Were[5], Olugbenga Mokuolu[5], Erkwagh Dagba[6], Veronica Momoh[6], Jules Mihigo[6]

[1]United States President's Malaria Initiative for States, Management Sciences for Health, Ebonyi, Nigeria, [2]United States President's Malaria Initiative for States, Management Sciences for Health, Cross River, Nigeria, [3]United States President's Malaria Initiative for States, Management Sciences for Health, Abuja, Nigeria, [4]State Malaria Elimination Program, Ministry of Health, Ebonyi, Nigeria, [5]United States President's Malaria Initiative for States, Management Sciences for Health, Arlington, VA, United States, [6]United States President's Malaria Initiative, United States Agency for International Development, Abuja, Nigeria

Nigeria accounts for 26.6% of global malaria cases according to the 2022 World Malaria Report. Surveillance is paramount to track malaria morbidity and guide decision-making for appropriate transmission-reducing responses. One tracking measure is the malaria test positivity rate (TPR) indicator which is used as an alternate indicator of malaria morbidity since it is based on parasitological confirmation. Over the years, TPR remained high regardless of season possibly due to poor quality of testing and documentation. This study investigates the correlation between the observed positive change in TPR and the interventions implemented to support the Ebonyi State Malaria Elimination Program (SMEP). These efforts include case and data management training, implementation of Behavior Economics (BE) prototypes to improve fever case management, supportive supervision and archiving of used rapid diagnostic test (RDT) cassettes to increase health provider adherence to national guidelines for fever management. This analysis consisted of a pre-post intervention comparison of TPR in similar periods over a 4-year period using secondary routine data from the National Health Management Information System across the 762 health facilities of the state. The data found that the pre-intervention TPR from January-March 2019 was 71% and remained high at 68% from January to March 2020. It is worth noting that COVID did not affect the TPR as only a total of 2,064 confirmed cases were reported in the state from 2020 to 2023. The intervention commenced in July 2020 and six -month post-intervention (January- March 2021), the TPR declined to 54% and further reduced to 50% from January to March 2022. While the reduction in TPR is promising, other factors such as bed net use can highly affect it. Nevertheless, it remains one measure of the effectiveness of the support to Ebonyi SMEP on the implementation of malaria program and suggests that training, supervision, archiving of RDT cassettes and BE prototypes implementation can influence the quality of malaria case management. These findings strongly present the opportunity to scale up our efforts in other states.

[1]Dhibiti Malaria project, Population Services International, Dar es Salaam, Tanzania, United Republic of, [2]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [3]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [4]PMI Impact Malaria Project, MCD Global Health, Nairobi, Kenya, [5]PMI Impact Malaria Project, MCD Global Health, Washington, MD, United States, [6]PMI Impact Malaria Project, Population Services International, Washington, DC, United States, [7]Population Services International (PSI), Washington, DC, United States, [8]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

Quality malaria microscopy relies on the skills of technicians to prepare and examine blood films, high quality reagents, and efficient internal and external quality assurance. Capacity development is necessary to improve quality of diagnosis; however, scarce resources limit the number of technicians able to participate in training. From 2021 to 2022, the U.S. President's Malaria Initiative (PMI) Impact Malaria project, in collaboration with the National Malaria Control Program and health management teams, conducted Malaria Services and Data Quality Improvement (MSDQI) supportive supervision visits for microscopy at 55 health facilities in four project-supported regions. We categorized an average score <50% in key indicators as poor and unacceptable, 50-75% moderate and needs improvement, and >75% as good performance. In 2021, 16 (29%) facilities scored below 50% in preparation, staining, and examination of malaria slides. Nine mentors who had previously successfully completed advanced Malaria Diagnostics Refresher Training (MDRT) provided on-the-job training to staff at these 16 facility laboratories on sample collection, blood film preparation, and examination. A follow-up MSDQI visit conducted in 2022 to assess the quality of microscopy services found that these 16 facilities scored above 75% in specimen collection after receiving the mentorship. The proportion of facilities with poor performance (<50%) in fixing and staining of blood films decreased from 20% to 0%, and the proportion of facilities with moderate scores (50-75%) improved from 20% to 50%. The proportion of facilities with good performance scores (>75%) in blood film examination improved from 60% to 100%. The onsite mentorship may have improved the quality of malaria microscopy among laboratory technicians at health facilities. The use of mentors from local health management teams can bridge the gap of limited resources to reach a larger group of laboratory staff who may not have access to formal MDRT.

6075

EXTERNAL VALIDATION OF THE WORLD HEALTH ORGANIZATION INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI) PROTOCOL FOR MALARIA TESTING IN LOW MALARIA RISK AREAS

Nadia Cattaneo[1], Alexandra V. Kulinkina[2], Chacha Mangu[3], Victor P. Rwandarwacu[4], Ludovico Cobuccio[1], Lameck Luwanda[5], Godfrey Kavishe[3], Sabine Renggli[5], Geofrey I. Ntinginya[3], Valérie D'Acremont[1], Rainer Tan[1]

[1]Center for Primary Care and Public Health (Unisanté), Lausanne, Switzerland, [2]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [3]National Institute of Medical Research – Mbeya Medical Research Center, Mbeya, Tanzania, United Republic of, [4]Swiss Tropical and Public Health Institute, Kigali, Rwanda, [5]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of

In low malaria risk areas, the WHO Integrated Management of Childhood Illness (IMCI) chart booklet recommends testing for malaria only in febrile sick children with no obvious cause of fever. The safety of this approach is unclear since the clinical presentation of malaria is unspecific. We performed an external validation study to assess the predictive performance of identifying malaria in febrile children using the IMCI protocol in low malaria risk areas. We used data from ePOCT+, a digital clinical decision support algorithm that helps primary care health workers in the management of sick children in Rwanda and Tanzania. Sick children aged 2-59 months, presenting with fever or a history of fever to a health facility located in a low malaria risk area (i.e. malaria positivity in <5% of febrile children) were included. Follow-up visits and presence of IMCI danger signs made up exclusion criteria. Primary outcome was a positive malaria rapid diagnostic test (mRDT) or the detection of Plasmodium spp by microscopy (thick blood smear). Two diagnostic strategies were evaluated: 1) malaria test only in patients with no obvious cause of fever, 2) malaria test in patients with no obvious cause of fever or with recent travel history. Between December 2021 and January 2023, 7'209 patients from 11 Tanzanian and 15 Rwandan health facilities tested for malaria were included. 126 (1.8%) cases had a positive malaria test. The first strategy had a sensitivity of 24.6% (95%CI 23.6-25.6%) and a specificity of 87.0% (86.2-87.8%). If health workers had adopted this testing strategy, 75.4% (95/126) of febrile children with malaria would not have been identified and thus probably not treated (symptomatic and incidental parasitaemia cases combined). When adding travel history, sensitivity rose to 27.0% (26.0-28.0%) and specificity stayed stable at 86.3% (85.5-87.1%). The sensitivity of the IMCI chart booklet was low and the inclusion of travel history did not increase it significantly. Given the results of this study and considering the trade-off between the need to detect malaria cases and the avoidance of wasted tests, alternatives to the IMCI approach should be explored.

6076

IMPROVING MALARIA DIAGNOSIS THROUGH QUALITY ASSURANCE IN RWANDA FY 2021-2022

Niyonzima Jean Damascene[1], Ndikumana Mangara NMJ Jean-Louis[1], Uwimana UA Aline[1], Kabera S. KSM Michee[1], Rucogoza R. A Aniceth[1], Tharcisse T. M. Munyaneza[1], Emmanuel E. R Ruzindana[1], Jean Bosco J B M Mucaca[1], Aimable A M Mbituyumuremyi[1], Noella N. U Umulisa[2]

[1]Rwanda Biomedical Center/ MOH, Kigali, Rwanda, [2]JHPIEGO, Kigali, Rwanda

Malaria remains a leading cause of morbidity and mortality in Rwanda, with almost 1 million malaria cases and 71 deaths reported in 2021-2022. Significant progress in malaria control has been made through the implementation of various interventions, including the scale-up of community-based management of malaria to include adults. However, the diagnosis of malaria continues to be a challenge, with the accuracy of diagnosis at health facilities (microscopy), and community level (malaria rapid diagnostic tests (mRDT)) needing improvement. To improve the quality of malaria diagnosis, an external quality assessment/quality control (EQA/QC) was conducted in selected health facilities and at the community level in all the 30 Rwanda districts. At the community level, the EQA/QC of mRDT was performed by direct observation of community health workers (CHWs) performing the test. At the hospital level, assessment of the laboratory settings and microscopy procedure was done. Fifteen slides per hospital visited were selected and retested by eight WHO accredited malaria microscopists from Rwanda National Reference Laboratory. A total of 704 CHWs were observed. 92% of these were trained on mRDT testing, and the main steps of performing mRDTs were correctly followed in 95% of cases. A total of 42 hospitals were visited and 630 slides retested. Discrepancy from two observers for positive and negative results was 1.5%. Two hospitals exceeded the acceptable range of discrepancy. Over 80% of the laboratories assessed had adequate laboratory space, infrastructure and good quality supplies to undertake microscopy work.

The staining SOPs were followed in 88% of cases. Improvements are needed in accurately recording the opening date and validation of new Giemsa solution, regularly undertaking QC of health centers' blood films, and reporting parasites density for positive blood films. Overall, the EQA/QC identified areas that need improvement. Performance of mRDT by CHWs was good. However, continuous monitoring and evaluation of malaria diagnosis is crucial for appropriate treatment and referrals.

6077

THE TESTSMART TRIAL: RESULTS FROM A CLUSTER-RANDOMIZED TRIAL OF MALARIA DIAGNOSTIC TESTING AND CONDITIONAL SUBSIDIES TO TARGET ACTS IN THE RETAIL SECTOR IN KENYA AND NIGERIA

Theodoor Visser[1], George Ambani[2], Mark Amunga[2], David Arthur[3], Tabitha Chepkwony[2], Nwamaka Eze[1], Chizoba Fashanu[1], John Gallis[3], Elizabeth Garber[1], Emmah Kimachas[2], Joseph Kipkoech[2], Jeremiah Laktabai[4], Diana Menya[5], Pamela Mudabai[1], Oluwatosin Ogunsola[1], Tayo Olaleye[1], Wendy Prudhomme-O'Meara[3], Emily Robie[3], Indrani Saran[6], Elizabeth Turner[3], Meley Wohldegebriel[1], Aaron Woolsey[1], Yunji Zhou[3]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]Academic Model Providing Access to Healthcare, Moi University, Eldoret, Kenya, [3]Duke University, Durham, NC, United States, [4]College of Health Sciences, Moi University School of Medicine, Eldoret, Kenya, [5]College of Health Sciences, Moi University School of Public Health, Eldoret, Kenya, [6]School of Social Work, Boston College, Boston, MA, United States

We present the results from an innovative, multi-country cluster-randomized trial (CRT) designed to improve targeting of artemisinin combination therapies (ACT) to individuals with confirmed malaria infection who seek treatment in private medicine retailers (PMR). The majority of ACTs in sub-Saharan Africa are distributed through PMRs. Unnecessary consumption of ACTs purchased over the counter in PMRs is widespread due to their low price, high perceived efficacy, and absence of diagnostic tools to guide drug use. We hypothesized that creating price differentials through targeted ACT subsidies dependent on malaria testing status (untested, negative, positive) could improve targeting and use of ACTs among clients of PMRs. From January 2021 to February 2023, we tested a client-directed intervention in the form of a diagnosis-dependent ACT subsidy combined with a provider-directed incentive for testing against a comparison arm in 48 PMRs in Lagos, Nigeria and 39 in Bungoma and Transnzoia counties, Kenya. All PMRs were provided access to low-cost malaria rapid diagnostic tests (RDT) which they sold to clients who wished to purchase one. PMRs in the intervention arm received 0.1 USD for performing a RDT and were instructed to give a free ACT to any client with a positive test for which they were reimbursed. Information from 5695 clients in Kenya and 3879 in Nigeria was collected through exit interviews.Preliminary results show that the program substantially increased testing uptake in both arms relative to baseline, which in turn improved targeting of ACTs. For example, in Kenya, 67.8% of untested clients received an ACT, compared to 24.1% of malaria negative clients. However, the price differentials did not have an additional impact on test uptake or ACT consumption in the intervention arm compared to the control. These findings provide additional insight into point-of-care decision making for fevers and suggest that although RDTs can be integrated into PMR practices, client level subsidies may not be optimal for modifying purchasing decisions. We plan to present final and detailed findings from Kenya and Nigeria during the scientific session.

6078

IMPLEMENTATION OF TWO-STEP MALARIA RDT DETECTIONPFHRP2/PLDH COMBINING WITH POINT-OF-CARE TESTS FOR BACTERIAL INFECTIONS IN THE MANAGEMENT OF FEBRILE DISEASES IN CHILDREN UNDER-5 YEARS IN BURKINA FASO

Francois Kiemde

Institut de Recherche en Science de la Sante-Clinical Research Unit of Nanoro, Ouagadougou, Burkina Faso

In low and middle incomes countries (LMICs) such as sub-Saharan Africa (SSA), the management of febrile diseases remains challenging given the lack of practical diagnostic tools to screen the real cause of fever and the limits of malaria rapid diagnostic tests. In order to improve the management of febrile diseases in children under 5 years, this study has been conducted. The study was conducted at the Field Station of Sigle, set-up by the Clinical Research Unit of Nanoro (CRUN). All patients from 6-59 months attending the outpatient clinic of the health facility of Bologho in the health district of Nanoro (Burkina Faso), with documented fever or history of fever within the pass 7 days were invited to participate to the study. Participants were randomized either the intervention package (e-Algorithm or RDT-decisional algorithm arm(RDT-DA)) or routine system. The intervention package was constituted by the following PoC tests: two-step malaria RDT detection PfHRP2 and pLDH, CRP, white blood cells (WBC) count, oximetry, Group A Streptococcus, and Salmonella/Shigella. Antimalarial prescription was 42.05% (164/390) in e-Algorithm arm, 43.65% (172/394) in RDT-DA and 52.30% (232/392) in standard practice system [risk difference (RD): -10.25% (p p<0.001) for e-Algorithm and -8.65% (p<0.001) for RDT-DA). Antibiotics were prescribed in 46.92% (183/390) in e-Algorithm arm, 50.25% (198/394) in RDT-DA arm and 76.28% (299/392) in routine system [RD: -29.36% (p<0.001) for e-Algorithm and -26.03% (p<0.001) for RDT-DA]. The reduction of antibiotic prescription greater in children without malaria [RD:-64.79% (p<0.001) for e-Algorithm arm and -61.62% (p<0.001) for RDT-DA algorithm arm. In conclusion, implementation of two-step malaria RDT and PoC tests for bacterial infections has potential to improve the management of febrile diseases in children under 5 years and reduce inappropriate prescription of antibiotics. Nevertheless, the use of CRP test is not suitable differentiate bacterial to non-bacterial infections in children with malaria.

Relapses from latent liver-stage parasites (hypnozoites) are a key challenge for Plasmodium vivax elimination. Relapses are responsible for >80% of blood-stage infections. There are currently no tools to detect hypnozoites, but P. vivax blood-stage infections induce strong antibody responses arising quickly after infection and decaying slowly over time. Antibodies are thus markers of both current and recent past infections, allowing identification of people recently exposed to P. vivax and thus at risk of carrying hypnozoites. This study aimed to test the ability of antibody signatures to a validated set of 13 antigens to predict relapse risk in two cohorts of soldiers (n =

592) who returned to a malaria-free area from a 9-month deployment to a malaria-endemic area between 2018 and 2022. All soldiers were assessed by Luminex serology on the day of recruitment and followed actively every two weeks and at time of febrile symptoms until first recurrent P. vivax parasitaemia, for up to 6 months. An optimised machine learning Random Forest classification algorithm was used to classify soldiers as exposed during the previous 9 months. Over 110 soldiers experienced relapses during follow-up with significant heterogeneity in relapse risk between the two cohorts (Cohort 1: 25, Cohort 2: >85). Soldiers who relapsed had higher median antibody titers for most of the biomarkers compared to those who did not relapse. In cohort 1, our diagnostic tool had 75% sensitivity and 93% specificity at identifying future relapses using blood samples from recruitment day. Recurrent infections strongly boosted antibody titres both in sero-positive and initially sero-negative soldiers. Analyses of the 2nd cohort are ongoing but preliminary results indicate a comparable performance. This demonstrates the ability of serological markers to identify people at risk of relapse with high accuracy. In our presentation, we will present the final results across both cohorts and discuss the implications of these results for the development of a novel public health intervention P. vivax serological testing and treatment (PvSeroTAT) for relapse prevention.

THRESHOLD LIMITS OF DETECTION AND QUANTIFICATION OF MALARIA PARASITES IN DRIED BLOOD SPOT: A COMBINED APPROACH OF MID-INFRARED SPECTROSCOPY AND MACHINE LEARNING

Issa H. Mshani[1], Fredros Okumu[1], Frank Musa[1], Rehema Mwanga[2], Doreen Josen[1], Emmanuel P. Mwanga[1], Prisca Kweyamba[2], Simon A. Babayan[3], Francesco Baldini[3]

[1]Ifakara Health Institute, Morogoro, Tanzania, United Republic of, [2]Ifakara Health Institute, Bagamoyo, Tanzania, United Republic of, [3]University of Glasgow, Glasgow, United Kingdom

Mid-infrared spectroscopy (MIRS) combined with machine learning (ML) have shown potential in detecting malaria infections. The technique is reagent-free, simple to use and cost-effective, but its malaria parasite detection thresholds remain unknown. This study aims to investigate the lower limits of detection and quantification of MIRS-ML approaches under different hematocrit levels, including anemia, to further evaluate its potential for malaria control. The study was conducted at the Ifakara Health Institute laboratory in Tanzania. Blood samples were obtained from PCR-tested malaria-free individuals, and parasite cultures were performed using Plasmodium falciparum strains of NF54 and FCR3. Hematocrit ratios (50%, 25%, and 12.5%) and malaria parasitemia levels (6%, 0.1%, 0.002%, 0.00003%, and 0%) were created through two-way matrix serial dilutions. Dried blood spots were analysed using MIRS and ML classifiers and regressors to detect and quantify malaria parasites at different parasitemia levels and in the presence of anemia.We created two logistic regression models, one including only the highest parasitemia (6%) and negative control, and a second model that included all parasitemia levels. The first detected malaria infections at accuracy of 97%, 90%, and 90% for Normal (50%), mild (25%), and severe (12.5%) anemia, respectively. The second model was 100% accurate in detecting malaria infections at 6%, 0.00003% and negative control, but less accurate in detecting of 0.1% and 0.002% (>80% and >50%, respectively). When Support vector machine regressor were used in the analysis, this model outperformed other regression ML models, quantifying five-class malaria parasitemia with a Root Mean Square Error, RMSE = 0. MIRS-ML approaches can detect and quantify at low parasitemia (1-10 malaria parasites/µl of blood) with > 95% accuracy. Importantly, malaria parasite detection and quantification by MIRS-ML approaches were not affected by anemia. These initial findings indicate that MIRS-ML approaches could be valuable for detecting and quantifying malaria infections, particularly in resource-limited settings.

DETECTION OF PLASMODIUM MALARIAE AND PLASMODIUM KNOWLESI THROUGH IMPROVEMENTS IN MICROSCOPY SERVICES IN CAMBODIA

John Hustedt[1], Sokomar Nguon[1], Samphornarann Top[1], Setha Hor[1], Rida Slot[2], Saad El-Din Hassan[2], Virak Khieu[3], Ly Po[3], Rekol Huy[3], Tha Meas[3], Dysoley Lek[3], Siv Sovannaroth[3], Saing Samath[3], Man Somnang[3]

[1]University Research Co., LLC, Phnom Penh, Cambodia, [2]U.S. President's Malaria Initiative, USAID, Phnom Penh, Cambodia, [3]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

The primary method of malaria diagnosis in Cambodia is the use of Rapid Diagnostic Tests (RDTs), particularly outside hospitals. Currently available RDTs only detect Plasmodium falciparum (Pf) and P. vivax (Pv). P. malariae (Pm) and P. knowlesi (Pk) are detected primarily in research studies using molecular diagnostic tools. Training and support for microscopy diagnosis has recently taken place in six provinces managed by the Ministry of Health, with financial and technical support from USAID/PMI through the Cambodia Malaria Elimination Projects (CMEP and CMEP2) and the World Health Organization. This includes 5-day training courses on microscopy diagnosis and organization of national competency assessments for malaria microscopists to ensure quality diagnosis at the point of care. If patients test negative by RDT but malaria symptoms continue, then a blood smear is taken for microscopy. If the blood smear is positive for Pm/Pk, a blood smear and dried blood spot are taken for confirmation at the National Center for Parasitology, Entomology and Malaria Control (CNM) through both microscopy and polymerase chain reaction (PCR). This investment has led to a corresponding rise in Pm and Pk cases diagnosed through routine CMEP2-supported activities from zero to 58 (Jan 2021-Feb 2023). Slide confirmation by CNM through microscopy examination classified 50 cases as Pm, six as Pk, and two were not definitive. PCR is used as it can be difficult to differentiate between Pm/Pk by microscopy. The PCR results showed that 42 cases were confirmed as Pm, nine as Pk, one as Pf/Pm and six were not definitive. The majority (79%, n=58) of these cases occurred during the rainy season (May-Oct 2022). These results suggest there is likely ongoing Pm/Pk transmission that is undetected in areas without microscopy services in Cambodia. Microscopy services at health centers remain limited and updates to the suspected case definition may be needed to ensure all Pm/Pk infected patents are tested. As Cambodia is aiming for the elimination of all human malaria species by 2025, introducing and sustaining quality microscopy will be essential to detect all forms of malaria species.

6082

LOW PREVALENCE OF PLASMODIUM FALCIPARUM HISTIDINE-RICH PROTEIN 2 AND 3 GENE DELETIONS—A MULTIREGIONAL STUDY IN CENTRAL AND WEST AFRICA

Tina Krueger[1], **Moses N. Ikegbunam**[2], Abel Lissom[3], Thaisa Lucas Sandri[1], Jacques D. Ntabi[3], Jean C. Djontu[3], Marcel T. Baina[3], Roméo A. Lontchi[4], Moustapha A. Maloum[4], Givina Z. [1]Institute for Tropical Medicine, Tübingen, Germany, [2]Nnamdi Azikiwe University, Awka, Nigeria, [3]Fondation Congolaise pour la Recherche Médicale,, Brazzaville, Congo, Republic of the, [4]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, [5]Fondation Pour la Recherche Scientifique (FORS), ISBA, Cotonou, Benin, [6]Tropical Infectious Diseases Research Centre (TIDRC), University of Abomey-Calavi, Cotonou, Benin

Treatment of malaria parasite-infected individuals and the effectiveness of malarial control efforts may be compromised by Plasmodium falciparum parasites with deletions of P. falciparum histidine-rich protein 2 (PFHRP2) and pfhrp3 genes because such parasites may not be detected by PfHRP2-based rapid diagnostic tests (RDTs). Here, we assessed the frequency of parasites with pfhrp2 and pfhrp3 deletions at four different

study sites: Gabon and Republic of Congo in Central Africa and Nigeria and Benin in West Africa. Using a highly sensitive multiplex qPCR (4plex qPCR), we analysed 534 samples from Gabon, 917 from the Republic of Congo, 466 from Nigeria, and 120 from Benin. Low prevalences of single deletions in pfhrp2 (ranging from 0% to 1%) and pfhrp3 (ranging from 0% to 0.03%) were observed across all study sites, namely Gabon, Republic of Congo, Nigeria, and Benin. In addition, P. falciparum parasites with two deletions were found exclusively in Nigeria, accounting for 1.6% of all samples that were analysed. Thus, our pilot investigation suggests that, currently in Central and West Africa, there is a low risk for false-negative RDT results caused by deleted pfhrp2/pfhrp3 genes. However, continuous, and comprehensive monitoring is warranted to detect any (potentially fast) changes in this status and to make sure that RDTs continue to be an appropriate method for monitoring and diagnosing malaria in these regions.

6083

HIGH PREVALENCE OF PLASMODIUM FALCIPARUM HRPII-DELETED VARIANTS ASSOCIATED WITH LOW RAPID DIAGNOSTIC EFFICACY 13 YEARS AFTER INTRODUCTION OF MALARIA RDTS IN EASTERN ZIMBABWE

Sungano Mharakurwa[1], Tanatswa Xuxa Gara-Mundere[1], Trust Nyakunu[1], Brenda Makonyere[1], Tariro Chikava[1], Natasha Mbwana[1], Charmaine Matimba[1], Nobert Mudare[1], Shungu Munyati[1], Munyaradzi Mukuzunga[1], Lovemore Gwanzura[1], Tamaki J. Kobayashi[2], Jeffrey Bailey[3], William J. Moss[2]

[1]Africa University, MUTARE, Zimbabwe, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Brown University, Providence, RI, United States

Malaria has receded from most of Zimbabwe over the past decade following scaled-up vector control and artemisinin-based combination therapy (ACT) interventions for possible elimination of the disease. The advent of Plasmodium falciparum histidine-rich protein II (PfHRPII)-based rapid diagnostic tests (RDTs) and ACTs at inception of the 21st millennium ushered in a new era of complementary test-and-treat campaigns to accelerate towards malaria elimination, including mandatory RDT confirmation of clinical cases before the administration of ACT. However, the emergence of PfHRPII-deleted parasite variants is undermining RDT accuracy and posing a growing threat to prompt/effective testing and treatment for malaria control and elimination. We examined P. falciparum HRP-II RDT diagnostic performance on 1,125 presenting febrile suspected malaria cases using microscopy as gold standard. We report poor RDT efficacy on the presenting febrile cases, at 49% sensitivity, highly associated with rampant (61%) PfHRPII-deleted malaria parasite variants (OR [95%CI]: 14 [6.6 - 29.6], n = 331) 13 years after introduction of RDTs in Mutasa, Zimbabwe. Our data show ten-fold higher odds (OR [95%CI]: 10 [3.2 - 31.0]) of PfHRPII-deleted variants among malaria cases of 2021 compared to 2004 (pre-RDT introduction). RDT false-negative rate correspondingly increased from baseline 9% to 51%, suggesting formidable parasite adaptation to RDT use. Akin to the Horn of Africa our study is concerning for emergence of diagnostic resistant parasites in Southern Africa that may undermine regional elimination efforts.

6084

A DIGITAL MICROSCOPE FOR THE DIAGNOSIS OF PLASMODIUM FALCIPARUM PARASITES WITH HRP2 AND HRP3 DELETION AND P. VIVAX

Yalemwork Ewnetu[1], Lise Carlier[2], Claudia A. Vera Arias[3], Jieun Shin[2], Chae Yun Bae[2], Hyun Cher Youm[2], Nega Berhane[1], Wossenseged Lemma[1], Soyeon Yi[2], **Cristian Koepfli**[3]

[1]Gondar University, Gondar, Ethiopia, [2]Noul Inc., Seoul, Korea, Republic of, [3]University of Notre Dame, Notre Dame, IN, United States

The most frequent and most sensitive class of rapid tests for Plasmodium falciparum diagnosis rely on detection of the HRP2 and HRP3 proteins. Deletions of the hrp2/3 genes are a major concern and where the frequency of the deletion is high, alternative diagnostic tools are needed. The Noul miLab is a portable digital microscope for malaria diagnosis. The miLab conducts smear preparation from a droplet of blood, staining, and imaging. An algorithm detects infected RBCs, and displays them on a screen. Time-to-result is approximately 20 minutes, with less than two minutes hands-on time. We evaluated the miLab among 659 febrile patients in Gondar, Ethiopia, where co-transmission of P. falciparum and P. vivax, and high frequency of hrp2/3 deletions make diagnosis challenging. By qPCR, 76.2% of patients tested positive; 40.4% for P. falciparum, 12.3% for P. vivax, and 23.8% with mixed infection. 34.7% of P. falciparum infections carried hrp2 deletion, and 91.5% hrp3 deletion. The miLab diagnosed 51/52 (98%) of P. falciparum infections with hrp2 deletion at densities >20 parasites/µL. The sensitivity of the miLab for P. falciparum at densities >200 parasites/µL (as determined by qPCR) was 93.6%, and 90.2% at densities >20 parasites/µL. The miLab was more sensitive than an LDH-based RDT and local microscopy with sensitivities of 80.3% and 82.1% at densities >20 parasites/µL. For P. vivax, the sensitivity of the miLab was 83.9% at densities >200 parasites/µL, and 82.7% at densities >20 parasites/µL (RDT: 64.4%, microscopy: 56.7%). Specificity of the miLab was 84.5%. At densities >20 parasites/µL, the miLab misclassified 4/100 P. falciparum mono-infections as P. vivax, and 4/36 P. vivax mono-infections as P. falciparum. Further, it identified only 5/23 mixed infections correctly. In conclusion, the Noul miLab is more sensitive than microscopy and thus a valuable addition to the toolkit for malaria diagnosis in particular in areas with high frequencies of hrp2/3 deletions. Incorrect diagnosis of species and low sensitivity for mixed-species infections are currently being addressed through updates to the algorithm.

6085

FITNESS COST OF PFHRP2/3 GENE DELETION & K13 R622I MUTATION IN NATURAL INFECTIONS IN ETHIOPIA: TRANSMISSION POTENTIAL OF PARASITES EVALUATED BY DIRECT MEMBRANE FEEDING ASSAYS

Ayalew Jejaw Zeleke[1], Migbaru K. Bezabih[2], Wakweya Chali[2], Lina Alemayehu[2], Melat Abdo[2], Abrham Gashaw[2], Adisu Gizat[2], Desalegn Nibrat[2], Sinknesh Wolde[2], Legesse Alamerie[2], Fikregabrail Aberra Kassa[2], Asrat Hailu Mekuria[3], Mulugeta Aemero[1], Fitsum Girma Tadesse[2]

[1]University of Gondar, Gondar, Ethiopia, [2]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [3]Addis Ababa University, Addis Ababa, Ethiopia

Parasites with pfhrp2/3 gene deletions are fast spreading, especially in the Horn of Africa. Its unique heterogeneous spatial distribution is also evident at lower scales. In our previous studies, we confirmed its co-occurrence with parasites carrying the R622I kelch mutation. From Sept 2022 - March 2023, we examined the transmissibility of P. falciparum parasites with & without pfhrp2/3 gene deletion to colony-maintained An. arabiensis mosquitoes (n=5290) in direct membrane feeding assays (DMFA) in Ethiopia. A total of 182 microscopy positive patients were screened & 53% had negative result using HRP2-based RDT. They had pfhrp2 (88%, 83/94) & pfhrp3 (95%, 89/94) gene deletion by digital PCR. The median HRP2 antigen concentration (multiplex bead-based assay) was higher in the RDT positive (1,060pg/mL; IQR 675-1284; p=0.001) than RDT negative samples (10; IQR 9-16). Transmissibility of parasites with pfhrp2 deletion was higher (80%, 20/25) than without deletion (70%, 19/27). Overall, 47% of mosquitoes were infected with no difference between the two groups. The oocyst density in infected mosquitoes was higher in parasite without deletion (median 13, IQR 4-53) than with gene deletion (4, 2-17; p=0.082). Infectivity to mosquitoes was strongly associated with total parasite by 18S based qPCR (ρ=0.376, p=0.006) & male (ρ=0.381, p=0.006) & female (ρ=0.375, p=0.007) gametocyte densities measured by sex specific RT-qPCR. These were not different between pfhrp2 deleted & undeleted parasites. In conclusion, the overall prevalence of pfhrp2 (50%, 89/179) & pfhrp3 (90%, 161/179) deletion substantially increased in this study compared to our previous study in 2021. Parasites with pfhrp2 deletion were as transmissible to mosquitoes as wild type parasites. Currently, we are analyzing sequence results from the amplicon NGS to examine the association of drug resistance markers such as R622I with the above

outcomes. Based on our previous study, the frequency of R622I mutation was high in the same area (49%). We are also collecting more samples & doing extra DMFAs to boost the observation in the short transmission season (April-May 2023).

PERCEPTIONS OF FACILITY-BASED AND COMMUNITY HEALTH WORKERS IN KENYA: IMPLICATIONS FOR PROGRAMS BASED ON FINDINGS FROM THE KENYA MALARIA BEHAVIOR SURVEY

Zoe M. Hendrickson[1], Elvis Oyugi[2], Jacinta Opondo[2], Daniel Wacira[3], Joseph Millward[1], James Andati[4], Jayme Hughes[1], Grace Miheso[4], Jennifer Boyle[1], Anna McCartney-Melstad[1], Carol Underwood[1]

[1]Breakthrough ACTION Project, Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [2]Division of National Malaria Programme, Ministry of Health, Nairobi, Kenya, [3]U.S. President's Malaria Initiative, USAID, Nairobi, Kenya, [4]Breakthrough ACTION Project, Johns Hopkins Center for Communication Programs, Nairobi, Kenya

Facility-based health workers and community health volunteers (CHVs) play essential roles in malaria prevention and treatment. Community perceptions of health workers, however, remain under-examined in Kenya. In 2022, Kenya's Division of National Malaria Program (DNMP) and Breakthrough ACTION Kenya implemented the Malaria Behavior Survey in the malaria-endemic Lake region of Western Kenya. 1,787 women and 466 male partners participated from 1,456 households. Descriptive and bivariate analyses assessed differences in community perceptions of health workers by socio-demographic characteristics. Perceptions of health workers were also key covariates in multivariable logistic regression models of prompt and appropriate care-seeking for fever. Favorable perceptions were based on agreement with statements about facility-based health workers and CHVs overall and for case management. Scores were summarized and dichotomized for analysis. Most respondents reported overall favorable perceptions of facility-based health workers (95%) and CHVs (82%). Favorable perceptions of both types of health workers were significantly higher among female than male respondents. 61% of respondents had favorable perceptions of CHVs regarding malaria care-seeking and treatment in particular, and this varied significantly by respondent sex (female: 64% vs. men: 57%; p<0.01). 43% and 50%, respectively, of respondents perceived that CHVs always have 1) medication to treat malaria and 2) rapid diagnostic test kits to see if a person has malaria. Caregivers reporting favorable perceptions of CHVs had 1.9 times increased odds of reporting prompt and appropriate care-seeking for a child under five who had a fever in the past two weeks (AOR: 1.9; 95% CI: 1.1-3.4). The associations between CHV perceptions and care-seeking are cross-sectional yet suggest that service delivery and social and behavior change programs can improve perceptions of the quality of care and trustworthiness of CHVs. Perceptions that CHVs do not have supplies they need could be addressed by correcting supply issues and subsequently assuring communities that supplies are available.

6087

A NOVEL HUMANIZED MURINE MODEL TO ASSESS PRIMAQUINE-INDUCED HEMOLYSIS IN G6PD DEFICIENCY

Karolina H. Dziewulska, Ariel M. Hay, **James C. Zimring**

University of Virginia, Charlottesville, VA, United States

Approximately half a billion humans have some form of glucose-6-phosphate dehydrogenase deficiency (G6PDd), limiting the ability to safely achieve radical cure of Plasmodium vivax using primaquine or tafenoquine due to risk of hemolysis. Because most G6PDd is caused by an unstable enzyme variant, very young RBCs have increased G6PD activity and are resistant to hemolysis. As such, primaquine can have a "self-limiting" character if given in regimens that promote controlled early hemolysis and reticulocytosis. Accordingly, modified primaquine regimens have the potential to be both safe and effective in G6PDd patients. Historically, there has been no mouse model of G6PDd that recapitulates an RBC age-dependent gradient of G6PD activity, limiting testing of primaquine dosing strategies. We report the generation of two new strains of mice in which the murine G6PD gene was replaced with either the (A-) deficient or non-deficient (ND) human genomic DNA. RBC G6PD activity and protein levels were measured by spectrophotometric assay and Western blot, respectively. In vivo biotinylation pulse chase was used to visualize "young RBCs" from 1-6 days of age, which were isolated by streptavidin-coated magnetic bead depletion. "All age" RBCs from A- mice had 12.8% normal G6PD activity (p<0.0001) and only trace amounts of G6PD protein. In contrast, 1-6 day old A- RBCs had 56% normal G6DP activity and easily detectable G6PD protein. qPCR showed no difference in G6PD mRNA in bone marrow from A- and ND mice. After 4 days of primaquine challenge (50mg/kg/day), A- mice had a 17% drop in hematocrit compared with ND mice (p<0.001). A- mice also had increased reticulocytes (14.5%) compared to ND mice (4.9%) (n=12, p=<0.0001). Essentially 100% of cleared RBCs were older than 6 days. RBCs from ND mice had normal G6PD activity and protein, with only subtle effects of primaquine challenge. 3 out of 3 primaquine challenge experiments had similar results. While great care must be taken in translation of therapeutic details from mice to humans, the newly described mice serve as a tractable platform to test general primaquine dosing strategies.

6088

PREDICTING OPTIMAL ANTIMALARIAL DRUG COMBINATIONS FROM A STANDARDIZED PLASMODIUM FALCIPARUM HUMANIZED MOUSE MODEL

Claudia Demarta-Gatsi[1], Nicole Andenmatten[1], María-Belén Jiménez-Díaz[2], Nathalie Gobeau[1], Mohammed H. Cherkaoui-Rabti[1], Aline Fuchs[1], Pablo Diaz[2], Sandra Berja[2], Rebeca Sanchez[2], Hazel Gomez[2], Estibaliz Ruiz[2], Paula Sainz[2], Eider Salazar[2], Rodrigo Gil-Merino[2], Luis Manuel Mendoza[2], Cristina Eguizabal[3], Didier Leroy[1], Joerg J Moehrle[1], Belen Tornesi[1], **Leyre Pernaute-Lau**[2], Iñigo Angulo-Barturen[2]

[1]Medicines for Malaria Venture, Geneva, Switzerland, [2]The Art of Discovery, Derio, Spain, [3]Biocruces Bizkaia Health Research Institute, Barakaldo, Spain

The development of new combinations of antimalarial drugs is urgently needed to prevent the spread of parasites resistant to drugs in clinical use and contribute to the control and eradication of malaria. In this work, we evaluated a standardized humanized mouse model of erythrocyte asexual stages of Plasmodium falciparum (PfalcHuMouse) for the selection of optimal drug combinations. Firstly, we showed that the replication of P. falciparum was robust and highly reproducible in the PfalcHuMouse model by retrospective analysis of historical data. Secondly, we compared the relative value of parasite clearance from blood, parasite regrowth after suboptimal treatment (recrudescence), and cure as variables of therapeutic response to measure the contribution of partner drugs to combinations in vivo. To address the comparison, we first formalized and validated the day of recrudescence (DoR) as a new variable and found that there was a log linear relationship with the number of 46 viable parasites per mouse. Then, using historical data on monotherapy and two small cohorts of PfalcHuMice evaluated with ferroquine plus artefenomel or piperaquine plus artefenomel, we found that only measurements of parasite killing, (i.e., cure of mice) as a function of drug exposure in blood allowed direct estimation of the individual drug contribution to efficacy by using multivariate statistical modelling and intuitive graphic displays. Overall, the analysis of parasite killing in the PfalcHuMouse model is a unique and robust experimental in vivo tool to inform the selection of optimal combinations by pharmacometric PK/PD modelling.

6089

MODELLING THE HAEM DETOXIFICATION PATHWAY IN PLASMODIUM FALCIPARUM TO AID IN TARGET DECONVOLUTION AND MECHANISM OF ACTION STUDIES

Larnelle Faye Garnie[1], Kathryn Jean Wicht[2], Timothy John Egan[1]

[1]University of Cape Town, Cape Town, South Africa, [2]Holistic Drug Discovery and Development (H3D), University of Cape Town, Cape Town, South Africa

The parasite Plasmodium falciparum (Pf) causes the deadliest form of malaria. Critical to parasite survival is the haem detoxification pathway. This biochemical pathway, which occurs in the parasite digestive vacuole (DV), results in the digestion of haemoglobin (Hb) and subsequent formation of an inert crystal, haemozoin (Hz). Disruption of this pathway is an attractive antimalarial target as it includes numerous biophysical and biochemical targets such as protease enzymes, endocytosis mediators, transporters and molecules required for Hz. Incorporating these parameters and others into a mathematical model would aid in mode of action studies and may inform rational drug design. Numerous parameters are imperative for model development. In the current study, the volume of the DV lumen and the rate of Hb uptake were found to be crucial to the model, and were studied herein using confocal microscopy techniques. Validation of the model, by way of pathway perturbation, was studied using a cellular fractionation assay that assessed the impact of inhibitory chemotypes on the levels of Hb, free haem and Hz. To study the lumen volume, red blood cells pre-loaded with pHrodo™ dextran beads were incubated with Pf trophozoites to allow reinvasion. Following incubation, individual parasites were visualised with an Airyscan LSM 980 confocal microscope and image processing was carried out using ImageJ. These studies revealed that lumen growth in NF54 followed a Gompertz growth curve, while Dd2 followed a sigmoidal growth trend. We also examined differences in lumen volume of other Pf strains with a varying degree of sensitivity to piperaquine. Finally, parasites were treated with a set of endocytosis and protease inhibitors to perturb the pathway. Using cellular fractionation assays, treatment with butanedione-2,3 monoxime (an endocytosis inhibitor) caused a decrease in the levels of haem and Hz; whereas E-64 (cysteine protease inhibitor) caused a dramatic increase in the levels of undigested Hb and a subsequent decrease in the levels of Hz. These mechanistic studies help define haem perturbation properties characteristic of various inhibitor classes.

6090

THE ACTIVITY OF NOVEL SLOW-ACTION ANTIPLASMODIAL 1,3,4-OXADIAZOLES IS ASSOCIATED WITH A PLASMODIUM FALCIPARUM PALMITOYLTRANSFERASE

Katherine T. Andrews

Griffith University, Nathan, Australia

New chemoprevention drugs are needed to help protect vulnerable populations in areas of high malaria endemicity as we move towards eradication. We have identified novel N,N-dialkyl-5-alkylsulfonyl-1,3,4-oxadiazol-2-amines as a new antiplasmodial chemotype with a different action to delayed-death slow-action drugs like clindamycin. Structure activity relationship analysis of >60 analogues identified multiple compounds with potent activity against drug-sensitive and drug resistant asexual stage Plasmodium falciparum parasites (IC50 <40 nM) and >2,500 selectivity for P. falciparum versus human cells. Genome sequencing of P. falciparum parasites selected for in vitro resistance to representative members of this series identified mutations in a palmitoyltransferase gene. This phenotype was confirmed using CRISPR/Cas9 mediated gene editing. Further studies are underway to investigate whether this P. falciparum palmitoyltransferase is the target of slow action 1,3,4-oxadiazoles and thus a new chemoprotection drug target, or alternatively, a mechanism of resistance to these compounds.

6091

A SYSTEMS BIOLOGY APPROACH TO UNDERSTAND THE MECHANISMS OF ACTION OF KALIHINOL, A POTENT NEW ANTIMALARIAL

Zeinab Chahine[1], Jacques Prudhomme[1], Steven Abel[1], I. Renard[2], JH Chun[3], Mary Beth Daub[3], JY Choi JY[2], V. Pratap[2], A. Pal[2], J. Kirkwood[1], Anita Saraf[4], Charles Banks[4], P. Castaneda[5], MC Cuevas[5], J. De Mercado-Arnanz[5], E. Fernandez-Alvaro[5], A. Garcia-Perez[5], N. Ibarz[5], S. Viera-Morilla[5], A. K. Bei[6], Laurence Florens[4], Choukri Ben Mamoun[2], Christopher D. Vanderwal[7], **Karine G. Le Roch**[1]

The Kalihinol analogues belong to the Isocyanoterpenes (ICT) family of chemical compounds. ICTs have been shown to have potent activity against multiple microbial pathogens including the human malaria parasite Plasmodium falciparum. Our work shows that the kalihinol derivative retains its potency against both drug-sensitive and -resistant parasites with IC50 values in the low nM range. This activity translates into transmission-blocking potential, as the compound inhibit sexual differentiation in vitro. Through phenotypic analyses and cell biological assays we demonstrate that the apicoplast is one of the sites of action of the drug in the P. falciparum-infected red blood cell. Drug-drug interaction studies as well as chemical rescue using isopentenyl pyrophosphate (IPP) confirmed that one Kalihinol analogue exerts its antimalarial activity through alteration of apicoplast metabolic processes. We also confirm, through metabolomic profiling and drug-protein interactions assays, that our analogue interacts with several proteins involved in apicoplast membrane biogenesis and lipid trafficking. Prolonged drug pressure assay followed by whole genome sequencing and CRISPR-cas9 genome editing, identify the mode of resistance acquired via the vesicular trafficking system. In vivo studies in humanized mice model demonstrate that Kalihinol analogues suppress P. falciparum growth with good pharmacokinetic and safety properties. We also confirmed the efficacy of the compound against P. knowlesi growth. Altogether our multi-omics approach not only unraveled a novel of mode of action for an antimalarial, but also mechanism involved in drug resistance. The unique properties of this class of antimalarials, their high potency, excellent therapeutic profile, and the limited capacity of the parasite to mount resistance make them ideal compounds to further develop as a potential next generation of drugs for the treatment and elimination of malaria infection.

6092

EVALUATION OF THE IN VITRO GAMETOCYTOCIDAL ACTIVITY OF TAFENOQUINE IN COMBINATIONS WITH METHYLENE BLUE AND OTHER ANTIMALARIAL COMPOUNDSTAFENOQUINE IN COMBINATIONS WITH METHYLENE BLUE AND OTHER ANTIMALARIAL COMPOUNDS

Jye A. Travis[1], Kerryn Rowcliffe[2], Luke W. Guddat[1], Christopher J. Parkinson[3], Richard K. Haynes[3], G. Dennis Shanks[2], Michael D. Edstein[2], Marina Chavchich[2]

[1]University of Queensland, Brisbane, Australia, [2]Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia, [3]Charles Sturt University, Orange, Australia

Resistance to artemisinin-based combinations in Southeast Asia is jeopardizing malaria control and elimination efforts. There is an urgent need for new antimalarial drugs, especially those with potent gametocytocidal properties to reduce malaria transmission. Tafenoquine (TQ) possesses hypnozoitocidal, but poor blood schizontocidal and gametocytocidal properties. Ideally, TQ should be used in combination with a partner drug with strong schizontocidal and gametocytocidal activities. We have

previously shown MB to synergise the in vitro blood schizontocidal activity of TQ. In the present study, we evaluated in vitro gametocytocidal activity of TQ in combinations with antimalarial drugs including chloroquine (CQ), dihydroartemisinin (DHA), lumefantrine (LUM), piperaquine (PPQ), pyronaridine (PRN), methylene blue (MB) and 10-aminoartemisinins compounds, artemiside and artemisone, with potent blood schizontocidal and gametocytocidal activities. Plasmodium falciparum 3D7c gametocyte viability was assessed by measuring adenosine triphosphate (ATP) production. TQ inhibited ATP production in stage II-III and stage IV-V gametocytes with IC50 values of 2,453 ± 1,054 nM and 3,616 ± 1,360 nM, respectively, whereas MB was highly active against stage II-III and stage IV-V gametocytes with IC50 values of 27.7 ± 6.5 nM and 50.9 ± 24.5 nM, respectively. Addition of MB synergised the gametocytocidal activity of TQ against stage II-III gametocytes with summary fractional inhibitory concentrations (ΣFIC) of 0.52-0.73, but was mildly antagonistic against stage IV-V gametocytes with ΣFIC of 1.37-1.60. TQ-DHA and TQ-artemisone combinations were additive against early and late stage gametocytes, while TQ-artemiside was mildly antagonistic with ΣFIC of 1.09-1.33 and 1.99-2.30 against stage early and late stage gametocytes, respectively. Addition of CQ, PPQ, LUM and PRN at fixed concentrations corresponding to their maximum physiologically achievable concentrations to TQ had no significant effect on gametocytocidal activity of TQ. Our data suggest that MB can be considered as a potential partner drug with TQ for malaria elimination.

A FIRST-IN-HUMAN SAFETY, TOLERABILITY, AND PHARMACOKINETICS STUDY OF MMV367, A NEW CANDIDATE ANTI-MALARIAL AGENT FOR ACUTE UNCOMPLICATED MALARIA

Andrea Kümmerle[1], Laura Sanz[2], Denis Gossen[1], Annick Janin[1], Raman Sharma[3], Tony Cahn[3], Rachel A. Gibson[3], Som Menakuru[4], Erin Lambourne[4], Tom Dove[4], Francisco-Javier Gamo[2], Nand Singh[4], Benoit Bestgen[1], **Stephan Chalon**[1]

[1]Medicines for Malaria Venture, Geneva, Switzerland, [2]GSK Global Health Medicines R&D, Tres Cantos, Spain, [3]GSK Pharmaceuticals, Stevenage, United Kingdom, [4]Quotient Sciences, Nottingham, United Kingdom

MMV367 is a first in class, fast acting, pyrrolidinamide blood stage inhibitor of Plasmodium falciparum co-developed by MMV and GSK with an anticipated novel antimalarial mechanism for treatment of acute uncomplicated P. falciparum malaria. It is highly active against mutant and resistant strains including field isolates, demonstrating absence of cross resistance. This FIH study sponsored by MMV (NCT05507970) evaluated the safety, tolerability, and PK of MMV367 in 47 healthy male and female volunteers. Part 1 was double-blind randomised, placebo (Pbo)-controlled with 4 sequential fasted cohorts (6 active and 2 Pbo, each) receiving a single, ascending dose of 100, 300, 750 and 1500 mg. Part 2 was an open-label, crossover, fed-fasted cohort (n=8) dosed with 440 mg. 400 mg QD for 3 days was tested in Part 3 (6 active and 2 Pbo). At the writing of this abstract, the study is completed, and data are still blinded. Unblinded study results will be presented. No serious or severe adverse events were reported. 14 treatment emergent adverse events (TEAEs) - all causality - were observed. 2 mild TEAEs (abdominal pain - epigastric pain) reported by the same participant in the 750 mg cohort, were judged as IMP-related. No other IMP-related TEAEs, clinically relevant ECG, vital signs or laboratory tests changes were reported. Cmax values were achieved 2 - 4 h post-dose in Part 1. MMV367 mean t½ values across cohorts ranged from 16.3 to17.5 h. Compared to the fasted state, geometric mean relative bioavailability after a high fat meal based on Cmax, AUC0-last and AUC0-inf were 161, 133 and 133%, respectively. Median Tmax were 3.5h (fasted) and 5h (fed) post-dose. Accumulation ratio after 3-day QD dosing was 2-fold. MMV367 demonstrated safety, tolerability and PK warranting further clinical development. This new candidate will be further tested against induced blood-stage malaria in healthy participants to provide a PK-PD model supporting Phase 2 study design.

6094

EFFICACY OF PRAZIQUANTEL FOR TREATMENT OF PLASMODIUM FALCIPARUM INFECTION IN ASYMPTOMATIC GABONESE ADULTS

Johannes Mischlinger[1], Klara Pechmann[1], Alex Hounmenou Zisou[2], Wilfrid Nzebe Ndoumba[2], Ayola Akim Adegnika[2], Peter G. Kremsner[3], Andrea Kreidenweiss[3], Francisca Sarpong[1], Lidwine Badjina[1], Michael Ramharter[1], Ghyslain Mombo-Ngoma[2]

[1]Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, [3]Institute of Tropical Medicine, Tübingen, Germany

To date praziquantel (PZQ) is the only licensed drug for the treatment of schistosomiasis. Also, there is preliminary evidence that PZQ may have an effect on Plasmodium parasites. This potential effect was assessed by the CORMA-MAL study, a phase 2a, single-center, randomized, blinded, placebo-controlled trial recruiting semi-immune, Gabonese adults with an asymptomatic Plasmodium falciparum parasitemia ranging from 200 to 5000 parasites/µl. PZQ was administered once daily as 40mg/kg dosage for three days (D0, D1, D2); Placebo was administered also once daily for three days. An effective antimalarial treatment was given to all participants at the end of study on D7, as well as to those reaching pre-defined rescue treatment criteria. Recruitment and follow-up of all 44 study participants was completed in February 2023 and the first preliminary results are presented here. 14% (3/22) of participants in the Placebo arm needed to receive the rescue treatment versus 5% (1/22) in the PZQ arm (p=0.29). The median (IQR) parasite reduction in the PZQ arm was 87% (0% to 99%) on D3 compared with 36% (-193% to 58%) in the Placebo arm (p=0.037) and 93% (45% to 100%) versus 68% (-228% to 100%), respectively on D7 (p=0.2). Linear regression models indicate a significant hourly decrease of log10(parasitemia) between D0 and D7 in the PZQ arm (y= -0.006*x + 2.4; p<0.0001), while there was a non-significant trend of decreasing log10(parasitemia) in the Placebo arm (y= -0.0018*x + 2.3; p=0.16). Out of 22 participants in the Placebo arm there were 3 (14%) participants with microscopic parasite clearance, compared with 7 (32%) out of 22 in the PZQ arm (log-rank test p=0.15). Computing the area under the curve (AUC) of log10(parasitemia) between D0 and D7 indicated that total parasite mass was lower in the PZQ arm (Mean AUC: 335) than in the Placebo arm (Mean AUC: 415), although not significantly (p=0.12). Concluding, preliminary data indicate some anti-plasmodial activity of PZQ in comparison to Placebo, however, further research is needed.

6095

ETHIOPIAN PLASMODIUM VIVAX HYPNOZOITES FOR MATION DYNAMICS AND THEIR SUSCEPTIBILITY TO REFERENCE ANTIMALARIAL DRUGS

Fanta Sogore, Ousmaila Diakite, Abdoulaye Djimde, Laurent Dembele

MRTC-Parasitology/USTTB, Bamako, Mali

One of the key obstacles to malaria elimination is largely attributed to Plasmodium vivax's ability to form resilient hypnozoites in the host liver that cause relapsing infections. As a result, interruption of P. vivax transmission is difficult. P. vivax transmission occurs in Duffy-positive individuals and have been mainly thought to be absent in Africa. However, increasing studies using molecular tools detected P. vivax among Duffy-negative individuals in various African countries. Studies on the African P. vivax has been severely limited because most of malaria control program focus mainly on falciparum malaria. In addition, there is a scarcity of laboratory infrastructures to overcome the biological obstacles posed by P. vivax. Herein, we established field transmission of Ethiopian P. vivax for routine sporozoite supply followed by liver stage infection in Mali. Furthermore, we evaluated local P. vivax hypnozoites and schizonts susceptibilities to reference antimalarial drugs. The study enabled the assessment of local African P. vivax hypnozoite production dynamics. Our data displayed the ability of the African P. vivax to produce hypnozoite forms ex vivo at different rates per field isolate. We report that while tafenoquine (1µM) potently inhibited both hypnozoites and

schizont forms; atovaquone (0.25μM) and the phosphatidylinositol-4-OH kinase (PI4K)-specific inhibitor KDU691 (0.5μM) showed no activity against hypnozoites forms. Unlike hypnozoites forms, P. vivax schizont stages were fully susceptible to both atovaquone (0.25μM) and the (PI4K)-specific inhibitor KDU691 (0.5μM). Together, the data revealed the importance of the local platform for further biological investigation and implementation of drug discovery program on the African P. vivax clinical isolates

Malaria control relies on treatment with effective antimalarials. Although artemisinin (ART) combination therapies (ACTs) are currently the first line of treatment for Plasmodium falciparum (P.f.). As part of identifying specific inhibitors and novel targets essential for P.f survival, we focus on histone deacetylase 1 protein (PF3D7_0925700, PfHDAC-1) as a potential protein target. To identify hits from natural compound libraries potentially able to block PfHDAC1, we performed CADD based screening of n=135,335. These screening efforts identified commonly found tricyclic diterpenes/ terpenoid compounds. The hit library was negatively screened against human HDAC proteins. Methyl grevillate (MetG) among others was found to the top interacting compound with PfHDAC1 and had no binding affinity with human orthologue. MD simulation studies were conducted to validate the top hits, MetG had an energy score of -56.32. The MetG along with other top compounds were tested against erythrocytic stages which showed IC50 of 35.298±2.63 nM. Enzymatic validation assay revealed that MetG specifically blocks with inhibition curve fitting on competitive inhibitor models. In-vitro antiplasmodial efficacy testing of MetG in asexual stages confirmed its potent activity against both PfD6 (CQ-sensitive) and PfW2 (CQ-resistant) parasites. Anti-gametocidal evaluation showed distorted morphological changes in the nucleus of the RBC-dwelling parasites. Further testing in mice models of P. berghei blood stage and liver-stage malaria, showed in-vivo inhibitory activities. Most importantly, the evaluation using field isolates from clinical samples showed equally effective inhibition with IC50 of 198.45±6.1 nM. In addition, cytotoxicity testing showed negligible toxicity with 100x the IC50 in PBMCs, HEK293 and Huh 7.1. Notably, MetG was active against the pathogenic liver stage of the malaria parasite with IC50 of 78.91 nm. Taken together, these results suggest that MetG is a potential target-specific multi-stage inhibitor of P.f. malaria.

POPULATION PK ANALYSIS OF CHLOROQUINE IN A HUMANIZED MOUSE MODEL OF PLASMODIUM FALCIPARUM MALARIA

Sandra Berja-Checa[1], Nerea Jauregizar[2], María-Belén Jiménez-Díaz[1], Pablo Díaz[1], Patricia Lorenzo[1], Rebeca Sánchez[1], Hazel Gómez[1], Eider Salazar[1], Judith Romero[1], Gabriela Popescu[1], Lara López[1], Cristina Eguizabal[3], **Iñigo Angulo-Barturen**[1]

[1]The Art of Discovery, Derio, Spain, [2]Pharmacology Department, Faculty of Medicine, University of the Basque Country (UPV/EHU), Derio, Spain, [3]BioCruces Bizkaia Health Research Institute and Basque Centre for Blood Transfusion and Human Tissues, Barakaldo-Galdakao, Spain

The Plasmodium falciparum humanized mouse model is a validated tool to predict the efficacy of new drugs in humans. The aim of this work was to develop a population PK model of chloroquine in a P. falciparum humanized mouse model to investigate the relationship between model PK parameters and evolution of parasitaemia. Thus, human erythrocytes were engrafted into 60 immunodeficient female NODscidIL2Rgammanull (NSG) mice and they were infected with P. falciparum intravenously. The pharmacological treatment started when the percentage of parasitaemia in mice reached either 1 or 10 %. Single and repeated doses of chloroquine from 2.5 to 300 mg/kg were administered orally once daily for 1 to 6 days. Drug concentration data from all dosing schedules were modelled using Phoenix® NLMETM 8.3 and FOCE method. The relationship between physiological or pathological covariates and parameter estimates were explored. Since the animals were examined at different occasions, the inter occasion variability in individual parameters was also evaluated. Model parameters, diagnostic plots and internal validation techniques (VPC and bootstrap) were evaluated for model performance. Overall, 466 chloroquine concentration data were available and were successfully characterized by a 1-compartment model with linear elimination associated to an additive error model. Of the covariables tested, concentration of parasitized erythrocytes significantly influenced volume of distribution. The volume of distribution was lower when the concentration of parasitized erythrocytes was higher. Our results demonstrate that the PK of chloroquine in this model is highly dependent on the concentration of P. falciparum in peripheral blood, suggesting that this fact should be taken into account to understand and model the PK behavior of chloroquine.

6098

WHOLE GENOME SEQUENCE ANALYSIS OF CANDIDATE GENES IDENTIFIED THREE LOCI POTENTIALLY RELATED TO MEFLOQUINE NEUROPSYCHIATRIC SIDE EFFECTS

Monique Hollis-Perry[1], Joshua Gray[1], Dutchabong Shaw[1], Daniel Hupalo[1], Heidi Adams[1], Xijun Zhang[1], Matthew D. Wilkerson[1], Louis R. Cantilena[2], Lydia D. Hellwig[1], Milissa U. Jones[1], Clifton Dalgard[1], Jeffrey Livezey[1], **David Saunders**[1]

[1]Uniformed Services University, Bethesda, MD, United States, [2]Deceased, Bethesda, MD, United States

Despite effective once-weekly antimalarial prophylaxis, mefloquine has fallen out of favor due to neuropsychiatric effects. While genetic susceptibilities have been identified, pharmacogenomic testing guidance is not currently available for mefloquine. Volunteers with a history of exposure to mefloquine with or without adverse neuropsychiatric symptoms were invited to participate in a cross-sectional case-control study based on medical review of past mefloquine exposures. Pharmacogenomic analysis was performed on previously suspected 7 genes with 15 associated variants including ORM1 (S, F1, F2); MTHFR (A1298C, C677T); MDR1 (C1236T, G2677T, C3435T); PYK2 (rs2883490); HT2A (rs7997012, rs1928040, rs6311, rs6313); ADA (G22A); and ADORA2A (A2A) (T1976C, C2592T). There were 50 participants enrolled into one of four groups: those who had 1) mefloquine exposure and long-term adverse effects (AEs) greater than 6 months (n = 23); 2) exposure with subsequent AEs less than 6 months (n = 12); 3) exposure and no AEs (n = 8); and 4) a control group with a history of post-traumatic stress disorder (PTSD) but no mefloquine exposure or

traumatic brain injury (n = 7). Among volunteers exposed to mefloquine, the rs141942830 ADORA2A variant was potentially over-expressed among volunteers who had either long-term or short-term AEs compared to those who did not. Two additional variants were under- or over-represented relative to the comparable gnomAD population frequency, suggesting differences from reference controls. MTFHR was enriched for variation for volunteers who had long-term side effects compared to those with short-term or no side effects. A pharmacogenomics approach may help develop a mechanism to integrate test data and clinical findings to guide safer mefloquine use. These non-silent variants may serve as mediators to alternate pathways for signal transduction or drug metabolism, which may be future routes of research.

6099

OPTIMAL DOSING OF SINGLE LOW DOSE PRIMAQUINE FOR TRANSMISSION BLOCKING OF P. FALCIPARUM IN CHILDREN.

Walter R. Taylor[1], Julie Nguyen Pouplin[2], Thoopmanee Kaendiao[1], Chiraporn Taya[1], Mavuto Mukaka[1], For The Primaquine Dosing Group --[3]

[1]MORU, Bangkok, Thailand, [2]ReMeD, Bordeaux, France, [3]

Single low dose primaquine (SLDPQ) to block the transmission of artemisinin-resistant Plasmodium falciparum and curtail its spread was first recommended in 2012 but insufficient data at that time precluded the WHO from suggesting age- and weight based dosing tables. Dosing in young children is challenging because limited if any suitable paediatric forms are available at the right tablet strength and a lack of pharmacokinetic data mean that approximation methods used for children, notably, allometric scaling are used to derive regimens. However, such regimens may not be optimal and require tablet fractions. Our group is developing child-friendly paediatric primaquine, in the form of flavoured uncoated tablets of 2.5, 3.75, 5, 7.5 & 15 mg, for optimal dosing regimens for transmission blocking and radical cure. Pharmacokinetic data from age dosed SLDPQ were analysed and models developed to predict primaquine maximum concentrations and exposures as surrogates of the bioactive oxidative metabolites that are gametocytocidal and haemolytic in G6PD deficiency. Analysis is ongoing and we will present optimal weight-based SLDPQ regimens for stand-alone use and adapted to the different dosing bands of the artemisinin based combination therapies in common use.

6100

ASSESSMENT OF PLASMODIUM VIVAX BURDEN IN A MALARIA PRE-ELIMINATION CONTEXT AMONG HARD-TO-REACH POPULATIONS: P. VIVAX SEROLOGY AND PCR AMONG CLANDESTINE GOLD-MINERS IN THE GUIANA SHIELD (2015-2019)

Alice Sanna[1], Stephane Pelleau[2], Lise Musset[3], Yann Lambert[1], Stephen Vreden[4], Louise Hureau[1], Michael White[2], Maylis Douine[1]

[1]Centre Hospitalier de Cayenne, Cayenne, France, [2]Institut Pasteur, Paris, France, [3]Institut Pasteur de la Guyane, Cayenne, France, [4]SWOS Foundation, Paramaribo, Suriname

In a context of malaria pre-elimination in Suriname and French Guiana, residual transmission persists among hard-to-reach and mobile populations such as illegal gold miners. Plasmodium falciparum has been adressed by specific strategies but P. vivax (Pv) is particularly challenging, due to high proportion of asymptomatic carriers and low access to radical treatment leading to relapse. Our work aims to estimate the burden of Pv in the gold miner population in this region and its evolution between 2015 and 2019. Data derived from two cross-sectional surveys, conducted in 2015 and 2019 at the border between Suriname and French Guiana. Illegal gold miners having returned for less than 7 days from a gold mining site located in French Guiana were enrolled (questionnaire and collection of a venous blood sample). Samples were analyzed by qualitative polymerase chain reaction (PCR) according to the Snounou method. A serology specfic for Pv (described by Longley et al. In 2020) was used to identify individuals who had probably presented with Pv infection during the last 9 months. A total of 411 individuals were included in 2015, 378 in 2019. Among them, 36 (8.7%) had PCR detected Pv parasitemia in 2015 and 15 (3.9%) in 2019. For serology, a threshold corresponding to 63% sensitivity and 90% specificity was identified as the most appropriate for the study population: under these conditions, 45% of the participants in 2015 and 28% in 2019 had probably had a recent acute Pv infection, and were therefore potentially carriers of hypnozoites. In total, 40 (13.9%) of the 288 seropositive individuals had a positive PvPCR. Among the 51 positive PvPCR, 78% were Pv seropositive. In a context of low malaria prevalence, the proportion of individuals with serological markers of recent exposure to Pv remains significant. This species represents a major challenge for malaria elimination, and must targeted by tailored interventions. Moreover, these biological methods could be used as evaluation methods for new strategies for Pv elimination.

6101

IMPLEMENTATION OF MALARIA COMMUNITY CASE MANAGEMENT (MCCM) IN TANZANIA: SUCCESSES, CHALLENGES, AND WAY FORWARD

Onesmo Mwegoha[1], Geofrey Makenga[2], Abdallah Lusasi[1], Saidi Mgata[2], Sigsibert Mkude[2], Samwel Lazaro[1], Naomi Serbantez[3], Erik Reaves[4], Daniel Mbwambo[1], Hassan M. Hassan[1], Chonge Kitojo[3]

[1]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [2]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [3]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

The World Health Organization recommends community case management of malaria to improve access to prompt, effective testing and treatment by trained community members living in proximity to patients. In Tanzania, many rural areas with high malaria endemicity are difficult-to-reach with malaria health services; however, Tanzania's new 2021 policy restricts community-based malaria testing and treatment only to licensed medical personnel called Community-Owned Resource Persons (CORPS), not Community Health Workers (CHWs). To evaluate the implications of this policy, the National Malaria Control Program conducted a pilot of malaria community case management (mCCM) between June and December 2022 in 311 villages across 10 councils with high malaria burden and low access to health services. One CORPS per village was recruited; following placement, CORPS conducted malaria rapid diagnostic testing (mRDT) for patients with suspected malaria and provided treatment for uncomplicated malaria following national guidelines. Cases exhibiting severe malaria were referred to the nearest health facility. During the pilot, 35,409 patients sought health services from the CORPS. Of these, 33,030 (93.3%) were tested by mRDT, and 10,631 (32.2%) were positive. Initially, only 104 CORPS could be recruited because of the licensing requirement, and only 77 (74.0%) of these CORPS were retained during the pilot, serving only 24.8% of the 311 villages. The most cited reason for leaving CORPS duties was other employment opportunities. Of the 77 CORPS, 23 (29.9%) were not residents of their assigned village, and among these 8 (34.8%) faced poor acceptability from the community. Meanwhile, there were 434 CHWs who also resided in the 311 villages. Studies in Tanzania have shown CHWs are widely accepted within their communities. Coverage of malaria diagnosis and treatment achieved by relying on CORPS was lower than expected. Further evaluation might identify successes in the provision of services and reasons for limited coverage and attrition of CORPS to help expand access to community case management.

LESSONS LEARNED FROM MADAGASCAR NATIONAL MALARIA PROGRAM PERFORMANCE REVIEW 2022

Urbain Rabibizaka[1], Omega Raobela[1], Sabas Rabesahala[1], Brune Estelle Ramiranirina[1], Solofo Razakamiadana[2], Lova Avotra Ralijaona[2], Laurent Kapesa[2], Maurice Ye[3]

[1]National Malaria Program, Antananarivo, Madagascar, [2]U.S. President's Malaria Initiative, USAID, Antananarivo, Madagascar, [3]ICF Macro, Rockville, MD, United States

To reduce the malaria burden in Madagascar and accelerate to elimination, the National Malaria Program (NMP) in collaboration with partners have implemented several interventions including free distribution of insecticide-treated bed nets (ITNs), targeted indoor residual spraying (IRS), prompt diagnosis and treatment, malaria surveillance, monitoring and evaluation (SME) between 2018 and 2022. The NMP and technical partners carried out a desk and document review of annual reports, specific study reports, from 2018-2022 to document progress and inform the development of the national strategic plan 2023-2027. Regarding reporting system performance, the completeness of reporting increased from 94.4% in 2018 to 97.9% in 2022, while timeliness of reporting increased from 46.7% (2018) to 90.4% (2022). The use of artemisinin combination therapies for treatment of confirmed malaria cases increased from 81% in 2018 to 96.6% in 2022, although this remained under the national target of 100%. The coverage (%) of three courses of Intermittent preventive treatment in pregnancy increased from 32.96% (190397/577582) in 2018 to 42.5% (302803/711426) in 2022, although below the national target of 60%. Overall, malaria incidence per 1,000 persons increased from 36.7 in 2018 to 81.9 in 2021, then decreased to 63.8 in 2022. Three regions (Atsimo Atsinanana, Anosy and Atsimo Andrefana) accounted for 60% of the malaria cases. The objective of reducing malaria morbidity by 30% by 2022 was not achieved; however, incidence decreased by 29% between 2021 and 2022. Regarding malaria mortality, a reduction of 69% was reported between 2018 (927 deaths) and 2022 (287 deaths). This review was useful to document progress toward the NMCP's objectives over the past five years. It also identified the main challenges to consider in the national strategic plan 2023-2027, which emphasize on subnational actions on hotspots and strategies to accelerate malaria elimination in Madagascar.

6103

GENERATION OF PLASMODIUM-RESISTANT ANOPHELES GAMBIAE

Emilia Cristiana Cuccurullo, Yuemei Dong, George Dimopoulos

Johns Hopkins Bloomberg school of public health, Baltimore, MD, United States

The vector-born parasite Plasmodium falciparum is the major etiological agent of human Malaria, causing more than 200 million clinical diseases per year and accountable for the majority of the deaths (~0.6 million per year globally). Vector control strategies like insecticide-treated nets (ITNs) or indoor residual spraying (IRS), have been the only effective approach leading to lasting malaria eradication. The reduction in efficacy of insecticides and parasite drug-resistance call for new tools to be developed to stop the transmission of the parasite. Advances in mosquito gene drive technologies has opened the door to develop the new approaches for malaria control. Our current strategies involve CRISPR-Cas9 mediated knockout (KO) of mosquito host factors that facilitate the parasite and transgenesis-based overexpression, or CRISPR-Cas9 mediated knock-in (KI), of effector molecules targeting malaria parasites at essential Plasmodium life cycle stages. One challenge with targeting the early parasite stages in the mosquito blood bolus using transgenic technology is the expression of effectors that can reach those parasites immediately upon ingestion of infected blood. Towards this goal, we are exploring the expression of early parasite stage -targeting effectors in the saliva that can be ingested, and blended, with the gametocyte-containing blood in the mosquito midgut. Here we discuss this approach along with other transgenic parasite-blocking approaches that show prominent reduction in prevalence and ookinetes number after an infectious blood meal.

6104

ENTOMOLOGICAL MONITORING IN ZANZIBAR TO SUPPORT MALARIA ELIMINATION EFFORTS

Bakari Khatibu[1], Juma Mcha[1], Kali Omar[1], Shija J. Shija[1], Safia Mohammed[1], Bilal Kabula[2], Erik Reaves[3], Naomi Serbantez[4], Khadija Ali[1], Zamzam Pandu[1], Ussi Ussi[1], Makame Makame[1], Badru Badru[1], Makame Kombo[1], Ramla Haji[1], Chonge Kitojo[4], Geofrey Makenga[5], Adelin Chan[6], Nicodemus Govella[5], Sigsibert Mkude[5]

[1]Zanzibar Malaria Elimination Program, Ministry of Health, Zanzibar, Tanzania, United Republic of, [2]Research Triangle International, Dar es Salaam, Tanzania, United Republic of, [3]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [5]Dhibiti Malaria project, Population Services International, Dar es Salaam, Tanzania, United Republic of, [6]Centre for Disease Control, Atlanta, GA, United States

Zanzibar is in the malaria pre-elimination phase with multiple ongoing vector control interventions, including the distribution of insecticide-treated nets (ITNs) and indoor residual spraying (IRS). The Zanzibar Malaria Elimination Program has 10 sentinel sites (6 in Unguja and 4 in Pemba) established for entomological monitoring of the malaria vector population and bionomics to track the impact and for timely adjustment of vector control strategies. Between October 2021 to September 2022, adult Anopheles mosquitoes were collected during two consecutive nights per month from each sentinel site. Methods for collecting mosquitoes included indoor and outdoor human landing catch, indoor CDC light-trap, pyrethrum spray catch, and pit trap. A total of 3,206 female Anopheles mosquitoes were collected (1,628 from Unguja and 1,578 from Pemba), with an average of 94% composed of Anopheles gambiae sensu lato, and the remaining a mixture of An. funestus s.l, An. coustani, and An. rufipes. Of the 2,813 successfully amplified specimens of An. gambiae s.l., 2,714 were An. arabiensis, dominating on average 96% of species across the two Islands, with An. merus and An. gambiae sensu stricto contributing the remaining proportion. An. arabiensis exhibited early peak biting time before typical sleeping hours (before 9:00 PM), and predominantly outdoor feeding. These feeding behaviors were generally consistent across sentinel sites. An. arabiensis is the predominant malaria vector in Zanzibar, and its early and predominantly outdoor biting behaviors may be attenuating the impact of personal protection provided by ITNs and IRS. This calls for complementary vector control strategies coupled with social behavioral change to address the risk of outdoor malaria transmission.

USING EVIDENCE-BASED RESEARCH TO IMPROVE TIMELY DETECTION, DIAGNOSIS, AND TREATMENT OF MALARIA IN GUATEMALA'S PUSH FOR ELIMINATION

Lily T. Bodinson[1], Diego Hernandez[1], Carlos Dionicio López[1], José Miguel Echeverría[2], Justin T. Lana[3], Kota Yoshioka[4]

[1]Clinton Health Access Initiative, Inc., Guatemala City, Guatemala, [2]National Malaria Control Program, Guatemala City, Guatemala, [3]Clinton Health Access Initiative, Inc., Panama City, Panama, [4]Nagasaki University, School of Tropical Medicine and Global Health, Nagasaki, Japan

Since 2012, reported malaria cases in Guatemala have fallen by nearly 70%, totaling fewer than 1,900 in 2022. In a 2021 surveillance assessment, the National Malaria Control Program (NMCP) estimated that only 44% of cases began treatment within the WHO-recommended 72 hours of symptom onset. To address this gap, the NMCP sought to describe the barriers and facilitators that cases experience in successfully starting treatment within three days of symptom onset. We conducted a mixed-methods study in 2022 in Alta Verapaz, Escuintla, and Izabal - Guatemala's

three most endemic regions comprising 89% of cases nationwide. We administered a cross-sectional survey to 160 randomly selected cases from the NMCP's 2021 database. We also conducted 60 semi-structured interviews with key stakeholders, including cases, vector control technicians (VCTs), and community health workers (CHWs). Our survey results showed that 41% of cases self-medicated with analgesics, antimalarials, or other medications prior to seeking care. Those who self-medicated were 37% less likely to initiate treatment within 72 hours compared to those who did not ($p < 0.02$). We also found that CHWs conducted just 9% of tests but captured 57% of all cases. However, cases captured by CHWs experienced more extreme delays in starting treatment compared to those captured by VCTs (median: 1 vs. 2 days; range: 0-42 vs. 0-16 days). Self-reported treatment completion was high (98%) and most cases (87%) received direct observed therapy (DOT) for the entire 14-day treatment scheme. In interviews, VCTs reported challenges with DOT and CHW supervision due to funding gaps for vehicles and fuel, while CHWs reported frequent stock outs of rapid tests. Cases reported that feeling too ill to leave home was their primary barrier to seeking care. Some did not associate their symptoms with malaria. Others delayed care seeking due to a fear of being tested or vaccinated for COVID-19. As Guatemala pushes towards their 2025 malaria elimination goal, there is an opportunity to use evidence-based research to plan targeted education campaigns, improve commodity access, and strengthen CHW supervision.

6106

CLUSTERING OF ASYMPTOMATIC MALARIA INFECTIONS IN NEIGHBORING HOUSEHOLDS: REACTIVE CASE DETECTION REVIEW AND META-ANALYSIS FROM 2010 TO 2022

Ebenezer K. Aidoo[1], Frank T. Aboagye[2], Felix A. Botchway[1], George Osei-Adjei[1], Michael Appiah[1], Ruth Duku-Takyi[1], Samuel A. Sakyi[3], Linda Amoah[4], Kingsley Badu[5], Richard H. Asmah[6], Bernard W. Lawson[5], Karen A. Krogfelt[7]

[1]Department of Medical Laboratory Technology, Accra Technical University, Accra, Ghana, [2]Biomedical and Public Health Research Unit, Council for Scientific and Industrial Research-Water Research Institute, Accra, Ghana, [3]Department of Molecular Medicine, Kwame Nkrumah University of Science & Technology, Kumasi, Ghana, [4]Department of Immunology, Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, [5]Department of Theoretical & Applied Biology, Kwame Nkrumah University of Science & Technology, Kumasi, Ghana, [6]Department of Biomedical Sciences, School of Basic and Biomedical Science, University of Health & Allied Sciences, Ho, Ghana, [7]Department of Science and Environment, Unit of Molecular and Medical Biology, The PandemiX Center, Roskilde University, Roskilde, Denmark

Progress toward malaria elimination is increasing as many countries near zero indigenous malaria cases. In elimination settings, interventions will be most effective at interrupting transmission when targeted at the residual foci of transmission. These foci may be missed due to asymptomatic infections. To solve this problem, the World Health Organization recommends reactive case detection (RACD) triggered in response to index cases. The rationale of RACD is that local transmission potential is higher around index case households, leading to infection clustering. To test this hypothesis, pooled data from different RACD studies were utilized to determine the average risk of malaria among index case households and neighbors. Published studies between January 2010 - September 2022 were identified through PubMed and Google Scholar. Search terms included malaria and RACD, contact tracing, focal screening, case investigation, focal screen and treat. MedCalc Software was used for data analyses and the pooled studies' findings were analyzed using a fixed effect model. Summary outcomes were presented as forest plots and tables based on 54 studies reviewed. Of these studies, 7 met the eligibility criteria based on the risk of malaria in individuals living with an index case < 5 years old, 13 met the eligibility criteria based on the risk of malaria in an index case household member compared with a neighbor of an index case, and 29 met the eligibility criteria based on the risk of malaria in individuals living with index cases and were included in the meta-analysis. Individuals living in index case households with average risk (odds ratio 2.58; 95% CI 2.54 - 2.61) were more at risk of malaria infection and showed pooled results of high variation heterogeneity chi-square = 235.60, ($p < 0.0001$) $I2 = 98.88$ [97.87-99.89]. The pooled results showed that neighbors of index cases were 0.35 [0.30-0.41] times more likely to have a malaria infection relative to index case household members and this result was significant ($p < 0.001$). Evidence to support infection clustering in neighborhoods that necessitates the inclusion of neighboring households in RACD was presented.

6107

ACCESS TO MALARIA DIAGNOSIS AND TREATMENT IN ZAMBIA IN THE CONTEXT OF SCALING-UP COMMUNITY CASE MANAGEMENT

Zhiyuan Mao[1], Irene Kyomuhang[1], Joshua Yukich[1], Andrew Andrada1[1], Refilwe Karabo1[1], Ruth Ashton[1], Adam Bennett[2], Justin Millar[2], Hannah Slater[2], John Miller[3], Kafula Silumbe[3], Thomas P. Eisele[1]

[1]Tulane University, New Orleans, LA, United States, [2]PATH, Seattle, WA, United States, [3]PATH, Lusaka, Zambia

The National Malaria Elimination Centre (NMEC) launched a pilot of community case management (CCM) for malaria in Southern Province, Zambia in 2009, and CCM was later scaled-up in an incremental fashion at national level between 2013-2020. The goal of this study was to: 1) examine the impact of CCM on treatment seeking behaviors among individuals of all ages with a febrile illness; and 2) assess the proportion of children less than five years old with malaria (defined as a positive rapid diagnostic test plus fever in the past two weeks) that received the first line malaria treatment artemether-lumefantrine (AL). We analyzed changes in these outcomes and their determinants over time using data from the Zambia Malaria Indicator Surveys (2012, 2015, 2018, and 2021) combined with distance to the nearest malaria provider at the time of survey from data on volunteer community health worker (CHW) expansion, as well as travel time from a friction surface from the Malaria Atlas Project. While results showed there was no significant increase in treatment seeking from 2012 to 2021 (overall seeking rate: 57.1% [52.7%, 61.0%]), time from fever onset to treatment seeking decreased significantly from 2.42 days [2.27 - 2.58] in 2012 to 1.71 days [1.56 - 1.86] in 2021. Children <5 with a fever in the previous two weeks were significantly more likely to have been taken for treatment compared to older age groups (ORs: 1.26 [1.12 - 1.42] for 5-19 years old and 1.48 [1.32 - 1.66] for 20 years and older). Respondents with a fever in the past two weeks who had access to a malaria provider (either CHW or health facility) within a 30-minute walking distance were significantly more likely to seek treatment compared to those further away (OR = 1.47 [1.29 - 1.67]). Across all survey rounds, among children with malaria and fever, 58.6% [51.2% – 65.5%] did not receive AL. Among children who had malaria and fever, those within a 30-minute walking distance to a malaria provider were significantly more likely to receive AL compared to those further away (OR = 1.59 [1.03 – 2.44]). While CCM in Zambia has been successfully scaled-up, gaps remain in malaria treatment access, especially in remote areas.

HALT THE MARCHING OF ANOPHELES STEPHENSI IN AFRICA: FOLLOW INDIA'S INTERVENTION STRATEGIES

Susanta Kumar Ghosh[1], Chaitali Ghosh[2]

[1]ICMR-National Institute of Malaria Research, Bangalore, India, [2]Tata Institute of Genetics and Society, Bangalore, India

Anopheles stephensi was reported from village Ellichpur (now Achalpur), Amravati district, Maharashtra, India. South Asia and the Arabian Peninsula is the home of this malaria vector. Now this species has been detected in Djibouti (2012), Ethiopia (2016), Sudan (2016), Sri Lanka (2017), Somalia (2019), and most recently in Nigeria (2020), Yemen (2021) and Ghana (2023). A recent modelling study using marine cargo traffic indicates that it may invade in more than half of the African countries. Since 2019 World Health Organization (WHO) to ASTMH 71st Annual Meeting at Seattle in 2022, and recently RMB Vector Control Working Group in Accra, Ghana

(6 to 8 February 2023) and WHO Regional Response meeting in Addis Ababa, Ethiopia (8 to 10 March 2023) have echoed the threat of perineal malaria transmission especially in urban settings. This species has three variants i.e. Type, Intermediate and mysorensis. They behave differently in terms of vector competence, bionomics and response to insecticides. Genomic studies and molecular diagnosis of these variants are possible developing isofemale homogenized lines. It is important to carry out detailed site-specific studies to plan strategic intervention strategies. Our study in Mangalore city, India revealed case-centric vector control response using smart digital surveillance devices brought down malaria at the lowest level leading to malaria elimination. Similar strategies would find a solution to prevent marching of Anopheles stephensi in Africa involving Indian scientists.

6109

REBOUND IN THE PLASMODIUM FALCIPARUM RESERVOIR FOLLOWING THE DISCONTINUATION OF INDOOR RESIDUAL SPRAYING AND IMPLEMENTATION OF SEASONAL MALARIA CHEMOPREVENTION IN NORTHERN GHANA

Kathryn E. Tiedje[1], Oscar Bangre[2], Dionne C. Argyropoulos[1], Samantha L. Deed[1], Cecilia Rios Teran[1], Sanjay S. Gautam[1], Kwadwo A. Koram[3], Mercedes Pascual[4], Patrick Ansah[2], Abraham R. Oduro[2], Karen P. Day[1]

[1]The University of Melbourne, Melbourne, Australia, [2]Navrongo Health Research Centre, Ghana Health Service, Navrongo, Ghana, [3]Noguchi Memorial Institute for Medical Research, Legon, Ghana, [4]The University of Chicago, Chicago, IL, United States

It is now understood that the large reservoir of asymptomatic Plasmodium falciparum infections in all ages sustains malaria transmission in sub-Saharan Africa. If we are to achieve malaria elimination, the impact of current interventions to reduce this reservoir must be investigated. Here we present one of few contemporary studies to assess the efficacy of short-term indoor residual spraying (IRS) with non-pyrethroid insecticides and seasonal malaria chemoprevention (SMC) to reduce the reservoir of infection in all ages. Using data collected from an interrupted time series study in northern Ghana (2012-2020), involving four surveys each of ~2,000 participants, we examined the impact of two sequential interventions, IRS and SMC in combination with long-lasting insecticide-treated nets (LLINs), on the P. falciparum reservoir. We showed that the addition of IRS to LLINs reduced the size of the P. falciparum reservoir as measured using PCR, with participants of all ages being significantly less likely to be infected post-IRS in 2015 (41.6%) compared to baseline in 2012 (73.8%). Despite this reduction, in 2017, 32-months after IRS was discontinued, there was a rebound in prevalence to 64.2%. This rebound in the size of the P. falciparum reservoir was found in all age groups, except for the younger children (1-5 years) directly targeted by SMC. In 2020, over five years after IRS was stopped, but during the continued implementation of SMC and LLINs, P. falciparum prevalence remained high (50.0%) with younger children still being significantly less likely to have an infection compared to the older age groups. This rebound was also associated with higher median P. falciparum densities in 2017 and 2020, suggesting a loss of immunity in all ages due to reduced exposure to infection during the IRS. Molecular surveillance data will also be discussed. These results show that if high-burden countries, like Ghana, are to achieve a 90% reduction in the burden of malaria by 2030, they must develop strategies that can both reduce clinical disease and target the P. falciparum reservoir.

6110

"DON'T WAIT FOR SYMPTOMS!": INCREASING ROUTINE MALARIA TESTING AMONG FOREST-GOERS IN CAMBODIA

Leakhena Ith[1], Ly Po[2], Tha Meas[2], Cheaty Ly[1], Sochea Phok[1], Saad El-Din Hussein Hassan[3], Sarath Mak[1], Andrea Ferrand[4]

[1]Population Services International Cambodia, Phnom Penh, Cambodia, [2]National Center for Parasitology, Entomology and Malaria Control (CNM), Phnom Penh, Cambodia, [3]U.S. President's Malaria Initiative, USAID, Phnom Penh, Cambodia, Phnom Penh, Cambodia, [4]Population Services International, Washington DC, MD, United States

Malaria transmission in Cambodia is highly localized among forest-goer populations. The Cambodia National Malaria Treatment Guideline includes systematic diagnostic testing for forest-goers exiting forests. Formative research indicated that adoption of routine malaria testing may be influenced by social norms and social support from family members to test. An SBC intervention was designed with communities to increase perceived social norms and social support among forest-goers for malaria testing after leaving the forest. Activities were implemented through various channels in 50 high-risk villages in three provinces under the slogan "Don't Wait for Symptoms!". Interpersonal communication was delivered by Village Malaria Worker (VMW) visits to forest-goer households to increase the positive social norm of testing and increase malaria risk perception. Additional behavioral nudges (banners, posters, audio messages) were delivered via placement close to forest exits and within forest-goer communities. Cross-sectoral surveys were conducted with random samples of forest-goers (n=360) from 50 villages before (May 2022) and after (December 2022) implementation to evaluate differences in perceived social norms and self-reported testing behaviors. No control group was interviewed, but routine data were compared with reports from non-intervention villages over the same period. Routine data recorded 12,338 VMW-performed community-wide tests of forest-goers upon returning from forest work during the intervention period, increasing 76% compared to the same period the previous year. VMWs in villages in the same catchment areas but not covered by the intervention recorded a 26% increase in testing. Survey data showed the percentage of forest-goers who believe other forest-goers consistently seek a malaria test when leaving the forest increased from 67% to 96% ($p<0.001$); self-reported malaria testing increased from 27% to 90% ($p<0.001$). Key messages reinforcing the social norm of malaria testing should continue, and explicit emphasis should be added on improving social support for forest-goer testing among family members.

6111

AN ONLINE SURVEY OF MALARIA ON MOBILE AND MIGRANT POPULATION AMONG INDONESIAN MALARIA MANAGERS: MINERS

Iqbal R. F. Elyazar[1], **Karina Dian Lestari**[1], Ahsyad Fahmi Abdillah[1], Rosa Nora Lina[1], Adhi A. Andrianto[1], Lenny L. Ekawati[2], Bimandra A. Djaafara[3], Henry Surendra[1], Sri Budi Fajariyani[4], Hellen Dewi Prameswari[4], Herdiana Herdiana[5]

[1]Oxford University Clinical Research Unit Indonesia, Jakarta, Indonesia, [2]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [3]MRC Centre for Global Infectious Disease Analysis, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [4]Sub-Directorate for Malaria Control, Ministry of Health, Jakarta, Indonesia, [5]World Health Organization Indonesia Country Office, Jakarta, Indonesia

Miners are one of the malaria high-risk populations since they do outdoors activities and have poor access to health facilities. We conducted online survey from February to September 2022, with 514 district health managers as our participant, to determine their understanding of malaria problem in miners. The survey, which was developed in SurveyMonkey, inquired about the presence of miners with malaria issues, including but not limited to population size, distribution, malaria detection and diagnosis, vector control, obstacles, and future control programs. From the responses gathered, 114 (22.1%) districts reported having mining sites, with 29 (25.4%) of those experiencing malaria problems among the workers. Workers who contracted malaria received treatment from nearby primary healthcare and were mostly diagnosed using RDT. The types of mining minerals that had malaria problem at the sites were gold, coal, nickel, and tin. The distance to the sites varied, but they typically had to travel on rocky, damaged, and muddy roads to reach the sites. Majority of the districts also have influx of workers from other districts who could stay for more than three months at the sites. However, their departure and arrival times was unknown due to the uncertainty of mining projects in the area. More

than half of the districts had implemented interventions to control malaria with the most common being distributing long-lasting insecticidal nets (LLINs), health promotion, and vector control with larvaciding. LLINs were reported as the most effective intervention. Poor access to the sites and lack of funding were among many reasons that hampered malaria control efforts in miners. District health managers planned to build a cross-sectoral collaboration, train cadres, and conduct more migration surveillance in the future. This study provides insights into the level of perception, knowledge, malaria control strategy and efforts among the miners. The study findings will support in reformulating strategies to address potential obstacle and contribute to the National Plan to Eliminate Malaria in 2030.

6112

SAVING LIVES FOR CHILDREN UNDER FIVE YEARS THROUGH STRENGTHENING COMMUNITY TO HEALTH FACILITY LINKAGE; A CASE OF ICCM IMPLEMENTATION IN NORTHERN UGANDA

Geofrey Beinomugisha[1], Francis Abwaimo[1], Anthrny Nuwa[1], James Tibenderana[2]

[1]Malaria Consortium Uganda, Kampala, Uganda, [2]Malaria Consortium United Kingdom, London, United Kingdom

Malaria Consortium is supporting 11 districts in Northern Uganda to improve community to health facility Linkage since September 2021. Several interventions have been undertaken and these include, among others, orientation of Village Health Teams (VHTs) Supervisors and VHTs on the new revised ICCM guidelines to manage HIV,AIDS,TB,Malaria,D iarrhorea,Pneumonia in the community and supporting quarterly VHTs coordination meetings with Health Facility health workers. Implementation is district led approach where District Health Teams (DHTs) are supported and facilitated to implement. Ministry of Health and TASO give technical support to ensure implementation according to the standard guidelines and policies. Community Data from District Health Information System 2 (DHIS 2) was downloaded and computations for selected ICCM indicators were done. Community reporting increased from 60.4% in September 2021 to 88.0% by the end of December 2022; the number of children under 11 months reportedly dying in the community decreased by 58.5%, from 270 to 112 children; the percentage of children with fever and danger signs reduced from 2.9% to 2.1%; the number of children under five years seen by the VHTs in the community every quarter increased from 120,281 to 350,890; the number average number of children seen by a VHT in a quarter increased from 11 to 33 children; the percentage of children with malaria treated within 24 hours increased from 59% when we started to 89% by the end of 2021. There have been challenges in stocks availability that have led to continuous low malaria testing rates (consistently below 80%) and significant referrals from the community, consistently at 15% - 16%, as reported previously. The results show that lives have been saved through interventions to strengthen health facility to community linkage in Northern Uganda. Demand and access to health services for children under five years from VHTs increased significantly during implementation. Gaps in stocks availability should be addressed to ensure access to quality services by the unreached vulnerable groups.

6113

CLINICAL PLASMODIUM FALCIPARUM DURING THE DRY SEASON IN AN ENDEMIC AREA OF MALI, TORODO.

Moussa Niangaly

Malaria Research and Training Center, Bamako, Mali

Plasmodium falciparum (Pf) clinical malaria is rare during the dry season in endemic countries, were the transmission mediating mosquitoes (Anopheles) are not prevalent at that time. Regarding all the effort made during transmission season and slow moving of the disease control and elimination program, additional strategies need to be explored to contribute to the existing one. Indeed, we addressed the following research question within one of our cohort studies: Can, Pf asymptomatic infected or non-infected individuals at the beginning of the dry season develop the disease at that period? Thus, from our cohort study of 250 participants (2 to 16 years old) in Torodo, 74 individuals (~29%) out of the 250 participants, were infected at the baseline (February 2022). Female represented ~44% of the positive group and the age group 7-11 years were more infected (13,2%). Looking at to the hemoglobin levels (which is one of the major indicators of Plasmodium falciparum acute or asymptomatic infection), it was higher in the negative group with a means around 11.5g/dl compared to the positive group (around 10.5). To track Pf clinical malaria during dry season we followed both group (Pf asymptomatic infected and non-infected groups) actively and/or passively from February to May 2022. During the follow-up, we observed 20 cases of Pf clinical malaria after PCR correction and 17 and 3 cases were respectively in the infected and non-infected groups from the baseline. These finding highlights that carrying asymptomatic Pf infection at the beginning of dry season can favor Plasmodium falciparum clinical malaria through all the dry season period, but also some new cases can happen in non-carriers, suggesting that an effort need to be addressed regarding malaria control and elimination program during that period.

6114

NEW SURVEILLANCE STRATEGIES FOCUSED ON ELIMINATION IN SOUTHERN ANGOLA

Paulo Máquina[1], José Franco Martins[2], Teresa Nobrega[3], Ana Direito[3], Sérgio Lopes[4], Bongani Dlamini[5]

[1]Elimination 8, Luanda, Angola, [2]National Malaria Control Programme, Ministry of Health, Luanda, Angola, [3]The Mentor Initiative, Luanda, Angola, [4]The Mentor Initiative, Haywards Health, United Kingdom, [5]Elimination 8, Windhoek, Namibia

Malaria incidence in southern border districts of Angola has seen a steady decline over the past years. This decrease in malaria cases is the result of joint efforts to reduce transmission and contribute to malaria elimination in neighbouring Namibia. As transmission declines, new surveillance approaches are required to tackle focal transmission. The objective of this study is to report the implementation of new surveillance strategies focused on elimination in southern Angola and to characterize transmission in line with case classification made. The implementation of case classification strategies started in November 2022 across 5 health facilities of Cunene and Cuando Cubango provinces. These health facilities have been shortlisted because they registered 5 or less cases per month on average over the past 3 years. Case classification was done for RDT/MO confirmed malaria cases using a structured questionnaire applied at health facility level focused on travel patterns and use of malaria preventive measures. Overall, 100% of the positive cases were classified (26). Of these, all were local, particularly 21 (81%) were considered as local L1 (own house) and the remaining L4 (out of usual accommodation but in the same province). Local cases had the following characteristics: 10 (38%) less than 15 years old, 16 (62%) more than 15 years old, 9 (35%) were females. It is likely to identify 12 foci of transmission based on the local guidelines that point out a focus of transmission to be the presence of more than 1 local case within a month. The data presented, the first of its kind in Angola, showcases the high proportion of local cases in areas targeted. Foci investigation, classification and response are key to tackle local transmission and gradually eliminate these scattered points of local transmission in the south.

6115

MATHEMATICALLY MODELLING THE IMPACT OF CASE MANAGEMENT AT BORDER AREAS ON MALARIA TRANSMISSION IN THE MOZAMBIQUE, SOUTH AFRICA AND ESWATINI REGION

Vusi Mpendulo Magagula, Sheetal Silal

University of Cape Town, Cape Town, South Africa

Eswatini and South Africa are in the path of malaria elimination but however, they share borders with Mozambique who has a high incident rate of malaria. Studies conducted show that most of the malaria cases recorded in both South Africa and Eswatini are imported cases from Mozambique. For these countries to attain their goal of malaria elimination, they need

to prioritise case management at border areas as their main strategy of malaria elimination. Will the use of rapid antigen tests at the border gate areas accelerate the elimination of malaria in the MOSASWA region? What impact will border management have on the malaria transmission in these countries? A Nonlinear stochastic ordinary differential equation model is used to simulate the impact of case management at border areas on malaria transmission in the MOSASWA region which consists of eastern Eswatini, the southern Mozambican provinces of Maputo, Gaza and Inhambane, and the north-eastern districts of the South African provinces of KwaZulu-Natal, Mpumalanga, and Limpopo. The results show us that malaria transmission can be reduced significantly if rapid antigen tests are conducted at the borders in the MOSASWA region. The results show us that malaria cannot be eliminated by this intervention but can reduce the malaria burden significantly in Eswatini and South Africa endemic regions. Border control is a vital strategy for malaria elimination in South Africa and Eswatini. However, malaria cannot be eliminated and hence this intervention combined with other interventions can contribute towards malaria elimination in the region.

6116

THE UGANDA HOUSING MODIFICATION STUDY - ASSOCIATION BETWEEN HOUSING CHARACTERISTICS AND MALARIA BURDEN IN A MODERATE TO HIGH TRANSMISSION SETTING IN UGANDA

Joaniter Nankabirwa[1], Samuel Gonahasa[1], Agaba Katureebe[1], Peter Mutungi[1], Martha Nassali[1], Moses R. Kamya[1], Nelli Westercamp[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Scale up of proven malaria control interventions has not been sufficient to control malaria in Uganda emphasizing the need to explore innovative approaches. Improved housing is one such promising strategy. We describe the housing characteristics and their association with malaria burden in a moderate to high transmission setting in Uganda. In October-November 2021, a household survey was conducted in 1500 randomly selected households in Jinja and Luuka districts. Information on demographics, housing characteristics, use of malaria prevention measures, and proxy indicators of wealth were collected for each household. A finger-prick blood sample was obtained for thick blood smears from all children aged 6 months to 14 years in surveyed households. Febrile children were tested for malaria by rapid diagnostics test (RDT) and positive cases were managed per national guidelines. Hemoglobin (Hb) concentration was assessed in children aged 2-4 years, with anemia defined as Hb < 8 g/dL. Mixed effect models adjusted for age and wealth were used to estimate association between malaria burden and house type. Forty-four percent of households lived in modern houses (defined as built with finished roofs/walls/floors materials combined with closed eaves); the rest lived in traditional houses built with unfinished/natural materials. While most houses had closed eaves (85.5%), the use of other protective features like window and vent screens and having ceilings installed was limited (0.4%, 2.8%, and 5.2%, respectively). Malaria prevalence was 31.4% in 3443 children with smears collected. RDT test positivity rate was 56.6% among 1851 children with fever. Participants living in modern houses had a significantly lower parasite prevalence (adjusted prevalence ratio [aPR]=0.80; 95% confidence interval [95%CI] 0.71-0.90) and RDT test positivity rate (aPR=0.90; 95%CI 0.81-0.99) compared to those in traditional houses, with no significant impact on anemia. Our study found that even after adjusting for wealth, higher quality housing had a moderate protective effect against malaria, on top of the protection already afforded by recently distributed nets.

Ethiopia has experienced several conflicts during the last several years that have negatively impacted its health systems. This study aims to assess the impact of the conflicts in Northern Ethiopia on malaria prevention and elimination efforts, as well as the malaria surveillance system. We used routine district health information system data to quantify the changes in the levels of malaria prevention and control services from 2019 to 2021. We used interrupted time-series analysis and descriptive statistics to estimate the changes in intervention levels within the conflict-affected and surrounding districts. The routine malaria surveillance data showed that the reported national malaria cases increased by 20% from 2019 to 2021. Disruptions were found to vary across zones and districts with clear patterns by the intensity and duration of the conflict. There was a significant difference in test and incidence rates between affected areas and surrounding affected/not affected areas. In conclusion, While data limitations made it difficult to describe the level of disruptions to malaria prevention and elimination measures during the conflict (particularly in conflict-affected areas), these findings highlight a strong variation in the malaria incidence between conflict-affected and unaffected areas. Our study highlights the importance of peace and stability and preserving a functioning health system to sustain Ethiopia's progress toward malaria elimination targets.

Among the Plasmodium species that infect humans, P. falciparum has been widely studied in malaria-endemic areas. However, P. malariae infection is less documented among the human population and mosquitoes. This study aimed to investigate the prevalence and distribution of P. malariae in southern Benin. A cross-sectional survey was conducted in Ouidah and Kpomasse from June to October 2019. At the time of blood collection from the participants and at the same time, mosquitoes were collected from the participants' households. Data on malaria infection were obtained by microscopic diagnosis and nested PCR in participants. In addition, the collected mosquitoes were identified morphologically and molecularly, and the infection status of Plasmodium species was investigated by qPCR. Considering the participants, according to microscopy, the prevalence of P. malariae mono-infection and P. falciparum/P. malariae co-infection was

2.3% and 1.2% respectively in our study area. This prevalence was higher ($P < 0.01$) than that reported ten years ago in the same study area with 0.7% and 0.3% of P. malariae and P. falciparum/P. malariae, respectively. Based on PCR analysis, the prevalence of P. malariae was 14.1%, of which 5.2% were mono-infected and 8.9% mixed with P. falciparum. Regarding the mosquito data, of the 415 mosquitoes collected, three species of Anopheles were identified with a predominance of An. gambiae s.l. (61%). Molecular speciation of this species revealed that An. coluzzii was the majority species 59.2% and 98.5% in Ouidah and Kpomassè respectively. The infection rate of Plasmodium spp. in An. gambiae s.l. revealed that 4.4% were infected with a predominance of P. falciparum (75%), followed by P. malariae (25%), and only An. coluzzii mosquitoes were infected. These results provide valuable evidence of the increasing prevalence of P. malariae infection and that An. coluzzii is the mosquito responsible for the spread of this parasite. This highlights the need for national malaria control programs to take P. malariae into account when designing future measures for effective malaria control and treatment.

EVALUATING THE EFFECTIVENESS OF TRIMETHOPRIM-SULFAMETHOXAZOLE PROPHYLAXIS IN PREVENTING MALARIA IN PREGNANCY

Samyukta Rao[1], Nginache Nampota-Nkomba[2], Osward Nyirenda[2], Rhoda Masonga[2], Felix Mkandawire[2], Rosita Asawa[3], Andrea Buchwald[3], Cristiana Cairo[3], Miriam Laufer[3]

[1]University of Maryland Baltimore County, Baltimore, MD, United States, [2]Blantyre Malaria Project, Blantyre, Malawi, [3]University of Maryland School of Medicine, Baltimore, MD, United States

In sub-Saharan Africa, malaria in pregnancy remains a critical health concern for mothers and their babies. The WHO recommends sulfadoxine-pyrimethamine (SP) for the prevention of malaria during pregnancy. However, pregnant women living with HIV infection receive daily trimethoprim-sulfamethoxazole (TS) prophylaxis and therefore cannot safely also take SP. Previous studies have produced conflicting evidence as to whether TS prophylaxis adequately prevents malaria during pregnancy in women with HIV infection. We had the opportunity to evaluate the effectiveness of intermittent preventative treatment of malaria in pregnancy using sulfadoxine-pyrimethamine (IPTp-SP) in pregnant women without HIV infection compared to daily TS prophylaxis in pregnant women with HIV infection. We screened pregnant women with and without HIV infection for malaria enrollment in a clinical study and collected placental blood at the time of delivery from a cohort in a semi-rural area at one clinical site in southern Malawi. Dried blood spots from the enrollment visit in the second trimester paired with dried blood spots from the placenta after delivery underwent extraction and qPCR for 18S ribosomal DNA. Among 290 samples from pregnant women with and without HIV, we detected no Plasmodium falciparum infection. Our findings suggest that IPTp-SP and TS prophylaxis are equally effective in preventing placental malaria infection. We are currently testing enrollment samples from this cohort to characterize the burden of malaria infection when pregnant women initiate antenatal care. This will allow us to determine if the interventions prevented placental infection or if malaria transmission in the area was lower than anticipated.

6120

SPATIOTEMPORAL CORRELATION OF MALARIA INTENSITY AND VECTOR ABUNDANCE IN A PRE-ELIMINATION SETTING OF CHOMA DISTRICT, SOUTHERN ZAMBIA

Mukuma Lubinda[1], Anne Martin[2], Japhet Matoba[1], Caison Sing'anaga[1], Harry Hamapumbu[1], Ben Katowa[1], Michael Musonda[1], Limonty Simubali[1], Twig Mudenda[1], Monicah Mburu[1], Mary Gebhardt[2], Edgar Simulundu[1], Timothy Shields[2], Douglas E. Norris[2], William J. Moss[2]

[1]Macha Research Trust, Choma, Zambia, [2]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States

Choma District in Southern Province, Zambia, with malaria parasite prevalence by rapid diagnostic test of 2%, has long been targeted for elimination. However, low-level transmission with seasonal outbreaks has persisted, perhaps exacerbated by infectious secondary vectors. Previous geospatial risk maps of the area derived from remotely sensed data found that parasitemic individuals tended to be clustered in areas near streams at lower elevations. In this way, spatiotemporal analysis of low-level parasite prevalence and vector abundance has been critical in informing strategies targeting malaria elimination. This study aimed to produce malaria risk maps by assessing the spatial and temporal correlation of individuals with parasitemia by quantitative polymerase chain reaction (qPCR) and vector breeding sites within rural health center (RHC) catchment areas. Malaria case and entomological data were collected in 2022 and 2023 in Macha, Mapanza, and Simaubi RHCs. Passively-reported index case households and neighboring households within 250 meters of the index case household were surveyed from April 2022 to April 2023. Residents were tested for parasitemia using qPCR from dried blood spots. In October 2022, entomological surveillance began at 38 sentinel households, where each household was visited bimonthly. CDC light traps were set indoors and outdoors at each house and larval breeding sites within 500 meters were sampled. All households and larval breeding sites were geolocated. Intensity maps were created of the households of qPCR-confirmed parasitemic residents and confirmed breeding sites using kernel estimation with optimized bandwidths. Clustering was assessed using the K-function. We further compared the two intensity maps and clustering patterns with each other using the cross-K function. Analysis was done in R and ArcGIS. We will present the results of the malaria intensity mapping, K-functions for clustering, and cross-K function, and expect the results will inform further malaria risk mapping and targeted interventions in this pre-elimination setting.

6121

PLASMODIUM FALCIPARUM MALARIA IS ASSOCIATED WITH INCREASED KSHV SEROPOSITIVITY AND HIGHER KSHV ANTIBODY BREADTH AND MAGNITUDE: RESULTS OF A CASE-CONTROL STUDY FROM RURAL UGANDA

Angela Nalwoga[1], Katherine Sabourin[1], Wendell Miley[2], Conner Jackson[1], Nazzarena Labo[2], Joseph Mugisha[3], Denise Whitby[2], Rosemary Rochford[1], Robert Newton[3]

[1]University of Colorado, Aurora, CO, United States, [2]Viral Oncology Section, AIDS and Cancer Virus Program, Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD, United States, [3]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda

We previously showed that children with asymptomatic Plasmodium falciparum (Pf) malaria infection had higher Kaposi sarcoma-associated herpes virus (KSHV) viral load, increased risk of KSHV seropositivity, and higher KSHV antibody levels. In the current study, we investigated the association between clinical malaria and KSHV seropositivity and antibody levels using an expanded immunoassay. Sick children (aged 5-10 years) presenting at a clinic in rural Uganda were enrolled in a case-control study. Pf was detected using malaria RDT and subsequently with qPCR. Children with malaria were categorized into two groups; RDT+/Pf PCR+ and RDT-/Pf PCR+. The seroprevalence of KSHV was 60% (47/78) among children who did not have malaria (RDT-/PfPCR-), 79% (61/77); among children who

were RDT-/PfPCR+ (Odds Ratio [OR] 2.41, 95% CI 1.15-5.02) and 95% (141/149) in children who were RDT+/Pf PCR+ (OR 10.52, 95% CI: 4.17-26.58; P (trend)<0.001). Furthermore, RDT+/PCR+ children followed by RDT-/PCR+ children had higher KSHV antibody levels and reacted to more KSHV antigens compared to malaria-uninfected children. Malaria infection in children is associated with both increased KSHV seroprevalence and antibody magnitude suggesting that malaria is affecting immunity to KSHV.

6122

TACKLING ASYMPTOMATIC MALARIA INFECTION IN PREGNANCY AS INTERVENTION TO IMPROVE PREGNANCY OUTCOMES IN BURKINA FASO

Christian Marc Tahita[1], Ousmane Traore[1], Bérenger Kaboré[1], Hamidou Ilboudo[1], Toussaint Rouamba[1], Adama Kazienga[2], Hyacinthe Sanou[3], Nadège Millogo[1], Dieudonné Ouattara[3], Hermann Sorgho[1], Pedro Berzosa[4], Halidou Tinto[1]

[1]Clinical Research Unit of Nanoro/IRSS-DRCO, Nanoro, Burkina Faso, [2]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium, [3]Clinical Research Unit of Nanoro, Nanoro, Burkina Faso, [4]4Malaria and Neglected Tropical Diseases Laboratory, National Centre of Tropical Medicine, Biomedical Research Networking Center of Infectious Diseases (CIBERINFEC), Instituto de Salud Carlos III, Madrid, Spain

Malaria in pregnancy is assumed to be asymptomatic in endemic area. The national malaria control program (NCMP) recommends to treat all malaria cases after confirmation either by microscopy or rapid diagnostic tests (RDT) before treatment. Asymptomatic infections have no clinical manifestation and thus remain undetected and untreated. Even asymptomatic, malaria infections are potentially harmful for both women and their offspring's. We therefore, sought to determine the prevalence of asymptomatic malaria infection among pregnant women at their first antenatal care (ANC) and the risk factors associated. A cross-sectional study was conducted in Nanoro district and all pregnant women attending the first ANC visit were recruited. Blood samples were collected to assess malaria infection using microscopy as gold standard and haemoglobin level using HemoCue®. Among the 418 pregnant women recruited, 318 were asymptomatic. The overall prevalence of asymptomatic malaria infection during first ANC was 25.5% (95% CI: 21.1 - 30.4) with a geometric mean parasite density of (95% CI): 790 (602 - 1036) parasites/µL. From the 86 pregnant women infected with malaria, those at the third trimester gestational age were significantly more prevalent 21.3% (13/61), followed by the second trimester 25.6% (66/258) and the first trimester 38.8% (7/18), P<0001. Younger age was associated with significantly higher odds of asymptomatic malaria compared to elder women. Furthermore, primigravida had 3.09 (95% CI: 1.52 – 6.26; p = 0.002) and secundigravida 3.02 (95% CI: 2.00 – 5.34; p = 0.001) folds higher risk than multigravida women. The mean haemoglobin concentration was 10.56 ± 1.55 g/dL and the prevalence of anemia was 59.1% (95% CI:53.9- 64.7). In multivariate analysis, asymptomatic malaria increased two times the likelihood of having anemia (AOR 2 95% CI:1.1-3.4; p < 0.001). Our findings highlight the importance of integrated strategies such as systematic screening with sensitive rapid diagnostic tests and treatment with effective malaria drugs during the first ANC to clear residual parasitaemia and thus improve pregnancy outcomes.

6123

INSIGHTS ABOUT MALARIA BURDEN AND CARE IN MALARIA-ENDEMIC, INDIGENOUS COMMUNITIES UNDER THE COVID-19 PANDEMIC USING CONVERGENT-PARALLEL APPROACH

Susan Cilene Paredes Fernandez[1], Luis Martín Rojas Muro[2], Paloma Diab García[3], Hilde Bastiaens[3], Sybil Athierens[3], Steven Abrams[1], Jean-Pierre Van geertruyden[1], Stella Chenet Carrasco[4], Christopher Delgado-Ratto[1]

[1]Malaria Research group, Global Health Institute, University of Antwerp, Antwerp, Belgium, [2]Dirección Regional de Salud Amazonas, Amazonas, Peru, [3]University of Antwerp, Antwerp, Belgium, [4]Instituto de Enfermedades Tropicales. Universidad Nacional Toribio Rodríguez de Mendoza de Amazonas, Chachapoyas, Peru

In Peru, the interruption of the malaria control program due to the COVID-19 pandemic increased the number of cases in urban areas. However, the impact on the burden and care in remote, indigenous areas was unknown. In this mixed-method study, we investigated malaria prevalence using molecular diagnosis and factors associated with malaria infections in indigenous communities in the Peruvian Amazon. Moreover, we explored the population's perceptions of the COVID-19 impact on malaria burden and care. We performed population surveys (2021 and 2022) and semi-structured interviews with inhabitants and local health workers (2022) in four indigenous communities of the Amazonas region. We identified the factors associated with malaria infection through multivariate modeling and assessed the participants' perceptions through a thematic analysis. The convergent parallel approach served to merge the quantitative & qualitative components through a pillar integration process resulting in a joint display. The overall prevalence of malaria varied between 2021 and 2022 (17.6% and 25.5%, n=528 participants). Living in some communities (OR=0.70) and having experienced previous malaria episodes (OR=0.07) reduced the likelihood of malaria infection.On the contrary, experiencing chills (OR=38.4) was associated with higher odds of malaria infection. Inhabitants and health workers pointed out the prioritization of COVID-19 interventions, leaving malaria control activities aside and affecting malaria prevalence. On the other hand, the population's behavior toward malaria prevention did not change during the pandemic. However, the participants highlighted the limited access to healthcare facilities during the pandemic and the absence of health posts in the two communities, which increased the likelihood of experiencing malaria (OR=0.19-0.47). The novel mixed methods approach facilitated the integration of quantitative and qualitative data to explain the malaria situation in indigenous areas better. Our findings provide relevant information to improve the current interventions for malaria control and elimination in Peru.

6124

TEMPORALITY AND MODALITY OF FIRST HEALTH CARE SEEKING AMONG MALARIA PATIENTS IN THE REPUBLIC OF GUINEA

Elhadj Marouf Diallo[1], Fatoumata Bintou Traore[2], Bienvenu Salim Camara[2], Abdourahamanne Diallo[3], Alioune Camara[4], Laurent Gerbaud[5]

[1]Université Gamal Abdel Nasser Conakry, Université Clermont-Auvergne, Conakry and Clermont-Ferrand, Guinea, [2]African Centre of Excellence for the Prevention and Control of Communicable Diseases, Conakry, Guinea, [3]National Malaria Control Program, Dixinn, Conakry, Guinea, [4]National Malaria Control Program, Conakry, Guinea, [5]Université Clermont Auvergne, Clermont-Ferrand, France

The temporality and modalities of seeking care are crucial in the fight against malaria. In Guinea, malaria is a public health problem, with a morbidity of 39.91% in health facilities. The prevalence among children under five of age was 17% in 2021. In addition, there are many opportunities to manage malaria, with conventional and non-conventional offers. The aim is to analyze the temporality and modalities of first health-seeking for malaria patients. This is a partial analysis of data from a cross-sectional study conducted between December 2022 and March 2023 in the health facilities of nine (9) health districts randomly sampled in the eight administrative regions. The data were collected using an Open Data Kit system and analyzed with R software. Early care-seeking was defined within 24 hours and late after 48 hours. The conventional modalities are the public and private health facilities and community health walkers, while the non-conventional are constituted by other offers not recommended by the national policy of malaria management. A total of 3300 confirmed malaria cases, of which 1632 (49.45%) were female, were interviewed in 60 health facilities. 1132 were less than 5 years old (34.30%) with a mean age of 27 months (SD=16). For the group of 5 years and older the mean age was 27 years (SD=18.7). Early care-seeking for all modalities was 53.2%, 95% CI [0.52-0.55]. With 63.60%, 95% CI [0.61-0.66] in the under 5 years and

47.83%, 95% CI [0.46-0.50] in the 5 years and older. The median time to first care-seeking was 24 and 48 hours, respectively. Early and appropriate seeking behavior was different in the age groups (p<0.0001) with 33.66% and 25.88% respectively. The median cost of the first referral varied according to age group, 54000 GNF and 49000 GNF, and referral modality, 110000 GNF for conventional and 6000 GNF for non-conventional. The partial analysis of this cross-sectional study shows proportions of early and appropriate care-seeking in the first intention, below 50%. This result demonstrates the importance of the next steps in this project whose goal is to provide evidence on patterns of malaria management service consumption and determinants.

6125

ANOPHELES MOSQUITO BITE EXPOSURE TESTING TO ASSESS THE IMPACT OF VECTOR CONTROL INTERVENTIONS IN THE COLOMBIAN PACIFIC REGION

Sara Harris[1], Alyssa R. Schwinn[1], Rebecca Levine[2], Olayinka Olajiga[1], Manuela Herrera-Varela[3], Martha Liliana Ahumada[4], Audrey Lenhart[5], Berlin Londono-Renteria[6]

[1]Tulane University, New Orleans, LA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]PMI VectorLink Colombia, Bogota, Colombia, [4]Instituto Nacional de Salud, Bogota, Colombia, [5]Center for Global Health/Division of Parasitic Diseases and Malaria, Atlanta, GA, United States, [6]Tulane University, New orleans, LA, United States

Previous studies have demonstrated that IgG antibodies against mosquito salivary proteins are a reliable tool to measure arthropod bite exposure and disease risk. In Colombia, Anopheles vectors belong to subgenus Nyssorhynchus (An. albimanus and An. darlingi) and subgenus Anopheles (An. pseudopunctipennis) among others. Thus, we measured IgG antibodies against four peptides designed from immunogenic salivary proteins of An. albimanus (Peroxi-P3 and Transferrin-2), An. darlingi (AnDar-Apy2) and the salivary biomarker gSG6-P1 to determine the degree of exposure to bites from mosquito species from subgroups other than Nyssorhynchus. In the first phase of the study, blood samples were collected from two regions of Cauca Department on the Pacific Coast of Colombia where two different malaria control interventions [insecticide treated bednets (ITNs) and indoor residual spraying (IRS)] are being implemented. To compare exposure to bites with previous exposure to Plasmodium parasites, we also determined the levels of IgG antibodies against Plasmodium vivax (PvCSP and PvMSP1) and P. falciparum (PfCSP and PfMSP1). The second phase of this study is underway, but our preliminary results from phase 1 showed a significant positive correlation between age and Peroxi-P3, Transferrin-2 and gSG6-P1 in people using bed nets. This correlation was not observed in people living in houses treated with insecticide suggesting that the type of mosquito control intervention shapes bite exposure dynamics in the population. So far in both study sites, we have observed a significant positive correlation between all salivary peptides and Plasmodium antigens suggesting an important association between exposure to mosquito bites and immune responses against Plasmodium in this area. Our results highlight the relevance of using antibodies against salivary proteins as an indirect tool to measure efficacy of vector control interventions in malaria endemic areas to support malaria elimination efforts.

6126

EPIDEMIOLOGIC RISK FACTORS TO URBAN MALARIA IN WESTERN AND COASTAL KENYA

Caroline Ichura[1], Bryson Ndenga[2], Francis Mutuku[3], Gladys Agola[4], Jael S. Amugongo[3], Zainab Jembe[3], Paul S. Mutuku[3], Charles M. Nganga[3], Mwangosho M. Mshahme[5], Said L. Malumbo[3], A.Desiree LaBeaud[1]

[1]Stanford School of Medicine, Palo Alto, CA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Technical University of Mombasa,, MOMBASA, Kenya, [4]Msambweni Hospital, MOMBASA, Kenya, [5]Technical University of Mombasa,, Mombasa, Kenya

Most countries in Sub-Saharan Africa are reporting an increase in urban population growth. With Kenya still reporting a high endemicity of malaria in various urban regions, it is not known how urbanization will affect vector populations, disease transmission and control measures. Our prospective cohort study was conducted at two urban towns in Coastal (Ukunda) and Western (Kisumu) Kenya with demographic and risk factor surveys administered every 6 months between December 2019- February 2022. Participants were also interviewed any time they had a fever during the duration of the study. Blood samples were collected during the community survey and febrile (sick) visits for the detection of malaria by microscopy. Only survey responses at enrollment were considered in this preliminary risk factor analysis due to a high attrition rate and non-response during the follow up periods. The overall study prevalence for malaria in our study was 12.8 % (578/4534) with a significantly higher seroprevalence in Kisumu (20.1%,518/2521) than in Ukunda (3.0%, 60/2013) ,(OR=8.42, 95% CI =6.40-11.08;(p<0.01). 63.3 % (366/578) of all confirmed malaria diagnosis were from a febrile (sick) visit, 29.8%(172/578)were detected during the community survey, and 6.9% (40/578) during both the community survey and sick visit. Among the malaria-positive patients, 98.6% (570/578) of them were positive for Plasmodium falciparum, and 1.4 % had mixed infections of P. falciparum and P. malariae. There was an increased likelihood of malaria among children (<16 Years), (OR =1.43,95% CI =1.20-1.70 ; P < 0.01), those who had moved from their primary residence 6 months prior to the administration of the survey (OR =9.5, 95% CI =7.28-12.35 ; P < 0.01),and those with indoor occupations (OR =1.43,95% CI =1.20-1.70 ; P < 0.01).There was a decreased likelihood of malaria among households that had window screens, (OR =0.30, 95% CI = 0.22-0.41 ; P < 0.001).Gender, water collection, and insecticide use were not associated with malaria positivity in our study.Further studies are still needed to understand the epidemiology of malaria in urban settings in Sub-Saharan Africa.

6127

MAXIMIZING THE USE OF HUMAN POPULATION MOVEMENT DATA FOR MALARIA CONTROL AND ELIMINATION

Greta Tam[1], Ipsita Sinha[1], Kulchada Pongsoipetch[1], Keobouphaphone Chindavongsa[2], Mayfong Mayxay[3], Sonexay Phalivong[1], Elizabeth Ashley[3], Benjamin Cowling[4], Olivo Miotto[1], Richard Maude[1]

[1]Mahidol Oxford Tropical Medicine Research Unit (MORU), Bangkok, Thailand, [2]Center of Malariology, Parasitology and Entomology (CMPE), Vientiane, Lao People's Democratic Republic, [3]Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Vientiane, Lao People's Democratic Republic, [4]University of Hong Kong, Hong Kong, Hong Kong

Malaria transmission through human population movement (HPM) poses a major obstacle to malaria elimination. We hypothesize that the collection of routine surveillance data on travel patterns of malaria patients in a country nearing malaria elimination could be used to maximize the use of HPM data for malaria elimination. From May 2017 to December 2021 we enrolled 6320 malaria patients from 107 health facilities Lao PDR. We obtained information on demographics, travel patterns, mobile phone use and ownership and collected dried blood spots. 27% were females, 73% males. Median age was 19 years. 58% had Plasmodium vivax, 40% P. falciparum, 1% mixed P. falciparum and P. vivax, 0.02% P. knowlesi and

0.02% P. ovale. The proportion of malaria patients travelling increased from 55% to 85%. Travel to the forest was most common, increasing from 53% to 75%. Attapeu was the most popular destination for inter-province travel (44-100%). During COVID, travel concentrated to Attapeu (from 46% to 60%) and Phouvong (from 26% to 53%), while inter-province and inter-district travel elsewhere decreased. The demographics of forest visitors remained unchanged. Males 25-49 years comprised the largest proportion of forest visitors and farmers remained the most popular occupation (59-69%). Visitors tended to stay overnight in the forest (71%). While mobile phone use in the general population was high (according to census), 24% of malaria patients owned or used a mobile phone. At district level, API was weakly negatively correlated with mobile ownership proportion (R2= 0.3, p-value= 0.005). Mobile phone ownership and use in both genders was significantly lower when compared to the general population (p<0.001), regardless of province, gender separated by province, age group and age groups separated by gender (P<0.001). In conclusion, routine collection of detailed travel surveys from malaria patients provide rich information to inform activities and future national malaria programmes. Low mobile phone ownership among malaria cases suggests use of cell phone data to analyze travel patterns will be relatively uninformative and travel surveys should be prioritized.

6128

POLICIES, KNOWLEDGE, ATTITUDES AND PRACTICES RELATED TO MALARIA, HELMINTHS AND SCHISTOSOMIASIS AMONG PREGNANT WOMEN IN GHANA: AN ETHNOGRAPHIC STUDY IN TWO GHANAIAN REGIONS

Matilda MA Aberese-Ako[1], Gifty Ampofo[1], Pascal Magnussen[2], Harry Tagbor[1]

[1]University of Health and Allied Sciences, Ho, Ghana, [2]University of Copenhagen, Copenhagen, Denmark

The sub-Saharan African Region is burdened with high prevalence of malaria, helminth infections and schistosomiasis, which makes pregnant women within this region susceptible to infections. The study sought to explore policies on dealing with infections during pregnancy in health facilities and to describe knowledge, attitudes and practices among pregnant women related to malaria, helminths infection and schistosomiasis. This ethnographic study was carried out in two administrative regions in Ghana. It employed non-participant observation, in depth interviews (IDIs), focus group discussions (FGDs) and key informant interviews. Two sets of data were collected: (1) IDIs with health workers and health managers and (2) community key informant interviews with gatekeepers, IDIs with husbands and FGDs with pregnant women and lactating women. NVivo Version 12 was used to support thematic coding and analysis of data. All the health facilities implemented treatment guidelines on malaria during pregnancy based on WHO recommendations, however there were no uniform guidelines on treatment of helminths and schistosomiasis. Most of the study participants in the communities had knowledge on the causes and effects of malaria in pregnancy, but had little knowledge on the causes and effects of helminths infections and schistosomiasis in pregnancy. They mentioned health facilities as the place to seek treatment for malaria. FGD participants claimed that when they were pregnant or during their current pregnancy, they were not given dewormers and medicine to treat schistosomiasis at the ante natal clinic, so they did not view helminths infection and schistosomiasis as serious health issues needing attention. It was revealed that some pregnant women visited multiple sources such as health facilities for the treatment of malaria and other illnesses, but if they still felt unwell, they visited herbalists or self-medicated. Education on other infections that can have a negative effects on pregnancy should be intensified. The health service authority needs to provide clear guidelines for dealing with parasitic infections during pregnancy.

6129

INCREASING PATTERN OF MALARIA CASES IN LOW ENDEMIC DISTRICTS IN RWANDA

Michee S. Kabera[1], Kaendi Munguti[2], Aimable Mbituyumuremyi[1], Noella Umulisa[3], Jean Louis MANGARA[1], Emmanuel Hakizimana[1]

[1]Rwanda Biomedical Center, Kigali, Rwanda, [2]U.S. President's Malaria Initiative, Kigali, Rwanda, [3]JHPIEGO, Kigali, Rwanda

Malaria remains a public health priority in Rwanda with the whole population being at risk of malaria infection. In 2016, Malaria stratification based on malaria incidence identified four epidemiological strata across the 30 districts of Rwanda. Since then, following core interventions have been deployed accordingly and based on availability of funds: early diagnosis and treatment both at health facility and community level, long Lasting insecticidal nets, indoor residual spraying in 12 high endemic districts, and information, education and communication as cross-cutting intervention. At National level, from 2020 to 2022, based on malaria cases reported from Health Management Information System, malaria incidence reduced from 114 to 76 per 1,000 persons with a 33% of reduction. While Rwanda malaria reduced in the last two years in high burden districts covered with core vector control interventions mainly IRS, low burden districts such as Musanze, Nyabihu, Burera and Gakenke mainly of Northern Province reported more malaria cases. Throughout this period, malaria incidence increased from 10 to 16 malaria cases per 1000 persons in these formerly lowest endemic districts, the number of malaria cases increased by 62% from 16,383 in 2020 to 26,591 cases in 2022. In Burera, malaria incidence remained constant at 5 per 1000 persons while in Gakenke malaria incidence increased from 25 to 41 per 1000 persons. Malaria incidence increased by 93% in Musanze and 67% in Gakenke. It was also found that malaria cases were heterogeneously distributed in sub-district in few sectors per each district. While the focus of malaria control over the last six years has been on high endemic districts, in low burden districts, malaria increase may not take adequate attention to malaria managers and pause a really threat to the population and sustainable of achievement in high endemic district. Therefore, it is important to continuously analyze data especially at sub-district levels, the sector, in order to determine most affected sub-areas and any changes in malaria epidemiology so as to deploy appropriate interventions in a timely manner

6130

THE ASSOCIATION BETWEEN MALARIA PARASITAEMIA, INTESTINAL PARASITE AND ANEMIA IN CHILDREN LESS THAN 6 MONTH IN SENEGAL: A CROSS SECTIONAL SURVEY

Lelo Souleye, Aly Gueye, Sylla Khadim, Cheikh Bintou Fall, Isacc Akheneton Manga, Doudou Sow, Magatte Ndiaye, Jean Abdourahim Ndiaye, Oumar Gaye, Roger Clement Tine, Babacar Faye

UCAD, Dakar, Senegal

Although malaria is declining in many countries in Africa, malaria and anaemia remain frequent in children. This study was conducted to assess the relationship between malaria parasitaemia, intestinal worms, and anaemia, in children under 6 months of age living in low transmission area in Senegal. A cross sectional survey was carried out in Lamarame in the central part of Senegal. A random sampling method was used to select study participant. Children under 6 months were enrolled after informed consent. For each child, blood thick and smear tests were performed, haemoglobin concentration was measured with HemoCue, and stool samples were collected and examined using the Ritchie technique. A total of 162 children were recruited. Malaria parasite prevalence was 0.75% (0.7-2.6); anaemia was found in 16.7% (11.3-23.3), while intestinal parasites and stunting represented 25.4% (18.5-33.4) and 22% (18.6-25.5), respectively. In a logistic regression analysis, anaemia was significantly associated with malaria parasitaemia (aOR= 6.3 (1.5-53.5)) and stunting (aOR = 2 (1.2-3.1)); The association was found between intestinal parasites and anaemia (OR=1.1(0.5-3.4). Malaria and anaemia remain closely associated

even when malaria is declining. Scaling up antimalarial interventions may contribute to eliminate malaria and reduce the occurrence of anaemia among children.

SEASONAL DYNAMICS OF COMPOSITION AND DENSITY OF CO-ENDEMIC PLASMODIUM FALCIPARUM AND P. VIVAX IN ELIMINATION SETTING, SOUTH ETHIOPIA: IMPLICATIONS FOR ELIMINATION

Eshetu Molla Belete, Lina Alemayehu, Legesse Alamerie, Jimma Dinsa, Melat Abdo, Migbaru Keffale, Sinknesh Wolde Behaksra, Sisay Dugassa, Endalamaw Gadisa Belachew, Fitsum Girma Tadesse, Hassen Mamo

Armauer Hansen Research Institute, Addis Ababa, Ethiopia

Malaria elimination requires targeting all remaining infections including the ones that do not elicit symptoms. It is important to evaluate the magnitude and parasite density of residual malaria in terms of species composition and season in elimination-targeted settings. To appraise these, longitudinal data were collected for one year between 2019 and 2020 covering major and minor transmission seasons and the dry season. Three elimination-targeted low transmission settings: Dilla town, Wonago, and Yirgacheffe were included. In each season, 504 individuals from 168 households were sampled. Microscopy, RDTs, ELISA, and 18S-based qPCR were performed. Overall, parasite prevalence was 7.3%, 6.8%, and 17.5% by microscopy, RDT, and qPCR, respectively. Microscopy (10.4%) and RDT (10.7%) missed infections detected by qPCR. The PvAMA1/PvMSP1/PfMSP1 antibody prevalence was 20.2%-30.4% based on the K-means algorithm. qPCR-based parasite prevalence showed seasonal variation with 12.5%, 18.3%, and 21.8% during the minor, peak, and dry seasons respectively ($p<0.05$). Of these, Plasmodium vivax infections were dominant during the minor (54.0%, 34/63) and dry (64.5%, 71/110) seasons. The highest malaria case burden was reported in the urban setting, Dilla town (29.6%, 149/504). High parasitemia was detected for both P. falciparum (median 159,44518S copies/µL) and P. vivax (median 140,321) for all seasons. A significant density of parasitemia was observed during the peak rain season ($p<0.05$). From the GEE model, study site, anemia, clinical status and bed net utilization ($p<0.001$) showed significant association with malaria. The over-dominance of P. vivax in two seasons implicates control measures need to consider tailored approaches. The considerable missing cases by conventional methods, even those parasite densities above the detection threshold of microscopy, may pose a challenge to elimination progresses. The noticed high malaria burden in urban settings and all seasons need spatial and year-round interventions through the elimination program. Also, the stratification of some settings as low transmission areas needs to be reconsidered.

6132

ASSOCIATION BETWEEN ANAEMIA AND PLASMODIUM FALCIPARUM AND HELMINTH INFECTIONS AMONG CHILDREN AND YOUNG ADULTS LIVING IN RURAL AREAS OF GABON, CENTRAL AFRICA

Jean Ronald Edoa[1], **Christian Lapue Chassem**[1], Jeannot Fréjus Zinsou[1], Yabo Josiane Honkpéhèdji[1], Romeo Adegbitè[1], Stravensky Térence Boussougou-Sambe[1], Tamirat Gebru Woldearegai[2], Benjamin Mordmüller[3], Ayôla Akim Adegnika[1], Jean Claude Dejon-Agobé[1]

[1]CERMEL, Lambarene, Gabon, [2]Institut für Tropenmedizin, Universitätsklinikum Tübingen, Tübingen, Germany, [3]Department of Medical Microbiology, Radboud University Medical Center, Nijmegen, Netherlands

The objective of this analysis was to describe in a cohort of school-aged children and young adults the profile of anaemia and its association with malaria and helminth infections. The study was longitudinal where participants were followed for 15-months. However, the present analysis was performed on data collected at six months follow-up. Blood samples were collected for the determination of haemoglobin parameters using an automated haematology analyzer, for the detection of malaria parasites using thick blood smear microscopy, and for the diagnosis of filariasis using leucoconcentration technique. Stool samples were collected for the diagnosis of soil-transmitted helminths (STH) while urine samples were collected for the diagnosis of schistosomiasis. Anaemia and its severity were defined using the WHO criteria for the level of the sea. General linear regression was used to assess factors associated with anaemia. A total of 217 participants were included in the present analysis. Of them, 73% (160, 95%CI: 67 - 79) were anaemic. Among the anaemic participants, most had a normal MCV value (42%, 95%CI: 34 - 50), compared to low (27%, 95%CI: 20-35) or high (31%, 95%CI: 24-39) values of the MCV. A low value of MCH (66%, 95%CI: 58 - 73) and MCHC (70%, 95%CI: 62 - 77) was observed in more than half of the participants. Anaemia was associated with Plasmodium infection (p-value=0.04) but not with STH infections (p-value=0.16), schistosomiasis (p-value=0.12) or filariasis (p-value=0.59). After multivariate analysis adjusted for age, sex, and helminth infections, participants with Plasmodium parasites had an adjusted odd of 2.44 (95%CI: 1.07 - 6.13), compared to those without Plasmodium infection. In conclusion, the prevalence of anaemia in children and young adults is high in rural areas surrounding Lambaréné, making anaemia a significant public health issue in our community. We reported malaria as the main parasitic infection associated with anaemia in the area also known to be endemic for STH infections, schistosomiasis, and filariasis. Our results, therefore, call for more interest in anaemia in the general population.

6133

ASSESSMENT OF THE BURDEN AND DETERMINANTS OF MALARIA TRANSMISSION IN SELECTED URBAN SETTLEMENTS IN NIGERIA

Eniola Adetola Bamgboye[1], Akintayo Ogunwale[2], Olabanji Surakat[3], Joshua O. Akinyemi[2], Adeniyi Fagbamigbe[2], Musa Bello[4], Al-Mukthar Adamu[4], Monsuru Adeleke[3], IkeOluwapo O. Ajayi[2], Ifeoma Ozodiegwu[1]

[1]NorthWestern University, Chicago, IL, United States, [2]University of Ibadan, Ibadan, Nigeria, [3]Osun State University, Osogbo, Nigeria, [4]Bayero University, Kano, Nigeria

Nigeria is the highest-burden malaria country. Unplanned urbanization may result in environmental conditions that promote heterogeneities in malaria risk. Identifying urban settlements with high malaria transmission risk will guide better targeting of interventions. We are conducting field epidemiological and entomological studies to understand the variations and drivers of malaria risk in formal and informal settlements, and slums in Kano and Ibadan cities. The design of our epidemiological and entomological assessments is informed by formative research. Study sites were chosen based on findings from multistakeholder dialogues which helped in defining and identifying settlement types. Focus group discussions, key informant interviews, and cognitive interviews were conducted to inform the design of quantitative instruments for epidemiological surveys. Our epidemiological surveys aim to estimate malaria prevalence and identify related factors among all ages, and pregnant women. To achieve this, we are conducting household and health facility cross-sectional surveys during the wet and dry seasons. We are also conducting 12-month longitudinal surveys to assess malaria seasonality and drivers among children under the age of 10 years. Dry and wet season entomological surveys (mosquito collection using CDC light trap and Pyrethrum Spray catches) are being conducted to establish the presence or absence of local transmission using various entomological indicators. Preliminary findings from the multi-stakeholders dialogue revealed that having a settlement plan, social amenities, and population densities were key factors useful for categorizing settlement types into formal, informal, and slums. During dry season entomological surveys, we captured two main malaria vectors - Anopheles Gambiae and Anopheles Funestus between the hours of 6 pm and 5 am in all settlement types, although most vectors were found in informal settlements. Results from the wet season cross-sectional surveys and early findings from the longitudinal surveys will be available for presentation at the annual meeting.

PLACENTAL MALARIA AND BLOOD PRESSURE AT AGE FOUR YEARS: EVIDENCE FROM THE GHANA RANDOMIZED AIR POLLUTION AND HEALTH STUDY

Seyram Kaali[1], Darby Jack[2], Mohammed Nuhu Mujtaba[1], Steven N. Chillrud[3], Musa Osei[1], Theresa Tawiah[1], Stephaney Gyaase[1], Prince Agyapong Darko[1], Blair J. Wylie[4], Kwaku Poku Asante[1], Alison G. Lee[5]

[1]Kintampo Health Research Centre, Kintampo, Ghana, [2]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, NY, United States, [3]Lamont-Doherty Earth Observatory of Columbia University, New York, NY, United States, [4]Department of Obstetrics and Gynecology Research, Columbia University Irving Medical Center, New York, NY, United States, [5]Division of Pulmonary, Critical Care and Sleep Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, United States

In sub-Saharan Africa, malaria and hypertension are one of the commonest causes of morbidity and mortality in children and adults respectively. Although previous studies have shown that malaria in pregnancy may increase the risk of gestational hypertension, the effect of placental malaria (PM) on blood pressure (BP) in childhood has not been well studied. The Ghana Randomized Air Pollution and Health Study recruited N=1414 non-smoking women prior to 24 weeks gestation in the Kintampo North Municipality and Kintampo South District of Ghana. PM was assessed by placental histology of full-thickness biopsies obtained at delivery. PM was first dichotomized as no infection or evidence of any infection followed by a more detailed classification: no infection, acute infection, chronic infection or past infection. At age four years, a subset of study children underwent two resting BP measurements, spaced five minutes apart after a 10-minute rest, using the digital OMRON BP742N BP monitor (OMRON Healthcare, CA, USA). We employed multivariable linear regression models to examine associations between PM and childhood systolic and diastolic BP. Of the N=1306 livebirths at 28+ weeks gestation, N= 639 had both valid PM and blood pressure data. The prevalence of PM was 24%. The mean systolic BP (SBP) and diastolic BP (DBP) at age four was 90.2 mmHg and 64.2 mmHg respectively. Following adjustment for child sex and BMI, maternal age and parity, wealth index and ethnicity, PM (any infection) trended towards increased DBP (β=1.51 mmHg; 95% CI -0.20 to 3.22; p=0.08) compared with no infection. Similarly, evidence of past PM showed a trend towards increased DBP (β=1.78 mmHg; 95% CI -0.27 to 3.82; p=0.09) compared with no infection. There was no evidence of an association between PM and SBP. PM may be associated with increased diastolic BP in early childhood. Given that childhood BP tracks into adulthood, larger longitudinal studies are needed to understand the effects of in-utero exposure to malaria and the risk of hypertension in childhood and whether this risk in sustained to adulthood.

EVALUATION OF THE SEASONALITY OF MALARIA TRANSMISSION THROUGH ROUTINE DATA FROM HEALTH FACILITIES IN BURKINA FASO

Alassane Haro[1], Issaka Zongo[1], Abdoul Aziz Sienou[1], Moussa Zongo[2], Yves Daniel Compaoré[1], Paul Snell[3], Jean-Bosco Ouedraogo[2]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]Institut des Sciences et Techniques, Bobo-Dioulasso, Burkina Faso, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Malaria transmission is strongly seasonal peaking in the rainy season.in Burkina Faso and the country counts for the “high burden to high impact” initiative launched by WHO and the roll Back Malaria Partnership. Despite combined effective control measures include large scale distribution of long-lasting insecticide treated bed nets, the chemoprevention in pregnant women and the seasonal malaria chemoprevention in children 3-59 months, prevalence and incidence of malaria remain high, even though high proportion of diagnosed malaria are unconfirmed (either microscopy or rapid diagnosis test) despite continued effort to confirm malaria diagnosis. Thus, in this project, we aimed to investigate how the diagnosis of malaria in the absence of microscopy or Rapid Diagnosis Test confirmation is impacting malaria seasonality appraisal. Through the ACCESS-SMC project, we conducted a retrospective extraction of routine data from 40 randomly-selected health facilities in 8 different health districts spread all over the country from 2012 to 2016. Data collected included gender, age, clinical signs (fever, vomiting, diarrhea and other signs suggestive of malaria), the performance of rapid diagnosis test or not and the final diagnosis along with the treatment administrated. Overall, 826,199 consultations for suspected malaria were recorded over the study period. There was 36,34% increase in the testing rate between 2012 and 2016 (43.32 versus 79.66%). January to June considered as the low transmission period there were respectively 59.21% [range: 58.79%-59.64%] and 46.34% [range: 45.89%-46.8%] of unconfirmed malaria recorded while July to December considered as the highest transmission period, we recorded respectively 33.63% [range: 33.29%-33.96%] and 46.64% [range: 46.22%-47.06%]. Comparing these periods, the proportion of confirmed malaria is different between the two periods compared to the unconfirmed cases.

6136

MEASURING IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON MALARIA CASE DISTRIBUTION FROM ROUTINE DATA SOURCES COMPARED TO MODELLED PREDICTIONS IN BURKINA FASO

Monica De Cola[1], Benoit Sawadogo[2], Cheick Campaore[2], Sidzabda Kompaore[3], Christian Rassi[4], Patrick Walker[1], Lucy Okell[1]

[1]Imperial College London, London, United Kingdom, [2]Malaria Consortium, Ouagadougou, Burkina Faso, [3]Ministry of Health; Permanent Secretary for Malaria Elimination, Ouagadougou, Burkina Faso, [4]Malaria Consortium, London, United Kingdom

Clinical trials assessing effectiveness of seasonal malaria chemoprevention (SMC) show high impact preventing around 80-85 percent of uncomplicated cases of malaria in children under 5. However, when implemented at scale, SMC programmes have not shown the expected impact in routine and administrative data. We are using a mathematical model to develop a framework for assessing impact of SMC programmes by bringing together relevant data such as prevalence, rainfall, health management information system (HMIS) case data, other interventions, implementation of SMC. We calibrated a malaria transmission model to malaria prevalence (Demographic Health Surveys [DHS]) over time for selected health districts in Burkina Faso using maximum likelihood methods by varying mosquito density. We simulated clinical cases in under 5’s during implementation of SMC in each district including rainfall, net use (Malaria Atlas Project), and treatment seeking (DHS). We compared model predictions of the proportion of clinical malaria cases in children under 5 out of children under 15 to district level rapid diagnostic test confirmed cases from the HMIS. The age distribution of cases aligns well with model simulations prior to SMC, however, model predictions show a larger change after SMC and this change varies by baseline transmission. This could be due to non-malarial fevers presenting at the health facility affecting seasonal patterns in routine data. We will present modelling analyses assessing the effect non-malarial fevers have on seasonal patterns and the extent to which these may mask the impact of SMC seen in routine data.

6137

MOLECULAR SCREENING SUGGESTS ANTAGONISM BETWEEN PARASITEMIA WITH PLASMODIUM FALCIPARUM AND P. OVALE IN TANZANIA

Kelly B. Carey-Ewend[1], Meredith Muller[1], Editruda Peter[2], Melic Odas[2], Srijana Chhetri[1], Christopher Basham[1], Jonathan J. Juliano[1], Billy Ngasala[3], Jessica Lin[1]

[1]University of North Carolina - Chapel Hill, Chapel Hill, NC, United States, [2]Muhimbili University of Health and Allied Sciences, Bagamoyo, Tanzania, United Republic of, [3]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

Even as Plasmodium falciparum burden has declined in parts of sub-Saharan Africa in recent years, the prevalence of non-falciparum species, such as P. ovale, appears to be rising in the same populations. We employed cross-sectional molecular screening of over 6000 participants >5 years of age residing in coastal Bagamoyo, Tanzania, to examine rates of mono- and co-infection with P. falciparum and P. ovale and investigate possible cross-species interactions. Specifically, we calculated the prevalence ratio of ovale parasitemia between individuals who were positive and negative for falciparum parasitemia using a binomial logistic regression adjusting for age, sex, and seasonality. Of 6,258 participants screened between October 2018 and November 2021,1,929 (31%) were positive for P. falciparum and 644 (10%) were positive for P. ovale. These distributions show evidence of an antagonistic interaction, with individuals positive for P. falciparum having 0.67 (95% CI: 0.56, 0.82) times the probability of also having P. ovale compared to falciparum-negative individuals. This finding of fewer mixed infections than expected by independent assortment was detected in all age groups except adolescents, with age-stratified P. ovale prevalence ratios (95% CI) comparing falciparum-positive to falciparum-negative participants of 0.71 (0.52, 0.97), 1.14 (0.76, 1.74), 0.44 (0.28, 0.69), and 0.62 (0.42, 0.92) among participants ages 6-12, 13-18, 19-30, and >30, respectively. Potential explanations for these results could be that cross-protective immunity or competitive inhibition from the more-common falciparum malaria reduces detected co-infection by decreasing P. ovale susceptibility or parasitemia, or by suppressing ovale relapse infections. We plan to replicate this analysis using data from other molecular surveys in Tanzania and elsewhere in sub-Saharan Africa; if replicated, this interaction may help explain the relative resilience of non-falciparum species amidst declining falciparum burden.

6138

INTRA-HOST CLONAL DYNAMICS SHAPE CHRONIC PLASMODIUM FALCIPARUM INFECTIONS THROUGH THE DRY SEASON

Manuela Carrasquilla[1], Pablo Cárdenas[2], Carolina M. Andrade[3], Jessica Briggs[4], Christina Ntalla[1], Tanto Situmorang[1], Martin Kampmann[1], Shanping Li[5], Safiatou Doumbo[6], Didier Doumtabe[6], Aissata Ongoiba[6], Kassoum Kayentao[6], Moussa Niangaly[1], Boubacar Traore[6], Bryan Greenhouse[4], Silvia Portugal[1]

[1]Max Planck Institute for Infection Biology, Berlin, Germany, [2]Department of Biomedical Engineering, MIT, Cambridge, MA, United States, [3]Institute for Molecular Life Sciences Radboud University, Nijmegen, Netherlands, [4]School of Medicine University of California San Francisco, San Francisco, CA, United States, [5]National Institute of Allergy and Infectious Disease, Bethesda, MD, United States, [6]Mali International Center of Excellence in Research, Malaria Research and Training Centre (MRTC), University of Sciences Techniques and Technologies of Bamako, Bamako, Mali, Bamako, Mali

Plasmodium falciparum can persist in asymptomatic individuals for extended periods of time, which is particularly relevant in regions where malaria transmission is almost entirely interrupted by a long dry season. In Mali, up to 30% of children carry P. falciparum throughout the dry season without symptoms, comprising a genetic reservoir that bridges two transmission seasons. Our data show that the decreased virulence of the parasite during the dry season is likely not influenced by sensing of seasonal cues, but rather by the timing of inoculation and number of replicative cycles that individual parasite clones undergo within a host. We applied amplicon sequencing of a highly polymorphic gene (apical membrane-antigen 1) on longitudinal samples collected fortnightly in Kalifabougou, Mali, from gender-and-age matched individuals during one transmission season that maintained P. falciparum persistent infections during the 6-month dry season (n=92) or that cleared them due to either treatment during the season or to natural clearance (n=38). We observed that children with persisting parasites had a higher overall within-host diversity (measured by Shannon evenness of clonal abundance), even when taking into account differences in complexity of infection or parasite density, than those who did not. The ability of children with dry season persistent infections to control parasites more broadly suggests that immunity plays a role in structuring this diversity, and that clonal abundance is a predictor of persistence. We apply these data to inform mathematical models and intra-host simulations to determine drivers of persistence throughout and evaluate our predictions with longitudinal data collected monthly during the dry season in Torodo, Mali (n=74). Our findings highlight how the within-host clonal dynamics over time promote persistence and may inform new strategies for elimination in areas with highly seasonal transmission.

6139

EVALUATING MALARIA PREVALENCE IN NON-HOMOGENEOUS FOR MAL AND INFORMAL COMMUNITIES IN FREETOWN SIERRA LEONE: A MULTIPHASE CROSS SECTION SECTIONAL STUDY

Joseph Lewinski[1], Abdul Koroma[2], Hilton Matthews[2], Akinola Shonde[3], Claudia Smith[2], Sulaiman Conteh[4], Mohammed Samai[4]

[1]Catholic Relief Services, Baltimore, MD, United States, [2]Catholic Relief Services, Freetown, Sierra Leone, [3]Catholic Relief Services, Abuja, Nigeria, [4]College of Medicine and Allied Health Sciences, Freetown, Sierra Leone

Limited resources for malaria, including in Sierra Leone, require national programs to stratify activities within urban areas. Simultaneously urbanization and changing transmission dynamics require innovative approaches for malaria control in urban areas. Catholic Relief Services (CRS) and the College of Health and Allied Sciences undertook a cross-sectional study from July 2021 to November 2022 to determine the prevalence of malaria in children 6-59 months old in four separate communities within Freetown. Two communities were identified as formal (Wilberforce and Hill Station) and two informal (Kolleh Town and Cockle Bay). Freetown, has two peak transmission seasons in May and the second in October/November, however, changing weather patterns have delayed rains in recent years. The three cross-sectional surveys were conducted within the four communities based on rainfall in the low transmission season (RD1, August 2021), mid-year transmission season (RD2, June/July 2022), and peak transmission seasons (RD3, November/December 2022). We observed a consistently higher malaria prevalence in the formal settlements [μ=14% - 11.1% RD1, 13.6% RD2 & 17.4% RD3] than informal settlements [μ=11.3%- 10% RD1, 8.7% RD2 & 15.2% RD3]. In formal areas 36% of houses were identified to be 'traditional' in construction suggesting that increased urbanization is leading to blended (non-homogeneous) formal areas. Other factors such as housing type, ITN ownership, and wealth quintile were variable in predictive association for malaria among households in formal and informal areas. The results demonstrate that increased urbanization has resulted in non-homogeneous areas of Freetown, and that malaria rates are higher than reported in national malaria surveys. New approaches including improved WASH, housing, and vector control are needed within urban areas to help stratify available malaria resources.

6140

HIGH-THROUGHPUT GENOTYPING OF PLASMODIUM VIVAX IN THE PERUVIAN AMAZON VIA MOLECULAR INVERSION PROBES

Zachary R. Popkin-Hall[1], Karamoko Niaré[2], Rebecca Crudale[2], Alfred Simkin[2], Abebe A. Fola[2], David J. Giesbrecht[2], Jeffrey A. Bailey[2], Jonathan J. Juliano[1], Hugo O. Valdivia[3]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Brown University, Providence, RI, United States, [3]NAMRU-6, Lima, Peru

Genomic epidemiology has enabled in-depth, high-throughput study of Plasmodium populations, antimalarial resistance, and importation. Molecular inversion probes (MIPs) have enabled efficient and affordable high-throughput genotyping of Plaasmodium falciparum populations in African contexts, but application to other species has lagged. P. vivax is the most widespread human malaria species and is an emerging threat in many areas with successful P. falciparum control. As such, there has been a recent proliferation in global P. vivax genomics studies facilitated by the superior PvP01 genome assembly. Leveraging the success of P. falciparum MIPs, we developed four P. vivax MIP panels covering: 1) known genes of interest (e.g. reticulocyte binding proteins, Duffy binding proteins, potential vaccine targets, potential drug resistance genes, and diversity markers); and SNPs identified in globally distributed (including Africa) whole genome sequences that are 2) highly geographically differentiating; 3) neutral and rare; and 4) neutral and common. We used these panels to study the population structure of 689 Peruvian P. vivax samples collected by NAMRU between 2011 and 2017 in the region around Iquitos. The panels consistently perform well with isolates at ≥ 200 p/µL, with some isolates <100 p/µL also performing well in initial sequencing. Across both our SNP panels and our genes of interest (e.g. RBP2), we detect a lack of rare alleles (Tajima's D > 2), which could indicate balancing selection in genes associated with RBC invasion that are under immune selection. Assessment of directional selection signatures in the population are ongoing, including evaluation of putative drug resistance alleles. Overall, we find minimal large-scale geographic or temporal structure among these samples based on PCA, consistent with a long-term panmictic population. However, at the local level we detect clusters within the same city and year that may represent local outbreaks and warrant further investigation. The new P. vivax MIP panels provide a high-throughput genotyping approach to interrogate genome-wide SNPs as well as genes of biological interest.

6141

PLASMODIUM VIVAX SHOWS HIGH GENETIC DIVERSITY AND RAPID LOCAL ADAPTATION IN A REMOTE COMMUNITY FROM THE PERUVIAN AMAZON REGION

Roberson Ramirez[1], Katherine Torres[2], Pamela Rodriguez[1], Alejandro Llanos-Cuentas[3], Joseph Vinetz[4], Dionicia Gamboa[5]

There is no a lot of information about Plasmodium vivax malaria transmission and parasite genetic diversity in remote hard to reach areas from the Peruvian Amazon that represent a challenge to achieve the long-awaited malaria elimination. The main objective of this work was to evaluate the P. vivax population genetics changes over time in the community of Santa Emilia, province of Loreto. Weekly active case detection and monthly screening were performed in 2013 and 2015-2016. A prevalence of 49% [IC 43-55] by microscopy and 82% [IC 77- 86] by PCR was found during all the surveillance activities. In addition, 350 out of 529 total samples were genotyped using sixteen neutral microsatellite markers. The result showed high genetic diversity (0.70 ± 0.10 in average) over time, high population differentiation (Fst> 0.5) between 2013-2015 and 2013-2016, and 40% of polyclonal infections. Additionally, we found the absence of a recent bottleneck in the population, with the presence of new alleles, supported by 14% of genetically unrelated parasites. Bayesian inference indicates that four more likely clonal populations (ΔK = 4) were circulating during this period of time. In conclusion, our results suggested that P. vivax had rapid adaptation and expansion in Santa Emilia and this community presents a high vulnerability to the importation of new parasites that support local transmission and high genetic diversity maintenance. This scenario may be due to the local human mobility, that should be better studied in these remote areas. This information is relevant to focalize or adapt the elimination strategies, already in place, mainly in remote communities.

6142

GENETIC ANALYSIS REVEALED HIGHLY RELATED LOCAL TRANSMISSION OF PLASMODIUM FALCIPARUM IN THE ISLAND OF SÃO TOMÉ

Ying-An Angie Angie Chen[1], Arlindo Vicente Carvalho[2], Peng-Yin Ng[3], Ju-Hsuan Huang[3], Yu-Wen Huang[3], Aaron Elliot[4], LienFen Tseng[5], KunHsien Tsai[6], Bryan Greenhouse[4], Hsiao-Han Chang[1]

The Democratic Republic of Sao Tome and Principe (STP) is approaching malaria elimination and aiming to eliminate it by 2025. However, continuous transmission and increasing cases have been seen in the past few years. To target effective control strategies, it is crucial to characterize local transmission and identify risk factors of transmission. Here, we collected 419 samples on the island of São Tomé between 2015 and 2016 and applied a multiplexed amplicon sequencing approach targeting 165 diverse microhaplotypes to obtain genetic data for each sample. To quantify transmission intensity and identify transmission clusters, we used MOIRE to estimate complexity of infection (COI) and within-host parasite relatedness, and Dcifer to estimate inter-sample relatedness. Preliminary results from 120 samples showed a very high proportion of monoclonal infections (96.7%, 116/120; average COI = 1.08) and high relatedness among a large proportion of samples. Most samples from 2016 (76.4%; 68/89) and a few from 2015 (9.7%; 3/31) were part of a single, predominant genetic cluster with high relatedness (range of pairwise relatedness from 0.9 to 1.0). The predominant cluster was transmitted throughout 2016 and sustained in Agua Grande (67.6%, 46/68) and Lobata (23.5%, 16/68) districts. Most 2015 samples outside the predominant cluster also showed a significant pairwise relatedness (> 0.5) to one or more samples from 2016. Overall, our results demonstrate extreme bottlenecking of parasite diversity in 2016, suggestive of sustained but low local transmission with limited importation of Plasmodium falciparum in the island of São Tomé. We are currently working with case surveillance data to identify risk factors of transmission, which may further guide targeted elimination strategies.

GENOME STRUCTURE OF PFHRP2/3-DELETED PLASMODIUM FALCIPARUM: DELETION BREAK-POINTS AND CONSEQUENCES OF THE DELETION

Irene Molina-de la Fuente[1], Jody Phelan[2], Debbie Nolder[3], Lindsay Stewart[2], Donelly A. van Schalkwyk[2], Susana Campino[2], Colin J. Sutherland[2], Khalid B. Beshir[2]

[1]National Centre of Tropical Medicine - Institute of Health Carlos III, Madrid, Spain, [2]Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Public Health England Malaria Reference Laboratory, London School of Hygiene and Tropical Medicine, London, United Kingdom

Deletions in Plasmodium falciparum histidine-rich proteins 2 and 3 (pfhrp2/3) cause false-negative RDT results, threatening malaria control efforts. These deletions occur as spontaneous rearrangements in P. falciparum, but the mechanism, break-points, and the extension of the deletions into flanking regions are not well-described. It is also unknown what impact these genome rearrangements have on the parasite genome, and on the phenotypic diversity and environmental adaptability of the parasite. In this study, we investigated the genome structure of P. falciparum with pfhrp2/3 deletions to understand how the deletions occur and the impact of the deletions on chromosome architecture. We derived whole genome sequence for two pairs of clinical and culture-adapted isolates using high-quality short-read genomic sequencing and carried out de novo assembly to investigate genome rearrangement. The genomes were annotated and synteny maps generated against the 3D7 reference genome. Genomic rearrangements including duplications, inversions and translocations were common in the sub-telomeric regions of most of the chromosomes in all parasite lines, suggesting this is a relatively common process in P. falciparum which can lead to pfhrp2/3 deletions. There is a clear common break-point for pfhrp2 at a location adjacent to it, spanning the distal 25-50 kb at the right end of chromosome 8. By contrast, pfhrp3 occurs at the end of a deletion block spanning 600 kb at the right end of chromosome 13. These differences may suggest that pfhrp2 deletion is a recent positive selection event but pfhrp3 deletion could be a passive consequence of genetic hitchhiking. The majority of genes deleted together with pfhrp2 and pfhrp3 encode variant surface antigens (VSA), possibly altering the parasite's immune evasion repertoire. We also observed gene deletions broadly involved in sexual cycle proteins predicted to impact the transmissibility of the parasites. Understanding whether the parasites acquire any advantage linked with deletions can aid in planning appropriate control strategies.

Although overall malaria incidence has decreased sharply over the past two decades, progress has stalled since 2015. Vaccination is a control strategy that could limit malaria burden. While multiple malaria vaccines have been tested in phase 2 or phase 3 trials, and only one progressing to phase 4 trials, no vaccine has induced an overall clinical efficacy greater than 50% except the R21 vaccine. Understanding the parasite genetic factors playing a role in malaria pathogenesis could help identify essential proteins and aide in the design of an effective malaria vaccine. We hypothesize that clinical malaria phenotypes are a function of parasite density, genetic makeup of both parasite and host, starvation, co-infection, environmental factors, and potentially parasite and host epigenetic factors. To investigate the relationship between parasite genetics and clinical phenotypes, we have focused on apical membrane antigen 1 (AMA1), a parasite antigen involved in red blood cell invasion, which contains a cluster one loop (c1L) fragment that interacts with anti-AMA1 antibodies. Using ama1 gene sequences generated from samples collected from 425 children during a three-year malaria incidence study conducted in Bandiagara, Mali, we assessed the relationship between individual haplotypes and clinical malaria symptoms and disease phenotypes of those presenting with clinical malaria symptoms. AMA1 haplotype dynamics showed a gene under balancing selection. After adjusting for study participant location, using logistic regression, c1L haplotypes were not associated with malaria symptoms or disease phenotypes. None of the most frequent haplotypes were linked to clinical malaria, defined as any temperature greater than 37.5 degree Celsius and a parasitemia greater or equal to 2,500 parasites per microliter. Our findings suggest a lack of association between AMA1 haplotypes and symptomatic malaria. Likely, multiple factors are related to malaria symptomatology.

A NOVEL PROBABILISTICALLY MODEL BASED ON GENETIC DATA FOR ESTIMATING PLASMODIUM VIVAX RELAPSES AFTER RADICAL CURE TREATMENT

Ivonne Melissa Ramírez[1], Alessandro Grosso[1], Steven Abrams[1], Verónica E. Soto-Calle[2], Annette Erhart[3], Alejandro Llanos-Cuentas[4], Umberto D'Alessandro[3], Anna Rosanas-Urgell[5], Jean-Pierre Van geertruyden[1], Dionicia Gamboa[6], Christopher Delgado-Ratto[1]

[1]Malaria Research Group (MaRch)-Global Health Institute, Faculty of Medicine, University of Antwerp, Antwerp, Belgium, [2]Ministry of Health of Peru, Lima, Peru, [3]Medical Research Council Unit at the London School of Hygiene and Tropical Medicine, Banjul, Gambia, [4]Grupo de Estudio de Leishmaniasis y Malaria (GELM). Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Malariology Unit, Department of Biomedical Sciences. Institute of Tropical Medicine in Antwerp, Antwerp, Belgium, [6]Laboratory of Malaria. Unit of Molecular Epidemiology. Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

The diverse potential origins of recurrent infections after treatment against Plasmodium vivax make it difficult to estimate treatment anti-relapse efficacy. However, the genetics of parasite populations can support a more realistic estimation of the anti-relapse efficacy. Hereby, we developed a probabilistic statistical framework based on P. vivax microsatellite genotyping data from a cohort treated with chloroquine and primaquine in the Peruvian Amazon, aiming to estimate relapse events after treatment translated into anti-relapse efficacy. First, we performed multiple imputations to deal with missing microsatellite data using polytomous logistic regression models. Then, we proposed a probability of relapse integrating the prevalence of allelic profile and allelic dissimilarity index (multilocus comparison of pre-/post-treatment isolates). This informed to the binomial probability process to randomly impute the recurrent status (i.e., either reinfection or relapse), and multiply repeated to evaluate the uncertainty. Finally, Rubin's rules were applied to the final pooled estimates. Of 302 participants, 197 (65.2%) had at least one P. vivax recurrence during the 2-year follow-up. The pooled mean Nelson-Aalen cumulative hazard estimate of first heterologous recurrences was 4,0% at day 28 and increased gradually up to 2 years after treatment (45.7% at 6 months, 66.7% at 1y, and 88.5% at 2y). On the contrary, the first homologous recurrences only occurred from day 52 (0.35%) and were less frequent afterward (11.5% at 6 months, 13.5% at 1y, and 15,0% at 2y). The final pooled 6-month and 2-year cause-specific cumulative incidence function of first relapses after treatment were 0.22 (95% CI 0.17-0.28) and 0.29 (95% CI 0.23-0.35) for the overall study population. Our study proposes a statistical approach to identify the origin of P. vivax recurrences after treatment with a comprehensive assessment of the treatment's efficacy considering the parasite population's genetic features and the probability of relapse.

MOLECULAR SURVEILLANCE OF MALARIA PARASITES IN AN INDIGENOUS COMMUNITY IN THE PERUVIAN AMAZON

Luis Cabrera Sosa[1], Oscar Nolasco[1], Johanna H. Kattenberg[2], Carlos Fernandez-Miñope[3], Hugo O. Valdivia[4], Silvia Arévalo de los Rios[5], Hugo Rodriguez Ferrucci[6], Joseph Vinetz[7], Anna Rosanas-Urgell[2], Jean-Pierre Van geertruyden[3], Dionicia Gamboa[1], **Christopher Delgado Ratto**[3]

[1]Laboratorio de Malaria: Parásitos y Vectores, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium, [3]Malaria Research group (MaRch), Global Health Institute, University of Antwerp, Antwerp, Belgium, [4]Department of Parasitology, U.S. Naval Medical Research Unit No. 6 (NAMRU-6), Lima, Peru, [5]Laboratorio de Salud Pública de Loreto, Gerencia Regional de Salud de Loreto, Iquitos, Peru, [6]Universidad Nacional de la Amazonia Peruana, Iquitos, Peru, [7]Section of Infectious Diseases, Department of Internal Medicine, Yale School of Medicine, New Haven, CT, United States

Hard-to-reach communities represent Peru's last challenge for malaria elimination, but information about epidemiology and transmission is scarce. We investigated the transmission dynamics/population genetics, drug resistance markers, and pfhrp2/3 deletions of Plasmodium vivax (Pv) and P. falciparum (Pf) in Nueva Jerusalén (NJ). NJ is a remote indigenous community in the Loreto region (~50 km from the Ecuador border) with persistent malaria transmission. We performed population surveys in 3 weekly consecutive active case detection (ACD) visits in November 2019 and by passive case detection (PCD) from December 2019 to May 2020. We analyzed a representative sample of positive-PCR isolates (Pv=70, Pf=64) using AmpliSeq NGS assays.The Pv population was genetically homogeneous during the study and had modest genetic diversity (He=0.27). In contrast, the Pf population had low diversity (He=0.08) and 3 clusters (one generated an outbreak).Moreover, Pf parasites carried resistance mutations in pfcrt (100%), pfdhfr (94%), and pfdhps (48%). No artemisinin resistance variants were found in pfK13. In addition, the most frequent haplotype was hrp2-/hrp3+ (62%). Compared to other remote areas, NJ's Pv parasites were highly differentiated from the ones from Yavari (district next to the Brazilian border, >480km distant from NJ) (Fst=0.45) but little differentiated from Mazan (riverine district, >350 km far away) (Fst=0.08). On the other hand, Pf in NJ had modest to high genetic differentiation with Santa Emilia (riverine community, >260 km from NJ) (Fst=0.19) and Mazan parasites (Fst=0.34). The Pf resistance markers and pfhrp2/3 haplotypes were similar among the areas, except in Mazan, where the double deletion was predominant. In this first report about malaria genomic surveillance in Peruvian indigenous communities, Pv & Pf population structure in NJ were different between them and also among other areas, highlighting the importance of performing regular surveillance in these communities in terms of imported infections and spread of drug resistance to promptly recommend the adaptation of the malaria elimination strategy in Peru.

A major motivation for developing molecular methods for malaria surveillance is to measure the impact of control interventions on the population genetics of Plasmodium falciparum as a potential marker of progress towards elimination. Here we assess three established methods (i) single nucleotide polymorphism (SNP) barcoding (panel of 24-biallelic loci), (ii) microsatellite genotyping (panel of 12-multiallelic loci), and (iii) varcoding (fingerprinting var gene diversity, akin to microhaplotyping) to identify changes in parasite population genetics in response to a short-term indoor residual spraying (IRS) intervention. Typical of high seasonal transmission in Africa, multiclonal infections were found in 82.3% (median 3; range 1-18) and 57.8% (median 2; range 1-12) of asymptomatic individuals pre- and post-IRS, respectively, in Bongo District, Ghana. Since directly phasing multilocus haplotypes for population genetic analysis is not possible for biallelic SNPs and microsatellites, we chose ~200 low-complexity infections biased to single and double clone infections for analysis. Each genotyping method presented a different pattern of change in diversity and population structure as a consequence of variability in usable data and the relative polymorphism of the molecular markers (i.e., SNPs < microsatellites < var). Varcoding and microsatellite genotyping showed the overall failure of the IRS intervention to significantly change the population structure from pre-IRS characteristics (i.e., many diverse genomes of low genetic similarity). The 24-SNP barcode provided limited information for analysis, largely due to the biallelic nature of SNPs leading to a high proportion of double-allele calls and a view of more isolate relatedness compared to microsatellites and varcoding. Relative performance, suitability, and cost of the methods relevant to sample size and local malaria elimination in high-transmission endemic areas will be discussed.

DIFFERENTIAL REGULATION OF PFMDR2 AND PFK13 TRANSCRIPTS IN KENYAN CHILDREN WITH SEVERE MALARIAL ANEMIA: POTENTIAL IMPACT ON ARTEMISININ-BASED COMBINATION THERAPY RESPONSES

Qiuying Cheng[1], Clinton Onyango[1], Samuel B. Anyona[2], Ivy Hurwitz[1], Sarah Kituyi[3], Evans Raballah[4], Beauty Kolade[5], Philip D. Seidenberg[6], Collins Ouma[2], Kristan Schneider[7], Ananias A. Escalante[8], Benjamin H. McMahon[5], Douglas J. Perkins[1]

[1]University of New Mexico HSC, Center for Global Health, Albuquerque, NM, United States, [2]Maseno University, Maseno, Kenya, [3]University of Embu, Embu, Kenya, [4]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [5]Los Alamos National Laboratory, Los Alamos, NM, United States, [6]University of New Mexico HSC, Dept of Emergency Medicine, Albuquerque, NM, United States, [7]University of Applied Sciences Mittweida, Mittweida, Germany, [8]Temple University, Philadelphia, PA, United States

Severe malarial anemia (SMA: Hb≤6.0 g/dL, with any density parasitemia) is a common clinical manifestation of severe malaria in children under five in holoendemic Plasmodium falciparum transmission regions, such as Siaya County, western Kenya, and a primary cause of morbidity and mortality. To explore the impact of parasite-derived factors on malarial disease severity, we performed transcriptomic analyses on whole blood collected from children (3-36 months) with non-SMA (Hb>6.0 g/dL, n=40) and SMA (n=20) prior to treatment with artemisinin-based combination therapy (ACT). Next-generation sequencing was performed at a depth of >20 million high-quality mappable reads using Illumina NovoSeq and subsequently mapped to a reference genome for a Kenyan P. falciparum isolate (pfKE01) using the HTSeq platform. This resulted in the annotation of ~3200 distinct P. falciparum transcripts. RNA reads for each sample was normalized by calculating transcripts per kilobase million (TPM) per transcript. There were 688 differentially expressed P. falciparum genes between the SMA and non-SMA groups (P<0.05): 649 upregulated and 39 downregulated. Two P. falciparum transcripts related to ACT treatment responses were differentially regulated. Specifically, children with SMA had upregulated levels of multidrug resistance protein 2 (MDR2; Log2foldChange=1.33) and downregulated levels of kelch protein K13 (Log2foldChange=-0.47). These results suggest that children with SMA may have altered susceptibility profiles to ACTs. Further research is required to determine if altered gene expression patterns for MDR2 and K13 affect drug effectiveness and if

the driving force behind these observed patterns is due to pressure from the human host immune response and/or inherent genetic changes in the parasite.

6149

SPATIAL CONNECTIVITY, IMPORTATION AND TRANSMISSION FLOW OF PLASMODIUM FALCIPARUM IN MOZAMBIQUE USING MICROHAPLOTYPE DATA

Arnau Pujol[1], Arlindo Chidimatembue[2], Clemente da Silva[2], Simone Boene[2], Henriques Mbeve[1], Dario Tembisse[2], Jose Inacio[2], Kiba Comiche[2], Pau Cisteró[1], Carla Garcia-Fernandez[1], Nanna Brokhattingen[1], Andrés Aranda-Diaz[3], Nicholas Hathaway[4], Glória Matambisso[2], Fabião Luis[2], Beatriz Galatas[5], Boaventura Cuna[2], Cardoso Melembe[2], Nelo Ndimande[2], Humberto Munguambe[2], Júlia Montaña[1], Lidia Nhamussua[2], Wilson Simone[2], Helena Martí-Soler[1], Llorenç Quintó[1], Sónia Maculuve[2], Anna Escoda[1], Judice Miguel[2], Elena Buetas[1], Ianthe de Jong[1], Gemma Porras[1], Haily Chen[1], Eusebio Macete[2], Eduard Rovira-Vallbona[1], Caterina Guinovart[1], Bryan Greenhouse[3], Sonia Maria Enosse[6], Francisco Saúte[2], Pedro Aide[2], Baltazar Candrinho[7], Alfredo Mayor[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Manhiça Health Research Center, Manhiça, Mozambique, [3]University of California San Francisco, San Francisco, CA, United States, [4]University of Massachusetts Medical School, Worcester, MA, United States, [5]World Health Organization, Geneva, Switzerland, [6]Malaria Consortium, London, United Kingdom, [7]National Malaria Control Program, Maputo, Mozambique

Malaria genomics represents a promising tool to improve current surveillance systems and tailor malaria control and elimination interventions. The GenMoz (Plasmodium falciparum genomic intelligence in Mozambique) project aims to operationalise a functional malaria molecular surveillance system in Mozambique to inform programmatic decisions on the use of effective diagnostic and treatment tools, targeted strategies for malaria elimination and effective intervention combinations to maximise burden reduction. For this purpose, a novel amplicon sequencing panel was developed to generate 272 genetic microhaplotypes targeting 250bp regions that are highly informative of diversity, misdiagnosis and drug resistance mutations, allowing precise estimates of relatedness for polyclonal infections. We studied the spatial structure of genetic connectivity of P. falciparum populations in Mozambique to assess the potential of genomics to characterise transmission flow and quantify the contribution of imported cases in low-transmission settings. We used the R package Dcifer to estimate identity-by-descent between sample pairs from various provinces, studying isolation-by-distance in a wide range of geographical distances, using Mandel tests. We quantified the contribution of imported cases in two low-transmission areas from the fraction of highly related pairs between samples from these areas and from other areas, correlating the statistics with travel history surveys. We found strong spatial genetic distinction across the country, with higher fractions of highly related pairs within regions (north-north or south-south) than between regions (north-south). The Mandel tests confirm strong isolation-by-distance at large scales (between provinces), but no statistical significance at small scales (within province). Few highly related pairs between samples in the targeted low-transmission areas and samples from different provinces of Mozambique were found, with no significant correlation with their travel history data, suggesting no significant contribution of imported cases in the low-transmission areas studied.

6150

EXPANDING THE GLOBAL WHOLE GENOME SEQUENCE DATASET OF PLASMODIUM FALCIPARUM

Richard D. Pearson on behalf of MalariaGEN

Wellcome Sanger Institute, Cambridge, United Kingdom

Malaria control and elimination requires decision making regarding the use of vaccines, diagnostics and treatments, all of which can be informed by genomic surveillance of the parasite. Whole genome sequencing can play an important role in detecting new molecular markers associated with drug resistance, identifying regions of the genome that are under selection, and better understanding host-parasite interactions. We previously released the largest global resource of genomic data on Plasmodium falciparum, comprising over 20,000 samples from 82 partner studies in 33 countries. Since then, we have released further whole genome sequence data to MalariaGEN partners. We are working towards publicly releasing an expanded set of curated genotype data. As with previous releases, this will include genotypes at SNPs and short indels genome-wide, in addition to copy number variation calls at genes related to drug resistance and failures of rapid diagnostic tests. The latest release will include sample QC, identification of populations and characterisation of samples by inferred resistance status to major frontline anti-malarial drugs. In addition to an expanded set of samples, we aim to enhance the value of this data resource by making jupyter notebooks of typical analyses publicly available using a free-to-use cloud-based platform.

6151

PREVALENCE OF CYP2C8 POLYMORPHISM IN CHILDREN AGED 3 TO 59 MONTHS IN BOBO DIOULASSO, BURKINA FASO

Guéswendé Armel Bienvenu Yarbanga[1], W. Jédida M. Ouédraogo[1], Seydou Bienvenu Ouattara[1], Souleymane Gnissi[1], K. Bienvenue Yaméogo[2], Fanck Yao[2], Parikh Sunil[3], Jose Pedro Gil[4], Rakiswendé Serge Yerbanga[1], Jean Bosco Ouédraogo[1]

[1]Institut des Sciences et Techniques (INSTech), Bobo-Dioulasso, Burkina Faso, [2]Institut de Recherche en Sciences de la Santé/Direction Régionale de l'Ouest (IRSS/DRO), Bobo-Dioulasso, Burkina Faso, [3]Yale University, New Haven, CT 06520, United State, New Haven, CT, United States, [4]Karolinska Institutet, Department of Microbiology, Tumor and Cell Biology (MTC) / Biomedicum, Stockholm, Sweden

Cytochrome P450 2C8 (CYP2C8) is a key enzyme responsible for the metabolism of many drugs such as amodiaquine (AQ), which is a component of artemisinin-based combination therapy (ACT) and seasonal malaria chemoprevention (SMC) drugs. Polymorphisms present in this gene may have an impact on the pharmacokinetics (PK), efficacy and safety of this antimalarial. The objective of this study was to determine the prevalence of CYP2C8 mutation, associated with Plasmodium falciparum in children under 5 years of age in Bobo Dioulasso, Burkina Faso. Dried blood spots were collected from 1083 participants and extracted using the Qiagen kit (DNeasy Blood & Tissue Kit). The prevalence of the human CYP2C8*2 and CYP2C8*3 genotypes were determined by PCR-RFLP, and the identification of P. falciparum was done by the microscopy. The prevalence of P. falciparum was 7.20% (i.e. 78/1083) and the prevalence of CYP2C8*2 was 28.72% (i.e. 311/1083) in the study population. homozygous (*2/ *2) and heterozygous (*2/*1) participants for the CYP2C8*2 were 26.41% (i.e., 286/1083) and 2.31% (i.e., 25/108) respectively. The proportion of participants with the CYP2C8 mutation and with positive for P. falciparum was 0.74% (i.e. 8/1083). The influence of these CYP2C8 mutations on the metabolism of antimalarial drugs, in particular amodiaquine (AQ), needs to be further evaluated.

6152

INFERRING FOR CE OF INFECTION FROM MOLECULAR-BASED ESTIMATES OF MULTIPLICITY OF INFECTION IN FALCIPARUM MALARIA WITH AN APPLICATION TO INTERVENTION IN NORTHERN GHANA

Qi Zhan[1], Kathryn Tiedje[2], Karen Day[2], Mercedes Pascual[1]

[1]University of Chicago, Chicago, IL, United States, [2]The University of Melbourne, Melbourne, Australia

Force of infection (FOI), defined as the number of new Plasmodium falciparum infections acquired by an individual host over a given time interval, is a direct measure of exposure to Plasmodium falciparum blood-stage infection. It reflects risk of infection and clinical episodes, and relates local variation in malaria burden to transmission. It is thus suitable for monitoring the impact of antimalarial interventions and assessing vaccine or drug efficacy in clinical trials. Despite being recognized as

a key epidemiological parameter, FOI remains difficult, expensive, and labor-intensive to accurately measure, either directly via cohort studies or indirectly via the fitting of epidemiological models to repeated cross-sectional surveys. Molecular advances to sequence and type the var multigene family encoding for the major surface antigen of the blood stage of infection, provide a basis to estimate a sister "static" quantity, the multiplicity of infection (MOI, the number of genetically distinct parasite strains co-infecting a single human host), typically under sparse sampling schemes. Having extended this approach to a Bayesian framework to account for measurement error, we propose a general approach to obtain FOI on the basis of MOI. We specifically adapt two methods from queuing theory to derive FOI, and evaluate these with numerical simulations with a stochastic agent-based model. We then apply the methods to longitudinal surveys from northern Ghana before, during, and after a three-round IRS (Insecticide Residual Spreading) intervention. Both methods give accurate and consistent FOI estimates across various simulated scenarios. Their application to field surveys shows that despite a pronounced 60% reduction in FOI during IRS, transmission intensity rebounds almost completely in 32 months following IRS interruption. The methods should be applicable to many geographical locations where cohort or frequently-sampled cross-sectional studies are lacking but single-time-point surveys under sparse sampling schemes are available. They should also apply to other infectious diseases for which MOI has been obtained.

6153

POPULATION DYNAMICS AND GENOTYPIC VARIATION OF PLASMODIUM VIVAX IN A LOW-ENDEMICITY AREA OF SOUTH AMERICA BETWEEN 2012 AND 2020

Camila Eduarda Cabezas[1], Eileen Velez-Alvarez[1], Bibiana Salazar[1], Cynthia Gordon[1], Manuel Calvopiña[2], **Fabian E. Saenz**[1]

[1]Pontificia Universidad Católica del Ecuador, Quito, Ecuador, [2]Universidad de las Américas, Quito, Ecuador

Ecuador is one of the countries that is part of the E-2025 initiative and would be able to eliminate malaria in the coming years. Nevertheless, elimination efforts have fallen short and cases have been increasing, particularly in the Amazon of the country. Plasmodium vivax is the main malaria parasite affecting the Ecuadorian population but little is known about the populations of P. vivax circulating in the country. We used nine microsatellite markers in 150 samples of P. vivax from the Ecuadorian Coast and Amazon regions collected between 2012 and 2020 to characterize their origin, distribution and population dynamics. We found that in Ecuador, there is higher genetic diversity and multiclonality of P. vivax in the Amazon region than in the coast of the country. In addition, there was evidence of gene flow and moderate genetic differentiation between Amazonian localities, but little gene flow between the Coast and Amazon. The coast of Ecuador shared lineages and had low/moderate genetic differentiation with coastal Colombian localities. Similarly, Amazon localities shared lineages and had low/moderate genetic differentiation with Peruvian Amazon localities. This study suggests a recent increase in P. vivax multiplicity of infection and diversity in the Amazon of Ecuador because of increased transmission. It confirms the importance of the Andes as a geographical barrier and underlines the importance of geographic corridors through the Pacific coast of South America and the Amazon rivers that help sustain malaria in the region and hamper elimination.

6154

GENETIC CONNECTIVITY AND TRANSMISSION METRICS OF PLASMODIUM FALCIPARUM IN ZAMBEZI REGION, NORTHERN NAMIBIA

Jennifer L. Smith[1], Andres Aranda-Diaz[2], Maxwell Murphy[3], Amy Wesolowski[4], Henry Ntuku[1], Adam Bennett[1], Roly Gosling[1], Davis Mumbengegwi[5], Bryan Greenhouse[2]

[1]Malaria Elimination Initiative, University of California San Francisco, San Francisco, CA, United States, [2]School of Medicine, University of California San Francisco, San Francisco, CA, United States, [3]Division of Biostatistics, University of California, Berkeley, Berkeley, CA, United States, [4]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [5]Centre for Research Services, University of Namibia, Windhoek, Namibia

As malaria transmission declines, an increasing proportion of the parasite reservoir is clustered in subpopulations with shared risk factors and spatial hotspots. While the WHO recommends a targeted response in high-risk populations, there is limited evidence quantifying transmission between populations and the impact of targeted interventions. As part of a population-based evaluation of targeted malaria interventions in seasonal agricultural workers in northern Namibia (2019-2020), epidemiological data and samples were collected from cases at agricultural sites (n=35) and those presenting to nearby health facilities (n=511). All samples with parasite density ≥10 parasites/μL of blood by qPCR were sequenced using amplicon deep-sequencing panels including 175 highly diverse and differentiated loci. Population level and within-host genetic diversity measures, including effective complexity of infection (eCOI) and within-host relatedness were estimated by population (nationality and worker/community) and study arm, using an MCMC based approach. Preliminary results are reported from 25 cross-sectional and 280 incident cases. There was no difference in eCOI between agricultural workers and communities in control and intervention areas at either time point, but non-Namibians had a higher eCOI than Namibians, potentially indicating parasite importation from or increased connectivity with higher transmission settings. At endline, eCOI was lower in the intervention arm within both worksites and surrounding communities (median = 1.14 (95% CI: 1.13-1.16) and 1.16 (1.15-1.18)) compared to the control arm (1.21 (1.20-1.22) and 1.22 (1.21-1.23)). A similar, non-significant trend was observed for within-host relatedness and proportion of polyclonal infections in agricultural workers. Results suggest an impact of the intervention on transmission at worksites that may have spilled over to communities. Additional analyses will include data from all cases and evaluate genetic relatedness between infections using identity by descent and transmission networks within and between subpopulations at different spatial scales.

BENCHMARKING IDENTITY-BY-DESCENT CALLERS FOR PLASMODIUM FALCIPARUM

Bing Guo[1], Michele Spring[2], Mariusz Wojnarski[2], Brian A. Vesely[2], Joana Carneiro Da Silva[1], Norman C. Waters[2], Shannon Takala-Harrison[3], Timothy D. O'Connor[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Genomic surveillance combined with traditional epidemiological analyses is important for identification of at-risk populations for targeted intervention in support of malaria control/elimination efforts. Identity-by descent (IBD) is one population genetic metric used to study genetic relatedness, effective population size (Ne), migration and population structure, and drug resistance-related selection in Plasmodium falciparum (Pf). Despite the wide use of IBD as a metric of genetic relatedness, a comprehensive evaluation of available tools for the identification of IBD segments in Pf has not been performed, and valuable information conveyed by individual IBD segments is not always well exploited. To date, existing IBD quality assessments either focus on the human genome (rather than Pf), use a loose definition of IBD accuracy or are biased toward long segments from pedigree-based simulations. In this study, we performed population-based simulations that account for the high recombination rate and shrinking Ne of Pf, and examine IBD segments spanning a wide length distribution. We benchmarked several IBD callers, including probabilistic (hmmIBD, isoRelate), Identity-By-State-based (hap-ibd, TPBWT), or other (Refined IBD, tree-based) methods, by comparing inferred IBD with genealogy-based true IBD. Our simulations suggest that hmmIBD-inferred IBD segments tend to be less biased for the determination of pairwise total IBD, length-specific population total IBD, and IBD-based demography estimates while remaining sensitive to IBD positional enrichment due to positive

selection. However, hmmIBD suffers from a high rate of false positive short IBD segments (<4cM), which should be excluded in sensitive analyses such as IBD-based Ne inference. Ongoing work will focus on the validation of benchmarking results in an empirical dataset with over 7000 worldwide Pf samples (including MalariaGen Pf6 and an in-house dataset) by evaluating the ability of different IBD callers to capture known selection signals and generate Ne and population structure estimates consistent with existing knowledge for each geographic region.

THE RISK OF VACCINE GENOTYPE REPLACEMENT FOR PLASMODIUM FALCIPARUM

Thiery Masserey, Tamsin Lee, Aurélien Cavelan, Josephine Malinga, Melissa Penny

Swiss Tropical And Public Health Institute, Allschwil, Switzerland

Malaria vaccines represent a vital new tool in the fight against Plasmodium falciparum. Vaccines administered to children aim to prevent morbidity, while deploying vaccines to all ages aims to reduce morbidity and transmission, thus accelerating elimination. The first malaria vaccine, RTS,S/AS01, was recently approved, and many anti-infective (AIV), blood-stage (BSV), and transmission-blocking (TBV) vaccine candidates are under development or early clinical trials, such as R21. If targets of these vaccines are not conserved, there is a risk that vaccines confer variable protection between parasite genotypes due to antigen diversity. The risk of spreading vaccine-resistant or partially resistant P. falciparum is unknown, as are the factors promoting this spread. We adapted an individual-based model of malaria transmission to assess the spread of parasites partially or fully resistant to AIV and BSV when deployed to children and the spread of parasites resistant to an AIV when deployed alone or in combination with a TBV to adults or the whole population. For each vaccine type and use case, we assessed which biological, epidemiological, vaccine properties, and deployment factors drive the spread of resistant parasites and the impact of this spread on vaccine effectiveness. We estimated that even genotypes with low degrees of resistance could spread quickly for both use cases. Therefore, developing vaccines targeting conserved antigens and monitoring allele frequency and vaccine efficacy in implementation settings is essential. The estimated spread was faster for BSV than AIV and faster for more efficacious vaccines having longer half-lives and higher initial efficacies. Moreover, while favouring vaccine effectiveness, resistance spread is faster with a higher frequency of vaccine deployment and more extensive population coverage. Deploying a drug with a vaccine both increases the public health impact and reduces resistance spread. Additionally, deploying a TBV with an AIV to the whole population strongly delays the spread of AIV-resistant genotypes and increases the chance of elimination in some settings.

INFLAMMATORY MARKERS ASSOCIATED WITH IN-HOSPITAL MORTALITY IN CHILDREN WITH SEVERE MALARIA

Grace Turyasingura[1], Ruth Namazzi[2], Kagan A. Mellencamp[1], Dibyadyuti Datta[1], Robert O. Opoka[2], Chandy C. John[1], Andrea L. Conroy[1]

[1]Indiana University School of Medicine, Indianapolis, IN, United States, [2]Makerere University, Kampala, Uganda

Despite treatment with efficacious antimalarial therapy, severe malaria (SM) in children is associated with high mortality. The contributions of different pro- and anti-inflammatory cytokines and chemokines to mortality in severe malaria (SM) is not fully characterized. To better understand the pathogenesis of SM, we evaluated serum levels of 40 markers of inflammation, angiogenesis and chemotaxis by a Luminex assay in 596 Ugandan children 6 months - 4 years of age with severe malaria (SM) and 120 community children (CC). Children with one or more of the 5 most common forms of SM in Uganda (cerebral malaria, respiratory distress, malaria with multiple seizures, severe malaria anemia and prostration) were enrolled in the study. Levels of 21 of the 40 markers tested differed significantly between children with SM and CC ($p<0.00125$). To evaluate which markers were associated with mortality in SM, we compared levels of these 21 markers in children with SM who died (n=43) vs. those who survived (n=553) during the initial admission. Five markers were significantly elevated in children with SM who died compared to the children who survived ($p<0.0024$): a pro-inflammatory cytokine (IL-6), an anti-inflammatory cytokine (IL-1ra), a soluble programmed cell death ligand involved in immune suppression (sPD-L1), and chemokines involved in eosinophil (CCL11) and lymphocyte (CCL20) chemotaxis. In-hospital mortality increased (adjusted odds ratio [95% confidence interval] with natural log increase in the levels of IL-1ra (2.7 [1.57, 4.64]), IL- 6 (1.3 [1.11, 1.55]), sPD-L1 (2.7 [1.58,4.63]), CCL11 (5.2 [2.72,9.95]) and CCL20 (1.94 [1.51,2.49]). The study findings suggest that a complex combination of factors that regulate inflammation and cell chemotaxis contribute to severe disease and death in malaria.

6158

SEVERE THROMBOCYTOPENIA IS ASSOCIATED WITH AUTOANTIBODIES TO PHOSPHATIDYLSERINE IN *PLASMODIUM VIVAX* INFECTION.

Marian Marcela Muskus Montiel[1], Maria Camila Velasco Pareja[1], Catalina Tovar[2], Ana Rodriguez[3], Maria Fernanda Yasnot[1]

[1]Universidad de Cordoba, Monteria, Colombia, [2]Universidad del Sinu, Monteria, Colombia, [3]New York University School of Medicine,, New York, NY, United States

One of the most frequent hematological findings during Plasmodium vivax infections is a decrease in platelet count. One of the pathophysiological mechanisms proposed to mediate this hematological alteration is the production of autoantibodies directed against components of platelets, in particular phosphatidylserine (PS), which is exposed in the membrane of activated platelets during infections such as malaria. We hypothesized that platelet elimination may be a consequence of a previously described autoimmune response during P. vivax infection that includes anti-PS antibodies (PMID: 32687495). The purpose of this study was to determine the association of anti-PS antibodies in thrombocytopenia during P. vivax infections. An analytical, cross-sectional study was carried out between 2017 - 2019 an endemic area of Tierralta, Córdoba, Colombia. 163 patients monoinfected by P. vivax with different levels of thrombocytopenia were included (P. vivax + mild thrombocytopenia n=42; P. vivax + moderate thrombocytopenia n=53; P. vivax + severe thrombocytopenia n=31; P. vivax without thrombocytopenia n= 37) and 60 healthy volunteers without malaria or thrombocytopenia. Determination of anti-PS antibodies in the plasma of patients was performed by indirect ELISA and confirmation of PS exposure in platelets was determined by flow cytometry using Annexin V. It was found that the levels of anti-PS antibodies in the P. vivax patient group without thrombocytopenia were significantly lower compared to the group with severe thrombocytopenia ($p<0.05$). When comparing all patients in the cohort, the correlation between platelet counts and anti-PS antibodies was inverse ($r= -0.19$, $p<0.05$), with higher PS exposure in platelets from patients with severe thrombocytopenia. The results suggest that anti-PS antibodies binding to PS exposed on platelet membranes during P. vivax infection may be one of the pathophysiological mechanisms mediating the onset of severe thrombocytopenia in patients.

Acquired humoral immunity to Plasmodium falciparum prevents clinical illness. It predominantly targets the blood stages, but antibodies are also acquired to the pre-erythrocytic stage. The relative contributions of antibodies to different life stages in acquired immunity is not well understood, nor whether antibodies to different stages can act additively or synergistically to prevent malaria infection or illness. We have quantified antibodies to merozoites, parasitized RBCs, and sporozoite antigens in a longitudinal cohort of children in Papua New Guinea. We analyzed their acquisition and associations with protection, as well as the relationships between acquired responses. We quantified antibody magnitude as well as functional activity including complement-fixation and activation, antibody interactions with Fc-receptors and phagocytic functions, and growth inhibitory activity. Antibodies to merozoites, including antibodies with Fc-mediated functional activities, were more strongly associated with protection from symptomatic malaria than antibodies to parasitized RBCs, PfEMP1 on the surface of pRBCs, or sporozoite antigens. Associations with protection varied for different antigens, and for different functional antibody response types. Functional antibodies to sporozoites were acquired more slowly and substantial functional activity was only observed among a minority of children. However, higher magnitudes of Fc-mediated functional activities to the most abundant sporozoite antigen (CSP) were significantly associated with a reduced risk of malaria. Further statistical analyses and modelling is investigating potential synergistic effects of antibodies to multiple stages and antigens. These findings provide new insights into protective acquired immunity across the life-cycle of P. falciparum and may help inform the development of multi-stage vaccines for malaria.

ASSOCIATION OF NOVEL IGG3 ALLOTYPE WITH MALARIA IN CHILDREN FROM SEPIK REGION OF PAPUA NEW GUINEA

Maria Saeed[1], Elizabeth Aitken[1], Myo Naung[2], Caitlin Bourke[2], Rhea Longley[2], Amy Chung[1], Timon Damelang[1], Benson Kiniboro[3], Ivo Mueller[2], Stephen Rogerson[1]

[1]The Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia, [2]Walter Eliza Hall Medical Institute, Melbourne, Australia, [3]Papua New Guinea Institute of Medical Research, Maprik, Australia

Malaria is a global health burden causing death and severe illness in children under five years of age in malaria endemic regions. Recent work has established the importance of malaria-specific IgG3 in malaria immunity. IgG3 via Fc region binds to Fcγ-receptors (FcγRs) on immune cell surface to instigate immunological defense against malaria. Changes in the amino acid sequences due to single nucleotide polymorphisms (SNPs) of IgG3-Fc regions give rise to IgG3 allotypes which can modulate IgG3 functions. A novel IgG3 allotype, G3m29, was recently reported in pregnant women from Sepik, Papua New Guinea, and has been shown to have enhanced affinity to FcγRIIa. We hypothesized that the prevalence of G3m29 in this population was associated with possible protection from severe or uncomplicated malaria in children. Here, we amplified the Fc region of IgG3 genes by polymerase chain reaction using heavy chain constant domains 2 and 3 specific primers, in a longitudinal study cohort of children aged 1 to 3 years (N=203) with multiple malaria episodes. We performed Sanger sequencing to identify SNPs and compared to the reference alleles of immunogenetics (IMGT) database. We identified that 78% of children in the cohort were either heterozygous (n=82, 40%) or homozygous (n=77, 38%) for G3m29 allotype. We also found a significant decrease in the total number of Plasmodium infections in children with G3m29 allotype compared to non-G3m29 allotype carriers (β= -1.736, 95% CI [-3.39, -0.079], p <0.05) via linear regression. This effect was most pronounced for effects of P. vivax infections. We are presently examining the relationship between allotypes and the levels of antimalarial antibodies and presence of anaemia in these children. Since polymorphisms arise in ethnic and isolated groups and persist in the population because of natural selection, the high prevalence of G3m29 allotype in Sepik region and its association with the number of malaria infections confirms that it is indeed under positive selection and might have a possible role in malaria immunity.

In placental Plasmodium falciparum infection, VAR2CSA is expressed on the surface of infected erythrocytes (IEs) and mediates their sequestration in the placenta. Antibodies to VAR2CSA are largely restricted to women infected during pregnancy. These antibodies protect women in subsequent pregnancies but in an allele-specific manner. We discovered that VAR2CSA antibodies could also be elicited by P. vivax Duffy binding protein (PvDBP). We proposed that infection with P. vivax in non-pregnant individuals can generate antibodies that cross-react with VAR2CSA. To better understand the specificity of these antibodies, we took advantage of a mouse monoclonal antibody (3D10) raised against PvDBP that cross-reacts with VAR2CSA and identified the epitopes targeted by this antibody. We screened two peptide arrays that span the entire ectodomain of VAR2CSA from the FCR3 and NF54 alleles. Based on the array data, we designed a 34 amino acid synthetic peptide called CRP1 that maps to a highly conserved sequence in DBL3X and overlaps a previously defined CSA binding site. We showed by Isothermal Titration Calorimetry that this peptide can bind directly to CSA, and antibodies to CRP1 raised in rats significantly block the binding of IEs to CSA in vitro. In our Colombian cohorts of pregnant and non-pregnant individuals, at least 45% were seroreactive to CRP1. Most exciting, antibody reactivities to CRP1 and the 3D10 natural epitope in PvDBP region II, subdomain 1 (SD1), were strongly correlated in both cohorts. These findings suggest that antibodies arising from PvDBP may cross-react with VAR2CSA through the epitope in CRP1. These antibodies could contribute to protection against VAR2CSA by blocking a CSA binding site in DBL3X.

THE PRESENCE OF DUFFY BINDING PROTEIN II PEPTIDES-SPECIFIC CD4+ T CELL RESPONSES IN PLASMODIUM VIVAX PATIENTS

Pongsakorn Thawornpan[1], Chayapat Malee[1], Piyawan Kochayoo[1], Kittikorn Wangriatisak[1], Chaniya Leepiyasakulchai[1], Francis B Ntumngia[2], Sai Lata De[2], John H Adams[2], Patchanee Chootong[1]

[1]Faculty of Medical Technology, Mahidol University, Nakhon Pathom, Thailand, [2]Center for Global Health and Infectious Diseases Research and USF Genomics Program, College of Public Health, University of South Florida, Tampa, FL, United States

Plasmodium vivax Duffy Binding Protein region II (PvDBPII) is a leading vaccine candidate against blood-stage vivax malaria. Anti-PvDBPII antibodies potentially block parasite invasion by inhibition of erythrocyte binding. However, knowledge of PvDBPII-specific T cell responses is limited. Here, to assess immunogenicity of PvDBPII epitopes for induction of memory T cell responses in natural P. vivax infections, three cross-sectional

studies were conducted in recovered subjects. In silico analysis was used for potential T cell epitope prediction identified total 492 predicted peptides, which were further selected to obtain 29 peptides with lowest percentile rank. PBMCs from P. vivax subjects were stimulated with selected peptides and examined for cytokine production by ELISPOT or intracellular cytokine staining. From our analysis, six dominant T cell epitopes were identified. Peptide-driven T cell responses showed effector memory CD4+T cell phenotype, secreting both IFN-γ and TNF-α cytokines. Single amino acid substitutions in three T cell epitopes altered levels of IFN-γ memory T cell responses. Further analysis of antibody response to PvDBPII in individuals enrolled for detection of PvDBPII-specific T cell responses showed that 27.8% (5/18) displayed both IFN-γ T cell and antibody response, while 66.7% (12/18) exhibited only IFN-γ T cell response. Altogether, these findings demonstrate the response of CD4+ T cells and antibody to PvDBPII in natural infection. The knowledge of antigenicity could facilitate development of an efficacious vivax malaria vaccine.

DYNAMICS OF NEUTROPHILS ACTIVITIES ACCORDING TO MALARIA INFECTION STATUS

Bérenger Kabore[1], Marc Christian Tahita[1], Salou Diallo[1], Annelies Post[2], Ousmane Traore[1], Palpougouni Lompo[1], Joel D. Bognini[1], Quirijn de Mast[2], Andre J.A.M. van der Ven[2], Halidou Tinto[1]

[1]IRSS/Clinical Research Unit of Nanoro, NANORO, Burkina Faso, [2]Department of Internal Medicine/Radboud University Medical Center, Nijmegen, Netherlands

Neutrophils are the highest population in human leucocytes. They are considered to be the front-line fighters of the immune system against any invading pathogens including malaria parasites. Over the recent years, more insight has been gained from their role in inflammation. In addition to their phagocytizing property, it has now been admitted that activated neutrophils produce variety of pro-inflammatory cytokines and surface molecules. Recent technology advancement allows haematology analysers to go beyond the simple counting of neutrophils. Their activation status would it be their metabolic activity (cytokines production) represented by their reactivity intensity (Neut-RI) as well as their density or complexity (phagocytosis), represented by the cell's granularity (Neut-GI) can be differentiated. To elucidate that question, we assessed the neutrophils activation status in healthy, asymptomatic and symptomatic malaria in children aged between 3 months to 14 years. Blood samples were collected for full blood count and malaria microscopy. Among the 902 participants recruited, the prevalence of asymptomatic malaria (AM) cases, no malaria (NM) and clinical malaria (CM) were respectively 42.57% (384/902), 38.47% (347/902) and 18.96% (171/902). Regarding the neutrophils metabolic activity, Neut-RI were significantly ($p<0.001$) higher in CM compared to both AM and NM as well as in AM compared to NM ($p<0.001$). For the phagocytizing activity, the Neut-GI were significantly ($p<0.001$) higher in CM compared to both AM and NM participants while the difference was not significant ($p=0.3$) between NM and AM groups. There was a significant positive correlation ($\rho=0.30$, $p=0.0001$) between the metabolic or cytokines production activity with malaria parasite density in clinical malaria (CM) while this was not the case for Neut-GI ($\rho=0.04$, $p=0.6$). The metabolic activity of neutrophils is enabled regardless of the symptomatic status of malaria, whereas their phagocytizing activity is primarily seen in symptomatic cases. Furthermore, the metabolic activity is positively correlated with parasite density in malaria clinical manifestations

6164

BRAIN SEQUESTERED M1-LIKE MACROPHAGES EXPRESS ABUNDANT LEVELS OF CD163 DURING EXPERIMENTAL CEREBRAL MALARIA IN MICE

Sidharth Srivastava, Victoria Majam, Hong Zheng, Sanjai Kumar, Miranda S. Oakley

FDA, Silver Spring, MD, United States

Brain sequestered macrophages are one of the mediators of the pathogenesis of experimental cerebral malaria in mice. Likewise, accumulation and sequestration of macrophages in the brain during human cerebral malaria has also been reported. Despite their prominent role in cerebral malaria, the macrophage population(s) involved in malaria pathogenic processes remain poorly defined. Macrophages polarize into proinflammatory classically activated M1 macrophages or anti-inflammatory alternatively activated M2 macrophages. We examined macrophage polarization by measuring the expression of M1 markers (CD80 and CD86) and M2 markers (CD163 and CD206) on brain sequestered CD11b+F4/80high macrophages during the cerebral phase of a Plasmodium berghei ANKA infection in mice. Flow cytometric analysis showed that 82% of brain sequestered macrophages coexpressed the M1 markers CD80 and CD86. However, the majority (93%) of these CD80+CD86+ brain sequestered macrophages also expressed CD163, a scavenger (mainly hemoglobin/haptoglobin) receptor and a known marker for immunosuppressive M2c macrophages. In contrast, a minority (7.3%) of CD80+CD86+ brain sequestered macrophages expressed CD206, the mannose receptor and a known marker for immunomodulatory M2a macrophages. Our results suggest that brain sequestered macrophages may have an intermediate phenotype with mixed M1 and M2 features and CD163 may function to diminish the inflammatory response of M1-like (CD80+CD86+) brain sequestered macrophages because of its ability to produce anti-inflammatory heme metabolites. Lastly, due to exclusive expression on the monocytic lineage and abundant expression on macrophages at sites of inflammation, CD163 is currently being assessed as a target of immunotherapy for cancer and autoimmunity and also warrants consideration as a target of adjunctive therapy for cerebral malaria.

6165

IMPACT OF PLASMODIUM FALCIPARUM MALARIA ON SARS-COV-2 ANTIBODY RESPONSES IN KENYA AND BURKINA FASO (MALCOV)

To investigate the impact of malaria co-infection on serological responses to SARS-CoV-2, we enrolled a cohort of 708 COVID-19 patients in Kenya and Burkina Faso, 139 (20%) of whom also had malaria. Median age was 33 years (IQR 24, 46), 10% were under age 15. We measured IgG antibody response against SARS-CoV-2 nucleoprotein (NP) and receptor binding domain (RBD) on days 1, 3, 7, 14, and 28 with a multiplex bead assay. Antibody responses with median fluorescence intensity (MFI) of ≥5000, >2000-5000, and ≤2000 were considered positive, intermediate and negative, respectively. At enrolment, 16.5% were positive for IgG against

both antigens simultaneously, 3% intermediate, 40% negative, and 40% had mixed responses to the different antigens. By Day 28, these were; 65% positive, 0.7% intermediate, 6% negative, and 29% mixed responses. Overall seropositivity at Day 28 was higher for NP than RBD (84% vs 67%) and lower in patients with recent or sub-patent (rapid diagnostic test-HRP2 positive, microscopy-negative) or patent malaria infection (microscopy-positive) than in malaria negative patients: 53%, 49% and 71%, respectively. The difference was mainly seen for RBD (NP: 75%, 77% and 88%; RBD: 53%, 49%, and 73%, respectively). There was no difference in the magnitude of antibody response in seropositive patients by malaria status. SARS-CoV-2 seroconversion occurred within one month in 35% of patients, regardless of the antigen. Persistent seropositivity, starting and remaining seropositive, was similar for RBD and NP (34% vs 29%), but persistent seronegativity was higher for RBD (15% vs 3.6%). Malaria co-infection had a limited impact on seroconversion. The largest observed difference was in the seroconversion to NP between patent malaria and malaria-negative patients: 45% vs 37%, respectively. Overall, antibody responses to SARS-CoV-2 RBD were lower than to NP. The effect of malaria on SARS-CoV-2 antibody response was dependent on antigen; there was no discernible effect on the response to NP, but responses to RBD were lower in individuals with patent or recent/sub-patent malaria.

6166

LOCAL GUT MICROBIOTA TOLEROGENIC HOMEOSTASIS NEGATIVELY IMPACTS ANTI-PLASMODIUM SYSTEMIC IMMUNITY

Rafael B. Polidoro, Olivia J. Bednarski, Nathan W. Schmidt
Indiana University School of Medicine, Indianapolis, IN, United States

Our laboratory researches the relationship between severe malaria and gut microbiome in mice. For that, we use Plasmodium yoelii and C57BL/6 mice from different vendors, which is sufficient for presenting diverse phenotypes in severity terms, recapitulated by introducing cecal or fecal material from the hyper-susceptible into the regular mouse, as well as onto germ-free mice. Although the causality is well established, the mechanisms are yet to be completed. Recently, we have shown that hypersusceptible mice present early contraction of germinal centers and consequently the lower quality of antibodies, leading to a parasitemia curve of 28 days instead of 14 and reaching up to 80% parasitemia instead of 20%. Tregs and T follicular regulatory cells are increased in the Peyer Patches and spleens of hyper-susceptible mice compared to the regular mice. Although both mice produced IL-10 on the serum and spleen on days 5-7 post-infection, the susceptible mouse failed to produce IFN-g, whereas the regular mice have a classic IFN-g/IL-10 ratio. To further evaluate the tolerogenic nature of the microbiota in the hypersusceptible mouse, we used sub-colitis doses of DSS, and they presented resistance to weight loss. In contrast, the regular mice showed weight loss and blood in their feces. Purified IgA-bound bacteria from the susceptible mice can recapitulate the phenotype in the regular mice. 16S sequencing of the IgA-bound bacteria presents an enrichment of invasive bacteria capable of causing septicemia in humans and rodents. These results provide insights into the impact of the gut microbiota on systemic immunity, an essential factor to consider in developing optimal malaria treatment and vaccines.

6167

ROLE OF IGE RESPONSE AGAINST MALARIA INFECTION IN CHILDREN UNDER FIVE YEAR OLD, LIVING IN MALARIA ENDEMIC RURAL AREA OF BURKINA FASO

Mariama K. Cherif[1], Issa Nebie[2], Alphonse Ouedraogo[2], Alfred Tiono Tiono[2], Marita Troye_Blomberg[3], Sodiomon B. Sirima[2]
[1]Université Nazi Boni (UNB), Unité de Recherche et de Formation en Sciences de la Vie et de la Terre (UFR/SVT), Groupe de Recherche Action en Santé (GRAS), Bobo-Dioulasso, Burkina Faso, [2]Groupe de Recherche Action en Santé (GRAS), Ouagadougou, Burkina Faso, [3]Department of Molecular Biosciences, the Wenner-Gren Institute, Stockholm, University, Stockholm, Sweden

Despite these various measures, malaria remains one of the major health problems in the world, mainly due to the various forms of Plasmodium, as well as to the increase in resistance of vectors to insecticides and parasite to antimalarial drugs. The understanding of IgE responses dynamic, in children living in endemic area may help to optimize design interventions tools that could be used in malaria vaccine development. This study aimed to assess the relationship between IgE responses to Plasmodium falciparum and incidence of clinical malaria in children naturally exposed to malaria infection in Saponé (Burkina Faso) It was a secondary analysis of blood samples collected in 2007. Samples were collected during malaria low transmission season and at the peak of the high transmission season in malaria endemic area of Saponé, Burkina Faso. Sandwich ELISA was used to quantify IgE antibodies. Thick drop and blood smear were used for microscopic diagnosis of malaria. We combined levels of IgE to P. falciparum in plasma samples from 325 children with age, P. falciparum density, malaria transmission season and incidence. IgE quantification shows that IgE responses were higher among the parasitized children compared to non-parasitized. The means of IgE were respectively 1079.924 IU (CI95%= 943.8103 -1102.744) for parasitized children and 899.1933 IU (CI95% =718.0199 – 918.5753) for non-parasitized (p=0.045). In additional, the results show a statistically significant difference in IgE production during the two malaria transmission seasons. The mean IgE were respectively 993.25 IU (CI 95% =986.74- 1169.76) during low transmission and 854.37 IU (CI 95%=692.98-885.77) for high transmission season (p= 0.000134). IgE responses increased with age in both low and high malaria transmission seasons with respective p=0.00196 for low transmission and p=0.0531 for high transmission. In conclusion, IgE antibodies were produced in malaria infection. Its responses were associated with P. falciparum density, malaria transmission season and age. Key words: malaria, IgE, age, season of transmission and P. falciparum density.

6168

COMPARATIVE ANALYSIS OF PLASMODIUM FALCIPARUM TRANSCRIPTOME PROFILES REVEALS UPREGULATION OF HEAT SHOCK PROTEINS AND KINASES IN PEDIATRIC SEVERE MALARIAL ANEMIA

Sarah Kituyi[1], Qiuying Cheng[2], Clinton O. Onyango[3], Ivy Hurwitz[2], Beauty Kolade[4], Philip D. Seidenberg[5], Kristan A. Schneider[6], Christophe G. Lamber[2], Benjamin H. McMahon[4], Ananias A. Escalante[7], Samuel B. Anyona[3], Collins Ouma[3], Douglas J. Perkins[2]

The rapid emergence of resistance to anti-malarial therapy calls for the exploration of more anti-malarial drug targets to boost existing therapies. This can be achieved by harnessing vital pathways for the survival of Plasmodium parasite, the causative pathogen of malaria, in both the arthropod vectors and human host. Heat shock proteins (HSPs) and their co-chaperones are components of such vital pathways in P. falciparum parasites. The HSPs regulate the folding and stabilization of their client proteins that are essential for the parasites to survive temperature changes in the host during febrile illness. Among the client proteins of these HSPs are kinases, which have been shown to play roles in mediating the motility of sporozoites towards the liver cells and the subsequent attachment and entry into the hepatocytes. In addition, the egress of merozoites, infection of red blood cells and the adherence of the parasites in the endothelial vessels are equally dependent on kinases. To determine if parasite gene

expression levels of these proteins are associated with severe malarial anemia [SMA, hemoglobin, Hb, ≤6.0g/dL] pathogenesis, we examined P. falciparum transcriptome profiles derived from whole blood samples from two groups of pediatric malaria patients in Siaya County Referral Hospital, Kenya: SMA (n=20) and non-SMA (Hb>6.0g/dL, n=40). Our data reveal significant (P<0.05) upregulation of transcripts for the following P. falciparum HSPs and kinases in children with SMA: HSP110 (Log2foldChange=1.19), HSP90 (Log2foldChange=2.26), HSP60 (Log2foldChange=4.2), HSP40 (Log2foldChange=1.67), guanylate kinase (Log2foldChange=2.13), serine/threonine protein kinases (Log2foldChange=1.19), pyruvate kinase 2 (Log2foldChange=2.35), and phosphoglycerate kinase (Log2foldChange=1.58). Collectively, these findings provide novel information about the differential regulation of Plasmodium HSPs and kinases in SMA pathogenesis, and have the potential to facilitate the identification of new therapeutic targets, particularly for severe cases.

Malaria remains one of the leading causes of childhood morbidity and mortality and manifests as severe malarial anemia [SMA, hemoglobin (Hb)<6.0g/dL] in western Kenya. Our recent studies revealed differential gene expression profiles of the host ubiquitination process in children with malarial anemia and temporal expression changes following ingestion of malarial pigment (hemozoin) by peripheral blood mononuclear cells. We extend these findings by determining the host transcript profiles of human ubiquitination process genes in children with non-SMA (Hb≥9.0g/dl, n=41) and SMA (n=25) presenting at Siaya County Referral Hospital in western Kenya. Total RNA was isolated from peripheral blood collected upon presentation at hospital for acute malaria prior to treatment. RNA sequencing was performed with coverage of >20 million high-quality mappable reads using the Illumina NovoSeq platform. Sequence reads were mapped to the human genome (GR-Ch38) using the STAR software. Differential gene expression analysis between the two clinical groups was performed using the EdgeR package. A MetaCoreTM network-building algorithm was used to identify direct functional interactions of significantly differentially expressed genes (DEGs). Results revealed 40 ubiquitination process DEGs (Padjust≤0.050) of which 26 were up-regulated and 14 were down-regulated in children with SMA. Specifically, 3 genes displayed a magnitude ≥1.5 fold-change (up-regulation) in SMA: UBE2H (Padj.=4.68E-19), RNF123 (Padj.=2.47E-10), and DDB1; (Padj.=9.73E-15). Functional analysis identified the βTrCP-MDM2-UBE2D2-UBE1L2-UBE2D1 network with UBE1L2 and MDM2 as central divergence and convergence hubs, respectively, both with 6 direct interactions. The top gene ontology process that emerged was Protein Ubiquitination (P=1.79e-60). Collectively, these results reveal DEGs in ubiquitination processes in children with SMA, suggesting that altered ubiquitination appears central to the pathogenesis of severe Plasmodium falciparum malaria.

Plasmodium falciparum erythrocyte membrane protein-1 antigens (PfEMP1s) play an important role in virulence and immune evasion. Antibodies against PfEMP1s have been associated with protection from severe malaria, and distinct gaps in antibodies have been shown in children with cerebral malaria (CM) and severe malarial anemia (SMA) compared to uncomplicated malaria. We conducted a case-control study of severe malaria in Mali, West Africa, including cases of CM, SMA, and concurrent CM + SMA matched to uncomplicated malaria controls with and without a history of severe malaria. Controls were matched on age, sex, ethnicity, and date of presentation. We have recently found that cases of severe malaria had higher expression of PfEMP1s that bind both endothelial protein C receptor (EPCR) and intercellular adhesion molecule 1 (ICAM-1). We tested the hypothesis that children with severe malaria lack antibody responses to these dual-binding PfEMP1s. Sera was collected at the time of acute illness, during convalescence at day 21, and in the dry season after illness. We fabricated a custom protein microarray containing 158 PfEMP1 fragments from the 3D7 reference genome and 78 fragments from PfEMP1s associated with severe malaria. We selected PfEMP1 fragments containing consecutive domains from domain cassettes (DCs) previously associated with severe disease, including DCs 1, 4, 5, 8, 13, and 15 from the lab strains IT4, HB3, and Dd2 as well DCs 8 and 13 from clinical isolates collected from Malian children. Serological responses to these fragments were measured in 88 cases of severe malaria, including 57 that were matched to uncomplicated cases of malaria. Serological responses were also compared at the time of acute illness to day 21 of convalescence and to the dry season following infection. The results of this study could inform the design of vaccines and treatments against severe malaria.

6171

ASSOCIATION BETWEEN THE GUT MICROBIOME AND MALARIA INCIDENCE IN INFANTS LIVING IN MALAWI

Esther Ndungo, Andrea G. Buchwald, Miriam K. Laufer, Marcela F. Pasetti, David A. Rasko

University of Maryland School of Medicine, Baltimore, MD, United States

Studies in infants living in malaria-endemic regions have suggested a role for the gastrointestinal microbiome in establishment of Plasmodium infection, disease progression, and severity of infection. We hypothesize that malaria infection impacts the developing microbial community in infancy and, conversely, disruptions in the gastrointestinal microbiome may predispose infants to infections. Using 16S rRNA amplicon sequencing, we characterized the gastrointestinal microbiota in a longitudinal birth cohort in Malawi with active and passive surveillance for malaria infection and clinical disease from birth up to 2 years of age. Clinical malaria was defined as symptoms of malaria and a positive rapid diagnostic test (RDT), and malaria infection as any visit with P. falciparum DNA detected from dried blood spots by qPCR. Rectal swab samples were collected every 6 months, starting at 6 months of age. To identify whether the gastrointestinal

microbiota was associated with occurrence of clinical malaria, we compared the microbial species diversity, as measured by the Shannon Diversity Index (SDI), at 6 months of age in children who had subsequent malaria infections to those who did not. Among 60 children included in the study, 24 had clinical malaria between 6 and 12 months of age with a mean SDI of 2.69 (SD = 0.62) compared to a mean SDI of 2.85 (SD = 0.47) among those without malaria (p = 0.28). To account for the time between measurement of SDI and occurrence of malaria, survival analysis, adjusted for month of year and length-for-age Z score (a predictor of malaria) identified SDI at 6 months as associated with a non-significant decrease in the hazard of clinical malaria during the next six months (HR = 0.71, 95%CI = 0.33,1.54). Further analysis will identify temporal changes in the gastrointestinal microbiota associated with incidence and symptoms of malaria infection in this cohort. Our findings highlight the need to better understand the association between onset of malaria and microbial communities to develop novel strategies to reduce malaria susceptibility in infants.

DEFINING THE PLASMODIUM PIPECOLIC ACID PATHWAY AND ROLE IN CEREBRAL MALARIA

Akua Mensah[1], Cheryl Sachdeva[2], Tarun Keswani[2], Edward Nieves[2], Photini Sinnis[3], Terrie Taylor[4], Karl Seydel[4], Kyu Rhee[5], Anas Saleh[5], Johanna P Daily[2]

[1]CUNY Lehman College, Bronx, NY, United States, [2]Albert Einstein College of Medicine, Bronx, NY, United States, [3]Johns Hopkins University, Baltimore, MD, United States, [4]Michigan State University, East Lansing, MI, United States, [5]Weill Cornell Medical College, New York, NY, United States

Cerebral malaria (CM) is a clinical syndrome and a leading cause of death from malaria, with a fatality rate between 15% to 30% in African children. CM occurs when Plasmodium falciparum infected erythrocytes accumulate within the cerebral microvasculature and cause vaso-occlusion, which is associated with high brain swelling, coma and seizures. The etiology of the coma is not well understood. Our prior studies demonstrated elevated blood pipecolic acid (PA) levels in children with CM and a corollary increase in PA in the brain lysate of mice during experimental cerebral malaria (ECM). PA is a non-proteinogenic amino acid metabolite of the lysine degradation pathway. PA has been associated with neuromodulation in humans and in animal models. Although Plasmodium generates PA, the parasite metabolic pathway is unknown. From this data, we will knock out pathway enzymes and measure pipecolic acid production to confirm the pathway model. Here, we will first confirm the production of PA in P. falciparum under in vitro growth conditions, using a quantitative liquid chromatography-mass spectrometry (LC-MS). Our second goal is to define lysine degradation pathway in P. falciparum using 13C labelled lysine in vitro to trace labeled pathway intermediates that gives rise to PA. Our preliminary data identified three 13-C labelled lysine pathway metabolites: (1) amino adipic semialdehyde. 2) piperideine-6-carboxylic acid and (3) pipecolic Acid. We mapped our model of lysine degradation pathway onto canonical KEGG pathway database which suggested that pyrroline-5-carboxylate reductase 1 (PF3D71357900) enzyme is involved in PA production in P. falciparum. To confirm the role of PF3D71357900 in PA production, we will use pargyline to inhibit PF3D71357900 in vitro. We will use the same labelling strategy to confirm this pathway model in vivo in P. berghei ANKA infected ECM model. This study informs our knockout strategy of pathway enzymes to disrupt PA production and examine the effect of PA on the neurological decline in ECM model.

MALARIA- INTESTINAL PARASITES CO-INFECTION AMONG CHILDREN IN A LYMPHATIC FILARIASIS ENDEMIC REGION OF GHANA

Amma A. Larbi[1], Rosemond Mawuenyega[1], Emmanuel Amewu[1], Stephen Opoku[1], Solomon Wireko[2], Alexander Kwarteng[1]

[1]KNUST(Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]Kumasi Technical University, Kumasi, Ghana

Malaria- intestinal parasites (IPs) co-infections are a major problem in tropical regions of the world including Ghana. This is mostly as a result of an overlap in their geographical distributions. Malaria and IPs are a major cause of morbidity in children, having severe consequences on their cognitive development and growth. This study was conducted to determine the prevalence of Malaria and IPs coinfections amongst children in the Ahanta West District of Ghana, a Lymphatic filariasis (LF) endemic region. The Study was done in the dry season where malaria transmission is expected to be low. Again, this region had ceased Mass drug administration for LF control for three years prior. The study utilized malaria rapid diagnostic tests (RDTs) such as NexTek, Bioline and First Response and microscopy to examine stool samples for IP. Out of 113 participants with a mean age of 12.10±2.3, 60 (53.1%) had malaria, 81 (71.7%) had IP, and 45 (39.8%) had malaria-intestinal parasite coinfection. Notably, 22.1% of participants had received malaria treatment three months prior to the study, and 66.4% had dewormed in the past three months. The overall prevalence of malaria, intestinal parasites and malaria-intestinal parasites coinfection were 60 (53.1%), 81 (71.7%) and 45 (39.8%), respectively. This high prevalence of asymptomatic malaria even during the dry season, may hinder current elimination strategies and drive malaria transmission. The impact of Malaria-IP coinfection is multifactorial, therefore, combatting parasitic infections simultaneously is essential to improve the health of these children.

6174

UNRAVELLING VAR COMPLEXITY: RELATIONSHIP BETWEEN DBLA TYPES AND VAR GENES IN PLASMODIUM FALCIPARUM

Mun Hau Tan, Heejung Shim, Yao-ban Chan, Karen P. Day

The University of Melbourne, Melbourne, Australia

The enormous diversity and complexity of var genes that diversify rapidly by recombination has led to the exclusion of assembly of these genes from major genome initiatives (e.g., Pf6). A scalable solution in epidemiological surveillance of var genes is to use a small 'tag' region encoding the immunogenic DBLα domain as a marker to estimate var diversity. As var genes diversify by recombination, it is not clear the extent to which the same tag can appear in multiple var genes. This relationship between marker and gene has not been investigated in natural populations. Analyses of in vitro recombination within and between var genes have suggested that this relationship would not be exclusive. Using a dataset of publicly-available assembled var sequences, we test this hypothesis by studying DBLα-var relationships for four study sites in four countries: Pursat (Cambodia) and Mae Sot (Thailand), representing low malaria transmission, and Navrongo (Ghana) and Chikwawa (Malawi), representing high malaria transmission. In all study sites, DBLα-var relationships were shown to be predominantly 1-to-1, followed by a second largest proportion of 1-to-2 DBLα-var relationships. This finding indicates that DBLα tags can be used to estimate not just DBLα diversity but var gene diversity when applied in a local endemic area. Epidemiological applications of this result are discussed.

6175

TRANSCRIPTOME ANALYSIS OF BLOOD-STAGE PLASMODIUM FALCIPARUM REVEALS UP-REGULATED PFHSP70 AND HISTONE TRANSCRIPTS IN SEVERE MALARIAL ANEMIA

Clinton Onyango[1], Qiuying Cheng[2], Samuel B. Anyona[1], Ivy Hurwitz[2], Sarah Kituyi[3], Evans Raballah[4], Beauty Kolade[5], Philip D. Seidenberg[6], Kristan Schneider[7], Collins Ouma[1], Ananias Escalante[8], Benjamin McMahon[5], Douglas J. Perkins[2]

[1]Maseno University, Maseno, Kenya, [2]University of New Mexico HSC, Center for Global Health, Albuquerque, NM, United States, [3]University of Embu, Embu, Kenya, [4]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [5]Los Alamos National Laboratory, Los Alamos, NM, United States, [6]University of New Mexico HSC, Dept of Emergency Medicine, Albuquerque, NM, United States, [7]University of Applied Sciences Mittweida, Mittweida, Germany, [8]Temple University, Philadelphia, PA, United States

Malaria-related morbidity and mortality remain as significant health burdens in sub-Saharan Africa, accounting for 95% of 247 million cases and 96% of 619,000 global deaths. In Siaya, western Kenya, a holoendemic Plasmodium falciparum transmission region, severe malaria in children <5 years primarily manifests as severe malaria anemia [SMA, hemoglobin (Hb)≤6.0 g/dL]. Although the P. falciparum genome contains multigene families that influence parasite survival, it is largely unclear how differential expression of parasite genes influence human malaria severity. As such, the entire P. falciparum transcriptome was captured in whole blood prior to antimalarial treatment in children (3-36 months) who presented at hospital with non-SMA (Hb>6.0 g/dL, n=40) or SMA (n=20). Next-generation sequencing was performed at a depth of >20 million high-quality mappable reads using the Illumina NovoSeq platform. Reads were mapped to a Kenyan isolate reference genome (pfKE01) using the HTSeq platform, revealing ~3200 distinct P. falciparum transcripts. Differential expression analysis revealed 688 significantly differentially expressed genes in SMA (P<0.05) for which 3 heat shock protein 70 genes and 3 histone genes were upregulated: PfKE01_110038600 (PfHSP70-3, Log2foldChange=1.01), PfKE01_080037100 (Log2foldChange=0.51), PfKE01_090022300 (Log2foldChange=0.70), PfKE01_060023900 (histone PfH2A, Log2foldChange=1.51), PfKE01_110009800 (PfH2B, Log2foldChange=1.40), and PfKE01_060016500 (PfH3, Log2foldChange=1.97). Previous studies illustrate that the PfHSP70 family facilitates parasite proteostasis and protection from cytotoxic drugs, thus mediating parasite survival and potential pathogenesis. The P. falciparum histone family regulates parasite gene expression associated with its developmental stages, with the release of parasite histones into circulation stimulating pro-inflammatory mediators known to influence the pathogenesis of SMA pathogenesis. Collectively, these results support the PfHSP70 and PfHistone families as targets for small molecule inhibitors for novel therapeutic development.

6176

SINGLE CELL SEQUENCING OF BRAIN SEQUESTERED CD8+ T CELLS DURING EXPERIMENTAL CEREBRAL MALARIA

Miranda S. Oakley, Victoria Majam, Hong Zheng, Mark K. Kukuruga, Sanjai Kumar

FDA, Silver Spring, MD, United States

Brain-sequestered CD8+ T cells play a prominent role in the pathogenesis of experimental cerebral malaria (ECM) in mice. A recent study has also shown that CD8+ T cells target the cerebrovasculature in children with cerebral malaria caused by Plasmodium falciparum. CD8+ T cells accumulate in the brain during the effector phase of a P. berghei ANKA (Pb-A) infection in mice and promote pathogenesis by inducing apoptosis of endothelial cells of the blood brain barrier. However, the molecular events associated with this CD8+ T cell-mediated pathogenesis remain poorly understood. To better characterize how brain-sequestered CD8+ T cells exert their pathogenic effect, we performed single cell sequencing of the transcriptome of CD8+ T cells isolated from perfused brain tissue of Pb-A infected moribund and non-moribund C57BL/6 mice and uninfected C57BL/6 mice. A single cell whole transcriptome library was prepared from RNA isolated from approximately 50,000 brain sequestered leukocytes that was also labeled with cell (TCRβ, CD3ε, and CD8α) and sample (mouse) specific antibody oligonucleotide conjugates. Approximately 2-2.5 billion clusters were then paired-end sequenced on a NovaSeq S4 PE100 flow cell and bioinformatic analysis was subsequently performed. Genes transcriptionally altered in brain sequestered CD8+ T cells and bioinformatic analyses-based biological pathways associated with the effector phase of ECM will be presented.

6177

IMPORTANCE OF INSULIN-LIKE GROWTH FACTOR : IGF-1 IN PLASMODIUM VIVAX MALARIA

Miriam Elena Cantero Guevara, María F. Acosta Yasnot, María C. Velasco Pareja, Luis S. Ramos González

University of Cordoba, Monteria - Cordoba - Colombia, Colombia

Malaria is a public health problem that causes millions of deaths a year. Plasmodium vivax is the most widely distributed etiological agent of malaria in the world. Malaria has been shown to have some relationship to insulin-like growth factor 1: IGF-1 is an important indicator of malnutrition, and acts as an acute phase reactant in infections and inflammation. The objective of this study was to evaluate the plasma concentration of IGF-1 and its relationship with fibrinogen, C-reactive protein CRP, body mass index, and anemia in patients with malaria caused by Plasmodium vivax. 23 individuals with malaria and 20 healthy individuals were included. This research was descriptive and analytical cross-sectional. Study zone: Tierralta, Córdoba, Colombia in a period of six months in the year 2022. Plasma fibrinogen concentration and IGF-1 were determined by ELISA and C-reactive protein was determined by latex agglutination in microtiter plates, using Anthro and Anthro Plus software, individuals were characterized according to height and body mass index according to age. The hemoglobin concentration was determined from automated blood table 7 of IV generation. A thick smear was made to calculate the density of parasites. The fibrinogen concentration increased significantly in patients with malaria (324.03± 59.87 mg/dl, compared to the control group 224.74± 34.88 mg/dl. The CRP increased significantly in patients infected with malaria 21.52± 35.59 mg/l compared to the control 2.43± 0.97 mg/l and the concentration of IGF-1 decreased 45.01± 0.53 significantly in malaria patients, who had a low body mass index, compared to controls. In conclusion, this study suggests that in patients with P. vivax malaria, a greater production of fibrinogen, C-reactive protein is induced, which promotes a decrease in IGF-1, associated with malnutrition and anemia.

NON-FALCIPARUM SPECIES INFECTIONS AND MALARIA SEVERITY: PRELIMINARY FINDINGS IN HIGH TRANSMISSION SETTINGS IN SENEGAL

Aissatou Diagne[1], Babacar Souleymane Sambe[1], Folly Mawulolo Gaba[2], Ousmane Sadio[1], Ibrahima Sarr[1], Arona Sabene Diatta[1], Serigne Ousmane Mbacké Diaw[1], Hélène Ataume Mawounge Diatta[1], Babacar Diouf[1], Ines Vigan-Womas[1], Babacar Mbengue[2], Makhtar Niang[1]

[1]Institut Pasteur de Dakar, Dakar, Senegal, [2]Université Cheikh Anta Diop de Dakar, Service d'Immunologie FMPO, Dakar, Senegal

In sub-Saharan Africa, non-falciparum species circulate at low prevalence and density of parasitemia, predominantly in co-infections with the dominant malaria Plasmodium falciparum species. The problematic diagnosis of non-falciparum parasites remains a challenge to accurately estimating their prevalence, contribution to the disease's burden, and potential role in severe malaria. This study assessed the contribution of non-falciparum parasites to malaria severity in Senegal. The study analyzed blood samples of 273 malaria patients (48,4% severe and 51,6% uncomplicated cases) enrolled in 2015, 2017 and 2020 from health facilities in Kolda, Tambacounda and

Kedougou, the three regions of Senegal with the highest malaria incidence. The Plasmodium positivity and Plasmodium species specific composition were determined by molecular methods. R Software was used for statistical analysis of non-falciparum species distribution concerning patients' demographics (age, sex), clinical malaria status (uncomplicated and severe), and the odds ratios of the relative risk of the disease severity associated with non-falciparum species infections. Non-falciparum species i.e P. ovale, P. vivax and P. malariae were retrieved at proportions of 37.36%, 28.20% and 1.83%, respectively, in tested samples. Among the non-falciparum species, P. ovale and P. vivax accounted for 6% of unique infections. Severe and uncomplicated cases are evenly distributed in age groups and gender. P. ovale infection was associated with a significant (OR=0,12) three-fold reduction of severe malaria, while P. vivax in co-infection increased, though non-significant (OR>1), the risk of malaria severity. These preliminary findings support a role of non-falciparum parasites species in the burden of malaria and potentially the severity of the disease in Senegal, and call for immediate attention from the control programs to sustain the limited success gained to date concerning malaria control in the areas.

6179

ACCEPTABILITY OF TECHNOLOGICAL INNOVATION IN MALARIA VECTOR CONTROL IN MALI: THE CASE OF ATTRACTIVE TARGETED SUGAR BAIT IN THE HEALTH DISTRICT OF KATI MALI

Samba Diarra, Mohamed Moumine Traore, Mahamoudou Toure, Seydou Doumbia
USTTB, Bamako, Mali

Malaria is the leading cause of morbidity and mortality in Mali and it's among the ten countries with the highest number of malaria cases and deaths, accounting for 3% of cases and deaths worldwide and 6% of cases in West Africa. In Mali Malaria is endemic, where about 90% of the population is concentrated. Given the increase in resistance to the current generation of insecticides and the behavioral plasticity of the vectors that result in continued transmission of malaria despite the use of insecticide-treated nets (ITNs) or indoor residual spraying. Insecticides with new modes of action are needed, hence the need for Attractive Targeted Sugar Bait (ATSB). This qualitative research explores and assesses the perceptions and community acceptability on ATSB in Mali. Focus group discussions (12) and in-depth interviews (10) were conducted, and a mapping of distrust was done. Data were analyzed using Sphinx software. The results provided an understanding of the factors influencing the supply and community acceptability of ATSBs. Our data also show that ATSBs are perceived in different ways. On the one hand, they are an alternative to vector control. On the other hand, they are subject to mistrust regarding possible long-term environmental risks. Interpersonal communication with community authorities is a guarantee of the acceptability of ATSBs. Some ideas and strategies have been developed for the introduction of ATSBs on a sub-regional scale. The use of ATSBs offers hope in the fight against malaria in malaria-endemic areas. As with any innovation, its full and complete adoption requires a period of appropriation by the users.

6180

EFFECT OF SEASONAL MALARIA CHEMOPREVENTION ON ASEXUAL PLASMODIUM FALCIPARUM INFECTION IN CHILDREN AGED 5 TO 14 YEARS IN DANGASSA, MALI

Ibrahim Sanogo[1], Drissa Konate[2], Sory Ibrahima Diawara[2], Bourama Keita[2], Djeneba Dabitao[1], Seydou Doumbia[1], Mahamadou Diakite[1]
[1]University Clinical Research Center, Bamako, Mali, [2]International Center for Excellence in Research, Faculty of Medicine and Odontostomatology, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali

The effectiveness of seasonal malaria chemoprevention (SMC) in reducing malaria-related mortality and morbidity has been demonstrated through several studies. However, its effect on parasite clearance in asymptomatic carriers needs more investigation. This study aimed to determine the effect of SMC on the prevalence of Plasmodium falciparum infection. A secondary analysis was performed using the data from an open randomized study conducted in children 5-14 years in Dangassa to estimate the effect of an additional fifth round to the current SMC regimen (four rounds). A monthly follow up was done from July to December to collect data on parasitemia using smear microscopy in both intervention and control groups. Binomial generalized linear mixed regression was performed to estimate the reduction in the prevalence of P. falciparum infection in children under SMC adjusted on the age groups and the use of long-lasting insecticidal nets (LLINs) with a threshold at 5%. At baseline, the prevalence of P. falciparum infection was similar between the two groups (12.5% for the control group vs 13.4% for the intervention group, p=0.942). After adjusting for age groups and long-lasting insecticidal nets (LLINs) usage, a reduction of 60% in the prevalence of P. falciparum infection was observed in the intervention group (OR = 0.40, 95%CI [0.30 to 0.54], p<0.0001) compared to control group. Stratified by age groups, the same trend was observed with 58% and 61% reduction in prevalence, respectively in children aged 5 – 9 years (OR = 0.42, 95%CI [0.28 to 0.63], p<0.0001) and 10 – 14 years (OR = 0.39, 95%CI [0.26 to 0.58], p<0.0001). Our finding demonstrated the effectiveness of SMC in the reduction of asymptomatic parasitemia carriage among older children in Dangassa. Nevertheless, a large-scale study is warranted to assess the contribution of SMC in malaria transmission.

6181

FACTORS AFFECTING PREGNANT WOMEN'S ADHERENCE TO INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN THE NANORO HEALTH DISTRICT

Kadija Ouedraogo[1], Marc Christian Tahita[2], Bérneger Kaboré[2], Hyacinthe Sanou[1], Toussaint Rouamba[2], Adélaïde Compaoré[1], Paul Sondo[3], Ilboudo Hamidou[2], Karim Derra[2], Macaire Nana[4], Léa Paré[5], Halidou Tinto[2]
[1]clinical Research Unit Of Nanoro, Ouagadougou, Burkina Faso, [2]clinical Research Unit Of Nanoro, Institut De Recherche En Science De La Santé/ Direction Régionale Du Centre-Ouest, Ouagadougou, Burkina Faso, [3]clinical Research Unit Of Nanoro, Institut De Recherche En Science De La Santé/ Direction Régionale Du Centre Ouest, Ouagadougou, Burkina Faso, [4]district Sanitaire De Nanoro, Ouagadougou, Burkina Faso, [5]institut De Recherche En Sciences De La Santé-Direction Régionale De L'ouest, Bobo Dioulasso, Burkina Faso

Malaria in pregnancy is still a public health issue despite progresses in case management and prevention. The later includes use of long-lasting insecticide treated nets (LLINs) together with administration of intermittent preventive treatment with sulfadoxine-pyrimethamine (IPTp-SP). The national malaria control program (NMCP) has recommended at least 3 doses of IPTp-SP but available information suggests that only 30% of eligible women received this in 2016 despite observed high levels of antenatal care (ANC) attendance. Importantly, adherence to IPTp-SP may be affected by perceptions, acceptability and contextual factors that need to be understood and thus improve the effectiveness of health interventions. Therefore, we conducted a qualitative study to explore the socio-cultural factors limiting pregnant women's adherence to IPTp-SP in Nanoro, Burkina Faso. We have carried out 43 individual interviews and 4 focus groups with 84 people, direct observations between August 2021 to June 2022, targeting pregnant women, husbands, mothers in-low, traditional healers, community health workers and health workers. Participants were selected purposively. Interviews were audio-recorded and transcribed. Data were coded and thematic analysis was conducted using Nvivo 12. The results indicate that although pregnant women have popular beliefs about the causes of malaria, they still rely on medical treatment and do not use traditional care. Adherence to IPTp-SP is compromised by pregnant women's late initiation of ANC visits because they believe that pregnancy does not need biomedical care, as long as they are healthy, they do not need care. Also, the lack of awareness of IPTp-SP, the low perception of the seriousness of malaria during pregnancy by pregnant women, the difficulties related to the supervised intake and the stock-outs of SP are other reasons that explain the low adherence of pregnant women to IPTp-SP. To improve

IPT-SP coverage, awareness for early initiation of ANC should be increased and the conditions of the health facilities offer in terms of maternal health should be improved.

LARGER FAMILIES ARE LESS LIKELY TO ACHIEVE UNIVERSAL LONG-LASTING INSECTICIDAL NETS COVERAGE IN ETHIOPIA

Misganu Endriyas Tantu[1], Tarekegn Solomon[1], Taye Gari[1], Teka Samuel[1], Bernt Lindtjørn[2]

[1]Hawassa University, Hawassa, Ethiopia, [2]Centre for International Health, University of Bergen, Bergen, Norway

In a population with a high risk of malaria infection, using long-lasting insecticidal nets (LLIN) is an essential malaria prevention method. Ethiopia has been distributing LLIN for free. However, ensuring sufficient access and use of LLINs requires close monitoring and evaluation. Hence, this study assessed ownership of LLINs in the Sidama Region in Southern Ethiopia. A community-based cross-sectional study was conducted in February and March 2023. Multi-stage cluster sampling was used to select representative households. We estimated LLIN coverage in terms of WHO's universal LLIN coverage (at least one LLIN for every two people) and national LLIN targets, which aim at 100% LLIN coverage of the population at risk with one LLIN per sleeping space. In addition, the LLIN distribution depends on the family size, with one LLIN for a family size of 1-2, two LLINs for a family size of 3-5, three for 6-7 and four for eight or more family members. We did not assess the quality of the LLIN. A total of 1647 households were included in the study. Most households were led by males (89%), farmers (63%) and persons who were unable to read and write (55%). The ownership of at least one LLIN per household was 85% (95% CI 83.5 - 86.9%; 1405 of 1647 households). About two-thirds (66%) of households had at least one LLIN for every sleeping space, and about half (49%) had the required LLIN per family size. Only 36% of households had universal access to LLIN. Moreover, only 33% of households with children less than under-five years of age or pregnant women had universal access to LLIN. Homes with larger families (Adjusted Odds Ratio (AOR): 8.14 [6.26, 10.58]) and female-headed households (AOR: 3.08 [1.47, 6.43]) were more likely to have unmet universal LLINs coverage. We conclude that the LLIN coverage was low compared to WHO-recommended universal LLIN coverage and national LLIN targets per sleeping space and family size. The National LLINs distribution standard should consider additional LLIN for larger families.

6183

CAREGIVER KNOWLEDGE AND CONFIDENCE IN SMC EFFECTIVENESS IN NIGERIA

Adaeze Catherine Aidenagbon, Taiwo Ibinaiye, Olabisi Ogunmola, Chibuzo Oguoma, Olusola Oresanya

Malaria Consortium, Abuja, Nigeria

In 2012, the World Health Organization (WHO) issued a policy recommendation for seasonal malaria chemoprevention (SMC) as an intervention against Plasmodium falciparum malaria. It is aimed to protect children by clearing existing infections and preventing malaria infections during the season of greatest malaria risk. Caregivers are provided with basic information on the purpose of SMC, eligibility of targeted children, importance of SMC doses, duration of treatment and timing of the intervention. Caregivers with more information are likely to adopt positive behavioral change attitudes. Overall confidence in SMC was measured as caregivers' whose children received day1 dose of Sulphadoxine Pyrimethamine+Amodiaquine (SPAQ), importance of day 2/3 doses of Amodiaquine (AQ), what to do if their children experience any adverse drug events, and caregivers who reported confidence in the efficiency of SMC. We assessed knowledge of caregiver against their overall confidence in SMC. Data was extracted from 2022 end-of-round SMC coverage survey and analyzed data of 11,880 caregivers - child peer of sample from nine SMC implementing states of Nigeria. Mixed-effects multivariable logistic regression models were fitted to explore the association between SMC knowledge and caregivers' confidence in SMC. The proportion of caregivers with overall knowledge of the four SMC knowledge indicators assessed was low (56.6%) however, there were high odds of confidence of SMC among caregivers with knowledge of the purpose of SMC (OR: 1.7, 95% CI: 1.3 - 2.4, p<0.001), SMC age eligibility (OR: 1.4, 95% CI: 1.1 - 1.9, p=0.013), importance of receiving day 2/3 doses (OR: 5.0, 95% CI: 3.7 - 6.7, p<0.001), and what to do if their children experience any adverse drug event (OR: 2.1, 95% CI: 1.7 - 2.5, p<0.001). The study shows direct relationship between SMC knowledge and caregiver's confidence in SMC. Therefore, there is need to review SMC messaging either through orientation or direct social behavior change (SBC) intervention to ensure the right information and knowledge permeates the entire community space. This will have a positive influence on effective delivery of SMC.

6184

UTILIZATION OF LONG-LASTING INSECTICIDAL NETS AT HOUSEHOLD AND INDIVIDUAL LEVELS IN SIDAMA REGION, SOUTHERN ETHIOPIA

Teka Samuel Debeko[1], Tarekegn Solomon Shanka[1], Taye Gari Ayana[1], Misganu Endriyas Tantu[1], Bernt Lindtjørn[2]

[1]Hawassa University, Hawassa, Ethiopia, [2]Centre for International Health, University of Bergen, Bergen, Norway

Malaria is an increasing public health problem in Ethiopia, sometimes occurring as epidemics. The utilization of long-lasting insecticidal nets (LLIN) is an essential malaria prevention tool, and there is limited information on its utilization in the Sidama Region in Southern Ethiopia. This study aims to assess LLIN use in rural Sidama. Using multi-stage cluster sampling, a cross-sectional study was conducted in two districts in February and March 2023, including 1,647 households with 8,054 individuals. LLIN utilization was measured by the self-report of sleeping under LLINs the day preceding the survey and was estimated at household and individual levels. Descriptive statistics and binary logistic regression were performed. The mean age of house members was 23 years; half of the participants were males, and 47% could not read and write. Of 1647 households, 85% (95% CI 83 - 87%) owned at least one LLIN, from which 78% (95% CI 76 - 80%) used at least one LLIN the preceding night. However, the individual-level LLIN use showed that only 31% slept under a bed net the previous day. Females (Adjusted Odds Ratio (AOR): 1.5 (1.4, 1.7)) and members from large families (AOR: 1.3; 95% CI 1.1, 1.4) were more likely not to sleep under LLIN. Meanwhile, literate household members (AOR 1.2; 95% CI 1.1, 1.4) were likelier to sleep under bed nets than those who couldn't read and write. Our study shows that the proportion of the population in a malaria-endemic area who slept under LLIN the previous night was far below what is required to control malaria. Furthermore, our study shows that measuring individual LLIN use may give more appropriate information for control than using the household as a unit, as often recommended.

6185

IMPACT OF SCALING UP SEASONAL MALARIA CHEMOPREVENTION ON COVERAGE AND QUALITY OF IMPLEMENTATION IN KARAMOJA REGION, UGANDA

Musa Odongo[1], Anthony Nuwa[1], Chucks Nnaji[2], Tonny Kyagulanyi[1], David Salandini Odong[1], Jane Nabakooza[3], Richard Kajubi[1], Maureen Nakirunda[1], Damian Rutazaana[3], Denis Rubahika[3], Godfrey Magumba[1], Jimmy Opigo[3]

[1]Malaria Consortium, Kampala, Uganda, [2]Malaria Consortium, London, United Kingdom, [3]Ministry of Health, Kampala, Uganda

Uganda scaled-up seasonal malaria chemoprevention (SMC) using sulfadoxine-pyrimethamine and amodiaquine (SPAQ) to eight districts in Karamoja region, where malaria transmission is highly seasonal targeting 209,405 children under five. This followed a pilot in 2021 that targeted 73,464 children in two districts. Delivery was through a door-to-door approach by village health teams (VHTs), supervised by health workers. In three districts, four cycles were delivered because of delays in finalizing funding arrangements. In five districts, five cycles were implemented in line

with the duration of peak transmission season. This study documented the impact of SMC scale-up on intervention fidelity. We assessed coverage, quality of delivery and beneficiary perceptions through end of round household surveys conducted before and after scale-up. A total of 1863 SMC eligible households were surveyed in 2021 and 1404 in 2022. Review of SMC implementation and adaptation processes and documents were conducted. In 2022, full coverage (proportion of eligible children who received all delivered cycles and the complete 3-day treatment course) was 78.2 % (95%CI: 76.0 - 80.3) across eight districts. Among eligible children who received day 1 SPAQ, 93.1% (95%CI: 91.6 - 94.4) received directly observed treatment (DOT). These were comparable to 2021 when 87.2% (95%CI: 85.2 - 89.1) of eligible children received all five cycles of SPAQ in the two districts, and 97.4% (95%CI: 96.4 - 98.3) received day 1 SPAQ by DOT. Similar to 2021, 98.0% of caregivers reported having heard of SMC in 2022, with VHTs a predominant source of information. Majority (> 90.0%) of caregivers knew the purpose, eligibility criteria, justification for giving SPAQ only to children under five, importance of amodiaquine doses on days 2 and 3, and how to respond when a child experienced an adverse event. Overall, 99.1% and 98.2% of respondents in 2021 and 2022 respectively, felt the program was effective in malaria control. SMC was successfully scaled-up in Karamoja region, increasing its access to beneficiaries at high coverage and quality, while adhering to the adapted implementation model.

STAKEHOLDER PERSPECTIVES ON INCORPORATING A NEW VECTOR CONTROL TOOL INTO THE KENYA NATIONAL MALARIA VECTOR CONTROL POLICY

Jane Klein A.Ikapesi[1], Prisca A. Oria[1], Lucy H. Baker[2], Julius I. Odero[1], Sheila Ekodir[1], Moureen Ekisa[1], Steven A. Harvey[2], Eric Ochomo[1], April Monroe[3]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States

New vector control tools are needed to reduce malaria transmission. It is essential to ensure the new tools reach the market as soon as possible and are accompanied by evidence-based policy recommendations. To complement a trial of the efficacy of a spatial repellent for malaria control, key informant interviews with national malaria control policy stakeholders were conducted. The national policy stakeholders were individuals or organisations that make and/or influence vector control policy and had first-hand knowledge about review, licensing, adoption, and distribution of vector control products. The interviews investigated the factors influencing policy adoption and the role that actors and evidence play in the policymaking process, to draw lessons to help accelerate the uptake of new vector control tools. The interviews were audio-recorded, transcribed, and analysed thematically. Stakeholders outlined the strengths and limitations of existing core interventions comprising long-lasting insecticidal nets, indoor residual spraying, and larval source management. The roles of various individuals and institutions in the processes of formulating vector control policies were also revealed. Upon submission of evidence of efficacy and safety of a proposed new tool, national experts and stakeholders hold discussions and critically analyse its strengths, weaknesses, opportunities, and threats. Additional considerations such as cost, acceptability, usability and complementarity to existing mosquito vector control tools, advocacy and buy in at various decision-making levels and source of funding are also key aspects influencing the adoption and integration of new vector control tools. This study provides insights into the nature of potential problems and solutions for adopting and integrating a new mosquito vector control tool into the national malaria control sphere.

6187

FACTORS ASSOCIATED WITH INSECTICIDE TREATED BED NET ACCESS AND USE IN SUSSUNDENGA, MOZAMBIQUE

Kelly M. Searle[1], Keeley Morris[1], Dominique E. Earland[1], Albino B. Francisco[2], Vali Muhiro[3], João L. Ferrão[4]

[1]University of Minnesota School of Public Health, Minneapolis, MN, United States, [2]Escola Secondária de Sussundenga, Sussundenga, Mozambique, [3]Sussundenga-Sede Rural Health Center, Sussundenga, Mozambique, [4]Consultores Associados de Manica, Chimoio, Mozambique

Insecticide treated bednets (ITNs) are the key malaria prevention tool used in endemic areas. However, there are several barriers to access and use of ITNs in many countries and particularly in rural areas. Mozambique has the fourth highest prevalence of P. falciparum malaria worldwide. Malaria incidence and prevalence follow a gradient of lowest in the south to highest in the north. Manica Province is located in the center of the country and has historically high malaria prevalence with seasonal peaks in incidence following the rainy season. The use of ITNs is the primary malaria prevention method available in this area. The aim of our study was to quantify access and use of ITNs in Sussundenga village, Manica Provice and determine factors associated with both access and use. Ninety-eight (98) households with 302 residents completed the study. The overall malaria prevalence by rapid diagnostic test (RDT) was 31%. Sixty-five percent (65%) of participants reported sleeping under an ITN the previous night. The primary reason given for not sleeping under an ITN was not having any in the household, or not having sufficient numbers for all of the residents of the household. ITN use the previous night was significantly associated with decreased risk of malaria infection measured by rapid diagnostic test (RDT). We constructed several generalized estimating equation (GEE) logistic regression models to quantify individual level and household level factors associated with access and ownership of ITNs, and use of an ITN the previous night. These finding are relevant for informing malaria control campaigns in the area to increase ITN ownership and usage. In 2020 this area was target with a large-scale ITN distribution, aiming to achieve universal coverage in Manica Province. The findings of this study can be used to improve use by identifying factors associated with regular use of ITNs.

PREDICTING MALARIA INFECTION AND ANEMIA IN PREGNANCY AT FIRST ANTENATAL CARE ATTENDANCE

Marc Christian Tahita[1], Bérenger Kaboré[1], Hamidou Ilboudo[1], Toussaint Rouamba[1], Adama Kazienga[2], Hyacinthe Sanou[3], Melika Helkanan Sougue[3], Nadège Zoma[3], Elodie Doda Sanou[3], Esther Nadia Ouedraogo[3], Bienevenu Nana[3], Hermann Sorgho[1], Halidou Tinto[1]

[1]Clinical Research Unit of Nanoro/IRSS-DRCO, Nanoro, Burkina Faso, [2]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium, [3]Clinical Research Unit of Nanoro, Nanoro, Burkina Faso

Malaria in pregnancy is responsible for adverse effects both on mothers and their offspring's. To tackle these adverse events, WHO recommends the promotion and use of long-lasting insecticide treated nets (LLINs) together with administration of intermittent preventive treatment with sulfadoxine-pyrimethamine (IPTp-SP) and appropriate case management through prompt detection and effective management. At least, 4 antenatal care visits (ANCs) and 3 doses of IPT-SP are recommended before delivery. Unfortunately, all these interventions are delivered through the antenatal care (ANC) channels. Knowing the characteristics of pregnant women attending ANC for the first time can help to customize interventions towards this specific group. We therefore, sought to determine the prevalence of malaria infection in pregnant women attending their first ANC visit and the risk factors associated. We conducted a cross sectional survey in 4 health centers of the district of Nanoro and all pregnant women attending their first ANC visit were recruited. Blood samples were collected to assess malaria infection using microscopy as gold standard and haemoglobin level using

HemoCue®. From the survey, less than 14% and less that 7% of pregnant women attended ANCs during the first and third trimester respectively. The prevalence of malaria infection and anemia were respectively 28.2% (n=118/418) and 70% (n=253/416). Being a primigravidae (Adj. OR=3, 95% CI:1.65-5.40) and at the first trimester of pregnancy (Adj. OR=0.28, 95% CI:0.08-0.91) were associated with higher risk of malaria infection. In addition, being primigravidae (Adj. OR=2.00, 95% CI:0.88-4.76), in the second trimester of pregnancy (Adj. OR=1.38, 95% CI:0.55-3.38) and malaria infection (Adj. OR=2.07, 95% CI:1.17-3.73) were strongly associated with the anemia. Socio-anthropologic studies with the objective to understand low and late ANC attendance should be performed and intervention strategies developed accordingly. Scale-up of these interventions is a key entry point for the effectivity of malaria prevention and control in pregnancy.

6189

IMPACT OF INDOOR RESIDUAL SPRAYING AT THE END OF THE RAINY SEASON IN A HOLOENDEMIC MALARIA TRANSMISSION SETTING IN NORTHERN ZAMBIA: A DEMONSTRATION PROJECT

Anne Martin[1], Mike Chaponda[2], Mbanga Muleba[2], James Sichivula Lupiya[2], Mary Gebhardt[1], Sophie Bérubé[1], Timothy Shields[1], Amy Wesolowski[1], Tamaki Kobiyashi[1], Douglas Norris[1], Daniel E. Impoinvil[3], Nduka Iwuchukwu[4], Gerald Chongo[5], Emmanuel Kooma[6], Paul Psychas[7], Matthew Ippolito[8], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Disease Research Centre, Ndola, Zambia, [3]U.S. President's Malaria Initiative (PMI), U.S. Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, [4]VectorLink, Lusaka, Zambia, [5]Ministry of Health, District Health Office, Nchelenge, Zambia, [6]National Malaria Elimination Center, Lusaka, Zambia, [7]U.S. President's Malaria Initiative (PMI), U.S. Centers for Disease Control and Prevention (CDC), Lusaka, Zambia, [8]Johns Hopkins School of Medicine, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Nchelenge District in northern Zambia experiences holoendemic, perennial malaria transmission. Pre-rainy season indoor residual spraying (IRS) has been deployed annually since 2008 with distribution of insecticide-treated nets, yet Plasmodium falciparum prevalence by microscopy remains above 30%. Anopheles funestus is the most abundant vector and peaks in the dry season (May-July). We conducted a pilot trial to assess the effect of adding IRS at the end of the rainy season to the current IRS program on parasite prevalence. Four clusters of households were selected and two were sprayed with clothianidin pre- and post-rainy season; the remaining two clusters were sprayed only pre-rainy season. A total of 401 residents among 65 households were surveyed monthly from March to September. The primary outcome, measured monthly, was the presence of a parasite-positive episode by microscopy. Multilevel logistic regression with adjustment for socio-demographic and geographic variables found no significant difference in the odds of a microscopy positive episode comparing sprayed and unsprayed clusters pre- and post-rainy season spray (adjusted ROR 0.11, 95% CI: 0.01-1.19, p = 0.07). This same model found no significant difference in odds comparing pre- and post-spray at the end of the rainy season (adjusted OR 5.5, 95% CI: 0.57-52.6, p = 0.14). A time to infection analysis using a log-rank test and a Nelson-Aalen Cox proportional hazards model with baseline risk stratification found a statistically significant difference in hazards of a microscopy positive event across the sprayed and unsprayed clusters (log-rank test p<1x10-5). While the second round of IRS reduced hazard rates, we did not find a measurable impact on overall parasite prevalence. Given the limitations of this analysis and the p-value associated with relative odds of parasite prevalence comparing sprayed and unsprayed clusters pre- and post-spray (p=0.07), further investigation is warranted. Disclaimer: The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the U.S. Centers for Disease Control and Prevention.

6190

FREE-LISTING OF MOSQUITO CONTROL STRATEGIES IN BUSIA COUNTY, WESTERN KENYA

Moureen Ekisa[1], Prisca A. Oria[1], Julius I. Odero[1], Sheila Ekodir[1], Jane Klein A. Ikapesi[1], April Monroe[2], Eric Ochomo[1], Steven A. Harvey[3]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Additional mosquito vector control interventions are needed, and their potential effectiveness will be improved if user perceptions and practices regarding existing strategies are integrated into their design. To complement a trial of the efficacy of a spatial repellent for malaria control, listing of existing mosquito control products and behaviours was included. The free-lists allowed inferences to be made about the cultural salience of the strategies in the participants' mosquito control domain. Listed products and behaviours will be ranked to help the project understand perceptions of existing mosquito prevention measures. The data obtained will inform the potential and strategies for introducing the spatial repellent at scale. Using a free-listing approach, 61 participants were asked to name all the mosquito control strategies they know. The individual lists were entered into Excel to generate frequencies for each mentioned product. The generated list will be a basis for further inquiry about the items such as when, where, why, how, and by whom these items are used in a ranking exercise. In all, 317 products/behaviours were coded into 47 categories. Participants often mentioned insecticide treated bed nets, mosquito coils, draining stagnant water, creating smoke, and clearing the compound. Other less commonly mentioned mosquito control strategies included spraying insecticide and closing doors/windows early, applying mosquito repellent, and clearing the compound of garbage. The most frequently mentioned strategies were eleven, each mentioned by more than 10% of the sample. Because the spatial repellent is a supplementary tool to existing mosquito control strategies, its introduction must be carried out in a way that optimizes the use of the recommended strategies. The data gathered from the free-listing shows the more widely used strategies and ranking will provide specific insights on characteristics that make those strategies popular. This information will be considered for designing and large-scale distribution of the spatial repellent.

6191

FEASIBILITY AND ACCEPTABILITY OF GROUP ANTENATAL CARE FOR MATERNAL HEALTH CARE PROVIDERS AND SUPERVISORS IN RURAL HEALTH CENTERS IN BENIN

Group antenatal care (GANC) is a model in which prenatal counseling and services are delivered monthly to groups of 8-15 pregnant women of the same gestational age starting in second trimester. This allows women to learn while building supportive social networks. GANC can increase uptake of key pregnancy interventions. We examined factors affecting the feasibility and acceptability of GANC for providers and their supervisors in rural Benin, in the context of a study assessing the effect of implementing GANC on uptake of antenatal care under routine programmatic conditions. Six health zone officials and 2-3 ANC providers (midwives, health aides) in each of 20 facilities with ~20-130 new ANC clients/month were trained on

GANC in 2021. Nine months after implementation began, semi-structured interviews (45-90 minutes long) were conducted with purposively selected supervisory health staff (7) and GANC providers (14) from 6 health centers selected to represent both low and high performing facilities with regard to GANC implementation. Data were analyzed through qualitative framework analysis. All participants expressed support for continued implementation and eventual scale-up of GANC. Providers appreciated the opportunity to build closer relationships with patients. They found GANC implementation challenging, particularly scheduling and reminding pregnant women about meetings, starting meetings on time, and accommodating late arrivals. Staffing shortages resulted in GANC meetings being disrupted so facilitators could attend to labor and delivery activities. Supervisors contended that additional supervisory personnel were required to support implementation, especially where there were shortages of qualified providers. Some facilities might need changes to physical layout, to make space for meetings. Providers appreciated the GANC model. Having an adequate number of providers is critical to implementation. Feasibility depends on identifying efficient GANC reminder systems, shortening meetings, and ensuring adequate personnel to support both meeting facilitation and care for emergencies and labor and delivery.

6192

INFLUENCE OF SEASONAL MALARIA CHEMOPREVENTION ON THE PREVALENCE OF MALARIA INFECTION, PLASMODIUM FALCIPARUM GENETIC DIVERSITY AND RESISTANCE PROFILE IN CHILDREN LIVING IN RURAL AREAS OF BURKINA FASO

Séni Nikiema[1], Issiaka Soulama[2], Salif Sombie[3], Samuel Sindie Serme[4], Noëlie Béré Henry[4], Florencia Wendkuuni Djigma[1], Alfred B Tiono[5], Sodiomon B Sirima[4], Jacques Simpore[1]

[1]université Joseph Ki-Zerbo,, Ouagadougou, Burkina Faso, [2]biomedical And Public Health Department, Institut De Recherche En Sciences De La Santé (Irss)/Centre National De Recherche Scientifiques Et Technologiques (Cnrst),, Ouagadougou, Burkina Faso, [3]research Department, Centre National De Recherche Et De Formation Sur Le Paludisme (Cnrfp)/Institut National De Santé Publique (Insp), Ouagadougou, Burkina Faso, [4]direction Scientifique, Groupe De Recherche Action En Santé, Ouagadougou, Burkina Faso, Ouagadougou, Burkina Faso, [5]research Department, Centre National De Recherche Et De Formation Sur Le Paludisme (Cnrfp)/Institut National De Santé Publique (Insp),, Ouagadougou, Burkina Faso

Seasonal Malaria Chemoprevention (SMC) is recommended since 2013 by WHO for the preventive treatment of malaria with sulfadoxine pyrimethamine (SP) plus amodiaquine (AQ) during periods of high or moderate transmission in endemic areas. Chemoresistance and genetic diversity of the parasite are among the major challenges in malaria control. The aim of this study was to assess the impact of SMC on the prevalence of malaria infection, Plasmodium genetic diversity and the prevalence of P. falciparum resistance molecular markers in rural children in Burkina Faso. The study consisted of 222 children participating in the SMC in the Saponé health district. Blood samples were taken for thick drop for microscopic diagnosis and blood spots for molecular analysis at Centre National de Recherche et de Formation sur le Paludisme molecular laboratory. Parasite DNA was extracted using Qiagen kits, the prevalence of malaria infection and genetic diversity were determined by nested PCR while molecular resistance markers were analysed by PCR/RFLP. The prevalence of malaria infection determined by PCR during SMC was 19.7%. The study of genetic diversity revealed a high polymorphism of the parasite during SMC. The prevalence of mutations associated with resistance to SP+AQ was very low in our study. However, the Pfdhfr59 mutation was very high in the study and averaged 92.31% respectively. These results showed a reduction in the mutation prevalence of Pfcrt genes associated with antimalarial drug resistance in Burkina Faso after the implementation of SMC. In addition, SMC contributes to the reduction of the prevalence of malaria infection, affects the genetic diversity of P. falciparum and the distribution of molecular markers of antimalarial drug resistance.

6193

ASSESSING THE IMPACT OF GROUP ANTENATAL CARE ON INTERMITTENT PREVENTATIVE TREATMENT IN PREGNANCY (IPTP3) UPTAKE IN ATLANTIQUE DEPARTMENT, BENIN: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Aurore Ogouyèmi-Hounto[1], Manzidatou Alao[2], Marie Adeyemi Idohou[2], Alexandre Binanzon[2], Faustin Onikpo[2], Julie Niemczura[3], Catherine Dentinger[4], Ahmed Saadani Hassani[5], Katherine Wolf[6], Stephanie Suhowatsky[6], Julie G. Buekens[3], Blaise Guezo Mevo[7], Cyriaque D. Affoukou[7], Camille Houetohossou[8], Julie R. Gutman[4]

[1]Unité de Parasitologie/Faculté des Sciences de la Santé /Université d'Abomey Calavi, Cotonou, Benin, [2]U.S. President's Malaria Initiative Impact Malaria project, MCD, Cotonou, Benin, [3]U.S. President's Malaria Initiative Impact Malaria project, MCD, Silver spring, MD, United States, [4]U.S. President's Malaria Initiative, Malaria Branch, CDC, Atlanta, GA, United States, [5]U.S. President's Malaria Initiative, CDC, Cotonou, Benin, [6]U.S. President's Malaria Initiative Impact Malaria project, Jhpiego, Baltimore, MD, United States, [7]Ministry of Health, Cotonou, Cotonou, Benin, [8]Ministry of Health, Cotonou, Benin

In 2020, an estimated 33.8 million pregnancies occurred in malaria endemic areas of sub-Saharan Africa. WHO recommends HIV-negative pregnant women in malaria endemic areas receive at least 3 doses of intermittent preventative treatment in pregnancy (IPTp3). However, coverage remains low at 32%. Group Antenatal Care (GANC) is a service delivery model in which 8-15 women are assigned to a group at their first ANC visit, and subsequent care is provided in the group setting. GANC has been associated with higher quality and greater retention in ANC care. We conducted a cluster-randomized controlled trial in Atlantique Department, Benin, to assess whether GANC improved retention in ANC and uptake of IPTp3. Forty purposively selected health facilities (HF) were randomized 1:1 to control or GANC. Cross sectional household surveys were conducted before and after implementation, among randomly selected women who had given birth in the previous 12 months from each HF catchment, to measure uptake of ANC and IPTp. Changes in coverage were assessed using a difference in difference approach, adjusting for HF clustering. At baseline (N=1259), coverage of at least 4 ANC visits (ANC4) and IPTp3 was 52.8% and 48.0%, respectively, in the intervention arm catchment areas and 44.9% and 49.4% in the control catchment areas. At endline (N= 1280), coverage of ANC4 improved in both arms, to 56.7% in the intervention and 46.1% in the control. Accounting for baseline differences, the increase in the intervention arm was not significant (p = 0.51). Coverage of IPTp3 also increased, to 53.2% (intervention) and 49.7% (control) but was not significant (p=0.26). Only 140 women reported participating in GANC- 99 (15.6%) from intervention and 41 (6.5%) from control arm. Participation in GANC improved coverage of both ANC4 (65.0% vs 50.5%, p=0.002; Odds ratio (OR) 1.9, 95%CI 1.4-2.5) and IPTp3 (64.0 vs 50.6%, p=0.004; OR = 1.8, 95%CI 1.2-2.6). Among women who participated, GANC improved retention in ANC and IPTp3 uptake, but participation was limited. Understanding and addressing the barriers to participation will be critical if GANC is to be used more widely to improve IPTp coverage.

6194

COMPARING THE DURABILITY OF SYNERGIST LONG-LASTING INSECTICIDAL NETS PERMANET®3.0 AND CONVENTIONAL NETS YORKOOL© IN SOUTHEAST BENIN REPUBLIC AFTER NATIONAL MASS CAMPAIGN IN 2020

Idelphonse Bonaventure Ahogni[1], Germain G. Padonou[2], Virgile Gnanguenon[3], Martin C. Akogbeto[2]

[1]CREC/LSHTM Collaborative Research Programme, Cotonou, Benin, [2]Centre de Recherche Entomologique de Cotonou (CREC), Cotonou, Benin, [3]US President's Malaria Initiative (PMI), US Agency for International Development (USAID), Cotonou, Benin, Cotonou, Benin

Long-lasting insecticidal nets (LLINs) based on pyrethroids have been important in significantly reducing malaria cases in Africa, but insecticide resistance in Anopheles mosquitoes threatens their impact. The synergists

could help control insecticide-resistant populations. The LLIN PermeNet 3.0 (pyrethroid-piperonyl butoxide (PBO)) is an example. However, the longevity of PBO nets in Benin is not well known. To provide the National Malaria Control Program with evidence of physical and insecticidal durability, two of the LLIN brands deployed in similar districts, Massè (PermaNet®3.0), Adja-Ouèrè (Yorkool®) and Adingnigon (PermaNet®3.0) in the southeast during the 2020 mass campaign were evaluated. This is a prospective cohort study enrolling a representative sample of households six months after distribution. Over a 21-month period, all nets from the campaign in these households were marked and monitored. The primary outcomes were the "proportion of nets in good condition" based on measures of integrity and attrition in years. Insecticide results were determined by bioassay using the WHO cone test. A total of 1559 campaign nets (109% of target) from 546 households were included in the study. Final results could be determined for 70% of the nets in the cohort in Massè, 54% in Adja-Ouèrè and 74% in Adingnigon. After 21 months, all-cause attrition was 31% in Massè, 13% in Adja-Ouèrè and 37% in Adingnigon (p=0.199) and attrition due to wear and tear was 2% in Massè, 5% in Adja-Ouèrè and Adingnigon (p≥0.05). Survival in use at the last survey was 39% in Massè, 53% in Adja-Ouèrè and 45% in Adingnigon (p≥0.05). The multivariate Cox proportional hazards models suggest that the difference between sites was not primarily attributable to LLIN brand. Insecticidal efficacy was optimal for 100% of PermaNet®3.0 tested compared to 67% for Yorkool© after 21 months. In the southeast Benin environment, the PermaNet®3.0 polyester LLIN performed significantly better than the Yorkool LLIN, but both were below a three-year survival rate. Improved net usage behavior should lead to increased physical durability.

6195

PERENNIAL MALARIA CHEMOPREVENTION (PMC) INTEGRATION INTO MOZAMBIQUE'S ROUTINE HEALTH SYSTEM: A PLUS PROJECT CASE STUDY

Baltazar Candrinho[1], Elsa Nhantumbo[2], Sergio Gomane[2], Marcos Chissano[2], Albertina Chihale[1], Sónia Mudengue[3], Sadate Soumahoro[2], Marguerite M. Clougherty[4], Malia Skjefte[4], Meredith Center[4]

[1]Ministry of Health Mozambique, Maputo, Mozambique, [2]Population Services International Mozambique, Maputo, Mozambique, [3]Provincial Health Directorate of Sofala/ Malaria Control Program, Mozambique, Sofala, Mozambique, [4]Population Services International, Washington, DC, United States

Malaria is endemic in Mozambique, accounting for 42.9% of cases among children under five in 2021. To develop a perennial malaria chemoprevention (PMC) model for Mozambique and discuss how PMC could be integrated into Mozambique's routine HMIS, the NMCP led a cascade of multi-day co-design meetings with participation from stakeholders and representatives from various health programs. In November 2022, Mozambique's Ministry of Health (MoH) adopted an overarching malaria chemoprevention strategy, which included PMC. In parallel with the design of a Mozambique-specific model of PMC resulting from the June workshop, additional work was required to fully integrate PMC into Mozambique's routine health system, which included updating paper-based data collection tools and the online HMIS database. A week-long workshop was held in September 2022 to adapt the existing healthy child consultation (HCC) data collection and reporting tools to include PMC data elements. The workshop was also spent discussing monitoring and evaluation plans, such as deciding on key performance indicators (% of sulfadoxine-pyrimethamine (SP) doses administered to target population, % of target population receiving one or more SP doses, % of PMC health facilities reporting no stockout of SP, and number of adverse events notified). Additional technical questions must still be resolved before PMC is fully integrated into the reporting system, such as the time it takes to fill SP information in the new register book column and plans for production of updated HCC register books. Integrating PMC reporting alongside routine health reporting is a vital step to ensuring timely data collection, accurate documentation, and comparable data sharing for this newly approved malaria chemoprevention policy. Results from this case study can be used by other provinces in Mozambique and other countries implementing PMC to ensure compatible data collection and sharing processes.

6196

EXPLORING NET USAGE, PREFERENCES, AND REPAIR HABITS: A QUALITATIVE STUDY ON MALARIA PREVENTION STRATEGIES IN KONONGO, GHANA

Michael Li, Benjamin Voller-Brown

Arizona State University, Tempe, AZ, United States

Understanding insecticide-treated net (ITN) usage and net care and repair (NC&R) are vital for enhancing prevention strategies. There is currently a lack of research on current net usage and NC&R inhibitors, especially among non-net users. This study explored factors affecting ITN usage, preferences, and repair behaviors in Konongo, Ghana. By understanding NC&R habits, overall net retention methods can be improved We conducted 60 in-depth interviews with maximum variation purposive sampling. Participants consisted of 30% non-net users and 70% net users. Interviews covered net usage habits/preferences, NC&R habits/messaging, net damage, and malaria incidence, then qualitatively analyzed using MaxQDA. Average net age and household net count indicated nets were not lasting long and were below the recommended amount. Experiences with net damages were common, with few users attempting repairs. Quantitatively, 40% of net-using households reported net repair inhibitors such as lacking materials or knowledge on how to repair, or exposure to repair messaging. Furthermore, only 13% of families have been exposed to any form of repair messaging. Because of this, the majority of participants expressed a desire for a net repair kit, highlighting a potentially unmet need. A preference for polyester over polyethylene nets suggests comfort and usability impact usage. Non-users cited net damage, heat, and irritation as reasons, revealing areas for improvement in net design, distribution, and education.: In conclusion, To increase net use, it is crucial to address net use, repair, and maintenance inhibitors, and their concerns about heat and irritation. Understanding these factors can also guide targeted interventions and behavior change communication strategies, ultimately increasing overall net retention. Further research is necessary to explore the potential benefits of integrating the provision of materials and education on net repair into standard net distribution programs.

6197

EMPOWERING COMMUNITY LEADERS TO INFLUENCE ACTIONS AGAINST MALARIA AT HOUSEHOLD LEVEL. LESSONS FROM MOYO DISTRICT, WEST NILE REGION, UGANDA

Felix Manano[1], Allan Matovu[2], Alex Ojaku[3], Robert Abiriga[1], Irene Ochola[1], Dorah Anita Talanta[1], Ambrose Okite[4], Amy Casella[5], Aliza Hasham[6], Benjamin Binagwa[1], Natalia Whitley[5]

[1]John Snow Inc, Kampala, Uganda, [2]Program for Accessible Health Communication and Education, Kampala, Uganda, [3]MCD Global Health, Kampala, Uganda, [4]Another Option LLC, Kampala, Uganda, [5]John Snow Inc, Boston, VA, United States, [6]John Snow Inc, Dar es Salam, Tanzania, United Republic of

Over 90% of Uganda's population is at risk of contracting malaria. The West Nile Region, with an estimated population of 3,404,800 has one of the highest malaria prevalence rates in Uganda at 22% as reported in the Malaria Indicator Survey 2019. Moyo District hosts approximately 23,000 registered refugees, and an unknown number of self-settled refugees, mainly from neighboring South Sudan and Democratic Republic of Congo, posing unique vulnerability to malaria and other diseases. Improving risk perception, building structures, and implementing targeted malaria prevention interventions to empower communities to own the response process requires intense leadership engagement at the grassroots. The USAID PMI Uganda Malaria Reduction Activity (MRA), implemented by JSI, identified high burden villages using HMIS data. Malaria interventions were implemented in 318 households in Lefori and Laropi sub counties in Moyo District. Community leaders were empowered to improve malaria prevention

at household level. Monthly data review meetings were held at the village level led by the community leaders to track progress in malaria response activities. Household malaria response plans were developed, awareness and knowledge on malaria prevention improved. A total of 214 households were followed up ; 85% of the household had children under five sleep under mosquito nets, 80% of the households had pregnant women who attended antenatal care. Data enabled stakeholders to harmonize interventions and implementation approaches, contributing to more effective resource allocation. Community leaders addressed negative myths and misconceptions and social norms that limited community access to correct malaria information and health services. Involvement of leaders, community and health service providers formed an important structure for a supportive environment for households most affected by malaria.

6198

"AFTER A LONG DAY OF PLAY, I GET TIRED AND FOR GET TO UNFURL MY BEDNET": EXPLORING BARRIERS AND FACILITATORS OF BEDNET USE IN EASTERN UGANDA

Deborah Ekusai-Sebatta[1], Sarah M. Alexander[2], John C. Rek[1], Moses Kamya[1], Grant Dorsey[3], Paul Krezanoski[3]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Children's National Hospital, Washington, DC, United States, [3]University of California San Francisco, San Francisco, CA, United States

Insecticide-treated bednets are the most common form of malaria prevention throughout the world and understanding the factors that affect their use is critical. Self-reported use may not accurately measure actual practice due to social desirability bias and temporal variations in use. Electronic bednet monitors can provide more precise measures of use. Households in Tororo and Busia districts who were enrolled in an ongoing study with electronic bednet monitors underwent in-depth interviews about bednet use. Household members aged 8 and older were eligible. A survey guide was developed using an Information-Motivation-Behavioral (IMB) framework. A simplified guide was used for children under age 15. Thematic analysis was done using the IMB framework to categorize the data according to barriers and facilitators of use. Fourteen participants from 4 households were interviewed, including 7 adults (mean age: 42 years) and 7 children (mean age: 11 years; range 8 to 17). Ten of 14 participants (64.3%) were female. Facilitators of bednet use included knowledge of bednets as a low cost way to prevent malaria, more rooms in a house and more stable sleeping arrangements. The presence of the electronic monitoring devices was noted to promote bednet use, as were habits such as unfurling the bednet before bed time. Age was a moderating factor, with older people more likely to use bednets compared to the younger children. Barriers to use of bednets included ignorance about the cost of treatment, excessive heat and tiredness after a long day of play for the children. Children depended on parents for bednet use, leading to non-adherence when parents were unavailable. In this qualitative study of individuals undergoing observation with electronic monitoring of their bednet use, multiple factors were identified with heterogeneity between age groups that may present targets for improving bednet use in this population at risk of malaria.

6199

PREDICTORS OF ACCESS TO SEASONAL MALARIA CHEMOPREVENTION MEDICINES OUTSIDE HOUSEHOLD VISITS IN NIGERIA IN 2021

Sikai Huang[1], Sol Richardson[1], Taiwo Ibinaiye[2], Olusola Oresanya[2], Chuks Nnaji[3], Kevin Baker[3]

[1]Vanke School of Public Health, Tsinghua University, Beijing, China, [2]Malaria Consortium Nigeria, Abuja, Nigeria, [3]Malaria Consortium UK, London, United Kingdom

In Nigeria, Seasonal Malaria Chemoprevention (SMC) medicines are typically delivered to children under five door-to-door through household visits by SMC community distributors during the high transmission season. Despite this recommended approach, some households access SMC through other means, including fixed point distributions, health facilities and private purchase. However, until now, analysis of access to SMC outside household visits has been limited. Our study aimed to identify household characteristics associated with access to SMC outside household visits. We analysed data from Malaria Consortium's 2021 Nigeria SMC end-of-round coverage survey, covering seven states. We described sources of SMC medicines using weighted percentages and performed univariate and multivariate logistic regression analyses to identify predictors of access to SMC outside household visits. We estimated adjusted odds ratios (AOR) with 95% confidence intervals (95% CIs). Of the 9,491 caregivers of eligible children included in our analysis, 96.32% received SMC, of which 1.36% accessed SMC outside household visits. The three most common alternative sources of SMC medicines were health facility personnel (36.29%), informal distribution in public by SMC distributors (25.81%), and family or friends (16.94%). Univariate model results showed that caregivers with higher educational attainment, being non-partnered, having less SMC-related knowledge, and not using indoor residual spray or mosquito nets were more likely to access SMC outside household visits. In the multivariate analysis with mutual covariate adjustment, we found higher levels of caregiver educational attainment are a positive predictor of accessing SMC outside household visits (AOR 2.30, 95% CI: 1.08–4.89 for post-secondary vs. none/informal) and having a household head born in the local state (AOR 0.46, 95% CI: 0.24–0.86) was a negative predictor. This analysis will be expanded to identify predictors of access to SMC via specific sources, and to explore the potential impacts of different SMC sources on caregiver SMC knowledge and adherence to the full course of SMC medicines.

6200

THE ROLE OF COMMUNITY DRUG DISTRIBUTORS IN THE QUALITY OF SEASONAL MALARIA CHEMOPREVENTION DELIVERY IN NIGERIA

Olabisi A. Ogunmola[1], Taiwo Ibinaiye[1], Adaeze Aidenagbon[1], Chibuzo Oguoma[1], Olusola Oresanya[1], Christian Rassi[2]

[1]Malaria Consortium, FCT, Nigeria, [2]Malaria Consortium, London, United Kingdom

Seasonal malaria chemoprevention entails the door-to-door distribution of four or five monthly cycles of sulfadoxine-pyrimethamine and amodiaquine (SPAQ) to children 3 - 59 months as a malaria prevention strategy delivered by community drug distributors (CDD). CDDs are responsible for ensuring the first dose of SPAQ is given as a Directly Observed Treatment (DOT) informing the caregiver how to administer subsequent doses of amodiaquine (AQ) of days 2 and 3 and what to do in the event of any adverse reaction. Adherence to the three-day complete course of SPAQ is a measure of quality of implementation and is critical to the impact of the intervention in reducing malaria morbidity and deaths in children. We analyzed reported CDDs compliance with protocol against caregivers' adherence to subsequent SMC doses. Data were collected from 11,188 primary caregivers of eligible children randomly sampled from nine SMC-implementing states in Nigeria during the 2022 end-of-round household survey. Of the 94.8% (10,606) caregivers visited by CDDs, 89.0% (9957) reported CDDs' directly observed them giving the children SPAQ on day 1, 82.1% (9185) of caregivers received information on how to administer days 2 and 3 doses of AQ and 81.1% (9073) on what to do in the event of adverse drug reaction. When CDD-related factors predicting adherence to days 2 and 3 AQ doses among caregivers were analyzed, after controlling for other confounders such as caregiver's background demographics and female peer influencers' visit, caregivers whose SPAQ administration on day 1 was supervised by CDDs were almost 3 times more likely to adhere (aOR = 2.75, 95% CI = 1.69 -4.47 p<0.001), there was no association between those who received information on what to do in the event of adverse drug reactions (aOR = 0.950, 95% CI = 0.53 -1.69 p=0.86) or those who were informed on how to administer Days 2 and 3 doses (aOR=0.89, 95% CI=0.54 - 2.39 p=0.72). The study underscores the importance of CDDs observance of directly observed treatment in caregivers' adherence and highlights the need for further studies on the content and delivery of key messages to caregivers to determine its effectiveness and benefits.

6201

PERCEIVED FACTORS IMPACTING COMMUNITY HEALTH WORKERS' CAPACITY TO IMPLEMENT SEASONAL MALARIA CHEMOPREVENTION ACROSS DELIVERY SETTINGS: QUALITATIVE SECONDARY ANALYSIS FROM RECENT STUDIES IN MOZAMBIQUE, NIGERIA, SOUTH SUDAN AND UGANDA

Erica Viganò[1], Maria Suau Sans[1], Ekechi Okereke[2], Helen Smith[3], Ivan A. Pulido Tarquino[4], Mercia Sitoe[5], Francis Okot[6], Maureen Nakirunda[7], Jennifer Ainsworth[1], Jamshed Khan[8], Anthony Nuwa[9], Sonia M. Enosse[4], Olusola Oresanya[2], Kevin Baker[1]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Abuja, Nigeria, [3]International Health Consulting Services Ltd, Wirral, United Kingdom, [4]Malaria Consortium, Maputo, Mozambique, [5]Malaria Consortium, Nampula, Mozambique, [6]Malaria Consortium, Aweil, South Sudan, [7]Malaria Consortium, Moroto, Uganda, [8]Malaria Consortium, Juba, South Sudan, [9]Malaria Consortium, Kampala, Uganda

Seasonal malaria chemoprevention (SMC) is the intermittent administration of antimalarials to children from age groups at risk of severe infection in areas of seasonal transmission. Since 2012, Malaria Consortium has been implementing SMC at scale in the Sahel region of Africa as recommended by the World Health Organization (WHO). More recently, SMC implementation has been expanded to new geographies, including countries in East and Southern Africa. During the SMC round, corresponding to the peak transmission period, monthly courses of antimalarials are administered to age-eligible children. Community health workers (CHWs) play a role in SMC campaigns across implementing countries, either as community distributors, in the case of Boma Health Workers (BHWs) in South Sudan and Village Health Teams (VHTs) in Uganda, as community-based support to caregivers, in the case of lead mothers (LMs) in Nigeria, or in other key intermediary roles such as Agentes Polivalentes Elementares (APEs) in Mozambique. Previous studies have looked at the role of CHWs in SMC, however, questions around what factors impact CHWs' capacity to implement SMC across different delivery settings have remained relatively unaddressed. Aiming to bridge this gap, we conducted secondary analysis of recent (2021/2022) qualitative SMC studies in Mozambique, Nigeria, South Sudan and Uganda, comprising of focus group discussion (FGDs) and key informant interviews (KIIs) with stakeholders at various levels of the health system, including CHWs. Thematic analysis is ongoing and preliminary results point to some factors affecting CHWs' capacity to implement SMC across countries: CHWs' proximity to, and rapport with community members and/or caregivers; feasibility of, and synergies between multiple tasks performed by CHWs; level of motivation; areas to cover and number of CHWs; remuneration and allowances; selection criteria. Complete results from this secondary thematic analysis will be presented, focusing on identifiable commonalities and points of differences across delivery settings, to support the development of improved engagement strategies at community level.

6202

POPULATION DIFFERENCES IN VACCINE RESPONSE: THE ROLE, REVERSIBILITY AND MEDIATORS OF IMMUNOMODULATION BY CHRONIC INFECTIONS IN THE TROPICS PROTOCOL B: THE EFFECT OF INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA WITH DIHYDROARTEMISININ-PIPERAQUINE ON RESPONSE TO VACCINES AMONG RURAL ADOLESCENTS

Ludoviko Zirimenya[1], Gyaviira Nkurunungi[1], Agnes Natukunda[1], Jacent Nassuuna[1], Emily Webb[2], Alison Elliott[1]

[1]MRC/UVRI & LSHTM Uganda Research Unit, Entebbe, Uganda, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Vaccines are key tools for infectious disease control, but several important vaccines differ in immune responses induced, and in efficacy between populations. We hypothesized that malaria infection suppresses responses to unrelated vaccines and that this effect can be reversed, at least in part, by monthly intermittent preventive treatment (IPT) of malaria in high-transmission settings. A randomized, double-blind, placebo-controlled trial was conducted to assess the effect of monthly intermittent preventive treatment of malaria with Dihydroartemisinin-Piperaquine (DP) on vaccine responses. Adolescents 9 to 17 years were recruited from primary schools in Jinja district, Uganda, where malaria is highly endemic, and randomized to monthly DP versus placebo. The DP/placebo was administered monthly, including twice prior to the first immunization. Participants received a standard portfolio of BCG, Yellow Fever (YF-12D), oral typhoid (Ty21a), HPV, and tetanus/diphtheria (Td) vaccines. There were three main immunization days (week 0 (BCG), week 4 (YF - 12D, Ty21a, and HPV), and week 28 (Td)). Primary outcomes were BCG-specific interferon-gamma ELISpot response at 8 weeks post-immunization, vaccine-specific IgG responses to YF - 17D, Ty21a, HPV at four weeks, and Td at 24 weeks post-immunization. The trial was conducted from May 2021 to August 2022. 341 participants were enrolled, 170 in the DP arm and 171 Placebo arm. 145 (85.3%) participants in the DP arm and 140 (81.9%) in the placebo arm were followed up to week 52. At enrolment, 60% of participants had malaria on PCR, this reduced to <5% among participants in the DP arm. The geometric mean ratio of BCG-specific interferon-gamma response at week 8 was 1.19 (95% CI 0.99-1.42) P = 0.064. There was no effect of DP versus placebo on IgG responses to TT (geometric mean ratio (95% CI) 1.12 (0.84-1.48), p=0.44), DT 0.97 (0.83-1.12), p=0.66), Ty21 (1.037 (0.82-1.32), p=0.76). Outcomes for YF-17D and HPV are being processed. IPT significantly reduced malaria in the DP arm. With exception of BCG, IPT did not affect immune responses to Td and Oral typhoid vaccines.

6203

COMMUNITY PERCEPTIONS ON FEASIBILITY AND ACCEPTABILITY OF SEASONAL MALARIA CHEMOPREVENTION IN AWEIL SOUTH COUNTY NORTHERN BAHR EL GHAZAL STATE SOUTH SUDAN

Francis Okot[1], Jamshed Khan[1], Abubaker R. Deng[1], Denis Mubiru[1], Maria Suau Sans[2], Erica Vigano[2], Christian Rassi[2], Kevin Baker[2]

[1]Malaria Consortium, Juba, South Sudan, [2]Malaria Consortium, London, United Kingdom

Seasonal malaria chemoprevention (SMC) is an effective intervention to prevent malaria infection in children. SMC was implemented in Aweil South County in South Sudan targeting 17,000 children aged 3-59 months. With boma health workers (BHWs) already active in the area, acting as community distributors, children received courses of sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) in five monthly cycles from July to November 2022. A qualitative study to assess the feasibility and acceptability of SMC was conducted at the end of SMC campaign round. We held key informant interviews with national ministry of health officials (3), gender experts (2), community leaders (4), health facilities in-charges (4) and state ministry of health officials (4). We also conducted focus group discussions with caregivers of SMC age-eligible children (6) and BHWs (4). Thematic analysis using an inductive approach was conducted. Most respondents perceived positive impacts of SMC through reduction of malaria cases in children aged 3-59 months. Many reported that acceptance increased over time due to the perceived effectiveness of SMC and use community distributors from the same community. Majority of the key stakeholders cited proper sensitization of caregivers, commitment of the service providers, proper planning, timely logistics supplies, community engagement through sensitization meetings, adequate number of boma health workers to cover vast geographical distances between households, and proper training of boma health workers as key determinants for successful implementation of SMC. Some respondents reported need for gender inclusiveness in household's healthcare seeking behaviors, quoting women as chief decision makers for children healthcare unlike men for non-health related issues in a household. While most stakeholders spoke of the successful implementation of SMC, some implementation challenges were outlined, including the effects of floodings in the area and long distances between households. Many of the respondents asked for SMC to be extended and scaled up to additional areas.

6204

ASSESSING THE IMPACT OF EXTENDING SEASONAL MALARIA CHEMOPREVENTION TO FIVE CYCLES: FINDINGS FROM AN ANALYSIS OF ROUTINE DATA OF 19 DISTRICTS IN BURKINA FASO (2015-2021)

Chukwudi A. Nnaji[1], Benoit Sawadogo[2], Sidzabda Kompaore[3], Monica A. de Cola[1], Cheick Compaore[2], Christian Rassi[1]

[1]Malaria Consortium UK, London, United Kingdom, [2]Malaria Consortium Burkina Faso, Ouagadougou, Burkina Faso, [3]Permanent Secretary, Malaria Elimination Department, Ministry of Health, Burkina Faso, Ouagadougou, Burkina Faso

Seasonal malaria chemoprevention (SMC) typically involves administering antimalarial medicines to eligible children over four monthly cycles, coinciding with the rainy season and period of high malaria transmission. In 2021, five monthly SMC cycles were introduced in some areas with longer high transmission seasons, including 19 of the SMC-eligible districts in Burkina Faso. There is not yet any evidence on impact of the additional cycle under programmatic conditions since 2021. We compared trends and estimates of key malaria outcomes between periods of four and five SMC cycles using routine health facility data (2015 to 2021) of 19 districts that transitioned from four to five SMC cycles in Burkina Faso. Newey-West interrupted time-series analysis (ITSA) was used to explore district-level monthly trends in malaria incidence and deaths from the period of four SMC cycles to that of five cycles. Negative binomial regression models were fitted to compare estimates of mean malaria incidence and deaths between four-cycle and five-cycle years. The models generated estimates of the impact of five SMC cycles relative to four cycles, in terms of incidence rate ratios (IRRs) and their corresponding 95% CIs, while controlling for district-level, time-varying factors such as population growth, health-seeking behaviour, health system capacity and seasonal trends in the outcomes of interest. ITSA trends showed a decline in the peak incidence of RDT-confirmed malaria cases in 2021 following the introduction of the fifth cycle. Compared with the four-cycle years, incidence of RDT-confirmed malaria was 10% lower in the five-cycle years, IRR 0.90 (95% CI: 0.84 - 0.97, p= 0.004). A more substantial decline in malaria-related deaths was observed in the five-cycle years relative to the four-cycle years, IRR 0.06 (95% CI: 0.04 - 0.08, p=0.001). The study provides early evidence on the additional impact of introducing the fifth SMC cycle in areas with longer high transmission seasons. Further research with more robust data over a longer period is needed for a better understanding of impact.

6205

EVALUATION OF THE LEVEL OF SATISFACTION OF AN INTEGRATED MALARIA INFORMATION SYSTEM USERS IN MOZAMBIQUE

Neide Canana[1], Arsenio Sergio[1], Edson Zandamela[1], Antonio Bulo[1], Sonia Maria Enosse[1], Baltazar Candrinho[1], Maria Rodrigues[1], Ruth Kigozi[2]

[1]Malaria Consortium, Maputo, Mozambique, [2]Malaria Consortium, Kampala, Uganda

In 2019, the Mozambique National Malaria Control Program (NMCP) developed and has been implementing an Integrated Malaria Information System (SIIM/iMISS) that enables all NMCP staff to monitor key indicators, assess the impact of interventions and provide evidence for decision making. The study evaluated the level of satisfaction of the SIIM/iMISS among users at provincial, district and health facilities level. A cross-sectional study with data collected using a self-administered online Google survey with the link sent to all 645 active and inactive users. Data collected included access; ease of navigation; impact in improving quality malaria data reporting timeless, completeness and accuracy and usefulness in decision making. The study explored satisfaction of the platform among users and associated factors. Descriptive statistics were used to summarize results and logistic regression was used to examine factors influencing satisfaction. 415(64.3%) users completed the online survey. Majority of respondents (63%) were from the district level. 92.5% are active users. Among active users, 19% were data entrants and over 81% had access to all visualizations and automated analyses (data users). Most user; data entrants (92%) and data users (88.9%) reported SIIM/iMISS to be easy to use and simple to operate. 74.5% of the active users agreed that the use of the SIIM/iMISS has had an impact on the quality of malaria data reported with 99.7% active users reporting that it is useful for decision making. Overall, satisfaction was high with 69.5% of active users reported being satisfied and 24.5% very satisfied. Factors significantly associated with satisfaction included features accessed, and whether the users reported fast data update. Data users were more likely to be satisfied compared to data entrants (OR 3.87) and those who reported no fast data updates were less likely to be satisfied compared to those who reported (OR 0.37). Further improvement to achieve more satisfaction can focus on ensuring access to visualization features even to data entrants.

6206

COMMUNITY DATA USE; PIVOTAL TO IMPROVING THE UPTAKE OF MALARIA SERVICES BY PREGNANT WOMEN AND THE RESILIENCE OF COMMUNITY HEALTH SYSTEMS - THE CASE OF PHCS IN CROSS RIVER STATE NIGERIA

Chinwe Nweze[1], Linda Lawrence[1], Abimbola Olayemi[2], Arja Huetis[3], Victor Bassey[1], Augustine Firima[1], Oluwatobiloba Akerele[1], Uyi Asuquo[4], Aderonke Omokhapue[2], IniAbasi Inglass[2], Abikoye Olatayo[2], Uchenna Nwokenna[2], Thomas Hall[3], Allan Were[3], Olugbenga Mokuolu[3], Erkwagh Dagba[5], Veronica Momoh[5], Jules Mihigo[5], Chukwu Okoronkwo[6], Perpetua Uhomoibhi[6]

Accurate, timely, and accessible health data is crucial for data use and evidence-based improvements of essential healthcare services during pregnancy. This study investigates the correlation between the change in some malaria indicators and the establishment of data quality and use teams. The teams were established across 20 high-volume facilities randomly selected in 7 LGAs of Cross River, Nigeria and trained on data quality and use in November 2021. Each team which comprised heads of facilities, record officers, representatives from all service delivery units, and the Ward Development Committee (WDC) held monthly meetings to present data and review the performance of malaria indicators. These routine meetings revealed issues such as low uptake of antenatal care services (ANC) and stock out of Sulphadoxine-Pyrimethamine (SP) in health facilities. The WDC used the data to engage communities on identified issues leveraging community development and religious meetings, and targeted advocacy on SP procurement to key stakeholders. These engagements helped communities mobilize pregnant women (PW) to attend ANC and further donate 10200 doses of SP to 15 out of 20 facilities, demonstrating ownership and resilience. A pre and post (twelve-month before and after the intervention) Wilcoxon signed rank test at 95% confidence level with an alpha value of 0.05 was conducted to assess malaria services uptake indicators for PW drawn from the National Health Management Information System. The findings revealed a significant improvement in PW receiving intermittent preventive treatment in pregnancy - second and third dose (IPTp2 & IPTp3) from 51% to 82% (p =0.008) and 27% to 51% (p=0.005) respectively. Similarly, the proportion of PW attending first ANC before 20 weeks and ANC 4th visit improved from 22% to 32% (p=0.009) and 27% to 40% (p=0.02) respectively suggesting an improved ANC early attendance and retention. The findings of this study support the hypothesis that data-driven community engagement may further improve the acceptability, accessibility, and uptake of ANC services with the potential to address and prevent health and gender inequities.

MENTORSHIP IMPROVES QUALITY OF MALARIA IN PREGNANCY SERVICES IN PMI-SUPPORTED REGIONS IN TANZANIA

Michael Gulaka[1], Goodluck Tesha[2], Stella Makwaruzi[1], Saidi Mgata[1], Geofrey Makenga[1], Nicodemus Govella[1], Abdallah Lusasi[3], Charlotte Eddis[4], Marguerite M. Clougherty[5], Albert Ikonje[6], Chonge Kitojo[6], Erik Reaves[7], Sigsibert Mkude[1], Samwel Lazaro[3], Lolade Oseni[8], Katherine Wolf[8]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Jhpiego, Dar es Salaam, Tanzania, United Republic of, [3]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [4]PMI Impact Malaria Project, Population Services International, Washington, DC, United States, [5]Population Services International (PSI), Washington, DC, United States, [6]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [7]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [8]PMI Impact Malaria Project, Jhpiego, Baltimore, MD, United States

Malaria Services and Data Quality Improvement (MSDQI) supportive supervision assesses the quality of services and competence of health workers at service delivery points including Reproductive and Child Health (RCH) clinics. It is expected that the competence gaps in the provision of quality services during antenatal care visits (ANC) identified during MSDQI assessments can be addressed through mentorship between MSDQI assessments. The PMI Impact Malaria project supported the regional and district health management teams to implement MSDQI at 512 health facilities in Lindi, Mtwara, and Katavi in Tanzania in 2021 using the RCH checklist and identified 47 facilities performing <50% in the key competence indicators of assessment of danger signs, clinical history taking and physical examination, laboratory testing, diagnosis and treatment, and counseling and communication. These facilities were later visited once by trained mentors to strengthen capacity. On average, the MSDQI visits in 2022 following mentorship revealed improvements in indicators from 2021 to 2022: assessment of danger signs (45% vs. 88%); clinical history taking and physical examination (35% vs. 82%); laboratory testing (43% vs. 76%); counseling and communication (65% vs. 82%); and diagnosis and treatment (35% vs. 88%). Facilities with high performance during MSDQI assessments in 2021 that received subsequent MSDQI visits in 2022 without intervening mentorship maintained performance in assessment of danger signs (78% vs. 79%), clinical history and physical examination (75% vs. 76%), laboratory testing (71% vs. 79%), and counseling and communication (91% vs. 90%); overall diagnosis and treatment performance increased from 79% to 90%. In poor performing facilities, mentorship led to improved competence in provision of malaria services to pregnant women.

QUANTIFYING THE ADDED BENEFIT TOWARD MALARIA ELIMINATION BY COMMUNITY CASE MANAGEMENT IN THE DOMINICAN REPUBLIC

Isabel Byrne[1], Luca Nelli[2], Nicole Michelen Strofer[3], Natalia Tejada Bueno[3], Claudia H. Rodriguez[4], Keyla Ureña[4], Manuel de Jesús Tejada[5], Jose Luis Cruz Raposo[5], Chris Drakeley[1], Luccene Desir[6], Gregory S. Nolan[6], Karen Hamre[6], Gillian Stresman[7]

[1]London School of Hygiene Tropical Medicine, London, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]Clinton Health Access Initiative, Santo Domingo, Dominican Republic, [4]Programa Nacional de Control de la Malaria de la República Dominicana, Santo Domingo, Dominican Republic, [5]Centro de Prevención y Control de Enfermedades Transmitidas por Vectores y Zoonosis, Santo Domingo, Dominican Republic, [6]The Carter Center, Atlanta, GA, United States, [7]University of South Florida, Tampa, FL, United States

A strong surveillance system is required to achieve certification of malaria elimination. As part of the elimination strategy in the Dominican Republic (DR), community health workers (CHWs) perform community case management in malaria outbreak-affected foci to supplement the passive surveillance system. We present a novel application of the previously reported "Freedom from Infection" (FFI) framework-- a set of surveillance methods adapted to malaria elimination settings that allow: (i) the estimation of the sensitivity of a surveillance system to detect cases in the community (SSe) and (ii) the probability that zero reported malaria cases effectively reflect the absence of transmission (Pfree). We aimed to estimate the added value of CHWs on the health system's ability to detect malaria. Routine malaria surveillance data from passive case detection (PCD) from 2018 to 2022 was collected in 47 health facilities, 9 of which included CHW data. Based on the results of the FFI model with the PCD data only, several facilities exhibited a high degree of uncertainty in the estimated SSe. Despite the high uncertainty, the preliminary results suggest that in some areas, malaria freedom is likely with 21/34 (0.62, 95%CI 0.44, 0.78) health facilities reaching Pfree equal to 1 in at least 1 month of observation based on the PCD data alone. However, where a high Pfree was achieved, it was only sustained between 1 to 50 of the 50 months of observation. When the CHW data was added, two additional facilities reached a high Pfree, and overall, the facilities with CHW data sustained Pfree from 48 to 52 months. The difference in the precision of estimates when CHW data was added to the model was 0.28, or a 0.4-fold increase in precision. Overall, results suggest that the addition of CHW data generally improves the sensitivity of a malaria surveillance system to detect infections if they are present.

OPTIMAL STRATIFICATION STRATEGIES IN THE SELECTION OF SENTINEL SITES FOR AN INTEGRATED MALARIA SURVEILLANCE IN BENIN

Didier Adjakidje[1], Florian D. Siaken Yabou[1], S. Emeric Chris Gbodo[1], Rock Aikpon[2]

[1]University of Abomey Calavi, Cotonou, Benin, [2]National Malaria Control Program, Ministry of Health, Cotonou, Benin

Despite massive investments in recent years, malaria remains the leading cause of care seeking in Benin with an incidence that has plateaued around 20% for several years and high mortality rate among children under 5 and pregnant women. This stagnation questions the effectiveness of current strategies and calls for a paradigm shift towards the improvement of the targeting of interventions. This is the rational of ongoing discussions around the selection of a set of sentinel sites that will allow for an integrated monitoring covering entomological, epidemiological, climatological… dimensions. This research is a contribution to these discussions. It aims to propose a stratification strategy based on the spatial distribution of malaria transmission risks, allowing for a data-informed choice of sentinel sites that ensures the representativity of the entire country in an integrated surveillance system. The methodology used, is based on the World Health Organization's conceptual framework for the control of Malaria from which, we selected several variables deemed to be determinants for malaria transmission. We then estimated a set of linear mixed-effects models on longitudinal data for all the country's districts over the period from January 2017 to December 2021, to confirm the validity of these determinants. Finally, using a hierarchical ascending classification consolidated with the k-means method, we classified the districts of the country, into reasonably homogeneous blocks that can shelter each, a sentinel site. The main contribution of this study is therefore to use statistical methods to propose a dynamic classification tool that allows the user to pick a number of sentinel sites to be operationalized, likely taking into account resource constraints, and to obtain in return, the optimal slicing with the selected number of geographical areas. Crafted on a rational basis, such optimal slicing of the national territory is expected to foster a well-tailored integrated surveillance system generating a better targeting of the interventions, for an effective reduction of the burden of the disease.

6210

IMPROVING MALARIA EPIDEMIC SURVEILLANCE THROUGH ACTIVE ENGAGEMENT OF DISTRICT LEADERS. LESSONS FROM BUSOGA REGION IN EASTERN UGANDA

Richard Opio Ongom[1], Irene Ochola[1], Edward Mugwanya[1], Patricia Mukose[1], Chris Mugenyi[1], Irene Ayaa[2], Susan Nabirye[1], Amy Casella[3], Aliza Hasham[4], Benjamin Binagwa[1], Natalia Whitley[3]

[1]John Snow Inc, Kampala, Uganda, [2]MCD Global Health, Kampala, Uganda, [3]John Snow Inc, Boston, VA, United States, [4]John Snow Inc, Dar es Salam, Tanzania, United Republic of

The World Health Organization surveillance guidelines 2018 consider transformation of malaria surveillance into a core intervention as one of the pillars of the global technical strategy. In 2001, Uganda adapted and began implementing the Integrated Disease Surveillance and Response developed by WHO for African region member states. However, human resource challenges and technical glitches with the online reporting system as well as stock out of HMIS tools have weakened malaria epidemic surveillance in Uganda. The PMI Uganda Malaria Reduction Activity implemented by JSI, works with the Ministry of Health to strengthen malaria prevention and response efforts at all levels in the five highest-burden regions of Uganda. A broad range of interventions to ensure data completeness, timeliness, and quality are implemented. In Busoga region, beginning in April 2022, technical assistance was provided to twelve districts to improve HMIS reporting rates and address existing data quality gaps. Weekly, surveillance data was shared on reporting rates, malaria diagnosis, case management and malaria commodities stock status. District health, administrative and political leaders from 12 districts were engaged to lead the process of following up with 517 health facilities to address reporting and data quality gaps. Monthly reporting rates improved from 76% between April and June 2022 to 99% between October and December 2022. The weekly surveillance reporting rates further increased from 55% in week 22 of 2022 to 84% in Week 37 and rose to 91% in week 48. As of 2023, in week 3 and week 4, the reporting rate peaked at 93%. District leaders made data reporting a key performance indicator for health facility managers in 9 of the 12 districts. Active participation of district leaders in data management triggers health workers to improve performance. Using data to inspire leaders to be involved in malaria epidemic surveillance and deploying the tools available is a critical approach in settings where human resources are less motivated to document and report quality malaria data.

PLASMODIUM FALCIPARUM MALARIA MOLECULAR INDICATORS IN SOUTH WEST BURKINA FASO: COMPARISON OF ACTIVE AND PASSIVE CASE DETECTION

Emilie S Badoum, Amidou Diarra, Ludovic Kouraogo, Daouda Ouattara, Issa Nebie, Alfred B Tiono, Alphonse Ouedraogo, Sodiomon B Sirima

Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso

The aim of this study was to compare the molecular indicators of P. falciparum during active and passive case detection. Samples of children aged from 1.5 to 12 years were collected from October 2020 to Mars 2021. Children below 5 years benefited on the National seasonal malaria chemoprophylaxis (SMC). All study participants received either supervised curative doses of artesunate (AS) or dihydroartemisinin-piperaquine (DHAPQ) to clear existing parasites prior their enrolment. Active and passive case detection methods were combined to capture all malaria clinical episodes during the follow up. Blood spots were collected and DNA extracted; alleles frequencies and msp-2 genes diversity investigated by nested polymerase chain reaction. A total of 458 (403 for active and 55 for passive cases) P. falciparum isolates collected from 176 participants (38.43%) were genotyped. The mean values of MOI were 2.91 [2.74-3.07] for active and 3.52 [3.04-4.00] for passive visit respectively (p=0.01) and those of FOI in active visit was 1.95 [1.76-2.15] versus 2.38 [1.75-3.01] in passive visit (p=0.16). No statistically significant difference in FOI values (p=0.92) was found between subjects who were on SMC (1.98 [1.57-2.39]) and those who were not (2.00 [1.82-2.18]). On average, 2.98 [2.83-3.14] clones parasitized our subjects during each infection and there was no statistically difference (p=0.75) between subjects on SMC (3.03 [2.69-3.38]) and the other group (2.97 [2.79-3.15]). This study shows that the molecular indicators of P. falciparum were higher in isolates from subjects with symptomatic malaria. Despite the current malaria control tools deployed in young subjects, variant patterns in young subjects, allelic variant profiles identical to those of subjects without SMC coverage are still observed. This may support the current hypothesis that school children should also be the target of malaria control tools.

6212

THE YELLOW FEVER OUTBREAK SHEDS LIGHT ON THE MISSED THREAT OF MALARIA IN ISIOLO COUNTY, KENYA 2022

Geoffrey K. Githinji[1], Serah Nchoko[1], Dorcas Ndunge[1], Nassoro Mwanyalu[1], Aricha Stephine[1], Maurice Owiny[1], Fredrick Odhiambo[1], Elvis Oyugi[2]

[1]Field Epidemiology and Laboratory Training Program - Kenya, Nairobi, Kenya, [2]Ministry of Health - Division of National Malaria Program, Nairobi, Kenya

Malaria and Yellow Fever can be difficult to differentiate based on symptoms and signs, leading to delayed diagnosis and increased morbidity and mortality. In March 2022, in a suspected febrile illness outbreak in Isiolo, some samples collected were confirmed malaria. We investigated by retrospectively reviewing patient records, conducting malaria data quality audit and surveillance capacity in 16 randomly selected facilities from October 2021 through March 2022. A suspected case was any patient's record that had presented with fever and any of the following - headache, backache, chills, sweat, myalgia, nausea, and vomiting in Isiolo County during the review period, a confirmed malaria case was any patient's record tested positive for malaria through a blood smear test or rapid diagnostic test within the same period. We abstracted data on age, sex, visit date, diagnostic test, and laboratory results. Data Quality Assessment (DQA) evaluated timeliness, completeness, and data. Descriptive statistics utilized means, medians, frequency and proportions. We reviewed 5,527 records from three sub-counties; Garbatula contributed 45.03% (2,489) of the cases, Isiolo 46.35% (2,562) and Merti 8.61% (476) cases. Median age was 15 Years (IQR 5 - 30). Attack rate for ages under five was 6.54% (86/1.315), and above five was 10.87% (458/4,212). Approximately 10.3% (571/5527) cases tested positive — a case attack rate of 2.08 per 1000 population for Isiolo county. Garbatula had highest case positivity rate — 57% (323/571) an attack rate of 4.64 cases per 1000 Population, Isiolo was 1.26 cases per 1000 population and, Merti was 1.01 cases per 1000 population. Undetected case upsurges to alert thresholds noted on the 3rd, 4th and 5th epidemic weeks of 2022. Data completeness was 83% and timeliness 71%. At least 25% (4/16) facilities had significant stock-outs of mRDTs and antimalarials. Weak surveillance systems could have contributed to the missed upsurge of cases. We recommend strengthening support supervision, improving mRDTs access in facilities without laboratories, and redistributing antimalarials to strengthen malaria control and surveillance

6213

PIONEERING ELECTRONIC FORMS AND REPORTING IN SEASONAL MALARIA CHEMOPREVENTION IMPLEMENTATION AMID INSECURITY IN ZAMFARA STATE

Comfort Kingsley-Randa[1], Abdulmajid Idris Safana[2], Abba Abdullahi Sagagi[2], Abimbola Olayemi[3], Arja Huestis[4], Aderonke Omokhapue[3], Kabiru Mohammed Bungudu[5], Mujahid Aliyu Idris[6], Yusuf Na Allah Jega[2], Muhammad Sahabi Gurusu[2], Munira Isma'il Mustapha[2], Sherifah Ibrahim[2], Shiwan Dlakwa[2], Murtala Muhammad[2], Olugbenga Mokuolu[4], Justice Adaji[3], IniAbasi Inglass[3], Uchenna Nwokenna[3], Chukwu Okoronkwo[7], Perpetua Uhomoibhi[7], Erkwagh Dagba[8], Veronica Momoh[8], Jules Mihigo[8]

[1]United States President's Malaria Initiative for States, Management Sciences for Health, Nasarawa, Nigeria, [2]United States President's Malaria

Initiative for States, Management Sciences for Health, Zamfara, Nigeria, [3]United States President's Malaria Initiative for States, Management Sciences for Health, Abuja, Nigeria, [4]Management Sciences for Health, Arlington, VA, United States, [5]State Malaria Elimination Program, Ministry of Health, Zamfara, Nigeria, [6]United States President's Malaria Initiative for States, Management Sciences for Health, Plateau, Nigeria, [7]National Malaria Elimination Programme, Abuja, Nigeria, [8]United States President's Malaria Initiative, United States Agency for International Development, Abuja, Nigeria

Malaria is the leading cause of morbidity and mortality in children under the ages of five (CU5) in Nigeria. In Zamfara state, SMC has been implemented among CU5 since 2015. SMC implementation contends with difficulties around payment of SMC personnel (Community Drug Distributors [CDD], health facility workers and Local Government teams) and incomplete submission of data, specifically, with heightened security risks. E-accountability tools - CDD nomination, CDD attendance, call-in data, and in-process monitoring forms were introduced in 2021 to overcome these challenges, and SMC personnel were provided practical training on their use. Throughout SMC implementation, monitoring and supervisory support was provided by state trainers on use of these tools. This assessment compared the SMC implementation processes and outcomes before (2020) and after the introduction of the e-tools in 2021. Deployment of CDDs e-nomination forms reduced the number of days for CDD selection and engagement from 6 to 2 working days, while deployment of the e-attendance increased CDDs daily attendance submission from 5% to over 85%. The daily call-in data received from health facilities on delivery of the SMC drugs increased from 14% to 80% and the field supervisors' submission of in-process monitoring reports increased from 35% to 100%. The duration of personnel replacement reduced from 20 to 3 working days, due to the establishment of a replacement protocol aided by the unique ID numbers linked to every registered personnel. The timeline for payment of SMC actors reduced from 30 to 3 working days. The e-tools improved microplanning by facilitating the inclusion of and provision for CU5 in internally displaced persons (IDP) camps and hard to reach communities. The introduction of e-tools during SMC implementation had a positive impact on overall program management, monitoring, commodity availability, personnel management, and payment processes. This has also contributed to the increased availability of real time data for prompt decision making, cost efficiencies throughout the process and improved SMC delivery including in security challenged area.

6214

INTEGRATING ANTENATAL CLINIC-BASED MALARIA SCREENING DATA AND MATHEMATICAL MODELLING TO CAPTURE THE TRAJECTORY OF MALARIA TRANSMISSION IN WESTERN KENYA IN THE CONTEXT OF THE COVID-19 PANDEMIC.

Patrick GT Walker[1], Joseph Hicks[1], Oliver Towett[2], Brian Seda[2], Ryan Wiegand[3], Simon Kariuki[2], Julie Gutman[3], Aaron Samuels[3], Feiko ter Kuile[4]

[1]MRC Centre for Outbreak Analysis & Modelling, Imperial College London, London, United Kingdom, [2]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [3]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Department of Clinical Sciences, Liverpool School of Tropical Medicine,, Liverpool, United Kingdom

In Siaya county, western Kenya, pregnant women are routinely screened for malaria at their first antenatal care (ANC) visit. Since 2016, screening has occurred alongside an all-age continuous household Malaria Indicator Survey (cMIS), providing a unique opportunity to understand how malaria infection trends at ANC map to general population prevalence, a metric by which ~85% of the world's malaria burden is estimated. As with much population-based disease surveillance, cMIS was halted in 2020 in the context of the emerging COVID-19 pandemic. Meanwhile, an insecticide treated net (ITN) campaign scheduled for mid-2020 was delayed to March 2021. In contrast, ANC surveillance remained ongoing and largely unaffected in 2020-2021. We assessed the relationship between ANC and population prevalence using binomial regression. We then incorporated this relationship within an existing dynamical malaria transmission model, using particle Markov Chain Monte Carlo to estimate transmission trends throughout the study period. Through k-fold cross-validation, we show that ANC-based surveillance accurately captured a rapid decline in population malaria prevalence from around 50% to 20% immediately after an ITN campaign in 2017. Our estimates suggest a near thirty-fold reduction in transmission from an entomological inoculation rate (EIR) of ~30 to ~1 during this period. By early 2020, both population prevalence and our estimates of transmission had rebounded to their pre-ITN peaks. During the pandemic, both ANC-based prevalence and our transmission estimates remained near their study-level peak throughout the year-long delay in ITN distribution, declining rapidly from March 2021 when ITNs were eventually distributed. This highlights the utility of ANC-based indicators in providing more granular estimates of population-level trends and as a data source likely to remain more robust to external shocks such as pandemics than other forms of population-based surveillance such as cMIS. These results also provide a quantitative example of the indirect impact the pandemic is likely to have had upon malaria control, transmission, and burden.

6215

TRACKING PROGRESS OF PROPORTIONAL USAGE ANTIMALARIALS FOR TREATMENT OF PLASMODIUM FALCIPARUM INFECTIONS IN CHILDREN, TWO DECADES OF ARTEMISININ-BASED COMBINATION THERAPY (ACT) POLICY IMPLEMENTATION

Susan F. Rumisha[1], Paul Castle[2], Jailos Lubinda[2], Jennifer A. Rozier[2], Joseph Harris[2], Camilo Vargas[2], Peter W. Gething[2], Daniel J. Weiss[2]

[1]National Institute for Medical Research, Dar es Salaam, Tanzania, United Republic of, [2]Telethon Kids Institute, Malaria Atlas Project, Perth, Australia

A policy shift to Artemisinin-based combination therapy (ACT) for managing malaria cases contributed substantially to the reduction of malaria burden globally. Unfortunately, in the past few years progress stalls and that plateau trend continues. Possible explanation for the slowing down could be inequalities in the uptake of interventions in specific transmission foci and sector specific performances. Studies suggest that unregulated private sector may allow the use of ineffective antimalarial medicines resulting to poor clinical outcomes. Additionally, undetected poor performance at subnational levels may mislead correct allocation of control strategies, hence, slowing down the progress in malaria control. This work assessed the public-private share and geographical variations of the proportional use of ACT in treatment of uncomplicated P.falciparum infections in children in malaria endemic countries two decades since the recommendation of the policy. Utilizing data from demographic health surveys, hierarchical Bayesian modelling framework were developed and deployed to estimate country-year, sector-specific and subnational distribution of the usage. The models were adjusted for treatment seeking rates, health system, socio-demographic, and environmental factors. Our findings indicate that rural and low-wealth areas have lower uptake of the ACT policy, despite an overall increase in the public sector's share of malaria services from 46.7% in 2001 to 61.8% in 2022. Overtime, use of ACT has significantly improved within both sectors. Over two decades, 79.8% of children treated in public sector received ACT contrary to 67.2% in private sector. Private sector increases in ACT use outpaced public sector increases by 75.6% to 64.5%. Regional, national and subnational variations exist, with the public sector dominating in provision of malaria services in most. SSA countries. In Nigeria, private sector is treating most cases mostly with ACT, however, in the Democratic Republic of Congo, despite public sector treating most almost a third receiving non-ACT.

6216

SPATIAL AND TEMPORAL VARIATION OF MALARIA CLINICAL INCIDENCE IN CHILDREN UNDER 10 YEARS OF AGE IN KOULIKORO, MALI

Soumba Keita[1], Mathias Dolo[1], Ibrahim Sanogo[1], Daouda Sanogo[1], Fousseyni Kane[1], Moussa Keita[1], Ayouba Diarra[1], Hamady Coulibaly[1], Nafomon Sogoba[2], Mahamadou Diakité[1], Mahamoudou Toure[1], Seydou Doumbia[1]

[1]University Clinical Research Center/ University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, Bamako, Mali, [2]2West African International Center for Excellence in Malaria Research (ICEMR-WAF), Bamako, Mali

Despite the wide deployment of malaria control interventions during the last decades, we are observing over the last 5 years a plateauing of the number of cases in many endemic countries like Mali. Thus, it is necessary to review and redirect malaria interventions specifically in low and middle-income countries with more malaria. The cost-effectiveness of malaria interventions will depend on the area' level of endemicity and seasonality of transmission. Spatiotemporal analysis of malaria burden variation in Koulikoro health district of Mali was used to determine the variation in malaria indicators such as incidence among children less than ten years of age.A total of 2,916 children were enrolled in July 2021 and followed up to April 2022 (a ten-month period). Households of participants were geolocated at enrolment and for the purpose of spatial analysis, locations were aggregated to 1km2 grid cells to calculate cumulative incidence rates (CIRs) per 100 persons. To assess the temporal variation of malaria both hot spots and cold spots within the study area, we used the Fish Model on SaTScan. To reduce the dimensions of environmental variables and avoid collinearity between environmental factors, we performed a principal component analysis (PCA) in the FactoMiner. Data were collected from all children visiting health care facilities for malaria symptoms using digital tablets. Overall, malaria incidence rate was 4.1 children per month in October and 70% of children had at least one malaria episode during the follow-up period. Peak of malaria incidence was observed in September and November and the maximum number of malaria episodes a child experiences was 4 over 10 months. Recurrent malaria events were frequently observed in villages along the Niger River with a heterogeneous distribution during the transmission season.

6217

THE VALUE OF END-USE VERIFICATION SURVEYS ON THE AVAILABILITY OF ANTIMALARIAL COMMODITIES IN MADAGASCAR, 2022

Patrick Harilanto Raherinjatovo[1], Aline Mukerabirori[1], Faratiana Michèle Randrianasolo[1], Jane Briggs[2], Luz Razafimbelo[1], Laurent Kapesa[3], Hasina Rabarijaona[4]

[1]Management Sciences for Health, IMPACT Program, Antananarivo, Madagascar, [2]Management Sciences for Health, Arlington, VA, United States, [3]The U.S. President's Malaria Initiative (PMI), USAID, Antananarivo, Madagascar, [4]National Malaria Control Program, Antananarivo, Madagascar

To monitor the availability of quality health commodities in Madagascar, the Malagasy Ministry of Public Health (MOPH) has implemented end-use verification (EUV) surveys—a USAID-funded standardized methodology for assessing the storage conditions and inventory management of antimalarial and other commodities. The USAID Improving Market Partnerships and Access to Commodities Together (IMPACT) project has been supporting the MOPH in conducting the EUV surveys and implementing corrective actions and recommendations in response to survey findings since 2020. EUV surveys are conducted every 6 months in around 100 randomly sampled health facilities: 3% hospitals, 17% district pharmacies (Pha-G-Dis), 64% basic health centers (CSBs) and 15% community health workers in USAID-supported regions with higher malaria incidence. Findings of each assessment are discussed among stakeholders at each administrative level and actions defined to address the challenges. The results of the malaria EUV survey in December 2022 in 109 facilities show that, on the day of the visit, 35% of 23 Pha-G-Dis had an appropriate stock of artemisinin combination therapy (ACTs) for infants, compared to 13% of 18 in May 2022; and 31% of Pha-G-Dis had an appropriate stock of injectable artesunate, compared to 21% in May 2022. From September to November 2022, all 109 structures recorded 0% stock out of ACTs for adolescents compared to 20% in May 2022; 0% stock out of ACTs for adults compared to 14% in May 2022; and 0% stock out of malaria rapid diagnostic tests compared to 7% in May 2022. At the health facility level, 81% of 72 facilities (both CSBs and hospitals) had a formulation of ACTs for children under 5 years old (compared to 76% of 70 facilities in May 2022) and the stock out rate of adult ACTs was 7% (compared to 12% in May 2022). The action plans developed and implemented by regional and district supply chain actors after reviewing EUV survey results have contributed to improvements in subsequent surveys. IMPACT continues to support the Madagascar MOPH in effective use of data for evidence-based decision making.

6218

ENGAGING HEALTH FACILITY TEAMS TO IMPROVE MALARIA DATA QUALITY, USE, AND SERVICE DELIVERY IN AKWA IBOM STATE

Aderonke Omokhapue[1], Chinwe Nweze[2], Abimbola Olayemi[1], Ubong Umoren[3], Ekaette Ekong[4], John Orok[4], IniAbasi Inglass[1], Uchenna Nwokenna[1], Arja Huestis[5], Thomas Hall[5], Olugbenga Mokuolu[5], Erkwagh Dagba[6], Veronica Momoh[6], Chukwu Okoronkwo[7], Perpetua Uhomoibhi[7], Jules Mihigo[6]

[1]United States President's Malaria Initiative for States, Management Sciences for Health, Abuja, Nigeria, [2]United States President's Malaria Initiative for States, Management Sciences for Health, Cross River, Nigeria, [3]United States President's Malaria Initiative for States, Management Sciences for Health, Akwa Ibom, Nigeria, [4]State Malaria Elimination Program, Ministry of Health, Akwa Ibom, Nigeria, [5]Management Sciences for Health, Arlington, VA, United States, [6]United States President's Malaria Initiative, United States Agency for International Development, Abuja, Nigeria, [7]National Malaria Elimination Programme, Abuja, Nigeria

The National Health Management Information System (NHMIS) is one of the six building blocks of health systems that integrates data collection, processing, reporting, and use (WHO, 2010). Data is critical to delivering high-quality malaria services and guides malaria elimination efforts in Nigeria. This study examines the utilization of health facility (HF)-based data quality teams set up in five high-volume HFs in Akwa Ibom state in July 2021. The objective of the data quality teams was to enable HFs to generate and use quality data for improvement of malaria services. The teams were trained and supervised for the first 6 months of implementation and their responsibilities included coordinating facility data validation and triangulation and conducting monthly HF data review meetings. A descriptive quantitative analysis of NHMIS data on the proportion of fever cases tested for malaria and confirmed uncomplicated malaria treated with artemisinin-based combination therapy (ACT) was conducted in the selected HFs for a 3-year period (January 2019 - December 2021). Data availability across the HFs improved from 91% in 2019 to 100% between July-December 2021 when the data quality team meetings were set up and conducting monthly data reviews. The data also showed an improvement in malaria service delivery. In 2019, 72% of data records of fever cases tested for malaria deviated from the national target of 100%; this dropped to 8% between July - December 2021. A similar pattern was reported for the proportion of confirmed uncomplicated malaria cases treated with ACTs, where service delivery gaps reduced from 55% in 2019 to less than 2%. Continuous review of data using HF-based data quality teams presents a sustainable and scalable approach for HFs, fosters continuous use of data to identify gaps, and supports adaptive and improved adherence to standards of care. Implementing this strategy should take into consideration factors that support sustainability and ownership, such as skills transfer from members of the data quality team to all relevant HF staff and continuous on-the-job mentoring from government supervisors to HF teams.

Battle[5], Joshua L. Proctor[5], Caitlin Bever[5], Daniel L. Hartl[6], Bronwyn MacInnis[2], Dyann F. Wirth[1], Daouda Ndiaye[3]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Broad Institute of MIT and Harvard, Cambridge, MA, United States, [3]International Research and Training Center for Applied Genomics and Health Surveillance (CIGASS) at the University Cheikh Anta Diop, Dakar, Senegal, [4]Senegal National Malaria Control Program, Dakar, Senegal, [5]Institute for Disease Modeling, Bill and Melinda Gates Foundation, Seattle, WA, United States, [6]Harvard University, Cambridge, MA, United States

Ongoing national surveillance of Senegal Plasmodium falciparum infections provides emerging threat detection including drug resistance to inform transmission patterns that can guide intervention use by the Senegal National Malaria Control Program (NMCP). Parasite genetic metrics such as the frequency of clonal and multiple strain (polygenomic) infections, and genetic relatedness are emerging as key indicators for both monitoring transmission trends and identifying transmission patterns for tailoring subnational intervention stratification. We surveyed parasite genetic parameters from Diourbel, a site of moderate transmission (annual incidence ~25 cases/1000/year). Genotyped samples were collected through passive case detection (PCD) at health facilities from 2018 to 2020 (n = 412) and active case detection (ACD) at large residential schools called Daaras in 2020 (n = 120). Based on the PCD samples, infections in Diourbel were unusually clonal and inbred relative to its reported incidence levels. Between 2018 and 2020, we did not observe an increase the frequency of polygenomic infections (0.13 [0.08, 0.20] in 2018 to 0.10 [0.07, 0.15] in 2020). Despite this, infections in Diourbel have become increasingly clonal and inbred over time. The proportion of monogenomic samples infected with a shared clone increased from 0.48 [0.39, 0.58] to 0.83 [0.76, 0.88]) and the relatedness of strains (measured with RH) within polygenomic infections increased from 0.03 [0, 0.08] in 2018 to 0.40 [0.35, 0.46] in 2020. Five persistent clonal parasite lineages were observed across multiple sampling years. This unusual clonal and inbreeding structure was not observed in nearby Touba, which has a similar incidence. Genetic metrics collected through PCD and ACD were similar except for RH, which was 0.10 (0.03, 0.18; compared to 0.40 overall) in the ACD samples collected in 2020. We hypothesize that this unusual population genetic structure represents a unique focal spatial structure in Diourbel and are working with the Senegal NMCP to map the spatial structure of clonal parasite populations to identify transmission sources for intervention targeting.

IMPROVING MALARIA SURVEILLANCE DATA: INSIGHTS FROM SOUTHERN ANGOLA

Ana Direito[1], **Teresa Nobrega**[1], Paulo Máquina[2], Fernanda Guimarães[3], José Franco Martins[3], Manuel Lando[1], Sérgio Lopes[4]

[1]The Mentor Initiative, Luanda, Angola, [2]Elimination 8, Luanda, Angola, [3]National Malaria Control Programme, Ministry of Health, Luanda, Angola, [4]The Mentor Initiative, Haywards Health, United Kingdom

Malaria in SADC region has significantly reduced over the last decade. As countries progress towards elimination, it is key to turn surveillance as a core programmatic component not only for first line elimination targeted countries but also for the second line countries which adequate control is essential to sustain elimination goals. In 2020, Angola started to implement aggressive activities focused on improving surveillance for elimination practices in southern border districts with Namibia. Surveillance activities integrated a combined approach that included support to routine collection of monthly reports, on site data quality assessments and on the job supportive supervision. The objective of this work is to highlight the achievements in core surveillance indicators achieved in 3 years of programmatic implementation. Reporting coverage was retrieved from National Health Information System to analyse progress of health facility reporting coverage over time. Information from data quality assessments was extracted from a database and simplified data quality indicators were analysed to understand trends in data quality over time. Results show that none of the 7 border districts targeted for intensive surveillance interventions had an annual reporting coverage above 90% in 2018, 1 in 2020 while all seven targeted districts had reporting coverages above 90% in 2022. Data quality shows that, in 2020, 58% of health facilities had incompletely filled reports whereas in 2022 this proportion dropped to 13%. In 2020 the accuracy of data between the consultation books and monthly reports was 93% but was improved to 99% in 2022. In 2020, 25% of the health facilities visited reported stock out of monthly reporting forms and 39% of consultation books. In 2022, those proportions changed to 5% and 17% respectively. A strong malaria surveillance system is highly dependent on availability and quality of data. Implementation of intense activities focused in improving data accessibility and quality showcase that it is possible to improve the system and sustain those gains over time.

DEFINING PCR-DETECTED PARASITEMIA THRESHOLDS FOR CLINICAL MALARIA FROM ACTIVE AND PASSIVE CASE DETECTION

Andrea G. Buchwald[1], Alick Sixpence[2], Ernest Matola[3], Charles Mangani[3], Alfred Matengeni[3], Mark L. Wilson[4], Don P. Mathanga[3], Miriam K. Laufer[1], Karl B. Seydel[5], Clarissa Valim[2], Lauren M. Cohee[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]Boston University, Boston, MA, United States, [3]Kamuzu University of Health Sciences, Blantyre, Malawi, [4]University of Michigan School of Public Health, Ann Arbor, MI, United States, [5]Michigan State University, Lansing, MI, United States

Historically, clinical malaria was defined as fever and a blood smear positive for Plasmodium parasites above a defined density threshold. Blood smears have since been replaced by rapid diagnostic tests for diagnosis and more sensitive molecular diagnostic tests for research purposes. Thus, sensitive and specific definitions of clinical malaria using parasite density thresholds based on molecular diagnostics in the absence of blood smears are needed in 1) clinical settings where they must account for community prevalence of infection and 2) community-based surveillance to quantify disease among those not seeking treatment. We calculated the threshold of PCR-detected P. falciparum parasitemia that indicated clinical malaria disease among 1) individuals seeking treatment at health care facilities, and 2) individuals included in active case detection (ACD). Infection was detected by qPCR (18SrRNA) in a cohort of 962 Malawians of all ages who were followed for one year, using monthly active, and continuous passive case detection. ROC curves for the total population and by age were used to identify the qPCR-detection thresholds for 1) clinical care-seeking with fever and positive RDT, and 2) fever measured or reported during ACD. Among 1949 episodes of infection without recent antimalarial treatment, median age was 11y (IQR = 7, 19); median parasitemia was 16.21 parasites/ul (IQR = 2.23, 350.15). There were 283 clinical episodes, with an AUC of 0.89, and the parasitemia threshold identified was 427/ul, with sensitivity and specificity = 0.88 and 0.76. During ACD, there were 487 febrile episodes, with an AUC of 0.72, and the parasitemia threshold was 519/ul, with sensitivity and specificity = 0.88 and 0.51. Thresholds were higher among children under age 5 (634 and 904/ul for the two case definitions, respectively) and significantly lower among individuals over age 15 (40 and 70/ul). Results on predictors of care seeking by age and season will also be presented. While

these thresholds are likely to be specific to our transmission setting, our results highlight the importance of age-specific parasite density cut-offs for clinical disease.

INTEGRATED AND INNOVATIVE DECENTRALIZED MALARIA RESURGENCE RESPONSES IN THE SOUTH EAST OF MADAGASCAR

Andry Patrick Raoiliarison[1], Omega Raobela[2], Yvette Razafimaharo[2], Andriamanga Benjatiana Ruffin[1], Sandy Mbolatiana Ralisata[1], Soza Andriamarovesatra[1], Ilo Andriamanamihaja[1], Martin Rafaliarisoa[1], Voahangy Razanakotomalala[3]

[1]PSI, Antananarivo, Madagascar, [2]Madagascar Ministry of Public Health, Antananarivo, Madagascar, [3]MCD Global Health Madagascar, Antananarivo, Madagascar

The Ministry of Health (MOH) sub-national team, supported by the National Malaria Control Program (NMCP) and partners conducted a package of response activities to address malaria resurgence in the districts of Farafangana and Vangaindrano in the South East region of Madagascar. The incidence of malaria cases increased from 63 per thousand inhabitants in Farafangana in October-December 2021 to 99.9 per thousand in 2022 in the same period. In Vangaindrano, incidence increased from 188.4 per thousand to 217.4 cases per thousand inhabitants from 2021 to 2022 for the same periods. The response package included: 1) mass behavior change communication; 2) active mass screening and treatment (MSAT); 3) Outreach Training Supportive Supervision (OTSS+) for targeted health facilities;4) in-service training on malaria case management. During the MSAT in Farafangana, 1,808 people of all ages were tested by malaria Rapid Diagnostic Test (RDT). The RDT test positivity rate was 47% and 84% were asymptomatic. In Vangaindrano district, 1,686 were tested by RDT. The RDT test positivity rate was 46.5% and 88% were asymptomatic. Most of these 1808 people tested received sensitizations on the prevention of malaria. In the four health facilities visited in Farafangana, the OTSS+ checklist showed the biggest gaps were register completeness (49%) and simple malaria case management competency (51%). The highest performance was on RDT competency (85%). In the three health facilities visited in Vangaindrano, the biggest gap was simple malaria case management competency (45%). Register completeness (60%) and RDT competency (86%) were slightly higher. Two in service medical training sessions for public and private providers were then conducted and tailored to address the subjects that OTSS+ showed poor performance on. The innovative decentralized response package to the malaria outbreak was accepted by health workers and the population. Malaria services delivery could be evaluated and strengthened through OTSS+. Community level can feasibly conduct mass active response to control malaria transmission in the context of high asymptomatic malaria cases rate.

6223

USING DATA INTEGRATION AND VISUALIZATION TO STRENGTHEN THE MALARIA SURVEILLANCE SYSTEM IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Jicko Bondole[1], Bruno Kapinga-Mulume[1], Jimmy Anzolo[1], Rova Ratsimandisa[1], Michael Hainsworth[2], Arantxa Roca Feltrer[3], Hyacinthe Kaseya[4], Alain Bokota[4], Marie-Julie Lambert[5], Hornel Lama[5], Alex Kaldjian[5], Grégoire Lurton[5]

[1]PATH, Kinshasa, Congo, Democratic Republic of the, [2]PATH, Seattle, WA, United States, [3]PATH, Maputo, Mozambique, [4]DRC National Malaria Control Program, Kinshasa, Congo, Democratic Republic of the, [5]Bluesquare, Etterbeek, Belgium

A robust malaria surveillance system is the backbone of malaria control and elimination. Data integration and visualization are critical components of enabling the use of large volumes of data and answering analytical questions. Integration consolidates data from different sources into a single database. Visualization allows for more intuitive manipulation and interpretation of large and complex datasets. In 2021 in DRC, Bluesquare's open-source data platform, OpenHEXA, was used to create an integrated database using routine data from the National Health Information System's DHIS2, weekly surveillance data from the Integrated Disease Surveillance and Response platform, and environmental data. DRC is now capable of automatically running data integration routines to ensure the most recent version of each data source is used at all times. Analytics dashboards using Tableau software were also developed, allowing an interactive exploration and use of the integrated data. Dashboards include a weekly National Malaria Control Program (NMCP) epidemiological bulletin; analytics down to the health area level to monitor malaria trends, commodities, and data quality; and monitoring of environmental data. Institutionalization of these tools included training Ministry of Health (MoH) staff at all levels of the health system to analyze, interpret, and use malaria data. Changes in data utilization were observed since the introduction of these dashboards at the government stakeholder level, including using dashboards for evidence-based planning of supervision, decision-making on rapid outbreak response, distributing malaria commodities, internal redeployment of malaria commodities between health facilities, identifying data outliers, active monitoring of indicator performance, providing feedback on data quality and on malaria case management data, and reducing data validation violations. Key next steps include integrating entomological data into the data integration and analytics platform, improving spatial granularity down to the health facility level, and improving coverage of trained MoH staff on the NMCP dashboards.

MODEL-BASED ESTIMATES OF LONG-TERM AND SEASONAL MIGRANTS IN NORTHWESTERN DISTRICTS OF ETHIOPIA

Amir Siraj[1], Mebrahtom Haile[2], Dereje Dillu[3], Asefaw Getachew[4], Gezahegn Tesfaye[4], Belendia Serda[4], Asnakew Yeshiwondim[4], Berhane Tesfay[4], Tesfaye Tilaye[5], Kassahun Alemu[6], Arantxa Roca-Feltrer[7], Adam Bennett[1], Hannah Slater[1]

[1]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States, [2]Ministry of Health, Addis Ababa, Ethiopia, [3]Ministry of Health, PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Addis Ababa, Ethiopia, [4]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Addis Ababa, Ethiopia, [5]Emergency Preparedness and Response Cluster, World Health Organization, Addis Ababa, Ethiopia, [6]Department of Epidemiology and Biostatistics, Institute of Public Health, University of Gondar, Gondar, Ethiopia, [7]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Maputo, Mozambique

Human mobility represents a major driver of the spread and persistence in Ethiopia's malaria epidemiology. Large scale movements of seasonal workers between areas of low and high malaria transmission have complicated efforts to reduce disease burden at both ends. In resource-poor farming settings where road transport or mobile-phone based data or large-scale population surveys are lacking, long-term migration patterns correlate with seasonal migration patterns and thus have been suggested for use in quantifying seasonal migration patterns. In this study, we used a five-year (2009-2013), survey-based internal migration dataset covering 78 zones in Ethiopia to develop a spatial-interaction model, and down-scaled estimates of migration to a finer spatial scale, in 816 districts (woredas). We also used the estimates to infer seasonal migration to woredas in northwestern Ethiopia identified as development corridors hosting seasonal workers. Accordingly, there were an estimated 1.53 million (95% CI: 1.51 - 1.56 million) long-term migrants crossing zonal borders annually, while 1.76 million (95 CI: 1.72 - 1.80 million) migrants crossed woreda borders, among them 10.6k (10.2 - 11k) migrated to the northwestern woredas. Based on our association model, this meant 294k (95% CI: 94k - 735k) seasonal migrants arriving at the northwestern woreda annually, which, according to reported prevalence of Plasmodium falciparum among seasonal migrants, translates to 37k (95% CI: 12k - 93k) positive cases returning to their home woredas annually. By applying a previously developed spatial downscaling approach and using secondary data on seasonal migration and prevalence of P. falciparum, our study inferred seasonal migration between a larger set of sources and destinations, thus filling a critical data gap. Results from this study are being used to inform meta-population disease transmission

models crucial in the identification of effective malaria control interventions in the presence of seasonal migration. This work constitutes an important part of the strategic plan aiming at malaria elimination in districts of moderate and low transmission risks.

6225

A SECOND BLOOD MEAL ELEVATES THE PLASMODIUM VIVAX SPOROZOITE LOAD IN ANOPHELES DIRUS SALIVARY GLANDS

Sirasate Bantuchai

Mahidol University, Bangkok, Thailand

Anopheles mosquitoes become infectious with Plasmodium sporozoites by taking blood from an infected human. The parasites undergo a series of developmental changes in the mosquito and mature to sporozoites capable of infecting the next human. The time duration required by the parasites to develop within the mosquito to become infectious sporozoites, known as the extrinsic incubation period (EIP), is a key determinant of the vectorial capacity of the mosquitoes. During their life span, mosquitoes naturally feed multiple times in order to complete gonotrophic cycles. Previously, our group examined the impact of the second blood meal on P. vivax sporogonic development and observed significantly larger oocysts and shorter EIP in twice-fed mosquitoes. In this study, we further investigated the influence of the second blood meal on the number of salivary gland sporozoites and evaluated the infectivity of these sporozoites. Salivary gland sporozoites were inoculated to a hepatocyte-derived cell line, HC-04, then the number of the liver stage parasites were counted at day 4 and day 7 post inoculation. With the same number of sporozoites per well, there was no significant difference in the number of infected hepatocytes between single and twice fed mosquitoes. From these results, we conclude that the additional blood meal not only accelerates the sporogonic development of the parasite within the mosquito, but also led to a higher number of sporozoites with unaltered hepatocyte infectivity.

6226

CLONAL TRANSMISSIBILITY AND FACTORS INFLUENCING HUMAN-TO-MOSQUITO TRANSMISSION OF ASYMPTOMATIC PLASMODIUM FALCIPARUM INFECTIONS OVER THE COURSE OF ARTEMISININ-BASED COMBINATION THERAPIES IN MALI

Leen N. Vanheer[1], Almahamoudou Mahamar[2], Emilia Manko[1], Sidi M. Niambele[2], Koualy Sanogo[2], Ahamadou Youssouf[2], Adama Dembele[2], Makonon Diallo[2], Seydina O. Maguiraga[2], Teun Bousema[3], Chris Drakeley[1], William Stone[1], Alassane Dicko[2], Susana Campino[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]University of Sciences Techniques and Technologies of Bamako, Bamako, Mali, [3]Radboud University Medical Center, University of Nijmegen, Nijmegen, Netherlands

Plasmodium falciparum malaria infections in high-transmission areas often consist of several distinct parasite clones. Few studies have directly investigated the complexity of Plasmodium falciparum malaria infections in both humans and the mosquitoes they infect. Molecularly undetectable circulating parasite clones were previously found to transmit to mosquitoes, leading to a high complexity of infection in mosquitoes post-feeding. This is likely due to asexual parasite clones being more abundant in peripheral blood than gametocyte clones, the parasite stages responsible for human-to-mosquito transmission. Artemisinin-based combination therapies (ACTs) are the first-line treatment for uncomplicated P. falciparum malaria and eliminate asexual parasites rapidly but have limited activity against mature gametocytes. It is unclear whether certain gametocyte clones persist longer than others post-ACT and whether there are any genetic characteristics that may influence their transmissibility. Using next-generation multiplex amplicon sequencing targeting heterozygous regions in Pfcsp and Pftrap, we analysed complexity of infection in human blood samples at six timepoints over the course of an ACT and in the midguts of the mosquitoes that became infected in membrane feeding experiments using the same blood material at these different timepoints. We found that after the elimination of asexual parasites by the ACT, parasite clones in human blood and cognate mosquito midguts largely match, although there is still some transmission of molecularly undetected circulating clones. In addition, data will be presented on genetic factors that may influence the level of transmission, such as molecular markers of drug resistance in Pfcrt, Pfmdr1, Pfdhps, Pfdhfr and PfK13 and genetic variability in the P. falciparum surface protein Pfs47 and the Pfs47 midgut receptor, by which parasites that express a compatible Pfs47 haplotype can evade the mosquito immune system.

6227

STUDY OF AN IMPORTANT GENE FOR SEXUAL REPRODUCTION OF PLASMODIUM BERGHEI AS A POTENTIAL TARGET FOR BLOCKING MALARIA TRANSMISSION

Leticia Morosini, Miriam Borges, Daniel Bargieri

University of São Paulo, São Paulo, Brazil

Through advances in genomics, proteomics and transcriptomics, currently studies analyzing these tools in search of new targets for potential drugs and vaccines are increasingly present in academia. Important targets to be studied are proteins involved in the life cycle of the protozoan Plasmodium, the malaria-causing agent, for potential vaccine formulations, such as vaccines with the transmission-blocking strategy. Recently, our research group identified a group of genes from P. berghei, conserved in different Plasmodium species, as essentials for the fertilization of the protozoan during its sexual reproduction phase. This project aims to deepen the studies on one of these genes and the protein it encodes, producing it recombinantly for antibody production, with the purpose of studying whether these antibodies would be able to inhibit protozoan fertilization, thus characterizing the protein as a potential candidate for the development of a transmission-blocking vaccine. Previously, a P. berghei ANKA knockout parasite was constructed for the studied gene. This knockout was carried out in a parasite previously constructed in the laboratory that has the luciferase gene linked to its ookinete formation process (PbOokluc). After obtaining the knockout, the characterization of the parasite phenotype was carried out through tests of parasitemia and gametocythemia curves, ookinete conversion and exflagellation assays. After these results, it was observed that the knockout parasite has a lower ookinete formation rate when compared to the Ookluc parasite. To obtain the recombinant protein for antibody production in mice, protein expression was performed in cultures of E. coli BL21 bacteria, and the protein is currently being purified so that it can be inoculated in mice for antibody production. After this step, it is expected to use these antibodies in P. berghei Ookluc parasites submitted to conversion assays to observe whether these antibodies are capable of inhibiting the sexual reproduction of the parasites.

EVALUATION OF THE ACTIVITY OF ESSENTIAL OILS OF HYPTIS SPICIGERA LAM. AND OCIMUM AMERICANUM L. IN THE MALARIA TRANSMISSION BLOCKING

W. Jedida M. Ouedraogo[1], Seydou B. Ouattara[1], G. Armel B. Yarbanga[1], Angela Traore[1], Christian Younga[1], Fulgence Da[1], Francois Hien[2], R. Serge Yerbanga[1], Jean-Bosco Ouedraogo[1]

[1]Institut des Sciences et Techniques (INSTech), Bobo-Dioulasso, Burkina Faso, [2]Institut de Recherche en Sciences de la Sante (IRSS), Bobo-Dioulasso, Burkina Faso

Medicinal plants are widely used, and many of them have already proven their therapeutic effects through scientific studies. African populations in developing countries rely greatly on medicinal plants for their healthcare. Malaria remains a global public health concern, with 247 million cases registered in the world in 2022 and 95% of which occurred in Africa (WHO, 2022). Control methods are developed continuously because of resistances observed with antimalarial drugs and insecticides. In the present study, we

assessed the antimalarial activity of essential oils from two medicinal plants of Burkina Faso.Hydrodistillation was performed on fresh leaves of Hyptis spicigera Lam. and Ocimum americanum L. collected in the Hauts-Bassins region of Burkina Faso. In a Direct Membrane Feeding Assay, lab-reared mosquitoes were fed with gametocytemic blood supplemented with the essential oils; control group only received plain gametocytemic blood. Seven days later dissection was performed, and oocysts prevalence and density were determined. H. spicigera had a density of 1 and a prevalence of 1.42%. O. Americanum had a density of 0.72 and a prevalence of 3.13%. As for the control group, density was 33.8 and prevalence was 54.5%. The transmission blocking activity was 97.17% and 92.22% for H. spicigera and O. americanum respectively.These results confirm the potential of medicinal plants in malaria control.

6229

MALARIA VECTOR NUTRITION PREDICTS RATE OF PLASMODIUM FALCIPARUM DEVELOPMENT AND INFECTIVITY

Philipp Schwabl[1], W. Robert Shaw[2], Shriya Anandjee[1], Maurice Itoe[1], Duo Peng[1], Angela Early[3], Flaminia Catteruccia[2], Daniel Neafsey[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Harvard T.H. Chan School of Public Health / Howard Hughes Medical Institute, Boston, MA, United States, [3]Broad Institute of MIT and Harvard, Cambridge, MA, United States

The malaria parasite Plasmodium falciparum must complete an intricate series of cell traversal and differentiation steps within the mosquito to enable transmission to the human host. This complex journey from the mosquito midgut to the salivary glands involves multiple parasite developmental stages and is fueled by mosquito nutritional resources that vary by environment. The rate of parasite development in the mosquito is a key determinant of malaria transmission because mosquito lifespan is short. Here we used single-cell RNA sequencing and in vitro hepatocyte infection to evaluate developmental progress of salivary gland sporozoites as a function of adult mosquito nutrition. Salivary gland sporozoites represent the final stage of parasite transcriptional and translational preparation for human liver infection. We specifically compared parasites developing in Anopheles gambiae mosquitoes provided with a single infectious blood feed (1BF) vs. an additional non-infectious blood feed 3 days post-infection (2BF). These treatments mimic natural mosquito gonotrophic variation. Our results demonstrate that transcriptional states of salivary gland sporozoites vary within and across treatments at 11 days post-infection. A marked transcriptional transition is observed during occupancy of the glands, and progress across this transition is significantly advanced in the 2BF treatment. 2BF sporozoites show significantly higher expression of genes associated with human infection whereas 1BF sporozoites show significantly higher expression of genes associated with earlier sporozoite functions. 2BF sporozoites also show upregulation of genes involved in lipid and fatty acid metabolism. Importantly, 2BF sporozoites show significantly higher rates of hepatocyte infection (1.9x rate of 1BF). Together, these results suggest that malaria parasites are not maximally effective at hepatocyte invasion upon initial arrival to the mosquito salivary glands, but undergo an additional maturation phase. Time to final parasite maturity also appears sensitive to mosquito feeding variability common to many malaria settings.

6230

PLASMODIUM FEMALE GAMETE SURFACE HSP90 IS A KEY DETERMINANT FOR MOSQUITO INFECTION

Sung-Jae Cha

Mercer University, Macon, GA, United States

Plasmodium female gamete surface HSP90 is a key determinant for mosquito infection Sung-Jae Cha1, Dingyin Tao1,2, Heather M. Kudyba3, Marcelo Jacobs-Lorena1, and Joel Vega-Rodriguez31 Johns Hopkins Bloomberg School of Public Health, Department of Molecular Microbiology and Immunology and Malaria Research Institute, 615 N. Wolfe St., Baltimore, MD, 21205, USA 2 Current address: National Center for Advancing Translational Sciences, National Institutes of Health, 9800 Medical Center Drive, Rockville, Maryland 20850, United States.3 Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD 20852, USA Abstract

Plasmodium fertilization is required for the development of the malaria parasite in the mosquito and is considered a prime target for strategies to block malaria transmission. Using phage peptide display screening we identified MG1, a peptide that binds to male gametes and inhibits mosquito infection, presumably blocking fertilization by competing with a female gamete ligand. Anti-MG1 antibodies bind to the female gamete surface and by doing so, inhibit oocyst formation in the mosquito. We determined that this antibody specifically recognizes HSP90 on the surface of Plasmodium female gametes. Our findings establish Plasmodium HSP90 as a potential target for the development of a transmission-blocking vaccine.

INVASION OF RED BLOOD CELLS BY PLASMODIUM MALARIAE: UNRAVELING INTRA-ERYTHROCYTE DEVELOPMENT AND MOLECULAR MECHANISMS

Francois Dao[1], Alejandro Marin Menendez[2], Abdoulaye Djimde[3], Arthur Talman[2], Laurent Dembele[3]

[1]MRTC-Parasitology/DERSP-FMOS/USTTB, Bamako, Mali, [2]IRD, Montpellier, France, [3]MRTC-Parasitology/USTTB, Bamako, Mali

The frequent low parasitemia in Plasmodium malariae natural infections, the common occurrence of co-infections with mainly P. falciparum, and the impossibility of long-term in vitro culture has limited the information available for this species. In particular, but not limited to, there are large gaps of knowledge on specific molecular mechanisms of red blood cell (RBC) invasion and on host-cell preference of differentially mature RBCs present in circulation. In this study we aim to address some of these issues using P. malariae parasites collected from infected individuals aged 1-14 years in Mali. Host cell preference was measured taking advantage of a fluorescently labelled anti-CD71 antibody and, both, a DNA and a mitochondrial dye. A robust assay that allows quantification of new invasions in vitro, permitted to characterize invasion phenotypes using enzymes, which differentially cleave receptors from the RBC surface, and also the blocking effect of antibodies against known essential and non-essential RBCs receptors in other Plasmodium spp (Basigin, CD55, Duffy Antigen, CD71, Band 3 and Glycophorin A, CR1 and Sema7A). Our results show this parasite displayed a clear preference for reticulocytes, opposite to current knowledge. Also, treatment of RBCs with different enzymes (i.e. neuraminidase, trypsin and chymotrypsin) showed a significant but not complete reduction in invasion with all enzymes tested. None of the three antibodies tested, some with known blocking effects in other Plasmodium spp, hampered RBC invasion.

THE ROLE OF THE PLASMODIUM FALCIPARUM ACETYL-COA SYNTHETASE IN GAMETOCYTOGENESIS AND TRANSMISSION

Robert Summers[1], Charisse Passaje[2], Barbera Forte[3], Madeline Farringer[1], Selina Bopp[1], Beatriz Baragaña[3], Jacquin C. Niles[2], Dyann F. Wirth[1], Amanda K. Lukens[4]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Massachusetts Institute of Technology, Cambridge, MA, United States, [3]University of Dundee, Dundee, United Kingdom, [4]The Broad Institute, Cambridge, MA, United States

Acetyl-CoA synthetase (PfAcAS) catalyzes the synthesis of acetyl-CoA, a key metabolite and histone acetylation donor in Plasmodium falciparum, the most lethal malaria parasite. Previous studies have shown that PfAcAS is essential for blood-stage growth and survival, and that specific

inhibitors of PfAcAS prevent growth by depleting cellular acetyl-CoA and disrupting histone acetylation. However, the role of PfAcAS in other parasite stages remains unknown. Here we investigated the function of PfAcAS in gametocyte and transmission stages using genetic manipulation, chemical inhibition, and functional assays. Using the NF54-iGP2 inducible gametocyte producing line, we generated highly synchronous gametocyte cultures to profile how PfAcAS inhibitors affect parasite viability and histone acetylation throughout gametocytogenesis. We found that inhibition of PfAcAS disrupted the development of early and late-stage gametocytes, and that histone acetylation was reduced in early gametocyte stages, consistent with previous observations in asexual-stage parasites. Using DDD9309, an optimized analogue of the PfAcAS inhibitor MMV019721 with improved biochemical and cellular potency (PfAcAS enzyme IC50 16 nM; 3D7 EC50 40 nM), we selected for resistance in the NF54-iGP2 line, and identified a novel T648A mutation in PfAcAS that conferred high level resistance to multiple PfAcAS inhibitors. We further characterized the ability of PfAcAS-T648A parasites to produce viable gametocytes and undergo transmission through mosquito stages of the parasite's lifecycle. Immunofluorescence assays showed that PfAcAS has a dynamic localization, changing from predominantly nuclear to cytosolic and back during gametocyte maturation, indicating that PfAcAS may perform multiple functions in gametocytes. Our study suggests that PfAcAS plays a role in the epigenetic regulation of gametocyte development, and reveals the essential role of PfAcAS in malaria parasite transmission stages. We propose that targeting acetyl-CoA biosynthesis could be a novel strategy to block malaria transmission.

MOUSE ERYTHROCYTE BASIGIN INTERACTS WITH PLASMODIUM YOELII ERYTHROCYTE BINDING LIKE PROTEIN

Takaaki Yuguchi[1], Bernard N. Kanoi[1], Hikaru Nagaoka[1], Toyokazu Miura[1], Daisuke Ito[2], Hiroyuki Takeda[3], Takafumi Tsuboi[1], Eizo Takashima[1], Hitoshi Otsuki[2]

[1]Division of Malaria Research, Proteo-Science Center,Ehime University, Matsuyama, Japan, [2]Division of Medical Zoology, Department of Microbiology and Immunology, Faculty of Medicine, Tottori University, Yonago, Japan, [3]Division of Proteo-Drug-Discovery Sciences, Proteo-Science Center, Ehime University, Matsuyama, Japan

Malaria merozoites invade host erythrocytes through multiple interactions between parasite and erythrocyte surface proteins. Erythrocyte-binding-like (EBL) proteins, type I integral transmembrane proteins released from the merozoite micronemes, are known to play an important role in the formation of tight junctions between the merozoite and the erythrocyte surface. In human malaria, Plasmodium falciparum encodes 4 EBLs (PfEBA175, PfEBA140, PfEBA181, and PfEBL1) and P. vivax 2 EBLs (PvDBP, PvEBP2). Therefore, it is difficult to elucidate the functions by the loss-of-function approach because they may compensate each other. In contrast, P. yoelii encodes only a single EBL protein, PyEBL, and a single amino acid substitution (C351Y) in the N-terminal cysteine-rich Duffy binding-like region 2 (R2) of PyEBL drastically changed the virulence of P. yoelii parasites suggesting the usefulness of P. yoelii for the functional discovery of EBL proteins. In this study, we sought to elucidate the erythrocyte receptor of PyEBL that mediates its role as an invasion ligand. First, using the eukaryotic wheat germ cell-free system, we developed a protein library consisting of 237 mouse erythrocyte surface proteins and screened the library with native PyEBL protein as a ligand using AlphaScreen technology. We found that PyEBL interacts with mouse basigin, an erythrocyte surface protein. Using surface plasmon resonance, we further confirmed that PyEBL-R2 is the binding region with basigin, and the C351Y mutation did not affect the binding capability. These results are consistent with previous results that the R2 of P. vivax and P. falciparum EBLs interact with their erythrocyte receptors. The identification of basigin as the putative PyEBL receptor offers new insights into the role of this molecule and provides an important base for in-depth studies toward developing novel interventions against malaria.

The prevalence of antibodies against sexual stage Plasmodium vivax parasites determines the success of transmission to mosquitoes, but their dynamics is not well characterized in homologous and heterologous recurrent infections. We evaluated the kinetics of transmissibility to mosquitoes and level of transmission blocking and enhancing antibodies among P. vivax infected patients (n=155) using direct membrane feeding assays (DMFAs) in 12 months follow up in Ethiopia. Of the 399 DMFAs done using 47,880 mosquitoes, 68% feeds were infectious with no difference between recruitment (67%, 169/252) and recurrent (70.7%, 104/147) infections. Of the feeds that involved serum replacement (n=146) using 23,993 mosquitoes, more feeds were infectious when naïve sera were used (80%) than feeds with patient's own sera (73%). Transmission reducing activity (TRA) >80% was observed in 16% (24/146) of these feeds. The mean oocyst density was higher in infected mosquitoes fed on naïve serum (42; 1-321) compared to autologous sera (21; 1-272; $p<0.001$). The proportion of infected mosquitoes associated with total (18S based qPCR) parasite ($\rho=0.32$; $p<0.001$) and gametocyte (sex specific RT-qPCR) densities ($\rho= 0.35$; $p=0.001$). Antibody responses against a panel of P. vivax gametocyte antigens are being quantified using ELISA. From a preliminary observation, antibodies against Pvs47, Pvs230 and Pvs25 were associated with reductions in mosquito infections and PvsHAP2 or Pvs47 antibodies were produced more likely in samples with TRA. The very high transmissibility of recurrent infections strengthens the need to implement radical cure strategies in P. vivax endemic settings. The sustained transmission blocking activity in recurrent infections hints the additional benefit transmission blocking interventions could add. Samples from patients at recruitment and recurrence were sequenced using short amplicon Next Generation Sequencing (NGS) using a panel of 100 P. vivax microhaplotype. We will apply a modelling framework that uses genotyping to determine the likelihood that recurrent infections derive from new (reinfection), recrudescent or relapse.

6235

A TWO PATCH MODEL FOR MUTASA AND NYANGA DISTRICTS IN MANICALAND PROVINCE ZIMBABWE INCORPORATING CLIMATIC CONDITIONS

Mandidayingeyi Hellen Machingauta, Silal Sheetal

University of Cape Town, Cape Town, South Africa

In Zimbabwe more than 50% of malaria cases are concentrated in Manicaland province, where seasonal malaria epidemics occur despite intensified control strategies. Understanding the local epidemiology of malaria, particularly diverseness across time and space is crucial to achieving control and elimination. Elimination and control efforts need to take cognisance of mobility patterns as well as climatic conditions as these can significantly influence prevalence and transmission of malaria. A two-patch model of non-linear differential equations for Mutasa and Nyanga district within Manicaland province is formulated and used to assess how variability in temperature and rainfall as well as mobility patterns affect the transmission dynamics of malaria in a population. The model is fitted using number of malaria cases, mean monthly temperature and rainfall data for the period 2005-2020. Sensitivity analysis using temperature and rainfall data highlighted that mosquito carrying capacity, and transmission

probability per contact for susceptible mosquitoes influence malaria transmission dynamics in the patches. The malaria burden within the two districts increases with increases in mean monthly temperature and mean monthly rainfall (|17-250C| and |32-110mm|) respectively. Numerical simulations reveal that mobility accounts for endemicity of the disease in both patches, in particular if biting intensity of the mosquitoes is high then infection prevalence increases with mobility. Incorporating variability in climatic conditions and mobility in the patch model helps forecast malaria transmission patterns and highlights which areas need interventions. The numerical simulations highlighted that perturbations as a result of major climatic changes also affect mobility patterns, therefore there is need to continually monitor and evaluate the implications of these changes.

Malaria is the deadliest mosquito-borne parasitic infection worldwide, with one parasite, Plasmodium falciparum (Pf), accounting for the majority of deaths, especially in Africa and Asia. Despite its tremendous impact on public health, much remains to be characterized in global populations of Pf, including existing structural variation among Pf genomes. Recent observations, based on whole genome sequencing data from Pf samples from Africa and Southeast Asia (SEA), suggest that the vector may have an underappreciated impact on Pf evolution. In particular, we have identified (nearly) fixed nonsynonymous SNPs in loci preferentially expressed during transmission-related stages of the life cycle. Now, based on whole genome assemblies for 19 Pf samples from countries in Africa and SEA, we have also identified fixed structural differences between African and SEAn Pf populations. AP2-G, a key transcription regulator of sexual stage commitment, harbors a 200 bp deletion at the 3' end of the gene in all African Pf samples, including the reference Pf3D7. This deletion spans the in-frame stop codon found in SEAn Pf strains, as well in outgroup Plasmodium species, resulting in a longer and quite different C-terminal AP2-G sequence in African strains. Here, we investigated if there are other genomic variants in allelic association with the AP2-G deletion, which could contribute to modulate its function. In addition to 4 additional genes containing fixed structural variants, there are 28 nonsynonymous SNPs, identified among 12 genes, in strong linkage disequilibrium (r2 >= 0.7) with the observed AP2-G deletion. These genes are enriched in biological processes such as responses to defenses of host. Most of these genes are primarily expressed in Pf sexual life-cycle stages. We are investigating possible interactions between these genes and AP2-G. Finally, several of these genes are transmission-associated loci targeted by vaccines currently in the developmental pipeline, including Pfs47 and the gene encoding TRP1, providing region-specific Pf transmission-associated haplotypes, which may be important to consider in vaccine formulations.

6237

DYNEIN HEAVY CHAINS IN PLASMODIUM FALCIPARUM DURING GAMETOCYTES DEVELOPMENT

Prem Prakash, Camilla V. Pires, Shulin Xu, Murrel Saldanha, John H. Adams

University of South Florida, Tampa, FL, United States

Plasmodium falciparum is the deadliest among the malaria causing parasites. The sexual conversion into the gametocyte and development (gametocytogenesis) is crucial step for the successful transmission of parasite in the mosquitos. Further, the gametocytogenesis is a response of the parasite to cope up with the continuous stresses that it faces during the asexual intra-erythrocytic development cycle (IDC) in the human host. In our previous genetic phenotype piggyBac mutagenesis screen we found that one of the Dynein Heavy Chains gene (DHC) Pf3D7_1122900, a microtubule associated protein, manifests the increased sensitivity to stress response pathways during IDC upon heat shock and Dihydroartemisinin (DHA) stress. Orthologs of these proteins known to act as the ATP dependent motor proteins on the microtubules for the cellular transportation of the cargos, positioning of the organelles and the structural integrity of the cells. However, these genes remain uncharacterized in the P. falciparum. Here we report the piggyBac screening for the gametocytogenesis and found that several piggyBac DHC mutants are involved in the induction of gametocyte conversion and the development. In order to characterize their functions, we used Lox-Pint mutagenesis and generated conditional Knock-out mutants for these genes. Dynein heavy chains and their associated proteins play an important role in the transport and structural integrity of the cells that is also an essential mechanism for the gametocytes to attain their specific falciform shape in order to get transmitted successfully. Therefore, functional characterization of this family would provide new drug targets to mitigate the malaria pathogenesis by inhibiting the transmission of parasite from human to mosquitos through breaking the survival chain of the parasite.

Halofuginone (HFG) is a potent antimalarial targeting the cytoplasmic proline-tRNA synthase of Plasmodium falciparum. We have previously demonstrated that resistance to HFG can be mediated through two distinct mechanisms: the Adaptive Proline Response (APR) and mutations in the active site of the target gene. In asexual parasites, the APR is characterized by accumulation of cytoplasmic proline that confers low level (20-fold) resistance to HFG by competing for binding the target protein. Whole genome sequencing identified frameshift and nonsense mutations in the major facilitator superfamily related protein 4 gene (pfmfr4, also known as ApiAT2) associated with the APR phenotype. Metabolic labelling experiments were used to demonstrate that during asexual blood-stages, MFR4 functions to export proline derived from hemoglobin degradation and biosynthesis from arginine. To understand whether HFG resistant parasites are transmissible, infectious bloodmeals containing drug-selected ΔMFR4 parasites were fed to Anopheles gambiae mosquitoes. ΔMFR4 parasites show no defect in infectivity to mosquitoes, but are dysfunctional in their development as oocysts. While ΔMFR4 parasites cannot complete development to sporozoites, a subset of the oocyst population demonstrates growth at a reduced rate. Previous work in the Plasmodium

berghei/Anopheles stephensi experimental system pointed to an essential role of MFR4 in transmission. Our data suggest that proline transport and metabolism play a critical, yet unknown role in the transmission stages of P. falciparum development, revealing a novel target for mosquito-based transmission blocking interventions.

A SINGLE FULL-LENGTH VAR2CSA ECTODOMAIN ELICITS HETEROLOGOUS FUNCTIONAL ANTIBODIES IN AOTUS NANCYMAAE

Almahamoudou Mahamar[1], Jonathan P. Renn[2], Bacary Soumana Diarra[1], Moussa Traore[1], Sidi Mohamed Niambele[1], Gaoussou Santara[1], Oulematou Ndiaye[1], Sekouba Keita[1], Oumar Attaher[1], Lynn E. Lambert[2], Sachy Orr-Gonzales[2], Alassane Dicko[1], Patrick E. Duffy[2], Michal Fried[2]

[1]Malaria Research & Training Center, Faculty of Pharmacy and Faculty of Medicine and Dentistry, University of Science, Techniques and Technologies of Bamako (USTTB), Bamako, Mali, Bamako, Mali, [2]Laboratory of Malaria Immunology and Vaccinology (LMIV), National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), Bethesda, MD, United States, Bethesda, MD, United States

Malaria caused by Plasmodium falciparum continues to be a global problem with devastating consequences. Pregnancy malaria is associated with poor outcomes including stillbirth, preterm delivery, and low birth weight. Placental malaria (PM) is caused by P. falciparum-infected erythrocytes that bind to the placental receptor chondroitin sulfate A (CSA) and sequester in maternal intervillous spaces. In first-time mothers, parasite sequestration in the placenta often induces a macrophage-rich inflammatory infiltrate associated with poor pregnancy outcomes. Women become resistant to pregnancy malaria as they acquire antibodies that target surface proteins expressed by placental parasites. VAR2CSA, a member of the PfEMP1 variant antigen family, is a surface protein of infected erythrocytes (IE) that mediates adhesion to CSA and is the leading target antigen for a vaccine to prevent PM. Here, we assessed the functional activity of antibodies raised against a recombinant full-length VAR2CSA ectodomain (NF54 variant). Plasma samples from Aotus (N=4) immunized with full-length VAR2CSA were tested in binding-inhibition assays that used freshly collected IE from 15 pregnant women in Ouelessebougou, Mali. All plasma samples inhibited IE binding to CSA (i.e., reduced the number of parasites bound >50%) in most isolates (range, 53-73% of isolates). These results suggest that a VAR2CSA vaccine using a single or limited VAR2CSA alleles can elicit broad heterologous functional activity.

6240

INITIAL EVALUATION OF THE PVS230D1-EPA CONJUGATE VACCINE CANDIDATE

Daming Zhu, Holly McClellan, Weili Dai, Alec Allee-Munoz, Timothy Daniel, Karine Reiter, Nicholas J. MacDonald, David L. Narum, Kelly M. Rausch, Patrick E. Duffy

Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Pvs230, a pre-fertilization gametocyte/gamete antigen of Plasmodium vivax, is a promising malaria transmission-blocking vaccine (TBV) candidate. Pvs230 is expressed by parasite gametocytes in the human host and displayed on the surface of gametes in the mosquito host. To increase immunogenicity, the recombinant, Pichia pastoris-expressed domain 1 of Pvs230 (Pvs230D1M) was conjugated to the recombinant, non-toxic Pseudomonas aeruginosa ExoProtein A (rEPA) in conformance with current good manufacturing practices (cGMP). In order to meet regulatory requirements prior to clinical trials, extensive evaluations of the conjugate must be conducted. In this study, the cGMP Drug Product Intermediate (DPI) Pvs230D1-EPA conjugate was evaluated by the following analyses: purity by visual inspection (appearance); limulus amebocyte lysate (LAL) for endotoxin; microbial enumeration tests for bioburden; general safety and rabbit pyrogenicity test; strength (protein content) by UV spectrum (A280) and BCA protein assay; identity by amino acid composition; pH; SDS-PAGE with Coomassie blue staining (migration pattern); Western blot using conformation-dependent monoclonal antibody 1H3 and an anti-exotoxin A polyclonal antibody; and integrity by SDS-PAGE, reverse phase ultra-performance liquid chromatography (RP-UPLC), size-exclusion ultra-performance liquid chromatography (SEC-UPLC) and size exclusion chromatography with inline multi-angle light scattering (SEC-MALS). Our results indicate the cGMP grade Pvs230D1-EPA meets regulatory requirements and is suitable for use in human clinical trials.

6241

SYSTEMS SEROLOGY OF PFSPZ VACCINE REVEALS IMPORTANCE OF NON-PFCSP ANTIBODY IMMUNITY IN LONG-LASTING PROTECTION

Jonathan D. Herman[1], Yonatan Zur[2], Wonyeong Jung[2], Nicole Muller-Sienerth[3], Gavin J. Wright[4], Douglas Laffenburger[5], B. Kim Lee Sim[6], Sumana Chakravarty[6], Robert Seder[7], Stephen L. Hoffman[6]

Malaria remains a major cause of morbidity and mortality across Sub-Saharan Africa as well as globally. PfSPZ Vaccine is a whole cell radiation attenuated Plasmodium falciparum (Pf) sporozoite (SPZ) vaccine that has demonstrated promising efficacy in multiple clinical trials. Previous work has suggested that liver resident CD8+ T cells are essential for long-last PfSPZ-mediated protection. Here we have applied high-dimensional antibody profiling to identify humoral correlates of long-lasting protection. Though Anti-PfCSP Ab titers and antibody-dependent complement deposition (ADCD) increase with PfSPZ vaccination and are associated with protection early on, their responses wane and are not central to long lasting-protection. Our machine learning and statistical methods showed a new role for non-PfCSP non-IgG and complement activity in PfSPZ-mediated long lasting protection and point to the importance of non-PfCSP functional antibody responses in pre-erythrocytic vaccine-mediated immunity.

6242

CHARACTERIZATION OF KENYAN PLASMODIUM FALCIPARUM FIELD ISOLATES FOR USE IN CONTROLLED HUMAN MALARIA INFECTION

Agnes Chelangat Cheruiyot[1], Dennis Juma[1], Redemptah Yeda[1], Farid Abdi[1], Edwin Mwakio[1], Benjamin Opot[1], Jackline Juma[1], Maurine Mwalo[1], Risper Maisiba[1], Raphael Okoth[1], Alexander Pichugin[2], Janette Moch[2], Timothy Egbo[3], Hosea Akala[1]

[1]KEMRI/USAMRD-A, Kisumu, Kenya, [2]Department of Genetics and Parasite Biology Malaria Vaccine Branch, Walter Reed Army Institute of Research, Walter Reed Army Research Institute USA, MD, United States, [3]United States Army Medical Research Directorate-Africa, Kenya (USAMRD-A, Kisumu, Kenya

Controlled human malaria infection (CHMI) is a critical tool for evaluating drug and vaccine efficacy in a controlled setting. However, CHMI studies have been conducted with limited number of parasite strains isolated from human more than 40 years ago. This could lead to false inferences due to lack of parasite diversity inherent in present-day natural infections. Only two unique cloned strains are available for use (NF54/3D7 from Africa and 7G8 from Brazil). To fill this gap this study is designed to identify, down select parasites sensitive to chloroquine (CQ), quinine (QN), atovaquone (AV), primaquine (PQ), artemether (AR), artesunic acid (AS), amodiaquine (AMQ), artemisinin (ART), halofantrine (HAL), and tafenoquine (TAF). Isolates should produce infective gametocytes and genetically diverse. A total of 56 individuals from WRAIRs 2454 protocol presenting symptoms of uncomplicated malaria were screened for blood borne pathogens before enrollment, and a total of 40 individuals were excluded. Immediate ex vivo

analysis was done for sensitivity testing and molecular analyses to confirm species composition, genotypes, gametocytes and drug resistance marker profile. Serum and plasma for n (16) was processed and sent to WRAIR for blood borne pathogen confirmatory testing. Of n=16, 10 were tested and had the following median drug concentration (IC50s) 14 ng/ml (7.946-14.78) for chloroquine, 29.04 ng/ml (21.71-57.17) for quinine, 4.955 ng/ml (3.631-6.173) for atovaquone, 870 ng/ml (622.6-900.1) for primaquine, 3824 ng/ml (1527-6569) for doxycycline, 5.796 ng/ml(3.941-8.531) for artemether, 3.627 ng/ml (3.299-6.829) for artesunic acid, 1.457 ng/ml (0.9395-1.666) for amodiaquine, 5.796 ng/ml (3.941-8.531) for artemisinin, 19.69 ng/ml (16.45-27.74) for halofantrine and 423.4 ng/ml (141.2-859.4) for tafenoquine. Of the 16 samples, 87.5% harbored gametocytes, 68.75% had falciparum only, and 12.5% had co-infection of either P. falciparum with P. malariae or P. falciparum with P. o.wallikeri respectively. These findings prequalify and support the identification of new isolates for consideration in future CHMI studies.

6243

CROSS-SECTIONAL ASSESSMENT OF FACTORS DRIVING PARTIAL VERSUS FULL UPTAKE OF RTS,SAS01 MALARIA VACCINE AMONG CHILDREN IN RARIEDA SUB-COUNTY, WESTERN KENYA, 2021 TO 2022

Victoria Seffren[1], Brian Seda[2], Oliver Towett[2], Nelli Westercamp[1], Julie Gutman[1], Simon Kariuki[2], Feiko O. ter Kuile[3], Aaron M. Samuels[1], Titus Kwambai[4]

[1]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [3]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]US Centers for Disease Control and Prevention, Kisumu, Kenya

Following the 2015 World Health Organization (WHO) recommendation, pilot implementation of the 4-dose RTS,S/AS01 (RTS,S) malaria vaccine began in western Kenya in September 2019 as part of the routine childhood immunization schedule at 6, 7, 9, and 24 months of age. We used data from a continuous Malaria Indicator Survey (cMIS), a cross-sectional survey conducted from November 2021-July 2022 in 847 households, to assess RTS,S coverage and uptake 2 years post-introduction in Rarieda sub-county. Of 148 children, 71 aged 12-23 mo and 77 aged 27-38 mo, 66% had a home-based vaccination record documenting vaccination status (12-23 mo: 72% and 27-38 mo: 60%). RTS,S1, RTS,S2, RTS,S3, and RTS,S4 coverage was 90.2% (95% CI: 78.5-96.7), 84.3% (95% CI: 71.4-93.0), 80.4% (95% CI: 66.9-90.2), and 26.1% (95% CI: 14.3-41.1), respectively. Corresponding mean age at vaccination was 6.6 (95% CI: 6.0-7.1), 7.7 (95% CI: 6.9-8.6), 9.9 (95% CI: 9.3-10.6), and 23.3 months (95% CI: 19.4-27.1). Benchmark measles vaccine coverage (dose 1 - RTS,S3; dose 2 - RTS,S4) was 88.2% (95% CI: 76.1-95.6) and 56.5% (95% CI: 41.1-71.0). Odds of being fully vs. partially RTS,S vaccinated (<3 doses by 23 mo and primary series only by 38 mo) did not differ significantly by gender, household wealth, caregiver education, or bednet use. Of children 12-23 mo, those who were the only child under 5yrs in the household were 9.6 times (95% CI: 1.5-190.9) more likely to have received all 3 RTS,S doses compared to those in households with more than 1 under 5 yrs. Of children 27-38 mo, those with measles dose 2 were 9.9 times (95% CI: 1.5-199.9) more likely to be fully vaccinated with 4 RTS,S doses vs. those without the 2nd dose. While not significant, those who were fully vaccinated with core EPI vaccines per WHO guidelines were more likely to be fully vaccinated with RTS,S (OR: 1.8 [95% CI: 0.2-10.6]). Our study found high uptake and moderate dropout for the primary series. RTS,S4 may face similar uptake barriers as other second-year of life vaccines. If RTS,S vaccination schedules are revised, understanding populations at greater risk for dropout can guide vaccination roll-out strategy to ensure optimal coverage.

6244

FEASIBILITY EVALUATION OF RTS,S/AS01 MALARIA VACCINE PILOT INTRODUCTION IN WESTERN KENYA: COVERAGE SURVEY RESULTS 30 MONTHS POST-INTRODUCTION

Nelli Westercamp[1], Dorcas Akach[2], Perez L. Siambe[2], Florence Wafula[2], Eunice Radiro[2], Isabella Nyangau[2], Victoria Seffren[1], Titus Kwambai[3], Simon Kariuki[2], Aaron M. Samuels[3]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Centers for Disease Control and Prevention, Kisumu, Kenya

RTS,S/AS01 (RTS,S) malaria vaccine was introduced in western Kenya in September 2019 through the World Health Organization-initiated pilot to evaluate the safety, impact, and feasibility of integrating the 4-dose schedule (at ages 6, 7, 9, and 24 months) into routine immunizations. Three large household surveys assessed RTS,S uptake of doses 1-3 among children aged 12-23 months, and dose 4 in children 27-38 months in 46 pilot sub-counties before (HHS1, July-October 2019), and 18 (HHS2, May-July 2021) and 30 (HHS3, April-June 2022) months post RTS,S introduction. RTS,S coverage was measured by vaccination cards, available for 86%, 88%, and 89% of children in HHS1, HHS2, and HHS3, respectively; or caregiver recall for those with no cards. In HHS3, the coverage for RTS,S doses 1-3 was 82.7% (95%CI 78.6-86.1), 78.1% (95%CI 73.7-81.9), and 68.9% (95%CI 63.9-73.6), respectively, with an improvement from HHS2 in coverage (dose 1-3: 78.6%, 71.4%, and 62.3%) and dropout rates (9.2% to 6.0% dose 1 to 2; 20.7% to 16.9% dose 1 to 3). RTS,S dose 4 coverage was 32.7% (95%CI 27.9-37.9), with 52.2% dose 3 to 4 dropout, and lower uptake than measles dose 2 (58.9% (95%CI 55.3-62.4)) given 6 months earlier. RTS,S coverage was lower among children not sleeping under a bednet the night before, compared to those who did (dose 1: 57.6% vs. 84.2%; dose 2: 55.1% vs 79.4%; dose 3: 46.9% vs. 70.2%; $p<0.05$); and in areas with indoor residual spraying (IRS), than areas without IRS (dose 3: 55.1% vs. 73.3%; dose 4: 10.6% vs. 40.1%; $p<0.05$). No differences in RTS,S uptake were noted by sex, caregiver's age or parity, or residence (urban vs. rural). Caregivers with secondary or higher education were 2.1 times (95%CI 1.5-3.1) more likely to bring their child for all 4 RTS,S doses than those with primary education only, and uptake increased with wealth. No negative impact of RTS,S introduction on other malaria (bednet use) and childhood interventions (vitamin A supplements, deworming), or uptake of other vaccines was observed 30 months into the pilot. Our study found that coverage of the first 3 RTS,S doses and the dropout rates improved over time, while low uptake of the fourth dose remains a challenge.

THE ADDITIVE VALUE OF RTS, S,AS01 MALARIA VACCINE IN REDUCING MALARIA INFECTION AMONG UNDER FIVE CHILDREN IN MALAWI

Christopher Chikhosi C. Stanley[1], Harrisson Msuku[1], Vincent S. Phiri[2], Tabither Kaunda[1], Lawrence N. Kazembe[3], Jobiba Chinkhumba[2], Atupele K. Tembo[2], Don P. Mathanga[1]

[1]Malaria Alert Centre, Kamuzu University of Health Sciences, Blantyre, Malawi, [2]School of Public Health, Kamuzu University of Health Sciences, Blantyre, Malawi, [3]Department of Statistics, University of Namibia, Windhoek, Namibia

The RTS, S/AS01 malaria vaccine was recently recommended by World Health Organization (WHO) for widespread use among under-five children in areas with moderate to high Plasmodium falciparum malaria transmission. As part of the Malaria Vaccine Implementation Program (MVIP), we estimated the additive value of RTS, S/AS01 in preventing malaria infection. We assessed prevalence of malaria in areas deploying: i) traditional mosquito nets, ii) Pyrethroid-piperonyl butoxide (PBO) or Interceptor G2 (IG2) nets only, iii) indoor residual spraying (IRS) only, vi) RTS, S/AS01 only, v) PBO/IG2 nets + RTS, S/AS01, vi) IRS + RTS, S/AS01. A total of 4,909 children aged 5-48 months were recruited for the survey. The mean age was 25 months (SD=11) and 2,456 (50.0%) were females. Out of the

enrolled children, 638 (13.0%), 1,256 (25.6%), 556 (11.3%), 323 (6.6%), 1,375 (28.0%) and 760 (15.5%) were from areas deploying traditional nets, with PBO/IG2 nets only, IRS only, RTS, S/AS01 only, PBO/IG2 nets + RTS, S/AS01 and IRS + RTS, S/AS01 respectively. Malaria prevalence was lowest in areas implementing PBO/IG2 nets + RTS, S/AS01 [4.8% (95% CI: 3.6%, 6.3%)], followed by PBO or IG2 nets only [5.4% (95% CI: 3.8%, 6.7%)], IRS + RTS, S/AS01 [13.8% (95% CI: 8.6%, 21.4%)], RTS, S/AS01 only [14.4% (95% CI: 4.6%, 37.2%)] then IRS only [23.2% (95% CI: 17.3%, 30.2%)] and highest in areas deploying traditional nets [25.2% (95% CI: 18.6%, 33.2%)]. To conclude, this survey has demonstrated that RTS, S/AS01 has substantial added value in reducing malaria infections when combined with existing standard vector control interventions such as the ITNs use or IRS. As malaria endemic countries are rolling out the RTS, S/AS01 malaria vaccine, policy makers and programmers should focus on promoting use of combined delivery of vector control interventions to rapidly reduce burden of malaria among children.

6246

RTS,S MALARIA VACCINE COMBINED WITH PYRETHROID-PIPERONYL BUTOXIDE-LONG-LASTING INSECTICIDAL NETS (PBO-LLIN) PROVIDES ADDED PROTECTION AGAINST PLASMODIUM FALCIPARUM INFECTION COMPARED WITH PBO-LLIN ALONE

Peter A. M. Ntenda[1], Alfred Matengeni[1], Lauren Cohee[2], Mark L. Wilson[3], Alick Sixpence[4], Noel Patson[1], Karl B. Seydel[5], Miriam K. Laufer[2], Clarissa Valim[4], Don P. Mathanga[1]

[1]Malaria Alert Centre, Kamuzu University of Health Science, Malawi, Blantyre, Malawi, [2]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, USA, Baltimore, MD, United States, [3]University of Michigan, Michigan, MI, United States, [4]Department of Global Health, Boston University, School of Public Health, Boston, MA, USA, Boston, MA, United States, [5]Department of Osteopathic Medical Specialties, College of Osteopathic Medicine, Michigan State University, East Lansing, Michigan, USA, Michigan, MI, United States

Both PBO nets and RTS,S vaccine have been shown to be independently effective against malaria in areas of high prevalence. However, the combined effects of these interventions have not yet been explored. The current study aimed to examine whether adding RTS,S to PBO nets is more effective in preventing Plasmodium falciparum infection compared with PBO nets alone. We analyzed data from 776 children aged 7 months to 10 years from a prospective community-based longitudinal study in Malawi. Index children aged 7-18 months received 3 doses of RTS,S, and PBO nets, while those aged 19 months to 10 years (siblings) received PBO nets only. Capillary blood samples were collected at enrollment (month 0), and at 2, 4, and 6 months thereafter, for detection and quantification of P. falciparum using qPCR targeting the 18s rRNA gene. The effect of adding RTSS+PBO nets compared to PBO nets only was estimated using multivariable generalized estimating equation models after adjusting for predictors including age. In total, 60% (469/776) of children received both PBO nets and RTS,S whilst 40% (307/776) received only PBO nets. In this analysis, all children contributed to 325 person-years of follow-up. There were 376 infection events/100 person-years at risk in the PBO nets alone group against 157 events/100 person-years at risk in the RTS,S+ PBO nets group. The adjusted incidence rate ratio (IRR) in children who had received only PBO nets was twice that of children who had received RTS,S+PBO nets (IRR: 2.11; 95% CI: 1.62-2.75). These results suggest that adding RTS,S vaccination to PBO nets intervention might be used to further reduce P. falciparum transmission and infection in areas where malaria is perennial.

6247

IMPACT OF RTS, S/AS01E VACCINATION ON PLASMODIUM SPECIES COMPOSITION IN INDIVIDUALS ENROLLED FOR AT BASELINE AND DURING THE SUBSEQUENT FOLLOW-UP PERIOD IN MALARIA ENDEMIC REGIONS OF WESTERN KENYA IN KISUMU COUNTY

Maurine Atieno Mwalo, Gladys C. Chemwor, Benjamin O. Opot, Raphael O. Okoth, Jackline A. Juma, Agnes C. Cheruiyot, Edwin W. Mwakio, Farid A. Salim, Risper N. Maisiba, Denis W. Juma, Hoseah Akala, Timothy Egbo

USAMRD-K, KISUMU, Kenya

RTS, S/AS01E is a recombinant protein-based malaria vaccine that elicits the production of antibodies against the Plasmodium falciparum (Pf) circumsporozoites, thereby blocking the establishment of the infection in the liver cells. In 2014, a phase 3 trial showed that RTS, S had high efficacy in infants and young children, and based on this, the World Health Organization recommended the vaccine roll-out of in selected regions of Africa. However, information on the potential of the vaccine to protect against the acquisition of non-Pf species, such as P. malariae (Pm), P. ovale curtisi (Poc), and P. ovale wallikeri (Pow), is limited despite the rising frequency of non-Pf species infections, which account for 25% of imported malaria cases worldwide.A total of 125 samples from African adults with sub-clinical PCR positive parasitemia in Kombewa, Kenya participating in a RTS, S vaccine efficacy study were characterized for Plasmodium species composition at enrolment versus subsequent follow up time-points. Concurrently, 153 samples were obtained from symptomatic individuals visiting Kombewa Sub County Hospital within the same catchment and characterized for species composition of the infections was established using rt-PCR at enrolment as well as upon subsequent infection detection. Infections containing Pf were most frequent among the symptomatic individuals enrolled from the same catchment, with 76.19% followed by P. malariae, with 27.38%, P. ovale wallikeri, 17.86% while P. ovale curtisi was least prevalent at 10.0%. Analysis of species composition for the samples from individuals who received vaccines at the initial timepoint and at subsequent time-points during follow-up visits is underway

6248

EFFICACY OF THE RTS, S/AS01E MALARIA VACCINE ADMINISTERED ACCORDING TO DOSAGE REGIMEN UNDER CONDITIONS OF NATURAL EXPOSURE IN AFRICAN CHILDREN AGED 5-17 MONTHS: INSIGHTS FROM EXTENDED GENOTYPING-BASED ENDPOINT RESULTS AND MALARIA INFECTION STATUS AT FIRST VACCINATION FROM A PHASE 2B RANDOMIZED CONTROLLED TRIAL

Angela M. Early[1], The MAL095 Study Group[2]

[1]Broad Institute of MIT and Harvard, Cambridge, MA, United States

A phase 3 trial showed moderate vaccine efficacy (VE) of RTS,S/AS01E against clinical malaria in African children when administered according to a 0, 1, 2-month (M) primary schedule (M012) with a 4th dose given at M20. We present initial results deriving from PCR-based genotyping endpoints of an ongoing phase 2b open-label, randomized, controlled trial (NCT03276962) evaluating efficacy of RTS,S in multiple full vs fractional (Fx) dose regimens under conditions of natural exposure. A total of 1500 children aged 5-17M were randomized (1:1:1:1:1) to receive RTS,S (2 full-dose and 2 Fx dose regimens) or a rabies control vaccine (M012). We evaluated two molecular endpoints: the time to the first new molecular infection, and the total number of new molecular infections, each during 32 months post-dose-1 and 24 months starting at 14 days post-dose-3, using Illumina-based amplicon sequencing of the CS C-terminus and a control antigen. As in a previous analysis with shorter follow-up periods, we observed significant VE, in the 26%-42% range (95% CI union, 11%-53%), against the first molecular infection for all 4 RTS,S regimens vs. control across both follow-up periods. VE against the first molecular infection was similar across the 4 RTS,S regimens, with no significant differences. Each RTS,S regimen significantly reduced the number of new

molecular infections. We also tested the hypothesis that VE of RTS,S might be reduced in participants with evidence of existing baseline infections at the time of first vaccination from microscopy and/or PCR amplicon data. Contrary to expectation, VE of RTS,S against the first infection was significantly higher (P=0.0015) in participants who were malaria-infected (67.8%; CI 50.5-79.0%) vs. uninfected (31.3%; CI 17.5-42.9%) at the first vaccination. Higher VE in baseline-infected participants could suggest new strategies for highly efficacious malaria vaccine development or implementation.

6249

THE EFFECT OF RTS,S, AND SEASONAL MALARIA CHEMOPROPHYLAXIS (SMC) ALONE OR COMBINED ON ANTIMALARIAL ANTIBODY RESPONSES

Katie Patterson[1], Seyi Soremekun[1], Kevin Tetteh[1], Issaka Zongo[2], Almahamoudou Mahamar[3], Daniel Chandramohan[1], Matthew Cairns Cairns[1], Rakiswendé Serge Yerbanga Yerbanga[2], Amadou Tapily[3], Fréderic Sompougdou[2], Djibrilla Issiaka[2], Charles Zoungrana[2], Koualy Sanogo[3], Alassane Haro[2], Mamamadou Kaya[3], Abdoul Aziz Sienou[2], Seydou Traore[3], Modibo Diarra[3], Ismaila Thera[3], Khalifa Diarra[3], Amagana Dolo[3], Irene Kuepfer[1], Paul Snell[1], Paul Milligan[1], Abdoulaye Djimde[3], Christian Ockenhouse[4], Opokua Ofori-Anyinam[5], Halidou Tinto[2], Issaka Sagara[3], Jean-Bosco Ouedraogo[2], Alassane Dicko[3], Brian Greenwood[1], Christopher Drakeley[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Institut des Sciences et Techniques/Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [3]Malaria Research and Training Center, University of Sciences, Technologies, and Techniques of Bamako, Bamako, Mali, [4]PATH, Seattle, WA, United States, [5]GlaxoSmithKline, Wavre, Belgium

The combination of the malaria vaccine RTS,S and seasonal malaria chemoprophylaxis (SMC) has been shown to have a significant reduction in malaria incidence in children up to 5 years old compared with either intervention delivered alone. However, it is likely interventions will effect the development of naturally acquired immunity to malaria; understanding this effect may help predict and mitigate any post intervention effects on incidence in children as they age. Dried blood spots were collected in November, the peak transmission season, in 2019 and 2020 from study children who had received the combination of RTS,S and SMC together or separately in Mali and Burkina Faso. Samples were assayed against ~ 30 malaria specific antigens classified into representing historical & recent exposure and protection associated. Continuous antibody responses were analysed using principal components analysis (PCA). As expected, responses to the RTS,S vaccine components were significantly higher in those that received the vaccine (linear regression coefficient 1.97 for RTS,S alone vs SMC P<0.001 & 0.00 RTS,S/SMC vs RTS,S alone p=0.99).This included antibody responses to MSP5 an 'off target' antigen response that has previously been associated with RTS,S vaccination. For other antigen groups, responses were typically higher in participants from Burkina Faso than those from Mali reflecting differences in malaria transmission intensity. Overall, responses showed broadly similar patterns: lowest in children receiving the combined intervention and highest responses in those that received the vaccine alone (e.g protective associated - linear regression coefficient 0.03 for RTS,S alone vs SMC P0.05 & -0.09 RTS,S/SMC vs RTS,S alone p<0.001). This most likely reflects the mode of action of the different study interventions. Preliminary data on antibody avidity suggest antigen specific differences that may be linked to the development of protective immunity. How meaningful these antibody responses will be determined by the ability of children in each arm to be naturally protected from malaria in an ongoing prospective study.

6250

ESTABLISHING RTS,S/AS01 AS A BENCHMARK COMPARATOR FOR NEXT-GENERATION MALARIA VACCINES IN THE TGPB-PFCSP MOUSE CHALLENGE MODEL

Yevel Flores-Garcia[1], **Emily Locke**[2], Randall S. MacGill[2], Bryan T. Mayer[3], Bhavesh Borate[3], C. Richter King[2], Fidel Zavala[1]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]Center for Vaccine Innovation and Access, PATH, Washington, DC, United States, [3]Vaccine Immunology Statistical Center, Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Mouse models using transgenic Plasmodium berghei sporozoite tgPb-PfCSP containing full-length P. falciparum CSP allow two assessments of efficacy: reduction in liver infection following IV challenge, and sterile protection against blood-stage infection following mosquito bite challenge. We introduce a clinically relevant benchmark for comparison of next-generation PfCSP targeted vaccines to the RTS,S/AS01E vaccine. We focus on reproducibility of antibody responses and functional activity in conjunction with robust statistical analyses. A 200-fold range of RTS,S was tested in a constant amount of AS01E adjuvant. Two or three doses were given intramuscularly at three-week intervals, with challenge two weeks after the last vaccination. Protection was highest with the three-dose schedule, but levels remained lower than those seen when potent anti-CSP mAbs, such as mAb317, are administered, indicating the range of this model is suitable for screening more potent vaccines. Induced sera anti-CSP antibody concentrations were also associated with activity: 141 µg/mL reduced liver infection by 50% relative to controls, whereas 300-350 µg/mL is required for 50% protection against blood-stage infection in the parasitemia model. These results provide guidance on using a mouse model of infection to compare vaccines against the only approved malaria vaccine to date. Accounting for assay variability, liver infection experiments are powered (80%) to detect a three-fold change in liver burden using at least eight mice per group and parasitemia studies are powered to detect a 35-40% improvement over three doses of RTS,S/AS01E using ten mice per group. With reasonable sample sizes, inter- and intra-assay variability remain within acceptable bounds for detecting improvement in vaccine function whether the result of greater levels or potency of the induced responses. This ability to compare advanced preclinical and clinical-stage CS-based vaccines to RTS,S/AS01 is now available to the broader malaria vaccine community.

6251

GENETIC PHYLOGENY OF DIARRHEAGENIC ESCHERICHIA COLI ISOLATED IN CHILDREN BELOW FIVE YEARS LIVING IN CLOSE CONTACT WITH FOOD ANIMALS, KISUMU COUNTY

Redemptah Yeda, George Makalliwa, John Gachohi, Gideon Kikuvi

Jomo Kenyata University of Agriculture and Technology, Nairobi, Kenya

Diarrheagenic Escherichia coli strains they cause diarrhea infection in children below five years and food animals. Focus of the study; understand the genetic phylogeny of diarrheagenic E.coli isolated in children below five years and that isolated from food animals in Kisumu County, to establish possibility of zoonotic transmission, and determine their antibiotic resistance patterns. Two hundred children samples and animal samples were collected and processed using traditional culture methods. The molecular identification of pathotypes was assayed using primer-specific polymerase chain reaction (PCR) targeting three virulence genes (lt, st, bfpA, eae, aatA and aaiC) related to three DEC pathotypes (EPEC, EAEC and ETEC). The antimicrobial susceptibility testing was carried out using the Kirby-Bauer disk diffusion method. Colonies from 156 study subjects (100 diarrhea children and 56 diarrhea food animals) were positive for E. coli isolates. Subsequent PCR detection discovered that 26% of children and 10.7% of diarrhea food animals' isolates were positive for one or more virulence genes typical of particular strains. Among those EAEC [(11%), (2%)] ETEC,

[(4%), (0%)] and EPEC [(3%), (8.9%) Of the identified E. coli isolates, about (4%%) were found to be mixed infections. ETEC/EAEC (2%) and EAEC/EPEC (2%) strains this were better detected in children with close contact with diarrhea food animals than children with no contacts. Most antibiotic resistances were obtained towards trimethoprim sulfamethoxazole (95.8%), tetracycline (91.7%), and ampicillin (91.6%). ninety percent of isolates were resistant to a minimum of three categories of antibiotics. Diarrheagenic E.coli is the key contributor of diarrhea in children below five years, there is risk of severe diarrhea from known pathogenic strains hence emergence of resistance narrows options of treatment. Sequencing of isolates is ongoing.

6252

CHANGES IN GROWTH OBSERVED IN DIFFERENT ANTHROPOMETRIC INDICES AT 90-DAY POST-DISCHARGE FOLLOW-UP AMONG CHILDREN AGED 2-23 MONTHS REQUIRING READMISSION COMPARED TO THOSE WHO DID NOT REQUIRE READMISSION

Md Farhad Kabir, Irin Parvin, MST Mahmuda Ackhter, Abu Sadat Mohammad Sayeem Bin Shahid, Tahmina Alam, Rina Das, Sharmin Khanam, Jannat Sultana, Sajeda Nasrin, Rumana Sharmin, Mehnaz Kamal, Md. Tanveer Faruk, Tahmeed Ahmed, Mohammod Jobayer Chisti

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

Due to availability of limited information on post-discharge growth follow-up among children requiring readmission, we sought to investigate whether post-discharge readmission at day-90 follow-up had any impact on growth in children aged 2 to 23 months. We conducted a case-control study and data extracted from “Antibiotic for Children with Diarrhea (ABCD)” trial which was a seven-country double-blind, randomized, placebo-controlled clinical trial. The Bangladesh site enrolled 1431 children aged 2 to 23 months who were dehydrated or severe stunted or moderately wasted or any combination of these. Among them, 145 children were readmitted to hospital (cases) within a 90-day post-discharge follow-up. Each cases were matched by age and sex to three controls (n = 435). Anthropometry of all children were measured at the time of enrolment and on the 90-day follow-up. The data were analysed using multivariate linear regression to assess the changes in growth at day-90 post-discharge follow-up. At 90 days of post-discharge follow-ups, the mean changes in growth among the cases using four anthropometric indices were found to be significantly reduced compared to the controls ($p<0.05$). After adjusting the potential factors, the anthropometric outcomes Δhaz (coef.-0.10, 95% CI -0.19, -0.01, p-0.036), Δwaz (coef.-0.22, 95% CI -0.32, -0.12, p-<0.001), Δwhz (coef.-0.21, 95% CI -0.35, -0.08, p-0.002) and Δmuac (coef.-0.15, 95% CI -0.28, -0.03, p-0.014) were found to have significant reduction of growth among the readmitted cases compared to their counterpart. In conclusion, the present study prevailed there was a significant reduction of growth in all anthropometric indices at day-90 post-discharge follow-up among children requiring readmission compared with those who didn`t require readmission. This finding underscores the importance of investigating the clinical and social risk factors of readmission that may help to design a post-discharge intervention that may further help to reduce the growth faltering by reducing post-discharge readmission.

6253

CLINICAL, SOCIO-ECONOMIC AND PATHOGENIC FACTORS OF WASTED AND OVERWEIGHT/OBESE UNDER-FIVE CHILDREN WITH DIARRHOEA: EXPERIENCE FROM AN URBAN HOSPITAL IN BANGLADESH

Md Ridwan Islam, Sharika Nuzhat, Jinat Alam, ASG Faruque, Tahmeed Ahmed

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Wasting (weight-for-height z score <-2 SD) and overweight/obese (weight-for-height z score >+2 SD) are two critical indicators of malnutrition. In recent years the burden of overweight (39 million) is increasing alongside a continuing problem of wasting, creating a “double burden” of nutrition-related health issues. Data are limited concerning the comparison of these two groups of under-five children with diarrhoea. Therefore, we aimed to compare the associated factors and outcomes of wasted children with overweight/obese children with diarrhea admitted to Dhaka hospital, icddr,b. Data from 15,795 children aged <5 years were extracted from the surveillance system of Dhaka Hospital between January 2012 and December 2021. After excluding the non-desired population (n=13,074), 2296 wasted and 425 overweight/obese children were analyzed. After adjusting age and sex, fever (aOR: 1.574, 95% CI:1.26,1.96, P<0.001), dehydration (aOR: 3.078, 95% CI:2.40,3.95, P<0.001), and use of IV fluid (aOR: 2.551, 95% CI:1.49,4.37, P=0.001) was more likely associated with wasted children compared to overweight/obese children. On the contrary father’s education (aOR:0.231, 95% CI:0.15,0.35, P<0.001), mother’s education (aOR: 0.260, 95% CI:0.16,0.42, P<0.001), antibiotic use before admission (aOR:0.520, 95% CI:0.39,0.69, P<0.001), use of sanitary latrine (aOR: 0.633, 95%CI:0.45,0.89, P=0.008), water purification (aOR: 0.737, 95% CI:0.60,0.91, P=0.004) were less likely associated with wasted children compared to their counterparts. Exposure to enterotoxigenic Escherichia coli (ETEC) (aOR: 2.603, 95% CI:1.12,6.04, P=0.026) was significantly associated with wasted children whilst rotavirus (aOR: 0.554,95% CI:0.37,0.83, P=0.004) exposure showed an opposite trend after adjusting age and sex. Clinical and microbiological presentations are different in these two nutritional groups of children with diarrhoea. This study may help the policy maker to establish better identification and management strategy for these vulnerable populations.

6254

TITLE: SOCIODEMOGRAPHIC AND CLINICAL DETERMINANTS OF DIARRHEA AFFECTED CHILDREN TREATED WITH ANTIBIOTICS EMPIRICALLY PRIOR COMING TO HEALTH CARE FACILITIES IN DEVELOPING COUNTRIES LIKE BANGLADESH

Mst Mahmuda Ackhter, Abu Sadat Mohammad Sayeem Bin Shahid, Irin Parvin, Tahmina Alam, Md Farhad Kabir, Mohammod Jobayer Chisti

icddr,b, Dhaka, Bangladesh

Scarcity of evidence, children are receiving antibiotics empirically in acute watery diarrhea. This study explores the sociodemographic and clinical determinants of children who received antibiotics in acute watery diarrhea. Secondary Data were extracted from the” Antibiotic for children with diarrhea” trial, Bangladesh site database. ABCD study was a randomized multi-country, multi-site, double- blinded, placebo -controlled trial, conducted on seven countries from 1st July 2017 to 10th July 2019 among the 2-23-month-old children. Among 35137 screened participants, total 13630 children received antibiotics prior seeking treatment in health facility. The prevalence of using antibiotics (52%) by literature review, 384 are randomly taken who received antibiotics as case. Control was selected 2 times more, matched with age and sex. Children treated with antibiotics has 3- 5 times/day,6.77%, less dehydration 0.8% than control, 10.6% and 3.4% respectively and also has higher proportion of no sign of dehydration (99%) rather than control (96%), showing statistically significant. Mother’s aged ≥30 Years, well-educated and having one parity treated their children with antibiotics more likely (57%, 88.54% and 87.24%) than Control (50.13%, 80.8% and 79.9%). Logistic regression summarized that the odds of case [aOR:3.5, (95%CI:1.23,9.96); p-value: 0.019] were more likely severely stunted. children passing stool > 10 in a day has more in case [aOR:1.67, (95%CI:1.01,2.76); p-value: 0.044.]. mother’s age ≥30 Years and well educated has strong association with case [aOR:2.12, (95%CI:1.39,3.23); p-value:<0.001], [aOR:2.79, (95%CI:1.63,4.79); p-value: <0.001.]. Mothers having two parity [aOR:0.62, (95%CI:0.43,0.90); p-value: 0.012.] were less likely treated their child with antibiotics. After adjusting all covariates, by logistic regression we found that case had hospitalized more [aOR:1.17, (95%CI:0.40,3.43); p-value: 0.772.] than control. Despite

well education and less parity of mother, they treated their young child with antibiotics without considering its severity, needs awareness at community specially caregivers.

6255

DIARRHEA IN A MILITARY SETTING: EPIDEMIOLOGY, ETIOLOGIES AND IMPACT OF THE DISEASE IN MILITARY PERSONNEL DEPLOYED AT CAMP LEMONNIER, DJIBOUTI

Rania Nada[1], Isabelle Nakhla[1], Rebecca Pavlicek[2], Alexandria Kesterson[2], Jae Dugan[3], Samuel Levin[1]

[1]U.S. Naval Medical Research Unit Number Three (NAMRU-3), Cairo, Egypt, [2]Naval Medical Research Command, Silver Spring, MD, United States, [3]U.S. Naval Medical Research Unit Number Three (NAMRU-3), Sigonella, Italy

Diarrhea has immense impact on military operational readiness. Overseas military personnel are at increased risk of exposure to enteric infections. We studied the epidemiology of diarrhea among US military personnel stationed at Camp Lemonnier, Djibouti, the primary US base of operations in the Horn of Africa. From May 2021 to March 2023, 201 diarrhea cases were enrolled, answered a questionnaire, and provided a stool sample. Samples were tested using FilmArray (FA) GI panel. For comparative purposes, a subset of 109 samples was evaluated using published qPCR assays for the detection of pathogenic E. coli, Salmonella, Shigella, Campylobacter, and norovirus. The majority (79%) of the 201 enrollees were males. Participants were Reserve (34%), Active Duty (33%), or National Guard (28%). Acute diarrheal episodes ranged between 1 to 13 days with an average of 4.2 days and a median of three days. Most reported symptoms were abdominal pain/cramps (87%), fatigue (76%), and malaise (73%). Signs of dehydration were observed in about one third, while impact on work performance was reported by 55% and ranged between reduced performance (48%) and loss of duty days (7%). FA identified at least one pathogen in 84% of cases and co-infections, up to 5 pathogens, in 56%. ETEC (54%), EAEC (47%), EPEC (29%), and STEC (24%), had the highest infection rates. Other pathogens ranged between 0.5% to 13% with V. cholerae in 3%. In the 109 samples tested by both techniques, 10 (67%) of 15 Shigella positive cases by qPCR were missed by FA; confirmation of qPCR data was performed using multiple assays targeting ipaH, virB, wbgZ, rfpB, and rfc genes. Of 29 STEC positive by FA, 21 (72%) were not O157 and were not detected by qPCR assays. For ETEC positives, CS1 (59%), CS6 (56%) and CS21 (53%) were the most identified colonization factors; CS1CS3CS21 was the common combination. The existence of multiple pathogens in more than half of the cases is a barrier against administration of successful treatment and prevention strategies. Also, data describes the epidemiology of diarrhea and its significant impact on work performance in a military setting.

6256

ASSOCIATION BETWEEN ENTEROPATHOGENS, THE GUT MICROBIOTA AND BIOMARKERS OF ENVIRONMENTAL ENTERIC DYSFUNCTION IN RURAL MALAWIAN CHILDREN

David Chaima[1], Lyson Samikwa[1], John Hart[2], Harry Pickering[2], Khumbo Kalua[1], Kenneth Maleta[1], Robin Bailey[2], Martin Holland[2]

[1]Kamuzu University of Health Sciences, Blantyre, Malawi, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Environmental Enteric Dysfunction (EED) is a subclinical condition of the gut that is characterized by changes in gut morphology and function due to chronic inflammation triggered by exposure to toxins and enteropathogens. There is limited data examining the link between exposure to enteric infections and EED. We aimed to estimate the prevalence of enteropathogens in rural Malawian children with signs of EED and examine associations with gut microbiota diversity. We used archival total genomic DNA samples extracted from stool, and corresponding demographic data from a nested cohort study conducted within the framework of a randomized controlled trial (NCT02047981). We analysed 102 baseline samples from children aged 1-59 months. We used 16S rRNA gene sequencing to generate data on gut microbiota and enzyme-linked immunosorbent assay to quantify selected fecal biomarkers of EED (myeloperoxidase, neopterin, and alpha-1 antitrypsin). Additionally, we customized an enteropathogen Taqman array card that could test for 20 different enteropathogens simultaneously, including viruses, bacteria, helminths, and protozoa. Out of the 20 enteropathogens tested, 11 were detected, with Giardia (45%) and adenovirus (24%) being the most common. Giardia carriage was highest in children between the age of 13-24 months. We found no significant differences in fecal levels of biomarkers of EED between children who tested positive and negative for any of the enteropathogens. Similarly, the microbiota alpha diversity index did not differ between the two groups of children. Our findings suggest that Giardia and adenovirus are prevalent enteropathogens in rural Malawian children and they may represent regular exposures in EED. However, despite their prevalence, we did not find any associations between the carriage of these enteropathogens and either gut microbiota diversity or biomarkers of EED. Given the potential health implications of these enteropathogens, it is critical to conduct more comprehensive studies to investigate the long-term consequences of their fecal levels on the gut microbiota and EED biomarkers.

6257

HYPERGLYCEMIA IN DIARRHEAL CHILDREN; CAN WE PREDICT CLINICAL STATUS?

Fardaus Ara Begum, Sharika Nuzhat, Abu Sayem Mirza MD Hasibur Rahman, MD Ahshanul Haque, MD Farhad Kabir, Paul Daru, Azharul Islam Khan, Sayera Banu, Tahmeed Ahmed, Mohammod Jobayer Chisti

International Centre for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

A high blood sugar level is indicative of various clinical disorders and has crucial implications. Our objective was to determine the relationship between clinical and laboratory alterations and hyperglycemia in diarrheal children under the age of five. This is a retrospective study using the electronic data system of Dhaka Hospital, icddr,b from March 2019 to December 2021. Out of 10828 diarrheal children under age five, 2167 were hyperglycemic (RBS >7.0 mmol/L), and 8661 (RBS 2.5 mmol/L–6.9 mmol/L) were normoglycemic children on admission. We analyzed two groups of children using STATA software. After adjusting age, sex and dehydration status, hyperglycemia was significantly associated with fever on admission [aOR = 1.16 (95% CI: 1.04, 1.29); p=0.006], anemia [aOR = 1.16 (95% CI: 1.01, 1.33); p=0.036], leukocytosis [aOR = 1.49 (95% CI: 1.27, 1.75); p<0.001], thrombocytosis [aOR = 1.39 (95% CI: 1.12, 1.73); p=0.003], hypernatremia [aOR = 3.48 (95% CI: 2.89, 4.18); p<0.001], hypokalemia[aOR = 1.85 (95% CI: 1.58, 2.18); p<0.001], raised creatinine [aOR = 2.69 (95% CI: 2.20, 3.30); p<0.001]. Death was more than three times higher among hyperglycemic cases than normoglycemic cases. Hyperglycemic children were less likely to be breastfed [aOR = 0.88 (95% CI: 0.78, 0.98); p=0.021], severely malnourished [aOR = 0.82 (95% CI: 0.71, 0.93); p=0.003]. Our examination demonstrated that hyperglycemia can be a significant risk factor for critical illness and aberrant electrolyte imbalances upon admission. Diarrheal children with hyperglycemia should have a proper evaluation and an intense monitoring system to avoid a fatal outcome.

6258

EPIDEMIOLOGICAL AND LABORATORY INVESTIGATION TO IDENTIFY SOURCES OF A COMMUNITY OUTBREAK OF CHOLERA

Gunaraj Dhungana[1], Pradip Gyanwali[1], Bishnu P. Marasini[1], Suman Pant[1], Shristi Karki[1], Anil Paudel[1], Meghnath Dhimal[1], Janak Koirala[2]

[1]Nepal Health Research Council, Kathmandu, Nepal, [2]Southern Illinois University School of Medicine, Springfield, IL, United States

An outbreak of cholera with 76 microbiologically confirmed cases were reported between June and September 2022, from Kathmandu, Nepal. Identification of risk factors are crucial for control and prevention of cholera.

We conducted an outbreak investigation utilizing both epidemiological and laboratory methods to identify potential sources. A descriptive epidemiological study was followed by an analytical study. A semi-structured questionnaire was used to capture hygiene behavior, education level, water source, latrine use, and environmental conditions of the cases. Water samples from community sources consumed by the cases were collected, filtered, and tested for the presence of Vibrio cholerae. Inspection of drinking water storage, decontamination and treatment methods, and waste management was conducted. To find asymptomatic V. cholerae carriers, stool samples from patient's immediate household members were collected and tested using rapid diagnostic test (RDT) and culture techniques using selective media. Total 283 water samples (262 household water, 21 river water) were collected for environmental assessment. Presumptive V. cholerae were isolated from 14 household water samples (7 tap, 5 well, 2 jar) of confirmed cases whereas none were isolated from river water samples and stool samples of family members. In household surveys, 27.3% reported recent diarrhea among family members, while 18.2% reported illness resembling cholera. Most of the affected individuals (70.8%) had consumed raw fruits within 5 days before illness. Common symptoms included body ache (29.7%), headache (25.2%) and nausea (15.3%). Only 38% households reported treating water before use (boiled 58%, filtered 26%). Hand hygiene using soap and water after toilet use was reported by 95.5%. Most households disposed of waste through waste collectors (75%), burnt (12%), or dumped in river (4.5%). Most households had private toilets (69%). In conclusion, environmental contamination of water source and untreated drinking water are the likely causes of this cholera outbreak.

6259

CHARACTERISTICS OF 2-23 MONTHS OLD CHILDREN WITH PROLONGED DIARRHEA COMPARED TO THOSE WITH ACUTE DIARRHEA AND THEIR IMPACT DURING POST-DISCHARGE FOLLOW-UP AT DAY 90

Irin Parvin, Abu Sadat Mohammad Sayeem Bin Shahid, Mst. Mahmuda Ackhter, Md. Farhad Kabir, Tahmina Alam, Mohammod Jobayer Chisti

icddr,b, Dhaka, Bangladesh

It is estimated that in 2019, about half a million under-5 children die annually due to causes attributed directly to diarrhea. A prolonged episode of acute diarrhea, defined as diarrhea lasting for 7–13 days, accounts for around 12 percent of all diarrheal episodes and over two-thirds of deaths associated with diarrhea. Here, we have compared the background characteristics of young children aged 2–23 months with acute diarrhea and prolonged diarrhea and also their impact at post-discharge follow-up at day 90. For this descriptive analysis, relevant data were extracted from the Antibiotics for Children with Diarrhea (ABCD) trial, which was a randomized, multi-country, multi-site, double-blind, placebo-controlled clinical trial. A linear regression model was used to compare the mean of the anthropometric outcome (ΔWLZ) across the two groups (prolonged diarrhea vs. acute diarrhea) in surviving children after adjusting for relevant covariates. A total of 8266 children were analyzed, of whom 756 had prolonged diarrhea and 7510 had acute watery diarrhea of <7 days duration. The overall prevalence of prolonged diarrhea was 9.15%. However, the highest prevalence was 15.7% in Pakistan, and the lowest was 1% in Tanzania. We observed that children aged 2–11 months who have more than three children under the age of 5 in their families and maternal illiteracy are at increased risk of developing prolonged diarrhea. At Day-90 follow-up, the children with prolonged diarrhea were found to have significantly lower weight for age Z score compared to those who suffered from acute diarrhea of <7 days duration, though their anthropometric indices were comparable at baseline. The mean± SD change in length-for-age z score from day 1 to day 90 was –0.09± 0.61 in the prolonged diarrhea group and –0.18± 0.60 in the acute diarrhea group ($p < 0.001$). There were 46 (6.1%) hospitalizations by day 90 in the prolonged diarrhea group compared with 335 (4.5%) hospitalizations in the acute diarrhea group ($p = 0.04$). Studies assessing the causes of prolonged diarrhea may be useful to predict children at risk and avert the long-term sequelae involving childhood growth.

6260

CLINICAL AND ENVIRONMENTAL EPIDEMIOLOGY OF VIBRIO CHOLERAE IN EASTERN DEMOCRATIC REPUBLIC OF THE CONGO, 2020-2022 (PICHA7 PROGRAM)

Christine Marie George[1], Lucien Bisimwa[2], Kelly Endres[1], Camille Williams[1], Jean-Claude Bisimwa[2], Presence Sanvura[2], Jamie Perin[1], Cirhuza Cikomola[2], Ghislain Maheshe[2], David Sack[1], Alain Mwishingo[2]

[1]Johns Hopkins Bloomberg School of Public Health, Maryland, MD, United States, [2]Université Catholique de Bukavu, Bukavu, Congo, Democratic Republic of the

Globally, there are an estimated 2.9 million cholera cases annually in cholera-endemic countries, which result in 95,000 deaths. The Democratic Republic of the Congo (DRC) is estimated to have 189,000 cholera cases each year, resulting in 7,100 deaths. The majority of cholera cases are found in cholera "hotspots", such as eastern DRC in the Great Lakes Region. However, there is limited longitudinal surveillance of cholera epidemiology in this region with most studies focusing on surveillance of suspected cholera cases rather than cases confirmed by bacterial culture. The objective of the Preventive Intervention for Cholera for 7 Days (PICHA7) program is to develop evidence-based water, sanitation, and hygiene interventions to reduce cholera in Eastern DRC. From March 2020 to December 2022, the PICHA7 program screened 644 diarrhea patients admitted to health facilities for cholera in urban Bukavu in South Kivu province of Eastern DRC. Diarrhea patient stool samples were collected within 24 hours of patient admission, and were analyzed by both rapid dipstick testing (RDT) using direct testing by the Crystal VC kit, and by bacterial culture for Vibrio cholerae. Both source and stored water samples were collected within 48 hours of patient admission for those patients confirmed to have cholera by RDT. Twenty six percent of diarrhea patients (166/644) had stool samples positive for cholera by RDT, and 21% (136/644) had stool samples positive for Vibrio cholerae by bacterial culture. The Crystal VC RDT by direct testing had moderate specificity and sensitivity compared to bacterial culture, 91% and 89% respectively. Nine percent of stored water samples (6/66) had detectable Vibrio cholerae by bacterial culture and 5% (3/64) of source water samples. These findings show a high prevalence of cholera among diarrhea patients presenting for treatment at health facilities in this cholera endemic setting in Eastern DRC and suggest that water is a transmission route for cholera infections in this setting.

6261

ACUTE FEBRILE ILLNESS IN PAKISTAN: ASSESSING CO-INFECTION OF MALARIA AND TYPHOID FEVER IN TERTIARY CARE FACILITIES IN KARACHI

Zoumana I. Traore[1], Afsheen Ghani[2], Zulfiqar A. Naqvi[3], Kausar A. Saldera[4], Furqan Hasan[5], Shamsul A. Qasmi[2], Claire J. Standley[1]

[1]Georgetown University, Washington, DC, United States, [2]Sky Blue Lab, Karachi, Pakistan, [3]Liaqat National Medical College & Hospital, Karachi, Pakistan, [4]Jinnah Postgraduate Medical Centre, Karachi, Pakistan, [5]National Institute of Child Health, Karachi, Pakistan

Acute Febrile Illness remains a major global public health threat. Historically, scholars have focused research on single disease etiologies, or exclude malaria-positive patients from further examination. To our knowledge, there have been few studies that investigated the co-infection of malaria and typhoid fever, and any related socio-demographic factors that might contribute to risk, in Pakistan. Furthermore, current diagnostic methods may represent a challenge in determining the exact etiology of acute febrile illness and can lead to misdiagnosis or improper differential laboratory diagnosis of these condition. Here, we present the result of a prospective cross-sectional study that evaluated the burden of malaria and typhoid fever single and co-infection. We also explored socio-demographic and cultural risk factors related to the occurrence of these two diseases. Overall, 550 participants (male:54%, female: 46%) aged from 2 to 80 years participated in our study and were screened using rapid diagnostic tests for typhoid and malaria. Among the study participants, 27.82% (153/550) were

typhoid positive (65 IgG and 153 IgM positive), P= 0.278, 95% CI [0.24-0.33]; and 4.91% (27/550), P=0.049, 95%CI [0.032-0.071] were malaria positive, constituting 6 cases of Plasmodium falciparum and 24 cases of P. vivax. The estimated co-infection rate for malaria and typhoid was 2.36% (13/550), P=0.24 95%CI [0.13-0.40]. Blood culture confirmed 49 typhoid cases (out of the 153 rapid test positives), of which 46 were identified as either extra- or multidrug resistant. The high prevalence of typhoid fever, and particularly drug resistant phenotypes, suggests the need for more research about risk factors contributing to typhoid transmission, and corresponding prevention strategies, in Pakistan. We observed a number of co-infections, highlighting the importance of comprehensive diagnostic testing to address multiple potential disease etiologies. We are conducting PCR testing and sequencing as next steps, which may help shed further light on risk factors and transmission dynamics.

6262

SIGNATURE OF EUKARYOTIC AND PROKARYOTIC GUT-MICROBIOME AMONG PATIENTS WITH GUT DISORDERS, SAUDI ARABIA

Ayman A. Elbadry, Reem Y. Al Jindan, Nehal M.M. Hosin, Abdulaziz Al Quorain

Department of Microbiology, College of Medicine, Dammam, Saudi Arabia

Gut disorders are important health problems globally and in Saudi Arabia. They include irritable bowel syndrome (IBS), gut immune-mediated inflammatory diseases (IMID) and non-IBS/IMID diseases. Gut microbiota includes prokaryotic microbiota (bacteria and viruses) and eukaryotic microbiota (one-cell animals, including protozoa, and fungi). Variations in gut microbiota have several outcomes which are linked to gut health and disease.Stool specimens were collected from 2109 patients attending the KFHU. Stool specimens were microscopically examined for the parasites and their genomic DNA was extracted. Protozoal DNAs were amplified using PCR assays and PCR products were cut by restrictive enzymes and sequenced to determine genotypes and subtypes. Amplicon sequencing of extracted DNA for gut bacteria (targeting the 16S rRNA gene) and gut eukaryotes (fungi) (targeting the internal transcribed spacer (ITS) sequence) was done for bacterial and eukaryotic profiling, through analysis of BION data. Bacterial and eukaryotic diversity was measured in correlation with patient-related data.There is an unclear increase in the IMID in studies individuals. There is a clear signature of gut eukaryotes and prokaryotes profile that was linked to IBS, IMID and non-IBS/IMID gut disorders. Other than Blastocystis, parasitic infections were very rare among the study population. Gut eukaryotes, mainly Blastocystis were much less prevalent in IMIDs patients and very rare in patients with bacterial colonization. Bacterial diversity was higher in asymptomatic patients. Gut microbiota showed a pattern of distribution among different age groups and sex. The Saudi community share a unique lifestyle, genetic exposure and ethnic background which may influence the correlation between gut microbiota and gastrointestinal disorders. Gut-associated eukaryotes may reshape bacterial diversity and virulence/outcome of gut pathogens, by influencing both gut health and gut disorders.

6263

USE OF BIOMARKERS TO MONITOR TRACHOMA PREVALENCE AFTER IMPLEMENTATION OF MORE FREQUENT THAN ANNUAL MDA IN MAASAI COMMUNITIES IN NORTHERN TANZANIA

Molly W. Adams[1], William E. Oswald[1], Veronica Kabona[2], Mabula Kasubi[3], Alistidia Simon[4], Jeremiah Ngondi[1], George Kabona[5]

[1]RTI International, Washington, DC, United States, [2]RTI International, Dar es Salaam, Tanzania, United Republic of, [3]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of, [4]Independent, Dar es Salaam, Tanzania, United Republic of, [5]Neglected Tropical Diseases Control Program – Ministry of Health, Dodoma, Tanzania, United Republic of

Through implementation of mass drug administration (MDA), Tanzania reduced prevalence of trachomatous inflammation - follicular (TF) and met the criteria to stop MDA in 60/69 endemic councils. The remaining 9 endemic councils have persistent or recrudescent TF. Four of these councils - Longido, Ngorongoro, Monduli, Simanjiro - are located in remote geographies and largely inhabited by migrant populations. These characteristics contribute to low MDA coverage and continued trachoma transmission. As such, Tanzania is implementing strategies to better reach these districts, including more frequent than annual (MFTA) MDA. To monitor TF during MFTA MDA and understand the impact of seasonal population movement on trachoma transmission, we implemented trachoma sentinel site monitoring (SSM) in two districts receiving MFTA MDA (Longido and Ngorongoro) and two receiving annual MDA (Monduli and Simanjiro). We surveyed 10 sites per district before each MDA, randomly selecting 50 children, 1-9 years per site. We conducted clinical grading for TF and collected ocular swabs to detect Chlamydia trachomatis (Ct) infection and dried blood spots (DBS) to detect antibodies to the pgp3 antigen. Quesionnaires were completed to measure acceptability of sample collection, household occupation, household migratory patterns, and water and sanitation access. After, samples were transported to Muhimbili Hospital for processing, using rapid real-time PCR nucleic acid amplified test and pgp3 lateral flow assay. Preliminary results prior to and following the first round of MDA showed TF prevalence for Longido and Ngorongoro changed from 23.0% to 10.8% and 14.7% to 17.0% respectively and TF prevalence for Monduli and Simanjiro changed from 19.2% to 33.0% and 3.7% to 0.4%. We will present prevalence of Ct infection and pgp3 antibodies across all three rounds at ASTMH. We will draw conclusions on TF prevalence at three points in a ~12-month period in districts receiving MFTA MDA verses annual MDA. We will provide evidence on the usefulness of alternative surveillance approaches in trachoma endgame districts where population migration may be affecting programming.

6264

QUALITY OF TRACHOMATOUS TRICHIASIS SURGERY IN 25 DISTRICTS OF SOUTHERN NATIONS NATIONALITIES AND PEOPLE'S AND SOUTHWEST ETHIOPIA REGIONS: SUMMARY FINDINGS OF 31 SURGICAL AUDITS IN 2022

Dawit Seyum Buda[1], Nigusie Fetene[1], Belay Bayissasse[1], Temesgen Kabeto[1], Tadesse Data[1], Doris Macharia[2], Alemayehu Sisay[1]

[1]Orbis, Addis Ababa, Ethiopia, [2]Orbis, New York, NY, United States

The success of trachomatous trichiasis (TT) surgery in preventing blindness depends on maintaining quality surgical outcome in the operated eyelids. Unfortunately, surgical failure of TT after surgery cannot be zero. World Health Organization suggests Integrated Eye Care Workers (IECWs) aim for a surgical failure of trachomatous trichiasis rate less than 10% at 3-6 month follow up. The main objective of TT surgical audit was to measure actual surgical outcomes and compares them to a desired quality standard and to determine the post-operative trachomatous trichiasis (PTT) rate for the selected IECWs at 3-6 months period. The TT surgical audit was carried out in 25 districts of Southern Nations Nationalities and People's and Southwest Ethiopia regions in 2022. It was conducted by experienced eye care workers from Secondary Eye Care and Tertiary Eye Care Units. Purposeful sampling technique and systematic sampling were used to select IECWs and operated TT cases for those IECWs who had greater than 40 cases at 3-6 months period respectively. For IECWs who had less than 40 cases, all the operated cases were included into the surgical audit. A total of 31 IECWs were audited. A minimum of 26 eyelids and a maximum of 50 eyelids were audited per IECW. A total of 1,207 eyelids (on average, 39 eyelids were audited per IECW) were audited, and of these, 50 eyelids had post op TT which makes the overall PTT rate 4.1%. However, the PTT rate ranges from 0% to 10.0%. In conclusion, all the audited IECWs had low PTT rate at 3-6 months post op period compared to the WHO standard. Overall, only 50 (4.1%) eyelids had post op TT at 3-6 months which remarkably met the WHO quality standard for TT surgical outcome.

6265

UTILIZING MOLECULAR DIAGNOSTICS TO SUPPORT THE TRACHOMA CONTROL PROGRAM IN NAURU

Carleigh Simone Cowling[1], Sue-Chen Apadinuwe[2], Anasaini Cama[3], Mitchell Starr[4], Sarah Boyde[5], Susana Vaz Nery[1]

[1]The Kirby Institute, Kensington, NSW, Australia, [2]Nauru Ministry of Health, Nauru, Nauru, [3]The Fred Hollows Foundation, N/A, Australia, [4]St. Vincent's Centre for Applied Medical Research, Sydney, Australia, [5]International Trachoma Initiative, Decatur, GA, United States

Trachoma is the world's leading infectious cause of preventable blindness, caused by the Chlamydia trachomatis bacteria. WHO simplified trachoma grading criteria are used to diagnose cases of trachomatous inflammation—follicular (TF) for field assessments of trachoma, including surveys to monitor progress toward elimination as a public health problem. Control of trachoma is through the SAFE strategy of surgery for trichiasis, antibiotic treatment for trachoma, promotion of facial cleanliness and implementation of environmental improvements. Recent reports of high TF in the absence of trichiasis, particularly in the Pacific region, suggest that TF presentations may be caused by infections other than C. trachomatis. Therefore, molecular diagnostic tools are required to confirm C. trachomatis infection to monitor the progress of eliminating trachoma as a public health problem. A baseline prevalence survey undertaken in 2019 found hyperendemic levels of trachoma in Nauru and 34.9% positive for C. trachomatis. Two rounds of MDA have been delivered, with the most recent survey reporting trachoma prevalence (TF) of 6.2%. In late 2022, the Nauru Ministry of Health, with the support of the Fred Hollows Foundation, Tropical Data and The Kirby Institute, undertook a trachoma impact study utilising the Tropical Data methodology. All consenting participants aged 1-9 years who were screened for TF were simultaneously asked to provide an ocular swab to be subsequently tested for the presence of C. trachomatis. DNA was extracted from the ocular swabs taken from one eye of the participants and tested for C. trachomatis via real-time PCR using the C. trachomatis/Neisseria gonorrhoeae (Ct/Ng) dual assay. Only C. trachomatis results were evaluated for this study. The samples of this study are still undergoing analysis and results are not ready at the time of this submission. This study will assess the impact of two rounds of MDA and whether trachoma continues to be a public health problem in Nauru. It is also anticipated that results will further support the growing supposition that molecular diagnostics is an important tool in trachoma elimination.

6266

NEARING ELIMINATION OF TRACHOMA AS A PUBLIC HEALTH PROBLEM IN AUSTRALIA

Carleigh Simone Cowling, Susana Vaz Nery, John Kaldor

The Kirby Institute, Kensington, NSW, Australia

Trachoma is an infectious disease of the eye, caused by Chlamydia trachomatis bacteria and is the world's leading infectious cause of preventable blindness. Australia is the only high-income country with endemic trachoma, found in First Nation populations in remote communities in central and northern Australia. The National Trachoma Management Program, initiated in 2006 follows national guidelines for the public health management of trachoma. The guidelines are based on the WHO SAFE strategy with key components being surgery for trichiasis, antibiotic treatment for trachoma, promotion of facial cleanliness and implementation of environmental improvements. First Nation children in remote communities previously identified at risk of trachoma are screened for clinical signs of trachoma, facial cleanliness, and treatment uptake. Data regarding trichiasis screening and surgery and implementation of health promotion activities are also collected at the community and regional levels by public health teams. These data are collated annually through programmatic reporting analysed to guide progress towards established targets. From 2007 to 2022, the number of remote communities identified as at risk of trachoma decreased from 229 to 84. The overall prevalence of trachoma in children aged 5-9 decreased from 14.3% to 2.2%. In 2007 65/123 communities screened reported trachoma prevalence above 5% compared to 30/84 in 2022. At the jurisdictional level, in 2007 prevalence's ranged from 13.5% to 15%, while in 2022 they were between 0% and 3.1%. With all jurisdictions now recording trachoma prevalence in at-risk communities below the WHO target of 5%, Australia needs to maintain these levels for 2 more years to be formally designated as having achieved elimination. Further, we need a plan to ensure trachoma prevalence continues to decrease, particularly in communities with ongoing endemicity, and elimination levels are sustained post-elimination

6267

OLDER AGE IN SUBARACHNOID NEUROCYSTICERCOSIS REFLECTS A LONG PRE-PATENT PERIOD

Fernando Nateros[1], Edith Saenz[2], Herbert Saavedra[2], Isidro Gonzales[2], E. Javier Pretell[3], Erika Perez[2], Yesenia Castillo[1], Javier A. Bustos[1], Hector H. Garcia[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurólogicas, Lima, Peru, [3]Hospital Nacional Alberto Sabogal Sologuren, Callao, Peru

Patients with subarachnoid neurocysticercosis (NCC) are usually older than those with parenchymal disease in all published series. Although it has been theorized that subarachnoid disease may have a prolonged incubation period, it is still unclear whether this age difference seen in clinical settings reflects an extended pre-symptomatic period or a delay in diagnosis owing to its insidious symptoms or poor healthcare access in endemic countries. Using available data from a large consecutive series of patients seen in a referral center in Lima, Peru, we compared the age at symptom onset between parenchymal and subarachnoid disease after adjusting for factors that could distort this relationship. Patients with mixed (parenchymal and subarachnoid) NCC or those with parenchymal cysts in different stages (viable and/or degenerating and/or calcified) were not included. From 408 eligible patients, we retrospectively compared the age at symptom onset in 140 patients diagnosed with parenchymal (pure viable or pure calcified) and subarachnoid NCC who had a confirmatory image available not more than two years after the beginning of symptoms. After controlling by sex and residence in rural endemic regions, the mean age at symptom onset in patients with subarachnoid disease was 13.69 years older than those with viable parenchymal disease (n = 140). Furthermore, our results showed consistency across all cut-off points of years between symptom onset and neuroimage evaluated in the total sample (n = 408). The design of this study allows an individual assessment of the contribution of the pre-patent period itself, adding evidence that this age difference seen on clinical grounds is not the product of delays in diagnosis, imaging, or access to care. Therefore, a long incubation period is a major contributing factor to older age at presentation in subarachnoid NCC.

6268

SEROPREVALENCE AND RISK FACTORS FOR NEUROCYSTICERCOSIS IN MEXICAN-AMERICANS IN STARR COUNTY, TEXAS

Megan M. Duffey[1], Elise M. O'Connell[2], Lauren M. Leining[3], Nina L. Tang[2], Craig L. Hanis[3], Eric L. Brown[3], Sarah M. Gunter[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [3]University of Texas School of Public Health, Houston, TX, United States

Neurocysticercosis (NCC) is an invasive cestode infection caused Taenia solium. It is a leading cause of epilepsy and chronic headaches in endemic areas including Latin America, Africa, and Asia. The epidemiology of NCC has not been well-studied in the United States to date, but small epidemiological studies have demonstrated NCC in populations in the US who have immigrated from endemic regions. There is a population living in Starr County, Texas along the Texas-Mexico border in whom the presence of other neglected tropical diseases has been demonstrated due to the intersection of poverty, climate, and high rate of immigration. Our study was a serologic survey and risk factor analysis of NCC in a pre-existing cohort of Mexican-Americans in Starr County, Texas. Using a triplex enzyme-linked immunoassay (ELISA) against NCC-specific antigens, we identified an

overall seropositivity to T. solium in 7.4% (45/605) in the cohort which likely represents a combination of parasite exposure, T. solium disease outside of the central nervous system, old calcified NCC, and viable or degenerating NCC. We used self-reported survey data and neighborhood-level variables to conduct a risk-factor analysis. Female gender, specific occupation and indoor versus outdoor occupation were found to be significantly associated with NCC seropositivity. Twenty-six of the 45 positive cases were employed in healthcare, caregiving, or social service (p 0.009), and 42 of the 45 were employed in an indoor occupation (p <0.001). These occupations could pose a risk for T. solium acquisition. A geospatial analysis of cases at the census tract level showed increased percentage of seropositivity centered around urban cities Rio Grande City and Roma, as well as smaller city La Grulla and census-designated place Alto Bonito. There is a critical need to investigate these seropositive cases of NCC and confirm the diagnosis with imaging, as well as conduct an epidemiological investigation to determine if disease transmission is occurring in Starr County.

THE POTENTIAL MECHANISTIC PATHWAYS LEADING FROM PARASITE INFECTION TO CHILDHOOD STUNTING

Isobel Litton Gabain[1], Anouschka S. Ramsteijn[2], Joanne P. Webster[3]

[1]Royal Veterinary College, Hatfield, United Kingdom, [2]Rowett Institute, Aberdeen, United Kingdom, [3]Royal Veterinary College, London, United Kingdom

In 2020, an estimated 149.2 million children under the age of 5 were physically stunted, defined as falling at least -2 standard deviations below the height-for-age World Health Organization (WHO) Child Growth Standards median. Stunting is a visible indicator of a deficient environment, the consequences of which include child morbidity and mortality, reduced and delayed neurocognitive development, and an increased risk of long-term chronic diseases. The underlying aetiology and pathophysiological mechanisms leading to stunting remain elusive, although parasites are thought to play a key role. Here, based on available studies, we present potential mechanistic pathways by which parasitic infection of mother and/or infant may lead to childhood stunting. The most well-recognised pathway to stunting is a 'vicious cycle' between deteriorating nutritional status and infection, which is evolving to encompass dysbiosis of the gut, local and systemic inflammation, alongside energetic, hormonal, and metabolic consequences. Anaemia, which is often presented as coexisting alongside stunting, may in fact be contributing. The bi-directional relationship between intestinal parasites and the microbiota in early life, and their combined effects, may also play a key role in stunting. Finally, epigenetic regulation of gene expression may link parasitic infections and poor gut health in early life to stunting. Guided by these plausible mechanisms, future multidisciplinary longitudinal studies and clinical trials should aim to elucidate the most influential factors, and synergies therein, that can lead to stunting, and ultimately towards finding solutions to successfully mitigate against it.

6270

PROTEOMIC AND IMMUNOINFORMATIC APPROACH TO IDENTIFY IMMUNE REACTIVE PROTEINS OF TAENIA SOLIUM CYSTICERCI FOR A POTENTIAL MULTIEPITOPE VACCINE CANDIDATE

Amit Prasad, Rimanpreet Kaur

Indian Institute of Technology Mandi, mandi, India

Metacestode larvae of Taenia solium is the causative agent for neurocysticercosis, which causes epilepsy. The unavailability of a vaccine against NCC for humans is a major cause for its widespread prevalence across the globe. Therefore, the development of a reliable vaccine against NCC is the need of the hour. We used proteomics along with immunoinformatics to develop a vaccine candidate. The immune reactive cyst fluid antigens (CF) of T. solium were identified by immune-blotting of two-dimensional gels with NCC patient's sera followed by Matrix-Assisted Laser Desorption-Ionization (MALDI) analysis. We performed a detailed proteomic study of these immune reactive proteins by using immune-informatics tools, identified the non-toxic, non-allergic, B-cell epitopes, and collected epitopes with the least sequence homology with human and other Taenia species. These epitopes were joined through linkers to construct a multiepitope vaccine. Different physiochemical parameters such as molecular weight (23.82kDa), instability (39.91), and aliphatic index (49.61) were calculated to ensure the stability of the linked peptides vaccine. The vaccine demonstrated stable interactions with different immune receptors like TLR4 and IgG confirming that it will effectively stimulate the host immune response. We anticipate that our designed B-cell linear epitope-based vaccine will show promising results in in vitro and in vivo assays. This study provides a platform that would be useful to develop other suitable vaccine candidates to prevent helminthic neglected tropical diseases in near future.

6271

NEUROCYSTICERCOSIS, NEUROLOGICAL DISEASE AND HIV IN THE EASTERN CAPE PROVINCE OF SOUTH AFRICA

Hélène Carabin[1], Humberto Foyaca-Sibat[2], Christine T. Benner[3], **Katrina Di Bacco**[1], Stephen Korsman[4], Lourdes de Fatima Ibanez-Valdez[5], Pierre Dorny[6], Sarah Gabriël[7]

[1]Université de Montréal, Saint-Hyacinthe, QC, Canada, [2]Walter Sisulu University, Mthatha, South Africa, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK, United States, [4]National Health Laboratory Service, Cape Town, South Africa, [5]Nelson Mandela Academic Central Hospital, Mthatha, South Africa, [6]Institute of Tropical Medicine, Antwerp, Belgium, [7]Ghent University, Ghent University, Belgium

Neurocysticercosis (NCC), caused by the infection with larval stages of the tapeworm Taenia solium, is a leading cause of epilepsy in the Eastern Cape Province of South Africa. Human Immunodeficiency Virus (HIV) is also endemic in the Eastern Cape. Limited literature is available about the epidemiology of co-infections with these two pathogens. This study investigated the difference in prevalence of NCC between patients with different HIV and neurological statuses in the Eastern Cape in 2009-2012. A total of 146 patients were recruited from two local hospitals and categorised into four groups according to HIV and neurological status (epilepsy or headache). Patients were asked to provide blood samples for detection of active infection with T. solium larvae using the B158/B60 antigen ELISA. Patients in groups with HIV or neurological symptoms were offered a CT-scan to detect NCC lesions. Of the 127 patients providing a blood sample, 8 (25%) tested positive for active cysticercosis in Group 1 (HIV+ and neurological disease status +), a percentage significantly higher than all other groups in which 2 (7%), 0 and 2 (7%) tested positive in Group 2 (HIV- and neurological disease status +), Group 3 (HIV+ and neurological disease -) and Group 4 (HIV- and neurological disease -), respectively. Of the 70 patients who underwent CT-scans, 10 (44%) in Group 1 (9 calcified and 1 active, transitory and/or calcified), 12 (41%) in Group 2 (11 calcified and 1 active), and 9 (52%) Group 3 (7 calcified and 2 active) had NCC lesions. There were no significant differences in imaging in the three groups. CD4 counts below 200 cells per cubic millimeter were also not associated with a higher prevalence with the AgELISA or CT imaging. Despite substantial limitations caused by the socio-political climate in South Africa at the time of this study, we demonstrate the relatively high prevalence of NCC in this population with mainly calcified cysts and an increased risk of active T. solium infection among patients with HIV and neurological symptoms. This study highlights the need for improved cost-effective tests, and for further research on this neglected disease in vulnerable populations.

6272

CONSISTENT MEASUREMENT OF PARASITE-SPECIFIC ANTIGEN LEVELS IN SERA OF PATIENTS WITH NEUROCYSTICERCOSIS USING TWO DIFFERENT MONOCLONAL ANTIBODY (MAB)-BASED ENZYME-LINKED IMMUNOSORBENT ASSAYS

Luz Toribio[1], Yesenia Castillo[1], Carolina Guzman[1], Gianfranco Arroyo[1], Cindy Espinoza[1], Herbert Saavedra[1], Javier Bustos[1], Pierre Dorny[2], Seth O'Neal[3], Hector Garcia[1]

[1]Center for Global Health, lima, Peru, [2]Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp-Belgium, lima, Peru, [3]School of Public Health, Oregon Health & Sciences, Portland State University, Oregon, USA, Portland, OR, United States

Diagnosis of human neurocysticercosis (NCC) is complex due to the lack of specific clinical manifestations, because of that the development of new techniques based in serology constitutes a major issue for public health since NCC is one of the principal causes of neurological pathology in most developing countries. Monoclonal antibody (mAb)-based enzyme-linked immunosorbent assay (ELISA) is a complementary diagnosis technique for NCC, which detects circulating parasite antigen (Ag) indicating the presence of viable infection and Ag levels also correlate well with parasite burden. We assessed agreement between two Ag-ELISA techniques for detection of NCC, our in-house TsW8/TsW5 Ag-ELISA based on T solium mAbs and the reference Ag-ELISA for NCC B158/B60 Ag-ELISA for measuring antigen levels in sera from 113 patients with subarachnoid, parenchymal and calcified NCC. Concordance was demonstrated evaluating limits of agreement (LoA) stratified by type of NCC. Both ELISA's detected 47/48 (97.8%) subarachnoid NCC cases. In parenchymal and calcified NCC, the B158/B60 Ag-ELISA detected 19/24 (79.2%) and 18/41 (43.9%) cases, while the TsW8/TsW5 Ag-ELISA detected 21/24 (87.5%) and 13/41 (31.7%), respectively. Parenchymal and calcified NCC obtained a perfect agreement (100%), indicating that all sample results were within the predicted LoA, while for subarachnoid NCC agreement was 89.6%. High concordance between assays was confirmed by Lin's concordance coefficient (LCC=0.97). Patients with viable parenchymal NCC (LCC = 0.95) obtained the highest concordance between assays, followed by subarachnoid NCC (LCC = 0.93) and calcified NCC (LCC=0.92). Antigen detection was highly concordant between assays, suggesting that the TsW8/TsW5 Ag-ELISA can be used as a new alternative tool for this purpose. The reliability of antigen detection assays could contribute to clarify the diagnosis of NCC when neuroimaging is not conclusive or available.

6273

MULTIPLEX BEAD ASSAY (MBA) FOR THE ASSESSMENT OF ANTIBODY RESPONSES DURING CYSTICERCOSIS IN EXPERIMENTAL INFECTED PIGS

Luz M. Toribio[1], Sukwan Handali[2], Sassan Noazin[3], Gianfranco Arroyo[1], Javier Bustos[1], Hector H. Garcia[1]

[1]Center for Global Health, Universidad Cayetano Heredia, Lima, Peru, [2]Division of Parasitic Diseases, Center for Disease Control and Prevention, Atlanta, GA, United States, [3]Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Taenia solium is the cause of cysticercosis and results in a neurologic disease (Neurocysticercosis, NCC) when the central nervous system is infected. Pigs are the natural hosts and the preferred animal model for NCC. Antibody responses are usually assessed by the serological gold standard, the Lentil-lectin enzyme-linked immunoelectrotransfer blot (LLGP-EITB) assay, but this format is technically challenging, not quantitative and needs complex antigen purification process to obtain the seven diagnostic glycoproteins. Our group has characterized 6 recombinant antigens that represent the main protein families in LLGP-EITB diagnosis. LLGP-EITB antibody patterns in NCC types and stages have been identified, but the response of simultaneous recombinant proteins has not yet been quantified. We developed an immunoassay based on magnetic microspheres (MBA) coupled with all 6 diagnostic recombinant antigens that allows a simultaneous quantification of antibody levels. We evaluated 162 serum samples from 18 pigs who were experimentally oral infected at 1 (n=6), 3 (n=6) and 5 (n=6) months-old, and were bled at 9 time points post infection (PI) until day 90PI. Necropsy data from the original study demonstrated more efficacious infections and more viable cysts in younger pigs, and more degenerated cysts in older pigs. In our 6 antigens-MBA, the high-performance antigens (rGP50, rT24H and sTs14) showed differences in their ability to differentiate pigs with different cyst viability conditions. rT24H and rGP50 detected antibodies in pigs with viable or no viable cysts and during all the course of infection, while sTs14 has a stronger response in viable infections. In addition, there was a progressive increase in the antibody response of rGP50 from day 21PI and from day 28PI for all the other antibodies. Pigs infected at 3 and 5 months-old showed a marked decrease from day 57PI until necropsy. Therefore, our new 6 antigens-MBA was a valuable tool to quantify and compare the simultaneous presence of antibodies against T solium recombinant antigens during the progress of the cysticercosis infection.

6274

LATERAL FLOW TEST FOR NEUROCYSTICERCOSIS - PRELIMINARY EVALUATION

Nadya Karaseva[1], Drew Miller[1], Elise M. O'Connell[2], **Andrew Levin**[1]

[1]Kephera Diagnostics, LLC, Framingham, MA, United States, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Neurocysticercosis (NCC) is an infection of the central nervous system with the cystic form of the pork tapeworm, Taenia solium. NCC accounts for approximately one third of all cases of seizures worldwide and is the most important neurologic disease of parasitic origin according to the World Health Organization. NCC affects over 25 million individuals in endemic, and increasingly non-endemic, regions. In the U.S., it has been found in 2% of seizure patients presenting to hospital emergency departments. Thus, NCC, an officially designated "neglected disease", is an underrecognized but significant global cause of morbidity and mortality. Serological testing has been useful in diagnosing NCC, either to supplement imaging or where imaging is not available. However, the gold standard EITB (enzyme immunotransfer blot) test developed by CDC is of limited availability, and no point-of-care tests for NCC are commercially available. We have developed a prototype lateral flow test for NCC based on recombinant versions of selected glycoprotein antigens used in the CDC EITB. The NCC lateral flow test was evaluated on a panel of 59 sera from NCC patients comprising both parenchymal and extraparenchymal cases, confirmed by imaging and clinical history, 200 sera from healthy blood donors and 38 sera from patients with other disease conditions. The overall sensitivity of the NCC lateral flow test on confirmed NCC sera was 98.3% (58/59) when read with a reader device, or 96.6% when read visually; the single undetected sample was from a patient with a single cyst that was marginally detectable by ELISA. Overall specificity was 99.6% (237/238), with a single false positive blood donor serum detected. The lateral flow assay appears to be a promising candidate for point-of-care use in diagnosis of NCC, subject to further clinical testing, which is underway.

6275

LATE POST-TREATMENT INFLAMMATORY RESPONSE AND RESIDUAL CALCIFICATION IN NEUROCYSTICERCOSIS

Laura E. Baquedano Santana[1], Noemi Miranda[1], Gianfranco Arroyo[1], Hector H. Garcia[2], Javier A. Bustos[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurologicas, Lima, Peru

Neurocysticercosis (NCC) is the leading cause of acquired epilepsy in developing countries. Cysts in the brain go from a viable resting state to complete resolution or calcification. Although it was previously believed that calcified lesions did not cause consequences, residual calcifications are associated with worse evolution of seizure disorders in NCC. We evaluated

the process of degeneration and calcification in the brain of pigs naturally infected with Taenia solium (n=15) and treated with 15 mg/kg albendazole and 25 mg/kg praziquantel orally. antiparasitic. The animals were divided into three groups of 5 animals each and the necropsy was performed at 4, 8 and 12 months post treatment. Inflammation and calcium deposits were evaluated by H&E, Masson's trichrome, Alizarin red, and Von Kossa stains, and immunomarkers such as GFAP, IBA, and neurofilament. The fifteen pigs showed 137 lesions, composed of 62 calcified cysts and 75 fibrotic lesions. The 4M group presented 13 calcified cysts, the 8M group had 35 calcified cysts, and the 12M group presented 14 calcified cysts. The 8M animals presented larger calcified lesions and greater intensity of calcium deposits compared to the other groups, as well as a greater amount of inflammatory cells that were distributed throughout the entire lesion. The 12M group has a greater number of fibrotic cells and has a greater area of fibrosis surrounding the lesion. This longitudinal study provides novel insight into the dynamics of inflammation and calcification and may contribute to the development of interventions aimed to reduce the likelihood of residual calcification.

6276

INFLUENCE OF EUKARYOTIC ENTERIC PATHOGENS ON THE GUT FUNGAL COMMUNITY IN MALIAN CHILDREN

Aly Kodio[1], Estelle Menu[2], Safiatou Doumbo[1], Drissa Coulibaly[1], Abdoulaye Kassoum Koné[1], Salimata Konaté[1], Lamine Tall[3], Abdoulaye Djimdé[1], Didier Raoult[3], Mahamadou Aly Thera[1], Stéphane Ranque[2]

[1]Malaria Research and Training Center, USTTB, Bamako, Mali, [2]Aix Marseille Université, Institut de Recherche pour le Développement, Assistance Publique-Hôpitaux de Marseille, Service de Santé des Armées, VITROME : Vecteurs – Infections Tropicales et Méditerranéennes, 19-21 Boulevard Jean Moulin, 13005 Marseille, Fr, Marseille, France, [3]Aix Marseille Université, Institut de Recherche pour le Développement, Assistance Publique-Hôpitaux de Marseille, Service de Santé des Armées, MEPHI : Microbes, Evolution, Phylogénie et Infection, 19-21 Boulevard Jean Moulin, 13005 Marseille, France., Marseille, France

Eukaryotic enteric pathogens (EEP) pose a worrying public health issue in tropical countries. Yet, the interactions between EEP and the gut fungal community remain poorly understood. To evaluate the impact of EEP on fungal community, we carried a case control study in Malian children living in Bandiagara, Mali. Cases were defined as children with at least one EEP and control as children without EEP. Sample stools were collected from 296 Malian children to explore gut fungal by qPCR and metagenomics targeting, rRNA ITS1 and ITS2 regions metabarcoding. The 100 (33.8%) children in whom no EEP was detected were considered as controls, and they were compared to: a) 196 (66.2%) children who had at least one EEP; b) 91 (30.7%) children who had only Blastocystis; c) 35 (11.8%) children who had only Giardia intestinalis; and d) 12 (4.0%) children who had another (<1% each) EPP. The gut fungal community structure was homogenous in each of the children's group. Linear size effect discriminant analysis highlighted five species, including Fusarium longipes and Penicillium caseilulvum, which were relatively more abundant in children with at least one EEP whereas 28, including Aspergillus sydowii and Microdochium colombiense were more abundant in controls. Regarding Blastocystis infected children, the abundance of Fusarium, Pyxidiophora, and Stereum genera was higher in infected children whereas Ogataea, and Allocryptovalsa were more abundant in controls. Regarding Giardia intestinalis, Sordariales and Mortierellales abundance was higher in infected children, whereas Agaricales and Capnodiales abundance was higher in controls. Overall, EEP do not significantly impact the global gut fungal community structure, but further studies are warranted to confirm our finding that taxa of the gut mycobiota are associated with susceptibility or resistance to specific EEP.

6277

HELMINTH INFECTION DRIVES REDUCED SERUM COMPLEMENT AND COMPLEMENT REGULATORY PROTEIN ACTIVATION IN INDIVIDUALS WITH COINCIDENT TYPE 2 DIABETES

Anuradha Rajamanickam[1], Bindu Dasan[1], Saravanan Munisankar[1], Pradeep Aravindan Menon[2], Fayaz Ahamed Shaik[1], Ponnuraja Chinnaiyan[2], Thomas B. Nutman[3], Subash Babu[1]

[1]NIRT-ICER, Chennai, India, [2]National Institute for Research in Tuberculosis, Chennai, India, [3]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Several clinical, epidemiological, and laboratory studies suggest that helminths could help mitigate the progression of Type 2 Diabetes Mellitus (T2DM) by modulating a host of pro-inflammatory pathways. Because complement hyperactivation has been observed in patients with T2DM and because the complement system can have unwanted consequences if not controlled appropriately (to prevent excessive activation), we sought to examine the effect of the helminth Strongyloides stercoralis (Ss) on the complement activation pathways in T2DM. We examined the circulating levels of the complement proteins C1q, C2, C3, C4, C4b, C5, C5a, and MBL and some of their regulatory components (Factor B, Factor D, Factor H, and factor I) in individuals with T2DM with (n=60; Ss+T2DM+) or without (n=58; Ss-T2DM+) concomitant Ss infection (n=58). Furthermore, we estimated the effect of anthelmintic therapy on complement pathway components 6 months after treatment. Complement levels of C1q (GM of 47.50 ng/ml in Ss+DM+ Vs 63.88 ng/ml in Ss-DM+; p=0.0065), C3 (GM of 125.5 ng/ml in Ss+DM+ Vs 150.1 ng/ml in Ss-DM+; p=0.0003), C4b (GM of 394.9 ng/ml in Ss+DM+ Vs 525.6 ng/ml in Ss-DM+; p=0.0024), C5a (GM of 1876 ng/ml in Ss+DM+ Vs 2319 ng/ml in Ss-DM+; p=0.0191), MBL (GM of 46.41 ng/ml in Ss+DM+ Vs 62.35 ng/ml in Ss-DM+; p=0.0016), Factor B (GM of 41.71 ng/ml in Ss+DM+ Vs 57.93 ng/ml in Ss-DM+; p=0.0010), and Factor D (GM of 38.40 ng/ml in Ss+DM+ Vs 56.11 ng/ml in Ss-DM+; p=0.0002) were significantly lower in Ss+DM+ compared to Ss-DM+ individuals. Following anthelmintic treatment the levels of C1q (an increase of 15%; p=0.0012), C4b (an increase of 11%; p<0.0001), and MBL (an increase of 11%; p=0.0201) were increased in T2DM+Ss+ individuals. Our data imply that Ss infection restricts complement activation and related pathological inflammatory process in T2DM individuals.

6278

DESCRIPTIVE AND PREDICTIVE ANALYSIS OF SOIL-TRANSMITTED HELMINTHIASIS IN SCHOOLCHILDREN OF TIERRALTA, CORDOBA, COLOMBIA

Ana Karina Nisperuza Vidal, Mayra Ligia Raciny Aleman, William Segundo Hoyos Morales, Maria Fernanda Yasnot Acosta

Universidad de Cordoba, Montería, Colombia

Soil-transmitted helminths (STH) infect more than two billion people worldwide, especially in developing countries located in tropical and subtropical regions. The department of Cordoba, Colombia is located in a region with a high prevalence of this parasitic infection. Given the great burden that STH represent in our community, their impact on the normal development of childhood, and the scarce studies with an integrative approach in our country, a descriptive and predictive study was carried out for the evaluation of STH. We sampled 70 children aged 4 to 17 years old from Santa Fe de Ralito School in the municipality of Tierralta, Cordoba. Epidemiological information was collected through surveys and the parasitological diagnosis was performed by Kato-Katz in stool samples. Blood samples were collected to measure hemoglobin and blood cells. A set of inflammatory, anti-inflammatory, and regulatory cytokines were measured by flow cytometry. The prevalence of STH infection was 55.7%. Trichuris trichiura was the most frequent parasite, being present in 92% of infected participants, either as mono-infection or co-infecting with Ascaris lumbricoides or hookworms. The hematological and immunological parameters showed suppression of the anti-inflammatory response with

a predominance of the regulatory cytokine Transforming growth factor-beta. The Monocyte chemoattractant protein-1 had higher levels in the infected participants. Interferon-ɣ-inducible protein-10 was higher in the ones co-infected with two or more parasites. These findings suggest an attenuated immune response against STH, with effectors mechanisms to protect the host's tissues but failing in expelling the parasites. Finally, using the epidemiological data, a statistical predictive model of STH infection was designed with good performance (accuracy: 0.714) as a pilot tool for the prevention of these pathologies at the community and rural levels.

6279

TRICHURIS TRICHIURA INFECTION ASSOCIATED WITH AN INCREASED RISK OF PLASMODIUM FALCIPARUM INFECTION AMONG POPULATION LIVING IN BATA DISTRICT, EQUATORIAL GUINEA

Gertrudis Ribado Meñè[1], Maxmillian G. Mpina[2], Alejando Lopelo Bolopa[3], Elizabeth L. Nyakarungu[2], José Raso Bijeri[3], Antonio Martin Elo Elo[4], Florentino Abaga Ondo[4], Guillermo A. García[5], Wonder P. Phiri[5], Mohamed Ali[2], Jean Claude Dejon Agobé[6], Ayola Akim Adegnika[7], Salim M. Abdulla[2]

[1]National University of Equatorial Guinea, Malabo, Equatorial Guinea, [2]Ifakara Health Institute, Dar-es-Salaam, Tanzania, United Republic of, [3]Laboratorio de Investigación de Baney, Baney, Equatorial Guinea, [4]Equatorial Guinea Ministry of Health, Malabo, Equatorial Guinea, [5]MCD Global Health, 8403 Colesville Rd, MD, United States, [6]Centre de Recherches Médicales Lambaréné, Lambaréné, Gabon, [7]Institut für Tropenmedizin, Universität Tübingen and German Center for Infection Research, Tübingen, Germany

Sub-Saharan Africa is known to be endemic for Plasmodium and Soil-Transmitted helminth (STH) infections, where both diseases very often occur in the same host. In the case of co-infection, studies report either a worse or a beneficial effect of STH species on plasmodium infection. The objective of the present analysis was to evaluate the effect of STH infection on malaria in the continental region of Equatorial Guinea, a central African country where such data are lacking. We performed a cross-sectional study between October 2020 and January 2021 in Bata district. Venous blood was collected for Plasmodium infection testing, using mRDTs while stool samples were collected for the diagnostic of Ascaris lumbricoides, Trichuris trichiura, and hookworm infections using Kato-Katz technique. A general linear model was used to assess the association between Plasmodium and STH infections. A total of 340 participants were included in the study with a mean (SD) age of 24.5 (23.7) and 1.22 female-to-male sex-ratio. The prevalence of Plasmodium infection was 52% (95%CI: 46 - 58) while the prevalence of any STH was 60% (95%CI: 55 - 65). The prevalence of Plasmodium and STH parasites co-infection was 37% (95%CI: 31 - 42). Assessing the association with Plasmodium infection, a statistically significant association was found at bivariable analysis for A. lumbricoides (cOR=1.71; 95%CI: 1.11 - 2.66, p-value=0.01) and T. trichiura (cOR=2.64; 95%CI: 1.69 - 4.16; p-value<0.001). After multivariable analysis adjusting for age, sex, and STH species, the association with Plasmodium infection remained statistically significative only for T. trichiura infection (aOR=2.03; 95%CI: 1.23 - 4.16; p-value=0.006). Our results reveal a high prevalence of Plasmodium and STH parasites co-infection in the district of Bata, Equatorial Guinea, where both diseases are highly prevalent and where T. trichiura infection increases the risk of Plasmodium infection. This result calls for more investigation of STH and malaria comorbidity, and more attention on the overlapping of both infections for tailored control programs of those two infections in the country.

6280

INTESTINAL PARASITIC INFECTIONS AND ASSOCIATED RISK FACTORS, KNOWLEDGE, ATTITUDE AND PRACTICES IN CALABAR, CROSS-RIVERS STATE, NIGERIA

Onyinye M. Ukpai

Michael Okpara University of Agriculture, Umudike, Nigeria

The prevalence of intestinal parasitic infections, associated risk factors, knowledge, attitude and practices among residents of two LGAs in Calabar, Cross-Rivers State, Nigena was determined. A total of 600 persons who gave their consent to be part of the study made up of 356 females 59.33% and 244 males 40.67% within different age-groups had their faecal samples examined using the formol-ether concentration technique. Structured questionnaires which sought information on socio-demographic data of respondents, risk factors and KAPs regarding IPIs were administered. The results revealed that 321 persons 53.5% were infected with one or more parasites. Ascaris lumbricoides. Entamoeba coli, Entamoeba histolytica, Taenia spp, Hookworm and Trichuris trichiura were the parasites observed. Mixed infections occured 5.83%. More females.53.6% than males 53.2% were infected. Infection was highest in the age group 50-59-years 58.11%, the unemployed 78.8%, persons with no formal education 64.8%, the widows 67.0%, those who did not wash their hands after toileting 94.19%. The highest infection rate occured among the Nsidung community. In terms of risk factors and KAPs, those who used stream 76.6% and rivers 74.3% recorded high prevalences of infection. Those who used the bush and streams as toilets recorded high infection rates of 76.6% and 73.4% respectively. Many knew about IPIs 81.17%. Mode of transmission was attributed to ingesting improperly cooked food 48.33%, infected water 10.33%, Skin penetration 8.33%. Many went to the hospital/ clinic for treatment 49.0%, while some resorted to self-medication 24.5% and use of herbs 10.34%. The Government should show political will by acting now and invest in NTDs. Health education becomes paramount. There is need to progress toward reduction of infection through the implementation of Water, Sanitation and Hygiene (WASH) intervention policy. All should act together to bring an end to these IPIs ravaging our communities in various nations.

6281

MOLECULAR CHARACTERIZATION OF A NOVEL GHANA STRAIN OF NECATOR AMERICANUS HOOKWORMS

Lisa M. Harrison[1], Emma Allen[1], Dickson Osabutay[2], Kelly Hagadorn[1], Santosh George[1], Claudia F. Gaither[3], Kaylee Herzog[4], Adalgisa Caccone[3], Joseph Fauver[4], Michael D. Wilson[2], Michael Cappello[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]University of Ghana, Accra, Ghana, [3]Yale University, New Haven, CT, United States, [4]University of Nebraska, Omaha, NE, United States

Laboratory passage of an African strain of Necator americanus hookworms has been sustained through 9 passages in outbred hamsters using larvae (L3) cultivated from human study subjects in Beposo, Ghana. Initial cutaneous infections of 2-day old hamsters were conducted in parallel with subcutaneous (SQ) infections of 21-day old weanlings, with animals provided ad libitum water containing dexamethasone. Subsequent passages were sustained in weanling hamsters by SQ infection. Fecal egg excretion was detected as early as 45 days post infection (PI) and continued beyond 150 days PI. Amplification of β tubulin genomic DNA sequences spanning resistance associated SNPs revealed wild type loci with intronic heterogeneity in 20 adult worms recovered from the initial (F0) hamster passage. Egg hatch assays revealed that the field strain showed comparable benzimidazole sensitivity to an established laboratory strain of Ancylostoma ceylanicum. In silico analysis of an N. americanus reference genome was used to develop methods for amplification of di, tri and tetranucleotide microsatellite repeats of 100, 200, 300 and 400 base pair fragment sizes. Of the 40 loci evaluated using 20 (F0) adult worms, 21 loci showed reliable amplification of the expected size, while 15/21 loci deviated from Hardy-Weinberg equilibrium (p< 0.05). PCR-amplification of COX1

mitochondrial DNA sequences from 20 (F0) adult worms revealed that the Ghana strain is distinct from previously characterized isolates from China and Brazil. A full mitochondrial genome was reconstructed from a single adult worm using long-read sequencing on the Oxford Nanopore MinION. A maximum-likelihood phylogenetic analysis using full mitochondrial genomes further demonstrated the Ghana strain is distinct from N. americanus samples from China and Togo. These data provide the first in vivo, in vitro and genomic analysis of a Ghana strain of N. americanus successfully adapted from humans to an animal model. Use of these methods and the resulting reagents will accelerate the development of geographically targeted therapeutics, vaccines and advanced diagnostics for use in West Africa.

6282

ASSOCIATED SOCIOECONOMIC AND DEMOGRAPHIC FACTORS WITH SOIL-TRANSMITTED HELMINTHIASIS IN FIVE PROVINCES IN GABON

Luice Aurtin Joel James, Noé Patrick M'Bondoukwé, Jacques Mari Ndong Ngomo, Reinne Moutongo, Denise Patricia Mawili Mboumba, Marielle Karine Bouyou Akotet

Université des Sciences de la Santé du Gabon, Owendo, Gabon

Soil-transmitted helminthiases are Neglected Tropical Diseases endemic in Central Africa including Gabon. Populations living in remote areas had a lack of water supply and live in poor hygienic conditions. These populations are not access to anthelminthic drug due to isolation caused by the absence of passable roads. In the aim to help the Parasitic Diseases National Control Programme in Gabon to reach the objective to control Soil-transmitted Helminthiasis until 2030, an epidemiological study was performed in five provinces according to the urbanization level to identifying risk factors. A cross-sectional study was conducted in five provinces in Gabon according to the urbanization between December 18th, 2018 to July 10th, 2019. Socioeconomic and demographic data were recorded in a standardized case report form. After explanations of the fecal collection to participants, samples were analyzed using Merthiolate-Iodine-Formaldehyde coloration and concentration techniques. Data were analyzed by descriptive statistics and Chi squared test. In total, 201 volunteers were included in the study with a sex ratio of 0.71 and a median age of 24.0 [6.0 - 51.5] years. Nearly 60.0% of them lived in rural areas (59.7%; n = 108/181). The proportion of helminth carriage was 11.9% (24/201) with Ascaris lumbricoides, Trichuris trichiura and Necator americanus detected respectively in 7.5 (15/201), 6.5 (13/201) and 1.0% (2/201) of samples. The only association Ascaris lumbricoides + Trichuris trichiura was found in 6/201 participants (3.0%). The factors presenting an association with the infestation by soil-transmitted helminths were the residence in a rural environment (p=0.0012), the level of primary education (p=0.001), the consumption of drinking water (p=0.02), use of toilets outside the main residence (p = 0.05) and use of modern toilets (p=0.04). In conclusion, soil-Transmitted Helminthiases are found in more than one tenth of the study population. Sensitization of the populations and Water, sanitation and Hygiene must to be implemented in rural area where the prevalence was higher.

6283

THERAPEUTIC EFFICACY OF MEBENDAZOLE AGAINST HOOKWORM INFECTION AMONG SCHOOL CHILDREN IN BAHIR DAR ZURIA DISTRICT, NORTHWEST ETHIOPIA

Woyneshet Gelaye Yalew[1], Sissay Menkir[2], Destaw Damtie[2], Hiwot Tadesse[3], Pedro Emanuel Fleitas[4], Wendemagegn Enbiale[3]

[1]Bahir Dar University, College of Medicine and Health Science; Bahir Dar University, Institute of Biotechnology, Bahir Dar, Ethiopia, [2]Bahir Dar University, College of Science, Department of Biology, Bahir Dar, Ethiopia, [3]Bahir Dar University, College of Medicine and Health Science, Bahir Dar, Ethiopia, [4]Barcelona Institute for Global Health (ISGlobal), Hospital Clínic - Universitat de Barcelona, Spain; Universidad Nacional de Salta, Instituto de Investigaciones de Enfermedades Tropicales/CONICET, Oran, Salta, Argentina

Soil-transmitted Helminths (STHs) are widely distributed in tropics and subtropics. Although MDA programs remain the cornerstone for controlling STHs, constant monitoring of benzimidazole resistance in areas where albendazole or mebendazole are periodically given is warranted to detect early rising of resistance in human STHs, prompting interventions to control this emergence in an early stage before genotypic and phenotypic resistance is widespread. This study was conducted to evaluate the efficacy of single-dose mebendazole against hookworm infection in school children. An open-label, single-arm trial was conducted in 4 primary schools from Bahir Dar Zuria district, Northwest Ethiopia from February, 2021 to March, 2022. Stool samples were collected and screened using double slide Kato Katz smear microscopy from 499 participants. A total of 132 hookworm-positive participants were treated with single-dose mebendazole (500 mg). Follow-up was done 21 days after treatment on 115 participants. Statistical analysis was performed by SPSS version 23 and R software version 4.2.1. P-values < 0.05 were considered statistically significant. Out of 132 participants, 50.8% participants were females. The mean age of the participants was 9.98 ±1.8. The mean egg counts per gram stool at baseline and after treatment (95% CI) were 180 (120, 251) and 68 (49, 91) respectively. The cure rate and egg reduction rate (95% CI) were 36.5% (28.3, 45.6) and 62.1% (59.2, 63.7) respectively. None of the variables considered for predicting cure were found statistically significant. The therapeutic efficacy of single-dose mebendazole against hookworm infection is below the WHO recommendation. Therefore; single-dose mebendazole should not be given as preventive chemotherapy against hookworm infection and another treatment regimen should be considered.

6284

DEVELOPMENT AND EFFICACY OF VARIOUS PAN-HOOKWORM VACCINE TARGETS

Hanchen Li[1], Nicholas Cazeault[1], Florentina Rus[1], Qian Ding[1], Duy Hoang[1], Erich M. Schwarz[2], Jeffrey Chicca[1], Carli Garceau[1], Jane Homan[3], Amy M. Weeks[4], Dante Zarlenga[5], Wenbin Tuo[5], Gary R. Ostroff[1], Raffi V. Aroian[1]

Over 500 million people worldwide suffer from hookworm infections and disease. Despite years of concerted effort at deworming campaigns, hookworm infections remain prevalent due to imperfect anthelmintic efficacies and ease of reinfection. Development of a pan-hookworm vaccine would significantly impact hookworm disease by limiting primary infection and mitigating reinfections. Here we describe the identification and testing of potential targets suitable for vaccine development using two distinct approaches. First, we are using proteomics, transcriptomics (tissue-specific), immunomodulation, comparative bioinformatics, and immunoinformatics to identify >30 hookworm vaccine targets. To date, in addition to our previously published CP1, we have identified at least one other vaccine antigen that shows provides some level of reproducible protection against hookworm infection. Studies are on-going with additional antigens. Second, we are using hookworm extracts of various sorts and stages and have identified two specific conditions that provide a very high level of infection. Current efforts are focused on identification of protective antigens in these mixtures. Here we will present an update on all of these efforts that are making excellent progress towards a protective hookworm vaccine.

NEW CURE FOR SOIL-TRANSMITTED HELMINTH INFECTIONS

Qian Ding, Kelly Flanagan, Duy Hoang, Nicholas Cazeault, Hanchen Li, Florentina Rus, Ernesto Soto, Gary R. Ostroff, Raffi V. Aroian

University of Massachusetts Chan Medical School, Worcester, MA, United States

Gastrointestinal nematodes (GINs; alternatively soil-transmitted helminths or STHs), most notably, hookworms, whipworms, and Ascaris, are nematodes that infect more than 1.5 billion of the poorest people and are amongst the leading causes of morbidity worldwide. For decades, infections by STHs have been treated with small-molecule anthelmintic drugs, the heavy use of which has often selected for drug-resistance or recalcitrance. Bacillus thuringiensis crystal (Cry) proteins are the most widely used biological insecticides in the world and are nontoxic to vertebrates. We have shown that Cry proteins, in particular Cry5B, are highly effective against a broad range of free-living and parasitic nematodes that infect plants and animals. Here, we discuss several new Cry proteins, CryH18, CryH1, and CryH13. CryH18 is highly active against C. elegans and is able to kill C.elegans resistant to Cry5B. We cloned CryH18 into our IBaCC (Inactivated Bacterium with Cytosolic Crystal) expression system. IBaCC takes advantage of dead bacteria to safely deliver recombinant Cry proteins. Here, we report Cry18H IBaCC is toxic in vivo against A. suum, Ancylostoma ceylanicum hookworms, and Heligmosomoides polygyrus bakeri infections. We are also expanding studies on CryH1 and CryH13, both of which have been shown to be highly active against A. ceylanicum infections in vivo. We hypothesize that we might be able to control GINs using Cry18H at a single dose or in combination with different cry proteins to combat GIN resistance and increase clinical efficacy.

6286

EFFECT OF SOIL-TRANSMITTED HELMINTH INFECTIONS ON THE CYTOKINE BALANCE IN CHILDREN FROM AN ENDEMIC AREA IN MONTERÍA - CÓRDOBA - COLOMBIA

Mayra Raciny - Aleman[1], María Fernanda Yasnot Acosta[1], Ana Rodriguez Fernandez[2]

[1]Cordoba University, Monteria, Colombia, [2]New York University, New York, NY, United States

Helminth infections can result in a strong immunoregulatory activity that affect the capacity of the host, mainly children population to develop co-infections, as well as being a risk factor in events such as asthma and atopy. The effect of these infections on the balance of pro- and anti-inflammatory cytokines in children from an endemic area in Córdoba - Colombia was measured. An analytical observational study was carried out, where seventy (70) school children were selected and studied and grouped into two groups (infected and control) and an epidemiological survey was carried out. Stool samples were processed by the Kato Katz method for identification and quantification of soil-transmitted helminths and blood plasma was used for flow cytometric quantification of cytokines and chemokines. The prevalence of STH was 56% (44.3-67.6); 77% (63.7-90.2) of the infections were mono infections and the remaining percentage were poly infections with at least two STH species. The intensity in most cases was moderate. When comparing cytokines and chemokines between the groups, TNF-α (P=0.0431) and IFN-γ (P=0.0484) had significant differences in both groups, for the chemokine MCP-1, the median values of the control group were significantly higher than that of the infected group (P=0.001). The anti-inflammatory profile cytokine TGF-β1 in the infected group had higher plasma concentrations than in the control group (P=0.0005). For IL4 and IL10, plasma concentrations were slightly higher in the control group than in the infected group, but there were no statistically significant differences between them; as was the case for TGF-β1, where the infected group had higher plasma concentrations than the control group. These data suggest that the STH infections presented by children in this endemic area have a behavior of chronic asymptomatic infections, established with a pattern of overdispersion and with a predominance of immune response with an anti-inflammatory and regulatory profile, apparently generated by TGF-β1.

6287

INTESTINAL PARASITE INFECTION AND RISK OF CONCOMITANT CERVICO-VAGINAL INFECTIONS IN THE PERUVIAN AMAZON

Paul C. Holden[1], Sory Vasquez Alves[2], Neusa Vasquez Alves[2], Xiaofan Huang[3], Charles Minard[3], Patti E. Gravitt[4], Robert H. Gilman[5], Eva H. Clark[6]

[1]Department of Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA, United States, [2]Asociación Benéfica PRISMA, Lima, Peru, [3]Institute for Clinical and Translational Research, Baylor College of Medicine, Houston, TX, United States, [4]Center for Global Health, National Cancer Institute, Rockville, MD, United States, [5]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [6]Department of Medicine, Section of Infectious Diseases, Baylor College of Medicine, Houston, TX, United States

Intestinal parasite infections, including helminths and protozoa, remain an important public health concern in tropical low- and middle-income countries, such as Peru, where cervico-vaginal (CV) infection rates are also high. As they establish chronic infection in the human gut, intestinal parasites must regulate the host's immune system to ensure their long-term survival, potentially impacting the host's defense against other pathogens. This cross-sectional study explored the relationship between intestinal parasite and CV co-infections, specifically bacterial vaginosis (BV) and Trichomonas vaginalis (TV) in 30–50-year-old Peruvian women. We enrolled 120 women undergoing routine cervical cancer screening in Iquitos, Peru, between August 2022 and February 2023. Participants provided demographic, clinical, and risk factor information, underwent testing for HPV, HIV, syphilis, chlamydia, BV (via Nugent score), and TV (via wet mount), and submitted specimens for stool ova and parasite microscopy. We used logistic regression to evaluate whether parasite infection was associated with BV or TV co-infection. Of 108 participants, 54.6% had intestinal parasite infection (9.1% (9/108) helminth [88.9% (8/9) Ascaris and 11.1% (1/9) hookworm] and 50.9% (55/108) protozoa [98.2% (54/55) Giardia and 1.8% (1/55) Entamoeba histolytica]). CV infections were: HPV 18.6% (19/102), HIV 0.9% (1/108), syphilis 0.9% (1/113), chlamydia 0% (0/50), BV 36.1% (39/108), and TV 6.5% (7/108). Whereas intestinal parasite infection overall was not associated with TV (p=0.89), participants with Ascaris lumbricoides were 12.84 times more likely to have TV (95% CI: 2.37, 69.52, p=0.0068). Intestinal parasite infection was positively associated with BV (adjusted OR 3.67, 95% CI: 1.02, 13.21, p=0.0466). Sexual and sanitation variables did not differ among women with and without parasite infection. These preliminary findings suggest that certain intestinal parasite infections may increase risk of CV co-infections like TV and BV. Thus, public health measures to reduce community intestinal parasite burden could reduce morbidity from CV infections.

6288

SUCCESSFUL TREATMENT OF CUTANEOUS LEISHMANIASIS WITH INTRAMUSCULAR INJECTION OF SODIUM STIBOGLUCONATE IN AN 18 MONTH OLD CHILD

Selamawit Girma Hailu

Addis Ababa University, Addis Ababa, Ethiopia

Cutaneous leishmaniasis is endemic in Ethiopia. It is one of the neglected tropical disease for which few treatments with variable success rate are available. Treatment varies depending on the site, size and number of the lesion, the leishmania species type, age of the patient etc. There are few reports available regarding the use of intramuscular sodium stibogluconate use for treatment of cutaneous leishmaniasis in children less than two years of age. In addition most guidelines do not clearly put the use of intravenous or intramuscular use of sodium stibogluconate in children less than two years. Here we present an 18month old male child treated with intramuscular injection of sodium stibogluconate for cutaneous

lesishmaniasis. The child presented with lesion over the face since four month which is asymptomatic. On physical examination there is 3cm x1.5cm erythematous indurated plaque just below the right lower eye lid and close to bridge of the nose with overlying hyperpigmented crust. On skin slit smear examination there is leishmania parasites (leishman Donovan bodies) seen. He was admitted and treated with daily intramuscular injection of 200mg of sodium stibogluconate. He was followed with weekly laboratory investigations which includes complete blood count, liver function test, renal function test, lipase, amylase and electrocardiograph. On the fourth week, 23rd day, he developed hepatotoxicty with more than five times elevation of liver enzymes and the drug was discontinued. At this moment the healing was adequate in which flattening of the lesion and reepithelization reached 80%. After a week the liver function test was normalizing and topical 15% parmomycin (approximately 3gm) was given and he applied it only for 6 days. After 2 months the child has complete flattening and reepithelization of the lesion. In conclusion, sodium stibogluconate can be used in children at least 18 month and older.

A NOVEL TREATMENT FOR SCABIES

Deepani Darshika Fernando, Sara Taylor, Gangi Samarawickrama, Nirupama Nammunige, Katja Fischer
QIMR Berghofer Medical Research Institute, Brisbane, Australia

Scabies is a highly contagious skin disease caused by Sarcoptes scabiei var hominis. It is associated with serious life-threatening secondary bacterial infections caused by Group A Streptococcus and Staphylococcus aureus. There is no vaccine and the most commonly used therapeutics, oral ivermectin and topical permethrin mainly target the parasite nervous system, killing only the motile stages. Therefore, they have sub-optimal efficacies and require repeat treatments. Prolonged use of current drugs and patient incompliance to repeat treatments have led to emerging parasitic resistance. This highlights the importance of a single dose treatment that targets all the stages of the S. scabiei life cycle. We tested two novel scabicides (ADF and FDF) in in vitro bio-assays and pre-clinical, using the porcine scabies model. In vitro results shows excellent miticidal and ovicidal effects of compounds ADF and FDF. When used in combination, the efficacy was significantly raised. The lethal time (LT100) to kill all mites and young eggs was 2h, and for late-stage eggs 8h. Four groups of 8 scabetic pigs were used in pre-clinical evaluation. Single topical application of the combined formulation on scabetic pigs for 4h or 8h resulted in complete cure of the infection by day 5 post-treatment and remained mite-free. The results were significantly better than two doses of ivermectin group and the un-treated control group remained infected. Pharmacokinetics of the compounds are being assessed by mass-spectrometry. In addition, combination treatment showed excellent anti-bacterial effects against scabies associated pathogens with significantly lower minimum bactericidal concentration (MBC) than the scabicidal concentration in vitro. We propose that our novel treatment is a promising next generation scabicide which only require a single application and likely prevents scabies associated secondary bacterial infections.

6290

KINETICS OF CARDIOVASCULAR AND INFLAMMATORY BIOMARKERS IN CHILDREN WITH DENGUE SHOCK SYNDROME

Ho Quang Chanh[1], Huynh Trung Trieu[2], Tu Qui Phan[2], Duyen Huynh Le[1], Bridget Wills[1], Sophie Yacoub[1]
[1]Oxford University Clinical Research Unit, Ho Chi Minh, Viet Nam, [2]Hospital for Tropical Diseases, Ho Chi Minh, Viet Nam

Vascular leak is the hallmark of dengue infections which in some patients can lead to the potentially fatal dengue shock syndrome (DSS). Early identification and quantification of leak remains challenging, yet crucial to optimise fluid therapy. Endothelial glycocalyx layer (EGL) disruption and inflammation are implicated in the pathogenesis of vascular leak, however little is known about their association with intravascular volume and clinical outcomes. We investigated the association of EGL and inflammatory biomarkers and their kinetics during fluid resuscitation in DSS patients admitted to ICU. Paediatric patients were enrolled on admission to ICU at shock onset. Three daily blood samples were taken during ICU stay and one at 1-month follow-up visit (FU), for measurements of plasma levels of syndecan-1 (SDC1), hyaluronic acid (HA), suppression of tumorigenicity 2 (ST2), ferritin, and N-terminal pro-B-type natriuretic peptides (NT-proBNP), and atrial natriuretic peptides (ANP). The primary outcome was intravascular volume defined by a percentage haematocrit (HCT) change (values taken at shock onset and baseline at FU). Secondary outcomes were the development of recurrent shock and respiratory distress. 90 patients were enrolled; the median age was 12 years. Recurrent shock occurred in 16 patients and 10 had respiratory distress. Ferritin and ST2 were highest at enrolment (ICU admission), whilst HA and SDC1 peaked 24-hours after admission. These biomarkers decreased over ICU stay and returned to normal at FU. The natriuretic peptides had different trajectories, with increasing trends from ICU stay to FU. HA had a positive correlation with %HCT change ($rho = 0.37$, $p = .02$). None of the biomarkers at admission associated with recurrent shock or respiratory distress. Ferritin had a positive correlation with HA ($rho = .59$, $p < .001$) and SDC1 ($rho = .60$, $p < .001$) at all timepoints. In summary, we have shown the host inflammatory response is associated with EGL breakdown and HA could be a useful surrogate marker of leak severity in patients with DSS.

6291

THE IMPACTS OF COVID-19 ON THE RESURGENCE OF LASSA FEVER IN NIGERIA

Praise Oyedepo Okunlola
Faculty of Dentistry, College of Medicine, University of Ibadan, Ibadan, Nigeria

The Coronavirus (COVID-19) pandemic is one of the worst pandemics in history. Lassa fever is a viral hemorrhagic fever endemic in Nigeria and some other West African countries. This study aims to identify the relationship between the incidence/reporting of COVID-19 and Lassa fever, factors affecting the trends of both illnesses in Nigeria, and how public health agencies can be better prepared for the effects of future pandemics on the incidence/reporting of other diseases. Data was extracted from the Nigeria Centre for Disease Control disease situation reports. Lassa fever reports for [24th to 31st Dec. 2018], [23rd to 29th Dec. 2019], [27th Dec. 2020 to 2nd Jan. 2021] and [26th Dec. 2022 to 1st Jan. 2023], as well as COVID-19 reports for [21st to 27th Dec. 2020], [20th to 26th Dec. 2021], and [5th to 18th Dec. 2022] were obtained. A systematic search was done on PubMed to include the keywords [COVID-19], [Lassa fever], [Nigeria] for the years [2020 to 2022]. The total number of confirmed cases of Lassa fever in Nigeria was 633 in 2018, 833 in 2019, 1,181 in 2020 and 511 in 2021; a 56.7% decrease in 2021. However, the total number of confirmed cases increased by 109% to 1,067 in 2022. As of 27th December 2020, a total of 88,414 COVID-19 cases had been recorded. On 26th December 2021, the figure rose by 168.7% to 237,561 and on 18th December 2022, the number of confirmed cases rose by only 12% to 266,415. While COVID-19 was prevalent, Lassa fever reportage declined. A few reasons that may account for this disparity in the incidence of both diseases, as obtained from the review of literature, include: similarities in clinical manifestations, insufficient modulator laboratories (only 8) for Lassa fever testing in Nigeria, and the similarities in the laboratory and management facilities of both diseases. The 'seasonal' timing and symptoms of Lassa fever and COVID-19 surge are similar. Hence, public health agencies in countries that have such occurrences must be better prepared to adequately test, manage or co-manage multiple disease conditions in the same facility. Such agencies must also increase public awareness of such related diseases occurring concurrently.

6292

SCRUB TYPHUS AND Q FEVER AMONG HOSPITALIZED PATIENTS WITH ACUTE FEBRILE ILLNESS IN BANGLADESH

Anik Palit[1], Tanzir Ahmed Shuvo[1], Mohammed Ziaur Rahman[1], Zubair Akhtar[1], Probir Kumar Ghosh[1], Muntasir Alam[1], Md. Mahfuzur Rahman[1], Mahmudur Rahman[2], Pawan Angra[3], Matthew Mikoleit[3], Daniel Martin[3], Fahmida Chowdhury[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Global Health Development, EMPHNET, Dhaka, Bangladesh, [3]Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Infection by Orientia tsutsugamushi (scrub typhus) or Coxiella burnetii (Q fever) have previously been reported in Southeast Asia, including Bangladesh, but remains underdiagnosed due to lack of diagnostic capacity and clinician awareness. From September 2021 to February 2023, we randomly enrolled 1,544 hospitalized AFI patients from five tertiary care hospitals across different geographical regions of Bangladesh; 778 were adults and 766 were infants and children (2 months-12 years). AFI was defined as a measured or history of fever (≥ 100.4°F) within the past 14 days. We detected 24 (1.5%) cases of scrub typhus and 7 (0.5%) cases of Q fever from blood samples by real-time PCR assay. Among the detected scrub typhus cases, 50% were male, and 19 (79%) were adult (25-75 years). Ceftriaxone (71%) was predominantly prescribed and doxycycline, the recommended drug, was only used in one patient. The average duration of hospital stay was five days. Of 24 patients, 10 (42%) were discharged with improved status, 13 (54%) left voluntarily before improving, and one died on the 11th day following admission. On follow-up in the 4th week, 54% of the cases reported improvement, 12% reported full recovery, 33% were lost to follow-up, and one additional death occurred.All seven Q fever positive cases were male and adult (20-55 years) and six were from Rangpur Division. Two of the cases reported contact with domestic cows and goats. All cases were treated with ceftriaxone. Only two patients reported improvement at discharge, and after 4 weeks, six reported full recovery.Scrub typhus and Q fever are not commonly detected in clinical settings in Bangladesh. Detection of hospitalized cases of scrub typhus and Q fever suggest that clinicians should consider these diseases as a differential diagnosis of severe AFI in Bangladesh. To support differential diagnosis and better management of these diseases, low-cost appropriate diagnostic tools along with education and knowledge of these diseases should be made accessible to clinicians at the point and time of care.

6293

TIMELY RETURN OF TEST RESULTS FOR MEASLES AND YELLOW FEVER: A SURVEY OF CARE PROVIDERS IN GHANA

Benedicta K. Atsu[1], Joseph Kenu[1], Benjamin Buade[1], Emma E. Kploanyi[1], David A. Opare[2], Franklin Asiedu-Bekoe[3], Lee F. Schroeder[4], David W. Dowdy[5], Alfred E. Yawson[6], Ernest Kenu[1]

[1]School of Public Health, University of Ghana, Accra, Ghana, [2]National Public Health Reference Laboratory, Ghana Health Service, Accra, Ghana, [3]Public Health Division, Ghana Health Service, Accra, Ghana, [4]Department of Pathology and Clinical Laboratories, University of Michigan, Ann Arbor, MI, United States, [5]Department of Epidemiology, John Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [6]Department of Community Health, University of Ghana Medical School and Dentistry, Accra, Ghana

Laboratory tests are ordered to diagnose and manage patients, but also are critical to outbreak detection. Timely return of results for clinical decisions and surveillance depends largely on the prompt reporting of laboratory results. This study surveyed health care providers for their assessment of the timely return of test results for two epidemic-prone diseases (Yellow fever and Measles) in Ghana.A survey of healthcare providers was carried out in 53 randomly selected health facilities from the three ecological zones in Ghana, stratified by remoteness and population density. Data were collected from providers in hospitals and subdistrict facilities from February 2021 to July 2022. Descriptive analysis characterized providers' assessment of the duration of time between patient onset of symptoms and presentation to health facilities as well as the return of test results for patient management.Providers estimated 9.1 days (95%CI 7.47-10.72) for patients with symptoms of non-severe YF to present for care, compared to 6.4 days (95%CI 4.7-8.02) for severe cases of YF. Patients with non-severe measles were estimated to present in 5.2 days (95%CI 4.08-6.34) and with severe measles in 6.8 days (95%CI 5.98-7.54). All testing was reported to occur by send-out. Both yellow fever and measles testing was estimated to return in a median of 30 days (IQR 14-90 days). The median percentage of yellow fever results estimated to occur in a timely manner for patient management was 0% (IQR 0-40%) and for measles was also 0% (IQR 0-30%). Return of test results for Measles and Yellow fever was delayed, hence the need to strengthen the laboratory network since the potential for the transmission of epidemic-prone disease depended on both the time between infection onset until presentation to health facilities, as well as the time to receive testing results.

6294

CEREBROSPINAL FLUID CHLORIDE IN THE DIAGNOSIS OF TUBERCULAR MENINGITIS- A PROSPECTIVE STUDY FROM JODHPUR, INDIA

Pankaj Sukhadiya[1], Maya Gopalakrishnan[1], Varatharajan Sakthivadivel[2], Gopal Krishna Bohra[1], Kamlakant Shukla[1], Mahendra Kumar Garg[1]

[1]All India institute of Medical Sciences, Jodhpur, India, [2]All India institute of Medical Sciences, Bibinagar, India

Tubercular meningitis presents a diagnostic challenge as uniform criteria are lacking, and no single test can definitively rule it out. We explored cerebrospinal fluid chloride and cerebrospinal fluid-serum chloride ratio as diagnostic tools for tubercular meningitis. Adults with clinical suspicion of meningitis were enrolled prospectively from March 2021-September 2022 after informed consent and ethical approval. Tubercular meningitis was diagnosed using a combination of clinical findings, CNS imaging, cerebrospinal fluid analysis and nucleic acid amplification tests. Sensitivity, specificity, and area under the curve for receiver-operating curve were calculated for cerebrospinal fluid chloride and cerebrospinal fluid-serum chloride ratio to diagnose tubercular meningitis. Of 209 included, 56 were diagnosed with tubercular and 61 with viral meningitis, rest were pyogenic and others. The mean cerebrospinal fluid chloride was low in tubercular meningitis (115.4±10.6 mmol/L), as compared to viral meningoencephalitis (127.0±7.5mmol/L, p <0.0001). The mean ratio of cerebrospinal fluid-serum chloride (1.18±0.09) was also significantly lower in patients with tubercular meningitis in comparison to patients with viral meningoencephalitis (1.24±0.06, p =0.04). Area under the curve of cerebrospinal fluid chloride levels for the diagnosis of tubercular meningitis was 0.76 (p <0.0001, 95% CI 0.68-0.84) and cerebrospinal fluid-serum chloride ratio was 0.67 (p <0.0001, 95% CI 0.58-0.75). Cerebrospinal fluid chloride <121 mmol/L had a sensitivity and specificity of 70.5% and the cerebrospinal fluid-serum chloride ratio had a sensitivity and specificity of 65% for diagnosis of tubercular meningitis. Our study showed that absolute cerebrospinal fluid chloride and cerebrospinal fluid-serum chloride ratio are sensitive diagnostic markers for diagnosis of tubercular meningitis and specially to differentiate it from viral meningoencephalitis in the initial course of illness.

6295

A CASE OF MONKEYPOX VIRUS REINFECTION

Frederique Jacquerioz[1], Stefano Musumeci[1], Iris Najjar[1], Emmanuelle Boffi El Amari[2], Laurent Kaiser[1], Alexandra Calmy[1], Manuel Schibler[1], Sabine Yerly[1]

[1]Geneva University Hospitals, Genève, Switzerland, [2]Private Practice, Genève, Switzerland

We present the case of a healthy man in his early 30's who presented with monkeypox virus infection six months after having completely recovered from a previous one. He identifies as a man having sex with men and is taking pre-exposure prophylaxis for HIV. The first episode was mild with a few umbilicated lesions on the penis. Cutaneous and pharyngeal swabs

were positive by real-time orthopoxvirus PCR. Within two weeks skin lesions resolved without complications. Six months later the patient was seen by his general practitioner for persistent anal pain. The pain had started after his return from Brazil where he had engaged in unprotected sexual intercourses including anal receptive intercourses with multiple partners. The last intercourse was reported two weeks before symptoms onset. He did not develop any skin lesions nor systemic symptoms. The anal swab came back positive for monkeypox virus by real-time orthopoxvirus PCR with a cycle threshold of 27, a repeated swab two week later was negative. Sexually transmitted disease (STD) screening was positive for Chlamydia trachomatis (non LGV) and negative for HIV and syphilis. A colonoscopy revealed an anal fissure but no typical mpox lesions. He was never vaccinated against mpox. Symptoms might have been due to mpox or to the concomitant presence of an anal fissure or Chlamydia trachomatis infection. It is therefore impossible to distinguish between a symptomatic or asymptomatic mpox reinfection. This case, although still anecdotal, suggests that certain individuals might not develop sufficient neutralizing immunity after natural infection and become reinfected when re-exposed to monkeypox virus. From a public health perspective, if reinfection become more prominent, it raises the questions of repeated testing of highly exposed symptomatic individuals regardless of prior infection or vaccination and of extending vaccination to individuals after an infection.

6296

IMPACT OF DIFFERENTIAL AND SYSTEMATIC DIAGNOSIS OF DENGUE, CHIKUNGUNYA AND MALARIA ON PATIENT MANAGEMENT AND ANTIBIOTIC USE IN BURKINA FASO AND IVORY COAST

Fanette Ravel[1], Serge Diagbouga[2], Aristophane Tanon[3], Kigninlman Horo[4], Solenne Robert[1]

[1]bioMerieux, Marcy L'Etoile, France, [2]Institut de Recherche en Sciences de la Santé, Ouagadougou, Burkina Faso, [3]AFS de Réanimation médicale, Université Félix Houphouët Boigny, Abidjan, Côte D'Ivoire, [4]Unité de formation et de Recherche en Sciences Médicales, Université Félix Houphouët-Boigny d'Abidjan, Abidjan, Côte D'Ivoire

Over the last several decades, dengue and chikungunya have become more geographically dispersed with common clinical outbreaks. They are responsible for high morbidity and mortality in endemic areas, such as West Africa where there is limited data. The health systems in these countries therefore face major challenges. This study aims to assess the impact of differential diagnosis of these two arboviruses on febrile patients clinical management, prevention of complications, antibiotic and antimalarial misuses. Differential diagnosis of dengue and chikungunya will be performed using the VIDAS® Diagnostic Tests for the detection of Dengue Virus NS1 Antigen, Anti-Dengue Virus IgM and IgG and VIDAS® anti-CHIKV IgM and IgG (technology developed at the US NIAID, Vaccine Research Center), whereas malaria will be diagnosed by RDTs. 800 subjects with acute undifferentiated febrile illness will be enrolled in a prospective cohort study carried out in two West African countries with respectively one interventional and one control sites per country. In interventional sites, all subjects will be tested for dengue and chikungunya (VIDAS®) in addition to malaria (RTDs). Clinicians' final diagnosis will consider the patients' clinical symptoms and diagnostic tests results. In control sites, on-site routine diagnosis will be used. In parallel, all the biological samples will be tested for dengue and chikungunya (VIDAS®) to obtain the real rate of positive subjects. Clinical outcomes are i) the comparison using a Chi-2 test of antibiotic use in control and interventional sites, ii) the healthcare resource utilization and productivity losses, iii) the subject quality of life using EQ-5D questionnaire. The enrollment is expected to start in April 2023 for a 5 months duration. Intermediate analysis will be performed on 400 subjects and presented in the poster. These findings should highlight the relevance of differential diagnosis in febrile subjects' clinical management, generate seroprevalence data and demonstrate the potential for avoiding antibiotic misuse which amplify the emergence of antibiotic resistance and lead to greater mortality.

6297

INTESTINAL IMMUNOHISTOCHEMISTRY AND HISTOLOGY RELATIONSHIPS WITH FECAL ENTERIC PATHOGENS IN A PEDIATRIC POSTMORTEM STUDY

David M. Coomes[1], Shyam Raghavan[2], Brooks Morgan[1], Robert H.J. Bandsma[3], Chelsea Marie[2], Sean Moore[2], Phillip I. Tarr[4], Wieger Voskuijl[5], Donna M. Denno[1]

[1]University of Washington, Seattle, WA, United States, [2]University of Virginia, Charlottesville, VA, United States, [3]The Childhood Acute Illness & Nutrition (CHAIN) Network, Nairobi, Kenya, [4]Washington University, St. Louis, MO, United States, [5]Kamuzu University of Health Sciences, Blantyre, Malawi

Postmortem (PM) intestinal minimally invasive tissue sampling (MITS) has previously been demonstrated feasible and histologically informative despite autolysis concerns. We aimed to determine the informative value of immunohistochemistry (IHC) and pathogen analysis on PM intestinal samples. PM duodenal and rectal biopsies from children with acute illness and/or undernutrition who died as inpatients (MITS in Malawi, n=23), and duodenal biopsies from live children with environmental enteric dysfunction (EED) (Zambia, n=59) or no pathologic abnormality (NPA) (U.S., n=25) were endoscopically biopsied and stained for both hematoxylin and eosin (H&E) and a 14-marker IHC panel. Pathologists semi-quantitatively scored H&E images using a validated EED histology index. IHC images were digitally quantified and normalized to account for tissue size. Enteric pathogens were sought by qPCR on MITS stool, duodenal, and rectal samples. We used multivariable linear regression to (1) compare duodenal IHC readouts from MITS to EED and NPA samples and (2) test associations between fecal pathogens with IHC readouts and histology scores in MITS samples. MITS IHC stain quantification were similar to those of EED and NPA cohorts, but B lymphocyte, intraepithelial lymphocyte (IEL), brush border, and leukocyte proliferation marker readouts were significantly lower in MITS samples while granzyme B signal was higher. At least one pathogen was found per MITS participant, although detection was much more frequent in stool samples and fecal pathogens did not clearly correspond in intestinal samples. Fecal enteropathogenic E. coli was inversely associated with rectal histology summative index score (-0.18; 95% CI: -0.32, -0.05). Stool pathogen-IHC associations included enteroaggregative E coli with duodenal intraepithelial CD3 (-0.06; 95% CI: -0.09, -0.03) and rectal MUC2 (-1.98; 95% CI: -2.59, -1.37), and norovirus with rectal defensin 5 (0.33; 95% CI: 0.21, 0.45) and MUC2 (1.27; 95% CI: 0.01, 2.52). These novel data support the use of IHC along with H&E for histopathologic assessment in PM intestinal samples to improve knowledge of host pathobiology.

6298

TRAVEL HEALTH NEEDS OF CHILDREN IN US MILITARY FAMILIES STATIONED ABROAD

Alexandra P. Mauro[1], Amy Davis[1], Patrick W. Hickey[2]

[1]Walter Reed National Military Medical Center, Bethesda, MD, United States, [2]Uniformed Services University, Bethesda, MD, United States

The Military Health System (MHS) provides care to 9.6 million beneficiaries including uniformed service members, military retirees, and their family members with the mission to provide a medically ready force both at home and abroad. The US Department of Defense requires certain preventative health measures for service members serving abroad; however, many of these service members are living with spouses and children who have their own preventative health needs. We characterize the MHS pediatric population living outside of the United States and the recommended travel health specific preventive services. We assessed the registered country of residence of Active Duty Service Members (ADSM) and their families based on the Defense Enrollment Eligibility Reporting System to quantify the children of ADSM, under the age of 18, living abroad. Data were sorted by age group and region, excluding those living in the continental United States, Alaska, and Hawaii, as well as Canada. Data from Reservists and Retirees were excluded; although also MHS beneficiaries, their location is less likely to be service-related. There are 63,443 children of ADSM living abroad and rotating on a 2-3 year cycle. Of those children, 26,269

are aged five or younger with 37,174 children 6 to 17 years old. The largest populations are in Asia (26,172) and Europe (31,243), reflecting long standing bases in Japan and Korea as well as Germany, the United Kingdom, and Italy, with a sizable population also in Oceania (3,676) due to the US military presence in Guam. Thousands of military children live in countries without permanent military bases and MHS medical assets in these regions and those in Mexico/Central America/the Caribbean (1,658), Africa (397), and South America (297). We map recommended travel specific interventions across this population distribution. The children of military families serving abroad are a unique population in need of a range of preventative health services that differ from their counterparts in the United States. Utilization of preventive services and health outcomes associated with living abroad have not been studied in this population.

6299

VALIDATION OF AN NS1 AND IGM RAPID TEST IN THE EARLY DIAGNOSIS OF DENGUE IN A PRIMARY HEALTH CARE CENTRE IN BUCARAMANGA, COLOMBIA DURING THE YEARS 2018-2020

Rosa-Margarita Gelvez Ramirez[1], Monika Patricia Consuegra Rodriguez[1], Maria Isabel Estupiñan[1], Adriana Torres Rangel[2], Victor Herrera[3], Luis Angel Villar Centeno[1]

[1]Centro de Atencion y Diagnostico de Enfermedades Infecciosas-CDI, INFOVIDA, Bucaramanga, Colombia, [2]Hospital Local del Norte, Instituto de Salud de Bucaramanga-ISABU, Bucaramanga, Colombia, [3]Universidad Industrial de Santander, Department of Public Health, Bucaramanga, Colombia

Dengue has a broad spectrum of manifestations that difficult the clinical confirmation in regions where the acute syndrome febrile is multi-aetiology. The laboratory diagnostic requires specific and sensitive tests with the good advantage of cost, time, and easier manipulation. The rapid tests to detect NS1, play an important role in the early diagnosis of dengue however the implementation in primary health care is not the rule and the routinary IgM detection may not be useful during the acute phase. This study aimed to validate the use of the NS1 and IgM rapid test in primary healthcare facilities in the early detection of dengue cases during an outbreak in Colombia. From 2018 to 2020, a system was established in the healthcare of public networks in Bucaramanga, Colombia. After the blood counts and using the remaining sample, a commercial rapid test was run for antigen NS1 and IgM. One RT-PCR was performed for the detection of Zika, chikungunya, and dengue viruses. The quick test and the RT-PCR were performed independently and in a specific order: first, the rapid test and second the RT-PCR were done blinding. We estimated sensitivity, specificity, and positive and negative predictive values (SE, SP, PPV and NPV, respectively) for NS1 and IgM against PCR stratifying by disease's duration, considering a range of prevalence between 10-50%. We evaluated 566 patients with complete clinical and diagnostic data (32% were PCR positive). Overall, SE and SP were 81% and 72% for NS1 and 38% and 62% for IgM, respectively. SE increased with the disease's duration from 33.3-54.0% for IgM but remained stable around 80.0% for NS1, whereas SP was similar for both tests and showed a decreasing trend at larger disease duration. PPV and NPV ranged from 52.9-74.2% and 73.6-100.0% for IgM, and from 58.7-95.9% and 98.7-100.0% for NS1 at the disease's onset, respectively. According to our results, testing for NS1 is not only feasible in the context of primary care but also a highly accurate approach to diagnose tools for dengue in endemic areas where the acute syndrome febrile is multi-aetiology, allowing an early and suitable diagnosis to reduce complications due to the disease.

6300

THE EFFECTS OF L-CARNITINE SUPPLEMENTATION ON RATE OF WEIGHT GAIN AND BIOMARKERS OF ENVIRONMENTAL ENTERIC DYSFUNCTION IN SEVERELY MALNOURISHED CHILDREN: A DOUBLE-BLINDED RANDOMIZED CLINICAL TRIAL

Jinat Alam, Shah Mohammad Fahim, Md Ridwan Islam, Md Ashraful Alam, Md Amran Gazi, Tahmeed Ahmed

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Severe Acute Malnutrition (SAM) and an asymptomatic small intestinal illness, Environmental Enteric Dysfunction (EED), are highly prevalent among children in resource-limited countries like Bangladesh. To best of our knowledge, limited trials have been conducted on malnourished children to evaluate the effects of carnitine, a vital micronutrient for ß-oxidation. Therefore, we sought to explore the role of L-carnitine on the rate of weight gain and EED biomarkers in SAM children. A prospective, double-blinded, placebo-controlled, randomized clinical trial (ClinicalTrials.gov# NCT05083637) was conducted at Dhaka Hospital of icddr,b. Participants were 9-24 months-old severely malnourished children who were randomly assigned to receive commercial L-carnitine syrup (100mg/kg/day) or a placebo for 15 days in addition to the protocolized treatment of SAM at the Nutritional Rehabilitation Unit (NRU). A total of 98 children with a weight-for-length z-score (WLZ) <-3 SD were enrolled between October 2021 and September 2022. All analyses were based on an intention-to-treat basis. The primary outcome variable, mean weight gain (g/kg/day), was comparable between the intervention and placebo groups [2.18 vs. 2.11; ß: 0.06, 95% CI: (-0.95, 1.07), p: 0.902], respectively. After the intervention, the mean difference between baseline and end line values of EED biomarkers were also comparable; for instances- Myeloperoxidase-ng/ml [-1129.99 vs. -152.93; ß: -977.06, 95% CI: (-8837.77, 6883.65), p: 0.806], Neopterin-nmol/L [166.67 vs. 342.44; ß: -175.78, 95% CI: (-719.78, 368.22), p: 0.523], Alpha-1 Antitrypsin-mg/ml [0.39 vs. 0.30; ß: 0.09, 95% CI: (-0.09, 0.27), p: 0.321], respectively, in L-carnitine and placebo groups. Our clinical trial results provided the best available information and laid the groundwork to show the effects of L-carnitine supplementation on the rate of weight gain and EED biomarkers in participants with severe acute malnutrition. A scaling-up of this intervention with high doses in contexts with limited resources should be considered.

BRAINSTEM ENCEPHALITIS AND EXTRAPYRAMIDAL SYNDROME AFTER ZIKA VIRUS INFECTION IN SALVADOR, BRAZIL

Lorena Martins[1], Mateus Rosário[1], Pedro Antônio Jesus[2], Marcos Vinicius Francisco[1], Cleiton Santos[1], Marta Giovanetti[3], Luiz Carlos Alcântara[3], Isadora Siqueira[1]

[1]Instituto Gonçalo Moniz, Fiocruz-BA, Salvador, Brazil, [2]Hospital Geral Roberto Santos (Secretaria Estadual da Saúde da Bahia), Salvador, Brazil, [3]Instituto René Rachou- Fundação Oswaldo Cruz (MG), Belo Horizonte, Brazil

Zika virus (ZIKV) is an emerging flavivirus that caused a widespread outbreak in Brazil in years 2015-2016. In addition, shortly after its introduction in 2015, a cluster of cases with Guillain-Barré syndrome and other neurologic syndromes were described in Brazil. Herein, we present a case of a brainstem encephalitis with extrapyramidal syndrome in a patient in Salvador, Brazil. A 21-year-old Brazilian woman presented with fever, maculopapular rash, pruritus, arthralgia, headache, and edema of hands and feet. She was admitted to the hospital seven days after the onset of viral symptoms when neurological symptoms began: confusion, somnolence, inability to walk, and impairment of speech. After a generalized seizure she was admitted to the intensive care unit (ICU). She was lethargic, had dysphonia and dysarthria, right facial nerve palsy, impaired palate elevation, and severe dysphagia. She had normal muscle strength and brisk deep tendon reflexes. Cerebrospinal Fluid (CSF) was collected seven

days after the onset of viral symptoms, and a serum sample 12 days after the onset of those symptoms. CSF revealed two cells/mm3 (lymphocytes), 43mg/dL (protein), and 64mg/dL (glucose). RT-PCR for ZIKV, CHIKV, and DENV were negative in serum samples. ELISA Anti-ZIKV IgM and IgG antibodies were detected, as well as the ZIKV PRNT. She recovered over the following 34 days. This case report highlights a rapid and severe evolution of symptoms, requiring hospitalization in the ICU, with long-term treatment. Brainstem encephalitis is a rare disease. Herein,it was clinically diagnosed through the presence of cerebellar disorders, altered level of consciousness, and hyperreflexia. ZIKV should be considered a potential etiological agent of encephalitis in endemic regions. Healthcare workers must be aware of the potential severe neurological syndromes associated with ZIKV infection and be prepared to provide prompt diagnosis and supportive care.

6302

EFFECT OF PRIOR DENGUE INFECTION AND SINGLE-DOSE DENGUE VACCINATION ON THE RISK OF SUBSEQUENT VIROLOGICALLY CONFIRMED DENGUE: A FIVE-YEAR PROSPECTIVE COHORT STUDY IN CEBU, PHILIPPINES

Michelle Ylade[1], Ma. Vinna Crisostomo[1], Jedas Veronica Daag[1], Kristal An Agrupis[1], Anna Maureen Cuachin[1], Ava Kristy Sy[2], Jesus Sarol Jr.[3], Cameron Adams[4], Laura White[4], Aravinda de Silva[4], Jacqueline Deen[1]

[1]University of the Philippines Manila, Manila, Philippines, [2]Research Institute for Tropical Medicine, Muntinlupa, Philippines, [3]University of Illinois at Urbana-Champaign, Urbana, IL, United States, [4]University of North Carolina School of Medicine, Chapel Hill, NC, United States

Dengue is a mosquito-borne viral illness causing significant morbidity and mortality. In 2015, a three-dose dengue vaccine (CYD-TDV,Dengvaxia) was licensed for those 9 years and older in dengue-endemic areas. In 2016, the World Health Organization (WHO) recommended that countries consider introduction of CYD-TDV in settings with at least 70% seroprevalence. The Philippines Department of Health (DOH) implemented a three-dose dengue vaccination program in high dengue burden regions targeting children aged 9 to 14 years old. In June 2017, the program was expanded to Cebu province. After a follow-up analysis of the CYD-TDV Phase 3 trials showed that vaccination conferred protection among dengue-seropositive but increased risk for severe dengue among dengue-seronegative participants, the dengue vaccination program was halted with children in Cebu offered only one dose. We conducted a prospective community-based cohort study in Cebu to evaluate the effect of baseline dengue serostatus and a single dose of CYD-TDV on the subsequent risk of virologically-confirmed dengue (VCD). We enrolled 2,996 healthy children 9 to 14 years of age in May 2017. Baseline sera were collected and batch tested by indirect IgG ELISA and focus reduction neutralization test (FRNT). From June to August 2017, 1,790/2,996 (59.7%) children received a single dose of CYD-TDV. Active surveillance for an acute febrile illness (AFI) in the cohort was conducted from November 2017 to October 2023 (5 years). Those who developed AFI were identified, epidemiological and clinical data were collected, and blood drawn for confirmation of dengue by RT-PCR. Incidence was 11 VCD cases/1,000 population/year. Crude (unadjusted) analyses showed that seronegative children at baseline who received one dose of CYD-TDV were more likely to develop VCD (RR 2.12, 95% CI 1.45-3.09), while those who were seropositive at baseline and received one dose of CYD-TDV were less likely to develop VCD (RR 0.47, 95% CI 0.32-0.69). Our findings support the 2018 revised WHO recommendation of pre-vaccination screening prior to administration of CYD-TDV.

6303

MOLECULAR SURVEILLANCE AND EPIDEMIOLOGY OF LEPTOSPIROSIS AND SCRUB TYPHUS FROM PATIENTS WITH FEVER OF UNKNOWN ORIGIN IN URBAN BANGALORE, INDIA

Mansi Malik

Tata Institute for Genetics and Society, Bangalore,Karnataka, India

Acute Febrile illnesses, usually accompanied by fever, malaise, and rashes could be associated with many infectious diseases transmitted by viruses, parasites, bacteria, or fungi in tropical countries. Leptospirosis and scrub typhus are neglected and re-emerging tropical infectious diseases, transmitted by gram-negative bacterium belonging to the Leptospiraceae family. and via the bites of infected chigger mites, spread through a bacterium Orientia tsutsugamushi belonging to the family Rickettsiaceae respectively. Sporadic outbreaks of both these infections have been concerning and over a million cases per annum, reported from South-Asian countries. Early detection and diagnosis of Leptospirosis and scrub typhus are challenging and rely usually on non-confirmatory detection tests such as ELISA respectively in both diseases, leading to underestimation of the actual disease burden. We conducted a molecular surveillance study screening 977 clinical samples across a metro city, Bangalore in South India, in collaboration with local municipal corporation-Bruhat Bengaluru Mahanagar Palike (BBMP). We aimed to understand the seroprevalence of Leptospirosis, Scrub typhus, and coinfections by ELISA and an inhouse designed multiplex TaqMan Probe-based RTPCR from the patient samples. We observed, 69/977 (7.06%) samples, tested positive for Leptospirosis, 134/ 977 (13.72%) for Scrub typhus and 21/977 (2.15%) had coinfection of both. Prevalence of both Leptospirosis and scrub typhus exhibited a significant decreasing trend from July to December ($\chi 2$= 123.44, df =3; P<0.001). The disease prevalence was compared across ELISA and q RT-PCR for both infections ($\chi 2$= 6.262, df =1). The study showcases a unique collaboration with local municipal corporation, contributing to public health surveillance. The study findings shall aid in understanding the actual disease incidence and prevalence using two different detection methods Further, this shall help in creating guidelines and detection protocols for, neglected infectious diseases from patient samples having febrile illnesses in low-resource settings.

6304

A CASE OF TYPE 1 LEPROSY REACTION WITH NASAL SEPTUM PERFORATION

Seble A. Areda

Addis Ababa University, Addis Ababa, Ethiopia

Leprosy reactions are caused by immune responses against M. leprae antigens. They are divided into Type 1 or reversal reaction (T1R), and Type 2 or ENL (T2R). Type 1 reaction can occur in up to 30% of patients usually after the start of treatment. The majority of the reactional episodes occur in borderline forms. It starts as a sudden worsening of skin lesions and nerve function impairment. Besides pre-reactional lesions presenting with more infiltration and desquamation, previous and newly developing lesions may be bright red, hot, and sensitive to the touch, sometimes ulcerated. We present the case of a 28-year-old male patient who presented to ALERT hospital Dermatology clinic with lesions on the face buttock and leg of 4 months duration. Nose lesion is associated with bleeding and stuffiness. On Physical examination, he had well-demarcated edematous erythematous plaque on the face involving the upper lip and nose with areas of hypopigmentation. The nasal septum is deviated and perforated (.5cm by 1cm). There is a hypo-pigmented erythematous anesthetic plaque of 10cm by 12 cm over the left buttock with ulcerations at the border and ulceration on the right malleolus. He had a hypopigmented patch with fine scales on the right dorsum of the hand. Sensory testing shows that there is loss of sensation on the hand and buttock lesions and the right foot over half of the plantar area. On Investigations slit skin smear is negative. Histopathology showed multiple well-formed granulomatous and giant cells along with mixed inflammatory cells composed of plasma cells and eosinophils. With

the diagnosis of Borderline tuberculoid leprosy with Type 1 reaction he started MDT ((Multi Drug Therapy) and prednisolone 1mg/kg. This case report highlights that new leprosy cases can present with reactions and reactions can occur before starting MDT treatment. Even though nasal involvement is common in the lepromatous leprosy type, it can occur as post-reaction tissue damage in T1R.

6305

PREDICTORS OF VIRAL UNSUPPRESSION AMONG ADOLESCENTS AGED 10 TO 19 ON ANTIRETROVIRAL THERAPY IN THE CITE VERTE HEALTH DISTRICT

Ayima Nigel Asa'ah

Catholic University of Central Africa, Yaounde, Cameroon

Globally, 37.7 million people were living with HIV in 2020. Adolescents living with HIV is on a steady rise from 1.65 million in 2018 to 1.8 million in 2021 yet very little evidence exists to comprehensively estimate adolescent viral suppression after initiation on antiretroviral therapy (ART). The National AIDS Control Committee 2020 report reveal a 29% viral suppression (<1000copies/ml) against a 93% target set for 2019. This greatly affects most HIV intervention programs as adolescents continue to lag behind in the HIV response with viral unsuppression thereby leading to increased drug resistance, transmission of HIV as well as increased morbididty and motality. This study therefore aims to identify Sociodemographic, Clinical and Behavioral predictors associated to viral unsuppression among adolescents aged 10 to 19. From a quantitative analytical study and using random probabilistic sampling, we collected data from 488 adolescents after informed consent and assent were obtained. Quantitative analysis revealed that59.2% were females, the mean age of adolescents was 15.19 years and median were 15.00 years. 16.4% of adolescent who participated still had an unsuppressed most recent viral load result. Age [(AOR = 1.10, 95% CI 0.51-0.88, P-value=0.017)], level of education [(AOR=1.46 95% CI: 0.84-2.55, P-value=0.007)] , religion [(AOR=0.25, 95% CI: 0.09-0.66)], caregiver type [(AOR=1.40, 95% CI: 0.78-0.99, P-value=0.025)], recieving care from a non-pediatric health facility {(AOR=0.51, 95% CI: 0.28-0.91, P-value=0.025)], treatment line [(AOR=3.81, 95% CI:1.88-7.74, P-vaalue<0.0001)], duration on treatment [(AOR=0.59, 95% CI, 0.34-0.81, P-value=0.044)] and poor adherence [(AOR=19.85, 95%CI, 9.53-41.36, P-value<0.0001)] were found to be predictors associated to viral unsuppression among adolescent. Hence, there is a great need to strengthen the health systems, intensify peer lead Differencial Service Deliver model, Enhanced Adherence Counselling, support groups, and therapeutic education amongs adolescents while promoting psychosocial suppor to both adolelescents and care gives.

6306

INTEGRATION OF FEMALE GENITAL SCHISTOSOMIASIS INTO HIV/SEXUAL AND REPRODUCTIVE HEALTH AND RIGHTS AND NEGLECTED TROPICAL DISEASES PROGRAMS AND SERVICES: A SCOPING REVIEW WITH A SYSTEMATIC SEARCH

Isis Umbelino-Walker[1], Felicia Wong[2], Matteo Cassolato[2], Anastasia Pantelias[1], Julie Jacobson[1]

[1]Bridges to Development, Vashon, WA, United States, [2]Frontline Aids, Brighton, United Kingdom

Female genital schistosomiasis (FGS) affects approximately 56 million women and girls across sub-Saharan Africa, and is associated with up to a threefold increased prevalence of HIV. Integrating FGS with HIV programmes as part of comprehensive sexual and reproductive health (SRH) services may be one of the most significant missed opportunities for preventing HIV incidence among girls and women. A search of studies published until October 2021 via Scopus and ProQuest was conducted using PRISMA guidelines to assess how FGS can be integrated into HIV/SRH and neglected tropical diseases (NTDs) programs and services. Data extraction included studies that integrated interventions and described the opportunities and challenges. A total of 334 studies were identified, with 22 eligible for analysis and summarised conducting a descriptive numerical analysis and qualitative review. We adapted a framework for integrated implementation of FGS, HIV and HPV/cervical cancer to thematically organize the results, classifying them into five themes: awareness and community engagement, diagnosis, treatment, burden assessment, and socio-economic evaluation. Most activities pertained to awareness and community engagement (n=9), diagnosis (n=9) and were primarily connected to HIV/AIDS (n=8) and school-based services and programming (n=8). The studies mainly described the opportunities and challenges for integration, rather than presenting results from implemented integration interventions, highlighting an evidence gap on FGS integration into HIV/SRHR and NTD programmes. Investments and will are needed to realise the potential of FGS integration to address the burden of this neglected disease and improve HIV and SRH outcomes for millions of women and girls at risk.

6307

DIAGNOSING A WOMAN PRESENTING WITH FOCAL WEAKNESS AND FACIAL PALSY IN MONROVIA, LIBERIA WITH PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY: A CASE REPORT

Joyce Bartekwa[1], **Jessica Tuan**[2]

[1]John F. Kennedy Medical Center, Monrovia, Liberia, [2]Yale University School of Medicine, New Haven, CT, United States

A 45-year-old Liberian female with recently diagnosed HIV-1, stroke, and diabetes mellitus presented to the hospital in Monrovia, Liberia with reported generalized weakness for 2 weeks. On exam, she was hemodynamically stable. She had left lower lung crackles. She had facial asymmetry with cranial nerve VII palsy and left-sided facial paralysis. Right lower extremity strength was 1/5 and left lower extremity strength was 3/5. Right upper extremity strength was 3/5 and left upper extremity strength was 4/5. Admission complete blood count and complete metabolic panel were unremarkable. A CD4 count lateral flow assay showed CD4 <200 cells/μL. HIV viral load was pending. CT head demonstrated non-enhancing white matter hypodensity in bilateral parietal lobes with extension into right anterior limb of internal capsule and right external capsule. Per radiology, there was non-enhancing white matter hypodensity with signals of mild gliosis in aforementioned areas most likely due to progressive multifocal leukoencephalopathy (PML). Brain MRI was recommended. Given cerebrospinal JC virus PCR testing was unavailable, lumbar puncture was not performed. She was re-initiated on an antiretroviral (ARV) regimen of tenofovir disoproxil fumarate/lamivudine/dolutegravir for HIV/AIDS to reconstitute the immune system, which is the mainstay of treatment for PML, and trimethoprim/sulfamethoxazole prophylaxis. She received a course of azithromycin for pneumonia. She clinically improved over her several weeks of hospitalization with increased strength, particularly in the right side of her body. Her caretaker noted her improved functional strength. In summary, clinical and radiologic findings are important tools to diagnose PML. Particularly in limited resource healthcare settings, when diagnostics such as JC virus cerebrospinal fluid testing are not readily available, a clinical syndrome must be recognized. Supportive diagnostics include immunocompromised host factors, clinical symptoms and exam findings of focal neurologic deficits, and congruent radiologic brain imaging findings which can include white matter lesions.

6308

BONE MARROW CRYPTOCOCCOSIS: A RARE PRESENTATION OF A COMMON INFECTION IN AN IMMUNOSUPPRESSED PATIENT

Dennys Jimenez, Anthony Hartzler, Ryan Wealther, Clarissa Meza, Alia Nazarullah

University of Texas Health Science Center at San Antonio, San Antonio, TX, United States

A 43-year-old man with AIDS (CD4 <40 cells/microliter and viral load 309,000 copies/mL) presented with right sided weakness with associated

6 months of general malaise with recent weight loss of 8kg. On exam, he was afebrile, but tachycardic up to 120. He was cachectic with marked hepatosplenomegaly but no adenopathy. His speech was dysarthric, had right facial paralysis, right hemiparesis with clonus. Labs revealed pancytopenia (Hb of 3.8 g/dL, platelets 31 and WBCs 1.66). CT scan of the chest, A/P and head were unrevealing, but MRI brain revealed a small acute infarct in the left globus pallidus and posterior limb of the internal capsule. CSF studies showed a Cryptococcus titer of 1:1997. Patient was subsequently started on amphotericin and flucytosine for induction therapy. Despite adequate coverage for Crypto, his pancytopenia persisted. This led to a bone marrow biopsy being obtained, which demonstrated Cryptococcus on mucicarmine, PAS fungus, and GMS stains. Due to concerns for bone marrow toxicity, flucytosine was held and ampho was continued. After a hiatus from flucytosine, his blood counts started to recover and normalize. After completing ampho induction, he was stabilized and discharged on fluconazole for maintenance therapy. Although Cryptococcus infection commonly presents with CNS, pulmonary, or skin involvement in patients with CD4 counts <100, bone marrow involvement has been previously described which can present with nonspecific symptoms such as fever, anorexia, weight loss, and fatigue. Bone marrow involvement will have certain implications on treatment as in this case. A known side effect of flucytosine is its bone marrow toxicity. It is important to recognize potential bone marrow involvement, as this makes flucytosine a relative contraindication. Continuing flucytosine in these cases will only worsen the pancytopenia which could cause other adverse outcomes (bleeding, worsening infection, etc.), but the goal should be to continue Ampho for induction therapy which also reaches good bone marrow concentrations and then transition to Fluconazole for consolidation and maintenance therapies respectively.

6309

TUBERCULOSIS CASE NOTIFICATIONS, TB/HIV CO-MORBIDITIES AND TREATMENT OUTCOMES IN AMHARA REGION, ETHIOPIA: A RETROSPECTIVE LONGITUDINAL PROGRAM BASED STUDY

Solomon Sisay

KNCV Tuberculosis Foundation, Addis Ababa, Ethiopia

Globally, TB still remains as one of the major public health problems. Poor treatment outcomes, low TB case detections and its high co-morbidities are the main challenges for the success of TB program in Ethiopia. Therefore, we assessed the effectiveness of national TB control strategies on TB case notifications, treatment outcomes, and its co-morbidities between 2009 and 2018 in Amhara Region, Ethiopia. We conducted retrospective longitudinal program based study to determine the trends of TB/HIV case notifications, treatment outcomes and to identify associated factors from the reports of DOTS (Directly Observed Treatment Short-course) implementing health facilities. We extracted data from the regional TB/HIV program databases using a modified WHO (World Health Organization) reporting formats. Data were entered, cleaned and analysed using R-programming R x64 3.6.1 packages. The Case Detection Rate (CDR) of all forms of TB had increased from 55% in 2009 (95% Confidence Interval (CI) = 54.5% - 55.4%) to 73% in 2018 (95% CI = 72.2% - 73.2%). Over the same period, TB/HIV co-morbidity rate had been reduced from 32.6% (95% CI =30.7% - 34.5%) to 8.4% (95% CI = 8.04% - 8.8%). The odds of being co-morbid with HIV was higher for those TB cases who were diagnosed as extra-pulmonary TB cases [Crude Odds Ratio (COR) [95% CI] =1.26(1.07, 1.47)] compared to other forms of TB. Apart from this, being co-morbid with HIV [COR (95% CI) = 5.91 (5.52, 6.33)] and being diagnosed as extra-pulmonary TB cases [COR (95% CI) = 1.40 (1.35, 1.45)] were important predictors to be significantly associated with unsuccessful treatment outcomes. In conclusion, a huge proportion of all forms of TB cases (36%) remained undetected. Therefore, access to quality of diagnostic services such as fluorescence microscopy and GeneXpert needs to be improved through designing targeted TB case finding strategies for risky groups to TB infection. Additionally, designing of early linkage and treatment follow-up strategies need to be tailored for those groups of TB cases who are at risk to unsuccessful treatment outcomes.

CLINICAL SIGNS AND IMMUNE RESPONSE CHANGES DURING PLASMODIUM FRAGILE CO-INFECTION OF ART-TREATED SIV+ RHESUS MACAQUES

Sydney Nemphos[1], Hannah Green[1], Sallie Fell[1], James Prusak[1], Kelly Goff[1], Matilda Moström[1], Coty Tatum[1], Robert Blair[1], Carolina Allers[1], Monica Embers[1], Nicholas Maness[1], Preston Marx[1], Brooke Gasperge[1], Amitinder Kaur[1], Berlin Londono-Renteria[2], Jennifer A. Manuzak[1]

[1]Tulane National Primate Research Center, Covington, LA, United States, [2]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Plasmodium co-infection in untreated people with HIV (PWH) results in increased viral load (VL), decreased CD4+ T cell counts, and greater incidence of clinical malaria and malaria-related mortality. However, the impact of Plasmodium co-infection in antiretroviral therapy (ART) treated PWH has not been well described. We hypothesized that P. fragile co-infection of ART-treated, SIV+ rhesus macaques (RMs) would result in elevated VL, decreased CD4+ T-cell counts, and neutrophil disruptions. Male RMs (n=4) were intravenously (i.v.) inoculated with SIVmac239 (TCID50=50); initiated daily antiretrovirals (ART) at Week (W) 8 post-SIV infection; i.v. inoculated with P. fragile (20x10^6 infected erythrocytes [iRBCs]) at W12 post-SIV; and received anti-malarial treatment at W14 post-SIV. Peripheral parasitemia, anemia, plasma VL, and CD4 and neutrophil dynamics were monitored via quantification of iRBCs in Giemsa-stained thin blood smears, plasma hematocrit levels, SIV qPCR, and flow cytometry, respectively. Peak VL (median=9.92x10^06 RNA copies/ul) occurred at W3 post-SIV and decreased after ART, with 2/4 RMs becoming undetectable. P. fragile parasitemia occurred at W14 post-SIV (median %parasitemia=25.5% iRBCs) and all animals became anemic (median=19.8% hematocrit). At W13 post-SIV, RMs exhibited detectable VLs, sustained until W17 post-SIV (median=9.34x10^02 RNA copies/ul). Compared to baseline (median=306.905 cells/ul), CD4+ T-cell counts declined by W8 post-SIV (median=140.5 cells/ul), increased after ART (median=193.5 cells/ul), followed by a sustained decline (median=173.59 cells/ul) after P. fragile. Compared to baseline (median=53.58%), neutrophil frequencies increased at W14 post-SIV (median=73.25%), then stabilized to baseline levels after anti-malarial treatment. Our data indicates that P. fragile co-infection lowered ART efficacy and resulted in increased peripheral neutrophil frequencies coinciding with peak parasitemia. Additional studies are underway to characterize the mechanisms by which this cell subset may contribute to disease pathogenesis during SIV/P. fragile co-infection.

6311

EPIDEMIOLOGY OF CO-INFECTIONS IN PREGNANT WOMEN LIVING WITH HUMAN IMMUNODEFICIENCY VIRUS 1 IN RURAL GABON: A CROSS SECTIONAL STUDY

Saskia Dede Davi[1], Dearie Glory Okwu[2], Marc Luetgehetmann[3], Frederique Mbang Abba[2], Martin Aepfelbacher[3], Lillian Rene Endamne[4], Ayodele Alabi[5], Rella Zoleko-Manego[6], Ghyslain Mombo-Ngoma[7], Saidou Mahmoudou[7], Marylyn Martina Addo[1], Michael Ramharter[1], Johannes Mischlinger[1]

[1]Bernhard Nocht Institute For Tropical Medicine, Hamburg, Germany, [2]Centre de Recherches Médicales de Lambaréné, Hamburg, Gabon, [3]Center for Diagnostics, Institute of Medical Microbiology, Virology and Hygiene, University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany, [4]Albert-Schweitzer Hospital, Lambaréné, Hamburg, Germany, [5]Centre de Recherches Médicales de Lambaréné, Lambaréné, Hamburg, Germany, [6]Centre de Recherches Médicales de Lambaréné, Lambaréné, Germany, [7]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon

There is a lack of recent epidemiological data on HIV infection during pregnancy in Gabon. Moreover, it is unclear if HIV-positive pregnant women are more prone to suffer from other common co-infections. Thus, an HIV-prevalence-study was conducted among pregnant women, followed

by a cross-sectional case-control study in which the prevalence of various co-infections was compared between HIV-positive and HIV-negative pregnant women. Data for the HIV prevalence survey were collected retrospectively using routinely collected diagnostic data from 21 antenatal care centres (ANCs). For the cross-sectional co-infection study, all HIV-positive pregnant women and a comparator sub-sample of HIV-negative pregnant women were recruited at the ANC in Lambaréné. Co-infection status of vector-borne (VBI) and sexually transmitted infections (STI) was assessed. HIV positivity was 3.93% (646/16,417) among pregnant women, and 185 pregnant women were recruited.Overall, 63% of HIV-positive and 75% of HIV-negative pregnant women were diagnosed with at least one co-infection. HIV-negative women were more often co-infected with STIs than HIV-positive women (Mean [SD] STIs: 2.59 [1.04] vs 2.16 [1.35], respectively; p=0.056). The crude odds for a concomitant STI was lower in HIV-positive than in HIV-negative women. The change of magnitude from the crude to adjusted OR indicates a differential sexual risk factor profile among HIV-positive and HIV-negative women in this population. This might potentially be explained by the availability of sexual health care counselling for HIV-positive women within the framework of the national HIV control programme, while no such similar overall service exists for HIV-negative women. In conclusion, e found a high prevalence of STIs among pregnant women, an important finding for national policymakers and STI control programmes.

6312

A DECADE IN CHANGING TRENDS IN HIV PREVALENCE AND INCIDENCE IN PREGNANT WOMEN IN SOUTHERN MOZAMBIQUE

Anete Mendes-Muxlhanga[1], Raquel Gonzalez[2], Arsénio Nhacolo[1], Antia Figueroa[2], Maura Mazuze[1], Alfredo Mayor[2], Anifa Vala[1], Esperança Sevene[1], Llorenç Quintó[2], Pedro Alonso[1], Clara Menendez[2], Tacilta Nhampossa[1]

[1]Centro de Investigação em Saúde da Manhiça, Maputo, Mozambique, [2]Barcelona Institute for Global Health, Barcelona, Spain

Monitoring HIV rates at the antenatal care (ANC) clinic is needed for evaluating and targeting HIV preventive interventions in this vulnerable group. This study describes the prevalence and incidence trends of HIV over 10 years in pregnant women attending the ANC clinic in southern Mozambique. We analysed data from three studies carried out in HIV-infected pregnant women attending the ANC clinic between 2010 and 2021. HIV incidence was estimated between prevalence points using two validated methods. Method one was based on mortality rates and method two was based on survival information after HIV infection. The trend over time was obtained by fitting a log-regression model. Changes in the prevalence of anemia and rates of HIV vertical transmission during same period were also analyzed. Overall, 10392 pregnant women attending their first ANC visit were included in the analysis. There was a decrease of the HIV prevalence to 21.4% (95% CI: 19.6-23.2%) in 2021, after a peak of 35.3% (95% CI: 30.1-40.8%) in 2016. The peak of HIV tended to increase with age group from 2010 to 2021. The prevalence was the highest in women aged 20-25 in 2010 and then became the highest in those aged 35-40 in 2021. The overall incidence significantly increased from 3.7 per 100 person-years during 2010-2016 to 10.1 per 100 person-years in 2018-2019 but then subsequently decreased to 6.2 per 100 person-years in 2020-2021. In the last decade, HIV burden in pregnant women has declined in this area of southern Mozambique. However, HIV prevalence remains unacceptably high in this particularly vulnerable group, calling for a need to strengthen HIV preventive strategies to ending HIV/AIDs in the country.

6313

DRUG RESISTANCE MUTATIONS DETECTED IN HIV-1 PROTEASE GENES ISOLATED FROM HIV-1 INFECTED PERSONS FROM EASTERN REGION OF GHANA

Asantewa Sisi Yaa Anang[1], Dennis Kushitor[2], Christopher Z. Abana[2], Evelyn Y. Bonney[2]

[1]University of Ghana, Accra, Ghana, [2]University of Ghana/ Noguchi Memorial Institute for Medical Research, Accra, Ghana

Human immunodeficiency virus (HIV) is an important public health concern with about 70% of the global burden in Africa. Since the introduction of antiretroviral therapy, a major problem is the emergence of drug resistance. HIV-1 protease (PR) is a retroviral aspartyl protease, an enzyme involved with peptide bond hydrolysis in retroviruses. Without effective HIV protease, HIV virions remain non-infectious. Protease inhibitors are mostly used as part of the 2nd line regimen following treatment failure. We therefore sought to determine the prevalence of drug resistance mutations in the HIV PR gene in the most endemic region in Ghana (Eastern Region) (2.8%) prevalence. We used purposive sampling to collect blood from 30 consented patients, confirmed as HIV-1 infections by serology. Twenty-one (21) of them were on triple combinations of five first line regimen (Zidovudine, Lamivudine, Nevirapine, Tenofovir, Efavirenz) and 9 were treatment naive. Ribonucleic acid was extracted using High Pure Viral RNA Kit from plasma, amplified via a nested RT-PCR assay and sequenced using gene-specific primers. The protease genes were analyzed for subtype and drug resistance mutations using the Stanford HIV Database. Five out of 30 samples were successfully amplified. The overall mean CD4 for the 30 samples collected was 473.4 and mean viral load was 31,226.17cps/ml. No trend was found between viral load and its implication on sequencing. Three (3) samples out of 5 were successfully sequenced. Two of these were recombinant subtype CRF02_AG and one was subtype G. HIV-1 unusual drug resistance mutations (N88K, K43T, I54N) were identified per patient. The mutations found had no PI drug resistance in the protease gene of the 3 sequenced samples. They did not carry resistant forms of HIV-1. Further investigations are needed on the unusual mutations at the known drug resistant positions. Continuous monitoring of drug resistance among HIV-1 infected patients is essential to improve their clinical management.

6314

CLOSING THE KNOWLEDGE GAP IN HUMAN IMMUNODEFICIENCY VIRUS PREVENTION AMONG ADOLESCENTS IN RURAL SETTINGS, BURKINA FASO

Noubar Clarisse Dah[1], Ourohiré Millogo[1], Lina Nurhussien[2], Pascal Zabré[1], Sachin Shinde[2], Valentin Boudo[1], Moustapha Nikiéma[1], Wafaie W. Fawzi[3], Ali Sié[1]

[1]Centre de Recherche en Santé de Nouna/Institut National de Santé Publique, Nouna, Burkina Faso, [2]Department of Global Health and Population, T. H. Chan School of Public Health, Harvard University, Massachusetts, MA, United States, [3]Department of Global Health and Population, T. H. Chan School of Public Health,Harvard Univer/Department of Epidemiology,T. H. Chan School of Public Health, Harvard University/ Department of Nutrition, T. H. Chan School of Public Health, Harvard University, Massachusetts, MA, United States

In sub-Saharan Africa (SSA), HIV continues to pose a significant public health problem despite a 32% reduction in new infections in 2021. Adolescents in SSA account for nearly four out of five HIV infections. There is a lack of knowledge about HIV prevention methods and testing rates remain low among adolescents in Burkina Faso. This study assessed adolescents' knowledge of HIV prevention and testing as well as sexual risk behaviors in Nouna, Burkina Faso.We conducted a cross-sectional survey using a community-based sampling frame with 1,202 adolescents aged 10-19 years via a standardized questionnaire in the Nouna Health and Demographic Surveillance System in Burkina Faso from March to April 2022. We present descriptive results regarding adolescents' knowledge of and behavior related to HIV.The average age of the participants enrolled in the study was 14.1 (95% CI: 13.9-14.3) years old, 43.5% were female, and 59.4 % were students. About 41.9% had never heard of HIV. The

main sources of HIV information were schools (53.6%) and friends (26.7%). Among participants who have heard about HIV, only 4.3% have been tested. Additionally, 15.8% of participants had sexual intercourse in the past and 47.1% of them used condoms. The mean age at sexual intercourse was 16.0 years (95% CI: 15.8-16.2).In rural areas of Burkina Faso, adolescents are poorly informed about HIV and do not use HIV prevention measures. Adolescents need better access to HIV prevention information through innovative interventions. Adolescent reproductive health and HIV prevention awareness will contribute to reaching the 2030 target of ending the HIV/AIDS epidemic. Key words: Adolescents, HIV prevention

6315

KNOWLEDGE AND PERCEPTIONS OF PRIMARY HEALTHCARE PROVIDERS TOWARDS INTEGRATION OF ANTIRETROVIRAL THERAPY SERVICES AT DEPARTMENTAL LEVELS AT SELECTED HEALTH FACILITIES LIRA DISTRICT, UGANDA

Steven Sean Puleh, Emmanuel Asher Ikwara, Syliviah Namutebi, Lakeri Nakero, Rogers Isabirye, Maxson Kenneth Anyolitho
Lira University, Lira, Uganda

Investigations conducted among healthcare providers to assess their knowledge and perceptions towards the integration of anti-retroviral therapy related services in Sub-Saharan Africa are limited. This study explored the knowledge and perceptions of primary healthcare providers towards the integration of ART management services at departmental levels in health facilities in Lira district. We conducted a descriptive cross-sectional survey that employed qualitative methods of data collection in four selected health facilities in Lira district between January and February 2022. The study involved in-depth interviews with key informants and focus group discussions. The study population consisted exclusively of primary healthcare providers; however, those who were not full-time employees of the participating health facilities were excluded. We used thematic content analysis. A significant proportion of staff especially those who are not directly involved in ART still lack full knowledge of ART services integration. There was generally a positive perception, with some suggesting ART integration can minimize stigma and discrimination. The potential barriers to integration included limited knowledge and skills for providing comprehensive ART services, insufficient staffing and space, funding gaps, and inadequate drug supplies, coupled with increased workload due to enlarged clientele. Whereas healthcare workers are generally knowledgeable about ART integration, but their knowledge was limited to partial integration. The participants had a basic understanding of ART services being provided by different health facilities. Furthermore, participants viewed integration as critical, but it should be implemented in conjunction with ART management training. Given that respondents reported a lack of infrastructure, increased workload, and understaffing, additional investments in staff recruitment, motivation through training and incentives, and other means are needed if ART integration is to be implemented.

6316

PREGNANCY OUTCOMES IN WOMEN WITH INFECTIOUS AND CHRONIC COMORBIDITY IN WESTERN KENYA

Beth A. Tippett Barr[1], Joyce Were[2], Gabriela Toledo[3], Sammy Khagayi[2], Richard Omore[2], Gregory Ouma[2], Dickens Onyango[4], Victor Akelo[5]
[1]Nyanja Health Research Institute, Salima, Malawi, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]University College London, London, United Kingdom, [4]Kisumu County Department of Health, Kisumu, Kenya, [5]US Centers for Disease Control and Prevention, Kisumu, Kenya

Antiretroviral therapy (ART) protects maternal health and prevents HIV transmission during pregnancy. However, there is evidence that ART started pre-pregnancy compared to during pregnancy increases the risk of other poor pregnancy outcomes. No studies have reported on the risk of poor pregnancy outcomes by timing of ART initiation, while accounting for comorbid infectious and chronic diseases. Here we present results from a large cohort of pregnant women in Western Kenya living without and with HIV (WLHA). Samples and data were collected to identify infectious and non-communicable diseases. Multivariable logistic regression was conducted to assess the effect of HIV on adverse maternal or infant outcomes. Sensitivity analysis further examined timing of ART initiation on poor outcomes. One in four of 1753 women experienced poor pregnancy outcomes. Anemia (57.7% vs 39.1%), malaria (15.2% vs. 11.7%) and COVID-19 (11.8% vs. 9.3%) in pregnancy were more common in WLHA, while obesity and hypertension were higher in women without HIV. By ART timing, malaria (19.0% vs. 12.1%) and hypertension (10.1% vs. 8.0%) were higher in women starting ART during pregnancy than before pregnancy, while obesity (24.1% vs. 30.3%) and diabetes (2.5% vs. 6.1%) were lower in those starting ART during pregnancy than before pregnancy. In multivariable logistic regression neither HIV nor ART timing had significant effect on maternal outcomes. However, women who started ART pre-pregnancy had increased risk of poor infant outcomes compared to women without HIV (aOR1.54 [95%CI 0.94-2.52], p=0.05). Our finding that WLHA on ART are at no significantly increased risk of poor maternal outcomes than HIV-uninfected women demonstrates the remarkable impact of PMTCT programming since the implementation of Option B+'s 'test-and-treat' approach nearly a decade ago. The benefits of ART to maternal health and the infant HIV-free survival are well-documented, and now that PMTCT coverage exceeds 90% in many high-burden settings, more research is needed on quantifying and mitigating other infectious and chronic disease effects on pregnancy outcomes.

6317

SOCIAL MOBILIZATION FOR ENHANCED MICROPLANNING IN DEWORMING PROGRAMS

Clare S. Amuyunzu, Mary Nyamongo, Alice S. Sinkeet
African Institute for Health and Development, Nairobi, Kenya

The goal was to design, operationalize and evaluate a Social Mobilization (SM) package specifically tailored to improve the quality of community-based treatment/ mass drug administration (MDA) for Soil Transmitted Helminthiasis (STH) and Schistosomiasis (SCH) as a pilot in Vihiga County. Tailoring SM messages and materials for the specific population groups at highest risk or with lower likelihood of participating in MDA and using the right channels of communication drives treatment coverage higher. This study was undertaken to (i) Assess the social contexts for community-based STH and SCH treatment; (ii) Identify potential population segments for tailored messaging; (iii) Development of a tailored social mobilization package in Vihiga county, Kenya; (iv) Produce user-friendly guides/standard operating procedure that other countries or implementing partners could readily adapt to their own contexts; and (v) To track progress and rigorously evaluate learnings. Conducting a formative and summative assessments using mixed methods; and developing and operationalizing a tailored social mobilization package. There was an increase in reach of the messages and materials from (29.9%, n=400) initially to (81%, n=402) during the summative assessment. Data indicated that the community had correct knowledge - transmission/spread of STH i.e., drinking / walking on water contaminated with faeces increased from 19.7% to 47.2% (by 28%) and ingestion of the worm's egg increased by 1% and on SCH, transmission/ spread of SCH i.e., penetration of the worm larvae through the skin and drinking or using contaminated water improved by 35.9% and 8.9%, respectively; the number of people treated in this county was STH (103%, 597,236) and SCH (94.91%28,858 94.91%). However, the community had limited knowledge about SCH. Findings from the pilot in Vihiga County informed scale-up of the SM process to include Bungoma, Kakamega and Trans Nzoia in the western region of the country.

6318

ENGAGING YOUNG PEOPLE AS AGENTS OF CHANGE: A PRIMARY SCHOOL EDUCATIONAL INTERVENTION TO DECREASE ARBOVIRAL AND PROTOZOAL RISK IN GRENADA

Bethel Bayrau[1], Nikita Cudjoe[2], Prathik Kalva[1], Zakaria Nadeem Doueiri[1], Basil Williams[2], Makeda Fletcher[2], Sarah Telesford[2], Arani Thirunavukarasu[2], Lashawnd Johnson[2], Calum Macpherson[2], Ann W. Banchoff[1], Abby C. King[1], Trevor Noël[2], A. Désirée LaBeaud[1]

[1]Stanford School of Medicine, Palo Alto, CA, United States, [2]Windward Islands Research and Education Foundation, St. George's University, St George, Grenada

School-based educational programs are effective in mitigating environmental health risks. In this ongoing randomized control study, we use a school-based educational intervention to improve knowledge, attitudes, and practices regarding arboviral and feco-orally transmitted protozoal diseases among 4th-grade students in Grenada. 27 case and 26 control schools were randomly assigned. Students completed pre- and post-intervention questionnaires at baseline and 3 months later. Case schools received a presentation, a video clip on mosquitos and demonstrations. School vector data was collected. Students at 10 case schools used the Our Voice Discovery Tool app to collect geotagged photographic and narrative data on aspects of their environment that make it easy or hard for mosquitoes to transmit diseases. Students have recorded 374 photos (135 good and 194 bad for environment) and 309 narrations. The intervention group reported significant improvements in arboviral and protozoal disease knowledge (53.3% increase), attitudes (15.1% increase), and practices (16.3% increase) at 3-month follow-up ($p<0.01$). In contrast, the control group only reported significant improvements in knowledge (20.9% increase, $p<0.01$), but not in attitudes (0.1% decrease, $p=0.96$) and behaviors (2.5% decrease, $p=0.28$). The intervention schools showed a more significant increase in knowledge (0.83 vs 0.36), attitudes (0.99 vs 0.02), and behaviors (0.55 vs -0.08) compared to the control schools ($p<0.01$). Among case schools, vector data show 26% and 100% reduction in total egg counts and total larvae counts, respectively, at follow-up ($p<0.01$). Among control schools, more indoor egg counts were recorded at follow-up, though they also showed a non-significant 11% reduction in total egg counts. Of 7 Parishes in Grenada, we found Aedes mosquitoes in all 7 regions and Culex in 6 but no Anopheles mosquitoes. 6-month follow-up will be completed by June 2023. Our intervention effectively improves knowledge, attitudes, and practices regarding arboviral and protozoal diseases among 4th-grade students in Grenada at follow-up and reduces vector abundance in schools.

6319

IMPROVING ACCESS TO MOBILITY MANAGEMENT AND DISABILITY PREVENTION MANAGEMENT OF LYMPHATIC FILARIASIS COMPLICATIONS TOWARDS THE WORLD HEALTH ORGANIZATION 2030 LYMPHATIC FILARIASIS ELIMINATION GOAL: A PILOT STUDY CONDUCTED IN LIBERIA 2022 TO CLOSE THE GAPS IN CASE MANAGEMENT NTDS CARE—LYMPHATIC FILARIASIS

N Peter Y. Flomo

Neglected Tropical Diseases Program, Ministry of Health, Monrovia, Liberia

Lymphatic Filariasis (LF) has high prevalence rate in sub-Saharan Africa with two major complications requiring case management: hydrocele and Lymphedema. In Liberia, LF is prevalent in 13 of the 15 counties survey conducted in 2012. The only strategy for prevention and control of LF has been Mass Drug Administration (MDA) and an evaluation of the intervention (Pre-transmission Assessment Survey and Transmission Assessment Survey (PRE-TAS and TAS). The case management aspect remains a challenge in achieving the elimination target for Lymphatic Filariasis, the WHO Road Map (2030). However, to manage the complications of LF, the Case Management Project of Liberia's Neglected Tropical Diseases Program with Lymphedema care in Liberia, (2016) by providing comprehensive Home-Based Self Care (HBSC) Kits to affected persons with basic training in managing their conditions. Furthermore, in November 2022, the Case Management Project, initiated an integrated campaign to scale up the Mobility Management and Disability Prevention (MMDP) Campaign Project supported by Sightsavers International. The Mobility Management and Disability Prevention (MMDP) Campaign started in late November 2022 in five (5) counties (Bomi, Bong, Lofa, Nimba, and Maryland) with a target to perform 300 hydrocelectomies and distribute additional 260 HBSC Kits to both old and new lymphedema clients. The results against the target are as follows: Bomi (21), Bong (44), Lofa (39), Nimba (54) and Maryland (23). A total of 181 (60.33%) Hydrocelectomies were performed in 11 hospitals with an unmet target of 119 (39.7%) hydrocele cases due to several factors. With resource constraints, the Neglected Tropical Diseases Program remains committed to accelerating the MMDP Project to the remaining 8 counties in Liberia while providing routine care for lymphedema clients. This abstract seeks to explore opportunities to close the service gaps for those affected by LF complications to have adequate access to NTDs services without experiencing any financial consequences.

6320

THE EFFECT OF AN INNOVATIVE COMMUNITY HEALTH EDUCATION ON TRACHOMA PREVENTION AND CONTROL IN NORTHERN NIGERIA

Toluwase Olufadewa, **Isaac Olufadewa**, Miracle Adesina, Ruth Oladele

Slum and Rural Health Initiative, Ibadan, Nigeria

Trachoma is a leading cause of infectious blindness worldwide and an endemic public health problem in Northern Nigeria. The currently recommended surgery for trichiasis/entropion, antibiotics for active disease, facial cleanliness, and environmental change to reduce transmission (SAFE) strategy targets all key elements believed to be necessary for a short- and long-term intervention program. This study investigated the effect of innovative community health education on trachoma prevention and control in northern Nigeria. This was quasi-experimental study among Internally Displaced Person in Northern Nigeria. Two IDP camps were selected purposively and simple random sampling were used to select final participants for the study. We used a quantitative method approach was using a semi-structured questionnaire developed using SAFE strategy among 294 participants. The SPSS software version 27 was used for all statistical analyses which descriptive and inferential statistics were done at 5% significance level. The mean age of the participants was 33.1±8.8 years, some (45.9%) were male which 17.0% had no formal education. There was increase in the awareness of trachoma from 28.6% to 100.0% after the educational intervention. However, at baseline, few believed that trachoma is caused by curse while no one mentioned that after the educational intervention and they all knew ways trachoma could be transmitted. There was a significant increase in the knowledge level among participants from 20.1% to 73.5% good knowledge ($p<0.001$, CI=5.735 - 4.891, $t=24.795$) as well as positive attitude to trachoma prevention and control from 15.3% to 77.2% after the intervention ($p<0.001$, CI=14.914 - 13.065, $t=29.784$). Also, there was improvement in the prevention and control practices from 56.1% to 94.2% ($p<0.001$, CI=1.114 - 0.648, $t=7.437$). In conclusion, this study revealed that educational intervention can greatly influence knowledge on trachoma as well as the prevention and control attitude and practice.

6321

GEOSPATIAL RISK PREDICTION OF SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTHS FOLLOWING A SCHOOL PREVENTIVE CHEMOTHERAPY PROGRAM IN HUAMBO, UIGE AND ZAIRE PROVINCES, ANGOLA

Adam W. Bartlett[1], Elsa P. Mendes[2], Marta S. Palmeirim[3], Ana Direito[4], Sergio Lopes[4], Susana Vaz Nery[1]

[1]Kirby Institute, University of New South Wales, Sydney, Australia, [2]National Directorate of Public Health, Ministry of Health, Luanda, Angola, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]The MENTOR Initiative, Huambo, Angola

A school preventive chemotherapy (PC) program for soil-transmitted helminths (STHs) and schistosomiasis has operated in Huambo, Uige and Zaire provinces, Angola, since 2013 and 2014, respectively, with an impact assessment conducted in 2021. Conventional methods to assess prevalence at province or district level to inform PC programs do not account for the environmental context of disease prevalence. This analysis provides geospatial risk predictions to provide a more detailed understanding of schistosomiasis and STH distribution to inform control strategies. A two-stage cluster survey design was used to select schools and schoolchildren to detect schistosomiasis and STHs in 2021 via rapid diagnostic tests (RDTs) and microscopy, respectively. School-level georeferenced parasitological data was incorporated with climatic, altitude, vegetation, landcover and distance to water bodies data to develop spatial regression models. Best fit multivariate generalised linear models were then used to develop risk prediction maps for schistosomiasis and STHs and ascertain areas of co-endemicity. Spatial regression models and risk prediction maps are being developed for the baseline survey to better assess the impact of the school PC program on the spatial distribution of these diseases. The impact assessment involved 17,880 schoolchildren from 599 schools for the schistosomiasis survey and 6,461 schoolchildren from 214 schools for the STH survey. Best fit regression models demonstrated considerable areas of moderate to high schistosomiasis risk (≥30% prevalence by RDTs) across all three provinces. For STHs, there remains substantial areas of high risk (≥50% prevalence by microscopy) in Uige province, with more focal areas of high risk in Huambo and Zaire provinces. There are considerable co-endemic areas in Zaire, but not Huambo or Uige. Despite regular school delivery of PC over several years, there remains considerable regions of Huambo, Uige and Zaire provinces that remain moderate to high risk for schistosomiasis and STHs, with focal areas of co-endemicity.

ENHANCING TIMELINESS OF REPORTING FOR TRACHOMA MASS DRUG ADMINISTRATION THROUGH ELECTRONIC DATA CAPTURE: A PILOT STUDY IN TWO DISTRICTS OF UGANDA

Edwin Mayoki[1], Joyce Achan[1], Stephen Begumisa[1], Rapheal Opon[2], Sharone Backers[1], Stella Agunyo[1], Clara Burgert-Brucker[3], Jeremiah Ngondi[3], Brian Allen[3], Erica Shoemaker[3], Charles Kissa[2], Alfred Mubangizi[2], Stephen Otim[4], Denis Olaka[5]

[1]RTI International, Kampala, Uganda, [2]Ministry of Health, Kampala, Uganda, [3]RTI International, Washington, DC, United States, [4]District Local Government, Moroto, Uganda, [5]District Local Government, Nabilatuk, Uganda

In 2023, The Uganda Ministry of Health supported by USAID's Act to End NTDs | East piloted an electronic data capture (EDC) mass drug administration (MDA) tally sheet in two trachoma persistent and recrudescent districts (Moroto, Nabilatuk). Previous, after-action review meetings had highlighted substantial delays (e.g. four months) in reporting the MDA data using a paper-based system that involved compiling, cleaning, and summarizing data. In this process one district lost their data when the computer they were using crashed. These delays and losses coupled with data quality issues that included arithmetic errors and wrong entries prompted development of an EDC tool using Open Data Kit (ODK). The EDC tool was rigorously tested and further improved for its accuracy to the original form, validation checks, and user friendliness. Data entry by the field supervisors started 10 days after the MDA field activities in January 2023. The central-level supervisors checked the inputs for accuracy and provided direct feedback to subcounty supervisors through their WhatsApp group and phone calls. The MDA results were produced one month after end of MDA activities. This approach improved MDA reporting turnaround time and 100% of the village level data was captured with no data loss. Furthermore, it was easy for the subcounty supervisors to easily identify errors from the hardcopy forms and fix them while in the field. Of note, this EDC approach did include additional cost including airtime, allowances, and training. These results illustrate the value of timely reporting of MDA data for decision making using EDC tools. This EDC approach also strengthened data ownership by subcounty supervisors who entered their own data, jointly reviewed, and provided feedback to the district-level biostatistician and central-level team. Finally, there was improved quality of data because of the data quality checks and validations embedded in the EDC forms. Expansion of this approach in all trachoma endemic districts would be valuable to the program for timely and accurate MDA data.

FROM PRIORITY TO PRACTICE: MAKING APPLICATION OF DIGITAL PLATFORMS FOR IMPROVING TRACHOMA MDA PERFORMANCE A REALITY TOWARDS ADDRESSING END GAME CHALLENGES IN LONGIDO TANZANIA

George E. Kabona[1], Ambakisye K. Mhiche[2], Molly Adam[3], Alpha Malishee[1], Veronica E. Kabona[4], Lalji Shabbir[4], Julius C. Masanika[4], Oswald Will[5], Jeremiah Ngondi[6]

[1]National Neglected Tropical Diseases Control Program, Dodoma, Tanzania, United Republic of, [2]RTI International, Dodoma, Tanzania, United Republic of, [3]RTI International, Washington DC, DC, United States, [4]RTI International, Dar Es Salaam, Tanzania, United Republic of, [5]RTI International, London, United Kingdom, [6]RTI International, Cambridge, United Kingdom

In the past 2 decades Tanzania has made a significant stride towards trachoma elimination. However, there are nine districts are considered persistent and recrudescent. Longido district is one of the persistent districts whose status is attributable to inadequate MDA coverage, mobile and migrant populations, thus required special strategies to address both challenges during MDA. Our objective is to present a case study on application of digital platforms to address MDA and other end game challenges in Longido, Tanzania, as a template for nationwide. We examine electronic data capture (EDC) and digitalized Supervisor Coverage (SCT) tool development, from inception, team selection, training and pilot testing to tool revision and improvement. The Unstructured Supplementary Service Data (USSD) was developed, and special code was enabled to community drug distributors (CDDs mobile phone for reporting daily MDA coverage summary. This summary was sent to a central server where national supervisors could review data daily on a dashboard. The platform was set to provide an automated text messages back to the village leaders and ward level supervisors with the daily MDA summary. To facilitate the SCT, an ODK collect application was installed in the smart phone for the district and ward level supervisor. GPS codes were captured to ascertain distribution of both CDDs and supervisors across the districts. We found that transitioning from paper-based monitoring tools to electronic motoring was feasible and effective. Daily feedback to village leaders prompted ownership and immediate action to troubleshoot poor coverage. CDDs and supervisors found the tools easy and simplified reporting and tracking. Few challenges, including some errors in the CDD reporting server spotty cellular network were noted for future improvement. Upon MDA assessment, reported coverage increased from 87% in 2019 to 97.5% in 2022.The results suggest that digital platforms to address the trachoma endgame challenges can support improved monitoring and evaluation of MDA and other SAFE relate interventions in line with the WHO target to eliminate trachoma by 2030

6324

THE IMPACT OF TEN ROUNDS OF TWICE-PER-YEAR TREATMENT WITH IVERMECTIN ON ONCHOCERCIASIS TRANSMISSION IN HYPERENDEMIC AREAS OF JIMMA AND ILLUBABOR ZONES, SOUTHWEST ETHIOPIA

Tekola Endeshaw[1], Aderajew Mohammed[1], Fanta Nigussie[1], Henok Birhanu[1], Tewodros Seid[1], Yewondwossen Bitew[1], Firdaweke Bekele[1], Fikresilasie Samuel[1], Jemal Moges[1], Yakub Ragu[1], Emily Griswold[2], Anley Haile[1], Zerihun Tadesse[1], Jenna E. Coalson[2], Frank O. Richards[2], Gregory S. Noland[2]

[1]The Carter Center, Addis Ababa, Ethiopia, [2]The Carter Center, Atlanta, GA, United States

Onchocerciasis is a disease caused by Onchocerca volvulus and transmitted by the bite of Simulium vectors. Control efforts began in Ethiopia in 2001 with annual mass drug administration (MDA) with ivermectin. MDA must be given for 10+ years to control disease transmission. The program shifted toward elimination of transmission in 2012, commencing semi-annual treatment and targeting MDA to all endemic districts. This decision followed refinement mapping studies done in 2011 that uncovered untreated hyperendemic areas with nodule prevalence >40%. We undertook baseline surveys to document the prevalence of skin microfilaria (mf) in first-line villages in 7 districts in Oromia region. After at least 10 rounds of semi-annual MDA with >80% reported coverage, impact assessments were conducted in these districts in 2016 and 2017. A convenience sample was used for skin snip testing in ≥50 adults per community aged ≥20 years who had lived in the area for ≥10 years. Dried blood spots (DBS) were also taken at this time from 300 children per district aged <10 years. All consented/assented individuals underwent skin snip examination and DBS collection for Ov16 antibody analysis using ELISA following standard methods. In Jimma, 4 districts (Goma, Sokoru, Sigmo, and Setema) showed decreases in mf prevalence. Mf prevalence in Goma declined from 45.2% at baseline (2012) to 5.3% in 2017 (p=0.0), Sokoru dropped from 2.4% to 0% (p=0.08), Sigmo from 6.3% to 1.3% (p=0.02), and Setema from 10.6% to 4.7% (p<0.05). Ov16 antibody prevalence ranged from 0% to 1.6% at the time of follow-up. Three districts were evaluated in Illubabor. Sale Nono had mf prevalence of 54.5% in 2012, with significant reduction to 4.9% at impact assessment in 2016 (p=0.0). Bure and Hallu likewise showed significant decreases in mf prevalence, 28.5% to 1.9% (p=0.0), and 34.9% to 0.5% (p=0.0), respectively in 2016. Ov16 antibody prevalence at the second timepoint ranged from 0.3% to 4%. Twice-per-year treatment with high coverage showed encouraging progress towards the elimination of onchocerciasis transmission in hyperendemic districts.

6325

ELIMINATING ONCHOCERCIASIS IN LOIASIS ENDEMIC AREAS: ADDED VALUE OF THE SLASH AND CLEAR STRATEGIES

Joelle L Siakam Tanguep[1], Phillipe B Nwane[2], Hugues C Nana-Djeunga[2], Sevilor Kekeunou[3], Joseph Kamgno[4]

[1]Higher Institute of Scientific and Medical Research (ISM)/ 2Zoology Laboratory, Department of Animal Biology and Physiology, Faculty of Science, Yaoundé, Cameroon, [2]Higher Institute of Scientific and Medical Research (ISM), Yaoundé, Cameroon, [3]Zoology Laboratory, Department of Animal Biology and Physiology, Faculty of Science, Yaoundé, Cameroon, [4]Higher Institute of Scientific and Medical Research (ISM)/Department of Public Health, Faculty of Medicine and Biomedical Sciences, Yaoundé, Cameroon

In areas where onchocerciasis and loiasis are co-endemic, the routine control strategy, community-directed treatment with ivermectin (CDTI) is prohibited as it can lead in potentially deadly serious adverse events (SAEs) in patients heavily infected with Loa loa. It appears compulsory to identify SAEs risk-free alternative or complementary interventions to guarantee complete elimination of onchocerciasis. For this purpose, we carried out our study to assess the efficacy of an environment-friendly vector control approach, so-called the Slash and Clear (S&C). Monthly (3 days per month) capture of blackflies carried out using human landing catching over a period of 12 months along the Kelle River for baseline data collection. The trailing vegetation constituting blackfly breeding sites were destroyed by trained community volunteers (Slash and Clear) every month of the second year (4-5 days/month), and the impact of this breeding site destruction on blackfly densities was assessed by harvesting flies following the same procedure as during the baseline entomological survey. A total of 11,142 flies were collected during the two years, 9,720 before S&C and 1,422 after S&C, for an overall reduction rate of 100% in the head. The average larval reduction rate was 74.5%. These results confirm the significant impact of Slash and Clear on the reduction of blackfly densities, and might help accelerating the elimination of onchocerciasis in areas where loiasis in endemic.

6326

STRENGTHENING OF THE LOCAL HEALTH CAPACITY FOR THE IMPLEMENTATION OF THE FRAMEWORK FOR ELIMINATION OF MOTHER-TO- CHILD TRANSMISSION OF HIV, SYPHILIS, CHAGAS DISEASE AND HEPATITIS B IN PAMPA DEL INDIO, CHACO, ARGENTINA

Mariana Fernández[1], Karina Duarte[2], Noelia Zalazar[2], Silvana Pividori[2], Graciela I. Martínez[1], Marcelo Wirtz[1], Favio Crudo[1], **Maria Victoria Periago**[3]

[1]Fundación Mundo Sano, Buenos Aires, Argentina, [2]Hospital Dr. Dante Tardelli, Pampa del Indio, Salta, Argentina, [3]CONICET/Fundación Mundo Sano, Buenos Aires, Argentina

Pampa del Indio is a small locality in the province of Chaco, Argentina, located in the Gran Chaco ecoregion, traditionally a hotspot for Chagas Disease (ChD) due to vector transmission. Continuous vector control and environmental/land changes have reduced this transmission route in the area and vertical transmission of ChD is gaining importance. Given the presence of Mundo Sano in this municipality since 2008, working on vector control in a public-private association with local authorities, activities have evolved to a focus on diagnosis and treatment of ChD and implementation of the Elimination of Mother-To- Child Transmission (EMTCT) Plus initiative recommended by the World Health Organization (WHO) to eliminate mother-to-child transmission (MTCT) of ChD together with HIV, syphilis, and Hepatitis B. The activities are centered on achieving and sustaining the EMTCT of the four infections and to promote comprehensive access for pregnant women to high-quality control of their pregnancy and post-partum, specially focused on ensuring access to health to pregnant women living in rural communities. This is possible due to bi-monthly visits by a local mobile specialized team that perform the controls using rapid tests and a mobile ultrasound (US). Since its implementation in April 2022 and up to December 2022, five visits were performed in the urban area and rural settlements of Pampa del Indio with a 92.0% coverage of pregnant women (450 out of 489 estimated annual pregnancies for the area). All 450 women were screened for the four infections, and they all had access to US controls with an average of 2.3 comprehensive controls per woman. Hepatitis B and HIV infections were not detected while the prevalence of ChD and syphilis was 4.2% (n = 19) and 2.4% (n = 11), respectively. The use of rapid tests assured immediate application of treatment protocols and the planning of epidemiological actions to test other family members.

6327

MONITORING TRACHOMA MASS ADMINISTRATION USING AN ELECTRONIC SUPERVISOR COVERAGE TOOL

Joyce Achan[1], Edwin Mayoki[1], Stephen Begumisa[1], Rapheal Opon[2], Charles Kissa[2], Sharone Backers[1], Stella Agunyo[1], Alex Rutagwabeyi[1], Denis Olaka[3], Stephen Otim[4], Alfred Mubangizi[2], Clara Burgert-Brucker[5], Brian Allen[5], Erica Shoemaker[5], Jeremiah Ngondi[5]

[1]RTI International, Kampala, Uganda, [2]Ministry of Health, Kampala, Uganda, [3]District Local Government, Nabilatuk, Uganda, [4]District Local Government, Moroto, Uganda, [5]RTI International, Washington, DC, United States

An electronic Supervisor Coverage Tool (SCT) was developed and deployed in trachoma endemic districts in Uganda during the mass drug administration (MDA) implemented in August 2022 (round one) and January 2023 (round two) with the aim of improving MDA coverage. The surveys were carried out in Moroto and Nabilatuk. The main aim of the SCT was to measure MDA coverage and take immediate corrective action related to low MDA coverage. The SCT uses lot quality assurance sampling to classify communities coverage. The levels of coverage for trachoma are good coverage (80% and above), cannot conclude that coverage is good (55% to less than 80%) and inadequate coverage (less than 55%). Communities (supervisory areas) with previously low MDA coverage were purposively sampled, 20 households randomly selected, and one respondent per household randomly selected to be surveyed. In each district, 21 communities were visited in round one while 89 were visited in round two. Data was collected with android phones using Open Data Kit. Central, district, and subcounty supervisors administered the SCT. Data was analyzed using real-time data monitoring within the data collection form followed by post survey analysis in Stata. The number of communities with good coverage increased from 17 (81%) in 2022 to 80 (90%) in 2023, while 2(9.5%) and 7(8%) had inadequate coverage, and 2 (9.5%) and 2 (2.2%) had bad coverage, respectively. In 2023, 98% of surveyed individuals had been offered medicines while in 2022 it was only 87%. The main reasons for not being offered medicines in both 2022 and 2023 were similar: not present at home, distributor not come to home, busy/occupied, and unaware of MDA. The main immediate action taken was mop-up by distributors targeting missed individuals. SCT results can be used to make changes or enhancements to MDA while in the field, identify low performing communities, proportion reached and those that swallowed the medicines. Additionally, use of electronic data collection allows for central display of real time results for all communities surveyed, timely follow-up with supervisors at different levels and immediate action taken as needed.

6328

THE ROLE OF MICROBIOTA AND CO-LOCALIZATION IN THE DISSEMINATION OF VECTOR TRANSMITTED PATHOGENS

Leon Dimitri Melo, Matheus Carneiro, Chukwunonso Nzelu, Nathan Peters

University of Calgary, Calgary, AB, Canada

Insect vectors are important agents in the transmission of infectious diseases. Through a processcalled dissemination, many pathogens can enter the body of a host through the bite of an insectvector and then exit the skin to cause a systemic infection. The details about how and whendissemination occurs are still unclear and elucidating this is important for understanding diseasepathogenesis and the development of new therapies and vaccines. Leishmaniasis is a vector-bornedisease, and in its visceral form, Leishmania spp. parasites can disseminate from the skin to internalorgans. Various factors from the host, vector and parasite have been implicated in thedissemination process, including the microbiota derived from the from the insect vector gut.However, while vector microbiota is required for dissemination, it is not sufficient. The goal ofthis study is to determine whether the micro-colocalization of parasites, vector- and host-derivedfactors, including the microbiota that occurs following sand fly bite versus bolus injection is arequirement to induce the physiological conditions that facilitate dissemination. The resultsobtained will contribute to a better understanding of the pathophysiology of leishmaniasis. Wehypothesize that bacteria, co-localized with other host and vector factors, influence the physiologyof the skin and facilitate the dissemination of Leishmania spp. To evaluate this, we will first studydissemination in wild type mice and mice deficient in several innate TLR-related signallingpathways employing a novel model of Leishmania spp. infection, the skin prick, that co-localizedthese factors in the skin. We will then determine the requirement of bacteria and co-localization,using skin-prick, bolus, and sand fly models of infection in Germ-Free (GF) mice allied with thetechniques of flow cytometry and Live Cell Imaging.

6329

INFECTION OF MONOCYTES WITH LEISHMANIA INFANTUM CAUSES DIFFERENCES IN EXTRACELLULAR VESICLE MIRNA PROFILES

Cinthia L. Hudachek, bayan Zhanbolat, Mary Wilson

university of iowa, iowa city, IA, United States

Leishmania infantum is an obligate intracellular protozoan that is spread through the bite of a sand fly and causes visceral leishmaniasis. Both the parasite and infected macrophages release extracellular vesicles (EVs), including exosomes. EVs contain proteins, lipids, mRNAs, and microRNAs that can spread widely and have biological activities throughout a host. Our lab has previously shown that the protein content of EVs from MDMs infected with L. infantum differs from uninfected MDMs. We wanted to question whether the miRNA content of EVs would differ between uninfected and infected MDMs. miRNA are potent regulators of post-translational gene expression. Blood from 3 healthy human donors were obtained from the University of Iowa blood bank. Monocytes were infected with L. infantum, and after 48 hrs EVs enriched in exosomes were purified from extracellular medium and analyzed on the nanosight to investigate concentration and size. Small RNAs were extracted from EVs, and the abundance of known or putative human miRNAs was screened using a NanoString human miRNA panel. There was a trending increase in the overall production of Evs from infected MDMs compared to uninfected control but no difference in mean or mode size. hsa-miR-29a-3p and hsa-miR-575 were significantly upregulated in EVs of infected MDMs and hsa-miR-1305 and hsa-miR-1285 were downregulated compared to EVs of uninfected MDMs. Known functions of these miRNAs include the upregulation of genes contributing to the M2 phenotype and possible suppression of proinflammatory response. Infection with L. infantum shows a trending increase of exosomes released from human MDMs as well as a change in miRNA content. Evs from infected cells show an increase in miRNAs that might influence M2-type polarization and target proinflammatory genes. These data suggest that Ev miRNAs of MDMs infected with L. infantum might alter the surrounding environment to potentially dampen local inflammatory or curative immune responses.

6330

PEOPLE WITH DIFFERENT CLINICAL PRESENTATIONS OF LEISHMANIA DONOVANI INFECTION HAVE DIFFERENT MICRO-RNA PROFILES IN CIRCULATING PLASMA

Ritirupa Roy[1], Cinthia Hudachek[2], Shashi Bhushan Chauhan[1], Vimal Verma[1], Sundaram Pandey[1], Shashi kumar[1], Rajiv Kumar[3], Mary E. Wilson[2], Madhukar Rai[1], Shyam Sundar[1]

[1]Institute of Medical Sciences, Banaras Hindu University, Varanasi, India, [2]University of Iowa and the Iowa City VA Medical Center, Iowa, IA, United States, [3]Centre of Experimental Medicine and Surgery, Banaras Hindu University, Varanasi, India

Visceral leishmaniasis (VL) is a tropical neglected disease caused by Leishmania donovani, results in significant mortality in the Indian subcontinent. Several microRNAs have been associated with either susceptibility or resistance to leishmaniasis, including miR-210 (Leishmania major), miR-122 and miR-146a (L. donovani), and miR-21 in (L. infantum). miRNAs are ~22 nt non-coding RNAs that can regulate many biological

and molecular functions at the post transcriptional level. Mainly they function by base pairing in the 3' or 5' UTR of target mRNAs and interfering with targeting the mRNA for degradation or modifying translation. Some miRNAs modify immune responses but the precise target of miRNAs implicated in leishmaniasis are unknown. There is a paucity of prior studies of miRNAs in primary human samples from subjects with VL. Most circulating miRNAs are packaged into micro vesicles called exosomes, which can circulate free of cells in the blood. Hence, we investigated the roles of miRNAs in circulating exosomes of patients from Bihar, India with different manifestations of L. donovani infection. We selected 6 candidate miRNAs to screen in human plasma: miR-21, miR-122, miR-155, miR-206, miR-146-a and miR-let-7c. Plasma from subjects with VL or post-kala azar dermal leishmaniasis (PKDL) were compared to healthy, endemic controls. We isolated plasma exosomes and confirmed isolation by transmission electron microscopy imaging and Nano particle tracking analysis. Small RNAs were extracted and differential expression of candidate miRNAs were evaluated by TaqMan miRNA assays. When compared to endemic control subjects, expression of miR-146a was increased plasma of both VL and PKDL patients compared to controls ($p<0.05$), whereas miR-206 was decreased in VL plasma compared to control samples. This is consistent with data from murine models and human monocyte derived macrophages indicating miR-146a skews infected macrophages from M1 to M2 phenotypes. miR-206 is reported to target FOXP-1 expression and influence macrophage function. We hypothesize these miRNAs may be critical determinants of immune response to L. donovani infection.

6331

PREVALENCE OF CUTANEOUS LEISHMANIASIS IN ENDEMIC COMMUNITIES OF THE VOLTA REGION, GHANA

Emmanuel Kwame Amoako[1], Seth O. Addo[1], Michael Amoa-Bosompem[2], Faustus Azerigyik[3], Thelma N. S Tetteh[1], Kwadwo Akyea-Mensah[1], Eric Kyei-Baafour[1], John A. Larbi[4], Mitsuko Ohashi[1], Michael D. Wilson[1], Ben A. Gyan[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]University of Tennessee, Knoxville, TN, United States, [3]Tokyo Medical and Dental University, Tokyo, Japan, [4]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Leishmaniasis continues to affect countries in the tropics and subtropics with previously non-endemic areas experiencing infections. In Ghana, an outbreak of suspected cases occurred in 1999 which led to the discovery of cutaneous leishmaniasis (CL) after Leishmania major was identified. Since then, various studies have been conducted in endemic communities that have revealed multiple Leishmania parasites. This has raised much public health concern, especially regarding effective control and treatment strategies. The study reports the baseline prevalence of CL infection in three communities in the Ho district of the Volta Region of Ghana. A total of 535 subjects were screened using Leishmanin Skin Test (LST) for detecting Leishmania exposure and finger prick blood for anti-leishmania IgG antibody levels. There was no significant difference ($p=0.9313$) in LST positivity (LST+) in all three communities. However, the highest LST positives were recorded by the age group 41-65 (62.8%) whiles the lowest (25%) was from the age group 6-18. It was also observed that the median levels of IgG units between both males and females were significant ($p=0.0002$). LST positivity correlated to higher levels of antibodies, suggesting their potential as a risk marker for CL acquisition in Ghana.Current reports from the Health Services of Volta region suggest ongoing infections in communities, thus control efforts need to be implemented to reduce the disease burden.

6332

EXPRESSION OF ENDOPLASMIC RETICULUM STRESS RESPONSE MARKERS IN CUTANEOUS LEISHMANIASIS

Nimesha M. Edirisinghe[1], Nuwani H. Manamperi[2], Harshima Wijesinghe[3], Vishmi Wanasinghe[1], Chamalka De Silva[1], Nadira D. Karunaweera[1]

[1]Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, [2]Department of Parasitology, Faculty of Medicine, University of Kelaniya, Kelaniya, Sri Lanka, [3]Department of Pathology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Cutaneous leishmaniasis (CL) is an intracellular parasitic infection that can cause loss of endoplasmic reticulum (ER) homeostasis by disrupting the protein folding process. This leads to the accumulation of unfolded proteins in the ER lumen and stimulates ER stress response to restore protein homeostasis in the ER. The present study aimed to immunohistochemically validate the endoplasmic reticulum stress response in CL by determining the expression of the Inositol Requiring Enzyme1 (IRE1), Protein Kinase RNA like ER kinase (PERK) and Activating Transcription Factor6 (ATF6) sensory proteins in lesion tissues. Sections (4 µm) of formalin-fixed paraffin-embedded tissue samples from thirty leishmaniasis-confirmed patients and thirty control participants were mounted on positively charged slides. The tissue sections were deparaffinization in xylene and rehydrated with graded alcohol. Antigen retrieval was conducted by microwave-boiling of the slides in 10mM Sodium citrate buffer (pH 6.0) for IRE1 and ATF6, and EDTA buffer (pH 9.0) for PERK. Endogenous peroxidase was blocked by incubating in 3% hydrogen peroxide for 10 minutes followed by washing in deionized water. The tissue sections were incubated overnight at 4°C with rabbit polyclonal antibodies against IRE1 (ab37073), PERK (ab79483), and ATF6 (ab203119). The antigen-antibody complex was detected with the labeled streptavidin-biotin (LSAB) method. Visualization was done by reacting with 3,3′-Diaminobenzidine (DAB) and counterstained with hematoxylin. Staining was observed by a histopathologist, and data were analyzed using SPSS (version 25.0). Staining was observed in the patient samples in contrast to the control samples which showed minimal staining. A significant difference ($p<0.05$) was observed between gender and expression of IRE1, PERK, and ATF6 markers and the histological grading of CL tissue and ER stress marker expression. In conclusion, this study demonstrates a significant difference in the expression of ER stress markers with regard to gender and histological grading of infected tissue.

6333

IMPACT OF DECLINING DISEASE TRANSMISSION ON MAINTENANCE OF IMMUNOLOGICAL MEMORY IN SUBJECTS WITH PAST HISTORY OF VISCERAL LEISHMANIASIS

Rahul Tiwari[1], Awnish Kumar[1], Vishal Kumar Singh[1], Shyam Sundar[2], Rajiv Kumar[1]

[1]Centre of Experimental Medicine and Surgery, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India, [2]Department of Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Visceral leishmaniasis (VL) is a visceralizing form of leishmaniasis caused by L. donovani and its cure is associated with IFNγ dominant Th1 immune response. Infection induced immunological memory and its maintenance is crucial for resistance to re-infection. A loss of recurrent antigenic exposer in areas with no transmission may lead to loss of memory T cells responsible for this resistance and may increase the possibility of disease re-emergence. Although India is marching towards achieving the goal of elimination and current transmission may be very low to absent, the risk of VL re-emergence and future outbreaks cannot be neglected. The present study aims to identify soluble leishmanial antigen (SLA) specific cytokine responses and reactive T central memory (Tcm) and effector memory (Tem) cells profile with effector and proliferative potential in subjects with past history of VL from area of no transmission (NT; areas with no reported cases in last five years), continuous transmission (CT; areas with continuous

reported cases) and outbreak (OB; areas with reappearance of cases after a brief period of absence). Th1, Th2 and Th17 cytokines production was determined in supernatants of SLA stimulated whole blood using cytometric bead array (CBA). Also, peripheral blood mononuclear cell (PBMC) treated with SLA was assessed for the frequency of Tcm and Tem cells expressing activation and proliferation markers using flowcytometry. A significant increase in pro-inflammatory cytokines like IFNγ, IL-6 and IL-2 along with anti-inflammatory IL-10 was observed in the SLA stimulated whole blood of NT and OB groups. In addition to this increased activation of Tcm and Tem cells of both CD4+ and CD8+ types were observed in response to the antigenic stimulation. Only CD4+ Tcm of OB group exhibited proliferative potential. Overall, our current findings are suggestive of a mixed cytokine profile in OB and NT groups which indicates the persistence of possible immune regulatory mechanisms, similar to the active disease and the proliferative response of CD4+ Tcm may be an implication of recent antigenic exposer due to ongoing transmission in OB group.

6334

MULTIMODAL THERAPEUTIC TREATMENT FOR CHRONIC CHAGAS DISEASE

Maria Jose Villar[1], Cristina Poveda[1], Ana Carolina de Araujo Leao[1], Yi-Lin Chen[1], Kris Eckols[2], Maria Elena Bottazzi[1], Peter J. Hotez[1], David J. Tweardy[2], Kathryn M. Jones[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]MD Anderson Cancer Center, Houston, TX, United States

Chagas disease is a neglected tropical disease that is caused by the parasite Trypanosoma cruzi, which is spread by a triatomine bug, also known as the “kissing” bug. The acute stage of this infection can result in flu-like symptoms and can be treated by killing the parasite with anti-parasitic treatments. Treatments such as Benznidazole and Nifurtimox are effective in the acute stage, though they may cause severe side effects. However, most infected patients will not present signs and symptoms until they have reached the chronic stage, which often leads to cardiomyopathy and enlargement of other internal organs. Unfortunately, antiparasitics have poor efficacy during chronic disease. Studies have shown that an appropriate immune response to the parasite, with a balanced TH1/TH2/TH17 cytokine response, correlates with better cardiac health.Our overall goal is to develop a multimodal therapeutic treatment strategy to improve treatment efficacy. Here we tested combination treatments using the small-molecule STAT3 inhibitor, TTI-101, as well as a recombinant protein vaccine containing the Tc24-C4 antigen and different doses of benznidazole. We infected female BALB/c mice with 5000 blood form bioluminescent H1 strain trypomastigotes and started treating these mice 70 days post infection (dpi). Vaccinations were given subcutaneously twice, three weeks apart. Benznidazole (100mg/kg and 25mg/kg) and TTI-101 (50 mg/kg) were administered orally once daily for 20 days. Mice were given one, two or three treatments sequentially. Mice were euthanized at 234 dpi, then blood and tissues were collected to evaluate cytokine responses. Our results show that combining our Tc24-C4 vaccine with a low dose of benznidazole and TTI-101 induced an antigen specific TH1/TH2/TH17 cytokine response with increased levels of IFNγ, IL-6, IL-2, IL-4, IL-10, IL-22 and IL-17A. This suggests that multimodal treatment induces a balanced cytokine response that could lead to reduced tissue pathology and improved cardiac health.

INTESTINAL MICROBIOTA MEDIATE PROTECTION AGAINST GIARDIA INFECTION INDEPENDENT OF HOST ADAPTIVE IMMUNITY

Renay Ngobeni[1], Kenneth Walsh[1], Jason Arnold[1], Jamie Xiao[1], Morgan Farmer[1], Shan Sun[2], Anthony Fodor[2], Luther Bartelt[1]

[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]The University of North Carolina Charlotte, Charlotte, NC, United States

Giardia lamblia (Giardia) is a nearly universal gut pathogen in undernourished children. In these children, Giardia frequently persists for long durations, however, the specific mechanisms underlying this susceptibility to persistent infections are poorly understood. Experimental murine models indicate that intestinal microbiota may contribute to Giardia clearance. Whether microbiota protect against Giardia colonization by enhancing host immunity and/or by non-immune mediated pathways is unknown. Using gnotobiotic techniques, we challenged germ-free (GF) wild-type (WT) or immunodeficient (Rag2-/-) mice with axenic Giardia cysts either alone or together with a standardized murine cecal intestinal microbiota transfer (cIMT). In all GF mice, small intestinal Giardia colonization persisted at high burdens (≥ 106/4 cm) and for at least 21 days after challenge, regardless of diet. In contrast, all mice conventionalized with IMT were protected against Giardia colonization. Immune responses to Giardia extracts in splenocyte recall assays were similar between cIMT-conventionalized and mono-associated WT mice. In addition, the standardized cIMT was equally protective against Giardia colonization in Rag2-/- mice, despite absence of T/B cells in these immunodeficient hosts. In contrast, a fecal IMT (fIMT) from a different mouse colony permitted high-burden and persistent colonization. 16S rDNA amplicon profiles demonstrated differences in Clostridium spp. among other sequence variants differentiating cIMT-conventionalized Rag2-/- mice that were protected against Giardia colonization and fIMT-conventionalized Rag2-/- mice that were not. Our models indicate a crucial role for intestinal microbiota-mediated protection against Giardia colonization that occur through pathways independent from host-dependent adaptive immunity. These findings warrant further studies to determine how specific intestinal bacteria may alter susceptibility to Giardia infection, and whether similar interactions occur in undernourished children who also demonstrate impaired immunity and disruptions in intestinal microbiota.

COMPARISON OF DERMAL AND SYSTEMIC IMMUNE RESPONSES IN PROGRESSIVE STAGES OF CANINE LEISHMANIOSIS

Max C. Waugh, Danielle Pessôa-Pereira, Christine A. Petersen

The University of Iowa, Iowa City, IA, United States

Canine leishmaniosis (CanL), caused by the zoonotic obligate intracellular protozoan parasite Leishmania infantum, is a significant public health concern for humans and domestic dogs, the primary reservoir. In endemic areas, vector transmission by sandflies predominates, while vertical transmission has been found as an alternate important means of transmission. Leishmania spp. has significant dermal tropism. However, in xenodiagnoses studies, the most severe CanL cases had less transmission to naïve sandflies than mild to moderate CanL cases, despite dermal parasite burden increasing as disease progressed. These results indicate that additional host-parasite factors influence transmissibility. The interplay between parasites and systemic host immune cells linked disease progression to immune exhaustion and a shift in the systemic immune response from pro-inflammatory to regulatory. Due to continuous environmental antigen exposure, the cutaneous immune environment is more immunotolerant, potentially influencing its responses during CanL progression and altering transmission. Cutaneous immune cells/parasite interactions, which affect transmissibility to competent vectors, have not been evaluated. RNAscope, a sensitive immunofluorescence technique, was used to assess how the cutaneous immune environment correlates

with parasite presence and burden across clinical stages, determined by the LeishVet staging guidelines. An amastin probe identified amastigotes, and dermal macrophages were marked with a CD14 probe. Parasite and macrophage counts, along with spatial relationships between amastigotes, dermal macrophages, and cutaneous structures were evaluated and correlated with H&E-stained slides. Future work will investigate lymphocyte responses in the dermal immune environment and integrate spatial transcriptomics data to further characterize the cutaneous immune environment across CanL clinical stages. This is essential for understanding the host-parasite interactions that influence transmission of Leishmania from canines to sandflies.

EVALUATION OF BLT2 RECEPTO IMMUNOREACTIVITY IN CARDIAC TISSUE FROM RATS INFECTED WITH TRYPANOSOMA CRUZI AT DIFFERENT POST-INFECTION STAGES

Carlos Javier Neyra Palacios[1], Edith S. Málaga Machaca[1], Jose O. Zapata More[1], Beth J. Condori[1], Maritza M. Calderón[2], Cesar Gavidia[3], Manuela R. Verástegui[3], Robert B. Gilman[4]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Peruana Cayetano Heredia, Infectious Diseases Laboratory Research-LID, Facul, Peru, [3]Universidad Peruana Cayetano Heredia, Infectious Diseases Laboratory Research-LID, Peru, [4]Universidad Peruana Cayetano Heredia, The Department of International Health, Bloomberg, MD, United States

Chagas disease is a public health problem caused by Trypanosoma cruzi. In the chronic stage of the disease, the leukotriene receptor type 2 (BLT2) pathway is linked to inflammatory mechanisms. BLT2 increases the mobilization of Ca2+, leading to a greater production of nitric oxide (NO). The released NO could interact with superoxide to form peroxynitrite, followed by nitration and dysfunction of cardiac cells with important pathological consequences, thus an exacerbated proinflammatory environment at the myocardial level could be involved in an increase in fibrosis at the cardiac level. In the present study, the immunoreactivity of the BLT2 receptor and its relationship with fibrosis were evaluated in a Chagas model using Holtzman rats infected with 2x104 trypomastigotes of Y strain, via the intraperitoneal route, thus having 7 groups, each group with 6 rats and the control groups. (uninfected rats). Sacrifices were made at 7, 15, 30, 3, 90, 6, 270, and 365 days post infection (DPI). Evaluation used immunohistochemistry, Masson's trichrome staining, and hematoxylin and eosin. Amastigotes were observed in cardiac tissue at 7 and 15 DPI. However, at 7 DPI it is possible to observe few mononuclear cells and an increase of these at 15 DPI. No nests of amastigotes were observed after 30 DPI; however, inflammatory foci were observed at the tissue level. Likewise, from 90 DPI, a slight increase in significant interstitial fibrosis/scarring is observed without mononuclear cells; on the other hand, it was found that the immunoreactivity of the leukotriene B4 type 2 receptor is higher in the acute phase and decreases after three months. To corroborate this, the analysis of BLT2 immunoreactivity was performed in infected rats and compared with controls, finding that this receptor is more expressed at 7 ($p<0.001$), 15 ($p<0.01$) and 30 DPI ($p<0.01$). Therefore, it is concluded that in the acute phase of the disease there is a correlation between inflammation and expression of the BLT2 receptor ($p<0.05$). This could be because LTB4 is a chemotactic eicosanoid. However, no relationship was found between increased fibrosis and expression of this receptor ($p>0.05$).

PEPTIDE SELECTION VIA PHAGE DISPLAY TO INHIBIT LEISHMANIA-MACROPHAGE INTERACTIONS

Juliane Buzzon Meneghesso Verga

São Paulo State University (UNESP), Araraquara, Brazil

Leishmaniasis represents a complex of diseases caused by protozoan parasites from the Leishmania genus that causes life-threatening manifestations depending on the species responsible for the infection. Given the high toxicity and cost of the current therapies, leishmaniasis is a public health problem. New interventions to hinder the interaction of the parasite with phagocytic cells are urgently needed to accelerate the development of new treatments or vaccines. Here, we used a phage display library to identify peptides targeting interaction of metacyclic promastigotes of L. amazonensis (causative agent for cutaneous leishmaniasis) and L. infantum (causative agent for cutaneous and visceral leishmaniasis) with phagocytic host cells. We identified one L. amazonensis binding peptide (La1), and two L. infantum binding peptides (Li1 and Li2). Importantly, peptide binding to the parasite surface impairs parasite internalization into THP-1 macrophages. The La1 peptide inhibits L. amazonensis only. However, Li1 and Li2 inhibit both L. amazonensis and L. infantum. Li1 and Li2 show promise for multi-species vaccine development, while La1 is an alternative option for species-specific vaccine development.

The presence of the RNA virus (LRV) in parasites of the genus Leishmania and its association with increased pathology and treatment failure in individuals with skin infections have been described. Categorized as LRV-2 in the Old World and LRV-1 in the New World, this virus was detected in Leishmania isolates in American countries such as Brazil, French Guyana, Colombia, Peru, Ecuador, and Costa Rica. However, in Panama it is unknown whether the presence of LRV in the Leishmania parasite influences the pathology and therapeutic response of cutaneous leishmaniasis (CL). It is hypothesized that LRV-1+ isolates are more infective, and therefore cause more severe pathologies. In this regard, in this study the in vitro behavior of LRV-1 positive and negative Leishmania isolates were studied, evaluating the differences in infectivity in U937 human macrophages at 24, 48 and 72 hours post infection. Ten fields were counted for each slide, obtaining a total of 100 cells per slide. This was done in triplicate for each isolate for the different infection times. To calculate the infection index, the percentage of infected macrophages was multiplied by the ratio of amastigotes/macrophages. Fourteen isolates were used, 7 LRV+ and 7 LRV-, including species of L. (Viannia) guyanensis, L. (V.) panamensis and L. Viannia sp. from the ICGES biobank. Additionally, 3 reference strains of L. (V.) guyanensisLRV+, L. (V.) panamensis LRV- and L. (V.) braziliensis LRV- were evaluated as controls. The presence of LRV was detected by the RT-PCR methodology with the primers LVR ORF-1/2 (850bp) and LVR-1F/1R (240bp) and confirmed by Sanger sequencing as LRV-1. Comparison analysis of infection index showed increased infectivity of Leishmania ViannaLRV+ compared to LRV- isolates. These results showed that Leishmania Viannia LRV+ isolates may be more infective than

LRV- for U937 human macrophages. Future studies are recommended to evaluate the anti and pro-inflammatory cytokine profile induced during in vitro infections with Leishmania LRV+ isolates.

6340

DETECTION OF LEISHMANIAVIRUS IN ISOLATES OF LEISHMANIA VIANNIA IN PANAMA, CENTRAL AMERICA

Armando Bonilla[1], Vanessa Pineda[2], José Calzada[3], Azael Saldaña[4], Marcia Dalastra Laurenti[5], Luiz Felipe Passero[5], Davis Beltran[6], Leyda Abrego[7], Kadir González[8]

[1]Faculty of Natural, Exact and Technology Sciences, Master's Program in Parasitological Sciences, University of Panama, University of Panama, Panama, [2]Gorgas Memorial Institute for Health Studies, Gorgas Memorial Institute for Health Studies, Panama, [3]Faculty of Veterinary Medicine, Gorgas Memorial Institute for Health Studies, National Research System, University of Panama, Panama, [4]National Research System, Center for Research and Diagnosis of Parasitic Diseases (CIDEP), Department of Human Microbiology, University of Panama, Panama, [5]Infectious Disorders Pathology Laboratory, Faculty of Medicine, University of São Paulo, Brazil, [6]Gorgas Memorial Institute for Health Studies, Department of Virology Research, Gorgas Memorial Institute for Health Studies, Panama, [7]National Research System, Gorgas Memorial Institute for Health Studies (ICGES), Department of Virology Research, School of Biology, Faculty of Natural and Exact Sciences and Technology, University of Panama, Panama, [8]Gorgas Memorial Institute for Health Studies (ICGES), Parasitology Research Department, National Research System, Department of Human Microbiology, Faculty of Medicine, University of Panama, Panama

Leishmaniasis is a vector disease caused by protozoa of the genus Leishmania that affect humans producing a wide spectrum of clinical forms. Recently, the association of some Leishmania species with the presence of an endosymbiont double-stranded ribonucleic acid virus from the Totiviridae family called leishmaniavirus (LRV) have been described, showing increased pathology and treatment failures in individuals with cutaneous and mucocutaneous forms of the disease. Two types of LRV have been describes, type 1 circulates in the Americas while type 2 in the Old World. In America, the presence of LRV has been reported in Leishmania isolates from French Guiana, Brazil, Peru, Colombia, Ecuador, and Costa Rica. In a recent pilot study in Panama, 10 L. (V.) panamensis LRV-1+ isolates were detected by RT-PCR. In Panama, it is unknown if there are other species of Leishmania Viannia (L. (V.) guyanensis and L. (V.) braziliensis) associated with the presence of LRV-1. Therefore, the aim of this study was to detect LRV-1 in 100 Leishmania Viannia isolates from different leishmaniasis-endemic areas in Panama cryopreserved at ICGES biobank. Samples were collected between 2015 and 2022. Two molecular methodologies were used based on a RT-PCR that amplify the RNA of the ORF1 and ORF2 regions of the viral capsid. The results show that, it was possible to detect seven L. Viannia LRV+ (7/100: 7%), characterized as LRV-1 by Sanger sequencing analysis. With the LRV ORF-1/2 primers (850bp), one isolate of L. (V.) guyanensis LRV+ was found, and seven with the LVR-1F/1R primers (240bp), including species of L. (V.) guyanensis, L. (V.) panamensis and L. Viannia sp. These results demonstrate the circulation of LRV-1 in leishmaniasis endemic areas of Panama, and in different Leishmania (Viannia) species.

CELL-BASED CARDIOMYOPATHY MODELS FOR CHAGAS DISEASE BIOMARKER DISCOVERY

Yu Nakagama[1], Masamichi Ito[2], Katherine Candray[3], Yasutoshi Kido[1]

[1]Osaka Metropolitan University, Osaka, Japan, [2]The University of Tokyo, Tokyo, Japan, [3]National Rosales Hospital, San Salvador, El Salvador

Chagas heart disease (CHD), the malignant cardiomyopathy triggered by Trypanosoma cruzi infection, is among the most prevalent neglected tropical diseases. Lacking relevant in vitro models, biomarker development for CHD prognostication and precision care has lagged.Methods; Murine and human cardiomyocytes were infected with trypanosomes to model CHD in vitro (CHD-CMs). Trypanosomes from variable genetic strains were assessed of cytopathogenicity (RTCA eSight). Motion vectors (SI8000 Imaging System) and calcium handling (FDSS/µCELL) analyses characterized CHD-CM excitation/contraction features. Transcriptomic analysis, in bulk and in single-cell resolution, and secretory phenotyping of CHD-CMs were applied for elucidating the host response signatures and its pseudotime trajectories.Results; 'Tc I/II' genetic strain Trypanosomes evoked evident cytopathogenic effects in vitro ($p < 0.05$). CHD-CMs recapitulated the excitation/contraction abnormalities in CHD and the extent of phenotypic deterioration was associated with tissue tropism per trypanosome genotype. Trypanosome infection led to differential expression of chemokine/cytokine activation-, heart beta-oxidation-, and oxidative stress-related genes. Along with known CCL/CXCL (MCP-1 and IP-10), an emerging signaling peptide GDF-15, was identified to be upregulated upon infection ($p < 0.001$). Co-culture experiments of CHD-CMs with other cardiac cell types (e.g. fibroblasts etc) indicated humoral factor-specific pathogenic roles in intra-cardiac cellular communication.Conclusions; Cardiomyocytes act as the upstream sentinels of pathogen encounter. Signatures of the CHD-CM response against trypanosome invasion constitute candidate CHD biomarkers.

GENETIC TAXONOMIC ANALYSIS OF CHILOMASTIX GENUS

Chuanhao Jiang[1], Siti Arifah Lacante[1], Tetsushi Mizuno[1], Din Syafruddin[2], Masaharu Tokoro[1]

[1]Department of Global Infectious Disease;Graduate School of Medical Science Kanazawa University, Kanazawa, Japan, [2]Eijkman Inst. for Mol. Biol., Indonesia & Dept of Parasitol. Fac. Med., Hasanuddin Univ., Indonesia, Makassar, Indonesia

There are many species named Chilomastix, such as C. caulleryi, C. cuspidata, C. wenrichi, C. cuniculi, C. bettencourti, C. caprae, C. gallinarum, C. equi, C. sulcatus, C. motellae Alexeieff. These species have been named based on morphology, with varying naming conventions such as author names or local host vocabulary, and generally lack gene-based evidence. To address the molecular taxonomy of Chilomastix species appropriately, the 18S small subunit of ribosomal RNA (18SrRNA) gene locus of Chilomastix spp. detected from 356 stool samples isolated from humans and 380 stool samples isolated from animals which were collected in Wainyapu Village, Sumba Island, Indonesia were analyzed. From 100 18SrRNA partial positive sequences, 52 unique genotypes (1,425-1,986 bp) were confirmed and phylogenetically analyzed with the references of GenBank. Based on estimated posterior probability values, we clustered the DNA haplotypes of Chilomastix spp. into Subgroup1 and Subgroup2. Subgroup 1-A (human-specific, containing C. mesnili reference sequences), Subgroup 1-B (pig/human/buffalo/dog specific), and Subgroup 1-C (chicken specific, which we consider C. gallinarum). Subgroup 2 is mainly Rodent-hosted. But divide into two separate subtypes Subgroup 2-A (rodent-single host) and Subgroup 2-B (Rodent-Duck-buffalo hybrid, which includes a C. caulleryi reference sequence). In conclusion, the Chilomastix species that infect each host have a certain degree of specificity, and although the number of examined samples was limited, we could address a wide variety of genetic diversity of this species. The accuracy of the molecular epidemiology of Chilomastix can be improved by further registering reference sequences.

6343

MOLECULAR STUDY OF THE NUCLEOLAR METHYLTRANSFERASE FIBRILLARIN OF THE HUMAN PATHOGEN LEISHMANIA MAJOR

Tomas Nepomuceno-Mejía, Sagrario Aguirre-González, Luis Enrique Florencio-Martínez, Santiago Martínez-Calvillo

Universidad Nacional Autónoma de México, Estado de Mexico, Mexico

Fibrillarin is the enzymatic component of box C/D small nucleolar ribonucleoparticles (snoRNPs) involved in early processing and modification of ribosomal RNA (rRNA) primary transcript, and ribosome subunits assembly. Despite its importance, little is known about the functions

that Fibrillarin performs in the ancestral protozoan parasites of the genus Leishmania, microorganisms that cause different debilitating to fatal diseases. In this work, we initiated the molecular characterization of the Fibrillarin orthologue of L. major (ID:LmjF.36.3070; LmFib). Our in silico results showed that LmFib possesses the typical and conserved GAR region and methyltransferase domain. In addition, the predicted three-dimensional structure of LmFib is similar to the one reported in Saccharomyces cerevisiae. Furthermore, we generated transgenic L. major parasites that express a PTP-tagged version of LmFib to identify proteins that interact with it. By tandem affinity purifications, mass spectrometry and bioinformatic analyses, we found several activities (RNA helicases, GTPases, methyltransferases, among others) reported in yeast and human to interact with Fibrillarin, as well as approximately 65 structural ribosomal proteins. Notably, we also purified several interesting nucleolar proteins whose function has not been described. We are currently identifying the snoRNAs to which LmFib binds and analyzing if LmFib interacts with rRNA genes. PAPIIT IA200623

ESTABLISHMENT OF AN IN VITRO CULTURE MODEL OF TOXOPLASMA GONDII BRADYZOITE CYSTS

Fabrizio C. Vasquez[1], Edith M. Malaga[1], Maritza Calderon[1], Juan C. Jimenez[1], Manuela Verástegui[1], Robert H. Gillman[2]

[1]Infectious Diseases Laboratory Research-LID, Faculty of Science and Philosophy, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]The Department of International Health, Bloomberg School of Hygiene and Public Health, Johns Hopkins University, Lima, Peru

Toxoplasma gondii is an apicomplexa with a prevalence of 30% worldwide. The presentwork focuses on the chronic stage of the disease that is produced by the bradyzoite tissue cyst, as it tends to be drug resistant and is of high risk in immunosuppressed patients, so the study of its biology is of great importance. In the present study, we developed an in vitro model of bradyzoite cysts using LLCMK2 cells as host, with the aim of obtaining the highest number of cysts, the cells were cultured in 6-well plates containing cover slips where we infected the monolayers with the RH strain in a 1:1, 1:5 and 1:10. The initial phase of infection was performed in RPMI medium with 2% FBS at pH 7.2, at 37°C in the presence of CO2 for 24 hours for the correct establishment of the parasite. After this time, the medium was changed to RPMI 2% FBS, pH 8.5, at 37°C and in the absence of CO2. Four times were analyzed after the change of culture conditions: 72, 96, 120 and 144 hours post-change (h.p.c.). To identify bradyzoite cysts, cover slips were fixed with methanol:acetone, then stained with Giemsa and another group was fluorescence assayed using biotinylated Dolichus biflorus agglutinin (DBA) as primary marker and Alexa 594 streptavidin as secondary marker, together with DAPI. It was observed under a confocal microscope and then bradyzoite cysts and tachyzoite were counted in 50 fields using epifluorescence microscopy. As a result, at 120 h.p.c there was a better yield of bradyzoites/tachyzoites in relation to the other 3 times, however, being still low (10%) and showing high loss of the monolayer due to the high amount of extracellular tachyzoites. It is expected that with the 1:5 and 1:10 concentration the yield will increase and the monolayer and monolayer will remain intact. The next strain to be tested will be ME49, known to be highly cystogenic. It is expected that the results from this strain will have a better yield and number of cysts. Once standardized, these bradyzoites will be used to generate specific chronic phase antigens and thus implement a chronic phase diagnosis.

6345

DRUG REPURPOSING AND SCREENING OF LIBRARIES OF CHEMICAL COMPOUNDS TO IDENTIFY NEW ANTI-PARASITIC AGENTS

Oluyomi Stephen Adeyemi

Landmark University, Omu-Aran, Nigeria

The Trypanosoma and Toxoplasma spp, are etiological agents of diseases capable of causing significant morbidity, mortality, and economic burden, predominantly in developing countries. Currently, there are no effective vaccines for the diseases caused by these parasites; therefore, therapy relies heavily on antiprotozoal drugs. Non-biased screening of libraries of chemical compounds including the repurposing of well-characterized compounds is emerging as viable approach in identifying lead candidates for early drug development against parasitic diseases. As a proof-of-principle screen to identify effective anti-parasitic agents, we evaluated libraries of natural product (503), FDA-approved (640) compounds as well as imidazole derivatives (26) for potential to inhibit T. gondii growth. We identified 39 new compounds that potently and selectively restrict the growth of T. gondii. Furthermore, we evaluated some these compounds for activity against Trypanosoma growth both in vitro and in animal models. Findings revealed eight (8) imidazole derivatives active against Trypanosoma growth. Together, the findings are new and promising, and do not only strengthens the prospects of drug repurposing and the screening of wide range of chemical compounds as a viable approach in drug discovery toward effective anti-parasite therapy but also support imidazole-based compounds as alternative source of effective anti-parasitic agents.

6346

DEEP LEARNING APPROACH SUCCESSFULLY IDENTIFIES FDA APPROVED MOLECULES TO PRESENT ANTI-LEISHMANIA EFFECT AT THE PROMASTIGOTE STAGE

Rafeh Oualha, Yosser Zina Abdelkrim, Ikram Guizani, Emna Harigua-Souiai*

Laboratory of Molecular Epidemiology and Experimental Pathology - LR16IPT04, Institut Pasteur de Tunis, Université de Tunis El Manar, Tunis, Tunisia

Drug repositioning, a cost-effective approach in drug discovery, identifies new therapeutic applications for existing 'drugs' against NTDs, including Leishmaniases. An example of a successfully repurposed molecule is the anticancer treatment, Miltefosine, the first oral drug licensed for the treatment of leishmaniases. In this context, we have conducted a computer-aided drug repositioning approach based on the deepDR pipeline, an artificial intelligence (AI) tool. Then, we evaluated their activities in vitro against the promastigotes of three strains belonging to L. infantum (2) and L. major (1) species, using an MTT assay with the standard anti-Leishmania drugs Amphotericin B and Miltefosine as positive controls. We have selected, in silico, 14 FDA approved drugs to be potentially effective against leishmaniases, out of which 6 were previously described as anti-Leishmania agents and 2 tested on human and/or in vivo. We could confirm the anti-Leishmania effects for 2 out of the 8 molecules previously described, Posaconazole and Ketoconazole. Their IC50 values ranged from 5 to 35 µg/mL on our strains, out of the most published range. As these molecules are azoles, known to interfere with the sterol biosynthesis, we investigated the effect of Fetal Bovine Serum (FBS) as an exogen source of cholesterol on their activities. The experimental conditions "in absence of FBS" improved the IC50s values of ketoconazole, and led to the identification of two active compounds belonging to another class of molecules. One of these compounds, never described for its anti-Leishmania effect, presented an IC50 < 5µg/mL on our strains in the absence of FBS suggesting that it may target the sterol pathway or be sensitive to FBS content. To conclude computer-aided repositioning of FDA approved molecules as anti-leishmanial agents identified azoles, already known as antileishmanial molecules that we reconfirmed as effective on additional Leishmania sp promastigotes, and another class of molecules among which one is highly promising and calls for further investigations on intracellular forms of the parasites and its mechanisms of action.

6348

IN VITRO ANTITRYPANOSOMAL, ANTIOXIDANT AND CYTOTOXICITY ACTIVITIES, LC-MS ANALYSIS AND MOLECULAR DOCKING ANALYSIS OF BIOACTIVE COMPOUNDS FROM ANOPYXIS KLAINEANA AGAINST TRYPANOSOMA BRUCEI'S UDP-GALACTOSE 4`-EPIMERASE (TBGALE)

Abdul Latif Adams[1], Siobhan Moane[1], Dorcas Obiri-Yeboah[2], Michelle Mckeon Bennett[1]

[1]Technological University of Shannon Midlands Midwest, Athlone, Ireland, [2]Department of Microbiology and Immunology, School of Medical Sciences, College of Health and Allied Sciences, University of Cape Coast, Cape Coast, Ghana, Cape Coast, Ghana

African Trypanosomiasis is a major public health concern worldwide, especially in developing countries. Current chemotherapies are highly toxic, resistant and ineffective. Hence, novel effective and potent trypanocides are needed. Medicinal plants have been documented to be a potential source for the development of antitrypanosomal compounds. Anopyxis klaineana is an ethnomedicinal plant used in west Africa to treat many ailments including protozoan diseases. In this study, we investigated the in-vitro effects of crude methanol extracts and fractions of A. klaineana for their antitrypanosomal activities against Trypanosoma brucei using Alamar blue assay. Additionally, the crude extract's antioxidant and cytotoxicity activities were also determined. The phytochemical profiling of the crude extract was determined using LC-ESI-QTOF-MS to identify major bioactive compounds present. A. klaineana crude extracts and fractions (hexane, chloroform and ethyl acetate) exhibited potential anti-trypanosomal activities with IC50values of 21.25,4.35,2.57and 22.92ug/ml respectively. Moreover, the crude extracts showed moderate cytotoxicity against HepG2 and PNT2 cells, with IC50 values of 68.0±2.05 and 78.7±2.63ug/ml respectively. Antioxidant potential was observed in the crude extracts of A. klaineana. LC-MS analysis revealed the presence of 24 bioactive compounds. Furthermore, the bioactive compounds identified were subjected to molecular docking studies to identify novel compounds against Trypanosoma brucei's UDP-Galactose 4`-Epimerase (TbGalE). Three potential leads CID 5078, CID 4615 and CID 10347880 with binding energies -10.8, -9.9 and -9.6 kcal/mol respectively were identified. Molecular Dynamics simulation and Molecular Mechanics-Poisson Boltzmann Surface Area calculation were performed to elucidate the stability and the binding free energy of the potential leads' complexes. These compounds will further be investigated experimentally to determine their potential efficacy and could serve as candidates for the design of novel anti-trypanosomal therapeutics.

HIGH LEVEL OF 'NEVER TREATMENT' IN MASS DRUG ADMINISTRATION AGAINST NEGLECTED TROPICAL DISEASES IN KENYA, NIGERIA, DEMOCRATIC REPUBLIC OF CONGO AND CAMEROON

Rogers Nditanchou[1], Anita Jeyam[2], Babacar Ngom[3], Christian Nwosu[1], Folake Aliu[4], Peter Otinda[5], Vincent Kamwasha[6], Arthur N. Shamba[6], Ndelle N. Makoge[1], Serge Akongo[1], Richard Selby[2], Laura Senyonjo[2]

[1]Sightsavers, Yaounde, Cameroon, [2]Sightsavers, London, United Kingdom, [3]Sightsavers, Dakar, Senegal, [4]Sightsavers, Kaduna, Nigeria, [5]Sightsavers, Nairobi, Kenya, [6]Sightsavers, Kinshasa, Congo, Democratic Republic of the

Mass Drug Administration (MDA) to eliminate Neglected Tropical Diseases (NTDs) has been ongoing for many years. Recently, there has been interest to measure the magnitude and impact of 'never treatment (NT)', understand the associated factors and how to address them within programmatic setup. 'Never treatment' refers to people in endemic areas (receiving MDA) who have never taken any MDA treatment. Sightsavers has been conducting coverage evaluation surveys (CES) in evaluation units in supported countries. We focus here on NT measurement nested within CES in the following EUs: four Local Government Areas for onchocerciasis and Lymphatic Filariasis MDA in Nigeria; one Sub-County in Kenya for trachoma following a failed impact survey; 12 Health Districts in Cameroon and four in Democratic Republic of Congo (DRC) for routine MDA programme evaluation for schistosomiasis and soil-transmitted helminthiasis (Shisto/STH). Within the selected EU, a two-stage cluster sampling with the village segment as the primary sampling unit and household the secondary sampling unit was employed to select participants. Sample size and selection were guided by the WHO coverage sample builder. At EU level: in Nigeria, NT varies from 15.4-69.9% among people ≥ 10 years of age; in DRC and Cameroon, from 1.7- 8.3% and from 0-25.5% among school aged children (10-14 years), respectively; and 29.6% in Kenya among ≥5 years. There was marked variation and more pronounced NT level among clusters within each EU - with some reaching 100% NT. Of those NT, a vast majority were not treated in the last round of MDA as a result of them not being offered the drug mostly due drug distributors failing to visit. Study is needed in districts/clusters with high NT levels to clarify drivers of low coverage, the transmission potential of these NT and highlight mitigating actions ensuring they are reached in future campaigns. Programmes should consider NT as a key indicator for programme performance for NTD elimination and as a potential proxy to failed impact survey and vice-visa.

OPHTHALMOLOGICAL COMPLICATIONS IN VISCERAL LEISHMANIASIS AND POST KALA-AZAR DERMAL LEISHMANIASIS

Sauman Singh-Phulgenda[1], **Prabin Dahal**[1], Rishikesh Kumar[2], Abdalla Munir[1], Caitlin Naylor[1], Manju Rahi[3], Eli Harriss[1], Niyamat Ali Siddiqui[4], Fabiana Alves[5], Ahmed Musa[6], Kasia Stepniewska[1], Shyam Sundar[7], Philippe J. Guerin[1], Krishna Pandey[1]

[1]University of Oxford, Oxford, United Kingdom, [2]Rajendra Memorial Research Institute of Medical Sciences (RMRIMS), Patna, India, Patna, India, [3]Indian Council of Medical Research (ICMR), New Delhi, India, [4]Rajendra Memorial Research Institute of Medical Sciences (RMRIMS), Patna, India, [5]Drugs for Neglected Diseases initiative, Geneva, Switzerland, [6]Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan, [7]Infectious Disease Research Laboratory, Department of Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Recent reports of ocular complications in post kala-azar dermal leishmaniasis (PKDL) patients have propelled ocular safety as a research priority in Leishmaniasis. A systematic review of all published studies was carried out to collate ophthalmological events reported in patients with Visceral Leishmaniasis (VL) or PKDL. A total of 1821 records were identified of which 1683 were excluded at title/abstract screening and 85 excluded at full-text stage leading to 53 unique records included (1924-2022). From 37 records in VL, 120 ocular events were reported of which 32 occurred at baseline, 61 following a treatment and the time of occurrence was unclear in 27. The following events were reported at baseline: uveitis (n=13), retinal haemorrhage (n=8), papillary alteration (n=2), ocular motor dysfunction (n=1), endophthalmitis (n=1), retinitis (n=1), foveal haemorrhage (n=1), conjunctival involvement (n=2), blindness (n=1), chorioretinitis (n=1), and roth spots (n=1). The following were reported following a treatment: night blindness (n=39), uveitis (n=6), conjunctivitis (n=7), retinal haemorrhage (n=3), eye movement disorder (n=2), blindness (n=2), keratitis (n=1), macular haemorrhage (n=1). The following had unclear occurrence time: retinal/foveal haemorrhage (n=12), cotton wool spots (n=2), retinal involvement/detachment (n=6), uveitis (n=5), conjunctivitis (n=1), and blindness (n=1). From 17 unique records in PKDL, 38 complications were reported of which 1 occurred at baseline (conjunctival involvement), 33 occurred after a treatment, and the time was unclear in 4. The following were reported after treatment: keratitis (n=10), uveitis (n=8), keratopathy (n=4), scleritis (n=4), blindness (n=2), Moreen's ulcer (n=2), corneal involvement (n=1), retinal involvement (n=1), and conjunctival oedema (n=1). The following reports had unclear time: conjunctivitis (n=1), blindness (n=1), uveitis (n=2). This preliminary research suggests that ophthalmological outcomes should be actively solicited in clinical studies and in surveillance programme. Further work is ongoing to collate the events by treatment regimens.

6351

HOST, PARASITE AND DRUG DETERMINANTS OF TREATMENT OUTCOMES IN VISCERAL LEISHMANIASIS: AN INDIVIDUAL PATIENT DATA META-ANALYSIS USING THE INFECTIOUS DISEASES DATA OBSERVATORY DATA PLATFORM

Prabin Dahal[1], Rishikesh Kumar[2], Sauman Singh-Phulgenda[1], Abdalla Munir[1], Niyamat Ali Siddiqui[2], Gemma Buck[1], Caitlin Naylor[1], Matt Brack[1], Manju Rahi[3], Paritosh Malaviya[4], Monique Wassuna[5], Francois Chappuis[6], Koert Ritjmeijer[7], Carlos Costa[8], Gustavo Romero[9], Vassiliki Syriopoulou[10], Ahmed Musa[11], Fabiana Alves[12], Kasia Stepniewska[1], Shyam Sundar[4], Philippe J. Guerin[1], Krishna Pandey[2]

[1]University of Oxford, Oxford, United Kingdom, [2]Rajendra Memorial Research Institute of Medical Sciences (RMRIMS), Patna, India, [3]Indian Council of Medical Research (ICMR), New Delhi, India, [4]Infectious Disease Research Laboratory, Department of Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India, [5]Drugs for Neglected Diseases initiative, Nairobi, Kenya, [6]Division of Tropical and Humanitarian Medicine, Geneva University Hospitals, Geneva, Switzerland, [7]Médecins Sans Frontières, Amsterdam, Netherlands, [8]Department of Community Medicine, Federal University of Piauí, Piauí, Brazil, [9]Center for Tropical Medicine, University of Brasilia, Brasilia, Brazil, [10]Faculty of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [11]Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan, [12]Drugs for Neglected Diseases initiative, Geneva, Switzerland

There is a geographical variation in the efficacy of the current first line therapies in use against Visceral Leishmaniasis (VL). An individual patient data meta-analysis (IPD-MA) was undertaken to explore the determinants of therapeutic outcomes using the Infectious Diseases Data Observatory (IDDO) VL data platform. Hierarchical logistic regression models were fitted in one-stage IPD-MA to identify risk factors associated with relapse; between study clustering was considered using random intercepts for study sites. Thirty-four studies (31 published; 3 unpublished; 2000-2019) from the IDDO VL data platform were included in the IPD meta-analysis. Of the 9,207 patients enrolled in these studies, 5,778 (62.8%) were from the Indian sub-continent (ISC), 2929 (31.8%) were from Eastern Africa (EA), 377 (4.1%) from Brazil and 123 (1.3%) were from Greece. Of the enrolled, 664 (7.2%) were <5 years old, 3,402 (37.0%) were 5-15 years old, 5,129 (55.7%) were aged 15 or older and age was missing in 12 (0.1%). Miltefosine was administered in 2,109 (22.9%), pentavalent antimony (PA) in 1,912 (20.8%) patients, amphotericin B (non-liposomal) in 1,213 (27.3%), liposomal amphotericin B (L-Amb) in 485 (5.3%), paromomycin in 900 (9.8%), combination of one or more drugs in 1,283 (13.9%), and placental extract in 5 (0.1%) patients. In univariable analysis, the following variables were associated with an increased risk of relapse: male sex and treatment with a monotherapy drug. Multivariable analysis was undertaken by including the following predictors: age, sex, geographical region, drug regimen, calendar year, and baseline haemoglobin measurement of which male sex and geographical region remained significantly associated with the increased risk of relapse. Males were at 1.61 [95% confidence interval (CI): 1.25-2.07] increased odds of relapse compared to females and patients from the ISC region were at 3.17 [95% CI: 1.24-8.07] increased odds of relapse compared to those from EA. Further analysis is ongoing to delineate the relationship between different host, parasite and drug related characteristics on initial cure, definitive cure, and mortality.

6352

SAROCLADIUM STRICTUM SECONDARY METABOLITES BLOCK PLASMODIUM FALCIPARUM TRANSMISSION TO MOSQUITOES

Changliang An, Jun Li

Biological Science Department, Florida International University, Miami, FL, United States

Malaria is a deadly disease caused by mosquito-transmitted protozoan Plasmodium parasites. There are more than 200 million malaria cases every year worldwide. Fungal secondary metabolites provide a great resource to discover malaria transmission-blocking drugs because of their structural and active diversity. We screened our Global Fungal Extract Library (GFEL) and found the 10 µg/ml Sarocladium strictum ethyl acetate extract could completely block the transmission from Plasmodium falciparum to Anopheles gambiae by using standard membrane feeding assays (SMFA). The fractionation of the extract was conducted by using column chromatography, thin layer chromatography (TLC) and high-performance liquid chromatography (HPLC), followed by the antimalarial activity-guided method. We found four fractions that significantly reduced the number of oocysts in mosquitoes compared to the control at 1 µg/ml. Two bioactive pure compounds are being isolated and identified from these activity fractions. The active fungal secondary metabolites are potent leads to stopping malaria transmission.

6353

VACCINE-LINKED CHEMOTHERAPY AS A NOVEL STRATEGY FOR CHAGAS DISEASE

Kathryn M. Jones[1], Sheraz Pasha[1], Kris Eckols[2], Yi-Lin Chen[1], Cristina Poveda[1], Ana Carolina de Araujo Leao[1], Maria Jose J. Villar[1], Christopher S. Ward[1], David J. Tweardy[2], Maria Elena Bottazzi[1], Peter J. Hotez[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]MD Anderson Cancer Center, Houston, TX, United States

Chagas disease, caused by infection with the protozoal parasite Trypanosoma cruzi, affects almost 7 million people globally. Parasite persistence causes chronic myocarditis and progressive fibrosis, which can manifest clinically as chronic Chagasic cardiomyopathy (CCC). Current antiparasitic treatments with either Benznidazole (BNZ) or Nifurtimox have limited efficacy beyond early disease and do not address the underlying host pathology. We developed a candidate therapeutic vaccine based on a mutated version of the T. cruzi calcium-binding flagellar protein, Tc24, designated Tc24-C4 that contains recombinant Tc24-C4 protein and a TLR4 agonist adjuvant. In mouse models of acute infection, the vaccine induces a balanced TH1/TH2/TH17 immune response, reduces tissue parasite burdens, and reduces cardiac inflammation and fibrosis. More recently we have demonstrated that vaccine-linked chemotherapy, combining a low dose of BNZ with therapeutic vaccination with the Tc24-C4 vaccine, leads to reduced cardiac inflammation and fibrosis in mouse models of acute T. cruzi infection and improved cardiac remodeling and function in a mouse model of chronic T. cruzi infection. In the current study, we evaluated a new vaccine-linked chemotherapy strategy in our mouse model of chronic infection that combined Tc24-C4 vaccine and BNZ with TTI-101, a small-molecule STAT3 inhibitor shown to reduce tissue fibrosis in non-infectious mouse models of lung and liver fibrosis. Female BALB/c mice were inoculated with bioluminescent T. cruzi H1 strain trypomastigotes. At 70 days, mice were administered the Tc24-C4 vaccine, BNZ, or TTI-101 alone or sequentially in combination. Vaccination was given subcutaneously twice, three weeks apart; BNZ and TTI-101 were administered orally once daily for 20 days. Cardiac structure and function were evaluated by echocardiography and electrocardiograms approximately once monthly, then endpoint cardiac fibrosis was evaluated by microscopy at approximately 8 months of infection. The impact of TTI-101 on further reducing cardiac fibrosis and improving cardiac structure and function over time will be discussed.

6354

SURVEILLANCE OF ENTERIC VIRUSES AND SARS-COV-2 IN SELECTED LEAFY VEGETABLES AND FARMERS IN THE OFORIKROM DISTRICT, KUMASI, GHANA

Emmanuella Nyarko-Afriyie

Kumasi Centre for Collaborative Research in tropical medicine, Kumasi, Ghana

The emergence and spread of enteric viruses and SARS-CoV-2 have increased concerns over food safety and the potential for foodborne

transmission. Green leafy vegetables such as cabbage, lettuce, and green onions are commonly consumed raw and have been implicated in outbreaks of enteric virus infections. Also, the recent pandemic has raised the question of whether the virus can be spread through the fecal-oral route or contaminated food. Farmers who work with these crops may also be at risk of infection. This suggests that there may be a high prevalence of enteric viruses and SARS-CoV-2 in green leafy vegetables and farmers may not be aware of the potential transmission of these viruses through the vegetables they cultivate. Therefore, this study sought to determine the burden of enteric viruses and SARS-CoV-2 in farmers and the green leafy vegetables they grow and identify potential sources of contamination. The study involved the collection of cabbage, lettuce, and green onions, oral swabs, and stool samples from 10 different farm sources followed by laboratory methods of detecting viral RNA by RT-PCR. The current results of the study for SARS-CoV-2 detection in vegetables and farmers are negative implying that they did not have an active infection with the virus at the time the samples were collected or the viruses were inactivated due to exposure time and some environmental factors. However, testing the samples for the other viruses is yet to be done. This study will highlight potential sources of contamination, reduce the risk of foodborne transmission and create awareness of the possible transmission of viruses through food.

6355

HOUSING STRUCTURES AND VISCERAL LEISHMANIASIS TRANSMISSION IN BARINGO COUNTY, KENYA

Katherine OBrien[1], Grace Kennedy[1], Hellen Nyakundi[2], Mwatela Kitondo[2], Wilson Biwott[3], Valaria Pembee[3], Richard Wamai[1]

[1]Northeastern University, Boston, MA, United States, [2]African Centre for Community Investment in Health, Chemolingot, Kenya, [3]Chemolingot Sub County Hospital, Chemolingot, Kenya

Visceral leishmaniasis (VL) is endemic in Baringo County, Kenya, and contributes significantly to the burden of disease in the region. Housing structures and other environmental risk factors contribute to transmission dynamics, but these have not been widely studied in Baringo. Drought, famine, and insecurity in the region have changed the disease landscape in recent years. This study aims to examine environmental risk factors in relation to VL transmission in Tiaty East and West sub-counties. Data collection began in February 2023 and will continue through May 2023 at Chemolingot Sub-County Hospital and patients' homesteads. Data collection is being performed via questionnaires of primary VL patients being treated and VL follow-up patients that still reside in the same house as when infection occurred. Factors being assessed are housing materials, distance to termite towers, proximity to animals and animal sheds, sleeping behavior, use and access to insecticides, and previous health education. 18 household interviews were performed in March 2023 where heads of households were asked in-depth questions about housing structure choices, behavior, and access to VL prevention materials. 3 key informant interviews were performed in March 2023 with community health volunteers (CHVs) regarding VL awareness and environmental challenges in the communities. A baseline assessment of housing types through direct observation including materials, distance to water sources, distance to vector sites, and overall homestead condition is ongoing. Preliminary data indicates that the majority of VL patients reside in stick and mud houses and within proximity to animals. Most patients do not take any actions to prevent sandfly bites or sandflies from entering their home. Preliminary data from household interviews indicate that some individuals would prefer to build their house out of iron sheet because it is more permanent but lack the finances to do so. Current household building materials do not allow for adequate protection from VL, and other environmental factors likely exacerbate this risk. Strategic environmental interventions are imperative.

6356

A PREDICTIVE MODEL ACCOUNTING FOR DEFORESTATION ACROSS TEMPORAL AND SPATIAL SCALES IDENTIFYING ANNUAL SHIFTS IN THE ODDS OF EBOLAVIRUS ZOONOTIC SPILLOVER

Carson T. Telford[1], Justin Lessler[2], Trevor Shoemaker[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]University of North Carolina, Chapel Hill, NC, United States

Outbreaks of filoviruses, such as ebolaviruses, typically result from zoonotic transmission from infected animals, and most recent outbreaks have resulted from zoonotic spillover. Past analyses of ebolavirus emergence have found relationships between ebolavirus spillover and forest loss (FL), however, FL data has not ever been incorporated into predictive analyses of ebolavirus emergence. We developed a novel predictive model of ebolavirus zoonotic spillover incorporating FL, vegetation, population, and meteorological data from 2001-2021 using model ensembles fit with boosted regression trees. FL was measured across multiple spatial and temporal scales, as it is unknown whether spillover is driven by FL on local or regional scales, and whether a temporal lag exists between FL and ebolavirus emergence. Models were fit for all ebolavirus species (All-species analysis) and Zaire virus only (Zaire-only analysis), as Zaire virus has a unique ecology compared to other ebolavirus species, and annual predictions of the relative odds of spillover were generated. Model fit was slightly better in the Zaire-only analysis (AUC: 0.91) compared to the All-species analysis (AUC: 0.87). Resulting predictions identified specific areas throughout equatorial Africa with elevated relative odds of spillover as high as 30 times the baseline odds, which shifted annually based on recent forest loss. Predictions which accounted for FL were distinct from previous models that ignored FL data, leading to identification of new locations where elevated spillover odds were driven by FL. Relative importance of FL variables in predicting spillover was higher in the Zaire-only model than in the All-species model, suggesting that FL may play a more important role in Zaire virus ecology compared to Sudan and Bundibugyo viruses. Spillover events from 2022-2023 in DRC and Uganda both occurred in locations predicted to have a relative odds ratio >5. FL variables improved the predictive ability of models, suggesting the importance of habitat disruption in ebolavirus ecology, and its value in prioritizing ebolavirus surveillance and prevention efforts.

INTEGRATING ECOLOGY AND EPIDEMIOLOGY TO EMPOWER ONE HEALTH: A STUDY OF RIFT VALLEY FEVER

Melinda K. Rostal[1], Ernest Guevarra[1], Whitney Bagge[1], Peter Thompson[2], Janusz T. Paweska[3], Veerle Msimang[3], Assaf Anyamba[4], Alan Kemp[5], Jacqueline Weyer[3], Claudia Cordel[6], Johana Teigen[1], Catherine Machalaba[1], Alison Lubisi[7], Harold Weepener[8], Zimbini Mdluwa[9], William B. Karesh[1], Noam Ross[1]

[1]EcoHealth Alliance, New York, NY, United States, [2]University of Pretoria, Onderstepoort, South Africa, [3]National Institute for Communicable Diseases, Johannesburg, South Africa, [4]Oak Ridge National Laboratory, Oak Ridge, TN, United States, [5]National Institute for Communicable Diseases (retired), Johannesburg, South Africa, [6]ExecuVet, Bloemfontein, South Africa, [7]Onderstepoort Veterinary Research, Agricultural Research Council, Onderstepoort, South Africa, [8]Soil, Climate, and Water, Agricultural Research Council, Pretoria, South Africa, [9]Economic Analysis Unit, Agricultural Research Council, Pretoria, South Africa

Emerging zoonoses, such as Rift Valley fever (RVF), require a One Health (OH) approach to predict, mitigate and prevent outbreaks. An arbovirus, RVF virus (RVFV) causes periodic, yet widespread outbreaks with high rates of abortion and death in ruminant livestock. People often have mild influenza-like symptoms with rare but serious complications: hemorrhagic fever, hepatitis, retinitis, and meningitis. Outbreaks have been linked to complex climatic events (El Niño/La Niña) that drive favorable environmental conditions for large populations of mosquito vectors. The integration of human, livestock, wildlife, and environmental health data requires multidisciplinary methods, integrating ecological and epidemiological

approaches. We conducted a OH study of RVFV seroprevalence in livestock and people in South Africa. Here we provide an example of an approach for the collection and analysis of OH zoonotic disease data. We used a systematic grid of geographic points to achieve a probability proportional to size sampling framework for each species (human, cattle, goats, and sheep). We demonstrate how joint models can be used to determine risk factors for RVFV seroprevalence in people, cattle, sheep and goats with demographic variables, risk behaviors, husbandry characteristics and environmental variables. This method improves the ability to identify and compare risk factors across species, is explicitly designed to account for correlation amongst species, reduces multiple testing and the need for p-value correction. Examples of multiple testing include using the same predictors for multiple outcomes (e.g. seroprevalence of RVFV and Sindbis virus), siloed analyses evaluating the results in people separate from those in animals and/or environmental data or variable selection resulting in higher false positive rates, requiring p-value correction (Bonferroni) and loss of statistical power. Joint estimation is suited for reducing multiple tests without the resultant loss of power. As OH study design becomes increasingly integrated, it is important to develop adequate analysis methods that can harness the power of a OH study design.

6358

EVIDENCE AND GAP MAP FOR MULTI-SECTOR AND ONE HEALTH RESEARCH IN ZOONOTIC NEGLECTED TROPICAL DISEASES

Cole Miller[1], Gabrielle Laing[2], Katie Greenland[3]

[1]University of Rochester School of Medicine and Dentistry, Rochester, NY, United States, [2]Unlimit Health, London, United Kingdom, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

Directly referenced in the WHO's 2030 road map for the Neglected Tropical Diseases is the need for a "One Health" approach in addressing diseases possessing zoonotic components. This report aims to map where the current research evidence lies across the human, animal, and environmental health sectors and multisector (human-animal, human-environment, animal-environment, One Health) regarding the transmission, surveillance, and control of the zoonotic Neglected Tropical Diseases (zNTDs) by presenting the information in simple, accessible Evidence and Gap Maps. These Maps may serve as interactive tools for users while providing a structured framework that serves to highlight current research gaps in the field. A comprehensive search strategy was implemented across MEDLINE, EMBASE, and GLOBAL HEALTH databases. Overall, 6920 records were screened by titles, abstracts, and keywords from articles published between 1990 and 2020. A total of 2269 articles were excluded for not being a journal article, not focusing on a zNTD, and not discussing transmission, surveillance, or control in some capacity, leaving 4732 records which met the inclusion criteria. These articles were subsequently coded using a standardized tool according to their relevant zNTD, health sectors, and areas of evidence (transmission, surveillance, control). Three evidence and gap maps were generated. In general, across all zNTDs, individual health sectors were disproportionately represented in the evidence, with multisector and One Health approaches lacking across the zNTDs. Despite the cross-sectoral aspects of zNTD transmission, surveillance and control, there is a clear segregation of the evidence into single-sector research. Visual presentation of the existing literature in the form of Evidence and Gap Maps should serve as a powerful tool for researchers, policymakers, and academics implementing and advocating for cross-cutting approaches to achieve the zNTD control targets set in the WHO's 2030 road map.

6359

PREVALENCE, DISTRIBUTION AND DIVERSITY OF BARTONELLA IN SMALL MAMMAL AND BAT COMMUNITIES ACROSS CAMBODIA

Sophie A. Borthwick[1], Alan T. Hitch[2], Dolyce H.W Low[1], Lena Chng[1], Sothyra Tum[3], Sorn San[3], Dany Chheang[4], Ian H. Mendenhall[5], Gavin J. Smith[1]

[1]Duke-NUS Medical School, Singapore, Singapore, [2]University of California, Davis, Davis, CA, United States, [3]General Directorate of Animal Health and Production, Phnom Penh, Cambodia, [4]Forestry Administration, Phnom Penh, Cambodia, [5]Duke-NUS Medical School, Maryland, MD, United States

Bartonella species are Gram-negative, facultative intracellular bacteria that represent the only genus in the family Bartonellaceae. Small mammals and bats are natural reservoirs of many Bartonella species. We investigated Bartonella presence, distribution and diversity in small mammals and bats across 249 locations in 23 provinces across different habitat types in Cambodia from 2016 to 2020. A total of 3,515 small mammal and bat blood and lung spleen kidney (LSK) samples were screened with pan-bartonella PCR primers targeting the beta subunit of bacterial RNA polymerase (rpoB) gene. Bartonella DNA was detected in 19.32% (337/1,744) of bats and 8.3% (147/1771) of small mammals collected during this project including 26 small mammal species and 61 bat species. Highest prevalence was detected in Rattus complex from deciduous forest (34%) and Rhinolophus acuminatus from evergreen forest (38.89%). Phylogenetic analyses of 203 rpoB gene sequences showing the Bartonella genotypes circulating in the small mammal (58) and bat (145) populations across Cambodia are presented.

6360

EPIDEMIOLOGY OF ANIMAL BITES AND POST-EXPOSURE PROPHYLAXIS (PEP) OF RABIES IN RUPANDEHI, NEPAL

Susma Reshmi Magar, Sirjan Bastola

Institute of Agriculture and Animal Science (IAAS), Paklihawa Campus, Bhairahawa, Nepal

Animal bites remain an important public health problem in Rupandehi District, Nepal. The secondary data from Jan to Dec, 2022 were obtained from Anti-rabies vaccination record of Bhim hospital, Bhairahawa. The data were entered into MS Excel and later analyzed by SPSS for descriptive statistics. The objective of the study was to estimate the burden of animal bite victims and the requirement of anti-rabies vaccines in Rupandehi District, Nepal. Out of total 3,617 cases of animal-bites reported, 65.00% (2,369) were males, 26.10% (944) were children of 0-10 years age group and 50.00% (1,823) victims hailed from urban areas. Dogs (93.22%, 3,372) were responsible for a majority of bites. The maximum number of bites were reported from January to April and in December of 2022. Leg (59.71%) was the commonest site of bite followed by hand, trunk and head. The majority of bites belong to Category II of the WHO classification (98.41%). Among the total bite victims, 94.91% (3,433) were found to complete the full course of vaccination. 13.98% of the victims received their first dose of PEP on the same day of exposure while 67.68% of the victims received it after 1 day of exposure. 90.36% and 89.23% of the bite victims received their 2nd and 3rd doses respectively on time. A well-planned vaccination program should be implemented to ensure the compliance with anti-rabies PEP schedule after animal bites. All age groups from both rural and urban areas should be prioritized for awareness and education programs to improve their treatment and PEP seeking behavior.

6361

DETECTION AND MOLECULAR CHARACTERIZATION OF MULTI-RESISTANT ENTEROBACTERIACEAE CARRIED BY HOUSEFLIES IN THE CITY OF BOBO-DIOULASSO, BURKINA FASO

Soufiane Do M. Sanou[1], Serge R. Yerbanga[2], Tinlé Bangre[2], Séverin N'do[3], Jean Bosco Ouedraogo[2]
[1]Centre MURAZ, Bobo dioulasso, Burkina Faso, [2]INSTech, Bobo dioulasso, Burkina Faso, [3]IRSS, Bobo dioulasso, Burkina Faso

Houseflies (Musca domestica) are synanthropic insects that are vectors of a wide range of pathogens (multidrug resistant) responsible for infectious diseases. This study aimed to detect and characterize multidrug-resistant Enterobacteriaceae carried by houseflies in the city of Bobo dioulasso. A total of 500 houseflies were captured in 25 hospital and non-hospital environments in the city of Bobo-Dioulasso. They were divided into 125 batches of 5 flies for bacteriological analysis. Multidrug-resistant bacteria, isolated on MacConkey agar supplemented with cefotaxime 4µg/ml, were identified on the basis of biochemical characteristics. Antibiotic susceptibility profiles were determined by the agar diffusion method. Detection of blaCTX-M resistance genes, quinolone resistance genes (PMQR) and determination of E. coli phylogroup were done by conventional PCR. Among 115 bacterial strains obtained, 26 were extended-spectrum beta-lactamase (ESBL)-producing enterobacteria: E. coli (15), Klebsiella pneumoniae (6), Enterobacter cloacae (4), Morganella morganii (1). This carriage was statistically more important in hospitals (9/30, p=0.03). No carbapenem-resistant strains were observed. ESBL resistance genes (CTX-M group 1) (25/26) and quinolone resistance genes (QnrS) (6/26) were found. Houseflies in the city of Bobo-Dioulasso are vectors of transmission of multidrug-resistant enterobacteria. Surveillance of the associated risks to public health is necessary.

6362

HIGH PREVALENCE OF TETRACYCLINE RESISTANT ESCHERICHIA COLI ISOLATES IN AMERICAN CROCODILE CROCODYLUS ACUTUS LIKE BIOINDICATOR IN CAÑAS GUANACASTE COSTA RICA

Verónica Arias Pérez[1], Elias Barquero Calvo[1], Ivan Sandoval Hernandez[1], Rafael Mateus Vargas[2]
[1]Universidad Nacional, Heredia, Costa Rica, [2]University of Göttingen, Göttingen, Germany

In recent years bacteria have acquired resistance genes causing "antibiotic resistance". The agricultural, animal, and aquaculture industries are one of the main causes, of the excessive use of antibiotics that are released into the environment. The American crocodile found in this type of ecosystem becomes a bioindicator. The aim of the research is to characterize antibiotic resistant bacterial isolates of Escherichia coli obtained from the American crocodile sewer in a tilapia production system. The study was in collaboration with the company AquaCorporación in Cañas and the samples were of 53 crocodiles captured in the tilapia ponds. Each of the captured animals made a swab of the cloaca and it is introduced to a nutritious broth and transported to the laboratory at a cool temperature. The swabs were inoculated on selective agars until obtaining pure isolates of E. coli were. Then an antibiotic sensitivity profile was performed with the Vitek 2 equipment on the isolates. Those for veterinary use were evaluated in dishes with antibiotics and the Minimum Inhibitory Concentration (MIC). Resistance isolates were sequenced from the entire genome by MicrobesNG on the Illumina HiSeq platform with a 250 bp end protocol. The results obtained from the resistant isolates were for florfenicol (11.8%), Ampicillin (16.4%), Ampicillin Sulbactam (7.3), Nalidixic Acid (3.6%), Trimethoprim/ Sulfamethoxazole (3.6), and a high prevalence of tetracycline (75%), with a MIC 50 of 32 µg/ml and MIC 90 of 128 µg/ml. Complete genome sequencing can visualize a variety of types of MLST and the transport of known mobile genes that encode resistance against antibiotics and, various plasmid sequences were detected. This work concludes that the information obtained in this research is important because resistance detected in wild animals is also associated with a production system and that in the future may become a risk to public health and the environment. Finally, it is important to assess in the future the role of dispersion of the resistance mechanisms detected and possible changes that may occur in the natural structure of ecosystems

6363

WHOLE GENOME SEQUENCING TO ELUCIDATE THE ZOONOTIC TRANSMISSION OF STRONGYLOIDES STERCORALIS AND ANCYLOSTOMA CEYLANICUM BETWEEN DOGS AND SCHOOL AGED CHILDREN LIVING IN THE SAME COMMUNITIES

Strongyloides stercoralis and Ancylostoma ceylanicum are parasitic soil-transmitted helminths that impact on the health of humans and dogs in the tropics. Both parasites are categorised as agent of neglected tropical diseases by the World Health Organization. The ability of these parasites to transmit between humans and dogs living in closed proximity via contaminated environments is of particular concern in areas characterised by poor sanitation . Despite this, there is a lack of understanding about the extent to which these parasitic nematodes are transmitted between different host species, particularly humans and community dogs. To quantify the zoonotic potential and transmission of S. stercoralis and A. ceylanicum, we isolated single eggs of A. ceylanicum from faecal samples of 14 children and 25 dogs and single larvae of S. stercoralis from 20 children and 35 dogs living in the same communities in Cambodia. Whole genome amplification was performed on extracted DNA to increase concentration for whole genome sequencing. By analysing genetic variation within and among parasites, the intra- and interspecies transmission and dispersal between communities of these parasites can be traced, with the ultimate goal of identifying genetic markers associated with specific human/animal host species. This information will help elucidate the risk of transmission from domestic animals to humans and inform the parameterisation of multi-host transmission dynamics models. These findings will be essential to the development of effective elimination strategies for these zoonotic parasites of major public health and socio-economic importance.

6364

DETECTION OF BRUCELLA IN HUMANS AT TEKNAF, COX'S BAZAR IN BANGLADESH

Ireen Sultana Shanta, Mohammed Rahman, Mohammad Hossain, Tareq Rakib, Ziaul Islam, Munirul Islam, Sayera Banu, Firdausi Qadri, Tahmeed Ahmed
icddr,b, Dhaka, Bangladesh

Human brucellosis is a serious infectious disease caused by a gram-negative bacteria of the genus Brucella. Brucellosis in humans is considered as a neglected and underreported disease. From February 12, 2022 to July 31, 2022, a routine examination was conducted to detect brucellosis in patients who presented with fever using a triple antigen test along with Salmonella and Rickettsia at Severe Acute Respiratory Infection, Isolation and Treatment Centre (SARI, ITC), icddr,b, Teknaf, Cox's Bazar, Bangladesh. From SARI, ITC, 120 patients were enrolled for the test. Based on the findings, we investigated the positive patients from August 03-05, 2022. Among 7 patients, we could trace 5 during this investigation. After taking verbal consent, we interviewed the patients and collected blood specimens for further investigation and laboratory confirmation by the TaqMan real-time PCR test at icddr,b Biosafety level 2 laboratory. Further, we conducted a small survey at the same hospital from October 4, 2022, to December 14, 2022. We enrolled the patients who were admitted to the hospital with ≥ 7 days of fever, muscle ache, headache and joint pain coming from different villages in the host population and from the refugee camps of Forcibly

Displaced Myanmar Nationals as well. We collected blood samples from 33 patients. We also collected demographic information and the history of exposure to livestock and livestock products of the patients to identify the source of infection. Among the patients tested by triple antigen, 7 were positive for Brucella spp (5.8%). Among them, 5 patients we could trace during the investigation, 1 confirmed positive by PCR. During the survey, out of 33 patients, 1 was found to be positive both by triple antigen test and PCR (3%). The positive patients, their families, and their neighbors had a history of raw milk consumption and exposure to livestock. Among the patients, enrolled for the survey, 21% reported consuming raw milk by them or their families. Consumption of raw milk might be considered as one of the important causes of Brucellosis in this area. Therefore, intervention should be carried out in this area to avoid raw milk consumption.

6365

MAPPING HOUSEHOLD-SCALE LIVESTOCK HUSBANDRY IN LOW- AND MIDDLE-INCOME COUNTRIES BY ANIMAL TAXON: A BAYESIAN PREDICTION MODEL OF A KEY INFECTIOUS DISEASES RISK FACTOR

Josh Michael Colston[1], Bin Fang[2], Margaret Kosek[1], Venkataraman Lakshmi[2]

[1]University of Virginia School of Medicine, Charlottesville, VA, United States, [2]University of Virginia, Charlottesville, VA, United States

Around 70% of the world's 880 million rural poor depend on traditional animal husbandry systems for their livelihoods which, while having numerous economic and health benefits, can be a significant source of infections through exposure to fecal contamination and respiratory pathogens. It is estimated that over 60% of human pathogens are zoonotic, and we are living in the age of pandemics resulting from the spillover of a zoonotic pathogen, such as Ebola, SARS-CoV2 and Mpox yet there have been few attempts to estimate the interphase of human and domestic animal interaction at a global scale. This represents a barrier to the improved understanding of the dynamics of both endemic and emerging infectious diseases. This analysis aimed to map the distribution of household-scale livestock husbandry in LMICs by animal taxon. Data on animal ownership were compiled from around 300 nationally representative, population-based household surveys, and species were classified into ruminants, monogastrics and poultry. A novel georeferencing methodology was implemented and a suite of time-static environmental and demographic spatial covariates were compiled based on their hypothesized associations with the outcome variables. Variable values were extracted at the georeferenced cluster locations and a Bayesian Multi-level based logistic regression approach was used to model associations and generate predictions for all LMICs at a 6km resolution. A Markov Random Field (MRF) smooth algorithm was employed to improve spatial correlation and continuity of the prediction maps. Model evaluation statistics were mixed, but weighted average recall was 0.89 for monogastric, 0.78 for ruminant and 0.74 for poultry ownership. High prevalence of poultry ownership was predicted across the Tibetan Plateau and in pockets in the Andes, Ethiopia, and Kenya, while ruminant ownership rates were high in parts of Amazonia, Syria and Yemen. The resulting prediction maps can be used by policymakers and program planners to generate disease burden estimates, target outbreak prevention interventions geographically and identify hotspots of risk for zoonotic spillover.

ISONIAZID URINE COLORIMETRY FOR EVALUATION OF TUBERCULOSIS PHARMACOKINETICS IN ADULTS AND CHILDREN

Prakruti Rao[1], Kyle Reed[1], Saningo Lukumay[2], Caroline Kimathi[2], Restituta Mosha[2], Sakina Bajuta[2], Mariamu Temu[2], Kristen Petros De Guex[1], Nisha Modi[3], Deborah Handler[3], Leonid Kagan[4], Navaneeth Narayanan[4], Charles Peloquin[5], Alfred Lardizabal[3], Christopher Vinnard[3], Tania Thomas[1], Yingda Xie[3], Scott Heysell[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Haydom Lutheran Hospital, Haydom, Tanzania, United Republic of, [3]Rutgers University, Newark, NJ, United States, [4]Rutgers University, Piscataway, NJ, United States, [5]University of Florida, Gainesville, FL, United States

Treatment failure and emergence of drug-resistance in tuberculosis (TB) can be caused by suboptimal pharmacokinetics. Dose adjustment can be personalized by measurement of peak serum concentrations; however, the process involves cold-chain serum preservation and sophisticated laboratory procedures unavailable in many high-burden TB settings. Isoniazid is an important drug in many TB treatment regimens. Urine colorimetry provides a low-cost alternative with simple sampling and quantification methods. We enrolled 56 adults and 89 pediatric patients in a prospective, observational study of patients taking first-line anti-TB medications that was conducted in Tanzania (children) and the United States (adults). Serum was collected pre-dose and 1, 2, 4, 6, and 8 hours post dose for measurement of isoniazid concentrations using validated LC-MS/MS methods. Urine was collected between 0-4, 4-8, and 8-24 hour intervals post dose, and pooling was done to determine concentrations at 0-8 and 0-24 hours, with urine concentrations measured using colorimetric methods. The average peak serum concentrations were 4.8 mg/L and 6.4 mg/L for adults and pediatric patients, respectively. The average total serum exposure over 24 hours was 16.4 mg*h/L for adults and 26 mg*h/L for pediatric patients. Correlation between serum parameters and urine values was highest at the 0-4 hour collection interval for adults (r=0.7) with area under receiver operator characteristic curve (AUC of ROC) of 0.9 (CI: 0.7-1) for urine values predicting subtherapeutic serum concentration for dose adjustment. Unexpectedly in children, correlation was lower than that observed in adults and occurred for urine at the 8-24 hour (r=0.5). Isoniazid urine absorbance correlated with serum concentrations at different urine collection intervals in adults and pediatric patients. Colorimetric methods may improve feasibility of personalized dosing in high-burden TB regions but requires further study of dose adjustment based on urine thresholds in adults, and exploration of urine trough measurements in children.

6367

PERFORMANCE OF SARS COV-2 IGG ANTI-N AS AN INDEPENDENT MARKER OF EXPOSURE TO SARS COV-2 IN AN UNVACCINATED WEST-AFRICAN POPULATION

Adam Abdullahi[1], Michael Owusu[2], Mark Cheng[1], Colette Smith[3], Sani Aliyu[4], Alash'le Abimiku[5], Richard Phillips[2], Ravindra K. Gupta[1]

[1]University of Cambridge, Cambridge, United Kingdom, [2]Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana, Kumasi, Ghana, [3]University College London, UK, London, United Kingdom, [4]Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK, Cambridge, United Kingdom, [5]Institute of Human Virology, Abuja, Nigeria, Abuja, Nigeria

The determination of previous SARS-COV-2 infection is hampered by the absence of an accurately sensitive standardised test. The most relevant marker used to assess previous exposure is IgG antibody to the nucleocapsid (IgG anti-N), although it is known to wane quickly from peripheral blood. The sensitivity and specificity of seven antibody tests either singly or in combination namely, virus neutralization test, IgG anti-N, IgG anti-S, IgG anti-RBD, IgG anti-N + anti-RBD, IgG anti-N + anti-S and IgG anti-S + anti-RBD were evaluated on 502 cryopreserved serum samples collected pre-vaccination rollout in 2021 in Kumasi, Ghana. Accuracy of each index test was measured using a composite reference standard based on a combination of type neutralization and IgG anti-N

antibody tests. According to the composite reference, the most sensitive test was virus neutralization test that yielded 95.4% sensitivity (95% CI: 93.6-97.3), followed by 79.8% for IgG anti-N + anti-S (95% CI: 76.3-83.3) and a ROC value of 0.98. The most specific tests were virus neutralization and IgG anti-N, both with specificity 100% (95% CI: 100-100). Arbitrarily, viral neutralization and IgG anti-N + anti-S were the overall most accurate tests with specificity/sensitivity of 100/95.2% and 79.0/92.1% respectively. In conclusion, our findings indicate that IgG anti-N alone is an inadequate marker of prior exposure to SARS COV-2 in an unvaccinated population. Virus neutralization assay appears to be the most accurate assay in discerning prior infection. A combination of IgG anti-N and IgG anti-S is also highly sensitive and specific, and suited to low resource settings in the assessment of SARS COV-2 exposure prior to vaccination.

6368

FEASIBILITY OF CASH TRANSFERS TO FACILITATE TUBERCULOSIS SCREENING AMONG HOUSEHOLD CONTACTS OF TUBERCULOSIS PATIENTS IN TANZANIA

Ghassan Ilaiwy[1], Saning'o Lukumay[2], Domitila Augustino[2], Paulo Mejan[2], Kusulla Simeon[2], Estomih Mduma[2], Scott K. Heysell[1], Tania A. Thomas[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Haydom Global Health Research Center, Haydom, Tanzania, United Republic of

Tanzanian tuberculosis (TB) guidelines recommends facility-based TB screening for household contacts (HHCs) of TB patients who are symptomatic or under the age of 5 years. However, many households are unable to complete HHC screening due to cost barriers. Here, we evaluate the feasibility of unconditional cash transfers to facilitate completion of HHC screening and explore factors that impact screening completion in a rural setting with high TB prevalence. In this prospective cohort study, we consecutively enrolled index TB patients within 8 weeks of TB treatment initiation from the TB clinic at Haydom Lutheran Hospital and surrounding dispensaries in Haydom, Tanzania. The study provided a cash transfer of up to 40,000 Tanzanian Shillings ($17.09) to affected households to facilitate HHCs TB screening and covered medical cost incurred from screening activities. In addition, telephone reminders occurred every 2 weeks for 2 months to follow up on screening progress. We collected data on demographics, TB diagnoses, and socioeconomic/household characteristics, as well as feedback on the utility of cash transfers and additional interventions. The study enrolled 120 index TB patients and their households from July 13th through December 21st, 2022 with total 397 HHCs. Median age for index patients 35 years, 63% males. 69 (58%) of participating households completed the recommended screening for all HHCs. Only 48 households (40%) were able to fully cover the cost of HHC screening. In a logistic regression model, households that were able to fully cover the cost of HHCs and households that received sputum collection containers through a separate program were significantly more likely to complete HHC screening for all members (aOR 3.46 and 3.98 respectively, $p<0.01$). The use of cash transfer is feasible and positively impacts the completion of HHC screening in Haydom, Tanzania. Exploring additional support to households impacted by TB including cash transfers to cover TB screening cost, telephone reminders, and sputum collection containers can further improve completion of HHC TB screening.

6369

THE EFFECT OF THE COVID-19 PANDEMIC ON HEALTHCARE SEEKING IN AN INFORMAL URBAN SETTLEMENT IN NAIROBI AND A RURAL SETTING IN WESTERN KENYA, JANUARY 2016 TO AUGUST 2022

George O. Agogo[1], Patrick Munywoki[1], Allan Audi[2], Joshua Auko[2], George Aol[2], Clifford Oduor[2], Samuel Kiplangat[2], Alice Ouma[2], Terry Komo[2], Peninah Munyua[1], Godfrey Bigogo[2]

[1]US Centers for Disease Control and Prevention, Nairobi, Kenya, [2]Kenya Medical Research Institute (KEMRI), Kisumu, Kenya

The COVID-19 pandemic caused widespread disruptions to healthcare seeking. There are limited studies on the effect of the COVID-19 pandemic on healthcare-seeking patterns in low-and middle-income countries (LMICs), especially in rural settings and informal urban settlements with limited access to healthcare. We investigated the effect of the COVID-19 pandemic on reported healthcare seeking at health facilities and pharmacies using household morbidity data among study participants in a well-established longitudinal disease surveillance platform located in two diverse sites in Kenya: Asembo, a rural setting in western Kenya, and Kibera, an urban informal settlement in Nairobi. We described healthcare seeking before (1st January 2016 to 12th March 2020) and during the pandemic (13th March 2020 to 31st August 2022) using frequencies and percentages. We used a generalized estimating equation with an exchangeable working correlation structure to assess the effect of the pandemic on healthcare seeking in the two sites. Overall, there was a 15% (adjusted odds ratio, aOR: 0.85; 95% CI: 0.82 -0.88) reduction in health facility-based healthcare seeking in Asembo during the pandemic, and 23% (aOR: 0.77; 95% CI: 0.74 -0.81) reduction in Kibera. The pandemic resulted in increased care seeking at pharmacies in the two surveillance sites (aOR: 1.25; 95% CI: 1.21-1.28 in the Asembo site, and aOR: 1.42; 95% CI: 1.36 -1.48 in the Kibera site). We observed higher odds of healthcare seeking among ill participants who reported respiratory syndromes (e.g., in Asembo, aOR (95% CI) for Acute Febrile Illness was 2.80 (2.69-2.92), Acute Respiratory Illness was 1.40 (1.30-1.51, and for Severe Acute Respiratory Illness was 3.75 (3.58-3.93)). However, there was a decrease in healthcare seeking at pharmacies among ill participants who reported severe acute respiratory illness. This study highlights interruptions to healthcare facility utilization in resource-limited settings due to the COVID-19 pandemic. Strategies are needed to optimize healthcare provision and utilization at health facilities during pandemics.

6370

HEPATITIS B AND INFLUENZA VACCINE COVERAGE AMONG HEALTHCARE WORKERS IN SELECTED HEALTH FACILITIES IN BANGLADESH

Ahamed Khairul Basher[1], Sazzad Hossain Khan[1], Md Abdullah Al Jubayer Biswas[1], Mahmudur Rahman[2], Fahmida Chowdhury[1], Md Zakiul Hassan[3]

[1]International Center for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [2]Global Health Development, EMPHNET, 69 Mohakhali, Dhaka 1212, Bangladesh, Dhaka, Bangladesh, [3]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Healthcare workers (HCWs) carry a higher risk of both hepatitis B and influenza virus infection due to occupational exposures. Despite the availability of a safe and effective vaccine, routine adult immunization programs against these infectious pathogens among HCWs are overlooked in low-middle-income countries like Bangladesh. This study aims to investigate the extent of hepatitis B and influenza vaccine coverage among HCWs. From July 2021 to March 2023 we recruited a cohort of healthcare workers from 13 primary, 2 secondary, and 5 tertiary care hospitals of four administrative divisions across Bangladesh. Field staff interviewed the HCWs to collect demographic information and records of hepatitis B, and influenza vaccination using a structured questionnaire. We summarized the data using descriptive statistics. We enrolled 3684 HCWs: 22% (810) physicians, 48% (1763) nurses, and 30% (1111) support staff. Of 3684,

70% (2583) were recruited from tertiary, 22% (793) from primary, and 8% (308) from secondary-level healthcare facilities. The median age of the HCWs was 35, (IQR= 29-44) years and 67% were female. In the cohort, 8% (289) of HCWs reported to receive the influenza vaccine for the current influenza season and 53% (1968) reported to complete three doses of the hepatitis B vaccine. Overall, 8% of physicians, 10% of nurses, and 6% of support staff reported to receive the seasonal influenza vaccine. Hepatitis B vaccine uptake was highest among physicians (81%), followed by nurses (56%), and support staff (28%). Seasonal influenza vaccine uptake was highest in tertiary-level facilities (10%) followed by secondary (5%) and primary-level facilities (3%). In contrast, hepatitis B vaccine uptake was highest in primary-level facilities (60%) followed by tertiary (54%) and secondary-level facilities (34%). Both hepatitis B and influenza vaccine coverage were low among HCWs in Bangladesh, especially among support staff. Educational interventions to build awareness and subsidized vaccination policies for HCWs may improve vaccine uptake among this high-risk group.

6371

ASSOCIATION OF ALTERED BASELINE HEMATOLOGICAL PARAMETERS WITH ADVERSE TUBERCULOSIS TREATMENT OUTCOMES

Arul Nancy Pandiarajan

National Institute for Research in Tuberculosis- International Center for Excellence in Research, Chennai, India

Tuberculosis (TB) treatment monitoring is an essential tool for effective TB treatment management. Identifying parameters that predict adverse TB treatment outcomes (failure, recurrence and death) could significantly improve clinical management. The association of hematological parameters with poor TB treatment outcomes is not well defined. To study the relationship of hematological parameters with TB treatment outcomes, we examined data from pulmonary tuberculosis (PTB) patients with successful and unsuccessful treatment outcomes. We enrolled 68 cases (poor treatment outcomes) and 133 controls (good treatment outcomes) through a nested 1:2 case; control study, matching for age, sex, body mass index, diabetes status, alcohol and smoking. Median age of the study population is 45 years and it ranges from 36 to 52 years. Hematological profiling showed significant differences in the absolute counts of white blood cells (WBC), lymphocytes, neutrophils and monocytes between cases and controls. In addition, increased neutrophil to lymphocyte (NL) ratio and monocyte to lymphocyte (ML) ratio were present in cases in comparison to controls. Similarly, decreased hematocrit and red blood cell counts were detected in cases when compared with controls. Univariate and multivariate analysis demonstrated a significant association of absolute counts of WBC, neutrophils, monocytes NL and ML ratios with poor treatment outcomes. Altered baseline hematological parameters are clearly associated with poor TB treatment outcomes, showing potential for clinical prediction to enhance the management of at-risk cases.

SARS-COV-2 OMICRON VARIANT DETECTION WITH BINAXNOW, PANBIO, AND ID NOW RAPID TESTS

Mark Charles Anderson[1], Austin Hodges[1], Ana Olivo[1], Vera Holzmayer[1], Yitz Goldstein[2], Julie Hirschhorn[3], Dariusz Pytel[3], Matthew Faron[4], Luis Gonzalez[5], Stephen Kovacs[6], Rich Roth[7], Mary Rodgers[1], Gavin Cloherty[1]

[1]Abbott Diagnostics Division, Abbott Park, IL, United States, [2]Montefiore Medical Center, Bronx, NY, United States, [3]Medical University of South Carolina, Charleston, SC, United States, [4]Medical College of Wisconsin, Milwaukee, WI, United States, [5]Abbott Rapid Diagnostics, Lake Forest, IL, United States, [6]Abbott Rapid Diagnostics, Scarborough, ME, United States, [7]Abbott Rapid Diagnostics, San Diego, CA, United States

The SARS-CoV-2 pandemic has seen multiple variants of concern arise and spread around the world. Throughout 2022 the omicron variant has diversified and spread, with dozens of subvariants in multiple waves. With each new variant, it is important to evaluate whether currently available diagnostic assays continue to accurately detect the virus. Here, we sequenced SARS-CoV-2 omicron variant lineages from patient nasal swabs collected over 12 months and tested them with Alinity m SARS-CoV-2, BinaxNOW COVID-19 Antigen Self Test, Panbio COVID-19 Ag Rapid Test Device, and ID NOW COVID-19 diagnostic tests. Patient nasal swabs in VTM from confirmed SARS-CoV-2 infections were collected between December 2021-November 2022 from South Carolina, Wisconsin, and New York. Viral load was measured on a quantitative research use only m2000 assay to determine genome equivalents per milliliter (GE/ml) and genomes were sequenced from xGen-enriched metagenomic libraries on Illumina platforms followed by classification with Pangolin and Nextclade tools. Sufficient genome coverage was achieved for classification of n=635 VTM samples. In parallel with viral load testing, VTM samples were tested on BinaxNOW (LOD; Log 4.5 GE/test) and Panbio (LOD; Log 5 GE/test) assays without specimen inactivation. Selected variants with sufficient volume were tested on ID NOW (LOD; Log 2.5 GE/test) and Alinity m (LOD; Log 10 copies/mL) assays after inactivation at 65oC for 30 minutes. Samples collected between January and November of 2022 spanned the full diversity of omicron, including BA.1, BA.2, BA.3, BA.4, and BA.5 variant waves and more than 70 subvariant lineages. All tested SARS-CoV-2 omicron variants were successfully detected by BinaxNOW, Panbio, Alinity m and ID NOW at levels consistent with expected assay limits of detection for freshly collected specimens. All four assays robustly detect circulating omicron variants, confirming that current rapid diagnostic tests are effective at detecting SARS-CoV-2 omicron infections at expected levels of sensitivity compared to previous variants of concern.

6373

ANALYTICAL PERFORMANCE OF 17 COMMERCIALLY AVAILABLE POINT-OF-CARE TESTS FOR C-REACTIVE PROTEIN TO SUPPORT PATIENT MANAGEMENT AT LOWER LEVELS OF THE HEALTH SYSTEM

Serafina Calarco[1], B. Leticia Fernandez-Carballo[1], Thomas Keller[2], Stephan Weber[2], Meike Jakobi[3], Patrick Marsall[4], Nicole Schneiderhan-Marra[4], Sabine Dittrich[1]

[1]Foundation for innovative New Diagnostic (FIND), geneva, Switzerland, [2]ACOMED statistik, Leipzig, Germany, [3] Natural and Medical Sciences Institute at the University of Tübingen (NMI), Reutlingen, Germany, [4]Natural and Medical Sciences Institute at the University of Tübingen (NMI), Reutlingen, Germany

C-reactive protein (CRP) is an acute phase biomarker. A glycoprotein produced by the liver and released into the blood stream within a few hours of tissue injury; occurring, at the start of an infection, or due to other sources of inflammation. CRP levels are typically below 3 mg/L in healthy patients, ranging from 10 to 100 mg/L during a mild infection, reaching as high as 500 mg/L in patients experiencing severe inflammatory responses. Point-of-care (POC) tests for CRP are increasingly used in primary care to assist general practitioners (GPs) in the case management of various health complaints, including acute cough and abdominal pain, and to differentiate between mild and severe respiratory tract infections. To support health care providers in the clinical management of patients, it is crucial that the CRP tests used are accurate, precise and reliable. In this study, we compared the performance of 17 commercially available POC CRP tests. Eight quantitative and nine semi-quantitative tests were evaluated using stored samples (n=660) which had previously been tested for CRP using the Cobas 8000 Modular analyzer (Roche Diagnostics International AG, Rotkreuz, Switzerland), which represented the reference standard for evaluation. CRP values fell within the clinically relevant range (10-100 mg/L) and were grouped into four categories (<10 mg/L, 10-40 mg/L or 10-30 mg/L, 40-80 mg/L or 30-80 mg/L, and > 80mg/L) for majority of the semi-quantitative tests. Of the eight quantitative POC tests evaluated, the QuikRead go and Spinit exhibited a higher level of agreement with the reference method, (slope =0.963 and 0.921, respectively). The semi-quantitative tests showed a poor percentage agreement for the intermediate categories and higher percentage agreement for the lower and upper limit categories. More generally, analytical performance varied

considerably for the semi-quantitative tests. Our findings suggest that the quantitative tests might represent the best choice for a variety of use cases, as they can be used across a broad range of CRP categories.

6374

EVALUATION OF TUBERCULOSIS TREATMENT OUTCOME AND THEIR PREDICTORS IN PUBLIC AND PRIVATE HEALTH INSTITUTIONS, SOUTHEAST, NIGERIA; AN IMPLICATION FOR POLICY IMPLEMENTATION, CLIENT CENTERED EDUCATION AND TREATMENT FOLLOW-UP

Nelson C. Eze

Federal Ministry of Health, Abuja, Nigeria

Although Tuberculosis (Tb) treatment centres exist in Nigeria, information on treatment outcomes and their predictors especially in private hospitals are poorly documented. Identification of predictors of poor treatment outcomes may enable understanding and development of interventions to improve outcome. This study therefore evaluated tuberculosis treatment outcomes and their predictors in public and private hospitals in Abakaliki, Nigeria. A retrospective study of clients managed in the two hospitals over a five year period (Jan 2018 to Dec 2022). All clients who have completed treatment over the study period were enrolled. Relevant information from the case register was retrieved and entered into proforma and study forms. Treatment outcomes were evaluated according to WHO and National Tuberculosis Control Program guidelines. A total of 522 and 732 clients were enrolled in AE-FUTHA and M-4H with mean ages 45.3±7.2 years and 46.1±3.8 years respectively. Majority (84%) were new cases with treatment success rate of 82.6% in both facilities. Treatment outcome showed that relapse, treatment failure and death were 1.5%, 1.0% and 4.6% respectively in AE-FUTHA, 1.4%, 1.2% and 6.4% respectively in M-4H with default averaging 10% in both facilities. Age (15-29), far distance to health facility (>5km) and Tb category (re-treatment) were predictors of poor treatment outcome in AE-FUTHA while area of residence (rural), far distance to health facility (>5km) and Tb category (re-treatment) were predictors of poor treatment outcome in M-4H. Clients were mostly males with twice (1.6%) DRTb than females. Although treatment success rate was close to the 85% WHO bench mark, there were still large pockets of default with similar predictors of poor treatment outcomes in both facilities. Young people on treatment need close monitoring for improved treatment outcome. Defaulter rate can be reduced by patient-centered education and counseling, follow-up reminder system, effective contact tracing, and referral to support group. Decentralization of treatment centres to rural areas would further reduce defaulter rate.

6375

ISONIAZID MONORESISTANT TUBERCULOSIS (HR-TB) IN ODISHA, INDIA, DURING 2019

Sidhartha Giri, Sujeet Kumar, Sunil Swick Rout, Sarita Kar, Sanghamitra Pati

ICMR Regional Medical Research Centre Bhubaneswar, Bhubaneswar, India

We conducted this study to determine the prevalence of Hr-TB (rifampicin-susceptible, isoniazid-resistant), and mutations in katG and inhA genes in Odisha, India, during 2019. The retrospective data analysis from January-December, 2019, was performed at the National Reference Laboratory (NRL), at ICMR-Regional Medical Research Centre Bhubaneswar, Odisha. NRL Bhubaneswar offers diagnostics services to 10 districts of Odisha under the National Tuberculosis Elimination Programme. The line probe assay (LPA) was performed using GenoType MTBDR plus assay version 2, (Hain Life Sciences, Germany). A total of 3282 Mycobacterium tuberculosis (MTB) positive samples from 8 districts of Odisha, for which LPA results were available, were analyzed. Of the 3282 samples, 90.2% (2961/3282) samples were smear positive, and LPA was performed directly from samples. For 9.8% (321/3282) samples which were smear negative, automated liquid culture using Mycobacteria Growth Indicator Tube (BACTEC MGIT 960 system, United States) was performed, followed by LPA assay from the positive liquid culture samples. Resistance patterns were observed in 60 isolates, of which 10 (16.7%, 10/60) had resistance to both RIF and INH, and 50 (83.3%, 50/60) had Hr-TB (INH resistance only). The prevalence of Hr-TB during the study period was 1.53% (50/3272) with a range of 0 to 3.4% in the 8 districts. Among the 50 Hr-TB strains, katG mutation and inhA mutations were seen in 74% (37/50) and 26% (13/50) strains respectively. In conclusion, compared to other Indian studies, the lower prevalence of Hr-TB in Odisha could be due to the success of Directly Observed Treatment Short-course (DOTS) leading to effective treatment of drug-susceptible TB cases in the state and decreased transmission from primary DR TB cases.

6376

INFLUENZA, RSV, AND SARS-COV2 SURVEILLANCE IN MACHA, ZAMBIA IN 2022

Mutinta Hamahuwa[1], Pamela Sinywimaanzi[1], Mathias Muleka[1], Passwell Munachoonga[1], Hellen Matakala[1], Stephanie M. Kenyon[2], Katherine Z.J. Fenstermacher[3], Richard E. Rothman[3], Andrew Pekosz[4], Mwaka Monze[5], Philip E. Thuma[1], Edgar Simulundu[1], Catherine G. Sutcliffe[6]

[1]Macha Research Trust (MRT), Choma, Zambia, [2]Department of International Health, Johns Hopkins Bloomberg School of Public Health,, Baltimore, MD, United States, [3]Department of Emergency Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, [4]Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [5]Virology Laboratory, University Teaching Hospital, Lusaka, Zambia, [6]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Respiratory infections are a major cause of morbidity and mortality worldwide but are relatively understudied in sub-Saharan Africa. In December 2018, surveillance for influenza-like illness (ILI), influenza virus, respiratory syncytial virus (RSV), and later SARS-CoV2, was established at Macha hospital, which is located in a rural part of southern Zambia, and is ongoing. Here, we report on the burden of ILI, influenza A/B virus, RSV, and SARS-CoV-2 among outpatients in 2022 and compare to prior years before (2019) and during the COVID-19 pandemic (2020-2021). All outpatients were screened for ILI and an age-stratified sample of outpatients with ILI were enrolled. A nasopharyngeal swab was collected for testing for influenza A/B virus, RSV, and SARS-CoV-2 using the GeneXpert platform. Testing of samples from 2022 is ongoing and will be completed by July 2023. The annual and monthly pathogen prevalence among outpatients with ILI will be estimated. From January 1 to December 31, 2022, 21,630 outpatients were screened for ILI and 1693 (7.8%) participants had ILI. The proportion with ILI in 2022 was comparable to 2021 (6.9%) and 2020 (9.7%) and lower than 2019 (16.9%) prior to the COVID-19 pandemic. In 2022, 502 outpatients with ILI were enrolled. In January and February 2022, 7 participants to date tested positive for influenza A virus and 12 for SARS-CoV-2. No participants tested positive for influenza B virus or RSV. Through this surveillance platform, we continue to document the burden of respiratory viruses in this underrepresented region and provide important information in this changing context to inform prevention and control efforts.

IMPORTANCE OF SEROLOGY DIAGNOSTICS FOR CHRONIC PULMONARY ASPERGILLOSIS IN POSSIBLE TUBERCULOSIS PATIENTS IN COTE D'IVOIRE

David Koffi[1], Borel Thierry N'dri-Kouadio[1], Francis Kouadjo[1], Andre Offianan Toure[1], Mireille Dosso[1], David W. Denning[2]

[1]pasteur Institute Of Cote D'ivoire, Abidjan, Côte D'ivoire, [2]university Of Manchester, Manchester, United Kingdom

Some patients with apparent pulmonary TB don't have TB but chronic pulmonary aspergillosis or CPA. However, the lack of diagnostic capacity for fungal infections and low index of suspicion for fungal respiratory infections among clinicians has been a challenge to CPA diagnosis and management in resource-limited settings. The most sensitive laboratory test for CPA is

Aspergillus IgG (doi: 10.3201/eid2408.171312) The study aimed to provide serological evidence of persistent Aspergillus infection among PTB patients in Cote d'Ivoire.This was a pilot cross-sectional laboratory-based study conducted in the last trimester of 2022. The study population was 39 adult patients with persistent clinical symptoms of pulmonary TB despite anti-TB treatment. Sputum samples were subjected to microscopy and standard fungal culture. Serological detection of Aspergillus fumigatus IgG was done using an enzyme-linked immunosorbent assay (BIO-RAD®). The procedures and results were done and interpreted according to the manufacturer's protocol. The cut-off value is 10 UA/mL for positive results and borderline when concentrations are between 5 and 10 AU/ml.Preliminary data showed that serological evidence of CPA or fungal sensitization was positive in 8 Xpert TB negative patients (20.5%); 5 (12.8%) positive and 3 (7.7%) borderline positive. The most common clinical features of the patients positive for Aspergillus IgG were productive cough and fever; 2 (25%) presented with hemoptysis. The most fungal isolates from positive sputum were Aspergillus fumigatus 4(50%).Our findings suggest that CPA is common in GeneXpert MTB/RIF® negative patients and could be the cause of persistent clinical symptoms in PTB patients in our setting, as described by others in West Africa. We recommend the validation of these findings in a larger cohort study. This will be important to contribute to efforts in the expansion of the TB program to include CPA as an integral component of care.

6378

SEX DIFFERENCES IN PLASMA CYTOKINE PROFILES BETWEEN TUBERCULOSIS PATIENTS BEFORE AND DURING TREATMENT

Elizabeth Ntapara[1], Lwitiho Sudi[1], Issa Sabi[1], Julieth Lalashowi[1], Jacklina Mhidze[1], Nyanda Ntinginya[1], Michael Hoelscher[2], Abhishek Bakuli[2], Andrea Rachow[2], Christof Geldmacher[2], Mkunde Chachage[3]

[1]National Institute for Medical Research- Mbeya Tanzania, Mbeya, Tanzania, United Republic of, [2]German Center for Infection Research, Partner Site Munich and Division of Infectious Diseases and Tropical Medicine, Klinikum of the University of Munich, Munich, Germany, [3]National Institute for Medical Research- Mbeya Tanzania, Division of Infectious Diseases and Tropical Medicine, Klinikum of the University of Munich and University of Dar es Salaam, Mbeya College of Health and Allied Sciences (UDSM-MCHAS), Mbeya, Tanzania, United Republic of

Tuberculosis (TB) remains a global public health threat, with men bearing a higher disease burden than women. Men's higher burden is associated with more significant socio-economic and cultural risk factors. Host biological factors may also account for this difference, yet there is little information on sex differences in host immunity to Mycobacterium tuberculosis (Mtb). This study, therefore, aimed to explore sex-specific differences in cytokines and inflammatory mediators in plasma supernatants before and during TB treatment to understand the sex bias in TB disease. Supernatants from whole blood of HIV-negative female (n=19) and male (n=21) adults with active pulmonary TB were collected at TB diagnosis, two and six months of treatment. Supernatants were then analyzed using Luminex Multiplex assay to quantify seventeen different cytokines and inflammatory mediators of importance in the pathogenesis of Mtb: MMP-1, MMP-2, MMP-8, MMP-9, Myeloperoxidase/MPO, S100A8, S100A9, TNF-alpha, IFN-gamma, IL-1 beta/IL-1F2, IL-8/CXCL8, IL-12/IL-23 p40, IL-10, IL-13, NCAM-1/CD56, CD40 Ligand/TNFSF5, GM-CSF. A similar proportion of men and women had moderate to far advanced TB disease at diagnosis (54.1% vs. 45.9%, p=0.7850), while more men had worse severity six months after treatment (88.2% vs. 11.4%, p<0.0001). Sixteen of the seventeen cytokines and inflammatory mediators in unstimulated samples were elevated at the time of TB diagnosis and significantly declined at two- and six months following treatment. The decline was observed in both men and women. Higher median levels of MMP1 and MMP8 were detected in men compared to women at baseline (MMP1: 3754 vs. 1507, p=0.0012; MMP8: 31623 vs. 16346, p<0.0001) at two months (MMP1: 1404 vs. 680.9, p=0.0028; MMP8:10405 vs. 6830, p=0.0204) and at six months post-treatment (MMP1: 1084 vs. 517.3, p=0.0230; MMP8: 7498 vs. 4910, p=0.1042). MMP1 and MMP8 levels are higher in men before and after treatment. Further understanding of the observed differences in the context of clinical disease outcomes may advance our understanding of sex biases in TB.

BURDEN OF TUBERCULOSIS AMONG CHILDREN UNDER FIVE HOSPITALIZED IN THE RESPIRATORY UNIT OF THE LARGEST DIARRHEAL DISEASE HOSPITAL IN BANGLADESH: A PROSPECTIVE CROSS-SECTIONAL STUDY

Tahmina Alam, Mohammod Jobayer Chisti, Lubaba Shahrin, Monira Sharmin, Abu Sadat Mohammod Sayeem, Tahmeed Ahmed

Interntaional centre for diarrheal disease and research, Bangladesh, Dhaka, Bangladesh

Detection of tuberculosis (TB) in children remains challenging even in high-risk populations. We sought to determine the burden of TB among hospitalized under-five children at risk of TB. In this prospective cross-sectional study we stratified three high-risk groups of 0 to 59 months children to screen them for TB disease between December 2020 and Dec 2021. Group I had conventional presumptive criteria of TB, group II had severe malnutrition with pneumonia, and group III was severely malnourished children unresponsive to nutritional rehabilitation. Here severe malnutrition included severe wasting z score weight for length less than -3 of the WHO median or nutritional edema or severe underweight z score weight for age less than -4 of the WHO median. Children unresponsive to nutritional rehabilitation were defined as failure to gain weight at least 5 gm/kg/day for 3 successive days during rehabilitation or the presence of edema by day 10 after admission. In addition to symptom-based history and clinical examination, we performed a tuberculin skin test, chest radiography, and Xpert Ultra of induced sputum and stool for diagnosing TB. During the study period, the burden of TB among 272 enrolled children was 22% (59/272). Our study confirmed tuberculosis by microbiological detection in 14.33% (39/272) of children, of whom 25 by Xpert Ultra in sputum, and 24 by Xpert Ultra in stool, and among them, ten children were confirmed in both sputum and stool samples. Twenty (7.35%, 20/272) children had been clinically diagnosed with tuberculosis. Our study affirms that the burden of childhood TB is as high as 14.3% among high-risk populations which underscores the importance of the introduction of routine screening of TB in such children in resource-limited settings.

HYPOXAEMIA PREVALENCE, MANAGEMENT AND OUTCOME AMONG CHILDREN PRESENTING TO LOW-LEVEL HEALTH FACILITIES IN TANZANIA AND RWANDA

Alix Miauton[1], Alexandra V. Kulinkina[2], Rainer Tan[1], Chacha Mangu[3], Victor P. Rwandarwacu[4], Ludovico Cobuccio[1], Lameck Luwanda[5], Godfrey Kavishe[3], Sabine Renggli[5], Geofrey I. Ashery[5], Magreth Joram[5], Ibrahim E. Mtebene[5], Peter Agrea[3], Humphrey Mhagama[3], Joseph Habakurama[4], Emmanuel Kalisa[4], Angelique Ingabire[4], Cassien Havugimana[4], Gilbert Rukundo[4], Honorati Masanja[5], Nyanda E. Ntinginya[3], Valérie D'Acremont[1]

[1]Center for primary care and public health (Unisanté), Lausanne, Switzerland, [2]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [3]National Institute of Medical Research – Mbeya Medical Research Centre, Mbeya, Tanzania, United Republic of, [4]Swiss Tropical and Public Health Institute, Kigali, Rwanda, [5]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of

Hypoxemia is a known predictor of death in acute respiratory infections. In primary care settings in low- and middle-income countries, oxygen is often not accessible. The Integrated Management of Childhood Illness (IMCI) chartbook recommends using pulse oximetry (POX) when available, to identify severely hypoxemic children (oxygen saturation <90%) for classification as severe pneumonia and referral to the hospital. Evidence on the impact of this approach is scarce. ePOCT+ is a digital clinical decision support algorithm that guides primary care clinicians in managing

acutely sick children aged 1 day to 14 years in Rwanda and Tanzania. The algorithm recommends POX for all young infants and older children with IMCI pneumonia. We conducted a post-hoc analysis of ePOCT+ data to assess the prevalence of severe hypoxemia among paediatric outpatients attending participating health facilities. We further analysed the overlap with IMCI danger signs, the referral status, and the 7-day outcome of severely hypoxemic children. Our analysis included 28'294 consultations from 36 health facilities conducted between December 2021 and October 2022. 4% of children were <2 months, 77% 2-59 months, and 19% 5-14 years. 4'003/28'294 (14%) children met the criteria for POX measurement, which was performed in 86% of these cases. 68/4'003 (1.7%) children had severe hypoxemia, including 8 aberrant results. The prevalence was lower in dispensaries than in health centres (1.3% and 2.0%, respectively). 14/68 (21%) children had at least one other IMCI danger sign warranting referral. Of the 54 children requiring referral based on the POX results alone, health workers referred only 14 children, and 6 were actually hospitalized. None of the severely hypoxemic children died. Our results show that prevalence of severe hypoxemia was low, and POX changed the actual management in only 0.05% of all children. Further studies are needed to assess the impact of POX on morbidity and mortality in low-level health facilities in resource-constrained settings. Training of health workers is essential to improve the quality of POX measurement and compliance with referral guidelines.

FACTORS CONTRIBUTING TO DISPARITIES IN RESPIRATORY CARE AT ADAMA HOSPITAL MEDICAL COLLEGE, ETHIOPIA

Bethlehem Atoma[1], Dawi Girma[2], William M. LeTourneau II[3], Bickey Chang[1], Sultan B. H/Gelete[2], Derebi Atoma[4], Sheiphali Gandhi[5], Dejene Dibaba[2], Endashaw Debela[2], Wajahat Khalil[6], Sarah Kesler[1], Anteneh Zewde[1], Anne C. Melzer[1]

[1]University of Minnesota, Minneapolis, MN, United States, [2]Adama Hospital Medical College, Adama, Ethiopia, [3]Mayo Clinic, Rochester, MN, United States, [4]Children's Minnesota, Minneapolis, MN, United States, [5]University of California San Francisco, San Francisco, CA, United States, [6]Minneapolis VA Health Care System, Minneapolis, MN, United States

Prior research suggests disparities exist in respiratory care in low- and middle-income countries. We assessed 1) the structure and processes in place for respiratory care, including mechanical ventilation (MV) management, at Adama Hospital Medical College (AHMC) in Ethiopia and 2) reported barriers faced by staff when caring for respiratory patients. We conducted a single-center cross-sectional study of healthcare workers (HCWs) and hospital leadership involved in respiratory care at AHMC between January and February 2023. We administered paper surveys, which included qualitative and quantitative items to assess the current care practices, educational background, the self-reported confidence level in the provision of respiratory care (including MV use), barriers encountered, and perceived impact on patient outcomes. Participants (n=90) mainly included 39 nurses, 35 nurse practitioners, and four physicians. Five are in hospital leadership. Most worked in the intensive care unit (ICU) (n=44) or emergency department (n=17). Among the HCWs who manage patients with MV, 62% provided daily care. However, most (82%) lacked specific training in managing MV, with 23.2% feeling uncomfortable and 24.4% feeling somewhat comfortable in managing MV. The most significant barriers to effective care were lack of training in MV management, difficulty troubleshooting malfunctioning ventilators, and lack of necessary diagnostic tests. The five leaders reported similar barriers to quality respiratory care, including a lack of trained staff in MV management, poor staff-to-patient ratios, limited equipment, diagnostic tests, and ICU beds. Nearly half (40%) of participants felt preventable MV-related complications increased ventilator days, while 60% believed these complications prolonged hospital stays, increasing healthcare costs and mortality. Lack of training and resources for healthcare workers managing respiratory illnesses and MV creates health disparities for patients at AHMC. This study highlights the need for targeted interventions, such as training programs to ensure equitable respiratory care for all patients at AHMC.

THE EFFECT OF SOAP USE CONDITIONS ON SCHISTOSOME CERCARIAE IN WATER

Jiaodi Zhang[1], Ana K. Pitol[2], Laura Braun[3], Michael R. Templeton[1]

[1]Imperial College London, London, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

To move towards eliminating schistosomiasis as a public health problem, a comprehensive control strategy which incorporates water, sanitation and hygiene (WASH) interventions is needed. Since the successful penetration of schistosome cercariae during water contact (e.g., washing clothes, bathing) is the key component in disease transmission, the use of soap, as part of good hygiene, might play a critical role in schistosomiasis prevention by reducing human exposure to cercariae. According to our recent systematic review, soap has the potential to reduce Schistosoma infection risk and there are two potential protective aspects of soap: (1) soap has direct adverse effects on cercariae (i.e. in terms of mortality, motility, morphology, infectivity, viability); (2) soap on the skin prevents cercariae from penetrating into skin, developing into adult worms and producing eggs in the human body. For the first protective aspect, laboratory experiments have been carried out to quantify the effect of different soaps on cercarial mortality, using two powder and two bar soaps which are commonly used in Tanzania. S. mansoni cercariae were exposed to different concentrations of soap from a few minutes up to one hour. All four soaps were able to kill cercariae, with their effectiveness related to the soap concentration and exposure time. We will also report on other protective mechanisms of soap (e.g. rendering cercariae incapable of finding a host's skin or penetrating skin) which will form the basis of comprehensive guidance for soap use in endemic regions to prevent schistosomiasis.

COST-EFFICIENT SURVEY DESIGNS FOR MONITORING AND EVALUATION OF SOIL-TRANSMITTED HELMINTHS CONTROL PROGRAMS

Adama Kazienga[1], Bruno Levecke[1], Sake J de Vlas[2], Luc E. Coffeng[2]

[1]Ghent University, Gent, Belgium, [2]Erasmus MC, University Medical Center, Rotterdam, Netherlands

To monitor and evaluate soil-transmitted helminth (STH) control programs, the World Health Organization (WHO) recommends screening stools from 250 children across 5 schools, deploying Kato-Katz thick smear (KK). However, it remains unclear whether these recommendations are sufficient to make adequate decisions about stopping preventive chemotherapy (PC) (prevalence of infection <2%) or declaring elimination of STH as a public health problem (prevalence of moderate-to-heavy intensity (MHI) infections <2%). We developed a simulation framework to determine the effectiveness and cost of survey designs for decision-making in STH control programs, capturing the operational resources to perform surveys, the variation in egg counts across STH species, across schools, between and within individuals, and between repeated smears. Using this framework and a lot quality assurance sampling approach, we determined the most cost-efficient survey designs (number of schools, subjects, stool samples per subject, and smears per stool sample) for decision-making. For all species, employing duplicate KK (sampling 4 to 6 schools and 64 to 70 subjects per school) was the most cost-efficient survey design to assess whether prevalence of any infection intensity was above or under 2%. For prevalence of MHI infections, single KK was the most cost-efficient (sampling 11 to 25 schools and 52 to 84 children per school). KK is valuable for monitoring and evaluation of STH control programs, though we recommend to deploy a duplicate KK on a single stool sample to stop PC, and a single KK to declare the elimination of STH as a public health problem.

ASSOCIATION OF FEMALE UROGENITAL SCHISTOSOMIASIS WITH HIGH-RISK HUMAN PAPILLOMAVIRUS AMONG WOMEN IN ZAMBIA: BASELINE RESULTS OF A LONGITUDINAL COHORT STUDY (THE ZIPIME WEKA SCHISTA STUDY)

Olimpia Lamberti[1], Helen Kelly[1], Rhoda Ndubani[2], Nkatya Kasese[2], Emily Webb[3], Beatrice Nyondo[2], Barry Kosloff[2], Jennifer Fitzpatrick[2], Bonnie Webster[4], Maina Cheeba[2], Helen Ayles[2], Kwame Shanaube[2], Amaya Bustinduy[1]

[1]Department of Clinical Research, London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Zambart, Lusaka, Zambia, [3]Department of Infectious Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Natural History Museum, London, United Kingdom

Female genital schistosomiasis (FGS), caused by Schistosoma haematobium (Sh) egg-deposition in the female genital tract, is highly prevalent in sub-Saharan Africa (SSA). Women in SSA also face the highest cervical cancer incidence and mortality rates globally, caused by high-risk (HR-) human papillomavirus (HPV) infection. FGS and HR-HPV infection share socio-demographical and behavioural risk factors related to disease exposure. Cross-sectional studies previously found an increased risk of HR-HPV infection in women co-infected with Sh compared to those without. Yet, the interplay of these infections is unknown. We explored the association between Sh and HR-HPV co-infection in two communities in Zambia from an ongoing longitudinal community-based study, the Zipime Weka Schista! Study. Women were recruited by community health workers at home. A urine sample, two cervicovaginal self-swabs, HIV and Trichomonas self-tests were obtained and a questionnaire completed. Clinic follow up was done by a midwife who performed point-of-care colposcopy and obtained genital samples. Urine microscopy was used for Sh-egg detection and cervicovaginal self-swabs were tested by GeneXpert and PCR for HR-HPV and Sh DNA detection respectively. A total of 2,511 women aged 15-50 years old have been recruited to date (median age 28 years, [IQR] 22-36). Preliminary results from 2,488 urine samples and 1,547 cervicovaginal self-swabs revealed a prevalence of egg-patent Sh and HR-HPV infection of 5.3% (131/2,488) and 27.4% (424/1,1547), respectively. Multivariable logistic regression adjusted for age and Trichomoniasis status, revealed women with egg-patent Sh were significantly more likely to be HR-HPV positive compared to those without (OR=1.9, p=0.03). Women aged 15-25 had 1.6 higher odds of having HR-HPV compared to women aged 26+ (OR=1.6, p<0.01). Further analysis exploring the association of HR-HPV infection and cervical precancer with FGS status by PCR and colposcopy is ongoing. These findings will inform possible points for integration of FGS and cervical cancer screening strategies.

6385

INVESTIGATING THE GENETIC DIVERSITY OF THE SCHISTOSOMA MANSONI TRANSIENT RECEPTOR POTENTIAL MELASTATIN (SMTRPMPZQ) CHANNEL IN RESPONSE TO PRAZIQUANTEL TREATMENT IN NATURAL UGANDAN S. MANSONI POPULATIONS

Shannan Summers[1], Fiona Allan[2], Tapan Bhattacharyya[1], Michael Miles[1], Bonnie Webster[2], Amaya Bustinduy[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Natural History Museum, London, United Kingdom

Schistosomiasis is a neglected tropical disease (NTD) caused by parasitic trematodes (Schistosoma genus), with the highest burden in sub-Saharan Africa. The disease is treated with praziquantel (PZQ) which is typically delivered annually through large scale mass drug administration programs in endemic countries. These programs have been successful in reducing the prevalence and intensity of infection but their impact on the evolution of drug resistance is unknown. As control efforts to eliminate schistosomiasis intensify to reach the WHO NTD roadmap targets, there is a need to detect and track PZQ resistant Schistosoma isolates. The transient receptor potential melastatin praziquantel channel (SmTRPMPZQ) is now recognised to be involved in the mode of action of PZQ with mutations in this target resulting in drug resistance. However, this was conducted in a single Brazilian S. mansoni laboratory-selected resistant strain; it is unclear if this mechanism will be conserved in African S. mansoni populations, in which little is known about the extent of genetic variation of SmTRPMPZQ in natural Schistosoma populations. This project aims to analyse natural Ugandan S. mansoni populations (pre- and post-PZQ treatment) to identify polymorphisms associated with drug resistance. We sequenced the whole genomes of single S. mansoni miracidia from a clinical trial in Lake Albert, Uganda. We developed a high throughput amplicon deep sequencing method to screen genomic regions encoding the PZQ binding site to identify PZQ resistance polymorphisms. Overall, our preliminary baseline (pre-treatment) data suggests that there is limited genetic diversity within the PZQ binding site in SmTRPMPZQ. Our data will provide valuable insights into the genetic variation SmTRPMPZQ in field collected schistosome populations and suggest how this may affect treatment efficacy. Monitoring for changes in the frequency of PZQ resistance mutations will reveal how natural S. mansoni populations are evolving in response to PZQ treatment.

6386

LIVESTOCK CATTLE AS PREDICTOR OF TRANSMISSION OF SCHISTOSOMIASIS IN NIGERIA

Oyetunde Timothy Oyeyemi, **Oluyemi Adewole Okunlola**

University of Medical Sciences, Ondo, Nigeria

Schistosomiasis, a neglected tropical disease, remains a parasitic disease of public health concern, especially in sub-Saharan African countries where reported cases are predominant. The focus of this study is to examine the relationship between prevalence of schistosomiasis and livestock cattle index in Nigeria. The study's data came from three sources: the demographic and health survey, the malaria indicators survey, and the expanded special project for the eradication of neglected tropical diseases. Analysis of variance, correlation, and logistic regression were used to investigate the mean difference in schistosomiasis prevalence across geopolitical zones, the association between schistosomiasis prevalence and livestock cattle, and the risk of schistosomiasis in each geopolitical zone when the cattle index was known, respectively. According to disaggregated and combined data for 2018 and 2021, the prevalence of schistosomiasis and livestock cattle index are highest in the country's North Central, North East, and North West geopolitical zones (P <0.05). The association between the prevalence of schistosomiasis and livestock cattle was found to be positive and statistically significant (r =0.029, P<0.05). The likelihood of schistosomiasis decreases in the North-Central, North-East, and South-South as livestock increases, while the chance increases in the North West, South East, and South West as livestock increases. The estimated risk difference of the disease from one geopolitical zone to the next is marginal; however, it is highest in the South East and North West zones and least in the South West. The possibility that livestock cattle are a predictor of transmission of schistosomiasis cannot be disparaged; hence, policies that will curtail this mode of transmission should be developed and implemented in the risk regions identified in this study.

6387

HUMAN SCHISTOSOMIASIS RISK AND SNAIL ABUNDANCE HAVE A UNIMODAL RELATIONSHIP IN THE NATURAL ENVIRONMENT

Sidy Bakhoum[1], Christopher J. E. Haggerty[2], Cheikh Tidiane Ba[3], Jason R. Rohr[4]

[1]Department of Animal Biology, University Cheikh Anta Diop, Dakar, Senegal, [2]University of South Florida, Florida, FL, United States, [3]Department of Animal Biology, University Cheikh Anta Diop, Dakar, Senegal, Dakar, Senegal, [4]Department of Biological Sciences, Eck Institute of Global Health, Environmental Change Initiative, University of Notre Dame, Indiana, IN, United States

Non-linear relationships in host-parasite interactions can complicate the prediction and control of human infectious diseases, including

schistosomiasis. Schistosomiasis affects 200 million people in 52 countries and is caused by parasites released by freshwater snails. A dynamic energy budget (DEB) model predicts that parasite production by snails should be low both when snail densities are low and also, paradoxically, when they are high (as there is less energy per capita for parasite production). To test whether such a unimodal relationship between parasite and snail densities occurs in nature, we estimated snail densities, environmental food availability for snails, and per capita parasite production every other week for a year at four water bodies in West Africa. Consistent with DEB theory, we show that unimodal patterns exist between snail host densities and per-capita parasite production for both Schistosoma haematobium and S. mansoni. The interaction between snail densities and food resources was significant and non-linear for total parasite production (human risk), likely because at high snail densities there is greater competition for food resources. These patterns may explain why field snail densities are often not associated positively with human schistosomiasis prevalence and suggest that the greatest risk to humans may not coincide with peak snail densities at sites. Further, epidemiologic models for schistosomiasis based on non-linear relationships between snails and parasites may improve predictions of risk to humans.

6388

RISK FACTORS AND PREVALENCE OF SCHISTOSOMIASIS AND INTESTINAL PARASITES INFECTIONS IN VILLAGES IMPACTED BY AGRICULTURAL ACTIVITIES IN THE NORTH AND SOUTH OF GABON

Ndong NJ Mari

Faculty of Medicine, Department of Parasitology, Owendo, Gabon

The installation of the Olam group in the North and South of Gabon has encouraged a migratory flow of populations from urban areas to rural areas and the creation of favorable conditions for the transmission of intestinal parasites and schistosomiasis. The aim of this study was to assess the prevalence and risk factors of schistosomiasis and intestinal parasitosis infections (IPIs) in Olam villages and surrounding villages. A cross-sectional study was conducted in the North (in Bitam and Minvoul) and in the South (in Mouila) of Gabon among school-age children and adults > 60 years old between August 2019 and January 2020. Each participant presenting eligibility criteria for inclusion and having given his consent by his guardian was included. A total of 419 participants were approached and 326 gave their consent to participate in the study. The median age of the participants was 11 [10-12] years old. Five cases of schistosomiasis were found mainly in Olam villages of Mouila. The IPIs were found in 65.7% (175/266) of cases. Among them, protozoa and nematodes were diagnosed in 36.4% (99/226) and 42.1% (122/226) participants respectively. The proportion of IPIs was similar between the villages of Olam (69.2%; 63/91) and the surrounding villages (66.2%; 116/175) (p = 0.9). On the other hand, it was significantly higher in Bitam (82.0%; 114/139) compared to Minvoul (52.8%; 28/53) and Mouila (44.5%; 33/74) (p=0 ,03). Living in Mouila (p=0.01), being between 11-16 years old (p=0.04), living in a Earthen house (p=0.02), the use of latrines (p=0.01) and medicinal plants (p=0.01) was risk factors associated with IPIs. Median parasite density of participants infected with T. trichiura was more higher in Olam villages compared in surrounding villages (p<0.001). This work revealed a predominance of schistosomiasis in Olam village of Mouila. IPIs were more frequent in Bitam and the intensity of the transmission of ascariasis and higher trichocephalosis in Mouila and Minvoul would make it possible to orient the interventions of the program.

6389

COMBINING GENOMICS DATA WITH SOCIAL AND ENVIRONMENTAL CONNECTIVITY MEASURES TO IDENTIFY PATHWAYS OF SCHISTOSOMA JAPONICUM IMPORT IN RURAL CHINA

Elise Grover[1], Katerina Kechris[1], Zachary Nikolakis[2], Yannick Francioli[2], Hannah Guss[2], Hamish Pike[3], Todd Castoe[2], David Pollock[3], Yang Liu[4], Elizabeth Carlton[1]

[1]University of Colorado School of Public Health, Aurora, CO, United States, [2]University of Texas at Arlington, Arlington, TX, United States, [3]University of Colorado Anschutz, Aurora, CO, United States, [4]Sichuan Center for Disease Control and Prevention, Chengdu, China

Persistent transmission hotspots remain for several high burden parasitic diseases despite control efforts. One hypothesis is that infectious parasites are moving along social and environmental gradients, by human or animal movement, or along hydrological channels. In this study, we investigate how import has contributed to infections in a region where schistosomiasis transmission has persisted in spite of aggressive control programs. We also evaluate whether import is linked to social and hydrological connectivity pathways. This study leverages data collected in 2007 from 53 rural farming villages located in Sichuan, China with recent schistosomiasis reemergence. Within each of our sampled villages, all household members over the age of five and all bovines were invited to participate in schistosomiasis infection surveys. Participant demographics, household GPS coordinates, and household- and village-level mobility were assessed via head of household and village leader surveys. Survey data was paired with open-source environmental data to generate metrics that describe each village's potential to attract migrant parasites along social and hydrological gradients, taking into account road networks, drainage patterns and attractive resources within villages (e.g., schools, commerce). Individual Schistosoma japonicum samples, collected from infected human and bovine hosts, were whole genome sequenced to estimate the genetic relatedness and historical migration patterns among villages. Multivariable regression models will be used to model the association between the inferred connectivity between villages using genetic data and our social and hydrological connectivity metrics. As a result of this analysis, we expect to obtain insight into the geographic scale, pathways of import, and overall importance of parasite migration events to residual infection hotspots. Additionally, our study allows us to evaluate the utility of pairing social, environmental and genomics data to identify likely sinks and sources of persistent infections for use in targeted end-stage parasite elimination programs.

PROTEOMICS OF ADULT PARAGONIMUS KELLICOTTI EXTRACELLULAR VESICLES RELEASED IN VITRO OR PRESENT IN LUNG CYSTS

Lucia S. Di Maggio, Kerstin Fischer, Devyn Yates, Kurt C. Curtis, Bruce A. Rosa, John C. Martin, Petra Erdmann-Gilmore, Robert S.W Sprung, Makedonka Mitreva, Reid R. Townsend, Gary J. Weil, Peter U. Fischer

Washington University in Saint Louis, saint louis, MO, United States

Paragonimiasis is an important zoonotic, food-borne trematode infection that affects some 21 million people (mostly in Asia). Trematode parasites release extracellular vesicles (EV) in vivo that contain parasite proteins and RNA cargo that may interact with other parasites and with the host. Here we detail the composition of Paragonimus kellicotti EVs purified from both adult worm excretion/secretion products in vitro (EV ESP) and from lung cyst fluid of infected gerbils (EV CFP). Electron microscopy showed that most of the EVs were 30-50 nm in diameter, but small (10-20 nm) and large (90-120 nm) subpopulations of vesicles were also present. We identified 548 P. kellicotti-derived proteins in EV ESP by mass spectrometry. The three most highly represented GO terms in the molecular function category were ATP hydrolysis activity, ATP-dependent activity and ribonucleoside triphosphate phosphatase activity. We detected 8 proteins in the EV CFP of which 7 were also present in EV ESP. A cysteine protease (MK050848,

CP-6, previously reported as useful for serology) was the most abundant protein found in EV CFP in all technical and biological replicates. Immunolocalization of CP-6 showed no staining in lung tissue of uninfected gerbils. However, strong labeling for CP-6 was observed in the tegument of adult P. kellicotti and in the diseased lung cyst tissue that contained worm eggs. These results suggest that CP-6 is released within EVs by adult worms in vivo. This study has provided new insights regarding interactions between Paragonimus worms and their mammalian hosts.

EFFECT OF INTENSIVE TREATMENT FOR SCHISTOSOMIASIS ON VACCINE SPECIFIC RESPONSES AMONG UGANDAN ISLAND ADOLESCENTS: THE POPVAC A TRIAL

Gyaviira Nkurunungi[1], Ludoviko Zirimenya[1], Jacent Nassuuna[1], Agnes Natukunda[1], Emily L. Webb[2], Alison M. Elliott[1]

[1]MRC/UVRI & LSHTM Uganda Research Unit, Entebbe, Uganda, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

Helminths have long been proposed as modulators of vaccine-specific responses. We hypothesised that Schistosoma mansoni (Sm) infection suppresses responses to unrelated vaccines, and that this effect can be reversed, at least in part, by intensive praziquantel treatment intervention. We conducted a randomised-controlled trial of intensive versus standard intervention against Sm among school children in Koome islands, Uganda. Participants in the intensive arm received three doses of praziquantel (40mg/kg) each two weeks apart (the last of these 2-4 weeks before the first immunisation, BCG, at week 0), followed by quarterly during follow up. Participants in the standard arm were not treated until the week 8 primary endpoint. Participants received five vaccines: BCG [week 0], Yellow Fever, oral typhoid, HPV prime [week 4], HPV booster, tetanus/diphtheria [week 28]. Data were collected at baseline and at each follow up visit; primary outcome was vaccine responses at week 8, and for tetanus/diphtheria, at week 52. Sm infection status was determined retrospectively through plasma measurement of circulating anodic antigen (CAA). We enrolled 478 participants, 239 in each arm. Among the Sm positive at baseline, preliminary data (intention to treat) indicates that intensive Sm treatment significantly reduced infection intensity by week 0 (median [IQR] CAA concentration, pg/ml, 29[7;226] vs 1527[317;9105] in the standard arm), and significantly improved the week 8 BCG-specific IFN-γ response as assessed by ELISpot: geometric mean ratio SFU/106 PBMC 1.30 (95%CI 1.03-1.64). There was no effect on the yellow fever-, oral typhoid- and tetanus/diphtheria-specific antibody response. Data analysis on HPV-specific IgG responses is underway. Our preliminary data support the hypothesis that current helminth infection reduces the BCG-specific response, and may have different impact on cellular versus humoral vaccine-specific responses. Our data contribute to the debate on whether effective control of Sm infection improves vaccine responses (and by extension efficacy) in endemic settings.

6393

TRANSFORMING GROWTH BETA LEVELS IN INDIVIDUALS WITH SCHISTOSOMIASIS IN FEDERAL CAPITAL TERRITORY, NIGERIA

Wellington A. Oyibo[1], Olubunmi Tosin Okurame[1], Uche Thecla Igbasi[2]

[1]Centre for Transdisciplinary Research in Malaria and Neglected Tropical Diseases,College of Medicine of the University of Lagos, Nigeria, Lagos, Nigeria, [2]2Centre for Infectious Diseases Research, Microbiology Department, Nigeria Institute of Medical Research, 6 Edmond Crescent, Yaba- Lagos, Nigeria, Lagos, Nigeria

Schistosomiasis is a public health concern, globally and specifically in Nigeria that has one of the highest burden. Morbidities occur with genito-urinary and gastrointestinal presentations such as haematuria, chronic anaemia, stunted growth, abdominal distention affecting multiple organs, female genital schistosomiasis etc and could lead to several complications. Transforming growth factor-β (TGF-β) signaling has been found to play vital role in pathogenesis of Schistosomiasis-associated complications. This study evaluated the profile of TGF-β in persons with Schistosomiasis. A descriptive, cross-sectional study design was conducted on eighty (80) individuals of different age groups with symptoms suggestive of schistosomaisis. Stool, urine and venous blood samples were collected from the individuals, screened for Schistosomiasis and TGF-β in plasma samples were quantified using Enzyme linked immune sorbent assay (ELISA).The prevalence of schistosomiasis in the study area was 58.8%, 46 (57.5%) females and 34 (42.5%) males participated in the study, their age ranged from 5-15 years and with mean age of 16.5±10.2 years. The geometric mean of TGF-β was 2194.1 (range of 49.0 - 48,780.3). The geometric mean TGF-β of female participants, 2220.6 was higher than that of male participants, 2007.1, though not significant (P=0.677). There was no association between TGF-β and age of the participants (P=0.080) although the geometric mean TGF-β decreased as age of participants increased from <10 years, 2875.7 to 16-20 years, 925.7 but increased to 2298.6 in those above 20 years. This study has demonstrated increased serum levels of TGF-β in patients with Schistosomiasis compared with uninfected patients. There was a negative correlation (γ = -0.097) between TGF-β level and density of eggs from the samples collected but not significant (P-value = 0.448). The level of TGF-β in individuals infected with schistosomes did not differ with the infecting schistosome specie. Increased serum levels of TGF-β in patients with Schistosomiasis suggests that this growth factor may contribute to pathophysiologic remodeling in the disease.

6394

MEASURING WATER QUANTITY USED FOR PERSONAL AND DOMESTIC HYGIENE IN A LOW-INCOME URBAN COMMUNITY IN BANGLADESH

Rebeca Sultana[1], Nazmun Nahar[2], Stephen P. Luby[3], Sayeda Tasnuva Swarna[1], Emily S. Gurley[4], Charlotte Crim Tamason[5], Shifat Khan[1], Nadia Ali Rimi[1], Humayun Kabir[1], Md. Khaled Saifullah[1], Sushil Ranjan Howlader[6], Peter Kjær Mackie Jensen[5]

[1]icddr,b, Dhaka, Bangladesh, [2]Department of Gastroenterology, Hepatology and Infectious Diseases, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University Düsseldorf, Düsseldorf, Germany, [3]Infectious Diseases and Geographic Medicine, Stanford University, Stanford, CA, United States, [4]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [5]Copenhagen Center for Disaster Research, Global Health Section, Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [6]Institute of Health Economics, University of Dhaka, Dhaka, Bangladesh

There is a paucity of recent research on direct water quantity measurement for personal and domestic hygiene. We aimed to measure the water quantity used for personal and domestic hygiene and to explore the reasons and determinants for variation of water usage. We conducted this study from September 2014 to June 2016 in a low-income urban community in Dhaka. In 12 households, the team conducted a day-long bimonthly ethnographic observation for one year to measure the volume of water used per activity per person. They conducted 28 in-depth interviews to explore the reasons for changes of water usage. Participants used a median of 75 L (61–100) of water per capita per day (LCPD) and of this 75 LCPD they used a median of 39 LCPD (26–58) for personal hygiene. Women used less water than men. Individual and social norms, beliefs, and weather determinants determined personal hygiene. Water availability determined domestic hygiene (e.g., washing dishes, toilets and bathrooms). This study helps to elucidate a range of determinants of water usage of the participants from the participants' perspective. The quantity of water used for domestic and personal hygiene and its relationship to fecal-oral transmitted disease can be explored in future research.

6395

SUPPORTIVE SUPERVISION IS ASSOCIATED WITH AVAILABILITY OF WORLD HEALTH ORGANIZATION INFECTION PREVENTION AND CONTROL CORE COMPONENTS IN HEALTH FACILITIES IN SOUTHWESTERN UGANDA

Cozie Gwaikolo[1], Bongomin Bodo[2], Doreen Nabawanuka[2], Michael Mukiibi[2], Emmanuel Seremba[3], Paul Muyinda[3], Andrew Bakainaga[2], Yonas T. Woldenmariam[2], Christopher C. Moore[4], Richard Ssekitoleko[5]

[1]University of California San Francisco, San Francisco, CA, United States, [2]World Health Organization, Kampala, Uganda, [3]College of Health Sciences, Makerere University, Kampala, Uganda, [4]Division of Infectious Diseases and International Health, university of Virginia, Charlottesville, VA, United States, [5]World Health Organization, kampala, Uganda

Core components for infection prevention and control (IPC) support recommended IPC practices, which can reduce nosocomial infections and antimicrobial resistance. Quality improvement, including supportive supervision, promotes adherence to IPC, which can be challenging in resource-limited settings. We assessed the ability of supportive supervision to improve the availability of the World Health Organization (WHO) core components for IPC at health facilities in southwestern Uganda. We employed a before and after study design that included a baseline assessment of the availability of the WHO IPC core components followed by supportive supervision activities for targeted areas for improvement. We conducted a second assessment and determined differences in the availability of the core components between assessments. A score less than 70% was inadequate, a score between 70 and 85% was intermediate, and a score greater than 85% was adequate. Re-assessment occurred at 23 (21%) of 111 health facilities. The number of facilities that were <70% for each core component stayed the same or decreased at each facility type, but there was an increase from five to six health center III facilities scoring <70% for personal protective equipment (PPE). Conversely, the number of facilities that scored >85% for each core component stayed the same or was increased at each facility type, but there was a decrease from 4 to 2 health center III facilities scoring >85% for instrument processing. There was an increase in the median (interquartile range [IQR]) overall score from baseline to follow-up assessment for all facilities (65 [54-72] vs 75 [68-73], p=0.0001). Supportive supervision activities were associated with improved availability of the core components of IPC at health facilities in southwestern Uganda. PPE availability remained inadequate across visits and should be prioritized in health care facilities in the study area.

6396

A SEMI-AUTOMATED SCOPING REVIEW OF MICROPLASTIC CONTAMINATION IN FOOD AND WATER BANGLADESH PERSPECTIVE

Tania Jahir[1], Jaynal Abedin[2], Farha Sharmin[3], John Newell[4]

[1]College of Medicine, Nursing, and Health Sciences, University of Galway, Galway, Ireland, [2]Center for Data Research and Analytics (CfDRA), Galway, Ireland, [3]Spreeha Bangladesh Foundation, Dhaka, Bangladesh, [4]School of Mathematical and Statistical Sciences, Galway, Ireland

Microplastic are fragments of plastic debris that are less than five millimetres usually generated from the breakdown of consumer products and industrial waste. Everyday millions of metric tons of industrial waste are disposed in the environment. The health impact of microplastic in food and water is yet to be fully understood. Plastic trash accounts for 60-80% of all marine litter and is one of the fastest-growing segments of urban garbage. The microplastic pollution is higher in LMICs. Bangladesh is recognized as a nation with a plastic pollution crisis. The objective was to explore the existing knowledge by analysing scientific abstracts relating to the research on microplastic pollution and its effect on human health. We conducted a literature search in the indexed databases using the keywords “Microplastic AND (food OR water) AND Bangladesh”. We then processed the text of abstracts and converted these into a data where a row contained an abstract and each column a unique word across all abstracts. The frequency of words is recorded. Fitted a Latent Dirichlet Allocation (LDA) model to find common sub-themes across the abstracts. We found 121 abstracts based on the search. The first abstract was dated back to 2014 and it could be an indicator that research in microplastic is emerging recently. After initial processing we found 1262 unique words across all abstracts. Using LDA we found ten sub-themes. During the COVID-19 pandemic the amount of plastic pollution increased and it can be seen that one of the themes is concentrated, with the keywords, mask, pandemic, PPE etc. The marine and urban settings are the most affected areas. Fish and freshwater pollution is a key research domain. None of the themes showed any evidence of research relating to interventions in reducing plastic pollution or the assessment of the health impact of microplastics in food and water. The findings shows that there is a lack of research on the effect of the presence of microplastics in food and water on human health in Bangladesh. A rigorous research study is required to identify the level of knowledge, attitude and practices on the use of plastic products to develop interventions.

6397

TOILET FUNCTIONALITY AND CLEANLINESS STATUS IN HEALTHCARE FACILITIES IN DHAKA, BANGLADESH

Nuhu Amin, Juliet Willetts, Tim Foster

University of Technology Sydney, Sydney, Australia

Lack of access to functional and clean toilets is a major public health concern in LMICs, including healthcare facilities (HCF), contributing to the spread of infectious diseases. Most recent sanitation assessments were conducted in sub-district level hospitals rather than larger hospitals in major cities. We conducted research in 10 government and 2 private hospitals to understand the availability, functionality, cleanliness, and toilet-user ratios in Dhaka. From Aug-Dec 2022, we conducted infrastructure assessments and collected information on toilet numbers and users from hospital daily registers. Given the heterogeneity of user numbers and structural complexity of different departments (inpatients vs. outpatient), we observed all toilets in selected hospitals. The number of toilet users was categorized into patients and their caregivers and hospital staff (doctor/nurse/cleaner). Cleanliness of the toilets was assessed using two parameters (clean/unclean) and associated criteria, and functionality was defined according to the WHO/UNICEF Joint Monitoring Programme definition for HCF. Amongst 2611 toilets, 2243 (86%) were directly observed, and more than 85% of toilets were functional. In government hospitals, 15% of toilets were not functional, and in private hospitals, 6% were nonfunctional. The main reasons for non-functionality were broken doors or locks (14%). Additionally, 84% (2200) of toilets were found clean in all hospitals. However, 16% of toilets were not clean in government hospitals, and 6% were not in private hospitals. An unacceptably high toilet:user ratio was observed with an average ratio of 1:51, whereas the national standard notes 1:6. The toilet:user ratio was higher in government hospitals (1:52) than in private hospitals (1:21), and the highest ratio was 1:395 for patients and 1:30 for staff. Overall, the study suggests that interventions are required to ensure adequate toilet facilities, maintenance, and cleanliness in hospital settings in Dhaka, which will require relevant leadership and resources to be allocated, including a significant augmentation of the number of toilets relative to users.

6398

ASSESSING FAECAL CONTAMINATION IN SOILS OF INFORMAL SETTLEMENTS- A COMPARATIVE STUDY OF TRADITIONAL SOIL TESTING AND INNOVATIVE BOOTSOCK TECHNIQUE

Lamiya Nerose Bata, Rebekah M. Henry, David T. McCarthy

Monash University, Clayton, Australia

Diarrhoeal transmission is commonly attributed to water, food, and sanitation (WaSH). However, recent research suggests that WaSH interventions must holistically consider the different pathways of the F-diagram. Soil transmission of diarrhoea, including through ingestion,

has been largely understudied despite evidence of high levels of microbes in soil environments. Gold standard soil sampling methods are unable to collect spatially representative data across community scales; requiring instead, the implementation of composite methods to increase our knowledge of direct soil transmission. Bootsock sampling, previously used for assessing diarrhoeal pathogens in poultry houses, was laboratory- and field-tested to collect surface soils within informal settlements for measuring E. coli concentrations. In the laboratory, a 5x1 m soil box was spiked with E. coli across the length of the walkway. E. coli was detected in 87% (n=24) of bootsock samples and 55% (n=20) of grab samples from the same uniformly inoculated transect. Paired bootsock and grab samples were also collected from 11 informal settlements in Suva, Fiji. In the field, 73% (n=33) of bootsock and 75% (n=79) of grab samples had detectable concentrations of E. coli. Bootsock estimations of E. coli levels were consistently higher than paired grabs. These findings demonstrated that bootsock results were comparable to those of the gold standard methods in measuring bacteria. Furthermore, a post-hoc power analysis also showed that a lower number of bootsock samples were needed to measure the same mean E. coli transect loads as grab samples. In this study, we demonstrated that alternative composite sampling methods, such as bootsock sampling, was able to consistently measure higher and more spatially representative levels of E. coli across the same transect. The successful optimisation and application of this method will increase the accuracy of faecal pollution and exposure assessment in contaminated settings. This would, in turn, add more information to our collective knowledge of soil transmission and risk, and thus, result in the development of better mitigation strategies.

6399

PREVALENCE OF PATHOGENIC MDR ESCHERICHIA COLI IN FAECAL SLUDGE TREATMENT PLANTS AND ADJACENT HOUSEHOLD DRINKING WATER OF ROHINGYA CAMPS, BANGLADESH

Zahid Hayat Mahmud[1], Mohammed Tanveer Hussain[1], Md. Sakib Hossain[1], Mohammad Atique Ul Alam[1], Amanta Rahman[1], Ashrin Haque[1], Faisal Chowdhury Galib[1], Md. Hajbiur Rahman[1], Md. Rafiqul Islam[1], Mahbubul H. Siddiqee[2], Md. Shafiqul Islam[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]BRAC University, Dhaka, Bangladesh

Extended-spectrum β-lactamase (ESBL) producing pathogenic E. coli are responsible for high rates of community acquired infections and are linked to high mortality rates, increased healthcare costs and longer hospital stays. The contamination of drinking water is one of the primary routes of ESBL E. coli transmission in the community. This study aimed to investigate the prevalence, characterization of major ESBL and pathogenic genes, antibiotic susceptibility patterns and biofilm formation capability of ESBL producing E. coli in treated and untreated faecal sludge and adjacent household drinking water samples of Rohingya camps, Cox's Bazar, Bangladesh. A total of 127 ESBL E. coli isolates were obtained of which 87 from faecal sludge and 40 from adjacent household drinking water samples. In regards to ESBL gene presence, blaCTX-M was the most prevalent, being present in 44.5% of the isolates, followed by blaTEM and blaSHV in 18.6% and 2.3% isolates respectively. The genes blaTEM and blaSHV were detected only among faecal sludge isolates, which also harbored a higher percentage of blaCTX-M. With respect to pathogenicity, a total of 9.3% and 9.9% were found to be ETEC and EAEC, which are pathotypes of diarrheagenic E. coli. Both ETEC and EAEC were found among fecal sludge samples, whereas only EAEC was present in only drinking water. In the case of extra-intestinal pathogenic genes, a total of 3.2% of the isolates were found to be ExPEC. In regards to antibiotic susceptibility patterns, 99.2% of the isolates were found to be multi-drug resistant. Strong biofilm formation was observed at 25°C and 37°C for 33.9% and 3.9% of isolates respectively. Contaminated household drinking water can be an important mode of transmission of ESBL E. coli, and the prevalence of ESBL E. coli in faecal sludge might be a point of origin for spreading in the community. The continued exposure of the Rohingya individuals to these organisms may explain the high rates of diarrheagenic diseases within the region.

ASSESSING THE IMPLEMENTATION OF WASH INTERVENTIONS IN A COASTAL DISTRICT WITH HIGH DIARRHOEA BURDEN, GHANA, 2022

Delia Akosua Benewah Bandoh[1], Ernest Kenu[1], Edwin Andrew Afari[1], Kwadwo Duah Dwomoh[1], Dzidzo Yirenya-Tawiah[2], Mawuli Dzodzomenyo[1]

[1]University of Ghana School of Public Health, Accra, Ghana, [2]Institue of Environmental Studies, University of Ghana, Accra, Ghana

WASH interventions have significantly reduced diarrhoeal diseases globally. However, marginal declines have been recorded in some coastal settlements in Ghana where WASH interventions Were initiated over 20 years ago. As communities vulnerable to climate change consequences, there was the need to identify implementation challenges to build resilience and improve WASH. We assessed the WASH implementation gaps in Anloga, a coastal district in Ghana.We conducted a process evaluation of WASH interventions implementations (provision of water, and sanitary facilities) in the district. We used the USCDC 4-level socio-ecological model assessing the problem from intrapersonal, interpersonal, community, and societal levels. We conducted 30 household interviews, four community focus group discussions, 10 in-depth interviews with community leaders and four key informant interviews with district staff. We observed newest structures for accessibility. We transcribed and identified gaps using thematic analysis.Most individuals (18/30) had no knowledge of the history of WASH structures around them and had not received education on its use. Community members reported being only engaged for labour during construction. Both community leaders and members confirmed receiving a one-time education at commissioning of interventions. Most community leaders(7/10) said implementation engagements were done with selected leaders. Leaders(8/10) reported community's main role in implementation as labour provision. All district staff (4/4) mentioned that community leaders were the main people engaged throughout the process and implementation of interventions were subject to availability of district funds. We found that inadequate education on intervention, poor information flow, and lack of extensive engagement led to poor utilisation. We recommend the district adapts an all-inclusive implementation approach to ensure community ownership and appropriate use. Also, periodic supervision of interventions by the district with short educational talks would remind community members of relevance of interventions available to them.

6401

DETECTION OF SARS-COV-2 AND ENTERIC PATHOGENS IN MEGACITY DHAKA WASTEWATER: FINDINGS FROM AN ENVIRONMENTAL SURVEILLANCE PLATFORM

Mahbubur Rahman[1], Md Rezaul Hasan[1], Md Ziaur Rahman[1], Mohammed Ziaur Rahman[2], Md Nuhu Amin[1], Rehnuma Haque Sarah[1], Md Shariful Islam[3], Afroza Jannat Suchana[1], Mohammad Enayet Hossain[2], Monju Mia[2], Suraja Raj[4], Pengbo Liu[4], Yuke Wang[4], Marlene Wolfe[4], Stephen Patrick Hilton[4], Chloe Svezia[4], Mahbubur Rahman[5], Ahmed Nawsher Alam[5], Zakir Hossain Habib[5], Aninda Rahman[6], Alamgir Hossain[7], Megan B. Diamond[8], Tahmina Shirin[5], Christine L. Moe[4]

[1]Environmental Interventions Unit, Infectious Diseases Division, International Center for Diarrheal Disease Research, Bangladesh (icddr,b), Dhaka1212, Bangladesh, [2]One Health Laboratory, Infectious Diseases Division, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka1212, Bangladesh, [3]School of Public Health, University of Queensland, Brisbane, Australia, [4]The Center for Global Safe Water, Sanitation, and Hygiene at Emory University, Atlanta, GA, United States, [5]Institute of Epidemiology, Disease Control, and Research (IEDCR), Dhaka1212, Bangladesh, [6]Communicable Disease Control (CDC) Program,

Directorate General of Health Services (DGHS), Dhaka1212, Bangladesh, [7]Dhaka Water Supply and Sewerage Authority (DWASA), Dhaka1215, Bangladesh, [8]The Rockefeller Foundation, New York, NY, United States

Environmental surveillance has proved to be a valuable tool to monitor trends of infections with SARS-CoV-2 and enteric pathogens in the population. Dhaka city, the capital of Bangladesh, faces considerable challenges with unimproved sanitation and poor fecal sludge management. In this city, 80% of areas are not connected to centralized sewers, and household toilets are directly connected with open drains. We conducted wastewater surveillance from October 2022 to February 2023 on open drains/canals of seven zones of Dhaka North (non-sewer area) and four sewage pumping stations of Dhaka South to monitor temporal and spatial trends in vaccine-preventable enteric (Group A Rotavirus, Salmonella typhi, and Vibrio cholerae) and respiratory (SARS-CoV2) infections. 180 wastewater samples (119 from open drains/canals and 61 from pumping stations) were collected and quantified through multiplex qPCR. High proportions of wastewater samples tested positive for Rotavirus (96%), V. cholerae (56%), SARS-CoV-2 (54%), and S.typhi (43%). A higher proportion of samples from open drains/canals were positive for S.typhi, V.cholerae, and SARS-CoV-2 (58%, 61%, and 69% correspondingly) compared to samples from pumping stations (13%, 41%, and 31% correspondingly). The median log10 concentration of Rotavirus gene copies/Liter was 8.7 (range=4.7-10.4), V. cholarae was 6.2 (range=4.5-7.8), SARS-CoV-2 was 4.8 (range=3.9-6.5), and S.typhi was 5.8 (range=4.3-7.6). V.cholerae (50% to 65%) showed an increasing temporal trend in positivity from October 2022 to January 2023, while the detection of the other three pathogens had no obvious temporal patterns. Environmental surveillance is a useful tool for monitoring temporal and spatial trends of existing and emerging infectious diseases and supports evidence-based public health measures. Historical evidence for SARS-CoV-2 suggests a strong correlation between clinical cases and the presence of pathogens in wastewater. Findings also suggest that wastewater surveillance could play a crucial role where clinical case detection and reporting are not optimal due to scarce resources.

6402

FINDINGS OF ENVIRONMENTAL SURVEILLANCE FOR SARS-COV-2 AND ENTERIC PATHOGENS TRIGGER FUTURE PATH: LEARNING FROM A MEGACITY AND HUMANITARIAN SETTINGS IN BANGLADESH

Md Ziaur Rahman[1], Zakir Hossain Habib[2], Rezaul Hasan[1], Nuhu Amin[1], Rehnuma Haque[1], Md Shariful Islam[3], Afroza Jannat Suchana[1], Mohammed Ziaur Rahman[4], Mohammad Enayet Hossain[4], Mojnu Miah[4], Suraja Raj[5], Pengbo Liu[5], Yuke Wang[5], Marlene Wolfe[5], Stephen Patrick Hilton[5], Chloe Svezia[5], Mahbubur Rahman[2], Ahmed Nawsher Alam[2], Aninda Rahman[6], Alamgir Hossain[7], Mahbubur Rahman[1], Megan B. Diamond[8], Tahmina Shirin[2], Christine L Moe[5]

[1]Environmental Interventions Unit, Infectious Diseases Division, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka-1212, Bangladesh, [2]Institute of Epidemiology, Disease Control, and Research (IEDCR), Dhaka, Bangladesh, [3]School of Public Health, University of Queensland, Brisbane, Australia, [4]One Health Laboratory, Infectious Diseases Division, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka-1212, Bangladesh, [5]The Center for Global Safe Water, Sanitation, and Hygiene, Emory University, GA, United States, [6]Communicable Disease Control (CDC) Program, Directorate General of Health Services (DGHS), Dhaka-1212, Bangladesh, [7]Dhaka Water Supply and Sewerage Authority (DWASA), Dhaka-1212, Bangladesh, [8]The Rockefeller Foundation, New York City, NY, United States

Environmental surveillance data have been recognized as a valuable supplement to epidemiological case data, especially in understanding the burden associated with enteric diseases. In low-income countries like Bangladesh, environmental surveillance can detect and quantify selected pathogens from wastewater and can be a useful and low-cost public health tool when limited epidemiological data are available. icddr,b conducted environmental surveillance in Dhaka city and Cox's Bazar (refugee camps and the municipality) with technical support from the Institute of Epidemiology Disease Control and Research. Wastewater samples were collected from open drains and sewage pumping stations that captured nearly one million people across 32 square kilometers. Transect walks, scoping visits, and GIS tools were used in 28 locations of Dhaka city, and finally, 11 sites were selected. In contrast, transect walks, stakeholder meetings, STRAVA mapping were used in 18 locations of Cox's Bazar, and 12 were finalized for wastewater sampling. Laboratory method optimization was completed with the development of the standard operating procedures for the detection of the Rotavirus, Salmonella typhi, Vibrio cholera, and SARS CoV-2 genetic markers by multiplex qPCR. Weekly samples across 23 sampling sides over 17 weeks provided insights on the presence/absence of the pathogens, as well as total viral concentration, enabling analysis of spatiotemporal trends. Multisectoral collaboration between the research team, government, and multinational stakeholders was established from the project onset. It will enable data-sharing health authorities to empower a more targeted and rapid public health response during outbreaks and infectious disease spikes. Environmental surveillance data will be compared to clinical data and analyzed in the context of climate variability to validate findings, explore changing patterns over time, and identify intervention points.

6403

HOUSEHOLD COPING STRATEGIES DUE TO WATER INTERMITTENCY: A MIXED-METHODS STUDY IN NORTHWESTERN ECUADOR

Andrea Sosa-Moreno[1], Gwenyth O. Lee[2], Karen Levy[3], Josefina Coloma[4], Joseph N.S Eisenberg[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Rutgers Global Health Institute, New Brunswick, NJ, United States, [3]University of Washington, Seattle, WA, United States, [4]University of California-Berkeley, Berkeley, CA, United States

While global access to improved water systems has increased, access to reliable piped water remains a concern. Intermittent water supply (IWS) systems are characterized by services being unavailable for hours or days at a time. How households cope with these two types of IWS are not well known. We collected data on household water supply and coping strategies (2019 – 2021) in response to IWS among three communities of different sizes and diverse access in northwestern Ecuador. We classified piped water service frequency (days/week) as low (<3), medium (3-5) and high (>5), and water service duration (hours/day) as low (<4), medium (4-8) and high (>8). We assessed the association between frequency and duration of piped water and household coping strategies using logistic models and complemented this analysis with in-depth qualitative interviews of residents. Intermittency patterns differed by community. Most households in the town of Borbon received a medium frequency and duration of water, the intermediate town of Maldonado received a high frequency but low duration of water, while the village of Timbire received a high frequency and high duration of water. Accordingly, communities responded differently to water intermittency. Compared to Timbire, households in Borbon and Maldonado were more likely to purchase bottled water, treat their domestic water, and store water. Compared with Borbon, households in Maldonado were more likely to purchase bottled water and treat their domestic water. Regardless of the community, households that received ≥5 days of water service had lower odds of purchasing bottled water for drinking and treating domestic water, but higher odds of using multiple drinking water sources. Households that received ≥8 hours of water service had lower odds of treating their domestic water source. Although being discontent with the water service was a recurrent theme during interviews, community members preferred the predictability of a high frequency, low duration water service. Household coping strategies depended on water supply characteristics, but all coping strategies incurred substantial financial and labor costs.

DENGUE SEROEPIDEMIOLOGY RELATED TO DEFORESTATION RATES IN RURAL VILLAGES OF THE PERUVIAN AMAZON COMMUNITIES

Edson J. Ascencio[1], Luca Nelli[2], Isabel Byrne[2], Monica Hill[2], Elin Dumont[2], Lynn Gringnard[2], Kevin Tetteh[2], Lindsey Wu[2], Alejandro Llanos-Cuentas[3], Chris Drakeley[2], Gillian Stresman[2], Gabriel Carrasco-Escobar[1]

[1]Institute of Tropical Medicine 'Alexander von Humboldt', Universidad Peruana Cayetano Heredia, Lima, Peru, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

Dengue fever, the most common arboviral disease in humans, has increased globally due to climate change and human activities. In Peru, more than half of its population is at risk of dengue infection, and its aggressive and precary urban expansion in the Amazon region could exacerbate dengue incidence. In this study we explore the relationship between deforestation, as a proxy of urban expansion, and dengue seropositivity in Peruvian Amazon communities. We conducted a cross-sectional analytical study in 19 communities of Indiana and Belen districts in Loreto, Peru. Socioeconomic and human behavior questionnaires were applied to individuals in each randomly selected household, which was geo-referenced. Dried blood spots were collected for serological analysis. Deforested area data was extracted in a buffer of 5 km of each community using the Hansen Global Forest Change collection from 2000 to 2021. Seropositivity was stratified by age groups. Finally, a population weighted linear regression model adjusted by age groups was used to explore the relationship between deforestation rates and seropositivity in each community. A total of 1114 individuals were analyzed across both districts. Our findings showed a total seropositivity of 59.1% (range from 41.4% to 85.7%). The mean annual forest lost area rate (km2/year) was 0.46 (SD= 0.15). Seropositivity in age groups between 0 to 5, 6 to 10, 11 to 15, 16 to 20, and 21 or more years old were 26.5%, 37.4%, 49.4%, 56.4%, and 78.0%, respectively. The weighted regression model reveals that the annual forest lost rate (km2/year) is positively associated (β= 0.33; 95% CI= 0.16 - 0.51) with an increase in seropositivity at community level after adjusting for age trends. The results of this study highlights that, even in rural communities, higher dengue seropositivity levels were found. Finally, this study provides evidence that higher rates of annual deforestation rates, controlled by age (time of exposure), were correlated with an increase in dengue seropositivity at community level, highlighting the impact of rural communities' growth speed on dengue seropositivity.

Brazil experiences large-scale annual outbreaks of dengue, chikungunya and zika virus infections, which are transmitted to humans by Aedes mosquitoes. The transmission of these three arboviruses is highly seasonal and their distribution is heterogeneous in space and time. There is evidence that dengue is expanding into previously protected regions in the north and south of Brazil, and previous analyses have demonstrated that transmission is associated with population demography, environmental temperatures and precipitation, with long-term hydrometeorological events such as drought and extreme wet periods also influencing the relative risk of dengue in Brazil. A key limitation of previous analyses is that they are often performed at coarse spatiotemporal resolution, for example using monthly dengue incidence data at the state or microregion level, or at the local level but for sub-national analyses. In this work, we aim to generate new evidence of the relative importance of demographic, socioeconomic, climatic and hydrometeorological factors in driving the observed seasonal transmission dynamics measured by dengue, chikungunya and zika virus incidence across Brazil at fine-scale temporal and spatial resolution. We analyse weekly case notification timeseries of chikungunya (between 2015-2020), zika (2015-2020) and dengue virus (2012-2020) at the municipality level (n = 5572) using spatiotemporal mixed-effects regression models, with climate predictors such as the range, average, and extremes of daily environmental humidity, temperature, and precipitation across different time periods, and long-term hydrometeorological events. We also explore the importance of socioeconomic factors, demography, land-use, human mobility and importation risk, and El Niño-Southern Oscillation (ENSO). Our results suggest that minimum humidity, long-term periods of extreme wetness and ENSO anomalies are important factors associated with increased human infections of all three arboviruses, thus highlighting the health impact of extreme weather conditions driven by changing climate on arbovirus transmission in Brazil.

6406

PRIOR ZIKA VIRUS INFECTION INCREASES RISK OF SUBSEQUENT SYMPTOMATIC INFECTION BY DENGUE VIRUS SEROTYPES 2 AND 4 BUT NOT SEROTYPES 1 AND 3

Jose Victor Zambrana[1], Chloe M. Hasund[2], Rosemary A. Aogo[2], Sonia Arguello[3], Cesar Narvaez[3], Karla Gonzalez[3], Damaris Collado[3], Tatiana Miranda[3], Guillermina Kuan[4], Angel Balmaseda[5], Leah Katzelnick[2], Eva Harris[6]

[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [2]Viral Epidemiology and Immunity Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [3]Sustainable Sciences Institute, Managua, Nicaragua, [4]Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua, [5]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [6]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

The 4 dengue virus serotypes (DENV1-4) and the related Zika virus (ZIKV) are major concerns worldwide. We have shown that primary (1°) ZIKV infection increases risk of symptomatic and severe disease caused by DENV2 in our long-standing Nicaraguan pediatric cohort. Further, we found prior DENV immunity differentially modulates secondary disease: enhancement of DENV2, protection vs DENV1, and protection and enhancement of DENV3, depending on antibody level and disease outcome. We hypothesized that prior ZIKV infection may have similar associations with secondary dengue by serotype. In 2022, DENV4 circulated for the first time, along with DENV1-3, enabling us to test these hypotheses for all 4 serotypes. We used ZIKV and DENV inhibition ELISAs, ZIKV NS1 BOB assay, and clinically confirmed case data to define prior infection histories. All analyses used linear mixed models adjusted for age and sex. Compared to naïve individuals, 1° ZIKV infection significantly increased probability of symptomatic dengue and Dengue with Warning Signs/Severe Dengue. Stratifying by serotype, 1° ZIKV infection increased disease risk with DENV4 (probability = 3.74% [2.5, 5.59] vs Naïve, prob = 1.31% [0.82, 2.08]) but not DENV1. Children with one prior DENV infection before ZIKV and vice versa (ZIKV-DENV) were also at increased risk of subsequent disease caused by DENV4 but not DENV1. We re-ran models across 18 years of cohort data and found flavivirus (FV)-immune individuals had a significantly higher risk of dengue disease overall, compared to naïve

individuals. By serotype, this effect was significant for DENV2 and DENV4, but not DENV3, while FV-immune individuals were at lower risk of DENV1. Pre-existing anti-DENV antibodies increased risk of dengue caused by DENV2 across all titers and DENV3 and DENV4 at low titers. Conversely, low titers showed no association with DENV1 disease, while high titers were protective vs DENV1 and DENV3. In sum, we show prior ZIKV infection, like prior DENV infection, increases disease caused by certain DENV serotypes. Considering serotype-specific effects is essential when assessing the safety and efficacy of ZIKV and DENV vaccines.

INVESTIGATING THE POTENTIAL OF DENGUE AND ZIKA VIRUS TO ESTABLISH A SYLVATIC TRANSMISSION CYCLE IN THE NEOTROPICS THROUGH A MODELING LENS

Hélène Cecilia[1], Benjamin M. Althouse[2], Sasha R. Azar[3], Shannan L. Rossi[3], Nikos Vasilakis[3], Kathryn A. Hanley[1]

[1]New Mexico State University, Las Cruces, NM, United States, [2]University of Washington, Seattle, WA, United States, [3]University of Texas Medical Branch, Galveston, TX, United States

Dengue (DENV) and Zika (ZIKV) virus are maintained in sylvatic cycles between non-human primate (NHP) hosts and arboreal mosquitoes in Africa and Asia. DENV was introduced to the Americas centuries ago, while ZIKV was introduced within the last decade. Despite its long residence in the neotropics, there is no evidence that DENV has established a sylvatic cycle there, but whether ZIKV will do so is an open and urgent question. Key determinants of sustained transmission in a novel environment are the replication of a virus within novel hosts and its transmission to vectors. We aimed to analyze parameters of DENV and ZIKV sylvatic transmission dynamics through statistical and mathematical modeling approaches. Recently, we used Aedes albopictus to infect novel hosts (squirrel monkeys, Saimiri boliviensis boliviensis) with sylvatic strains of DENV and ZIKV. We monitored host viremia and transmission to mosquitoes over the course of infection. Individuals infected with DENV showed low levels of virus replication, but we were able to fit a mechanistic within-host compartmental model to ZIKV viral dynamics in squirrel monkeys. We estimated the within-host basic reproduction number R0 to be 3.7 (median, 95% highest density interval [2.3 ; 5.1]), consistent with previous estimates in rhesus macaques using needle delivery of the virus. Lastly, we coupled viral dynamics with dose-response relationships within-vector, and estimated the probability to produce a saliva-positive Ae. albopictus upon bite on a ZIKV-infected squirrel monkey to be above 50% between days 3 and 5 post-infection. Transmission could be further enhanced if vectors are more likely to feed on infected than uninfected hosts. We therefore assessed the effect of host sex, temperature, weight, and viral load, as well as virus species, mosquito infection status, and time of feeding, on the proportion of mosquitoes taking a blood meal. None of these were significantly associated with Ae. albopictus feeding behaviour, in contradiction with recent results in mice. Nonetheless, our results suggest that a neotropical ZIKV sylvatic cycle may be imminent.

Getah virus (GETV) is an important Alphavirus of the Togaviridae family. Its genome is made up of a single-stranded positive sense RNA and it is transmitted by mosquitoes. Although no known clinical symptoms in people, GETV has been linked to epidemics in animals. Serological proof of GETV exposure and the threat of zoonotic transmission, however, makes GETV an important arbovirus in the field of veterinary medicine. With inadequate investigations into the vector transmission of GETV, there is very little information on the variables influencing the spread and the sporadic outbreaks of GETV infections. As a result, we assessed the GETV's host range in both in vitro and in vivo models. Cell lines derived from selected species of mosquitoes with medical importance were assessed by plaque assay to determine their susceptibility and replication under in vitro laboratory conditions. Conversely, quantitative Real Time Polymerase Chain Reaction and a plaque assay was carried out to evaluate the susceptibility and transmission potential of mosquito species to GETV infection in vivo. All examined mosquito-derived cell lines were GETV-susceptible with detectable cytopathic effects. The highest replication titres of GETV were recorded in C6/36 and NIID-CTR cell lines derived from Aedes albopictus and Culex tritaeniorhynchus mosquitoes, respectively. Comparisons of the infection, dissemination and transmission rates across species varied significantly with Cx. tritaeniorhynchus colony being the most effective species in GETV vector competency. This study is also the first account of An. stephensi and Ae. albopictus capability to transmit GETV under laboratory conditions, highlighting the potential risks of GETV transmission in nature, especially in unidentified potential vectors of GETV transmission in endemic regions where these vectors are prevalent.

6409

EXPOSURE TO WEST NILE VIRUS AND STRAIN-SPECIFIC DIFFERENCES SHAPE TRANSMISSION BY CULEX PIPIENS UNDER CLIMATE CHANGE

Rachel Fay[1], Mauricio Cruz-Loya[2], Elyse Banker[3], Jessica Stout[3], Anne Payne[3], Erin Mordecai[2], Alexander Ciota[3]

[1]School of Public Health, State University of New York Albany, Albany, NY, United States, [2]Biology Department, Stanford University, Stanford, CA, United States, [3]Arbovirus Laboratory, Wadsworth Center, New York State Department of Health, Slingerlands, NY, United States

Arthropod-borne viruses are associated with over 140 human diseases. The most widespread arboviruses belong to the flavivirus family, which includes West Nile virus (WNV), Zika virus, dengue virus, and several others. Across the globe, temperature is increasing and such increases influence the distribution and prevalence of vector-borne disease transmission. Life history traits of both the mosquito and pathogen have been utilized in modeling vector-borne diseases, thus far, models for WNV have identified species and vector population-specific differences. Previous studies have demonstrated that exposure and infection with WNV can influence mosquito longevity, fecundity, and blood-feeding behavior, yet trait-based R0 models have historically been generated using data from unexposed mosquitoes. The purpose of this study is to determine the interactions among temperature, infection status, viral strain, and WNV transmission in order to create more accurate predictive models of WNV transmission under climate change. Culex pipiens were fed a blood meal containing genetically distinct strains (WN02 or NY10) or a noninfectious blood meal. Following feeding, lifespan, biting rate, ovipositing, vector competence, and pathogen development rate were recorded at constant temperatures ranging from 10°C to 33°C and a mean cycling around 25°C. Bodies and legs of dead females were harvested to determine infection and dissemination rates of exposed mosquitos and qPCR was used to quantitate viral load. These data were used to generate thermal performance curves in conjunction with previously published life-history data, which were then used to inform R0 models. Our results demonstrate that WNV infection significantly influences the relationship between temperature and Cx. pipiens life-history traits, and that these relationships are strain-specific. Consideration of infection status and viral genetics, therefore, is necessary to improve models of WNV transmission under climate change. These results have broader implications for understanding the role of heterogeneity in vector-borne disease modeling.

IDENTIFICATION OF ZIKA VIRUS GENES INVOLVED IN MOSQUITO TRANSMISSIBILITY

Shiho Torii[1], Alicia Lecuyer[1], Caroline Manet[1], Matthieu Prot[1], Cheikh T. Diagne[2], Oumar Faye[2], Ousmane Faye[2], Amadou A. Sall[2], Etienne Simon-Lorière[1], Xavier Montagutelli[1], Louis Lambrechts[1]
[1]Institut Pasteur, Paris, France, [2]Institut Pasteur de Dakar, Dakar, Senegal

Zika virus (ZIKV) is a flavivirus mainly transmitted by Aedes aegypti mosquitoes that recently emerged across the Pacific region and Latin America, causing large human outbreaks associated with birth defects and neurological disorders. Phylogenetic analyses show that ZIKV genetic diversity can be divided into an African lineage and an Asian lineage. Although to date, human outbreaks have exclusively been associated with strains from the Asian lineage, a growing body of evidence points towards higher transmissibility of ZIKV strains from the African lineage. To elucidate the viral genetic determinants underlying differential transmissibility between African and Asian ZIKV strains, we used a combination of viral reverse genetics and mosquito transmission assays in vivo. We constructed a set of six chimeric ZIKV strains from two parental strains with different levels of transmissibility by swapping the genome fragments encoding structural proteins, non-structural proteins or untranslated regions. We compared the in vivo transmissibility of the chimeric viruses in mosquitoes experimentally exposed to an artificial infectious blood meal. We detected viral genomes in mosquito head and infectious viruses in saliva and calculated transmission prevalence as the proportion of virus-positive head with a virus-positive saliva. We found that replacing the genome region encoding structural proteins of the low-transmissibility Asian strain with the same region from the high-transmissibility African strain significantly increased transmission prevalence. The reciprocal replacement resulted in the opposite pattern. Swapping the genome fragments encoding the structural proteins also resulted in significant changes in viral growth kinetics in mosquito cells in vitro. We concluded that the difference in mosquito transmissibility between African and Asian ZIKV strains is due to genetic variation in the viral structural proteins. Future work will provide mechanistic insights into these data using a mathematical model of within-mosquito infection dynamics and extend the results in a mouse-to-mosquito ZIKV transmission assay.

CRYPTOSPORIDIUM PARVUM: THIOREDOXIN REDUCTASE ACTS AS THE PRIMARY REGULATOR OF GLUTATHIONE AND THIOREDOXIN REDOX PATHWAYS AND IS A TARGET FOR DRUG DISCOVERY FOR CRYPTOSPORIDIOSIS

Jala Bogard[1], Federica Gabriele[2], Matteo Ardini[2], Marta Palerma[2], Xian-Ming Chen[1], Francesco Angelucci[2], David Williams[1]
[1]Rush University Medical Center, Chicago, IL, United States, [2]University of L'Aquila, L'Aquila, Italy

Cryptosporidium parvum (Crypto) is a protozoan parasite that causes cryptosporidiosis, a highly contagious disease with nearly 30% of the global population potentially exposed to the parasite. The options for treatment are severely limited; only a single drug (Nitazoxanide) is currently approved by the FDA and it is not fully effective in the young, elderly, or immunocompromised patients. Auranofin, which is clinically used for rheumatoid arthritis and in clinical trials for cancer and other infectious diseases, was shown to be active against Crypto in vitro. Auranofin is thought to function, in part, through inhibition of thioredoxin reductase (TrxR). While TrxR has numerous functions, some of its most important are regulating cellular redox balance and preventing damage caused by reactive oxygen species generated by the host immune response. In humans, TrxR and glutathione reductase (GR) are responsible for regulating thioredoxin (Trx) and glutathione (GSH) dependent pathways, respectively. No GR is present in the Crypto genome. We hypothesize that TrxR is the primary regulator of both Trx and GSH in Crypto and that its inhibition would disrupt both pathways and be lethal. To test this hypothesis, C. parvum (Cp)TrxR and CpTrx proteins were expressed and characterized. CpTrxR was found to have Trx reducing activity, but no GR activity. However, the combination of CpTrxR and CpTrx had high levels of GR activity. An IC50 was determined to be 2.4 nM for auranofin against CpTrxR. These results indicate that CpTrxR is an essential protein for both TrxR and GR activities, meaning that this protein acts at the primary regulator for both Trx and, subsequently, GSH pathways. We have identified crystallization conditions and successfully determined the structure of CpTrxR in complex with auranofin. These findings are significant in providing a foundation for future structure-guided drug development studies and redox biochemistry for improved cryptosporidiosis treatment.

6412

PROGRESS IN DEVELOPING METHIONYL-TRNA SYNTHETASE INHIBITORS FOR CHAGAS DISEASE

Frederick S. Buckner, Zhongsheng Zhang, Aisha Mushtaq, John R. Gillespie, Zackary M. Herbst, Sayaka Shibata, Erkang Fan
University of Washington, Seattle, WA, United States

The protozoan parasite, Trypanosoma cruzi, infects 6-8 million people primarily in Latin America. Antiparasitic drugs for chronic T. cruzi infection (Chagas disease) are inadequate due to bad side-effects and poor efficacy. T. cruzi has a single methionyl-tRNA synthetase (MetRS) which is essential for protein synthesis. We are developing inhibitors of the T. cruzi MetRS as therapeutics for CD. The MetRS inhibitors were initially developed against the T. brucei MetRS guided by crystal structure of that enzyme bound to inhibitors. Over 550 MetRS inhibitors synthesized by our group have been screened against mammalian-stage T. cruzi cultures establishing structure activity relationships. Nearly 150 compounds have been identified with EC50 values <10 nM. Most compounds are highly selective with cytotoxicity (CC50) values on mammalian cells of greater than 20,000 nM. An exemplary compound was tested in an in vitro washout assay (16-day exposure at 25X the EC50) and shown to have trypanocidal activity (with no outgrowth in the 60 day observation period) comparable to the clinical drug, benznidazole. Work has focused on two areas for lead development: 1) optimizing pharmacological properties to maximize exposure of free compound in mammalian models, and 2) maximizing the therapeutic window to avoid potential toxicity to mammalian cell mitochondrial function. A subset of lead compounds is being tested in the murine chronic T. cruzi infection model with results to be presented. MetRS inhibitors represent a promising class of compounds for treating Chagas disease.

6413

METABOLOMIC ANALYSIS REVEALS A NOVEL IMMUNOMODULATORY ROLE OF LYSOPHOSPHATIDYLCHOLINES IN IMMUNIZATION WITH A GENETICALLY MODIFIED LIVE ATTENUATED PARASITIC VACCINE

Parna Bhattacharya[1], Jinchun Sun[2], Nazli Azodi[1], Hannah Markle[1], Sreenivas Gannavaram[1], Richard Beger[2], Hira Nakhasi[1]
[1]FDA, Silver Spring, MD, United States, [2]FDA, Jefferson, AR, United States

Leishmaniasis is a spectrum of diseases caused by the blood borne protozoan parasites belonging to several different Leishmania species. Currently, there are no FDA-licensed vaccines against human leishmaniasis. Centrin-deleted Leishmania major (LmCen-/-) parasites were developed as a vaccine candidate for leishmaniasis using CRISPR/Cas9 gene-editing technology. Preclinical research has demonstrated the safety of LmCen-/- parasites in animal models and significant efficacy against sand fly-mediated infections with parasites causing either cutaneous or visceral disease. Substantial variations between the LmCen-/- and LmWT infections were seen in the immunological properties of the innate and adaptive responses. Since neutrophils are the first innate cells to arrive at the site of infection, it is hypothesized that metabolic reprogramming occurring in these cells could mediate the immune mechanisms of the protection using LmCen-/- and LmWT parasite strains. C57Bl/6 mice were intradermally infected with LmWTmCherry or LmCen-/-mCherry parasites. At 48h post-infection, 2.5-3x106 parasitized and non-parasitized neutrophils were sorted by flow cytometry and quenched immediately. Untargeted

metabolomic analyses were performed on the neutrophil populations using mass spectrometry. Three analytical runs per sample were performed. Mass spectrometric analyses showed that neutrophil populations isolated from ear draining lymph nodes of mice infected with LmCen-/-contained higher levels of lysophospatidylcholines (LPC), a class of metabolites that are derived from phosphatidylcholines, compared to neutrophils isolated from naïve or LmWT infected mice. The role of LPCs in immune regulation of neutrophils are further being explored using a LPC receptor antagonist in in vitro and in vivo studies. These investigations will shed light on immune defense processes and aid in the discovery of novel biomarkers for vaccine-induced immunity.

NEW TRYPANOSOME GENOMES DEMONSTRATE THE CO-EVOLUTIONARY RELATIONSHIP BETWEEN ENERGY SOURCE AND SURVIVAL STRATEGY

Ross Stuart Low[1], Kevin Tyler[2], Neil Hall[1]

[1]The Earlham Institute, Norwich, United Kingdom, [2]University of East Anglia, School of Medicine, Norwich, United Kingdom

African (Salivarian) trypanosomes persist in the host bloodstream where they are exposed to the full force of the mammalian immune system. However, Trypanosoma cruzi (Stercoria) can invade host blood cells and tissues allowing the parasite to hide from the immune response. Fundamentally, these environments differ greatly in terms of the metabolic stress experienced by the parasite. The intracellular environment is rich in triacylglycerides, a frequently targeted energy source by pathogenic microbes, and extracellular parasites have access to soluble sugars, amino-acids and lipids. We predict that by assessing the metabolic capabilities between groups of trypanosomes it may be possible to link these traits with survival strategy. Further, it may be possible to predict the survival strategy of novel or understudied parasites based on this information. In this study we present three novel trypanosome genomes and one reassembled genome that allow us to investigate the genomic basis for differences in metabolic capability between trypanosomes with different survival strategies. We show that loss of genes in fatty acid metabolism pathways may have facilitated the switch to an extracellular lifestyle in the Salivaria. We also demonstrate that metabolic information, along with other genomic information, can allow us to make predictions about the survival strategy of understudied trypanosome species and give insight into the evolutionary history of these important pathogens of humans and livestock.

6415

FACING ADVERSITY: CHAGAS DISEASE TREATMENT TOLERABILITY AND ADVERSE EVENTS AT AN ACADEMIC SAFETY-NET HOSPITAL IN NEW ENGLAND

Alyse Wheelock[1], Katherine Reifler[1], Alejandra Salazar[2], Samantha Hall[3], Natasha Hochberg[2], Davidson H. Hamer[3], Daniel Bourque[1]

[1]Boston University Medical Center, Boston, MA, United States, [2]Boston Medical Center, Boston, MA, United States, [3]Boston University, Boston, MA, United States

Anti-trypanosomal therapy is generally recommended for individuals under age 50 with the indeterminate form of Chagas disease to prevent progression to cardiac or gastrointestinal (GI) disease. However, benznidazole (BNZ) and nifurtimox (NTX) carry a substantial risk of adverse drug reactions. We performed a cross-sectional retrospective chart review of treatment tolerability among patients with confirmed Chagas disease referred to Boston Medical Center from June 2017 to June 2021. Ninety patients with confirmed Chagas disease were evaluated, of whom 17 (18.9%) had contraindications to treatment. Fifty-eight patients started on therapy, with dosing and monitoring co-managed by an infectious diseases physician and pharmacist. Following initiation of BNZ as first-line therapy, 53 patients (91.4%) had at least one adverse event, of which GI side effects (27/58, 46.6%), rash (26/58, 44.8%), and symptoms of potential peripheral neuropathy (16/58, 27.6%) were most common. Rashes led to treatment discontinuation in 14 patients (24.1%) and met criteria for grade 3 severity in 9 patients (15.5%). Adjunctive therapies for rash included topical and systemic steroids and systemic antihistamines. Concern for peripheral neuropathy led to treatment cessation for 8 patients (13.8%). GI side effects occurred in 27 patients (46.6%), were relatively mild, and commonly managed with famotidine. Adverse events necessitated cessation of BNZ for 18 patients (31.0%), of whom 12 went on to receive NTX. NTX was associated more frequently with GI side effects (10 patients or 83.3%). Ultimately, a total of 53 patients (91.4%) received at least one month and 42 patients (72.4%) completed at least 60 days of either BNZ or NTX. Multiple strategies were used to prevent and alleviate adverse events; co-management with a multi-disciplinary team was essential to assist patients in tolerating therapy. Even so, most patients experienced some adverse events, of which rash and peripheral neuropathy were most concerning. These findings underscore the grave need for expanded safe and effective treatment options for patients living with Chagas disease today.

INTRA-SPECIES GENETIC CLASSIFICATION OF ENTEROMONAS SP. DETECTED FROM HUMAN AND ANIMAL HOSTS IN INDONESIA

Siti Arifah Lacante[1], Chuanhao Jiang[1], Tetsushi Mizuno[1], Din Syafruddin[2], Masaharu Tokoro[1]

[1]Kanazawa University, Kanazawa, Japan, [2]Universitas Hasanuddin, Makassar, Indonesia

Due to its non-pathogenic characteristic, Enteromonas sp. has been rarely studied, despite its widespread prevalence in both human and animal hosts, especially in low-hygiene tropical areas. As a result of such neglect, only a few genetic references of Enteromonas sp. are available in the GenBank, and the intra-species genetic diversity remains unrevealed. In this study, we aimed to address the genetic classification of Enteromonas sp. among humans and animals through a molecular epidemiological study conducted in Wainyapu village, where humans and animals live closely, in Sumba Island, Indonesia. Stool samples were collected from 2013 to 2016. The total DNA was extracted from the stools for the Polymerase Chain Reaction (PCR) screening of the 18S small subunit ribosomal RNA (18S rRNA) gene locus Enteromonas species. All the PCR amplicons confirmed approximately 1,400 base pairs of DNA sequences. The prevalences of Enteromonas sp. were 33.9% (73/215) in humans and 25.2% (68/270) in animals, including unique DNA haplotypes of 61 in humans and 90 in animals. On the reconstructed phylogenetic tree, we observed at least four clusters among the intra-species genetic diversity of Enteromonas species. Haplotypes from goats, rodents, and buffalos were clustered separately from other clusters indicating the presence of animal-specific groups. The human-derived haplotypes were grouped into another cluster at the same Operational Taxonomic Unit (OTU) level as the animal-specific ones. Among the human-derived haplotypes, three sub-clusters were also observed. The molecular taxonomy of minor intestinal protozoans, especially commensal types like Enteromonas sp., is essential to investigate and understand human gut microbiota dynamics. The classification proposed in this study will pave the way for investigating the roles of Enteromonas sp. in host gut homeostasis.

6417

CHEMICAL AND GENETIC INVESTIGATIONS ON LEISHMANIA DEXD/H-BOX PROTEINS AS POTENTIAL DRUG TARGETS AGAINST LEISHMANIASIS

Yosser zina Abdelkrim É. Guediche[1], Emna Harigua[1], Imen Bassoumi-Jamoussi[1], Molka Mokdadi[1], Mourad Barhoumi[1], Josette Banroques[2], Lucien Crobu[3], Yvon Sterckers[3], Khadija Essafi-Benkhadir[1], Michael Nilges[4], Arnaud Blondel[4], N. Kyle Tanner[2], Ikram Guizani[1]

[1]Institut Pasteur de Tunis, Tunis, Tunisia, [2]Institut De biologie Physico-chimique, Paris, France, [3]C.H.U. de Montpellier, Montpellier, France, [4]Institut Pasteur de Paris, Paris, France

Leishmaniases, ill controlled and neglected diseases, constitute major public health problems. Besides the limited repertoire of obsolete 'drugs', current challenges also include high costs, toxicity, adverse effects, and emergence of drug resistance. Thus, identification of novel drugs constitutes a global research priority. Our objective is to validate members of the Leishmania DExD/H-box protein family, particularly DEAD-box proteins, also known as a rich source of drug targets in humans, as potential Leishmania drug targets, using chemical and genetic validation approaches. First, biochemical and genetic expression in yeast of the Leishmania infantum initiation factor 4A (LieIF) have shown its potential as a drug target. Then, we identified, through in silico modelling and virtual screens of small molecules, different ligands, which were screened on the ATPase activity of this protein. This allowed the selection of 6-aminocholestanol as LieIF inhibitor; this molecule presented an anti-Leishmania activity against promastigotes and intracellular amastigotes, which confirmed 6-aminocholestanol as a selective inhibitor and confirmed the chemical validation of LieIF as a drug target. Thus, we expanded our interest to other members of the DExD/H- box protein family. Our second target was encoded by L. infantum LINF_080005700 (LINF08), which has been identified as a close member to the Ded1/DDX3 protein by phylogeny and in silico search of conserved sequence motifs within sequence alignments of a large collection of DEAD-box proteins from various organisms. We interestingly demonstrated peculiar enzymatic characteristics of the recombinant protein so far not described for DExD box proteins; we have also demonstrated using CRISPR technology its nuclear localization both in promastigotes and axenic amastigotes. We are currently investigating its essentiality, which would genetically validate it as a drug target. To conclude, this study delivers two promising drug targets against leishmaniases that deserve further investigation for the development of novel therapeutic drugs.

6418

EFFICACY OF MOXIDECTIN VS. IVERMECTIN COMBINATION TREATMENTS FOR BANCROFTIAN FILARIASIS IN COTE D'IVOIRE: PRELIMINARY 24 MONTH RESULTS

Benjamin G. Koudou[1], Philip J. Budge[2], Allassane F. Ouattara[1], Pascal T. Gabo[3], Peter U. Fischer[2], Christopher L. King[4], Gary J. Weil[2], Catherine M. Bjerum[4]

[1]Centre Suisse de Recherche Scientifique, Abidjan, Côte D'Ivoire, [2]Washington University, St. Louis, MO, United States, [3]Hôpital Générale d'Agboville, Agboville, Côte D'Ivoire, [4]Case Western Reserve University, Cleveland, OH, United States

Lymphatic filariasis (LF) remains endemic in much of Africa despite many years of annual mass drug administration with ivermectin (IVM) and albendazole (ALB). Moxidectin (Mox) is a macrocyclic lactone that is superior to IVM for long-term clearance of onchocerciasis microfiladermia. To determine whether Mox combination therapy might also be superior for LF, we are conducting a phase III, open label, randomized trial in Côte d'Ivoire to compare the standard mass drug administration regimen of annual IVM+ALB (IA) vs. a single dose of Mox+ALB (MoxA) and Mox+DEC+ALB (MoxDA) vs. IVM+DEC+ALB (IDA) in persons with Bancroftian filariasis. The primary study endpoints are Mf clearance at 12 (IA vs. MoxA) or 24 (IDA vs. MoxDA) months post-treatment, as assessed by 1ml filtration of night blood. Secondary endpoints include decrease in circulating filarial antigen (CFA) (based on semiquantitative reading of filarial test strips, FTS) and clearance of adult worms nests in men as assessed by scrotal ultrasound. Enrolment for the study began in August 2020, and to date we have 24-month efficacy data for 66 of 121 (54%) participants infected with >40 Mf/mL of blood at baseline. At 24 months 9 of 19 (47%) participants in the IA arm (after two annual doses) had undetectable Mf compared to 13 of 14 (93%) participants in the single dose MoxA arm (p=0.006). There was no difference in Mf clearance between single dose IDA and MoxDA (81% vs 88% respectively, p=0.576). Adult worm nests were cleared in 2 of 11 (18%) men after IA and 7/8 (88%) of men after MoxA. Sixty percent of men (3 of 5) cleared their worm nests after IDA compared to 100% (9/9) after MoxDA (p=0.171). There was no difference in reduction of CFA between IA and MoxA (11% vs 36%, p=0.08) at 24 months, however more people in MoxDA compared to IDA (53% vs 19%, p=0.041) had reduction in CFA. These preliminary data strongly suggest that MoxA is superior to IA and comparable to IDA and MoxDA for clearance of W. bancrofti microfilaremia and inactivation of adult worm nests at 24-months. Additional 24-month data will be available after August 2023. Additional studies are needed to determine whether MDA with MoxA can accelerate LF in Africa.

6419

EFFICACY AND SAFETY OF ALBENDAZOLE 400 AND 800 MG ON HYPERMICROFILAREMIC LOIASIS: PRELIMINARY RESULTS OF A PHASE IIB, RANDOMIZED, SINGLE-BLIND CLINICAL TRIAL IN NORTHERN GABON

Noé Patrick M'Bondoukwé, Luccheri Ndong Akomezogho, Jacques Mari Ndong Ngomo, Bridy Chesly Moutombi Ditombi, Roger Hadry Sibi Matotou, Meredith Flore Ada Mengome, Denise Patricia Mawili Mboumba, Marielle Karine Bouyou-Akotet

Université des Sciences de la Santé du Gabon, Owendo, Gabon

Albendazole (ALB) is used safely for the reduction of Loa (L.) loa microfilaremia. However, there is no official recommendation. This molecule could be used routinely in onchocerciasis outbreaks in case of coendemicity with loiasis, in order to make hypermicrofilaremia carriers eligible for mass treatment with ivermectin. The purpose of this study is to compare the efficacy and safety of two ALB treatment regimens in the management of hypermicrofilaremic loiasis. The study was conducted in the Woleu-Ntem region of northern Gabon. Socioeconomic, demographic and clinical data as well as parasitological results were collected on a standardized form. Patients were to be divided into 3 groups: 2 groups of hypermicrofilaremia (≥8000 mf/mL) treated with 400 mg and 800 mg for 30 days and a control group consisting of patients with low microfilaremia (<8000 mf/mL) treated with ALB 400 mg for 30 days. Microfilaremia and adverse events were investigated and monitored weekly until day 30. Of 1363 individuals screened for loiasis, 72 were included and followed for 30 days on daily ALB administration. The control group consisted of 38 patients with microfilaremia less than 8000 who received ALB 400 mg. Of the remaining 34 patients with microfilaraemia greater than 8000 mf/mL, 16 received ALB 400 mg and 18 received 800 mg. L. loa microfilaremia and eosinophilia were measured at day (D) 0, 2, 7, 14, and D30. Clinical data were monitored daily before each ALB dose administration. Microfilaremia decreased at D30 in 82.3% of hypermicrofilaremic subjects to below 8000 mf/mL. No serious adverse events were recorded; 30.0% had clinical manifestations after ALB, and for 20.0%, the main adverse event recorded was pruritus. No difference between the two groups of hypermicrofilaremic patients was observed in the reduction of microfilaremia and the occurrence of clinical manifestations. In conclusion, treatment of hypermicrofilaremic loiasis with ALB dosed 400 mg and 800 mg for 30 days, significantly reduces microfilaremia and can be used for eligibility of microfilariae carriers for mass treatment with ivermectin.

6420

DEVELOPMENT OF AN ELISA TO DETECT ANTIBODY TO ONCHOCERCA VOLVULUS INFECTION USING A MAMMALIAN EXPRESSED RECOMBINANT ANTIGEN OV16

Sylvia Ossai, Eric S. Elder, Won Y. Kimberly, William E. Secor, Sukwan Handali

Centers for disease control and Prevention, Atlanta, GA, United States

The World Health Organization (WHO) recommends serological assessments to document onchocerciasis elimination. National onchocerciasis programs are hindered by the lack of diagnostic tests that meet WHO target product profile (TPP) criteria. One of the tests used by onchocerciasis programs, an ELISA based on the Ov16 antigen expressed in bacteria, has had several challenges when performed in endemic country laboratories. Ov16 produced in bacterial expression systems may have different conformation than the native antigen, may lack posttranslational modifications like glycosylation, and infected individuals may have antibodies to bacterial proteins that are difficult to remove in the Ov16 purification process; any of which could result in decreased assay performance. In addition to the issues related to bacterially expressed protein, the current ELISA takes 7 hours to complete, lacks standardized quality controls and is not available as a commercial kit. We sought to overcome the challenges of the current assay with a new ELISA utilizing a mammalian-expressed protein and decreased time to final result. We engaged a commercial company to express Ov16 in a Chinese Hamster Ovary mammalian expression system and purified the antigen using GST-tag and sizing column chromatography. The resulting 47-kDa purified protein, Ov16m, was used to optimize the ELISA. Using pre-coated and blocked plates, the total assay time was 1.5 hours. We also added a standard curve using a humanized IgG4 monoclonal anti-Ov16 antibody to improve assay comparability. Both sera and dried blood spots (DBS) were used to test the performance of the assay in receiver operating characteristic analysis. The sensitivity and specificity of the assay using 94 negative and cross-reactor sera and 134 Onchocerca volvulus positive sera, confirmed by skin snip microscopy or PCR, were 92% and 100%, respectively. In addition, 39 confirmed positive and 170 confirmed negative DBS were tested, yielding 100% sensitivity and 100% specificity. This Ov16m ELISA satisfies WHO TPP requirements and may be useful for informing programmatic decisions for onchocerciasis elimination.

6421

LABORATORY EVALUATION OF ONCHOCERCIASIS RAPID DIAGNOSTIC TESTS (RDTS)

Eric S. Elder[1], Marco Biamonte[2], Lily Sullins[2], Pete Augostini[1], William E. Secor[1], Kimberly Y. Won[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Drugs and Diagnostics for Tropical Diseases, San Diego, CA, United States

Reliable diagnostic tests are needed to support onchocerciasis programs, especially in low prevalence settings. Recently two target product profiles (TPPs), one for disease mapping and one for stopping mass drug administration (MDA) were developed. The TPPs outline performance characteristics required for new tests, including clinical sensitivity (F60% for mapping and ≥89% for stopping) and specificity (≥99.8% for both). Two antibody detection rapid diagnostic tests (RDTs) developed by DDTD were independently evaluated at CDC. Test A, previously described in 2022, contained Ov16 in one band. Test B included four antigens in two bands: Ov16 and Ov33.3 (band 1) and OvOC10469 and OvOC3261 (band 2); both bands must be visible for a positive result. Tests were performed according to manufacturer instructions using two independent readers. A panel of serum samples (n=146) from persons who were skin snip positive for Onchocerca volvulus by microscopy or PCR was used to evaluate sensitivity. A specificity panel included subpanels of Mansonella perstans and/or Loa loa (n=26), Wuchereria bancrofti (n=50), Plasmodium falciparum and/or P. vivax (n=16), Schistosoma mansoni (n=40), Strongyloides stercoralis (n=9), Rheumatoid factor/Type 1 diabetes (n=20) and North Americans with no history of international travel (n=50). Sensitivity and specificity of Test B were 90.4% and 94.3%, respectively. The two tests were then directly compared on a subset of 20 positive and 150 negative samples, Test A was 90% sensitive and 97% specific, and Test B was 85% sensitive and 92% specific. Both tests met the TPP sensitivity requirements for mapping or stopping MDA but not the specificity requirements. While the specificity issues may arise in part from the choice of biomarkers, it should be noted that nearly all problematic samples were M. perstans+/O. volvulus– but from an O. volvulus endemic country. Based on these data, development of an improved version of Test B is underway. In addition, the results show that to validate any new test for onchocerciasis, there is a need for M. perstans and L. loa samples from areas where O. volvulus exposure can be rigorously ruled out.

6422

WB5, A NOVEL BIOMARKER FOR MONITORING EFFICACY AND SUCCESS OF MASS DRUG ADMINISTRATION PROGRAMS FOR WUCHERERIA BANCROFTI ELIMINATION

Rachel E. Pietrow, Thomas B. Nutman, Sasisekhar Bennuru

National Institutes of Health, Bethesda, MD, United States

The success of mass drug administration (MDA) at reducing the prevalence of lymphatic filariasis (LF) in endemic countries has led to an increased need for diagnostic targets designed to monitor for recrudescence and ongoing transmission. While diagnostic targets exist for detecting Wuchereria bancrofti [Wb] and Brugia malayi [Bm] infections, additional targets may increase the sensitivity of these tests. For Wb at least, new biomarkers (in conjunction with Wb123) may be needed to supersede the current WHO recommendations which fail to reflect microfilariae (mf) clearance. Hence, diagnostic tools that reflect the presence/clearance of mf or early infection could be instrumental for not only MDA stopping decisions but also for monitoring. To this end, bioinformatic analyses coupled with stage-specific expression data for Wb and/or Bm resulted in the identification of 12 targets that were: 1) present in Wb and/or Bm; 2) have very little to no homology with proteins from other filariae; and 3) were enriched in the mf or L3 stages. Screening of these 12 antigens by a Luciferase Immunoprecipitation System (LIPS) assay for IgG with serum from Wb-infected (n=170) and uninfected individuals (n=60) identified a single antigen, termed Wb5, that was specific for Wb infections only. Recombinant Wb5 proteins were generated in multiple expression systems for use in a variety of IgG4-based immunoassays. Preliminary screening indicated a very high degree of correlation ($p<0.0001$) between the data derived from LIPS and those determined by more standard immunoassays. To assess if Wb5 could provide additional sensitivity to assays already using IgG4 antibodies to Wb123, head-to-head comparisons were performed using serum from 381 samples (231 Wb-infected; 150 controls). Using IgG4 based immunoassays at 100% specificity, Wb5 and Wb123 had individual sensitivities of 60.2% and 75.3%, respectively, while a combination resulted in 81.0% sensitivity. Moreover, kinetic studies of patients that were treated and followed up longitudinally demonstrated a sharper decline in Wb5 titers compared to Wb123, thus paving the way for Wb5 as a complementary tool to Wb123.

6423

PROTEIN INVENTORY OF ONCHOCERCA VOLVULUS NEOPLASMS IDENTIFIED BY DEEP VISUAL PROTEOMICS

Kerstin Fischer[1], Lucia S. Di Maggio[1], Bruce A. Rosa[1], Makedonka Mitreva[1], Jessica K. Lukowski[1], Minsoo Son[1], Byoung-Kyu Cho[1], Young Ah Goo[1], Nicholas Opoku[2], Gary J. Weil[1], Peter U. Fischer[1]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]University of Health and Allied Sciences, Ho, Ghana

The nematode Onchocerca volvulus is the agent of river blindness and targeted by WHO for elimination. The main strategy for elimination is mass administration of ivermectin to endemic populations. The drug is microfilaricidal, but weak macrofilaricidal effects have been reported after many rounds of treatment. A small fraction of adult O. volvulus contain pleomorphic neoplasms, and their development is more common after

ivermectin. We analyzed 428 female worms by histological evaluation of paraffin embedded nodule sections as part of a trial of ivermectin combination treatments. Neoplasms were present in 5.6% of these worms. The purpose of this study was to compile protein inventories of adult worm tissues to identify protein profiles associated with neoplasms. We used digital image analysis of histological sections, laser capture microscopy and highly sensitive mass spectrometry analysis (ThermoScientific, Eclipse). Neoplasm tissue from three female worms was analyzed, and compared with normal tissues from the body wall, uteri and intestine of these worms and also tissues from a healthy female without neoplasm. Unlike healthy females, females with neoplasms did not show any signs of embryogenesis. A protein was called present, if supported by 2 peptides and found in at least 2 of the 3 biological replicates. In worms with neoplasms, we detected 151 proteins in the body wall, 215 proteins in the intestine, 47 proteins in the uterus and 1577 proteins in the neoplasms. The uterus of the healthy female with intact embryogenesis had a high number (1710) of proteins detected that was similar to that of neoplasms. A majority of the 20 most abundant proteins detected in neoplasms was highly conserved, and only two proteins were nematode specific. Proteins that were found in neoplasms but not in the other analyzed tissues included peroxiredoxins, proteases, and proteins related to signal transduction, and ribosomal or proteasome activity. In conclusion, we have successfully used deep visual proteomics to analyze the proteome of individual O. volvulus tissues in nodule sections and identified proteins that are overexpressed in neoplasms.

6424

ASSOCIATION BETWEEN ALTERED COGNITION AND LOAISIS: FIRST EVIDENCE FROM A CROSS-SECTIONAL STUDY IN A RURAL AREA OF THE REPUBLIC OF CONGO

Thomas Checkouri[1], Francois Missamou[2], Sebastien D. S. Pion[3], Paul Bikita[2], Marlhand C. Hemilembolo[2], Michel Boussinesq[3], Cédric B. Chesnais[3], **Jérémy T. Campillo**[3]

[1]AP-HP, Paris, France, [2]PNLO, Brazzaville, Congo, Republic of the, [3]Institut de Recherche pour le Développement, Montpellier, France

Individuals with high Loa loa microfilarial densities are at risk of developing severe encephalopathy after administration of antiparasitic drugs. Recent epidemiological data suggest an increased mortality and morbidity in L. loa infected individuals and a systematic review of atypical cases of Loa loa revealed that many organs appear to be affected by the parasite, including the brain. Apart from these findings, loiasis is still considered benign and studies are mandatory to evaluate the possible neurological morbidity associated with loiasis. We conducted a cross-sectional study to assess cognitive alteration in a population living in a rural area endemic for loiasis in the Republic of Congo. Fifty individuals with high L. loa microfilarial densities (MFD) were matched on sex, age and residency with 50 individuals with low MFD and 50 with no MFD. MoCA (Montreal Cognitive Assessment) tests and neurological ultrasounds were performed for all participants. For the main analysis, individuals with MoCA scores below 23/30 were considered to have altered cognition. Altered cognition was analyzed by L. loa MFD, sociodemographic characteristics and neurological ultrasound results. Mean MoCA score was 15.6/30 (range : 3/30 -28/30). Individuals with more than 15,000 microfilariae per milliliter of blood (mean predicted score:14.0/30) are more than twenty times more likely to have an altered cognition, compared to individuals with no microfilaremia (mean predicted score: 16.3/30). Duration of schooling were strongly associated with better MoCA results. Extracranial and intracranial atheroma were not associated with L. loa MFD with respectively 7 (14.9%) and 13 (13.7%) individuals with atheroma in microfilaremic and amicrofilaremic individuals. Loaisis microfilaremia is probably involved in cognitive impairment, especially when the MFD are high. These results add to the evidence that the burden of loaisis is highly underestimated and highlight the urgent need to better understand loaisis-induced neurological morbidity.

6425

DEVELOPING NOVEL FLATWORM ION CHANNEL LIGANDS TO TREAT NEGLECTED TROPICAL DISEASES

Daniel J. Sprague[1], Sang-Kyu Park[1], Claudia M. Rohr[1], Simone Häberlein[2], Jonathan S. Marchant[1]

[1]Medical College of Wisconsin, Milwaukee, WI, United States, [2]Institute of Parasitology, Justus Liebig University Giessen, Giessen, Germany

Praziquantel (PZQ) is the mainstay for treatment of parasitic flatworm infections. After ~40 years of clinical usage, a putative target for PZQ was identified: a transient receptor potential ion channel in the melastatin subfamily (TRPMPZQ). This channel is conserved across all profiled parasitic flatworm species, and in vitro potency at each ortholog mirrors the known clinical sensitivity of each parasite. Notably, Fasciola spp. are insensitive to PZQ mirroring the lack of activation of Fasciola spp. TRPMPZQ in vitro. It was discovered that there are residues in the binding pocket of TRPMPZQ responsible for the observed differential sensitivity, and this knowledge prompted the development of molecules that could tolerate this variation. Given the increasing resistance of Fasciola spp. to triclabendazole, the discovery of new fasciolicidal targets is timely. Therefore, for proof-of-principle the decision was made to interrogate the druggability of F. hepatica TRPMPZQ (Fh.TRPMPZQ). Employing a target-based screen of >600,000 small molecules against both Sm.TRPMPZQ and then Fh.TRPMPZQ, a series of chemotypes that activate both channels were identified, and the pharmacophore shown to be most potent at Fh.TRPMPZQ was selected for further development. A library of molecules was synthesized to interrogate structure-activity relationships around the core of this molecule resulting in S55, a new molecule with submicromolar potency at both channels. When applied ex vivo to Schistosoma mansoni, S55 produced rapid contraction of the flatworm with concomitant tegument damage, phenocopying PZQ. Likewise, S55 produced an identical phenotype on freshly excised triclabendazole-sensitive and triclabendazole-resistant F. hepatica. S55 was non-toxic in HepG2 assays and is active and well-tolerated in vivo. Given these results, the data show that there is differential druggability among flatworm TRPMPZQ orthologs and demonstrate that Fh.TRPMPZQ is a druggable target that warrants further exploration.

6426

NOVEL INHIBITORS OF THIOREDOXIN GLUTATHIONE REDUCTASE WITH SCHISTOSOMICIDAL ACTIVITY

Samuel Y. Aboagye[1], Valentina Z. Petukhova[2], Matteo Ardini[3], Rachel P. Lullo[1], Margaret Byrne[1], Lucy M. Martin[1], Gregory Effantin[4], Wai-Li Ling[4], Gregory RJ Thatcher[5], Francesco Angelucci[3], Pavel A. Petukhov[6], David Williams[1]

[1]Rush University Medical Center, Chicago, IL, United States, [2]University of Illinois at Chicago, Chicago, IL, United States, [3]University of L'Aquila, L'Aquila, Italy, [4]University of Grenoble Alpes, Grenoble, France, [5]University of Arizona, Tucson, AZ, United States, [6]University of Illinois at Chicago, Chicago, Chicago, IL, United States

Over 200 million people are infected with schistosomiasis resulting in more than 200,000 deaths annually. Schistosomiasis control strategies rely almost exclusively on mass drug administration (MDA) using praziquantel (PZQ) monotherapy, which is ineffective against juvenile worms. There are currently no available alternatives to PZQ, and few drugs or vaccines are in the clinical pipeline. Of immediate concern are results from MDA campaigns finding that PZQ cure rates are often less than 50%, and the possibility of emergence of PZQ resistant parasites is inevitable. Our aim is to develop new compounds that are effective against different developmental stages and species of the schistosome parasite. We have shown that S. mansoni thioredoxin glutathione reductase (TGR) is essential for worm survival in the mammalian host and druggable. Compounds targeting TGR identified to date are irreversible and/or covalent inhibitors with unacceptable side effects. To identify TGR inhibitors for clinical use, small molecule fragments obtained by X-ray crystallography screening were ligated and partially optimized as first-in-class non-covalent inhibitors of TGR. A first cryo-EM structure of TGR demonstrated that these inhibitors bind at a secondary

site adjacent to the NADPH binding site, blocking enzyme function. All compounds are found to be reversible via jump dilution experiments. These compounds display schistosomicidal activity against cultured worms equal to or better than praziquantel and superior to thresholds set by the WHO. Most importantly, several novel TGR inhibitors demonstrated efficacy against schistosome infections in mice, including treatment targeting juvenile worms, significantly outperforming praziquantel. These findings open a new avenue for the design of non-covalent inhibitors of TGR for the treatment of schistosomiasis.

6427

HIGH SENSITIVITY BUT LOW SPECIFICITY OF FEMALE GENITAL SCHISTOSOMIASIS SYMPTOMS AND RISK FACTORS DIAGNOSTIC TOOL ON GENITAL LESIONS ASSOCIATED WITH FEMALE GENITAL SCHISTOSOMIASIS IN ADOLESCENT GIRLS AND WOMEN IN MASWA DISTRICT, TANZANIA

Gladys Mbwanji, Humphrey Mazigo

Catholic University of Health and Allied Sciences, Mwanza, Tanzania, United Republic of

Female Genital Schistosomiasis (FGS) is a clinical feature of urogenital schistosomiasis caused by S. haematobium. Chronic FGS affect the women's reproductive system and even cause irreversible changes. The Liberia Ministry of Health developed the symptoms and risk factors checklist to help healthcare workers at primary healthcare facilities in endemic areas to identify and manage FGS. However, the sensitivity and specificity of the tool were not known. In that view, we hypothesized that the FGS checklist would have high sensitivity and specificity for diagnosis of FGS in women compared to colposcope and hence would improve early diagnosis of FGS among women in Tanzania. A community-based cross-sectional study was conducted among sexually active women at Maswa District. Women with informed consent, who produced 10mls of urine for urine filtration test were recruited and underwent thorough speculum examination by trained gynaecologists using a portable digital colposcopy to capture images of the cervix and vagina. A total of 347 adolescent girls and women aged 18-45 years were screened between October and November 2022. The mean age of women was 30 years (±0.414). Majority of women were aged 25-34, 153/347(44.09%), 186/347(54.07%) contacted fresh water bodies and 313/347 (90.20%) of the women had never used praziquantel. Among the 177 women who underwent a thorough colposcopy examination, the overall prevalence of genital schistosomiasis was 15.82% (28/177). Common FGS features detected were 14/28 (50%) homogenous yellow sandy patches, and 7/28(25%) abnormal blood vessels. The prevalence of urogenital schistosomiasis was 3.48% (13/345) among the study participants. The sensitivity, specificity, positive and negative predictive values of symptom and risk factor diagnostic tools were 85.71%, 8.72%, 15.00% and 76.47% among women who underwent gynaecological examination. Through this observational study, this diagnostic tool has shown high sensitivity but low specificity in diagnosing FGS. Studies with longer follow-ups and larger samples are needed to assess its validity in diagnosing FGS in endemic areas.

6428

OPTIMISATION OF THE DNA DIPSTICK AS A RAPID EXTRACTION METHOD FOR SCHISTOSOMA JAPONICUM IN INFECTED MICE SAMPLES AND SPIKED HUMAN CLINICAL SAMPLES

Oyime Poise Aula[1], Donald P. McManus[1], Malcolm K. Jones[2], Hong You[1], Pengfei Cai[1], Mary Duke[1], Catherine A. Gordon[1]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]University of Queensland, Gatton, Australia

Schistosomiasis remains a public health issue and the need for accurate and affordable diagnostics is crucial in the elimination of the disease. While molecular diagnostics is highly effective, it is expensive, with the main costs been associated with DNA extraction. The DNA dipstick is a rapid, affordable and simple DNA purification method that allows DNA to be extracted from diagnostic samples within 30 seconds. We aimed to optimise the DNA dipstick method for samples from mice and egg-spiked human samples. Urine, blood and faeces were collected from mice exposed to Schistosoma japonicum infection at weekly intervals from Day 0 to Day 42. Urine and faecal samples were collected from volunteer, uninfected humans and spiked with S. japonicum eggs. All samples were subject to several optimisation procedures and DNA extracted with the DNA dipstick. Amplification of the target DNA was carried out using LAMP and visualised using agarose gel electrophoresis and flocculation. The DNA dipstick successfully identified S. japonicum from infected mice and human clinical samples spiked with cracked eggs or genomic DNA from S. japonicum. The DNA dipstick combined with LAMP has huge potential in providing cost-effective, simple and accurate detection of schistosomiasis infection in endemic regions.

6429

ACCEPTABILITY OF GENITAL SELF-SAMPLING FOR THE DIAGNOSIS OF FEMALE GENITAL SCHISTOSOMIASIS IN HARD-TO-REACH COMMUNITIES

Emmanuel Timmy Donkoh[1], Edward T. Dassah[2], Samuel Fosu Gyasi[1], Oksana Debrah[3], Dodzi Amelor[4], Richard Asmah[5], Ahmed Ramseyer[6], Kwame O. Boadu[7], Emma Donkoh[8], Angelina Kantam[1], Lois Kyeretwie[1], Esther Owusu Yawson[1], Nathanael Agyapong-Apraku[1], Josephine Opoku-Agyemang[1]

[1]University of Energy and Natural Resources, Sunyani, Ghana, [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [3]University of Cape Coast, Cape Coast, Ghana, [4]Ghana Health Service, Accra, Ghana, [5]University of Health and Allied Sciences, Ho, Ghana, [6]Ghana Health Service, Yeji, Ghana, [7]Ghana Health Service, Kumasi, Ghana, [8]Ghana Health Service, Tain, Ghana

Female genital schistosomiasis (FGS), caused by the waterborne parasite Schistosoma haematobium, is a debilitating gynaecological disorder that is difficult to diagnose. The 2022 WHO guideline on the control and elimination of human schistosomiasis anticipates that a screen-and-treat approach will be a useful programmatic strategy in certain contexts. We investigated the acceptability of a home-based genital self-sampling strategy for screening in two districts in Ghana. From October 2021 to January 2022, 250 non-pregnant, sexually active women were recruited from the Tain and Yeji Districts after community engagement and documentation of voluntary consent. Women were recruited using lot quality assurance sampling and trained to provide self-sampled cervicovaginal swabs and urine specimens for parasitological analysis. Women were subsequently invited to the community health centre for repeat sampling after a week. The mean age was 26.3±7.6. The prevalence of S. Haematobium ova by urine microscopy was 9.6%. Most participants rated self-sampling to be "very easy" or "easy" (82.4%: n=206), and "painless" (70.4%: n=176) and were confident that the sample was collected as they had been directed (81.2%: n=203). In addition, most women were willing to take another sample for FGS screening in future (96.8%: n=242) and were willing to recommend self-sampling to a close friend or family member by sending a customized text message (89.6%: n=224). Preference for sampling strategy was based on concerns of convenience, privacy and the need for supervision. Key informant interviews uncovered negative partner sentiments regarding genital screening programmes at health facilities in study communities. The self-sampling strategy can be successfully implemented for women in hard-to-reach communities as a patient-centred diagnostic strategy for FGS to improve screening coverage and promote healthcare equity. Opportunities to integrate self-sampling strategies into community health and extension services exist and should be explored in order to accelerate action towards schistosomiasis elimination targets.

6430

EXPANDING FEMALE GENITAL SCHISTOSOMIASIS LEARNING AND APPLICATION THROUGH AN ONLINE TRAINING FOR MIXED CADRES OF HEALTH CARE WORKERS IN FRANCOPHONE AFRICA

Martha N. Mberu[1], Kelly Yotebieng[1], Isis Umbelino-Walker[2], Anastasia Pantelias[2], Julie Jacobson[2]

[1]The END Fund, New York, NY, United States, [2]Bridges to Development, Vashon, WA, United States

Female Genital Schistosomiasis (FGS), a tropical disease caused by a parasitic worm (Schistosoma haematobium), is estimated to affect up to 56 million women and girls. It is a leading neglected issue in sexual and reproductive health in sub-Saharan Africa. Women and girls with FGS suffer physiological and social consequences from the infection which is associated with a three-fold increase in the risk of HIV acquisition. Most research on FGS focuses on epidemiology and treatment options. However, little attention is given to effective methods for awareness and education on FGS in healthcare workers (HCWs) and communities. Addressing the FGS knowledge gap in endemic areas is imperative. HCWs are generally unfamiliar with the effects of parasitic diseases on women's reproductive and sexual health as it is not typically included in medical training. FGS is often misdiagnosed and left untreated as symptoms mimic sexually-transmitted infections. HCWs need the expertise and tools to identify and treat FGS. Exacerbating this knowledge gap in Francophone countries, the English language dominates scientific literature and training. Therefore, the scientific community in Francophone Africa is isolated from contributing to and using this knowledge, limiting the uptake of research for decision-making. To help address these gaps, we are implementing an interactive online training in French to increase health capacity for FGS in Francophone countries by (i) training HCWs on FGS and its manifestations and presentations, (ii) supporting HCWs to develop action plans to integrate FGS into their practice and establish a culture of awareness in their local context, and (iii) creating an independent network of HCWs across Francophone Africa, linking them with a broader FGS network across endemic countries. Building a grassroots strategy advances economic and social well-being as it supports opportunities for communities to overcome health and education barriers. This presentation will share lessons from this experience developing a new cadre of Francophone FGS subject matter experts and review the local solutions detailed in the action plans developed.

THE STATUS OF SCHISTOSOMIASIS AFTER A DECADE OF MASS DRUG ADMINISTRATION IN SIERRA LEONE

Ibrahim Kargbo-Labour[1], Mohamed S. Bah[2], **Victoria Turay**[2], Abdulai Conteh[1], Abdulai Koroma[1], Elisabeth Chop[3], Patricia Houck[3], Anna Phillips[4], Angela Weaver[3], Steven D. Reid[3]

[1]Neglected Tropical Diseases Program, Ministry of Health and Sanitation, Freetown, Sierra Leone, [2]Helen Keller International, Freetown, Sierra Leone, [3]Helen Keller International, New York, NY, United States, [4]FHI 360, Washington, DC, United States

In 2008, schistosomiasis (SCH) was found to be endemic in 14 health districts (HDs) of Sierra Leone. Endemic HDs were classified as low (≥1 and <10%) in the five coastal HDs; moderate (≥10 and <50%) in five HDs; and high (≥50%) prevalence in four HDs. Schistosoma mansoni is present in all nine high/moderate endemic HDs and S. haematobium in three HDs. Annual MDA began in 2009 to target school aged children (SAC) in six high/moderate endemic HDs and was scaled up in 2010 to all SAC and at-risk adults in the nine high/moderate endemic HDs. In 2016, a SCH impact assessment was conducted in the nine HDs; results showed an overall reduction in prevalence from 42.2% to 20.2%. MDA was subsequently revised to a sub-district (chiefdom) level treatment strategy. In 2022, after five rounds of MDA with effective SAC coverage, another school-based impact assessment was conducted in the same nine HDs. The sampling was statistically powered to estimate chiefdom prevalence; a total of 201 sites were selected using probability proportional to estimated population size of the chiefdoms with special consideration for large towns and small chiefdoms. In each site, a total of 24 children aged 5-14 years were tested. Fresh stool samples were examined by Kato Katz. Urine samples were tested by Haemastix with haematuria positive urines only tested by filtration technique. A total of 4,736 (male: 51%, female: 49%) and 4,618 (male: 51%, female: 49%) children were examined for S. mansoni and S. haematobium, respectively. Overall prevalence for S. mansoni was 16.3% (95% CI: 15.3-17.4), for S. haematobium was 2.0% (95% CI: 1.6-2.4), and for any SCH was 17.7% (95% CI: 16.7-18.8). The arithmetic mean intensity for S. mansoni and S. haematobium was 30.0 epg (95% CI: 24.8-35.2 epg) and 4.0 eggs/10ml (95% CI: 3.9-4.1 eggs/10ml), respectively. Of the 201 sites surveyed, 11 (5.5%) had high prevalence of S. mansoni versus 23 of 60 sites (38%) at baseline and 5 of 40 sites (12.5%) in 2016. Although prevalence remains high in a limited number of communities, SCH prevalence in Sierra Leone has overall reduced significantly. A more focused and intensive strategy could help reach Sierra Leone reach SCH control.

[1]Yale School of Public Health, New Haven, CT, United States, [2]Yale School of Medicine, New Haven, CT, United States, [3]Instituto Gonçalo Moniz (Fiocruz), Salvador, Brazil, [4]SUNY Upstate Medical University, Syracuse, NY, United States, [5]University of Florida, Gainesville, FL, United States, [6]Universidade Federal da Bahia, Salvador, Brazil

The contribution of mucosal antibody responses to protection from SARS-CoV-2 infection and pathogenicity in humans remains understudied. We examined the systemic and mucosal immune responses elicited by varying exposures to infection and/or vaccination among a community-based cohort of urban slum residents from Salvador, Brazil, followed before and during the pandemic. We collected serum, nasal and saliva samples over the course of two sequential surveys (Survey 1, November 2020 to February 2021; Survey 2, July to October 2021) among 1,570 participants. We selected a stratified sample of 137 participants and examined the relationships of antibody responses within and between the serum, nasal, and salivary compartments. Of the 137 participants, 19 individuals were seronegative, 53 were vaccinated and had no serologic evidence of infection, 30 had experienced one infection, 14 had experienced two infections, and 21 had experienced both infection and vaccination. We found that 10/19 (52.6%, 95% CI 29.5-74.8%) individuals who were unvaccinated and seronegative had detectable antibodies in the nasal compartment, and 12/19 (63.2%, 95% CI 38.6-82.8%) had detectable antibodies in the salivary compartment. Furthermore, mucosal IgA responses remained detectable 6 months after infection. An unsupervised hierarchical clustering analysis identified discordance of antibody responses between the serum, nasal, and salivary compartments. Individuals with high serum neutralization activity against the ancestral, Gamma, Delta and Omicron variants exhibited increased and coordinated antibody response in their mucosal compartments compared to individuals with poor serum neutralization activity. Our findings suggest that measurement of serum antibody responses may underestimate the true prevalence of SARS-CoV-2 exposures and the degree of functionally relevant immunity in previously exposed populations. Various sequences of exposure to infection and vaccination can induce effective mucosal antibody responses and confer protection from infection and severe disease.

DIFFERENTIAL PROTEOME EXPRESSION IN A DIVERSE POPULATION OF HOSPITALIZED PATIENTS WITH COVID-19

Douglas J. Perkins[1], Qiuying Cheng[1], Clinton Onyango[1], Kristan Schneider[2], Ivy Hurwitz[1]

[1]University of New Mexico HSC, Center for Global Health, Albuquerque, NM, United States, [2]University of Applied Sciences Mittweida, Mittweida, Germany

The role of differential proteome expression in the pathogenesis of COVID-19 remains largely undefined, particularly in diverse racial/ethnic groups of hospitalized patients. As such, proteomic profiling of plasma was performed upon the initial phase of hospitalization (≤ 3 days) in a subset of COVID-19 patients (n=40) admitted to the University of New Mexico Hospital, matched according to age, sex at birth, race/ethnicity, time from admission, duration of symptom onset, and time since first PCR-confirmed infection. Patients were stratified as either (a) severe (n=20): defined as admission to the ICU and/or death, or (b) non-severe (n=20): defined as non-ICU requirements and survival. Proteomic analysis was performed using an aptamer-based technology for which 6,628 circulating proteins were quantified. There were 339 differentially expressed proteins (DEPs) at P<0.05 between the groups: 302 were up-regulated and 37 were down-regulated with a log2 mean fold-change between 3.29 to -1.08. Enrichment analyses revealed that the top-ranked pathway maps were Vascular Endothelial Cell Damage (FDR-adj. P=1.136x10-4) and Blood Coagulation (FDR-adj. P=1.370x10-4). Consistent with this finding, Blood Coagulation emerged as a top process network (FDR-adj. P=4.765x10-3). Canonical network analyses revealed IL6-HSP70-IL18R1-BAFF(TNFSF13B)-CCL2 as a central regulatory interaction with TRAF6 as the convergence hub (14 edges) and NF-kB as the divergence hub (13 edges). Collectively, these proteomic results in diverse populations illustrate that endothelial cell damage and coagulopathy are central pathogenic features of severe COVID-19 in which aberrant intracellular responses to protein folding are a substantial component.

6434

EXTENSIVE TRANSMISSION OF SARS-COV-2 BQ.1 VARIANT IN A POPULATION WITH HIGH LEVELS OF HYBRID IMMUNITY

Juan P. Aguilar Ticona[1], Meng Xiao[2], Dan Li[3], Nivison Nery Jr[1], Matt Hitchings[4], Emília M. M. De Andrade Belitardo[5], Mariam O. Fofana[6], Renato Victoriano[5], Jaqueline Cruz[5], Laise Eduarda Paixão de Moraes[5], Icaro Morais Strobel[5], Jessica Jesus Silva[5], Ananias Sena do Aragão Filho[5], Guilherme S. Ribeiro[5], Mitermayer G. Reis[5], Federico Costa[1], Ricardo Khouri[5], Albert I. Ko[6], Derek A. T. Cummings[7]

[1]Instituto de Saúde Coletiva, Universidade Federal da Bahia, Salvador, Brazil, [2]Department of Laboratory Medicine, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [3]Public Health Emergency Center, Chinese Center for Disease Control and Prevention, Beijing, China, [4]Department of Biostatistics, University of Florida, Gainesville, FL, United States, [5]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Ministério da Saúde, Salvador, Brazil, [6]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [7]Department of Biology, University of Florida, Gainesville, FL, United States

The SARS-CoV-2 BQ.1* variant spread globally in late 2022, yet there is limited data available regarding the transmission and disease severity caused by this variant. This study aimed to determine the incidence and severity of BQ.1* infection in a population with high levels of hybrid immunity. As part of a long-term cohort study, we conducted a prevalence survey during the BQ.1* wave between Nov 16th and Dec 22nd, 2022 in Salvador, Brazil. We performed interviews and collected nasal samples for SARS-CoV-2 antigen and RT-PCR testing and whole genome sequencing. Cumulative incidence was estimated by using RT-PCR positivity and cycle threshold values, together with external data on RT-PCR positivity following infection, to estimate daily probability of infection. Of 535 cohort participants, 54% had a documented SARS-CoV-2 exposure and 74% received COVID-19 vaccination prior to the survey. Among these, 79 (14.3%) had a positive SARS-CoV-2 test with BQ.1* identified in 90.7% of positive samples. The prevalence was highest (32.1%) in the week of Nov 23 – 29th, 2022. The cumulative incidence was estimated to be 56% (95% CI, 36 – 88%). Of 79 positive participants, 38 (48.1%) had a symptomatic illness and a lower proportion had fever (37% vs. 51%, p=0.221) and fulfilled the WHO COVID-19 case definition (47% vs. 70%, p=0.023) than cases identified from the cohort in prior Omicron waves. No participants required medical attention. Early exposure to SARS-CoV-2 during the pandemic was associated with a lower risk of infection during the survey (multivariate OR= 0.50, 95% CI=0.25 – 0.97). By reconstructing transmission dynamics from PCR prevalence data, we found that the BQ.1* variant disseminated widely (attack rate of 56%) despite high population-level hybrid immunity. The lower disease severity associated with BQ.1*, as compared with prior Omicron variants, contributed to significant under-reporting of infection. As observed for BQ.1* in this study, hybrid immunity may provide weak protection against future SARS-CoV-2 variants and may not prevent widespread transmission after their introduction.

PERFORMANCE OF A NOVEL REALTIME-TIME PCR DEVICE FOR DETECTION OF SARS-COV-2, RESPIRATORY SYNCYTIAL VIRUS AND INFLUENZA VIRUSES FROM AUGUST 2022 TO JANUARY, 2023

Michael Owusu[1], Bernard Nkrumah[2], Godfred Acheampong[3], Stephen Opoku Afriyie[3], Richard Larbi[3], Richard Owusu-Ansah[3], Chrysantus Kubio[4], Farouk Saeed[5], Nana Kwame Ayisi-Boateng[6], Eric Darko[6], James Frimpong[6], Veronica Bannor[7], Frederick Ayensu[8], Pawan Angra[9], Danielle T. Barradas[10]

[1]Kwame Nkrumah University of Science and Technology, Centre for Health System Strengthening, Kumasi, Ghana, [2]US Centers for Disease Control and Prevention, Kumasi, Ghana, [3]Centre for Health System Strengthening, Kumasi, Ghana, [4]Regional Health Directorate, Savannah Region, Kumasi, Ghana, [5]Regional Health Directorate, Ghana Health Service, Savannah Region, Kumasi, Ghana, [6]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [7]Asokwa Children Hospital, Kumasi, Ghana, [8]HopeXchange, Kumasi, Ghana, [9]US Centers for Disease Control and Prevention, Georgia-Atlanta, GA, United States, [10]US Centers for Disease Control and Prevention, Atlanta, Ghana

Real-Time PCR (RT-PCR) is the gold standard for the detection of respiratory viruses. Despite high sensitivity and specificity, RT-PCR method is sophisticated, expensive, time-consuming, laboratory-based and unsuitable for point-of-care (POC) use in resource-limited settings. We evaluated the novel Lab-On-An-Array (LOAA) digital real-time PCR (dPCR) analyzer for the detection of SARS-CoV-2, Respiratory Syncytial Viruses (RSV) and influenza viruses type A and B.A cross-sectional multi-centre hospital-based study was conducted between August 2022 to January 2023 in Ashanti and Savannah Regions of Ghana. Oropharyngeal swabs from 356 patients were tested for respiratory viruses by LOAA and RT-PCR simultaneously. Nucleic acids were extracted using Qiagen Viral Mini kit (QIAGEN Diagnostics GmbH, Germany). LOAA tests were done using LOAA dPCR analyzer and GenoplexorTM COVID-19/Flu/RSV Detection Kit (Optolane Technologies Inc, South Korea) while RT-PCR tests were done using Bio-Rad CFX96 and FluoroType SARS-CoV-2/Flu/RSV kits (Hain lifesciences, Germany). Sensitivity, specificity, accuracy, kappa (κ), positive, and negative predictive values (PPV and NPV) were assessed for LOAA using RT-PCR as the gold standard. Overall positivity rate for respiratory viruses was 106 (29.8%) for LOAA and 116 (32.6%) for RT-PCR. The sensitivity of LOAA to detect RSV was 87.8% (95%CI: 84.1-90.9), SARS-CoV-2 87.5% (95%CI: 84.1- 90.9), influenza B 80.7% (95%CI: 76.5-84.8) and influenza A 75.0% (95% CI: 70.5-79.5). Specificity for LOAA was ≥98.0%. The accuracy of LOAA was 98.9% for SARS-CoV-2, 98.0% for both RSV and influenza A, and 97.8% for Influenza B. The PPV for RSV (97.7%), SARS-CoV-2 (95.5%), Influenza B (92.6%), and Influenza A (69.2%). The NPV was ≥98.0% for all respiratory viruses. There was very good agreement for RSV (κ=0.91), SARS-CoV-2 (κ=0.91), influenza

B (κ=0.85), and substantial for influenza A (κ=0.71).LOAA showed strong diagnostic agreement and comparable accuracy with RT-PCR for detecting SARS-CoV-2, RSV, and influenza B infections and moderate agreement for influenza A in low-resource clinical settings.

PATHWAYS & MORTALITY OF UNDER 5 CHILDREN IDENTIFIED AS SEVERE CASES WITH ROUTINE PULSE OXIMETRY USED INTO THE INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS GUIDELINES AT PRIMARY HEALTH CENTERS IN WEST AFRICA, JUNE 2021 TO JUNE 2022

Gildas Boris HEDIBLE[1], Desire Neboua[2], Lucie Peters Bokol[1], Gildas ANAGO[2], Zineb ZAIR[1], Severin Lenaud[3], Honorat Agbeci[1], Abdoul Guaniyi SAWADOGO[4], Désiré KARGOUGOU[5], Bertrand Meda[6], Jacques Séraphin Kolié[7], Sandrine Busiere[8], Franck Lamontagne[9], Sarah Louart[10], Valery Ridde[11], Valériane Leroy[1]

[1]CERPOP UMR 1295 INSERM UT3, Toulouse, France, [2]ALIMA, Dakar, Senegal, [3]PACCI, Abidjan, Côte D'Ivoire, [4]Tdh, Ouagadougou, Burkina Faso, [5]ALIMA, Bamako, Mali, [6]SOLTHIS, Niamey, Niger, [7]ALIMA, Conakry, Guinea, [8]Tdh, Dakar, Senegal, [9]Solthis, Paris, France, [10]ALIMA & 8.University Of Lille, CLERSE - Centre Lillois d'Études Et De Recherches Sociologiques Et Économiques, Dakar, Senegal, [11]IRD, Paris, France

The Integrated Management of Childhood Illness (IMCI) guidelines for children under5 is a symptom-based algorithm, adapted for resource-limited countries at primary health center (PHC) level. To improve the diagnosis & care-management of severe cases with hypoxemia, the AIRE project, UNITAID-funded, has implemented the routine Pulse Oximeter (PO) use into IMCI consultations at PHCs in Burkina Faso, Guinea, Mali & Niger. The purpose of this study was to describe the care pathway & mortality of children with serious illness. In 16 AIRE PHC research sites (4/country), all under5 children attending IMCI consultations with routine use of PO & classified as severe cases were enrolled in a prospective short cohort study with 14-Days of follow-up, with parental consent. From June 2021 to June 2022, 39,360 children attended IMCI consultations at the research PHCs. Among the 3,163 identified as severe cases, 1998 were followed of whom 463 (23.2%) were referred to district hospital (DH) while 1499 (75%) were treated at PHC & 36 (1.8%) were neither referred nor treated at PHC. The D14-mortality rate was at 4.7% (95/1998 - 95% CI: 3.9-5.8). It was significantly different among children managed at hospital level with 14.7% (68/463 - 95% CI: 11.5 -18.2) & those treated at PHC level with 1.3% (19/1499 - 95%CI: 0.8 -2.0). Among the 1998 followed, severe hypoxemia (SpO2<90%) was detected in 142 children of whom 117 (82.4%) were referred at DH vs 17 (12%) treated at PHC. Their D14-mortality rate was estimated at 26.1% (37/142; 95%CI: 19.1-34.1). In conclusion, unexpectedly, referral of severe case to hospital is not systematic even for hypoxemia for whom oxygen therapy was not available at PHC level. The D14-mortality rate remain high especially at hospital level. The proper management of severe case (transfer and oxygen therapy) remain challenges in West Africa.

6437

IMPACT OF PNEUMOCOCCAL CONJUGATE VACCINES ON PENICILLIN RESISTANT STREPTOCOCCUS PNEUMONIAE

Sebastian Loli[1], Theresa Ochoa[1], Stephen Bentley[2], Stephanie Lo[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Wellcome Sanger Institute, Hinxton, Cambridgeshire, United Kingdom

The use of Pneumococcal Conjugate Vaccine (PCV) has effectively reduced antimicrobial resistance in pneumococci. This study assessed the prevalence of penicillin resistance in carriage pneumococci from children under 2 years old pre-PCV (2006-2008) and after PCV13 (2018-2019) introductions. In this study nasopharyngeal swabs were collected from healthy children <2yo in Lima, Peru before PCV (n=999) and after PCV13 (n=996). We whole-genome sequenced all pneumococcal isolates from the carriers on an Illumina MiSeq. In silico serotype and antimicrobial susceptibility were predicted from the genomes using CDC analysis pipeline. Changes were indicated by odds ratio (OR) and 95% confidence interval using logistic regression. Logistic regression models were adjusted for sex, age, hospital, previous hospitalization, attending daycare, and the number of children at home. The pneumococcal carriage rate was 25% (253/999) in pre-PCV and 19% (193/996) in post-PCV13 period. The prevalence of penicillin-non-susceptible isolate did not change between pre-PCV and post-PCV13 periods (12% vs. 14%, p-value>0.05). However, the odds ratio of penicillin-resistant pneumococcal carriers due to PCV13 vaccine serotypes decreased from 10% to 3% (adjusted OR= 0.29, 95% CI 0.19-0.45; p value <0.001). Conversely, the odds of penicillin-resistant pneumococcal carriers due to non-PCV13 vaccine serotypes increased from 3% to 10% (adjusted OR= 4.64, 95% CI 2.85-7.54, p value <0.001). The PCV has reduced overall penicillin resistance in pneumococci from healthy children in Peru. However, penicillin resistance was observed to increase in pneumococci that are not targeted by PCV13.

MULTIPLEXED ANTIGEN SPECIFIC ANTIBODY FC PROFILING FOR POINT OF CARE DIAGNOSIS OF TUBERCULOSIS

Sarah Ali, Preetham Peddireddy, Abhipsa Panigrahi, Asma Hashim, Aniruddh Sarkar

Georgia Institute of Technology, Atlanta, GA, United States

Tuberculosis (TB) is a leading cause of infectious disease related deaths despite the existence of effective treatments. Lack of accurate yet rapid and inexpensive diagnostics contributes to a significant proportion of TB deaths. Key challenges in TB diagnostics include the heterogenous spectrum of disease, ranging from latent TB infection (LTBI) to active TB (ATB), and difficulty in obtaining and processing sputum samples, especially from children. Antibody (Ab) titer-based serological tests, which are used as a simple means to detect many infections, have failed for TB. Recently, we and others have observed that the inflammatory state of Mtb-specific Abs, driven by changes in Fc-glycosylation, differs across LTBI and ATB. Here, we report the discovery of a M. tuberculosis (Mtb)-specific Ab Fc profile based biomarker for TB to distinguish ATB from LTBI and a method for its point-of-care (POC) detection using an inexpensive, multiplexed and high throughput optical biosensing method. First, highly multiplexed bead-based Ab biophysical profiling (both Fab and Fc) was applied to sera from a set of ATB and LTBI patients. Antigen-coated barcoded beads were incubated with serum and probed with fluorescently-labeled isotype and subclass probes, tetramerized Fc receptors and lectins. Machine-learning based methods (LASSO-SVM) applied to the resultant high-dimensional dataset, revealed a minimal Ab Fc profile biomarker. Next, a POC detection method was developed where multiple TB antigens (Ag85A, PPD, Esat6, HspX) immobilized on laser cut PDMS microwells, are incubated with drops (<10μL) of TB patient serum. Horseradish peroxidase labelled Fc and lectin probes are added, followed by silver substrates to produce a quantitative and sensitive enzymatic metallization based optical readout which can be read out using a cellphone camera. Application of this to two geographically distinct cohorts of TB patients (South Africa and Vietnam, n=40), achieved a high diagnostic accuracy (AuROC~0.9). Thus, a non-sputum based Ab Fc profile biomarker for TB and a method for its inexpensive yet accurate POC detection from a drop of serum was developed.

6439

THE IMPACT OF NEXT-GENERATION DUAL-ACTIVE INGREDIENT LONG-LASTING INSECTICIDAL NET DEPLOYMENT ON INSECTICIDE RESISTANCE IN MALARIA VECTORS DURING A THREE-YEAR CLUSTER-RANDOMIZED CONTROLLED TRIAL IN TANZANIA

Mosha[3], Robert Kaaya[4], Oliva Moshi[4], Bethanie Pelloquin[2], Katherine Fullerton[2], Alphaxard Manjurano[3], Franklin W. Mosha[4], Thomas Walker[5], Mark Rowland[2], Manisha A. Kulkarni[6], Natacha Protopopoff[2]

[1]University of Nevada, Las Vegas, Las Vegas, NV, United States, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [4]Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of, [5]University of Warwick, Waarwick, United Kingdom, [6]University of Ottawa, Ottawa, ON, Canada

Insecticide resistance among malaria vector species is now a pervasive problem, which threatens to jeopardize global disease control efforts. Novel vector control tools, including long-lasting insecticidal nets (LLINs) incorporating new active ingredients (A.I.s), with different modes of action, are urgently needed to delay the evolution and spread of resistance.During a four-arm cluster-randomised controlled trial in Tanzania, evaluating the effectiveness of three dual-A.I. LLINs compared to pyrethroid-LLINs (PY-LLINs), we measured longitudinal phenotypic and genotypic insecticide resistance profiles among 47,258 female Anopheles mosquitoes collected over 36 months. In the PY-LLIN arm, a significant increase in alpha-cypermethrin and permethrin resistance intensity and concomitant decline in mortality, following exposure to the synergist PBO, was observed in An. funestus s.l. (the predominant vector species complex) over 24 months. A similar phenomenon was apparent in the pyriproxyfen-PY LLIN arm over three years, with the greatest escalation in resistance intensity evidenced in the PBO-PY LLIN arm. The chlorfenapyr-PY LLIN arm had no significant effect on pyrethroid resistance, supported by minimal reductions in chlorfenapyr susceptibility. By comparison, An. funestus s.l. populations displayed limited sterility following pyriproxyfen exposure. Highly over-expressed detoxification enzymes presented dynamic patterns of selection throughout the trial. Phenotypic data strengthened trial epidemiological findings; chlorfenapyr-PY LLINs provided superior protection from malaria across multiple transmission seasons, with little impact on insecticide resistance. Rapid fifty-fold pyrethroid resistance intensification in the PBO-PY LLIN arm and pre-existing tolerance of vector populations to pyriproxyfen in the trial site may explain the poorer performance of these two interventions on malaria outcomes. Ongoing work is elucidating potential mechanisms driving cross-resistance between pyrethroids and novel A.I.s, to better inform pragmatic design of resistance management schemes.

6440

WHOLE GENOME SEQUENCING AND RNASEQ IDENTIFIES POTENTIAL MOLECULAR MARKERS OF INSECTICIDE RESISTANCE WITHIN THE ANOPHELES GAMBIAE SPECIES COMPLEX

Juan Carlos Lol[1], Antoine Sanou[2], Marion Morris[3], Wasim Hussain[1], Hilary Ranson[3], **Victoria A. Ingham**[1]

[1]Heidelberg University Hospital, Heidelberg, Germany, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Liverpool School of Tropical, Liverpool, United Kingdom

The Anopheles gambiae species complex represents the major malaria vector species across the African continent. Insecticide-based vector control is the single most important tool in combating malaria, with insecticide treated bed nets being the most important intervention. All bed nets contain insecticides from the pyrethroid class leading to widespread insecticide resistance to these chemistries. Despite the importance of tracking the evolution and spread of new and described resistance mechanisms, the number of markers to track insecticide resistance in endemic settings are minimal. Here, we use whole genome sequencing on seven insecticide resistant colony populations from West Africa, a foci of intense insecticide resistance. Within this study 157 individual female mosquitoes from insecticide resistance An. coluzzii, An. gambiae and An. arabiensis were analysed. The results reveal evidence of shared haplotypes between An. arabiensis and An. coluzzii at loci putatively involved in insecticide resistance. Of particular note is evidence of the 'new' kdr mutation I1527T in An. arabiensis which was confirmed using TaqMan analysis. Further, a clear haplotype spanning the GSTE cluster was shared between An. arabiensis and several An. coluzzii populations, including four non-synonymous SNPs in GSTE1 and GSTE8. To determine the impact of these SNPs on pyrethroid resistance, two colonies were generated differing in this haplotype and changes to resistance scored. Finally, the availability of RNAseq data for these populations also allowed elucidation of potential eQTL markers linked with resistance loci.

6441

EFFICACY OF DUAL-ACTIVE INGREDIENT LONG-LASTING INSECTICIDAL NETS RELATIVE TO STANDARD NETS, AGAINST HIGHLY PYRETHROID-RESISTANT ANOPHELES MOSQUITOES IN TANZANIA: AN EXPERIMENTAL HUT TRIAL

Jackline L. Martin[1], Louisa Messenger[2], Franklin W Mosha[3], Nancy Matowo[4], Jacklin F Mosha[1], Mark Rowland[4], Manisha Kulkarni[5], Natacha Protopopoff[4]

[1]NIMR Mwanza, Mwanza, Tanzania, United Republic of, [2]Department of Environmental and Occupational Health, School of Public Health, University of Nevada, Las Vegas, NV, United States of America, Las vegas, FL, United States, [3]1Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, Moshi, Tanzania, United Republic of, [4]London School of Hygiene and Tropical, London, United Kingdom, London, United Kingdom, [5]University of Ottawa, Canada, Ottawa, ON, Canada

The global fight against malaria vectors has been threatened by widespread insecticide resistance across multiple chemical classes. There is a need for new vector control tools with different modes of action to combat the issue of resistance. This study aimed to evaluate the bio-efficacy of Olyset Plus (combining PBO and permethrin), Interceptor G2 (chlorfenapyr and alpha-cypermethrin), Royal Guard (pyriproxyfen and alpha-cypermethrin) long-lasting insecticidal nets (LLINs), compared to a standard pyrethroid-only net (Interceptor) across their operational lifespan in experimental hut trials. a total of thirty nets were withdrawn from the community at 12, 24 and 36 months, as part of a large-scale cluster-randomized controlled trial. Hole size and number were recorded. A Latin square design was used to rotate net type and sleepers between huts. The following morning mosquitoes were collected, and mortality monitored every day up to 72 hours. Live, blood fed female Anopheles at 72 hours, collected from the huts with Royal Guard, Interceptor and untreated nets were dissected to assess the effect of pyriproxyfen on egg development. Interceptor G2 LLIN induced significant superior 72-hour mortality compared to standard LLINs at 12 months (43% vs 13%); 24-hour mortality was also higher with Royal Guard LLINs compared to standard LLINs (21% vs 13%), and marginally higher also with Olyset Plus (19%). Seventy-two-hour mortality was still slightly higher at 24 months for Interceptor G2 LLINs compared to standard LLIN (24% vs 11%). None of the other nets showed higher mortality at 24 months. The effect of the second active ingredient or synergist was not observed at 36 months for any of the LLINs. The effect of pyriproxyfen on Anopheles mortality was not observed at any of the time point. All dual active ingredient (dual-A.I.) LLINs performed better than standard Interceptor nets up to 12 months of field use.

EVIDENCE SUPPORTING DEPLOYMENT OF NEXT GENERATION INSECTICIDE TREATED NETS IN BURKINA FASO: BIOASSAYS WITH CHLORFENAPYR AND PIPERONYL BUTOXIDE INCREASE MORTALITY OF PYRETHROID-RESISTANT ANOPHELES GAMBIAE

Aristide S. Hien[1], Dieudonné Diloma Soma[2], Adama Koné[3], Birame Mame Diouf[4], Sheila Barasa Ogoma[5], Allison Belemvire[6], Djenam Jacob[5], Roch Kounbobr Dabiré[1]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]Institut de Recherche en Sciences de la Santé / UNB, Bobo-Dioulasso, Burkina Faso, [3]PMI VectorLink Project, Abt Associates, Ouagadougou, Burkina Faso, [4]US President's Malaria Initiative, US Agency for International Development, Ouagadougou, Burkina Faso, [5]PMI VectorLink Project, Abt Associates Inc, Rockville, MD, United States, [6]US President's Malaria Initiative, US Agency for International Development, Washington, DC, United States

Before deploying alternative insecticide treated nets (ITNs) on a large scale, it is crucial to characterize the resistance profiles of primary malaria vector species for evidence-based decision making. Anopheles gambiae (s.l.) were collected in 2020 from 15 sites located throughout Burkina Faso for synergist and WHO bottle bioassays with chlorfenapyr at a dose of 100µg/bottle. An. gambiae s.l. were found resistant to all pyrethroid insecticides in all sites. The piperonyl butoxide synergist (PBO) pre-exposure followed by deltamethrin restored full susceptibility in one site. The PBO pre-exposure followed by permethrin partially restored susceptibility in 12 sites. There was no significant increase in permethrin mortality after PBO pre-exposure in 3 out of 15 sites; while in Seguenega, Orodara and Bobo-Dioulasso there was a significant increase in mortality. Susceptibility to chlorfenapyr was confirmed in 14 sites. Based on these results, PBO+deltamethrin ITNs would likely provide greater protection than pyrethroid only nets. Since susceptibility in bioassays was not restored in most sites following pre-exposure to PBO, chlorfenapyr ITNs may likely provide greater protection as susceptibility was recorded to chlorfenapyr in nearly all sites. This study provides evidence supporting the 2019 mass distribution of next generation ITNs, such as Interceptor G2 nets and PBO nets, rather than pyrethroid only ITNs

PHENOTYPIC RESISTANCE TO PYRETHROID ASSOCIATED TO METABOLIC MECHANISM IN VGSC-L995F RESISTANT-ANOPHELES GAMBIAE MALARIA MOSQUITOES

France Paraudie A. Kouadio[1], Angele N. Sika[2], Behi K. Fodjo[1], Christabelle G. Sadia[1], Sébastien K. Oyou[3], Allassane F. Ouattara[1], Chouaïbou S. Mouhamadou[3]

[1]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Université Nangui Abrogoua, Abidjan, Côte D'Ivoire, [2]Université Nangui Abrogoua, Abidjan, Côte D'Ivoire, [3]Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire

The indiscriminate use of insecticides in agriculture and public health lead to a selection of resistance mechanisms in malaria vectors compromising vector control tools and strategies. This study investigated the metabolic response in the Vgsc-L995F Anopheles gambiae Tiassalé resistance strain after long-term exposure of larvae and adults to deltamethrin insecticide. We exposed, over 20 generations, Vgsc-L995F An. gambiae Tiassalé strain larvae to deltamethrin (LS) and adults to PermaNet 2.0 (AS) and combining exposure at larvae and adult stages (LAS) and compared to unexposed (NS) group. All four groups were subjected to the standard World Health Organization (WHO) susceptibility tube tests using deltamethrin (0.05%), bendiocarb (0.1%) and malathion (5%). Vgsc-L995F/S knockdown-resistance (kdr) mutation frequency was screened using multiplex assays based on TaqMan real-time polymerase chain reaction (PCR) method. Additionally, expression levels of detoxification enzymes associated to pyrethroid resistance, including CYP4G16, CYP6M2, CYP6P1, CYP6P3, CYP6P4, CYP6Z1 and CYP9K1, and glutathione S-transferase GSTe2 were measured. Our results indicated that deltamethrin resistance was a response to insecticide selection pressure in LS, AS and LAS groups, while susceptibility was observed in NS group. The vectors showed varied mortality rates with bendiocarb and full susceptibility to malathion throughout the selection with LS, AS and LAS groups. Vgsc-L995F mutation stayed at high allelic frequency level in all groups with a frequency between 87% and 100%. Among the overexpressed genes, CYP6P4 gene was the most overexpressed in LS, AS and LAS groups. Long-term exposure of larvae and adults of Vgsc-L995F resistant-An. gambiae Tiassalé strain to deltamethrin and PermaNet 2.0 net induced resistance to deltamethrin under a significant effect of cytochromes P450 detoxification enzymes. These outcomes highlights the necessity of investigating metabolic resistance mechanisms in the target population and not solely kdr resistance mechanisms prior the implementation of vector control strategies for a better impact.

Chlorfenapyr (CFP) has shown great promise at controlling pyrethroid-resistant malaria vectors, but its sustained use can be threatened by the evolution of CFP resistance. An understanding of how CFP interacts with other insecticides used in vector control and the molecular basis of CFP resistance is needed to achieve successful malaria control. Here, we assessed the resistance status of the major malaria vectors to CFP across Africa and performed RNA-seq to detect the major genes conferring CFP resistance. Resistance to CFP (100µg/ml) was detected in Anopheles gambiae populations from DRC (Kinshasa) (mortality rate: 64.3 ± 7.1%), Ghana (Obuasi) (65.9 ± 7.4%), and Cameroon (Mangoum ;75.2±7.7% and Nkolondom; 86.1 ± 7.4) whereas all An. funestus populations were fully susceptible. After RNA-seq, commun metabolic genes ussually associated with pyrethroid resistance (e.g: CYPs, GSTs···) were down-regulated in CFP-resistant samples compared to the susceptible lab-strain Kisumu. Carboxylesterases and transcriptions factors were among the predominant over-expressed genes in CFP-resistant mosquitoes with fixed mutations detected and reduced susceptibility observed in the resistant strain. Also, a negative association was observed between the L1014F-kdr mutation and CFP resistance with a greater frequency of homozygote-resistant mosquitoes among the dead after exposure compared to alive (OR=0.5; P=0.02).This study reveals a greater risk of CFP resistance in An. gambiae populations than in An. funestus although most pyrethroid-resistant individuals were more vulnerable to this insecticide. Ongoing functional validation will help to establish the contribution of carboxylesterases and other transcription factors or P450/GST's suppressors to CFP resistance and to design a DNA-based diagnostic tool for the rapid detection and monitoring of the resistant markers in the field. This will help preserve the efficacy of chlorfenapyr-based control interventions such as Interceptor G2 which is currently largely distributed across Africa for malaria control.

6445

INSECTICIDE RESISTANCE AND WHOLE TRANSCRIPTOME PROFILES OF ANOPHELES FUNESTUS POPULATION IN WESTERN KENYA

Isaiah Debrah[1], Daibin Zhong[2], Linda E. Amoah[3], Andrew K. Githeko[4], Yaw A. Afrane[5], Guiyun Yan[2]

[1]West African Centre for Cell Biology of Infectious Pathogens (WACCBIP),University of Ghana, Accra, Ghana, [2]University of California, Irvine, CA, United States, [3]Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, [4]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [5]Department of Medical Microbiology, University of Ghana Medical School, Accra, Ghana

Anopheles funestus is an efficient vector of Plasmodium falciparum malaria in Africa. The resurgence of An. funestus in western Kenya was partly attributed to insecticide resistance. However, there is a limited body of evidence on the molecular basis of pyrethroid resistance in western Kenya. Indoor resting An. funestus mosquitoes were collected by aspiration in Bungoma, Teso, Siaya, Port Victoria and Kombewa in western Kenya. The F1 progenies were exposed to deltamethrin (0.05%), permethrin (0.75%), DDT (4%) and pirimiphos-methyl (0.25%) following WHO guidelines for insecticide susceptibility test. A synergist bioassay using Piperonyl butoxide (PBO) (4%) was conducted to determine cytochrome P450s role in pyrethroid resistance. Illumina RNA-seq was performed on a pool of specimens which were 1) Resistant, 2) susceptible and 3) unexposed to unveil the molecular mechanisms of pyrethroid resistance. Pyrethroid resistance was observed in all the sites with a mortality rate (MR) ranging from 11% to 87%). Port Victoria had the highest level of resistance to permethrin (MR=53%, n=217) and deltamethrin (MR=11%, n=100) pyrethroids. Teso had the lowest level of resistance to permethrin (MR=70%, n=100) and deltamethrin (MR=87%, n=100). Resistance to DDT was observed only in Kombewa (MR=89%, n=100) and Port Victoria (MR=85%, n=100). A full susceptibility to pirimiphos- methyl (0.25%) was observed in all the sites. PBO synergist assay revealed high susceptibility (>98%) to the pyrethroids in all the sites except for Port Victoria (MR=96%, n=100). Whole transcriptomic analysis revealed that the main enzyme families associated with pyrethroid resistance are cytochrome P450s, GSTs, COEs, cuticular proteins and salivary gland proteins. The highly upregulated genes include P450s (CYP4H18, CYP4H17, CYP9J3, CYP4G16, CYP6Y1, CYP18A1, AFUN008357, CYP4D17, AFUN019401 and CYP4C25), GSTs (GSTE2, GSTE1, GSTE5, GSTU2, GSTU3 and GSTD6), and others (AFUN002514, AFUN010203, AFUN016508, AFUN000373 and AFUN001273). This study unveils novel insights into the molecular mechanisms underlying the pyrethroid resistance of An. funestus in western Kenya.

6446

THE THREE-DIMENSIONAL APPROACHES BY MULTIPLE CORRESPONDENCE ANALYSIS CAN DIFFERENTIATE LEPROSY DISEASE STATES AND HOUSEHOLD CONTACTS WITH HIGH ACCURACY

Pedro Marcal[1], Marcio Souza[1], Rafael Gama[2], Lorena Oliveira[2], Marcos Pinheiro[1], Thalisson Gomides[2], Heloine Leite[1], Suely Rodrigues[2], Marileny Brandao[2], Leonardo Silva[2], Roberta Pinheiro[3], Jessica Fairley[4], Lucia Fraga[1]

[1]Universidade Federal de Juiz de Fora (UFJF-Campus GV/PMBqBM), Governador Valadares, Brazil, [2]Universidade Vale do Rio Doce - Univale, Governador Valadares, Brazil, [3]Fundacao Oswaldo Cruz - FIOCRUZ/RJ, Rio de Janeiro, Brazil, [4]Emory University, Atlanta, GA, United States

The development of clinical leprosy is multifactorial; however, there are still gaps in our knowledge about risk factors and predictors of disease. Multiple Correspondence Analysis (MCA) is a statistical tool that can characterize associations between immunologic and sociodemographic parameters and the presence/absence of M. leprae infection. MCA works based on the reduction of dimensionality and considers each variable as a dimension of space. We conducted MCA on data from 101 participants from Minas Gerais, Brazil: 14 paucibacillary leprosy [L(PB)], 14 multibacillary leprosy [L(MB)], 42 household contacts of PB disease HHC(PB), and 31 household contacts of MB disease HHC(MB). Blood was collected for cytokine measurement and interviews were done to obtain demographic data. The MCA allowed for the disposition and association of laboratory and sociodemographic variables in the Euclidean space with two Dimensions representing more than 40% of the total variability of parameters (Dimension 1 [DM1 = 28.73%, x axis] and Dimension 2 [DM2 = 15.36%, y axis]. Cytokines production from M.leprae-stimulated culture allowed for better discrimination of the study groups, by showing defined clusters according to the operational classification of each group. The cytokine IFN-γ was more associated with (Dim2), as was the L(PB) group (y-axis associated). On the other hand, cytokines IL-4 and IL-10 were more related to (Dim1), in the same way as the L(MB) group, the x-axis associated group. Using these associations, the mathematical model then classified the individuals with an accuracy of 0.8317. The sensitivity and specificity for L(PB) (0.7778, 1.00); L(MB) (0.8333, 0.9550); HHC(PB) (0.8409, 0.9123); and HHC(MB) (0.8519, 0.8919) were respectively, established. By incorporating immunological and demographic parameters in an advanced model, MCA allowed for the classification of leprosy cases and contacts with high sensitivity and specificity. Consequently, this approach holds promise for using these statistical models for predicting disease and complementing clinical diagnosis.

LEPTOSPIROSIS SEROPREVALENCE AND RISK FACTORS AMONG SLAUGHTERHOUSE WORKERS IN BURKINA FASO

Sylvie Zida[1], Henri Gautier Ouédraogo[1], Tegwinde Rebeca Compaoré[1], Tani Sagna[1], Serge Théophile Soubeiga[1], Bienvenu Banhoro[1], Abdou Azaque Zouré[1], Dinanibè Kambiré[1], Amadou Dicko[2], Elsio A. Wunder Jr.[3], Seni Kouanda[1]

[1]Institut de Recherche en Sciences de la Santé (IRSS), Ouagadougou, Burkina Faso, [2]Centre Muraz, Bobo Dioulasso, Burkina Faso, [3]3Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States

Leptospirosis is an occupational disease affecting risk groups that are exposed to animal reservoirs. Given the general lack of awareness of the disease and difficulties in its diagnosis, the epidemiological status of human leptospirosis in Burkina Faso has not been well defined. The objective of this study was to determine the seroprevalence and risk factors of leptospirosis among slaughterhouse workers in Burkina Faso. We have performed a cross-sectional survey of slaughterhouse workers from Ouagadougou and Bobo Dioulasso between March and April 2021. Questionnaires were used to collect information from these workers on socio-demographic characteristics, work activities, knowledge of zoonotic diseases, and risk behaviors. Blood was collected by venipuncture and serum samples were tested for leptospirosis using Enzyme-Linked Immuno Assay (ELISA): “SERION ELISA classic Leptospira IgG and IgM”, and Microscopic Agglutination Test (MAT). Of the 172 subjects investigated, 28 (16.28%) were found positive for leptospirosis using ELISA or MAT. The main Leptospira infecting serogroups were: Mini, Autumnalis, Canicola, Copenhageni, L. mayottensis (ND), Icterohaemorrhagiae, Pyrogenes/ Tarassovi (cross reaction), Panama, and Ballum. Risk factors included: residence in Bobo Dioulasso (Odds Ratio ajusté: ORa=2.53; 95% CI: 1.11-15.00; p = 0.02), working at the bleeding station (ORa=5.51; 95% CI: 1.19-29.5; p = 0.03), contact with feces and urine (ORa=2.50; 95% CI: 0.97-6.65; p = 0.04), and the practice of agriculture outside the slaughterhouse (ORa=4.28; 95% CI: 0.79-20.80; p = 0.05). However, working at the stunning station (ORa=3.57; 95% CI: 0.79-15.00; p = 0.08) had a higher risk of Leptospira seropositivity without statistical significance. These findings indicate that a significant proportion of slaughterhouse workers is being exposed to pathogenic Leptospira. Public-health interventions against leptospirosis are needed to target this occupational group.

6448

LEPTOSPIROSIS OUTBREAK AFTER HURRICANE FIONA, PUERTO RICO, 2022

Forrest Kirby Jones[1], Abigail G. Medina[2], Kyle R. Ryff[2], Jessica Irizarry-Ramos[3], Joshua M. Wong[1], Eduardo O'Neill[3], Ismael A. Rodríguez[2], Alfonso C. Hernandez-Romieu[1], Maile T. Phillips[1], Michael A. Johansson[1], Tesfaye Bayleyegn[1], Christine Atherstone[4], Katherine R. Debord[4], Maria E. Negron[4], Renee Galloway[4], Laura E. Adams[1], Melissa Marzan-Rodriguez[2]

[1]CDC Dengue Branch, San Juan, PR, United States, [2]Puerto Rico Department of Health, San Juan, PR, United States, [3]CDC Office of Island Affairs, San Juan, PR, United States, [4]CDC Bacterial Special Pathogens Branch, Atlanta, GA, United States

Leptospirosis is a bacterial disease endemic to Puerto Rico, which reported 51% of all cases nationally during 2016-2019 and historically reported increased cases after hurricanes. On September 18, 2022, Hurricane Fiona hit Puerto Rico, leading to major flooding. In response, we investigated leptospirosis cases and characterized temporal and spatial patterns. The Puerto Rico Department of Health expanded leptospirosis laboratory testing, increased messaging to providers, and used existing surveillance to investigate cases reported with clinical suspicion for leptospirosis. Confirmed cases had a positive PCR result for pathogenic Leptospira, probable cases only had a positive IgM result, and suspected cases had negative or no laboratory results. We compared cases in the 37 weeks before Hurricane Fiona (January 2-September 17, 2022) and during the 11 weeks after Hurricane Fiona (September 18-December 3, 2022). Before Hurricane Fiona, 173 leptospirosis cases were reported including 16 (10%) confirmed, 90 (52%) probable, and 67 (38%) suspected cases. After Hurricane Fiona, 743 cases were reported, including 31 (4%) confirmed, 84 (12%) probable, and 628 (84%) suspected cases; median age was 41 (interquartile range: 25-59) years, 486 (65%) were male, 375 (50%) were hospitalized, and 6 (1%) died. After Hurricane Fiona, the mean weekly number of confirmed or probable cases was 10.5, 3.6 (95% CI: 2.5-5.3) times higher than before (2.9 cases). Confirmed and probable cases were identified in 42/78 (54%) municipalities before Hurricane Fiona versus 47/78 (60%) municipalities after; 32 municipalities reported cases in both periods. For both periods, the four municipalities with the highest attack rates were western inland municipalities. We identified an outbreak of leptospirosis that lasted >2 months after Hurricane Fiona, using existing surveillance built after previous hurricanes. In endemic areas, health departments should reinforce leptospirosis surveillance and increase clinician awareness, particularly during hurricane season.

OCULAR CHLAMYDIA TRACHOMATIS INFECTION MONITORING WITHIN DISTRICT-LEVEL TRACHOMA IMPACT AND SURVEILLANCE SURVEYS: RESULTS AND LESSONS LEARNED 2018-2021

Scott D. Nash[1], Ambahun Chernet[2], Eshetu Sata[2], Mulat Zerihun[2], Demelash Gessese[2], Kimberly A. Jensen[1], Zebene Ayele[2], Berhanu Melak[2], Taye Zeru[3], Gizachew Yismaw[3], Abdulkerim Mengistu[4], Adisu Abebe[4], Fikre Seife[5], Zerihun Tadesse[2], E. Kelly Callahan[1]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center, Addis Ababa, Ethiopia, [3]Amhara Public Health Institute, Bahir Dar, Ethiopia, [4]Amhara Regional Health Bureau, Bahir Dar, Ethiopia, [5]Ministry of Health, Addis Ababa, Ethiopia

A World Health Organization (WHO) report has recently recommended monitoring for ocular Chlamydia trachomatis (Ct) infection within districts experiencing persistent trachoma. The Trachoma Control Program in Amhara, Ethiopia, has monitored ocular Ct since 2011 to provide prevalence data at the zonal and regional levels. Beginning in 2018, the Program has focused on collecting Ct data to generate district level estimates with the aim of better understanding infection patterns within trachoma persistent districts. Trachoma impact surveys (TIS) and trachoma surveillance surveys (TSS) conducted in the Amhara Region of Ethiopia as part of this study were population-based, multi-stage cluster random surveys. Persistent districts were defined as having ≥2 trachoma impact surveys (TIS2) with a trachomatous inflammation-follicular (TF) ≥5%. Following a household questionnaire, certified graders assessed participants for trachoma signs using the WHO simplified grading system. After grading, children ages 1-5 years were swabbed for infection. All samples were pooled 5 samples to 1 pool and tested using the Abbott Real Time PCR at the Amhara Public Health Institute. Between 2018 and 2021, Ct monitoring was included in 35 TIS and 4 TSS. Among the TIS districts, 34/35 were considered persistent districts (16 TIS2, 17 TIS3, 1 TIS5). A total of 17,534 children ages 1-5 years were swabbed in 1170 communities. Among TIS districts, the TF ranged from 4.1% to 42.6%, and the trachomatous inflammation-intense (TI) ranged from 0.05% to 6.6%. The mean, standard deviation (SD) and range of Ct infection among TIS districts overall was 6.0% (6.8), 0-34.4%, while among districts with TF ≥30% it was 15.2% (10.2), 7.1-34.4%. Among the 4 TSS, 2 districts had Ct infection, 1 district with TF <5% (Ct=1.2%) and 1 district with TF ≥5% (Ct=2.2%). Across all 39 districts, the correlation between Ct and both TF (r=.67) and TI (r=.72) was high. Considerable Ct infection was present among trachoma persistent districts in Amhara. The experience from Amhara demonstrated that with the proper systems and processes in place, monitoring Ct infection at a programmatic scale is possible.

PHOTOGRAPHIC GRADING OF TRACHOMATOUS SCARRING AMONG ADULTS IN TRACHOMA ENDEMIC AMHARA REGION OF ETHIOPIA

Jaymie A. Bromfield[1], Ugochi T. Aguwa[2], Kimberly A. Jensen[1], Fetene Mihretu[3], Eshetu Sata[3], Meraf Wolle[2], E. Kelly Callahan[1], Sheila K. West[2], Scott D. Nash[1]

[1]The Carter Center, Atlanta, GA, United States, [2]Dana Center for Preventative Ophthalmology, Wilmer Eye Institute, Johns Hopkins Hospital, Baltimore, MD, United States, [3]The Carter Center, Addis Ababa, Ethiopia

Trachomatous scarring has been shown to progress regardless of active Chlamydia trachomatis infection, indicating that drivers may be unrelated to ongoing transmission. Scarring prevalence has been associated with older age, and women are more likely to develop signs of severe trachoma such as entropion and trichiasis. This study aimed to characterize the magnitude of scarring in a trachoma endemic setting using a validated 5-point severity scale and to elucidate contributing factors to different stages of scarring. This analysis used conjunctival photographs collected during trachoma impact surveys conducted in 2017 within Amhara, Ethiopia. Photographs of left and right upper tarsal conjunctiva of adults (ages >15 years) in 10 survey districts were collected by a trained photographer. Two graders, trained at Johns Hopkins Hospital and masked to each other's scores, examined each photograph for signs of scarring to record eye-level data based on a 5-point severity scale. Concordant grades were aggregated to the participant level. Discordant grades were adjudicated by another experienced grader. Scarring scores were generated for 729 individuals and 19 individuals were excluded due to poor photograph quality. The mean age of the sample was 38 years and 62.8% were female. Overall, most cases (19.9%) fell within the highest level of scarring category (S4), categorized as scarring comprising more than 90% of the upper tarsal conjunctiva, compared to the prevalence of S3a and b (11%), S2 (8%), and S1 (18.8%). Scarring at every stage was observed among the youngest age group (15-19 years old). Older participants, particularly those over age 60 years, experienced a greater burden of scarring than their younger counterparts, with an S4 prevalence reaching 32.6%. While early stages of scarring were more comparable between women and men, the prevalence of severe scarring (S4) among women was 1.74 times the prevalence observed among men (CI: 1.14-2.7, p<0.01). The prevalence of trachomatous scarring, and its potential for progression to trichiasis, may prove a considerable barrier to achieving the elimination of trachoma as a public health problem.

6451

IMPACT OF PARTNERS IN SCALING UP THE PREVENTION OF BLINDNESS FROM TRACHOMA IN SOUTH SUDAN

Kenneth Ladu Lino Sube[1], Lubari Loro[2], Joseph Lako[3]

[1]College of Medicine, University of Juba, Juba, South Sudan, [2]Christian Blind Mission, Juba, South Sudan, [3]South University of Medicine, Science and Technology, Juba, South Sudan

South Sudan has one of the region's most significant burdens of Neglected Tropical Diseases (NTDs). Out of the 17 NTDs identified by the World Health Organization (WHO), South Sudan harbors 13. Trachoma, an infectious disease caused by Chlamydia trachomatis, is one of the causative agents of preventable, irreversible blindness worldwide. The Ministry of Health (MoH) engaged and collaborated with partners in trachoma surveys, mass drug administration, and trachomatous trichiasis (TT) surgeries to eradicate trachoma. One of the strategies to eliminate trachoma is developing a system that can identify and manage incident TT cases and have the financial resources to implement these strategies. To show the results of the collaborative efforts of the MoH with partners in reducing the backlog of TT in some of the endemic areas, we reviewed the data collected in areas where activities had been conducted by Christian Blind Mission (CBM) project in Unity State (UNS) in Mayom county and Ruweng Administrative Area (RAA) in Abiemnom county, and the Ophthalmological Association of South Sudan (OASS) in Jonglei State (JS) in Old Fangak, Ayod, Akobo, and Waat counties). Out of the 9,632 patients who attended the trachoma program services, 59.5% (5,728) were from JS, 31% (2,988) from RAA, and 9.5% (916) from UNS. TT cases were 21.7% (2,094) of the screened cases, in which the majority, 49.7% (291), were from JS, 36.4% (762) from RAA, and 13.9% (291) from UNS. In addition, a total of 54.3% (2,272) underwent trachoma lid correction surgery, with 53.6% (1,055) in JS, 25.3% (576) in RAA, and 21.1% (479) in UNS. The number of males and females who received eyelid surgery was 74.5% (1,713) and 25.5% (579), respectively. Through collaborative efforts with partners, the MoH has reached a milestone in increasing access to TT surgeries to prevent corneal scarring and irreversible blindness in the affected regions. Urgent scaling up of the program is needed in the endemic/hyper-endemic states with the involvement of different partners, using integrated approaches, capacity building, and community initiatives to reach the global elimination targets for trachoma in South Sudan.

AN RNA VACCINE FOR PLAGUE

R. Shattock[1], V. Andrianaivoarimanana[2], **M. Rajerison**[2], L. Randriantseheno[2], K. Moore[3], R.V d'Elia[3], T.R Laws[3], J.L Prior[3], E.D Williamson[3]

[1]Dept of Infectious Disease, Imperial College London, United Kingdom, [2]Institut Pasteur de Madagascar, Tananarive, Madagascar, [3]CBR Division, Dstl Porton Down UK, United Kingdom

Plague is a dangerous zoonotic disease which can present in two forms: bubonic and pneumonic. The death rate is 50 to 70 % for the bubonic form and can reach 100 % for the pneumonic form if not treated properly. Despite the threat that this disease poses, no approved vaccine is currently available for prevention. Self-amplifying RNA vaccine for F1 and V antigen of Yersinia pestis were prepared, formulated in 20 % v/v alhydrogel and tested on mice model. Groups of OF1 mice (8/group) were immunized by the intra-muscular route with the saRNA vaccine at 1 µg (group 1 and 4) and 5 µg (group 2 and 5) using 2 immunizations (at day 0, then boost dose at day 28). Results were then compared to a positive control those immunized with a reference vaccine (group 6) and the negative controls which consisted of the injection of equivalent doses of irrelevant RNA in LNP (group 3 and 7) or 20 % v/v alhydrogel (group 8). Immunized mice were challenged with Y. pestis at day 56 (28 days post-boost) at doses of 180 or 1800 cfu and monitored for 14 days. Spontaneous deaths not related to vaccine dose-level and to plague were observed in group 1, 2 , 4, 7 and 8 (1death/group). RNA vaccine protected 5 of 7 mice at either 1µg or 5µg for both of the challenge doses compared to just 1 survivor in the negative control groups (group 3, 7 and 8) and to the reference vaccine which protected 7 out of 8 mice for the challenge at 1800 cfu. Post-mortem culture of the survivor's spleen on CIN agar and BHI broth were negative for Y. pestis. SaRNA vaccine showed protective effect against plague in these preliminary results giving this approach a potential for further development.

A SALIVA-BASED, DNA-EXTRACTION-FREE APPROACH FOR THE MOLECULAR DETECTION OF STREPTOCOCCUS PNEUMONIAE

Tzu-Yi Lin, Chikondi Peno, Maikel Stefano Hislop, Amy Bei, Anne L. Wyllie

Yale School of Public Health, New Haven, CT, United States

Streptococcus pneumoniae is a common cause of severe diseases including meningitis, pneumonia, and sepsis. Pneumococcal carriage is a prerequisite for pneumococcal disease and surveillance is crucial for evaluating the performance of current vaccines and informing new vaccination strategies. In recent years, molecular methods have improved the sensitivity of pneumococcal carriage detection as compared to the gold standard culture-based method. However, nucleic acid extraction from samples collected is resource-intensive, limiting scalability for extensive surveillance particularly in low-resource settings. We previously developed a saliva-based PCR test for SARS-CoV-2, having identified that nucleic acid extraction can be omitted and replaced with a simple enzymatic lysis or heat treatment step without compromising the accuracy and efficiency of testing. Here, we compared pneumococcus detection in saliva samples collected weekly from an observational longitudinal study in childcare centers in New Haven (CT, USA), using our standard protocol (culture-enrichment followed by DNA extraction) and a DNA extraction-free protocol (addition of proteinase K then incubation at 95°C for 5 min). The presence of pneumococcus was determined by qPCR detection of pneumococcal genes, piaB and lytA, when Ct values <40 for both targets. A total of 754 saliva samples were collected from 92 children (median age 3.65 years; IQR:2.46-4.78). Pneumococcus was detected in 356 (47.2%) samples by the extraction-free protocol and in 367 (48.7%) samples by the culture-enrichment protocol. There was a substantial agreement (Cohen's kappa: 0.62) and a high Ct-value correlation (r=0.92) between the two methods, though the extraction-free protocol reported lower bacterial loads (ΔCt -3.16, $p<0.05$). Our findings suggest that this DNA-extraction-free protocol offers a cost-effective alternative to the resource-intensive culture-enrichment method for pneumococcal carriage detection and offers a sustainable approach for pneumococcal carriage surveillance particularly in resource-limited settings.

PNEUMOCOCCAL CARRIAGE IN THE SAHEL REGION OF BURKINA FASO BEFORE A 13 VALENT PNEUMOCOCCAL CONJUGATE VACCINATION CAMPAIGN

Zoma L. Robert[1], Issa Ouedraogo[2], Lana Childs[3], Guetwendé Sawadogo[1], T. Félix Tarbangdo[1], Aristide Zoma[4], Soufiane Sanou[4], Brice Bicaba[5], Simon Sanou[5], Lesley McGee[6], Miwako Kobayashi[6], Jennifer R. Verani[6], Flavien H. AKE[1], Mahamoudou Ouattara[6]

[1]Davycas International, Ouagadougou, Burkina Faso, [2]Ministry of health, Ouagadougou, Burkina Faso, [3]National Foundation for the Centers for Disease Control and Prevention, Inc., Atlanta, GA,, GA, United States, [4]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [5]Centre des Operations de Réponse aux Urgences Sanitaires, Ouagadougou, Burkina Faso, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States

Burkina Faso introduced 13-valent pneumococcal conjugate vaccine (PCV13) among infants in 2013 and subsequently achieved more than 90% three-dose coverage nationally. PCV13 coverage in the Sahel region has been substantially lower due to an ongoing security crisis, resulting in reduced access to health services and an increased number of internally displaced persons. In 2022, a PCV13 catch-up campaign was conducted among children aged 9-59 months in the Dori and Gorom-Gorom districts of the Sahel region. We conducted a cross-sectional, age-stratified

pneumococcal carriage study in Dori to describe vaccine-type (VT) carriage before the catch-up campaign. Healthy individuals were recruited into five age groups: 1 month to less than 1 year, 1 year, 2-4 years, 5-14 years, and more than 15 years. We collected nasopharyngeal swabs (participants of all ages) and oropharyngeal swabs (participants age more than 5 years). Each swab was immediately placed in a cryotube containing skim milk, tryptone, glucose, and glycerol, vortexed, and frozen at -80°C until laboratory analysis. Pneumococcal carriage was determined by culture and isolated pneumococci were serotyped by polymerase chain reaction. For this analysis, any serogroups containing PCV13 serotypes were considered VT strains. We evaluated preliminary overall and VT carriage and serotype distribution by age group. Among 1080 participants, overall pneumococcal carriage was 60%; carriage was highest among children 1 year of age (77%) and lowest among participants more than 15 years (32%). VT carriage ranged from 14% (31/217) to 17% (37/215) in the age groups less than 15 years and was 7% (14/213) in participants more than 15 years. Among 691 pneumococcal isolates from all ages, the most common VT were 6A/6B/6C/6D (9%) and 19F (4%); the most common non-VT were 11A/11D (6%) and 21 (6%). These results will serve as the baseline for assessing the impact of the catch-up campaign through future carriage studies and will help inform future strategies to reduce VT carriage in settings with low vaccine coverage and disrupted health services.

6455

PNEUMOCOCCAL CARRIAGE AND CHANGES IN SEROTYPE DISTRIBUTION AFTER A SWITCH FROM PCV10 TO PCV13 IN CHILDREN IN A RURAL SITE IN MATIARI, PAKISTAN

Shahira Shahid, Izn Iqbal, Samiah Kanwar, Furqan Kabir, Sheraz Ahmed, Aneeta Hotwani, Sehrish Munir, Muhammad Farrukh Qazi, Fyezah Jehan, Muhammad Imran Nisar

Aga Khan University, Karachi, Pakistan

In 2021, the 10-valent Pneumococcal conjugate vaccine (PCV10) was replaced with the 13-valent in Pakistan's Expanded Program on Immunization. We aim to study the effect of the switch from PCV10 to PCV13 on the nasopharyngeal carriage in the same population carriage in children under 2 years of age in Pakistan. Children< 2 years were randomly selected from a line listing in two rural union councils of Matiari, Sindh, Pakistan. Nasopharyngeal swabs were collected using standard WHO guidelines by trained staff and were processed at Infectious Disease Research Laboratory at The Aga Khan University, Karachi using culture on sheep blood agar. Whole genome sequencing (WGS) was performed on culture-positive isolates. Analysis was done using Pathogenwatch. The serotypes were then classified as either vaccine type (VT) or non-vaccine type (NVT). Of the 200 children enrolled, pneumococcal isolates were detected in 140 (70%). However, WGS could only be performed in 100 isolates. The proportion of children who had received all 3 doses of PCV13 was 55.0%. Overall carriage remained similar when compared to the pre-PCV13 data from 2018 (70% vs 72.8%). PCV13-specific serotype carriage decreased from 16.6% in 2017/18 to only 5% in the current survey. Thus, we saw a rapid decline in PCV13-specific serotype 18 months after switch to PCV13 from PCV10 with modest vaccine coverage. Most of this decline could be attributed to decrease in serotype 19A. Epidemiology of the prevalent serotypes in a population is extremely useful to guide vaccine introduction in a country.

ANTIBIOTIC USE AMONG ADULT PATIENTS WITH SEVERE ACUTE RESPIRATORY INFECTION IN TERTIARY LEVEL HOSPITALS ACCORDING TO THE WHO ACCESS, WATCH, AND RESERVE (AWARE) CLASSIFICATION IN BANGLADESH

Fahmida Chowdhury, Md. Ariful Islam, Tanzir Ahmed Shuvo, Md. Kaousar Ahmmed, Probir Kumar Kumar Ghosh, Syeda Mah-E-Muneer Mah-E- Muneer, Md. Zakiul Hassan

icddr,b, Dhaka, Bangladesh

Acute respiratory infections, often caused by viruses, are a leading cause of antibiotic use contributing the exponential growth of antimicrobial resistance. To promote rational antibiotic use, the world health organization (WHO) introduced Access, Watch, and Reserve (AWaRe) classification system. We investigated antibiotic use among adult patients with severe acute respiratory infection (SARI) according to the AWaRe classification in Bangladesh. We analyzed data for adult (≥18 years) SARI patients collected during January 2013-December 2022 from the hospital-based influenza surveillance platform at nine tertiary-level hospitals in Bangladesh. Surveillance physicians identified inpatients meeting the WHO-SARI case definition and recorded patient demographics, and antibiotics received during hospitalization. Surveillance tested nasopharyngeal swabs for influenza by rRT-PCR. We used descriptive statistics to summarize the data. We enrolled 17,358 adult SARI patients [median age: 45 years (IQR: 30-60); 64% male]. Of them, 3,045 (18%) had influenza. Of enrolled patients, 14,989 (86%) received at least one antibiotic and 22% received >1 different course of antibiotics. Around 2,547 (84%) patient with lab-confirmed influenza received antibiotics. Most of the antibiotics prescribed were from Watch group (12,149; 81%) followed by Access group (4,791; 32%) and none received Reserve group of antibiotics. The most frequently used antibiotics were ceftriaxone (7,427; 40%), followed by amoxicillin+clavulanic acid (3,823, 21%), azithromycin (2,757, 15%), clarithromycin (1,470, 8%) and cefuroxime (645, 4%). Among these frequently used antibiotics all were from Watch group except amoxicillin+clavulanic which is not recommended by WHO for clinical use. Over four of five adult SARI patients received antibiotics despite a confirmed viral etiology indicating irrational antibiotic use. Predominant use of Watch group antibiotics is also concerning. Strengthening hospital antimicrobial stewardship programs can reduce inappropriate antibiotic use and help mitigating antimicrobial resistance.

PREVALENCE OF SOIL-TRANSMITTED HELMINTH CO-INFECTION AMONG PERSONS WITH TUBERCULOSIS

Pranay Sinha[1], Prakash B. Narasimhan[2], Madolyn Dauphinais[1], Komal Jain[2], Subitha L. Lakshminarayanan[2], Nonika Rajkumari[2], Madeline Carwile[1], Scott K. Heysell[3], Natasha S. Hochberg[1]

[1]Boston University, Boston, MA, United States, [2]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, [3]University of Virginia, Charlottesville, VA, United States

Tuberculosis (TB) remains an enduring threat to human health. In 2021, 10.6 million individuals developed active TB and 1.6 million died of TB. When we map the global distribution of TB, the parts of the globe that light up are overwhelmingly in tropical and sub-tropical areas. Intestinal parasitic infections are also concentrated in these regions and the geographic overlap is striking. An estimated one billion people are infected with soil-transmitted helminths. As such, the probability of intestinal parasitic infections in persons with latent and active TB is high. Very few studies have described the prevalence of parasitic infections in persons with TB (PWTB). A key limitation of these studies is that they used stool microscopy which may have underestimated the prevalence of parasitic infections. The prevalence of intestinal parasitic infections among PWTB in India has not been well documented. The TB LEOPARD study was designed to assess the prevalence of parasitic infections among PWTB in Puducherry and rural areas of Tamil Nadu in India. This study is currently in the recruitment phase. We present preliminary data from this study. Fresh stool samples from 38 persons with TB were collected. After sonication of the stool

specimen, we extracted DNA and conducted multiplex polymerase chain reaction testing for Ascaris lumbricoides, Strongyloides stercoralis, Trichuris trichuria, Necator americanus, and Ancylostoma duodenale. We found that 14 (39.4%) participants tested positive for at least one helminth infection and 3 (7.8%) tested positive for 2 helminths. The most common parasite detected was Necator americanus which constituted 78.4% of the heminth infections. These preliminary data are intriguing as the prevalence of helminth infections considerably exceeds the expected rate of helminth infection (20-30%) for the general population. Future studies should assess the significance of asymptomatic carriage of helminths among PWTB given the potential impact of parasitic infections on the immune response to TB. Additionally, the value of systematic screening and treatment of helminths for PWTB in India should be assessed.

ASSESSING PROGRESS TOWARDS THE WORLD HEALTH ORGANIZATION TARGET OF ZERO CATASTROPHIC COSTS DUE TO TUBERCULOSIS BY 2035

Paula P. Jimenez[1], Sumona Datta[2], Luz Quevedo Cruz[1], Matthew J. Saunders[1], Carlton A. Evans[1]

[1]Innovation For Health and Development, London, United Kingdom, [2]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

When the total of household expenditures and lost income due to tuberculosis (TB) exceeds 20% of pre-illness annual household income these costs are termed 'catastrophic' because it is unlikely that it will allow treatment completion to be affordable. The World Health Organization End TB strategy prioritizes the target of zero catastrophic costs. Costs due to TB have been assessed by repeatedly surveying patients throughout treatment about their recent costs; or by asking patients once at the end of treatment to recall all costs due to TB over more than 6 months since their illness began. There is little evidence comparing these strategies. The optimal approach depends on how long patients with TB can reliably remember their costs. To address this important research question, 174 patients newly diagnosed with TB recalled their recent pre-diagnosis costs due to TB to have been USD$=437 (IQR=95-1450). Then, 6 months later, without being reminded of their previous answers, patients again recalled these pre-diagnosis costs to be median USD$=660 (IQR=100-1880). Between both assessments, the Spearman correlation coefficient was 0.68, ($p<0.001$). The costs due to TB during treatment were median USD$782 (IQR=210-3200). Pre-illness annual household income was median USD$=15,960 (IQR=10,200-24,000). Thus, if pre-diagnosis costs due to TB were assessed recently at the time of diagnosis then catastrophic costs due to TB affected 34% of households (95% confidence interval, CI=27-42, 60/174). This was not significantly different (P=0.5) if pre-diagnosis costs due to TB were assessed later at the time of treatment completion then catastrophic costs due to TB affected 38% of households (95% CI=31-45, 66/174). Thus, patients with TB can usually reliably recall costs due to TB for many months, and catastrophic costs due to TB can be reliably assessed with a questionnaire applied only once at the end of treatment.

6459

THE EPIDEMIOLOGICAL SHIFTS OF DRUG-RESISTANT TUBERCULOSIS IN SABAH, EAST MALAYSIA DURING THE COVID-19 PANDEMIC: A 6-YEAR REVIEW OF THE GAINS AND LOSSES FROM 2016 TO 2021

Yao Long Lew[1], Roddy Teo[2], Amabel Min Hui Seow[2], Tsin Wen Yeo[3], Anne B. Chang[1], Christopher P. Lowbridge[1]

[1]Menzies School of Health Research, Darwin, Australia, [2]Tuberculosis and Leprosy Control Unit, Sabah State Health Department, Kota Kinabalu, Sabah, Malaysia, [3]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore

As the world's oldest pandemic, TB has been the world's leading cause of death by a single infectious agent, usurped only by Covid-19 in 2020 and 2021. In 2019, TB incidence in Malaysia was at 92 per 100,000 people, with an "upper-moderate" categorization. These cases were not evenly distributed, with the eastern-most state of Malaysia, Sabah, reporting 135 cases per 100,000 in the same period, qualifying as an endemic region. There is an evidence gap on the burden of multidrug-resistant TB (MDR-TB) in Sabah, we aim to describe the epidemiology and clinical characteristics of MDR-TB to inform public health measures. All cases of TB between 2016 to 2021 from the state TB registry was reviewed, with a focus on MDR-TB. The impact of Covid-19 was evaluated by designating 2016-2019 as pre-Covid, and 2020-2021 as Covid years. Factors under investigation include age, citizenship, and other indicators. A descriptive analysis of characteristics and logistic regression of variables associated with poor MDR-TB treatment outcomes was done using R software. Sabah reported an average of 5027 TB cases annually pre-Covid, declining by 10.3% to 4508 per year during Covid. Within study period, there were 97 MDR-TB cases, with median age of 38 years, and 33% of these being non-citizens (n=32). The proportion of notified MDR-TB cases in Sabah was 0.27% of all TB cases pre-Covid, but rose to 0.47% of all TB cases reported during Covid years. A marked increase in MDR-TB cases means the actual burden remains unknown. The proportion of MDR-TB cases treated successfully decreased from 60% to 24% between pre-Covid and Covid periods (OR=3.45, $p<0.01$); in this time, proportion of non-citizens who successfully completed MDR-TB treatment decreased from 47.4% to 10.0% ($p>0.05$). Improving adherence to MDR-TB treatment and adequate management of side effects could reduce likelihood of poor outcomes. While the proportion of MDR-TB in Malaysia and the state of Sabah remains relatively low compared to endemic countries, vigilant surveillance is needed to detect, isolate, and treat new cases to prevent future outbreaks.

6460

MALARIA IN CAMEROON: A RETROSPECTIVE ANALYSIS

Sophie Diarra[1], Mar Velarde[1], Christian Selinger[1], Branwen Owen[1], Emilie Pothin[1], Jean Fosso[2], Moise Abomabo[2]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Ministry of Health Cameroon, Yaoundé, Cameroon

The Cameroon National Malaria Control Programme (NMCP) sought to understand the epidemiological situation and to assess the impact of malaria control interventions deployed over the period 2015 to 2020. Using DHIS2 data and programmatic data from the NMCP, key malaria indicators - on incidence, mortality rate, case management and preventative interventions were analyzed at the regional and district level, disaggregated by demographic group. The impact of seasonal malaria chemoprevention (SMC) was also assessed using differences in differences analysis to compare districts receiving SMC to adjacent districts not receiving SMC. Malaria incidence had an upward trend with the Centre region seeing the greatest increase, with higher incidence in pregnant women across all regions compared to other groups. Mortality decreased over the study period at the national level, however some regions still had more than 100 deaths per 100,000 in the under 5's, namely the North, Extreme North and Adamoua. For case management there was a large improvement in testing rates in health facilities increasing to over 80% in most districts by 2020 with test positivity rate increasing to above 50% in most districts. Treatment of simple malaria with first-line ACT was over 50% nationwide by 2020, and the proportion of severe malaria cases receiving third-line treatment quinine increased, with second-line treatment artemether decreasing. In terms of the impact of SMC, the 2016 and 2017 campaigns had a statistically significant impact, decreasing under 5 incidence, however this effect was not seen in later campaigns. The results highlight the efforts of the NMCP to reduce the malaria burden across the country and the heterogeneous epidemiology of malaria across regions. Focus on protecting vulnerable groups such as pregnant women and children under 5 from malaria illness must continue. SMC has had a positive impact in reducing malaria illness in the under 5's and there should be more research to assess factors that could be limiting the effectiveness of SMC in later years as there could be scope to expand the geographical reach of the intervention or expand to the over 5's.

6461

QUANTIFYING THE IMPACT OF MALARIA IN PREGNANCY ON MATERNAL ANEMIA AND ITS ASSOCIATED BURDEN ACROSS AFRICA

Sequoia I. Leuba[1], Robert Verity[1], Julie R. Gutman[2], Meghna Desai[2], Kassoum Kayentao[3], Simon Kariuki[4], James Dodd[5], Daniel Chandramohan[6], Daniel J. Weiss[7], Brian Greenwood[6], Patrick G.T. Walker[1]

[1]MRC Centre for Global Infectious Disease Analysis, School of Public Health, Imperial College London, London, United Kingdom, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Malaria Research and Training Center, Mali International Center for Excellence in Research, University of Sciences, Techniques, and Technologies of Bamako, Bamako, Mali, [4]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [5]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]Malaria Atlas Project, Telethon Kids Institute, Perth Children's Hospital, Nedlands, Australia

Plasmodium infection during pregnancy causes maternal anemia but quantitative estimates of the burden of malaria on maternal anemia are lacking, in part because the impact of untreated infections cannot be ethically measured. To address this gap, we used individual-level data on hemoglobin (Hb) concentrations and malaria PCR status at enrolment into 4 recent trials of alternative approaches to malaria prevention in pregnancy, involving 12,608 women in seven countries (Burkina Faso, The Gambia, Ghana, Kenya, Malawi, Mali, and Tanzania). We developed a Bayesian inferential framework to account for the various exclusion criteria of the trials, using data on gestational age at enrolment as a proxy measure for the length of time an infection was left untreated to capture Hb dynamics up to the end of the second trimester (T2). We estimate that among primigravid women, reductions in Hb associated with malaria infection increase throughout gestation, reaching a reduction of 1.24 [95% Credible Interval (CI) 1.13, 1.36] g/dL at the end of T2. Accounting for concomitant declines in Hb throughout gestation in non-infected women, we estimate that, in primigravidae with ongoing infection, the risk of malaria-associated severe anemia (Hb < 7 g/dL) increases from 2.2% [95% CI 1.1-3.5] to 14.3% [95% CI 10.8-17.9] between the ends of the first trimester (T1) and T2. The impact of malaria upon Hb in multigravid women varied by transmission intensity, with the impact similar to primigravidae in areas of lower prevalence but increasingly diminishing in areas of higher transmission, following well-understood patterns in acquisition of pregnancy-specific malaria immunity. Using modelling, we estimate that among women who have experienced infection in one previous pregnancy, the reduction in Hb concentration associated with ongoing infection at end of T2 is 0.38 [95% CI 0.21, 0.55] g/dL, and no reduction in Hb concentration in any subsequent pregnancies. Using this framework, we will extrapolate the associated burden across Africa using estimates of fertility and malaria endemicity collated by the Malaria Atlas Project and the World Health Organization.

A GLOBAL MALARIA CASE-MANAGEMENT MODEL CASCADE WITH AN INTERACTIVE TOOL FOR POINT-OF-CARE CONSUMPTION ANALYSIS

Tasmin L. Symons, Susan Rumisha, Paulina Dzianach, Francesca Sanna, Mauricio Van Den Berg, Sarah Connor, Camilo Vargas, Daniel J. Weiss, Tolu Okitika, Peter W. Gething

Telethon Kids Institute, Perth, Australia

Quality malaria case management is essential for preventing severe disease and death, both from malaria and other severe illness. In preventative intervention mix planning, consensus has emerged that data-driven decision making - supported by models - is necessary for optimal allocation of resources. But limited evidence exists on the (relative) impact of each component of the post-infection care cascade on population-level outcomes. This work represents a step towards treating post-infection intervention policy planning with the same rigour as preventative interventions. Here we present an interactive online tool, using which policy-designers can easily explore the impact of case-management policy initiatives on coverage and consumption of malaria drugs and diagnostics. Retaining the ease of 'back of the envelope' calculations, our tool captures nuances including community-based positivity rates and the age structure of symptomatic malaria. For such scenario analysis to be worthwhile one must first estimate the status quo in absolute terms. We have developed a complete case-management modelling framework which produces estimates for each step in the logical flow through the health-system: an individual developing symptoms; seeking medical advice; receiving a diagnostic test; and, finally, being treated with an antimalarial. The natural conditionality here poses challenges to quantifying coverage - both routine and survey data suffer from increasingly small sample sizes, variations in interpretation, and recall biases. Our framework is statistical, leveraging multiple sources of data including cross-sectional surveys and a comprehensive literature review, and provides baseline estimates of point-of-care malaria commodity consumption across 75 malaria-endemic countries reflecting an estimated 448mil RDTs consumed in public-sector clinics in 2021, and 314mil ACTs, of which 75% were consumed in malaria-endemic Africa.

6463

MALARIA AS A RISK FACTOR FOR COVID-19 IN WESTERN KENYA AND BURKINA FASO (MALCOV)

Soulama[3], Aissata Barry[3], Emilie Badoum[3], Julian Matthewman[6], Helena Brazal-Monzó[4], Jennifer Canizales[4], Anna Drabko[7], William Wu[7], Simon Kariuki[1], Maia Lesosky[5], Sodiomon B. Sirima[3], Chris Drakeley[4], Feiko O. ter Kuile[5]

[1]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [2]Department of Clinical Research, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Groupe de Recherche Action en Santé (GRAS), Ouagadougou, Burkina Faso, [4]Department of Infection Biology, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]Department of Non-Communicable Disease Epidemiology, Faculty of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]Quantitative Engineering Design (QED.ai), Warsaw, Poland

It is unknown whether malaria affects COVID-19 severity or duration. We conducted a cohort study in newly diagnosed COVID-19 patients of all ages in western Kenya and Burkina-Faso. Participants were screened for SARS-CoV-2 using rapid antigen tests. Patients co-infected with Plasmodium falciparum malaria were treated with 3-day artemether-lumefantrine or pyronaridine-artesunate. COVID-19 disease progression was assessed daily by Flu-Pro+ questionnaires until day 14 by mobile phone or at clinic visits. Nasal swabs and blood samples were taken on days 1, 3, 7, 14, and 28. SARS-CoV-2 and viral load were assessed by RT-PCR. All analyses were adjusted for enrolment age, disease severity, and viral load. From February 2021 to January 2022, 708 COVID-19 patients were enrolled; 139 (20%) had malaria. Malaria patients were younger: 43/139 (31%) were aged <15 yrs vs 31/569 (5%) without malaria (P<0.0001). SARS-CoV-2 clearance in the first week was slower among malaria patients (aHR=0.59 95% confidence interval 0.45-0.76, p<0.001). By day 7, 71/131 (54%) and 319/481 (66%) had cleared SARS-CoV-2 in the malaria and non-malaria group (adjusted RR=0.90, 0.78-1.04, p=0.2) and this was 118/132 (89%) and 418/468 (89%) by Day-14 (aRR=0.98, 0.79-1.21, p=0.90). There were no differences in viral load on Day-7. Patients with malaria were more likely to have moderate-to-severe disease at enrolment (all ages: 70% vs 60%, aRR=1.25, 1.09-1.41, p<0.001; <15 years: aRR=1.61, 0.97-2.95,

p=0.085; >=15 years: aRR=1.23, 1.06-1.39, p=0.002), but the time to clearance of moderate-to-severe symptoms (aHR= 1.04, 0.85-1.28, p=0.7) and duration of any symptoms were similar (aIRR=1.01, 0.89-1.16, p=0.8). Overall, 3 (2.0%) and 7 (1.2%) patients with and without malaria had to be hospitalised, and 2 (1.3%) and 3 (0.5%) died. Patients co-infected with SARS-CoV-2 and P. falciparum malaria were more likely to have moderate-to-severe disease at enrolment. SARS-CoV-2 clearance was slower in malaria patients, but malaria did not affect COVID-19 disease progression or the duration of illness after successful antimalarial treatment of malaria.

6464

PREVALENCE OF MALARIA INFECTION AND COVERAGE OF KEY CONTROL INTERVENTIONS AMONG SEASONAL MIGRANT WORKERS AT FARM SITES AND SURROUNDING RESIDENT POPULATIONS IN NORTHWEST AMHARA REGION, ETHIOPIA

Melkamu Tiruneh[1], Berhane Tesfay[1], Henry Ntuku[1], Adem Agmas[1], Asefaw Getachew[1], Laura Merriman[1], Belay Bezabih[2], Gudissa Assefa[3], Hiwot Solomon[4], Endalamaw Gadisa[5], Dereje Dillu[1], Asnakew Yeshiwondim[1], Gezahegn Tesfaye[1], Belendia Serda[1], Caterina Guinovart[6], Jennifer Smith[7], Amir Siraj[1], Adam Bennett[1]

[1]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Addis Ababa, Ethiopia, [2]Amhara National Regional State Health Bureau, Bahir Dar, Ethiopia, [3]Ministry of Health, Ethiopia, Addis Ababa, Ethiopia, [4]Ministry of Health, Addis Ababa, Ethiopia, [5]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [6]PATH Malaria Control and Elimination Partnership in Africa, Barcelona Institute for Global Health, Barcelona, Spain, [7]Univeresity of California, San Francisco, San Francisco, CA, United States

In many malaria-endemic countries, population mobility presents a key challenge to malaria elimination efforts due to the potential importation of infection. In Amhara Region, Ethiopia, the expansion of large-scale agricultural development in lowland areas attracts close to half a million seasonal migrant workers annually, mainly from highlands where malaria transmission is low. These groups are at a higher risk of malaria due to poor living conditions, and behavioral and occupational factors at farms. A cross-sectional study was conducted to estimate the prevalence of malaria infection and coverage of key interventions among seasonal migrant workers and the surrounding resident population in the Delello farm site, Metema District, northwest Amhara Region in October 2022 following the major rainy season. Through multistage cluster sampling, 1,900 seasonal migrant workers from 32 farms and 1,001 residents from 15 hamlets were randomly selected and tested for malaria using rapid diagnostic tests (RDTs). Dried blood spots (DBS) were collected for molecular analysis. Half (50.4%) of participants in the resident population were male, compared to 96.8% of the seasonal migrant workers. Malaria infection prevalence by RDT was 19.5% [95% CI: 17.8-21.4] in seasonal migrant workers, and 8.5% [95% CI: 6.9-10.4] in the resident population. Only 8.0% [95% CI: 6.9-9.3] of seasonal migrant workers and 74.2% [95% CI: 71.4-76.8] of the resident population owned mosquitoes net, and 6.5% of seasonal migrant workers and 68.4% [95% CI: 64.9-71.6] of the resident population slept under a net the previous night. The proportion of households covered with indoor residual spraying in the last 12 months was 76.1% [95% CI: 70.2-81.1] among the resident population, whereas seasonal migrant workers slept in un-sprayable structures or worked outdoors at night. These results indicate high malaria prevalence and low coverage of vector control interventions among seasonal migrant workers and suggest the need for targeted interventions to reduce the malaria burden in these populations and the potential importation of infection in low-transmission areas.

MALARIA SEROEPIDEMIOLOGY IN VERY LOW TRANSMISSION SETTINGS IN THE PERUVIAN AMAZON

Bryan Fernandez-Camacho[1], Brian Peña-Calero[1], Martina Guillermo-Roman[1], Jorge Ruiz-Cabrejos[1], Jose Luis Barboza[1], Lucia Bartolini-Arana[1], Hugo Rodriguez-Ferrucci[2], Veronica Soto-Calle[3], Luca Nelli[4], Isabel Byrne[4], Monica Hill[4], Elin Dumont[4], Lynn Grignard[4], Kevin Tetteh[4], Lindsey Wu[4], Alejandro Llanos-Cuentas[5], Chris Drakeley[4], Gillian Stresman[4], Gabriel Carrasco-Escobar[1]

[1]Health Innovation Laboratory, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional de la Amazonía Peruana, Iquitos, Peru, [3]Dirección de Prevención y Control de Enfermedades Metaxénicas y Zoonosis - Ministerio de Salud, Lima, Peru, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

Peru is on track to malaria elimination, due to control programs such as the Zero Malaria Plan (2017) and the National Malaria Elimination Plan (2022). However, measuring malaria exposure in low transmission areas remains essential to gain insight in these contexts and achieve elimination. This study aims to determine malaria exposure and associated risk factors according to distance to facility as a proxy for access to care in two very low transmission areas of Loreto. A cross-sectional analytical study was conducted in 38 communities in Indiana and Belen districts. Standardized questionnaires were applied to capture socio demographic and behavioural information, households were geo-referenced and blood samples were collected for serological and molecular analysis. Local Getis-Ord Gi* statistic was performed to identify clusters of households with high (hotspots) or low (coldspots) seroprevalence. A total of 4000 individuals were analyzed across both districts. Our findings show an overall malaria seropositivity of 9.3% (95%CI: 8.4%-10.2%). We also found a seropositivity level to any exposure (recent or historical) of 2.5% (95%CI: 2.0%-3.0%) and 7.8% (95%CI: 7.0%-8.7%) for P. falciparum and P. vivax, respectively. The seropositivity trend in P. Vivax changed in the [40-50) age group ($\beta 1 = 0.04$, $p = 0.003$), while in P. Falciparum occurred in the [50-60) age group ($\beta 1 = 0.004$, $p = 0.010$). Moreover, distant and extra distant villages were more exposed to any malaria (recent or historical) than those classified as proximate (DSCFdistant = 16.29, p<.001; DSCFextra distant = 18.86, p<.001) and moderate (DSCFdistant = 10.48, p<.001; DSCFextra distant = 12.53, p<.001). The spatial analysis showed that cold spots were located mostly in the center of Belen district, while hot spots were located on the border, and hot spots were located near the Amazon river in Indiana. Higher concentrations of malaria exposure were found in more distant communities. This information may be useful for the redesign of control strategies focused on distant subpopulations to improve malaria surveillance and continue on the path to elimination.

Globally, 2.8M deaths occur yearly among children aged 1-60 months (53% of all deaths in children <5 years). Detailed characterization of childhood deaths could inform interventions to improve child survival. The Child Health and Mortality Prevention Surveillance (CHAMPS) Network conducts childhood mortality surveillance in sub-Saharan Africa and South Asia using innovative postmortem minimally invasive tissue sampling (MITS). We describe the causes of child deaths across CHAMPS sites in 7 countries. From 2016 to 2020, 632 MITS (331 in 1-11 months; 301 in children 12-59 months) were completed on decedents. Expert panels determined locally the underlying, intermediate, and immediate conditions in the chain of events leading to death, based on histopathology, microbiological diagnostics, clinical data, and verbal autopsies. The six most common underlying causes of death were malnutrition (104; 16.5%), HIV (75, 11.9%), malaria (71, 11.2%), congenital birth defects (64, 10.1%), lower respiratory tract infections (LRTI; 53, 8.4%) and diarrheal diseases (46; 7.2%). Infection was present in the causal chain in 549/632 (87%) of deaths with Klebsiella pneumoniae (155/549, 28.2% of all infectious deaths; 82% considered nosocomial) Plasmodium falciparum (122/549; 22.2%) and Streptococcus pneumoniae (109/549; 19.9%) being the commonest pathogens contributing to infectious deaths. Cytomegalovirus (57; 10.4%) or Acinetobacter baumannii (39; 7.1%; 35/39 [89.7%] considered nosocomial), also played important roles. Expert panels considered 78% (494/632) of all deaths preventable and 4% (26/632) preventable under certain conditions. CHAMPS results show that, in high-mortality settings, infectious diseases continue to cause most deaths in infants and children, often in conjunction with malnutrition. Results highlight opportunities for action to prevent fatalities and reveal common interactions of various etiologies in the path towards death. The previously unrecognized significance of pathogens such as Klebsiella pneumoniae and cytomegalovirus highlights the need to focus on them to improve child survival.

6467

INFANT MORTALITY AND GROWTH FAILURE AFTER ORAL AZITHROMYCIN AMONG LOW BIRTHWEIGHT AND UNDERWEIGHT NEONATES

Ali Sie[1], Mamadou Bountogo[1], Alphonse Zakane[1], Guillaume Compaore[1], Thierry Ouedraogo[1], Elodie Lebas[2], Benjamin F. Arnold[2], Thomas M. Lietman[2], **Catherine Oldenburg**[2]

[1]Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, [2]University of California, San Francisco, San Francisco, CA, United States

Biannual mass azithromycin distribution has been shown to reduce all-cause child mortality, with the largest effects in children aged 1 to 11 months, who have the highest mortality rates. Low birthweight (birthweight <2500 grams, g) and underweight (weight-for-age Z-score, WAZ, < -2) infants have higher risk of poor outcomes compared to their well-nourished peers. Interventions to improve growth and reduce mortality must not interfere with breastfeeding. If effective, azithromycin could represent an easily implementable intervention for infants. We evaluated the role of azithromycin for reducing mortality and improving growth outcomes in low birthweight and/or underweight infants in Burkina Faso. Infants aged 8-27 days of age weighing ≥2500 g at enrollment in Burkina Faso were randomized 1:1 to a single, oral dose of azithromycin (20 mg/kg) or matching placebo. Birthweight measurements were extracted from each child's government-issued health card. We evaluated mortality and anthropometric outcomes in four subgroups: 1) both low birthweight and underweight at enrollment; 2) low birthweight-only; 3) underweight-only; 4) neither low birthweight nor underweight. Of 21,832 enrolled infants, 21,320 (98%) had birthweight measurements and included in this analysis. Of these, 747 (3%) were both low birthweight and underweight, 972 (5%) were low birthweight-only, 825 (4%) were underweight-only, and 18,776 (88%) were neither low birthweight nor underweight. Infants who were both low birthweight and underweight receiving azithromycin had lower odds of underweight at 6 months compared to placebo (OR 0.65, 95% CI 0.44 to 0.95), but the treatment group by subgroup interaction was not statistically significant (P=0.06). We did not find evidence of a difference between groups for other outcomes in any subgroup. In conclusion, azithromycin may have some growth-promoting benefits for the highest risk infants, but we were unable to demonstrate a difference in most outcomes in low birthweight and underweight infants. As a secondary analysis of a trial, this study was underpowered for rare outcomes such as mortality.

6468

EFFECT OF A SINGLE DOSE OF PROPHYLACTIC AZITHROMYCIN TO INFANTS ON FECAL CARRIAGE OF ENTEROPATHOGENS IN PAKISTANI INFANTS

Aneela Pasha[1], Ameer Muhammad[2], Furqan Kabir[1], Waqasuddin Khan[1], Yasir Shafiq[1], Imran Nisar[1], Iqbal Azam[1], Najeeha Iqbal[1], **Fyezah Jehan**[1]

[1]Aga Khan University, Karachi, Pakistan, [2]Vital Pakistan Trust, Karachi, Pakistan

Azithromycin (AZ), a macrolide, is recommended by the World Health Organization (WHO) for mass drug administration (MDA) in low-middle-income countries (LMICs) for treatment of infections. MDA-AZ improves child survival and may have a role in improving infant growth outcomes. Concerns about antimicrobial resistance gene (ARG) carriage and enteropathogen burden remain even in antibiotic naïve infants. The study aimed to assess AZ impact on ARG carriage and enteropathogen burden in 8-week-old infants. Mumta study was a 1:1:1 randomized controlled trial of malnourished lactating women (LW) and their infants (n=957 dyads). Interventions were lactation counseling (LC) only, LC and balanced energy protein (BEP) sachet for the mother, and LC, BEP with one dose of AZ to the infant at day 42 of birth. Fifty infants from each arm were randomly selected for biomarker and microbiome analysis at day 56 of birth. Enteropathogen burden and ARG carriage were assessed using a customized TaqMan Array Card (TAC). There was no difference between enteropathogen burden in healthy infants who received AZ and those who did not. Enteropathogen count in infants was strongly associated with mothers (p<0.001) even at 8 weeks after birth, regardless of place, mode of delivery and exclusive breastfeeding. In our study of 150 infants, 91.3% of infants were positive for ARG CTX-M type extended-spectrum β-lactamases. The prevalence of fluoroquinolone resistance genes with the gyrA mutation was 66.7%, and the parC mutation was 45.3%. There was no difference between ARG carriage between infants who received AZ and those who did not. Factor analysis of TaqMan data showed three distinct factors: the Campylobacter family, E. coli family, and ARGs (CTX-M, gyrA, and parC types). Enteropathogen count was predicted by an increase in three infant EED biomarkers MPO, LCN-2 and CALPR, and CRP. In conclusion, we show early vertical transmission of enteropathogens in infants, with substantial antimicrobial carriage irrespective of AZ use. Our study lends insight into mechanistic pathways for AZ action in low-resource malnourished settings.

EVALUATING THE ACCURACY OF INTERVA-5 AND INSILICOVA ALGORITHMS IN DETERMINING THE LEADING CAUSES OF MORTALITY IN INFANTS AND CHILDREN UNDER-5 IN WESTERN KENYA

Joyce Akinyi Were[1], Victor Akelo[2], David Obor[1], Sammy Khagayi[1], Benard Asuke[1], Aggrey Igunza[1], Cynthia Whitney[3], Dianna Blau[4], Beth Barr[5]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]US Centers for Disease Control and Prevention, Kisumu, Kenya, [3]Emory Global Health Institute, Emory University, Atlanta, GA, United States, [4]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Nyanja Health Research Institute, Salima, Malawi

Verbal autopsy (VA) guides public health priorities in communities where physician certification of deaths is largely unavailable. VA has been frequently validated against physician coding of causes of death (CoD), but none have done so with CoDs rigorously determined from multiple data sources, including minimally invasive tissue sampling (MITS) and post-mortem laboratory and pathology testing. Child Health and Mortality Prevention Surveillance (CHAMPS) investigates causes of death in children under 5 using MITS, post-mortem laboratory and pathology testing, VA, and clinical and demographic data in seven countries. The CHAMPS Determination of Cause of Death (DeCoDe) expert panel analyses all available data, and ascertains the immediate, underlying and other antecedent causes of death. We compared results of the VA algorithms InterVA-5 and InSilicoVA to the CHAMPS-Kenya site DeCoDe CODs in children 1 to 59 months of age. InterVA and InsilicoVA had closer agreement with each other than with DeCoDe. The highest agreement across three systems was for malaria as a cause of death (Kappa=0.29 [CI:0.17-0.41]). Both VA systems indicated that gastroenteritis and 'other causes' were in the top five causes of death (24.3% and 15.3% respectively) but had low agreement on meningitis (15.8% and 5.0%), which wasn't detected by DeCoDe in any cases. DeCoDe indicated malnutrition was responsible for 26.6% of deaths, while the VA algorithms indicated this as causing 2.7% and 3.2% of deaths. Both InterVA-5 and InsilicoVA underestimated malnutrition, malaria, sepsis and HIV disease. InterVA-5 overestimated diarrheal diseases and InsilicoVA overestimated respiratory infections including pneumonia. The VA algorithms performed suboptimally in determining the leading causes of mortality, likely because they cannot accurately differentiate between conditions with similar symptoms and because recall bias may confuse results where no medical records exist. Our findings underscore the importance of maintaining gold standard surveillance systems in countries where VA is widely relied on and to use rigorous results to validate and refine VA algorithms.

6470

IDENTIFYING RISK FACTORS FOR MATERNAL NEAR MISS AMONG RURAL PREGNANT WOMEN ADMITTED TO A TERTIARY PUBLIC HOSPITAL IN BANGLADESH: A CASE-CONTROL STUDY

Rajib Biswas[1], Emily S. Gurley[2], Kazi Munisul Islam[1], Mohammad Sabbir Ahmed[1], Shovo Debnath[1], Hafsa Hossain[1], Salma Afroz Shifa[1], Dilruba Zeba[3], Qazi Sadeq-ur Rahman[1], Sanwarul Bari[1], Shams El Arifeen[1], Mohammad Zahid Hossain[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Bangabandhu Sheikh Mujib Medical College, Faridpur, Bangladesh

Maternal near miss (MNM) refers to women who experienced complications during pregnancy, childbirth, or within 42 days of termination and narrowly escaped death. The Child Health and Mortality Prevention Surveillance (CHAMPS) network is conducting health and demographic surveillance in Baliakandi, a rural sub-district of Bangladesh and tracking each pregnancy and its outcome. We studied risk factors and pregnancy outcomes of MNM in women from Baliakandi admitted to Bangabandhu Sheikh Mujib Medical College Hospital (BSMMCH), a tertiary-level hospital. We conducted an unmatched case-control study using WHO clinical and laboratory criteria for MNM to identify cases and randomly selected women from Baliakandi who gave birth without experiencing significant morbidity at BSMMCH in 2022 as controls using a 1:1 ratio. We examined demographic, obstetric, and treatment-related characteristics using multivariate logistic regression controlling for age, education, and parity. HDSS 2022 data recorded 5930 pregnancy outcomes in Baliakandi; 219 got admitted to BSMMCH, 62 experienced MNM, and controls shared similar demographic profiles to cases. Hypertensive disorders (60%) and obstetric hemorrhage (32%) were common admission complaints of MNM cases compared to 2% hypertensive disorders and 5% obstetric hemorrhages in controls. No antenatal care (ANC) (adjusted odds ratio [aOR]: 3.23, 95% CI: 1.73 - 6.38) and >4 hours delay in seeking care from the onset of the complaints (aOR: 1.89, 95% CI: 1.10 - 3.37) was associated with a higher risk of MNM. No significant association with age and parity with MNM was found. Most (88%) MNM cases and half (58%) of controls were referred from other healthcare facilities. MNM was significantly associated with increased risk of stillbirth (aOR: 5.8, 95% CI: 2.27 - 16.95, p: <0.001) and cesarean delivery (aOR: 2.07, 95% CI: 1.01 - 4.30, p: 0.04). Implementing interventions that address reduction of first-step delay, improvement of quality antenatal care and establishment of effective referral systems in low-resource settings is crucial to decrease MNM events, improve maternal health, and increase child survival.

6471

ANTENATAL CARE SERVICES IN BENIN AND TANZANIA, 2021-2022: AN EQUITY ANALYSIS STUDY

Anna Munsey[1], Alen Kinyina[2], Melkior Assenga[2], Faustin Onikpo[3], Alexandre Binazon[3], Marie Adeyemi Idohou[3], Manzidatou Alao[3], Sijenunu Aron[4], Samwel L. Antenatal care (ANC) improves maternal and neonatal outcomes, yet access to ANC and quality of care (QoC) may be inequitable due to sociocultural factors and monetary and time costs. Examining drivers of ANC disparities may identify those amenable to policy change. We conducted an ANC equity analysis of public facilities in Tanzania, where services are free, and in Benin, where there is cost-recovery. Using data from representative household surveys in the catchment of 40 clinics per country, we assessed total ANC visits in last pregnancy, QoC indicators (e.g., blood pressure (BP) and urinalysis), and wait times, disaggregated by education and wealth quintiles. We used indices of inequality, concentration indices, and Oaxaca-Blinder decompositions to determine the distribution, direction, and magnitude of inequalities and the contributing factors. We assessed out-of-pocket (OOP) expenses associated with ANC visits relative to income. Wealthier individuals had more ANC visits than poorer ones at every education level in both countries, with the wealthiest and most educated having two visits more than the poorest, least educated. In Benin, individuals who attend ANC receive similar care regardless

of socioeconomic status; BP was measured for 98% of women in the highest and lowest wealth quintiles. In contrast, in Tanzania, there are wide disparities in QoC received by education or wealth; 83% of the wealthiest women had BP measured versus 64% of poorest. In Tanzania, wealthier and more educated clients spent 27 fewer minutes at ANC. In Benin, OOP expenses are 2.7% of annual income for women in the lowest wealth quintile compared to 0.8% for the highest; cost recovery is the primary cost. In Tanzania, the values are 3.1% and 0.5%, respectively; transportation is the main cost. We identified inequities in total ANC visits, favoring wealthier, more educated individuals. In Benin, removal or reduction of cost-recovery could improve ANC access. In Tanzania, ensuring healthcare staff have necessary training and supplies will help ensure uniform and high-quality care, while community health services could address the transportation cost barrier.

6472

COSTING OF A COMBINATION INTERVENTION (KYATEREKERA) ADDRESSING SEXUAL RISK-TAKING BEHAVIORS AMONG VULNERABLE WOMEN IN SOUTHWESTERN UGANDA

Yesim Tozan[1], Joshua Kiyingi[2], Sooyoung Kim[1], Ozge Bahar Sensoy[2], Proscovia Nabunya[2], Larissa Jennings Mayo-Wilson[3], Joseph Kagaayi[4], Mary M. McKay[2], Susan S. Witte[5], Fred M. Ssewamala[2]

[1]New York University School of Global Public Health, New York, NY, United States, [2]Brown School, Washington University in Saint Louis, Saint Louis, MO, United States, [3]Gilling School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [4]International Center for Child Health and Development, Washington University in St. Louis, Uganda Field Office, Masaka, Uganda, [5]Columbia University School of Social Work, New York, NY, United States

In Uganda, women engaged in sex work (WESW) have an HIV prevalence of 31.3% and account for 18% of all new HIV infections in the country. This marginalized population is at the intersection of multiple vulnerabilities. The Kyaterekera intervention is targeted at WESW in Rakai and the greater Masaka regions in Uganda and combines a traditional HIV risk reduction (HIVRR) approach with a savings-led economic empowerment intervention and financial literacy training (FLT).We estimated the economic costs of the Kyaterekera intervention from a program provider perspective using a prospective activity-based micro-costing method. All program activities and resources used were identified, measured, and valued across the two study arms: 1) control arm (7 clusters, 186 women) receiving a traditional HIVRR intervention; 2) treatment arm (12 clusters, 356 women) receiving a matched individual development savings account (IDA) and FLT on top HIVRR. Estimated costs were summed per each arm and divided by the participant numbers to calculate the per-participant cost by arm. All costs were adjusted for inflation, discounted at an annual rate of 3%, and presented in 2019 US dollars.The total per-participant cost of HIVRR and HIVRR+IDA+FLT arms was estimated at $323 and $1,435, respectively, using the treatment-on-the-treated (TOT) sample. When calculated based on the intent-to-treat (ITT) sample, the per-participant costs were reduced to $183 and $588, respectively. The key cost drivers were the capital invested in IDAs at opening and through matched contributions and the personnel and transportation costs for program operations, linked to WESW's higher mobility and the dispersed pattern of hot spot locations.This is the first study to estimate the costs of a combined HIVRR and economic empowerment intervention for WESW in Uganda. The findings contribute to a dearth of evidence on the economic costs of implementing a targeted intervention for this marginalized population in resource-constrained settings and sheds light on the scale of potential investment needed to better achieve the health equity goal of HIV prevention strategies.

6473

THE COLLABORATIVE CROSS REVEALS A SINGLE LOCUS REQUIRED FOR PROTECTIVE IMMUNITY AGAINST HIGHLY VIRULENT TOXOPLASMA GONDII STRAINS

Juan C. Sánchez-Arcila[1], Arlon Wizzard[1], Litzy Lemus[1], Jennifer Eggleston[1], Darian Galvez[1], Scott P. Souza[1], Kirk Dc Jensen[2]

[1]Department of Molecular and Cell Biology, University of California, Merced, CA, United States, [2]Health Sciences Research Institute, University of California, Merced, CA, United States

We employed an unbiased forward genetics screen to determine new requirements for immunity to Toxoplasma gondii against a highly virulent strain of T. gondii, the causative agent of human toxoplasmosis. To detect immunity QTLs generated by vaccination or natural infection with a low-virulent strain, we screened the available panel of 59 lines of the Collaborative Cross (CC), a highly diverse genetic panel of inbred mice captures ~90% of the genetic variation within the Mus musculus species. We challenged immunized mice with a highly virulent French Guyana strain, GUY-DOS, capable of evading immunological memory responses in some but not all founder CC lines. We found one highly significant Quantitative Trait Locus (QTL) in a small region on chr11 that correlated with survival to GUY-DOS secondary infections in vaccinated or naturally infected animals. The chr11 QTL accounts for 70% of the total phenotypic variance in the CC. The protective effects to GUY-DOS in the CC mice were related to PWK/PhJ (Mus m. musculus) and CAST/EiJ (M. m. castaneous) alleles but not those from common laboratory mice (M. m. domesticus) at this locus. The number of mutations and GO enrichment of genes in the chr11 QTL indicates that the most probable candidate in the region corresponds to Tcf7, a known regulator of CD4+ T follicular and CD8+ T central memory lymphocytes. A further evaluation revealed enhanced central memory CD8+ T cells and higher frequencies of TCF-1+ in CD8+CD44+ lymphocytes in resistant CAST/EiJ and PWK/PhJ compared to susceptible C57BL/6J mouse genetic backgrounds. To test the genetic effect of the chr11 QTL, we applied the same infection model to congenic B6.PWD-chr11.1 mice and observed complete protection against challenge with the highly-virulent strain VAND but partial protection to GUY-DOS, suggesting that chr11 7-60 Mb from the M. m. musculus genetic background promotes immunity to atypical strains in a strain-specific manner. Furthermore, we utilized a Tcf7 deficient mouse line (Tcf7 P45-/-), whereby TCF1 expression is reduced but not abrogated, and observed that vaccinated Tcf7 P45-/- mice succumbed to a challenge with the Type I RH T. gondii strain, typically non-lethal in vaccinated C56BL/6J mice. Together, these results show the contribution of Tcf7 in immunity to T. gondii and reinforce the importance of Tcf7/TCF-1 regulation in vaccination against T. gondii and other parasitic diseases.

6474

EXPLORING NATURALLY ACQUIRED IMMUNITY TO PLASMODIUM FALCIPARUM IN A GENOTYPIC ANALYSIS OF A LONGITUDINAL COHORT STUDY

Emily LaVerriere[1], Zachary M. Johnson[2], Meg Shieh[2], Charlotte Switzer[1], Caroline O. Buckee[1], Peter D. Crompton[3], Boubacar Traore[4], Tuan M. Tran[5], Daniel E. Neafsey[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Broad Institute of MIT and Harvard, Cambridge, MA, United States, [3]National Institutes of Health, Rockville, MD, United States, [4]University of Sciences, Technique and Technology of Bamako, Bamako, Mali, [5]Indiana University School of Medicine, Indianapolis, IN, United States

We genotypically profiled six thousand samples from a longitudinal cohort study in Kalifabougou, Mali to characterize malaria infection dynamics with unprecedented clarity. In this cohort which spanned May 2011 to January 2012, about half of the subjects were infected with Plasmodium falciparum at enrollment into the cohort, across all ages (3 months-25 years old). To better understand the distribution and prevalence of polyclonal infections, particularly as they relate to naturally acquired immunity (NAI) development, we generated Illumina amplicon sequencing data from 464 subjects in this cohort. We estimated complexity of infection (COI), the

number of genetically distinct clones within a sample and found that over 50% of the P. falciparum positive samples (1210 of 2315 samples) were polyclonal, regardless of subject age. This finding is consistent with previous findings from this cohort showing similar times to first PCR-detectable infection, regardless of age, suggesting that NAI does not reduce rates of infection or the clonality of infection. We also compared the time to the first new infection across multiple subject groups. We found that subjects who were already infected with parasites at study enrollment, before the transmission season, acquired a new infection more quickly during the transmission season itself than those who were uninfected at baseline, suggesting that ongoing blood-stage infections may not protect against superinfection. As this pattern was also unchanged with subject age, as well as with stratification by number of new infections, as a proxy for heterogeneity in exposure, the rate of superinfection establishment does not appear to be impacted by NAI. Future work will screen for elusive signs of immunity at a molecular level, including analyses of allelic exclusion, spontaneous infection resolution, and duration between infection onset and presentation of symptoms. This work highlights the utility of longitudinal amplicon sequencing data to provide a deeper look at molecular signatures, suggesting that both COI and rates of superinfection establishment are not molecular signs of naturally acquired immunity.

Subclinical Plasmodium spp. infection is attributed to the acquisition of non-sterilising antimalarial immunity, particularly antibodies. The spontaneous clearance of subclinical peripheral Plasmodium spp. parasitemia, including P.vivax, occurs frequently in low transmission settings. Subclinical Plasmodium spp. infections contribute significantly to ongoing malaria transmission, therefore understanding the role of antibody mediated immunity in the spontaneous clearance of parasitemia is essential to the broader understanding of the epidemiology and transmission potential of P.vivax. We sought to identify IgG responses associated with subclinical P.vivax infection and clearance of peripheral parasitemia. IgG to a suite of 30 P.vivax antigens was determined by Luminex assay in participants of a nested cohort study of subclinical Plasmodium spp. infection in Laos (n=202) and Cambodia (n=150). Participants were sampled monthly for 12 months (n=3041), and Plasmodium spp. infections detected by high-volume ultrasensitive qPCR. Mixed effects regression models were used to determine the association between antigen specific IgG levels and spontaneous clearance of peripheral P.vivax parasitemia. Over 12 months, a total 610 subclinical Plasmodium spp. infections were detected, including 293 P.vivax infections. Spontaneous clearance of peripheral P.vivax infection was observed in 79% and 67% of participants and the median time to clearance of peripheral P.vivax parasitemia was 93 and 68 days in Laos and Cambodia, respectively. Anti-P.vivax IgG responses were higher in participants with detectable P.vivax infection compared to those free of P.vivax during the study period, for all 30 antigens investigated. Individual antigen-specific IgG responses were not associated with clearance of peripheral P.vivax parasitemia. Future investigations will include analysis of multi-antigen responses and time to clearance of peripheral P.vivax parasitemia. These findings will further our understanding of acquired immunity in the maintenance, clearance and ultimately the transmission and epidemiology of P.vivax infections.

NEW INSIGHTS INTO SCHISTOSOMIASIS MANSONI PATHOGENESIS: EVIDENCE FOR BACTERIAL TRANSLOCATION, INFLAMMASOME ACTIVATION, AND UPREGULATION OF PROINFLAMMATORY CYTOKINES IN HEPATOSPLENIC PATIENTS

Thiago Almeida Pereira[1], Jailza Lima Rodrigues[2], Izabela Voieta[2], José Roberto Lambertucci[2], Stefan M. Geiger[2], Deborah Negrão-Corrêa[2]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Federal University of Minas Gerais, Belo Horizonte, Brazil

IL13 drives schistosomiasis fibrogenesis, but growing evidence suggests that IL1β and IL17 contribute to severe disease. Our aims were to evaluate the immune response in patients with schistosomiasis and determine if liver fibrosis is associated with bacterial translocation, inflammasome activation, and Th17 response. Plasma samples from controls (n=30) and patients with acute (n=22), hepatointestinal (n=40), and hepatosplenic (n=26) schistosomiasis mansoni were collected. ELISA was performed for IL1β, IL5, IL6, IL10, IL13, IL17, TNFα, IFNγ, CCL11, and CCL17. Snap-frozen liver biopsies from controls (n=6) and hepatosplenic patients (n=36) were also included. Real-time PCR was performed for genes related to bacterial translocation, inflammasome activation, immune response, and fibrogenesis. Liver fibrosis was assessed by ultrasound (WHO protocol). Patients with acute schistosomiasis had higher levels of IL1β, IL5, IL6, IL10, IL13, IL17, TNFα, CCL11, and CCL17 than hepatointestinal patients or controls. Hepatosplenic patients had higher IL13, IL5, IL1β, TNFα, and CCL11, but lower CCL17 levels than hepatointestinal patients or controls. IL-5, IL-13, IL-1β, TNFα, and CCL11 positively correlated with the degree of fibrosis, while CCL17 levels were negatively correlated. Hepatosplenic patients had increased liver expression of markers of bacterial translocation (16S rRNA, LPS binding protein), inflammasome activation (NLRP3, Caspase 1, IL1β, IL18), Th1 (IL12p35, TNFα), Th2 (IL5, IL13, GATA3, CCL11, CCL17), Th17 (IL17A, IL17RC, IL17RC, IL23, IL23R, IL6), Treg (IL10, TGFβ), myofibroblast activation (αSMA, Vimentin) and collagen deposition (type I, III and VI). Bacterial translocation, inflammasome activation, Th2, and Th17 cytokines correlated with myofibroblast activation, collagen deposition, and fibrosis staged by ultrasound. Liver fibrosis in hepatosplenic schistosomiasis is associated not only with Th2 response

but also with NLRP3 inflammasome activation and Th17 immune response, probably exacerbated by bacterial translocation. Dual targeting of IL13/IL17 may benefit patients with severe disease.

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]The Department of International Health, Bloomberg School of Hygiene and Public Health, Johns Hopkins University,, baltimore, MD, United States

Neurocysticercosis (NCC) is an infection of the central nervous system (CNS) caused by the metacéstode helminth Taenia solium. In NCC, brain lesions depend on the host-immunoinflammatory response interaction. However, it is not clear how is the inflammatory response in the early stage and throughout the infection process over time. We generated a rat model for NCC in which activated T. solium oncospheres were inoculated intracranially. 10 groups were used: 1, 1.5, 2, 2.5, 3, 4, 6, 8, 10 and 12 months post-infection (MPI). It was shown that in parenchymal cysts of 1 MPI more than 60% of the area around the cyst present macrophages organized in palisades without fibrosis, and from 3 MPI the presence of macrophages with fibrosis begins to be observed, as the post-infection time progresses this fibrosis increases, being 40% around the cyst for the 3 MPI, in the 4 with 70% and 80% in groups of 6 MPI. Picrosirius Red staining shows that the predominant type of collagen in the fibrotic tissue for 3 MPI is type III, with green fibrosis being observed; then, as the post-infection time progresses, the presence of red/yellow type I collagen is observed with greater predominance. On the other hand, a striking characteristic of meningeal and ventricular cysts is the presence of a higher percentage of moderate to severe inflammation score of 30% around the cyst compared to parenchymal cysts with only 10% around the cyst. The microglial cells of the groups of 1 to 2.5 MPI are found forming a layer of cells around the cyst and mainly with ameboid/phagocytic morphology. While in cysts from 3 MPI was located both in the fibrotic tissue that borders the cyst and continuous to this tissue are the astrocytic cells; microglia morphology was rod-shaped for the 3 to 4 MPI; in those of the 6 and 12 MPI, the microglia had a branched/debranched hypertrophic and dystrophic morphology. Concluding that the type of cellular infiltrate, macrophages, the formation of fibrosis and glial cells participate in the modulation of the host's immune response throughout the post-infection time in NCC.

TRANSCRIPTOMIC IDENTIFICATION OF BIOMARKERS FOR CHAGAS DISEASE PROGRESSION

Carolina Duque[1], Jill Hakim[1], Kelly DeToy[1], Shilah Waters[1], David Martin[1], Rachel Marcus[2], Manuela Verastegui[3], Robert H. Gilman[1], Monica R. Mugnier[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]Medstar Union Memorial Hospital, Baltimore, MD, United States, [3]Universidad Peruana Cayetano Heredia, Lima, Peru

Chagas disease affects approximately 8 million individuals worldwide. Of those infected, 20-40% will go on to develop chronic Chagas cardiomyopathy (CCC) and ultimately heart failure. There is currently no way to predict which patients will develop CCC, and the mechanisms underlying CCC progression are poorly understood. This study aims to discover biomarkers of disease progression by using whole blood samples that were obtained from individuals prior to disease progression (stage A). These individuals were evaluated yearly for any electrocardiogram (EKG), echocardiogram, or symptomatic changes suggestive of CCC. We then randomly selected patients who went on to develop EKG changes to stage B heart failure (asymptomatic progressors), those who went on to develop reduced ejection fractions and symptoms of stage C heart failure (symptomatic progressors), and age and sex matched non-progressors that remained in stage A. We performed RNA-sequencing on these blood samples to investigate differential gene expression, immune cell composition and HLA type. For symptomatic progressors compared to non-progressors, we identified various differentially expressed genes (DEGs) and significantly enriched biologic processes. These pathways included muscle morphogenesis, regulation of cell-cell adhesion, and defence response to intracellular pathogens. Notably, for very early-stage progression to asymptomatic disease compared to non-progressors we also identified DEGs related to immunologic and remodelling functions, and significant increases in memory B cells, M2 macrophages and eosinophils. No significant difference was detected in HLA type with disease progression. Overall, these findings indicate RNA transcripts detected in the blood of Chagas patients can differentiate those individuals who will go on to progress in CCC from those who will not, and suggest that there are notable physiologic changes that precede clinically detectable CCC progression. Our findings may help inform screening strategies for risk of disease progression and to develop novel therapeutic strategies that target these early dysregulated genes.

REDUCTION OF SEXUALLY TRANSMITTED INFECTIONS FOLLOWING AZITHROMYCIN MASS DRUG ADMINISTRATION FOR TRACHOMA IN NAURU

Lucia Romani[1], Sue-Chen Apadinuwe[2], Aisling Byrne[1], Mitchell Starr[3], Kathleen Lynch[4], Susan Star[2], Philip Cunningham[3], Stephen Lambert[4], Susana Vaz Nery[1]

[1]Kirby Institute, UNSW, Sydney, Australia, [2]Ministry of Health and Medical Services, Denig, Nauru, [3]NSW State Reference Laboratory for HIV, Sydney, Australia, [4]UQ Centre for Clinical Research, Brisbane, Australia

Sexually transmitted infections (STIs) are a major public health problem globally, particularly in low-and middle-income countries (LMIC). STIs are common in the Western Pacific region, including Nauru. The strategy of syndromic STI management, relying on clinical findings alone without laboratory confirmation, has long been endorsed by the World Health Organization but misses more than 80% of asymptomatic infections, especially common during pregnancy. Screen and treat strategies are not currently affordable or feasible at scale in LMIC. In areas where trachoma or yaws are endemic, mass drug administration (MDA) with azithromycin might offer an alternative approach to the population control of STIs as well as Neglected Tropical Diseases (NTDs). In Nauru, we evaluated the impact of an azithromycin-based MDA for trachoma control on bacterial STIs in a population aged 18-29 years, by conducting a before and after community survey pre and post MDA with 8-month follow-up to determine long-term impact on genital infections. The study enrolled 381 participants at baseline and 360 post-MDA. At baseline C. trachomatis infection was diagnosed in 21.7% of participants (95% CI 17.6% - 26.3%) T. vaginalis and M. genitalium were also common (21.2% and 10.9%, respectively) as well as N. gonorrhoeae 2.7% (95% CI 1.3% - 4.9%). Eight months following azithromycin MDA a reduction in prevalence was observed in all STIs except for T. vaginalis. The relative reduction in the prevalence of C. trachomatis was 34.6% (95% CI 25.7 - 45.2) and that of N. gonorrhoeae was 66.7% (95% CI 56.9 - 76.1). This study is the first to investigate the reduction of STIs using azithromycin-based MDA in the general population, not restricted to the female population and/or pregnant women. The significant decrease in STI prevalence seen in this study 8 months after azithromycin MDA is encouraging in island populations such as this, where populations are less mobile. Azithromycin MDA is a well-established and safe intervention which has been successfully adopted for NTD control. Prospective evaluations of MDA strategies specifically targeting common STIs should be undertaken.

THE SECONDARY EFFECTS OF IVERMECTIN MASS DRUG ADMINISTRATION DESIGNED FOR MALARIA ON ECTOPARASITIC INFESTATIONS IN MOPEIA, MOZAMBIQUE: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

Joanna Furnival-Adams[1], Amelia Houana[2], Hansel Mundaca[1], Aina Casellas[1], Patricia Nicolas[1], Julia Montaña[1], Eldo Elobolobo[2], Samuel Martinho[1], Aida Xerinda[2], Arlindo Soares[2], Almudena Sanz[1], Victor Mutepa[1], Mary Mael[1], Felisbela Materula[2], Marta Ribes[1], Valeria Lopez[1], Antonio Macucha[2], Paula Ruiz-Castillo[1], Mussa Sale[2], Jenisse Mbanze[2], Humberto Munguambe[1], Francisco Saute[2], Regina Rabinovich[1], Daniel Engelman[3], Carlos Chaccour[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Centro de Investigação em Saúde de Manhiça (CISM), Manhica, Mozambique, [3]Murdoch Children's Research Institute, Melbourne, Australia

Ectoparasitic diseases such as scabies are severely neglected, despite the existence of effective treatments. There is limited data on their prevalence in Africa, and no published reports assessing the prevalence of scabies in Mozambique at scale. Ivermectin Mass Drug Administration (iMDA) is currently being studied as a potential malaria vector control tool. Given the substantial overlap between populations at risk of malaria, scabies and headlice, and the known efficacy of ivermectin against scabies and headlice, it is likely that in co-endemic areas there will be collateral benefits. During a cluster randomised controlled trial (BOHEMIA), which aimed to assess the effect of iMDA against malaria, we monitored the prevalence of scabies, headlice and bedbugs. The intervention consisted of a single dose of 400 mcg/kg ivermectin given monthly to eligible humans or humans and livestock in 3 consecutive months during the rainy season. The control group received albendazole (humans only). 39 of 100 total clusters were randomly selected and monitored for ectoparasitic infestations (scabies, headlice and bedbugs) among the three study arms. Cross-sectional surveys took place in adults and children at 3 months after the first dose (1,341 participants) and in untreated children under 5 (382 participants) at 6 months. Scabies and headlice diagnosis were determined by a questionnaire and examination of exposed skin/scalp by non-experts after intense training. Bedbug infestation was based on a short questionnaire. The baseline prevalence of scabies, headlice and bed bugs were 10.14% (95%CIs 8.58-11.88), 9.80 (95%CIs 8.23-11.55) and 16.70 (95%CIs 14.15-19.52), respectively. A semi-blinded and unadjusted analysis suggests a reduction in scabies prevalence of up to 88% (RR 0.12 (95%CI 0.06-0.25) after 3 months and up to 87% (RR 0.13 (95%CIs 0.04-0.41) in untreated children after 6 months. For headlice, the data suggests a reduction of up to 74% (RR 0.26 (0.13-0.49)) and no effect in untreated children after 6 months. The data suggests no significant effect on bed bugs at any time point. A full unblinded analysis will be available during the meeting.

6481

ASSESSING THE PREVALENCE OF SOIL TRANSMITTED HELMINTHS AND TUNGIASIS DURING LYMPHATIC FILARIASIS SURVEILLANCE IN THE COASTAL REGION OF KENYA

Michael O. Ofire[1], Wyckliff P. Omondi[2], Sultani H. Matendechero[2], Sammy M. Njenga[3], Collins O. Okoyo[3], Stella Kepha[3], Lynne Elson[4], Joseph O. Oloo[2], Gerald G. Gakuo[2]

[1]Amref Health Africa, Nairobi, Kenya, [2]Ministry of Health, Nairobi, Kenya, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Kenya Medical Research Institute-Wellcome Trust, Nairobi, Kenya

The World Health Organization encourages Neglected Tropical Diseases (NTD) programs to employ integrated approaches to disease surveys for NTDs with similar epidemiology for efficient resource utilization and to avoid duplication of efforts. During Lymphatic Filariasis (LF) treatment, albendazole is co-administered with diethylcarbamazine and, as such soil-transmitted helminths (STH) are secondarily treated. A cross-sectional survey conducted in Kilifi and Kwale counties in 330 randomly selected schools to establish if LF transmission is ongoing assessed the impact of LF treatment on STH. The survey also collected relevant WASH data and assessed the prevalence of Tungiasis, which is known to occur widely and is prevalent among school-age children. 17,602 children aged 6-7 years were tested for circulating filarial antigen using the rapid filariasis test strip. All those positive were further tested for microfilaria using microscopy. For STH and Tungiasis, 60 children per school of ages 10-14 years were randomly selected, 12 children from each of grades 4 to 8. All sampled children were asked to provide stool samples for STH testing. Their feet were further washed, dried, and carefully examined for the presence of Tunga penetrans fleas. They were also interviewed on individual WASH characteristics. LF positive results were only reported in two sub-counties- Rabai 2/1,655; 0.12% (95%CI: 0.03-0.47) and Magarini 1/1,624; 0.06% (95%CI: 0.01-0.46). All three positive cases were negative by microscopy. For STH, the highest prevalence was in Msambweni sub-county (15.1%, 95%CI: 12.2-18.6). For Tungiasis, the highest median school prevalence was also recorded in Msambweni Sub-County (6.8%, 95%CI: 5.2-8.9). However, the highest intensity of infection was recorded in Kinango Sub-County with a median of 8.0 (IQR 2.8-8.0) embedded fleas. Schools with the highest prevalence of Tungiasis were in the same wards as schools with a high prevalence of STH. This study demonstrates that implementing integrated surveys for NTDs with similar epidemiology was feasible and enabled the evaluation of Tungiasis prevalence for the first time in Kenya.

ESTIMATING THE BURDEN OF MALARIA-HELMINTH CO-INFECTIONS AMONG CHILDREN LIVING IN A SETTING OF HIGH COVERAGE OF STANDARD INTERVENTIONS FOR MALARIA AND HELMINTHS

Muhammed O. Afolabi[1], Doudou Sow[2], Ibrahima Mbaye[3], Marie Pierre Diouf[3], Mor Absa Loum[3], Elhadj Babacar Fall[3], Amadou Seck[3], Isaac A. Manga[4], Cheikh Cisse[3], Baba Camara[5], Awa Diouf[3], Ndéye Aida Gaye[3], Aminata Colle Lo[6], Brian Greenwood[1], Jean Louis A. Ndiaye[7]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Université Gaston Berger de Saint-Louis, Saint-Louis, Senegal, [3]Université de Thies, Thies, Senegal, [4]Université Cheikh Anta Diop, Dakar, Senegal, [5]Saraya Health Centre, Saraya, Senegal, [6]Université Cheikh Anta Diop, Dakar, United Kingdom, [7]University of Thies, Thies, Senegal

Concurrent infections of Plasmodium falciparum with Soil Transmitted Helminths (STH) and Schistosoma spp are still a major public health problem among children living in sub-Saharan Africa. We conducted two prospective studies among children living in urban and rural settings of Senegal, where control programs have been sustained, to determine the prevalence of malaria-helminth co-infection. We enrolled 910 children aged 1-14 years from Saraya and Diourbel districts of Senegal in June and November 2021. Finger-prick blood samples were obtained from the children for malaria microscopy and PCR methods. Stool samples were also collected. Kato-Katz and PCR methods were used to detect STH and S. mansoni, and Merthiolate-iodine-formalin test for other intestinal protozoans. Urine samples were analyzed using a filtration test, Point of Care Circulating Cathodic Antigens, and PCR methods for detection of S. haematobium. Continuous and categorical variables were compared across the two study sites and adjusted Odds ratios were used to explore risk factors for malaria-helminth co-infections. The overall prevalence of polyparasitism with P. falciparum, STH, S. haematobium and S. mansoni among children was 2.2% (20/910) while prevalence of P. falciparum-S. haematobium co-infection was 1.1% (10/910); P. falciparum-S. mansoni 0.7% (6/910) and P. falciparum with any intestinal protozoan 2.4% (22/910). Co-infection was slightly higher among 5-14-year-old children (17/629,2.7%; 95% CI:1.43-3.97) than 1-4 years (3/281,1.1%; 95% CI:–0.12-2.32) and, in boys (13/567,2.3%; 95%CI:1.27-3.96) than girls (7/343, 2.1%; 95% CI:0.52-3.48). Children aged 5-14 years (aOR=3.37; 95% CI:0.82-13.77, p=0.09), who were boys (aOR=1.44; 95% CI: 0.48-4.36, p=0.51) and lived in Saraya (aOR=1.27; 95% CI: 0.24-6.69, p=0.77) had a higher risk of the co-infection. Living in houses with spaces between the walls and frequent contact with water were statistically significant risk

factors for malaria-helminth co-infection. These findings could help to develop and implement strategies that would lead to elimination of malaria and helminths in the study areas.

6483

INTEGRATED NEGLECTED TROPICAL DISEASES SURVEYS TO ASSESS IMPACT OF INTEGRATED MASS DRUG ADMINISTRATION IN VANUATU

Elizabeth Nguyen[1], Md Saiful Islam[1], Fasihah Taleo[2], Clare Dyer[1], David S. Kennedy[1], Macklyne Katenga[3], Stephanie Tabe[3], Prudence Rymill[3], Sze F. Hii[4], Vito Colella[4], Rebecca Traub[4], Anastasia Pantelias[5], Julie Jacobson[5], John M. Kaldor[1], Susana Vaz Nery[1]

[1]Kirby Institute, University of New South Wales, Sydney, Australia, [2]World Health Organization, Port Vila, Vanuatu, [3]Ministry of Health, Government of Vanuatu, Vanuatu, [4]The University of Melbourne, Victoria, Australia, [5]Bridges to Development, Seattle, WA, United States

Soil transmitted helminths (STH), scabies and yaws are neglected tropical diseases (NTDs) endemic to Vanuatu. To control and eliminate these NTDs, the Vanuatu Ministry of Health, with the support of the non-profit organisation Bridges to Development, is implementing large-scale innovative integrated control programs including two rounds of mass drug administration (MDA) with albendazole, azithromycin and ivermectin, concurrent with active surveillance of yaws and leprosy. To monitor and evaluate the impact of this program, cross-sectional parasitological surveys will be conducted before and after MDA. A cross-sectional baseline prevalence survey was conducted in 92 villages across three provinces. In each village the aim was to recruit 100 residents of skin examination and 50 to provide stool samples. One day prior to the MDA, field teams visited selected households, sought consent, and provided a stool collection kit to be returned the following day. On the day of MDA, a nurse performed a skin examination for scabies, yaws and leprosy. The dual path platform (DPP) rapid diagnostic test (RDT) was used to confirm suspected yaws cases. Stool samples were tested for STH species using sodium nitrate flotation (SNF) technique and qPCR. At the time of writing this abstract, a total of 4815 individuals in 2 provinces participated in the baseline survey that took place in Tafea in November 2021 and Sanma in September 2022. A baseline survey is planned for Shefa in May 2023. In the first 2 provinces, the prevalence of any STH by SNF was 28.3%, Ascaris lumbricoides 16.7%, Trichuris trichuria 11.4%, and hookworm 12.1%. The prevalence of scabies was 14.0% in Tafea vs 2.6% in Sanma. Active surveillance of yaws and leprosy identified 15 cases of confirmed yaws (13 in Tafea and 2 in Sanma) and 6 cases of suspected leprosy. Our study suggests that there is a high prevalence of STH and skin diseases among Vanuatu population. The implementation of surveys integrated with MDA is a novel approach that allows more cost-efficient collection of data necessary to monitor and evaluate impact of the MDA.

6484

COMMUNITY DIALOGUE AS AN INNOVATIVE APPROACH TO IMPROVE THE EFFECTIVENESS OF NEGLECTED TROPICAL DISEASE (NTD) CONTROL PROGRAMS TO IMPROVE MASS DRUG ADMINISTRATION (MDA) COVERAGE FOR LYMPHATIC FILARIASIS IN BURKINA FASO

Clarisse Bougouma[1], Mamadou Serme[1], Christophe Nassa[1], Kima Appolinaire[1], Zoromé Harouna[1], Cathérine Kabré[1], Ilboudo Adama[1], Georges Diminthe[2], Regina Khassanova[2], **Dieudonné Naré**[2], Micheline Ouedraogo[2], Lucien Mano[2], Elisabeth Chop[3], Angel Weng[3], Patricia Houck[3], Yaobi Zhang[3], Benoit Dembele[4], Steven D. Reid[3], Angela Weaver[3]

[1]NTD Control Program - Ministry of Health, Ouagadougou, Burkina Faso, [2]Helen Keller International, Ouagadougou, Burkina Faso, [3]Helen Keller International, New York, NY, United States, [4]Helen Keller International, Dakar, Senegal

Burkina Faso has implemented mass drug administration (MDA) for lymphatic filariasis (LF) for over 20 years in all 70 health districts (HD). Currently, 62 of the 70 districts have stopped treatment. However, LF transmission has persisted in 8 HDs despite multiple rounds of MDA with good, reported coverage and implementation of additional MDA quality improvement strategies since 2018. In order to identify the factors for the persistence of transmission, the National Neglected Tropical Disease Program (PNMTN) implemented a community dialogue in 2022 in the districts of Gaoua, Batié, Bogodogo, Ouargaye and Tenkodogo. A total of 52 villages were selected based on the following criteria: therapeutic coverage rate ≤65%, antigenic prevalence ≥2%, and accessibility from a security perspective. Data collection of the community dialogue was done through individual interviews and focus groups, which were then qualitatively analyzed by theme. In total, the dialogue was conducted in 47 of the 52 villages targeted (90.4%) due to the deteriorating security situation. The individual interviews involved 346 people, including head nurses (5.2%), community distributors (27.1%) and community leaders (67.6%); 15.3% of participants were women. A total of 92 people (47 women) participated in the focus groups. The main factors for the persistence of LF were determined to be non-adherence to treatment and missed opportunities for treatment. The reasons mentioned by participants were lack of knowledge about LF, insufficient social mobilization, visits to the home at inconvenient times by distributors, the delay in providing financial resources available to implementing actors and MDA conducted in the rainy season. Some recommendations from the community dialogue, including improved planning, social mobilization, training, supervision, and distribution, were implemented during an MDA two months later; reported therapeutic coverages increased by an average of 4% in all districts. The remaining recommendations will be implemented in 2023.

6485

CHARACTERISTICS OF NON-TREATED POPULATIONS AMONG SELECT NEGLECTED TROPICAL DISEASE (NTD) MASS DRUG ADMINISTRATION (MDA) CAMPAIGNS IN WEST AFRICA: RESULTS FROM MULTI-LEVEL MODELING USING COVERAGE EVALUATION SURVEYS

Maureen K. Headland[1], Kaustubh Wagh[1], Andres Martinez[2], Vance Harris[2], Elisabeth Chop[3], Caleb Parker[2], Diana Stukel[1]

[1]FHI 360, Washington, DC, United States, [2]FHI 360, Durham, NC, United States, [3]Helen Keller International, Washington, DC, United States

Effective mass drug administration (MDA) is the cornerstone of preventive chemotherapy (PC) neglected tropical disease (NTD) programs. USAID's Act to End NTDs | West program supports Ministries of Health to eliminate or control five PC NTDs across 11 West African countries by assisting with MDAs and disease specific assessments. Coverage evaluation surveys (CES) are used to validate coverage shortly after MDA. Non-treated populations (MDA eligible people in endemic districts who do not participate in the treatment campaign) are of concern as they may enable ongoing transmission of infection. If these populations can be better characterized, programs can take more precise actions to identify and target them. Three-level (persons/households/villages) hierarchical models of non-treatment were built using Act | West CES data from six surveys (39,705 MDA-eligible respondents) conducted in 24 districts across Ghana, Niger, Senegal, and Sierra Leone. We employed a range of explanatory variables from the CES and using geospatial techniques, we estimated travel time between households and the closest health facility as an additional explanatory variable. The overall model results showed odds of non-treatment were higher among males compared to females in all age groups except under 5. The highest odds of non-treatment were observed in males compared to females in the age group 25-34 (OR=2.55, 95% CI = 2.08, 3.13). People living in household more than one hour away from the closest health facility had 1.7 times higher odds (95% CI = 1.25, 2.34) of non-treatment compared to those living closer. Not having prior knowledge of the MDA campaign was also a significant predicter of non-treatment (OR=6.45, 95% CI = 5.46, 7.62). Country-specific models indicated that the drug distribution platform and an individual's time living in the community were also significant covariates. Our findings suggest the most influential programmatic response could include implementing age and sex specific

MDA mop-up, increasing the information coming through the health system to raise awareness of MDA, and focused attention on facilities serving relatively remote areas.

6486

A SEMI-QUANTITATIVE DIPSTICK ASSAY IN SERUM FOR THE FOLLOW-UP OF PATIENTS WITH SUBARACHNOID NCC

Luz M. Toribio[1], Sukwan Handali[2], Carolina Guzman[1], Erika Perez[1], Yesenia Castillo[1], Javier Bustos[1], Herbert Saavedra[3], Seth O'Neal[4], Hector H. Garcia[1]

[1]Center for Global Health, Universidad Cayetano Heredia, Lima, Peru, [2]Division of Parasitic Diseases, Center for Disease Control and Prevention, Atlanta, GA, United States, [3]Instituto Nacional de Ciencias Neurológicas, Lima, Peru, [4]Oregon Health & Sciences University-Portland State University, Portland, OR, United States

Neurocysticercosis (NCC) is one of the most frequent parasitic diseases in the human central nervous system. Clinical manifestations rely principally on cyst localization, being subarachnoid NCC (SANCC) the most severe clinical form of NCC. Taking leverage of the enormous quantities of antigens released into circulations in SANCC, we evaluated the utility of a dipstick assay based on monoclonal antibodies (mAbs) anti-T solium (TsW8 and TsW5) in serum samples of SANCC patients for the follow-up after antiparasitic treatment; and compared its performance with a standard Ag-ELISA using the same pair of mAbs . Fifteen patients were included, with a total of 45 samples collected over 3 months. Under the hypothesis that a low mAb concentration would only detect high levels of circulating antigen, whereas when antigen level decrease, it would only be detectable using high mAbs concentrations; we developed a dipstick format with two different mAb concentrations: TsW8 at 3mg/ml and 0.5 mg/ml. Our results demonstrated that initially all SANCC cases presented saturating antigen levels the new dipstick assay (3+++ intensity bands) and Ag-ELISA (Ag ratio ranging from 104.73 to 21.00). Second and third bled showed a drastic reduction in antigen levels, obtaining one (n=10) or absent (n=1) bands and negative antigen ratios ranging from 0.92 to 0.25. As shown, the presence and intensity of reactive bands in our dipstick assay correlated strongly with antigen levels measured by Ag-ELISA. This new dipstick assay is a cheap, practical and reliable tool for the follow-up of patients with the NCC type with the worse prognosis (SANCC) reflecting the efficacy of cysticidal treatment. Hopefully, subsequent work will assess whether this dipstick assay can be used with non-invasive samples such as urine and in rural cysticercosis endemic communities.

OPTIMIZATION OF A PCR ASSAY TO DETECT URINARY PARASITE DERIVATE DNA IN PATIENTS WITH NEUROCYSTICERCOSIS

Luz M. Toribio[1], Mariel Almanza[1], Isidro Gonzales[2], Alan Scott[3], Javier Bustos[1], Hector H. Garcia[1], Clive Shiff[3]

[1]Center for Global Health, Universidad Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurologicas, Lima, Peru, [3]Department of Molecular Microbiology and Immunology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Neurocysticercosis (NCC) is one of the main causes of epilepsy and other neurological morbidity in most of the world. Definitive diagnosis is based on technically demanding and costly imaging approaches that are impractical for routine screening or monitoring treatment effectiveness. Specific molecular diagnosis of helminth-derived cell-free DNA (cfDNA) in body fluids has shown promise as a tractable approach monitoring infection status through measuring parasite cfDNA fragments in blood or urine by PCR. In this study, we explored the utility of a PCR-based detection of T. solium cfDNA for diagnosis of NCC. First, we tested the difference in stability and yield of parasite cfDNA from urine samples stored/processed under different conditions (fresh urine extracted immediately after collection, fresh urine in filter paper, frozen urine at -20C and frozen urine at -80C). Urine stored at -80°C gave the highest DNA yield and, when combined with a new 30-minute extraction protocol, requires as little as 4 ml of urine for sufficient cfDNA for analysis. We also evaluated and standardized 15 different sets of primers using urine samples from 6 subarachnoid and 6 parenchymal NCC cases. Primer pairs that resolved the amplicons pTsol9 (116 bp), TsollTS (86 bp) and Tsol13(<100 bp) demonstrated that T. solium cfDNA could pass the glomerular barrier and be detected in urine. Cross reaction analysis with T. multiceps, the closest related brain parasite in humans, revealed that none of the primer pairs generated amplicons from T. multiceps DNA. For the urine samples tested, all three primers pairs detected T. solium cfDNA; however, the pTsol9 amplicon showed the highest intensity band after electrophoresis. In a second phase of this study, we will increase our sample size to better assess the performance of the cfDNA detection system. This molecular test, based on the detection of parasite-derived cfDNA, could serve to categorize populations with viable cysts as an initial screen prior to confirmatory diagnosis and could also function as a sensitive biomarker for monitoring treatment efficacy using a non-invasive sampling method.

6488

DETECTION OF TAENIA SOLIUM ANTIGENS IN PAIRED SERUM AND URINE SAMPLES FROM PATIENTS WITH NEUROCYSTICERCOSIS USING THE TSW8/TSW5 ANTIGEN ENZYME-LINKED IMMUNOSORBENT ASSAY (AG- ELISA)

Carolina Guzman[1], Luz M. Toribio[1], Yesenia Castillo[1], Mirla Villafuerte[2], Cindy Espinoza[3], Javier Bustos[1], Herbert Saavedra[4], Seth O'Neal[5], Hector Garcia[1]

[1]Center for Global Health, Universidad Peruana Cayetano Heredia, lima, Peru, [2]Hospital Nacional Edgardo Rebagliati Martins, lima, Peru, [3]Universidad Peruana Cayetano Heredia, lima, Peru, [4]Instituto Nacional de Ciencias Neurológicas, lima, Peru, [5]School of Public Health, Oregon Health & Sciences, Portland State University, Oregon, USA, Oregon, OR, United States

Neurocysticercosis (NCC) is a frequent parasitic disease of the human central nervous system and is caused by the accidental ingestion of Taenia solium eggs. NCC is endemic in most developing countries, estimating that the third part of epilepsy cases are attributable to this parasitosis. The diagnosis of NCC is based on radiological images due to the heterogeneous clinical manifestations, which principally depend on its localization within the CNS. Detection of circulating parasite antigen marks the presence of live parasites, but it is usually assessed in serum sampling, which is poorly accepted by patients. On the other hand, urine antigen detection has been lately shown as an alternative non-invasive sample to detect parasite antigens. However, the correlation between paired samples of serum and urine has not been assessed with TsW8/TsW5 Ag-ELISA. We evaluated the correlation between paired serum and urine samples of 172 NCC patients using a T solium monoclonal antibody based enzyme-linked immunosorbent assay TsW8/TsW5 Ag-ELISA expressed as optical density (OD) and OD ratios. Study samples included subarachnoid (n=51), parenchymal (n=18) and calcified (n=103) NCC cases. Correlation between LogOD (rho=0.79) and antigen ratio (rho=0.66) of all samples was statistically significant (p=0.000). When separated by type of NCC, positive correlations were found between the urine and serum LogOD and ratio of subarachnoid (rho=0.71/rho=0.53), parenchymal (rho=0.83/rho=0.79), and calcified (rho=0.66/rho=0.64) NCC cases. Our results showed a strong correlation between paired serum/urine samples, guiding our perspective to a less invasive form of diagnosis.

6489

PRESENTATION, COMPLICATIONS, AND OUTCOMES OF CYSTIC ECHINOCOCCOSIS IN CUSCO, PERU

Roberto Pineda-Reyes[1], Angel Gamarra[2], Ramiro Hermoza[2], Rocio Cuaresma[2], Maria L. Morales[3], Karen Mozo[3], Maria A. Caravedo[1], Miguel M. Cabada[1]

[1]Infectious Disease Division, University of Texas Medical Branch, Galveston, TX, United States, [2]Hospital Regional del Cusco, Cusco, Peru, [3]Cusco Branch - Alexander von Humboldt Tropical Medicine Institute. Universidad Peruana Cayetano Heredia, Cusco, Peru

Cystic echinococcosis (CE) morbidity and mortality are associated with size, delayed care, and cyst complications. Data on CE outcomes are scant in endemic countries. We characterized the clinical presentation, complications, and outcomes of CE in two tertiary hospitals in Cusco, Peru. We reviewed available medical records from patients discharged with a diagnosis of CE between January 2009 and December 2019. Medical records of 489 patients with over 821 cysts were included, the median age was 23 years (IQR 29), 50% were female, and 40% were referred from another health center. The most common occupations were student (43%) and homemaker (21%). Lung (64%) and liver (42%) CE were the most common. Other locations included other intraabdominal organs, brain, and pelvis. Most liver (60%) and lung (54%) CE had a diameter larger than 10 cm. Most lung (76%) and 42% of liver cysts were complicated on admission. Common complications of lung CE were hemoptysis, vomica, and bronchial fistulas. Leukocytosis (21%) and eosinophilia (10.6%) were uncommon. Surgery was performed on 72% of lung and 45% of liver cysts. Twenty-three percent of patients had a second related hospital admission and 4.7% had a third one. Three patients died in the hospital and 23.6% had a discharge status of "worse or unchanged". Patients with lung cysts (OR=1.92; 95%CI 1.07-3.44) and those reporting contact with dogs (OR 1.53; 95%CI 1.15-2.05) were more likely to have more than one admission. Patients with complicated cysts on admission (OR=1.9; 95%CI 0.99-3.66) and those treated medically (OR= 5.5; 95%CI 2.21-13.67) were more likely to meet a composite outcome of death or "worse/unchanged" discharged status. Patients receiving post-surgical medical treatment (OR=0.43; 95%CI 0.22-0.82) and those referred from another health center (OR=0.22; 95%CI 0.12-0.42) were less likely to have the composite outcome. Advanced and complicated CE were common and associated with worse outcomes. Readmission and worse/unchanged discharge status rates suggest a large burden affecting patients and the health system. Early detection and treatment may decrease the disease impact in the Cusco Region.

6490

DEVELOPMENT OF A HIGHLY SENSITIVE QPCR ASSAY FOR DETECTION OF ECHINOCOCCUS MULTILOCULARIS AND FURTHER MAPPING THE EXTENT OF EUROPEAN-LIKE STRAINS IN NORTH AMERICA

Jiana Blaha[1], Sasisekhar Bennuru[1], Michael Grigg[1], Tammy Chen[1], Yang Chen[1], Stephen Raverty[2], Rick McKown[3], Brian Xi[1], Jennifer Noyes[4], Roger Ramirez Barrios[5], Elise M. O'Connell[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]Animal Health Center, Vancouver, BC, Canada, [3]USDA Meat Animal Research Center, Clay Center, NE, United States, [4]Hollins University, Roanoke, VA, United States, [5]Virginia-Maryland College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, United States

Echinococcus multilocularis (Em) is a severe invasive parasitic disease. Humans are exposed through eggs shed primarily in the stool of wild canids, the definitive host. Almost all human cases of Em have been reported in Europe and Asia, despite the fact that North American strains of Em were previously known to circulate in wild canids in the Northern US and Canada. With the recent reporting of several human and canid cases of Em in Canada and the US due to a more aggressive European-like strain, we sought to develop a highly sensitive qPCR assay for detection of Em in stool samples that could be used for high throughput screening. Using RepeatExplorer, the Em genome was mined for unique, highly abundant interspersed repeats. We then developed and compared 15 new Em qPCR assays against the 5 found in the literature. The most sensitive assays were tested for cross reactivity to E. granulosus, E. ortleppi, and E. vogeli. New Em assay 17S2 was 2-fold more sensitive than any previously reported assay, had a threshold of detection of 25fg (at 97.7% sensitivity) and was specific to Em. We then screened wild canid stool samples from across the US and Canada (n=261), specifically from Virginia, Maryland, Nebraska, and British Columbia. A total of 13 samples (5%) were positive for Em. Mitochondrial sequencing is underway to determine the haplotype of these isolates. One of the positive isolates from a red fox in a Washington, DC suburb had a European haplotype at the gene loci COB and NAD2. This highly sensitive and specific qPCR assay for the detection of Em can be used to identify the prevalence of wild canid infection. Understanding the true extent of European-haplotype Em in North American wildlife will help better understand the risk to human disease and inform preventative measures.

6491

EVALUATION OF ETIDRONATE IN CALCIFIED CYSTS IN THE PIG MODEL OF NEUROCYSTICERCOSIS

Laura Baquedano Santana[1], Noemi Miranda[1], Gianfranco Arroyo[1], Hector H. Garcia[2], Javier A. Bustos[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurologicas, Lima, Peru

Neurocysticercosis (NCC) is the most important factor associated with late-onset epilepsy in developing countries. Cysts in the brain go through a process of complete resolution or calcification and these calcifications would be associated with epilepsy and seizures. Bisphosphonates, such as etidronate, have been shown to have an effect in reducing the ectopic calcification process in soft tissues, which would probably cause a decrease in epileptic activity. The objective was to evaluate the calcification process in pigs treated with etidronate in a natural infection of neurocysticercosis. This was an experimental study consisting of fourteen pigs naturally infected with Taenia solium and treated with 15 mg/kg albendazole and 25 mg/kg praziquantel orally. Then the animals were divided into two groups, one treated with etidronate for 10 weeks orally (n=7) and the other control group without treatment (n=7). After 8 months, the necropsy was performed and calcifications were evident on CT scan and SEM. Inflammation and calcium deposits were assessed with H&E, Masson's trichrome, Alizarin Red, and Von Kossa stains. In naturally infected pigs, we assessed the likelihood of residual calcification calcification after 8 months in 240 cysts from ten NCC pigs treated with either antiparasitic drugs plus etidronate antiparasitic only. Etidronate was associated with a significantly lower risk (49% 67/137 vs 77.67% 80/103 RR:0.63 $p<0.05$). Calcifications in pigs receiving etidronate had a non-statistically significant reduction in density measured on CT as Hounsfield units (80.8 ± 15.5 vs 100.6 ± 31.4). On SEM, calcifications in pigs receiving etidronate demonstrated significantly lower proportions of weight (Wt%) of phosphorus (2.68 vs 4.19 $p=0.02$) and calcium (4.2 vs 8.21 $p=0.01$). Etidronate also prevented the aggregation of macrophages, which are associated with calcification. This study shows the evaluation of the calcification process in animals treated with etidronate, observing less calcification in these, serving as a basis for future drug treatments in neurocysticercosis.

6492

DYSREGULATED AUTOPHAGY LEADS TO AXONAL SWELLING IN NEUROCYSTICERCOSIS

Gino Castillo[1], Katty Ore[1], Oscar Ramos[1], Ana Claudia Palacios[1], Nancy Chile[1], Edson Bernal[1], Dina Luz Patilla Chihuan[1], Dina Maria Ramirez Cubas[1], Danitza Davila[1], Cesar Gavidia[2], Manuela Verastegui[1], Robert Gilman[3], Cysticercosis Working Group of Peru[1]

[1]Laboratorio de Investigación en Enfermedades Infecciosas, LID, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]School of Veterinary Medicine, Universidad Nacional Mayor de San

Marcos, Lima, Perú., Lima, Peru, [3]Department of International Health, Johns Hopkins School of Public Health, Baltimore, Maryland, USA., Baltimore, MD, United States

Neurocysticercosis is a central nervous system disease caused by infection with the larval stage of Taenia solium (cysticercus). We have published novel neuropathological findings in neurocysticercosis, such as axonal swellings, which other studies linked to seizures and cognitive decline, common symptoms in neurocysticercosis. As axonal swellings indicate an impairment in axonal transport and accumulation of cargos throughout the neurons, autophagy was proposed as a possible mechanism involved in axonal swelling formation. We aimed to understand the role of autophagy in the axonal swelling formations in neurocysticercosis. Using our rat model of neurocysticercosis, we analyzed secretory cysticerci antigens and different markers for autophagy, like Beclin-1, p62, and LC3B, in brain sections by immunohistochemistry. We found overexpression of autophagy markers, and this autophagy was dysfunctional where p62 was increased in the tissue surrounding the parasite, and neurons mainly overexpressed autophagy markers, unlike glial cells. Although microglia engulfed most parasite antigens, secretory cysticerci antigens were found within the neuron, which co-localized within autophagosomes. The results suggest an important role of autophagy in disease development in neurocysticercosis and may afford attention toward improved disease management.

[1]Infectious Diseases Laboratory Research-LID, Faculty of Science and Philosophy, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Bloomberg School of Hygiene and Public Health, Johns Hopkins University, Baltimore, MD, United States, [3]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru

An important cause of seizures, epilepsy and other neurological manifestations is the infection by Taenia solium, which is endemic in developing countries and currently a public health problem worldwide due to migration. In recent years, studies have increased trying to understand the pathogenesis of the disease and the host's inflammatory response using animal models. The unpredictable nature of the host's immune reaction in response to the presence of the parasite and the various pathological mechanisms that this reaction induces in the nervous system, make this a complex disease. When the cysticercus begins to degenerate due to it's development or in response to antiparasitic drugs, it triggers an exacerbated inflammatory response. This could cause damage to neuronal and glial cells, a central feature of neurodegenerative diseases, nevertheless; there are no studies in Neurocysticercosis that confirm this information. Recent evidence suggests that apoptosis process plays a key role in nerve cell death in acute and chronic diseases of the nervous system. In the present study, we proposed to evaluate whether the presence and subsequent inflammation caused by the cysticercus of Taenia solium would be associated with damage and death by apoptosis of neuronal and glial cells in an animal model. To achieve this, by the colocalization of biomarkers by immunofluorescence; The TUNEL technique and activation by Caspase-3, the presence of apoptotic cells will be determined in an animal model of NCC using laboratory rats. We found that colocalization of TUNEL essay and active Caspase-3 was performed, suggesting the presence of cell death by apoptosis, with an evident increase in rats infected with NCC, predominantly in those that were sacrificed 24 hours after treatment. In addition, an increase in immunoreactivity to the apoptotic marker Caspase-3 was demonstrated, with an increase predominant in NCC-infected rats sacrificed 24 hours after treatment. In addition, cellular colocalization of active Caspase-3 was demonstrated with GFAP and NeuN but not with Iba-1, suggesting that apoptosis mainly affects astrocytes and neurons but not microglia.

6494

LEAKY GUT MECHANISMS IN GIARDIASIS

Vanessa V. Angelova, Erqiu Li, Brooke Fiedler, Haley Wexelblatt, Rita Kosile, Matthew Darmadi, Eleanor Miskovsky, Steven Singer

Georgetown University, Washington, DC, United States

Giardia duodenalis is an intestinal parasite endemic worldwide and commonly transmitted via contaminated water. Infection in children under 2 is one of the top 5 infectious causes of childhood growth stunting. Growth faltering is a complex pathology facilitated by changes in the intestinal barrier and enzymatic deficiencies. This pathology is predictive of later delays in cognitive and motor development. However, while infection is widely associated with barrier damage in vitro, in animal models, and in patient studies, the mechanisms behind this process are not well understood. The Protease-activated receptor 2 (PAR2) has a prominent role in modulating intestinal tight junction permeability in Celiac disease. Co-culture of Giardia and Caco2 cells similarly results in altered tight junction morphology as revealed by staining for the tight junction-associated protein Zonula occludens 1 (ZO-1); these changes are reduced by treatment with a PAR2 antagonist. Effects of Giardia-induced PAR2 signaling on barrier function are being assessed further by measuring transepithelial electrical resistance (TEER) in Caco2 cells and PAR2+/- and PAR2-/- organoids cultured on transwell filters. Additionally, infected mice lacking PAR2 and fed a low-protein diet gain weight normally over time, while wildtype C57BL/6 animals under the same conditions arrest growth post infection. These data indicate that PAR2 signaling contributes to intestinal permeability defects and growth faltering. Identifying parasite factors that activate PAR2 will provide novel targets for development of pharmaceuticals and vaccines to improve child growth.

6495

DISRUPTION OF HUMAN LYMPHATIC EPITHELIAL CELL CONTACT INTEGRITY PROTEINS BY FILARIAL MIRNAS

Denis Voronin, Hailey Johnson, Elodie Ghedin

Systems Genomics Section, Laboratory of Parasitic Diseases, NIAID, NIH, Bethesda, MD, United States

Parasitic filarial nematodes Wucheria bancrofti, Brugia malayi, and Brugia timori are the causative agents of the debilitating, yet neglected, infectious disease lymphatic filariasis. Adult worms reside in the human lymphatic system where they can survive and reproduce for 8-10 years. The worms can damage the lymphatics and cause lymphedema, however the mechanism by which this occurs is unclear. As filarial worms are in contact with lymphatic endothelial cells (LECs) we used an in vitro model to study interactions between the parasite and human LECs. Filarial worms have been shown to secrete microRNAs (miRNAs) that can be detected in the biofluids of infected animals and humans. We tested if secreted B. malayi miRNAs were involved in the damage to lymphatic cells, which could lead to lymphedema. We used miRanda, an algorithm to predict miRNA-mRNA pairs, to find potential human mRNA targets of B. malayi miRNAs that were previously found to be secreted by worms. First, we prioritized the human targets that encode proteins involved in cell-to-cell connection and the extracellular matrix: fibronectin, integrins, as well as proteins of tight junctions (claudins) and adherens junctions (VE-cadherin). We identified 2 Brugia miRNAs—bma-mir-86 and bma-mir-5864—that have potential target sites in these genes. To validate the interactions predicted and determine their effects on target genes, we treated LECs with miRNA-mimics, which mimic selected parasite miRNAs, and analyzed the expression of the human proteins to determine if there was suppression. We showed that the 2 parasite miRNAs tested significantly decreased the expression of human fibronectin and VE-cadherin. We also observed a reorganization of integrins in treated cells. As these parasite miRNAs are secreted by the worms in the lymphatics, they could participate in the

pathology by reducing cell-to-cell connection and adhesion of the cells, as well as increase the permeability of the endothelial monolayer. Defining the role filarial miRNAs play in the pathogenesis could help establish a mechanism that could be targeted therapeutically.

6496

A HUMAN PLURIPOTENT STEM CELL DERIVED MODEL OF THE BLOOD-BRAIN BARRIER IN CEREBRAL MALARIA

Adnan Gopinadhan[1], Jason M. Hughes[2], Andrea L. Conroy[1], Chandy C. John[1], Scott G. Canfield[3], Dibyadyuti Datta[1]

[1]Indiana University School of Medicine, Indianapolis, IN, United States, [2]Indiana University School of Medicine, Terre Haute, IN, United States, [3]Indiana University School of Medicine, Terre Hatue, IN, United States

Blood-brain barrier (BBB) disruption is a central feature of cerebral malaria (CM), a severe neurologic complication of Plasmodium falciparum (Pf) infections that presents clinically as an unarousable coma and is a significant driver of childhood mortality. The pathogenesis of CM involves sequestration of Pf-infected red blood cells (Pf-iRBCs) to the brain microvasculature. In-vitro BBB model-based studies have provided insight into CM-mediated brain injury, but limitations of these models include endothelial monolayers in the absence of cells like astrocytes and neurons and reliance on immortalized or primary brain microvascular endothelial cell (BMECs) that lack physiologically relevant barrier properties and show batch-to-batch variability. We have developed a multicellular BBB model comprised of human-induced pluripotent stem cell (iPSC) derived BMECs, neurons, and astrocytes representing a physiologically relevant BBB as determined by elevated trans-endothelial electrical resistance (TEER). Using the HB3var03 parasite strain that expresses proteins bind to endothelial cells, we conducted co-culture experiments with multiple timepoints over 9 hours. By the 6-and 9-hour timepoint, in iPSC-derived BMECs co-cultured with Pf-iRBC but not uninfected RBC controls, we observed disruptions in barrier integrity measured by TEER and confirmed by immunofluorescence imaging to visualize changes in the localization of tight junction (TJ) proteins occludin and zona-occludin-1. Western blots of BMEC lysates to determine Pf-iRBC co-culture mediated changes in TJ protein expression on BMECs, and immunoassays with co-culture supernatants to detect changes in expression of angiogenesis, and endothelial activation markers are ongoing. Furthermore, we will validate the effects of Pf-iRBC in a co-culture model of the BBB comprising of BMECs, astrocytes, and neurons to investigate neuronal injury. Upon completion, this work aims to establish the iPSC-derived multicellular BBB model as a new in vitro standard for investigating pathways underlying neuronal injury in clinical CM.

THE BRCT DOMAIN FROM LEISHMANIA MAJOR LMJPES PROMOTES MALIGNANCY AND DRUG RESISTANCE IN MAMMALIAN CELLS

Paul Nguewa[1], Esther Larrea[1], Celia Fernandez-Rubio[1], José Peña-Guerrero[1], Elizabeth Guruceaga[2]

[1]Institute of Tropical Health University of Navarra (ISTUN), Pamplona, Spain, [2]Bioinformatics Platform, Center for Applied Medical Research, University of Navarra (ISTUN), Pamplona, Spain

According to IARC, 15% of cancer cases are attributable to pathogens including parasites. Epidemiological studies suggest an association between cancer and leishmaniasis. Recently, the homologue of the human oncogene PES1 was identified in Leishmania major and named LmjPES encoding a conserved protein containing a BRCT domain. This domain is a key factor in DNA damage-response checkpoints. Interestingly, previous results have demonstrated that LmjPES is involved in parasite infectivity. In addition, BRCT domain was used as a therapeutic target and new antileishmanial drug candidates were identified. Our work aimed to elucidate the hypothetical oncogenic implication of BRCT domain from LmjPES in host cells. We generated a lentivirus carrying this BRCT domain sequence (lentiBRCT) and a lentivirus expressing the luciferase protein (lentiLuc), as control, and used them to infect mammalian cells. We observed that the expression of BRCT domain from LmjPES conferred to HEK293T and NIH/3T3 mammal cells a greater replication rate and higher survival in vitro. Moreover, such lentiBRCT infected cells were less sensitive to genotoxic drugs 5-FU and etoposide. In addition, lentivirus infected cells were used to induce tumorigenesis process. The in vivo experiments showed faster tumor growth in mice inoculated with lentiBRCT respect to lentiLuc HEK293T infected cells. To shed some light on the molecular mechanisms involved in the cellular alterations described after the expression of the studied domain in mammalian cells, we performed a high-throughput RNA sequencing of LentiBRCT- and Lentiluc-infected HEK293T cells. The gene expression profiling analysis revealed that BRCT domain from LmjPES altered the expression of proliferation- (DTX3L, CPA4, BHLHE41, BMP2, DHRS2, S100A1 and PARP9), survival- (BMP2 and CARD9) and chemoresistance-related genes (DPYD, Dok3, DTX3L, PARP9 and DHRS2). Altogether, our results reinforced the idea that in eukaryotes, horizontal gene transfer might also be achieved by parasitism like Leishmania infection driving therefore to some crucial biological changes such as proliferation and drug resistance.

6498

SUPER RESOLUTION IMAGING REVEALS CYTOSKELETON REGULATION IN PLASMODIUM SEXUAL STAGE DEVELOPMENT

Jiahong Li, Sophie Collier, Emma Pietsch, Sash Lopaticki, Paul McMillan, James McCarthy McCarthy, Leann Tilley, **Matthew Dixon**

University of Melbourne, Melbourne, Australia

The transmission of Plasmodium falciparum parasites from human to mosquito relies on the formation of a specialised sexual form known as the gametocyte. The gametocyte develops through five distinct morphological stages over a period of 10 days, adopting a unique crescent shape upon reaching sexual maturity. Formation of these mature stage V gametocyte is essential for transmission. The distinct morphology of the gametocyte is driven by the assembly of a dense microtubule (MT) network that assembles under an additional cisternal compartment called the inner membrane complex (IMC). In addition, the parasite also has an actin cytoskeleton which accumulates at the apical tips of the parasite and co-locates with the MT network across gametocyte development. Despite the importance of these structures to maintaining parasite morphology, we know very little about how these networks are regulated and how they work together to control gametocyte shape and transmission. In our work we investigate IMC proteins (GAPM 1-3), the actin nucleating protein formin 2 and important proteins of mitosis (centrin 1-3 and NDC80). To investigate the function of these proteins we have employed a conditional knockout approach and combined this with ultra-expansion microscopy, super-resolution imaging and electron microscopy. We show that early gametocyte have novel non-mitotic microtubules within their nuclei that bind and redistribute chromatin inside the nucleus of gametocytes. In addition, these novel MTs function in positioning the nascent IMC and subpellicular microtubules, initiating gametocyte elongation. We show that deletion of GAPM proteins ablates IMC expansion leading to an inability of the MT network to align and elongate the gametocytes. Lastly, we demonstrate that Formin 2 locates at the apical tips of the gametocyte interleaving between the actin and MT networks, stabilising the crescent shape. Deletion of Formin 2 results in a collapse of gametocyte shape. In this work we reveal a holistic picture of the function and interplay between key proteins controlling IMC, MT and actin cytoskeletons dynamics across gametocyte development.

DEVELOPMENT OF AN IN VIVO MOUSE MODEL FOR TRANSMISSION BLOCKING STUDIES WITH HUMAN MALARIA PARASITE PLASMODIUM FALCIPARUM

Abhai K. Tripathi, Godfree Mlambo, Tassanee Thanakornsombut, George Dimopoulos

Johns Hopkins University, Baltimore, MD, United States

Malaria elimination/eradication will need a coordinated effort involving multiple strategies including those that interrupt transmission of malaria parasites from humans to mosquitoes. Transmission blocking drugs, vaccines and genetically modified mosquitoes represent an appealing approach. Standard membrane feeding assay (SMFA), which involves feeding mosquitoes with cultured Plasmodium falciparum gametocytes using glass membrane feeders is used as primary screen for different transmission blocking interventions (TBI). However, further development of TBI is hindered by the lack of a reliable P. falciparum small animal model to test TBI before proceeding to the controlled human malaria infection studies or field trials. To develop the mouse model for assessment of TBI we have utilized extremely immunodeficient NSG (NOD-scid IL2Rgammanull) mouse. The immunodeficiency allows the mice to be humanized by the engraftment of human red blood cells. P. falciparum asexual blood stages, when inoculated in RBC humanized NSG mice, are promptly cleared from circulation, either by macrophages or through splenic clearance. However, when we inoculated mature stage V gametocytes, they remained in circulation for at-least a week, which allows us to use these mice to feed Anopheles stephensi mosquitoes. Mosquitoes fed on NSG mice inoculated with P. falciparum mature gametocytes developed midgut oocyst and passive transfer of transmission blocking monoclonal antibody to Pfs25 (4B7) significantly reduced the transmission. To further standardize the assay, we are currently testing known transmission blocking drugs and antibodies.

GLOBAL RELEASE OF TRANSLATIONAL REPRESSION ACROSS PLASMODIUM'S HOST-TO-VECTOR TRANSMISSION EVENT

Kelly T. Rios[1], James P. McGee[1], Kristian E. Swearingen[2], **Scott E. Lindner**[1]

[1]Pennsylvania State University, University Park, PA, United States, [2]Institute for Systems Biology, Seattle, WA, United States

Malaria parasites must be able to respond quickly to their environment, including during their transmission between mammalian hosts and mosquito vectors. Therefore, before transmission, female gametocytes proactively produce and translationally repress mRNAs that encode essential proteins that the zygote requires to establish a new infection. This essential regulatory control requires the orthologues of DDX6 (DOZI) and LSM14 (CITH), which along with ALBA proteins, form a translationally repressive complex in female gametocytes that associates with many of the affected mRNAs. However, while the release of translational repression of individual mRNAs has been documented, the details of the global release of translational repression have not. Moreover, the changes in spatial arrangement and composition of the DOZI/CITH/ALBA complex that contribute to translational control are also not known. Therefore, we have conducted the first comparative transcriptomics and proteomics of Plasmodium parasites across the host-to-vector transmission event to document the global release of translational repression. Using female gametocytes and zygotes of P. yoelii, we find that over 150 transcripts are released for translation soon after fertilization, including those with essential functions for the zygote. However, we also observed that some transcripts remain repressed beyond this point. In addition, we have used TurboID-based proximity proteomics to interrogate the spatial and compositional changes in the DOZI/CITH/ALBA complex across this transmission event. Consistent with recent models of translational control, proteins that associate with either the 5' or 3' end of mRNAs are in close proximity to one another during translational repression in female gametocytes and then dissociate upon release of repression in zygotes. These interactions in female gametocytes were further validated through Structured Illumination Microscopy and Ultrastructure Expansion Microscopy. Together, these data provide a model for the essential translational control mechanisms used by malaria parasites to promote their efficient transmission.

DYNAMICS OF ASYMPTOMATIC PLASMODIUM FALCIPARUM AND P. VIVAX INFECTIONS AND INFECTIOUSNESS TO MOSQUITO IN LOW TRANSMISSION SETTING OF ETHIOPIA: A LONGITUDINAL OBSERVATIONAL STUDY

Elifaged Hailemeskel[1], Surafel K. Tebeje[1], Temsgen Ashine[1], Sinknesh W. Behaksra[1], Tadele Emiru[1], Tizita Tsegaye[1], Kjerstin Lanke[2], Abrham Gashaw[1], Wakoya Chalie[1], Endashaw Esayas[1], Temesgen Tafesse[1], Mikiyas Gebremichael[1], Girma Shumie[1], Beyene Petros[3], Hassen Mamo[4], Jordache Ramjith[2], Chris Drakeley[5], Endalamaw Gadisa[1], Teun Bousema[2], Fitsum G. Tadesse[1]

[1]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [2]Radboud Institute for Health Science, Radboud University Medical Center, Nijmegen, Netherlands, [3]Department of Biomedical Sciences, College of Natural and Computational Sciences, Addis Ababa university, Addis Ababa, Ethiopia, [4]Department of Biomedical Sciences, College of Natural and Computational Sciences, Addis Ababa university, Ethiopia, Addis Ababa, Ethiopia, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

The natural history of Plasmodium falciparum and P. vivax asymptomatic infections and the magnitude of their contribution to onward transmission in co-endemic low transmission settings is incompletely studied. We conducted a 15-month longitudinal study in asymptomatic PCR-detected asymptomatic parasite carriage with mosquito membrane feedings every 14 days for 2.5 months and subsequent monthly parasitology assessments in Adama, Ethiopia. Transmission results were compared with passively recruited clinical malaria cases from the same setting. From 596 feeding experiments in 162 asymptomatic individuals, 0.3% (69/24,966) of mosquitoes were infected by 4 individuals. Two microscopy detectable asymptomatic P. falciparum carriers infected 18.8% (15/80) of mosquitoes and one sub-microscopic P. falciparum carrier infected 30% (14/46) of mosquitoes. No sub-microscopic P. vivax mono-infection was infectious. Among clinical cases, P. falciparum clinical patients were less infectious (2.7% infected mosquitoes, 38/1389) compared to P. vivax patients (42.4% infected mosquitoes; 1068/2519). When analyzing infection duration at a continuous scale, the median duration of infection was 33 days (IQR:15-56) for individuals who were P. falciparum microscopy positive at enrolment and 30 days (IQR:15-48) for individuals who were P. falciparum PCR positive (but microscopy negative) at enrolment. The longest infection duration we observed was 363 days. For P. vivax parasite carriers who were PCR positive at enrolment, the median duration was 33 days (IQR:15-60). We conclude that a minority of asymptomatic infections are of long duration and infectious to mosquitoes. Clinical cases are a relevant source of transmission for P. vivax.

6502

EFFECT OF CHLOROQUINE ON PLASMODIUM VIVAX PARASITE TRANSMISSION TO MOSQUITOES IN THE EARLY POST-TREATMENT HOURS, ARBA MINCH, ETHIOPIA

Girum Datanbo[1], Biniam Wondale[1], Nigatu Eligo[1], Endalamaw Gadisa[2], Bernt Lindtjørn[3], Fitsum Girma[2], Fekadu Massebo[1]

[1]Arba Minch University, Arba Minch, Ethiopia, [2]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [3]Centre for International Health, University of Bergen, Norway

Ethiopian malaria guidelines prescribe chloroquine (CQ) for Plasmodium vivax. Data on human-mosquito malarial parasite transmission in the initial days following CQ therapy is scarce. This study examines CQ's early transmission-blocking impact. Thirty microscopically confirmed P. vivax patients in Arba Minch, Ethiopia, participated in an open-label

experimental follow-up investigation. Participants were treated with CQ for three days and observed for 42 days. Clinical, microscopic blood film and quantitative polymerase chain reaction (qPCR) tests were performed. Anopheles arabiensis colony mosquitoes were tested using artificial membrane feeding. While nested polymerase chain reaction (nPCR) was used to measure the clearance of asexual parasites, qPCR was used to measure the clearance of mature gametocytes. 67% (20/30) were positive for P. vivax alone, 7% (2/30) for both P. vivax and P. falciparum, and 10% (3/30) were positive for P. falciparum by nPCR. Plasmodium vivax mono-infection cases confirmed by nPCR were included in the analysis. 85% (17/20) of confirmed cases were infectious to mosquitoes before treatment and 59% (10/17) after 8 and 24 hours of treatment. The median oocyst infection rate dropped from 51% (245/480 mosquitoes) (ranges: 14-83%) at baseline to 36% (209/522 mosquitoes) after 8 hours and 17% (81/440 mosquitoes) at 24 hours post-treatment. The circumsporozoite protein rate of An. arabiensis was 3% (95% CI: 1-7) before treatment, 3% (CI: 1-5) at 8 hours post-treatment, and 0.7% (CI: 0.1-2.5) at 24 hours post-treatment. Eight hours post-treatment, all patients had gametocytes and sexual parasites. After 24 hours of treatment, positive cases dropped to 50%, but mosquitoes continued to transmit parasites. On day three post-treatment, 19 of 20 patients obtained gametocyte clearance and all patients showed complete asexual parasite clearance. This finding implies that the P. vivax-positive cases continue supporting parasite transmission for at least 24 hours after treatment; therefore, protective intervention and anti-malarial medications that immediately kill mature gametocytes could be recommended.

6503

CLINICAL INVESTIGATION STUDY TO EVALUATE THE CONSISTENCY AND REPRODUCIBILITY OF TWO CONSECUTIVE MOSQUITO FEEDING ASSAYS IN ADULTS WITH VARYING PLASMODIUM FALCIPARUM GAMETOCYTE DENSITIES

New malaria control tools are needed to prevent the transmission of parasites from host to the mosquito vector and vice versa. Infectiousness of Plasmodium falciparum gametocytes obtained from individuals to lab reared mosquitoes should be estimated and quantified in order to apply assays that are easily applicable for evaluating transmission-blocking interventions. The aim of this of this study was to establish relationship between parasite transmission from humans to mosquitoes both within a person and across persons by assessing the variation in the proportion of infected mosquitoes with at least one oocyst (oocyst prevalence) in direct membrane feeding assay (DMFA) and direct skin landing feeding assay (DSFA) performed at two consecutive time points in the same human subject with P. falciparum gametocytemia. A total of 400 adults residing in Western Kenya without symptoms of malaria were enrolled. A blood sample was tested for the presence of P. falciparum gametocytes. Subjects that tested positive for gametocytes had both direct membrane feeding assays (DMFA) and direct skin landing feeding assay (DSFA) on day 1 and day 2 to compare infection rates between the two feeds. Blood samples from 42/400 individuals testing positive for gametocytes underwent mosquito infection assays. Survival rates of mosquitoes at initial day 1 and subsequent feeding day 2 were 12.1 and 11.4 days for DSFA, and 13.2 and 11.6 days for DMFA. The mean oocyst prevalence by DSFA on days 1 and 2 was 5.2% and 2.3% on days 1 and 2; and 6.3% and 2.2% for DMFA, respectively, suggesting comparable readouts for initial versus subsequent feeding timepoints. The correlation between day 1 and day 2 and between assays was low. Exploratory analysis suggests a lower probability of infection the second day, with lower oocyst density. We will discuss the implications for future study designs in testing transmission-blocking interventions based on these results.

HYPER-DIVERSE ANTIGENIC VARIATION AND RESILIENCE TO TRANSMISSION-REDUCING INTERVENTION IN FALCIPARUM MALARIA

Qi Zhan[1], Kathryn Tiedje[2], Qixin He[3], Karen Day[2], Mercedes Pascual[1]

[1]University of Chicago, Chicago, IL, United States, [2]The University of Melbourne, Melbourne, Australia, [3]Purdue University, West Lafayette, IN, United States

In falciparum malaria under high transmission, high asymptomatic prevalence co-occurs with incomplete immunity given vast antigenic variation of the parasite. The var multigene family encodes for the major surface antigen of the blood stage of infection. A field longitudinal study in northern Ghana relied on deep sampling of var sequences from individual isolates to monitor response to transient IRS (Indoor Residual Spraying) intervention. Resulting estimates of parasite population size and structure showed persistent features of high transmission regions despite considerable decrease in prevalence, consistent with a rapid rebound post-IRS. To ask whether the transmission system had been brought closer to losing its persistence, we investigate with a stochastic agent-based model (ABM) the existence of a sharp transition with intervention intensity. We also seek molecular indicators capable of revealing proximity to such a transition in the model, and apply those to the field molecular data on var genes across multiple surveys and the IRS intervention. The ABM explicitly incorporates the evolution of var genes and the acquisition of specific immunity by individual hosts. A sharp transition occurs in the model across a narrow region of intervention intensity in the capacity of the transmission system to rapidly rebound to high prevalence. Molecular indicators are identified, informative about the approach to this transition. Their application to the field data indicates that the system was brought close to transition by IRS, so that sustaining and intensifying intervention could have pushed it to a slow-rebound regime with a high probability of extinction. Our results establish a link between population dynamics of the disease and observations of parasite population genomics from the perspective of hyper-variable antigen-encoding genes. They indicate that the structure of diversity revealed via molecular surveillance can inform intervention against malaria in high-transmission endemic settings. These findings should be relevant to other pathogens with similar immune evasion strategies based on high antigenic diversity.

DENGUE SEVERITY BY SEROTYPE IN 17 YEARS OF A PEDIATRIC HOSPITAL STUDY IN NICARAGUA

Federico Narvaez[1], Karla Gonzalez[2], Elsa Videa[1], Cesar Narvaez[1], Sonia Arguello[1], Carlos Montenegro[1], Jose Juarez[1], Eva Harris[3], Angel Balmaseda[2]

[1]Sustainable Science Institute, Managua, Nicaragua, [2]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [3]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

The four dengue virus serotypes (DENV1-4) cause a range of clinical manifestations, from mild to severe and potentially fatal disease. Understanding dengue severity by serotype is critical, particularly in the context of the introduction of new vaccines that have differential efficacy by serotype. We studied the clinical spectrum of all 4 DENV serotypes over 17 years in the Nicaraguan National Pediatric Reference Hospital. Study participants 6 months to 14 years of age were followed during their hospital stay or as ambulatory patients. Cases were confirmed by molecular, serological and virological methods. A clinical report form with >150 variables with detailed clinical information was completed daily. Cases were classified according to the World Health Organization 1997 (Dengue Fever/Dengue Hemorrhagic Fever/Dengue Shock Syndrome; DF/DHF/DSS) and 2009 (Dengue without Warning Signs/Dengue with Warning Signs/ Severe Dengue) guidelines. A total of 2,811 participants were enrolled, with 1,570 (56%) laboratory-confirmed as DENV-positive. Of 1,355 cases with serotype result by RT-PCR, 281 corresponded to DENV1, 572 to DENV2, 466 to DENV3 and 36 to DENV4. With DENV2 and DENV4, secondary (2°) cases were more prevalent, with 478 (88.7%) and 30 (93.8%), respectively, while with DENV1 and DENV3, 136 (51.1%) and 237 (53.1%) were primary cases, respectively. Plasma leakage was associated with DENV2 (OR: 1.46; 95% CI: 1.16-1.85) and DENV3 (OR: 1.3; 1.02-1.66), with 190/572 (33.2%) DENV2 and 105/466 (22.5%) DENV3 cases resulting in DHF/DSS, respectively. Of the DHF/DSS cases, 167/178 (93.8%) of DENV2 cases were 2°, compared to 63/103 (61.2%) of DENV3 cases and 22/36 (61.1%) of DENV1 cases. Comparing serotypes, DENV2 was associated with DHF/ DSS (OR: 2.06; 1.67-2.75), while DENV3 was associated with Severe Dengue (OR: 2.08; 1.60- 2.70). Overall, we found that clinical manifestations of dengue differ by serotype and immune response, with DENV2 and DENV3 being most associated with severity. Our findings indicate that the clinical spectrum of all serotypes should be considered in the development of a safe and effective DENV vaccine.

COMPARATIVE EVALUATION OF FIVE RAPID DIAGNOSTIC TESTS FOR DENGUE DIAGNOSIS

Jyotshna Sapkota[1], Rumina Hasan[2], Zahida Azizullah[2], Hina Shams[2], Berra Erkosar[1], Sabine Dittrich[3], Kevin Tetteh[1]

[1]FIND, Geneva, Switzerland, [2]Aga Khan University, Karachi, Pakistan, [3]Deggendorf Institut of Technology, Pffarrkirchen, Germany

Every year, dengue outbreaks cause substantial humanitarian and economic hardship worldwide. Dengue causes a wide spectrum of symptoms. Primary dengue can range from subclinical disease to flu-like symptoms. Although less common secondary dengue is associated with increased morbidity and mortality. Accurate, efficient and rapid diagnosis of dengue in acute stage is essential as delay in diagnosis increases the risk of severe dengue and can lead to poor disease outcome. In dengue-endemic areas, laboratories and clinics have to date relied on simple and cost-effective serological rapid diagnostic tests (RDTs) to diagnose dengue. This study evaluated the performance of five commercially available RDTs which can detect NS1 antigen and IgM/IgG antibodies: SD Bioline Dengue Duo, Atron Dengue virus IgG/IgM and Ag cassette, Standard Q Dengue Duo, Humasis Dengue combo kit and ALL Test Dengue Combo Rapid Test. Well characterized archived dengue and non-dengue serum samples at Aga Khan University, Pakistan were screened. Each RDT was evaluated separately and in combination to determine diagnostic parameters [non-structural (NS1) antigen and/or immunoglobulin M (IgM) positive]. 430 serum samples were evaluated (255 NS1 ELISA positive and 175 negative NS1 ELISA). Compared to the reference NS1 enzyme-linked immunosorbent assay (ELISA) samples, sensitivity of RDTs ranged from 69.8% to 94.12% with best overall sensitivity shown by Atron Dengue virus IgG/IgM and Ag cassette (94.12%) All RDTs showed a specificity of >99%. Atron Dengue virus IgG/IgM and Ag cassette (96.78%) had the highest diagnostic accuracy. In conclusion, Atron Dengue virus IgG/IgM and Ag cassette showed the highest sensitivity and diagnostic accuracy, while Standard Q Dengue Duo and ALL Test Dengue Combo Rapid Test showed the highest specificity. Moreover, these results confirm that combining antigen- and antibody-based RDTs can have huge value for dengue diagnosis and that very good commercial tests exist and should be used.

6507

POTENTIAL UTILITY OF CONTINUOUS PPG MONITORING IN THE MANAGEMENT OF SEVERE DENGUE

Ngan H. Lyle[1], Chanh Q. Ho[1], Huy Q. Nguyen[1], Giang T. Nguyen[1], Huyen T. Vu[1], Van-Khoa D. Le[1], Damien K. Ming[2], Stefan Karolcik[3], Hao V. Nguyen[4], Qui T. Phan[4], Trieu T. Huynh[4], Sophie Yacoub[1]

[1]Oxford Clinical Research Unit Vietnam, Ho Chi Minh City, Viet Nam, [2]Centre for Antimicrobial Optimisation (CAMO), Imperial College London, London, United Kingdom, [3]Centre for Bio-Inspired Technology, Imperial College London, London, United Kingdom, [4]Hospital for Tropical Diseases, Ho Chi Minh City, Viet Nam

Dengue infection can progress to shock, driven by increased intravascular permeability and plasma leakage. Management of patients with dengue shock is challenging as the risk of repeated episodes of shock (reshock) due to insufficient fluid replacement and ongoing plasma leakage must be weighed against the risk of volume overload when too much fluid is given. Therefore, a dynamic measure of intravascular volume to guide fluid management has the potential to improve clinical outcomes. We investigated the use of continuous photoplethysmogram (PPG) monitoring using a wearable device for the management of dengue in a prospective study involving 250 patients who were admitted to the Hospital for Tropical Diseases in Ho Chi Minh City, Vietnam in 2020 to 2022. Detailed clinical data were collected and PPG monitoring was performed for 24 hours after enrollment. We hypothesized that the PPG waveform can provide actionable information about a patient's volume status. The 2-hour time window preceding a reshock event, was predefined as an "empty" intravascular state, while the 2-hour time window between 1 to 3 hours following a fluid bolus, was predefined as "full". We then sampled PPG segments (1 minute duration) from these time windows and, accordingly, labelled each as "empty" or "full". Labelled segments were transformed into spectrograms and used to train and test a convolutional neural network model. There were 96 patients with sufficient data for the analysis. Data from 67 patients (70%) were used to train the model and the remaining data were reserved for testing. We repeated the analysis 3 times using 3 different patient splits. The overall performance of our model included accuracy of 0.76 (range 0.73-0.80), F1 score of 0.84 (range 0.84-0.85) and ROC-AUC of 0.77 (range 0.73-0.82). In summary, preliminary analyses suggest that information regarding intravascular volume during severe dengue can be extracted from real-life PPG recordings. Since PPG signals are measured continuously, there is the potential for dynamic guidance. We are continuing to refine our model and will present our updated analysis.

METFORMIN AS ADJUNCTIVE THERAPY IN OVERWEIGHT AND OBESE PATIENTS WITH DENGUE: AN OPEN-LABEL SAFETY AND TOLERABILITY TRIAL (MEDO)

Tam Dong Thi Hoai[1], Nguyet Nguyen Minh[1], Phong Nguyen Thanh[2], Tai Luong Thi Hue[2], Tam Cao Thi[2], Kieu Nguyen Tan Thanh[1], Thuy Huynh Le Phuong[1], Van Nguyen Thanh[1], Chau Nguyen Thi Xuan[1], Chanh Ho Quang[1], Duyen Huynh Thi Le[1], Vi Tran Thuy[1], Ronald Geskus[1], Evelyne Kestelyn[1], Vuong Nguyen Lam[1], Sophie Yacoub[1]

[1]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam, [2]Hospital for Tropical Diseases, Ho Chi Minh City, Viet Nam

Dengue is a major public health burden for Vietnam and globally. Patients with certain risk factors, including obesity, are at higher risk of developing severe disease. There is no antiviral for dengue and novel host-directed therapeutics are urgently needed, particularly in high-risk patients. We conducted an open-label trial using Metformin as an adjunctive therapy for dengue patients with obesity. Our hypothesis was metformin would attenuate obesity-induced lipid-inflammatory mediators, improve clinical parameters and reduce viral replication through AMPK activation and immunomodulation mechanisms. This trial recruited 120 overweight/obese patients with dengue who were admitted to the Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam between 2020 and 2022. Patients were eligible for enrolment if they were 10- 40 years old, had a BMI > 25kg/m2 or BMI-for-age > 1SD, were within 72 hours of fever, and had a positive NS1 test. Sixty patients were treated with metformin (treatment group) and compared with 60 patients receiving standard of care (untreated group). Following a pilot of 10 patients given a low dose of metformin, the dosing for the remaining 50 patients was weight-based, with patients receiving either 1g or 1.5g per day in divided doses for 5 days. The primary outcome was number of adverse events (AEs) and secondary outcomes included comparisons of clinical, laboratory parameters, plasma viraemia, NS1 antigenaemia and biomarker kinetics. Majority of patients enrolled were male (68% in treatment group versus 73% in untreated) with a mean age of 18.4 ± 7.9 years in both groups. Preliminary analysis shows most of the patients developed more than 1 warning sign during their hospitalization (85% versus 88%) and 10% developed dengue shock syndrome (in both groups). Twenty-five patients (42%) had to discontinue metformin due to predefined AEs, including hypoglycemia (7%), severe diarrhea (22%), increased lactate > 3mmol/L (13%). The full trial results will be presented at the conference. ClinicalTrials.gov identifier: NCT04377451

AFTERSHOCK: PERSISTENT INFLAMMATION AND ENDOTHELIAL ACTIVATION IN ADULT SURVIVORS OF DENGUE SHOCK

Angela McBride[1], Phan Vinh Tho[2], Luong Thi Hue Tai[2], Nguyen Thanh Phong[2], Nguyen Thanh Ngoc[3], Duyen Huynh Thi Le[3], Nguyen Lam Vuong[3], Louise Thwaites[3], Martin J Llewelyn[1], Nguyen Van Hao[4], Sophie Yacoub[3]

[1]Brighton and Sussex Medical School, Brighton, United Kingdom, [2]Hospital for Tropical Diseases, Ho Chi Minh City, Viet Nam, [3]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam, [4]University of Medicine and Pharmacy, Ho Chi Minh City, Viet Nam

Dengue shock (DS) is the most severe complication of dengue virus infection; the syndrome results from plasma leak through an activated, disrupted endothelial barrier and may be complicated by hyperinflammation. It is assumed that inflammation and endothelial disruption subside with clinical recovery, but no studies have followed up survivors to confirm this. We conducted a prospective observational study of adults (age≥16 years) with DS in Vietnam between 2018-2022. Patients completed the following assessments at hospital discharge, 1-, 3- & 6-months follow-up: health related quality of life (HRQOL) (EQ-5D-5L), cognitive function (Montreal Cognitive Assessment, MoCA), plasma inflammatory (IL-6, ferritin) and endothelial (Ang1, Ang2, VCAM1) biomarkers & endothelial function testing (EndoPAT). Healthy controls (HC) and survivors of septic shock (SS) participated as comparators. Survivors of DS (n=125) experienced rapid functional recovery, with median EQ-5D-5L visual analogue score >90/100 at all timepoints. MoCA scores were lower than normal (≥26) at hospital discharge (med:23/30, IQR:20-26), but scores had largely normalized by 3 months (med:27/30, IQR:25-29). However, compared to HC (n=25), DS patients had persistent subclinical inflammation (elevated IL-6 & ferritin vs HC, p<0.01 at all timepoints), endothelial activation (lower Ang1 and elevated VCAM1 vs HC, p<0.01 at all timepoints) and impaired endothelial function (median Reactive Hyperaemia Index below normal threshold of 1.67 at 1-,3-&6-months). Survivors of SS (n=26) also had persistent inflammation, with worse functional and cognitive outcomes than DS survivors. This is the first report that survivors of DS have persistent inflammation, endothelial activation, and impaired endothelial function for at least 6 months after discharge. Further study is needed to determine the duration of this phenomenon, and whether individual or repeat infections have an impact on long term cardiovascular health; if so, these findings could have important public health implications for dengue endemic regions.

Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil, [7]Vaccine Development Laboratory, Department of Microbiology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil, [8]Faculty of Medicine of Bahia, Federal University of Bahia, Salvador, Brazil, [9]Department of Biology, University of Florida, Gainesville, FL, United States

Key questions remain on the impact of Zika virus (ZIKV) exposure on long-term developmental outcomes, especially among infants who were exposed in utero during the pandemic in the Americas but did not develop congenital Zika syndrome (CZS) at birth. Therefore, we prospectively evaluated the clinical and developmental outcomes of a cohort of children with two years of age who were born during the Zika epidemic in Salvador, Brazil. We enrolled mothers and their newborn infants at a maternity hospital between Oct 01, 2015 and Jan 31, 2016. Performed anthropometric, auditory, ophthalmologic evaluations, Hammersmith Infant Neurological Examination and Bayley Scales of Infant and Toddler Development-3 assessment. We ascertained ZIKV exposure in utero by assaying for neutralizing antibodies in sera from mothers during childbirth and evaluated the association with clinical and developmental outcomes. Among 469 children enrolled at birth, 364 (78%) completed follow-up evaluations at a mean age of 26.9 (±4.0) months. Of these, 214 (58.8%) were born to mothers with serologic evidence of ZIKV exposure. Of these, 22 (10.2%) were identified to have neurodevelopmental impairment (31.8% cognitive, 45.5% language and 22.7% motor domains). After adjusting for maternal age, ZIKV exposure was not associated with specific domain impairments but was associated with a higher risk (OR=2.36; 95% CI 1.05-5.80) for global neurodevelopmental impairment. The attributable fraction of neurodevelopmental impairment associated with ZIKV exposure was 36.0%

(95% CI 3.4 to 68.6%). Significant associations were not observed between exposure and anthropometric, auditory or ophthalmologic deficits. Our study found that ZIKV exposure in utero imparts mild neurodevelopmental deficits, primarily associated with language acquisition, in a significant proportion of children without CZS by two years of life. Given the large numbers of infants that had unapparent ZIKV exposures during the pandemic, routine screening and intervention will be needed in affected regions of the Americas to mitigate these impacts on development, especially as these children enter schools.

PERSISTENT RHEUMATOLOGICAL DISEASE AFTER SEVEN YEARS OF CHIKUNGUNYA VIRUS INFECTION: RESULTS FROM A COHORT STUDY IN PIEDECUESTA, COLOMBIA

Anyela Lozano-Parra[1], Carlos Andrés Calderón[2], Reynaldo Badillo[3], Luis Angel Villar[2], Victor Herrera[4], Rosa Margarita Gelvez[2], Jose Fernando Lozano[2], Maria Isabel Estupiñan[2], **Elsa Marina Rojas**[2]

[1]Centro de Investigaciones Epidemiológicas, Universidad Industrial de Santander, Bucaramanga, Colombia, [2]Centro de Atención y Diagnóstico de Enfermedades Infecciosas-CDI, Fundación INFOVIDA, Bucaramanga, Colombia, [3]RBA. Director Departamento Medicina Interna. Universidad de Santander-UDES, Bucaramanga, Colombia, [4]Department of Public Health, Universidad Industrial de Santander, Bucaramanga, Colombia

Chikungunya virus (CHIKV) has circulated and caused outbreaks in the Americas region since 2014. There is a need to better characterize post-CHIKV chronic rheumatism and its impact on quality of life (QoL). The objective was to estimate the prevalence of post-CHIK chronic rheumatism in adult patients 7 years after the CHIKV outbreak (2014-2015) in Piedecuesta, Colombia.We evaluated 106 patients, 94 (88.7%) of which had symptomatic infection. The exposure was determined by RT-qPCR, IgG/IgM ELISA, or the ArboMIA multiplex immunoassay. In 2022, approximately 7 years post-infection, all patients completed a set of surveys (screening for rheumatic disorders [GALS], stiffness [MSQ], functional capacity [HAQ]), provided a blood sample, and were examined by physicians who were trained by a rheumatologist. A subgroup completed the surveys fatigue [FSS], and QoL [SF-36]. A second evaluation was performed by a rheumatologist to those patients (n=46; 43.3%) who screened positive to GALS but whose clinical findings were not associated with trauma.The prevalence of post-CHIK chronic inflammatory rheumatism (pCHIK-CIR) was 10.8% (IC95%: 5.5, 18.5) whereas 35.3% (95%CI: 26.0, 45.4) had a diagnosis of Non-inflammatory pain likely degenerative. Among patients with pCHIK-CIR, 4 (36.4%) had oligoarthritis/polyarthritis, 4 (36.4%) post-viral arthralgia, 2 (18.1%) fibromyalgia, and 1 (9.1%) fasciitis; moreover, 63.4% (n=7) of pCHIK-CIR cases had arthralgia (pain scale median=7), and the joints most affected were hands (57.1%), knees (57.1%) and feet (42.9%). A small proportion had stiffness (n=2; 18.2%; stiffness scale median=9). In addition, overall, 33.7% of participants screened positive for fatigue, whereas those with pCHIK-CIR scored lower than the recovered cases in the QoL questionnaire (medians: 37.4% vs. 49.4%, p=0.001; and 46.1% vs 55.8%, p=0.000; for mental and physical domains, respectively). This study implemented a comprehensive clinical assessment to objectively estimate and characterize the prevalence of chronic rheumatological disease attributed to CHIKV infection. These results correspond to a preliminary analysis.

MAPUTO SANITATION TRIAL 60-MONTH FOLLOW-UP ANTHROPOMETRIC MEASUREMENTS AND CHILD HEALTH

Erin Kowalsky[1], Drew Capone[2], Oliver Cumming[3], Márcia Chiluvane[4], Victória Cumbane Cumbane[5], David Holcomb[1], Amanda Lai[1], Yarrow Linden[1], Elly Mataveia Mataveia[5], Vanessa Monteiro[5], Gouthami Rao[1], Edna Viegas[5], Joe Brown[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Indiana University, Bloomington, IN, United States, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Instituto Nacional de Saúde, Mozambique, Maputpo, Mozambique, [5]Instituto Nacional de Saúde, Mozambique, Maputo, Mozambique

Safe water, sanitation, and hygiene (WASH) can interrupt enteric pathogen transmission and may improve growth outcomes in children. Growth deficits manifest as children age, with early childhood the critical window for interventions. We conducted a cross-sectional assessment of long-term growth outcomes in a cohort of children exposed to differential sanitation infrastructure from birth in Maputo, Mozambique. We enrolled 1014 children aged 1 - 60 months living in household clusters in two arms: those having received improved shared sanitation (n = 473) intervention and those from matched clusters with unimproved sanitation (n = 541) but meeting eligibility criteria for the intervention. We used standard length, height, and weight measurement methods with appropriate quality control checks to reduce measurement bias. We calculated height/length-for-age (HAZ) and weight-for-age (WAZ) and weight-for-height (WHZ) z-scores and compared them with the 2010 WHO Child Growth Standards reference dataset, utilizing the R package z-scorer. We estimated the prevalence of stunting, wasting, and underweight children in both arms. Approximately 26% (95% CI: 23%, 30%), 4.6% (95% CI: 3.1%, 6.7%), and 6.1% (95% CI: 4.4%, 8.4%) of control children were stunted, wasted and underweight, respectively, compared with 16% (95%CI: 13%, 20%), 4.6% (95% CI: 3.1%, 6.9%), and 4.6% (95% CI: 3.1%, 6.9%) of children in the intervention arm, suggesting visible reductions in stunting among children born into better sanitation conditions. Mean differences in HAZ/LAZ, WAZ and WHZ z-scores between treatment arms are shown HAZ 0.32 (95% CI: 0.129, 0.51), WAZ: 0.20 (95% CI: 0.06, 0.33), and WHZ: -0.028 (95% CI: -0.20, 0.14). We estimate that children in the safe sanitation group experienced 41% reduced odds of stunting (OR 0.59, 95% CI: 0.43 - 0.82), after controlling for age, sex, household wealth indicators, and caregiver education. Because interventions were not randomly assigned, we cannot rule out unmeasured confounding. Ongoing analyses will account for associations with enteric pathogen gut carriage to interrogate sanitation-related drivers of undernutrition.

6513

EFFECT OF A WATER, SANITATION AND HYGIENE PROGRAM ON HANDWASHING WITH SOAP AMONG DIARRHEA PATIENTS AND ATTENDANTS IN HEALTHCARE FACILITIES IN THE DEMOCRATIC REPUBLIC OF THE CONGO: A RANDOMIZED PILOT OF THE PICHA7 PROGRAM

Alain Mwishingo[1], Kelly Endres[2], Presence Sanvura[1], Jean-Claude Bisimwa[1], Lucien Bisimwa[1], Camille Williams[2], Jamie Perin[2], Justin Bengehya[1], Cirhuza Cikomola[1], Ghislain Maheshe[1], Christine Marie George[2]

[1]Université Catholique de Bukavu, Bukavu, Congo, Democratic Republic of the, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Healthcare-acquired infections are a major problem in healthcare facility settings globally. The Democratic Republic of the Congo (DRC) has over 2 million diarrhea patients admitted to health facilities annually. Health facilities can be a high-risk environment for transmission of diarrheal diseases. The objective of the Preventative Intervention for Cholera for 7 Days (PICHA7) program is to develop evidence-based water, sanitation, and hygiene (WASH) interventions to reduce cholera and other severe diarrheal diseases in DRC. This study evaluated the effectiveness of PICHA7 program delivery in increasing handwashing with soap at stool, vomit, and food related events in a healthcare facility setting among diarrhea patients and their attendants. A randomized pilot of the PICHA7 program was conducted among 284 participants from 27 health facilities from March 2020 to November 2021 in urban Bukavu in South Kivu Province of DRC. The 'Standard Message' Arm received the standard message given in DRC to diarrhea patients on the use of oral rehydration solution. The PICHA7 arm received the PICHA7 WASH pictorial communication module bedside to the diarrhea patient, and a soapy water bottle in the healthcare facility during the time of treatment. Within 24 hours of intervention delivery, three-hour

structured observation of handwashing practices at stool, vomit, and food related events (key events) was conducted in healthcare facilities of diarrhea patients and their attendants. Compared to the Standard Message Arm, there was significantly higher handwashing with soap at key events in the PICHA7 Arm (39% vs. 12 %) (Odds Ratio: 5.32; (95% Confidence Interval (CI): 2.00, 14.10). These findings demonstrate that delivery of the PICHA7 WASH pictorial communication module and provision of a soapy water bottle to diarrhea patients and their attendants presents a promising approach to increase handwashing with soap among this high-risk population in healthcare facilities in eastern DRC.

6514

THE LONG-TERM EFFECTS OF IMPROVED WATER, SANITATION, AND HYGIENE (WASH) AND IMPROVED COMPLEMENTARY FEEDING ON SCHOOL-AGE GROWTH AND DEVELOPMENT IN RURAL ZIMBABWE: FOLLOW-UP OF THE SHINE CLUSTER-RANDOMIZED TRIAL

Joseph Daniel Piper[1], Clever Mazhanga[2], Marian Mwapaura[2], Idah Mapurisa[2], Gloria Mapako[2], Tsitsi Mashedze[2], Eunice Munyama[2], Maria Kuona[2], Thomizodwa Mashiri[2], Kundai Sibanda[2], Dzidzai Matemavi[2], Monica Tichagwa[2], Soneni Nyoni[2], Asinje Saidi[2], Mwanasa Mangwende[2], Dzvaidzo Chidhanguro[2], Eddington Mpofu[2], Joice Tome[2], Batsirai Mutasa[2], Bernard Chasekwa[2], Melanie Smuk[1], Laura Smith[2], Virginia Sauramba[2], Lisa Langhaug[2], Naume Tavengwa[2], Melissa Gladstone[3], Jonathan Wells[4], Elizabeth Allen[5], SHINE Follow-up trial Team[2], Jean Humphrey[6], Robert Ntozini[2], Andrew Prendergast[1]

[1]Queen Mary University of London, LONDON, United Kingdom, [2]Zvitambo Institute of Maternal and Child Health Research, Harare, Zimbabwe, [3]University of Liverpool, Liverpool, United Kingdom, [4]UCL Institute of Child Health, LONDON, United Kingdom, [5]London School of Hygiene and Tropical Medicine, LONDON, United Kingdom, [6]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

The SHINE cluster-randomised trial tested the effects of a household WASH intervention and/or infant and young child feeding (IYCF) on child stunting and anemia at age 18 months in rural Zimbabwe. SHINE showed that IYCF increased linear growth and reduced stunting by age 18 months, while WASH had no effects. Here, we present long-term follow-up data from 1000 HIV-unexposed children (250 in each intervention arm) who were re-enrolled at age 7 years to evaluate growth, body composition, cognitive and physical function. We measured cognition using the Kaufman Assessment Battery for Children (KABC-II) as a primary outcome, and executive function, literacy, numeracy, fine motor skills and socioemotional function as secondary outcomes. Physical function was assessed by handgrip strength, broad jump and shuttle-run test. Growth was assessed by anthropometry, body composition (using bioimpedance analysis) and skinfold thicknesses. Contemporary household socioeconomic status, demographics, nurturing, food and water insecurity were measured by a caregiver questionnaire. Data were analyzed using generalized estimating equations with an exchangeable working correlation structure to account for clustering. Of 1000 children assessed, 10 were excluded from analysis for severe disability. Children (51% female) were median 7.2 years old (IQR 7.1, 7.4). IYCF and WASH each had no effect on the primary outcome (KABC-II score) or secondary cognitive outcomes, except a small difference in socioemotional function in the WASH arms (-1.2 marks, 95%CI -2.0, -0.5, p=0.002) which remained in adjusted analyses. Children in IYCF arms had a greater handgrip strength (+0.3 Kg, 95% CI 0.0, 0.5, p=0.03), which remained in adjusted analyses. There were no significant effects of IYCF or WASH on growth or body composition measures at 7 years. Overall, long-term follow-up of a subgroup of children enrolled to SHINE showed minimal long-term effects of early-life IYCF and WASH on school-age function, despite improved linear growth following IYCF in the original trial.

SURPRISE SOAP: EFFECT OF A NOVEL HYGIENE INTERVENTION ON OLDER CHILDREN'S HANDWASHING IN COMPLEX HUMANITARIAN SETTINGS: RESULTS OF TWO CLUSTER-RANDOMIZED CONTROLLED EQUIVALENCE TRIALS

Julie Watson[1], Claudio Deola[2], Mohamed Abji Haji[3], Mohamed Rashid Sheikh[3], Feysal Abdisalan Mohamud[3], Salman Yasin Ali[3], Ibtihal Osman[4], Maud Akissi Amon-Tanoh[1], Amy MacDougall[1], Oliver Cumming[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Save the Children International, London, United Kingdom, [3]Action Against Hunger, Mogadishu, Somalia, [4]Care International, Khartoum, Sudan

Children in emergencies are particularly vulnerable to infectious diseases such as diarrhoea and respiratory infections. Improving handwashing with soap (HWWS) can greatly reduce transmission, however, there is limited evidence on which approaches to child targeted HWWS promotion are effective. One recent innovation - the "Surprise Soap" intervention - was successful in a small-scale efficacy trial in an IDP camp in Iraq. This novel intervention includes transparent soap with embedded toys delivered in a short household session comprising a glitter game, instruction of how to wash hands, and HWWS practice. Whilst promising, this approach has not been evaluated at programmatic scale in a complex emergency setting. To address this gap, we conducted two cluster-randomised controlled equivalence trials, one across IDP camps in Somalia, and one in a refugee settlement in Sudan. In each trial, 200 households were randomly allocated (1:1) to receive the Surprise Soap intervention or an active comparator intervention including plain soap delivered in a short household session involving standard health-based messaging and instruction of how to wash hands. The primary outcome was the proportion of pre-specified occasions when HWWS was practiced by children aged 5-12, measured at baseline, 4-weeks, 12 weeks, and 16 weeks post intervention delivery. In both trials, we observed a large and sustained increase in HWWS in both arms (Somalia: 48 and 51 pp increase in the intervention and comparator arm, respectively; Sudan: 27 and 23 pp increase, respectively). However, there was no difference in HWWS between the two arms. In these two settings, where soap availability and past exposure to HWWS promotion was low, it appears that interventions that directly target children at the household-level and provide soap can increase their HWWS and potentially reduce disease risk. Here the Surprise Soap intervention offers no marginal benefit over providing plain soap within a household-level "standard" intervention that would justify the additional costs. Applying contextual knowledge to decisions on Surprise Soap implementation is recommended.

EFFECTIVENESS OF SEWAGE INTERVENTION ON LEPTOSPIRA TRANSMISSION AMONG RESIDENTS OF URBAN INFORMAL SETTLEMENTS

Fábio N. Souza[1], Freya Clark[2], Max T. Eyre[3], Juliet O. Santana[4], Nivison Nery[4], Fabiana A. Palma[4], Daiana Oliveira[1], Jaqueline S. Cruz[5], Mitermayer G. Reis[5], Emanuele Giorgi[2], Cleber Cremonese[1], Albert I. Ko[6], Federico Costa[1]

[1]Institute Collective Health, Federal University of Bahia, Salvador, Brazil, [2]Centre for Health Informatics, Computing, and Statistics, Lancaster University Medical School Lancaster, Lancaster, United Kingdom, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Institute Collective Health,Federal University of Bahia, Salvador, Brazil, [5]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Salvador, Brazil, [6]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States

Leptospirosis is an environmentally-transmitted zoonotic disease that affects impoverished urban and rural populations worldwide. In informal settlements, leptospirosis is associated with precarious sanitary infrastructure. Yet, the role of sewerage in reducing Leptospira transmission has not yet been rigorously evaluated. We conducted a cluster-controlled

natural experiment in a slum community in the city of Salvador, Brazil to prospectively evaluate the effectiveness of a government sewerage intervention. We selected two intervention clusters which comprised of a regions where open sewers were closed without implanting rainwater drainage in 2018 and 2021 and one control cluster for each period, which did not receive the intervention. As part of an on-going cohort study, we performed biannual serosurveys of the study community during the study period from 2015 to 2022. Leptospira infection was ascertained by detecting seroconversion or a four-fold rise in titer during microscopic agglutination testing and used in time series analysis to estimate effectiveness of the intervention using generalized estimating equations models. Age, sex, and elevation level were used to adjust estimates. Among 1,058 residents who were enrolled and followed during the study period, the Leptospira infection rates varied between 13 and 48 per 1000 follow-up events. A significant difference was not observed in the odds of Leptospira infection between control and intervention clusters in the post-intervention period (OR: 0.78; 95% CI 0.35-1.13). After the closure of sewage, residents in intervention clusters reported frequently exposed to flooding, mud, and soil. Our findings suggest that isolated closure of human fecal sewage without implanting enclosed rainwater drainage systems was not effective in reducing Leptospira transmission. Effective interventions in high-risk slum communities must therefore incorporate multiple sanitation dimensions and ensure sustainability.

6517

IMPACT OF THE WASH IN SCHOOLS FOR EVERYONE (WISE) PROGRAMME ON CHILD HEALTH AND SCHOOL ATTENDANCE IN ADDIS ABABA, ETHIOPIA: A CLUSTER-RANDOMISED CONTROLLED TRIAL

Sarah Bick[1], Charles Opondo[1], Baptiste Leurent[2], Oliver Cumming[1], Alem Ezezew[3], Elizabeth Allen[1], Robert Dreibelbis[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Holster International Research and Development Consultancy, Addis Ababa, Ethiopia

Water, sanitation and hygiene (WASH) interventions in schools (WinS) have been proposed to reduce morbidity in schoolchildren, including gastrointestinal and respiratory infection, and improve school attendance, particularly among post-menarcheal girls. However, evidence of the impact of WinS interventions on pupil health and educational outcomes has been mixed. We evaluated the WASH in Schools for Everyone (WISE) programme implemented by US-based NGO Splash in partnership with the Government of Ethiopia, which aims to achieve universal WASH coverage in schools in Addis Ababa, Ethiopia over a five-year period. We conducted a cluster-randomised trial among 60 randomly selected primary schools and randomly assigned them 1:1 to receive the intervention during the 2021/22 academic year or the following year (waitlist control). The intervention comprised WASH infrastructure improvements, including water storage and filtration, drinking water / handwashing stations and upgraded sanitation facilities, and behaviour change promotion. Within each participating school, we enrolled between 2 and 4 randomly selected classes in to reach a total school enrolment of approximately 100 pupils. Individual pupils (ages 7 - 16) were enrolled in November 2021. At four follow-up visits between March and July 2022, enumerators recorded roll-call absence, pupil-reported illness (diarrhoea, respiratory infection) and pupil-reported absence in past week among pupils present. Secondary outcomes including wellbeing and menstrual hygiene self-efficacy were recorded at the final follow-up. We found a 17% reduction in odds of pupil-reported respiratory infection in the past week during the follow-up period among pupils in intervention vs. control schools (OR: 0.83, 95% CI: 0.70, 0.99), notable in the context of the COVID-19 pandemic. No impacts on diarrhoea or absence were observed. There was evidence of greater intervention effects among boys vs. girls. The Splash intervention was delivered with high fidelity. Further analyses will explore the heterogeneity in effects and the link between compliance and observed outcomes.

6518

PROCESS EVALUATION OF THE PREVENTATIVE INTERVENTION FOR CHOLERA FOR SEVEN DAYS (PICHA7) WATER, SANITATION AND HYGIENE MOBILE HEALTH PROGRAM

Presence Sanvura[1], Kelly Endres[2], Jean-Claude Bisimwa[1], Alain Mwishingo[1], Lucien Bisimwa[1], Camille Williams[2], Jamie Perin[2], Justin Bengehya[1], Cirhuza Cikomola[1], Ghislain Maheshe[1], Christine Marie George[2]

[1]Université Catholique de Bukavu, Bukavu, Congo, Democratic Republic of the, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In the Democratic Republic of the Congo (DRC) there are estimated to be 85 million diarrhea episodes annually. Effective and scalable water, sanitation, and hygiene (WASH) interventions are urgently needed to reduce diarrheal diseases globally. Phone-based reminders of public health information have been shown to reduce disease morbidity and increase health-protective behaviors. The objective of the Preventative Intervention for Cholera for 7 Days (PICHA7) program is to develop evidence-based WASH interventions to reduce cholera and other severe diarrheal diseases in DRC. The PICHA7 mobile health (mHealth) program delivers weekly voice, text, and interactive voice response (IVR) messages to diarrhea patient households promoting handwashing with soap and water treatment and safe water storage. The randomized pilot of the PICHA7 program demonstrated this intervention was effective in increasing handwashing with soap and water treatment behaviors during the three-month program period compared to the standard message given in DRC on the use of oral rehydration solution for rehydration. The objective of this study was to assess the implementation of the PICHA7 mHealth program during this randomized pilot to determine the feasibility of delivering this program in urban Eastern DRC. This study was conducted in Bukavu in South Kivu province in eastern DRC. Three hundred fifty-six participants were in households that received weekly text, voice and IVR messages from the PICHA7 mHealth program over the 3-month program pilot. Outcome indicators included unique text, voice, and IVR messages received (fidelity) and % of unique messages fully listened to (dose). Eighty three percent of text messages were received by program households. Eighty seven percent of voice and 88% of IVR messages sent were answered by at least one household member. Ninety percent of voice messages were fully listened to, and 62% of IVR messages. These findings have shown high fidelity and dose of mobile messages delivered for the PICHA7 mHealth program, demonstrating the feasibility of delivering the PICHA7 mHealth program in our study setting in Eastern DRC.

6519

BACTERIAL ZOONOSES DETECTED BY 16S RRNA METAGENOMICS AMONG FEBRILE ADMISSIONS IN KILIMANJARO, TANZANIA, 2007-2009

Robert J. Rolfe, Jr[1], Matthew P. Rubach[1], Venance P. Maro[2], Grace Kinabo[2], Wilbrod Saganda[3], Jeannine M. Petersen[4], Luke C. Kingry[4], Sarah Sheldon[4], John A. Crump[5]

[1]Duke University, Durham, NC, United States, [2]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of, [3]Mawenzi Regional Referral Hospital, Moshi, Tanzania, United Republic of, [4]Bacterial Diseases Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [5]Centre for International Health, University of Otago, Denedin, New Zealand

Bacterial zoonoses are prominent causes of severe febrile illness in East Africa. While most of these diseases are highly treatable, many require specific therapies beyond standard empiric antimicrobials. Diagnosis remains a challenge, as these fastidious or non-culturable organisms thwart conventional culture and serologic diagnosis requires convalescent sample collection. Within a well-characterized fever etiology cohort, we applied a high-throughput 16S rRNA metagenomics assay validated for targeted detection of bacterial zoonotic pathogens. A prospective cohort study enrolled pediatric and adult medical patients admitted with fever

to 2 referral hospitals in Moshi, Tanzania, September 2007- April 2009. Red cell pellets were archived at -70ºC after plasma fractionation of EDTA whole blood obtained from participants within 24 hours of admission. DNA extracts from the cell pellets were subjected to PCR targeting the V1-V2 of 16S rRNA, followed by metagenomics deep-sequencing of V1-V2 amplicons.Taxonomic identifications were analyzed after subtraction of background taxonomic identifications of ubiquitous DNA contamination from the environment. Among 788 participants enrolled the median (interquartile range) age was 20 (2-38) years, 239 (32.1%) were HIV-infected, 384 (50.4%) were male, and 314 (47.3%) lived in an urban setting. A bacterial zoonotic pathogen was detected in 10 (1.3%): 3 Rickettsia typhi, 1 Rickettsia conorii, 2 Bartonella quintana, 1 Leptospira borgpetersenii, 1 Leptospira species, 1 Coxiella burnetii, 1 sample with reads for an apparently novel organism in the Anaplasmataceae family. This targeted 16S metagenomics approach made important identifications: a potentially novel agent of anaplasmosis; and to our knowledge the first molecular evidence of R. conorii in East Africa, improving our understanding of the species responsible for spotted fever group rickettsioses in the region.

6520

DETERMINING FLEA VECTOR SUSCEPTIBILITY TO INSECTICIDES AS PART OF PLAGUE RISK MONITORING IN MADAGASCAR

Mireille Harimalala[1], Soanandrasana Rahelinirina[2], Sarah Zohdy[3], Minoarisoa Rajerison[2], Romain Girod[1]

[1]Medical Entomology Unit, Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Plague Unit, Institut Pasteur de Madagascar, Antananarivo, Madagascar, [3]US President's Malaria Initiative, Malaria Branch, US Centers for Disease Control and Prevention, Atlanta, GA, United States

Fleas have medical importance in Madagascar in relation to human plague. Through infected bites, they transmit Yersinia pestis from rodents to humans. Two species, Xenopsylla cheopis and Synopsyllus fonquerniei, are known vectors. Insecticides are the primary response tool to control fleas; therefore, susceptibility monitoring is essential to ensure this intervention is effective. We aimed to determine susceptibility of plague flea vectors to insecticides. Between 2019 and 2022, fleas were collected alive then reared in insectary. Following WHO protocols, eighteen, twelve and ten assays were performed using fenitrothion, permethrin and deltamethrin respectively. Per assay, 40 fleas were exposed to paper impregnated with the following concentration/duration combinations: fenitrothion 1% for 5h (organophosphate), permethrin 0.75% or deltamethrin 0.05% for 8h each (pyrethroids). After 24 hours, mortality rates (MR) were recorded. Fleas were either resistant (MR < 80%), tolerant (80% ≤ MR < 98%) or susceptible (98% ≤ MR ≤ 100%). Sixteen populations (sites) from eight districts were tested. Eighteen, twelve and ten assays were performed using fenitrothion, permethrin and deltamethrin respectively. Susceptibility to fenitrothion was heterogenous but 50.0% of populations remained susceptible, two were tolerant (11.1%) and seven were resistant (38.9%). All S. fonquerniei were fenitrothion susceptible whereas X. cheopis showed heterogenous responses. Two S. fonquerniei populations were permethrin tolerant (16.7%) and ten were resistant (83.3%). Almost all districts showed permethrin resistant X. cheopis. Nine X. cheopis populations were deltamethrin resistant and one was tolerant. These findings showed heterogeneity responses to insecticides considering sites and species. All populations were non-susceptible to pyrethroids. Susceptibility to fenitrothion persisted although trends indicate resistance emergence which may be related to plague control or other usage. Monitoring flea susceptibility to insecticides should be continued to guide data driven decision making for plague control.

6521

RISK FACTORS ASSOCIATED WITH RURAL HOUSEHOLD FLEA INFESTATIONS IN THE PLAGUE ENDEMIC AREA OF MADAGASCAR

Adélaïde Miarinjara[1], Annick O. Raveloson[2], Stephen G. Mugel[1], Nick An[1], Andry Andriamiadanarivo[3], Romain Girod[2], Thomas R. Gillespie[1]

[1]Emory University, Atlanta, GA, United States, [2]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [3]Centre ValBio Ranomafana, Ranomafana, Madagascar

Human and domestic animals may experience skin reactions and discomfort due to heavy flea bites. Some species are vectors of pathogens such as Yersinia pestis, the agent of bubonic plague. In this study, we are interested in the species composition, prevalence, abundance, seasonality, and risk factors for the host-seeking fleas infesting households in plague endemic areas of Madagascar. We used a structured questionnaire and observational checklist to collect data from households in 4 villages. Fleas were sampled during the dry and the rainy season using a candle trap for 3 consecutive nights. We used a generalized linear mixed model to identify the factors that are associated with flea abundance in households. We found that more than 98% of the households were infested by fleas, dominated by the species Pulex irritans (98.18%, n=9,352). No seasonal pattern was found in flea abundance, but the number of fleas detected per household was highly variable with an average of 37.16 fleas per household during the dry season and 45.66 during the wet season. Our model showed that flea infestation was associated with having a male head of the household (aOR=1.75), reported rodent activity (aOR=1.31), mat floor (aOR=1.98), and thatched roof (aOR=1.22). The risk increased with the number of chickens (aOR=1.03), pigs (aOR=1.07), and household size (aOR = 1.09). Head of the household education level above primary school (aOR=0.58), sleeping two stories away from the ground floor (aOR=0.81) where livestock was kept at night, and the proximity of a separated livestock housing (aOR=0.91) were found to be protective against flea infestation. High flea burden in the household motivated the use of insecticide, which may induce resistance among the vectors. Interventions targeting an increased quality of life, access to education, and security may alleviate the flea burden in rural villages experiencing high flea infestation. The human flea, P. irritans is one of the probable vectors in Madagascar and the present description of its infestation ecology is a first step toward understanding its potential role in plague transmission.

6522

SURVEILLANCE FOR METASTRIATE TICKS AND SPOTTED FEVER GROUP RICKETTSIOSES IN SOUTHERN ILLINOIS

Victoria Phillips[1], Matt Flenniken[1], Levi Mick[1], Leta Chesser[1], Edna Alfaro[1], Chang-Hyun Kim[1], April Holmes[2], Samantha Kerr[2], Holly Gaff[3], Brian Allan[1], Chris Stone[1], **Holly Tuten**[1]

[1]University of Illinois Urbana-Champaign, Champaign, IL, United States, [2]Illinois Department of Public Health, Springfield, IL, United States, [3]Old Dominion University, Norfolk, VA, United States

Reported human cases of Spotted Fever Group Rickettsioses (e.g., Rocky Mountain Spotted Fever) have been increasing in Illinois over the past few decades. The majority of SFGR cases have been reported from the southern region of the state. However, until beginning the Illinois statewide active tick surveillance program in 2019, relatively little information was available regarding population densities and SFGR pathogen prevalence in Illinois ticks, and there was a need to address gaps in understanding of human exposure risk to different tick-borne Rickettsia sp. pathogens. Based on the hypothesis that some of the reported human SFGR cases in southern Illinois could be due to Rickettsia sp. other than R. rickettsii, and possibly due to R. parkeri, we designed a sampling strategy to identify environments most likely to harbor the Gulf Coast tick (Amblyomma maculatum), the vector of R. parkeri. During targeted collection events, we also retained any other tick species encountered. Sampling yielded collections of A. americanum, A. maculatum, and D. variabilis. We collected

782 adult Gulf Coast ticks in 8 southern Illinois counties in summer 2020, a 30-fold increase over the sum total of all prior historical reports in Illinois. We tested all three metastriate tick species for Rickettsia amblyommatis, R. parkeri, and R. rickettsii. Tick infection prevalences and densities of adult and nymphal ticks were compared to the incidence of reported human SFGRs. Gulf coast ticks were strongly overdispersed, as they were found to be highly abundant in specific focal locations. Overall, 17.4% of Gulf Coast ticks were positive for R. parkeri, 48.5% of lone star ticks were positive for A. amblyommatis, and we detected no R. rickettsii in the 3,324 ticks tested. The standardized incidence ratio of SFGRs at the county level was most strongly associated with the density of R. amblyommatis-infected A. americanum nymphs and adults. Understanding the distribution of tick species and Spotted Fever Group Rickettsiae diversity in southern Illinois is essential for accurate and timely diagnosis of tick-borne disease and design of effective tick-bite prevention messaging.

6523

SEROLOGIC TESTING FOR THE DIAGNOSIS OF BARTONELLA INFECTIONS IN PATIENTS IN MARYLAND

Kristin E. Mullins, Robert H. Christenson

University of Maryland School of Medicine, Baltimore, MD, United States

Bartonella species are gram negative, vector-borne bacteria which cause a range of human disease. Bartonella species are an underrecognized pathogen and infections are often missed by routine microbiological testing. Bartonella infections in the United States are initially diagnosed by serologic testing for antibodies to B. quintana, the causative agent of trench fever, and Bartonella henselae, the causative agent of cat scratch disease, however the number of Bartonella species that are known to cause human disease is growing each year. To better understand the prevalence and diagnosis of Bartonella infections in Maryland a retrospective analysis of all serologic testing for Bartonella species through the University of Maryland Medical System from 2020-2022 was conducted. 271 serologic tests were ordered between 2020-2022. Clinical indications for testing included homelessness, contact with cats, fever, lymphadenopathy, animal bites, and endocarditis. However, in many cases there were no clinical indications for testing. Overall, twenty were positive for IgM and/or IgG to B. quintana and/or B. henselae. Eight were positive for IgM and IgG and twelve were positive for IgG alone. While molecular testing following serologic diagnosis indicated that B. henselae and quintana along with B. rochalimae were causes of positive serologic results, several cases were complicated by false positive serology for Chlamydia, Coxiella and/or Brucella, confusing those who are unfamiliar with serologic testing causing delayed treatment. Additionally, false positive/borderline positive serologic results and/or results due to previous infection delayed treatment in cases where clinical syndromes were mistakenly ascribed to acute Bartonella infections. Results from serologic testing show that Bartonella is an important yet poorly understood human pathogen with the potential to cause significant morbidity. Lack of appropriate laboratory tests and education result in treatment delays and increased morbidity in patients with suspected Bartonella infections. Increased awareness of Bartonella as a human pathogen is imperative.

6524

MOLECULAR SURVEY OF ANAPLASMATACEAE AGENTS AND BARTONELLA SPP IN COATIS NASUA NASUA FROM URBAN FORESTED AREAS IN BRAZIL

Lívia Perles[1], Wanessa Barreto[2], Gabriel de Macedo[3], Heitor Herrera[3], Rosangela Machado[1], **Marcos Rogério André**[1]

[1]Universidade Estadual Paulista (UNESP), Jaboticabal, Brazil, [2]Universidade Federal do Mato Grosso do Sul, Campo Grande, Brazil, [3]Universidade Católica Dom Bosco, Campo Grande, Brazil

The Anaplasmataceae and Bartonellaceae families encompasses vector-borne obligate and facultative, respectively, intracellular αproteobacteria of human and veterinary medicine importance. While Ehrlichia and Anaplasma are tick-borne agents, Neorickettsia can be transmitted through the ingestion of intermediate hosts harboring trematodes infected with Neorickettsia. Depending on the species, Bartonella can be transmitted by fleas, lice, bites and scratches. This study investigated the molecular occurrence of Ehrlichia, Anaplasma, Neorickettsia, and Bartonella in coati's blood samples in Midwestern Brazil. Twenty-five out of 165 samples, 15.1%, were positive in the screening PCR based on the dsb gene of Ehrlichia spp. and were characterized using 16S rRNA, sodB, groEL, and gltA genes and the 23S-5S intergenic space region ITS. Phylogenetic analyses based on all six molecular markers positioned the sequences into a new clade, with a common origin of Ehrlichia ruminantium. Genotype analyses of 16S RNA sequences revealed the presence of two distinct Ehrlichia genotypes. Six samples, 3.6%, were positive in the screening nPCR for the 16S rRNA gene of Anaplasma spp. and were submitted to an additional PCR targeting the ITS for molecular characterization. Phylogenetic analyses based on both 16S rRNA gene and ITS positioned the Anaplasma sp. detected in the present study in a large clade with other Anaplasma sp. previously detected in ticks and wild animals and in a clade with Candidatus Anaplasma brasiliensis, respectively. Neorickettsia sp. 16S rDNA, showing high identity to Neorickettsia risticii, was detected in 6 coati blood samples. None of the coati blood samples was positive for Bartonella spp. in a combined approach using BAPGM (Bartonella AlphaProteobacteria Growth Medium) and isolation onto chocolate agar followed by a qPCR based on the nuoG gene. The present work described a putative novel Anaplasmataceae agent, namely Candidatus Ehrlichia dumleri, Anaplasma sp. closely related to the previously described Candidatus Anaplasma brasiliensis, and Neorickettsia sp. in coatis from urban forested areas in Brazil.

6525

DOGS AS RICKETTSIA SPP. SENTINELS IN A PERUVIAN AMAZON NATURAL RESERVE BUFFER ZONE

Oliver A. Bocanegra[1], Cusi Ferradas[1], Winnie Contreras[1], Diana León-Luna[1], Andres M. Lopez[2], Raul Bello[3], Andres G. Lescano[1]

[1]Emerge, Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Department of Medicine and Epidemiology, School of Veterinary Medicine, University of California, Davis, CA, United States, [3]Kawsay Biological Station, Puerto Maldonado, Peru

Countries neighboring Peru, such as Brazil and Colombia, have reported human cases of high and mildly pathogenic Spotted Fever Group rickettsiae (SFGR), including R. rickettsii and R. parkeri strain Atlantic rainforest, respectively; however, these species have not been reported in the Peruvian Amazon basin. Dogs play essential roles in the transmission cycles of these spp, since they serve as amplifying hosts. We conducted a cross-sectional study in a rural community of Madre de Dios (MdD) to characterize the species of ticks in dogs and to determine the presence of ticks and dogs positive to Rickettsia spp. We collect whole blood and ticks (n=23) from 23 dogs living around Kawsay Biological Station, located in the Tambopata National Reserve buffer zone. We collected 23 ticks from 23 dogs, including Amblyomma ovale (n= 22) and Rhipicephalus sanguineus (n=1). We tested blood samples and ticks by real time-PCR targeting the rickettsial conserved gene gltA. We found 2 (8.2%) Rickettsia-positive dogs and 12 (54.2%) ticks. Of the 12 positive ticks, 11 were identified as A. ovale (50% of all 22 A. ovale) and one as R. sanguineus. Our results indicate that dogs living in rural areas of MdD are infected with Rickettsia spp. Moreover, we have found that, as has been reported in Brazil, A. ovale, which normally infests rodents and wild carnivores, is infesting pet dogs in MdD, bringing ticks into the households and surrounding environments. Since, A. ovale and R. sanguineus are well known vectors of two of the most important rickettsial agents, R. parkeri strain Atlantic rainforest and R. rickettsii, our results suggest these pathogens may be circulating in rural communities of MdD. This study is still ongoing, and we will sequence the positive samples to determine the circulating Rickettsia species in rural areas and also we will explore the role of pet dogs as sentinels of rickettsia infections in rural areas of MdD. The role of dogs as rickettsia sentinels has been proven in

developed countries; however, in developing countries this may be different due to different dog ecology and human-dog interactions, especially in rural areas where dogs are allowed to roam free

6526

BIOMETRICS DATA COLLECTION FOR TRACHOMATOUS TRICHIASIS SURGERY PROGRAM IN OROMIA, SNNP AND SIDAMA REGIONS, ETHIOPIA: LESSONS LEARNT

Nigusie Fetene, Dawit Seyum Buda, Belay Bayissasse, Mulatu Gebre, Getachew Mekonnen, Doris Macharia, Alemayehu Sisay
Orbis, Addis Ababa, Ethiopia

Trichiasis patient identification, documenting Trachomatous Trichiasis (TT) cases known to the health system is a challenge using paper based records. Paper based data systems are vulnerable for loss, wear and tear as well as mis location, which leads to loss of medical history, making post operative follow up overtime challenging. To register all TT cases with biometrics and provide biometrically verified TT management, get real-time data for program monitoring and decision making. The paper form trichiasis patient register has been changed into digitized form using SurveyCTO (SCTO) to capture trichiasis patient records that works with or without internet connectivity. SCTO has been linked to a data system that captures unique fingerprint using scanning technology. Enrolment and identification are the two steps in the system. The system allows health service providers to identify patients any time when they seek care. 283 IECWs were trained from three regional states. A total of 6,970 patients have been enrolled into the system so far. Of which, 5,303 (76%) were enrolled through biometrics. Electronic data collection was considered as empowering by health service providers; Biometrically verifiable digital trichiasis recording system is found more convenient, reliable, accurate and timely recording and reporting system; Due the implementation of the system, no data duplication, no misuse of standard formats, no missing records, no delay of reports; Got real-time information dashboard that auto update as soon as data is submitted and is capable of transitioning into the mainstream health information system run by the Ministry of Health. The dashboard is accessible to the health systems staff, implementing partners and program leaders, which facilitated timely evidence based action and decision making. Train IECWs in Amhara region, refresh and closely support the already trained IECWs and work to simplify SCTO dataset and dashboard.

6527

SPATIAL VARIATION IN HOUSING CONSTRUCTION MATERIAL IN LOW- AND MIDDLE-INCOME COUNTRIES: A BAYESIAN PREDICTION MODEL OF A KEY INFECTIOUS DISEASES RISK FACTOR AND SOCIAL DETERMINANT OF HEALTH

Josh Michael Colston[1], Bin Fang[2], Margaret Kosek[1], Venkataraman Lakshmi[2]
[1]University of Virginia School of Medicine, Charlottesville, VA, United States, [2]University of Virginia, Charlottesville, VA, United States

Housing quality is a well-recognized social determinant of health. Many infectious diseases of global concern are transmitted within and between households and features of the built peridomestic environment and infrastructure can promote or impede the spread of pathogens and their insect vectors. In tropical and rural regions where vector borne and neglected tropical diseases circulate, dwellings are often constructed using locally available, naturally occurring materials and traditional techniques. Disease-causing insects and microbes are well-adapted to exploit the ecological niches that such buildings provide. This study modeled spatial variation in housing material types using covariates with global coverage to map predicted coverage across LMICs. Data on materials used in construction of dwelling floors, walls and rooves were compiled from 334 nationally representative, population-based household surveys, and classified into natural, rudimentary, and finished types. A novel georeferencing methodology was developed and implemented here for the first time. A suite of time-static environmental and demographic spatial covariates in raster format were compiled based on their hypothesized associations with the outcome variables. Variable values were extracted at the georeferenced cluster locations and a Bayesian Multi-level based logistic regression approach was used to model associations and generate predictions for all LMICs at a 6km resolution. A Markov Random Field (MRF) smooth algorithm was employed to improve spatial correlation and continuity of the prediction maps. Models for wall and roof material performed better than for floors giving a precision of 0.82 for the finished category and a weighted average precision of 0.7 and 0.73 respectively. Cropland areas, urbanization, and distance to water source were important variables in all models. Resulting prediction maps enable the identification of areas of low coverage of improved housing material across large areas of Sub-Saharan Africa, South Asia, and Amazonian South America among others, and can be used to prioritize populations for housing improvements.

6528

USE OF MATHEMATICAL MODELING TO INFORM INSECTICIDE-TREATED BEDNET DISTRIBUTION CAMPAIGNS: A HAITIAN CASE STUDY

Billy Bauzile[1], Clara Champagne[1], Punam Amratia[2], Ewan Cameron[2], Peter Gething[2], Nick Ruktanonchai[3], Marc A. Telfort[4], Valerian Turbé[5], Justin T. Lana[6], Emilie Pothin[1]
[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Malaria Atlas Project, Telethon kids Institute, Perth Children's Hospital, Perth, Australia, [3]Virginia Tech, Blacksburg, Virginia, VA, United States, [4]Programme National de Contrôle de la Malaria, Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti, [5]Clinton Health Access Initiative, Port-au-Prince, Haiti, [6]Clinton Health Access Initiative, Panama, Panama

Despite numerous natural- and human caused disasters, Haiti has made significant progress towards malaria elimination. In 2021, the number of presumed and confirmed malaria were 10642, down from over 84153 in 2010. As cases have fallen, they have become increasingly concentrated; thus, interventions such as insecticide treated bednets should be strategically targeted to reach maximal epidemiological impact. In order to identify the optimal set of communes in which bednet distribution would result in the most cases averted through the once-every-three years distribution campaign, we use a metapopulation model that was fitted on historical reported cases between 2014 and 2021 and on spatial data estimates from the Malaria Atlas Project. The model includes past bednet distributions, case management indicators and human inter-commune mobility as informed by mobile phone data. Several versions of the model are compared to evaluate the sensitivity to the input data. The fitted model was used to identify the communes in which the intervention would have the most impact at the national scale. The model ranked 125 communes, of which we selected the top 25 given the diminishing benefit of each additional commune and the defined number of bednets the country would receive. The selected communes accounted for 82% of observed cases in 2021. As this model combines the effects of connectivity, past interventions and local trends in transmission intensity, it provides a useful additional piece of information in prioritized communes for interventions such as LLIN distributions and communication campaign aiming at increasing bednet usage. The results provided insights about the impact of the targeted communes at the national scale and identified communes to be targeted with communication campaign. Finally, this calibrated model provides an additional tool to support routine campaign planning including the 2023-2026 Global Fund application.

6529

NET WORTH: A MODELING EXPLORATION OF COST AND COST-EFFECTIVENESS IN INSECTICIDE-TREATED NET INTERVENTIONS

Amelia Bertozzi-Villa, Daniel Bridenbecker, Caitlin Bever
Institute for Disease Modeling, Seattle, WA, United States

As the malaria funding envelope plateaus while burden grows and the number of people in need of protection continues to rise, it becomes ever

more crucial to ensure that every dollar spent on malaria interventions is utilized as efficiently and effectively as possible. Insecticide-treated nets (ITNs) are one of the largest line items in global malaria expenditures, making this intervention a major target for improving cost-effectiveness. This is especially true in the rapidly diversifying landscape of ITNs, with multiple novel products on the market and a growing understanding of this intervention's multifaceted nature and heterogeneous historical effectiveness. We utilized the mechanistic modeling software EMOD to explore three common operational questions across a range of transmission intensities, climates and vector mixes: First, is it more cost-effective to attain a specified coverage level by distributing more nets, or by improving the efficiency of net campaigns such that nets are more appropriately allocated? Second, at what level of insecticide resistance does it become cost-effective to move from pyrethroid-only ITNs to pyrethroid + piperonyl-butoxide (PBO) ITNs? And finally, in a situation in which one could either increase pyrethroid-only ITN coverage or maintain current coverage levels with PBO nets, which is more cost-effective? Results show that increasing campaign efficiency is more cost-effective than distributing additional nets, and that a switch to PBO nets is generally cost-effective in areas with high insecticide resistance, though the specific magnitude varies meaningfully depending on the local context. This analysis only scratches the surface of possible operational tradeoffs to explore, but demonstrates the power of modeling for optimal intervention planning and provides insight into best practices for future ITN campaigns.

MULTIFACETED INTERVENTIONS FOR UNINTERRUPTED MALARIA COMMODITIES: LESSONS FROM MALAWI

Daniel Taddesse[1], Elias Mwalabu[1], Fikadu Deme[1], Lumbani Makwakwa[2], Charles Nzawa[1], Lumbani Munthali,[3]

[1]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project., Washington DC, DC, United States, [2]USAID, Washington DC, DC, United States, [3]Ministry of Health Malawi, Lilongwe, Malawi

There has been significant progress in malaria control in Malawi. The malaria incidence rate reduced by almost 50%, from 407/1,000 population in 2016 to 208/1,000 population in 2022. Malaria mortality declined from 23/100,000 population in 2016 to 8/100,000 population in 2022. In fighting malaria, the Ministry of Health (MOH) implemented malaria case management and vector control programs. To support the National Malaria Control Program, in 2017, the USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project made some changes to the parallel supply chain program, which was instituted in 2012 to ensure uninterrupted availability of malaria commodities. GHSC-PSM engaged third-party logistics (3PL) firms to run its in-country warehousing and distribution of malaria commodities to all the 716 service delivery points in the country. The 3PLs use all modes of transportation including boats, motorbikes, and trucks, to ensure that the products reach their destination. Further, GHSC-PSM provided a comprehensive support to the malaria program supply chain with periodic forecast reviews; developing coordinated procurement plans with other funders; procurement and delivery of malaria commodities, including pipeline monitoring, and capacity strengthening of MOH staff to manage their supplies. This multifaceted support helped the NMCP track commodities from 716 SDPs with a 92% average reporting rate in 2022 resulting in a sustained supply of malaria commodities in health facilities and communities through the parallel supply chain program. From 2017 and 2022, there has been less than 1% stockout rate of first-line malaria treatment at service delivery points and this is likely contributing to the significant decrease in the malaria burden in the country.

6531

MULTI-OBJECTIVE CALIBRATION OF THE AGENT-BASED MALARIA TRANSMISSION MODEL, EMOD, TO SYMPTOM, PARASITE, GAMETOCYTE, AND MOSQUITO INFECTION DATA FROM A TRIAL OF ASYMPTOMATIC SCREENING IN SAPONE, BURKINA FASO

Tobias M. Holden[1], Katharine A. Collins[2], Teun Bousema[2], Chris Drakeley[3], Aurélien Cavelan[4], Melissa Penny[4], Anne Stahlfeld[1], Manuela Runge[1], Jaline Gerardin[1]

[1]Northwestern University, Chicago, IL, United States, [2]Radboud University Medical Center, Nijmegen, Netherlands, [3]London School of Tropical Medicine and Hygiene, London, United Kingdom, [4]Swiss Tropical and Public Health Institute, Allschwil, Switzerland

Mathematical models of malaria transmission have been used to predict the impact of various screening and treatment interventions where clinical trials may not be feasible. To make accurate predictions, models must reproduce key quantitative relationships between parasites, symptoms, gametocytes, and infectiousness within modeled human and mosquito hosts, all of which can vary between malaria-endemic settings. With many variable inputs and desired outputs, manual calibration of mathematical models is complex and tedious, making automated calibration algorithms an attractive alternative. We adopted a Bayesian optimization framework employing Gaussian process emulators to simultaneously calibrate 15 core parameters of the complex agent-based malaria transmission simulator, EMOD. These parameters describe aspects of modeled vector life cycles, parasite dynamics, human host immunity and symptom development, and vector-human interactions that are assumed to be constant across modeled settings. We evaluate each possible core parameter set against 8 fitting objectives describing key epidemiological and within-host relationships observed from field data. Compared to previous calibration approaches, ours leveraged data from the INDIE-1a trial in Sapone, Burkina Faso, which included detailed P. falciparum parasite and gametocyte data from human blood samples, and mosquito infection data from direct membrane feeding assays. We first calibrated core model parameters to data from the INDIE control arm, and then validated the effect size of simulated screening interventions in the recalibrated model against primary endpoints from the trial. This approach resulted in a better fit compared with the previous parameterization more quickly than sequential calibration approaches. The reparametrized model will be used in future modeling studies to predict the impact of proposed interventions on population-level malaria transmission.

6532

IMPLEMENTING A LARGE-SCALE COMMUNITY DIGITAL HEALTH PLATFORM IN MOZAMBIQUE: LESSONS LEARNT FROM UPSCALE

Maria Rodrigues

Malaria Consortium, MAPUTO, Mozambique

From 2009 to 2016, MC tested interventions to improve the quality of care provided by community health workers in Mozambique, locally known as (APEs), including a smartphone application introduced in Inhambane province through the inSCALE project. Building from this success and in order to link APEs with the national HIS, MC worked in collaboration with the MOH and UNICEF to develop the upSCALE platform - a digital strategy to strengthen health systems and community health delivery. The upSCALE APE and supervisor apps are built using CommCare, an open source, multi-media rich software running on Android that can work offline. Dashboards on DHIS2 can then display the aggregate data for all APE monthly indicators, as outlined in the MoH's Monitoring and Evaluation plan for the APE programme.Automated performance reports on how APEs and supervisors are using the applications are emailed on a weekly and monthly basis to district, provincial and national levels.Implemented in 7 out of 11 provinces, with over 2,778 APEs and 777 supervisors using the app. MoH is planning to roll out the platform to all 8,800 APEs and 1,300 supervisors nationally by the end of 2024. Lessons learned from upSCALE implementation in large scale, we used desk review interviews from March

to May 2021 with 12 key stakeholders who had significant involvement with upSCALE. We led discussions with all of whom gave their consent for verbatim notes. We analysed notes in four categories: advocacy, engagement and acceptability; data collection and uptake; technology and usability; and ownership and sustainability. Finds shows established relationships at the beginning, accompanied by close engagement on planning promoted successful implementation; data quality and timeliness are key considerations for decision-making; linking data, uptake and use at various levels of the health system presents a challenge; the integration of data into the national health information system is key for sustainability and fostering a data-to-action the provision of equipment, is a valuable investment, training, is essential to promote accurate use of technology and knowledge retention.

PREDICTIVE MODEL FOR REAL WORLD PERFORMANCE OF RAPID ANTIGEN TESTS BASED ON LABORATORY EVALUATION

Irene Bosch, Miguel Bosch, Dawlyn Garcia, Lindsey Rudtner, Nol Salcedo, Sina Hoche, Jose G Arocha, Helena de Puig, Helena del Corral, Lee Gehrke, Alfred Harding, Laura Holberger

IDX20 Inc., Boston, MA, United States

Controlling spread of disease due to infectious agents require a quick response from the public health sector. In the ongoing COVID-19 pandemic, the use of antigen tests (ATs) has shown to be an excellent tool to inform users and help mitigate the spread of the disease. In this communication we demonstrated how performance of an antigen test -- as a diagnostic in vitro device -- can be properly validated using a combination of quantitative laboratory experimentation and self-testing data from a clinical study. Furthermore, the work demonstrates that the clinical performance of an antigen test can be predicted using mathematical modeling based on laboratory validations. The proposed appraisal methodology of antigen test performance under real-world conditions could be a useful tool to inform the decision making of regulatory officials. This approach standardizes, simplifies and quickens the process of validation, analysis, and comparison of antigen rapid tests. If accepted as a standard, it will help democratize the process of compliance to show test performance to the public (and regulatory agencies) and ultimately will help with the execution of effective public health responses.

6534

EVALUATING A DHIS2 BASED PLATFORM FOR REAL TIME MONITORING OF MASS DRUG ADMINISTRATION OF NEGLECTED TROPICAL DISEASES MEDICINES: LEARNINGS FROM NIGERIA

Martins Imhansoloeva[1], Christian Nwosu[1], Ruth Dixon[2], Omosefe Osinoiki[1], Chukwuma Anyaike[3], Perpetua Amodu-Agbi[3], Ununumah Egbelu[3], Richard Selby[4], Sarah Bartlett[4], Sunday Isiyaku[4]

[1]Sightsavers, Abuja, Nigeria, [2]Technopolis, Brighton, United Kingdom, [3]Federal Ministry of Health, Abuja, Nigeria, [4]Sightsavers, Haywards Heath, United Kingdom

Mass drug administration (MDA) of Neglected Tropical Diseases (NTDs) medicines has proven to be the most effective NTD prevention strategy globally. MDA is implemented annually in endemic areas in Nigeria, where campaigns are tracked using a combination of paper and spreadsheet-based methods. This tracking system is inefficient, slow, and prone to errors. In collaboration with Nigeria's Federal Ministry of Health (FMoH), Sightsavers developed a DHIS2-based tool for real-time capture, analysis, and reporting of MDA data. We assessed the tool's accessibility, data quality, and utility for MDA planning, monitoring, and reporting, as well as its scalability regardless of funding source or location. Data was collected at the local government level (LGA), state, and federal levels during the pilot and scale-up phases using a combination of qualitative and quantitative methods. We investigated the potential for use at scale by evaluating in three Nigerian states (Jigawa, Enugu, and Kwara) with different support models and partners. The ability of DHIS2 to detect and address a variety of MDA-related technical and programmatic issues was generally highlighted as beneficial by participants. The tool reportedly improved timeliness in tracking incoming data, detecting data inconsistency and flagging data quality issues, as well as identifying areas of low coverage, informing supervisory visit decisions, and tracking drug inventory. Our findings showed that scaling-up to different settings was feasible; however, plans would need to address several challenges including insufficient funding, poor internet infrastructure, particularly in rural areas, increased workload, and high staff attrition rate from the NTD program. Furthermore, because of differences in operating models, cultural contexts, technology capacity, and levels of willingness to change, successful scale-up into new locations will not be a one-size-fits-all approach. The Nigerian FMoH has taken these findings and recommendations into account as they scale up the system across the country.

6535

A PROBABILISTIC FRAMEWORK OF MALARIA EPIDEMIOLOGY USING AGE OF INFECTION

John M. Henry[1], Austin R. Carter[1], Juliet N. Nsumba[2], Doreen M. Ssebuliba[2], David L. Smith[1]

[1]University of Washington, Seattle, WA, United States, [2]Makerere University, Kampala, Uganda

The epidemiology of Plasmodium falciparum malaria can be understood jointly through observed prevalence, parasite densities, measures of cumulative exposure, and outcomes of infection. Malaria epidemiology has proven difficult to capture using simple models because of complex, heterogeneous infection dynamics and a biased, noisy observational process. Parasite densities, which are highly variable over long infections and controlled by immunity, act as strong predictors of infectiousness, detection rates, and disease. Exposure stimulates immunity, but infections are also modified by treatment and chemoprotection, superinfection, and various sources of population heterogeneity. Immunity is presumed to develop with cumulative exposure, decreasing the 'typical' parasite density below the baseline naïve infection. To deal with all these features in compartmental models, the number of state variables would increase combinatorically and become unwieldy. Stochastic models that include all these sources of heterogeneity are complex and implemented as agent-based models to be simulated. These models are effectively black boxes and are difficult to analyze or fit to data without a heavy computational burden. Here, departing from traditional compartmental or agent-based models, we present a new, probabilistic approach using a semi-Markov framework for modeling both infection age and multiplicity of infection, which jointly can predict statistical properties of individual infections in a cohort of humans as it ages. Using the distributions of parasitemia fitted to a model of the time since first patency in malaria-naïve human subjects from the malaria therapy dataset, we can use our infection age distribution to produce a dynamic predictor of parasitemia with the effects of immunity. Ultimately, using a state-space modeling approach, we can derive equations that model the distributions of both observable (e.g., observed prevalence, fever) and unobservable (e.g., true prevalence, immunity) quantities, allowing for both qualitative analysis of the expected behavior and quantitative measures of uncertainty.

6536

DENGUE--AN EMERGING THREAT WORLDWIDE: A MATHEMATICAL MODEL EXPLORING GLOBAL RELATIVE RISK USING CLIMATIC, GEOLOCALIZED ECONOMIC, AND VECTOR DISTRIBUTION DATA

Amber F. Britt, Sina Mokhtar, Rebecca Fischer, Patrick Tarwater, Angela Clendenin, Martial Ndeffo-Mbah

Texas A&M, College Station, TX, United States

Dengue is a vector-borne viral disease affecting humans that is endemic in tropical and subtropical areas worldwide. A complicated web of factors that determine disease transmission dynamics, including the human

host's infection status the age of the mosquito vector and the ingested viral dose during bloodmeal acquisition, specific viral characteristics, and environmental conditions, such as temperature and humidity. The aim is to evaluate the impact of temperature and precipitation on the global risk of dengue outbreaks at a 5x5 km2 resolution.A spatiotemporal model using an extended version of the Ross-Macdonald theory calculated a Relative Global Dengue Basic Reproductive Model (R0). It included temperature, rainfall, Aedes aegypti vector distribution, and geolocalized economic factors to evaluate disease transmission dynamics. The geolocalized economic data integrated the association between mosquito and human interaction and economic prosperity, which is heavily dependent on the availability of running water, access to air conditioning, and screens on the windows.Overall, the R0 model's projections align with the observed distribution of the Dengue virus. The Brière and Quadratic Functional forms of precipitation demonstrate widespread dengue risk throughout the year in equatorial regions and a coordinating increase in R0 values at higher latitudes in the northern hemispheres during the summer months and lower latitudes in the southern hemisphere during the summer months. The model predicts a global relative Dengue outbreak risk profile and demonstrates its spatiotemporal heterogeneity by identifying areas at risk of high virus transmission throughout the various months of the year. It shows an increase in the geographic risk during summer temperatures, demonstrating an optimal temperature and precipitation range for the genesis and proliferation of an outbreak. For simplicity, our model considers the impact of precipitation and temperature on Ae. Aegypti life cycle as independent variables. Future work should investigate their potential synergistic impact on mosquito population dynamics and outbreak risks.

6537

THE SINGLE PATCH PLASMODIUM FALCIPARUM APPLICATION - A TOOL FOR MALARIA MODELLING IN LMIC

Sheetal P. Silal

Modelling and Simulation Hub, Africa (MASHA), University of Cape Town, Cape Town, South Africa

With a global push towards malaria elimination, modellers are increasingly supporting national and regional policy design in LMIC, and have the ability to contribute directly towards achieving malaria elimination in these countries. Innovations in modelling and scientific communication become necessary as timelines for decision-making vary. One such innovation is to develop user-friendly computer applications designed to allow policy-makers to run simple mathematical models and navigate the output of millions of simulations of more complex models with the aid of interactive graphs. The primary novelty is the focus on implementation and translation of the modelling results allowing policy-makers to design an elimination/control strategy incrementally by combining candidate interventions to predict the desired impact and cost. The Single Patch Plasmodium falciparum (SPPf) tool is disease modelling software that simulates Plasmodium falciparum malaria transmission for a population of interest. The software allows the user to simulate malaria policies and intervention strategies, alone and in combination, to determine the impact on malaria incidence and the cost thereof. The tool has been developed in the open-source RShiny Application framework and can be made available to the user in both an online and offline format. Beyond allowing the user to upload local data into the tool, the SPPf tool simulates key interventions such as scaling up or down of vector control activities including long lasting insecticide treated bednets and indoor residual spraying, health systems strengthening through improved access to and receipt of care, chemoprevention during pregnancy and seasonally, and the impact of the RTS,S vaccine. Both the epidemiological and cost results are available for download for further analysis. The SPPf tool has already been used to design malaria policy in South Africa, Ghana and several other settings. The principal benefit of the SPPf tool is to allow the modeller to co-design malaria policy with the decision-maker to enable true participatory modelling.

RESPONSIBLE ACCESS TO DATA FOR ANALYSIS AND RESEARCH (HEALTH: RADAR) – A PROJECT FOR BETTER CLIMATE SENSITIVE INFECTIOUS DISEASE MODELS IN THE GLOBAL SOUTH AFRICA

Jared M. Norman[1], Christopher Lennard[2], Sadiq Wanjala[3], Rajendra Maharaj[4], Sheetal P. Silal[1]

[1]Modelling and Simulation Hub, Africa (MASHA), University of Cape Town, Cape Town, South Africa, [2]Climate Systems Analysis Group, University of Cape Town, Cape Town, South Africa, [3]Clinton Health Access Initiative, South Africa Office, Cape Town, South Africa, [4]South African Medical Research Council, Durban, South Africa

A recent literature review by the Wellcome Trust found that the majority of digital tools related to Climate Sensitive Disease Modelling (CSID) have been developed by institutions in the global North, while the major burden of disease remains in the global South. Disease models accounting for local context, diversity and culture in model development can lead to recommendations that are more implementable and acceptable to the populations on whom these models are based. This is maximised when the models and analysis are generated by modellers from the geographies under study. One of the greatest obstacles to CSID modelling in LMIC is accessibility to operationalisable datasets in a format that is digestible and acceptable to modellers and analysts. Health: Responsible Access to Data for Analysis and Research (Health: RADAR) is a project funded by the Wellcome Trust which seeks to contribute to the development of useful CSID models within an African context. The project partners include the Modelling and Simulation Hub Africa (MASHA), the Climate Systems Analysis Group (SAG), the Clinton Health Access Initiative (CHAI) and the South African Medical Research Council (SAMRC). A key project output is an open-source online resource where users can access contextually enriched data sources for climate sensitive infectious disease models. For this project, the pilot application is on Malaria in the Southern African region though the nature of the project allows for more general scope at a later stage. Another key output is the establishment of a community of users who contribute to the online resource through procedures developed over the coming years. Data included in the resource should follow certain criteria - it should be readily accessible and befitting of the context focused on by the tool and citeable. The data should be incorporated in a way which adds contextual relevance as to how it could be incorporated into a CSID model, with example code on how one might work with the data.

6539

A PREDICTIVE MODEL FOR NON-INVASIVE ANEMIA DIAGNOSIS

Jia Ying Jennifer Teo[1], Sophie Wu[2], Kartik Pejavara[3], Dominic Garrity[4], Adam Wax[2], Nirmish Shah[5]

[1]Duke University School of Medicine, Durham, NC, United States, [2]Department of Biomedical Engineering, Duke University, Durham, NC, United States, [3]Department of Computer Science, Duke University, Durham, NC, United States, [4]Global Alliance for Medical Innovation, Boston, MA, United States, [5]Department of Medicine, Duke University Medical Center, Durham, NC, United States

Anemia, a disease characterized by impaired tissue oxygen supply, is a condition that affects about a fifth of the world's population and is the second leading cause of disability. Individuals in western and central sub-Saharan Africa and South Asia are disproportionately affected by anemia, with young children and pregnant individuals experiencing the highest prevalence with life-threatening consequences. The objective of this study is to develop a predictive model which accurately estimates hemoglobin concentrations from nail bed images. Predictive models, including logistic regression and random forest, are trained on a data set that maps hemoglobin concentrations to patient nail bed images. Preliminary results are promising, suggesting that these predictive models have the potential to develop a cheaper and more accessible diagnostic tool for anemia diagnosis. Future work will focus on implementing additional predictive models such as a binary classification model or deep learning to improve

predictive performance. Ultimately,these results will be used to improve point-of-care anemia diagnostics by developing a better hematology tool that is non-invasive, accurate, and affordable for low-resource settings.

IMPACT OF GOVERNMENT-REGULATED LOCKDOWNS DURING THE COVID-19 PANDEMIC ON ACCESS TO MENTAL HEALTH SERVICES THROUGH A TERTIARY PSYCHIATRIC CARE FACILITY AND THE NATIONAL MENTAL HEALTH CALL HELPLINE IN SRI LANKA

Madhubhashinee Dayabandara[1], **Chaminda Prasad Gigummaduwa Liyanage**[2], Pushpa Ranasinghe[3], Dhammika Wijesinghe[3], Charith Pathirana[3], Suhashini Ratnatunga[1], Shenal Madhushan[1], Yasasvi Dewasirinarayana[1], Kasuni Hasintha[1], Dharani Rajahewa[1], Shakthi Wijesekara[1], Ayodya Amarasinghe[1], Joacim Rocklöv[4], Yesim Tozan[2]

[1]Department of Psychiatry, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, [2]School of Global Public Health, New York University, New York, NY, United States, [3]National Institute of Mental Health, Angoda, Sri Lanka, [4]Heidelberg Institute of Global Health & the Interdisciplinary Center for Scientific Computing, University of Heidelberg, Heidelberg, Germany

During the COVID-19 pandemic, many countries imposed restrictions on human mobility, limiting access to healthcare. We examined how these measures affected access to psychiatric services in Sri Lanka. We analyzed 15,122 outpatient presentations (OPs) to tertiary care psychiatric service at the National Hospital of Sri Lanka, and 56,363 calls to the national mental health helpline of the National Institute of Mental Health between 2019 and 2021. Selected presentations for pre-pandemic (01.01.2019-20.03.2020) and pandemic (21.03.2020-31.12.2021) periods were compared using Chi-Square test at a significance level of 0.05. Using the Google residential mobility index as a proxy for the intensity of community response to nationwide lockdown, we evaluated its delayed association with OPs and helpline calls using distributed lag non-linear models. Statistically significant increases in OPs were observed for females (10%), somatic (28%) and mood (10%) symptoms, and behavioral changes (18%) during the pandemic while OPs for self-harm and substance use decreased significantly by 22% and 25%, respectively. Treatment termination rate by provider was significantly higher among patients during the pandemic. Compared to pre-pandemic period, we observed a significant increase in calls for mental health concerns and a significant reduction in calls for domestic violence and alcohol use during pandemic period. Similarly, relative to the pre-pandemic period, increases in residential mobility index were associated with statistically significant increases in risk of OPs due to mood, somatic and behavioral symptoms, and self-harm with a lag of 21 days. The risk of helpline access due to mental health concerns, relationship issues, and suicidal ideation increased significantly with a lag of 3-5 days. Our findings indicate that OPs and psychiatric service provision patterns changed significantly during the pandemic. The shorter lags for helpline calls, when compared to OPs, indicate the importance of providing continued access to mental health services through telephone helplines during times of mobility restrictions and lockdowns.

CREATING A DATA LIBRARY USING PUBLICLY AVAILABLE RESEARCH DATA ON NEGLECTED AND EMERGING INFECTIOUS DISEASES

Michael Anthony Vizcaino

CUNY SPH, Manhattan, NY, United States

Neglected and emerging infectious diseases are vastly understudied due to being uncommon in high income countries and the lack of resources in low-income countries have led to underfunding for research. The goal is to search for publicly available data on neglected diseases so that researchers can utilize them to answer research questions they may have on neglected diseases. A search was conducted for data on each neglected disease through data repositories including Harvard Dataverse, Cliniclatrials.gov, zenodo.org, All of Us Cohort Study, and Data dryad.org. The research studies with data were collected and a data library was developed including each neglected disease, the name of the study, a brief description of the research, the origin of the research data, and links to the research data. The results from the search revealed that data is publicly available on each neglected disease with some diseases having more research results compared to others. A search for Schistomiasis on Harvard Dataverse yielded only 6 studies while Chagas disease generated 4694 results on research with data on zenodo.org. More than 50 studies with data on neglected diseases within the last 5 years were obtained from the online data repositories which makes the limited data available and can facilitate research.

6542

FEASIBILITY AND ACCEPTABILITY OF MOBILE TECHNOLOGY TO IMPROVE ONE HEALTH OUTBREAK REPORTING IN BWINDI, UGANDA

Julia Lippert[1], Nahabwe Haven[2], Scott Kellermann[2], Latha Rajan[1], Tierra Smiley Evans[3]

[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, [2]Bwindi Community Hospital, Buhoma, Uganda, [3]One Health Institute, UC Davis, Davis, CA, United States

The Bwindi Impenetrable National Park (BINP) in Southwest Uganda is an extremely dense and biodiverse forest. A highly dense human population living in proximity to forest animals results in numerous opportunities for zoonotic spillover. This work was part of NIAID CREID Network's Epicenter for Emerging Infectious Disease Intelligence (EEIDI) that investigates regional emerging infectious diseases (EIDs). A One Health, transdisciplinary strategy is used for surveillance and response for EIDs of pandemic potential.This exploratory study was undertaken as a needs assessment and acceptability study to inform a large technology-development project intended to improve data reporting and outbreak responses in areas at high risk for zoonotic spillover. Methods employed primarily focus group discussions (FGDs) in both hard-to-reach rural communities around BINP, and the urban setting of Kabale city. Though smartphone app-based technology is replacing SMS-based technology, local communities rely solely on simple button phones to communicate. This study had the goals of 1) determining the primary methods of mobile communication and 2) estimating community acceptance of a mobile reporting system to report and record location.Ten rural FGDs were conducted around BINP in 3 districts (Kanungu, Rubanda, and Kisoro), and 5 FGDs were conducted in the urban setting in Kabale district. Each FGD had 6-8 participants, totaling 102 people. With written informed consent from each participant, we recorded the discussions, translated them from the local language into English, and transcribed them. Line by line coding of major categories and themes was performed using NVivo software. This analysis revealed that all 15 FGDs reported simple button (SMS based) phones as the predominantly available cell phone type. All 15 FGDs also reported willingness to participate in a mobile outbreak reporting system and willingness to have their geolocation data reported. Communities in Bwindi have access to, and prefer, Simple button (SMS) phones. Community acceptance was very high. These results combined reveal high potential for a new mobile reporting system.

6543

INVESTMENT CRITERIA FOR THE DEVELOPMENT OF NEW DIAGNOSTICS

Sally M. McFall[1], Robert L. Murphy[3], **Chad J. Achenbach**[3], Kara M. Palamountain[2], Mamoudou Maiga[3], Matthew R. Glucksberg[2], Lesley Scott[4], Grant Theron[5], Thomas Franz[6], Eligius Lyamuya[7], Akinniyi Osuntoki[8], Akinwale Coker[9], Oche Agbaji[10], Seydi Moussa[11], Almoustapha Maiga[12]

[A]Biomedical Engineering, [1]Northwestern University, Evanston, IL, United States, [2]Northwestern University, Chicago, IL, United States, [3]University of the Witwatersrand, Johannesburg, South Africa, [4]Stellenbosch University, Cape Town, South Africa, [5]University of Cape Town, Cape Town, South Africa, [6]Muhimbili University, Dar es Salaam, Tanzania, United Republic of,

[7]University of Lagos, Lagos, Nigeria, [8]University of Ibadan, Ibadan, Nigeria, [9]University of Jos, Jos, Nigeria, [10]Université Cheikh Anta Diop, Dakar, Senegal, [11]University Of Science Of Technical And Technology De Bamako, Bamako, Mali

When making decisions to invest in the development of new diagnostics, most manufacturers from high-income countries (HIC) require extraordinarily high prerequisite levels of projected annual sales, market growth and rates of return. Because of these investment criteria, medical technologies are rarely designed for use in low- and middle-income countries (LMICs). Transferring healthcare solutions and technologies from HIC to LMICs is slow, expensive and challenging if not impossible. Appropriate diagnostic products designed specifically for implementation in LMICs are best developed with local knowledge and understanding of needs, context, and available resources. For local innovation of health technologies to become a new standard, capabilities in health technology are required for needs assessment, market analysis, product design, prototyping, validation testing, manufacturing and management. The NIH-funded Center for Innovation in Point-of-Care Technologies for HIV/AIDS and Emerging Infectious Diseases at Northwestern (C-THAN) is one of the Point-of-Care Technology Research Network (POCTRN) centers of the NIH that supports biomedical engineering capacity in LMIC-centered diagnostics. C-THAN includes 9 academic centers across Africa that catalyzes innovation in diagnostic technologies through a model that enhances complementary strengths to build multidisciplinary partnerships across technology platforms, clinical, regulatory and commercialization domains with a specific focus on HIV/AIDS and emerging infectious diseases. During C-THAN's first five years, 43 projects were successfully supported, 26 involved technology development, 9 clinical validation, and 9 technology dissemination. 34% of projects have African Principal Investigators and most involve collaborations between HIC and LMIC investigators. In the next 5 years, C-THAN will emphasize specific technologic domains by establishing working groups in molecular, lateral flow, synthetic biology, and product engineering in HIV and emerging infectious diseases related diagnostics.

6544

CLOSE ENCOUNTERS OF THE ENVENOMATING KIND: MISSIONARIES, INSECTS, AND SNAKES DURING THE SCRAMBLE FOR AFRICA, 1885 - 1914

David P. Adams[1], Michael Kent[2]

[1]National University of Ireland-Galway, Galway, Ireland, [2]Point University, Savannah, GA, United States

Encounters with envenomating insects and reptiles of all kinds were, and remain, common in sub-Saharan regions throughout Africa. As Europeans, whether secular, military, or religious, pushed more deeply into these areas, these meetings grew increasingly likely. Missionaries who worked for the Church Missionary Society (CMS), an evangelical Anglican organisation founded in 1804, provide an excellent case in point. They provide vivid, humorous, and sometimes tragic, encounters with arthropods and reptiles. Naïve newcomers, blissfully ignorant of hazards that might await them in the bush, faced particular risk. Relying on published and archival contemporary accounts by CMS missionaries during the late 19th century Scramble for Africa, this presentation will highlight encounters, both comical and tragic, with envenomating insects in sub-Saharan Africa.

6545

IMPACT OF AN ANCILLARY CARE POLICY DURING AN EBOLA VACCINE TRIAL IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Gwen Lemey[1], Ynke Larivière[1], Trésor Zola[2], Solange Milolo[2], Engbu Danoff[2], Emmanuel Esanga[2], Junior Matangila[2], Raffaella Ravinetto[3], Jean-Pierre Van geertruyden[1], Vivi Maketa[2], Patrick Mitashi[2], Pierre Van Damme[1], Hypolite Muhindo Mavoko[2]

[1]University of Antwerp, Antwerp, Belgium, [2]University of Kinshasa, Kinshasa, Congo, Democratic Republic of the, [3]Institute of Tropical Medicine, Antwerp, Belgium

Between 2019 and 2022, the Universities of Antwerp (Belgium) and Kinshasa (DRC) conducted an Ebola vaccine trial (clinicaltrials.gov: NCT04186000) in the remote area of Boende in DRC, characterized by insufficient access to essential health care and a previous Ebola outbreak. After the trial started, a policy with decision algorithm was developed to support participants' concomitant medical events. To evaluate its impact on the management of related and unrelated (Serious) Adverse Events ((S) AE), we assessed for each event reported if and which type of support was provided. Potential outcomes were administering medication, direct payment or reimbursement of medical costs, or no support possible. Data was summarized using descriptive statistics. In total, 629 AE and 62 SAE were reported; the majority (613 and 58 respectively) were unrelated to the investigational product or to trial participation. Medication from the study pharmacy was administered to 555 AE and 18 SAE. Additionally, for 155 cases the medical costs were directly covered by the study budget. Reimbursements were provided for 20 AE and 24 SAE, but for 17 AE and 24 SAE this was impossible. With AE, treatment consisted of medication (from multiple sources) in 611 cases, 32 were hospital consultations. The remaining 12 were managed otherwise, e.g. via blood checks, observation, or surgical interventions. With SAE, 52 participants were hospitalized, 50 were treated with medication and 13 received surgery. The policy's largest impact lays with the provision of medication, offered directly or reimbursed when coming from other sources. Study pharmacies can thus contribute majorly to participant care. Financial support, although not the largest support outcome, had a considerable impact on reducing participants' out of pocket payments for health care. Unsupported medical costs were mostly due to (unrelated) events occurring prior to policy implementation, or to the absence of documentation. This underlines the importance of planning an ancillary care policy upfront, and of informing participants at recruitment in order to adequately address their health needs during research.

The South and Southeast Asian Community-based Trials Network (SEACTN) was launched in October 2019 to establish the foundational infrastructure for monitoring the incidence, causes and outcomes of febrile illnesses in rural communities in these regions, and later the trialling of interventions delivered by village health workers and rural clinics to improve their diagnosis and treatment. SEACTN activities span approximately 750 villages across five South and Southeast Asian countries (Bangladesh, Myanmar, Laos, Cambodia, and Thailand). It is a uniquely multi-national network with governmental, non-governmental, and academic partners focused on rural and remote healthcare provision in areas often neglected by the health system, and with data being collected electronically and collated in real time. As of March 2023, over 60,000 patients with a febrile illness have been recruited in these remote and underserved communities, as well as over 2100 patients admitted in higher level facilities. Multiplex serological and molecular assays have been developed to establish the causes of illness in these patients. In parallel, over a thousand deaths have been investigated with verbal autopsies, and household health surveys are being conducted in hundreds of villages. This is providing an unprecedented account of the incidence, morbidity and mortality associated with acute febrile illness as well as other causes of morbidity and mortality in rural South and Southeast Asia. This will support evidence-based decisions as to which interventions are likely to have the largest positive impact on population health in these remote, underserved, and understudied communities and these interventions will later be trialled in the same network. This session will provide an overview of SEACTN and interim findings on presenting syndromes and outcomes in the community and hospital-based cohorts.

6547

FEEDBACK FROM THE FAMILY FOLLOW-UP SESSIONS WITH DECEASED FAMILIES TO SHARE THE CAUSE OF DEATH REPORT: LESSON LEARNT FROM THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) PROGRAM IN BANGLADESH

Dalia Yeasmin[1], Sazzad Hossain Khan[1], Tonmoy Sarkar[1], Afroz Zahan[1], Abdus Suban Mulla[1], Aziz Ahamed[1], Shikha Datta Gupta[1], Farhana Hasnat Khan[1], Syead Tamim Mahmud[1], Afruna Rahman[1], Faruqe Hussain[1], Mohammad Sabbir Ahmed[1], Shovo Debnath[1], Rajib Biswas[1], Mohammad Zahid Hossain[1], Maria Amixenchs[2], John Blevins[3], Shams EL Arifeen[1], Emily S Gurley[4], Shahana Parveen[1]

[1]icddrb, Dhaka, Bangladesh, [2]ISGlobal, Hospital Clinic Universitat De Barcelona, Spain, Spain, [3]Emory Global Health Institute, Atlanta, GA, USA, American Samoa, [4]Department of Epidemiology, Bloomberg School of Public Health. Johns Hopkins University, USA, MD, United States

In Bangladesh, determination of cause of death (CoD) is often imprecise due to under-resourced diagnostic facilities and culturally low acceptance of full autopsy. The Child Health and Mortality Prevention Surveillance (CHAMPS) offers minimally invasive tissue sampling (MITS) at Baliakandi sub-district and Faridpur district to identify the cause of stillbirth and of <5 deaths. The team promised families to return the CoD report determined by an expert panel within 120 days of the death, but if delayed team informed them the cause of delay. The CoD reports were prepared in a descriptive format and a trained, gender balanced team including a physician and community engagement staff shared the report to families in their home through an interactive session. To make it more effective, we observed 110 sessions between 2018 to 2020 and documented participants' acceptance, queries, opinions and our team's responses. The parents, key decision makers, relatives and some neighbors attended the sessions with duration of 35 minutes. Families generally appreciated that our team returned to them with CoD report. In the initial sessions, families requested to share the case specific preventions. Subsequently, the panel prepared cause specific and general prevention messages that the team shared with families. Although families accepted the report; some perceived that the child death was expected as some maternal factors mentioned as CoD i.e. high blood pressure, diabetes and domestic violence. After explaining how such conditions were treatable, families stated that now they realized the death occurred due to their negligence, not sending mother for antenatal care and some families argued, the death occurred due to physicians' negligence. Families common queries were how to prevent future deaths and how CHAMPS can support mother during subsequent pregnancies i.e. for treatment and team explained the need for ANC and CHAMPS could support mother to receive it in CHAMPS facilities. Our findings suggest that such interactive session could sensitized families about CoD and need for ANC or required treatment during pregnancy to prevent unwanted child death.

6548

HOW DO SUBSTANDARD AND FALSIFIED ANTIMICROBIALS AFFECT THE EMERGENCE AND SPREAD OF ANTIMICROBIAL RESISTANCE?

Sean M. Cavany, Stella Nanyonga, Cathrin Hauk, Céline Caillet, Paul Newton, Ben Cooper

University of Oxford, Oxford, United Kingdom

Approximately 10% of antimicrobials used by humans in low- and middle-income countries are estimated to be substandard or falsified (SF). In addition to their negative impact on morbidity and mortality, they may also be important yet neglected drivers of antimicrobial resistance. Despite concern over their potential role in the emergence and spread of antimicrobial resistance, and the consequences this would have on public health, our current understanding of this relationship is rudimentary. In this study, we used mathematical models to examine the relationship between SF medicines and antimicrobial resistance. Combining observed distributions of active pharmaceutical ingredients in randomly sampled antibiotics with different assumptions about the relationship between dosing level and resistance emergence, we quantified the expected rate of population level resistance emergence. Results suggested that when ~10% of medicines are SF, the effect on resistance may be relatively small. However, in pockets where SF medicines are more common, representing ~50% or more of antimicrobials, SF medicines may have a substantial effect on resistance emergence. Second, we combined these outputs with epidemiological models to understand the role that both transmission of resistant microbes and heterogeneity in the frequency of SF medicines play in driving the spread of resistance. This suggested that those pockets with higher frequencies of SF medicines have the potential to drive resistance in other areas too. Together, our results add to our understanding of this important and neglected global health problem, and provide a framework for future work assessing the importance of different intervention points to reduce the impact of SF medicines on resistance.

6549

THE DEVILS INVADE THE HOUSE THROUGH THE HOLES IN THE BAMBOO BOOTH: A NARRATIVE OF LOKU AND TAKAYA FEVER ILLNESS AMONG CHILDREN IN EASTERN INDONESIA

Lenny L. Ekawati[1], I Nyoman I.K. Wijaya[1], Benidiktus Delpada[1], Iqbal Elyazar[1], Adrian D. Smith[2], J. Kevin Baird[1], Philip Kreager[3]

[1]Oxford University Clinical Research Unit (OUCRU), Jakarta, Indonesia, [2]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, [3]Institute of Human Sciences, University of Oxford, Oxford, United Kingdom

Fever is the most prevalent presenting ailment during childhood. On the eastern Indonesian island of Alor, the Abui people recognize two fatal fever-

related folk illnesses called Loku and Takaya. From June 2021 to July 2022, an ethnographic study was done using in-depth interviews, participant observation, and informal interactions. Following the ethnographic work, census, and behavioral surveys were carried out to measure the impact of distance to a health facility and degree of illness on treatment seeking behavior for fever. The study explored how people perceive and seek treatment for childhood fever. Five individuals were purposively chosen from 50 key informants. The narratives of two eminent healers and three mothers of feverish children illustrate the cultural understandings of febrile illness. The mothers consulted traditional healers and home remedies or holy water were offered. When illness progressed to severe, mothers acknowledged that the child may need to be admitted to a health facility. However, cost and poor service quality were cited as impediments to that treatment-seeking. Consequently, mothers often opted to care for their children at home, even understanding the danger that imposed. The healers believed both Loku and Takaya would be diagnosed as malaria at the health facility. Yet, they believed that antimalarials are unable to cure due to its supranatural causes. In summary, traditional understanding and management of febrile illness and treatment seeking behavior within this impoverished rural community continues and leads to potentially dangerous delays in treatment of feverish children. Health promotion and community engagement by public health workers who understand local perceptions of fever are more likely to devise more effective health interventions and mitigate preventable infectious harm to Abui children.

6550

PREVALENCE OF ANTIBIOTIC USE AMONG THREE SELECTED TERTIARY LEVEL HOSPITALIZED PATIENTS, A POINT PREVALENCE SURVEY FINDING IN BANGLADESH

Dr. Ayesha Afrin[1], Md. Mahbubur Rashid[1], Md. Kamal Hossain[1], Nitish Debnath[2], Aninda Rahman[3], Fahmida Chowdhury[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Fleming Fund Country Grant to Bangladesh, DAI Global, LLC,, Dhaka, Bangladesh, [3]Communicable Disease Control (CDC), Directorate General of Health Services, Government of Bangladesh, Dhaka, Bangladesh

Irrational use of antimicrobials in both humans, animals, and the food chain led to the emergence of antimicrobial resistance (AMR). Due to antibiotic resistance, patients are more likely to remain infectious for a longer time, increasing the risk of spreading resistant microorganisms to others. For supporting antibiotic stewardship interventions, the World Health Organization (WHO) categorized antibiotics according to AWaRe (Access, Watch, Reserve) classification. We aimed to describe the prevalence of antibiotic use (ABU) as stated by AWaRe classification in tertiary level acute care hospitals in Bangladesh. A point prevalence survey (PPS) was conducted adopting WHO PPS design among inpatients of three tertiary level public hospitals in Bangladesh from June to September 2022. Among the enrolled 1634 inpatients, 52% (860) were female and 66% (1093) were from the 15-64 years age group. Nearly, 75% (1241) of patients received at least one antibiotic during the survey period. Proportioning for different departments, 90% of the patients from burn ward, 87% of pediatric, 75% of gynae and obstetric, 72% of surgery, and 69% of medicine wards received at least one antibiotic. Third-generation cephalosporins (43%), imidazoles (15%), penicillins (13%), aminoglycosides (8.5%), and second-generation cephalosporin (8%) were documented as top 5 antibiotics. Different group of antibiotic usage at the same time was a common phenomenon. In the course of a single admission patients received ranging from single to seven antibiotics. Overall, 63% of Watch, 36% of Access, and 1% of Reserve group antibiotics were used for treatment. The use of watch group antibiotics is quite high in public hospitals. Our PPS findings underscores the need for urgent nationwide antibiotic stewardship progam for physicians along with development of disease specific and department-wise standard treatment guidelines and in-service training on ABU for the containment of AMR.

6551

IMPROVING MALARIA COMMODITY ACCOUNTABILITY: - THE CASE OF MALAWI

Elias Mwalabu[1], Daniel Taddesse[1], Elizabeth Mkandawire[2], Dennis Chali[3], Fikadu Deme[1]

[1]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project., Washington DC, DC, United States, [2]Ministry of Health Malawi, Lilongwe, DC, United States, [3]USAID, Lilongwe, Malawi

In Malawi, before 2016, reports showed limited availability of malaria medicines with 10% facilities reporting stock out of first line malaria treatment. The discrepancy ratio between the number of commodities issued and the number of cases treated was also high (1.53 compared with 1.15 target); the base line documented that 10,178,5929 treatments were issued to treat 6,647,163 cases. The potential factors contributing for this discrepancy were identified as poor recording and pilferage at treatment site level. The USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM), project devised a Commodity Accountability and Performance Tracking (CAPeT) initiative. This initiative targets 30-60 health facilities with high discrepancies based on data analysis on malaria cases and first-line treatments reported through District Health Information Software 2 (DHIS2) and Open Logistics Management Information System (OpenLMIS) quarterly. It identifies the factors (such as missing records and data aggregation errors) responsible for the discrepancies and offers solutions at various levels of implementation to address these factors. GHSC-PSM engages facility staff to verify reports and review performance, identifying discrepancies as a measure of accountability and developing action plans shared with the district and central-level health offices for further follow-up. Results from the activity show a general decrease in the discrepancy ratio of 1.38 (2019), 1.26 (2020), 1.20 (2021), and 1.23 (2022). The proportion of facilities with a discrepancy ratio of less than or equal to 1.15 increased from 10% (3/30) in the initial visit to 50% (15/30) in the revisit. Similarly, the average national discrepancy ratio reduced from 1.53 before 2016 to 1.23 in 2022. Results showed that ensuring the accountability of health commodities in the supply chain plays a critical role in improving the availability of life-saving drugs at service delivery points, as evidenced by consistently low stock-out stock rate (<1% for ACT) and decreased discrepancy ratio.

6552

ANTIMICROBIAL STEWARDSHIP IN SOUTH ASIA: A SYSTEMATIC REVIEW OF QUALITATIVE LITERATURE

Jennifer L. Murray[1], Daniel Leung[1], Olivia R. Hanson[1], Sharia M. Ahmed[1], Ashraful I. Khan[2], Debashish Biswas[2], Melissa H. Watt[1]

[1]University of Utah, Salt Lake City, UT, United States, [2]International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh

Antibiotic resistance is a global public health crisis. Effective antibiotic stewardship requires an understanding of the factors and context that contribute to inappropriate use of antibiotics. The goal of this qualitative systematic review was to synthesize themes across levels of the social ecological framework that impede antimicrobial stewardship in South Asia. In July 2022, a systematic search was conducted using the electronic databases Medline and Embase. Search terms were identified a priori, based on eligibility criteria of methods (qualitative), location (eight countries of South Asia), topic (antimicrobial and antibiotic stewardship; drug resistance), and English language. 130 articles were identified; after removing duplicates (n=11) and excluding articles that did not meet eligibility criteria (n=96), 34 articles were included in the review, with publications ranging from 2010 to 2022. Methodological quality was assessed using the qualitative Critical Appraisal Skills Program checklist. The studies represented six countries in South Asia, and included data from patient populations, health care providers, community members, and policy members. For each paper, a summary memo was written to extract the factors that impede antimicrobial stewardship. NVivo software was then used to code the memos; codes were organized by levels of the social

ecological framework. Themes emerged at the level of the individual patient (access to medical care, patient expectations, rationing of antibiotics, and perceived value of antibiotics), the formal provider (antibiotics as the first line of therapy, gaps in knowledge and skills, and financial or reputational incentives), the clinical setting (lack of resources, and poor regulation of the facility), the community (informal drug vendors, and social norms), and policy (lack of legislation, and poor implementation of existing policies). The findings highlight the importance of working across multiple sectors to build commitment for antibiotic stewardship in South Asia.

A PHYSICIAN-LED PRIMARY PREVENTION CARE ON RISK OF CARDIOVASCULAR DISEASE: A RANDOMIZED CONTROLLED TRIAL (PRIMCARD STUDY)

Isaac Olugbenga Aladeniyi[1], Olufunmilayo Fawole[2], Adesegun Fatusi[3], Folukemi Bosede Aladenola[4], Ikeola Adeoye[5], Olayemi Rhoda Aladeniyi[6]

[1]University of Medical Sciences, Ondo State, Nigeria, Akure, Nigeria, [2]University of Ibadan, Ibadan, Nigeria, [3]University of Medical Sciences, Ondo State, Nigeria, Ondo, Nigeria, [4]Ministry of health, Ondo State, Nigeria, Akure, Nigeria, [5]University of Ibadan, Ibadan, Oyo State, Nigeria, Ibadan, Nigeria, [6]College of Health Technology, Ondo State, Nigeria, Akure, Nigeria

Cardiovascular diseases account for more than 36% of deaths among adults younger than 60 years in Nigeria. The WHO advocated primary prevention care as the cheapest and most cost-effective approach to managing cardiovascular risk. Even with standard guidelines, caregivers, especially physicians are yet to accept primary prevention in practice. Major barriers include its time-consuming nature and low yield of immediate effects. This study compared the effects of physician-led primary prevention care versus usual care on cardiovascular risk reduction among at-risk institutional workers.A parallel randomized control trial was conducted. A total of 223 respondents with moderate and high risk were enrolled and randomized into physician-led intervention (n = 118) and usual care (n = 105) and followed up for six months. Respondents in the intervention arm were offered a physician-led total cardiovascular risk management approach, while the control arm continued with their usual care. The primary outcome measure was cardiovascular risk score while secondary outcome measures were: blood pressure, fasting blood sugar and body mass index and waist-to-hip ratio. Data were analyzed using descriptive statistics, paired t-test and independent t-test at α0.05.Respondents were similar in both arms for baseline sociodemographic, behavioral and cardiometabolic characteristics. Between groups, the intervention arm achieved greater reduction in blood sugar and BMI, with a mean difference of -13mg/dl and -0.6kg/m2 respectively; there was a marginal mean difference in CV risk score of -0.1% with the number needed-to-treat being ten. Within the groups, the intervention arm demonstrated significant effects on systolic blood pressure(5.0mmHg), blood sugar(9.8mg/dl), and BMI (0.8kg/m2) at endline. The control arm only affected the systolic blood pressure(8.6mmHg).The physician-led primary prevention intervention was effective in reducing individual cardiovascular risk factors and may serve a beneficial prophylactic effect on the reduction of absolute cardiovascular risk at a population level.

HYDROCEPHALUS - TWENTY YEAR TRENDS IN UGANDA

Edith Mbabazi Kabachelor

CURE Children's Hospital, Uganda, Mbale, Uganda

Hydrocephalus is a life-threatening condition due to excessive accumulation of cerebral spinal fluid within the brain's fluid spaces (ventricles). Untreated progressive hydrocephalus in children below two years of age leads to further brain damage, resulting in the majority dying and survivors left with severe cognitive and physical disabilities. It is thus critical to access early proper neurosurgical treatment in order to prevent the long-term deleterious effects and complications. Hydrocephalus is an underrecognized global health problem, and a major cause of childhood disability worldwide; with more than 400,000 new cases occuring annually; 100,000 of them from sub-Saharan Africa alone. These are additionally faced with the challenges of poverty, limited access to care, and low advocacy. Uganda is a low-income sub-Saharan country with high rates of both congenital and acquired hydrocephalus.CURE Uganda is a center of excellence for peadiatric neurosurgery treatment, training and research. Located in the Eastern part of the country, it is the main referral center for patients all over the country with hydrocephalus and spina bifida, including neighboring ones like Kenya, Tanzania, DRC, Rwanda, and South Sudan.It's estimated that 3,600 - 5,400 children in Uganda are born with or acquire hydrocephalus each year or 2 to 3 / 1,000 births (based on 1,800,000 new births per year). CURE Uganda is currently providing surgery for only approximately 20-30% of the estimated annual country need. Over the past two decades (2001-2020), CURE Uganda has provided care for 10,919 children with hydrocephalus (74%) and spina bifida (26%). The majority of the causes of Ugandan infant hydrocephalus are neonatal infections (67%) and spina bifida; both of which are preventable. The early neonatal infections have been attributed to the bi-annual rainfalls; and have a spatiotemporal distribution although the exact pathogenesis is not very clear. The recent novel discovery of the pathogens presents the perfect opportunity for preventative strategies in tropical medicine that will have huge impacts in addressing these growing disparities in global health.

MALAWI INTEGRATED TYPHOID CONJUGATE VACCINE CAMPAIGN AND ROUTINE INTRODUCTION

Latif Ndeketa, Melita Gordon, Donnie Mategula

Malawi-Liverpool-Wellcome Research Programme, Blantyre, Malawi

It is estimated that in Malawi in 2017, for all ages, there were 32,747 typhoid cases (191 cases per 100,000), 435 deaths, and 32,787 disability-adjusted life years lost to typhoid. Sixty-one percent of all cases and 65% of all deaths were in children under 15 years. The Ministry of Health in collaboration with its partners, will conduct an integrated Typhoid Conjugate Vaccine (TCV) and Measles Rubella (MR) vaccination campaign and later introduce TCV into routine immunization. The main objective for TCV introduction is 1) To provide typhoid vaccine to all the children aged 9 months to 14 years through the campaign by reaching ≥ 95 % of the target population 2) To introduce TCV into routine immunization at age of 9 months by targeting at least 80% of eligible children aged 9 to 23 months at their 9 month immunization visit. The integrated TCV MR supplemental immunization activity (SIA) will be conducted for five days in April 2023.In addition, bivalent Oral Polio Vaccine (bOPV) and Vitamin A will be administered to children aged 0 - 59 months and 6 to 59 months respectively. There will be static, outreach clinics and mobile sites that will be opened for five days. Static sites are located at permanent government and private health facilities which will also serve as storage and distribution points of vaccines and other supplies to outreach sites. The rationale for the for the integrated SIA is; 1) To efficiently use of scarce human, financial resources and easier logistics 2) a high demand for one intervention can boost coverage of others given at same time 3) to reach the marginalized with more services 4) to respond to the public's demands for broader services during campaigns 5) for easier management of logistics and management. The campaign is currently planned whilst Malawi is battling cholera and polio outbreaks which could contribute to staff fatigue and poor quality of services. There could be challenges establishing causality when serious adverse events following immunization occur due to similar administration routes. Flooding caused by climate change will decrease access to vaccines whilst increasing transmission of waterborne diseases such as typhoid.

6556

THE NUTRITIONAL IMPACT OF THE COVID-19 PANDEMIC ON YOUNG CHILDREN IN PERI-URBAN PERU: A MIXED METHODS STUDY

Jessica Rothstein[1], Emma Fletcher[2], Riley Wilgenbusch[2], Robert Gilman[2]

[1]University of Illinois at Chicago, Chicago, IL, United States, [2]Johns Hopkins University, Baltimore, MD, United States

Peru has experienced immense suffering due to the Covid-19 pandemic, with the highest per capita Covid-related mortality in the world. In peri-urban areas, strict control measures and loss of work in the informal sector affected already vulnerable communities' ability to seek healthcare and provide nutritionally adequate food to their families. The goal of this study is to assess the pandemic's impact on child nutrition in peri-urban Lima by (1) examining the prevalence of household food insecurity and stunting, as compared to pre-pandemic levels; and (2) qualitatively exploring caregivers' experiences feeding their children since March 2020. The study employed three data collection methods. First, field workers administered a structured questionnaire to 300 caregivers of children 6-23 months of age to assess socio-economic status, food insecurity, and infant and young child feeding practices. Second, anthropometric measurements (weight and length) were taken for each. Third, in-depth interviews were conducted with a subset of 30 caregivers. Data are being analyzed for key trends and themes using Stata 16 and Dedoose. Preliminary statistical analyses indicate that 79.0% of participating households are moderately or severely food insecure according to USAID's Household Food Insecurity Access Scale, and that 10.3% of children 6-23 months of age are stunted. Future analyses will compare these data to data collected during a 2016-2019 cohort study in the same setting to estimate the pandemic's effects on food insecurity and child growth. Qualitative data analysis will shed light on how economic factors, food access, the healthcare system, and interruptions in social assistance programs affected child feeding during the early stages of the pandemic, as well as the coping strategies that caregivers have developed. In conclusion, study findings will contribute to our understanding of how low-resource, peri-urban households have been affected by the pandemic and its aftershocks, and how officials may better safeguard child health and nutrition in their responses to future public health emergencies.

6557

CONTRIBUTION OF VERBAL AUTOPSY INFORMATION TO CAUSE OF DEATH ATTRIBUTION AMONG CASES UNDERGOING MINIMALLY INVASIVE TISSUE SAMPLING: FINDINGS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) BANGLADESH

Afruna Rahman[1], Afsana Afrin[1], Muntasir Alam[1], Md. Mamunur Rashid[1], Md. Abu Bakkar Siddique[1], Qazi Sadeq-ur Rahman[1], Mohammad Zahid Hossain[1], Md. Atique Iqbal Chowdhury[1], Mohammad Sabbir Ahmed[1], Rajib Biswas[1], Shovo Debnath[1], Emily S. Gurley[2], Shams El Arifeen[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States

Postmortem examination is a gold standard procedure for determining the cause of death (CoD). CHAMPS uses minimally invasive tissue sampling (MITS) with other information to assign specific CoD to stillbirths and under-five children. A panel of clinical and laboratory experts reviews each case's histology, laboratory, medical records, including maternal clinical records, if available, and a verbal autopsy (VA). The panel assigns underlying, immediate, morbid, and maternal conditions attributed to the death, including prevention recommendations. In this study, we examined how and to what extent VA data contributed to understanding CoD. From December 2022 to February 2023, the panel reviewed all existing data except the VA for 25 cases (7 were stillbirths and 18 neonatal deaths) and assigned CoD, maternal condition, and preventive actions. Then the panel re-evaluated the case, including the VA, and identified changes to CoD with this additional data point. After reviewing VA data for stillbirths, the underlying cause remained the same. However, a maternal condition was identified for one where maternal clinical record was missing, and the panel revised their prevention recommendations in 29% (2/7) cases. VA data changed the causal chain in 28% (5/18) of neonatal cases. In two cases, the lung histology was unremarkable, and the panel assigned underlying CoD as intrauterine hypoxia based on medical records. After reviewing the VA, CoD was changed from intrauterine hypoxia to sepsis and respiratory distress syndrome. A morbid condition was added in 11% (2/18) cases and excluded in one case. In 33% (6/18) cases, a maternal condition was detected. For one case, the condition was revised from oligohydramnios (identified through ultrasound record) to premature rupture of membrane. Overall, the VA data were a helpful adjunct to understanding CoD for stillbirths and early neonatal deaths, especially for deaths with no or poor clinical or laboratory records. In the context of poor medical records, VA advances the accuracy and completeness of MITS procedures for CoD determination in stillbirths and neonatal deaths.

6558

ASSESSING THE ESSENTIAL DATA SOURCES FOR PRECISE CAUSE OF DEATH DETERMINATION USING MINIMALLY INVASIVE TISSUE SAMPLING: FINDINGS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) BANGLADESH

Afsana Afrin[1], Afruna Rahman[1], Muntasir Alam[1], Md. Atique Iqbal Chowdhury[1], Kazi Munisul Islam[1], Afsana Rashed[1], Shams El Arifeen[1], Emily S. Gurley[2], Mohammad Zahid Hossain[1]

[1]International Centre for Diarrhoeal Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States

CHAMPS is a multi-country project aimed at determining the precise causes of stillbirths and under-five child deaths. CHAMPS utilizes various data sources including maternal and child data abstracted from medical records, histopathology, microbial culture, and molecular detection using multiple specimens, postmortem examination, and verbal autopsy (VA) for the determination of the cause of death (CoD). The aim of this study is to assess the contribution of each data source to increase the competence of the CoD determination process which is essential to develop actionable prevention strategies. From March 2018 to February 2023, an expert panel of pediatrician, neonatologist, obstetrician, pathologist, epidemiologist, and microbiologist reviewed 535 deaths and assigned CoD to 529 (99%) cases in Bangladesh. Of these, 51% (275/535) were stillbirths, 43% (228/535) were early neonatal deaths (0 to 6 days), and 6% (32/535) were child deaths (7 days to under 60 months). Maternal clinical abstracted data was used to detect maternal conditions directly attributed to causing death in 69% (191/275) of stillbirths and 51% (117/228) of early neonates. Child clinical abstracted data contributed to understanding the causes of early neonatal and older child deaths in 59% of cases and 75% (24/32) of cases, respectively. Histopathology reports contributed to CoD determination in 52% of stillbirths and 59% of early neonates. Infection was the cause of stillbirths and under-five child deaths in 12% of cases where postmortem culture (64/535) and molecular detection (66/535) assisted to identify pathogens. In 74% of stillbirths and 58% of early neonatal deaths, VA data aided in detecting maternal conditions. Also, VA data contributed to ascertaining the causes of child deaths in 68% (22/32) of cases. Due to the inconclusiveness of data, CoD could not be assigned for only 1% (6/535). The study highlights the contribution of each data source to determining a definitive CoD. However, it is contingent upon the extent to which the data is available, reliable, and comprehensive.

6559

DETERMINANTS OF NEONATAL MORTALITY IN RIVERCESS: SECONDARY DATA ANALYSIS OF NEONATAL DEATH IN HEALTH FACILITIES IN RIVERCESS, 2016-2020

Jusu Kamara

Global Humanitarian Initiative Inc., Monrovia, Liberia

Globally more than 6.3 million young adolescents and children died regularly from neonatal death causes. About 2.6 million newborn die in their first 28 days of life annually. Most newborn deaths, about 99% happen in countries that had limited income. Increased access to skilled birth attendants is another strategy that had been implemented in the reduction of newborn rate in Liberia. Liberia had made substantial improvement towards the decrease of neonatal death since 1970 till today's date. The research seeks to estimates live births and deaths of neonates in health facilities in Rivercess from 2016-2020. The research was conducted using a quantitative approach. Data was collected through reviewing the health facilities Health Management Information System (HMIS) report and neonatal deaths audit forms that were used by the twenty health facilities in Rivercess. The study population encompass all live born neonates and neonatal deaths records. The results revealed that the overall neonatal mortality rates (NMR) in Rivercess was 94 deaths per 11313 births or 8.3 per 1000 live birth of children occurred within the 5 year period preceding the study. The total number of neonatal deaths over this period was 94. The research revealed that neonatal deaths were most common among neonates born asphyxiated and with difficulty breathing. However, neonates who died at an early age were asphyxiated than neonates who died at late age. Another factor which was significantly associated with neonatal death at later ages was neonatal infection. The need to implement facility based newborn care interventions particularly educating midwives, nurses and traditional birth attendants about safe delivery practices is limited and therefore need improvement. Additionally, MoH should put in place a timely referral system and retain healthcare providers especially midwives to manage delivery complications and need to implement effective interventions to reduce risk of neonatal death in Rivercess.

6560

PROGRESS VS PERSISTENT CHALLENGES- WHAT WE HAVE HEARD: CHALLENGES AND OPPORTUNITIES

Jackson K. Miller

Liberia Agriculture Commodity Regulatory Authority, Monrovia, Liberia

The rate of maternal mortality in Liberia has been and still is one of the highest in the world. In contrast, the rate of neonatal mortality in Liberia—which had been one of the highest globally—has steadily reduced over the last decade. This study aims to synthesize existing evidence on the current state of maternal and neonatal health in Liberia, including approaches to intervention. In-depth interviews were conducted with a range of key stakeholders in Maternal and Neonatal Health in Liberia. These included policymakers in Monrovia, service providers in government facilities/NGO programs, community health workers and community leaders. Additionally, a series of Focus Group Discussions (FGDs) in communities across three of the most affected counties were conducted to explore perspectives regarding maternal and neonatal health in Liberia. Thematic content analysis was to determine emerging themes and Nvivo 12 software was used to structure the analysis. Key themes emerged around challenges to receipt and delivery of high-quality maternal and neonatal health in Liberia, as well as advances that have led to improvements in care. These included 1) Financial constraints exist due to disparate yet insufficient funding across multiple sources: the government, development partners and out of pocket expenses (OOP). 2) Management, accountability, and leadership in healthcare are clearly defined as priorities but not monitored. Policy documents provide clear descriptions of the authority, responsibilities, and competencies for leadership roles at all levels of the health system in Liberia. However, there seems to be a disconnect between what the policies state and the actualities due to a lack of leadership, political will, management skills, coordination and monitoring and evaluation 3) Health facilities, infrastructure and accessibility are generally poorly maintained. 4) Human resource capacity and training is limited due to relatively low numbers of trained health workers compromise adequate coverage in remote areas

6561

ASSOCIATED FACTORS WITH THE POOR PERFORMANCE OF THE MATERNAL DEATH SURVEILLANCE SYSTEM IN CAMEROON, 2020-2022

Antsele Onanena Blondel[1], Mendjime Patricia[2], Akame Roland[3], Otthou Messinde[4], Tonye Hagbe[5], Gavli Dongoa[6], Kenfack Nicole[7], Aminatou Kouotou[8], Linonge Christiana[9], Kinyuiy Emmanuella[10], Panmo Elianne[11], Atouba Benjamin[12], Ntsimi Brice[13], Ngassa K. Flore[13], Yopa Sandra[13], Kouamen Gael[13], Etoundi Mballa Georges Alain[13]

[1]ministry Of Public Health, Adamawa, Cameroon, [2]ministry Of Public Health, Department For The Control Of Disease Epidemics, Cameroon, [3]ministry Of Public Health, Far North, Cameroon, [4]ministry Of Public Health, Center, Cameroon, [5]ministry Of Public Health, Est, Cameroon, [6]ministry Of Public Health, North, Cameroon, [7]ministry Of Public Health, West, Cameroon, [8]ministry Of Public Health, Family Health Department, Cameroon, [9]ministry Of Public Health, South West, Cameroon, [10]ministry Of Public Health, North West, Cameroon, [11]ministry Of Public Health, Littoral, Cameroon, [12]ministry Of Public Health, South, Cameroon, [13]ministry Of Public Health, Department For The Control Of Disease, Cameroon

In 2014, Cameroon decided to reduce preventable maternal mortality. Surveillance data reviews shows under-reporting. We aimed to identify factors associated with poor performance of Maternal Death (MD) surveillance in Cameroon. An analytical cross-sectional study was conducted in all 10 regions from January 2020 to June 2022. A multi-stage stratified sampling helped to include randomly 13 urban and 13 rural Health Districts (HD). Health facilities (HF) were divided into six categories: all category 1-3 and 2 in category 4-6 per HD were included. Two quarters/villages were randomly chosen in Health Area (HA) hosting the mean HF. All consenting Traditional, religious and administrative leaders, Community Health Workers (CHW), traditional birth attendants and tradipratician were interviewed. Health care workers (HCW) were randomly included depending on the units. The 2001 CDC guidelines of Robert German group work was used to evaluate attributes of MD surveillance system. A KAP survey of community actors was done throw a pre tested questioner. Kobo collect software helped for data collection and Excel software for analyses. OR (CI: 95%, P<0,005) used to identify associations. A total of 2425 people were interviewed, with 1356(56%) female (F/H sex ratio of 1:1). The median age was 34(15-85) years and 1285(53%) aged 25-40 years. HCW were 1106(46%) and CHWs 1041(43%) of the interviewed. DHIS2 recorded 3046 MDs but only 1964(64.5%) were founded in HF's registers. MD causes were mostly unknown, with 80(21%). Littoral region had highest maternal mortality rate either 380 MD for 100000 live births. The surveillance system was moderately simple, unacceptable and sensitive. The promptness and completeness were acceptable. Only 6681(55,8%) MD were reviewed with 29(28%) review's recommendations fully implemented. The MD surveillance system sensitivity is significantly associated with the area (urban or rural) of implementation (OR=1.534; CI: [1,18-1,99]; P<0.001). The MD surveillance system shows globally shortcomings. We recommend training all level actors, surveillance tools elaboration, and resources allocation for activities.

6562

ASSESSMENT OF KNOWLEDGE, ATTITUDES, AND PRACTICES (KAP) TOWARD COVID-19 IN KINSHASA, DRC

Kristin Banek[1], Melchoir M. Kashamuka[2], Delphin Mubanga[3], Sadie J. Ryan[4], Jean-Claude Biayi Kalenga[2], Georges Emo Mahilu[2], Joseph Atibu[2], Latifeh Dahmash[4], Richard R. Luce[5], Jonathan B. Parr[1], Jonathan J. Juliano[1], Rhoel R. Dinglasan[4], Antointte K. Tshefu[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Kinshasa School of Public Health, Kinshasa, Congo, Democratic Republic of the, [3]Univeristy of Kinshasa, Kinshasa, Congo, Democratic Republic

of the, [4]University of Florida, Gainsville, FL, United States, [5]US Centers for Disease Control and Prevention (CDC), Kinshasa, Congo, Democratic Republic of the

The Democratic Republic of the Congo (DRC) has reported fewer COVID-19 cases and deaths compared to other countries. Determining the community-level prevalence of infection, knowledge, and behaviors that may mediate transmission is essential for improving COVID-19 control measures. The Seroepidemiological Insight into COVID-19 transmission in Africa study (SICA) aims to measure host and ecological factors influencing incidence in Kinshasa Province, DRC. This sub-study assessed the knowledge, attitudes, and practices (KAP) surrounding COVID-19. SICA study participants >15 years were administered a KAP survey. The World Health Organization Social and Behavioral Insights on COVID-19 Data Collection Tool (SBI Tool) was adapted, and included six sections: knowledge of transmission and symptoms, perceived risk and impact, prevention practices, prior illness and testing, trusted information sources, and vaccination. The frequency and proportions of the KAP indicators were calculated. From August to September 2022, 420 participants were interviewed. The median respondent age was 42 years, and 254 (61%) were female. Only 12% rated their knowledge of COVID above average, but the knowledge of one or more specific symptoms of COVID was high (86%). The two most common symptoms mentioned were cough (71%) and fever (59%). Almost three-quarters of participants (72%) considered COVID-19 a problem for their community. Most respondents (72%) reported currently practicing preventative measures, the most common of which were wearing a mask (58%), hand washing (40%), avoiding shaking hands (25%), and physical distancing (23%). Twenty-three percent of respondents reported receiving the COVID vaccine. Of those not yet vaccinated, 40% reported that they would not be vaccinated against COVID-19 in the future, due to a lack of confidence in all vaccines (43%) and unsure of its efficacy (38%). Despite self-reporting a low knowledge of COVID-19, this study population had a good level of knowledge about COVID-19. However, improvements in attitudes and practices toward preventative behaviors could further reduce transmission during seasonal peaks.

6563

PROFILING THE QUALITY OF LIFE OF SLUM RESIDENTS DURING THE COVID-19 PANDEMIC, AND THE EFFECTS OF SOME SOCIO-DEMOGRAPHIC AND ECONOMIC MEASURES

Hammed O. Mogaji[1], Nivison N. Junior[1], Hernan D. Argibay[1], Jaqueline S. Cruz[1], Ianei O. Carneiro[1], Ricardo Lustosa[1], Albert I. Ko[2], Federico Costa[1], Mike Begon[3], Hussein Khalil[4]

[1]Institute of Collective Health, Salvador, Brazil, Salvador, Brazil, [2]Yale School of Public Health,, New Haven, CT, United States, [3]University of Liverpool, , Liverpool, United Kingdom, [4]Swedish University of Agricultural Sciences, Umeå, Sweden

Brazil has recorded over 36 million cases and 650,000 deaths due to COVID-19 and remained the most affected country in Latin America. Efforts targeted at stemming transmission through non-pharmaceutical interventions (NPIs) have impacted on the socio-economic status of slum populations, however, little is known on their impact on the quality of life (Qol). We describe the Qol of residents in one of the largest slum communities in the city of Salvador, Brazil, and explored the effects of socio-demographic and economic predictors on QoL during the pandemic. We performed a cross-sectional study between November 2021 and July 2022, and administered questionnaires to obtain information on demography, employment, income, access to COVID-emergency and family support fund, food insecurity, physical health and mental health. We explored the effects of socio-demographic and economic data on physical and mental health scores using generalized linear mixed models. Among the 907 eligible participants, 633 (69.8%) with age greater than 18 years were recruited (61% females; 39% males). Unemployment rate increased from 49.9% before the pandemic to 87.8% during the pandemic. Only 53.6% received COVID-emergency funds, and 67.3% reported lack of food. Regression models found that physical health was significantly associated with age, education and losing a job during the pandemic. Scores for physical health were significantly low among participants aged 41-60 (-4.10, 95CI: -6.21, -1.98, p<0.01), those who had no formal education (-16.34, 95CI: -25.77, -6.91, p<0.01), and those who lost their job (-2.21; 95CI: -4.15, -0.26, p<0.01). In contrast, mental health was significantly associated with age and gender, with lower scores among females (-5.09; 95CI: -3.02, -3.12, p<0.01) and participants above age 60 (-0.20; 95CI: 3.69, 4.43, p<0.01). The lower quality of life observed in our study, especially for adults, females and those who have lower school attainment, supports the importance to sustain and increase the coverage of financial aids in these slums, in addition to interventions targeted at improving school enrollment and food insecurity.

6564

AN IN -SILICO APPROACH ON THE EFFECT OF LOPHENOL AND ITS DERIVATIVES ON PANCREATIC LIPASE, ALDOSE REDUCTASE AND DIPEPTIDYL PEPTIDASE-IV AS POTENTIAL TARGET FOR DIABETES MELLITUS(TYPEII)

Patience Akosua Darko[1], Michael Buer Adinortey[2], Rusell Koranteng[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]University of Cape Coast, Cape Coast, Ghana

Diabetes mellitus is a metabolic disorder that is characterized by persistent hyperglycaemia. Aloe vera has been reported to have anti-hyperglycaemic effect on diabetic patients which is reported to be due to the presence of phytosterols. The protein receptors: pancreatic lipase, aldose reductase and dipeptidyl peptidase-IV were retrieved from the PDB. Their energy was minimized using Gromacs. The targeted phytosterols of aloe vera was retrieved from PubChem and virtually docked against the targeted protein receptors using AutoDock Vina. The drug likeness and the pharmacological profiling of lophenol, methylene lophenol, methylene cycloartanol, ethylidene lophenol and ethyllophenol were evaluated using Lipinski rule of 5 and ADMET properties. Results of the pancreatic lipase, aldose reductase and dipeptidyl peptidase-IV after the molecular dynamics showed the energy of the three protein receptors were reduced and was found to be stable. All the ligands that were docked was found to have binding affinities between -6.8 and -9kcal/mol and docked firmly to the protein. All the ligands were found to be drug-like except for methylene cycloartanol that violated two rules of Lipinski rule of 5.

6565

EVERY CASE CONFIRMED: EXPANDING UGANDA'S INTEGRATED COMMUNITY CASE MANAGEMENT THROUGH INNOVATIVE PARTNERSHIP

Maureen Amutahaire[1], Jimmy Opigo[1], Catherine Maiteki-Sebuguzi[1], Ruth Nabwire[1], Steven Shepelwich[2], Adriana Lanting[1], Dorothy Echodu[3], Ken Mugishu[4], Brian Gower[5], Fred Bukenya[6], Wycliff Odude[7], Chrispus Hyuha[8], Victoria Nabunya[1]

[1]National Malaria Control Division, Kampala, Uganda, [2]Malaria Partners International, Seattle, WA, United States, [3]Pilgrim Africa, Seattle, WA, United States, [4]PDG, Rotary District 9211, PP, Muyenga Rotary Club, Kampala, Uganda, [5]World VIsion US, Seattle, WA, United States, [6]Pilgrim Africa, Kampala, Uganda, [7]Pilgrim Africa, Soroti, Uganda, [8]World Vision Uganda, Soroti, Uganda

Uganda is aiming for 100% success in parasitological confirmation of all suspected malaria cases before prompt and accurate treatment of positive cases with ACTs, at all levels of care. For community based health care, the Ministry of Health has adopted a strategy for integrated community case management (iCCM) to facilitate access to and reduce the treatment gap for malaria, pneumonia and diarrhea, a strategy proven to reduce severe illness and death. The iCCM program uses ACTs to treat malaria after confirmation with malaria RDTs, amoxicillin for prompt treatment of pneumonia and oral rehydration solution and zinc for the management of diarrhea at the community level. Every district in Uganda is expected to employ iCCM per the national strategic plan, but many gaps remain, even in high burden districts-- particularly after unexpected early withdrawal of bilateral funding for iCCM in 27 districts in 2021. Uganda's funding for

iCCM through the Global Fund 2020-2023 provided only for ongoing supervision and supply, and not for start-up training and equipping. In 2022, the National Malaria Control Division (NMCD) partnered with The Rotary Foundation, the Muyenga Rotary Club, the Oklahoma Rotary Club, Malaria Partners International, The Aids Support Organization (TASO), World Vision, Pilgrim Africa and the Bill & Melinda Gates Foundation to start up iCCM in Katakwi District, a high transmission district in NW Uganda, by training and equipping 1100 community health workers. This unusual partnership, in which iCCM scale-up was funded by three partners new to malaria implementation funding in Uganda, required coordination with, and adjustment of, the country's current Global Fund grant (2020-2023) and the cooperation of all its sub-recipients for its success. NMCD program staff were able to arrange this, and in early 2023, after successful scale up in 2022, iCCM in Katakwi was sustainably transitioned to ongoing support through Uganda's Global Fund grant, proving a model for successful large-scale engagement of Rotary in creatively aiding in the achievement of national malaria reduction strategic goals.

6566

FEASIBILITY OF A SOUTH SOUTH NORTH COLLABORATION ON IMPLEMENTING A STUDY TO COMPARE VACCINATION COVERAGE SURVEY METHODS: CASE OF DEMOCRATIC REPUBLIC OF CONGO AND CENTRAL AFRICAN REPUBLIC

Jean-Bosco Kasonga[1], Emmanuel Fandema[2], **Nkamba Mukadi Mukadi Dalau**[1], Nicole A. Hoff[3], Sylvia Tangney[4], Eric Mafuta[1], Amine El Mourid[5], Katie Stahley[5], Patrice Feilema[6], Jean De Dieu Longo[7], Alexandre Manirakiza[8], Didine Kaba[1], Anne W. Rimoin[4]

[1]Kinshasa School of Public Health, Kinshasa, Congo, Democratic Republic of the, [2]2.Department of Public Health, Faculty of health sciences, University of Bangui, Bangui, Central African Republic, [3]Department of Epidemiology, UCLA, Kinshasa, Congo, Democratic Republic of the, [4]Department of Epidemiology, UCLA, Los Angeles, CA, United States, [5]Bill and Melinda Gates Foundation, Kinshasa, Congo, Democratic Republic of the, [6]Mcking Consulting, Ministry of Health and Population, Bangui, Central African Republic, [7]National Reference Centre for Sexually Transmitted Diseases and Antiretroviral Therapy, Bangui, Central African Republic, [8]Service d'épidémiologie, Institut Pasteur de Bangui, Bangui, Central African Republic

In 2018, the World Health Organization (WHO) established a revised method for assessing vaccination coverage using either a one-stage or two-stage cluster sampling design. This WHO method is considered as a gold standard to assess vaccine coverage. However, the method requires a large number of small clusters which makes the technique prohibitive when sub-national estimates are wanted in low- and middle-income countries (LMIC) such as the Democratic Republic of Congo (DRC) and Central African Republic (CAR), highlighting the need to evaluate alternative coverage survey methods. We describe the feasibility of a South-South-North (S-S-N) collaboration in implementing a study to compare the WHO method with alternatives methods, including Lot Quality Assurance Sampling (LQAS) method, the WHO method modified by the Kinshasa School of Public Health (KSPH), and a grid-based Geographic Information System (GIS) method, in terms of efficiency, cost and time. We used a participatory approach whereby the team from KSPH in DRC and the team appointed by the Ministry of Health in CAR, with technical support from the training program of the University of California Los Angeles in DRC (UCLA-DRC) set a collaborative network through both online and in-person meetings. The team developed the study protocol and had it approved by both local ethic committees. Joining expertise from all collaborators, the teams produced mapping for application of the GIS method in DRC and CAR. As of March 20, 2023, two meetings - one in each country had been held, protocols had been approved and the DRC team was preparing for field deployment. Deployment in CAR will follow - with all collaborators involved. The teams will thereafter jointly proceed to data management, analysis, and dissemination The S-S-N collaboration was feasible with involvement of local stakeholders and was an important way for both LMIC countries to share their experience in implementing coverage survey.

6567

DISTRIBUTED MANUFACTURING STRATEGIES TO CIRCUMVENT SUPPLY CHAIN COMPLEXITIES, LOWER COST, AND INCREASE ACCESS TO COMPOSTABLE MENSTRUAL HYGIENE PRODUCTS

Anton Molina[1], Anesta Kothari[1], Alex Odundo[2], Manu Prakash[1]

[1]Stanford University, Stanford, CA, United States, [2]Olex Technoenterprises, Kisumu, Kenya

Agaves are robust, drought-tolerant plants that have been cultivated for their high-strength fibers for centuries and they hold great promise as a crop in the face of increasing water scarcity associated with a warming planet. Meanwhile, millions of women lack access to sanitary products to safely manage their menstruation particularly in LMIC countries characterized by a dry climate. To address this issue, we show a processing route (involving mild delignification and mechanical fluffing) that transforms the leaves of succulent Agave sisalana into a highly absorbent and retentive material. We find that this process leads to a material with an absorption capacity exceeding those found in commercially available menstrual pads. We show that the carbon footprint associated with this process is comparable with common alternatives with the added benefit that it can be carried out at small scales while remaining environmentally sustainable. This work paves the way for developing partnerships between technologists, agriculturists, and entrepreneurs to enable sustainable manufacturing of compostable menstrual pads rooted in the communities.

6568

SOCIAL DETERMINANTS OF COVID-19 VACCINE ACCEPTANCE AND UPTAKE IN A BRAZILIAN SLUM COMMUNITY: A LONGITUDINAL TIME-TO-EVENT STUDY

Murilo Dorion[1], Juan Pablo A. Ticona[2], Mariam O. Fofana[1], Margaret L. Lind[1], Nivison Nery Jr.[2], Renato Victoriano[3], Ananias S. do Aragão Filho[3], Mitermayer G. Reis[3], Federico Costa*[2], Albert I. Ko[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Instituto de Saúde Coletiva, Universidade Federal da Bahia, Salvador, Brazil, [3]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Ministério da Saúde, Salvador, Brazil

Slum residents are at high risk for involuntary COVID-19 exposure and are the least likely to access medical care, thus making vaccine-driven prevention critical in this at-risk population. Despite robust vaccination campaigns in Brazil, uptake and timing continue to be influenced by social factors and contribute to health disparities. To address this, we conducted a sequential survey in a cohort of 952 residents of an urban favela in Salvador, Brazil where participants were interviewed in 2020, before vaccines were rolled out, and in 2022. We collected data on demographics, social characteristics, and COVID-19 vaccination status and intent. Primary series uptake was high (87% for 1st dose and 85 % for 2nd dose among those eligible); however, booster uptake was lower (63% of eligible population) at the time of the second interview, suggesting a decreasing interest in vaccination. To account for both vaccine refusal and delays, we conducted a Cox time-to-event analysis of dose uptake using sequential independent outcomes. Exposure times were determined by dose eligibility date to account for age and comorbidities. Intent to vaccinate in 2020 was associated with higher vaccination rates for the 1st (0.257, CI: [0.063, 0.452]) and 2nd (0.301, CI: [0.068, 0.534]) doses. We also found that uptake was associated with a better physical health score (0.147, CI: [0.014, 0.280]) for the 3rd dose. Men were less likely to receive the 1st dose (-0.244, CI: [-0.413, -0.075]), and 2nd dose uptake was lower for employed participants (-0.250, CI: [-0.443, -0.057]). The results show that vaccination beliefs in 2020 are still associated with uptake, suggesting a level of crystallization of COVID-19 beliefs that was not addressed by subsequent campaigns. The fact that healthier and unemployed individuals are more likely to receive certain doses may suggest that those factors ease navigating the vaccination system or are associated with receptivity to

health messaging. Gender also plays an important role. The data, together with qualitative evidence from the community, offers policy lessons to build a long-term COVID-19 vaccination strategy beyond availability.

6569

MEASLES OUTBREAKS IN REGIONS NEIGHBORING ARMED CONFLICT ZONES; EXPERIENCES FROM THE WEST REGION OF CAMEROON, 2018 TO 2022

Gael T. Kouamen

Cameroon Field Epidemiology Training Program (CAFETP), YAOUNDE, Cameroon

In 2019, a nationwide measles/rubella vaccination campaign was organized in Cameroon. However, in 2022, 67 districts reported measles outbreaks. The West region (WR) reported outbreaks in seven districts among which four border the Northwest region (NWR). Since 2016, an armed conflict in the NWR and Southwest region has caused massive influx of people into the WR. Population displacement negatively affects routine immunization and favors outbreaks. We therefore aimed to determine factors associated with measles outbreaks in the WR of Cameroon. A retrospective study of the West regional surveillance data was carried out from 2018-2022. Data on the classification, demographics and vaccination status of measles cases were retrieved. Data was analysed and trends, seasonality by moving means method and Odds Ratios (OR) were determined and; logistic regression used within 95% confidence limits. A total of 878 cases were reported from 2018-2022. The number of cases/years progressively increased from 106 in 2018 to 309 in 2022. The median age was 34 months (2 months – 57 years), 55% were male and a majority (74%) lived in rural areas. Seventeen percent (n=149) of cases were laboratory confirmed while 30% (n=271) were epi linked; 2.4% (n=21) were Rubella cases. About half (n=441) had received at least one dose of measles containing vaccine. Through the years 60% of symptom onset occurred during epi weeks 1 and 13 with a peak at week 11. Trends showed seasonality. Risk factors identified were living in a health district neighboring the NWR, OR 5.7 (95%CI, 3.7- 8,7) and being unvaccinated OR 5.8 (95%CI, 4.1- 8.4). In conclusion, population displacement due to the armed conflict in the NWR has created pockets of susceptible children in the WR. Periodic intensification of routine immunization should be organized in the affected districts while emphasizing on vaccination in hard-to-reach populations.

6570

HEAT EXPOSURE AND IMPACTS ON HEALTH AND PRODUCTIVITY OF READY-MADE GARMENT WORKERS BANGLADESH: A QUALITATIVE STUDY

Farzana Yeasmin[1], Aaron Bach[1], Jean Palutikof[1], Fahim Tonmoy[1], Fahmida Tofail[2], Mahbubur Rahman[2], Shannon Rutherford[1]

[1]Griffith University, Gold Coast, Australia, [2]icddr,b, Dhaka, Bangladesh

The ready-made garment (RMG) sector is key to growing Bangladesh's economy, providing export opportunities and employment for its majority female workers. To ensure sustained productivity and a thriving workforce, workplace hazards like heat, must be acknowledged, assessed and managed. The existing heat experienced in the sector is set to worsen as temperatures in the country increase due to global warming. For example, under a high emissions scenario (i.e. RCP 8.5) the estimated average annual temperatures will increase by 3.9 degreeC by the end of this century. This study highlights the impact of heat on health and productivity and explores heat management through the eyes of workers, managers and other sector stakeholders. Qualitative data were collected from workers of two RMG factories in Dhaka in 2022 to identify perceived heat related health and productivity impacts and explore barriers to workers accessing cooling options and heat-related medical care. Key-informant-interviews were conducted with factory officials, onsite health professionals, government officials, the RMG peak body, and NGOs. Workers and health professionals attribute symptoms like headaches, dizziness, fatigue and nausea to heat during summer months. Factory health professionals also observed high blood pressure in workers during summer and other informants identified higher absenteeism in summer. Heat was identified as an important influence on productivity by workers themselves and others working in or with the sector. Workers felt a high degree of pressure to meet daily quotas and the impacts of heat on worker performance and subsequent productivity were identified by workers, managers and health professionals. This production quota pressure also impacted on workers taking rests or hydrating sufficiently – both of which are important heat mitigation strategies. Factories provide some medical services including dedicated infrastructure, though during the hottest periods, they were reported to be insufficiently cooled. The key-informants ranked improved ventilation and space cooling solutions as the most feasible heat mitigation strategies.

6571

TOO HOT FOR BED NETS IN A CHANGING CLIMATE: SPATIAL ANALYSIS AND RISK MODELLING OF MALARIA INDICATOR SURVEY DATA IN SUB-SAHARAN AFRICA 2018-2022

Morgan E. Lemin, Louise Kelly-Hope

University of Liverpool, Liverpool, United Kingdom

Bed nets are a cornerstone of malaria control. However, with increasing global temperatures driven by climate change, survey participants in the Malaria Indicator Survey (MIS) now select "too hot" as a key reason for not using a bed net. This study aimed to examine the factors associated with selecting this reason at a community and household level in Sub-Saharan Africa. MIS data from 2018-2022 were reviewed for survey questions related to temperature factors and bed net usage. All countries in Sub-Saharan Africa with georeferenced MIS data since 2018 were included. The "too hot" for a bed net response proportions were summarised. The spatial distribution of this response was analysed, and the Getis-Ord Gi* statistic used to detect significant clustering of high values (hot spots). Regression analysis was conducted at two spatial levels with various environmental covariates. First, temperature, rainfall, humidity, and elevation data were used to determine the ecological factors associated at a community level. Second, data on building materials (e.g. mud, tin), access to electricity, and ownership of electric fans were used to determine the characteristics at the household level. MIS data from seven (44%) of the 16 countries surveyed had responses including "too hot" for a bed net, with a marked difference in the proportion of this response: Ghana (25%), Nigeria (16%), Senegal (4.8%) and Mali (1%). In Nigeria, for example, there was significant spatial clustering (Z-score = 3.69, P-value <0.001). Survey participants in the south, particularly the Akwa Ibom region, were four times more likely to have a "too hot" response than further north. This region had the highest average temperature and precipitation ranges and a statistically significant negative correlation with electric fan ownership. Further spatial and regression analyses are underway in all countries and will be presented in full. The possibility that global warming plays a role in the non-use of bed nets is alarming, and more information is needed to better understand the problem's scale. This may help national malaria programmes to develop strategies to overcome this challenge.

6572

CLIMATE CHANGE ADAPTATION MEASURES INFLUENCE HOUSEHOLD FOOD INSECURITY IN SOUTHERN ETHIOPIA

Taye Ayana[1], Bethlehem Mezgebe[1], Mehretu Belayneh[1], Bernt Lindtjørn[2]

[1]Hawassa University, Hawassa, Ethiopia, [2]University of Bergen, Bergen, Norway

As part of the project "Co-producing Gender-responsive Climate Services for Enhanced Food and Nutrition Security and Health (COGENT)" project in Ethiopia and Tanzania, we evaluated how the variation in rainfall and potential climate change adaptation measures influence household food insecurity. We did a quarterly survey involving 910 households from nine randomly selected rural kebeles (lowest political administration unit) in the Boricha district between June 2021 and March 2022. The data were collected using pretested, structured questionnaires, and potential causal

links between weather variability, such as rainfall, and food insecurity were measured after controlling for possible confounding variables. The household food insecurity rate (HFI) was highest in June (89.3 %) and lowest in December (67.7 %) after the harvesting season. Months with high rainfall were followed by improved food security, coinciding with increased household wealth. Furthermore, the average Body Mass Index (BMI) in September was the lowest, followed by an increment of 0.35 in December 2021. Households whose heads had not attended formal education [Adjusted Odds Ratio (AOR) 6.02, 95 % confidence interval (CI) 4.70, 7.71], had low-income (AOR 1.30, 95 % CI 1.07, 1.57), households with poor dietary diversity score (AOR 1.43, 95% CI 1.21, 1.63), who were not beneficiaries of the Food safety net programme (AOR 1.77, 95 % CI 1.51, 2.01), and who were not members of the community-based health insurance (AOR 3.49, 95 % CI 2.83, 4.30) had higher risks of food insecurity. Our study shows that better education, higher economic status, participation in the Food safety net programme and community-based health insurance membership reduce the population's vulnerability to food insecurity.

6573

LABEAUD LAB WASTE AUDIT

Esra Buyukcangaz, Bethel Bayrau, A.Desiree LaBeaud
Stanford University, Stanford, CA, United States

Reducing medical waste is a critical mitigation strategy to reduce health care's contribution to greenhouse gas emissions. In order to understand our lab's waste generation, we conducted a waste audit in our laboratory at the Stanford School of Medicine in the Division of Pediatric Infectious Disease. For two weeks (16-27 January 2023) waste was collected and sorted into three categories (recyclable, compostable and landfill). All waste was then weighed using Fisher Science Education precision balance and Tanta BVB-800 scale equipment with a resolution of 0.1 lb. Two authors were present and led all waste sorting and weighing. All study personnel wore isolation PPE throughout the waste audit and upon completion of the waste audit; all waste was disposed of in compliance with Stanford Environmental Health & Safety policy. Over the two weeks of the study period, we generated a total of 716 gr (24%) of compostable waste and 1316 gr (43%) of recyclable and 995gr (33%) landfill waste. Cardboard boxes, pipette tips, tubes (PCR, conical), gloves, gallon-size liquid containers, and pipet tip boxes were the largest categories comprising 597gr, 546 gr, 406.9 gr 359 gr, 200 gr and 200 gr, respectively. Cardboard boxes comprised 75% of our compostable waste, followed by paper towels (10%). Bio-hazardous solid waste made up 100% of our landfill category. Hazardous waste disposal costs 10–20 times more than non-hazardous waste disposal and our study revealed that one third of our waste was considered hazardous. Other studies have documented 20 - 34% of healthcare waste (HCW) is infectious and hazardous, similar to our results of 33%. Although this audit was performed during a period when fewer individuals were actively working in the lab, we are using this data to first educate ourselves on our waste generation and management, and to highlight opportunities to encourage reuse and decrease waste streams significantly.

6574

ASSESSING DISTRIBUTIONAL CHANGES OF BULINUS TRUNCATUS, INTERMEDIATE SNAIL HOST OF SCHISTOSOMA HAEMATOBIUM, UNDER CLIMATE CHANGE USING AN INTEGRATED APPROACH

Tim Maes[1], Julie Verheyen[1], Tiem van der Deure[2], Bruno Senghor[3], Aspire Mudavanhu[4], Ruben Schols[5], Anna-Sofie Stensgaard[2], Filip A.M. Volckaert[1], Tine Huyse[5]
[1]KU Leuven, Leuven, Belgium, [2]University of Copenhagen, Copenhagen, Denmark, [3]UMR VITROME, Dakar, Senegal, [4]Bindura University of Science Education, Bindura, Zimbabwe, [5]Royal Museum for Central Africa, Tervuren, Belgium

Climate change influences species' distributions, including those of disease vectors and their associated diseases. However, accurate range shift predictions remain scarce due to a lack of ecological data on most of these species. Bulinus truncatus is an intermediate snail host of Schistosoma haematobium and Schistosoma bovis, causing human and animal schistosomiasis, respectively. It's broad distribution represents the maximum geographic spread of schistosomiasis in Africa, Europe and the Middle East. There is, however, a general lack of data on the ecology of B. truncatus, precluding reliable forecasts of this species' distribution and the associated schistosomiasis risk under climate change. Here, we performed experimental tests with 2500 second generation snails from different field-collected origins (France, Senegal and Zimbabwe), subjecting them to chronic temperature treatments ranging from 4°C to 36°C. Life-history and physiological data were collected on the performance of the snails at each temperature. The data shows that cold origin snails have faster growth rates overall, and that warm origin snails have higher mortality rates at warm temperatures that might be offset by their increased fecundity. The warm origin snails had a higher available energy budget, lower respiration rates and lower hemoglobin levels than cold origin snails, indicating a more efficient energy use at high temperatures. They also showed a stronger immune response, which could translate in a stronger defense response to parasite infections. Furthermore, population genetic analyses based on 4913 single nucleotide polymorphisms show a high genetic differentiation between snail origins that can be linked to adaptation to local climatic conditions. All collected data is used to assess the species' distribution at present and in the future using mechanistic niche models that are compared to more established correlative niche models. The mechanistic niche models consider the differences in life history traits between different origins and the implications on B. truncatus distribution and the associated schistosomiasis risk.

6575

THE PLANETARY CHILD HEALTH AND ENTERICS OBSERVATORY (PLAN-EO): AN INTERDISCIPLINARY RESEARCH INITIATIVE AND WEB-BASED DASHBOARD FOR MAPPING ENTERIC INFECTIOUS DISEASES AND THEIR RISK FACTORS AND INTERVENTIONS IN LOW- AND MIDDLE-INCOME COUNTRIES

Josh Michael Colston
University of Virginia School of Medicine, Charlottesville, VA, United States

Diarrhea remains a leading global cause of childhood illness and is caused by various species of climate-sensitive pathogens. The emerging Planetary Health movement emphasizes the interdependence of human health with natural systems, with much of its focus on infectious diseases and their interactions with environmental and human processes. Meanwhile, the era of big data has transformed the curation, aggregation and dissemination of health information engendering a public appetite for open access, web-based repositories of infectious disease data. However, enteric infectious diseases (EID) have largely been overlooked by these developments. The Planetary Child Health and Enterics Observatory (Plan-EO) is a new initiative that builds on existing partnerships between epidemiologists, climatologists, bioinformaticians, and hydrologists as well as investigators in numerous low- and middle-income countries (LMICs). Its objective is to provide the research and stakeholder community with an evidence base for the geographical targeting of EID-specific child health interventions. The initiative will produce, curate, and disseminate spatial data products relating to the distribution of enteric pathogens and their environmental and sociodemographic determinants, making them available to decisionmakers via an online dashboard. To date Plan-EO has compiled microdata from 23 studies with ~80,000 diagnostic results from 35,000 children aged 0 - 59 months at sites in 24 LMICs and georeferenced to over 9,000 unique locations and outreach to additional studies is ongoing. An initial published analysis of Shigella has yielded detailed prediction maps and insights into the mechanisms underlying transmission. These approaches will be extended to other pathogens and their findings used to assess their relative sensitivity to changes in climate compared to other determinants such as sanitation improvements. Plan-EO will eventually develop a scenario-

based framework to support decision-making, resource allocation and identification of priority populations for targeting EID-specific interventions such as novel vaccines.

6576

ADAPTING TO CLIMATE CHANGE IN SUB-SAHARAN AFRICA: ONE MALARIA INTERVENTION AT A TIME

Jemima Andriamihamina[1], Solofo Razakamiadana[1], Aboubacar Sadou[2], Presley Musonda[3], Colin Quinn[4], Radina P. Soebiyanto[4], Ashley Garley[4]

[1]US Agency for International Development (USAID), Antananarivo, Madagascar, [2]US Agency for International Development (USAID), Dakar, Senegal, [3]US Agency for International Development (USAID), Lusaka, Zambia, [4]US Agency for International Development (USAID), Washington, DC, United States

Climate change is making malaria-endemic countries especially vulnerable and causing operational challenges for National Malaria Programs (NMPs). Unprecedented fluctuations in rainfall and extreme weather events are changing the seasonality and distribution of Anopheles mosquitoes and transmission patterns of malaria - a disease that caused 593,000 deaths and 234 million cases in sub-Saharan Africa in 2021. We present here climate-related actions that have been integrated in malaria prevention and control programs in several countries, that were designed to adapt to the shift in climate so as to keep effective interventions. In Madagascar, mosquitoes are biting earlier and longer than before (~ 4-fold increase in biting rate). To adapt, the NMP targeted messaging to address population behavior to consistently use insecticide treated nets regardless of the temperature. Several districts in Senegal added another round of seasonal malaria chemoprevention (SMC) in order to account for the 1-month shift in the rainfall peak and/or longer rainy season where total rainfall at the end of the season in October were, on average, 13 mm above normal in the past 3 years. Proactive community case management operations were increased from 6 months to year round in 5 districts. The Zambia NMP prioritized IRS in flood prone communities before the onset of the rainy season and front loaded essential medicines to 140 out of 3,000 health facilities to increase resilience of communities that become inaccessible during the rainy season and avoid interruption of services. These operational challenges affect NMP budgets and personnel needs. Hence, highlighting the need for monitoring climatic indicators (ie. rainfall and temperature) alongside malaria incidence to identify correlations between climate related events and malaria incidence and implement early warning systems. These systems can better inform NMP decision-making to ensure effective interventions. Ultimately, NMPs need budget flexibility and better access to temperature and rainfall data to make evidence-informed decisions to improve prevention and control interventions.

6577

MALARIA MANAGEMENT IN AN ERA OF CLIMATE CHANGE

Ravikanthi Rapiti, Wisam Haddadin

Abbott Rapid Diagnostics, Woodmead, South Africa

Africa has experienced temperature increases 1.5 faster than the global temperature . For malaria elimination, strategies and opportunities in mitigating the impact for the most vulnerable populations requires an understanding of the climate change. A pragmatic approach has been used to inform the Climate changes and the relationship with malaria. How rapid diagnostics can influence malaria diagnosis? Implications of early diagnosis to address the spread of malaria. The UN has presented the argument, leading to the increase in the literature around climate events and the complex relation with malaria. The literature has noted substantive arguments that climate change as noted in the last 10 years may impact vector borne diseases especially Malaria. The World Bank has been capturing trends that have monitored temperature changes yearly and seasonally. The question arises: is this adequate in addressing an increase in Malaria and other vector borne diseases? Early diagnosis to address the spread of Malaria, especially, during climate events during seasonal - or approximately 4 months post heavy rainfalls and/or temperatures that cause high precipitation. This includes an increased budget allocations for widespread and real-time testing in affected geospatial areas. There is thus a conclusive argument that increasing RDT testing may be an opportunity for countries to address climate changes. Noting, the elements contributing to an increase in malaria prevalence, governments cannot be complacent around the issues of climate change and the health associations. There needs to be an intention to prepare budgets, programs, and implementation of malaria RDTs. Abbott Rapid Diagnostics has sought to understand this issue and aims to accelerate and cement the implemental intervention that moves the dial gauge towards malarial elimination. Furthermore, supporting the monitoring of malaria prevalence to strengthen programs. Malaria control programs will demand timely responses to mitigate negative impacts on populations and their health.

6578

FROM FOOD SECURITY TO PUBLIC HEALTH - HOW CLIMATE INFORMATION CAN BE USED IN EARLY WARNING SYSTEMS AND PREPAREDNESS FOR DISEASE THREATS

Tashiana Osborne[1], Colin Quinn[2], Elizabeth Daut[2], Shaina Craige[2], Kiersten Johnson[2], Janine Mitchell[3], Nicole DeCastro[4], Omer T. Njajou[4], Rhiannon T. Gulick[4]

[1]United States Agency for International Development, and the American Association for the Advancement of Science, Washington D.C., DC, United States, [2]United States Agency for International Development, Washington D.C., DC, United States, [3]Development Alternatives Incorporated Global, Ottawa, ON, Canada, [4]Development Alternatives Incorporated Global, Bethesda, MD, United States

Climate change has been called the biggest global health threat. Rising temperatures, increased incidence of severe weather, and shifting precipitation patterns can increase disease transmission, create the conditions for existing and emergent pathogens to thrive, and exacerbate disease burden on human populations. This is especially true in countries that suffer from myriad climate-sensitive health challenges and lack the information, resources, or capacity to fully address these challenges. In Somalia and Mozambique, the United States Agency for International Development (USAID) is implementing a set of pilot projects to expand the use of health data in the Famine Early Warning System Network (FEWS NET), a leading provider of early warning and analysis on acute food insecurity around the world. Each pilot spans eight months. Multisectoral data, including climate data, will support decision-makers and health practitioners to access information about how climate change impacts public health risks. The FEWS NET Health Threat Extension pilot activity results from a partnership between USAID, the National Oceanic and Atmospheric Administration (NOAA), and the United States Geological Survey (USGS). The following USAID Bureaus jointly manage the pilots and offer technical support: Development, Democracy, and Innovation; Global Health; Africa; and Humanitarian Assistance. Lessons learned from these pilots can be used to extend efforts and to include additional data to inform climate-sensitive health threats and regions. Pilot activities aim to emphasize the role and importance of a One Health approach to inform sustainable development efforts and can contribute to ongoing early warning systems for preparedness and response to disease threats.

6579

COVID-19 VACCINE BOOSTER DOSE UPTAKE AMONG A COHORT OF HEALTHCARE WORKERS IN BANGLADESH

Md Zakiul Hassan[1], Ahamed Khairul Basher[1], Aninda Rahman[2], Md. Abdul Aleem[1], Mahmudur Rahman[3], Fahmida Chowdhury[1]

[1]icddrb, Dhaka, Bangladesh, [2]Communicable Disease Control, the Director General of Health Services, the Ministry of Health and Family Welfare Government of Bangladesh, Dhaka, Bangladesh, [3]Global Health Development/EMPHNET, Dhaka, Bangladesh

The WHO recommended COVID-19 vaccine booster dose for high-priority groups, including healthcare workers (HCWs). We explored COVID-19 vaccine booster dose uptake among front-line HCWs in Bangladesh. icddr,b in collaboration with the Communicable Disease Control of DGHS,

established a cohort of HCWs to record COVID-19 illness prospectively. The cohort enrolled HCWs from purposively selected 20 hospitals of four divisions across Bangladesh. At enrolment, we collected HCW's demographics, COVID-19 infections since the start of the epidemic, and vaccination records. The study physician followed the enrolled HCWs biweekly and recorded any change in vaccination status, including booster uptake. We summarised the data using frequency and percentages. Between July 2021-March 2023, the cohort included 3684 HCWs: nurses (1763), doctors (810), ward boy/Aya (439), health assistants (226), cleaners (155), community health care providers (125), medical technologist (108), lab attendant (30), receptionist (17), and ambulance driver (12). The median age of the HCWs was 35 years (IQR, 29-44), and 67% (2,465/3,684) were female. Overall, 90% (3,309/3,684) of the HCWs completed the primary series (first and second doses) of the COVID-19 vaccine. However, only 55% (2,020/3,684) of the HCWs received the first booster dose (third dose), and only 24 of them reported receiving the second booster dose (fourth dose). 55% (446/810) doctors and 54% (968/1,763) nurses received the first booster vaccination. The booster uptake was higher among lab attendants (93%) and medical technologists (76%) and lower among receptionists (29%) and cleaners (37%). HCWs in primary health facilities (68%) had a higher booster uptake compared to those in secondary (54%) and tertiary-level facilities (51%). The overall COVID-19 vaccine booster uptake among front-line HCWs in Bangladesh remains suboptimal. Identifying the reasons for low booster dose uptake and implementing a tailored vaccine program to address those factors can safeguard HCWs and maintain critical health services during future waves of SARS-CoV-2.

ADAPTING SUB-NATIONAL PUBLIC HEALTH EMERGENCY MANAGEMENT: THE MBALE REGIONAL EMERGENCY OPERATIONS CENTER EXPERIENCE IN EASTERN UGANDA

Isabirye Herbert Kiirya[1], Benjamin Fuller[2], Simon Kyazze[3], Anita Kisakye[3], Nabukenya Immaculate[4], Nanyondo Judith[4], Makumbi Issa[5], Kesande Maureen[4], Tugaineyo Emmanuel[6], Obbo Stephen[7], Maiteki Robert[1], Mohamed Larmode[4], Otto Emmanuel[8], Felix Ocom[5], Henry Bosa Kyobe[9], Peter Babigumira[4], Ssekitoleko Richard[10], Christopher C Moore[2]

[1]Mbale Regional Public Health Emergency operations center, Mbale city, Uganda, [2]University of Virginia, Charlottesville, VA, United States, [3]National public health emergency operations Center, Kampala, Uganda, [4]Infectious Diseases Institute, Kampala City, Uganda, [5]National public health emergency operations Center, Kampala City, Uganda, [6]Naguru National Referral Hospital, Kampala City, Uganda, [7]Mbale Regional Refferal Hospital, Mbale city, Uganda, [8]World Health Organization, African regional office, Brazzaville, Congo, Republic of the, [9]Ministry of Health, Kampala City, Uganda, [10]World Health Organization Uganda Office, Kampala City, Uganda

The COVID-19 pandemic has tested the capacity for emergency responses in low- and middle- income countries (LMICs), which has highlighted the importance of local public health interventions. Uganda has a robust national response coordination mechanism; however, limited capacities exist at the sub-national level. In 2020, the Uganda Ministry of Health established the Mbale regional emergency operations center (REOC) to coordinate responses to public health and natural disasters in eastern Uganda. The Mbale REOC multidisciplinary regional response team works closely with the Ministry of Health, regional referral hospitals, implementing partners, and academia. We aimed to describe the experience of the Mbale REOC over the 3 years from inception including during the COVID-19 pandemic. We conducted a qualitative study including a review of key documents and reports, and semi-structured interviews of participants involved in the establishment of the Mbale REOC and subject matter experts. We used a thematic approach and framework analysis using NVivo 12 software to analyze qualitative data. After the establishment of the Mbale REOC, complete daily regional surveillance reporting increased from 43% to 93%. Over 12 months, the REOC conducted on average 15 partner coordination meetings. The REOC supported 16 districts with logistics and inventory management including coordination of material supply transfer between districts. The REOC provided training in laboratory outbreak monitoring and evaluation to 21 regional trainers, 72 district mentors, and 256 facilities. The REOC established a mobile laboratory in the region that reduced COVID-19 PCR sample result turnaround time from ≥7 to ≤2 days and increased the number of tested samples from 200 to 500 per day. The Mbale REOC improved the sub-national response to infectious diseases outbreaks and disasters in eastern Uganda and was recognized by the Ministry of Health as a model for sub-national public health emergency management. A regional REOC strategy could be adopted by other LMICs to build local public health emergency response capacity.

AN ASSESSMENT OF RESEARCH, SURVEILLANCE, LABORATORY, AND OUTBREAK RISK MANAGEMENT CAPACITIES FOR NIPAH AND AVIAN INFLUENZA VIRUSES IN BANGLADESH

Md Mustafizur Rahman[1], Tristan Burgess[2], Syed Moinuddin Satter[1], Mohammad Enayet Hossain[1], Jeffrey C. Mariner[3], Jonathon D. Gass[3], Elizabeth Gold[4], Nadia Ali Rimi[1], Ausraful Islam[1]

[1]icddr,b (International Centre for Diarrhoeal Disease Research, Bangladesh), Dhaka, Bangladesh, [2]Center for Wildlife Studies, Camden, ME, United States, [3]Tufts University, Boston, MA, United States, [4]John Snow Research & Training Institute, Inc., Boston, MA, United States

In 2021, as part of USAID STOP Spillover activities in Bangladesh, and based on priorities established by stakeholders, we assessed research, surveillance, laboratory, and outbreak risk management capacities for avian influenza virus (AIV) and Nipah viruses (NiV) to appraise the current capacity of different institutions within the country. Both in-person and virtual meetings were arranged for data collection using structured and semi-structured questionnaires. We conducted 49 interviews with stakeholders from government and research organizations, and academia. We collected data on six research projects and three surveillance systems focusing on NiV, 11 surveillance systems and 16 research projects for AIV. Gaps for AIV surveillance include a lack of community-based, farm-based, and wild bird surveillance and the unavailability of sustainable funding. Lack of community-based surveillance, limited integration of human and animal data, and donor-dependency for funding were the gaps in NiV surveillance. Transmission dynamics and spillover risks for both pathogens are understudied. The causes of Nipah's high case fatality rate are yet to be explored. Six laboratories were reported as capable of testing samples for AIV, while the NiV can be tested in only two laboratories. None of these laboratories has BSL-3 facilities. These laboratories reported inadequate sample storage facilities, a lack of skilled human resources, and funding challenges. One government organization conducts outbreak investigations of different zoonotic diseases with the support of other government and research institutions and development partners. Sampling wild birds and nearby poultry to compare strain similarity and estimate the frequency of spillover events is needed to understand AIV transmission dynamics. Community-based surveillance of NiV is necessary to detect missing cases and understand the spillover of these viruses from animals to humans. Increased laboratory capacity, including a BSL-3 laboratory in the country, is required for rapid diagnosis and control measures for infectious disease outbreaks.

COVID-19 VACCINE ACCEPTABILITY AMONG HEALTH WORKERS IN THE DEMOCRATIC REPUBLIC OF CONGO

Kristen Stolka[1], Anselme Manyong[2], **Claire Standley**[3], Alanna Fogarty[3], Shanice Fezeu Meyou[1], Pia MacDonald[1], Dana Sessoms[1], Jean de Dieu Kamenga Asiley[2], Michel Nzaji[2]

[1]RTI International, Research Triangle Park, NC, United States, [2]RTI International, Kinshasa, Congo, Democratic Republic of the, [3]Georgetown University, Washington D.C., DC, United States

COVID-19 vaccination coverage in sub-Saharan Africa countries has lagged behind the rest of the world, with the Democratic Republic of Congo (DRC) having one of the lowest rates. Health workers are a high-risk exposure group and key actors in vaccination response and risk communication. The objective of this study was to conduct a survey among health workers in

seven DRC provinces, and determine factors associated with COVID-19 vaccine acceptance. This survey was administered from January to October 2022 and included questions on demographics and health history, COVID-19 vaccine uptake, risk perception and exposure to COVID-19, confidence in the COVID-19 response, reasons for acceptance or rejection of the COVID-19 vaccine, exposure to information about COVID-19 and intention to self-vaccinate. Health facilities were selected through simple random sampling, and convenience sampling utilized to administer the questionnaire to personnel in health facilities. A total of 5,102 health worker responses were collected. Results showed while 75.9% of respondents perceived a moderate or high risk of contracting COVID-19, almost half reported receiving at least one dose of the COVID-19 vaccine. Differences in vaccine coverage varied across provinces with significant factors amongst vaccinated health workers in age, gender, occupation, rural settings, and having received other adult vaccines. Among vaccinated health workers, the most frequently reported reason for vaccine acceptance included protection of oneself and others, whereas the top reasons for refusal among non-vaccinated was insufficient safety data, concern about side effects, and vaccine effectiveness. As influential community members, health workers' reasons for acceptance and refusal of the COVID-19 vaccine can help inform strategies to improve vaccine uptake among the general population. Risk communication and engagement efforts among health workers in DRC should emphasize COVID-19 vaccine safety and efficacy as potential opportunities for improving uptake.

NATIONAL AND SUB-NATIONAL AUTHORITIES' DECISION-MAKING PROCESSES DURING THE COVID-19 PANDEMIC: LESSONS FROM NIGERIA

Sanjana Mukherjee[1], Sumegha Asthana[1], Winifred S. Ukponu[2], Adachioma C. Ihueze[2], Ibrahim B. Gobir[2], Claire J. Standley[1], Alexandra L. Phelan[3]

[1]Georgetown University, Washington, DC, United States, [2]Georgetown University, Abuja, Nigeria, [3]Johns Hopkins University, Baltimore, MD, United States

Public health decision-making during the COVID-19 pandemic was challenging for decision-makers due to the dynamic epidemiological situation combined with time constraints and immense public pressure. In this study, we analyzed the process of COVID-19 response decision-making in Nigeria. We undertook a desk review to gather information on the country's context and conducted a series of key informant and focus group discussions with a range of stakeholders including national and sub-national officials, civil society representatives, development partners, and academics in Nigeria. Several important themes and perspectives emerged through this analysis. First, Nigeria's previous experiences responding to disease outbreaks provided lessons for establishing health emergency decision-making structures and mechanisms. Second, the establishment of high-level decision-making taskforces at both the national and subnational levels facilitated coordination among different levels of government. However, there is a need for enhancing collaboration due to the emergence of conflicts between levels of government, hindering a cohesive and coordinated pandemic response. Additionally, while decision-makers relied on input from academic experts and civil society members as part of advisory bodies, stakeholders emphasized the need for additional efforts to engage partners and actors in decision-making processes, particularly during the early preparedness and response stages of a health emergency. Third, adapting decisions to account for emerging technical information and the social and economic context enabled the response to be context specific and evidence based. However, more efforts are needed to ensure that decision-making is inclusive, equitable and transparent, to help improve public trust in governance processes, thus increasing compliance with public health measures. By understanding the process of decision-making during health emergencies, we can identify opportunities to improve and strengthen pandemic preparedness efforts.

GLOBAL ARBOVIRUS INITIATIVE: TACKLING MOSQUITO BORNE VIRUSES WITH EPIDEMIC AND PANDEMIC POTENTIAL

Diana P. Rojas, Raman Velayudhan, Laurence Cibrelus, Ingrid B. Rabe, Qingxia Zhong, Maria D. Van Kerkhove, Soce Fall, Sylvie Briand

World Health Organization, Geneva, Switzerland

The risk of emergence and re-emergence of arboviruses with epidemic and pandemic potential has increased as a global public health threat and will continue to do so in the years to come. The geographic range of arboviruses will also keep extending due to increased human movement, urbanization, climate change with environmental adaptation and uncontrolled expansion of mosquito vector populations. WHO has been working on strategic plans for multipathogen pandemic preparedness and response for health emergencies to strengthen capacities in vulnerable countries from local to national, regional, and global levels. In March 2022 WHO and partners launched the Global Arbovirus Initiative, comprised of six pillars: 1)Monitoring risk and anticipation; 2)Reducing epidemic risk; 3) Strengthening Vector Control; 4)Preventing and preparing for pandemics; 5)Enhancing innovation and new approaches; and 6)Building a coalition of partners. This initiative is convening partners across multiple sectors including health, agriculture, urban administration, and environment, as well as national, academic and private sector partners to forge a collaborative approach that builds on existing disease-specific programs to strengthen national integrated arbovirus disease programs. This will enable optimal use of limited resources to achieve the greatest impact. Epidemic response must be grounded in strengthening of ongoing national efforts to surveil for and respond to endemic transmission and localized outbreaks. Over the first year since the launch of the Initiative, WHO and collaborators have progressed in developing integrated risk maps for Aedes-borne arboviruses, appointed regional arbovirus consultants to drive implementation at regional level, and worked with WHO Regional Offices and Member States to adapt the approach to their specific priorities, frameworks, and needs. The successful implementation of the Initiative hinges on continued and political will, development of a sustainable funding model, and ever greater collaboration by partners to advance the objectives of pandemic preparedness and reduction of disease burden.

DESIGN AND STANDARDIZATION OF MOLECULAR SYSTEMS BASED ON CRISPR-CAS TECHNOLOGY FOR THE IDENTIFICATION OF GENES ASSOCIATED WITH ANTIBIOTIC RESISTANCE

Maryhory Vargas Reyes[1], Roberto Alcántara[1], Mónica Pajuelo[2], Pohl Milón[1]

[1]Peruvian University of Applied Sciences, UPC, Lima, Peru, [2]Peruvian University Cayetano Heredia, UPCH, Lima, Peru

Design and standardization of molecular systems based on CRISPR-Cas technology for the identification of genes associated with antibiotic resistanceEscherichia coli bacteria are commonly found in both community and hospital environments, where they can cause infections and develop antibiotic resistance. Recent studies have reported high prevalence of the resistance genes CTX-M-15 and floR, indicating the rapid dissemination of resistance genes that should be closely monitored. CRISPR-Cas12a technology has successfully detected carbapenem resistance genes and even viral sequences. In this study, we optimized the PCR-CRISPR-Cas12a system as a proof-of-concept for detecting the CTX-M-15 and floR resistance genes in E. coli. Locally produced Cas12a and Taq Polymerase proteins were used for this purpose, and E. coli isolates were obtained from 40 positive and negative samples that were confirmed by targeted sequencing. Taq Polymerase was used at 1 ng/ µl in 25 cycles for conventional PCR, while 2 crRNA were designed per resistance gene for the CRISPR-Cas system. The PCR-CRISPR-Cas12a system can detect up to 2 pg/µl of total DNA. The results compared with susceptibility tests

such as microdilution and disk diffusion and achieved a concordance index by Kappa ranging between 0.8 and 0.9, categorized as excellent. Unfortunately, in most low-resource laboratories only tests such as antibiograms are currently available. These laboratories may not have the financial resources to purchase and maintain high-tech equipment, such as next-generation sequencing platforms, which are commonly used for monitoring antimicrobial resistance. Therefore, technologies that use basic equipment such as PCR-CRISPR-Cas12a would help shorten the technical gap for early and timely detection of antimicrobial resistance. The implementation of this system can greatly support the One Health approach, which recognizes the interconnectedness of human, animal, and environmental health. Contributing to the surveillance of antibiotic resistance in both human and animal populations, as well as in environmental reservoirs in order to mitigate their spread.

EFFECTS OF INTERPREGNANCY INTERVAL AND MATERNAL AGE ON GESTATIONAL DIABETES MELLITUS: FINDINGS FROM CHAMPS PREGNANCY SURVEILLANCE IN BANGLADESH

Shovo Debnath[1], Emily S. Gurley[2], Atique Iqbal Chowdhury[1], Kazi Munisul Islam[1], Mohammad Sabbir Ahmed[1], Rajib Biswas[1], Afruna Rahman[1], Mohammad Abdus Salam[1], Abu Mohammad Saleheen[1], Mamunur Rashid[1], Qazi Sadeq-ur Rahman[1], Sanwarul Bari[1], Shams El Arifeen[1], Mohammad Zahid Hossain[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [2]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Gestational diabetes mellitus (GDM) is a disorder of glucose intolerance that arises for the first time during pregnancy and is a significant health concern during pregnancy in Bangladesh. The relationship between maternal age, interpregnancy interval, and GDM remains unclear due to limited inference with small sample sizes, hospital-based cohort, and biased interval measurements (birth-to-birth intervals rather than birth-to-conception). Understanding the relationship would help healthcare providers to identify high-risk women and provide appropriate interventions. Child Health and Mortality Prevention Surveillance (CHAMPS) is conducting pregnancy surveillance in Baliakandi, a rural sub-district of Bangladesh, which tracks every pregnant woman to identify any health-related complications and outcomes. This analysis examined the association of interpregnancy interval and maternal age on GDM using multivariate logistic regression adjusted for other covariates such as socioeconomic status and education. We collected demographic and pregnancy data of all mothers who had two consecutive deliveries with at least 28 weeks of gestation in Baliakandi, Rajbari District, between February 2017 and February 2023. A total of 3168 women had ≥ 2 viable births, and among them, 2697 women were included after excluding previous diabetes and unknown GDM (15%) in the index pregnancy. Interpregnancy interval was measured in months difference between last delivery and next conception. Intervals were categorized as <6, 6-11, 12-17, 18-24 (reference), >24 months, and maternal age as <18, 18-24 (reference), >24 years. A total of 33 (1.3%) women had GDM in the subsequent pregnancy. A very short interval (< 6 months) is significantly associated with higher odds of GDM in the subsequent pregnancy (adjusted odds ratio [aOR]: 3.80; 95% CI: 1.14-12.65). Additionally, compared to women aged 18-24 years, women older than 24 years had higher odds of developing GDM (aOR: 3.48; 95% CI: 1.84-8.98). An integrated strategy combining intensive health education for longer intervals and early detection of GDM among older pregnant women should be strengthened.
